LIST OF MAPS

VOLUME II.

BIOGRAPHIES.

In Volume XII. will be found biographical sketches of the following persons, not treated of in this volume, and not to be found in the English edition:

Atkinson, Edward.
Auerbach, Berthold.
Augur, Christopher Colon, Gen.
Aumale, Duc d' (Henri d'Orleans).
Averill, William Woods, Gen.

Babcock, Orville E.
Bacon, Delia.
Bacon, Leonard, D.D.
Bacon, Leonard Woolsey, D.D.
Badeau, Adam.
Bagehot, Walter.
Bailey, James Montgomery.
Bainbridge, William.
Baird, Henry Carey.
Baird, Spencer Fullerton.
Baker, Sir Samuel White.
Bakunin, Michael.
Balch, George B.
Balfour, Arthur James, M.P.
Balfour, John Hutton, F.R.S.
Ball, Thomas.
Balmaceda, José Manuel.
Bancroft, George.
Bancroft, Hubert Howe.
Banks, Nathaniel Prentiss.
Baratieri, Oreste.
Barlow, Samuel.
Barney, Joshua.
Barnum, Phineas Taylor.
Barnum, William H.
Barrett, Lawrence.
Barrett, Wilson.
Barrios, Justo Rufino.
Barron, James Commodore.
Barry, John.
Bartholdi, Frédéric Auguste.
Barton, Clara.
Bartram, John.
Bartram, William.
Bates, Edward.
Bayard, James Asheton.
Bayard, Nicholas.
Bayard, Thomas Francis.
Bayley, James Roosevelt, Archbishop.
Bazaine, François Achille, Marshal.
Beaconsfield, Earl of (Benjamin Disraeli).
Beard, George Miller, M.D.
Beard, William Holbrook.
Beauregard, Pierre Gustave Toutant de, Gen.
Beaver, James A., Gov.
Bebel, August.
Beck, Theodoric Romeyn, M.D.
Beecher, Henry Ward, Rev.
Beecher, Lyman, Rev.
Belford, Charles.
Bell, Alexander Graham.
Bell, John.
Bellamy, Edward.
Bellows, Albert F.
Bellows, Henry Whitney, D.D.
Belmont, August.
Benedek, Ludwig von, Gen.
Benedetti, Vincent.
Benedict, Sir Julius.
Benjamin, Judah Philip.
Benjamin, Park.
Bennett, James Gordon, Jr.
Benson, Edward White, Archbishop.
Benton, Thomas Hart.
Beresford, William Charles, Lord.
Bergh, Henry.
Berkeley, Sir William.
Bernhardt, Sara.
Bert, Paul.
Berthelot, Pierre Eugène.
Besant, Annie.

VOLUME II.

AST

ASTRONOMY is the science which deals with the distribution, motions, and characteristics of the heavenly bodies. Astronomy may probably be regarded as the most ancient of the sciences. Even the least civilized races must have recognized the regular vicissitudes of day and night (and, therefore, the diurnal course of the sun), while before long the variety and succession of the seasons would be noted, and their cause—the oblique annual motion of the same luminary—would be recognized. The moon in the sun's absence is so conspicuous and so useful that her motions, her various phases, and her regular disappearance and return after equal intervals of time, must have been watched in the earliest times with attention and interest. The occurrence of eclipses and other unusual phenomena would stimulate closer scrutiny. The spectacle of the starry heavens, seemingly unchangeable, save for the motions of a few wandering orbs along a certain zone of the star-sphere, early suggested an association between the fates of men and nations and these emblems of unchanging destiny on the one hand and of the changeful lot of mankind on the other.

But though mankind were probably first impelled by motives of mere curiosity to observe the courses of the stars, no great length of time could have elapsed ere they perceived that the regular and uniform revolutions of the heavens might be rendered subservient to their own wants and conveniences. By the help of the stars the shepherd, during the night, could count the hours, the traveler track his course through the uniform wastes of the desert, and the mariner guide his bark over the ocean; the husbandman, also, learned to regulate his labors by the appearance of certain constellations, which gave him warning of the approaching seasons. The indications derived from the simple observation of such phenomena were doubtless extremely vague; but as civilization advanced, the necessity of determining accurately the length of the solar year and of the lunar month, in order to regulate the calendar and the religious festivals, led to the accumulation and comparison of different observations, whereby errors were gradually diminished, and the foundations laid of a more perfect science. Astronomy thus presenting so many objects of curiosity and interest, and having so many practical uses, could not fail to be one of the sciences first cultivated by mankind. Its origin is, consequently, hid amidst the obscurity of remote ages, and is, in fact, coeval with the earliest development of the human intellect. The records or traditions of almost every ancient nation furnish some traces of attention to the state of the heavens, and of some rude attempts to discover the laws, the order, and the period of the most remarkable phenomena, such as eclipses of the sun and moon, the motions of the planets, and the heliacal risings of the principal stars and constellations. The Chaldeans and Egyptians, Chinese and Indians, Gauls and Peruvians, equally regard themselves as the founders of astronomy,—an honor, however, of which Josephus deprives them all, in order to ascribe it to the antediluvian patriarchs. The fables relating to the two columns of brick and marble which these sages are said to have erected, and on which they engraved the elements of their astronomy, to preserve them from the universal destruction by fire and water to which they are said to have learned from Adam the earth was doomed, are not worth the trouble of repetition; nor is there any better proof than the assertion of that credulous historian, of their acquaintance with the *annus magnus*, the astronomical cycle of 600 years, which brings back the sun and moon to the same points of the heavens so nearly, that its discovery implies a pretty correct knowledge of the solar and lunar motions.

According to the unanimous testimony of the Greek historians, the earliest traces of astronomical science are to be met with among the Chaldeans and Egyptians. The Egyptians were in ancient times the rivals of the Chaldeans in the cultivation of astronomy; and although they have left behind them still fewer monuments of their labors, they have obtained, through the exaggerated statements of the Greeks, even a greater reputation. The Greeks acknowledge themselves indebted to the Egyptians for their science and civilization; but regarding themselves likewise as descendants of that ancient people, they indulged their vain-glory in magnifying the accounts of the antiquity and knowledge of their supposed ancestors.

The Phœnicians are also generally enumerated among

the nations who cultivated astronomy at a very early period, though it does not appear, from any facts mentioned by ancient authors, that they devoted themselves specially to the observation of the heavens, or made any discoveries relative to the motions of the planets.

In China, astronomy has been cultivated from the remotest ages, and has always been considered a science indispensably necessary to the civil government of the state. The Chinese boast of a series of eclipses, recorded in the annals of the nation, extending over a period of 3,858 years, all of which, they affirm, were not only carefully observed, but were calculated and figured previous to their occurrence..

The astronomy of the Indians forms one of the most curious problems which the history of science presents, and one which, notwithstanding much discussion, still continues involved in great uncertainty.

The origin of astronomy in Greece, as in other early nations, ascends beyond the period of authentic history. The true foundations of Grecian science were laid by Thales, who was born at Miletus 640 years before our era. He formed a sect which has been distinguished by the title of the "Ionian School." Thales was succeeded by Anaximander, to whom also is attributed a knowledge of the sphere and of the zodiac. Anaximenes succeeded Anaximander in the Ionian school, and maintained nearly the same doctrines.

While the Ionian sect was so successfully employed in cultivating and propagating a knowledge of nature in Greece, another, still more celebrated, was founded in Italy by Pythagoras. Pythagoras is said to have acquired in Egypt the knowledge of the obliquity of the ecliptic, and of the identity of the morning and evening stars. What he chiefly deserves to be commemorated for in the history of astronomy, is his philosophical doctrine regarding the motion of the earth. He taught publicly that the earth is placed at the center of the universe; but among his chosen disciples he propagated the doctrine that the sun occupies the center of the planetary world, and that the earth is a planet revolving round the sun. This system, which still retains his name, being called the old or Pythagorean system of the universe, is that which was revived by Copernicus. Philolaus of Crotona, a disciple of Pythagoras, embraced the doctrine of his master with regard to the revolution of the earth about the sun. He supposed the sun to be a disk of glass which reflects the light of the universe. He made the lunar month consist of 29½ days, the lunar year of 354 days, and the solar year of 365½ days. Nicetas of Syracuse seems to have been the first who openly taught the Pythagorean system of the universe.

Although Plato can hardly be cited as an astronomer, yet the progress of the science was accelerated by means of the lights struck out by his penetrating genius. He seems to have had just notions of the causes of eclipses; and he imagined that the celestial bodies originally moved in straight lines, but that gravity altered their directions, and compelled them to move in curves. He proposed to astronomers the problem of representing the courses of the stars and planets by circular and regular motions. Geometry was assiduously cultivated in the school of Plato; and on this account he claims a distinguished place among the promoters of true astronomy.

Astronomy is also under some obligations to Aristotle. In a treatise which he composed on this science, he recorded a number of observations which he had made; and, among others, mentions an occultation of Mars by the moon, and another of a star in the constellation Gemini by the planet Jupiter. As such phenomena are of rare occurrence, their observation proves that he had paid considerable attention to the planetary motions.

The first astronomers of the Alexandrian school were Aristillus and Timocharis, who flourished under the first Ptolemy, about 300 years B. C. The chief object of their labors was the determination of the relative positions of the principal stars of the zodiac instead of merely announcing their risings and settings, as had been the practice of the Orientals and the ancient Greeks. The observations of these two astronomers conducted Hipparchus to the important discovery of the precession of the equinoxes, and served as the basis of the theory which Ptolemy, some centuries afterward, gave of that phenomenon.

About this time the science of astronomy was enriched by the discoveries of some of the distinguished geometricians whose labors have so greatly extended the glory of the Alexandrian school. Euclid, the celebrated author of the *Elements*, lived in the reign of the first Ptolemy. He composed a book on the sphere, which probably served as a model for future works of the same kind, and was the first who treated in a geometrical manner the phenomena of the different inclinations of the sphere.

Astronomy, which had as yet only consisted of a knowledge of isolated facts, acquired a systematic form, and almost a new existence, from the genius of Hipparchus, perhaps the greatest of all ancient philosophers in the sciences which are not purely speculative. This illustrious founder of astronomical science was born at Nicæa in Bithynia, and observed at Rhodes. After the death of Hipparchus nearly three centuries elapsed before any successor arose worthy of the name. During this long period astronomy made no essential advancement.

Ptolemy was born at Ptolemais in Egypt, and flourished at Alexandria about the 130th year of our era, under the reigns of Hadrian and Antoninus. This illustrious ornament of the Alexandrian school is entitled by his own discoveries to the high rank among astronomers which has universally been assigned to him; but the most signal service which he conferred on science was the collection and arrangement of the ancient observations. Ptolemy has been called The Prince of Astronomers,—a title which may perhaps be justified by the universal and long-continued prevalence of his system, but to which he has no claim from the number or value of his own observations. After a laborious and minute examination of the *Almagest*, Delambre doubts whether anything is contained in that great work, beyond the author's own statement, from which it can be decisively inferred that Ptolemy ever observed at all. He, indeed, frequently makes mention of observations made by himself; but his solar tables, rate of the precession, eclipses, determination of the moon's motion and parallax, and above all his catalogue of stars, render it impossible to doubt that the greater part of the results which he has given as observations are merely computed from the tables of Hipparchus.

The most celebrated of the Arabian astronomers was Albategni, or Muhammed Ben Geber Al-Batani, so-called from Batan, a city of Mesopotamia, where he was born about 850. He was a prince of Syria, and resided at Rakka in Mesopotamia, but many of his observations were made at Antioch. Having studied the *Syntaxis* of Ptolemy, and made himself acquainted with the methods practiced by the Greek astronomers, he began to observe, and soon found that the places assigned to many of the stars in Ptolemy's tables were considerably different from their actual situations, in consequence of the error which the latter had committed, with regard to the precession of the equinoxes.

Ulugh Begh, a Tartar prince, and grandson of the great Tamerlane, not only encouraged the study of astronomy, but was himself a diligent and successful observer. At Samarcand, the capital of his dominions, he established an academy of astronomers, and caused the most magnificent instruments to be constructed for their use. By means of a gnomon 180 feet in height, he determined the obliquity of the ecliptic to be 23° 30′ 20″, the precession of the equinoxes at 1° in 70 years, and obtained elements for the construction of tables which have been found to be scarcely inferior in accuracy to those of Tycho Brahe. The ancient astronomy had produced only one catalogue of the fixed stars,—that of Hipparchus. Ulugh Begh has the honor of having formed a second, after an interval of sixteen centuries. After the death of Ulugh Begh, astronomy received no farther accessions in the East. But the seeds of knowledge had now begun to take root in a more propitious soil, and Europe, destined to carry the development of the human energies to its fullest extent, began to awake from the lethargy in which it had continued during so many ages.

We come now to the period of the overthrow of the Ptolemaic system and the total renovation of the science of astronomy, which was due to the labors of Copernicus. The system which is associated with the name of Copernicus is now so familiar to every one, that it is almost unnecessary to describe it. The heaven, composed of stars perfectly at rest, occupies the remotest bounds of space, then the orbit of Saturn, next Jupiter, Mars, the Earth (accompanied by its moon), Venus, Mercury, and, lastly, the Sun immovable at the center. By this arrangement the stations and retrogradations of the planets became simple mathematical corollaries, following from the differences of the radii of their orbits and their unequal motions. The diurnal rotation of the earth explained more simply and rationally the apparent daily revolution of the heavens; and the precession of the equinoxes was referred to a small variation in the inclination of the earth's axis to the plane of the ecliptic. But the simplicity of the system, and its consequent probability, were the only arguments which Copernicus was able to bring forward in proof of its reality. The motion of the earth can, indeed, never be made an object of ocular demonstration; but after Richer's discovery of the diminution of gravity toward the equator, it was impossible to doubt longer of the existence of its rotary motion; and when Roemer had measured the velocity of light, and Bradley observed the phenomena of aberration, the evidences of its annual revolution were rendered equally convincing. For the events of his life see COPERNICUS.

Tycho Brahe stands next in chronological order on the roll of those who have contributed to the progress of astronomy. As an indefatigable and skillful observer, he is justly considered as far superior to any astronomer who had preceded him since the revival of the science in Europe. His ample fortune gave him the means of procuring the best instruments which the age could produce; and by his ingenuity and persevering application, he was admirably qualified to employ them to the best advantage. For an account of his life see BRAHE, TYCHO.

The great mass of accurate observations accumulated by Tycho furnished the materials out of which his disciple Kepler may be said to have constructed the edifice of the universe. The observations of the Danish astronomer had furnished the latter with the means of establishing with certainty the truth or inaccuracy of the various hypotheses which he successively imagined; and the diligence with which he labored in comparing and calculating these observations during twenty years, was finally rewarded by some of the most important discoveries which had yet been made in astronomy. (See Kepler's laws *supra*.)

Contemporary with Kepler was the illustrious Galileo whose discoveries, being of a more popular nature, and far more striking and intelligible to the generality of mankind, had a much greater immediate effect on the opinions of the age, and in hastening the revolution which was soon about to change the whole face of physics and astronomy. While residing at Venice, he heard it reported that Metius, a Dutch optician, had discovered a certain combination of lenses, by means of which distant objects were approximated to the sight. This vague and scanty intelligence sufficed to excite the curiosity of Galileo, who immediately set about inquiring into the means whereby such an effect could be produced. His researches were attended with prompt success, and on the following day he had a telescope which magnified about three times. It was formed by the combination of two lenses, a plano-convex and plano-concave, fitted in a leaden tube. In a second trial he obtained one which magnified seven or eight times; and subsequent essays enabled him to increase the magnifying power to thirty-two times. On directing his telescope to the moon, he perceived numerous inequalities on her surface, the diversified appearances of which led him to conclude almost with certainty that the moon is an opaque body similar to the earth, and reflecting the light of the sun unequally, in consequence of her superficial asperities. The planet Venus exhibited phases perfectly similar to those of the moon.

Science is indebted to Galileo for two other discoveries of a different kind, less brilliant perhaps, but of far greater importance than those which we have yet enumerated. These are the isochronism of the vibrations of the pendulum, and the law of the acceleration of falling bodies. His telescopic discoveries could not have remained long unknown; in fact, with the exception of those of the phases of Venus, and of the triple form of Saturn, they were all fiercely disputed, even during his own lifetime. It is now universally admitted that he was the first who discovered the satellites of Jupiter, and the spots of the sun; but the very circumstance of other claimants to these discoveries having arisen, proves that they were within the reach of ordinary observers. For an account of his eventful life see GALILEO.

While astronomy was making these rapid advances in the hands of Kepler and Galileo, an event occurred in Scotland which contributed, though less directly, no less powerfully, to the acceleration of its progress. This was the invention of logarithms by Lord Napier, baron of Merchiston. "An admirable artifice," says Laplace, "which by reducing to a few days the labor of many months, doubles the life of the astronomer, and spares him the errors and disgust inseparable from long calculations—an invention of which the human mind has the more reason to be proud, inasmuch as it was derived exclusively from its own resources."

Few individuals have rendered more important services to science than Huyghens. His improvement of the telescope and his application of the pendulum to clocks were valuable additions to the machiney of astronomical investigation. By means of his telescopes he discovered that the extraordinary appearance exhibited by Saturn was occasioned by a ring surrounding the body of the planet, and inclined to the ecliptic in an angle which he estimated at 21°. He lived to witness the discovery of four more satellites belonging to the same planet. (See HUYGHENS.)

The application of telescopes and micrometers to

graduated instruments forms an important epoch in the history of astronomy. The Royal Observatory of Paris was completed in 1670, and its direction intrusted to Dominic Cassini, who enriched astronomy with a great number of valuable observations and new discoveries. He determined the motions of Jupiter's satellites from observations of their eclipses, and constructed tables of them, which were found to be remarkably exact. He observed that the ring of Saturn is double, and discovered four of the satellites of that planet. He also determined the rotation of Jupiter and Mars, and made a number of observations on Venus with the same view. He observed the zodiacal light, and made a near approximation to the parallax of the sun. We also owe to him the first table of refractions calculated on correct principles, and a complete theory of the libration of the moon.

There is no period in the history of mankind so distinguished by great and important discoveries, or so remarkable for the rapid development of the human intellect, as the seventeenth century. We have already noticed the invention of the pendulum, and its application to regulate the motion of timekeepers; the invention of the telescope, bringing within the range of vision the phenomena of new worlds; of logarithms, by which computations are so much abridged; and of the mechanical contrivances for measuring minute angles in the heavens. The same century witnessed the application of algebra to geometry, the discovery of the laws of the planetary motions, the infinitesimal calculus, the acceleration of falling bodies, the sublime theory of central forces, and the great principle of gravitation which connects the celestial orbs, and regulates the motions which it had been the business of the astronomer to observe since the earliest ages of the world. The service which the discovery of these primary laws rendered to the progress of astronomy can scarcely be exaggerated.

By the discovery of the law of gravitation, Newton laid the foundations of physical astronomy; and by the consequences which he deduced from that law, he proceeded far in the erection of the superstructure. While physical astronomy was undergoing a complete revolution in the hands of Newton, the practical part was receiving great improvement from Flamsteed, the first astronomer royal, who conducted the Greenwich Observatory. This celebrated institution, from which so many important discoveries have emanated, was erected under the reign of Charles II, in 1675. Flamsteed was appointed to it in 1676, and continued with indefatigable zeal to discharge the duties of the office during the long period of thirty-three years.

Flamsteed was succeeded in the observatory by Halley, who held a prominent place among English astronomers. From early youth he applied himself with ardor to the study of mathematics and astronomy; and having procured a few instruments, he began to make observations, by which he was led to remark the inaccuracy of the tables of Jupiter and Saturn. In his nineteenth year he published a direct and geometrical method of finding the eccentricities and aphelia of the orbits of the planets, and in the year following he undertook a voyage to St. Helena, with a view to form a catalogue of the stars in the southern hemisphere. In 1720 Halley was appointed to succeed Flamsteed in the Royal Observatory.

The discoveries of Bradley, who succeeded Halley as astronomer royal, form a memorable epoch in the history of the science. It was reserved to him to give the theoretical explanation of a singular motion of the polar star which had been first observed by Picard, who had remarked that the inequality was annual, and amounted to about forty seconds, but had been unable to refer it to any law.

While England was witnessing the brilliant discoveries of Bradley, France produced a number of excellent astronomers, by whose successful labors every department of the science was signally promoted. Among these Lacaille is distinguished, both by his scientific zeal and the importance of his observations.

The question of the figure of the earth furnished ample materials for the practical as well as the speculative astronomer during the eighteenth century. The results of the measurement of the meridian by Cassini were at variance with the theories of Newton and Huyghens; and the Academy of Sciences resolved on making a decisive experiment by the actual measurement of the lengths of two degrees, one at the equator, and another at as high a latitude as could be reached. In the year 1735, three astronomers—Godin, Bouguer, and La Condamine—were commissioned by the French Government to accomplish the first of these objects in Peru; and the year following, Maupertuis, Clairaut, Camus, and Lemonnier went to Lapland to execute the second under the polar circle.

Maskelyne, the second English astronomer royal after Bradley, was appointed, in 1761, to observe the transit of Venus at the island of St. Helena. In the year 1765 he was appointed astronomer royal, and soon after recommended to the Board of Longitude the general adoption in the navy of the lunar method of finding the longitude, and proposed that tables for facilitating that method should be calculated and published in the *Nautical Almanac.*

Sir William Herschol, born in Hanover in 1738, has rendered his name immortal by the discovery of a new planet beyond the orbit of Saturn, and thereby doubling the ancient boundaries of the solar system. His observations on nebulæ and double stars opened up a new field of research, boundless in extent, and interesting by reason of the variety of the objects it presents to the attention of the observer. The extraordinary activity with which ne pursued his favorite occupation is attested by sixty-seven memoirs communicated by him from time to time to the Royal Society.

In the year 1764, the Academy of Sciences of Paris, which had so successfully promoted the great efforts that had already been made to perfect the theory of attraction, proposed for the subject of a prize the theory of the libration of the moon. Lagrange had the honor of carrying off the prize; but although he treated the subject in a manner altogether new, and with extraordinary analytical skill, he did not on this occasion arrive at a complete solution of the problem. In 1766 he obtained another prize for a theory of Jupiter's satellites. Of all the grand discoveries by which the name of Lagrange has been immortalized, the most remarkable is that of the invariability of the mean distances of the planets from the sun.

On account of the brilliant discoveries and important labors which we have just briefly noticed, Lagrange must be considered as one of the most successful of those illustrious men who have undertaken to perfect the theory of Newton, and pursue the principle of gravitation to its remotest consequences. But the value of his services to science is not limited to his discoveries in physical astronomy, great and numerous as these were. After Euler, he had contributed more than any other to increase the power and extend the applications of the calculus, and thereby to arm future inquirers with an instrument of greater efficiency, by means of which they may push their conquests into new and unexplored fields of discovery.

With the name of Lagrange is associated that of La-

place, their rival labors dividing the admiration of the scientific world during half a century. Like Newton and Lagrange, Laplace raised himself at an early age to the very highest rank in science. Before completing his twenty-fourth year he had signalized himself by the important discovery of the invariability of the mean distances of the planets from the sun, on an hypothesis restricted, indeed, but which, as we have already mentioned, was afterward generalized by Lagrange. About the same time he was admitted into the Academy of Sciences, and thenceforward devoted himself to the development of the laws which regulate the system of the world, and to the composition of a series of memoirs on the most important subjects connected with astronomy and analysis. His researches embraced the whole theory of gravitation, and he had the high honor of perfecting what had been left incomplete by his predecessors.

In the other departments of astronomy, also, numerous questions still remain to be discussed, the solution of which will occupy and reward the future labors of astronomers, and in which much progress has been made during the present century, by means of the powerful instruments now employed at the great observatories of every civilized country, and the improved methods of analysis brought to bear upon the results of observation. The curious phenomena of double and multiple stars, some of which are found to form connected systems of bodies revolving about one another, or a common center of motion—the variable stars—the proper motions of the stars—the translation of the solar system in space—the progressive condensation of nebulæ—are subjects still in a great measure new; for it is only of late years that observers have begun to direct the requisite attention toward them, or indeed have been in possession of instruments of sufficient power and delicacy to observe and measure the minute changes which take place beyond the boundaries of our own system. The discoveries in astronomy during the present century have been so brilliant and numerous, and the progress in every department is so rapid, and involves so many details, that it would be impossible to give here a detailed account of that progress.

PART II.—THEORETICAL ASTRONOMY.

When we look at the heavens on a clear night, we perceive a concave hemisphere on which are strewn multitudes of bright points. As we watch these hour after hour, we find that they are carried round precisely as though they were fixed on the interior surface of a spherical shell turning on a fixed axis. New groups are seen to rise above the eastern horizon, while those above the western horizon descend and finally disappear. Turning toward the south, we see that the groups of stars which pass above the horizon somewhat to the east of the south attain but a slight elevation when at their highest in the south, and then descending set as far to the west of the south point as they had risen to the east of it. Turning to the north, we see that there are groups of stars which remain visible the whole night, wheeling around a fixed point, and describing circles of greater or less magnitude according as they are at a greater or less distance from that point. Supposing our standpoint to be in or near London, the point thus remaining fixed is due north, and about 51½° above the horizon—therefore, about 38½° from the point directly overhead. If the heavens be observed night after night, similar phenomena are seen; and we recognize the uniformity of the motion of the (imaginary) star-sphere about its (imaginary) axis; for in any assigned interval, on any night in the year, the star-sphere turns by the same amount. It is soon found that the rate of turning is such that a complete rotation is effected in the course of about one day. But before many days have passed we find that this uniform turning motion does not correspond exactly to our common day. For though on several successive nights the stars may appear to be nearly in the same situation with respect to the horizon at any assigned hour, yet before long (or even in twenty-four hours if exact observation be made) it is found that the stars occupy the same position, *not* at the same hour on successive nights, but about four minutes earlier night after night. Thus, in the course of about fifteen days, the star-sphere has gained one hour's rotation; in about thirty days, two hours' rotation, and so on; until in the course of a year the star-sphere has gained a complete rotation, and the stars have the same apparent position at any assigned hour of the night as they had when the observations were commenced.

Limiting our attention for the present to the stars—though already, in speaking of the common day, we have in fact referred to the sun—the idea suggested by the observed phenomena is that the apparent star-sphere revolves around the earth precisely as it seems to do, turning about an axis, with a perfectly uniform motion, completing one rotation in twenty-four hours, less about four minutes. The natural steps for determining whether this really is the case, are—first, a series of careful observations at one fixed station; and, secondly, a study of the effects produced by change of station.

The altitude of the star, being in this case measured from the north, point N, is the supplement of the arc obtained by thus adding the north declination to the meridional altitude of the equator.

We see then that the declination of a star (or its north polar distance) determines the altitude of its culminating point. To determine the time at which the star culminates it is necessary that another co-ordinate should be known.

As we measure the declination from the equator, or in other words, determine the altitude of culmination by a reference to the equator, it is manifestly convenient to measure the time of a star's culmination by referring it to the time of culmination of some selected point on the equator. This is the course adopted by astronomers. The point selected for the purpose is one of the two points in which a great circle on the celestial sphere, called the ecliptic, cuts the equator. This point is called the first point of Aries, and is indicated by the sign T. At present it is only necessary to note that this point is in reality affected by a slow motion on the star-sphere, due to the fact that the axis on which the star-sphere apparently turns undergoes a slow change of position within the star-sphere itself, so that the equator is not really a fixed circle on the heavens. But for the purpose we have at present in view this slow change may be neglected; and we assume that the observer on earth has the equator as a fixed circle from which to measure the declination of stars, and that he also has a fixed point on the equator by which to time the culmination of each star. Knowing the declination of a star, he knows at what altitude it will culminate as viewed from the fixed station at which thus far we have supposed him to be placed. Let him now note the exact moment at which the first point of Aries culminates, and let him observe the precise interval in time between that moment and the moment when a star of known declination culminates; this interval is constant, and thereafter he will always know not only at what altitude that star will culminate, but at what time after the culmination of the point T. The interval in time between the culmination of T and the culmination of a given star is called the *right ascension* of the star. It may be measured, indeed, as an arc, viz.—

as the arc on the equator intercepted between T and that point in which a meridian circle through the star intersects the equator, the arc being measured in the direction opposite to that in which the star-sphere rotates. But the right ascension is more conveniently and now almost always measured in time.

The time measurement employed is the rotation of the star-sphere itself. The interval in time between the successive culminations of T is called a *sidereal day*. It is divided into 24 hours (numbered 0, 1, 2, 3 . . . to 24), each hour into 60 minutes, each minute into 60 seconds. If we have a clock showing 24 hours, and so rated as always to show 0 hour 0 min. 0 sec., when T is at its culmination, that clock will always show true sidereal time. Such a clock would gain nearly 4 min. a day as compared with an ordinary clock; but we need not at present dwell upon this point. Now the right ascension (or, as it is written, the R.A.) is indicated in sidereal time, and therefore corresponds to the time shown by the sidereal clock when that star is culminating. Thus, if a star's right ascension is 3 h. 2 m. 6 s., then when the sidereal clock shows time 3 h. 2 m. 6 s., that star is culminating. Whether it be day or night the astronomer knows this certainly, that is, if his sidereal clock is trustworthy.

It will be manifest that an observer at a fixed station, as we have thus far supposed our observer to be, requires to have the means of determining—(1) the moment at which a star culminates (or is on the meridian), and (2) the star's altitude when at its culmination. We have seen how the movement of the star-sphere determines the *cardinal points* of the horizon. Suppose now a telescope or pointer, so set as to turn upon a horizontal axis lying exactly east and west. We see that when the telescope is rotated on this axis, the line of sight, or the optical axis of the telescope, sweeps round in the plane of the meridian. It can be directed due south toward S, or to Æ (the culminating point of the celestial equator), or to *s*, a star on the meridian, or to the zenith Z, or to the pole P, or to the north point N—in fine, to any point on the celestial meridian. Now, if any contrivance be adopted to enable the observer to note the exact moment of sidereal time when a star crosses the middle of the field of view of such a telescope, then the right ascension of that star is known at once. Such an instrument, if devised simply or mainly for noting the moment of culmination, is called a *transit instrument*. If arranged with circles so that angles can be determined, the instrument is called a *transit circle*. An arrangement, now little used, in which a meridional circle bearing a telescope works against a fixed plane surface or wall (necessarily standing in a north-and-south position) is called a *mural circle*. The point to be specially noted in this plan is that, from observations of the star-sphere, we determine the cardinal points; and then the position of any star in the heavens can be determined by an instrument contrived so as to swing in the plane of the meridian. This done, a clock, carefully rated to show sidereal time, enables the astronomer at a fixed station to turn his transit instrument to the point of culmination of a star at the exact time when the star will culminate, and at the true place of such culmination.

But now let us suppose our observer to travel in a north-and-south direction, in order to determine what change, if any, will be produced by such voyage. The first effect noticed is that the pole of the heavens rises higher and higher above the northern horizon, as he travels farther and farther north, whereas the pole sinks lower and lower down toward the northern horizon the farther the observer travels toward the south. Close observation shows that the change of the pole's elevation is either exactly proportional to the observer's change of place in a north-and-south direction, or so nearly so that any discrepancy will require the closest and most exact scrutiny. The observer also notices that the stars retain their relative positions absolutely unaltered, but that new stars are seen in the south when he travels southward. This shows that the star-sphere is either truly a spherical enclosure—all the stars lying at the same distance—or else that the distances of the stars are so enormous that the displacement of the observer on the earth, even by several hundred miles, is as nothing by comparison. The uniform change in the pole's elevation cannot be explained, however, by merely supposing the stars very far away compared with terrestrial distances. It is manifest that we can only explain the observed facts by assuming that the course pursued by the supposed observer is not a straight line, but curved, and that it is curved uniformly, since the polar elevation changes uniformly when the observer travels at a uniform rate. It follows, therefore, that the path of the observer must be part of a circular arc. In other words, to an observer traveling uniformly along an arc toward the south, the angular elevation of the pole would diminish uniformly, as it is observed to do, *if* (1) the arc is circular, and (2) the pole of the heavens so far from the observer that lines drawn to it are appreciably parallel. Similarly the uniform increase of the polar elevation, to an observer traveling northward along the arc is explained.

Continuing this voyage southward, the observer finds the pole continues to sink, until at length the north pole of the heavens is on the horizon due north. All the phenomena of celestial rotation continue unchanged, except that toward the south many new stars have come into view. Moreover, the south pole of the heavens has now risen to the horizon, and lies due south. If the observer were now to retrace his course, he would, of course, find the north pole of the heavens rising uniformly again. But if instead of this he continue his journey southward, he finds the south pole of the heavens rising uniformly.

We see that journeys taken in a north-and-south direction lead to apparent changes of the dome of the heavens, only explicable on the assumption that the path traversed is a circular arc, or nearly so. It is clear also that the radius of this circular arc is determinable if the observer notes how much the elevation of the pole is changed for any given distance traversed by him in a north-and-south direction. Suppose for instance that in traveling he finds the elevation of the pole diminished by 7°, and that he has traveled about 480 miles, then (as already shown) he knows that ab=*ab*=change in polar elevation=an arc of 7° of the circumference of the circle along which he is traveling. Hence the whole circumference $= \frac{360}{7} \times 480$ miles $= 24{,}686$ miles; whence the diameter of the circle=(roughly) $24{,}686 \times \frac{7}{22} = 7855$ miles. This is not the true diameter of the earth's globe, being supposed to be the result of only a rough observation; but the method serves sufficiently to show how in very early times astronomers obtained a measure of the earth. For from whatever station the observer starts on north-and-south journeys, the same uniform elevation or depression of the visible pole as he travels toward or from it is observed; and the inference, therefore, is that the earth is a globe, since all the lines drawn on it in a north-and-south direction are circular arcs of equal radius. The points where the poles are both on the horizon, mark the

place of the *terrestrial equator;* and the points on the earth (which have never yet been reached), where the north and south celestial poles are respectively vertical, are the *terrestrial* or *geographical poles.*

Thus far we have considered only journeys made along a north-and-south course. Journeys pursued due east or due west, that is, always toward the point of the horizon which is 90° to the right or to the left of the north point, show equally that the observer is traveling on the surface of a globe, though they produce no apparent change either in the elevation of the pole or in the position of the points at which known stars rise, culminate, and set. We have seen that the observer who remains always at one station can determine the absolute time when any given star will culminate. Let us suppose that when journeying eastward or westward he can carry with him his sidereal time-measure, and that this continues throughout to show the true sidereal time of his original station. Then if he is traveling eastward he will find that any given star, instead of culminating at the time noted for that star as observed at his original station, will culminate earlier. The right ascension of the star will remain unchanged. On the contrary, if the observer travels westward from his original station, he finds that each star culminates later. Moreover, the observer finds that the amount of change in point of time corresponds to the distance he travels. Then the observer finds that the change in the time of a star's culmination corresponds exactly, to the length of arc traversed by him round the circle on the assumption that a complete circumference of this circle corresponds to 24 hours of sidereal time. This corresponds with the result of the former series of observations in showing that the earth is a globe, suspended, as it were, within the star-sphere; and that either the star-sphere turns uniformly around this terrestrial globe from east to west once in 24 sidereal hours, or else the terrestrial globe turns uniformly round its axis once in 24 sidereal hours from west to east.

The earth has now been shown to be a globe within the star-sphere, and whether the earth rotates within the star-sphere, or the star-sphere rotates round the earth, or both the earth and the star-sphere rotate, it is known that, *relatively to the earth*, the star-sphere rotates from east to west once in 24 sidereal hours. This rotation, whether apparent or real, takes place without any appreciable change in the relative position of the fixed stars. And the law of rotation having once been ascertained, it follows that the time of culmination of any star, and the position of the star at the time, are known, insomuch that a telescope or pointer can be directed to the place of the star at the moment of culmination with perfect exactness. Moreover, a star can be followed by an instrument properly devised, in such sort that a pointer shall continue directed upon the star all through the 24 sidereal hours.

We perceive, then, that if any celestial object is visible, whether by day or night, then by simply directing toward it a telescope we can ascertain in what part of the stellar heavens that celestial object lies. And if the object is moving upon the stellar heavens—or, in other words, it is other than one of these fixed stars with which we have hitherto been dealing—then by turning a telescope toward it from time to time we can determine its apparent path among the stars. So that in the case of the sun, which is never seen in company with the stars simply because his light, by illuminating our air, veils the stars from view, we can nevertheless ascertain exactly along what path on the star-sphere he seems to move, at what rate, and whether the rate is uniform or variable.

But before we examine the results of observations carried out for this purpose, it will be well to consider a circumstance affecting observations made in this manner. We refer to the refractive action of the earth's atmosphere, by which the apparent positions of the celestial bodies are to some degree affected. This is the proper place to mention the effects of refraction, because there can be little doubt that it was during observations of the sun that the refractive action of the atmosphere was first discovered. However, in explaining this action, reference will be made to the stars as heretofore, in order that the inquiry into the sun's apparent motions may be referred solely to the sphere of the fixed stars.

By a well-known optical law, a ray of light in passing obliquely from one medium to another of greater density is refracted or bent toward the normal to their common surface. We may regard our atmosphere as composed of an infinity of concentric spherical shells, whose densities increase the nearer they are to the earth's surface. When a ray of light from a star enters the atmosphere, therefore, it is inflected toward the earth, and the inflection is increased by every successive stratum of the atmosphere through which the light passes. The decrease of the density of the atmosphere, from the surface of the earth upward, follows the law of continuity, or takes place by insensible degrees; so that the luminous ray, in traversing the atmosphere, enters at every instant into a denser medium, and is therefore continually brought nearer and nearer to the vertical direction. Hence the true path of the ray is curvilinear, and concave toward the earth. This is equivalent to the supposition that the thickness of the different concentric strata of uniform density is infinitely small, and that the light, as it successively penetrates each, deviates from its former path by an infinitely small angle, which may be considered as the differential of the refraction, the total amount of which will therefore be obtained by integration. It is evident that the amount of the refraction is greater in proportion as the observed star is nearer to the horizon; for in this case the luminous rays strike the tangent planes of the atmospherical strata more obliquely, and have besides to traverse a greater extent of atmosphere before they arrive at the eye of the observer. On determining by experiment the refraction at every altitude from zero to 90°, tables of *Refraction* may be constructed, which will furnish the means of discovering the law of its diminution; but as such a process would be exceedingly tedious, and likewise apt to lead to erroneous results on account of the inevitable errors of observation, it is found more convenient to assume some hypothesis for a basis of calculation, and to verify the results which it leads to by comparing them with observation. In regard to media, which may be said to be permanent —such, for instance, as water and glass—the determination of the refraction is not attended with great difficulty; but the circumstances are greatly altered when we come to make experiments on the atmosphere. In this case the difficulty arises from the incessant changes which the atmosphere is undergoing relatively to its refractive power—changes which it is impossible for the observer fully to appreciate, inasmuch as he can only determine its physical state within a short distance of the earth, while that of the upper strata remains wholly unknown to him. The refractive power of the atmosphere is affected by its density and temperature. The effects of the humidity are insensible; for the most accurate experiments seem to prove that the watery vapors diminish the density of the air in the same ratio as their refractive power is greater. It is therefore only necessary, even in delicate experiments, to have regard

to the state of the barometer and thermometer at the time the observation is made.

It may be explained that the refraction of the rays of light in traversing the earth's atmosphere is the cause of *Twilight*, which sensibly lengthens the duration of the day, and prevents a sudden transition from light to darkness on the disappearance of the sun. When the sun is more than 33′ below the horizon, the refraction is not powerful enough to bring his rays sufficiently near the earth to reach our eyes; they pass over our heads, and are irregularly reflected by the molecules of the atmosphere. By this means a portion of the celestial vault is enlightened, while the sun is invisible. This illumination of the upper regions is called the twilight. It commences as soon as objects can be distinguished before sunrise, and terminates when they cease to be visible after the sun has set. The time, however, at which the twilight commences and terminates cannot be assigned with any degree of precision. It is generally supposed to be limited by the depression of the sun 18° below the horizon. Lacaille found the limit in the torrid zone to be between 16° and 17°. According to Lemonnier, it varies in France between 17° and 21°. The duration of the twilight will evidently be longer or shorter, according as the inclination of the sun's motion to the horizon is more or less oblique.

The apparent enlargement of the sun and moon near the horizon is an optical illusion, connected in some measure with the atmosphere, of which various explanations have been given since the time of Ptolemy. According to the ordinary laws of vision, the celestial bodies, particularly the moon, which is nearest to the earth, ought to appear largest in the meridian, because their distance is then less than when they are near the horizon; yet daily experience proves that the contrary takes place. The mean apparent diameter of the moon, at her greatest height, is 31′ in round numbers, but in the horizon she seems to the eye two or three times larger. The commonly received explanation of this phenomenon was first given by Descartes, and after him by Dr. Wallis, James Gregory, Malebranche, Huyghens, and others, and may be stated as follows:—The opinion which we form of the magnitude of a distant body does not depend exclusively on the visual angle under which it appears, but also on its distance; and we judge of the distance by a comparison with other bodies. When the moon is near the zenith there is no interposing object with which we can compare her, the matter of the atmosphere being scarcely visible. Deceived by the absence of intermediate objects, we suppose her to be very near. On the other hand we are used to observe a large extent of land lying between us and objects near the horizon, at the extremity of which the sky begins to appear; we therefore suppose the sky, with all the objects which are visible in it, to be at a great distance. The illusion is also greatly aided by the comparative feebleness of the light of the moon in the horizon, which renders us in a manner sensible of the interposition of the atmosphere. Hence the moon, though seen under nearly the same angle, alternately appears very large and very small. Desaguliers illustrated the doctrine of the horizontal moon by the supposition of our imagining the visible heavens to be only a small portion of a spherical surface, in which case the moon, at different altitudes, will appear to be at different distances, and will therefore seem to vary in magnitude.

Correction being made for refraction, the true position of the sun on the star-sphere can be ascertained day after day; and thus his apparent motions, as we have said, can be determined.

The result of such observations is to show that in a period of about 365 days the sun traverses a great circle of the star-sphere inclined to the equator. This period is called a *year*, and is familiar to all as the period in which the sun's varying positions, alternately north and south of the equator, bring about the circuit of the seasons. For we have already seen that a star to the north of the equator is above the horizon more than half the sidereal day, and at its meridian culmination has an altitude exceeding that of the south point of the equator. When the sun is north of the equator he has a daily arc like that of a star similarly placed, so that day lasts longer than night, and at mid-day the sun pours his heat more directly on the earth than if he were on the equator. In like manner it is shown that, when the sun is south of the equator, night lasts longer than day, and the sun at mid-day has a smaller altitude than if he were on the equator. The result of constant experience shows, that the sun's declination reaches its maximum on the south side of the equator about December 22, when it amounts to 23°.465. From this time it gradually diminishes till about March 21, when the sun reaches the plane of the equator. At this time the days and nights are of equal length all over the earth, and the instant of time at which the sun's center is in the equatorial plane is called the instant of the equinox. The sun then passes to the northern side of the equator, and his declination or meridional altitude continues to increase till about June 22, when he becomes stationary, and then again shapes his course toward the equator. His maximum declination on the north side of the equator is exactly equal to that on the south, amounting to 23°.465. The sun now continues to approach the equator till about September 24, when he again reaches that plane, and a second equinox succeeds. Continuing still to move in the same direction, he declines from the equator southward, till he reaches his former limit about December 22; and so on continually.

The two small circles of the sphere, parallel to the equator, which pass through the two points where the declination is greatest, are called the *Solstices* or the *Tropics;* that on the northern hemisphere is called the *Tropic of Cancer*, and the other is called the *Tropic of Capricorn.*

These two parallels, which mark the extreme limits of the sun's declination, are, as has just been stated, equally distant from the equator, with regard to which the variations of declination on either side are perfectly symmetrical and uniform.

The observations of the sun's right ascensions and meridional altitudes, which have been made daily during so great a number of years, and under so many different meridians, furnish complete proof that the projection of the sun's orbit is a great circle of the celestial sphere, and that the orbit itself is wholly confined to the same plane.

The great circle which the sun describes in virtue of his proper motion is called the *Ecliptic.* It has received this name from the circumstance that the moon, during eclipses, is either in the same plane or very near it. These phenomena can, in fact, only happen when the sun, earth and moon are nearly in the same straight line, and consequently, when the moon is in the same plane with the earth and the sun. The angle formed by the planes of the ecliptic and equator, which is measured by the arc of a circle of declination intercepted between the equator and tropic, is called the *Obliquity of the Ecliptic.* The two points in which the equator and ecliptic intersect each other are called the *Equinoctial Points;* they are also denominated the *Nodes of the Equator;* and the straight line conceived to join them is the *Line of the Equinoxes*, or the *Line of the*

Nodes. The node through which the sun passes on coming from the south to the north of the north of the equator is called the *Ascending Node*, the opposite node is the *Descending Node.* A straight line passing through the center of the earth, perpendicular to the plane of the ecliptic, is called the *Axis of the Ecliptic*, and the points in which its prolongation meets the sphere are called its *Poles*—these denominations being analogous to those of the axis and poles of the equator. The two small circles of the sphere which pass through the poles of the ecliptic, and are parallel to the equator, are called the *Polar Circles.*

The ecliptic has been divided by astronomers, from time immemorial, into twelve equal parts, called *Signs*, each of which consequently contains 30 degrees. The names by which they are characterized are as follows:—

North of the Equator.—Aries, Taurus, Gemini, Cancer, Leo, Virgo; South of the Equator.—Libra, Scorpio, Sagittarius, Capricornus, Aquarius, Pisces.

In each of these signs the ancients formed groups of stars, which they denominated the *Zodiacal constellations*, not confined to the ecliptic, but included within an imaginary belt, extending 9° on each side of it, to which they gave the name of *Zodiac (circle* or *zone of the animals).* The term *sign* is now employed only to denote an arc of 30°, and will probably soon be banished entirely from astronomical tables. It is now seldom used even for tables of the planets.

As the greater part of the celestial phenomena connected with the planetary system takes place either in the ecliptic or in planes not greatly inclined to it, it is found to be most convenient to refer the positions of the planets, and frequently those of the stars also, to that plane. The first point of Aries, which is the technical expression for the intersection of the ecliptic and equator, or the place of the sun at the vernal equinox, is assumed as the origin from which the degrees of the ecliptic, as well as of the equator, are counted from west to east, or in the direction of the sun's annual motion. The angular distance of the sun from this point is called his *Longitude*, and the longitude of a star is the arc intercepted on the ecliptic between the same point and a great circle passing through the star perpendicular to the ecliptic. The arc of this circle intercepted between the star and the ecliptic, or, which is the same thing, the complement of the star's distance from the pole of the ecliptic, is called the *Latitude* of the star; so that longitude and latitude bear the same relation to the ecliptic that right ascension and declination bear to the equator.

The sun's motion along the ecliptic is found not to be strictly uniform. In this place, let it suffice to notice that the sun is found to move more quickly in winter than in summer, the rate of motion changing from its maximum nearly in mid-winter to its minimum nearly in midsummer, and thence to its maximum again. But at no time does the motion differ greatly from its mean rate of very nearly 59′ in a sidereal day. If we call the mean rate 10,000, then the greatest and least rates of motion are represented by the members 10,336 and 9,664 respectively.

The direction in which the sun travels round the ecliptic, and in which longitude is measured, is from west to east, that is, it is contrary to the direction in which the star-sphere rotates.

Since the sun travels thus around the celestial sphere, it is manifest that the successive returns of the sun to the meridian cannot recur after the same interval of time as the successive returns of any given star. If on any day the sun's center when he is crossing the meridian has a particular position on the star-sphere, then when that point of the star-sphere next returns to the meridian—that is, one sidereal day later—the sun has traveled about 1° from that point, moving along the ecliptic in a direction opposed to that in which the star-sphere rotates. The star-sphere must, therefore, rotate a little further round before the sun will be on the meridian. As a convenient first approximation to the actual effects, let us make the supposition that the sun moves along the equator instead of the ecliptic, and that he moves exactly 1° in a sidereal day. In this case he would be exactly 1° from the meridian when the point he had occupied on the meridian the day before had reached the meridian. The point on the star-sphere would have completed the full circuit of 360° of rotation while the sun had completed only 359°, and his diurnal motion being therefore only $=\frac{359}{360}$ of the star-sphere's, it follows that the solar day (or the interval between the sun's successive returns to the meridian) would be greater than the sidereal day in the ratio of 360 : 359. Therefore, the solar day being divided into 24x60 minutes, the sidereal day would manifestly be 4 min. shorter.

But as the sun moves in a circle inclined more than 23° to the equator, and as the sun's motion is slightly variable, and the mean rate less than 1° per sidereal day, these relations are not exactly presented.

Let us, as a next approximation, suppose the sun to move uniformly round the equator once in the course of a year of 365¼ days, and determine the length of a solar day on this assumption. It is clear that whatever the sun's daily retardation may be, he loses one complete circuit of the heavens in a year of 365¼ solar days. In other words, while the sun has been carried round 365¼ times by the diurnal rotation, the star-sphere has been carried round 366¼ times. Therefore, on our assumption

$$365\tfrac{1}{4} \text{ solar days} = 366\tfrac{1}{4} \text{ sidereal days}$$

$$\text{and a sidereal day} = \frac{365\tfrac{1}{4}}{366\tfrac{1}{4}} \text{ solar day}$$

$$= 23 \text{ h. } 56 \text{ m. } 4 \text{ s., approximately.}$$

This, in fact, indicates roughly the manner in which the mean solar day is connected with the sidereal day. It is only necessary in the above process to substitute the true length of the year for the value 365¼ days—meaning by the year, the year of seasons, measured by the successive returns of the sun to the equator as he crosses that circle with northward motion.

As the sun moves at a varying rate, it is manifest that the actual solar day measured by the successive returns of the sun to the meridian could not be constant in value, even if the sun moved round the equator. For the excess of a solar day over the sidereal day is caused by the motion of the sun on the star-sphere, and will be therefore greater or less according as the sun's motion on the star-sphere is greater or less. The actual solar day, therefore, exceeding the constant sidereal day by a variable quantity, must necessarily be itself variable. It is greater than the mean in December and January, when the sun is moving at a rate greater than his mean rate, and less in June and July when he moves at a less rate. And it is clear that if at the end of December the moment of the real sun passing the meridian were taken as the beginning of the mean solar day of twenty-four hours, then the next passage of the meridian by the actual sun would occur after the twenty-four hours of mean solar time had elapsed. Day after day the sun would come to the meridian at a later and later hour of mean solar time, until toward the end of March, when, the sun's rate having acquired its mean value, the actual sun would not lag any farther behind. From this time he would gain, until toward the end of June he would come to the meridian at noon of mean solar

time. In the remaining half year he would be in advance, that is, he would cross the meridian before noon of mean solar time. Toward the end of September he would have made his greatest advance compared with mean time, and in the remaining quarter of the year he would gradually lose more and more of that gain, until at the end of December he would again cross the meridian at noon of mean solar time.

But besides this cause of variation in the length of the true solar day, there is another depending on the inclination of the sun's apparent path on the heavens to the celestial equator. To conceive the effect of this cause, it is necessary to have regard to the motion of the sun with reference to the equator. The sun describes every day a small arc of the ecliptic. Through the extremities of this arc suppose two meridians to pass; the arc of the equator, which they intercept, is the sun's motion for that day referred to the equator, and the time which that arc takes to pass the meridian is equal to the excess of the astronomical day over the sidereal. But it is obvious that at the equinoxes the arc of the equator is smaller than the corresponding arc of the ecliptic, in the proportion of the cosine of the obliquity of the ecliptic; at the solstices, on the contrary, it is greater in the proportion of the secant of the same obliquity. The astronomical day is diminished in the first case, and lengthened in the second.

To have a mean astronomical day independent of these causes of inequality, astronomers have supposed a second sun to move uniformly on the ecliptic, and to pass over the extremities of the axis of the sun's orbit at the same instant as the real sun. This removes the inequality arising from the inequality of the sun's motion. To remove the inequality arising from the obliquity of the ecliptic, conceive a third sun to pass through the equinoxes at the same instant with the second sun, and to move along the equator in such a manner that the angular distances of the two suns at the vernal equinox shall be always equal. The interval between two consecutive returns of this third sun to the meridian forms the *mean astronomical day*. *Mean time* is measured by the number of the returns of this third sun to the meridian; and *true time* is measured by the number of returns of the real sun to the meridian. The arc of the equator, intercepted between two meridian circles drawn through the centers of the true sun and the imaginary third sun, when reduced to time, is what is called the *Equation of Time*.

The inclination of the ecliptic to the equator results necessarily, as already mentioned, in a difference of seasons. When on the equator, the sun, like an equatorial star, is above the horizon during one-half of the day, and below the horizon during the other half. When he is north of the equator he is above the horizon for more than half the day, and reaches a higher altitude at noon than when on the equator. When south of the equator he is below the horizon for more than half the day, and does not reach so great an altitude at noon as when he is on the equator. As he is perceptibly the source of light and heat, it follows that when he is north of the equator we receive (in our northern latitudes) more light and heat than when he is on the equator, and so much the more as his northerly declination is greater; while, when he is south of the equator we receive less light and heat than when he is on the equator, and so much the less as his southerly declination is greater. These results are equally accounted for whether we regard the earth as fixed, and the sun as really traveling round the heavenly sphere on his inclined path, or whether we suppose the sun to be fixed, and the earth to travel around him on a correspondingly inclined path. Let us follow the earth round, noting how the sun would appear to move on the ecliptic, and also how the length of day would be affected by the varying position of the earth's axis with respect to the sun. When the earth is at the beginning of Libra, about March 20, the sun, as seen from the earth, appears at the beginning of Aries in the opposite part of the heavens, the north pole is just coming into light, and the sun is vertical to the equator, which, with all its parallels, is divided into two equal parts by the circle which forms the boundry between the dark and illuminated hemispheres, and therefore the days and nights are equal all over the earth. As the earth moves in the ecliptic, the north pole comes more and more into the light, and the days increase in length at all places north of the equator. When the earth comes to the beginning of Capricorn, the sun, as seen from the earth, appears at the beginning of Cancer about June 21; and the north pole of the earth inclines toward the sun, so as to bring into light all the north frigid zone, and more of each of the northern parallels of latitude in proportion as they are farther from the equator. As the earth advances from Capricorn towards Aries, and the sun appears to move from Cancer toward Libra, the north pole recedes from the light, which causes the days to decrease and the nights to increase in length till the earth comes to the beginning of Aries, and then they are equal as before—the boundary of light and darkness cutting the equator and all its parallels equally. The north pole then goes into the dark, and does not emerge till the earth has completed a semi-revolution of its orbit, or from September 22 till March 20. Similar changes occur, *mutatis mutandis*, in the southern hemisphere. For the purpose of actually picturing the relations of the various members of the solar system to his mind, the reader may conveniently use Sir J. Herschel's illustration, as follows:—Choose any well-leveled field. On it place a globe two feet in diameter to represent the sun; Mercury will be represented by a grain of mustard seed, on the circumference of a circle 164 feet in diameter for its orbit; Venus a pea, on a circle 284 feet in diameter; the earth a (somewhat larger) pea, on a circle of 430 feet; Mars a rather large pin's head, on a circle of 654 feet; the asteroids grains of sand, in orbits of from 1,000 to 1,200 feet; Jupiter a moderate-sized orange, on a circle of half a mile; Saturn a small orange on a circle of four-fifths of a mile; Uranus a full-sized cherry, on a circle more than one and a half miles; Neptune an extra-sized cherry, on a circle of two and a half miles in diameter.

We have seen that while the stars remain fixed, to all appearance, on the celestial concave, the sun circuits around a great circle of the star-sphere, moving always in one direction, and at a rate which, though variable in different parts of the circuit, does not vary largely, and is constant for each part of the ecliptic. Moreover, to ordinary observation, continued for periods of a few years, the sun's path in the heavens appears to remain always the same, and to bear the same relation to the poles and equator of the rotating star-sphere.

But we have now to consider bodies which neither remain fixed like the stars, nor move in a constant apparent path like the sun

The moon is the most noteworthy of these bodies, because of her apparent size and brightness, and also because of the remarkable changes of appearance which she presents according to her varying position with reference to the sun. When she is seen near him in the heavens, she appears always like a fine sickle of light, with the horns turned away from him. When she is in the path of the heavens directly opposite to the sun, she appears with a full orb. When she is exactly midway between the point occupied by the sun and that

opposite to him, she appears as a semicircle of light, with the convexity toward the sun; and in positions intermediate to these she appears with more or less of her circle illuminated, according as she is nearer to or further from the point directly opposite the sun. All this corresponds with what would happen if the moon were an opaque orb nearer to the earth than the sun, and illuminated by him.

Now, when the moon is watched, even for a few hours only, she is found to be traveling on the star-sphere in the same direction as the sun (and, like him, on a path inclined to the equator), but much more rapidly than the sun travels. It is impossible to watch the moon completely round the heavens, because she is found to pass close to the sun once in each circuit, and when very near to him cannot be seen. But while she is visible, she travels continuously in one direction, and when she reappears, after having been for a day or two lost in the sunlight, she is seen to have shifted her place as though, during that interval, she had traveled continuously onward.

The moon's circuit of the star-sphere is found to be completed in about twenty-seven and one-third solar days. But her circuit, considered with reference to the sun, occupies a longer interval. Thus, suppose we observe her when she is opposite to the sun, or "full." Then she is in the same (or very nearly the same) place among the stars about twenty-seven and one-third days later. But in the meantime the sun has advanced along the ecliptic about 27°, and the point now directly opposite the sun has, of course, advanced by the same amount. The moon has, therefore, to travel further on before she is again exactly opposite the sun. It is found that this happens rather more than two days later; or in other words, that the interval between successive full moons amounts to about twenty-nine and one-half days. This interval is called a *lunar month*, or *lunation;* the period during which the moon completes the circuit of the heavens being called a *sidereal month*. The lunation is also called a *synodical month*.

The path in which the moon travels is found to be inclined at an angle of about 5° 9′ to the ecliptic. But continued observation shows that the path, while retaining this inclination, shifts slowly in position—the points where it intersects the ecliptic gradually retrograding (on the whole) until, in the course of about eighteen and one-half years, they have made a complete circuit of the ecliptic. It is also found that the moon moves, like the sun, with variable velocity in her apparent course. The parts of her path, however, where she moves most and least rapidly are not fixed in position like the corresponding parts of the sun's apparent circuit, but advance, traveling round in 8.85 years.

It follows, from the varying position of the moon's apparent path with respect to the ecliptic, that her range north and south of the equator is variable. When she crosses the ecliptic, at or near the two points where the ecliptic crosses the equator, the inclination of her path to the ecliptic is either added to or substracted from the inclination of the ecliptic to the equator, so that her range in declination is, in one case, 23° 27′ + 5° 9′, or 28° 36′; and in the other, 23° 27′ − 5° 9′, or 18° 18′. When she crosses the ecliptic at or near the two points where the ecliptic is furthest from the equator, the inclination of her path to the equator is nearly the same as that of the ecliptic, the two paths—the ecliptic, or sun's path, and the apparent lunar path—crossing the equator at different points.

From the observed parallactic displacement of the moon it is manifest, apart from the lunar phases, that the moon's orbit relatively to the earth lies within the sun's. While observing the stars, which maintain apparently a constant position on the uniformly rotating star-sphere, the ancients early noted five bodies, which seem to travel among the stars like the sun and moon, but not always in one direction. To these bodies they gave the name of planets, or wanderers (a term which also included the sun and moon, so that there were seven in all). Three could be seen sometimes throughout the night, sometimes in the morning, sometimes in the evening. To these were given the names Saturn, Jupiter and Mars; and careful observation showed that these bodies, when visible all through the night, always travel among the stars in a direction contrary to that of the sun's yearly and the moon's monthly motion, but that this retrograde motion continues only for a certain length of time, being preceded and followed by an advancing motion, which is greater in amount than the retrograde motion, so that, on the whole, these bodies are carried round in the same direction as the sun and moon. But this peculiarity was noticed, that when any planet was at the outermost parts of the successive loops the planet was lost to view in the sun's rays, lying nearly in the same part of the sky, whereas, when a planet was at the innermost parts of the successive loops the planet was always opposite the sun. This exact agreement between the times when the planet and sun were in *conjunction* or in *opposition*, and the tracing out of the apparent planetary loops, should have suggested, it would seem, a connection between the sun and planets; for if the earth were the center of the sun's motion, and each of the three planets had its looped path wherein to travel around the earth, there could be imagined no reason why the planet's motion round its loops should synchronise with the sun's motion on his nearly circular path.

This view should have been confirmed by the apparent motions of two other planets, Venus and Mercury, which were found to remain always within a certain apparent distance from the sun, never being seen on the part of the sky opposite to him. Venus, the brighter, was observed to have the greater range on either side of the sun, moving from about 46° on the east of the sun, when she is seen as the Evening Star, to about the same distance on the west of the sun, when she is seen as the Morning Star; while Mercury's greatest range on either side of the sun is more variable, being sometimes as great as 27°, and at other times not greater than 18°. So far as the motion of these planets on the star-sphere could be traced they appeared to follow looped paths, somewhat like the outer planets; but the nearer and farther parts of the successive loops were *both* lost to view, the two planets being always too near the sun's place in the heavens to be visible when tracing those parts of their paths.

The five planets were found to travel always within a certain range on either side of the ecliptic, Venus, which has the greatest range, being sometimes as far as 9° north, or 9° south of the equator. A zone, or band, having the ecliptic for its central circle, and bounded by circles 9° north and south of the ecliptic, so as to be 18° wide, came thus to be regarded as a sort of celestial roadway, outside of which the planets were never seen. This zone was called the *zodiac*, and it was probably in connection with the planetary rather than the solar motions that the zodiacal constellations were originally formed.

Considering the observed relation between the motions of all the five planets and those of the sun, it is remarkable that any of the astronomers of old time should have regarded the earth as the common center of solar and planetary movement. It is true that, by supposing each planet to travel around a center which

itself traveled round the earth, the looped paths of the planets might be explained. Yet the synchronism between all the movements in these small circles and the sun's supposed motion round the earth, was left wholly unexplained by that theory.

Far more reasonable was the ancient Egyptian system, by some described as identical with, but in any case closely resembling in essentials, the system of Tycho Brahe. Here the earth is the center of the motions of the sun and moon, but all the planets circle around the sun, Venus and Mercury moving in orbits passing between the earth and sun, while Mars, Jupiter, and Saturn move in orbits passing outside the earth. All the observed movements, and all the peculiarities of the observed relations, were fully explained by this system. It is not too much to say that Tycho's system is not only fully equal to the Copernican in its fitness to explain the observed relations, but that, until the law of gravitation had been established, the arguments for the Tychonic system, modified so as to correspond to Kepler's discovery of the shapes of the different orbits, were almost equal in weight to those used by the disciples of Copernicus. The slight advantage of the Copernican system in point of simplicity was counterbalanced by the difficulty of accepting, in those days, the belief that the stars lie at so inconceivably vast a distance that the motion of the earth in an enormous orbit around the sun (for the sun was known even then to lie many millions of miles from us) produces no perceptible change in the appearance and rotation of the star-sphere. That the whole span of the earth's orbit was as a mere point compared with the distance of the stars, so that the earth on one side of the sun was, in effect, at the center of the star-sphere, while it was equally at the center when on the opposite side, or many millions of miles from its former position, was not unreasonably regarded by Tycho Brahe as scarcely credible.

Leaving the rotation of the star-sphere out of consideration, the apparent motions of the sun, the moon, and the five planets known to the ancients, are most naturally explained by regarding the sun as the center around which Mercury, Venus, the earth, Mars, Jupiter and Saturn revolve in that order as to distance, while the moon revolves round the earth. For though there are thus two centers of motion, yet only a small body traveling in a relatively small orbit is set revolving round the earth, now presented as a subordinate orb in the system; and the whole family, including the moon, are set revolving around the sun, for the moon accompanies the earth in her circuit. In the Tychonic system the sun, though presented as a subordinate orb, because traveling round the earth, was yet set as the center round which all the planets revolved. Either system was, however, altogether more reasonable than the Ptolemaic, in which all the planets were supposed to move around imaginary centers. It is hardly necessary to point out that the arrangement suggested by Copernicus explains the motions of the sun and moon as readily as the system which presents both these bodies as moving around the earth. Peculiarities in the motions of the earth and moon are indeed left unaccounted for by a simple theory of uniform circular motion around the sun and earth as centers; but so they were in the Ptolemaic system until eccentric and epicyclic movements were provided, and these were as admissible in the Copernican theory as in the Ptolemaic. But although the Copernican theory explains the general features of planetary motion, it could not, as originally advanced, explain those features which had rendered necessary the eccentrics and the subordinate epicycles of the Ptolemaic system. It was known to Copernicus that the earth does not move uniformly in a circle around the sun as center, but by an eccentric path with varying velocity. He might, therefore, reasonably assume that the other planets have paths similarly eccentric, and move with varying velocities. But he thought it necessary to explain the planetary motions by uniform motion in circles, using such contrivances to save appearances as the Ptolemaic system had rendered familiar to astronomers. Tycho Brahe, having completed a series of observations of Mars, the nearest planet moving on a manifestly eccentric orbit, Kepler tested the theory of Copernicus in order to ascertain whether any eclipse could account for the observed positions of the planet. Kepler was led at last to abandon the attempt to explain the motions of Mars by combining circular uniform motions. Passing to the ellipse, as the curve which Mars appeared to follow, and testing various empiric laws of motion in an elliptic orbit, he at length lighted upon the actual relation, presented in his first two laws as true for all the planets, though actually proved only in the case of Mars. The laws are these:—

1. *Every planet moves in an elliptical orbit, in one focus of which the sun is situated.*

2. *The line drawn from the sun to a planet, or the radius-vector of the planet, sweeps over equal areas in equal times.*

It remained now to discover if any law connected the periods in which the planets pursue their different paths. He did not at first try to connect the periods and the distances by any direct numerical relation, probably because he had recognized in the second law the probable existence of geometrical relations. But after many years of inquiry he arrived at the conclusion, that probably the required law connected the powers of the numbers representing the periods and the distances. It affords a strange evidence of the ponderous nature of Kepler's movements, that after this idea had occurred to him, ten weeks, instead of some ten minutes, elapsed before he had verified it. The law connecting the periods and distances—Kepler's third law—is this:—

3. *The squares of the numbers representing the periodic times of the planets vary as the cubes of the numbers representing their mean distances.*

The three laws of Kepler are approximately true for bodies circling around the same center. They do not apply to bodies circling around different centers. It was probably the recognition of this fact which first put astronomers on the track of the theory that the law depends on some force residing in the centers round which different bodies move. Newton certainly had given attention to this influence before he dealt with the moon's attraction earthward as a case of the action of terrestrial gravity. But, be that as it may, it is certain that so soon as the action of the earth's attraction on the moon had been demonstrated by him he extended the law of gravitation to all cases of motion around a central orb. It then became clear that the laws of Kepler are consequences of the general law of gravitation—the law, viz., that

Every particle of matter in the universe attracts every other particle with a force varying directly as the masses, and inversely as the square of the distances.

The proof of the law of gravitation divides itself into three distinct parts:—

First, The proof that the force acting on the moon is equal to the force of terrestrial gravity, reduced as the inverse squares of the distances of the moon and of a point on the earth's surface, from the center of the earth.

Secondly, The proof that a system of bodies circling around a central body like the sun, attracting them with a force inversely proportionate to their respective distances, would obey the laws of Kepler, or some modification of those laws, giving results according with the motions actually observed.

Thirdly, The proof that the mutual attractions of the several members of any system, and the attractions of members of one system on bodies belonging to another system (as, for instance, of the sun upon the moon regorded as a dependent of the earth), would result in such perturbations from the paths due to the attractions of the central body as are observed actually to take place.

The moon is, roughly, at a distance from the earth's center equal to 60 radii of the earth, and therefore the earth's moving force is less on her than on a body at the earth's surface as 1 to 3600. Now, regarding the moon's orbit as a circle, it is easily shown that, if at any moment the earth's attraction ceased to act, so that for the next second the moon moved on a tangent to her present course, her distance from the earth's center at the end of that second would be rather more than $\frac{1}{19}$th of an inch greater than at the beginning of the second. It follows that her fall toward the earth in a second on account of the earth's attraction amounts to rather less than $\frac{1}{19}$th of an inch. But the fall of a body near the earth's surface is about $16\frac{1}{10}$th feet, or nearly 193 inches per second, or nearly 193x19 times greater than the fall of the moon toward the earth per second; that is, about 3600 times greater. In other words, the moon is attracted toward the earth precisely as she would be if the force of gravity acting on bodies near her surface ruled her also, the law of variation of the force with distance being that of the inverse squares.

This relation which is true for elliptic orbits, is general for all systems, and gives the means of comparing the masses of different systems. But it is necessary to observe a modification which Kepler's third law and this extension of it have to undergo to make them strictly true (as regards, at least, the unperturbed motions of the planets). The masses of the planets, though very small, yet bear definite relations to the sun, and instead of considering each planet as swayed by the sun's mass, we must regard each as swayed by the sum of its own mass and the sun's, supposed to be gathered at the sun's center. Thus we must regard the planets as revolving around centers of different attractive energy; Jupiter round a center equal in mass to Jupiter and the sun; Saturn round a center equal in mass to Saturn and the sun, etc. Instead, then, of the ratio being constant for the solar system, we find that this ratio for any given planet is proportional to the sun's mass added to that planet's.

These laws suffice to enable us to deduce from the observed periods of the planets their true mean distances, velocities, etc., and from the observed period of the satellite of any planet, the ratio of the planet's mass to the sun's. The eccentricities of the planetary orbits are partly deduced from observation, and partly from the law of the equable description of areas. The inclinations of the orbits, and, of course, all elements relating to the planets' own globes, their dimensions, compression, inclination, rotation, and so on, are obtained by telescopic observation and measurement.

The sun, the central and ruling body of the planetary system, and the source of light and heat to our earth and all the members of that system, is a globe about 852,900 miles in diameter. So far as observation extends, his figure is perfectly spherical, no difference having been observed between his polar and spherical diameters. It has been well remarked, indeed, by Sir G. Airy, that if any observer could by ordinary modes of measurement satisfy himself that a real difference existed between the diameters, that observer would have proved the inexactness of his own work; for the absence of any measurable compression comes out as the result of comparisons between thousands of observations of the sun's limbs made at Greenwich and other leading observatories. The volume of the sun exceeds the earth's 1,252,700 times. His mean density is almost exactly one-fourth of the earth's, and his mass exceeds hers about 316,000 times. Gravity at the surface of the sun exceeds terrestrial gravity about 27.1 times, so that a body dropped from rest near the sun's surface would fall through 436 feet in the first second, and have acquired a velocity of 872 feet per second.

Viewed with the naked eye, the sun appears only as a luminous mass of intense and uniform brightness; but when examined with the telescope, his surface is frequently observed to be mottled over with a number of dark spots, of irregular and ill-defined forms, constantly varying in appearance, situation, and magnitude. These spots are occasionally of immense size, so as to be visible even without the aid of the telescope; and their number is frequently so great that they occupy a considerable portion of the sun's surface. Sir W. Herschel observed one in 1779, the diameter of which exceeded 50,000 miles, more than six times the diameter of the earth; and Scheiner affirms that he has seen no less than fifty on the sun's disk at once. Most of them have a deep black nucleus, surrounded by a fainter shade, or *umbra*, of which the inner part, nearest to the nucleus, is brighter than the exterior portion. The boundary between the nucleus and umbra is in general tolerably well defined; and beyond the umbra a stripe of light appears more vivid than the rest of the sun.

The discovery of the sun's spots has been attributed to Fabricius, Galileo, and Scheiner, and has been claimed for the English astronomer Harriot. Among these conflicting pretensions it is perhaps impossible to arrive at the truth; but the matter is of little importance; the discovery is one which followed inevitably that of the telescope, and an accidental priority of observation can hardly be considered as establishing any claim to merit.

The solar spots furnish an extensive subject of curious speculation. They are interesting on account of their establishing the fact of the rotation of the sun, and affording the means of determining its period.

Sir William Herschel, with a view to ascertain more accurately the nature of the sun, made frequent observations upon it from the year 1779 to the year 1794. He imagined the dark spots on the sun to be mountains, which, considering the great attraction exerted by the sun upon bodies placed at its surface, and the slow revolution it has upon its axis, he thought might be more than 300 miles high, and yet stand very firmly. He says that in August, 1792 he examined the sun with several powers from 90 to 500, when it evidently appeared that the dark spots are the opaque ground or body of the sun, and that the luminous part is an atmosphere, through which, when interrupted or broken, we obtain a view of the sun itself. Hence he concluded that the sun has a very extensive atmosphere, consisting of elastic fluids that are more or less lucid and transparent, and of which the lucid ones furnish us with light. This atmosphere, he thought, cannot be less than 1,843 nor more than 2,765 miles in height; and he supposed that the density of the luminous solar clouds needs not be much more than that of our aurora borealis, in order to produce the effects with which we are acquainted. The sun, then, if this hypothesis be admitted, "is similar to the other globes of the solar system with regard to its

solidity, its atmosphere, its surface diversified with mountains and valleys, its rotation on its axis, and the fall of heavy bodies on its surface; it therefore appears to be a very eminent, large, and lucid planet, the primary one in our system, disseminating its light and heat to all the bodies with which it is connected."

Herschel supposed that there are two regions or strata of solar clouds; that the inferior stratum is opaque, and probably not unlike our own atmosphere, while the superior is the repository of light, which it darts forth in vast quantities in all directions. The inferior clouds act as a curtain to screen the body of the sun from the intense brilliancy and heat of the superior regions, and, by reflecting back nearly one-half of the rays which they receive from the luminous clouds, contribute also greatly to increase the quantity of light which the latter send forth into space, and thereby perform an important function in the economy of the solar system. The luminous clouds prevent us in general from seeing the solid nucleus of the sun; but in order to account for the spots, he supposes an empyreal elastic gas to be constantly forming at the surface, which, carried upward by reason of its inferior density, forces its way through the planetary or lower clouds, and mixing itself with the gases which have their residence in the superior stratum, causes decomposition of the luminous matter, and gives rise to those appearances which he describes under the name of *corrugations*. Through the openings made by this accidental removal of the luminous clouds, the solid body of the sun becomes visible, which, not being lucid, gives the appearance of the dark spots or nuclei seen through the telescope. The length of time during which the spots continue visible renders it evident that the luminous matter of the sun cannot be of a liquid or gaseous nature; for, in either case, the vacuity made up by its accidental removal would instantly be filled up, and the uniformity of appearance invariably maintained.

But, perhaps, the most important of all the discoveries which have been made respecting the sun spots, are those which relate to the variation of these objects in number, and in the amount of solar area which they cover. We owe the initiation of observations on these points to Schwabe of Dessau. They were commenced in the year 1826, and continued without intermission, except in one case, during the astronomer's illness, for forty-six years. Before many years had elapsed, Schwabe discovered that the spots wax and wane in frequency in a period of about eleven years. At the time of spot-minimum the sun remains often for several days not only clear of spots, but with a singular smoothness of aspect, even the minute mottlings ordinarily seen on his surface either passing away for a time or becoming less conspicuous than usual. From such an epoch there is a gradual return to the spotted condition, and usually in four or five years the maximum of spot-frequency is reached; then there is a more gradual reduction, until, in rather more than eleven years on the average, the minimum is reached.

Among the most interesting discoveries in solar physics are those which have been effected by means of the spectroscopic analysis, not only as regards the constitution of the sun himself, but as to the nature of the solar spots and faculæ, as well as of the various objects which lie outside the sun's visible surface, and are only rendered discernible during the darkness of total solar eclipses.

The evidence of the spectroscope respecting the sun's constitution is too intimately associated with the history of spectroscopic analysis to be properly discussed at any length in this place. We propose, therefore, to present results, rather than to describe in detail the processes by which these results have been obtained, or the considerations on which must be based the interpretation of such results.

It has been shown, then, that the light of the sun comes from an orb glowing with intense *white* light—that is, light of all refrangibilities. Hence the sun is either liquid or solid, or if vaporous, then so greatly compressed that, in fact, the condition of its vapors is unlike that of any gases with which we are familiar. But inasmuch as the rainbow-tinted streak constituting the solar spectrum is crossed by a multitude of dark lines, it is seen that the glowing mass of the sun is surrounded by a complex vaporous envelope at a lower temperature. Nevertheless we are not to suppose that the vapors constituting the solar atmosphere are in any sense cool. In fact, we find from the position of the dark lines of the solar spectrum that the vapors of magnesium and sodium, of iron, copper, and other metals, exist in the true solar atmosphere, which implies an excessive intensity of heat. We know also that the vapors of the solar atmosphere, although less intensely hot than the glowing mass of the sun, are yet so hot as to be brightly luminous. It must not be supposed either that no other terrestrial elements exist in the sun, or that no other coincidences are recognizable. With each improvement in spectroscopic appliances fresh coincidences are determined. Moreover, it is certain that many elements existing in the sun may forever escape notice, simply because their vapors in the solar atmosphere may be either insufficient in quantity, or too low down to produce any recognizable effect.

The evidence given by the spectroscope respecting the solar spots confirms the theory that these are due to the existence of masses of relatively cool vapors at a lower level, and therefore relatively more compressed than the vapors elsewhere existing in the solar atmosphere. For the spectrum of the umbra of a spot differs chiefly from the spectrum of the solar photosphere in the greater strength and breadth of some of the dark lines.

Another very curious phenomenon connected with the sun is the faint nebulous aurora which accompanies him, known by the name of the *Zodiacal Light*. This phenomenon was first observed by Kepler, who described its appearance with sufficient accuracy, and supposed it to be the atmosphere of the sun. Dominic Cassini, however, to whom its discovery has been generally but erroneously attributed, was the first who observed it attentively, and gave it the name which it now bears. It is visible immediately before sunrise, or after sunset, in the place where the sun is about to appear, or where he has just quitted the horizon.

The general opinion respecting the zodiacal light at the present day is, that it forms the outer part of the solar corona, so that if the light of the sun could be for a time obliterated without rendering his appendages invisible, we could see the corona merging gradually into the faint glow of the zodiacal light.

Mercury and Venus.

Mercury is a small body, but emits a very bright white light, though he is seldom to be seen, always keeping near the sun.

Mercury is about 3,060 English miles in diameter, and his mean distance from the sun about thirty-five millions of miles. On account of his smallness and brilliancy, it is extremely difficult to find any spot on his disk so distinctly marked as to afford the means of determining his rotation. An attentive observation of the variation of the phases of Mercury led Schröter to infer that the planet revolves about its axis in a period of twenty-four hours five minutes thirty seconds. M. Harding discovered in 1801 an obscure streak on the southern hemisphere of the planet, the observations of

which, together with those of a spot discovered by Schröter, gave the same period of rotation. Schröter states that Mercury's form is spherical, exhibiting no sensible compression; that his equator is very considerably inclined to his orbit, and the differences of his days and seasons must consequently be very great; and that there are mountains on his surface which cast very long shadows, and of which the height bears a greater proportion to the diameter of the planet than those of the Earth, the Moon, or even of Venus. The height of Chimborazo is $\frac{1}{1017}$ of the radius of the earth; one of the mountains in the moon has been estimated at $\frac{1}{214}$ of her radius; the highest in Venus at $\frac{1}{144}$; and one in Mercury at $\frac{1}{126}$. But recent observations render it exceedingly doubtful how far Schröter's observations can be trusted. There are no observations to prove decisively whether Mercury is surrounded by an atmosphere.

Venus, the most beautiful object in the heavens, is about 7,510 English miles in diameter, and is placed at the distance of sixty-six millions of miles from the sun. Although the oscillations of this planet are considerably greater than those of Mercury, and she is seldom invisible, yet on account of the uniform brilliancy of her disk, it is extremely difficult to ascertain the period of her rotation. Dominic Cassini, after having long fruitlessly attempted to discover any object on her surface so well defined as to enable him to follow its motions, at length, in 1667, perceived a bright spot, distant from the southern horn a little more than a fourth part of the diameter of the disk, and near the eastern edge. By continuing his observations of this spot, Cassini concluded the rotation of Venus to be performed in about twenty-three hours; but he does not seem to have considered this conclusion as deserving of much confidence. In the year 1726 Bianchini, an Italian astronomer, made a number of similar observations for the same purpose, from which he inferred that the rotation of the planet is performed in twenty-four days eight hours. The younger Cassini has shown, however, that the observations of Bianchini, as well as those of his father, could be explained by a rotation of twenty-three hours and twenty-one or twenty-two minutes, whereas the rotation of twenty-four days eight hours cannot be reconciled with the appearances observed by the elder Cassini. The determination of Cassini was regarded by astronomers as the more probable of the two, particularly as Bianchini was not able to make his observations in a connected manner, because a neighboring building intercepted his view of the planet, and obliged him to transport his telescope to a different situation. The question of the rotation of Venus was again attacked by Schröter, who found it to be performed in twenty-three hours twenty-one minutes nineteen seconds. Each of the three observers found the inclination of the axis of rotation to the axis of the ecliptic to be about 75°. Much doubt, however, still exists with respect to the value of this element, which De Vico sets at little more than 50°.

Since the time of rotation of Mercury and Venus is nearly equal to that of the earth, the compression of these planets at the poles, which results from the centrifugal force, ought also to be nearly in the same proportion. But at the distance of the earth the compression must be imperceptible even in the case of Venus; for, supposing it to amount to $\frac{1}{300}$, the difference between the radius of her poles and that of her equator would only amount to a tenth of a second as seen from the earth.

During the transits of Venus over the sun's disk in 1761 and 1769 a sort of penumbral light was observed round the planet by several astronomers, which was occasioned, without doubt, by the refractive powers of her atmosphere. Wargentin remarked that the limb of Venus which had gone off the sun, showed itself with a faint light during almost the whole time of emersion. Bergman, who observed the transit of 1761 at Upsal, says that at the ingress the part which had not come upon the sun was visible, though dark, and was surrounded by a crescent of faint light; but this appearance was much more remarkable at the egress; for as soon as any part of the planet had disengaged itself from the sun's disk, that part was visible with a like crescent, but brighter. As more of the planet's disk disengaged itself from that of the sun, the part of the crescent farthest from the sun grew fainter, and vanished, until at last only the horns could be seen. The total immersion and emersion were not instantaneous; but as two drops of water, when about to separate, form a ligament between them, so there was a dark shade stretched out between Venus and the sun; and when this ligament broke, the planet seemed to have got about an eighth part of her diameter from the limb of the sun. The numerous accounts of the two transits which have been published abound with analogous observations, indicating the existence of an atmosphere of considerable height and density. During the transit of 1874 these appearances were so satisfactorily seen, that no doubt can remain as to their reality. Schröter calculated that the horizontal refraction of the atmosphere of Venus must amount to 37′ 34″, differing little from that of the terrestrial atmosphere. A twilight which he perceived on the cusps afforded him the data from which he deduced this conclusion, on which, however, very little reliance can be placed.

The atmosphere of Venus has been analysed with the spectroscope by Vogel, and the existence of aqueous vapor is regarded as demonstrated. On the occasion of the late transit (1874) Tacchini made spectroscopic observations, which seem more satisfactorily to establish the fact that there is water on Venus, than Vogel's observations.

Cassini and Montaigne imagined that they had observed a satellite accompanying Venus; but this appears to have been an optical illusion arising from the strong light of the planet reflected back from the convex surface of the eye upon the eye-glass of the telescope, and thence reflected a second time back to the eye. During the transits of Venus in 1761 and 1769, and in the transit of 1874, no trace of a satellite was seen; and there can be now no doubt whatever that Venice is without a satellite.

The Earth.

The earth is the third member of the solar system in order of distance from the sun. From what has been already shown, in determining the relative position of the earth and the celestial bodies seen in our skies, we know that the earth is a globe, rotating on her axis once in a day, and circling around the sun in an orbit of great extent once in a year.

It has been found by numerous and accurate experiments, that the lengths of arcs of 1° on the same meridian are greater in proportion as we advance nearer the pole. Hence, on account of the similarity of the isosceles triangles of which these arcs form the bases, their sides, or the terrestrial radii, must also be longer, and consequently the convexity of the earth is less toward the poles than at the equator. The surface of the earth is extremely irregular, even independently of the inequalities occasioned by mountains and cavities; yet it has been discovered that the meridional curves differ almost insensibly from ellipses; whence it is concluded that the figure of the earth is an ellipsoid of revolution about its shortest axis. In comparing the results of the

various measurements which have been made with the formulæ belonging to the dimensions of such a body, this conclusion has been fully verified; and the lengths of the arcs, the ellipticity, the distance of the pole from the equator, and, in short, all the elements of the spheroid, have been determined.

An arc of the meridian in India was measured by Col. Lampton in the early part of this century. But its value has been much increased by Col. Everest's extension of the arc. The arc of Lambton, extending from Punnæ (lat. 8° 9′ 35″) to Damargidą (lat. 18° 3′ 15″), was measured after the model of the English trigonometrical survey. From Damargida, where Lambton's arc terminated, another was measured by Col. Everest to Kaliana (lat. 29° 30′ 48″), a space of 797 miles, covering an arc of 11° 27′ 33″, the latest geodetical improvements being introduced. The whole extent of Lambton's and Col. Everest's operations includes a continuous arc of 21° 21′ (1,477 miles). The work was rivaled in extent by a vast operation executed in Russia and other northern countries of Europe, by which an arc of 25° 20′, extending from the banks of the Danube to the shores of the Arctic Sea, near the North Cape, was measured under the general superintendence and direction of W. Struve.

The arcs of India and of Russia include a space from lat. 8° to lat. 71°, with the exception of only about sixteen degrees, and are unquestionably the most important which exist for the determination of the earth's figure. When to them we add the French arc of 12° 22′ in a medium latitude, it will scarcely be necessary to take into account any other, at least for the northern hemisphere.

Capt. A. R. Clark, R. E., combining all the results obtained up to the year 1860, arrived at conclusions thus stated by Sir J. Herschel:—"The earth is not exactly an ellipsoid of revolution. The equator itself is slightly elliptic, the longer and shorter diameters being respectively 41,852,864, and 41,843,096 feet. The ellipticity of the equatorial circumference is therefore $\frac{1}{4\cdot 8\,3}$, and the excess of its longer over its shorter diameter about two miles. The vertices of the longer diameter are situated in longitude 14° 23′ E. and 194° 23′ E. of Greenwich, and of its shorter in 104° 23′ E. and 284° 23′ E. The polar axis of the earth is 41,707,-796 feet in length, and consequently the most elliptic meridian (that of longtitude 14° 23′ and 194° 23′) has for its ellipticity $\frac{1}{2\,8\,7\cdot 5}$, and the least (that of longitude 104° 23′ and 284° 23′) an ellipticity of $\frac{1}{3\,0\,8\cdot 3}$."

Gen. Schubert, using a method which Sir J. Herschel justly regards as less trustworthy, "makes the ellipticity of the equator $\frac{1}{8\,8\,8\,5}$, and places the verticles of the longer axis 26° 41′ to the eastward of Capt. Clark's. His polar axis, as deduced from each of the three great meridian arcs, the Russian, Indian, and French respectively, is 41,711,000 feet, 41,712,534 feet, and 41,697,-496 feet, the mean of which, giving to each a weight proportional to the length of the arc from which it is deduced, is 41,708,710 feet."

The figure and volume of the earth being thus determined, we require only to ascertain its mean density in order to know its mass. But this problem has not been solved, probably cannot be solved, with any very near approach to exactness.

It may be fairly assumed that the earth's mean destiny amounts to about 5·6 times the density of water, combining which with the known dimensions of the earth, we find that the earth's weight in tons may be roundly expressed by the number 6,000,000,000,000,000,000,000.

We have next to inquire into the rotation of the earth about its axis, and especially into the position of that axis.

The longitudes of the stars are measured on the ecliptic from the vernal equinox; and therefore, if the line of the equinoxes, which is the same as the line of the nodes, is invariable, the longitude of any star will always be the same, whatever interval of time may elapse between two observations of that longitude. But on comparing the actual state of the heavens with the observations recorded by ancient astronomers, it is perceived that the longitudes of all the stars are considerably increased. The phenomenon is to be explained by attributing to the equinoctial points a retrograde motion from east to west, in consequence of which the sun, whose motion is direct, arrives at them sooner than if they remained at rest; and therefore the equinoxes, and spring, autumn, and the other seasons happen before the sun has completed an entire circuit. On this account the motion has been denominated the *Precession of the Equinoxes*. As this motion is extremely slow, its exact amount can be discovered only by a comparison of observations separated from each other by long intervals of time. The comparison of modern observations with those of Hipparchus gives as its annual amount 50⅔″. The mean result of the observations of Tycho, compared with those of Lacaille, gives 50⅓″. On comparing modern observations with one another, we find 50″·06. Delambre, in his solar tables, supposes the annual precession to be equal to 50″·1. According to this estimate the equinoctial points go backward at the rate of 1° in 71·6 years nearly, and therefore, will make a complete revolution of the heavens in about 25,868 years.

If the sun and moon moved in the plane of the equator, there would evidently be no precession; and the effect of their action in producing it varies with their distance from that plane. Twice a year, therefore, the effect of the sun in causing precession is nothing; and twice a year, namely, at the solstices, it is a maximum. On this account the obliquity of the ecliptic is subject to a semi-annual variation; for the sun's force, which tends to produce a change in the obliquity, is variable, while the diurnal motion of the earth, which prevents the change from taking place, is constant. Hence the plane of the equator is subject to an irregular motion which is technically called the *Solar Nutation*. The existence of the solar nutation is, however, only a deduction from theory, for its amount is too small to be perceptible by observation; but a similar effect of the moon's action is sufficiently appreciable, and was, in fact, discovered by Bradley before theory had indicated its existence. Its period, however, is different, and depends on the time of the revolution of the moon's nodes, which is performed in eighteen years and about seven months. During this time the intersection of the lunar orbit with the ecliptic has receded through a complete circumference; and the inequality of the moon's action will consequently in the same time, have passed through all its different degrees. Bradley observed that the declinations of the stars continued to augment during the nine years, that they diminished during nine years following, and that the greatest change of declination amounted to 18″. He remarked further, that this motion was connected with an irregularity of the precession of the equinoxes, which followed exactly the same period; whence he concluded that the motion of the poles of the equator, occasioned by this vibration of its plane, was not confined to the solstitial colure. A series of observations on stars differently situated proved that all the phenomena could be explained on the hypothesis that the pole of the equator describes in eighteen years a small circle of 18″ diameter, contrary to the order of the signs; or that the axis of the earth, following the circumference of this circle, describes the

surface of a cone, the axis of which forms with its side an angle of 9″. This apparent vibratory motion is denominated the *Nutation of the Earth's Axis.*

While the shape of the earth's orbit and the position of its center (whose longitude=long. of perih. x 180°) thus undergo continual alteration, her mean distance from the sun remains appreciably constant. This we know from the length of the year, which certainly has not changed ten seconds in length since the time of the Chaldean determination of that element.

There are various ways of determining the sun's distance from the earth in terms of the earth's semidiameter. The distance of a planet from the sun may likewise be obtained if we can find the means of measuring its distance from the earth at any epoch, for the geocentric positions of the sun and the planet being known from the theory of their motions, the radius vector of the orbit, or planet's distance from the sun at that epoch, may be found by a simple trigonometrical computation. To determine the distance of a planet from the earth it might seem only necessary to determine its horizontal parallax; but in general the parallaxes of the planets are quantities by far too small to be directly observed.

The application of the transits of Venus to the determination of the sun's distance was first pointed out by Dr. Halley, when he announced the transit of 1761. The transit of Venus in 1769 was observed in many different parts of the world. The result of the whole of the observations led to the conclusion, that the parallax of the sun is included within the limits 8″·5 and 8″·7. The mean 8″·6 was adopted by Delambre and Lalande; and later the value 8″·5776 was deduced by Encke from a careful re-examination of all the observations made in 1761 and 1769. But several methods have been since applied to the determination of the solar parallax, with results which appear to agree in indicating a larger value for the parallax, or in other words, a smaller value for the sun's distance, than had been deduced from the transits of 1761 and 1769.

One of these depends on the moon's motions, and was first indicated by Laplace toward the close of the last century. Since the moon's distance from the earth, though small compared with the sun's, bears yet a measurable ratio thereto, it follows that there is not a perfect symmetry between the perturbations produced by the sun when the moon is passing from third to first quarter, and from first to third. The effect of this circumstance is recognizable in the lunar motions, which are affected by a minute variation arising from this cause, and called the *Parallactic Inequality.* It amounts at the maximum to about 2′; and as it depends on the proportion of the sun's distance to the moon's known distance, its amount supplies a means of determining the solar parallax. In 1854 Hansen announced, in a letter addressed to the astronomer royal, that this method, applied to his new tables of the lunar motions, gives a parallax of 8″·9159.

A second method depends on the fact, that the earth in reality revolves, in the course of a lunar month, around the common center of gravity of her own globe and the moon's. The diameter of the orbit thus circuited by the earth (in the same sense, at least, as the moon may be said to circuit in her monthly orbit) amounts to about 6,000 miles, and by the radius of this small orbit the earth is sometimes in advance of and sometimes behind her mean position in heliocentric longitude. The sun's geocentric longitude is affected to precisely the same degree as the earth's heliocentric longitude; and by determining the actual amount of the sun's displacement, we can ascertain what angle the mean diameter of the earth's monthly orbit subtends at the sun. Leverrier, by the careful study of a great number of observations of the sun made at the principal observatories in Europe, came to the conclusion that the solar parallax is 8″.95. But Mr. Stone of Greenwich detected a numerical error in Leverrier's computations, and when this is corrected, the value 8″.91 results. Prof. Newcomb of Washington has by the same method deduced the value 8″.84.

The Moon and its Motions.

The different appearances or phases of the moon were probably thefirst celestial phenomena observed with any degree of attention. The following definitions may conveniently be given in this place. When the moon passes the me-ridian at the same time with the sun, she is said to be in *Conjunction.* The two points of her orbit in which she is situated when in opposition and conjunction are called the *Syzygies;* those which are 90° distant from the sun are called the *Quadratures;* and the intermediate points between the syzygies and quadratures arecalled the *Octants.*

A slight attention to the lunar phases during a single revolution will be sufficient to prove that they are occasioned by the reflection of the sun's light from the opaque spherical surface of the moon. This fact, which was recognized in the earliest ages, can be made obvious by the help of a diagram. If the moon is an opaque body, we can only see that portion of her enlightened side which is toward the earth.

Since the parallax of the moon is subject to incessant variation, it is necessary to assume a certain mean value, about which the true and apparent values may be conceived to oscillate. This is called the constant of parallax. The best modern observations assign 57′ 2″.7 as the value of the lunar mean equatorial horizontal parallax, corresponding to a distance of 238,813 miles.

The *Ascending Node* of the lunar orbit is that point of the ecliptic through which the moon passes when she rises above the ecliptic toward the north pole. The *Descending Node* is the opposite point of the ecliptic, through which she passes when she descends below that plane toward the south. The position of the nodes is not fixed in the heavens. They move in a retrograde direction, or contrary to the order of the signs; and their motion is so rapid that its effects become very apparent after one or two revolutions.

The mean retrograde motion of the nodes is found, by the comparison of observations made at distant epochs, to amount to 19° 21′ 18″.3 in a mean solar year, and the time in which they make a tropical revolution is consequently 6793.391 mean solar days. The inclination of the lunar orbit is observed to vary between 5° 3′ aud 5° 13′. The mean inclination may be taken at 5° 8′.

The inclination of the lunar orbit to the plane of the terrestrial equator occasions considerable differences in the intervals between the moon's rising or setting on successive days, and gives rise to the phenomenon of the *Harvest Moon.*

The moon's orbit at any moment is an ellipse, having the earth at one of the foci; but this orbit is continually changing in form and position, but on the whole advancing at an average rate of 40⅔° per annum, so as to complete a sidereal revolution in 3232.575 mean solar days. These changes, like those which affect the inclination of the orbit and the position of the nodes, are due to the perturbing influence of the sun on the moon's motions relatively to the earth. The consideration of these perturbations, whether as affecting the figure and position of the moon's orbit, or her motions in that orbit, constitutes what is called the *Lunar Theory.*

Understanding by the term *month* the time which the moon employs to make an entire revolution relatively

to any given point, movable or fixed, we have as many different species of months as there are different motions with which that of the moon can be compared. For example, if we estimate her revolution relatively to the sun, the month will be the time which elapses between two consecutive conjunctions or oppositions. This is called the *synodic month*, *lunar month*, or *lunation*. If we consider her revolution as completed when she has gone through 360° of longitude counted from the movable equinox, we shall have the *tropical* or *periodic month*. The interval between two successive conjunctions with the same fixed star is the *sidereal month*. A revolution with regard to the apsides of her orbit, that is to say, the time in which she returns to her perigee or apogee, gives the *anomalistic month*. And, finally, the revolution with regard to the nodes is the *nodical month*.

The moon at all times presents very nearly the same face to the earth. It is proved by observation, that there are some variations in the apparent position of the spots on the lunar disk. Those which are situated very near the border of the disk alternately disappear and become visible, making stated periodical oscillations, which indicate a sort of vibratory motion of the lunar globe (apparent only), which is known by the appellation of the *Libration*.

The rotation of the moon is sensibly uniform, while the motion of revolution is variable. The apparent rotation occasioned by the revolution of the moon round the earth is, consequently, not exactly counterbalanced by the real rotation, which remains constantly the same. Hence the different points of the lunar globe must appear to turn about her center, sometimes in one direction, and sometimes in the contrary, and the same appearances be produced as would result from a small oscillation of the moon, in the plane of her orbit, about the radius vector drawn from her center to the earth. The spots near the eastern or western edge of her disk disappear according as her motion in her orbit is more or less rapid than her mean motion. This is called the *Libration in Longitude*. Its maximum value corresponds to a rotation through 7° 45′.

Further, the axis of rotation of the moon is not exactly perpendicular to the plane of her orbit; hence the two poles of rotation, and those parts of her surface which are near these poles, are alternately visible from the earth. This is called the *Libration in Latitude*. Its maximum value amounts to 6° 44′.

Again, the observer is not placed at the center of the earth, but at its surface. Thus in the course of a day the moon appears to oscillate about her radius vector because of the earth's rotation. This phenomenon constitutes what is called the *Diurnal Libration*, and is evidently the effect of the lunar parallax, and corresponds to it in amount, measured in minutes of arc. It therefore never exceeds 1° 1′ 28″.8.

The libration in latitude and the diurnal libration were discovered by Galileo soon after the invention of the telescope. It was Hevelius who discovered and first explained the libration in longitude..

The coincidence of the nodes of the lunar equator and orbit ranks among the most curious discoveries of modern astronomy. It was shown by Lagrange to be a necessary consequence of the attraction which the earth exercises on the lunar spheroid.

The various features of the moon's surface have been observed with great interest since the discovery of the telescope, and astronomers have been at much pains to determine their selenographic positions. On account of their number, it has been found necessary to distinguish them by particular names. Riccioli designated the most conspicuous of them by the names of astronomers and other eminent men. Hevelius gave them the names belonging to countries, islands, seas, and regions on the earth, without reference to situation or figure. The nomenclature of Riccioli is now universally followed. Delineations of the lunar disk have been given by Hevelius, in his *Selenographia*, by Cassini, Russell, Schröter, Lohrmann, and others.

That there are great inequalities on the surface of the moon is proved by looking at her through a telescope at any other time than when she is full; for then there is no regular line bounding the dark and illuminated parts, but the confines of these parts appear as it were toothed and cut with innumerable notches and breaks; and even in the dark part, near the borders of the enlightened surface, there are seen some small spaces illuminated by the sun's beams. It is impossible that this should be the case, unless these shining points were higher than the rest of the surface, so that the rays of the sun may illumine their summits before they reach their basis. Portions of considerable extent are also perceived on the lunar surface, which are never brilliant like the other parts, but remain constantly obscure. These are thought by some to be old sea-bottoms; they were formerly supposed to be seas, but this idea has been abandoned. Some of these cavities are upward of four English miles in depth, and forty in circumference at the orifice. An insulated mountain is frequently observed to rise in the center of these enormous pits or caverns, and they are surrounded by high annular ridges, the masses of which would fill the inclosed cavities. Herschel imagined that he even observed volcanoes in activity; but it is now known that he mistook for volcanic light the effects of earth-light reflected from those parts of the moon's surface which have the highest reflective capacity.

Eclipses.

Strictly speaking, the term eclipse extends to all cases in which one celestial body is wholly or partially obscured by another, either by direct intervention or by the interception of light illuminating the former, so that the term includes transits of inferior planets, the concealment of stars by the moon or by a planet, or the concealment of a satellite by its primary. But the term eclipse is for convenience limited to the three following orders of phenomena: (1) The total or partial concealment of the sun by the moon, called a *solar eclipse*. (2) The obscuration of the moon by the shadow of the earth, called a *lunar eclipse*. (3) The concealment of a satellite of a planet by the shadow of the primary, called *eclipses of satellites*, and distinguished from *occultations* in which the *disk* of the primary hides the satellite from view.

Solar and lunar eclipses can be considered together, so far as the general law of their sequence is concerned. From what has been already shown, it follows that, if the motions of the sun and moon could be watched continuously from the center of the earth, the moon would be seen to pass round the star-sphere once in each sidereal month on a path inclined about 5° 8′ to the ecliptic, while the sun would complete the circuit of the ecliptic once in a sidereal year; and the moon would pass the sun's place once in each synodical month. The place of conjunction of the sun and moon would clearly pass round the star-sphere, advancingly, making the complete circuit of the heavens once in each year on the average; and the same would happen with the place of conjunction of the moon and the point directly opposite the sun. Moreover, as the moon at these conjunctions would, of course, be on her own apparent orbit, and that orbit is inclined to the sun's, it is clear that, supposing the moon's orbit fixed, the conjunction of sun and moon during one-half of the year would

occur with the moon in the northern half of her apparent orbit, and those in the other half would occur with the moon in the southern half of her orbit. The same would be true of the conjunctions of the moon with the point opposite the sun, only, of course, the halves of the lunar orbit would be interchanged. At or near the time when the place of either conjunction was crossing from the northern to the southern side of the moon's orbit, or *vice versa*, the conjunction would occur with the moon so near to the ecliptic, that if the conjunction were one of sun and moon, she would hide the sun's disk wholly or partially, while, if the conjunction were one of the moon with that point opposite the sun toward which the earth's shadow is thrown, she would enter that shadow wholly or partially. In other words, at two seasons separated by six months there would be eclipses of the sun or moon, or both, whereas during the intervening months no eclipses would occur.

The number of eclipses which could occur in either eclipse-season would depend on the rate at which the points of successive conjunction approached and left the ecliptic, on the proximity necessary for the occurrence of an eclipse of either sort, and also on the manner in which the lunar node happened to be passed. For example, suppose that a conjunction of the sun and moon occurred when the moon was exactly at a node, so that a central eclipse of the sun occurred; then, half a synodical month before and half a synodical month after that conjunction, there would be a conjunction of the moon with the point opposite the sun, and the moon being only half a month's journey from her node, would be at a point of her orbit not far from the ecliptic. But the extent of the earth's shadow is such, that the moon would only be partially in the penumbra, and penumbral lunar eclipses are not considered by astronomers. There would therefore be only one eclipse in such an eclipse-season, viz., a central solar eclipse. Next, suppose that when the moon was at her node, she was exactly opposite the sun, then there would be a total lunar eclipse. Half a lunation later and earlier she would be in conjunction with the sun, and she would be at a point of her orbit not far from the ecliptic. In this case, although during half a month from nodal passage, the moon, supposed to be viewed from the earth's center, gets to a distance from the ecliptic exceeding the sum of her own and the sun's semidiameters, and therefore *so viewed* would pass clear of the sun, yet for the earth, regarded as a whole, she would not pass quite clear of the sun. In this case, then, there would be three eclipses, one lunar and total, the other two solar and partial. These results would be approximated to if the conjunction of sun and moon in the first case, or of moon and sun-shadow in the second case, occurred with the moon very near a node. But otherwise there would be an eclipse either solar or lunar a few days before her nodal passage, and another either lunar or solar a few days after her nodal passage, and no other eclipse of either sort in that eclipse-season.

All this corresponds to the actual conditions except in one respect. The lunar nodes retrograde, so as to meet the advancing conjunction-points of either kind; and thus, instead of a year being occupied in the complete circuit of the conjunctions, the actual interval has for its mean value the mean interval between the successive conjunctions of the sun with the rising node of the moon's orbit, or 346.607 days. Accordingly, the average interval between successive eclipse-seasons is 173.3 days instead of half a sidereal year.

Noting that eclipse-seasons last on the average about thirty-three days, and that three eclipse-seasons each having three eclipses cannot occur in succession, it is easy to determine the greatest and least number of eclipses which may occur in any single year. The average interval between successive eclipse-seasons is 173.3 days. Two such intervals amount together to 346.6 days, or fall short of a year by about nineteen days. Hence there cannot be three eclipse-seasons in a year; for each eclipse-season lasts on the average thirty-three days. But there may be two seasons, each containing three eclipses, followed by a season containing two eclipses, only one of which can occur in the portion of the eclipse-season falling within the same year. In this case there would be seven eclipses in the year. So also there would be seven if in the first season there were three, in the second two, and in the third three, for then the portion of the third falling within the year, being rather more than one-half, would comprise two eclipses. So also if the three successive seasons comprise severally two, three, and three eclipses.

There may then be as many as seven eclipses in a year, in which case at least four eclipses will be solar, and at least three of these partial, while of the lunar eclipses two at least will be total.

As regards the least possible number of eclipses, it is obvious that, as there must be two eclipse-seasons in the year, and at least one eclipse in each, we cannot have less than two eclipses in the course of a year. When there are only two, each eclipse is solar and central.

The Planet Mars.

After Venus, Mars is the planet whose orbit is nearest to the earth. His diameter is about 4,400 miles, and his volume about one-sixth of the earth's; his mass, however, is little more than one-ninth of hers, his density being estimated at only seven-tenths of the earth's. His mean distance from the sun is about 139,000,000 miles; but the eccentricity of his orbit amounting to 0.093262, his greatest and least distances differ considerably from this mean value, amounting to 152,304,000 and 126,318,000 miles respectively. It follows that his distance from the earth when in opposition varies largely—in opposition near his perihelion his distance is about 33,800,000 miles, whereas, when he is near aphelion, his opposition distance amounts to 61,800,000 miles. As he is also more brightly illuminated by the sun when in perihelion, it follows that he appears much brighter when in opposition at that part of his orbit.

In other words, the planet is nearly five times as bright at one of the favorable oppositions as at one of the unfavorable. The planet's synodical period being 779.936 days, or two years and about 49½ days, it follows that the place of opposition performs a complete circuit of the ecliptic in an average period of rather more than seven times the synodical period, so that the change in the place of opposition nearly corresponds to the earth's yearly motion. It is said that Fontana first noted the spots of Mars, and suspected the planet's rotation. But Fontana's credit is shaken by his alleged discovery of *seven* Jovian satellites. Cassini observed the spots at Bologna in 1666, and having continued his observations for a month, determined the planet's rotation-period as 24 h. 40 m. Cassini in 1670 again observed the planet, obtaining the same rotation-period as before. Maraldi in 1704 noted changes in the shape of the spots; but from some which underwent little change, he deduced the rotation-period 24 h. 39 m. In 1719, when Mars was exceedingly well placed for observation, Maraldi again carefully observed the planet, deducing from the observations of thirty-seven days a rotation-period identical with Cassini's.

Besides the dark spots, which have a somewhat greenish color, the rest of the disk being mostly ruddy, astronomers had noticed a portion of the disk around the south pole which was brightly white. The bright

appearance so remarkable about the poles of Mars was ascribed by Herschel to the reflection of light from mountains of ice and snow accumulated in those regions.

Asteriods.

On the first day of the present century a new planet was discovered, which, although in one sense seeming to fill up a gap in the solar system, was yet unlike any hitherto known member of the planetary family. Kepler and Titius, followed in later times by Bode, had adopted the view that a planet was wanting to complete the symmetry of the solar system, as indicated by a certain law of progression in the planetary distances. Toward the close of the last century, when Uranus had but lately been discovered and found to obey the law of distances, it was natural that the attention of astronomers should be directed to the strange gap in the series between Mars and Jupiter. So great was the confidence with which many now regarded the law, that the theory was advanced that a planet invisible to the naked eye was traveling within the seemingly vacant space; and through the exertions of Baron de Zach, an association of twenty-four astronomers was formed to search the zodiac for the unseen planet. Yet the discovery was not made by any member of this society. Wollaston had laid down a star in his catalogue where no star could be seen. Piazzi carefully examined the neighborhood, to determine whether some star really existing there had been misplaced by Wollaston. On January 1, 1801, he noted a small star in Taurus, which on January 3 had changed its place. He wrote to Oriani and Bode; but the planet, which was at its stationary point, following opposition, on January 12, had become invisible owing to its approach to the sun, before the letter reached them, and Piazzi himself fell ill soon after. But Gauss, the eminent mathematician, undertook to compute the new planet's orbit and motions from the observations made by Piazzi, and at length, after long searching, De Zach rediscovered the planet on December 3, 1801, Olbers independently discovering it on the following evening. Piazzi gave to the new planet the name Ceres. Besides differing from the other known planets in being so small as apparently to belong to a different order, Ceres was found to have an inclination (of more than 10½°) exceeding largely even that of Mercury. But these anomalous relations were soon found to be but the first indications of a discovery altogether more remarkable.

During his long and arduous search for Ceres, Dr. Olbers of Bremen had had occasion to examine with peculiar care the stars near her path. On March 28, 1802, he observed a star near Bode's stars 20 and 191 Virginis, where he felt sure that no star had existed during his former observations. After two hours it had moved very much as Ceres had done when he had first seen her almost in the same spot. Subsequent observations showed that this was a small planet (to which the name Pallas was given) traveling in an orbit having a mean distance of about 2.770 (earth's as 1), slightly exceeding, therefore, that of Ceres, but with an eccentricity of .248, considerably exceeding that of any known planet, and an inclination of 34° 39′, exceeding the sum of the inclinations of all the other planets together. The effect of this great inclination on the geocentric position of the planet is even more remarkable than the heliocentric range of more than 69° in latitude. For when Pallas is at her greatest heliocentric latitude, and near opposition, her geocentric latitude exceeds 42°. This is very different from Venus's range of less than 9° in geocentric latitude, which had been regarded as the maximum, and had led astronomers to assign to the zodiac a breadth of 18°. A zodiac to include the asteroids should be 90° in breadth, and would cover seven-tenths of the whole heavens.

While Harding of Lilienthal was charting the stars near the paths of Ceres and Pallas in the region thus indicated, he determined, on September 2, 1804, the position of a small star in Pisces, near 93 and 93 of Bode's catalogue. On September 4 the star was no longer in the same position. It was found to be a planet (to which the name Juno was given) traveling at a mean distance of 2.67 (considerably less than that deduced for Ceres and Pallas), in an orbit having eccentricity 0.257, and inclination 13° 1′. The effect of this great eccentricity is remarkable, as may be thus indicated—supposing the apsides of the orbit to correspond to the planet's solstices, then the summer of one hemisphere is only half as long as the winter of that hemisphere, or as the summer of the other.

Next Olbers, pursuing the same method, discovered Vesta, moving in an orbit having mean distance 2.373 (far less even than Juno's), eccentricity 0.0898, and inclination 7° 71′.

A long interval then elapsed without the discovery of any new members of this remarkable family. It was not until December 8, 1845, that the fifth was recognized. On that night M. Hencke, an amateur astronomer of Driessen, discovered the body since named Astræa. He communicated his discovery to Encke and Schumacher, who confirmed it by observations made with more powerful telescopes. M. Hencke also discovered the sixth planet, on July 1, 1847. Since that time not a year has passed without the discovery of one or more minor planets; and in some years as many as ten or twelve have been added.

Jupiter and Saturn.

Jupiter is the largest planet of the solar system. Indeed he surpasses the rest so greatly, that the combined mass of all of them together would barely exceed two-fifths of his. This superiority is deserving of more consideration than it has commonly received. If we are justified in regarding our moon or the asteroids as belonging to a different order of bodies from the earth, Venus, Mars, and Mercury, because so much less than them in mass, we may not unreasonably regard Jupiter as belonging to a different order, because so much exceeding in mass the planets which travel within the zone of asteroids. The earth exceeds the moon only eighty-one times in mass, but Jupiter exceeds the earth in mass more than 300 times.

Jupiter travels at a distance from the sun exceeding the earth's five and one-fifth times, or at a mean distance of 475,692,000 miles. The eccentricity of his orbit is considerable, amounting to 0.048239, so that his greatest and least distances amount respectively to 498,639,000 miles and 452,745,000 miles. When in opposition, and at his mean distance, his distance from the earth amounts to about 361,000,000 miles. His orbit is inclined about 1° 18′ 40.3″ to the eclipse. His sidereal revolution is completed in 4332.5°48 days, or 11 years 314.92 days; whence it is easily calculated that his synodical period, or the interval separating his mean returns to opposition, has a mean value of 398.867 days. His mean diameter is nearly 85,000 miles in length. His volume exceeds the earth's 1233.205 times, but his density is only about one-fourth of hers, and his mass does not exceed hers more than 301 times.

Although the actual order of discovery would lead us to speak of the satellites of Jupiter before considering the features of his globe, it will be for several reasons more convenient to describe these features first. Cassini was the first to discover that Jupiter's globe is surrounded by belts apparently belonging to his surface. The features of these belts, as described by Cassini, are

those which still continue to be recognized. Their number is variable; sometimes only one can be readily discerned, while at others the whole surface is covered by them. They are generally parallel to one another, but not always so. Their breadth is likewise variable, one belt having been observed to grow narrow, while another in its neighborhood has increased in breadth, as if one had partially flowed into the other; and in this case a part of an oblique belt is commonly recognized between them, as if forming the channel of communication. Sometimes the belts remain unchanged for months; at others, new belts have formed in an hour or two. Although his surface appears thus variable, yet at times spots have been visible for several weeks, whose motions have served to indicate the law of the planet's rotation.

In 1665 Cassini observed a spot near the large central belt of Jupiter. It moved more quickly when near the middle of the disk than when near the edge, and also appeared narrower when at the edge, showing that it belonged to the surface (that is, to what appears as the surface) of the planet. This principal or ancient spot, as it is called, is the largest and most permanent of any yet discovered. It appeared and vanished eight times between the years 1665 and 1708, then continuing invisible till 1713. The spot has been frequently observed since, sometimes remaining visible for two or three years in succession, at others being unseen for as long or longer.

The equator of Jupiter is inclined only 3° $5'$ $30''$ to the planet's orbit, so that there can be no appreciable seasonal changes. We should expect, therefore, a great calm to reign in the atmosphere of this planet, the more so that the sun's heat poured upon each square mile of it is (on the average) less than the 27th part of that received by each square mile of the earth's surface. Moreover, the seasons of Jupiter last nearly twelve times as long as ours, so that we should expect all changes in his atmosphere produced by solar action to take place with exceeding slowness.

Soon after the invention of the telescope, Galileo discovered that four small orbs or satellites circle around Jupiter. Galileo soon found that their orbits are nearly circular, and their motions nearly uniform. They revolve in planes inclined little to the plane of the ecliptic, so that as viewed from the earth they appear to traverse very narrow ellipses.

Saturn is the largest planet but one of the solar system, being surpassed in mass by Jupiter alone. His mass exceeds the combined mass of all the other planets (Jupiter excepted) nearly three fold. He is the sixth planet in order of distance from the sun, and was the remotest planet known to the ancients. He travels at a mean distance of 872,137,000 miles from the sun, his greatest distance being 920,973,000 miles, his least distance 823,301,000 miles. The eccentricity of his orbit is 0.055996, and the inclination 2° $29'$ $28''$ to the plane of the ecliptic. Saturn's mean sidereal period of revolution in his orbit is 29 years 167 days (see the *Elements*, p. 782); his mean synodical revolution, or the mean interval between his successive returns to opposition, is 378.090 days. The planet's mean diameter is about 70,000 miles, his polar diameter about 3,500 miles less, his equatorial diameter about 3,500 miles greater. In volume he exceeds the earth nearly 700 times, but in mass only about 90 times, his density being less than the earth's in the proportion of about 13 to 100. He rotates on his axis in about 10½ hours, the plane of his equator being inclined nearly 27° to the plane of his orbit.

This planet, in consequence of a luminous ring with which he is surrounded, is one of the most interesting objects in the heavens. This singular appendage was first noticed by Galileo, to whom the planet presented a *triple* appearance, as if a large orb were situated between two small bodies or *ansæ*. He observed that sometimes the ansæ were so enlarged as to present the appearance of a continuous ring; at other times they entirely disappeared, and Saturn appeared round like the rest of the planets. After a certain time they again became visible, and gradually increased in magnitude. These curious appearances were shown by Huyghens to be occasioned by an opaque, thin, circular ring surrounding the equator of Saturn, and at a considerable distance from the planet. Saturn moving in the plane of his orbit, carries the ring along with him, which, presenting itself to the earth under different inclinations, occasions all the phenomena which have been described.

Among the most remarkable discoveries of recent times with regard to the rings of Saturn is that of the *inner dusky or semi-transparent ring*, sufficiently obvious to any observer capable of using well a moderately good telescope, but which, previously to the year 1850, was only once mentioned by any astronomer. Dr. Galle of Berlin saw this ring with the Berlin refractor in 1838, but the attention of the scientific world was not generally drawn to it. The account of Galle's observations is accompanied by drawings exhibiting the trace of the dusky ring where it crosses the body of the planet. In the year 1850 the ring was recognized almost simultaneously by two observers, namely, by Prof. Bond of the Cambridge Observatory, U. S., and by Mr. Dawes. Since that time there has been no difficulty in seeing this appendage, though it requires a practiced eye and a good telescope. The opinion now generally entertained respecting the Saturnian ring-system is, that it is composed of multitudes of minute satellites, probably intermixed with vapor, traveling independently around the planet. On no other supposition, indeed, can the permanence of the ring-system be explained.

From observations of some obscure belts, and a very conspicuous spot on the surface of Saturn, Sir W. Herschel concluded that his rotation is performed in 10 hours 16 min. He also observed that the globe of Saturn appeared to be flattened at the equator as well as at the poles.

Saturn is surrounded by a system of eight satellites—the most extended as well as most numerous subordinate system within the sun's domain. The span of the orbit of the outermost satellite amounts to nearly four millions of miles. This satellite is probably larger than our moon, while Titan, the 6th satellite, is nearly as large as the planet Mercury.

Uranus and Neptune.

Uranus is the seventh primary planet in order of distance from the sun, and, with the exception of Neptune, the remotest. His mean distance from the sun exceeds the earth's more than nineteen times, and amounts to 1,753,869,000 miles. But the eccentricity of the orbit is considerable, amounting to 0.0466; consequently, the variation of the planet's distance is also great, his greatest distance amounting to 1,835,561,000 miles, his least to 1,672,177,000 miles. The sidereal revolution of Uranus is performed in 30,686 days, or 84 years 6½ days. His mean diameter is about 33,000 miles. The apparent diameter of the sun seen from Uranus is less than $\frac{1}{19}$th of the diameter of the sun as we see him, or is but about $1\frac{2}{3}'$; and the apparent surface of the sun is but about the 367th part of the apparent surface of the sun we see. Accordingly, the light and heat received by Uranus are less in the same proportion. It has been asserted that Uranus turns upon an axis in about 9½ hours, but the evidence on which this statement rests is slight and insufficient.

Uranus was discovered by Sir W. Herschel on March 13, 1781, while he was examining the small stars in the neighborhood of Geminorum. Being struck with the enormous magnitude of a star in this region, he suspected it to be a comet. He examined it with higher power, and found the disk enlarged, which would not be the case with a star. He therefore announced the discovery of a comet. But it was found to be moving in a nearly circular path, and was presently recognized as one of the principal planets of the solar system. Herschel gave it the name of Georgium Sidus, and foreign astronomers called it Herschel, but the name Uranus, suggested by Bode, of Berlin, is now universally adopted. In 1787 Herschel discovered that it was attended by two satellites, and he subsequently supposed that he had discovered four others; but there is great reason to believe that he had mistaken small stars near the planet for satellites. Two other satellites inferior to the rest have been discovered by Mr. W. Lassell, completing the series of four satellites.

Little of interest has rewarded the telescopic study of Uranus; nor has the spectroscope given any trustworthy evidence, though Secchi, Huggins, and Vogel recognize peculiarities distinguishing the spectrum of Uranus from that due to reflected sun-light.

The discovery of the planet Neptune ranks amongst the most brilliant of the scientific feats of the present century.

For many years the orbit of Uranus had been the occasion of great embarrassment to astronomers, from the impossibility of adequately reconciling the ancient and modern observations by any one set of elements, and from the rapid increase of the error from year to year. Bouvard early suggested that some planet exterior to Uranus caused these apparent irregularities. Among the astronomers who entered seriously upon the task of determining the position of such a disturbing planet two arrived at a successful solution of the problem, namely, Mr. Adams and M. Leverrier.

Almost immediately after the discovery of Neptune, it was found to be attended by one satellite. This discovery was made by Mr. Lassell in October, 1846. The orbit of the satellite is inclined to the ecliptic at an angle of about 29°.

Comets and Meteors.

The comets form a class of bodies belonging to the solar system, distinguished from the planets by their physical appearance and the great eccentricities of their orbits.

While the orbits of all the planets are confined within a narrow zone, or to planes not greatly inclined to the ecliptic, those of the comets are inclined in all possible angles. They have received the name of comets (*coma*, hair) from the *bearded* appearance which they frequently exhibit.

One of the most remarkable periodic comets with which we are acquainted is that known to astronomers as Halley's. Having perceived that the elements of the comet of 1682 were nearly the same as those of two comets which had respectively appeared in 1531 and 1607, he concluded that all the three orbits belonged to the same comet, of which the periodic time was about 76 years. After a rough estimate of the perturbations it must sustain from the attraction of the planets, Halley predicted its return for 1757—a bold prediction at that time, but justified by the event, for the comet again made its appearance as was expected, though it did not pass through its perihelion till the month of March, 1759, the attraction of Jupiter and Saturn having caused, as was computed by Clairaut previously to its return, a retardation of 618 days. This comet had been observed in 1066, and the accounts which have been preserved represent it as having then appeared to be four times the size of Venus, and to have shone with a light equal to a fourth of that of the moon. History is silent respecting it from that time till the year 1456, when it passed very near to the earth; its tail then extended over 60° of the heavens, and had the form of a saber. It returned to its perehelion in 1835, and the splendor of its appearance rendered it once more an object of universal interest; it was well observed in almost every observatory.

Another famous comet, whose periodic returns have been verified by observation, received the name of Encke, the astronomer who first recognized it as having been observed in previous revolutions. It returns to its perihelion in 1,208 days. Encke's comet, although its identity was not discovered till 1818, had been frequently observed, as in 1789, 1795 and 1805; and on these occasions it exhibited very different appearances, having been seen with and without a nucleus, and with and without a tail—circumstances which account for its having so long escaped being recognized as a regular attendant on the sun.

The appearances exhibited by comets are diversified, and sometimes remarkable. That which appeared in the year 134 B.C., at the birth of Mithridates, is said to have had a disk equal in magnitude to that of the sun. Ten years before this, one was seen which, according to Justin, occupied a fourth part of the sky (that is, extended over 45°), and surpassed the sun in splendor. Another, equally remarkable, appeared in the year 117 of our era; and in 479 there was one, of which the disk, according to Freret, was of such magnitude, that it might have occasioned the extraordinary eclipse of the sun which took place about that time. In 400 one was observed, which is said to have resembled a sword, and to have extended from the zenith to the horizon. That of 531 was of greater magnitude still, and its appearance more terrific. Those which appeared in 1066 and 1505 exhibited disks larger than that of the moon. It is, however, probable that these accounts were exaggerated; for since comets have been observed by astronomers, no instances have occurred in which their magnitudes and appearances have been so extraordinary. The most remarkable among those of which we possess accurate accounts appeared in the years 1456, 1618, 1680, 1744, 1759, 1769, 1807, 1811, 1841, 1858, 1861 and 1874.

It is only of late years that the study of meteors or falling stars has come to be regarded as belonging to astronomy. Even now the discovery of the connection of meteors and comets is so recent, and the aspect under which the new department of astronomy presents itself varies so continually as fresh relations are recognized, that it seems desirable to limit our remarks to the statement of a few broad facts. It has been shown, then, that meteors travel in systems round the sun, and that displays of falling stars occur when the earth passes through a meteor-system.

There are already recognized more than one hundred meteor-systems, known by the direction in which the corresponding falling stars encounter the earth.

The best-known meteor-systems are those which produce a shower on November 13-14 in certain years, and those which usually produce a display on August 10-11. The former have been called the Leonides, because the part of the stellar sphere whence the meteors appear to radiate is in the constellation Leo. The latter, for a like reason, appearing to radiate from Perseus. have been called the Perseides

The great multitude of stars visible even to the naked eye renders it impossible to distinguish each by a particular name; astronomers, accordingly, for the sake of

reference, have formed them into groups, known as *Constellations* or *Asterisms*. To these the early astronomers gave the names of men and animals and other objects from fancied resemblances or analogies, for the most part not easily traced. These denominations are preserved in modern catalogues, and the practice of delineating the object itself on celestial globes and charts has been only recently, if it has yet been altogether abandoned. The ancients distinguished some of the brightest stars in the different constellations by particular names; but to include others less conspicuous, it became necessary to adopt a different mode of proceeding. According to the usual method, first introduced by Bayer in his *Uranometria*, each of the stars in every constellation is marked by a letter of the Greek alphabet.

ASTURIAS, one of the ancient provinces of Spain, formerly (from 1388 downwards) conferred as a principality on the heir-apparent to the throne. By the new division of Spain in 1833, the province took the name of Oviedo, though not to the exclusion, in ordinary usage, of the older designation. It is bounded on the N. by the Bay of Biscay, on the S. by Leon, on the W. by Galicia, and on the E. by Santander, which is now incorporated with Old Castile. It consists of a portion of the northern slope of what is properly a part of the Pyrenean system, and is covered in all directions with offshoots from the main chain, by which it is almost completely shut in on all sides. Only a few of the passes across the mountains are practicable for carriages, and most of them are difficult even for horses. Along the coast there is a narrow strip of level ground, which consists largely of bare and moor-like reaches, covered with furze. The province, as might be supposed, is watered by numerous streams and rivers, which have hollowed out beautiful and picturesque valleys; but owing to the narrowness of the level tract, their courses are short, rapid, and subject to floods. The most important is the Nalon or Pravia, which receives the waters of the Caudal, the Trubia, and the Narcea, and has a course of 62 miles; after it rank the Navia and the Sella. Along the whole extent of the coast, a distance of 130 miles, there is not one good port. In that of Riba de Sella a large frigate may anchor, and Gijon will admit a vessel drawing 16 or 17 feet of water; but the entrance is in both cases difficult and dangerous. The climate of the district is generally mild, but overcharged with humidity, and in the higher regions the winters are protracted and severe. The broken character of the surface prevents anything like extensive agricultural industry, but abundant pasturage is found in the valleys. The wheat crop frequently fails. Rye succeeds better, and is often mixed with the maize which forms the principal food of all but the higher classes. Chestnuts — here, as elsewhere in Spain, an important article of diet — are very abundant on the hills, and the tree supplies valuable timber. Other timber-trees, such as oak and beech, are found in the mountains, along with various medicinal plants, such as hellebore, angelica, and valerian. Apples are abundant, and cider forms the common drink of the people; but little attention is paid to vines. The horses of Asturias are specially gentle and sure-footed, ranking among the best in Spain, and excelling those of Andalusia in strength, though surpassed by them in beauty. Wild deer, boars, and bears are not uncommon among the mountains; and the sea-coasts, as well as the streams, abound with fish of various kinds, including salmon and lampreys, which are sent to the markets of Madrid.

The capital of the province is Oviedo, and the other towns of importance are Gijon, Aviles, Llanes and Luarca.

ASUNCION, or ASSUMPTION, the capital of the Republic of Paraguay in South America. It is situated in the midst of a fertile territory on the eastern bank of the River Paraguay (here upwards of 600 yards in width), about 18 miles above the most northerly mouth of the Pilcomayo. It was one of the earlier Spanish settlements in this part of America, being founded in 1535 by Gonzalo de Mendoza and Juan de Salazar y Espinosa, and receiving its name of *Nuestra Señora de la Asuncion*, in honor of the festival of the Assumption. Originally a small fort, it soon became, from the convenience of its situation, a town of considerable importance, and in 1547 was erected into a bishopric. Formerly, while the Jesuits were masters of the country, it consisted of a rather irregular assemblage of one story houses, relieved by ecclesiastical buildings of varying pretension, from the cathedral downwards; but under the dictatorship of Francia, the streets were more symmetrically arranged, and a number of secular buildings erected. These were greatly increased under the rule of his successors, and Asuncion was brought into similarity with a European city of corresponding rank, having its government house, its president's palace, its arsenal, custom-house, barracks, military hospital, theater, and railway station. While the war between Paraguay and the neighboring states lasted, Asunçion suffered greatly, being taken and plundered in 1869 by the Brazilian forces, who had already bombarded it from the river. The population, Spanish for the most part in language, but of various races, was estimated, late in 1889, at 24,843, and carried on a somewhat extensive trade in Paraguay tea, or *Yerba Maté*, hides, tobacco, fruits, molasses, and rum.

ASYLUM, in *Greek Antiquities*, a temple enclosure, within which protection from bodily harm was afforded to all who sought it and could prove their danger. In a general sense, all Greek temples and altars were *asyla*, that is, it was a religious crime to remove by force any person or thing once under the protection of the deity. But it was only in the case of a small number of temples that this protecting right of a deity was recognised with common consent, and, apparently, these were among the oldest temples of Greece. Such, for example, was the temple of Athena Alea at Tegea in Arcadia, where King Pausanias II. spent the remainder of his days after the battle of Haliartus; or the temple of Ganymeda (Hebe) at Philus, where, it is said, persons who had escaped from prison hung up their chains in the sacred grove. Other instances are the sanctuaries of Poseidon at Calauria and Tænarum, of Athena at Chalcioecus at Sparta, and of Amphiarus at Oropus.

ASYLUM, a term now usually applied to homes for lunatics and idiots, deaf mutes and the blind. The word is used in some cases as a synonym for a refuge, for a sheltering place for orphans.

ASYMPTOTE (Gr. not coinciding), a line that continually approaches nearer and nearer to some curve, but only meets it at an infinite distance.

ATACAMA, a district of South America. (1.) The Chilian province has an area of about 38,000 square miles, with a population of 82,300. It is bounded S. by the province of Coquimbo, W. by the Pacific, and E. by the Argentine Republic. It is one of the richest copper and silver districts in the world, nearly 1000 mines being worked for the former metal, and about 250 for the latter. The silver ore was first discovered in 1832, by a shepherd, Juan Godoy, at a place which has since been occupied by a village that bears his name. The ores of lead and zinc are frequently found, and sulphur, alum, and salt are all of them abundant, the deposit of the last article alone covering about 50 square miles at the Laguna Salada. Gold likewise occurs in sufficient quantity to be mentioned in the list of exports

The capital of the province is Copiapo, with 13,380 inhabitants, and the population is principally clustered in the valleys of Copiapo and Huasco, and in the neighborhood of the various mines. Caldera is the principal port, and is connected with the capital and the eastern districts by the first railway constructed in South America. The value of the mineral exports through this and the adjacent ports was in 1889 estimated at 6,218,275 dollars. (2.) The Bolivian department has an area of about 70,000 square miles, with a population of about 18,000, which is rapidly increasing. It also owes its prosperity almost solely to its wealth in copper and silver. The mines of Caracoles, recently discovered, are said to be the most productive silver mines in the world. In other products it coincides with the Chilian province, with the addition, however, of meteoric iron, which has been found in remarkable masses. A large part of what is more especially designated the Desert of Atacamá is included in the department. It is not, as the name might suggest, a sandy, but for the most part a rocky and rugged, tract, with the merest patches and strips of vegetation. The capital of the department is Cobija, or, as it is officially called, Puerto de la Mar; but its prosperity is in some degree threatened by the rise of Mejillones, a seaport which has recently been connected by railway with the principal mining districts. See Phillippi, *Reise durch die Wüste Atacama*, Halle, 1860; Tchudi, *Reise durch die Andes*, a supplement to Petermann's *Mittheil.*, 1860; *Journ. Roy. Geog. Soc.* 1851, 1855.

ATAHUALLPA (*atahu*, Latin *virtus*, and *allpa*, sweet), called the last of the Incas, was the son of Huayna Capac, eleventh Inca of Peru, by the daughter of the conquered sovereign of Quito. His brother Huascar succeeded Huayna Capac; for, as Atahuallpa was not descended on both sides from the line of Incās, Peruvian law considered him illegitimate. He obtained, however, the kingdom of Quito, whether by stratagem or not is uncertain. A jealous feeling soon sprang up between him and Huascar, who insisted that Quito should be held as a dependent province of his empire. A civil war broke out between the brothers, and, though the details of it are not accurately known, it appears that just about the time when Pizarro was beginning to move inland from the town of San Miguel, Huascar had been defeated and thrown into prison, and Atahuallpa had become Inca. Pizarro set out in September, 1532, and made for Cassamarca, where the Inca was. Messengers passed frequently between them, and the Spaniards on their march were hospitably received by the inhabitants. On the 15th November, Pizarro entered Cassamarca, and sent his brother and Fernando de Soto to request an interview with the Inca. On the evening of the next day, Atahuallpa entered the great square of Cassamarca, accompanied by some five or six thousand men, who were either unarmed, or armed only with short clubs and slings concealed under their dresses. Pizarro's artillery and soldiers were planted in readiness in the streets opening off the square. The interview was carried on by the priest Vicente de Valverde, who addressed the Inca through an interpreter. He stated briefly and dogmatically the principal points of the Christian faith and the Roman Catholic policy, and concluded by calling upon Atahuallpa to become a Christian, obey the commands of the Pope, give up the administration of his kingdom, and pay tribute to Charles V., to whom had been granted the conquest of these lands. To this extraordinary harangue, which from its own nature and the faults of the interpreter must have been completely unintelligible, the Inca at first returned a very temperate answer. He pointed out what seemed to him certain difficulties in the Christian religion, and declined to accept as monarch of his dominions this Charles, of whom he knew nothing. He then took a Bible from the priest's hands, and, after looking at it, threw it violently from him, and began a more impassioned speech, in which he exposed the designs of the Spaniards, and upbraided them with the cruelties they had perpetrated. The priest retired, and Pizarro at once gave the signal for attack. The Spaniards rushed out suddenly, and the Peruvians, astonished and defenceless, were cut down in hundreds. Pizarro himself seized the Inca, and in endeavoring to preserve him alive, received, accidentally, on his hand the only wound inflicted that day on a Spaniard. Atahuallpa, thus treacherously captured, offered an enormous sum of money as a ransom, and fulfilled his engagement; but Pizarro still detained him, until the Spaniards should have arrived in sufficient numbers to secure the country. While in captivity, Atahuallpa gave secret orders for the assassination of his brother Huascar, and also endeavored to raise an army to expel the invaders. His plans were betrayed, and Pizarro at once brought him to trial. He was condemned to death, and, as being an idolater, to death by fire. Atahuallpa, however, professed himself a Christian, received baptism, and his sentence was then altered into death by strangulation. His body was afterwards burned, and the ashes conveyed to Quito. From the reports of the Spanish historians, it is impossible to gain an accurate idea of the character and abilities of the Peruvian monarch, and we have no other notices by which to test their account.

ATALANTA, in *Greek Legend*, (1) was connected with Arcadia, where, at her birth, she had been exposed on a hill, her father Jaison having expected a son. At first she was suckled by a she-bear, and then saved by huntsmen, among whom she grew up to be skilled with the bow, swift, and fond of the chase, like the virgin goddess Artemis. At the hunt of the Calydonian boar her arrows were the first to hit the monster, for which its head and hide were given her by Meleager. At the funeral games of Pelias, she wrestled with Peleus, and won. Melanion, with intense love, followed, fought, and toiled in her service, she despising love, and remaining true to Artemis long, but yielding at last. She was the mother of Parthenopæus. But there was (2) another Atalanta in Bœotian legends, who was to be obtained in marriage only by him who could outstrip her in a race, the consequence of failure being death. Hippomenes, before starting, had obtained from Aphrodite three golden apples, which at intervals in the race he dropped, and Atalanta, stopping to pick them up, fell behind. Both were happy at the result; but forgetting to thank the goddess for the apples, they were led by her to a religious crime, and for this were transformed into lions. Latterly the adventures of these two separate heroines were united and told as of one.

ATAXY, LOCOMOTOR (*a* priv., *τάξις* order—Synonyms, *Progressive locomotor ataxy*, *Tabes dorsalis*, *Posterior spinal sclerosis*), a disease of the nervous system, manifesting itself principally by disordered movements of the limbs in locomotion. This disorder is not, as was once supposed, a form of paralysis (there being no diminution of muscular strength), but is dependent on the loss of power of co-ordinating the muscles into harmonious action, which is essential to the proper performance of the voluntary movements of the body, and the maintenance of its equilibrium. Although the disease had been previously noticed both by Professor Romberg and Dr. R. B. Todd, it was first fully described and named by Dr. Duchenne in 1858. Its pathology has subsequently been investigated by Mr. Lockhart Clarke.

Locomotor ataxy usually begins insidiously, and advances slowly.

The pathelogical condition giving rise to locomotor ataxy is disease of a certain portion of the spiral cord, viz., the posterior columns and the posterior nerve roots. These undergo various transformations, which result in their ultimately becoming atrophied and indurated, When affecting, as this lesion most commonly does, the lower dorsal and lumbar regions of the cord, the ataxic symptoms are chiefly confined to the legs; but when it affects the cervical portion, the arms are involved. Occasionally the whole posterior columns of the cord are found diseased. The exciting causes of this malady are but ill understood. Exposure to cold and privation, intemperance, over exertion, and mental anxiety have been supposed to give rise to it.

ATBARA (Bahr-el-Aswad, or Black river), an important river of Eastern Africa. It rises in the mountains of Abyssinia, and unites with the Nile at El-Damer. During the rains it has an average depth of from thirty-five to forty feet.

ATCHAFALAYA (the Lost Water), a river of Louisiana, or secondary channel of the Mississippi, by which a portion of its water flows off from the main trunk into the Mexican Gulf. Its mouth is 120 miles west of the principal embouchure of the Mississippi.

ATCHISON, the county seat of Atchison county, Kan., is situated on the right bank of the Missouri river, equidistant from Leavenworth and St. Joseph. The railway facilities available are exceptionally complete and desirable, embracing the Atchison, Topeka and Santa Fé; Chicago, Rock Island and Pacific; Burlington and Missouri River; Kansas City, St. Joseph and Council Bluffs; Missouri Pacific; and Leavenworth Northern and Southern systems. The city also has communication with points on the Missouri and Mississippi rivers by steamers. Within the past ten years Atchison has grown rapidly in wealth and population, being to-day one of the most promising and enterprising cities of the West, and the railroad center of the State. It has thirteen churches, nine banks, three daily and three weekly papers, a court-house, high school, and five public school buildings, three colleges, a public library and an abbey conducted by the Society of St. Benedict, half-a-dozen large and well equipped hotels, an elegantly finished opera-house and a number of public halls, besides very many handsome private residences. A large iron railway and foot bridge spans the river opposite the city. The manufactures are numerous and varied, including carriages, furniture, hardware, oil, canned goods, lumber products, etc. The city is also the location of the machine and repair shops of the Burlington and Missouri River railroad. It is lighted by gas and electricity, enjoys street railway conveniences, and has a population (1890 census) of 14,222.

ATE, in *Greek Mythology*, a personification of criminal folly. She had misled even Zeus to take a hasty oath, when Heracles was born, for which, seeing his folly, he cast her by the hair out of Olympus, whither she did not again return. She fell, it was in later times said, on the hill where Troy was built.

ATELLA, an ancient city of Campania, about nine miles from Naples. In the second Punic war it sided with Hannibal, and, in consequence, its inhabitants were dispersed by the Romans, and their places supplied by the people of Nuceria. It is now after various fluctuations of fortune, a mere mass of ruins.

ATH, or AETH, a city of Belgium, in the province of Hainaut, situated on the river Dender, a navigable confluent of the Schelde, rather more than thirty miles by rail from Brussels. Population, 10,081.

ATHABASCA, or ATHAPESCOW, a river in the north-western territory of British North America, which flows into a lake of the same name. It rises in the Rocky Mountains, and has a long and tortuous course in a north-eastern direction, during which it receives the Lesser Slave River, the Red Deer, and several others. The lake is about 230 miles in length, with a breadth varying from 30 to 14 miles, lying in a direction almost E. and W. It communicates with Hudson's Bay on the one hand, and with the Polar Sea on the other.

ATHALIAH, the daughter of Ahab and wife of Jehoram, king of Judah, who, after the death of King Ahaziah, her son, caused all the male members of the royal house of Judah to be massacred, in order that she might usurp the throne. Among the victims were her own grandchildren, except the youngest, Joash, who was concealed in the temple by his aunt, Jehosheba, wife of the high priest, Jehoiada.

ATHANASIUS, ST., Bishop of Alexandria, and one of the most illustrious defenders of the Christian faith, was born at Alexandria about the year 297. Of his family, circumstances, or early education nothing can be said to be known, although a legendary story has been preserved by Rufinus of Aquileia as to the manner in which he came, while yet a boy, under the notice of his predecessor, Alexander. It seems certain that Alexander became his patron, took him as a youth into his house, and employed him as his secretary. This was probably about 313, and from this time Athanasius may be said to have been devoted to the Christian ministry. He was, no doubt, a student in the "Didascaleion," or famous "catechetical school" of Alexandria, which included amongst its already illustrious teachers the names of Clement and Origen. In the museum, the ancient seat of the Alexandrian university, he may have learned grammar, logic, and rhetoric. His mind was certainly well disciplined, and accustomed to discuss from an early period the chief questions both in philosopy and religion. The persecution under which the Alexandrian Church suffered at this time, and his intimacy with the great hermit Antony, of which he himself has told us, had all their effect upon his character, and served to nurture in him that undaunted fortitude and high spirit of faith by which he became distinguished. At the Council of Nicæa, in the year 325, he appears prominently in connection with the dispute. He attended the council, not as one of its members (who were properly only bishops or delegates of bishops), but merely as the attendant of Alexander. In this capacity, however, he was apparently allowed to take part in its discussions, for Theodoret (i. 26) states that "he contended earnestly for the apostolic doctrines, and was applauded by their champions, while he earned the hostility of their opponents. Within 'five months' after the return of Alexander to the scene of his episcopal labors he expired, and his friend and archdeacon was chosen to succeed him. He was elected 'in the sight and amidst the acclamations of the people.' He was now about 30 years of age, and is spoken of as remarkable both for his physical and mental characteristics."

The first few years of the episcopate of Athanasius were tranquil; but the storms in which the remainder of his life was passed soon began to gather around him. The Council of Nicæa had settled the creed of Christendom, but had by no means composed the divisions in the church which the Arian controversy had provoked. Arius himself still lived, and his friend Eusebius of Nicomedia rapidly regained influence over the emperor Constantine. The result of this was a demand made by the emperor that Arius should be re-admitted to communion. Athanasius stood firm, and refused to have any com-

munion with the advocates of a "heresy that was fighting against Christ." Constantine was baffled for the moment; but many accusers soon rose up against one who was known to be under the frown of imperial displeasure. The archbishop of Alexandria was charged with cruelty, even with sorcery and murder. It was reported that a Meletian bishop in the Thebaid, of the name of Arsenius, had been unlawfully put to death by him. He was easily able to clear himself of such charges, but the hatred of his enemies was not relaxed, and in the summer of 335 he was peremptorily ordered to appear at Tyre, where a council had been summoned to sit in judgment upon his conduct. He did not venture to disobey the imperial order, and a commission was appointed to inquire into an alleged instance of cruelty urged against him, notwithstanding the explanations which he had made. There appeared plainly a predetermination to condemn him, and he fled from Tyre to Constantinople to appeal to the emperor himself. "He resolved," says Gibbon, "to make a bold and dangerous experiment, whether the throne was inaccessible to the voice of truth." He presented himself suddenly with five of his suffragans before the emperor, while riding into his new capital. Refused at first a hearing, his perseverance was at length rewarded by the emperor's consent to his reasonable request — that his accusers should be brought face to face with him in the imperial presence. The leaders of the Tyrian council, amongst the most conspicuous of whom were the two Eusebii, were accordingly summoned to Constantinople, just after they had celebrated, at a great dedication festival at Jerusalem, the condemnation of Athanasius and the restoration of Arius to church communion. In confronting the former before Constantine they did not attempt to repeat the charge of cruelty, but found a more ready and effective weapon to their hands in a new charge of a political kind — that Athanasius had threatened to stop the Alexandrian corn-ships bound for Constantinople. Here, as in other matters, it is very difficult to understand how far there was any truth in the persistent accusations made against the prince-bishop of Alexandria. Probably there was in the very greatness of his character and the extent of his popular influence a certain species of dominance which lent a color of truth to some of the things said against him. On the present occasion his accusers succeeded in at once arousing the imperial jealousy; and the consequence was, that, notwithstanding his earnest denial of the act attributed to him, he was banished to Trier, or Treves, the capital of Gaul.

This was the first banishment of Athanasius, which lasted about two years and a half. It was only brought to a close by the death of Constantine, and the accession of Constantine II. as emperor of the West. It is recorded by himself that, on his return to Alexandria, "the people ran in crowds to see his face; the churches were full of rejoicing; thanksgivings were offered up everywhere; the ministers and clergy thought the day the happiest in their lives." But this period of happiness was destined to be short-lived. His position as patriarch of Alexandria placed him, not under his friend Constantine II., but under Constantius, another son of the elder Constantine, who had succeeded to the throne of the East. He in his turn fell, as his father had done, more and more under the influence of Nicomedian Eusebius, now transferred to the see of Constantinople. A second expulsion of Athanasius was accordingly resolved upon. The old charges against him were revived, with the addition of his having set at naught the decision of a council. It was further resolved on this occasion to put another bishop in his place. Accordingly, in the beginning of the year 340, a Cappadocian named Gregory, said to be an Arian, was installed by millitary force on the throne of the great defender of the faith, who, to save his followers from outrage, withdrew to a place of concealment. As soon as it was possible he repaired to Rome, to "lay his case before the church." He was declared innocent at a council held there in 342, and in another held at Sardica some years later. Julius, the bishop of Rome, warmly espoused his cause, and, generally, it may be said that the Western Church was Athanasian in its sympathies and its creed, while the majority of the Eastern bishops sided with the Eusebian party. This severance was clearly shown at the Council at Sardica, where the Orientals refused to meet with the representation of the Western Church, because the latter insisted on recognising the right of Athanasius and his friends to attend the council as regular bishops. The commonly received date of this council is 347, but the rediscovered *Festal Letters* of Athanasius have had the effect of throwing back this date for some years. It has been placed by some as early as the end of 343, by Mansi and others in the end of 344. The decision of the Council of Sardica, however, had no immediate effect in favor of Athanasius. Constantius continued for some time implacable, and the bold action of the Western bishops only incited the Arian party in Alexandria to fresh severities. Gradually, however, the excesses of the Arian party brought their own revenge, while the death of the intruded bishop Gregory, in the beginning of 345, opened up the way for a reconciliation betwixt the Eastern emperor and the banished prelate. The result was the restoration of Athanasius for the second time, amidst the enthusiastic demonstrations of the Alexandrian populace, which is represented by his panegyrist, Gregory Nazianzen, as streaming forth "like another Nile" to meet him in the distance as he approached the city. His restoration is supposed to have taken place, according to the more accurate chronology based upon the *Festal Letters*, in October 346.

For years at this time Athanasius held his ground in Alexandria. But the intrigues of the Arian or court party were soon renewed against him, and the feeble emperor, who had protested that he would never again listen to their accusations, was gradually stimulated to new hostilities. A large council was held at Milan in the spring of the year 355, and here, notwithstanding the vigorous opposition of a few faithful men amongst the Western bishops, a renewed condemnation of Athanasius was procured. This was followed up by the banishment of the faithful prelates, even of Hosius of Cordova, whose conciliatory character and intimate connection with the imperial family had not prevented him from addressing to Constantius a pathetic remonstrance against the tyranny of the Arian party. When his friends were thus scattered in exile, their great leader could not long escape; and on the night of the 8th of February 356, while he was engaged in service in the church of St. Thomas, a band of armed men burst into the sacred building. He has himself described the scene (*Apol. de fuga*, 24). Here for a time he maintained his composure, and desired the deacon to read the psalm, and the people to respond — "*For His mercy endureth for ever*;" and how, as the soldiers rushed forward with fierce shouts towards the altar, he at length made his escape in the crowd, and sought once more a place of safe retirement. The solitudes of Upper Egypt, where numerous monasteries and hermitages had been planted, appear to have been his chief shelter at this time. Here, protected from pursuit, he spent his time in literary labors in behalf of his cause; and to this period, accordingly, belong some of his most important writings, above all the great *Orations*,

or Discourses against the Arians, which furnish the best exposition of his theological position and principles.

For six years at this time Athanasius continued in exile, till the death of Constantius in November 361 opened once more the way for his return to his episcopate. Julian, the successor to the imperial throne, professed indifference to the contentions of the church, and granted permission to the bishops exiled in the late reign to return home. Amongst others, Athanasius took advantage of this permission, and seated himself once more upon his throne, amidst the jubilations of the people. He had begun his episcopal labors with renewed ardor, and summoned a council to Alexandria to decide various important questions, when an imperial mandate yet again drove him from his place of power. The faithful gathered around him weeping. "Be of good heart," he said, "it is but a cloud: it will soon pass." His forecast proved true; for within a few months Julian had closed his brief career of Pagan revival, and Anathasius "returned by night" to Alexandria. He received a letter from the new emperor, Jovian, praising his Christian fidelity, and encouraging him to resume his work. With the emperor he continued to maintain friendly relations, and even drew out for him a synodal letter embodying the Nicene Creed, which was graciously received. During the brief reign of this bluff soldier-prince, comparative quiet prevailed in the church. But the repose was of short duration. In the spring of 365, after the accession of Valens, troubles reappeared. An order was issued for the expulsion of all bishops who had been expelled by Constantius, and Athanasius was once more forced to take refuge in concealment from his persecutors. His concealment, however, only lasted for four months, when an order came for his return; and from this time (Feb. 366) he was left undisturbed to pursue his episcopal labors. Those labors were unceasing in refuting heretics, in building churches, in rebuking rapacious governors, in comforting faithful bishops, and in strengthening the orthodox everywhere, till at length, in the spring of 373, "in a good old age," he ceased from all his work. Having consecrated one of his presbyters his successor, he died quietly in his own house. His "many struggles," according to his panegyrists, won him "many a crown." He was gathered to his fathers, patriarchs, prophets, apostles, and martyrs, who had contended for the truth. Even those who fail to sympathise with the cause which Athanasius steadfastly maintained, cannot refuse their tribute of admiration to his magnanimous and heroic character. The cynic eloquence of Gibbon grows warm in recounting his adventurous career, and the language of Hooker breaks into stately fervor in celebrating his faith and fortitude. "The whole world against Athanasius, and Athanasius against it; half a hundred of years spent in doubtful trial which of the two in the end should prevail — the side which had all, or else the part which had no friends but God and death — the one a defender of his innocency, the other a finisher of all his troubles." If imperious in temper and inflexible in dogmatic determination, Athanasius had yet a great heart and intellect, enthusiastic in their devotion to Christ, and in work for the good of the church and of mankind.

His chief distinction as a theologian was his zealous advocacy of the essential divinity of Christ as co-equal in substance with the Father. This was the doctrine of the Homoousain, proclaimed by the Nicene Creed, and elaborately defended by his life and writings. Whether or not Athanasius first suggested the use of this expression, he was its greatest defender; and the catholic doctrine of the Trinity has ever since been more identified with his "immortal" name than with any other in the history of the church and of Christian theology. (For an exposition of the Athanasian Creed, see the article CREEDS.)

ATHEISM is the doctrine that there is no God. The word, which first appears in English literature in the latter part of the sixteenth century, is derived from Greek negative prefix *a*, and *Theos*, "God." The name atheist is said to have been first applied in Greek literature to one of the followers of the materialistic philosopher Democritus.

ATHELSTAN, or ÆTHELSTAN, son of King Edward the elder, and grandson of Alfred the Great, was born in 895. There has been much doubt with regard to his legitimacy, as his mother, Ecgwyn, is said to have been of humble origin; but these suspicions appear to rest on slight foundations. On the death of Edward in 925, Athelstan, who had been named by him as his successor, was elected king by the Mercians and West Saxons, and crowned at Kingston in Surrey. Anlaf, a Danish chief, or, according to some accounts, a son of Sihtric, with the king of Scotland, the Welsh, and the Danes of the north, invaded England. Athelstan, with his half brother Edmund, met and signally defeated the invaders in the battle of Brunanburh, celebrated in the "Brunanburh War-Song." In 940 or 941 Athelstan died at Gloucester.

ATHENA, in *Greek Mythology*, a goddess who, from being originally a personification of the clear, bright upper region of the sky, had, as early as the time of the epic poets, changed, or advanced, so as to embody under a divine form a conception of the clear insight of the human mind in its various functions. This upper air or ether seemed to be a distinct element in the universe. From it came the light of morning before sunrise and of evening after sunset, reminding us of the light which, in the Mosiac account of the Creation, existed before the sun and moon were placed in the sky. In the first stage of her character, in which, like the other deities of Olympus, she was directly identified with an element of nature and supposed to act as it acted, Athena bore the name of Pallas, and was thought of more in connection with the storms than with the serenity or light of the heavens. The obvious counterpart of a storm was a raging battle, and, accordingly, she became a goddess of war, armed with spear and helmet, and with the *ægis*, or storm-shield, of her father, resistless among men, hurling to the ground the giant Enceladus, and even superior in might to Ares himself, the god of war. The storm sweeps sorest round high citadels, where also the storms of war rage fiercest; and on such places was her favorite abode. But a storm is followed by serenity brighter than before, more enjoyable, and more exciting to activity of every kind; and then the goddess lays aside her armor to encourage and foster skill and industry. Her title is then Ergane. To her was ascribed the invention of spinning and weaving; of taming horses, bridling and yoking them to the war-chariot; of the flute, and in some way of the healing art. This is the second stage of her character, which the myth, agreeably to its principle, explains in a different fashion, when it says that she sprang into existence from the brain of the all-wise ruler of the world, Zeus, and that he had before swallowed his wife, Metis (intelligence). She must therefore have been in a measure a complement of him, created for the purpose of carrying out among men what was in his mind, but what yet he could not himself, as the supreme and impartial ruler, execute. As his substitute, she lent her aid to Heracles in all his hardships and adventures; to Theseus under similar circumstances; to the Greeks in their war against Troy; to Perseus in slaying the Gorgon Medusa, whose head she afterwards bore upon her *ægis*, from which she obtained the name of Gorgophone; and to the Argonatus on their expedition to Colchis.

She maintained always her character as a virgin, and, to express this, bore, at Athens in particular, the name of Parthenos. Her birth took place in Olympus, in presence of the other deities, Hephæstus aiding it, as it is coarsely said, by splitting open with his hatchet the skull of Zeus, a subject often represented on the ancient painted vases. This was also the subject of the sculptures in the front pediment of her greatest temple, the Parthenon at Athens. From the fact that in the other pediment the sculptures represented her contest with Poseidon for divine supremacy over Attica, it might perhaps seem that the first act of her existence was to claim this sovereignty. Foremost in her character always is her protection of high citadels, like that of Athens. Yet it was not for this, but for her causing an olive to grow on the bare rock of the Acropolis, that she was chosen rather than Poseidon, whose claim was that he had raised on the same rock a spring of brackish water. The olives of Attica were a source of great wealth, and the light supplied by their oil may have seemed not unlike the light of the ether. As the defender of citadels her title was Polias.

ATHENÆUM, a name originally applied to buildings dedicated to Athena (Minerva), was specially used as the designation of a temple in Athens, where poets and men of learning were accustomed to meet and read their productions. The academy for the promotion of learning which the Emperor Hadrian built at Rome, near the Forum, was also called the Athenæum. Poets and orators still met and discussed there, but regular courses of instruction were given by a staff of professors in rhetoric, jurisprudence, grammar, and philosophy. This species of university continued in high repute till the 5th century. The same name was afterwards applied to similar institutions in Lyons and Marseilles; and it has become a very general designation for literary clubs or academies. It has also been used as the title of literary periodicals, particularly of the journal of art criticism edited by the brothers Schlegel, and the two well-known modern papers published in London and Paris.

ATHENÆUS, a Greek rhetorician and grammarian, or man of letters, was a native of Naucratis, a town in Egypt, near the mouth of the Nile. Exceedingly little is known of his life, but from one or two references to known events which occur in his works it may be gathered that he flourished about the end of the 2d and the beginning of the 3d century A.D.

ATHENAGORAS, a Christian apologist, was a native of Athens, and lived during the 2d century A.D.

ATHENODORUS, surnamed CANANITES or SANDONUS, a Stoic philosopher, was born at Tarsus. He probably gave instruction to Augustus when he was at Apollonia; and on proceeding to the Roman courts, he was made tutor to Tiberius. The emperor esteemed him greatly for his proved virtue and probity. He was in the habit of giving his opinion very freely, and warned Augustus, whenever he found himself giving way to anger, to rehearse the twenty-four letters of the alphabet before saying or doing anything. Retiring late in life to his native town, he died there at the age of 82.

ATHENRY, a decayed town in Ireland, county of Galway, and province of Connaught, 14 miles E. of Galway.

ATHENS (*Ἀθῆναι*, ATHENÆ) was the name of as many as nine towns in various parts of the Grecian world, among which *Athenæ Diades*, in the N.W. of Eubœa, a town belonging to the Athenian confederation, is worthy of mention. But it was the capital of Attica which invested the name of Athens with an undying charm for the poet, the artist, the philosopher, the historian, for all time. Towards the south of the central plain of Attica, about 4½ miles from the harbor of Piræeus, and nearly 4 from the Bay of Phalerum. The survey of Pausanias, when compared with existing remains, and supplemented by the numerous incidental notices of ancient authors, enables us to form a more perfect conception of the topography of ancient Athens than of any other Greek city. Recent excavations have added greatly to our knowledge of it, and the literature of the subject is very extensive.

There seems little reason to doubt that the earliest settlement on Athenian soil was upon the cliff afterwards famous as the Acropolis. The earliest inhabitants appear to have been Pelasgians; and though it was the boast of the Athenians that they alone of all Greek states were indigenous, yet their town would from the first have received acessions from various parts of the continent, the peaceful poverty of Attica affording a welcome refuge in those early and unsettled times. The most accessible portion of the Acropolis is the western side, where it is joined by a neck of hill to the Areopagus. On this side there existed down to later times the remains of fortifications built by the earliest inhabitants, with nine doorways, one within the other. This fort protected the only entrance to the citadel, which was surrounded by a wall, and artificially levelled for the reception of buildings. Within this fortified enclosure stood the shrine of Athena Polias afterwards known as the Erechtheium,—and an altar of Zeus Polieus, where the strange sacrifices of the Dipolia were celebrated. A Prytaneium, containing the hearth-fire of the state, and serving as the residence of the king, would be another indispensable feature in the primitive town.

To the west of the Acropolis there extends from N. to S. a range of hills, the three most prominent heights of which are commonly known respectively as the Hill of the Nymphs, the Pnyx, and the Museium,— the Nymphs' Hill being separated from the Acropolis by the Areopagus, which intervenes between. Everywhere upon the slopes of the hills just mentioned traces have lately been discovered of ancient dwellings hewn out of the solid rock. But while all these rock-dwellings are exceedingly ancient, yet some appear less primitive than others; it is remarked that those which exist on the Areopagus and on the hill-sides nearest to the Acropolis are of a smaller and ruder type, those more distant from the citadel being somewhat more convenient in plan and extent. Legend declares the Athenians to have originally dwelt in rock-hewn caves, and it would seem that primitive Athens gradually extended itself from the Acropolis in this W. and S.W. direction. This quarter was afterwards known as the intramural deme of Melite, a name derived, perhaps from the balm which then grew there. As the population of the early town continued to increase, two more districts seem to have been incorporated — Collytus, extending from the east of Melite, between the Acropolis and Areopagus, and Cerameicus, or the "Potters' quarter" ("Tuileries"), which extended from the same two hills towards the north and north-west. The regions we have now described appear to have made up the Athens of Solonian times. The earliest historical event which illustrates Athenian topography is the rising of Cylon. The narratives of that event imply that the Acropolis was already fortified by the Enneapylum, that the Areopagus was already the seat of the court which bore its name (see AREOPAGUS), and that near the entrance of the citadel stood an altar of the Semnæ, or Furies, at which Cylon and his partisans were slain. This altar has been immortalised by Æschylus in the splendid conclusion of the *Eumenides*.

The reign of the Pisistratidæ was recognised by the ancients as marking an important era in Athenian topography. It was Pisistratus who laid the foundation for the great temple of Zeus Olympius upon the ancient site above mentioned. His magnificent design had an eventful history: left unfinished by its author, the Athenians, perhaps from dislike to the "tyrant," made no effort to complete it. At length, after receiving additions from various foreign princes, it was completed by Hadrian (*c.* 130 A.D.), and formed the grandest edifice in the region of the city which, in acknowledgment of the imperial munificence, was called Hadrianopolis. The Olympium was one of the largest temples in the world; but of its 124 Corinthian columns only 15 are now standing. The *Pythium*, or sanctuary of the Pythian Apollo, near the Olympium, was also ascribed to Pisistratus, whose grandson and namesake dedicated an altar within it (Thucyd., vi. 54). To Pisistratus was ascribed the founding of the *Lyceium*, or temple of Apollo Lyceius, which stood on the right bank of the Ilissus, a short distance from the city. The names both of Pericles and Lycurgus the orator are also associated with this building; yet it is not known who added the gymnasium close by, which afterwards became famous as the favorite haunt of Aristotle, and the birthplace of the Peripatetic philosophy. The yet more famous seat of the rival philosophy seems also to have owed something to the Pisistratidæ, for Hipparchus was said to have enclosed the *Academy* with a wall.

The revolution which expelled the Pisistratidæ (510 B.C.), and gave Athens a free government, left its mark upon the topography of the city. The old Pelasgic fortress, in which "the tyrants" had for a time held out, was now broken down, and the site occupied by its ruins was devoted by the Delphic oracle to eternal desolation. Only in the Peloponnesian war, when the country population was crowded within the city walls, do we read of this spot being occupied by dwellings. Another work which may probably be assigned to the age of Clisthenes is the first arrangement of the Pnyx, or place of public assembly.

A building of greater architectural importance and of equal interest belongs to this same period. Dramatic performances at Athens originally took place in wooden theatres extemporised for the occasion; but the fall of one of these led, in the year 500 B.C., to the erection of the marble theatre on a site already consecrated to Dionysus as the Lenæum, upon the S.E. slope of the Acropolis. We may be sure that the first stone theatre was comparatively simple in construction, consisting of an auditorium, with tiers of rock-hewn seats, and an *ὀρχήστρα*, or space for the chorus, while the stage itself and its furniture were of wood. The excavation of the Dionysiac theatre in 1862 has made every one familiar with the row of marble thrones for the various priests and officers of state, the elaborate masonry of the stage, the orchestra floor, and other features. But these and other interesting decorations of the theatre belong to a later age. It was under the administration of Lycurgus the orator (337 B.C.) that the building was first really completed; and many of the sculptures which have been lately brought to light belong to a restoration of the theatre in the 2d, or perhaps even the 3d, century A.D.

Enough has now been said of the condition of Athens before the Persian War. It was surrounded by a ring-wall of narrow circuit, some doubtful traces of which are supposed to remain. At its centre stood the Acropolis, already crowded with temples and sanctuaries, some upon the summit, some built at its foot, and others — like the famous grotto of Pan, on the N.W. slope — mere caves in its rocky sides.

The Persian invasion, which forced the Athenians to take refuge in their "wooden walls," and to leave their city at the mercy of the barbarians, marked an important epoch in the annals of Athenian building. Upon the retreat of Mardonius, the Athenians returned to Attica to find their city virtually in ruins. Its fortifications and public buildings had been destroyed or burnt, and the private dwellings had been wantonly defaced or ruined by neglect. Amid the enthusiasm of hope which followed upon the great deliverance of Greece, a natural impulse led the Athenians to rear their city more glorious from its ruins. Themistocles fanned their patriotism with the foresight of a statesman, and Athens rose again with marvellous rapidity. This haste, however, though creditable to their patriotism, and, indeed, necessary in order to forestall the jealous opposition of Sparta, was not without its evils. The houses were rebuilt on their old sites, and the lines of the old streets, narrow and irregular as they had been, were too readily followed. A similar haste marked the rebuilding of the city walls, a work in which men and women, old and young, took zealous part, not scrupling to dismantle any building or monument, private or public, which could supply materials for the building. But in rebuilding the walls Themistocles gave them a wider circuit, especially towards the N. and N.E. (Thucyd., i. 90, 93). At the same time he determined to construct new harbors, and to fortify the Piræeus, regarding the navy of Athens as her principal source of strength. It is doubtful whether the "Long Walls" formed a distinct portion of his designs; but he may certainly be regarded as the founder of the greatness of Athens, the works and embellishments carried out by Pericles being only a fulfilment of the far-sighted aims of Themistocles. Thucydides makes the circuit of the city wall to be 43 stades (about 5½ miles), exclusive of the unguarded space between walls; this is found to correspond accurately enough with the existing remains. Having completed the defences of the city proper, among which must be included the building of the north wall of the Acropolis, Themistocles proceeded to fortify the Piræeus.

Athens, like most of the old Greek towns, was built, for greater security, at a distance from the coast, and only when more settled times brought her greater prosperity was a harbor formed at the nearest bay of Phalerum, near the modern church of St. George. It is said that Themistocles would gladly have transported the Athenian population bodily from the upper city to the coast, there to form a great maritime state. Though this was impossible, yet he could strengthen Athens on the seaward side. The isthmus of Piræeus, though somewhat more distant than Phalerum, presented obvious advantages as a seaport.

If not a part of the original designs of Themistocles, it was at least a natural development of them, to carry the "Long Walls" from the newly-fortified Piræeus to the upper city, and thus combine them both into one grand system of fortification. The experiment of connecting a town by long walls with its port had been already tried between Megara and Nisæa, and it was now repeated on a grander scale under Cimon. It was Cimon who first set the example of providing the citizens with agreeable places for promenade (Plutarch, *Cimon*, xiii.), by planting the Agora with plane trees, and laying out the Academy with trees and walks. It is probable that some of the porticoes in the Agora were built by Cimon; at all events, the most beautiful one amongst them was reared by Pisianax, his brother-in-law, and the paintings with which Polygnotus, his sister's lover, adorned it (representing scenes from the military history of Athens, legendary and historical) made it ever famous. One more building, the most perfect existing relic of ancient

Athens, was also built by Cimon. The Theseium is a hexastyle Doric temple standing on an eminence due N. of the Areopagus, and is the first object which meets the eye of the tourist who approaches the city from the Piræeus. Having served in Byzantine times for a Christian church, it is now a museum of antiquities, and contains some of the choicest treasures discovered by recent excavations.

We have now brought this sketch of Athenian topography down to the most distinguished period of Athenian history and Athenian architecture — the era of Pericles. As the champion of Hellenic freedom against the Persians, as the head of the Ionic confederation, Athens had suddenly grown to be the foremost city in Greece. But when one by one the confederate states sank into the position of subject-allies; when the supremacy of Athens passed insensibly into a tyranny; when the contribution of ships and men was commuted in most cases for a money payment, and the funds of the confederation were transferred from the Apollonium at Delos to the Athenian Acropolis,—an enormous revenue became at the disposal of the Athenian Government. It is to their credit that so little of it found its way into private pockets. It was natural for the thoughts of a Greek, especially of an Athenian, to turn to the decoration of his city; it was politic that the central city of the Ionian confederacy should be adorned with a beauty equal to her prestige. The buildings connected with the name of Cimon had been chiefly for utility or defence; those of Pericles were mainly ornamental. The first edifice completed by him seems to have been the Odeium, on the E. of the Dionysiac theatre, to serve as a place for recitations by rhapsodists, and for musical performances. It was burnt by Aristion during Sulla's siege of Athens, but afterwards rebuilt. Mention has already been made of the building of the Long Walls and the laying out of the Piræeus by Pericles; but it was the Acropolis itself which witnessed the greatest splendors of his administration. Within its limited area arose buildings and statues, on which the genius of Phidias the sculptor, of Ictinus and Mnesicles the architects, were employed for years; while multitudes of artists and craftsmen of all kinds were busied in carrying out their grand designs. The spoils of the Persian War had already been consecrated under Cimon to the honor of the national goddess, in the erection of a colossal statue of Athena by Phidias between the entrance of the Acropolis and the Erechtheium; her warlike attitude gained her the title of *Προμαχος*, and the gleam of her helmet's plume and uplifted spear was hailed by the homeward seaman as he doubled Cape Sunium (Pausan., i. 28). But the national deity was to receive yet greater honors at the hand of Pericles. He proceeded to rear what has since been known as the Parthenon. It was completed in the year 438 B.C. It stood upon the highest platform of the Acropolis, so that the pavement of the peristyle of the Parthenon was on a level with the capitals of the columns of the east portico of the Propylæa. The temple was built entirely of white marble from the quarries of Mount Pentelicus. Ascending a flight of three steps, you passed through the great east entrance into the Pronaos, wherein was stored a large collection of sacred objects, chiefly of silver. From the Pronaos a massive door led into the *cella*, called Hecatompedos, because it measured in length 100 Attic feet. The treasure here bestowed consisted chiefly of chaplets and other objects of gold. The west portion of the cella was railed off, and formed the *Parthenon* proper, *i.e.*, the adytum occupied by the chryselephantine statue by Phidias of Athena Parthenos, —a work which yielded the pre-eminence only to one other statue by the same artist, viz., the Zeus at Olympia. In this adytum were stored a number of silver bowls and other articles employed at the Panathenaic festivals. The westernmost compartment at the rear of the cella was the Opisthodomus, which served as the national treasury; hither poured in the tribute of the Athenian allies. It is important to remember that the Parthenon was never intended as a temple of worship; for this purpose there already existed another temple, presently to be described as the Erechtheium, —standing upon the primeval site of that contest between Athena and Poseidon which established the claim of the goddess to the Attic citadel and soil. The Parthenon was simply designed to be the central point of the Panathenaic festival, and the storehouse for the sacred treasure. The entire temple should be regarded as one vast *ἀνάθημα* to the national deity, not as a place for her worship. Thus directly in front of her statue in the cella there stood an erection, which has been mistaken for an altar, but which is more probably to be regarded as the platform which the victorious competitors in the Panathenaic contests ascended to receive, as it were from the hand of the goddess, the golden chaplets and vases of olive oil that formed the prizes. This consideration lends significance to the decorations of the building, which were the work of Phidias. Within the outer portico, along the outside of the top of the wall of the building, ran a freize 3 feet 4 inches in height, and 520 feet in total length, on which were sculptured figures in low relief, representing the Panathenaic procession. Nearly all of these sculptures are in the British Museum, and the entire series has been recently made complete by casts from the other fragments, and arranged in the order of the original design. The marvellous beauty of these reliefs, which was heightened originally by color, has been long familiar to all the world from numerous illustrated descriptions. The processions of youths and maidens, of priests and magistrates, of oxen for sacrifice, of flute-players and singers, followed by the youthful chivalry of Athens on prancing steeds — is represented as wending its way from the west towards the eastern entrance. Outside of the building, on the N. and S. sides, the metopes between the Doric triglyphs were filled with sculptures representing scenes from the mythical history of Athens. But the glory of the Parthenon were the sculptures of the E. and W. pediments. Unhappily but a few figures remain, and none are wholly perfect, of the statues which formed these groups; and Pausanias appears to have thought it superfluous to give a minute description of objects so familiar to every connoisseur and traveller.

Opposite to the Parthenon, on the northern edge of the Acropolis, stands another remarkable temple, far smaller in size, and built in the most graceful forms of the Ionic order. The Erechtheium appears to be designed expressly to contrast with the severe sublimity of the Parthenon; and on the side which confronts those mighty Doric shafts, the columns of the smaller building are allowed to transform themselves into Canephori. The temple of Athena Polias, which contained the ancient wooden image of the Goddess, and formed the centre of her worship, suffered from fire in the Persian War (479 B.C.) A building so sacred would hardly have been allowed to remain for long in ruins; but it was reserved for Pericles to set about a complete restoration of it.

Among the many glories of the Acropolis, the Propylæa are described by Pausanias as being exceptionally magnificent (i. 22). They rivalled even the Parthenon, and were the most splendid of all the buildings of Pericles.

From the disastrous termination of the Peloponnesian war to the yet more fatal defeat at Chæroneia, the

architectural history of Athens is a blank, only interrupted by the restoration of the Long Walls and the rebuilding of the fortifications of Piræeus by Conon, both of which had been destroyed by Lysander. The financial genius of the orator Lycurgus, whose administration lasted from 338 to 325 B.C., replenished to some extent the exhausted resources of his country.

The Macedonian period again marks a new epoch in the history of Athenian topography. Hencefoward almost every embellishment Athens received was at the hands of the various foreign princes, whose tastes inclined them to patronise a city so rich in historical associations, and so ready to reward each new admirer with an equal tribute of servile adulation. But whatever decoration the city might owe to royal vanity or munificence, her connection with these foreign potentates brought her far more of injury than advantage. She became entangled in the wars, and usually found herself upon the losing side.

Upon the death of Alexander the Athenians claimed their liberty, but they at once had to submit to Antipater (322 B.C.), who placed a garrison in Munychia. It perhaps was he who defaced the ancient Pnyx; at all events, from this time forward the political oratory of Athens became silent for ever.

Under the rule of the Romans Athens enjoyed the privileges of a *libera civitas*, *i.e.*, no garrison was introduced into the town, no tribute was levied upon it, and the constitution was left unaltered. The Areopagus, indeed, under Roman influence, recovered some of its ancient power, and was made to take precedence of the more democratic assemblies of the Boule and Ecclesia. The revision also of the laws by Hadrian would, of course, introduce some changes. Yet it may surely be maintained that Athens under the Roman dominion was in a far better position than in the days before the taking of Corinth by Mummius, when she had been at the mercy of each successive Macedonian pretender. The Romans appear to have shown a remarkable respect for the feelings of the Athenian people. It would be superfluous here to recall the warm expressions of admiration which fall from Cicero and Horace when speaking of Athens. A visit to Athens was regarded by the educated Roman as a kind of pilgrimage. One great disaster Athens did indeed undergo at the hands of Rome; this was the siege and plunder of the city by Sulla in the Mithridatic War.

It is uncertain at what exact date the Horologium of Andronicus of Cyrrhus was erected, which is generally known as the Tower of the Winds. It is first mentioned by Varro, and is therefore older than 35 B.C., though certainly not earlier than the Roman conquest. This monument, so familiar to every scholar, is described by Virruvius (i. 6, 4) as an octagonal tower of marble. It stands at what anciently formed the eastern extremity of the Roman Agora, presently to be described. On each face, beneath the cornice, is sculptured the figure of the wind which blew from the corresponding quarter; on the top of the roof was a pedestal supporting a bronze triton (now destroyed), which was constructed to turn with the wind, and to point out the wind's quarter with a wand which he held in his hand. The sculptured figures of the winds are in good preservation, though of a declining period of art. They represent the four cardinal points and the intermediate quarters between these. Each has his emblems: Boreas, the north wind, blows his noisy conch; Notus, the rainy south wind, bears his water-jar; Zephyrus, the west wind, has his lap full of flowers, and so on. Under each figure are the remains of a sun-dial; and besides all these external features, the interior was constructed to form a water-clock, supplied with water from the spring at the Acropolis called Clepsydra. Thus in cloudy weather a substitute was provided for the dial and the sun.

The reign of Hadrian made literally a new era in the history of Athens. For Greece, and especially for Athens, this emperor entertained a passionate admiration. He condescended to hold the office of archon eponymus; in his honor a thirteenth tribe, Hadrianis, was instituted; and the emperor shared with Zeus the title of Olympius, and the honors of the newly-finished temple. While, however, many portions of the city bore witness to his munificence, it was in the south-eastern quarter that most of his new buildings arose, in the neighborhood of the Olympium. This suburb was accordingly styled Hadrianopolis, or New Athens, to distinguish it from the old city of Theseus and of Themistocles. The arch of Hadrian still stands in a fairly perfect state, and marks the boundary between the ancient town and the new suburb embellished by Hadrian. At the same time many of the older buildings underwent restoration at his command. Nor was his bounty shown in works of building alone. He ceded to the Athenians the island of Cephallenia, and bestowed upon them large presents of money, and an annual largess of corn.

The immediate successors of Hadrian were guided by his example. Antonius Pius completed an aqueduct which Hadrian had commenced for bringing water into the town from Cephisus. Marcus Aurelius visited Athens for the purpose of initiation at the Eleusinian mysteries.

A few words may suffice to describe the ultimate fate of Athens. In the reign of Valerian the northern barbarians first appeared in the north of Greece, where they laid seige to Thessalonica. This extraordinary apparition having alarmed all Greece, the Athenians restored their city wall, which Sulla had dismantled, and otherwise placed the town in a state of defence sufficient to secure it against a *coup-de-main*. But under Gallienus, the next emperor, Athens was beseiged, and the archonship abolished, upon which the strategos or general, who had previously acted as inspector of the Agora, became the chief magistrate. Under Claudius the city was taken, but recovered soon afterwards. Constantine the Great gloried in the title of General of Athens, which had been conferred upon him, and expressed high satisfaction on obtaining from the people the honor of a statue with an inscription, — a distinction which he acknowledged by sending to the city a yearly gratuity of grain. He also conferred on the governor of Attica and Athens the title of *Μέγας Δοῦξ*, or Grand Duke, which soon became hereditary; and his son Constans bestowed several islands on the city, in order to supply it with corn. In the time of Theodosius I., that is, towards the end of the 4th century, the Goths laid waste Thessaly and Epirus; but Theodorus, general of the Greeks, acted with so much prudence, that he saved the Greek cities from pillage and the inhabitants from captivity, a service which was most gratefully acknowledged. But this deliverance proved only temporary. The fatal period was now fast approaching, and, in a real barbarian, Athens was doomed to experience a conqueror yet more remorseless than Sulla. This was Alaric, king of the Goths, who, under the Emperors Arcadius and Honorius, overran both Italy and Greece, sacking, pillaging, and destroying. Never, indeed, did the fury even of barbarian conquest discharge itself in a fiercer or more desolating tempest. The Peloponnesian cities were overturned; Arcadia and Lacedæmon were both laid waste; the gulfs of Lepanto and Ægina were illuminated with the flames of Corinth, and the Athenian matrons were dragged in chains to satisfy the brutal desires of the barbarians. The invalu-

able treasures of antiquity were removed; stately and magnificent structures were reduced to heaps of ruin; and Athens, stripped of the monuments of her ancient splendor, was compared by Synesius, a writer of that age, to a victim of which the body had been consumed, and the skin only remained.

From the period of the Ottoman conquest, 1455, to the commencement of the insurrection in 1821, Athens was only known in history by two attempts, on the part of the Venetians, to expel the Turks and make themselves masters of the city. The first of these took place in 1464, only nine years after its capture by the Osmanlis, and proved an entire failure. But the second, which was undertaken in 1687, more than two centuries later, was crowned with a temporary and fatal success. In the month of September of that year, Count Königsmark, a Swede in the service of Venice, having disembarked at the Piræeus a force of 8000 foot and 870 horse, forming part of the armament under Francesco Morosini, afterwards doge, marched to Athens, and having summoned the citadel without effect, he erected a battery of heavy ordnance on the hill of the Pnyx, and placing two mortars near the Latin convent at the western foot of the Acropolis, bombarded it for several days. The fire of the cannon was chiefly directed against the Propylæa, and the modern defences below that edifice, whilst the mortars continued, without intermission, to throw shells into the citadel. The consequence was, that the beautiful little temple of Nike Apteros, the frieze of which is now at the British Museum, was completely destroyed by the breaching battery; and the Parthenon, besides being greatly injured by the bursting of the shells, was, towards the close of the attack, almost rent in pieces by the explosion of a powder magazine, which reduced the middle of the temple to a heap of ruins, threw down the whole of the wall at the eastern extremity, and precipitated to the ground every statue on the eastern pediment. The western extremity was fortunately less injured, and a part of the Opisthodomos was still left standing, together with some of the lateral columns of the peristyle adjoining to the cell. But the shock was nevertheless abundantly disastrous; and when the Turks afterwards regained possession of the citadel (from which, on this occasion, they were expelled), they did all in their power to complete the destruction which the Venetians had so vigorously begun, by defacing, mutilating, or burning for lime every fragment of the edifice within their reach.

In the course of the revolutionary war Athens sustained three sieges. The first was that by the Greeks in 1822. Having carried the town by storm, and driven the Turks into the citadel, they established a strict blockade of the fortress, which was continued until the advance of the Pasha with 4000 men induced them to abandon their enterprise, and fly, with the Athenians, to Salimis and Ægina. Two months afterwards, the Pasha having left Athens to the defence of 1500 men, the Greeks again ventured to attack the town, and succeeded in obliging the Turks to seek refuge in the citadel, which they forthwith determined to besiege; but, from ignorance and want of means, no progress whatever was made in the operation until they obtained possession of the well which supplied the garrison with water, when the Turks agreed to capitulate upon condition of being immediately embarked with their families and sent to Asia Minor.

With the liberation of Greece from the yoke of Turkey, begins the history of Modern Athens. Before the transfer of the capital from Nauplia by King Otho, who had been chosen to the throne of the new kingdom, Athens was a wretched village of a few hundred houses. Since that time it has enjoyed a prosperous growth. Modern Athens has been built chiefly on the Eastern and Northern sides of the Acropolis, while the ancient city lay chiefly on the Southern and Western sides, and in its public buildings and newer parks, it reminds one of the better-built German cities. Its present population is about 85,000, that of the Piræus being more than 30,000. It has a gymnasium on the German model, a school for the higher education of girls; several private schools of excellent character; a polytechnic school and a university, which numbers more than fifty professors in the various faculties, and about 1,400 students. A railway connects Athens with the Piræus; and street railroads run to outlying villages. Except in the back streets and remote corners, one would hardly think of Athens as at all an Oriental city. Its two chief business streets, "Hermes" and "Æolus," cross each other at right angles, and divide the city into four nearly equal parts. Of modern public buildings, the most noteworthy are the University, the Academy, which is built almost wholly of marble, and shows with beautiful effect the polychromatic decorations of the ancient Doric style, the Exposition Hall, and the Palace externally an ugly square building, but containing some spacious and handsome salons. Among the most recent erections are a magnificent building for the National Library and a fine theater. Both these structures, as well as the Academy and the Exposition Hall, are the gifts of wealthy Greeks, who reside mostly abroad and take this way of showing their interest in the prosperity of their native country. Athens has become a center of archæological interest and study. Aside from the monuments mentioned above, it has many remains of antiquity stored and exhibited in its three museums. At the Eastern end of the Acropolis, the Archæological Society of Athens has erected a low building in which are preserved the remains and fragments of ancient art, which had been exhumed on the Acropolis. The most noteworthy of these are several slabs of the Parthenon frieze; a few reliefs of the beautiful balustrade of the Temple of Wingless Victory; fragments of the frieze of the Erechtheum, and the fourteen archaic statues of divinities or priestesses found in 1886 west of the Erechtheum. The museum contained in the Polytechnicum embraces the Mycenæ collection made by Doctor Schliemann; a large number of figurines from Tanagra, Myrina and other places, and a collection of vases, illustrative of every period in the history of vase painting.

ATHÊNS, the name of several towns in the United States of America, the chief of which are the following: —(1.) The capital of a county of the same name in the S.E. of the state of Ohio, finely situated on the Hocking river. It is the seat of the Ohio University, and contains 3,000 people. (2.) The capital of Clark county, Georgia, on the W. bank of the Oconee River. It is the seat of the Georgia university, which was founded in 1801, and the central town of a large cotton-growing district. Population (1890), 8,627.

ATHERTON or CHOWBENT, a township in the parish of Leigh and hundred of West Derby, in Lancashire 200 miles from London. It is one of those places which have grown to wealth and populousness through the extension of the cotton trade. Besides its factories, it has collieries and ironworks. Population (1890), 9,000.

ATHIAS, JOSEPH, a celebrated rabbi and printer at Amsterdam, whose editions of the Hebrew Bible are noted for the general correctness of the text.

ATHLETÆ, among the Greeks and Romans, was the designation of persons who contended for prizes in the public games, exclusive of musical and other contests, where bodily strength was not called into play, though

here also the word was sometimes applied, and it was even extended to horses which had won a race, and again metaphorically, *e.g.*, to persons who had exerted themselves in good deeds. On the other hand, the term was restricted so as to exclude those, who, for mere exercise, without the incentive of a prize, practised in the daily gymnastic competitions. Yet it was not the value of the prizes themselves which led men to devote their lives to athletic exercises. That was at most very insignificant. But from the heroic legends of competitions for prizes, such as those at the obsequies of Patroclus, from the great antiquity of the four national games of Greece (the Olympian, Pythian, Nemean, and Isthmian, with the local Panathenæa at Athens), and from the high social position of the competitors in early times, there gradually became attached to victory in one of these games so much glory that the townsmen of a victor were ready to, and frequently did, erect a statue to him, receive him in triumph, and care for him for the rest of his life. Against specially trained athletes the better class of citizens refused to compete, and the lists of the public games being thus left practically open only to professionals, training became more a matter of system and study, particularly in regard to diet, which was rigorously prescribed for the athletes by a public functionary, styled the Aleiptes, who also had to salve their bodies when practising. At one time their principal food consisted of fresh cheese, dried figs, and wheaten bread. Afterward meat was introduced, generally beef or pork; but the bread and meat were taken separately, the former at breakfast, the latter at dinner. Except in wine, the quantity was unlimited, and the capacity of some of the heavy weights must have been, if such stories as those about Milo are true, enormous. Cases of death from apoplexy are not unknown among them. The Tarentine Iccus was an example of the strictest abstinence. Their instruction consisted, besides the ordinary gymnastic exercises of the palæstra, in carrying heavy loads, lifting weights, bending iron rods, striking at a suspended leather sack filed with sand or flour, taming bulls, &c. Boxers had to practice delving the ground, to strengthen their upper limbs. The competitions open to the athletes were in running, leaping, throwing the discus, wrestling, boxing, and the Pancratium, or combination of boxing and wrestling. Victory in this last was the highest achievement of an athelete, and was reserved only for men of extraordinary strength. The competitors were naked, having their bodies salved with oil. Boxers wore the *cæstus*, *i.e.*, straps of leather, round the wrists and forearms, with a piece of metal in the fist, which was sometimes employed with great barbarity. An athlete could begin his career as a boy in the contests set apart for boys. He could appear again as a youth against his equals, and though always unsuccessful, could go on competing till the age of 35, when he was debarred, it being assumed that after this period of life he could not improve. It sometimes happened that an athlete would agree to allow his rival to win; but for that and other cases of dishonesty a fine was imposed, and the money expended in erecting statues, with warning inscriptions. The most celebrated of the Greek athletes whose names have been handed down are Milo, Hipposthenes, Polydamas, Promachus, and Glaucus. Cyrene, famous in the time of Pindar for its athletes, appears to have still maintained its reputation to at least the time of Alexander the Great; for in the British Museum are to be seen six prize vases carried off from the games at Athens by natives of that district. These vases found in the tombs, probably, of the winners, are made of clay, and painted on one side with a representation of the contest in which they were won. and on the other side with a figure of Pallas Athena, with an inscription telling where they were gained, and in some cases adding the name of the eponymous magistrate of Athens, from which the exact year can be determined. Among the Romans, fond as they were of exhibitions of physical skill and strength, the profession of athletes was entirely an exotic, and was even under the empire with difficulty transplanted from Greece. The system and the athletes themselves were always purely Greek.

ATHLETIC SPORTS. Although this term is undoubtedly derived from the ancient, the derivation does not exactly indicate its present meaning, inasmuch as our modern athletes are distinctly defined to be amateurs, in contradistinction to professionals. In fact, the former pursue the agonistic art, and should be styled "agonistics," if we may be allowed to invent such a word, rather than athletes. How the pastime came to be thus named in Britain some thirty years ago it is hard to say. Till about 1860, all exercises wherein the feet played the principal part were rightly styled "pedestrianism." Up to that period all prizes, whether contended for by amateurs or professionals, were invariably in money. As the practice of the pastime, however, rapidly spread amongst the former, it was naturally found they were loth to compete on the same terms with, and for similar trophies as, the latter. Hence arose the modern definition of an amateur athlete, viz., "Any person who has never competed in an open competition, or for public money, or for admission money, or with professionals for a prize, public money, or admission money; nor has ever at any period of his life, taught, or assisted in the pursuit of athletic exercises as a means of livelihood; nor is a mechanic, artisan, or laborer." The moment this definition was brought into force a wide barrier arose between the two classes, and amateurs ceased to compete for money prizes amongst themselves, or against professionals, on any terms, unless they were willing to forfeit their status.

ATHLONE, a market-town and parliamentary borough of Ireland, lying partly in West Meath and partly in Roscommon, 76 miles west of Dublin. The river Shannon divides the town into two portions, which are connected by a handsome bridge, opened in 1844. The rapids of the Shannon at this point are avoided by means of a canal about a mile long, which renders the navigation of the river practicable for 71 miles above the town. Population (1890), 9,000.

ATHOL, a thriving town, situated in Worcester county, Mass., and the center of considerable commercial enterprise. Population (1890), 6,318.

ATHOR, ATHYR, HATHOR, the name of the Egyptian divinity corresponding to Aphrodite or Venus. Her name meant "the abode of Hor" or Horus, and she was the mother of that deity in some of his types, and as such a form of Isis, of whom she was a higher or celestial manifestation. Her name occurs as early as the 4th dynasty, when she is styled the mistress of the tree, or sycamore, *neha*, or the tree of the south. The solar deities Shu and Tefnut were her children. In certain legends she is mentioned as the seven cows of Athor, which appear in the Ritual or Book of the Dead. These cows, like the *Moiræ*, or fates of Greek mythology, appeared at the birth of legendary persons, and predicted the course and events of their lives. It is in this capacity that Athor is connected with Ptah, or the Egyptian Hephæstus, and is allied to Sekhet or Bast, called the wife or mistress of Ptah, the seven cows being the mystical companions of the Apis, the second life or incarnation of the god of Memphis. She was also represented under the attributes and with the titles of the goddess Nut, or the Egyptian Rhea. The cow of Athor wore on its head the solar disk. and hawk feather

plumes; like Amen Ra; and in this character as the great cow she has on some monuments her human head replaced by that of a cow wearing a disk, or the disk and plumes. This emblem also appears in her type at a later period, when her head is represented with long tresses curled into a spiral at the end, and the has the ears of a cow instead of human ears. Her head is then surmounted by a doorway or its cornice, emblem of the abode of the sun, which she represented. This is sometimes surmounted by the disk and horns. The third month of the Egyptian year was named Athor after her, and the fish *aten* or latus, a kind of carp, was sacred to her.

ATHOS is, strictly speaking, the terminal peak of the most eastern of the three peninsular promontories which stretch south from the coast of Turkey (*Macedonia*), like the prongs of a trident, into the Archipelago. The name is, however, frequently extended to the whole peninsula which was formerly known as Acte. The peak rises like a pyramid, with a steep summit of white marble, to a height of 6780 feet, and can be seen at sunset from the plain of Troy on the one hand, and on the other from the slopes of Olympus. The whole peninsula is remarkable for the beauty of its scenery, with rocky heights and richly-wooded flanks, ravines "embowered from the light," and glimpses of free outlook over the surrounding sea. The climate is for the most part healthy and pleasant, though the western side is perhaps too much exposed to the heats of summer; and Lucian assures us that in ancient times the inhabitants were famous for longevity. Several towns, such as Sane, Dium, Olophyxus, Cleonæ, are mentioned by Greek and Latin writers as existing in the Peninsula; but none of them seem to have attained any great importance, and the most remarkable event in the ancient history of Athos is the construction by Xerxes of a ship-canal across the isthmus between the outer sea and the Singitic gulf. Traces of this canal, which was regarded by Juvenal as a Greek myth, have been found almost right across the neck of land, and leave no doubt of the truth of the story. In more modern times the district of Athos has been famous for the number of hermits and monks that have found shelter in its retreats. No fewer than 935 churches, chapels, and oratories are said to exist, and many of the communities possess considerable wealth. It is believed that, with the exception of the dwellings of Pompeii, some buildings in Athos are the oldest specimens of domestic architecture in Europe; the shrines are in many cases richly decorated with goldsmith's work of great antiquity; the wealth of the monastic libraries in illuminated manuscripts has been long celebrated; and nowhere can the Byzantine school of painting be studied with equal advantage. The date of the oldest religious foundation in the peninsula is not clearly ascertained, and the traditional chronology of the monks themselves can hardly be trusted.

ATHY, a market-town of Ireland, county of Kildare, 34 miles S.W. of Dublin. It is a station on the Great Southern and Western Railway, and is intersected by the river Barrow, which is here crossed by a bridge of five arches. Population (1890) 48,000.

ATINA, a town of Naples, province of Terra di Lavoro, near the Melfa and 12 miles S. E. of Sora. It has a cathedral, convent, and hospital, and about 5000 inhabitants; but it is chiefly remarkable for its ancient remains, consisting of portions of its walls, the ruins of an extensive aqueduct, and numerous other structures, besides monuments and inscriptions. The city is of great antiquity, and was a place of importance down to the days of the Roman empire. It is remarkable now, as of old, for the exceptional coolness of its situation.

ATITLAN, a lake in the department of Solola, in Guatemala, 20 miles long, with an average breadth of 9 miles. It seems to occupy the crater of an extinct volcano, and its depth is reported to be very great.

ATLANTA, the capital of Georgia, is situated about seven miles southeast of the Chattahoochee river, at an elevation of 1,100 feet above the sea. It was laid out in 1845, and became a city in 1847. It is the seat of extensive manufacturing interests, there being 590 factories, with an invested capital of $14,500,000 and an annual product of $29,000,000. Eight large trunk lines of railroad center here. Atlanta contains the State capitol (cost $1,000,000), court-house, United States building, chamber of commerce, Confederate Home, many hospitals and asylums; sixteen schools, costing $320,000, and seventy-three churches, valued at $1,500,000. The city is lighted by gas and electricity, has twenty-five miles of main sewers, and new water-works taking an unlimited supply from the Chattahoochee river. There are fifty-five miles of electric, steam, dummy, and other street railroads; a fire department of fifty-five men, and a police force of 106 men. The city receipts in 1889 were $1,168,518; the expenditures $944,952. The assessed valuation is $75,000,000, and the tax levy is limited to one-half per cent. During the war Atlanta was the scene of extensive military operations. (See UNITED STATES, JOHNSTON, JOS. E., and SHERMAN, WM. T.) The census of 1890 shows a population of 67,515.

ATLANTIC, capital of Cass county, Iowa, eighty-two miles west by south of Des Moines. It has two banks, printing offices, graded schools, and six churches, and a population (1890) of 4,300.

ATLANTIC CITY, a watering place on the eastern coast of New Jersey, in Atlantic county. Population, 13,000, largely increased in the summer season.

ATLANTIC OCEAN. This designation, originally given to the sea that lies beyond the range of Atlas in North-western Africa, has come to be applied, with the extension of geographical knowledge, to the whole of that vast ocean which occupies the wide and deep trough that separates the New from the Old World. Its limits are variously defined; some geographers regarding it as extending from pole to pole, whilst others consider it as bounded at its northern and southern extremities by the Arctic and Antarctic circles respectively. As the peculiarity of the physical conditions of the Polar Seas renders it on every account more appropriate to describe them under a separate head (POLAR REGIONS), the Atlantic will be here treated as bounded at the north by the Arctic circle, which nearly corresponds with the natural closing-in of its basin by the approach of the coasts of Norway and Greenland with Iceland lying between them; while at the south, where the basin is at its widest, its only boundary is the Antarctic circle. The line which separates its southern extension from the Indian Ocean may be considered to be the meridian of Cape Agulhas, the southernmost point of the African continent; whilst the boundary between the South Atlantic and South Pacific would be formed in like manner by the meridian of Cape Horn. Although the Baltic and Mediterranean are commonly regarded as appendages to the Atlantic, yet their physical conditions are so peculiar as to require separate treatment.

Every physical geographer who has written upon the Atlantic has noticed the curious parallelism between its eastern and its western borders,—their salient and retiring angles corresponding very closely to each other. Thus, beginning at the north we see that the projection formed by the British Islands (which extends much further westwards at 100 fathoms below the surface than it does above the sea-level), answers to the wide entrance to Baffin's Bay; whilst, on the other hand, the projection of the American coast at Newfoundland answers to

the Bay of Biscay. Further south, the great rounded prominence of Northern Africa corresponds with the vast bay that stretches from Nova Scotia to St. Thomas; whilst the angular projection of South America towards the east corresponds with that receding portion of the mid-African coast-line which is known as the Gulf of Guinea.

This correspondence suggested to Humboldt the idea that the Atlantic basin was originally excavated by a very violent rush of water from the south, which, being repulsed by the mountain ranges of Brazil, was directed by them towards the coast of Africa, and formed the Gulf of Guinea; being there checked and turned to the west by the mountains of Upper Guinea, the stream excavated the Caribbean Sea and the Gulf of Mexico; and issuing thence, it ran between the mountains of North America and Western Europe, until it gradually diminished in velocity and force, and at length subsided. Another writer speaks of the basin of the Atlantic as an immense rift, made by some terrible force, which rent the surface-land asunder, but left the edges of the ravine to show by their form that they had once been connected. For neither of these speculations, however, is there the smallest foundation in fact. What has to be accounted for, indeed, in regard to either of the great areas at present covered by water, is not so much the excavation of its sea-bed, as its segregation from an ocean originally universal by the boundaries that now enclose it; in other words, not so much the depression of the bottom of its basin as the elevation of its sides. Not only is the proportion of the land-surface of the globe to its water surface scarcely more than one-third (being as 1 to 2.78), but the entire mass of the land which thus covers little more than one-fourth of the surface of the globe is quite insignificant in comparison with that of the water which covers the remaining three-fourths. For whilst the average elevation of the whole land is certainly less than one-fifth of a mile, giving from 9 to 10 millions of cubic miles as the total mass of land that rises above the sea-level, the average depth of the sea (so far as at present known) may be taken at about 2 miles, giving a total of nearly 290 millions of cubic miles of water, which is therefore about *thirty times* the mass of the land. From the computation of Keith Johnston, it appears that, "if we conceive an equalising line, which, passing around the globe, would leave a mass of the earth's crust above it, just sufficient to fill up the hollow which would be left below it, this line would then fall nearly a mile below the present level of the sea." This is tantamount to saying that, if the solid crust of the earth could be conceived to be smoothed down to one uniform level, its entire surface would be covered with water to the depth of about a mile. Hence it is obvious that as the elevation of that crust into land over certain areas must be accompanied by a corresponding depression of the sea-bed over other areas, such depression, augmenting in those areas the previous depth of the aqueous covering of the globe, would be quite sufficient to account for the existence of the great oceanic basins, without any excavating action. And a confirmation of this view is found in the fact, ascertained by recent surroundings, that the deepest local depressions of the sea-bed are met with in the neighborhood of islands that have been raised by volcanic agency. Further, as the quantity of solid matter that must have been removed (on Humboldt's hypothesis) in the excavation of the Atlantic valley must have been nearly four times as great as that which forms the whole known land of the globe, and as it is impossible to conceive of any mode in which such a mass can have been disposed of, we may dismiss that hypothesis as not only untenable in regard to the Atlantic basin, but as equally inapplicable to any other valley of similar width and depth.

The general direction of geological opinion, indeed, has of late been, on physical grounds, towards the high antiquity of the great oceanic basins, not exactly as at present bounded, but as areas of depression having the same relation as they have now to the areas of elevation which form the great continents. Thus Sir Charles Lyell was strongly impressed by the fact that the mean depth of the sea is not improbably fifteen times as great as the mean height of the land; and that the depressions of the sea-bottom to a depth of three miles or more extend over wide areas, whilst elevations of the land to similar height are confined to a few peaks and narrow ridges. Hence, he remarked, "while the effect of vertical movements equalling 1000 feet in both directions, upward and downward, is to cause a vast transposition of land and sea in those areas which are now continental, and adjoining to which there is much sea not exceeding 1000 feet in depth, movements of equal amount would have no tendency to produce a sensible alteration in the Atlantic or Pacific Oceans or to cause the oceanic and continental areas to change places. Depressions of 1000 feet would submerge large areas of the existing land; but fifteen times as much movement would be required to convert such land into an ocean of average depth, or to cause an ocean three miles deep to replace any one of the existing continents." And Professor Dana, who, more than any other geologist, has studied the structure of the existing continents and the succession of changes concerned in their elevation, has been led, by the consideration of the probable direction of the forces by which that elevation was effected, to conclude that the defining of the present continental and oceanic areas began with the commencement of the solidification of the earth's crust. "The continental areas are the areas of the least contraction, and the oceanic basins those of the greatest, the former having earliest had a solid crust. After the continental part was thus stiffened, and rendered comparatively unyielding, the oceanic part went on cooling, solidifying, and contracting throughout; consequently, it became depressed, with the sides of the depression somewhat abrupt. The formation of the oceanic basins and continental areas was thus due to 'unequal radial contraction.'" In the opinion of Professor Dana, there has never been any essential change in the relations of these great features. "It is hardly possible," he says, "to conceive of any conditions of the contracting forces that should have allowed of the continents and oceans in after time changing places, or of oceans, as deep nearly as existing oceans, being made where are now the continental areas; although it is a necessary incident to the system of things that the continental plateaus should have varied greatly in their outline and outer limits, and perhaps thousands of feet in the depths of some portions of the overlying seas, and also that the oceans should have varied in the extent of their lands." . . . "The early defining, even in Archæan times, of the final features of North America, and the conformity to one system visibly marked out in every event through the whole history — in the positions of its outlines and the formations of its rocks, in the character of its oscillations, and the course of the mountains from time to time raised — sustain the statement that the American continent is a regular growth. The same facts also make it evident that the oceanic areas between which the continent lies have been chief among the regions of the earth's crust that have used the pent-up force in the contracting sphere to carry forward the continental developments. If this was true of the North American continent, the same in principal was law for all continents."

Dimensions of the Atlantic.—The length of the At-

lantic basin, considered as extending from the Arctic to the Antarctic circle, is nearly 8000 geographical miles. The nearest approach of its boundaries is between Greenland and Norway, whose coasts are only about 800 miles apart. They thence recede from each other towards the south, as far as the parallel of 30° N. lat., where, between the peninsula of Florida and the western coast of Marocco, there is an interval of 70° of longitude, or about 3600 geographical miles. The channel then rapidly narrows as it passes southward, so that between Cape St. Roque in Brazil (5° S. lat.) and the coast of Sierra Leone (between 5° and 8° N. lat.) the African and American continents approach within 1500 miles of each other. The sudden eastward recession of the African coast as it approaches the equator, and the westward trend of the South American coast-line between Cape St. Roque and Cape Horn, widen out the South Atlantic basin to the same breadth as that of the North Atlantic in the parallel of 30° N., — the interval between the Cape of Good Hope and the estuary of La Plata, in the parallel of 35° S., being no less than 73½° of longitude, or about 3600 geographical miles.

The depth of the North Atlantic has been more carefully and systematically examined than that of any other oceanic basin; and the general contours of its undulating sea-bed may now be regarded as pretty well determined. The greatest depth determined by the recent "Challenger" soundings, which was that of a limited depression about a hundred miles to the north of St. Thomas, is 3875 fathoms, or about 4.4 miles. Except in the neighborhood of its coast-lines, and in certain shallower areas to be presently specified, the floor of the basin at its widest part seems to lie at a depth of from 2000 to 3000 fathoms, its slopes being extremely gradual. The central portion of the principal basin of the North Atlantic, however, is occupied by a plateau of irregular shape, of which a considerable part lies at a less depth than 2000 fathoms. Of this plateau the Azores may be regarded as the culmination; and that group being taken as its centre, it may be said to extend to the north as far as lat. 50°, and to the south-west as far as the tropic of Cancer. The northern extension of this plateau narrows out into a sort of isthmus, which connects it with the plateau that occupies a great part of the Atlantic basin to the north of 50° N. lat.; and it is across this isthmus, and along the bottom of the deep narrow valley on either side of it, that the telegraph cables are laid between Ireland and Newfoundland.

Generally speaking, the depths of these valleys increase pretty rapidly with the distance from the shore-line, so that the contour-lines of one and two miles follow the shore-lines pretty closely. But there are two localities in which shallow water extends to a much greater distance from land than it appears to do elsewhere. One of these lies in the neighborhood of the British Isles. For a distance of about 230 miles to the westward of Ireland there is a slope of only about 6 feet in a mile; but in the next 20 miles there is a fall of 9000 feet, after which there is little change of level for 1200 miles. Hence as the depth of the sea immediately surrounding the British Isles is nowhere 100 fathoms (so that an elevation of their whole area to that amount would unite these islands not only to each other but also to the continent of Europe), it is obvious that the platform on which they rest is really, although now submerged, a part of the land-mass of Europe. Another of these extensive shallows is that of which the Banks of Newfoundland form the highest part; and of the existence of this a probable explanation may be found in the accumulation of the rock-masses that are brought down by icebergs every summer from the coasts of Greenland and Labrador. For it is now generally admitted that these icebergs are really parts of glaciers, that were originally formed on the mountain-slopes of Greenland and Labrador, and then descended valleys which open out on their coasts, so as, on arriving at the mouths of these valleys, to detach themselves and float away, being borne southwards by the Polar Current to be presently described. Most Arctic icebergs of which a near view can be obtained are observed to have upon them a considerable number of pieces of rock, sometimes of a very considerable size; and these are of course deposited on the sea-bed when the icebergs melt (which they usually do on the borders of the Gulf Stream), thus forming a vast conglomerate bed, to which parallels are not improbably to be found in various geological epochs.

Geological Age of the Atlantic Basin. — Guided by the principle that great oceanic basins are to be considered rather as original marine areas that have been limited by the elevation of their boundaries, than as having been formed by the excavation of terrestrial areas, we have to inquire what evidence there is that the basin of the Atlantic has undergone any considerable change within a comparatively recent period.

As has been pointed out by Prof. Wyville Thomson, it is difficult to show that any oscillations have occurred in the north of Europe since the termination of the Secondary period, to a greater extent than from 4000 to 5000 feet, — this being the extreme vertical depth between the base of the Tertiaries and the highest point at which Tertiary or post-Tertiary shells are found on the slopes and ridges of mountains. Such oscillations, while considerably modifying the boundaries of the Atlantic, would not seriously affect the condition of the deeper parts of its sea-bed; and hence it may be concluded that the two deep valleys, one on the European side of the modern volcanic platform of the Azores, and the other on the American, each having a width of 600 or 700 miles, and an average depth of 15,000 feet, could neither have been formed by such oscillations, nor could, when once formed, have been converted into dry land. It will be presently shown that this idea of the existence of an Atlantic basin corresponding generally to that now existing, as far back as the later Secondary period, is strongly supported by the evidence recently obtained of the continuity of animal life on the Atlantic sea-bed from the Cretaceous epoch to the present time.

Important information as to the changes which the sea-bed of the Atlantic has undergone within the later geological periods, may be gathered from the structure of the islands which lift themselves above its surface. Along its eastern border, at no considerable distance from the coast of North Africa, there are three principal groups, — the Madeiras, Canaries, and Cape Verd, — all of which have an evidently volcanic origin, and rise up from the eastern slope of the basin, where it is progressively shallowing towards its continental shore-line. Further out, in mid-ocean, lies the group of the Azores, which also is volcanic, and rises from the plateau already spoken of; but between this area and the slope from which the Maderias and Canaries are based is a very deep channel, ranging downwards to at least 15,000 feet; and a like depth is also found between the Azores and the coast of Portugal. The structure of all these groups of islands gives obvious indications of their formation by separate igneous eruptions in a sea of great depth; and the earliest of these eruptions seems to have taken place in the later Miocene period. As soon as the first solid lavas raised their heads above water, and were thus exposed to the action of the waves, fragments were detached and rounded on the shore; and these being swept off, with the *débris* resulting from their attrition, formed deposits of various kinds upon the slope of the cone, in which corals, shells, &c., were imbedded. These

fossiliferous deposits have been subsequently elevated to heights from 1500 to 2000 feet above the level of the sea, showing a rise of the base of the craters; progressive additions have been made to their upper part by the piling up of basaltic and trachytic lavas. That this state of activity still continues is proved by the fact that in 1811 a new island was temporarily formed in the Azores group, off St. Michael, by the throwing-up of ashes, and the formation of a cone about 300 feet high, with a crater in the center. This island, to which the name Sabrina was given, was soon washed away by the waves. And only a few years since, another submarine eruption in this neighborhood was indicated by earthquakes, jets of steam and columns of smoke, and floating masses of scoriæ. All these considerations concur (as Sir Charles Lyell, *loc. cit.*, justly urges) to negative on geological grounds the hypothesis which has been advocated by some eminent naturalists, that the Azores, Madeiras, and Canaries are the last remaining fragments of a continuous area of land which once connected them with the west of Europe and North Africa.

Proceeding to the south of the equator, we meet with similar evidence of volcanic activity in the structure of the only two islands, Ascension and St. Helena, which lie near the line stretching from the Cape Verd group to the Cape of Good Hope; and these also arise from a plateau of considerably less depth than the circumjacent area whose eastern slope gradually shallows to the coast of South Africa. This plateau stretches in a north-westerly direction towards the equator, so as to meet it from 20° to 22° W. long.; and here indications of volcanic activity — earthquakes, troubled water, floating scoriæ, and columns of smoke — have been several times observed since the middle of the last century, betokening the probable formation of an island or an archipelago in that locality.

Nearly midway between the southern prolongations of the African and American continents, the solitary peak of Tristan da Cunha lifts itself above the ocean; this also is volcanic, and seems to rise from a broad base of general elevation, resembling the plateau of the North Atlantic.

The entire chain of the Greater and Lesser Antilles, which stretches from the delta of the Orinoco to the peninsula of Florida, and forms the eastern boundary of the Carribbean Sea, seems to have been in like manner elevated by volcanic action. That this elevation, like that of the groups of islands on the eastern side of the Atlantic, took place for the most part during the later Tertiary period, is shown by the occurrence of shells, corals, &c., of upper Miocene age, in the upraised sedimentary beds of several of the islands; while the presence of "fringing reefs" of coral around the shores of many of the West India islands is an indication that they lie in a area in which elevation is still proceeding. The channels by which they are separated are so deep as to render it very unlikely that there was ever a continuity of land between them; and the occasional recurrence of earthquakes and volcanic eruptions at different points of this "line of fire," shows that the plutonic action by which the islands were raised is still going on beneath.

The case is very different, however, in regard to the Bermuda group, which constitutes a singular exception to the general fact of the absence in the Atlantic of those coral islands that are so numerous in the Pacific. This group consists of about 300 islands, of which, however, only five are of any considerable size; and these rise from a shoal or platform of about 23 miles long by 13 miles broad, the channels between the islands being very shallow, while at a small distance from the edge of the shoal, the bottom rapidly deepens to 15,000 feet. The islands are entirely composed of upraised beds of coral, shells, &c. (the highest elevation being only about 180 feet above the sea-level); and the shoal itself appears to have the like structure throughout, no traces of any other rock than a limestone formed by the metamorphoses of coral being anywhere met with. Hence, as this insular platform proves to be the summit of a submarine column of 15,000 feet high, rising from a very small base, and as nothing we know of the structure of mountains—volcanic or other—would justify us in supposing that a column of such a height could be formed in any other way than by coral growth, the structure of the Bermuda group would seem to indicate a progressive subsidence of the bed of this part of the Atlantic during its formation, corresponding to that which (according to the well-known views of Mr. Darwin) is at present in progress over a large area of the Pacific. It is probable that this coral growth was determined in the first instance by the existence of a submarine mountain, of which the summit lay near the surface, or lifted itself above it; that as soon as this came to be submerged, the coral formation commenced; and that by its continued growth at the summit, at a rate equal to that of the subsidence of its base, the platform has been kept up to the sea-level. The slight elevation which has raised its highest portion above that level may not improbably have taken place in connection with the much larger recent elevations already referred to.

Thus, then, we have evidence of considerable recent local modifications in the level of the Atlantic sea-bed, without any such change as would affect its general character as an ocean basin; while all geological probability seems in favor of the remoteness of the principal depression of the Atlantic area, even if we do not regard it as dating back to the period when the surface of the globe was first undergoing solidification.

Currents of the Atlantic.—By the term "current" will be here meant that *sensible* movement of ocean water in particular directions which can be generally traced, directly or indirectly, to the action of wind upon its surface. A current thus directly impelled by wind is termed a "drift-current," whilst a current whose onward movement is sustained by the *vis a tergo* of a drift-current" is called a "stream-current." But there is another source of current-movement, which has been overlooked by most writers on this subject, namely, the indraught which necessarily takes place to keep up the level of any area from which the surface-water is constantly being drifted away. Such currents, which may be designated as "indraught" or "supply currents" complete the "horizontal circulation" that must necessarily take place in any oceanic area of which one part is subjected to the action of a wind almost constantly blowing in the same direction. Of such a circulation we have a very characteristic example in the South Atlantic, the principal currents of which we shall see to be very easily accounted for.

The initial movement of the current-system, alike of the North and of the South Atlantic, is given by the trade-winds, which are continually driving the water of the inter-tropical region from the African towards the American side of the basin, so as to produce what is known as the *Equatorial Current.* The position of the northern and southern boundaries of this current shifts, like the area of the trade winds, in accordance with the northward and southward declination of the sun;—a steady westward drift being generally met with to the north of the tropic of Cancer in the summer of the northern hemisphere, and to the south of the tropic of Capricorn in the summer of the southern, whilst in the winter of each hemisphere the border of the drift

lies within the tropic of that hemisphere. But as the *thermal* equator lies from two to three degrees to the north of the *geographical* equator, the entire zone of the trade-winds, and of the Equatorial Current propelled by them, is wider on the northern than on the southern side of the latter; and while the northerly trade often reaches 30° N. in July, and rarely extends south in January within 2° or 3° of the geographical equator, the southerly trade does not extend farther than 25° S. in January, and generally crosses the equator in July, even extending occasionally as far as 5° N. As between the northerly and southerly trades there is a region of "equatorial calms," so there is a corresponding interval between the northern and southern divisions of the Equatorial Current; and in this interval there is a counter-current (resembling the "back-water" often to be noticed in a stream that is flowing rapidly past some obstacle, such as a vessel at anchor, or a projecting river-bank), that runs eastwards, sometimes with considerable velocity, towards the Bight of Biafra, which may be considered the "head-water" of the Equatorial Current. From the recent observations of Capt. Nares in the "Challenger," it appears that the Equatorial Current, like other drift-currents, is very shallow, its depth being not much greater than 50 fathoms. He estimates its rate at the surface to be about 0.75 miles per hour, or 18 miles per day, whilst at 50 fathoms it only moves at about half that rate. Its surface temperature generally ranges between 75° and 80°; but the thermometer falls to 60° at a depth of little more than 100 fathoms,—the temperature of this belt of water, as will be hereafter shown, being kept down by the continual rising of polar water from below.

The Equatorial Current passes directly across the Atlantic towards the chain of the Antilles and the coast of South America; and as not only the whole of the northern division, but a considerable part of the southern, strikes the American coast-line to the north of the salient angle of Cape St. Roque (about 5° S. lat.), the portion of the current which is deflected into the northern hemisphere is much greater than that which is turned to the southward. It is a general fact, that where a current encounters any partial obstruction,—such as a coast-line meeting obliquely, a narrowing of its channel, the lateral pressure of another current, or even that of a mass of stationary water,—its velocity increases; and so the portion of the Equatorial Current that is pressed to the northward by the coast-line between Cape St. Roque and the mouth of the Orinoco (known in the first part of its course as the *Cape St. Roque Current*, and afterwards as the *Guiana Current*) acquires a greatly augmented rate, running ordinarily at the rate of from 30 to 50 miles, and occasionally at a rate of 80 miles, in the 24 hours. Entering the Caribbean Sea, it is reinforced by the portion of the Equatorial Current which flows in between the Lesser Antilles; and it then passes westwards along the northern coast of South America, until it is deflected northwards by the coast-line of Central America, and driven between the peninsula of Yucatan and the western extremity of Cuba into the Gulf of Mexico, at the rate of from 30 to 60 miles per day. A portion of it passes direct to the N.E. along the northern shore of Cuba; but by far the larger part sweeps round the gulf, following the course of its coast-line, and approaches the coast of Cuba from the N.W. as a broad deep stream of no great velocity, seldom running at more than 30 miles per day. The reunited current, being met by the Equatorial Current from the outside, which is pressing to the west along the north coast of Cuba and between the Bahama isles, is deflected northwards through the passage termed the Florida Channel, which is bounded on the one side by the southern extremity of the peninsula of Florida, and on the other by the coast of Cuba and the Bahamas. The rate of movement of the powerful current that flows through this channel, henceforth known as the *Gulf Stream*, is considerably augmented in its narrowest part, which is also its shallowest; but although its velocity sometimes reaches 4 (nautical) miles per hour, or even more, its *average* rate through the whole year may be confidently stated at not more than 2 miles per hour, or 48 miles per day.

The Gulf Stream current, however, does not by any means occupy the whole of the sectional area of the Florida Channel; for it is separated from the American coast by a band of cold water, which occupies about three-eighths of its total breadth of 40 miles, and which also dips under the outflowing current. The movement of the cold superficial band is perceptibly inwards, and that of the cold under-stratum is presumably so; and it is the opinion of the American surveyors that the depth of the warm outward current is not more than one-third of that of the channel through which it flows. It is probable that the rate of movement decreases from the surface downwards; but upon this point we have as yet no certain information. The meaning of the cold inflow will hereafter become apparent.

The course taken by the Gulf Stream in the first instance is nearly parallel to the line of the United States coast, from which it is everywhere separated by a band of cold water,—the boundary line between the two being so distinct as to be known as the "cold wall." It does not show for some time any great disposition to spread itself out laterally, though a division into alternate bands of warmer and colder water, the cause of which seems to lie in the contour of the bottom of the Florida Channel, becomes perceptible before it reaches Charleston, and is very marked off Cape Hatteras. The Stream there presents the form of a fan, its three warm bands spreading out over the Atlantic surface to an aggregate breadth of 167 miles, whilst two cold bands of an aggregate breadth of 52 miles are interposed between them. The innermost warm band is the one which exhibits the highest temperature and greatest rate of flow, its velocity being greatest where it is pressed on laterally by the Arctic Current, so that a rate of 4 miles per hour is occasionally observed. Capt. Nares estimates the depth of the Stream in this part of its course at about 100 fathoms, and its rate of flow in the line of most rapid movement at 3 miles per hour. The outermost band, on the other hand, graduates insensibly, both as to temperature and rate of movement, into the general surface-water of the Atlantic. It is when passing Sandy Hook that the Gulf Stream takes its decided turn eastwards,—this change in its direction being partly due to the eastward bend of the United States coast-line, and partly to the *excess of easterly momentum* which it brings from the lower latitude in which it issued from the Florida Channel. Its general rate of flow past Nantucket seems not to exceed 1 mile per hour, and to be frequently less; but several degrees to the eastward of this, the current has been found occasionally running at the rate of 4 miles an hour,—this acceleration being probably due to the lateral pressure of the *Arctic Current*, which, during the early months of the year, is driven southwards at the rate of 10 or 12 miles per day by the N. and N.W. winds then prevailing along the coast of Labrador, and which, turning westwards round the south of Newfoundland, keeps close to the coast of the United States (being left behind in the rotation of the earth, in consequence of its *deficiency* of easterly momentum), and follows it southwards, everywhere separating it from the Gulf Stream.

By the gradual thinning-out and expansion of the

Gulf Stream after passing the Banks of Newfoundland, by the progressive reduction of its rate of movement, and by the loss of that excess of temperature which previously distinguished it, as well as of its peculiar blue color (which probably depends on its holding in suspension the finest particles of the river-silt brought down by the Mississippi), this remarkable current so far loses all its special attributes, as to be no longer recognisable to the east of the meridian of 30° W. long.,—there degenerating into the general easterly drift of that region of the Atlantic which is kept up by the prevalence of westerly winds, sometimes called "anti-trades." When the Florida Current or true Gulf Stream can last be distinctly recognised, it forms a stratum not more than 50 fathoms in thickness; and it is there flowing *almost due east*, at a rate which would require about 100 days to bring it to the Land's End. The only valid evidence of the extension of any part of it to the western shores of Europe (the amelioration of their temperature being otherwise accounted for, while the transport of trunks of trees, drift-timber, fruits, shells, &c., to the Western Hebrides, the Orkney, Shetland, and Faroe islands, and the coast of Norway, may be fairly set down to the surface-drift sustained by the prevalence of S.W. winds) is afforded by the variable current known as *Rennell's*, which, flowing eastwards into the southern part of the Bay of Biscay, is deflected in a N.W. direction by the trend of its coast-line, so as to cross the British Channel towards the Sicilly Islands, whence it passes to the S.W. coast of Ireland, its strength mainly depending on the continued prevalence of the westerly anti-trades.

Of the whole mass of water, on the other hand, that is brought into the mid-Atlantic by the Gulf Stream, it may be stated with confidence that the larger proportion turns southward to the east of the Azores, and helps to form the *North African Current;* the other tributary of which may be considered as originating as far north as Cape Finisterre, under the influence of the northerly winds which prevail along the coast of Portugal. As this current flows past the entrance to the Strait of Gibraltar, a part of it, forming what is known as the *Gibraltar Current*, is drawn in to keep up the level of the Mediterranean, which would otherwise be reduced by the excess of evaporation from its surface; but the greater part keeps its course southwards along the Marocco coast, reinforcing the south-flowing extension of the Gulf Stream. On arriving at the border of the northerly trade, the North African Current divides into two parts,—the western division being at once carried into the course of the equatorial drift, whilst the eastern, which may be considered as essentially an indraught or supply current follows the African coast-line, and turns eastward into the Gulf of Guinea, forming the *Guinea Current*, which, coalescing with the eastward "back-water" already mentioned, flows pretty constantly, sometimes with considerable rapidity, towards the Bight of Biafra. There it meets the *South African Current*, which forms the other great feeder of the Equatorial Current; and the circulation thus completed may be considered as recommencing from the "head-water." The large area of comparatively still water which lies in the interior of this North Atlantic circulation is called the *Sargasso Sea*,—a corruption of the name (Mar de Sargaço) which it received from Columbus and the early Spanish navigators, on account of the quantity of sea-weed that floats on its surface. The boundaries of this area, which is of an irregularly elliptical shape, and nearly equals that of Continental Europe, are somewhat variable; but it may be considered to lie between the parallels of 20° and 35° N., and between the meridians of 30° and 60° W. Into it is collected a large proportion of the drift or wreck which floats about the North Atlantic.

Proceeding now to the South Atlantic, we meet with a circulation of the same kind, uncomplicated by any embaying of the Equatorial Current. The smaller division of this current which strikes the coast of South America to the south of Cape St. Roque flows along the coast of Brazil at the rate of from 12 to 20 miles a day, forming the *Brazil Current*, which, however, is separated from the land by an intervening band of lower temperature, that has, during the winter months, a distinct flow towards the equator. The Brazil Current can be traced southwards, by its temperature rather than by its movement, as far as the estuary of the La Plata, before reaching which, however, a great part of it takes an easterly direction, and crosses the Atlantic towards the Cape of Good Hope, forming what is known as the *Southern Connecting Current*. The easterly movement of this current seems to be partly due to the westerly anti-trades, and partly to the excess of easterly momentum which is retained by the Brazil Current in its southward course from Cape St. Roque; whilst it partly depends also on the junction of an Antarctic current that flows N.E. from Cape Horn, meeting the Brazil Current off the estuary of La Plata, just as the Arctic Current meets the Gulf Stream off Newfoundland,—dense fogs being produced, in the one case as in the other, through the precipitation of the vapor overlying the Equatorial Current, by the colder air that overlies the Polar. On meeting the coast of South Africa, the Southern Connecting Current turns northwards, and runs towards the Bight of Biafra, forming the *South African Current*, the movement of which is partly sustained by the southerly winds which prevail along that coast, but is partly attributable to the indraught set up to supply the efflux of the Equatorial Current. In its passage thither, however, the part of it most distant from the land is draughted westwards by the southern trade, forming the most southerly portion of the equatorial drift. Between this and the Southern Connecting Current is a central space, lying between the parallels of 20° and 30° S., and the meridians of 0° and 25° W., over which there are no regular currents; and to this the name Sargasso Sea is sometimes applied by analogy, although its surface has no covering of sea-weed.

Temperature of the Atlantic.—The distribution of surface temperature over the area of the Atlantic has now been made out with considerable accuracy; and it corresponds closely with what has been already stated as the course of the surface currents. There is, of course, a seasonal change, alike in its northern and in its southern division, this change being more and more marked as we recede from the equator. Following the course of the mean annual isotherms, however, we find that they cross the South Atlantic at nearly regular intervals, in an east and west direction, the principal departure from that direction being shown at their western end in the bend they take towards the south under the influence of the warm Brazil Current, and at their eastern in the still stronger bend they take towards the north under the influence of the cold South African Current, which reduces to about 75° the temperature of the southern equatorial that flows alongside the Guinea Current, whose temperature is 82°. In the North Atlantic, however, the influence of the movement of oceanic water on the surface-temperature is very much more marked. The annual isotherms, which cross the Sargasso Sea with nearly regular parallelism, and on the African side tend somewhat to the south, where they meet the colder water of the North African Current, show a strong northward bend on the American side,

along the early course of the Gulf Stream ; but as its excess of temperature above that of the Atlantic generally diminishes as we trace it towards the Banks of Newfoundland, this northward deflection progressively becomes less. The marked contrast in temperature which is often there exhibited between two contiguous bands of water,— a thermometer hanging from a ship's bow showing a temperature of 70°, whilst another hanging from the stern shows only 40°,— is due not so much to the elevation produced by the Gulf Stream as to the depression produced by the Arctic Current. This depression manifests itself in the southward bend given, on the American side; alike to the summer and the winter isotherms, beyond the summer isotherm of 70° and the winter isotherm of 60°, which may be considered as having nearly their normal position ; whilst the northward tendency of these same isotherms on the European side not less conspicuously indicates a flow of warm water towards the western coasts of the British Isles, Norway, and even Iceland and Spitzbergen. It has been customary to regard this flow as an extension of the Gulf Stream ; but if that term be limited (as it ought) to the current that issues from the Gulf of Mexico through the Florida Channel, the hypothesis is found to be untenable so soon as the thermal phenomena of that current are carefully examined. For, in the first place, the popular idea that the Gulf Stream retains it high temperature with little diminution during its passage first northwards and then eastwards is clearly disproved by observation.

From this it appears that, while the high surface-temperature with which the Gulf Stream leaves the Florida Channel is retained in summer with only 5° reduction as far as Nova Scotia, there is a reduction of 5° in winter during its northward passage to Cape Hatteras, and a further reduction of no less than 10° during its eastward passage from Cape Hatteras to Nova Scotia, making it a total reduction of 15°. In spring, again, there is a total reduction of 11°, and in autumn of 13°; and in both cases the reduction during the *eastward* flow under the parallel of 35° N. is greater than the reduction in the *northward* flow from 25° N. to 35° N. The explanation of this is plainly to be found in the fact that in the early part of the course of the Gulf Stream its superheated stratum is a thick one, so that when its superficial film is cooled down by a superincumbent atmosphere of lower temperature, it is replaced by the uprising of a deeper stratum having nearly its original temperature. But as the stream spreads out superficially, its superheated stratum becomes proportionally thinner, and will consequently be more and more rapidly cooled down by the superincumbent atmosphere. Even supposing, therefore, that it were not subjected to any special cooling influence, it appears certain that, as the rate of the current slackens and its depth diminishes, the cooling process must continue at an increased rate, so as to bring down the surface-temperature of the stream to the normal isotherm of the locality, long before it could reach the shores of Europe. But it has been shown that when it passes Newfoundland the Gulf Stream *is* subjected to a special cooling influence — that of the Labrador Current with its fleet of icebergs, which melt away when borne into it ; and this produces such an immediate reduction of its surface-temperature, that it thenceforth shows very little excess, although its sub-surface stratum still appears to be warmer than that of the ocean through which it flows.

But, further, the Gulf Stream, where it is last recognisable as a current, is flowing due east, and its southern portion turns first south-east and then south, whilst on the other hand, the course of the isothermal lines clearly shows that the flow of warm water which carries them northward spreads across the whole breadth of the Atlantic, from the British Isles to Labrador, even extending up to the west of north into Baffin's Bay. When we contrast this immense body of north-moving water with the thinned-out film of what is by comparison a mere rivulet, it becomes obvious (1) that its northward flow cannot be attributable to the *vis a tergo* of the Florida Current, whilst (2) its convection of heat to the Arctic Sea cannot be accounted for by any amount of excess of temperature that is limited to a small depth, since the temperature of such a stratum, moving north-east at a rate of (at most) 4 or 5 miles per day, must soon be brought down to that of the atmosphere above it.

Influenced by these considerations, several eminent hydrographers, both British and American, have been disposed to deny, not only that the temperature of the North Atlantic is modified in any considerable degree by the true Gulf Stream, but that any other agency than that of warm S.W. winds is concerned in producing the climatic amelioration popularly attributed to it. They maintained, in fact, that the surface-temperature of the North Atlantic and Arctic Seas *follows* that of the superincumbent air,— the atmospheric temperature not being in any degree raised by that of warmer water beneath. This doctrine, however, is found to be inconsistent with the results of careful comparisons recently instituted between marine and atmospheric temperatures along the western coasts of Scotland, the Orkney, Shetland, and Faroe Islands, and especially with those obtained along the western coast of Norway. For it is found that during the winter months there is a constant *excess* of sea-temperature above that of the air, averaging 6°.2 Fahr. along the western coast of Scotland and its islands, and rising to 14°.5 at Fruholm near the North Cape. And it is also a very significant fact (ascertained by the careful inquiries of Mr. Buchan), that while the *summer* isotherms cross the British Islands nearly east and west (the temperature diminishing pretty regularly from south to north), the *winter* isotherms traverse them nearly north and south (the temperature diminishing from west to east); whilst in Ireland the isotherms seem to envelope the islands in their folds, which increase in warmth from the centre of the island to its sea-board. So in Norway the isothermal lines run parallel with the coast-line, and this alike in summer and winter,— the temperature falling in winter, and rising in summer, with the increase of distance from the sea. Nothing could prove more conclusively than such facts as these (taken in connection with the absence of ice in the harbors of Norway, even as far north as Hammerfest, through the whole winter) the dependence of the mild winter climate of the north-western coasts of Europe upon the proximity of a sea which is warmer than the superincumbent atmosphere; and we have now to inquire how this great N.E. movement of a stratum of warm water sufficiently thick to retain a surface-temperature considerably higher than that of the air above it is to be accounted for.

The solution of the problem seems to be afforded by the doctrine of a *General Oceanic Circulation*, sustained by opposition of temperature only, which was first distinctly propounded in 1845 by Professor Lenz of St. Petersburg, on the basis of observations made by him during the second voyage of Kotzebue (1825–1828). Others had been previously led to surmise that "Polar Currents" flow along the floors of the great oceans, even as far as the equator, balancing the superficial counter-currents which are observable in the opposite direction. But Lenz was led to conclude that the

whole of the deeper portion of the great ocean-basins in communication with the polar areas is occupied by polar water, which is constantly, though slowly, flowing towards the equator; whilst conversely the whole upper stratum of equatorial water is as constantly, though slowly, flowing towards one or both of the poles. And he particularly dwelt on the existence of a belt of water under the equator, colder than that which lies either north or south of it, as an evidence that polar water is there continually rising from beneath towards the surface,— a phenomenon which, he considered, admits of no other explanation. He further adduced the low salinity of equatorial water (previously noticed by Humboldt, and confirmed by his own observations), compared with that of tropical water, as evidence that the equatorial water of the surface is derived from the polar underflow. And he attributed the maintenance of this circulation to the continually renewed disturbance of equilibrium between the polar and equatorial columns,— the greater lateral (because downward) pressure of the former causing a *bottom outflow* of polar water in the direction of the latter, whilst the reduction of level thus occasioned will produce a *surface indraught* from the warmer towards the colder areas.

The doctrine of Lenz, so far from meeting with the general acceptance to which it had a fair claim,— alike on theoretical grounds and from its accordance with the facts ascertained by careful observation,— seems to have been put aside and forgotten, a preference being given to the doctrine of the prevalence of a uniform deep-sea temperature of 39°, which was supposed to be established by the thermometric observations made in the voyages of D'Urville and Sir James Ross. No such precaution, was taken in these observations as to that which Lenz had recourse, to obviate the effects of the tremendous pressure (1 ton per square inch for every 800 fathoms of depth) to which deep-sea thermometers are exposed; and it is now certain that the temperatures at great depths recorded by D'Urville and Ross were several degrees too high.

It was in entire ignorance of the doctrine of Lenz, and under the influence of that of D'Urville and Ross, which had been stamped with the great weight of Sir John Herschel's weight of authority, that Dr. Carpenter commenced in 1868 (in concert with Professor Wyville Thomson) a course of inquiry into the thermal condition of the deep sea, which at once convinced him of the fallacy of the uniform 39° doctrine, and led him to conclusions essentially accordant with those of Lenz. For in the channel of from 500 to 600 fathoms' depth between the north of Scotland and the Faroe Islands, they found the deeper half to be occupied by a stratum of glacial water, whose temperature ranged downward from 32° to 29°.5; whilst the upper half was occupied by a stratum warmer than the normal temperature of the latitudes. This phenomenon was interpreted by Carpenter as indicating a deep glacial flow from N.E. to S.W., and a warm upper flow from S.W. to N.E.; and finding that to the west of this channel, on the border of the deep Atlantic basin, the excess of warmth extended to a depth of more than 500 fathoms, he came to the conclusion that the north-moving stratum which brought it could not be an extension of the true Gulf Stream, but must be urged on by some much more general force. A series of temperature-soundings taken along the west of Ireland, the Bay of Biscay, and the coast of Portugal, confirmed him in this view, by showing that the division between an upper warm stratum and a cold under-stratum exists in the North Atlantic at a depth of from 700 to 900 fathoms, the whole mass of water below this having either flowed into the basin of the polar area, or having had its temperature brought down from 39° to 36°.5 by mixture with the polar inflow. And this conclusion was confirmed by the result of temperature-soundings taken at corresponding depths and under the same parallels of latitude in the Mediterranean; for as they showed a uniform temperature of from 54° to 56°, from beneath the stratum of 100 fathoms that was superheated by direct insolation, to the very bottom, it became clear that depth *per se* could have no effect in reducing the bottom-temperature; and that the cause of the excess of temperature in the mass of water occupying the Mediterranean basin above that of Atlantic water at the same depths, lies in the seclusion of the former from the polar underflow which brings down the deep temperature of the latter. This conclusion having received marked confirmation from temperature soundings taken in the Eastern seas, was put forward by Carpenter as justifying the doctrine of a *vertical* oceanic circulation sustained by opposition of temperature only, quite independent of and distinct from the *horizontal* circulation produced by wind,— which doctrine he expressed in terms closely corresponding with those that had been used by Lenz. And the collection of data for the establishment or confutation of this doctrine was one of the objects of the "Challenger" expedition, which has already made, in the determination of the thermal stratification of the Atlantic between 38° N. lat. and 38° S. lat., what may fairly be characterised as the grandest single contribution ever yet made to terrestrial physics.

Distribution of Organic Life.— All that will be attempted under this head will be to indicate the general conditions that seem, from recent researches, to have the greatest influence on the distribution of plants and animals through this great oceanic basin.

The distribution of marine plants seems mainly determined by light, temperature, and depth,— a further influence being exerted by the character of the shores. The diminution of light in its passage through sea-water is so rapid, that the quantity which penetrates to a depth of 250 or 300 fathoms may be regarded as almost infinitesimal; and in conformity with this we find a very rapid diminution of Algal life below the depth of 100 fathoms. The upper stratum is occupied for the most part by the larger and coarser forms of the *Fucaceæ*, or olive-green sea-weeds, whilst the more delicate *Ceramiaceæ*, or red sea-weeds, frequent deeper waters; and, as it appears from experiments made in aquaria that the latter do not flourish in full light, but grow well in shadow, it may be concluded that their preference for a moderate depth is rather for reduced light and stillness than for depth *per se*. At a depth of 150 fathoms very few ordinary sea-weeds maintain their ground; and below this we seldom find any Algæ, save the Corallines and Nullipores consolidated by calcareous deposit. The distribution of particular types over different parts of the Atlantic area appears to be mainly regulated by temperature; and this would seem to be remarkably the case with the floating *Diatomaceæ*, which, though they form green bands in the surface-water of polar seas, have not been encountered in like abundance in the Atlantic, and do not contribute largely, by the subsidence of their siliceous *loricæ*, to the composition of its bottom-deposit. Although it is the habit of the larger Algæ to grow from a base of attachment (their roots serving no other purpose however, than that of anchorage), the enormous mass of Gulf-weed found in the Sargasso Sea seems quite independent of any such attachment. It was at one time supposed that this originally grew on the Bahama and Florida shores, and was torn thence by the powerful current of the Gulf Stream; but it seems certain that if such was its original source, the "Gulf-weed" now lives and propagates whilst freely

floating on the ocean-surface, having become adapted by various modifications to its present mode of existence.

The distribution of the animals that habitually live in that upper stratum of the ocean whose degree of warmth varies with the latitude, seems mainly determined by temperature. Thus the "right whale" of Arctic seas, and its representative in the Antarctic, seems never to enter the inter-tropical area, generally keeping away from even the temperate seas, whilst, on the other hand, the sperm whale ranges through the parts of the ocean where the "right-whales" are never seen.

The distribution of fishes seems generally to follow the same rule; as does also that of floating mollusks. Thus the little *Clio* (a Pteropod mollusk), which is a principal article of food of the "right whales" in polar seas, is rarely met with in the Atlantic, where, however, other pteropods, as *Hyalæa*, present themselves in abundance. On the other hand, the warmer parts of its area swarm with Salpa-chains, which are not frequent in higher latitudes; and the few representatives of the Nautiloid Cephalopods, that were so abundant in Cretaceous seas, are now restricted to tropical or sub-tropical areas. And the distribution of the mollusks, echinoderms, and corals, which habitually live on the bottom, seems to be determined, within certain limits at least, by temperature rather than by depth.

The bathymetrical range to which animal life of any higher type than the Rhizopodal might extend, was until recently quite unknown; but the researches initiated by Prof. Wyville Thompson and Dr. Carpenter, in 1868, and since prosecuted by the "Challenger" expedition, have fully established the existence of a varied and abundant fauna in ocean-depths ranging downwards to 2000 fathoms. And these researches have further established that the distribution of this fauna is mainly determined by the temperature of the sea-bed; so that whilst in the channel between the north of Scotland and the Faroes there were found at the same depths, and within a few miles of each other, two faunæ almost entirely distinct — one a boreal and the other a warmer-temperate — on sea-beds having respectively the temperatures of 30° and 43°, various types to which a low temperature is congenial are traceable continuously along the whole abyssal sea-bed that intervenes between those northern and southern polar areas within which they present themselves at or near the surface. And hence it becomes clear that, since glacial types are even now being embedded in the strata which are in process of formation beneath the equator, no inferences as to terrestrial climate can be drawn from the character of marine deposits.

One very remarkable feature which presents itself over a large proportion of the Atlantic basin is the abundance of the minute *Globigerinæ* and other Foraminifera, the accumulation of whose shells, and of their disintegrated remains, is giving rise to a calcareous deposit of unknown thickness, that corresponds in all essential particulars to Chalk. This deposit, in some parts of the North Atlantic, is replaced by an Arctic drift of fine sand, whilst in other parts there is a mixture of arenaceous and of calcareous components, such as is found in certain beds of the Cretaceous formation. Now on the surface of this deposit there have been found so many living types, especially belonging to the groups of Echinoderms, Corals, Siliceous Sponges, and Foraminifera, which closely correspond with types hitherto regarded as characteristic of the Cretaceous epoch, that the question naturally suggests itself whether the existing are not the lineal descendants of the fossil types,— the differences they present being not greater than may be fairly attributed to the prolonged action of differences of temperature, food, pressure, &c. And when these facts are taken in connection with those previously stated as to the probable remoteness of the period when (if ever) the present sea-bed of the Atlantic was dry land, the doctrine first put forth by Prof. Wyville Thomson, that there has been a continuous formation of Globigerina-mud on the bottom of the Atlantic from the Cretaceous epoch to the present time — or, in other words, that the formation of chalk on the sea-bed of the Atlantic did not cease with the elevation of the European area, but has been going on through the whole Tertiary period,— must be admitted as (to say the least) a not improbable hypothesis. That some considerable change took place at the conclusion of the Cretaceous epoch, by which the temperature of the upper stratum was lowered, so as to be no longer compatible with the existence of the fishes and chambered cephalopods characteristic of the Cretaceous fauna, may be fairly assumed from their disappearance; but this would not so much affect the deeper part of the basin, in which those lower types that seem more capable of adapting themselves to changes in external conditions would continue to hold their ground. That the like conditions had prevailed also through long previous geological periods, may be surmised from the persistence, over various parts of the Atlantic sea-bed, of the *Apiocrinite* type, which carries us back to the Oolitic formation, and of the *Pentacrinus* type, which has come down with very little alteration from the Liassic; whilst many existing *Terebratulidæ* do not differ more from Oolitic types that the latter differ among each other. Going back still further, we find in the persistence of certain Foraminiferal types from the Carboniferous limestone to the present time, and in the character of its deep-sea beds, a strong indication that they originated in a Foraminiferal deposit, representing in all essential particulars that which is now going on; while the persistence of the *Lingula* from the early Silurian strata to the present time suggests the question whether certain oceanic areas may not have remained in the condition of deep sea throughout the whole subsequent succession of geological changes.

ATLANTIS, ATALANTIS, or ATLANTICA, an island mentioned by Plato and other classical writers, concerning the real existence of which many disputes have been raised. In the *Timæus*, Critais relates how his grandfather Critais had been told by Solon some remarkable events in early Athenian history which he had learned from the Egyptian priests at Sais, whose records went much further back than the native accounts. "The most famous of all the Athenian exploits," Solon had been told, "was the overthrow of the island Atlantis. This was a continent lying over against the pillars of Hercules, in extent greater than Libya and Asia put together, and was the passage to other islands and to another continent, of which the Mediterranean Sea was only the harbor; and within the pillars the empire of Atlantis reached to Egypt and Tyrrhenia. This mighty power was arrayed against Egypt and Hellas and all the countries bordering on the Mediterranean. Then did your city bravely, and won renown over the whole earth, for at the peril of her own existence, and when the other Hellenes had deserted her, she repelled the invader, and of her own accord gave liberty to all the nations within the pillars. A little while afterwards there was a great earthquake, and your warrior race all sank into the earth; and the great island of Atlantis all disappeared into the sea. This is the explanation of the shallows which are found in that part of the Atlantic ocean." Such is the main substance of the principal account of the island furnished by the ancients,—an account which, if not entirely fictitious, belongs to the most nebulous region of history. The story may

embody some popular legend; and the legend may have rested on certain historical circumstances; but what these were it is (as the numerous theories advanced on the subjected may be held as proving) impossible now to determine.

ATLAS, in *Greek Mythology*, called sometimes a son of Japetus and the nymph Asia, or of Uranus and Gaia, and at other times traced to a different parentage, but always known as the being who supported on his shoulders the pillars on which the sky rested.

ATLAS, a mountain-chain of Northern Africa, between the great desert of the Sahara and the Mediterranean. The range has been but partially explored, and geographers differ as to its extent, some considering it to reach from Cape Ghir on the Atlantic to Cape Bon, the north-east point of Tunis, while others include under the name the whole mountain system between Cape Nun und the great Syrtis. In this latter sense it forms the mountain-land of the countries of Marocco, Algeria, Tunis, and Tripoli. It is composed of ranges and groups of mountains, enclosing well-watered and fertile valleys and plains, and having a general direction from W. to E. The highest peaks are supposed to attain an elevation of nearly 15,000 feet; and although none of them reach the height of perpetual snow, some of their loftiest summits are covered with snow during the greater part of the year. Mount Miltsin, 27 miles S.E. of the city of Marocco, was ascertained by Captain Washington to be 11,400 feet high. The greatest heights are in Marocco, from which point they appear to diminish in elevation as they extend towards the east.

ATMOSPHERE is the name applied to the invisible elastic envelope which surrounds the earth, the gaseous matter of which it is composed being usually distinguished by the name of air. Storms and weather generally, solar and terrestrial radiation, the disintegration of rocks, animal and vegetable life, twilight, and the propagation of sound, are some of the more striking phenomena which are either to a large extent or altogether dependent on the atmosphere. That air possesses weight may be shown by the simple experiment of taking a hollow globe filled with air and weighing it; then removing the contained air by means of an air-pump, and again weighing the globe, when it will be found to weigh less than at first. The difference of the two results is the weight of the air which has been removed. From Regnault's experiments, 100 cubic inches of dry air, or air containing no aqueous vapor, under a pressure of 30 English inches of mercury, and at a temperature of 60° Fahr., weigh 31.03529 grains; and since 100 cubic inches of distilled water at the same pressure and temperature weigh 25,252½ grains, it follows that air is 813.67 times lighter than water.

Air as an elastic fluid exerts pressure upon the earth or any substance on which it rests, the action of a boy's sucker and of a water-pump being familiar instances showing the pressure of the atmosphere. When air is removed from a water-pump, the water rises in the pump only to a certain height; for as soon as the water has risen to such a height that the weight of the column of water in the pump above the level of the surface of the water in the well just balances the pressure exerted by the atmosphere on the surface of the well, it ceases to rise. If the pressure of the atmosphere be increased, the water will rise higher in the pump; but if diminished, the level of the water will sink. The height to which the water rises within the pump thus varies with the pressure of the atmosphere, the height being generally about 34 feet. Since a given volume of mercury weighed *in vacuo* at a temperature of 62° Fahr. is 13.569 times heavier than the same volume of water it follows that a column of mercury will rise *in vacuo* to a height 13.569 times less than a column of water, or about 30 inches. If we suppose, then, the height of the mercurial column to be 30 inches, which is probably near the average height of the barometer at sea-level, and its base equal to a square inch, it will contain 30 cubic inches of mercury; and since one cubic inch of mercury contains 3426.7 grains, the weight of 30 cubic inches will be nearly 14.7304 lb. avoirdupois. Thus the pressure of the atmosphere is generally at sea-level equal to 14.7304 lb. on each square inch of the earth's surface. Sir John Herschel has calculated that the total weight of an atmosphere averaging 30 inches of pressure is about 11⅔ trillions of pounds; and that, making allowance for the space occupied by the land above the sea, the mass of such an atmosphere is about $\frac{1}{1\,200\,000}$ part of the earth itself. This enormous pressure is exerted on the human frame in common with all objects on the earth's surface, and it is calculated that a man of the ordinary size sustains a pressure of about 14 tons; but as the pressure is exerted equally in all directions, and permeates the whole body, no inconvenience arises in consequence of it.

A pressure agreeing approximately with the average atmospheric pressure at sea-level is often used as a unit of pressure. This unit is called *an atmosphere*, and is employed in measuring pressures in steam engines and boilers. The value of this unit which has been adopted, in the metrical system, is the pressure of 760 millimètres (29.922 Eng. inches) of the mercurial column at 0° C. (32° Fahr.) at Paris, which amounts in that latitude to 1.033 kilogrammes on the square centimètre. In the English system, *an atmosphere* is the pressure due to 29.905 inches of the mercurial column at 32° Fahr. at London, amounting there to nearly 13¾ lb. weight on the square inch. The latter atmosphere is thus 0.99968 of that of the metrical system.

As regards the distribution of atmospheric pressure over the globe, there was little beyond conjecture, drawn from theoretical considerations, and for the most part erroneous, till the publication in 1868 of Buchan's memoir "On the Mean Pressure of the Atmosphere and the Prevailing Winds over the Globe." By the monthly isobaric charts and copious tables which accompanied the memoir, this important physical problem was first approximately solved. Since then the British Admiralty has published charts showing the mean pressure of the atmosphere over the ocean. The more important general conclusions regarding the geographical distribution of atmospheric pressure are the following:—

There are two regions of high pressure, the one north and the other south of the equator, passing completely round the globe as broad belts of high pressure. They enclose between them the low pressure of tropical regions, through the centre of which runs a narrower belt of still lower pressure, towards which the north and south trades blow. The southern belt of high pressure lies nearly parallel to the equator, and is of nearly uniform breadth throughout; but the belt north of the equator has a very irregular outline, and great differences in its breadth and in its inclination to the equator,—these irregularities being due to the unequal distribution of land and water in the northern hemisphere. Taking a broad view of the subject, there are only three regions of low pressure,—one round each pole, bounded by or contained within the belts of high pressure just referred to, and the equatorial belt of low pressure. The most remarkable of these, in so far as is yet known, is the region of low pressure surrounding the south pole, which appears to remain pretty constant during the whole year. The depression round the north pole is divided into two distinct centres, at each of which there is a diminution of pressure greatly lower than the average

north polar depression. These two centres lie in the north of the Atlantic and Pacific Oceans, respectively. The distribution of pressure in the different months of the year differs widely from the annual average, particularly in January and July, the two extreme months. In January the highest pressures are over the continents of the northern hemisphere, — and the larger the continental mass the greater the pressure, — and the lowest pressures are over the northern portions of the Atlantic and Pacific, South America and South Africa, and the Antarctic Ocean. In the centre of Asia the mean pressure of the atmosphere in this month is fully 30.400 inches, whereas in the North Atlantic, round Iceland, it is only 29.340 inches, or upwards of an inch lower than in Central Asia.

In July, on the other hand, the mean pressure of Central Asia is only 29.468 inches, or nearly an inch lower than during January; or, putting this striking result in other words, about a thirteenth of the pressure of the atmosphere is removed from the region during the hottest months of the year as compared with the winter season. The lowest pressures of the northern hemisphere are now distributed over the continents, and the larger the continental mass the greater is the depression.

Over the ocean, if we accept the higher latitudes, atmospheric pressure is more regular throughout the year than over the land. In the ocean to westwards of each of the continents there occurs at all seasons an area of high pressure, from 0.10 inch to 0.30 inch higher than what prevails on the coast westward of which it lies. The distance of these spaces of high pressure is generally about 30° of longitude; and their longitudinal axes lie, roughly speaking, about the zones of the tropics. The maximum is reached during the winter months, and these areas of high pressure are most prominently marked west of those continents which have the greatest breadth in 30° lat.; and the steepest barometric gradients are on their eastern side. It is scarcely possible to over-estimate the importance of these regions of high and low mean pressures, from their intimate bearing on atmospheric physics, but more particularly from their vital connection with prevailing winds and the general circulation of the atmosphere. This relation will be apprehended when it is considered that winds are simply the flowing away of the air from regions where there is a surplus (regions of high pressure) to where there is a deficiency of air (regions of low pressure). Everywhere over the globe this transference takes place in strict accordance with Buys-Ballot's "Law of the Winds," which may be thus expressed: — The wind neither blows round the space of lowest pressure in circles returning on themselves, nor does it blow directly toward that space; but it takes a direction intermediate, approaching, however, more nearly to the direction and course of circular curves than of radii to a centre. More exactly, the angle is not right angle, but from 45° to 80°. Keeping this relation between wind and the distribution of pressure in mind, the isobaric lines give the proximate causes of the prevailing winds over the globe, and through these the prominent features of climates. As regards the ocean, the prevailing winds indicate the direction of the drift-currents and other surface-currents, and thereby the anomalous distribution of the temperature of the sea as seen in the Chili, Guinea, and other ocean currents, and the peculiarly marked climates of the coasts past which these currents flow, are explained; for observations have now proved that the prevailing winds and surface-currents of all oceans are all but absolutely coincident.

As regards the annual march of pressure through the months of the year, curves representing it for the different regions of the earth differ from each other in every conceivable way. It is only when the results are set down in their proper places on charts of the globe that the subject can be well understood. When thus dealt with, many of the results are characterised by great beauty and simplicity. Thus, of all influences which determine the barometric fluctuation through the months, the most important are the temperature, and through the temperature the humidity. Comparing, then, the average pressure in January with that in July, which two months give the greatest possible contrasts of temperature, the following is the broad result:—

Atmospheric pressure is more uniformly distributed over the globe in April and October than in any of the other months. In May and November, being the months immediately following, occur the great annual rise and fall of temperature; and since these rapid changes take place at very different rates, according to the relative distribution of land and water in each region, a comparison of the geographical distribution of May with that for the year brings out in strong relief the more prominent causes which influence climate, and some of the more striking results of these causes. This comparison shows a diminution of pressure in May over tropical and sub-tropical regions, including nearly the whole of Asia, the southern half of Europe, and the United States. An excess prevails over North America to the north of the Lakes, over Arctic America, Greenland, the British Isles, and to the north of a line passing through the English Channel in a north-easterly direction to the Arctic Sea. The excess in the southern hemisphere includes the southern half of South America and of Africa, the whole of Australia, and adjacent parts of the ocean. The influence of the land of the southern hemisphere, which in this month is colder than the surrounding seas, brings about an excess of pressure; on the other hand, the influence of land over those regions which are more immediately under the sun brings about a lower pressure, interesting examples of which occur in India, the Malayan Archipelago, and the Mediterranean, Black, and Caspian Seas. In many cases the lines of pressure follow more or less closely the contours of the coasts. Thus the diminution is greater over Italy and Turkey than over the Adriatic and Black Seas. The greatest diminution occurs in Central Asia, where it exceeds 0.200 inch, and the greatest excess round Iceland, where it exceeds 0.200 inch. It is to the position of Great Britian, with reference to the deficiency of pressure on the one hand and the excess on the other, that the general prevalence of east winds at this season is due. These easterly winds prevail over the whole of Northern Europe, as far south as a line drawn from Madrid and passing in a north-easterly direction through Geneva, Munich, &c. To the south of this line the diminution of pressure is less, and over this region the winds which are in excess are not easterly, but southerly. Crossing the Mediterranean, and advancing on Africa, we approach another region of lower pressure, towards which easterly and north-easterly winds again acquire the ascendency, as at Malta, Algeria, &c.

This, in many cases great, variation of the pressure in the different months of the year must be kept carefully in view in deducting heights of places from observations made by travellers of the pressure of atmosphere, by the barometer or the temperature of boiling water. In reducing the observations, it is necessary to assume a sea-level pressure if the place is at a considerable distance from any meteorological observatory. Previous to the publication of Buchan's *Mean Pressure of the Atmosphere*, it appears that a mean sea-level pressure of 29.92 or 30.00 inches was in such cases universally assumed. The mean pressure at Barnaul, Siberia, being

29.536 inches in July, 30.293 inches in January, and 29.954 inches for the year, it follows that, by the former method of calculating the heights, observations made in January to ascertain the height of Lake Balkash would make the lake 350 feet too high, and observations made in July would make it 330 feet too low,—the difference of the two observations, each set being supposed to be made under the most favorable circumstances, and with the greatest accuracy, being 680 feet. This illustration will serve to account for many of the discrepances met with in books regarding the heights of mountains and plateaus.

Of the periodical variations of atmospheric pressure, the most marked is the daily variation, which in tropical and sub-tropical regions is one of the most regular of recurring phenomena. In higher latitudes the diurnal oscillation is marked by the frequent fluctuations to which the pressure is subjected. If, however, hourly observations be regularly made for some time, the hourly oscillation will become apparent. The results show two maxima occurring from 9 to 11 A.M. and 9 to 11 P.M., and two minima occuring from 3 to 6 A.M. and 3 to 6 P.M.

Though the diurnal calometric oscillations are among the best-marked of meteorological phenomena, at least in tropical and sub-tropical regions, yet none of these phenomena, except perhaps the electrical, could be named respecting whose geographical distribution so little is really known, whether as regards the amount of variation, the hour of occurrence of the critical phases, or, particularly, the physical causes on which the observed differences depend. This arises chiefly from the want of a sufficient number of ascertained facts; and to remedy this deficiency observations have, in the preparation of this present article, been collected and calculated from upwards of 250 places in different parts of the globe, and the data set down on charts. The chief results of this inquiry are the following, attention being entirely confined to the chief of oscillation, viz., that occurring from the A. M. maximum to the P. M. minimum.

Since the two maxima of daily pressure occur when the temperature is about the mean of the day, and the two minima when it is at its highest and lowest respectively, there is thus suggested a connection between the daily barometric oscillations and the daily march of temperature; and similarly a connection with the daily march of the amount of vapor and humidity of the air. The view entertained by many of the causes of the daily oscillations may be thus stated:—The *forenoon maximum* is conceived to be due to the rapidly increasing temperature, and the rapid evaporation owing to the great dryness of the air at this time of the day, and to the increased elasticity of the lowermost stratum of air which results therefrom, until a steady ascending current has set in. As the day advances, the vapor becomes more equally diffused upwards through the air, an ascending current, more or less strong and steady, is set in motion, a diminution of elasticity follows, and the pressure falls to the *afternoon minimum*. From this point the temperature declines, a system of descending currents set in, and the air of the lowermost stratum approaches more nearly the point of saturation, and from the increased elasticity, the pressure rises to the *evening maximum*. As the deposition of dew proceeds, and the fall of temperature and consequent downward movement of the air are arrested, the elasticity is again diminished, and pressure falls to the *morning minimum*. Since the view propounded some years ago, that if the elastic force of vapor be subtracted from the whole pressure, what remains will show only one daily maximum and minimum, has not been confirmed by observation, it follows that the above explanation is quite insufficient to account for the phenomena; indeed, the view can be regarded in no other light than as a tentative hypothesis.

Singularly enough, Lamont and Broun, a few years ago, were led, independently of each other, to form an opinion that the daily barometric oscillations were due to the magneto-electric influence of the sun. It admits of no doubt, looking at the facts of the case so far as they have been disclosed, that the daily barometric oscillations originated with the sun, and that more than the sun's influence as exerted on the diurnal march of the temperature and humidity of the atmosphere is concerned in bringing them about. But from the facts adduced, it is equally certain that, be the originating cause what it may, its effects are enormously modified by the distribution of land and water over the globe, by the wind, and by the absolute and relative humidity of the atmosphere. The smallness of the amount of the summer oscillation from the forenoon maximum to the afternoon minimum over the North Atlantic as far south as lat. 30°, and its diminished amount, as far south at least as the equator, will no doubt play an important part in the unravelling of this difficulty.

One of the most important steps that could be taken would be an extensive series of observations from such countries as India, which offers such splendid contrasts of climate at all seasons, has a surface covered at one place with the richest vegetation, and at others with vast stretches of sandy deserts, and presents extensive plateaus and sharp ascending peaks—all which conditions are indispensable in collecting the data required for the solution of this vital problem of atmospheric physics.

The ancients thought that air was one of the four elements from which all things originated; this doctrine continued to prevail till 1774, when Priestly discovered oxygen gas, and showed it to be a constituent part of air. Nitrogen, the other constituent of air, first called *azote*, was discovered soon after, and the marked differences between these two gases could not fail to strike the most careless observer. It is remarkable that Scheele independently discovered both oxygen and nitrogen, and was the first to enunciate the opinion that air consists essentially of a mixture of these two gases. From experiments made by him to ascertain their relative volumes he concluded that the proportions are 27 volumes of oxygen and 73 volumes of nitrogen. It was left to Cavendish to show from 500 analyses that the relative proportions were practically constant, and that the proportion is 20,833 per cent. of oxygen. The results obtained by Cavendish, though not attended to for many years after they were published, have been shown by recent and more refined analyses to be wonderfully exact. The most recent analyses of specimens of air collected under circumstances which ensure that it is of average purity, give as a mean result the following:—

	Volume.
Oxygen.	20.96 per cent.
Nitrogen.	79.00 "
Carbonic acid.	0.04 "
	100.00

The circumstances under which these proportions vary, and the other gases and substances which are found in the air, will be afterwards adverted to. Besides these three constituents of air, there is a fourth, viz., the vapor of water, from which no air, even at the lowest temperature yet observed is wholly free, so that absolutely dry air does not exist in the free atmosphere. The dry air of the atmosphere—oxygen (inclusive of ozone) nitrogen and carbonic acid—is always a gas

and its quantity is constant from year to year; but the vapor of water does not always remain in the gaseous state, and the quantity present in the atmosphere is, by the processes of evaporation and condensation, varying every instant. Water evaporates at all temperatures, even the lowest, and rises into the air in the form of an invisible elastic gas called aqueous vapor. The elasticity of vapor varies with the temperature.

The relative humidity of the air may be regarded as the degree of approach to saturation. It is greatest near the surface of the earth during night, when the temperature, being at or near the daily minimum, approaches the dew-point; it is also great in the morning, when the sun's rays have evaporated the dew, and the vapor is as yet only diffused a little way upwards; and it is least during the greatest heat of the day.

Between the humidity, both absolute and relative, of the air and the temperature there is a vital and all-important connection. Observation shows that when the quantity of vapor in the air is great, and also when the relative humidity is high, temperature falls little during the night, even though the sky be perfectly clear; but when the quantity of vapor is small, or the relative humidity is low, temperature rapidly falls. On the other hand, during the day the temperature rises slowly, when the quantity of vapor is great, or relative humidity high, even though the sky be clear, but when the quantity of vapor is small, and humidity low, temperature rapidly rises. These facts are explained by the circumstance that perfectly dry air is diathermanous, that is, it allows radiant heat to pass through it without being sensibly warmed thereby. Add vapor to this air, and its diathermancy is diminished. The diathermancy is also reduced if the temperature approach nearer to the dew-point; in other words, if the relative humidity be increased. Hence, with an increase of vapor or with increased humidity, the effects of both solar and terrestrial radiation are much less felt on the surface of the earth—the vapor screen performing, in truth, one of the most important conservative functions of the atmosphere.

Since ascending currents fall in temperature as they ascend, through diminished pressure and consequent dilatation, they increase their relative humidity; and since descending currents increase in temperature, and consequently reduce their relative humidity, it follows that, over a region from which ascending currents rise, solar and terrestrial radiation is very considerably obstructed, but over a region upon which currents descend, radiation is much less obstructed. Most of our exceptionally hot summer and cold winter weather is to be explained in this way, on which occasions there is generally observed a high barometric pressure overspreading a comparatively limited region, on which a slow downward movement of the air proceeds.

Of the solar heat which reaches the surface of the globe, that part which falls on the land may be regarded as wholly absorbed by the thin superficial layer exposed to the heating rays; and since there is no mobility in the particles of the land, the heat can be communicated downwards only by conduction. On the other hand, the solar heat which falls on water is not, as in the case of land, arrested at the surface, but penetrates to a considerable depth, the heating effect being in the case of clear water appreciably felt at a depth of from 500 to 600 feet. Since the heat daily received by the ocean from the sun is diffused downwards through a very considerable depth, the surface of the ocean on which the atmosphere rests is much less heated during the day than is the surface of the land. Similarly it is also less cooled during the night by terrestrial radiation.

This points to a chief acting force on which the great movements of the atmosphere depend, viz., simultaneous local irregularities in the distribution of temperature in the atmosphere. The local expansion of the atmosphere by heat during the day is greatest over land, where the air is clear, dry, and comparatively calm, and least over the ocean, where the sky is clouded, and the air loaded with moisture. On the other hand, the local contraction by cold during night is greatest over land, where the air is clear, dry, and calm, or nearly so, and least over the ocean, where the air is clouded, and loaded with moisture. As familiar illustrations of atmospheric movements resulting from local expansions by heat and contractions by cold, we may refer to the land and sea breezes, and what depend upon exactly the same principle, the dry and rainy monsoons in different parts of the globe. But the illustration of the principle on the broadest scale is the system of atmospheric circulation known as the equatorial and polar currents of the atmosphere, which originate in the unequal heating by the sun of the equatorial, temperate, and polar regions.

The other principal motive force in atmospheric circulation depends on the aqueous vapor. The many ways in which this element acts as a motive force will be seen when it is considered that a large quantity of sensible heat disappears in the process of evaporation, and reappears in the process of condensation of the vapor into rain or cloud; that saturated air is specifically lighter than dry air; and that the absolute and relative amount of the vapor powerfully influences both solar and terrestrial radiation. The question to be carefully considered here is how in these ways the vapor produces local irregularities in the distribution of atmospheric pressure, thus giving rise to aerial movements which set in to restore the equilibrium which has thus been disturbed.

It is from these local irregularities—using the word local in a very wide sense—in the distribution of atmospheric pressure, whether the irregularities originate in the temperature or aqueous vapor, that all winds, from the lightest breeze to the most destructive hurricane, take their rise; for, as already stated, wind is merely the flowing away of the air from where there is a surplus of it to where there is a deficiency.

In examining weather charts embracing a considerable portion of the earth's surface, there are seen two different systems of pressure, changing their forms and positions on the globe from day to day—one set being systems of low pressure marked off by concentric isobarics enclosing pressures successively lower as the central space is approached, and the other set being systems of high pressure marked off by roughly concentric isobarics bounding pressures successively higher towards their centres. These two systems are essentially distinct from each other, and without some knowledge of them the circulation of the atmosphere cannot be understood.

Observations of the winds cannot be conducted, and the results discussed, on the supposition that the general movement of the winds felt on the earth's surface is horizontal, it being evident that the circulation of the atmosphere is effected largely through systems of ascending and descending currents. The only satisfactory way of discussing the winds, viewed especially in their climatic relations, is that recently proposed by Köppen of St. Petersburg, and applied by him with very fruitful results in investigating the weather of that place during 1872 and 1873. In attempting an explanation of these phenomena, we are met with several as yet insuperable obstacles:—(1.) An imperfect knowledge of the mode of formation and propagation of low-pressure systems; (2.) Imperfect knowledge of the relations of the formation of cloud and aqueous precipita

tion to barometric fluctuations; (3.) A want of information with reference to the merely mechanical effects of ascending, descending, and horizontal currents of air on the barometric pressure; in other words we do not know how far the barometric pressure is an indication of the mass of air in the column vertically over it, when that column is traversed by air-currents; (4.) An almost total absence of really good wind observations; and (5.) Deficient information in nearly everything that respects aqueous vapor — its relation to radiant heat, both solar and terrestrial; its mode of diffusion vertically and horizontally in the free atmosphere, especially from an evaporating surface; the influence which its condensation into cloud and rain exerts on aerial currents, — in regard to all which more satisfactory methods of observing this vital element, and discussing the results of observation, are greatly to be desired. There are here large important fields of inquiry awaiting experimental and observational physicists.

The law of the dilatation of gases, known as the "Law of Boyle" or "Law of Mariotte," is this: The volume occupied by a gas is in reverse ratio to the pressure under which it exists, if the temperature remains the same; or the density of a gas is proportioned to its pressure. Consequently, air under a pressure equal to that of two atmospheres will occupy only half the volume it occupied under the pressure of one atmosphere; under the pressure of three atmospheres, one-third of that volume, &c. By doubling the pressure we double the elasticity. If, however, the temperature be increased, and the air occupy the same space, the pressure will be increased; but if the pressure is to remain the same, the air must occupy a larger space. From Regnault's experiments, it is concluded that the co-efficient which denotes increase of elasticity for 1° Fahr. of air whose volume is constant equals .002036; and that the co-efficient which denotes increase of volume for 1° Fahr. of air whose elasticity is constant equals .002039.

These portions of the atmosphere in contact with the earth are pressed upon by all the air above them. The air at the top of a mountain is pressed upon by all the air above it, while all the portion below it, or lying between the top of the mountain and the surface of the sea, exerts no pressure whatever upon it. Thus the pressure of the atmosphere constantly diminishes with the height. If, then, the pressure of the atmosphere at two heights be observed, and if at the same time the mean temperature and humidity of the whole stratum of air lying between the two levels were known, the difference in height between the two places could be calculated. For the development of this principle, see BAROMETRIC MEASUREMENTS OF HEIGHTS.

The air thus diminishing in density as we ascend, if it consists of ultimate atoms, as is no doubt the case, it follows that the limit of the atmosphere will be reached at the height where the force of gravity downwards upon a single particle is equal to the resisting force arising from the repulsive force of the particles. It was long supposed, from the results of observations on the refraction of light, that the height of the atmosphere did not exceed 45 miles; but from the observations of luminous meteors, whose true character as cosmical bodies was established a few hundred years ago, it is inferred that the height of the atmosphere is at least 120 miles, and that, in an extremely attenuated form, it may even reach 200 miles.

Great differences have been observed by Dr. A. Smith between country rain and town rain: country rain is neutral; town rain, on the other hand, is acid, and corrodes metals, and even stones and bricks, destroying mortar rapidly, and readily spoiling many colors. Much information has been obtained regarding impurities in the air of towns and other places by examining the rain collected in different places. The air freest from impurities is that collected at the sea-coast and at considerable heights. Again, ammonia is found to diminish, while nitric acid increases, in ascending to, at least, habitable heights. As regards organic matter in the air, it corresponds to a considerable extent with the density of the population. As might have been supposed from the higher temperature, more nitric acid is contained in rain collected on the Continent than in the British Islands. This inquiry, which is only yet in its infancy, will doubtless continue to be vigorously prosecuted, particularly since we may hope thereby to arrive at the means of authoritatively defining the safe limits of the density of population, and the extent to which manufactures may be carried on within a given area. The influence of atmospheric impurities on the public health has received a good deal of attention.

The relation of weather to mortality is a very important inquiry, and though a good deal has been known regarding the question for some time, yet it has only recently been systematically inquired into. Considering the weather of the year as made up of several distinct climates differing from each other according to temperature and moisture and their relations to each other, it may be divided into six distinct climates, characterised respectively by cold, cold with dryness, dryness with heat, heat, heat with moisture, and cold with moisture. Each of these six periods has a peculiar influence in increasing or diminishing the mortality, and each has its own group of diseases which rise to the maximum, or fall to the minimum mortality, or are subject to a rapid increase or a rapid decrease. The mortality from all causes and at all ages shows a large excess above the average from the middle of November to the middle of April, from which it falls to the minimum in the end of May; it then slowly rises, and on the third week of July suddenly shoots up almost as high as the winter maximum of the year, at which it remains till the second week of August, falling thence as rapidly as it rose to a secondary minimum in October. Regarding the summer excess, which is so abrupt in its rise and fall, it is almost altogether due to the enormous increase of the mortality among mere infants under one year of age; and this increase is due not only to deaths at one age, but to deaths from one class of diseases, viz., bowel complaints. If the deaths from bowel complaints be deducted from the deaths from all causes, there remains an excess of deaths in the cold months, and a deficiency in the warm months. In other words, the curve of mortality is regulated by the large number of deaths from diseases of the respiratory organs.

ATMOSPHERIC RAILWAY, a railway in which the pressure of air is used directly or indirectly to propel carriages, as a substitute for steam. It was devised at a time when the principles of propulsion were not so well understood as they are now, and when the dangers and inconveniences attendant on the use of locomotives were very much exaggerated. It had been long known that small objects could be propelled for great distances through tubes by air pressure, but a Mr. Vallance, of Brighton, seems to have been the first to propose the application of this system to passenger traffic. He projected (about 1825) an atmospheric railway, consisting of a wooden tube about 6 feet 6 inches in diameter, with a carriage running inside it. A diaphragm fitting the tube, approximately air-tight, was attached to the carriage, and the air exhausted from the front of it by a stationary engine, so that the atmospheric pressure behind drove the carriage forward. Later inventors, commencing with Henry Pinkus (1835), for the most part kept the carriages altogether outside the tube, and

connected them by a bar with a piston working inside it, this piston being moved by atmospheric pressure in the way just mentioned. The tube was generally provided with a slot upon its upper side, closed by a continuous valve or its equivalent, and arrangements were made by which this valve should be opened to allow the passage of the driving bar without permitting great leakage of air. About 1840, Messrs. Clegg & Samuda made various experiments with an atmospheric tube constructed on this principle upon a portion of the West London Railway, near Wormwood Scrubs. The apparent success of these induced the Dublin and Kingstown Railway to adopt Clegg & Samuda's scheme upon an extension of their line from Kingstown to Dalkey, where it was in operation in 1844. Later on, the same system was adopted on a part of the South Devon line and in several other places, and during the years 1844–1846 the English and French patent records show a very large number of more or less practicable and ingenious schemes for the tubes, valves, and driving gear of atmospheric railways. The atmospheric system was nowhere permanently successful, but in all cases was eventually superseded by locomotives, the last atmospheric line being probably that at St. Germains, which was worked until 1862.

ATOM is a body which cannot be cut in two. The atomic theory is a theory of the constitution of bodies which asserts that they are made up of atoms. The opposite theory is that of the homogeneity and continuity of bodies, and asserts, at least in the case of bodies having no apparent organisation, such, for instance, as water, that as we can divide a drop of water into two parts which are each of them drops of water, so we have reason to believe that these smaller drops can be divided again, and the theory goes on to assert that there is nothing in the nature of things to hinder this process of division from being repeated over and over again, times without end. This is the doctrine of the infinite divisibility of bodies, and it is in direct contradiction with the theory of atoms.

The atomists assert that after a certain number of such divisions the parts would be no longer divisible, because each of them would be an atom. The advocates of the continuity of matter assert that the smallest conceivable body has parts, and that whatever has parts may be divided.

In ancient times Democritus was the founder of the atomic theory, while Anaxagoras propounded that of continuity, under the name of the doctrine of homœomeria, or of the similarity of the parts of a body to the whole. The arguments of the atomists, and their replies to the objections of Anaxagoras, are to be found in Lucretius.

In modern times the study of nature has brought to light many properties which appear to depend on the magnitude and motions of their ultimate constituents, and the question of the existence of atoms has once more become conspicuous among scientific inquiries.

We shall begin by stating the opposing doctrines of atoms and of continuity before giving an outline of the state of molecular science as it now exists. In the earliest times the most ancient philosophers whose speculations are known to us seem to have discussed the ideas of number and of continuous magnitude, of space and time, of matter and motion, with a native power of thought which has probably never been surpassed. Their actual knowledge, however, and their scientific experience were necessarily limited, because in their days the records of human thought were only beginning to accumulate. It is probable that the first exact notions of quantity were founded on the consideration of number. It is by the help of numbers that concrete quantities are practically measured and calculated. Now, number is discontinuous. We pass from one number to the next *per saltum*. The magnitudes, on the other hand, which we meet with in geometry, are essentially continuous. The attempt to apply numerical methods to the comparison of geometrical quantities led to the doctrine of incommensurables, and to that of the infinite divisibility of space. Meanwhile, the same considerations had not been applied to time, so that in the days of Zeno of Elea time was still regarded as made up of a finite number of "moments," while space was confessed to be divisible without limit. This was the state of opinion when the celebrated arguments against the possibility of motion, of which that of Achilles and the tortoise is a specimen, were propounded by Zeno, and such, apparently, continued to be the state of opinion till Aristotle pointed out that time is divisible without limit, in precisely the same sense that space is. And the slowness of the development of scientific ideas may be estimated from the fact that Bayle does not see any force in this statement of Aristotle, but continues to admire the paradox of Zeno. Thus the direction of true scientific progress was for many ages towards the recognition of the infinite divisibility of space and time.

It was easy to attempt to apply similar arguments to matter. If matter is extended and fills space, the same mental operation by which we recognise the divisibility of space may be applied, in imagination at least, to the matter which occupies space. From this point of view the atomic doctrine might be regarded as a relic of the old numerical way of conceiving magnitude, and the opposite doctrine of the infinite divisibility of matter might appear for a time the most scientific. The atomists, on the other hand, asserted very strongly the distinction between matter and space. The atoms, they said, do not fill up the universe; there are void spaces between them. If it were not so, Lucretius tells us, there could be no motion, for the atom which gives way first must have some empty place to move into.

The opposite school maintained then, as they have always done, that there is no vacuum—that every part of space is full of matter, that there is a universal plenum, and that all motion is like that of a fish in water, which yields in front of the fish because the fish leaves room for it behind.

Of the different forms of the atomic theory, that of Boscovich may be taken as an example of the purest monadism. According to Boscovich matter is made up of atoms. Each atom is an indivisible point, having position in space, capable of motion in a continuous path, and possessing a certain mass, whereby a certain amount of force is required to produce a given change of motion. Besides this the atom is endowed with potential force, that is to say, that any two atoms attract or repel each other with a force depending on their distance apart. The law of this force, for all distances greater than say the thousandth of an inch, is an attraction varying as the inverse square of the distance. For smaller distances the force is an attraction for one distance and a repulsion for another, according to some law not yet discovered. Boscovich himself, in order to obviate the possibility of two atoms ever being in the same place, asserts that the ultimate force is a repulsion which increases without limit as the distance diminishes without limit, so that two atoms can never coincide. But this seems an unwarrantable concession to the vulgar opinion that two bodies cannot co-exist in the same place. This opinion is deduced from our experience of the behavior of bodies of sensible size, but we have no experimental evidence that two atoms may not sometimes coincide. For instance, if oxygen and hydrogen combine to form

water, we have no experimental evidence that the molecule of oxygen is not in the very same place with the two molecules of hydrogen. Many persons cannot get rid of the opinion that all matter is extended in length, breadth, and depth. This is a prejudice of the same kind with the last, arising from our experience of bodies consisting of immense multitudes of atoms. The system of atoms, according to Boscovich, occupies a certain region of space in virtue of the forces acting between the component atoms of the system and any other atoms when brought near them. No other system of atoms can occupy the same region of space at the same time, because, before it could do so, the mutual action of the atoms would have caused a repulsion between the two systems insuperable by any force which we can command. Thus, a number of soldiers with firearms may occupy an extensive region to the exclusion of the enemy's armies, though the space filled by their bodies is but small. In this way Boscovich explained the apparent extension of bodies consisting of atoms, each of which is devoid of extension. According to Boscovich's theory, all action between bodies is action at a distance. There is no such thing in nature as actual contact between two bodies. When two bodies are said in ordinary language to be in contact, all that is meant is that they are so near together that the repulsion between the nearest pairs of atoms belonging to the two bodies is very great.

Thus, in Boscovich's theory, the atom has continuity of existence in time and space. At any instant of time it is at some point of space, and it is never in more than one place at a time. It passes from one place to another along a continuous path. It has a definite mass which cannot be increased or diminished. Atoms are endowed with the power of acting on one another by attraction or repulsion, the amount of the force depending on the distance between them. On the other hand, the atom itself has no parts or dimensions. In its geometrical aspect it is a mere geometrical point. It has no extension in space. It has not the so-called property of Impenetrability, for two atoms may exist in the same place. This we may regard as one extreme of the various opinions about the constitution of bodies.

The opposite extreme, that of Anaxagoras — the theory that bodies apparently homogeneous and continuous are so in reality — is, in its extreme form, a theory incapable of development. To explain the properties of any substance by this theory is impossible. We can only admit the observed properties of such substance as ultimate facts. There is a certain stage, however, of scientific progress in which a method corresponding to this theory is of service. In hydrostatics, for instance, we define a fluid by means of one of its known properties, and from this definition we make the system of deductions which constitute the science of hydrostatics. In this way the science of hydrostatics may be built upon on experimental basis without any consideration of the constitution of a fluid as to whether it is molecular or continuous. In like manner, after the French mathematicians had attempted, with more or less ingenuity, to construct a theory of elastic solids from the hypothesis that they consist of atoms in equilibrium under the action of their mutual forces, Stokes and others showed that all the results of this hypothesis, so far at least as they agreed with facts, might be deduced from the postulate that elastic bodies exist, and from the hypothesis that the smallest portions into which we can divide them are sensibly homogeneous. In this way the principle of continuity, which is the basis of the method of Fluxions and the whole of modern mathematics, may be applied to the analysis of problems connected with material bodies by assuming them. for the purpose of this analysis, to be homogeneous. All that is required to make the result applicable to the real case is that the smallest portions of the substance of which we take any notice shall be sensibly of the same kind. Thus, if a railway contractor has to make a tunnel through a hill of gravel, and if one cubic yard of the gravel is so like another cubic yard that for the purposes of the contract they may be taken as equivalent, then, in estimating the work required to remove the gravel from the tunnel, he may, without fear of error, make his calculations as if the gravel were a continuous substance. But if a worm has to make his way through the gravel, it makes the greatest possible difference to him whether he tries to push right against a piece of gravel, or directs his course through one of the intervals between the pieces; to him, therefore, the gravel is by no means a homogeneous and continuous substance.

In the same way, a theory that some particular substance, say water, is homogeneous and continuous may be a good working theory up to a certain point, but may fail when we come to deal with quantities so minute or so attenuated that their heterogeneity of structure comes into prominence. Whether this heterogeneity of structure is or is not consistent with homogeneity and continuity of substance is another question.

The extreme form of the doctrine of continuity is that stated by Descartes, who maintains that the whole universe is equally full of matter, and that this matter is all of one kind, having no essential property besides that of extension. All the properties which we perceive in matter he reduces to its parts being movable among one another, and so capable of all the varieties which we can perceive to follow from the motion of its parts. Descarte's own attempts to deduce the different qualities and actions of bodies in this way are not of much value. More than a century was required to invent methods of investigating the conditions of the motion of systems of bodies such as Descartes imagined. But the hydrodynamical discovery of Helmholtz that a vortex in a perfect liquid possesses certain permanent characteristics, has been applied by Sir W. Thomson to form a theory of vortex atoms in a homogeneous, incompressible, and frictionless liquid, to which we shall return at the proper time.

Outline of Modern Molecular Science, and in Particular of the Molecular Theory of Gases.

We begin by assuming that bodies are made up of parts, each of which is capable of motion, and that these parts act on each other in a manner consistent with the principle of the conservation of energy. In making these assumptions, we are justified by the facts that bodies may be divided into smaller parts, and that all bodies with which we are acquainted are conservative systems, which would not be the case unless their parts were also conservative systems.

We may also assume that these small parts are in motion. This is the most general assumption we can make, for it includes, as a particular case, the theory that the small parts are at rest. The phenomena of the diffusion of gases and liquids through each other show that there may be a motion of the small parts of a body which is not perceptible to us.

We make no assumption with respect to the nature of the small parts—whether they are all of one magnitude. We do not even assume them to have extension and figure. Each of them must be measured by its mass, and any two of them must, like visible bodies, have the power of acting on one another when they come near enough to do so. The properties of the

body, or medium, are determined by the configuration and motion of its small parts.

The effect of the direct action of the molecules on each other depends on the number of pairs of molecules which at a given instant are near enough to act on one another. The number of such pairs is proportional to the square of the number of molecules in unit of volume, that is, to the square of the density of the gas. Hence, as long as the medium is so rare that the encounter between two molecules is not affected by the presence of others, the deviation from Boyle's law will be proportional to the square of the density. If the action between the molecules is on the whole repulsive, the pressure will be greater than that given by Boyle's law. If it is, on the whole, attractive, the pressure will be less than that given by Boyle's law. It appears, by the experiments of Regnault and others, that the pressure does deviate from Boyle's law when the density of the gas is increased. In the case of carbonic acid and other gases which are easily liquefied, this deviation is very great. In all cases, however, except that of hydrogen, the pressure is less than that given by Boyle's law, showing that the virial is on the whole due to *attractive* forces between the molecules.

Another kind of evidence as to the nature of the action between the molecules is furnished by an experiment made by Dr. Joule. Of two vessels, one was exhausted and the other filled with a gas at a pressure of 20 atmospheres; and both were placed side by side in a vessel of water, which was constantly stirred. The temperature of the whole was observed. Then a communication was opened between the vessels, the compressed gas expanded to twice its volume, and the work of expansion, which at first produced a strong current in the gas, was soon converted into heat by the internal friction of the gas. When all was again at rest, and the temperature uniform, the temperature was again noted. In Dr. Joule's first experiments the observed temperature was the same as before. In a series of experiments, conducted by Dr. Joule and Sir W. Thomson on a different plan, by which the thermal effect of free expansion can be more accurately measured, a slight cooling effect was observed in all the gases examined except hydrogen. Since the temperature depends on the velocity of agitation of the molecules, it appears that when a gas expands without doing external work the velocity of agitation is not much affected, but that in most cases it is slightly diminished. Now if the molecules during their mutual separation act on each other their velocity will increase or diminish according as the force is repulsive or attractive. It appears from the experiments on the free expansion of gases, that the force between the molecules is small, but on the whole attractive. Having thus justified the hypothesis that a gas consists of molecules in motion, which act on each other only when they come very close together during an encounter, but which during the intervals between their encounters which constitute the greater part of their existence, are describing free paths, and are not acted on by any molecular force, we proceed to investigate the motion of such a system.

The mathematical investigation of the properties of such a system of molecules in motion is the foundation of molecular science. Clausius was the first to express the relation between the density of the gas, the length of the free paths of its molecules, and the distance at which they encounter each other. He assumed, however, at least in his earlier investigations, that the velocities of all the molecules are equal. The mode in which the velocities are distributed was first investigated by the present writer, who showed that in the moving system the velocities of the molecules range from zero to infinity, but that the number of molecules whose velocities lie within given limits can be expressed by a formula identical with that which expresses in the theory of errors the number of errors of observation lying within corresponding limits.

The mean kinetic energy of a molecule, however, has a definite value, which is easily expressed in terms of the quantities which enter into the expression for the distribution of velocities. The most important result of this investigation is that when several kinds of molecules are in motion and acting on one another, the mean kinetic energy of a molecule is the same whatever be its mass, the molecules of greater mass having smaller mean velocities. Now, when gases are mixed their temperatures become equal. Hence we conclude that the physical condition which determines that the temperature of two gases shall be the same is that the mean kinetic energies of agitation of the individual molecules of the two gases are equal. This is of great importance in the theory of heat, though we are not yet able to establish any like result for bodies in the liquid or solid state.

Our definition of a molecule is purely dynamical. A molecule is that minute portion of a substance which moves about as a whole, so that its parts, if it has any, do not part company during the motion of agitation of the gas. The result of the kinetic theory, therefore, is to give us information about the relative masses of molecules considered as moving bodies. The consistency of this information with the deductions of chemists from the phenomena of combination, greatly strengthens the evidence in favor of the actual existence and motion of gaseous molecules.

Another confirmation of the theory of molecules is derived from the experiments of Dulong and Petit on the specific heat of gases, from which they deduced the law which bears their name, and which asserts that the specific heats of equal weights of gases are inversely as their combining weights, or, in other words, that the capacities for heat of the chemical equivalents of different gases are equal.

The determination of the molecular volume of a gas is subject as yet to considerable uncertainty. The most obvious method is that of compressing the gas till it assumes the liquid form. It seems probable, from the great resistance of liquids to compression, that their molecules are at about the same distance from each other as that at which two molecules of the same substance in the gaseous form act on each other during an encounter. If this is the case, the molecular volume of a gas is somewhat less than the volume of the liquid into which it would be condensed by pressure, or, in other words, the density of the molecules is somewhat greater than that of the liquid.

The first numerical estimate of the diameter of a molecule was that made by Loschmidt in 1865 from the mean path and the molecular volume. Independently of him and of each other, Mr. Stoney, in 1868, and Sir W. Thomson, in 1870, published results of a similar kind—those of Thomson being deduced not only in this way, but from considerations derived from the thickness of soap bubbles, and from the electric action between zinc and copper.

The diameter and the mass of a molecule, as estimated by these methods, are, of course, very small, but by no means infinitely so. About two millions of molecules of hydrogen in a row would occupy a millimetre, and about two hundred million million million of them would weigh a milligramme. These numbers must be considered as exceedingly rough guesses; they must be corrected by more extensive and accurate experiments as science advances; but the main result, which appears to be well established, is that the determination of the

mass of a molecule is a legitimate object of scientific research, and that this mass is by no means immeasurably small.

Loschmidt illustrates these molecular measurements by a comparison with the smallest magnitudes visible by means of a microscope. Nobert, he tells us, can draw 4000 lines in the breadth of a millimetre. The intervals between these lines can be observed with a good microscope. A cube, whose side is the 4000th of a millimetre, may be taken as the *minimum visible* for observers of the present day. Such a cube would contain from 60 to 100 million molecules of oxygen or of nitrogen; but since the molecules of organised substances contain on an average about 50 of the most elementary atoms, we may assume that the smallest organised particle visible under the microscope contains about two million molecules of organic matter. At least half of every living organism consists of water, so that the smallest living being visible under the microscope does not contain more than about a million organic molecules. Some exceedingly simple organism may be supposed built up of not more than a million similar molecules. It is impossible, however, to conceive so small a number sufficient to form a being furnished with a whole system of specialised organs.

Thus molecular science sets us face to face with physiological theories. It forbids the physiologist from imagining that structural details of infinitely small dimensions can furnish an explanation of the infinite variety which exists in the properties and functions of the most minute organisms.

A microscopic germ is, we know, capable of development into a highly organised animal. Another germ, equally microscopic, becomes, when developed, an animal of a totally different kind. Do all the differences, infinite in number, which distinguish the one animal from the other, arise each from some difference in the structure of the respective germs? Even if we admit this as possible, we shall be called upon by the advocates of Pangenesis to admit still greater marvels. For the microscopic germ, according to this theory, is no mere individual, but a representative body, containing members collected from every rank of the longdrawn ramification of the ancestral tree, the number of these members being amply sufficient not only to furnish the hereditary characteristics of every organ of the body and every habit of the animal from birth to death, but also to afford a stock of latent gemmules to be passed on in an inactive state from germ to germ, till at last the ancestral peculiarity which it represents is revived in some remote descendant.

Some of the exponents of this theory of heredity have attempted to elude the difficulty of placing a whole world of wonders within a body so small and so devoid of visible structure as a germ, by using the phrase structureless germs. Now, one material system can differ from another only in the configuration and motion which it has at a given instant. To explain differences of function and development of a germ without assuming differences of structure is, therefore, to admit that the properties of a germ are not those of a purely material system.

The evidence as to the nature and motion of molecules, with which we have hitherto been occupied, has been derived from experiments upon gaseous media, the smallest sensible portion of which contains millions of millions of molecules. The constancy and uniformity of the properties of the gaseous medium is the direct result of the inconceivable irregularity of the motion of agitation of its molecules. Any cause which could introduce regularity into the motion of agitation, and marshal the molecules into order and method in their evolutions, might check or even reverse that tendency to diffusion of matter, motion, and energy, which is one of the most invariable phenomena of nature, and to which Thomson has given the name of the dissipation of energy.

Thus, when a sound-wave is passing through a mass of air, this motion is of a certain definite type, and if left to itself the whole motion is passed on to other masses of air, and the sound-wave passes on, leaving the air behind it at rest. Heat, on the other hand, never passes out of a hot body, except to enter a colder body, so that the energy of sound-waves, or any other form of energy which is propagated so as to pass wholly out of one portion of the medium and into another, cannot be called heat.

We have now to turn our attention to a class of molecular motions, which are as remarkable for their regularity as the motion of agitation is for its irregularity.

It has been found, by means of the spectroscope, that the light emitted by incandescent substances is different according to their state of condensation. When they are in an extremely rarefied condition the spectrum of their light consists of a set of sharply-defined bright lines. As the substance approaches a denser condition the spectrum tends to become continuous, either by the lines becoming broader and less defined, or by new lines and bands appearing between them, till the spectrum at length loses all its characteristics and becomes identical with that of solid bodies when raised to the same temperature.

Hence the vibrating systems, which are the source of the emitted light, must be vibrating in a different manner in these two cases. When the spectrum consists of a number of bright lines, the motion of the system must be compounded of a corresponding number of types of harmonic vibration.

In order that a bright line may be sharply defined, the vibratory motion which produces it must be kept up in a perfectly regular manner for some hundreds or thousands of vibrations. If the motion of each of the vibrating bodies is kept up only during a small number of vibrations, then, however regular may be the vibrations of each body while it lasts, the resultant disturbance of the luminiferous medium, when analysed by the prism, will be found to contain, besides the part due to the regular vibrations, other motions, depending on the starting and stopping of each particular vibrating body, which will become manifest as a diffused luminosity scattered over the whole length of the spectrum. A spectrum of bright lines, therefore, indicates that the vibrating bodies when set in motion are allowed to vibrate in accordance with the conditions of their internal structure for some time before they are again interfered with by external forces.

It appears, therefore, from spectroscopic evidence that each molecule of a rarefied gas is, during the greater part of its existence, at such a distance from all other molecules that it executes its vibrations in an undisturbed and regular manner. This is the same conclusion to which we were led by considerations of another kind at p. 626.

We may therefore regard the bright lines in the spectrum of a gas as the result of the vibrations executed by the molecules while describing their free paths. When two molecules separate from one another after an encounter, each of them is in a state of vibration, arising from the unequal action on different parts of the same molecule during the encounter. Hence, though the centre of mass of the molecule describing its free path moves with uniform velocity, the parts of the molecule have a vibratory motion with respect to the

centre of mass of the whole molecule, and it is the disturbance of the luminiferous medium communicated to it by the vibrating molecules which constitutes the emitted light.

We may compare the vibrating molecule to a bell. When struck, the bell is set in motion. This motion is compounded of harmonic vibrations of many different periods, each of which acts on the air, producing notes of as many different pitches. As the bell communicates its motion to the air, these vibrations necessarily decay, some of them faster than others, so that the sound contains fewer and fewer notes, till at last it is reduced to the fundamental note of the bell. If we suppose that there are a great many bells precisely similar to each other, and that they are struck, first one and then another, in a perfectly irregular manner, yet so that, on an average, as many bells are struck in one second of time as in another, and also in such a way that, on an average, any one bell is not again struck till it has ceased to vibrate, then the audible result will appear a continuous sound, composed of the sound emitted by bells in all states of vibration, from the clang of the actual stroke to to the final hum of the dying fundamental tone.

But now let the number of bells be reduced while the same number of strokes are given in a second. Each bell will now be struck before it has ceased to vibrate, so that in the resulting sound there will be less of the fundamental tone and more of the original clang, till at last, when the peal is reduced to one bell, on which innumerable hammers are continually plying their strokes all out of time, the sound will become a mere noise, in which no musical note can be distinguished.

In the case of a gas we have an immense number of molecules, each of which is set in vibration when it encounters another molecule, and continues to vibrate as it describes its free path. The molecule is a material system, the parts of which are connected in some definite way, and from the fact that the bright lines of the emitted light have always the same wave-lengths, we learn that the vibrations corresponding to these lines are always executed in the same periodic time, and therefore the force tending to restore any part of the molecule to its position of equilibrium in the molecule must be proportional to its displacement relative to that position.

From the mathematical theory of the motion of such a system, it appears that the whole motion may be analysed into the following parts, which may be considered each independently of the others : — In the first place, the centre of mass of the system moves with uniform velocity in a straight line. This velocity may have any value. In the second place, there may be a motion of rotation, the angular momentum of the system about its centre of mass remaining during the free path constant in magnitude and direction. This angular momentum may have any value whatever, and its axis may have any direction. In the third place, the remainder of the motion is made up of a number of component motions, each of which is an harmonic vibration of a given type. In each type of vibration the periodic time of vibration is determined by the nature of the system, and is invariable for the same system. The relative amount of motion in different parts of the system is also determinate for each type, but the absolute amount of motion and the phase of the vibration of each type are determined by the particular circumstances of the last encounter, and may vary in any manner from one encounter to another.

The values of the periodic times of the different types of vibration are given by the roots of a certain equation, the form of which depends on the nature of the connections of the system. In certain exceptionally simple cases, as, for instance, in that of a uniform string stretched between two fixed points, the roots of the equation are connected by simple arithmetical relations, and if the internal structure of a molecule had an analogous kind of simplicity, we might expect to find in the spectrum of the molecule a series of bright lines, whose wave-lengths are in simple arithmetical ratios.

But if we suppose the molecule to be constituted according to some different type, as, for instance, if it is an elastic sphere, or if it consists of a finite number of atoms kept in their places by attractive and repulsive forces, the roots of the equation will not be connected with each other by any simple relations, but each may be made to vary independently of the others by a suitable change of the connections of the system. Hence, we have no right to expect any definite numerical relations among the wave-lengths of the bright lines of a gas.

The bright lines of the spectrum of an incandescent gas are therefore due to the harmonic vibrations of the molecules of the gas during their free paths. The only effect of the motion of the centre of mass of the molecule is to alter the time of vibration of the light as received by a stationary observer. When the molecule is coming towards the observer, each successive impulse will have a shorter distance to travel before it reaches his eye, and therefore the impulses will appear to succeed each other more rapidly than if the molecule were at rest, and the contrary will be the case if the molecule is receding from the observer. The bright line corresponding to the vibration will therefore be shifted in the spectrum towards the blue end when the molecule is approaching, and towards the red end when it is receding from the observer. By observations of the displacement of certain lines in the spectrum, Dr. Huggins and others have measured the rate of approach or of recession of certain stars with respect to the earth, and Mr. Lockyer has determined the rate of motion of tornadoes in the sun. But Lord Rayleigh has pointed out that according to the dynamical theory of gases the molecules are moving hither and thither with so great velocity that, however narrow and sharply-defined any bright line due to a single moleclue may be, the displacement of the line towards the blue by the approaching molecules, and towards the red by the receding molecules, will produce a certain amount of widening and blurring of the line in the spectrum, so that there is a limit to the sharpness of definition of the lines of a gas. The widening of the lines due to this cause will be in proportion to the velocity of agitation of the molecules. It will be greatest for the molecules of smallest mass, as those of hydrogen, and it will increase with the temperature. Hence the measurement of the breadth of the hydrogen lines, such as C or F in the spectrum of the solar prominences, may furnish evidence that the temperature of the sun cannot exceed a certain value.

We must now leave these speculations about the nature of molecules and contemplate the material universe as made up of molecules. Every molecule, so far as we know, belongs to one of a definite number of species. The list of chemical elements may be taken as representing the known species which have been examined in the laboratories. Several of these have been discovered by means of the spectroscope, and more may yet remain to be discovered in the same way. The spectroscope has also been applied to analyse the light of the sun, the brighter stars and some of the nebulæ and comets, and has shown that the character of the light emitted by these bodies is similar in some cases to that emitted by terrestrial molecules, and in others to light from which the molecules have obsorbed certain rays. In this way a considerable number of

coincidences have been traced between the systems of lines belonging to particular terrestrial substances and corresponding lines in the spectra of the heavenly bodies.

The value of the evidence furnished by such coincidences may be estimated by considering the degree of accuracy with which one such coincidence may be observed. The interval between the two lines which form Fraunhofer's line D is about the five hundredth part of the interval between B and G on Kirchoff's scale. A discordance between the positions of two lines amounting to the tenth part of this interval, that is to say, the five thousanth part of the length of the bright part of the spectrum, would be very perceptible in a spectroscope of moderate power.

If we adopt the theory of Boscovich, and assert that the primitive atom is a mere centre of force, having a certain definite mass, we may get over the difficulty about the equality of the mass of all atoms by laying it down as a doctrine which cannot be disproved by experiment, that mass is not a quantity capable of continuous increase or diminution, but that it is in its own nature discontinuous, like number, the atom being the unit, and all masses being multiples of that unit. We have no evidence that it is possible for the ratio of two masses to be an incommensurable quantity, for the incommensurable quantities in geometry are supposed to be traced out in a continuous medium. If matter is atomic, and therefore discontinuous, it is unfitted for the construction of perfect geometrical models, but in other respects it may fulfil its functions.

But even if we adopt a theory which makes the equality of the mass of different atoms a result depending on the nature of mass rather than on any quantitative adjustment, the correspondence of the periods of vibration of actual molecules is a fact of a different order.

We know that radiations exist having periods of vibration of every value between those corresponding to the limits of the visible spectrum, and probably far beyond these limits on both sides. The most powerful spectroscope can detect no gap or discontinuity in the spectrum of the light emitted by incandescent lime.

The period of vibration of a luminous particle is therefore a quantity which in itself is capable of assuming any one of a series of values, which, if not mathematically continuous, is such that consecutive observed values differ from each other by less than the ten thousandth part of either. There is, therefore, nothing in the nature of time itself to prevent the period of vibration of a molecule from assuming any one of many thousand different observable values. That which determines the period of any particular kind of vibration is the relation which subsists between the corresponding type of displacement and the force of restitution thereby called into play, a relation involving constants of space and time as well as of mass.

It is the equality of these space- and time-constants for all molecules of the same kind which we have next to consider. We have seen that the very different circumstances in which different molecules of the same kind have been placed have not, even in the course of many ages, produced any appreciable difference in the values of these constants. If, then, the various processes of nature to which these molecules have been subjected since the world began have not been able in all that time to produce any appreciable difference between the constants of one molecule and those of another, we are forced to conclude that it is not to the operation of any of these processes that the uniformity of the constants is due.

The formation of the molecule is therefore an event not belonging to that order of nature under which we live. It is an operation of a kind which is not, so far as we are aware, going on on earth or in the sun or the stars, either now or since these bodies began to be formed. It must be referred to the epoch, not of the formation of the earth or of the solar system, but of the establishment of the existing order of nature, and till not only these worlds and systems, but the very order of nature itself is dissolved, we have no reason to expect the occurrence of any operation of a similar kind.

In the present state of science, therefore, we have strong reasons for believing that in a molecule, or if not in a molecule, in one of its component atoms, we have something which has existed either from eternity or at least from times anterior to the existing order of nature. But besides this atom, there are immense numbers of other atoms of the same kind, and the constants of each of these atoms are incapable of adjustment by any process now in action. Each is physically independent of all the others.

Whether or not the conception of a multitude of beings existing from all eternity is in itself self-contradictory, the conception becomes palpably absurd when we attribute a relation of quantitative equality to all these beings. We are then forced to look beyond them to some common cause or common origin to explain why this singular relation of equality exists, rather than any one of the infinite number of possible relations of inequality.

Science is incompetent to reason upon the creation of matter itself out of nothing. We have reached the utmost limit of our thinking faculties when we have admitted that, because matter cannot be eternal and self-existent, it must have been created. It is only when we contemplate not matter in itself, but the form in which it actually exists, that our minds find something on which it can lay hold.

The matter, as such, should have certain fundamental properties, that it should have a continuous existence in space and time, that all action should be between two portions of matter, and so on, are truths which may, for aught we know, be of the kind which metaphysicians call necessary. We may use our knowledge of such truths for purposes of deduction, but we have no data for speculating on their origin.

But the equality of the consants of the molecules is a fact of a very different order. It arises from a particular distribution of matter, a *collocation*, to use the expression of Dr. Chalmers, of things which we have no difficulty in imagining to have been arranged otherwise. But many of the ordinary instances of collocation are adjustments of constants, which are not only arbitrary in their own nature, but in which variations actually occur; and when it is pointed out that these adjustments are beneficial to living beings, and are therefore instances of benevolent design, it is replied that those variations which are not conducive to the growth and multiplication of living beings tend to their destruction, and to the removal thereby of the evidence of any adjustment not beneficial.

The constitution of an atom, however, is such as to render it, so far as we can judge, independent of all the dangers arising from the struggle for existence. Plausible reasons may, no doubt, be assigned for believing that if the constants had varied from atom to atom through any sensible range, the bodies formed by aggregates of such atoms would not have been so well fitted for the construction of the world as the bodies which actually exist. But as we have no experience of bodies formed of such variable atoms this must remain a bare conjecture.

Atoms have been compared by Sir J. Herschel to manufactured articles, on account of their uniformity. The uniformity of manufactured articles may be traced to very different motives on the part of the manufacturer. In certain cases it is found to be less expensive as regards trouble, as well as cost, to make a great many objects exactly alike than to adapt each to its special requirements. Thus, shoes for soldiers are made in large numbers without any designed adaptation to the feet of particular men. In another class of cases the uniformity is intentional, and is designed to make the manufactured article more valuable. Thus, Whitworth's bolts are made in a certain number of sizes, so that if one bolt is lost, another may be got at once, and accurately fitted to its place. The identity of the arrangement of the words in the different copies of a document or book is a matter of great practical importance, and it is more perfectly secured by the process of printing than by that of manuscript copying.

In a third class not a part only but the whole of the value of the object arises from its exact conformity to a given standard. Weights and measures belong to this class, and the existence of many well-adjusted material standards of weight and measure in any country furnishes evidence of the existence of a system of law regulating the transactions of the inhabitants, and enjoining in all professed measures a conformity to the national standard.

There are thus three kinds of usefulness in manufactured articles—cheapness, serviceableness, and quantitative accuracy. Which of these was present to the mind of Sir J. Herschel we cannot now positively affirm, but it was at least as likely to have been the last as the first, though it seems more probable that he meant to assert that a number of exactly similar things cannot be each of them eternal and self-existent, and must therefore have been made, and that he used the phrase "manufactured article" to suggest the idea of their being made in great numbers.

ATOOI, one of the larger Sandwich Islands, in the South Pacific Ocean. Towards the N.E. and N.W. the country is rugged and broken, but to the southward it is more level. The hills rise from the sea with a gentle acclivity, and, at a little distance back, are covered with wood; the central peaks attain an elevation of 7000 feet. The chief ports are Waimea and Hanalei. The island was one of the stations chosen for the observation of the transit of Venus in 1874. It is nearly 40 miles in length, and contains about 10,000 inhabitants.

ATRATO, a river of Colombia, South America, which, after a course of 250 miles, almost due N., for the most part through a low and swampy region, falls into the Gulf of Uraba or Darien. The gold and platinum mines of Choco were on some of its affluents, and its sands are still auriferous. The river has attracted considerable attention in connection with schemes for the construction of a ship-canal across the isthmus. It is navigable for small vessels for about 140 miles.

ATREK or ATTRUCK, a river which rises in the mountains of Khorasan, and flows W. along the borders of Persia and the Russian possessions, till it falls in the south-eastern corner of the Caspian, a short distance to the N. of Ashurada.

ATREUS, in *Greek Legend*, a son of Pelops, had, with his brother Thyestes, settled in Mycenæ, where he succeeded Eurystheus in the sovereignty, in which he was secured by the possession of a lamb or ram with a golden fleece. His wife Aërope, a daughter of Minos, bribed by Thyestes, assisted the latter to carry off the ram. But Zeus, in the interest of Atreus, wrought a miracle, causing the sun which before had risen in the west to rise in the east. Thyestes was driven from Mycenæ, but returned to his brother begging to be forgiven. Atreus, appearing to welcome him, invited him to a banquet to eat of his own son, whom he had slain. From this crime followed the ills which befel Agamemnon, the son of Atreus.

ATRI or ATRIA, the ancient *Hadria*, a town of Naples, in the province of Abruzzo Ulteriore I., situated on a steep mountain 5 miles from the Adriatic, and 18 miles S.E. of Teramo. Remains of the ancient city have been discovered to the S. of the present site, consisting of the ruins of a theatre and baths, with pavements, and vases of Greek manufacture.

ATRIUM, the principal apartment in a Roman house, was entered through the *ostium* or *janua*, which opened off the *vestibulum*, a clear space between the middle of the house and the street, formed by the projection of the two sides. It was generally quadrangular in shape, and was roofed all over, with the exception of a square opening, called *compluvium*, towards which the roofs sloped, and by which the rain-water was conducted down to a basin (*impluvium*) fixed in the floor. In the early periods of Roman civilisation, the atrium was the common public apartment, and was used for the reception of visitors and clients, and for ordinary domestic purposes, as cooking and dining. In it were placed the ancestral pictures, the marriage-couch, the hearth, and generally a small altar. Here, too, were kept the looms at which the mistress of the house sat and span with her maid-servants. At a somewhat later period, and among the wealthy, separate apartments were built for kitchens and dining-rooms, and the atrium was kept as a general reception room for clients and visitors.

ATRIUM, in *Ecclesiastical Antiquities*, denotes an open place or court before a church. It consisted of a large area or square plat of ground, surrounded with a portico or cloister, situated between the porch or vestibule and the body of the church. In the centre was placed a fountain, wherein the worshippers washed their hands before entering church. In the atrium those who were not suffered to advance farther, and more particularly the first class of penitents, stood to solicit the prayers of the faithful as they went into the church. It was also used as a burying-ground, at first only for distinguished persons, but afterwards for all believers.

ATROPHY, a term in medicine used to describe a a state of wasting due to some interference with the function of healthy nutrition. In the living organism there are ever at work changes involving the waste of its component tissues, which render necessary, in order to the preservation of life, the proper assimilation of nutritive material. It is also essential for the maintenance of health that a due relation exist between these processes of waste and repair, so that the one may not be in excess of the other. When the appropriation of nutriment exceeds the waste, hypertrophy or increase in bulk of the tissues takes place. (See HYPERTROPHY.) When, on the other hand, the supply of nutritive matter is suspended or diminished, or when the power of assimilation is impaired, atrophy or wasting is the result. Thus the whole body becomes atrophied in many diseases; and in old age every part of the frame, with the single exception of the heart, undergoes atrophic change. Atrophy may, however, affect single organs or parts of the body, irrespective of the general state of nutrition, and this may be brought about in a variety of ways. One of the most frequently observed of such instances is atrophy from disuse, or cessation of function. Thus, when a limb is deprived of the natural power of motion, either by paralysis or by painful joint disease, the condition of exercise essential to its nutrition being no longer fulfilled, atrophy of all its textures

ooner or later takes place. The brain in imbeciles is frequently observed to be shriveled, and in many cases of blindness there is atrophy of the optic nerve and optic tract. This form of atrophy is likewise well exemplified in the case of those organs and structures of the body which subserve important ends during fœtal life, but which, ceasing to be necessary after birth, undergo a sort of natural atrophy, such as the thymus gland, and certain vessels specially concerned in the fœtal circulation. The uterus after parturition undergoes a certain amount of atrophy, and the ovaries, after the child-bearing period, become shrunken. Atrophy of a part may also be caused by interruption to its normal blood supply, as in the case of the ligature or obstruction of an artery. Again, long standing disease, by affecting the nutrition of an organ and by inducing the deposit of morbid products, may result in atrophy, as frequently happens in affections of the liver and kidneys. Parts that are subjected to continuous pressure are liable to become atrophied, as is sometimes seen in internal organs which have been pressed upon by tumors or other morbid growths, and is well illustrated in the case of the feet of Chinese ladies, which are prevented from growing by persistent compression exercised from birth.

ATROPIA, or ATROPINE, $C_{17}H_{23}NO_3$, is an alkaloid existing in all parts of the deadly night-shade (*Atropa belladonna*). The seed of the thorn-apple (*Datura stramonium*) also contains an alkaloid, deturine, which long was believed to be identical with atropia. Recent researches seem to indicate that it is, however, only isomeric, and that it is only half as poisonous as atropia. A solution of sulphate of atropia in water dropped into the eye is now generally preferred to belladonna lotions or ointments for eye diseases.

ATROPOS, the eldest of the three Moirai, Parcæ, or Fates. Her name, the Unalterable, indicates the part generally played by her, viz., that of rendering the decisions of her sisters irreversible or immutable.

ATTACHE (Fr.), one attached to or connected with another, as a part of his suite of attendants. The term is specifically applied to young diplomatists on the staff of an ambassador.

ATTACHMENT, in *Law*, is a process from a court of record, awarded by the court at its discretion, on a bare suggestion, or on its own knowledge, and is properly grantable in cases of contempt. It differs from arrest, in that he who arrests a man carries him to a person of higher power to be forthwith disposed of; but he that attaches keeps the party attached, and presents him in court at the day assigned, as appears by the words of the writ. Another difference is, that arrest is only upon the body of a man, whereas an attachment is often upon his goods. It is distinguished from distress in not extending to lands, as the latter does; nor does a distress touch the body as an attachment does. Every court of record has power to fine and imprison for contempt of its authority. Attachment being merely a process to bring the defendant before the court, is not necessary in cases of contempt in the presence of the court itself.

ATTACHMENT OF DEBTS.— It was suggested by the common law commissioners in 1853 that a remedy analogous to that of Foreign Attachment might be made available to creditors, after judgment, against debts due to their debtors. Accordingly, the Common Law Procedure Act, 1854, enacted that any creditor, having obtained judgment in the superior courts, should have an order that the judgment debtor might be examined as to any debts due and owing to him before a master of the court. On affidavit that the judgment was still unsatisfied, and that any other person within the jurisdiction was indebted to the judgment debtor, the judge was empowered to attach all debts due from such third person to the judgment debtor.

In the United States attachment may be defined as the taking into the custody of the law the person or property of one who is already before the court, or of one whom it is sought to bring before the court; also a writ for this purpose. To some extent it is of the nature of a criminal process. In some States attachments are distinguished as foreign and domestic—the former issued against a non-resident having property within the jurisdiction of the State, the latter against a resident in the State, jurisdiction over the person or property being necessary for an attachment. An attachment issued under a State law which has not been adopted by Congress, or by a rule of court, cannot be sustained in a United States court. Money due to a seaman for wages is not attachable in the hands of a purser, the purser being a distributing agent for the government, and in no sense the debtor of the seaman.

ATTAINDER, in the *Law of England*, was the immediate and inseparable consequence from the common law upon the sentence of death. When it was clear beyond all dispute that the criminal was no longer fit to live, he was called *attaint*, *attinctus*, stained or blackened, and could not be a witness in any court. This attainder took place after judgment of death, or upon such circumstances as were equivalent to judgment of death, such as judgment of outlawry on a capital crime, pronounced for absconding from justice. Conviction without judgment was not followed by attainder. The consequences of attainder were Forfeitures. On attainder for treason, the criminal forfeited to the Crown his lands, rights of entry on lands, and any interest he might have in lands for his own life or a term of years. For murder, the offender forfeited to the Crown the profit of his freeholds during life, and in the case of lands held in fee-simple, the lands themselves for a year and a day; subject to this, the lands escheated to the lord of the fee. These forfeitures related back to the time of the offence committed. Forfeitures of goods and chattels ensued not only on attainder, but on conviction for a felony of any kind, or on flight from justice, and had no relation backwards to the time of the offence committed. Provision is made for the due administration of convicts' estates in the interests of themselves and their families. Forfeiture consequent on outlawry is exempted from the provisions of the Act.

ATTALIA, an ancient city of Pamphylia, named from Attalus II, king of Pergamus.

ATTAR, or OTTO, of ROSES, a well-known perfume of great strength, is an essential oil of roses, prepared chiefly in Hindustan and Persia. See OILS and PERFUMERY.

ATTENTION, in *Psychology* may be defined as the concentration of consciousness, or the direction of mental energy upon a definite object or objects.

ATTERBOM, PETER DANIEL AMADEUS, a Swedish poet, was born in Ostergöthland in 1790, studied in the University of Upsala from 1805 to 1815, became Professor of Philosophy there in 1828, and died in 1855. He was the leader in the great romantic movement which revolutionised Swedish literature.

ATTERBURY, FRANCIS, a man who holds a conspicuous place in the political, ecclesiastical, and literary history of England, was born in the year 1662, at Middleton in Buckinghamshire, a parish of which his father was rector. Francis was educated at Westminster School, and carried thence to Christ Church a stock of learning, which, though really scanty, he through life exhibited with such judicious ostentation that superficial observers believed his attainments to be immense. In

1687 he distinguished himself among many able men who wrote in defence of the Church of England, then persecuted by James II., and calumniated by apostates who had for lucre quitted her communion. Among these apostates none was more active or malignant than Obadiah Walker, who was master of University College, and who had set up there, under the royal patronage, a press for printing tracts against the established religion. In one of these tracts, written apparently by Walker himself, many aspersions were thrown on Martin Luther. Atterbury undertook to defend the great Saxon Reformer, and performed the task in a manner singularly characteristic. Whoever examines his reply to Walker will be struck by the contrast between the feebleness of those parts which are argumentative and defensive, and the vigor of those parts which are rhetorical and aggressive.

ATTICA, the most famous district of ancient Greece, is a triangular piece of ground projecting in a south-easterly direction into the Ægean Sea, the base line being formed by the continuous chain of Mounts Cithæron and Parnes, the apex by the promontory of Sunium. It is washed on two sides by the sea, and this feature seems to have given rise to the name. The coast is broken up into numerous small bights and harbors, which, however, are with few exceptions exposed to the south wind; the irregularity of the outline accounts for its great length in comparison of the superficial area of the country. The surface of Attica, as of the rest of Greece, is very mountainous, and between the mountain chains lie several plains of no great size, open on one side to the sea. On the west its natural boundary is the Corinthian Gulf, so that it would include the district of Megaris; and, as a matter of fact, before the Dorian invasion, which resulted in the foundation of Megara, the whole of this country was politically one, being in the hands of the Ionian race.

The central position of Attica in Greece was one main cause of its historical importance.

The mountains of Attica, which form its most characteristic feature, are to be regarded as a continuation of that chain which, starting from Mount Tymphrestus at the southern extremity of Pindus, passes through Phocis and Bœotia under the well-known names of Parnassus and Helicon; from this proceeds the range which, as Cithæron in its western and Parnes in its eastern portion, separates Attica from Bœotia, throwing off spurs southward towards the Saronic Gulf in Ægaleos and Hymettus, which bound the plain of Athens.

The soil is light and thin, and requires very careful agriculture to develop its produce. This feature belongs not only to the rocky mountain sides, but to some extent also to the maratime plains, and had considerable influence on the development of the inhabitants, both by enforcing industrious habits, and in leading them at an early period to take to the sea. Still, the level ground was sufficiently fertile to form a marked contrast to the rest of the district, and this fact is represented in the mythical genealogy of the early kings, which embodies several geographical features.

But whatever drawbacks the people of Attica experienced in respect of the soil were more than compensated by the fineness of the climate. In this point they enjoyed a great advantage over their neighbors the Bœotians; and while at the present day travellers speak of the excessive heat in summer and cold in winter which they have experienced in Bœotia, Attica has always been famous for its mildness.

When we turn to the vegetation of Attica, the olive first calls for our attention. This tree, we learn from Herodotus, was thought at one time to have been found in that country only; and the enthusiastic praises of Sophocles teach us that it was the land in which it flourished best. So great was the esteem in which it was held, that in the early legend of the struggle between the gods of sea and land, Poseidon and Athena, for the patronage of the country, the sea-god is represented as having to retire vanquished before the giver of the olive; and at a later period the evidences of this contention were found in an ancient olive tree in the Acropolis, together with three holes in the rock, said to have been made by the trident of Poseidon, and to be connected with a salt well hard by. The fig also found its favorite home in this country, for Demeter was said to have bestowed it as a gift on the Eleusinian Phytalus, *i.e.*, "the gardener."

Having thus noticed the general features of the country, let us proceed to examine it somewhat more in detail. It has been already mentioned that the base line is formed by the chain of Cithæron and Parnes, running from west to east; and that from this transverse chains run southward, dividing Attica into a succession of plains. The westernmost of these, which is separated from the innermost bay of the Corinthian Gulf, called the Mare Alcyonium, by an offshoot of Cithæron, and is bounded on the east by a ridge which ends towards the Saronic Gulf in a striking two-horned peak called Kerata, is the plain of Megara. It is only for geographical purposes that we include this district under Attica, for both the Dorian race of the inhabitants, and its dangerous proximity to Athens, caused it to be at perpetual feud with that city; but its position as an outpost for the Peloponnesians, together with the fact of its having once been Ionian soil, sufficiently explains the bitter hostility of the Athenians towards the Megarians. The great importance of Megara arose from its commanding all the passes into the Peloponnese. These were three in number: one along the shores of the Corinthian Gulf, which, owing to the nature of the ground, makes a long detour; the other two starting from Megara, and passing, the one by a lofty though gradual route over the ridge of Geraneia, the other along the Saronic Gulf, under the dangerous precipices of the Scironian rocks. The town of Megara, which was built on and between two low hills rising out of the plain rather more than a mile from the sea, had the command of both gulfs by means of its two ports—that of Pegæ on the Corinthian, and that of Nicæa on the Saronic.

To the east of the plain of Megara lies that of Eleusis, bounded on the one side by the chain of Kerata, and on the other by that of Ægaleos, through a depression in which was the line of the sacred way, where the torchlight processions from Athens used to descend to the coast, the "brightly-gleaming shores." Here a deep bay runs into the land, opposite to which, and separated from it by a strait, which forms a succession of graceful curves, was the rocky island of Salamis, at all times an important possession to the Athenians on account of its proximity to their city. The scene of the battle of Salamis was the narrowest part of this channel, where the island approaches the extremity of Ægaleos. The eastern portion of this plain was called the Thriasian plain, and the city of Eleusis was situated in the recesses of the bay. The coast-line of this part, between the sanctuary of Poseidon at the isthmus, which was originally Ionian, and Athens, is the principal scene of the achievements of Theseus, a hero who holds the same relation to the Ionians of Greece proper as Hercules does to the Greeks at large, viz., that of being the great author of improvements in the country.

Next in order to the plain of Eleusis came that of Athens, which is the most extensive of all, reaching from the foot of Parnes to the sea, and bounded on the

west by Ægaleos, and on the east by Hymettus. Its most conspicuous feature is the broad line of dark green along its western side, formed by the olive-groves of Colonus and the gardens of the Academus, which owe their fertility to the waters of the Cephisus, by which they are irrigated. This river is fed by copious sources on the side of Mount Parnes, and thus, unlike the other rivers of Attica, has a constant supply of water; but it does not reach the sea, nor did it apparently in classical times, having been diverted, then as now, into the neighboring plantations; for this is what Sophocles means when he speaks of "the sleepless fountains of Cephisus, which stray forth from their channels." The position of Colonus itself is marked by two bare knolls of light-colored earth, which caused the poet in the same chorus to apply the epithet "white" to that place. On the opposite side of the plain runs the other river, the Ilissus, which rises from a beautiful fountain in Mount Hymettus, and skirts the eastern extremity of the city of Athens; but this, notwithstanding its celebrity, is a mere brook which stands in pools a great part of the year, and in summer is completely dry. The situation of Athens relatively to the surrounding objects is singularly harmonious; for, while it forms a central point, so as to be the eye of the plain, and while the altar-rock of the Acropolis and the hills by which it is surrounded are conspicuous from every point of view, there is no such exactness in its position as to give formality, since it is nearer to the sea than to Parnes, and nearer to Hymettus than to Ægaleos. The most striking summit in the neighborhood of the city is that of Lycabettus, now Mount St. George, on the north-eastern side; and the variety is still further increased by the continuation of the ridge which it forms for some distance northwards through the plain. Three roads lead to Athens from the Bœotian frontier over the intervening mountain barrier — the easternmost over Parnes, from Delium and Oropus by Deceleia, which was the usual route of the invading Lacedæmonians during the Peloponnesian War; the westernmost over Cithæron, by the pass of Dryoscephalæ, or the "Oak-heads;" leading from Thebes by Platæa to Eleusis, and so to Athens, which we hear of in connection with the battle of Platæa, and with the escape of the Platæans at the time of the siege of that city in the Peloponnesian War; the third, midway between the two, by the pass of Phyle, near the summit of which, on a rugged height overlooking the Athenian plain, is the fort occupied by Thrasybulus in the days of the Thirty tyrants.

It still remains to mention the most famous spot of ground in Attica, the little plain of Marathon, which lays in the north-east corner, encircled on three sides by Parnes and Pentilicus, while the fourth faces the sea and the opposite coast of Eubœa. It was on the mountain slopes that the Greeks were stationed, while the Persians with their ships occupied the coast; and on the two sides the marshes may still be traced by which the movements of the invader's host were impeded The mound, which at once attracts the eye in the centre of the level plain, is probably the burial-place of the Athenians who fell in the battle. The bay in front is sheltered by Eubœa, and is still more protected from the north by a projecting tongue of land, called Cynosura. The mountains in the neighborhood were the seat of one of the political parties in Attica, the Diacrii or Hyperacrii, who, being poor mountaineers, and having nothing to lose, were the principal advocates of change; while, on the other hand, the Pedieis, or inhabitants of the plains, being wealthy landholders, formed the strong conservative element and the Parali, or occupants of the sea-coast, representing the mercantile interest, held an intermediate position between the two.

Of the condition of Attica in mediæval and modern times little need be said, for it has followed for the most part the fortunes of Athens. The population, however, has undergone a great change, independently of the large admixture of Slavonic blood that has effected the Greeks of the mainland generally, by the immigration of Albanian colonists, who now occupy a great part of the country.

ATTICA, a city of New York, situated in the northern part of Wyoming county, is on the Erie and the New York Central railways, thirty-one miles east of Buffalo and forty-three miles southwest of Rochester. Among the industries are flour mills, carriage shops and tanneries. The population is 5,000.

ATTICUS, Titus Pomponius, the friend of Cicero, was one of the most distinguished men during the period of the decline and fall of the Roman republic. His life gives an admirable picture of the classical man of culture, who, withdrawing from the stir of political affairs, devoted himself to literary and artistic pursuits. He was born at Rome 109 B.C., and was thus three years older than Cicero, along with whom he and the younger Marius were educated. He did not marry till he was 53 years of age, and his only child became the wife of Vipsanius Agrippa, the distinguished minister of Augustus. His large fortune was increased on the death of his uncle, L. Cæcilius, who bequeathed to him the greater part of his property. He formed a large library at Athens, and kept a staff of slaves engaged in making copies of valuable works. He probably derived considerable profits from the sale of these books. In 32 B.C., he was seized with an illness believed to be incurable. He resolved not to protract a painful and hopeless struggle, and died after five days of voluntary starvation.

ATTICUS HERODES, Tiberius Claudius, a very wealthy citizen of Athens, was born about 104 A.D. His grandfather's estates had been confiscated for treachery, but the fortunes of the family had been restored by the discovery in his father's house of an enormous sum of money, which the Emperor Nerva permitted them to retain. This great wealth Herodes afterwards increased by his marriage. He received a careful education under the most distinguished masters of the time, and specially devoted himself to the study of oratory, to excel in which seems to have been the ruling motive of his life. While very young he delivered a speech before one of the emperors; but it was so ill received that he was with difficulty restrained from throwing himself into the Danube. He ultimately attained to great celebrity as a speaker and as a teacher of rhetoric. Among his pupils were Marcus Aurelius and Lucius Verus. He was highly esteemed by the Antonines, particularly by Aurelius, and received many marks of favor, among others the archonship at Athens and the consulate at Rome. Atticus is principally celebrated, however, for the vast sums he expended on public purposes. He withdrew from Athens, and resided at his villa near Marathon, where he died about 180 A.D. None of his writings are extant.

ATTILA, or Etzel, the famous leader of the Huns, surnamed the "Fear of the World," or the "Scourge of God," was born probably about 406 A.D. His father Mundzuk, king of the Huns, was succeeded by his brothers Octar and Rhuas; and on the death of Rhuas, in 434, Attila and his brother Bleda together ascended the throne. They ruled not only over the Huns, but over nearly all the tribes north of the Danube and the Black Sea; under their banners fought Ostrogoths, Gepidæ, Alani, Heruli, and many other Teutonic peoples. Their dominions are said to have extended from the Rhine to the frontiers of China. Attila was

superstitiously reverenced by his countrymen; he was said to possess the iron sword of the war-god, Mars, and he proclaimed himself to be the man-child born at Engaddi, who was destined to rule over the whole world. In 441 and 442 the brothers ravaged Thrace and Illyria, defeated the troops of the Eastern Empire in three great battles, and penetrated as far as Thermopylæ. Peace was made on the Romans agreeing to pay a heavy tribute. About this time Attila contrived to make away with his brother Bleda, and thus secured undivided supremacy. In 445 and the following years, he again directed his attacks against the Eastern Empire, and laid waste the whole country round Constantinople. Nowhere did he meet with resistance save from the brave little town of Azimus. The empire seemed about to succumb, when Theodosius entered into negotiations and made terms with his conqueror. While matters were being arranged, a plot was laid to assassinate Attilla, in which the emperor was implicated. The conspiracy was discovered, and the barbarian upbraided the Christian monarch with his want of honor and manly courage. . Theodosius died soon after, and his successor, Marcian, returned a firm refusal to Attila's demands for tribute. War seemed inevitable; but at this time the attention of the Hun was drawn to the Western Empire. It is said that the Princess Honoria, sister of Valentinian, tired of her life of enforced celibacy, sent her ring and an offer of her hand to Attila, who upon this grounded his claim to a part of the empire. It is probable, however, that he merely used this as a pretext, and that his real designs were more comprehensive. He evidently thought it a favorable opportunity for taking advantage of the enmity between the Romans and the Visigoths; and to this plan he was also induced by the proposals of Genseric, king of the Vandals, who offered to unite with him against his rival, Theodoric, king of the Visigoths. In 451 Attila assembled his forces, it is said 700,000 strong, led them through the centre of Germany, probably by Franconia, and crossed the Rhine, at what place cannot be determined. He defeated the Burgundians, and pushed on through the heart of Gaul, until his centre was checked by the valiant resistance offered by Orleans. Meanwhile, Theodoric and Aëtius, the Roman general, had collected and united their forces, and marching with all speed, arrived in time to raise the siege of Orleans. Attila retreated to a position in the plain of Chalons, and there concentrated his forces for a great engagement. A tremendous battle ensued—one of the most gigantic as well as most important contests recorded in history. The Romans, who formed one wing, were driven back, and although they kept together, and at nightfall retired to the camp of the Visigoths, Aëtius had given up the day as lost. The Visigoths, who were on the other wing, had also been repulsed, and were discouraged by the fall of their leader Theodoric. But the fortune of the day was changed by the impetuous bravery of Thorismund, Theodoric's son, who, burning to avenge his father's fall, led on the infuriated Visigoths, and drove Attila back to his camp. He even penetrated into the fortifications, but was wounded and thrown from his horse, and his followers with difficulty carried him off. Next day, Attila remained in camp in expectation of an attack, and having thrown all his baggage into a gigantic pile in the centre of the camp to be burned in case of defeat, resolved to sell his life dearly. But no attack was made; for Thorismund was persuaded by Aëtius to march to Toulouse in order to obtain his father's kingdom. Attila was thus enabled to retire in perfect security. Next year he poured his forces through the defiles of the Alps, and laid waste the whole north of Italy. Rome itself seemed likely to fall before the invader, when his course was arrested by an embassy headed by Pope Leo. Attila at once withdrew from Italy, but the motive which led him to act thus is not known. At the time his retreat was ascribed to the miraculous interposition of Providence, Peter and Paul having appeared in the camp of the Huns along with the embassy; the whole matter is, on the whole, rather obscure. Attila died in the year 453, from the bursting of a blood vessel, and his empire broke up immediately after his death.

ATTLEBOROUGH, a town of Bristol county, Mass., thirty-one miles southwest of Boston. It has good railroad connections, and contains national banks, newspaper offices, several churches, and a system of graded schools. The town is the seat of several important industries, the chief of which is the manufacture of jewelry and electro-plate. There are also manufactories of cotton, woolen and knit goods, and of boots and shoes. The township contains a large village known as North Attleborough, where similar industries are carried on. Attleborough has a population (1890) of 7,575.

ATTOCK, a town and fort of British India, in the Panjáb, situated on the eastern bank of the Indus. The place is both of political and commercial importance.

ATTORNEY, in *English Law*, signifies, in its widest sense, any substitute or agent appointed to act in "the turn, stead, or place of another." The term is now commonly confined to a class of qualified agents who undertake the conduct of legal proceedings for their clients. By the common law the actual presence of the parties to a suit was considered indispensable, but the privilege of appearing by attorney was conceded in certain cases by special dispensation, until the statute of Merton and subsequent enactments made it competent for both parties in all judicial proceedings to appear by attorney. Solicitors appear to have been at first distinguished from attorneys, as not having the attorney's power to bind their principals, but latterly the distinction has been between attorneys as the agents formally appointed in actions at law, and solicitors who take care of proceedings in Parliament, Chancery, Privy Council, &c. In practice, however, and in ordinary language, the terms are synonymous.

In the United States, legal counsel, of whatever nature, whether in criminal or civil procedure, is styled an attorney — comprehending at once the functions of the English solicitor, attorney, counsel and barrister—no distinction being made, the practising *lawyer* combining in his person all legal attributes of these professions.

ATTORNEY-GENERAL, the chief law officer appointed to manage all the legal affairs and suits in which the government is interested.

ATTRACTION. That the different parts of a material system influence each other's motions is a matter of daily observation. In some cases we cannot discover any material connection extending from the one body to the other. We call these cases of action at a distance, to distinguish them from those in which we can trace a continuous material bond of union between the bodies. The mutual action between two bodies is called stress. When the mutual action tends to bring the bodies nearer, or to prevent them from separating, it is called tension or attraction. When it tends to separate the bodies, or to prevent them from approaching, it is called pressure or repulsion. The names tension and pressure are used when the action is seen to take place through a medium. Attraction and repulsion are reserved for cases of action at a distance. The configuration of a material system can always be defined in terms of the mutual distances of the parts of the system. Any change of configuration

must alter one or more of these distances. Hence the force which produces or resists such a change may be resolved into attractions or repulsions between those parts of the system whose distance is altered.

There has been a great deal of speculation as to the cause of such forces, one of them, namely, the pressure between bodies in contact, being supposed to be more easily conceived than any other kind of stress. Many attempts have therefore been made to resolve cases of apparent attraction and repulsion at a distance into cases of pressure. At one time the possibility of attraction at a distance was supposed to be refuted by asserting that a body cannot act where it is not, and that therefore all action between different portions of matter must be by direct contact. To this it was replied that we have no evidence that real contact ever takes place between two bodies, and that, in fact, when bodies are pressed against each other and in apparent contact, we may sometimes actually measure the distance between them, as when one piece of glass is laid on another, in which case a considerable pressure must be applied to bring the surfaces near enough to show the black spot of Newton's rings, which indicates a distance of about a ten thousandth of a millimetre. If, in order to get rid of the idea of action at a distance, we imagine a material medium through which the action is transmitted, all that we have done is to substitute for a single action at a great distance a series of actions at smaller distances between the parts of the medium, so that we cannot even thus get rid of action at a distance.

The study of the mutual action between the parts of a material system has, in modern times, been greatly simplified by the introduction of the idea of the energy of the system. The energy of the system is measured by the amount of work which it can do in overcoming external resistances. It depends on the present configuration and motion of the system, and not on the manner in which the system has acquired that configuration and motion. A complete knowledge of the manner in which the energy of the system depends on its configuration and motion, is sufficient to determine all the forces acting between the parts of the system. For instance, if the system consists of two bodies, and if the energy depends on the distance between them, then if the energy increases when the distance increases, there must be attraction between the bodies, and if the energy diminishes when the distance increases, there must be repulsion between them.

Newton, in his *Principia*, deduces from the observed motions of the heavenly bodies the fact that they attract one another according to a definite law. This he gives as a result of strict dynamical reasoning, and by it he shows how not only the more conspicuous phenomena, but all the apparent irregularities of the celestial motions are the calculable results of a single principle. In his *Principia* he confines himself to the demonstration and development of this great step in the science of the mutual action of bodies. He says nothing there about the means by which bodies gravitate towards each other. But his mind did not rest at this point. We know that he did not believe in the direct action of bodies at a distance. And we also know that he sought for the mechanism of gravitation in the properties of an ætherial medium diffused over the universe.

In his *Optical Queries*, indeed, he shows that if the pressure of this medium is less in the neighborhood of dense bodies than at great distances from them, dense bodies will be drawn towards each other, and that if the diminution of pressure is inversely as the distance from the dense body the law will be that of gravitation. The next step, as he points out, is to account for this inequality of pressure in the medium; and as he was not able to do this, he left the explanation of the cause of gravity as a problem to succeeding ages. As regards gravitation the progress made towards the solution of the problem since the time of Newton has been almost imperceptible. Faraday showed that the transmission of electric and magnetic forces is accompanied by phenomena occurring in every part of the intervening medium. He traced the lines of force through the medium; and he ascribed to them a tendency to shorten themselves and to separate from their neighbors, thus introducing the idea of stress in the medium in a different form from that suggested by Newton; for, whereas Newton's stress was a hydrostatic pressure in every direction, Faraday's is a tension along the lines of force, combined with a pressure in all normal directions. By showing that the plane of polarisation of a ray of light passing through a transparent medium in the direction of the magnetic force is made to rotate, Faraday not only demonstrated the action of magnetism on light, but by using light to reveal the state of magnetisation of the medium, he "illuminated," to use his own phrase, "the lines of magnetic force."

From this phenomenon Thomson afterwards proved, by strict dynamical reasoning, that the transmission of magnetic force is associated with a rotatory motion of the small parts of the medium. He showed, at the same time, how the centrifugal force due to this motion would account for magnetic attraction.

It is remarkable that of the three hypotheses, which go some way towards a physical explanation of gravitation, every one involves a constant expenditure of work. That of the generation or absorption of fluid requires, not only constant expenditure of work in emitting fluid under pressure, but actual creation and destruction of matter. That of waves requires some agent in a remote part of the universe capable of generating the waves.

According to such hypotheses we must regard the processes of nature not as illustrations of the great principle of the conservation of energy, but as instances in which, by a nice adjustment of powerful agencies not subject to this principle, an apparent conservation of energy is maintained. Hence, we are forced to conclude that the explanation of the cause of gravitation is not to be found in any of these hypotheses.

ATTWOOD, THOMAS, musical composer, was born in London in 1767, and died in 1838.

ATWOOD, GEORGE, an author celebrated for the accuracy of his mathematical and mechanical investigations, and considered particularly happy in the clearness of his explanations, and the elegance of his experimental illustrations, was born in the early part of the year 1746, and died in 1807.

ATYS, ATTIS, or ATTES, in the *Phrygian and Lydian Mythology*, a youth beloved for his beauty by the goddess Rhea, there called Agdistis. Like Adonis, he was the personification of the changes in nature, from the beauty of spring and summer to the severity and darkness of winter. The story, as told at Pessinus, the centre of the worship of the goddess, was that she had borne to Zeus a being both male and female; that the gods displeased, had transformed this being into a tree, from the fruit of which the daughter of the river-god Sangarius bore a boy, who grew up among herdsmen marvellous in his beauty so as to win the love of Agdistis. This was Atys, and he was about to be married to the king's daughter of Pessinus, when the goddess appeared among the guests, terrified them, and caused Atys to run to the woods, where he maimed himself and was transformed into a pine tree; from his blood sprang violets.

AUBAGNE, a town of France, in the department of Bouches-du-Rhône, with a population of 7408, who

carry on the manufacture of wine, pottery, leather, coarse cloth, &c.

AUBE, a department of France bounded on the N. by the department of Marne, N. W. by Seine-et-Marne, W. by Yonne, S. by Cote-d'Or, and E. by Haute-Marne. It consists of a portion of Champagne and Vallage, with a small part of Burgundy, and has an area of 2317 square miles. Its general inclination from S. E. to N. W. presents little variety of surface, the only elevations being a double line of hills along the course of the Seine, never exceeding 1150 feet in height. The department belongs to the Seine basin, and is watered by that river and its tributaries, the Ource, the Sarce, the Melda, and the Aube, &c. The climate is comparatively mild, but damp. Among the celebrated men connected with Aube are Villehardouin, Pope Urban IV., Mignard, Danton, Beugnot, and Ulbach. The capital is Troyes, and the arrondissements are Troyes, Arcis-sur-Aube, Nogent-sur-Seine, Bar-sur-Aube, and Bar-sur-Seine. Population in 1890, 260,000.

AUBENAS, a town of France, department of Ardèche, near the river of that name, 14 miles S. W. of Privas. It is beautifully situated on the slope of a hill, but its streets generally are crooked and narrow. Population 7694.

AUBER, Daniel François Esprit, musical composer, the chief representative of the French school, was the son of a Paris printseller. He was born at Caen, in Normandy, on the 29th January 1782, while his mother was on a visit to that town. Destined by his father to the pursuits of trade, he was allowed, nevertheless, to indulge his fondness for music, and learnt to play at an early age on several instruments, his first teacher being the Tyrolean composer, Ladurner. Sent at the age of twenty to London to complete his business training, he returned after the rupture of the peace of Amiens. He had already attempted musical composition, and at this period produced several *concertos pour basse*; in the manner of the violoncellist, Lamare, in whose name they were published. The praise given to his concerto for the violin, which was played at the Conservatoire by Mazas, encouraged him to undertake the resetting of the old comic opera, *Julie*. Conscious by this time of the need of regular study of his chosen art, he placed himself under the severe training of Cherubini, by which the special qualities of the young composer were admirably developed. In 1813 he made his *début* in an opera in one act, the *Séjour Militaire*, the unfavorable reception of which put an end for some years to his attempts as composer. But the failure in business and death of his father, in 1819, compelled him once more to turn to music, and to make that which had been his pastime the serious employment of his life. He produced another opera, the *Testament et les Billets-doux*, which was no better received than the former. But he persevered, and the next year was rewarded by the complete success of his *Bergère Châtelaine*, an opera in three acts. This was the first in a long series of brilliant successes, terminating only in the eighty-sixth year of his age. In 1822 began his long association with M. Scribe, who shared with him as librettist the success and growing popularity of his compositions. The opera *Leicester*, in which they first worked together (1823), is remarkable also as showing the first evidences of the influence of Rossini on Auber's style. This style was, however, distinctly original, and was easily recognisable. A phrase of Auber, said his friend Théodore Gautier, is not the phrase of any one else. His characteristics are lightness and facility, sparkling vivacity, grace and elegance, clear and piquant melodiousness,—these marking him out as a true son of France, and making him her darling singer. Depth of thought, elevation of sentiment, intensity of passion, inspiration which grasps the sublime and the infinite,—these are not in Auber.

Devoted by preference to the comic opera, as the most fitting field for his talents, he ventured on more than one occasion to pass into the field of grand opera, and in his *La Muette de Portici*, familiary known as *Masaniello*, he achieved his greatest musical triumph. Produced at Paris in 1828, it rapidly became a European favorite, and its overture, songs, and choruses were everywhere heard. The duet, *Amour sacré de la patrie* was welcomed like a new *Marseillaise;* sung by Nourrit at Brussels in 1830, it became the signal for the revolution which broke out there. Among his other works, about fifty in all, the more important are—*Fra Diavolo* (1830), *Lestocq* (1834), *L'Ambassadrice* (1836), *Le Domino Noir* (1837), *Le Lac des Fées* (1839), *Les Diamants de la Couronne* (1841), *Haydée* (1847), *Marco Spada* (1853), and *La Fiancée du roi de Garbe* (1864). Official and other dignitaries testified the public appreciation of Auber's works. In 1829 he was elected member of the Institute, in 1830 he was named director of the court concerts, and in 1842 he succeeded Cherubini as director of the Conservatoire. He was also a member of the Legion of Honor from 1825, and attained the rank of commander in 1847. One of Auber's latest compositions was a march, written for the opening of the International Exhibition in London in 1862. His fascinating manners, his witty sayings, and his ever ready kindness and beneficence won for him a secure place in the respect and love of his fellow-citizens. He remained in his old home during the German siege of Paris, 1870-71, but the miseries of the Communist war which followed sickened his heart, and he at last refused to touch his beloved instrument, or to take food. He died May 13, 1871.

AUBIN, a town of France, in the department of Aveyron and arrondissement of Villefranche, principally remarkable for its extensive mines of coal, sulphur, and alum. It also carries on an active trade in sheep, iron goods, &c.

The name Aubin, or St. Aubin, is one of the most frequent in France, being borne by upwards of fifty villages from the Pyrenees to Jersey.

AUBURN, the capital of Cayuga county, in the state of New York, on the railway between Albany and Buffalo, 174 miles W. of the former. The irregularity of the surface on which the city is built has prevented the complete carrying out of the rectangular arrangement of streets, which is so much in favor in the United States, but the thoroughfares are wide and lined with trees, and the houses for the most part well built. The principal public buildings are in Genesee Street. The most remarkable of the institutions is the state prison, founded in 1816, which is conducted on the "silent system," and usually contains upwards of 1000 prisoners, who are employed each in the work to which he has been trained. Population, 30,000.

AUBURN, the county seat of Androscoggin County, Me. It is a place of some importance as a commercial centre. Pop. 10,000.

AUBUSSON, a town of France, situated in a picturesque valley on the banks of the Creuse, in the department to which that river gives its name. Population 3,000.

AUCH, the ancient *Climberrum* or *Augusta Auscorum*, one of the most ancient cities of France, capital of the department of Gers. In Cæsar's time this was the chief town of the Ausci. In the 8th century it became the capital of Gascony; and when that district was divided into countships, was the capital of Armagnac.

AUCHTERARDER, a town and parish of Scotland, county of Perth, 15 miles W.S.W. of Perth.

AUCHTERMUCHTY, a royal burgh and parish of Scotland, county of Fife, 8 miles W.S.W. of Cupar.

The town is irregularly built on an elevated site, and is divided by the Leverspool, a rapid streamlet which runs down its center. The manufacture of linen is carried on. The population of the burgh in 1891 was 1,600.

AUCKLAND, the northern provincial district of New Zealand, includes fully a half of North Island, and is about 400 miles long by 200 wide at its greatest breadth. The bays of its coast-line afford safe harborage, and its rivers serve as highways for the produce of the interior, There are three almost natural divisions of this district: North Peninsula, East Coast and the Waikato Country—the latter two, which had been mainly in the hands of the natives, have lately been opened up for European settlements. The land is chiefly of two kinds—a light volcanic loam, and a stiff yellow clay. For the most part it is broken, with low ranges of hills and broad shallow valleys covered to a great extent with dense forests. It is less suited for grazing than for agricultural purposes. Gold, copper, tin, iron, coal, and other minerals exist in Auckland, which is also very rich in timber, the most important tree being the Kauri pine. The fossil gum of ancient forests of this pine is dug up in large quantities, and exported. Much New Zealand flax is grown and manufactured. About 200 miles of railway give connection with the agricultural districts. The annual value of the exports, including wool, Kauri gum, timber, flax, and gold, average $5,000,000; the imports are double that amount. The value of the gold exported from 1857 to 1890 was over $33,000,000. The climate is pleasant and healthy, and owing to sea-breezes, the summer heat is not so great as in other parts of Australasia in the same latitude. Ferns grow in perfection, upwards of 130 species being found. Volcanic action has deeply left its mark on the surface of Auckland; there is still an active volcano near the city of Auckland; and the warm lake and geyser scenery of the region, about ninety miles Southeast from Auckland, below the Bay of Plenty, is considered by travelers the most remarkable in the world. The "Hot Lake" district covers an area about 120 miles long, by ten to fifteen miles wide, and includes hot springs, cisterns of hot water, and mud volcanoes. A sanatorium for bathing purposes exists near Lake Taupo and at Ohinenutu on Rotoma. The other lakes are Tarawera, Rotoiti and Rotomahana. The wonderful pink and white terraces near Tarawera Lake were destroyed by a volcanic eruption in 1886. The white terrace, which had the appearance of a crystal staircase, glittering and stainless, as of ice, was produced by deposits of silica from the boiling springs; the pink terrace, its companion, was flushed with a pale rose color, believed to have been caused by the presence of oxide of iron. Auckland was the scene of the labors of Bishops Selwyn and Patteson. The population in 1875 was 79,104; 1881, 99,451; 1889, 150,000.

For a descriptive account of a large part of the province, the reader is referred to Dr. Hochstetter's valuable works, especially to his *New Zealand*, 1863. A very graphic sketch of some of the natural curiosities is furnished by Anthony Trollope in his *Australia and New Zealand*, vol. ii.

AUCKLAND, the capital of the above province, is finely situated on an isthmus in the N.W. peninsula, on the S. shore of the Waitemata harbor, which is formed by an inlet of the Hauraki Gulf. Lat. 36° 51′ S., long. 174° 50′. On the other side of the isthmus lies the harbor and town of Manukau, which serves as a supplementary port to the city. Auckland was founded in 1840 by Governor Hobson, and became a burgh in 1851. It was till 1865 the seat of government, which is now situated at Wellington. The city has a fine appearance, especially from the harbor, and is surrounded by a number of flourishing suburban villages, with several of which it is connected by railway. Pop. 59,000.

AUCKLAND ISLANDS, a group discovered in 1806 by Captain Briscoe, of the English whaler "Ocean," about 180 miles S. of New Zealand. The islands, of volcanic origin, are very fertile, and are covered with forest.

AUCKLAND, WILLIAM EDEN, BARON, an eminent diplomatist and politician, third son of Sir Robert Eden, Bart., of West Auckland, was born in 1744. He was educated at Eton and Oxford, and adopted the profession of the law. At the age of twenty-seven he resigned his practice at the bar, and engaged in political life as under-secretary to Lord Suffolk. By the favor of the duke of Marlborough, he obtained a seat for Woodstock, and soon gave proof of his ability in the House. He attached himself to Lord North's party, and after serving under Lord Carlisle on the unsuccessful commission to the colonists in America, acted as secretary to that nobleman, when he held the post of viceroy in Ireland. During this time he had obtained the offices of director and auditor of Greenwich Hospital, which probably yielded him an income sufficient for carrying on his political career. In 1783 he took a leading part in negotiating the remarkable coalition between North and Fox, and was rewarded by being made vice-treasurer of Ireland. In 1784 he opposed Pitt's proposal for commercial reciprocity with Ireland, but in so doing contrived to separate himself to some extent from his own party, and shortly after accepted from Pitt the office of plenipotentiary at Paris. Here he successfully negotiated the important commercial treaty with France; and after his appointment as embassador to Spain, he rendered valuable service in settling the dispute between the British and French Governments with regard to the affairs of Holland. In 1789 he was made an Irish peer, with the title of Baron Auckland, and in 1793 he was raised to the British peerage as Baron Auckland, of West Auckland, Durham.

AUCKLAND, GEORGE EDEN, EARL OF, Governor-General of India, born 20th August 1784, was the second son of the foregoing. He died January 1, 1849.

AUCTION, a mode of selling property by offering it to the highest bidder in a public competition. It is the duty of an auctioneer to sell for the best price he can obtain, and his authority cannot be delegated to another unless by special permission of his employer. The auctioneer's name must be exhibited on some conspicuous place during the sale. Sales by auction usually take place under certain conditions, which it is the duty of the auctioneer to read to the bidders before the sale begins. To complete a sale by auction there must be a *bidding* by, or on behalf of, a person capable of making a contract, and an *acceptance* thereof by the auctioneer, and until the bidding is accepted both vendor and bidder are free, and may retract if they choose.

AUDÆUS, or AUDIUS, a reformer of the 4th century, by birth a Mesopotamian. He suffered much persecution from the Syrian clergy for his fearless censure of their irregular lives, and was expelled from the church. He was afterwards banished into Scythia, where he gained many followers and established the monastic system. He died there at an advanced age, about 370 A.D.

AUDE, a southern department of France, forming part of the old province of Languedoc, bounded on the E. by the Mediterranean, N. by the departments of Hérault and Tarn, N.W. by Upper Garonne, W. by

Ariége and south by that of the Eastern Pyrenees. Area, 2,341 square miles. Population, 352,160.

AUDEBERT, JEAN BAPTISTE, a distinguished French naturalist and artiste, was born at Rochefort in 1759 and died 1800.

AUDITOR, a person appointed to examine the accounts kept by the financial officers of the government, public corporations, or private persons, and to certify as to their accuracy.

AUDOUIN, JEAN VICTOR, a distinguished French entomologist, was born at Paris, April 27, 1797. He began the study of law, but was diverted from it by his strong predilection for natural history. He became eminent as an anatomist and died 1841.

AUDRAN, the name of a family of French artists and engravers, who for several generations were distinguished in the same line. The first who devoted himself to the art of engraving was Claude Audran, born 1592, and the last was Benoit, Claud's great-grandson, who died in 1712. The two most distinguished members of the family were Gerard, or Girard Audran, born 1640, and Jean Audran, born 1657, and died in 1767.

AUDUBON, JOHN JAMES, a well-known naturalist, was born in 1781, in Louisiana, where his parents, who were French Protestants, had taken up their residence while it was still a Spanish colony. They afterwards settled in Pennsylvania. From his early years he had a passion for observing the habits and appearances of birds, and attempting delineations of them from nature. At the age of fifteen he was sent to Paris, and remained there about two years, when, among other studies, he took some lessons in the drawing-school of David. On returning to America his father established him in a plantation in Pennsylvania, and he soon after married. But nothing could damp his ardor for natural history. For fifteen years he annually explored the depths of the primeval forests of America in long and hazardous expeditions, far from his family and his home. In these excursions he acquired the facility of making those spirited drawings of birds that give such value to his magnificent work, *The Birds of America*. At that period he had not dreamed of any publication of his labors; as he informs us, "it was not the desire of fame that prompted to those long exiles; it was simply the enjoyment of nature." He afterwards removed with his family to the village of Henderson on the banks of the Ohio, where he continued his researches in natural history for several years, and at length set out for Philadelphia with a portfolio containing 200 sheets filled with colored delineations of about 1,000 birds. Business obliged him to quit Philadelphia unexpectedly for some weeks, and he deposited his portfolio in the warehouse of a friend; but to his intense dismay and mortification, he found, on his return, that these precious fruits of his wanderings and his labors had been totally destroyed by rats. The shock threw him into a fever of several weeks' duration, that well-nigh proved fatal. But his native energy returned with returning health; and he resumed his gun and his game-bag, his pencils and his drawing-book, and plunged again into the recesses of the backwoods. In about three years he had again filled his portfolio, and then rejoined his family, who had in the meantime gone to Louisiana. After a short sojourn there he set out for the Old World, to exhibit to the ornithologists of Europe the riches of America in that department of natural history.

In 1826 Audubon arrived at Liverpool, where the merits of his spirited delineations of American birds were immediately recognized. An exhibition of them to the public in the galleries of the Royal Institution of that town was so successful that it was repeated at Manchester and at Edinburgh, where they were no less admired. When he proposed to publish a work on the birds of America, several naturalists advised him to issue the work in large quarto, as the most useful size for the lovers of natural history, and the most likely to afford him a sufficient number of subscribers to remunerate his labors. At first he yielded to this advice, and acknowledged its soundness; but finally he decided that his work should eclipse every other ornithological publication. Every bird was to be delineated of the size of life, and to each species a whole page was to be devoted; consequently the largest *elephant folio* paper was to receive the impressions. This necessarily increased the expense of the work so much as to put it beyond the reach of most scientific naturalists—which accounts for the small number of persons who for a considerable time, could be reckoned among his supporters in the gigantic undertaking. The exceptionally high character of the work, however, gradually became known; and a sufficient number of subscribers was at length obtained in Great Britain and America, during the ten or twelve years that the work was going through the press, to indemnify him for the great cost of the publication—leaving him, however, a very inadequate compensation for his extraordinary industry and skill. The first volume was published at New York in the end of the year 1830, the second in 1834, the third in 1837, and the fourth and last in 1839. The whole consists of 445 colored plates containing 1,055 figures of birds the size of life. It is certainly the most magnificent work of the kind ever given to the world, and is well characterized by Cuvier, "C'est le plus magnifique monument que l'Art ait encore élevé à la Nature."

During the preparation and publication of his great work Audubon made several excursions from Great Britain. In the summer of 1828 he visited Paris, where he made the acquaintance of Cuvier, Humboldt, and other celebrated naturalists, and received from them every mark of honor and esteem. The following winter he passed in London. In April of 1830 he revisited the United States of America, and again explored the forests of the central and southern federal territories. In the following year he returned to London and Edinburgh, but the August of 1831 found him again in New York. The succeeding winter and spring he spent in Florida and South Carolina; and in the summer of 1832 he set out for the Northern States, with an intention of studying the annual migrations of birds, particularly of the passenger pigeon, of which he has given a striking description; but his career was arrested at Boston by a severe attack of cholera, which detained him there till the middle of August. After that he explored the coasts, lakes, rivers and mountains of North America, from Labrador and Canada to Florida, during a series of laborious journeys, that occupied him for three years. From Charleston, accompanied by his wife and family, he took his third departure for Britain. During his earlier residence in Edinburgh he had begun to publish his *American Ornithological Biography*, which at length filled five large octavo volumes. The first was issued by Adam Black in 1831; the last appeared in 1839. This book is admirable for the vivid pictures it presents of the habits of the birds, and the adventures of the naturalist. The descriptions are characteristically accurate and interesting. In 1839 Audubon returned to America, and shortly afterward commenced the publication of his two last works, *The Quadrupeds of America* and a *Biography of American Quadrupeds*. The latter was issued in 1850. On January 27, 1851, Audubon died at New York.

AUGEIAS (Αὐγείας, Αὐγεας, *cf.* ἡλίου αὐγή), in *Greek Legend*, a son of Helios, the sun. He was a prince of Elis, and, consistently with his being a descendant of the sun-god, had an immense wealth of herds, including twelve bulls sacred to Helios, and white as swans. He lived beside the stream Menios (Μήν = moon); and his daughter Agamede was, like Medeia and Circe, skilled in witchcraft, and connected with the moon goddess. The task of Hercules was to clear out all his stalls in one day, and without help. This he did by making an opening in the wall and turning the stream through them. Augeias had promised him a tenth of the herd, but refused this, alleging that Hercules had acted only in the service of Eurystheus.

AUGEREAU, Pierre François Charles, Duke of Castiglione, was the son of obscure parents, and born in 1757. After serving for a short period in the armies of France, he entered the Neapolitan service, and for some time supported himself by teaching fencing at Naples. In 1792 he joined the Republican army that watched the movements of Spain. He rose rapidly to the rank of brigadier-general, and commanded a division in the army of Italy. Here he distinguished himself in numerous engagements by his energy, skill, and vigorous rapidity of action. To him were due in great measure the brilliant victories of Millesimo, Dego, and Castiglione, and he led the decisive charges at the bloody combats of Lodi and Arcola. In 1797 he took part with Barras and the Directory, and was an active agent in the revolution of the 18th of Fructidor; but his jealousy of his former comrade, Bonaparte, prevented their intimacy; and he was one of the general officers not privy to the noted revolution of the 18th of Brumaire (Nov. 9) 1799. He received, however, the command of the army of Holland and the Lower Rhine, but was superseded in 1801. From that time he lived in retirement, till 1804, when he was made a marshal of the French empire, and in the following year he was appointed to the command of the expedition against the Vorarlberg, which he quickly subdued. He also distinguished himself greatly in the battles of Jena and Eylau. In 1809–10 he commanded the French in Catalonia, and tarnished his laurels by his great cruelty to the Spaniards, but he was again more honorably conspicuous in the campaign of 1813, especially in the terrible battle of Leipsic. In 1814 he had the command of a reserve army at Lyons, and might have made a diversion in favor of Napoleon, but he preferred to submit, and retained a command under the Bourbons. In the following year he at first refused to join Napoleon on his escape from Elba, and when he would afterwards have accepted a command his services were declined. He also failed to obtain military office under the new dynasty, and, after having had the painful task of being one of the commission on the trial of Ney, he returned to his estates, where he died of dropsy in 1816.

AUGSBURG, a celebrated city of Germany, capital of the circle of Swabia and Neuburg in Bavaria, the principal seat of the commerce of South Germany, and of commercial transactions with the south of Europe. It derives its name from the Roman Emperor Augustus, who, on the conquest of Rhætia by Drusus, established a Roman colony named *Augusta Vindelicorum* (about 14 B.C.). In the 5th century it was sacked by the Huns, and afterwards came under the power of the Frankish kings. It was almost entirely destroyed in the war of Charlemagne against Thassilon, duke of Bavaria, and after the dissolution and division of that empire, it fell into the hands of the dukes of Swabia. After this it rose rapidly into importance as a manufacturing and commercial town, and its merchant princes, the Fuggers and Welsers, rivalled the Medici of Florence; but the alterations produced in the currents of trade by the discoveries of the 15th and 16th centuries occasioned a great decline. In 1276 it was raised to the rank of a free imperial city, which it retained with many changes in its internal constitution, till 1806, when it was annexed to the kingdom of Bavaria. Meanwhile, it was the scene of numerous events of historical importance. It was besieged and taken by Gustavus Adolphus in 1632, and in 1635 it surrendered to the imperial forces; in 1703 it was bombarded by the electoral prince of Bavaria, and forced to pay a contribution of 400,000 dollars; and in the war of 1803 it suffered severely. Its most memorable conventions are those which gave birth to the Augsburg confession (1530) and to the Augsburg alliance (1686).

The city is pleasantly situated in an extensive and fertile plain, between the rivers Wertach and Lech, 36 miles W.N.W. of Munich, lat. 48° 21′ 44″ N., long. 10° 54′ 42″ E. Its fortifications were dismantled in 1703, and have since been converted into public promenades. Maximilian street is remarkable for its breadth and architectural magnificence. One of its most interesting edifices is the Fugger House, of which the entire front is painted in fresco. Among the public buildings of Augsburg most worthy of notice is the town-hall, said to be one of the finest in Germany, built by Elias Holl in 1616–20. One of its rooms, called the "Golden Hall," from the profusion of its gilding, is 113 feet long, 59 broad, and 53 high. The palace of the bishops, where the memorable Confession of Faith was presented to Charles V., is now used for Government offices. The cathedral dates in its oldest portions from the 10th century. There are also various churches and chapels, a school of arts, a polytechnic institution, a picture gallery in the former monastery of St. Catherine, a museum, observatory, botanical gardens, an exchange, gymnasium, deaf-mute institution, orphan asylum, public library, several remarkable fountains dating from the 16th century, etc. The "Fuggerei," built in 1519 by the brothers Fugger, consists of 106 small houses, let to indigent Roman Catholic citizens at a merely nominal rent. The manufactures of Augsburg are various and important, consisting of woolen, linen, cotton, and silk goods, watches, jewelry, and goldsmith work, mathematical instruments, machinery, leather, paper, chemical stuffs, types, etc. One of the best-known Continental newspapers is the *Allgemeine Zeitung* or *Augsburg Gazette*. Augsburg is an important railway junction. On the opposite side of the river, which is here crossed by a bridge, lies the little village of Lechhausen. Population in 1890, 68,500.

AUGSBURG CONFESSION. This document, compiled by Melanchthon in 1530, forms the doctrinal definition of the Lutheran faith. It consists of twenty-one articles, in which the belief of the signers is set forth in terse and dignified language. A supplementary Confession known as the *Apologia Confessionis Augustanæ* was also prepared by Melanchthon, and was published a year or two later. In 1536 Luther promulgated the "Articles of Smalkald," and forty years later still another "Confession" appeared. The documents are not all considered of equal authority, but taken as a whole they represent the confessional theology of Lutheranism. The two catechisms prepared by Luther are also accepted as standards of faith, and the collective documents are issued as a Concordia or *Liber Concordiæ*.

AUGURS, in *Roman Antiquities*, a college or board appointed to interpret, according to the books (*libri augurales*) in which the science of divination was laid

down, the *auspicia* or signs of approval or disapproval sent by Jupiter on the occasion of any public transaction. At first, it is said, there were only two augurs, one from each of the tribes Ramnes and Tities. Two more were added by Numa, and again other two for the third tribe of Luceres, that is six altogether. But in the year 300 B.C. it is certain that there were only four, to which number five plebeia places were added by the *lex Ogulnia*. Sulla increased the number to fifteen, at which it continued, with the exception that Cæsar appointed a sixteenth, and the emperors frequently added as *supra numerum* persons of distinction, or of their own family. An augur retained his office and sacred character for life. The college had the right of election of new members. The insignia of their office were the *lituus*, or crook, and the dress called *trabea*. The natural region to look to for signs of the will of Jupiter was the sky, where lightning and the flight of birds seemed directed by him as counsel to men. The latter, however, was the more difficult of interpretation, and upon it, therefore, mainly hinged the system of divination with which the augurs were occupied, and which is expressed in the terms *augurium* and *auspicium*. The presence of augurs was required only in observing signs in the sky, where their first duty was to mark out with the *lituus* a space or *templum* in the sky within which the omen must occur. Such observations being properly made only in the city of Rome, augurs are not found elsewhere. Signs of the will of the gods were of two kinds, either in answer to a request (*auspicia impetrativa*), or incidental. Of such signs there were five classes:—(1.) *Signs in the sky* (*cœlestia auspicia*), consisting chiefly of thunder and lighting, but not excluding fallen stars and other phenomena. Lightning from left to right was favorable, from right to left unfavorable; and this being a very direct and impressive token of the will of Jupiter, the observation of it was held to apply to all public transactions fixed for the day on which it occurred. Whether favorable or the reverse in its direction, the appearance of lightning was held as a voice of the god against business being done in the public assemblies. But since the person charged to take the auspices for a certain day was constitutionally subject to no other authority who could test the truth or falsehood of his statement that he had observed lightning, it happened that this became a favorite means of putting off meetings of the public assembly. Restrictions were, however, imposed on it in the latter times of the republic. When a new consul, prætor, or quæstor entered on his first day of office and prayed the gods for good omens, it was a matter of custom to report to him that lightning from the left had been seen. (2.) *Signs from birds*, with reference to the direction of their flight, and also to their singing or uttering other sounds. In matters of ordinary life on which divine counsel was prayed for, it was usual to have recourse to this form of divination. For public affairs it was, by the time of Cicero, superseded by the fictitious observation of lightning. (3.) *Feeding of birds*, which consisted in observing whether a bird,—usually a fowl,—on grain being thrown before it, let fall a particle from its mouth. If it did so, the will of the gods was in favor of the enterprise in question. The simplicity of this ceremony recommended it for very general use, particularly in the army when on service. The fowls were kept in cages by a servant, styled *pullarius*. In imperial times are mentioned the *decuriales pullarii*. (4.) *Signs from animals*, *i.e.*, observation of the course of, or sounds uttered by, quadrupeds and serpents within a fixed space, corresponding to the observations of the flight of birds, but much less frequently employed. It had gone out of use by the time of Cicero. (5.) *Warnings*, consisting of all unusual phenomena, but chiefly such as boded ill. Being accidental in their occurrence, they belonged to the *auguria oblativa*, and their interpretation was not a matter for the augurs, unless occurring in the course of some public transaction, in which case they formed a divine veto against it. Otherwise, references were made for an interpretation to the Pontifices in olden times, afterwards frequently to the Sibylline books, or the Etruscan haruspices, when the incident was not already provided for by a rule, as, for example, that it was unlucky for a person leaving his house to meet a raven, that the sudden death of a person from epilepsy at a public meeting was a sign to break up the assembly, not to mention other instances of adverse omens. A Roman, however, did not necessarily regard a warning as binding unless it was clearly apprehended. Not only could an accidental oversight render it useless, but to some extent measures could be taken to prevent any warning being noticed.

AUGUST, originally *Sextilis*, as being the sixth month in the pre-Julian Roman year, received its present name from the Emperor Augustus. The preceding month, *Quintilis*, had been called July after the great Julius Cæsar, and the senate thought to propitiate the emperor by conferring a similar honor upon him. August was selected, not as being the natal month of Augustus, but because in it his greatest good fortune had happened to him.

AUGUSTA, the capital of the State of Maine, and seat of justice, is situated on the Kennebec River (in Kennebec county), 43 miles from its mouth, in lat. 44° 19′ N., long. 69° 50′ W. The city lies mainly on the right bank of the Kennebec River, which is here crossed by a bridge 520 feet long. The business portion of the city was destroyed by fire in 1865, but has since been rebuilt. Its principal public buildings are the State house, State insane asylum, and United States' arsenal. It has several banks, daily and weekly newspapers, and numerous churches. The population of Augusta, in the census of 1890, was 10,521

AUGUSTA, a city of Georgia, in the United States of America, the capital of the county of Richmond. It is situated in a beautiful plain, on the Savannah River, 231 miles from its mouth, and has extensive railway communication. Like other American cities it is spacious and regular in its plan, Greene Street, for example, being 168 feet in width, with a row of trees extending along each side. The principal buildings are the city hall, a Masonic hall, an Oddfellows' hall, the Richmond academy, the Georgia medical college, the opera-house, and an orphan asylum. Besides these, the city possesses an arsenal, water-works, a number of banks, newspaper offices, extensive cotton factories and flour mills, several foundries, two tobacco factories, &c. Water-power is abundantly supplied from the river by the Augusta canal, which was constructed in 1845. Augusta was an important place during the revolutionary war, and continued to flourish amazingly till the opening of the Georgia railway. A temporary decline then took place, owing to the change in the methods of traffic; but a new current of prosperity speedily set in, which still continues. Population in 1890, 33,150.

AUGUSTAN HISTORY is the title bestowed upon a collection of the biographies of the Roman emperors, from Hadrian to Carinus, written under Diocletian and Constantine, and usually regarded as the composition of six authors,—Ælius, Spartianus, Julius Capitolinus, Ælius Lamprididius, Vulcatius Gallicanus, Trebellius Pollio, and Flavius Vopiscus. Upon investigation, however, there appears good reason for reducing those writers to four. The distribution of the respective

biographies among them, according to the arrangement of the MSS., is supported by no extraneous authority, and depends upon no intelligible principle.

No biographical particulars are recorded respecting any of these writers. From their acquaintance with Latin and Greek literature they must have been men of letters by profession, and very probably secretaries or librarians to persons of distinction. They appear particularly versed in law. Spartianus's reference to himself as "Diocletian's own" seems to indicate that he was a domestic in the imperial household. They address their patrons with deference, acknowledging their own deficiencies, and seem painfully conscious of the profession of literature having fallen upon evil days.

AUGUSTI, JOHN CHRISTIAN WILLIAM, a distinguished German theologian, was born at Eschenberga, near Gotha, 1772, and died in 1841.

AUGUSTINE (AURELIUS AUGUSTINUS), one of the four great fathers of the Latin Church, and admittedly the greatest of the four, more profound than Ambrose, his spiritual father, more original and systematic than Jerome, his contemporary and correspondent, and intellectually far more distinguished than Gregory the Great, the last of the series. The theological position and influence of Augustine may be said to be unrivalled. No single name has ever exercised such power over the Christian church, and no one mind ever made such an impression upon Christian thought.

Aurelius Augustinus was born at Tagaste (Tajelt), a town of Numidia, on the 13th of November 354 A.D. His father, Patricius, was a burgess of this town, and was still a pagan at the time of his son's birth. His mother, Monica, was not only a Christian, but a woman of the most elevated, tender, and devoted piety, whose patient prayerfulness for both her husband and son (at length crowned with success in both cases), and whose affectionate and beautiful enthusiasm have passed into a touching type of womanly saintliness for all ages. She early instructed her son in the faith and love of Jesus Christ, and for a time her instruction seems to have impressed his youthful mind. Falling ill he wished to be baptised; but when the danger was passed, the rite was deferred, and, notwithstanding all his mother's admonitions and prayers, he grew up without any profession of Christian piety, or any devotion to Christian principles. Inheriting from his father a vehement and sensual disposition, he early gave way to the unbridled impulses of passion, and, while still a mere youth, formed a connection, common enough at the time, but at variance with the principles of Christian morality. As the result of the connection he became the father of a son, whom he named Adeodatus in a fit of pious emotion, and to whom he was passionately attached.

In the midst of all his youthful pleasures Augustine was an earnest student. His father, observing the early development of his talents, formed the ambition of training him to the brilliant and lucrative career of a rhetorician, and he seems to have spared no expense to equip him for the career. The youth studied not only at his native town, but at Maduara and Carthage, and especially devoted himself to the Latin poets — many traces of his love for which are to be found in his writings. His acquaintance with Greek literature was much more limited, and, indeed, it has been doubted whether he could use, in the original, either the Hebrew or Greek Scriptures. Apparently, he was in the habit of using translations of Plato; but, on the other hand, Greek words frequently occur in his writings, correctly rendered and discriminated; and he speaks in one of his epistles to Marcellinus of referring to the Greek Psalter and finding, in reference to certain difficulties, that it agreed with the Vulgate.

While a student at Carthage he was particularly attracted by the theatre, the spectacles at which were of unusual magnificence. To his enthusiastic and sensuous spirit they were irresistible, and the extent to which he seems to have yielded to the fascination is sufficient proof of his active alienation from Christianity at this period.

Cicero's *Hortensius*, which he read in his nineteenth year, first awakened in Augustine's mind the spirit of speculation. He engaged restlessly in philosophical studies, and passed from one phase of thought to another, unable to find satisfaction in any. Manichæism first enthralled him. Its doctrine of two principles, one of good and one of evil, seemed to answer to the wild confusion of his own heart, and the conflict of higher and lower impulses which raged within him. It seemed to solve the mysteries which perplexed him in his own experience and in the world. He became a member of the sect, and entered into the class of *auditors*. His ambition was to be received among the number of the *Elect*, and so get to the heart of what he believed to be their higher knowledge. But falling in with Faustus, a distinguished Manichæan bishop and disputant, and entering into discussion with him, he was greatly disappointed. The system lost its attraction for him; he gradually became disgusted, and abandoned it. But before this he had left Carthage, shocked with the licence of the students, and had betaken himself for a time to Rome in the pursuit of his profession. There he also became dissatisfied, and accepted an invitation to proceed to Milan, where the people were in search of a teacher of rhetoric. He travelled thither at the public expense, and was welcomed by friends who already seem to have recognised his distinction.

At Milan the conflict of his mind in search of truth still continued. He was now in his thirtieth year, and for eleven years he had been seeking for mental rest, unable to find it. "To-morrow," he said to himself, "I shall find it: it will appear manifestly, and I shall grasp it" (*Confess.*, vi. 18). But it still eluded his grasp, and he sunk back again into despondency. The way, however, was being prepared for his conversion. Ambrose was bishop of Milan, and, although he had a weak voice, was noted for his eloquence. Augustine was attracted by his reputation, and went to hear the famous Christian preacher in order, as he himself relates "to see whether his eloquence answered what was reported of it. I hung on his words attentively," he adds, "but of the matter I was but an unconcerned and contemptuous hearer." He confesses his delight so far: "The bishop's eloquence was more full of knowledge, yet in manner less pleasurable and soothing, than that of Faustus." He wished an opportunity of conversation with him, but this was not easily found. Ambrose had no leisure for philosophic discussion. He was accessible to all who sought him, but never for a moment free from study or the cares of duty. "Augustine used to enter, as all persons might, without being announced; but after staying for a while, afraid of interrupting him, he departed again." He continued, however, to hear Ambrose preach, and gradually the gospel of divine truth and grace was received into his heart. First Plato and then St. Paul opened his mind to higher thoughts, and at length certain words of the latter were driven home with irresistible force to his conscience. He was busy with his friend Alypius in studying the Pauline epistles. His struggle of mind became intolerable; the thought of divine purity fighting in his heart with the love of the world and of the flesh. He burst into an incontrollable flood of tears and rushed out into his garden, flinging himself under a fig tree that he might allow his tears to have full vent, and pour out his heart to

God. Suddenly he seemed to hear a voice calling upon him to consult the divine oracle, "Take up and read, take up and read." He left off weeping, rose up, and sought the volume where Alypius was sitting, and opening it read in silence the following passage: "Not in rioting and drunkenness, not in chambering and wantonness, not in strife and envying. But put ye on the Lord Jesus Christ, and make not provision for the flesh to fulfil the lusts thereof." He adds, "I had neither desire nor need to read further. As I finished the sentence, as though the light of peace had been poured into my heart, all the shadows of doubt dispersed. Thus hast Thou converted me to Thee, so as no longer to seek either for wife or other hope of the world, standing fast in that rule of faith in which Thou so many years before hadst revealed me to my mother."

Augustine went back to Rome for a short period and then returned to his native city, where he took up his abode in retirement, forming, with some friends who joined him in devotion, a small religious community, which looked to him as its head. They had all things in common, as in the early church, and fasting and prayer, Scripture reading and almsgiving, formed their regular occupations. Their mode of life was not formally monastic according to any special rule, but the experience of this time of seclusion was, no doubt, the basis of that monastic system which Augustine afterwards sketched, and which derived from him its name.

Henceforth Augustine's life is filled up with his ecclesiastical labors, and is more marked by the series of his numerous writings and the great controversies in which they engaged him than by anything else. Already he had distinguished himself as an author. He had written several philosophical treatises; he had combated the scepticism of the Academy; he had treated of the "Blessed Life" and of the "Immortality of the Soul;" he had defended the church against the Manichæans, whose doctrines he had formerly professed.

But the time was one of almost universal ecclesiastical and intellectual excitement; and so powerful a mental activity as his was naturally drawn forth in all directions. Following his writings against the Manichæans come those against the Donatists. This controversy was one which strongly interested him, involving as it did the whole question of the constitution of the church and the idea of catholic order, to which the circumstances of the age gave special prominence. The Donatist schism sprang out of the Diocletian persecutions in the beginning of the century. A party in the Church of Carthage, fired with fanatical zeal on behalf of those who had distinguished themselves by resistance to the imperial mandates and courted martyrdom, resented deeply the appointment of a bishop of moderate opinions, whose consecration had been performed, they alleged, by a *traditor*. They set up, in consequence, a bishop of their own, of the name of Majorinus, succeeded in 315 by Donatus. The party made great pretensions to purity of discipline, and rapidly rose in popular favor, notwithstanding a decision given against them both by the bishop of Rome and by the Emperor Contantine, to whom they personally appealed. Augustine was strongly moved by the lawlessness of the party, and launched forth a series of writings against them, the most important of which survive, though some are lost.

The third controversy in which Augustine engaged was the most important, and the most intimately associated with his distinctive greatness as a theologian. As may be supposed, from the conflicts through which he had passed, the bishop of Hippo was intensely interested in what may be called the anthropological aspects of the great Christian idea of redemption. He had himself been brought out of darkness into "marvellous light," only by entering into the depths of his own soul, and finding, after many struggles, that there was no power but divine grace, as revealed in the life and death of the Son of God, which could bring rest to human weariness, or pardon and peace for human guilt. He had found human nature in his own case too weak and sinful to find any good for itself. In God alone he had found good. This deep sense of human sinfulness colored all his theology, and gave to it at once its depth — its profound and sympathetic adaptation to all who feel the reality of sin — and that tinge of darkness and exaggeration which as surely have repelled others. When the expression Augustinianism is used, it points especially to those opinions of the great teacher which were evoked in the Pelagian controversy, to which he devoted the most mature and powerful period of his life. His opponents in this controversy were Pelagius, from whom it derives its name, and Cœlestius and Julianus, pupils of the former. Pelagius was a British monk. Augustine calls him Brito; and Jerome points to his Scottish descent, in such terms, however, as to leave it uncertain whether he was a native of Scotland or Ireland. He was a man of blameless character, devoted to the reformation of society, full of enthusiasm, and that confidence in the natural impulses of humanity which often accompanies philanthropic enthusiasm. Travelling to Rome about the beginning of the 5th century, he took up his abode for a time there, and soon made himself conspicuous by his activity and opinions. His pupil Cœlestius carried out the views of his master with a more outspoken logic, and was at length arraigned before the bishop of Carthage for the following, amongst other, heretical opinions: — (1.) That Adam's sin was purely personal, and affected none but himself; (2.) That each man, consequently, is born with powers as incorrupt as those of Adam, and only falls into sin under the force of temptation and evil example; (3.) That children who die in infancy, being untainted by sin, are saved without baptism. Views such as these were obviously in conflict with the whole course of Augustine's experience, as well as with his interpretation of the catholic doctrine of the church. And when his attention was drawn to them by the trial and excommunication of Cœlestius, he undertook their refutation, first of all, in three books on *Forgiveness of Sins and Baptism*, addressed to his friend Marcellinus, in which he vindicated the necessity of the baptism of infants because of original sin and the grace of God by which we are justified. This was in 412. In the same year he addressed a further treatise to the same person, "My beloved son Marcellinus," on *The Spirit and the Letter*. Three years later he composed two further treatises on *Nature and Grace*, and the relation of the *Human to the Divine Righteousness*. The controversy was continued during many years in no fewer than fifteen treatises. Upon no subject did Augustine bestow more of his intellectual strength, and in relation to no other have his views so deeply and permanently affected the course of Christian thought. Even those who most usually agree with his theological stand-point will hardly deny that, while he did much in these writings to vindicate divine truth and to expound the true relations of the divine and human, he also, here as elsewhere, was hurried into extreme expressions as to the absoluteness of divine grace and the extent of human corruption. Like his great disciple in a later age — Luther — Augustine was prone to emphasise the side of truth which he had most realised in his own experience, and, in contradistinction to the Pelagian exaltation of human nature, to depreciate its capabilities beyond measure. There are few thoughtful minds who would not concede the deeper truthfulness of Augustine's

spiritual and theological analysis, in comparison with that of his opponent, as well as its great consistency with Scripture; but there are also few who would now be disposed to identify themselves with the dogmatism of the orthodox bishop any more than with the dogmatism of the heretical monk. And on one particular point, which more or less runs through all the controversy—the salvation of infants—the Christian consciousness, in its later and higher growth, may be said to have pronounced itself decisively on the side of the monk rather than of the bishop.

The character of Augustine, both as a man and a theologian, has been briefly indicated in the course of our sketch. Little remains to be added without entering into discussions too extended for our space. None can deny the greatness of Augustine's soul—his enthusiasm, his unceasing search after truth, his affectionateness, his ardor, his self-devotion. And even those who may doubt the soundness or value of some of his dogmatic conclusions, cannot hesitate to acknowledge the depth of his spiritual convictions, and the strength, solidity, and penetration with which he handled the most difficult questions, and wrought all the elements of his experience and of his profound Scriptural knowledge into a great system of Christian thought.

AUGUSTINE, or AUSTIN, ST., the first archbishop of Canterbury, was originally a monk in the Benedictine convent of St. Andrew at Rome, and was educated under the famous Gregory, afterwards Pope Gregory I., by whom he was sent to Britain with forty monks of the same order, to carry out the favorite project of converting the English to Christianity. Having sent interpreters to explain their mission to King Ethelbert, whose queen, Bertha, was a Christian, they received from him permission to preach and to make converts. He treated them with great favor, held a public conference with them, and assigned them a residence at Durovernum, now Canterbury. His own conversion to the Christian faith, which took place shortly afterwards, had a powerful influence with his subjects, who joined the new church in great numbers. Augustine passed the remainder of his life principally at Canterbury, where he died, probably in 607, on the 26th May.

AUGUSTINIANS, a monastic order of the Roman Catholic Church, claiming to have received its rule from St. Augustine.

AUGUSTOVO, a city in Russian Poland, in the government of Suvalki, situated on the river Netta, near a lake, which abounds in fish. Population, 14,018.

AUGUSTULUS, ROMULUS, the last emperor of the western half of the old Roman Empire. He was defeated in 476 A. D. and was pensioned by his conquerer, Odoacer.

AUGUSTUS AND THE AUGUSTAN AGE. The name of Augustus was the title of honor given by the Romans to the Emperor Caius Julius Cæsar Octavius, or, as he was originally designated, Caius Octavius. The era of Augustus formed an illustrious epoch in Roman history, and was distinguished for its splendid attainments in arts and arms, and more especially in literature. The Romans in later times looked back to the age of Augustus with great complacency, as the most prosperous and the most distinguished in their annals. The name of the "Augustan Age" has been specially applied to it in modern times, and the same title has been given, with more or less justice, to certain epochs in modern history as the highest compliment to their glory. The reign of Louis XIV., is called the Augustan age of France; the reign of Anne, the Augustan age of England.

Caius Octavius was the son of a noble Roman of the same name, of the plebian order. The father had married Atia, the daughter of Julia, sister to the great C. Julius Cæsar, who was accordingly great-uncle to the young Octavius. Cæsar, the dictator, having no son of his own, took an interest in this youth, caused him to be enrolled among the Patricians, and bred him with a view to the highest honors of the republic. Already, in his eighteenth year, he had chosen him for his "master of the horse," but this was a merely nominal distinction. The young man was sent to carry on his education at the camp at Apollonia in Illyricum, and there, at the age of nineteen, he heard of his great kinsman's assassination (44 B.C.). He had already become a favorite with the soldiers, who offered to escort him to Rome, and follow his fortunes. But this he declined, and crossed over alone to Italy. On landing he learned that Cæsar had made him his heir and adopted him into the Julian gens, whereby he acquired the designation of C. Julius Cæsar Octavius. The inheritance was a perilous one; his mother and others would have dissuaded him from accepting it, but he, confident in his abilities, declared at once that he would undertake its obligations, and discharge the sums bequeathed by the dictator to the Roman people. M. Antonius had possessed himself of Cæsar's papers and effects, and made light of his young nephew's pretensions. The liberators paid him little regard, and dispersed to their respective provinces. Cicero, much charmed at the attitude of Antonius, hoped to make use of him, and flattered him to the utmost, with the expectation, however, of getting rid of him as soon as he had served his purpose. Octavianus conducted himself with consummate adroitness, making use of all competitors for power, but assisting none. Considerable forces attached themselves to him. The senate when it armed the consuls against Antonius, called upon him for assistance; and he took part in the campaign in which Antonius was defeated at Mutina, but both the consuls, Hirtius and Pansa, slain. The soldiers of Octavianus demanded the consulship for him, and the senate, though now much alarmed, could not prevent his election. He now effected a junction with Antonius, who quickly overthrew the power of the republican party in their stronghold, the Cisalpine provinces, with the death of Decimus Brutus, the ablest of the liberators. Thereupon Octavianus and Antonius, taking Lepidus into union with them, met on the river Rhenus near Bononia, and proclaimed themselves a triumvirate for the reconstitution of the commonwealth. They divided the western provinces among them, the east being held for the republic by M. Brutus and Cassius. They drew up a list of proscribed citizens, entered Rome together, and caused the assassination of three hundred senators and two thousand knights. They further confiscated the territories of many cities throughout Italy, and divided them among their soldiers. Cicero was murdered at the demand of Antonius. The remnant of the republican party took refuge either with Brutus and Cassius in the East, or with Sextus Pompeius, who had made himself master of the seas.

Octavianus and Antonius crossed the Adriatic 42 B.C. to reduce the last defenders of the republic. Brutus and Cassius were defeated, and fell at the battle of Philippi. War soon broke out between the victors, the chief incident of which was the siege and capture by famine of Perusia, and the alleged sacrifice of three hundred of its defenders by the young Cæsar at the altar of his uncle. But peace was again made between them. Antonius married Octavia, his rival's sister, and took for himself the eastern half of the empire, leaving the west to Cæsar. Lepidus was reduced to the single province of Africa. Meanwhile Sextus Pompeius made himself formidable by cutting off the supplies of

grain from Rome. The triumvirs were obliged to concede to him the islands in the western Mediterranean. But Octavianus could not allow the capital to be kept in alarm for its daily sustenance. He picked a quarrel with Sextus, and when his colleagues failed to support him, undertook to attack him alone. Antonius, indeed, came at last to his aid, in return for military assistance in the campaign he meditated in the East. But Octavianus was well served by the commander of his fleet, M. Vipsanius Agrippa. Sextus was completely routed, and driven into Asia, where he perished soon afterwards. Lepidus was an object of contempt to all parties, and Octavianus and Antonius remained to fight for supreme power.

The alliance of Antonius with Cleopatra, queen of Egypt, alienated the Romans from him. They now gladly accepted the heir of Cæsar as the true successor of the most illustrious of their heroes. It was felt almost universally that the empire required a single head, and that repose could only be assured by the sovereignty of the chief of its armies. The battle of Actium, followed by the death of Antonius, 31 B.C., raised the victor to universal empire. Nevertheless, Octavianus did not hasten to assume his position. He first regulated the affairs of Egypt, which he annexed to the Roman dominions, then lingered for a time in Greece, and entered upon a fifth consulship at Samos, 29 B.C. On his return to Rome he distributed the vast sums he had accumulated among the people and the soldiers, while he soothed the pride of the nobles by maintaining unchanged the outward show of republican government. Of his personal history from this period there remains little to be said. He continued to reside almost constantly at Rome and in the neighborhood, making one expedition into Spain, 27 B.C., and a journey through Greece in 21, on which occasion he advanced into Syria, and received back the standards taken by the Parthians from Crassus. In 16 B.C. he went to Gaul to regulate the affairs of that province, an expedition which he repeated 9 B.C. But from thenceforth he intrusted the defence of the position to his lieutenants, and more especially to the young princes of his own family. The empire continued to enjoy profound internal tranquillity. More than one plot was formed against the head of the state by some of the discontented nobility, but these were discovered and disconcerted; and when it was evident that they met with no favor from the people generally, he could afford to treat them with a signal clemency, which seems to have secured him from any further attempts. The serenity and placability which he displayed in his latter years form a marked contrast to the jealousy and ferocity at an earlier period; and the character of the Emperor Augustus Cæsar has been a problem to historians in consequence. The life of the emperor was prolonged to the year 14 A.D. He died at Nola in his seventy-fifth year, after holding supreme power in the state for nearly half a century.

During the years which had intervened between his accepting the inheritance of Cæsar, and his attaining to Cæsar's undivided sovereignty, the young aspirant had been meditating how to secure the retention of his power. At first, excited by fears for his own personal safety, and urged by the examples of party leaders around him, and of others who had gone before him, he plunged into a career of wholesale bloodshed, and cut off without scruple every public man from whose principles or whose passions he might have cause of apprehension. A large proportion, perhaps, of the senators and nobles had perished in the proscriptions and bloody wars of the triumvirate. Still it could not be expected that the germs of republican sentiment would ever be wholly eradicated. The sense of patriotism and the sense of interest would not fail to raise up enemies to the sovereign ruler of the Roman commonwealth. The conquerer's first object was to protect himself by force of arms, his next to soothe the passions of the class from whose resentment he had most cause of fear, and after that to raise up another class in direct sympathy with himself to balance the power which the first must necessarily attain in a well-ordered government. It was to the attainment of these three objects that Octavius directed his organisation of the commonwealth.

The powers of the imperator or commander of the Roman army ceased on his return to the city. He then became once more a plain citizen. If war again arose he must seek his reappointment to command with the usual forms. Cæsar had not trusted his countrymen so far. He had claimed from them the title of imperator in perpetuity. With this title prefixed to his name, he continued to be still the commander of the legions, whether in the city or in the provinces. With this power his successor dared not dispense. On his arrival at Rome from the East he at once required the senate to accord it to him, as to his uncle before him; but he pretended only to ask it for a limited period of five years. At the expiration of that term, however, he assumed it again and again, though each time for ten years only, but never actually relinquished it to the end of his career. He thus received authority to command the whole force of the state in chief, and the officers who acted under him became simply his lieutenants. If they gained victories, the honors of the triumph were reserved for the imperator "under whose auspices" they were reputed to have served. It followed that all the provinces on the frontiers, or in which armies were maintained, were placed under the emperor's direct authority, while it was only the central and peaceful portions of the empire that were handed over to the government of the senate. The imperial provinces were administered by the legati Cæsaris, the senatorial by proconsuls.

The person of the emperor was thus secured as far as the power of the sword could secure it. But he was anxious that the source of his power should not be too apparent. The second Cæsar wished to maintain the appearance at least of government by the constitutional powers of the republic. The senate had once been practically the ruling power, as far as it was not actually controlled by the masters of the legions. He would not degrade it in its own estimation, or in the estimation of the people, any further, at least, than might be necessary for his main object. He caused himself to be appointed censor, not for one but for five years, in order to give him full time to revise the list of senators, to supply the fearful gaps in the ranks of the old nobility, and to expel such members, and many they were, who seemed unworthy, from their foreign extraction, their low birth, their scanty means, or their bad character, to have a place in that august assembly. The irregularities of the epoch which he hoped now to close had filled its benches with personages who degraded the order in the eyes of genuine citizens. The nobles and good citizens generally hailed this revision with deep satisfaction. It accorded with the national taste as well as with historical traditions. From the individual resentments it provoked, it was an act of some personal danger to the censor; but the danger was more than repaid by the popularity attending upon it, which was enhanced to the utmost by the liberality with which provision was made for raising some of the poor but honorable members of the order to the standard of property now to be required of them.

The emperor placed himself at the head of this reconstituted body, by assuming the office and title of *Princeps Senatus*. The office was indeed little more than nom-

inal; it gave the right of proposing measures and of speaking first in the highest legislative assembly of the state, and having been borne in earlier times by some of the most distinguished of Roman patriots, it carried with it the respect and affection of the people. The titular precedence it gave was all the more valuable, inasmuch as it might be conceded without a blush by the sturdiest republican in the senate. But it was the consul who possessed practically the chief authority in the assembly. Octavianus had been already five times consul, and he shrank from seizing in perpetuity an office which, according to Roman ideas, differed in nothing from royalty, except that it was elective, and that it was limited to the tenure of a single year. Yet he could hardly afford to yield it to the citizen whom the people might at any time elect to thwart or to rival him. What should he do? He took what was certainly a bold step. It was a manifest innovation upon the forms of the free state when he required from the citizens the perpetual "potestas," or power of the consulship, at the same moment that he resigned the office itself, and suffered consuls to be annually elected to sit, one on each side of him, in the senate. The potestas which was thus conceded to him rendered him the head of the state, both in its legislative and executive departments. When he quitted the city he carried with him into the provinces a proconsular authority, and became to all intents and purposes king for life of the Romans and of their subjects. Even in the senatorial provinces he was now recognised as supreme; and thus it was that in him were centred all the great political functions which had been hitherto divided by the great assembly of the Roman magnates.

But the emperor did not limit his views to becoming the chief of the nobles. It was the part of a wary statesman to associate himself not less intimately with the opposite faction, which, under the name of the plebeians, had aimed at securing co-ordinate power with the patricians. The original meaning of these designations had indeed long been lost. The plebeians could boast many families as eminent both for honors and possessions as their haughty rivals. Step by step they had won an equal share with them in political privileges. But the class which still bore the title of plebeian was much more widely extended, and embraced the great mass of the knights and men of business in the city, and also of the citizens settled throughout the provinces. This large class had for more than a century contended with the nobles for the perquisites of office, and their mutual rivalry had armed Sulla against Marius and Cæsar against Pompeius. The heir of Cæsar inherited the favor of the plebeians, and was bound to requite it by distinguised patronage. The plebeians were still the electors to the tribunate, and still regarded the tribunes as their protectors against the encroachments of the patricians represented by the senate. The tribunes had proved themselves most useful allies to Cæsar, and might yet again array themselves in support of the faithful inheritor of his principles. The emperor proposed to balance the consular potestas by assuming at the same time a tribunician potestas also. He thus endowed himself with the authority of the tribune for life, and assured the commons of the city and empire that he could at any time exercise the formidable veto upon the proceedings of the consuls which had served them so well, even down to recent times. Thus did he become emperor indeed,—the sovereign both of the nobles and the people in the city, as well as the commander of the army in the field and in the provinces.

There remained yet another sovereign authority in the state, namely, that which the chief pontiff exercised over the affairs of religion. However much the religious sentiment had been weakened throughout the Roman world, there was yet enough superstition left among the citizens to confer great and sometimes overwhelming influence upon the legitimate interpreter of divine things to the nation. The senate had exercised this power with great effect, as long as the appointment to the chief pontificate rested with the patrician curiæ. Of late years, however, this important dignity had been thrown open to the commons also. Octavianus was well pleased to accept it on the nomination of the whole people combined. He allowed, indeed, his former colleague Lepidus to retain it unmolested during his lifetime, but upon his death he assumed himself the exalted position which he might hesitate to intrust to any other. With this last addition to his prerogatives the emperor might well be contented. The name of king he had from the first utterly repudiated. The office of dictator approached too near to that of a king to be acceptable to a ruler, who studied to confine himself within the limits of the republican constitution. Yet there still lacked some general appellative which might reflect in a single world the full dignity and power resulting from the combination of so many honors and prerogatives. The emperor proposed at first, it is said, to assume the name of *Romulus;* but Romulus had been a king; and further, Romulus had been destroyed, according to the tradition, by the senate, just as Cæsar had been in later times. Such associations were ominous. At last he fixed upon the epithet *Augustus*, a name which no man had borne before, and which, on the contrary, had been applied to things the most noble, most venerable, and most sacred. The rites of the gods were called *august;* their temples were *august.* The word itself was derived from the holy *auguries;* it was connected in meaning with the abstract term *authority*, and with all that increases and flourishes upon earth. The use of this glorious title could not fail to smooth the way to the general acceptance of the divine character of the mortal who was deemed worthy to bear it. The senate had just decreed the divinity of the defunct Cæsar; the courtiers were beginning now to insinuate that his successor, while yet alive, enjoyed an effluence from deity; the poets were even suggesting that altars should be raised to him; and in the provinces, among the subjects of the states at least, temples to his divinity were actually rising, and the *cult* of Augustus was beginning to assume a name, a ritual, and a priesthood.

Augustus, as we may now call him, viewed all this with secret satisfaction. It was one of his first objects, indeed, to restore the outward show at least of reverence for divine things, and re-establish the old Roman religion on its firm political basis. It was easy to rebuild, or cause to be rebuilt, the fallen or dilapidated temples of the national gods. The nobles paid their court to their master by seconding his efforts in this direction. The Pantheon, the temple of all the gods, if such was its original destination, remains still as a monument of his minister Agrippa's munificence; but Virgil would assure us that not less than three hundred "grand" temples were erected throughout the city. Perhaps, indeed, these were mostly the sacella or chapels of the Lares, which are placed at the corners of the streets. Augustus took the sentiment of the people at a favorable moment. They were thoroughly sickened by the miseries of the civil wars; they were ashamed of the crimes for which the whole nation were more or less responsible; they were eager to rush into any scheme of expiation and reparation that should be offered to them, and lend their hands to the material work of restoring at least the outward semblance of penitence for sin, and thankfulness for the mercy vouchsafed them. There can be no doubt that the conscience of

the nation was awakened to a sense of the divine retribution under which they had suffered, but which had been at last averted under the blessed influence of the ruler whom they had at last chosen. The Romans had not lost their belief in a divine Providence, which oppressed them with anxiety and terror, however little they connected it with a sense of moral duty.

The spirit of materialistic philosophy had, however, been rife among them, and during the past century the anti-religious dogmas of Epicurus had sapped the belief of the educated and literary classes. The patrician youth of Rome had been trained in the schools of Greece, and especially at Athens, or had been placed under the teaching of Greek instructors at home; and of the three contending schools, the Stoics, the Epicureans, and the Academics, the second was that which had carried off far the greater number of disciples. The men of books or of speculative character might be generally Academics, and claim Cicero as their noblest leader; the men of imagination and deep religious fervor might follow, with Cato and Brutus, the teaching of the Stoics; but the practical men, the men of arts and arms and business, if they adhered to any school of thought at all, were almost all, like Cæsar himself and his associates generally, addicted to the easy precepts and still laxer morality of Epicurus. This philosophy was noted for its utter denial of Providence and, for all practical objects, of divinity altogether. None of these rival systems, whatever degrees of right sense and reason they might embrace respectively, could sanction any real belief in the still current mythology of the national worship, which was assailed and derided on all sides. Nevertheless, such was the pertinacious adherence of the Roman people to their ancient forms, especially where they had any connection with their national polity, that the outward ritual of their religion was still maintained, though a mere shadow of its former substance. Statesmen, indeed, had invented a formula for reconciling their actual unbelief with their outward profession. Varro had said, and the dictum was favorably accepted, that the ancient beliefs were to be upheld as a matter of public policy. Such, no doubt, was the principle on which Augustus, who was himself neither a believer nor a philosopher, but a politician only, proceeded, when he assumed the part of a restorer of the national religion. He touched, with great sagacity, a chord which vibrated to the heart of the people, who firmly believed that the destinies of the city were bound up with the due observance of the ancient rites, and statesmen looked on with decorous acquiescence at shows and ceremonies to which they attached no significance whatever.

The world "composes its countenance to the expression assumed by the king." Such was the aphorism of the man of the world, and in this particular Augustus was a king indeed.. The Romans rushed forward in the course he marked out for them. His word dictated the fashions of the day, not in sentiment only, but in many particulars of external conduct. He was anxious to restore the dignity of the Roman citizen, as one of the conquering race which ruled its subjects as much by the prestige of its character as by its arms, and he resented all relaxation from the strait-laced discipline of the ancients, even to the petty matters of their dress and deportment. He marked his sovereign displeasure at the degenerate Romans who indulged in the loose habiliments of Greece. "Are these," he exclaimed, in the language of Virgil, "the rulers of the world, the nation of the gown?" And in order to keep up the high distinction of Roman citizenship at a period when provincials from all sides were crowding into it, he reversed, in this single instance, the policy of Cæsar, and was very sparing in granting admission to the Roman franchise. He was, indeed, extremely careful in striking a balance between the tendency of the age to a general fusion of castes and privileges and the ancient spirit of exclusion, in which he thought the strength of the republic still really reposed. The policy of Augustus was one, on the whole, of cautious and moderate reaction. He made an effort to stay the process of disintegration, which he found so rife throughout the vital forces of the empire. The lawlessness of his own usurpation did indeed combine with the gross selfishness of his personal character to sap the moral principles of society, and render its ultimate dissolution inevitable; but he made a vigorous effort to stem the tide, and succeeded in giving the Roman world a period of rest in the downward path which it was generally pursuing.

AUGUSTUS II. (also, and more accurately, designated FREDERICK AUGUSTUS I.), Elector of Saxony and King of Poland, second son of John George III. of Saxony, was born at Dresden, 12th May 1670. His personal beauty was remarkable, and from his great physical strength he received the surname of The Strong, by which he is commonly distinguished. He was very carefully educated, and spent several years travelling in Europe, visiting most of the courts, and taking part in some campaigns against the French. In 1694 he succeeded his elder brother as elector of Saxony, and shortly after, having entered into alliance with Austria, was appointed to the chief command of the imperial forces against the Turks. In 1697, after having suffered a defeat at Olasch, he resigned this office, and proceeding to Vienna, entered into negotiations with regard to the throne of Poland, left vacant by the death of John Sobieski in 1696. As a preliminary step in his candidature, Augustus renounced the Protestant faith, and proclaimed himself a Catholic. Among his rivals the most formidable was the French prince of Conti. Both expended enormous sums in buying over the Polish nobles, and both claimed to be elected at the general diet. Conti, however, was not on the spot, and Augustus, marching into Poland with his Saxon forces, gained possession of the kingdom. Scarcely was he settled on the throne, when he entered into alliance with Russia and Denmark against the young king of Sweden, and with his Saxon troops (for the Poles would not unite with him) invaded Livonia. In the campaigns which followed (1700–1704), he was completely worsted by the extraordinary military genius of his opponent, the celebrated Charles XII. of Sweden; he was driven from Poland, and Stanislaus Leszczinski was crowned in his place. The Swedes, following up their victories, invaded Saxony, and in 1706, at Altranstädt, Augustus was compelled to make peace, to repay the expenses of the Swedish army, to acknowledge Stanislaus as king of Poland, and to congratulate him on his accession. After these reverses he spent some time as a volunteer in the Netherlands, but the defeat of Charles at Pultowa (1709) again raised his hopes. He at once declared the Altranstädt treaty null and void, and having received promises of assistance from Russia, entered Poland, drove out Stanislaus, and was a second time proclaimed king. During the following years he continued to carry on the war with Sweden, while at the same time his kingdom was distracted by the jealousy with which the Poles regarded the Saxon troops who were compelled to leave Poland in 1717. In 1718 Charles XII. was killed at Fredericshall, and from that time the reign of Augustus was marked by no important event. His court became celebrated as the most extravagant and luxurious in Europe, and he himself as the most dissolute and magnificent of princes. His lavish expenditure, though it enriched his capital

with treasures of art, impoverished both Poland and Saxony, and laid the foundations for the future misfortunes of those countries. He died 1st February 1733, from mortification of an old wound. Of his numerous natural children, the most famous was the distinguished general, Maurice of Saxony.

AUGUSTUS III., or FREDERICK AUGUSTUS II., Elector of Saxony and King of Poland, only legitimate son of Augustus the Strong, was born at Dresden, 7th October 1696. He was brought up in the Protestant faith, but in 1712, while on his travels, he entered the Church of Rome, though his change of opinion was not publicly known till 1717. In 1733 he succeeded his father as elector of Saxony, and put forward claims to the kingdom of Poland. The Polish nobles, however, had become dissatisfied with foreign rule, and endeavored to reinstate Stanislaus Leszczinski, whose daughter was married to Louis XV. of France. Russia and Austria, probably bribed, but certainly dreading French influence in Poland, supported Augustus, who was elected, though in an informal manner, and by their aid established himself in the kingdom. On the death of Charles of Austria in 1740, Saxony at first joined the league against Maria Theresa, but jealousy of the Prussian successes in the first campaign caused Augustus to unite with the empress when the war broke out a second time in 1744. His forces were completely defeated by Frederick, and Saxony was overrun and pillaged by the Prussian troops. Eleven years later Augustus joined the alliance against Frederick, which gave rise to the Seven Years' War. He was again unfortunate; the whole Saxon army was surrounded and compelled to surrender at Pirna in 1756, and during the remainder of the war Saxony and Poland were the seats of operations, and suffered severely. Augustus died 5th October 1763, surviving only by a few months the peace of Hubertsburg. During his reign considerable additions were made to the collections of art treasures formed by his father, and Dresden began to be celebrated throughout Europe for its china and pictures.

AUK, a name common to several species of sea-fowl belonging, with one exception, to the family *Alcidæ*. Of these, special interest attaches to the Great Auk, or Gare-fowl (*Alca impennis*), from the circumstance that there is no authentic record of its having been taken, or even seen alive, for more than a quarter of a century. In the autumn of 1821 Dr. Fleming, while on a cruise through the Hebrides, observed and described one which had been taken alive in the sea off St. Kilda and put on board the yacht. With a rope attached to one of its legs, this specimen was occasionally allowed to disport itself in its native element, where it astonished every one by the rapidity with which it swam under water. On one of these occasions it got loose from its bonds, and was soon beyond reach of pursuit. Another specimen had been observed a few years before off Papa Westra, one of the Orkney Islands, but in spite of the exertions of a crew of a six-oared boat, continued for several hours, the auk could not be overtaken. This specimen, however, was afterwards secured, and is now in the British Museum.

AULIC COUNCIL (from the Latin *aula*, a hall, in German, *Reichshofrath*), one of the two supreme courts of the old Germanic empire, the other being the imperial chamber (*Reichskammergericht*). It was called into existence in 1501 by the Emperor Maximilian, and was by him intended to counterbalance the influence of the imperial chamber, which he had been compelled to form by the states six years before. The Aulic Council had in many respects equal power with the chamber; from its decisions there was no appeal, and under its special jurisdiction were included the consideration of the imperial reserved rights, fees, and privileges, the settlement of disputes as to precedence among the several states, and the arrangement of matters relating to the Italian possessions of the empire. All questions of law could be submitted either to this council or to the chamber. At the dissolution of the old Germanic imperial system in 1806, the Aulic Council in its former signification came to an end, though an Austrian court bearing the same title still continued to sit in Vienna.

AULIS, a town in Bœotia, supposed to have been situated on a rocky peninsula between two bays, about three miles S. of Chalcis. During the Trojan war it was the rendezvous of the Greek fleet, and has obtained celebrity as the scene of the sacrifice of Iphigenia.

AUMALE, formerly ALBEMARLE, from the Latin *Alba Maria*, a town of France, in the department of Seine Inférieure, on the banks of the Bresle, 35 miles N.E. of Rouen.

AUNGERVYLE, RICHARD, commonly known by the name of *Richard de Bury*, was born in 1281, at Bury St. Edmund's in Suffolk, and educated at the university of Oxford. He entered the order of Benedictine monks, but was shortly afterwards appointed tutor to the prince of Wales. On the accession of his pupil to the throne as Edward III., he was promoted to various offices of dignity, and was finally made bishop of Durham, as well as lord high-chancellor and treasurer of England.

AURAY, a small town of France, situated on the slope of a hill near the mouth of the river of the same name, in the department of Morbihan, 10 miles W. of Vannes.

AURELIANUS, CÆLIUS, a celebrated Latin physician, born probably at Sicca in Numidia, but regarding whose life scarcely anything is known. The writings of Aurelianus, which are composed from the point of view of the methodical school, show considerable practical skill in the diagnosis of ordinary and even of exceptional diseases.

AURELIUS ANTONINUS, MARCUS, the noblest of all pagans, the crown and flower of Stoicism, was born at Rome 121 A.D., the date of his birth being variously stated as the 21st and the 26th of April. His original name was Marcus Annius Verus. His father Annius Verus, died while he was prætor; his mother who survived her husband, was Domitia Calvilla or Lucilla. The noble qualities of the child attracted the attention of the Emperor Hadrian, who, playing upon the name Verus, said that it should be changed to Verissimus. When Marcus reached the age of seventeen, Hadrian adopted, as his successor, Titus Antoninus Pius (who had married Annia Galeria Faustina, the sister of Annius Verus, and was consequently the uncle of Marcus), on condition that he in turn adopted both his nephew and Lucius Ceionius Commodus, the son of Ælius Cæsar, whom Hadrian, being childless, had originally intended as his successor, but who had died before him. It is generally believed that, had Marcus been old enough, Hadrian would have adopted him directly.

After the death of Hadrian, and the accession of Antoninus Pius to the throne, it became at once apparent that a distinguished future was in store for Marcus. He had been, at the age of fifteen, betrothed to the sister of Commodus; the engagement was broken off by the new emperor, and he was instead betrothed to Faustina, the daughter of the latter. In 139 A.D. the title of Cæsar was conferred upon him, and he dropped the name of Verus. The full name he then bore was Marcus Ælius Aurelius Antoninus, Ælius coming from Hadrian's family, and Aurelius being the original name of Antoninus Pius. He is generally known as Marcus Aurelius or Marcus

Aurelius Antoninus. In 140 A.D., he was made consul, and entered fully upon public life.

The education of Aurelius in his youth was so minute, and has been so detailed by himself, that it ought not to be passed over without notice. He never attended any of the Roman public schools, and this he makes a matter for self-congratulation. He was trained by tutors, in whom, particularly in Rusticus, he appears to have been very fortunate, and to whom he showed gratitude when he reached the throne by raising them to the highest dignities of the state. But, at the early age of eleven, he entered upon another course of study, in which he may be said to have continued more or less till the end of his life. He became acquainted with Diognetus the Stoic, was fascinated by the philosophy he taught, assumed the dress of his sect, and ultimately abandoned rhetoric and poetry for philosophy and law, having among his teachers of the one Sextus of Chæronea, and of the other L. Volusianus Marcianus, a distinguished jurist. He went thoroughly and heartily into the practice as well as the theory of Stoicism, and lived so abstemious and laborious a life, that he injured his health. It was from his Stoical teachers that he learned so many admirable lessons,—to work hard, to deny himself, to avoid listening to slander, to endure misfortunes, never to deviate from his purpose, to be grave without affectation, delicate in correcting others, "not frequently to say to any one, nor to write in a letter, that I have no leisure," nor continually to excuse the neglect of ordinary duties by alleging urgent occupations. Through all his Stoical training, Aurelius preserved the natural sweetness of his nature, so that he emerged from it the most lovable as well as the saintliest of Pagans.

Antoninus Pius reigned from 138 to 161 A.D., and the concord between him and his destined heir was so complete, that it is recorded that during these twenty-three years Marcus never slept oftener than twice away from the house of Pius.

Antoninus Pius died of fever, 161 A.D., at his villa of Lorium at the age of seventy-five. As his end approached, he summoned his friends and the leading men of Rome to his bedside, and recommended to them Marcus, who was then forty years of age, as his successor, without mentioning the name of Commodus, his other adopted son, commonly called Lucius Verus.

The early part of the reign of Aurelius was clouded by various national misfortunes: an inundation of the Tiber swept away a large part of Rome, destroying fields, drowning cattle, and ultimately causing a famine; then came earthquakes, fires, and plagues of insects; and finally, the unruly and warlike Parthians resumed hostilities, and under their king, Vologeses, defeated a Roman army and devastated Syria. Verus, originally a man of considerable physical courage and even mental ability, went to oppose the Parthians, but, having escaped from the control of his colleague in the purple, he gave himself up entirely to sensual excesses, and the Roman cause in Armenia would have been lost, and the empire itself, perhaps, imperilled, had Verus not had under him able generals, the chief of whom was Avidius Cassius. By them the Roman prestige was vindicated, and the Parthian war brought to a conclusion in 165, the two emperors having a triumph for their victory in the year following. Verus and his army brought with them from the East a terrible pestilence, which spread through the whole empire, and added greatly to the horrors of the time. The people of Rome seem to have been completely unnerved by the universal distress, and to have thought that the last days of the empire had come. Nor were their fears without cause. The Parthians had at the best been beaten, not subdued, the Britons threatened revolt, while signs appeared that various tribes beyond the Alps intended to break into Italy. Indeed, the bulk of the reign of Aurelius was spent in efforts to ward off from the empire the attacks of the barbarians. To allay the terrors of the Romans, he went himself to the wars with Verus, his headquarters being Carnuntum on the Danube. Ultimately, the Marcomanni, the fiercest of the tribes that inhabited the country between Illyria and the sources of the Danube, sued for peace in 168.

Aurelius was thenceforth undisputed master of the Roman empire, during one of the most troubled periods of its history.

Peace was not long allowed the emperor. The year after the death of his partner, two of the German tribes, the Quadi and the Marcomanni, renewed hostilities with Rome, and, for three years, Aurelius resided almost constantly at Carnuntum, that he might effectually watch them. In the end, the Marcomanni were driven out of Pannonia, and were almost destroyed in their retreat across the Danube. In 174 Aurelius gained a decisive victory over the Quadi, to which a superstitious interest is attached, and which is commemorated by one of the sculptures on the Column of Antonine. The story is that the Roman army had been entangled in a defile, from which they were unable to extricate themselves, while at the same time they suffered intensely from thirst. In this extremity a sudden storm gave them abundance of rain, while the hail and thunder which accompanied the rain confounded their enemies, and enabled the Romans to gain an easy and complete victory. This triumph was universally considered at the time, and for long afterwards, to have been a miracle, and bore the title of "The Miracle of the Thundering Legion."

Even after this Aurelius was not allowed to rest. From Rome, to which he had returned, he marched to Germany to carry on the war against the tribes which harassed the empire. There the alarming news reached him that Avidius Cassius, the brave and experienced commander of the Roman troops in Asia, had revolted and proclaimed himself emperor. But the rebellion did not last long. Cassius had only enjoyed his self-conferred honor for three months, when he was assassinated, and his head was brought to Marcus. With characteristic magnanimity, Marcus did not thank the assassins for what they had done; on the contrary, he begged the senate to pardon all the family of Cassius, and to allow his life to be the only one forfeited on account of the civil war. This was agreed to, and it must be considered as a proof of the wisdom of Aurelius's clemency, that he had little or no trouble in pacifying the provinces which had been the scene of rebellion. He treated them all with forbearance, and it is said that when he arrived in Syria, and the correspondence of Cassius was brought him, he burnt it without reading it. During this journey of pacification his wife Faustina, who had borne him eleven children, died.

The one blemish in the life of Aurelius is his hostility to Christianity, which is the more remarkable that his morality comes nearer than any other heathen system to that of the New Testament. Attempts have been made to show that he was not responsible for the atrocities with which his reign is credited, but the evidence of Justin, of Athenagoras, of Apollinaris, and above all, of Melito, bishop of Sardis, and of the Church of Smyrna, is overwhelmingly to the effect that not only were there severe persecutions of Christians, in which men like Polycarp and Justin perished, but that the foundation of these persecutions was certain rescripts or constitutions issued by Aurelius as supplementary to the milder decrees of his predecessors Hadrian and Antoninus Pius.

In explanation, however, if not in extenuation, of the attitude of Aurelius towards Christianity, several circumstances should be taken into consideration. In the first place, it is evident that he knew little of the Christians, and absolutely nothing of Christian ethics. In his *Meditations* he makes only one reference to the adherents of the new creed, and that of the most contemptuous character, showing that he confounded them all with certain fanatics of their number, whom even Clemens of Alexandria compares, on account of their thirst for martyrdom, to the Indian gymnosophists. How far this ignorance was culpable it is impossible at so remote a date to say. Further, it should be noted, in regard to the rescripts upon which the persecutions were founded, that, although they were in the name of the emperor, they may not have proceeded directly from him. There is no evidence that he was an active persecutor, except a passage in Orosius to the effect that there were persecutions of the Christians in Asia and Gallia "under the orders of Marcus;" and it should not be kept out of consideration that he was to some extent a constitutional monarch, and had to pay deference both to the *consulta* of the senate and the precedents of previous emperors. At the time there was a great popular outcry against the Christians on social and political, even more than on religious, grounds; and Aurelius may have been as much at the mercy of intriguers or fanatics when he gave his sanction to the butcheries of Christians in Asia Minor, as William III. was at the mercy of Stair and Breadalbane, the real authors of the massacre of Glencoe.

The book which contains the philosophy of Aurelius is known by the title of his *Reflections*, or his *Meditations*, although that is not the name which he gave to it himself, and of the genuineness of the authorship no doubts are now entertained. It is believed that the emperor also wrote an autobiography, which has perished with other treasures of antiquity. The *Meditations* were written, it is evident, as occasion offered,—in the midst of public business, and even on the eve of battles on which the fate of the empire depended,—hence their fragmentary appearance, but hence also much of their practical value and even of their charm. It is believed by many critics that they were intended for the guidance in life of Aurelius's son, Commodus. If so, history records how lamentably they failed in accomplishing their immediate effect, for Commodus proved one of the greatest sensualists, buffoons, and tyrants that disgraced even the Roman purple. But they have been considered as one of the most precious of the legacies of antiquity,—as, in fact, the best reflections on practical morality. They have been recognised as among the most effectual stimuli to strugglers in life, of whatever class and in whatever position, in the field of speculation as in that of action.

Antoninus died as he had lived, a Stoic philosopher. After the death of his wife, Faustina, he visited Lower Egypt, Greece and Italy. In 177 he was called to Germany to suppress a rebellion, and he died, it is believed, near Vienna, on March 17, 180.

AUREOLA, AUREOLE, the radiance or luminous cloud which, in paintings of sacred personages, is represented as surrounding the whole figure. In the earliest periods of Christian art this splendor was confined to the figures of the persons of the Godhead, but it was afterwards extended to the Virgin Mary and to several of the saints. The aureola, when enveloping the whole body, is generally oval or elliptical in form, but is occasionally circular or quatrefoil. When it is merely a luminous disk round the head, it is called specifically a *nimbus*, while the combination of nimbus and aureole is called a *glory*.

AURICH, a town of Prussia, in the province of Hanover, with a population of 5,399.

AURICULA, a genus, and AURICULIDÆ, a family, of Gasteropod Mollusca (Lat. *auricula*, a little ear). Some inhabit fresh water marshes, while others prefer the vicinity of salt water. They generally belong to warm climates, and some of them attain a large size. *Auricula midæ*, a native of the East Indies, is known to shell-collectors by the name of Midas' ear.

AURICULA (*Primula auricula*), a congener of the Primrose, much cultivated in flower gardens. It was highly esteemed by the Romans, and has, at least since the seventeenth century, received particular attention from the florists of England and Holland. A fine dust appears on the flowers and adds much to their beauty. Hence the name in Scotland of "Dusty Miller."

AURIFABER (the Latinized form of the name GOLDSCHMIDT), JOHANNES, a Lutheran divine, celebrated as the friend of Luther and as one of the editors of his works, was born in 1519 in the county of Mansfeldt, and died in 1575.

AURIFABER, JOHANNES, a Lutheran divine, born in Breslau in 1517. He was educated at Wittenberg, and was there specially attracted to Melanchthon, with whom he ever afterward remained on terms of close friendship. He died 19th October, 1568.

AURILLAC, the capital of the department of Cantal, France, situated on the right bank of the Jourdanne, which is here crossed by a handsome bridge. It contains tribunals of primary instance and commerce, a communal college, societies of agriculture, arts, and commerce, a public library, and a museum. Population (1889), 13,860.

AUROCHS is properly the German name of the extinct species of wild ox, called by Cæsar, *Urus*. Recently the name has been erroneously used for the Bison, still found in Lithuania.

AURORA, the Roman personification of the dawn of day, corresponding to the Greek goddess Eos (*q. v.*)

AURORA POLARIS, AURORA BOREALIS and AUSTRALIS, POLAR LIGHT, NORTHERN LIGHTS, or STREAMERS, an electrical meteor, appearing most frequently in high latitudes, in the form of luminous clouds, arches, and rays, of which the latter sometimes meet at a point near the zenith, and form what is called a *boreal crown*. The arches are sometimes single; sometimes several concentric ones are seen, and they are usually nearly stationary, or move slowly southward. The rays rise perpendicularly from the arches, but are sometimes seen detached, or when the arch is below the horizon.

The only thing resembling a distinct history of this phenomenon is that which has been given by Dr. Halley, in the *Philosophical Transactions*, No. 347. The first account he gives, taken from a book entitled *A Description of Meteors*, by W. F., D.D., reprinted at London in 1654, describes the appearance of what is called by him *burning spears*, which were seen at London on the 30th January 1560. The next appearance, according to the testimony of Stow, was on the 7th October 1564. In 1574 also, according to Camden and Stowe, an aurora borealis was observed two nights successively, viz., on the 14th and 15th of November, having much the same appearances as that described by Dr. Halley in 1716. Again, an aurora was twice seen in Brabant, in the year 1575, viz., on the 13th of February and 28th of September. Both appearances were described by Cornelius Gemm, professor of medicine at Louvain, who compares them to spears, fortified cities, and armies fighting in the air. Michael Mæstlin, tutor to Kepler, states that at Backnang in Würtemberg these phenomena, which he styles *chasmata*, were

seen by himself no less than seven times in 1580. In 1581 they again appeared in great splendor in April and September, and in a less degree in some other months of the same year. In September 1621, a similar phenomenon was observed all over France, and described by Gassendi, who gave it the name of *aurora borealis;* yet neither this, nor any similar appearance posterior to 1574, is described by English writers till the year 1707. From 1621 to 1707, indeed, there is no mention made of an aurora borealis having been seen at all; and, considering the number of astronomers who during that period were continually scanning the heavens, it might almost be supposed that nothing of the kind really made its appearance until after an interval of eighty-six years. A small one was seen in November 1707; and during that and the following year the same appearances were repeated five times. The next on record is that mentioned by Dr. Halley in March 1716, which from its brilliancy attracted universal attention, and was considered by the common people as marking the introduction of a foreign race of princes. Since that time these meteors have been much more frequent, and most of our readers must have seen the brilliant displays within the last few years which have been visible over the northern zone.

One singular phenomenon which seems to be connected with the aurora is that of a dark bank of cloud below the arches, and usually just above the northern horizon. Although this appears decidedly darker than the uncovered portion of the sky, it is of so thin a character that stars can be seen through it, as well as through the auroral arches and rays, with but little diminution of brightness. It is, however, quite possible that this cloud is only the somewhat misty open sky near the horizon, which appears darker by contrast with the bright arch above it.

It has been repeatedly affirmed that cracking, hissing, or whizzing sounds have been heard proceeding from the polar lights, and the natives of high latitudes are almost unanimous in alleging that this is sometimes the case.

Numerous observers have attested the occasional visibility of aurora by daylight. In the *Transactions of the Royal Irish Academy*, 1788, Dr. H. Ussher notices that aurora makes the stars "flutter" very much in the telescope, and states that, having noticed this effect strongly one day at 11 A.M., he examined the sky, and saw an auroral corona with rays to the horizon. Others have seen aurora which could not be distinguished from clouds, till the further development of the display made their real nature evident. Dr. Richardson thinks he has observed a polarity in the masses of cloud belonging to a certain kind of cirro-stratus approaching to cirrus, by which their long diameters, having all the same direction, were made to cross the magnetic meridian nearly at right angles. But the apparent convergence of such masses of cloud towards the opposite points of the horizon, which have been so frequently noticed by meteorologists, is an optical deception, produced when they are situated in a plane parallel to that on which the observer stands. These circumstances, says Dr. Richardson, are here noticed, because if it shall hereafter be proved that the aurora depends upon the existence of certain clouds, its apparent polarity may, perhaps, with more propriety, be ascribed to the clouds themselves which emit the light; or, in other words, the clouds may assume their peculiar arrangement through the operation of one cause (magnetism, for example), while the emission of light may be produced by another, namely, a change in their internal constitution, perhaps connected with a motion of the electrical fluid. D. Low states that he has witnessed as complete a display of auroral motions in the cirrus cloud as he ever beheld in a midnight sky. He thinks that all clouds are subject to magnetic or diamagnetic polarisation, and states that when the lines converge towards the magnetic pole, fine weather follows; when they are at right angles to this position, wet and stormy. The aurora appears in these latitudes usually to occur at a height much greater than that of ordinary clouds. Dr. Richardson's observations seem to show, however, that, in the Arctic regions, the aurora is occasionally seated in a region of the atmosphere below a kind of cloud which is known to possess no great altitude, namely, that modification of cirro-stratus which, descending low in the atmosphere, produces a hazy sheet of cloud over head, or a fog bank in the horizon. Indeed, Dr. Richardson is inclined to infer that the aurora borealis is constantly accompanied by, or immediately precedes, the formation of one or other of the forms of cirro-stratus. On the 13th of November and 18th December 1826, at Fort Enterprise, its connection with a cloud intermediate between cirrus and cirro-stratus is mentioned; but the most vivid coruscations of the aurora were observed when there were only a few thin attenuated shoots of cirro-stratus floating in the air, or when that cloud was so rare that its existence was only known by the production of a halo round the moon. The natives of the Arctic regions of North America pretend to foretell wind by the rapidity of the motions of the aurora; and they say that when it spreads over the sky in a uniform sheet of light, it is followed by fine weather, and that the changes thus indicated are more or less speedy, according as the appearance of the meteor is early or late in the evening,—an opinion not improbable, when it is recollected that certain kinds of cirro-stratus are also regarded by meteorologists are sure indications of rain and wind. Dr. Richardson frequently observed the lower surface of nebulous masses illuminated by polar lights,—a fact illustrative of the comparatively low situation of these auroræ. Biot, also, in the island of Uist, observed many auroræ that could not be higher than the region of clouds. Sir John Franklin in like manner observed low auroræ. "The important fact," says he, "of the existence of the aurora at a less elevation than that of dense clouds was evinced on two or three occasions this night (13th February 1821, at Fort Enterprise), and particularly at 11 hours 50 min., when a brilliant mass of light, variegated with the prismatic colors, passed between a uniform steady dense cloud and the earth, and in its progress completely concealed that portion of the cloud which the stream of light covered, until the coruscation had passed over it, when the cloud appeared as before." Captain Parry, as stated in his third voyage, observed auroræ near to the earth's surface. It is said while Lieutenants Scherer and Ross and Captain Parry were admiring the extreme beauty of a polar light, they all simultaneously uttered an exclamation of surprise at seeing a bright ray of the aurora shoot suddenly downward from the general mass of light, and between them and the land, which was only 3000 yards distant. The ray or beam of the polar light thus passed within a distance of 3000 yards, or less than 2 miles, of them. Further, Mr. Farquharson observed in Aberdeenshire an aurora borealis not more than 4000 feet above the level of the sea. Fitzroy believed that aurora in northern latitudes indicates and accompanies stormy weather at a distance, and that straining and cracking of the ice may cause the hissing and whizzing sounds.

M. Silbermann notes facts which strongly confirm the connection of aurora with some form of cirrus cloud. He says (of the aurora of 15th April 1869),—"At 11 hours 16 min. the phenomenon disappeared in a singular

fashion. It appeared as if the columns of the aurora were still visible, but the stars were hidden, and it soon became obvious that fan-like cirrus clouds, with their point of divergence in the north, had taken the place of the aurora. Between 1 and 2 in the morning these clouds had passed the zenith, and let fall a very fine rain. On stretching out the back of the hand one felt a pricking of cold, and now and then there were minute scintillations in the nearest strata of air, like a hail of tiny crystals of ice, which afterwards turned to a rain of larger and larger drops. At 4 o'clock in the morning the cirrus of the false aurora was still visible, but deformed towards the top, and presenting a flaky aspect. One interesting point is, that the cirrus never appeared to replace the aurora either from the right or the left, but to substitute itself for it, like the slow changes of a dioramic view." "I had previously observed a fall of small ice crystals on the 30th April 1865. At 6 P.M. Paris seemed enveloped in a cirrus of vertical fibres, recalling those of amianthus, and more or less wavy. It was a rain of little sparkling prisms. At the same time I heard a rustling or crepitation, and on extending my hand I felt a pricking sensation of cold, and distinguished the crystals which fell and melted immediately."

In a later memoir he remarks that many storm-clouds throw out tufts of cirri from their tops, which extend over a great portion of the sky, and resolve themselves into a very fine and cold drizzle, which frequently degenerates into a warmer and more abundant rain. Usually the fibres are more or less sinuous, but in much rarer cases they become perfectly rectilinear, and surround the cloud like a glory, and occasionally shine with a sort of phosphorescence. As an illustration he quotes his observations on the night of the 6th September 1865: — "A stormy cloud was observed about 11 P.M. in the N.N.W., and lightning was distinctly visible in the dark cumulous mass. Around this mass extended *glories* of a phosphorescent whiteness, which melted away into the darkness of the starry sky. Round the cloud was a single and uninterrupted corona, and outside this, two fainter coronæ broken by rifts which corresponded with each other. After the cloud had sunk below the horizon the *glories* were still visible. The light could not have been due to the moon or any foreign cause. The rays showed great mobility, and a sort of vibration intermediate between that of the aurora and the 'brush discharge' of the electric machine."

A still more curious fact is mentioned by Sabine, who, during his magnetic survey, anchored some days at Loch Scavaig in Skye. This loch is surrounded by high and bare mountains, one of which was nearly always enveloped in a cloud, resulting from the vapors which almost constant west winds brought from the Atlantic. This cloud at nights was permanently self-luminous, and Sabine frequently saw rays similar to those of the aurora. He entirely repudiates the idea that the rays could be due to auroræ beyond the mountain, and is sure that these phenomena, whatever their nature, were produced in the cloud itself.

Silbermann asserts that auroræ are preceded by the same general phenomena as thunderstorms, and concludes that everything had happened as if the auroræ of 1859 and 1869 had been storm-clouds, which, instead of bursting in thunder, had been drawn into the upper parts of the atmosphere, and their vapor being crystallised in tiny prisms by the intense cold, the electricity had become luminous in flowing over these icy particles. This view is very strongly supported by the observation of Professor Piazzi Smyth that the monthly frequency of aurora varies inversely with that of thunderstorms. It must, however, be remembered that the observed frequency of auroræ is much affected in Scotland by the continuous twilight during the summer months. If there be this connection between thunder-clouds and auroræ, it is not improbable that the "dark segment" is sometimes a real cloud or mist, situated at a height where the density of the air is too great for luminous discharge; and in several cases Silbermann has seen auroral rays rise from small clouds, which gradually melted entirely away, or left a small non-luminous nucleus when their electricity was discharged.

If, as would certainly be the case in a mist, any portion of the auroral light is reflected, whether it be its own or derived from some other body, it should be polarised; but so far polariscope observations are deficient, and give no certain information. It is difficult to separate the proper polarisation of the aurora from the mere atmospheric polarisation of the sky. Mr. Ranyard, who appears to have used a double-imaged prism and Savart during the great aurora of Feb. 4, 1872, and also to have made some observations on that of Nov. 11, 1871, did not detect polarisation. On the other hand, Prof. Stephen Alexander, in his report on his expedition to Labrador, found strong polarisation with a Savart, and, singularly enough, thought it strongest in the dark parts of the aurora. The observations were made in lat. about 60°, in the beginning of July, and near midnight, but he does not state whether there was twilight or any trace of air polarisation at the time, nor does he give the plane of polarisation.

With regard to the height of auroræ, Sir W. R. Grove states that he saw an aurora some years ago at Chester in which the rays came between him and the houses; and Mr. Ladd observed a similar case in which the lighthouse at Margate was visible through a ray. The evidence, however, appears strong that aurora is usually at a very great height. Dalton calculated the height of an auroral arch, which was seen as far north as Edinburgh, and as far south as Doncaster, and at most intermediate places, from its apparent altitude, as measured by its position in relation to the stars seen from Kendal and Warrington, 83 miles apart. The resulting height was about 100 miles, and the position slightly south of Kendal. An observation at Jedburgh confirmed this, but some taken at Edinburgh placed it above Carlisle at a height of 150 miles. Dalton, however, considered the former reckoning the more trustworthy. Backhouse has made many calculations, and considers the average height of auroræ ranges from 50 to 100 miles, and numerous other observers have calculated similar heights. All these observations, however, are liable to the objection, that different observers may really have seen different arches, of which, as has been remarked, there are often several concentric ones. It is not likely that this was really the case in most instances, but it has, no doubt, sometimes occurred, and may account for the heights of 500 to 1000 miles calculated by early observers.

Early observers, and especially Mr. Canton, conjectured that the aurora was an electric discharge in the rarefied upper atmosphere, and the resemblance between it and the phenomena exhibited by discharges in an air-pump vacuum confirmed the idea. Recent spectroscopic observations have thrown some little doubt on this conclusion, or at least have shown that there is still a mystery left unexplained. When the light of any flowing gas is analysed by the prism, it is found to consist of a series of colored lines and bands, of which the number and position are dependent on the nature of the gas, and which is called its spectrum. The light of the aurora gives a spectrum usually consisting of a single line in the greenish yellow, which does not coincide with a

principal line of any known substance,—a spectrum totally different from those of the gases of the atmosphere. Besides this line there is occasionally visible a sharp line in the red, and several fainter and more refrangible bands.

To give some idea of the extent of magnetic perturbations, we may mention that during the aurora of 13th May 1869, the declination at Greenwich varied 1° 25′, while the vertical force experienced for four successive maxima, and the greatest oscillation amounted to 0.04 of its total mean value. The horizontal force at the same time only varied 0.014 of its mean value. During the aurora of the 15th April of the same year the declination at Stonyhurst varied 2° 23′ 14″ in nine minutes.

The electric currents produced at such times in telegraph wires, though transient, are often very powerful. Loomis mentions cases where wires had been ignited, brilliant flashes produced, and combustible materials kindled by their discharge. It often happens that the ordinary signals are completely interrupted during their continuance.

In addition to the resemblance between the auroral phenomena and those of electric discharges in rarefied gases, we have seen that auroral displays are accompanied by marked disturbances both in the direction and force of terrestrial magnetism. This fact is in itself almost proof of their electrical character, and, taken in conjunction with the strong "earth-currents" which are at such times produced in lines of telegraph, and with the manifest polarisation of the arches and rays with regard to the magnetic meridian, may be considered as conclusive that the aurora is some sort of electric discharge. There are still some points with regard to the origin of this electricity which are unexplained, and it is uncertain whether the magnetic disturbance causes the electrical phenomena, or *vice versa*. It has been shown by Prof. Plücker that when an electric discharge takes place through rarefied gas in the field of a magnet, it is concentrated in the magnetic curves, which are the only paths in which it can move without being disturbed by the magnet. This is well shown in De la Rive's well-known experiment, in which an electromagnet is set in action, the discharge, which had before filled the egg, is concentrated into a defined band of light, which rotates steadily round the magnet,—the direction of its rotation being changed by reversal either of the current or of the polarity of the magnet. If we suppose that the aurora is an electric discharge passing from one magnetic pole to the other, and following the terrestrial magnetic curves, we shall find that the theory agrees with observed facts even in its lesser details. In these latitudes the magnetic curves are sensibly straight and parallel, and are inclined S.E. at an angle of about 70° from the perpendicular, and, by the well-known laws of perspective, will appear to converge towards this point, as, in fact, the auroral streamers do. The streamers should move from east to west, or from west to east, according as the discharge is from north to south, or *vice versa*, and, in fact, they are in constant motion. Professor Loomis gives a catalogue of forty-six cases of such movement, of which thirty-one were from E. to W. and only fifteen in the opposite direction; and as part of these apparent motions are due to a real motion from N. to S., he concludes that the actual motion of the streamers is from about N.N.E. to S.S.W. This would make the north pole the negative electrode, which is most likely usually the case. Prof. Loomis has shown that during auroral displays electrical currents traverse the earth's surface in the same general direction, though subject to great variation in intensity and even to reversal. Waves of magnetic disturbance are also propagated in the same direction.

With regard to the arches it is evident that they are generally circles concentric to the magnetic poles, and it is very probable that they are analogous to the striæ often seen in discharges in rarefied gases. Gassiot describes an experiment with his great Grove's battery of 400 cells, in which the exhausted receiver was placed between the poles of the large electro-magnet of the Royal Institution:—"On now exciting the magnet with a battery of ten cells, effulgent strata were drawn out from the positive pole, and passed along the under or upper surface of the receiver according to the direction of the current. On making the circuit of the magnet and breaking it immediately, the luminous strata rushed from the positive, and then retreated, cloud following cloud with a deliberate motion, and appearing as if swallowed up by the positive electrode." This, as Mr. Marsh remarks, bears a very considerable resemblance to the conduct of the auroral arches, which almost invariably drift slowly southward; and we cannot do better than sum up his theory in his own words—"The foregoing considerations seem to render it probable that the aurora is essentially an electric discharge between the magnet poles of the earth leaving the immediate vicinity of the north magnetic pole in the form of clouds of electrified matter, which float southward through the atmosphere at a height of 40 miles or more from the earth, sometimes to a distance of more than 30° from the pole; that whilst they are thus moving forward, with a comparatively slow and steady motion, or sometimes even remaining almost stationary for a long time, bright streams of electricity are from time to time suddenly shot out from them in a nearly vertical direction, that is to say, in the magnetic curves corresponding to the points from which they originate; that these curves, ascending to a great height beyond the atmosphere, then bending more and more southward and downward until they finally reach corresponding points in the southern magnetic hemisphere, are the pathways by which the electric currents pass to their destination; and that for several hundred miles from the earth these curves are thus 'traced through space and illuminated with bright electric light;' and further, that the magnetism of the earth also causes these luminous currents and the electrified matter composing the arch to revolve round the magnetic pole of the earth, giving them the motion from east to west, or from west to east, which the components of the arch are observed to have."

The principal difficulties and deficiencies of this hypothesis, which was first suggested by De la Rive, are that it makes no attempt to account for the origin of such an electrical discharge, and that it is difficult to understand how an electric current can traverse vast spaces of the almost perfect vacuum which must exist at the distance from the earth (many hundreds of miles) which is attained by the magnetic curves, since, in the best vacuums of our Sprengel pumps, discharge will not take place even across the interval of a few centimetres. It is not, however, certain that the stellar space is an insulator, and it is possible, moreover, that the auroral currents do not follow the magnetic curves through their whole course, since electric discharge is always in the path of least resistance, and this is modified not only by the magnetic forces, but by atmospheric density, and it is possible that on attaining a certain height the current may proceed horizontally on a stratum of least resistance. It need create no surprise that the discharge is generally invisible in the intermediate zone of low latitudes, since this is well accounted for not only by the large surface over which it is spread at great heights, but because this part of its course it at right angles to the line of sight, while in higher latitudes we look at the streamers almost "end-on," and thus have before our eyes a very great depth of luminous gases. It is common enough,

too, in discharges in rarefied gases to see the two poles surrounded by luminous auræ, while the intermediate space is almost or quite dark, or consists of luminous disks or striæ separated by dark spaces. It seems probable that this "glow" discharge in rarefied gases is really a sort of electrical convection, which is propagated comparatively slowly, and from particle to particle; and that the striæ are surfaces at which the difference of potential of the moving molecules is so great as to cause discharge between them, while in the intermediate dark spaces the electric force is carried mechanically and silently by the particles moving in regular currents under the repulsive and attractive forces of electrification. On this hypothesis the auroral discharge becomes comprehensible, since we have only to suppose that the electricity is carried mechanically, as it were, through the vacuous spaces, which, if they contain no matter to conduct electricity, can contain none to impede the motion of the molecules. It is, moreover, by no means certain that the bright rays indicate actual currents. They may simply consist of matter rendered luminous in the arches, and projected by magnetic or electrical repulsion in the curves of magnetic force, since Varley shows that when a glow discharge in a vacuum tube is brought within the field of a powerful magnet, the magnetic curves are illuminated beyond the electrodes between which the discharge is taking place as well as within the path of the current; and also that this illumination is caused by moving particles of matter, since it deflected a balance plate of tale on which it was caused to impinge. It has also been shown that in electrical discharges in air at ordinary pressures, while the spark itself was unaffected by the magnet, it was surrounded by a luminous cloud or aura, which was drawn into the magnetic curves, and which might also be separated from the spark by blowing upon it. It is evident, therefore, that any mechanical force may separate the luminous particles from the electric discharge which produces them.

With regard to the geographical distribution of aurora, Prof. Loomis laid down a series of zones of equal auroral frequency, and in Petermann's *Mittheilungen* for October 1874, Prof. Fritz has given a chart embodying the results of his extensive researches on the same subject. He finds, like Prof. Loomis, that the frequency of auroral display does not continue to increase to the pole, but reaches a maximum in a zone which, for the northern hemisphere, passes through the Faroe Islands, reaches its most southern point, about 57°, nearly south of Greenland, passes over Nain on the Labrador coast, then tends northwards, across Hudson's Bay (60° N. lat.), and through great Bear Lake, and leaves the American continent slightly south of Point Barrow. It then skirts the northern coast of Asia, reaching its most northerly point, about 76° N., near Cape Taimyr, passing through the north of Nova Zembla, and skirting the N.W. coast of Norway. Not only are auroral displays less frequent in Iceland and Greenland than further south, but it is found that while south of this zone auroræ appear usually to the north of the observer, north of it they are generally to the south, and within it, north or south indifferently. South of this lie other zones approximately parallel to it, and of constantly diminishing frequency. That in which the average yearly number of auroræ is 100 passes through the Drontheim, the Orkneys, and the Hebrides, and reaches the American coast just north of Newfoundland. South of this the frequency diminishes rather rapidly. At Edinburgh the annual average is 30, at York 10, in Normandy 5; while at Gibraltar the average is about 1 in ten years.

These curves, which Prof. Fritz calls *isochasmen*, are nearly normal to the magnetic meridians, and bear a close relation to the curves of equal magnetic inclination, especially with those laid down by Hansteen in 1730, while they noticeably diverge in some places from those of Sabine of 1840. They also approximate to the isobaric curves of Schouw, and Prof. Fritz remarks that the curves of greater frequency tend towards the region of lowest atmospheric pressure. It is not unlikely that there may be such a connection, since Prof. Airy has showed a relation between barometric and magnetic disturbances.

It will be noticed that, eastward from England, the isochasmic curves tend rapidly northward, Archangel being only on the same auroral parallel as Newcastle. Prof. Fritz points out that they bear some relation to the limit of perpetual ice, tending most southward where, as in North America, the ice limit comes furthest south. He also endeavors to establish some connection between the periods of maximum of auroræ and those of the formation of ice, and considers ice as one of the most important local causes which influence their distribution. He quotes a curious fact mentioned by several Arctic voyagers, that aurora was most frequently seen when open water was in sight, and usually rather in the direction of the water than of the magnetic north. In this connection it may be well to remind our readers that the water of the Arctic regions is always warmer than the ice fields, and must cause upward currents of damp air. For the southern hemisphere there are not yet sufficient observations to make any determination of geographical distribution. The correspondence of sunspots and auroræ is here shown for 66 years.

Although no daily periodicity of the aurora can be affirmed, there are two well-marked annual maxima in March and October, of which the latter is the greater, and two minima — the greater in June and the less in January. In this respect the aurora differs from the sporadic meteors, which have a maximum in autumn and a minimum in spring. It also differs from meteors in the hours of its appearance, the former being most frequent before and the latter after midnight.

Although the electric hypothesis is the one generally accepted by scientific men, it is only fair to allude to one that has been recently proposed independently by Dr. Zehfuss. According to this view, the light of the aurora is caused by clouds of ferruginous meteoric dust, which is ignited by friction with the atmosphere. Groneman has shown that these might be arranged along the magnetic curves by action of the earth's magnetic force during their descent, and that their influence might produce the observed magnetic disturbances. The arches may be accounted for by the effects of perspective on columns suddenly terminated at a uniform height by increase of atmospheric density, while the correspondences with iron lines in its spectrum are sufficiently close to favor the idea. Ferruginous particles have been found in the dust of the polar regions, but whether they are derived from stellar space or from volcanic eruptions is uncertain. The yearly and eleven-yearly periodicity of auroræ tends to support the theory, but it is a formidable difficulty that, while shooting stars are more frequent in the morning, or on the face of the earth which is directed forwards in its orbit, the reverse is the

case with auroræ. Groneman meets this difficulty by supposing that in the first place the velocity may be too great to allow of arrangement by the earth's magnetic force, and that, consequently, only diffused light can be produced. He accounts for its unfrequency in equatorial regions by the weakness of the earth's magnetic force, and the fact that, when it does occur, the columns must be parallel to the earth's surface. Without pronouncing in favor of this hypothesis, it must be admitted that it furnishes a plausible explanation of the phenomenon, although we have no evidences that meteoric dust, even if it exists, would produce the observed spectrum, and, as has been already remarked, the iron coincidences are of little weight.

AURORA, a city of Kane county, Ill., on the Fox river, which affords magnificent water power. There are twenty-six large factories, with a capital stock of $6,100,000, and representing all branches of business. The city has eight public schools, twenty-three churches and a population (1890) of 19,634. It has ample railroad facilities, is lighted by gas and electricity, and has waterworks and a fire and police department. Assessed valuation $3,200,000. Aurora contains the car-shops of the Chicago, Burlington and Quincy railroad, which employ over 1,000 men. It has a fine city hall and other public buildings, and is the seat of a seminary.

AURORA, a city of Dearborn county, Ind., on the Ohio river. four miles from Lawrenceburg. It contains a national bank, breweries and distilleries, a nail factory, and several cooper shops, and has a population of 3,928.

AURUNGABĀD, or AURANGÁBÁD, a city of India, in the native state of Haidarábád, or the Nizám's dominions, 138 miles from Púna, 207 from Bombay *via* Púna, and 270 from Haidarábád. It was founded about the year 1620, under the name of Gurka, by Malik Ambar, an Abyssian, who had risen from the condition of a slave. It is now greatly fallen from its ancient grandeur.

AURUNGZÉBE, one of the greatest of the Moghul emperors of Hindustan, was the third son of Shah Jehan, and was born in October 1618. His original name, Mahomet, was changed by his father, with whom he was a favorite, into Aurungzebe, meaning ornament of the throne, and at a later time he assumed the additional titles of Mohi-eddin, reviver of religion, and Alam-gir, conqueror of the world. At a very early age, and throughout his whole life, he manifested profound religious feeling, perhaps instilled into him in the course of his education under some of the strictest Mahometan doctors. He was employed, while very young, in some of his father's expeditions into the country beyond the Indus, gave promise of considerable military talents, and was appointed to the command of an army directed against the Usbeks. In this campaign he was not completely successful, and soon after was transferred to the army engaged in the Deccan. Here he gained several victories, and in conjunction with the famous general, Meer Jumla, who had deserted from the king of Golconda, he seized and plundered the town of Haidarábád, which belonged to that monarch. His father's express orders prevented Aurungzebe from following up this success, and, not long after, the sudden and alarming illness of Shah Jehan turned his thoughts in another direction. Of Shah Jehan's four sons, the eldest, Dara, a brave and honorable prince, but disliked by the Mussulmans on account of his liberality of thought, had a natural right to the throne. Accordingly, on the illness of his father, he at once seized the reins of government and established himself at Dehli. The second son, Soojah, governor of Bengal, a dissolute and sensual prince, was dissatisfied, and raised an army to dispute the throne with Dara. The keen eye of Aurungzebe saw in this conjecture of events a favorable opportunity for realising his own ambitious schemes. His religious exercises and temperate habits gave him, in popular estimation, a great superiority over his brothers, but he was too politic to put forward his claims openly. He made overtures to his younger brother Murad, governor of Guzerat, representing that neither of their elder brothers was worthy of the kingdom, that he himself had no temporal ambition, and desired only to place a fit monarch on the throne, and then to devote himself to religious exercises and make the pilgrimage to Mecca. He therefore proposed to unite his forces to those of Murad, who would thus have no difficulty in making himself master of the empire while the two elder brothers were divided by their own strife. Murad was completely deceived by these crafty representations, and at once accepted the offer. Their united armies then moved northward. Meanwhile Shah Jehan had recovered, and though Dara resigned the crown he had seized, the other brothers professed not to believe in their father's recovery, and still pressed on. Soojah was defeated by Dara's son, but the imperial forces under Jesswunt Singh were completely routed by the united armies of Aurungzebe and Murad. Dara in person took the field against his brothers, but was defeated and compelled to fly. Aurungzebe then, by a clever stroke of policy, seized the person of his father, and threw him into confinement, in which he was kept the remaining eight years of his life. Murad was soon removed by assassination, and the way being thus cleared, Aurungzebe, with affected reluctance, ascended the throne in August 1658. He quickly freed himself from all other competitors for the imperial power. Dara, who again invaded Guzerat, was defeated and closely pursued, and was given up by the native chief with whom he had taken refuge. He was brought to Dehli, exhibited to the people, and assassinated. Soojah, who had been a second time defeated near Allahabad, was attacked by the imperial forces under Meer Jumla and Mahomet, Aurungzebe's eldest son, who, however, deserted and joined his uncle. Soojah was defeated and fled to Aracan, where he perished; Mahomet was captured, thrown into the fortress of Gwalior, and died after seven years' confinement. No similar contest disturbed Aurungzebe's long reign of forty-nine years, which has been celebrated, though with doubtful justice, as the most brilliant period in the history of Hindustan. His last years were embittered by remorse, by gloomy forebodings, and by constant suspicion, for he had always been in the habit of employing a system of espionage, and only then experienced its evil effects. He died, on the 21st February 1707 at Ahmadnagar, while engaged on an extensive but unfortunate expedition against the Mahrattas.

AUSCHWITZ, or OSWIECIM, a town in Galicia, Austria, on the right bank of the Sola, a tributary of the Wechsel, 33 miles W.S.W. of Cracow. Population, 4,000.

AUSCULTATION (*auscultare*, to listen), a term in medicine, applied to the method employed by physicians for determining, by the sense of hearing, the condition of certain internal organs. The ancient physicians appear to have practised a kind of auscultation, by which they were able to detect the presence of air or fluids in the cavities of the chest and abdomen. Still no general application of this method of investigation was resorted to, or was indeed possible, till the advance of the study of anatomy led to correct ideas regarding the locality, structure, and uses of the various organs of the body, and to the alterations produced in them by disease. In 1761 Auenbrugger of Vienna introduced the art of percussion in reference more especially to diseases of the chest. This consisted in tapping with the fingers the surface of the body, so as to elicit sounds by which the comparative resonance of the subjacent parts or organs

might be estimated. Auenbrugger's method attracted but little attention, till Corvisart, in 1808, demonstrated its great practical importance; and then its employment in the diagnosis of affections of the chest soon became general.

In 1819 the distinguished French physician, Laennac, introduced the method of auscultation by means of the stethoscope (στῆθος, the chest, and σκοπέω, I examine), with which his name stands permanently associated. For some time previously, physicians, more especially in the hospitals of Paris, had been in the habit of applying the ear over the region of the heart for the purpose of listening to the sounds of that organ, and it was in the employment of this method that Laennec conceived the idea that these sounds might be better conveyed through the medium of some solid body interposed between his ear and the patient's chest. He accordingly, by way of experiment, rolled up a quire of paper into the form of a cylinder and applied it in the manner just mentioned, when he found, as he states, that he was able to perceive the action of the heart more distinctly than he had ever been able to do by the immediate application of his ear. He thence inferred that not merely the heart's sounds, but also those of other organs of the chest might be brought within reach of the ear by some such instrument, and he, therefore, had constructed the wooden cylinder, or stethoscope, which bears his name. This consisted of a cylindrical piece of wood, about 12 inches long, with a narrow perforation from end to end, the extremity for applying to the chest having a movable piece of conical form fitting into the cylinder, which was withdrawn by the physician while listening to the sounds of respiration, the complete instrument being used for examining the sounds of the voice and those of the heart.

The whole subject of auscultation has been greatly elaborated since the time of Laennec, and while some of his opinions have been found to require modification, continued investigation only serves more clearly to demonstrate the value of this method of diagnosis, and to elicit fresh and more accurate results from its employment. Although much remains to be done in the way of the correct interpretation of the phenomena observed in auscultation, yet the facts already established are among the most important acquisitions in the whole domain of practical medicine.

AUSONIUS, Decimus Magnus, a Roman poet of the 4th century, was the son of an eminent physician, and born at Burdigala *(Bordeaux)* about 310 A.D. He was appointed consul by the Emperor Gratian in the year 379, after having filled other important offices; for besides the dignity of quæstor, to which he had been nominated by Valentinian, he was made præfect of Latium, of Libya, and of Gaul, after that prince's death. The time of his death is uncertain, but he was alive in 388, and probably survived till about 394.

AUSPICIA. See Augurs.

AUSSIG, Aussyenad, or Labem, a town of Austria, in Bohemia, situated in a mountainous district, at the confluence of the Bila and the Elbe. It carries on a large manufacturing trade. Population, 12,000.

AUSTEN, Jane, one of the most distinguished modern British novelists, was born December 16, 1775, at the parsonage of Steventon, in Hampshire, of which place her father was for many years rector. Her life was singularly tranquil and void of incident, so that but few facts are known concerning her from which an idea of her character can be formed. She was tall and attractive in person, and of an extremely kind and gentle disposition. Under her father's care she received a sound education, though she had few of the modern accomplishments. She had a fair acquaintance with English literature, her favorite authors being Richardson, Johnson, Cowper, and Crabbe; she knew French well and Italian slightly, had some taste for music, and was noted for her skill in needlework. In 1796 her first large work, *Pride and Prejudice*, was begun and completed in about ten months; *Sense and Sensibility* and *Northanger Abbey* were written soon after, during 1797 and 1798. Many years elapsed before these works were published. Miss Austen died July 18, 1817.

AUSTERLITZ, a small town of Moravia, 12 miles E. S. E. of Brünn, containing a magnificent palace belonging to the prince of Kaunitz-Rietberg, and a beautiful church. It has been rendered memorable by the great victory obtained in its vicinity, on the 2d of December, 1805, by the French under Napoleon, over the united forces of Austria and Russia. Pop., 3,450.

AUSTIN, John, one of the ablest English writers on jurisprudence, was born on the 3d or March, 1790. Austin wrote one or two pamphlets, but the chief work he published was his *Province of Jurisprudence Determined* (1832.) He died in 1859.

AUSTIN, Sarah Taylor, translator and miscellaneous writer, was born in 1793. She grew up a beautiful and cultivated woman, and in 1820 became the wife of John Austin, noticed above. Mrs. Austin is best known as a singularly skillful translator of German and French works. She died on August 8, 1867.

AUSTIN, Stephen F., founder of the State of Texas, was the son of Moses Austin, a pioneer in the same region, and in 1821 conducted a party of settlers to where the city of Austin now stands, thus carrying out a work his father had begun. In 1833 Austin went to the city of Mexico to secure the admission of his settlement into the Mexican Confederacy, and was imprisoned there till 1835. He died in December, 1836.

AUSTIN, the capital of Texas, is a city of 15,324 people, situated in Travis county, on the left bank of the Colorado river. Its chief attraction is the magnificent capitol building, erected at a cost of nearly $5,000,000. In addition to this Austin contains other public buildings, costing over $1,000,000. It has eight churches, a public library, first-class schools, gas and electric lights, street cars and electric railroads, a well-organized fire department and an efficient police service. The assessed valuation in 1890 was $9,000,000; city tax rate, $1 per $100; the fiscal receipts, $125,000. The city is an important shipping point for cotton.

AUSTRALASIA, one of the six great geographical divisions of the globe, is situated, as its name indicates, south of Asia. It comprises the island-continents of New Guinea, Australia, Tasmania, and New Zealand, and the conterminous archipelagoes of New Britannia, Solomon Islands, New Hebrides, Loyalty Islands, and New Caledonia, which will be treated of under special headings.

AUSTRALIA or New Holland, the largest island-continent of Australasia, measures 2500 miles in length from west to east, by 1950 miles in breath from north to south, and contains an area of about 3,000,000 square miles — nearly the same as that of the United States of America, exclusive of Alaska. It is surrounded on the west by the Indian Ocean, and on the east by the South Pacific. In the north it is separated from New Guinea by Torres Strait, which is 80 miles broad, and from the Eastern Archipelago by Arafura Sea; while on the south Bass Strait, 140 miles wide, separates it from Tasmania. The neighboring colony of New Zealand lies 1200 miles opposite its south-east coast.

Owing to its position at the antipodes of the civilized world, Australia has been longer a *terra incognita* than any other region of the same extent. Its

first discovery is involved in considerable doubt, from confusion of the names which were applied by the earlier navigators and geographers to the Australasian coasts.

The ancients were somehow impressed with the idea of a *Terra Australis* which was one day to be revealed. The Phœnician mariners had pushed through the outlet of the Red Sea to Eastern Africa, the Persian Gulf, and the coasts of India and Sumatra. But the geographer Ptolemy, in the 2d century, still conceived the Indian Ocean to be an inland sea, bounded on the south by an unknown land, which connected the *Chersonesus Aurea* (Malay Peninsula) with the promontory of *Prasum* in eastern Africa. This erroneous notion prevailed in mediæval Europe, although some travellers like Marco Polo heard rumors in China of large insular countries to the south-east.

The investigations of Mr. R. H. Major make it appear probable that the Australian mainland was known as "Great Java" to the Portuguese early in the 16th century; and the following passage in the *Descriptionis Ptolemaicæ Augmentum* of Cornelius Wytfliet, printed at Louvain in 1598, is perhaps the first distinct account that occurs of the country:—"The *Australis Terra* is the most southern of all lands, and is separated from New Guinea by a narrow strait. Its shores are hitherto but little known, since, after one voyage and another, that route has been deserted, and seldom is the country visited, unless when sailors are driven there by storms. The *Australis Terra* begins at one or two degrees from the equator, and is ascertained by some to be of so great an extent, that if it were thoroughly explored it would be regarded as a fifth part of the world."

It was in 1606 that Torres, with a ship commissioned by the Spanish Government of Peru, parted from his companion Quiros (after their discovery of Espiritu Santo and the New Hebrides), and sailed from east to west through the strait which bears his name; while in the same year the peninsula of Cape York was touched at by a vessel called the "Duyfhen" or "Dove" from the Dutch colony of Bantam in Java, but this was understood at the time to form a part of the neighboring island of New Guinea. The Dutch continued their attempts to explore the unknown land, sending out in 1616 the ship "Endraght," commanded by Dirk Hartog, which sailed along the west coast of Australia from lat. 26° 30′ to 23° S. This expedition left on an islet near Shark's Bay a record of its visit engraved on a tin plate, which was found there in 1801. The "Pera" and "Arnhem," Dutch vessels from Amboyna, in 1618 explored the Gulf of Carpentaria, giving to its westward peninsula, on the side opposite to Cape York, the name of Arnhem Land. The name of Carpentaria was also bestowed on this vast gulf in compliment to Peter Carpenter, then governor of the Dutch East India Company. In 1627 the "Guldene Zeepard," carrying Peter Nuyts to the embassy in Japan, sailed along the south coast from Cape Leeuwin, and sighted the whole shore of the Great Bight. But alike on the northern and southern sea-board, the aspect of New Holland, as it was then called, presented an uninviting appearance.

An important era of discovery began with Tasman's voyage of 1642. He, too, sailed from Batavia; but, first crossing the Indian Ocean to the Mauritus, he descended to the 44th parallel of S. lat., recrossing that ocean to the east. By taking this latter course he reached the island which now bears his name, but which he called Van Diemen's Land, after the Dutch governor of Batavia. In 1644 Tasman made another attempt, when he explored the northwest coast of Australia, from Arnhem Land to the 22d degree of latitude, approaching the locality of Dirk Hartog's discoveries of 1616. He seems to have landed at Cape Ford, near Victoria River, also in Roebuck Bay, and again near Dampier's Archipelago. But the hostile attitude of the natives, whom he denounced as a malicious and miserable race of savages, prevented his seeing much of the new country; and for half a century after this no fresh discoveries were made.

The English made their first appearance on the Australian coast in 1688, when the north-western shores were visited by the famous buccaneer Captain William Dampier, who spent five weeks ashore near Roebuck Bay. A few years later (1697) the Dutch organised another expedition under Vlamingh, who, first touching at Swan River on the west coast, sailed northward to Shark's Bay, where Hartog had been in 1616. Dampier, two years later, visited the same place, not now as a roving adventurer, but with a commission from the English Admiralty to pursue his Australian researches. This enterprising navigator, in the narrative of his voyages, gives an account of the trees, birds, and reptiles he observed, and of his encounters with the natives. But he found nothing to invite a long stay. There was yet another Dutch exploring squadron on that coast in 1705, but the results were of little importance.

It was Captain Cook, in his voyages from 1769 to 1777, who communicated the most important discoveries, and first opened to European enterprise and settlement the Australian coasts. In command of the bark "Endeavour," 370 tons burden, and carrying 85 persons, amongst whom were Sir Joseph Banks and Dr. Solander, returning from the Royal Society's expedition to observe the transit of Venus, Cook visited both New Zealand and New South Wales. He came upon the Australian mainland in April 1770, at a point named after Lieutenant Hicks, who first sighted it, on the shore of Gipps' Land, Victoria, S. lat. 38°, E. long. 148° 53′. From this point, in a coasting voyage not without peril when entangled in the barrier reefs of coral, the little vessel made its way up the whole length of the eastern side of Australia, rounding Cape York, and crossing Torres Strait to New Guinea. In his second expedition of Australasian discovery, which was sent out in 1773, Cook's ship, the "Resolute," started in company with the "Adventure," commanded by Captain Furneaux. The two vessels separated, and Cook went to New Zealand, while Furneaux examined some parts of Tasmania and Bass Strait. The third voyage of Cook brought him, in 1777, both to Tasmania and to New Zealand.

Next to Cook, twenty or thirty years after his time, the names of Bass and Flinders are justly honored for continuing the work of maritime discovery he had so well begun. To their courageous and persevering efforts, begun at their private risk, is due the correct determination of the shape both of Tasmania and the neighboring continent. The French admiral Entrecasteaux, in 1792, had made a careful examination of the inlets at the south of Tasmania, and in his opinion the opening between Tasmania and Australia was only a deep bay. It was Bass who discovered it to be a broad strait, with numerous small islands. Captain Flinders survived his friend Bass, having been associated with him in 1798 in this and other useful adventures. Flinders afterwards made a complete survey in detail of all the Australian coasts, except the west and northwest. He was captured, however, by the French during the war, and detained a prisoner in Mauritius for seven years.

The shores of what is now the province of Victoria were explored in 1800 by Captain Grant, and in 1802 by Lieutenant Murray, when the spacious land-locked bay

of Port Phillip was discovered. New South Wales had already been colonised, and the town of Sydney founded at Port Jackson in 1788. West Australia had long remained neglected, but in 1837, after the settlement at Swan River, a series of coast surveys was commenced in H.M.S. "Beagle." These were continued from 1839 to 1843 by Mr. Stokes, and furnished an exact knowledge of the western, north-western, and northern shores, including four large rivers.

Inland Exploration.—The geographical position of the Australian continent had now been sufficiently determined, and what remained for discovery was sought, not as hitherto by coasting along its shores and bays, but by striking into the vast tract of *terra incognita* that occupied the interior. The colony of New South Wales had been founded in 1788, but for twenty-five years its settlers were acquainted only with a strip of country 50 miles wide, between the Blue Mountains and the sea-coast, for they scarcely ever ventured far inland from the inlets of Port Jackson and Botany Bay. Mr. Bass, indeed, once while waiting for his vessel, made an attempt to cross the Blue Mountains, and succeeded in discovering the River Grove, a tributary of the Hawkesbury, but did not proceed further. An expedition was also conducted by Governor Hunter along the Nepean River west of the settlement, while Lieutenant Bareiller, in 1802, and Mr. Caley, a year or two later, failed in their endeavor to surmount the Blue Mountain range. This formidable ridge attains a height of 3400 feet, and being intersected with precipitous ravines 1500 feet deep, presented a bar to these explorers' passage inland. At last, in 1813, when a summer of severe drought had made it of vital importance to find new pastures, three of the colonists, Messrs. Wentworth and Blaxland and Lieutenant Lawson, crossing the Nepean at Emu Plains, gained sight of an entrance, and ascending the summit of a dividing ridge, obtained a view of the grassy valley of the Fish River. This stream runs westward into the Macquarie, which was discovered a few months afterwards by Mr. Evans, who followed its course across the fertile plains of Bathurst.

In 1816 Lieutenant Oxley, R.N., accompanied by Mr. Evans and Mr. Cunningham, the botanist, conducted an expedition of great interest down the Lachlan River, 300 miles to the north-west, reaching a point 34° S. lat., and 144° 30′ E. long. On his return journey Oxley again struck the Macquarie River at a place he called Wellington, and from this place in the following year he organised a second expedition in hopes of discovering an inland sea. He was, however, disappointed in this, as after descending the course of the Macquarie below Mount Harris, he found that the river ended in an immense swamp overgrown with reeds. Oxley now turned aside—led by Mr. Evans' report of the country eastward—crossed the Arbuthnot range, and traversing the Liverpool Plains, and ascending the Peel and Cockburn Rivers to the Blue Mountains, gained sight of the open sea, which he reached at Port Macquarie. A valuable extension of geographical knowledge had been gained by this circuitous journey of more than 800 miles. Yet its result was a disappointment to those who had looked for means of inland navigation by the Macquarie River, and by its supposed issue in a Mediterranean sea.

During the next two or three years public attention was occupied with Captain King's maritime explorations of the north-west coast in three successive voyages, and by explorations of West Australia in 1821. These steps were followed by the foundation of a settlement on Melville Island, in the extreme north, which, however, was soon abandoned. In 1823 Lieutenant Oxley proceeded to Morton Bay and Port Curtis, the first place 7° north of Sydney, the other 10°, to choose the sight of a new penal establishment. From a shipwrecked English sailor he met with, who had lived with the savages, he heard of the river Brisbane. About the same time, in the opposite direction, south-west of Sydney, a large extent of the interior was revealed. The River Murrumbidgee—which unites with the Lachlan to join the great River Murray—was traced by Mr. Hamilton Hume and Mr. Hovell into the country lying north of the province of Victoria, through which they made their way to Port Phillip. In 1827 and the two following years, Mr. Cunningham prosecuted his instructive explorations on both sides of the Liverpool range, between the upper waters of the Hunter and those of the Peel and other tributaries of the Brisbane north of New South Wales. Some of his discoveries, including those of Pandora's Pass and the Darling Downs, were of great practical utility.

By this time much had thus been done to obtain an acquaintance with the eastern parts of the Australian continent, although the problem of what could become of the large rivers flowing north-west and south-west into the interior was still unsolved. With a view to determine this question, Governor Sir Ralph Darling, in the year 1828, sent out the expedition under Captain Charles Sturt, who proceeding first to the marshes at the end of the Macquarie River, found his progress checked by the dense mass of reeds in that quarter. He therefore turned westward, and struck a large river, with many affluents, to which he gave the name of the Darling. This river, flowing from north-east to south-west, drains the marshes in which the Macquarie and other streams from the south appeared to be lost. The course of the Murrumbidgee, a deep and rapid river, was followed by the same eminent explorer in his second expedition in 1831 with a more satisfactory result. He travelled on this occasion nearly 2000 miles, and discovered that both the Murrumbidgee, carrying with it the waters of the Lachlan morass, and likewise the Darling, from a more northerly region, finally joined another and larger river. This stream, the Murray, in the upper part of its course, runs in a north-westerly direction, but afterwards turning southwards, almost at a right angle, expands into Lake Alexandrina on the south coast, about 60 miles S.E. of the town of Adelaide, and finally enters the sea at Encounter Bay in E. long. 139°.

After gaining a practical solution of the problem of the destination of the westward-flowing rivers, Sir Thomas Mitchell, in 1835, led an expedition northward to the upper branches of the Darling; but the party meeting with a sad disaster in the death of Mr. Cunningham, the eminent botanist, who was murdered by the natives on the Bogan River, further exploration of that region was left to be undertaken by Dr. Leichardt, nine years later, and by the son of Sir Thomas Mitchell. Meantime, from the new colony of Adelaide, South Australia, on the shores of Gulf St. Vincent, a series of adventurous journeys to the north and to the west was commenced by Mr. Eyre, who explored a country much more difficult of access, and more forbidding in aspect, than the "Riverina" of the eastern provinces. He performed in 1840 a feat of extraordinary personal daring, travelling all the way along the barren sea-coast of the Great Australian Bight, from Spencer Gulf to King George's Sound. Mr. Eyre also explored the interior north of the head of Spencer Gulf, where he was misled, however, by appearances to form an erroneous theory about the water-surfaces named Lake Torrens. It was left to the veteran explorer, Sturt, to achieve the arduous enterprise of penetrating from the Darling northward to the very centre of the continent. This

was in 1845, the route lying for the most part over a stony desert, where the heat (reaching 131° Fahr.), with scorching winds, caused much suffering to the party. The most northerly point reached by Sturt on this occasion was about S. lat. 24° 25′. His unfortunate successors, Burke and Wills, travelled through the same district sixteen years later; and other expeditions were organised, both from the north and from the south, which aimed at learning the fate of these travellers, as well as that of Dr. Leichardt. These efforts completed our knowledge of different routes across the entire breadth of Australia, in the longitude of the Gulf of Carpentaria, while the enterprising journeys of MacDouall Stuart, a companion of Sturt, obtained in 1862 a direct passage from South Australia northward to the shores of the Malayan Sea. This route has been utilised by the construction of an overland telegraph from Adelaide to the northern coast.

A military station having been fixed by the British Government at Port Victoria, on the coast of Arnhem Land, for the protection of shipwrecked mariners on the north coast, it was thought desirable to find an overland route between this settlement and Moreton Bay, in what then was the northern portion of New South Wales, now called Queensland. This was the object of Dr. Leichardt's expedition in 1844, which proceeded first along the banks of the Dawson and the Mackenzie, tributaries of the Fitzroy River in Queensland. It thence passed farther north to the Burdekin, ascending to the source of that river, and turned westward across a table-land, from which there was an easy descent to the Gulf of Carpentaria. Skirting the low shores of this gulf all the way round its upper half to the Roper, Leichardt crossed Arnhem Land to the Alligator River, which he descended to the western shore of the peninsula, and arrived at Port Victoria, otherwise Port Essington, after a journey of 3000 miles, performed within a year and three months. In 1847 Leichardt undertook a much more formidable task, that of crossing the entire continent from east to west. His starting point was on the Fitzroy Downs, north of the River Condamine, in Queensland, between the 26th and 27th degrees of S. latitude. But this eminent explorer had not proceeded far into the interior before he met his death, his last despatch dating from the Cogoon, April 3, 1848. In the same region from 1845 to 1847, Sir Thomas Mitchell and Mr. E. B. Kennedy explored the northern tributaries of the Darling, and a river in S. lat. 24°, named the Barcoo or Victoria, which flows to the south-west. This river was more thoroughly examined by Mr. A. C. Gregory in 1858. Mr. Kennedy lost his life in 1848, being killed by the natives while attempting to explore the peninsula of Cape York, from Rockingham Bay to Weymouth Bay.

Among the performances of less renown, but of much practical utility in surveying and opening new paths through the country, we may mention that of Captain Banister, showing the way across the southern part of West Australia, from Swan River to King George's Sound, and that of Messrs. Robinson and G. H. Haydon in 1844, making good the route from Port Phillip to Gipps' Land with loaded drays, through a dense tangled scrub, which had been described by Strzelecki as his worst obstacle. Again, in West Australia there were the explorations of the Arrowsmith, the Murchison, the Gascoyne, and the Ashburton Rivers, by Captain Grey, Mr. Roe, Governor Fitzgerald, Mr. R. Austin, and the brothers Gregory, whose discoveries have great importance from a geographical point of view.

These local researches, and the more comprehensive attempts of Leichardt and Mitchell to solve the chief problems of Australian geography, must yield in importance to the grand achievement of Mr. Stuart in 1862. The first of his tours independently performed, in 1858 and 1859, were around the South Australian lakes, namely, Lake Torrens, Lake Eyre, and Lake Gairdner. These waters had been erroneously taken for parts of one vast horseshoe or sickle-shaped lake, only some twenty miles broad, believed to encircle a large portion of the inland country, with drainage at one end by a marsh into Spencer Gulf. The mistake, shown in all the old maps of Australia, had originated in a curious optical illusion. When Mr. Eyre viewed the country from Mount Deception in 1840, looking between Lake Torrens and the lake which now bears his own name, the refraction of light from the glittering crust of salt that covers a large space of stony or sandy ground produced an appearance of water. The error was discovered, after eighteen years, by the explorations of Mr. Babbage and Major Warburton in 1858, while Mr. Stuart, about the same time, gained a more complete knowledge of the same district.

A reward of £10,000 having been offered by the Legislature of South Australia to the first man who should traverse the whole continent from south to north, starting from the city of Adelaide, Mr. Stuart resolved to make the attempt. He started in March 1860, passing Lake Torrens and Lake Eyre, beyond which he found a pleasant, fertile country till he crossed the M'Donnell range of mountains, just under the line of the tropic of Capricorn. On the 23d of April he reached the mountain in S. lat. nearly 22°, and E. long. nearly 134°, which is the most central marked point of the Australian continent, and has been named Central Mount Stuart. Mr. Stuart did not finish his task on this occasion, on account of indisposition and other causes. But the 18th degree of latitude had been reached, where the watershed divided the rivers of the Gulf of Carpentaria from the Victoria River, flowing towards the north-west coast. He had also proved that the interior of Australia was not a stony desert, like the region visited by Stuart in 1845. On the first day of the next year, 1861, Mr. Stuart again started for a second attempt to cross the continent, which occupied him eight months. He failed, however, to advance further than one geographical degree north of the point reached in 1860, his progress being arrested by dense scrubs and the want of water.

Meanwhile, in the province of Victoria, by means of a fund subscribed among the colonists and a grant by the Legislature, the ill-fated expedition of Messrs. Burke and Wills was started. It made for the Barcoo, with a view to reach the Gulf of Carpentaria by a northerly course midway between Stuart's track to the west and Leichardt's to the east. The leading men of the party were Mr. Robert O'Hara Burke, an officer of police, and Mr. William John Wills, of Melbourne observatory. Messrs. Burke and Wills, with two men named Gray and King, left the others behind at the Barcoo on 16th December 1860, and proceeded, with a horse and six camels, over the desert traversed by Stuart fifteen years before. They got on in spite of great difficulties, past the M'Kinlay range of mountains, S. lat. 21° and 22°, and then reached the Flinders River, which flows into the head of the Gulf Carpentaria. Here, without actually standing on the sea-beach of the northern shore, they met the tidal waters of the sea. On February 23, 1861, they commenced the return journey, having in effect accomplished the feat of crossing the Australian continent. Unhappily, three of the party perished on the road home. Gray, who had fallen ill, died on the 16th of April. Five days later, Burke, Wills, and King had repassed the desert to the place on Cooper Creek (the Barcoo, S. lat. 27° 40′, E. long. 140° 30′), where

they had left the depot, with the rest of the expedition. Here they experienced a cruel disappointment. The depot was abandoned; the men in charge had quitted the place the same day, believing that Burke and those with him were lost. The main body of the expedition, which should have been led up by a Mr. Wright, from Menindie, on the Darling, was misconducted and fatally delayed. Burke, Wills, and King, when they found themselves so fearfully left alone and unprovided in the wilderness, wandered about in that district till near the end of June. They subsisted miserably on the bounty of some natives, and partly by feeding on the seeds of a plant called nardoo. At last both Wills and Burke died of starvation. King, the sole survivor, was saved by meeting the friendly blacks, and was found alive in September by Mr. A. W. Howitt's party, sent on purpose to find and relieve that of Burke.

Four other parties, besides Howitt's, were sent out that year from different Australian provinces. Three of them, respectively commanded by Mr. Walker, Mr. Landsborough, and Mr. Norman, sailed to the north, where the latter two landed on the shores of the Gulf of Carpentaria, while Mr. Walker marched inland from Rockhampton. The fourth party, under Mr. J. M'Kinlay, from Adelaide, made for the Barcoo by way of Lake Torrens. By these means, the unknown region of Mid Australia was simultaneously entered from the north, south, east, and west, and important additions were made to geographical knowledge. Landsborough crossed the entire continent from north to south, between February and June 1862; and M'Kinlay, from south to north, before the end of August in that year. The interior of New South Wales and Queensland, all that lies east of the 140th degree of longitude, was examined. The Barcoo and its tributary streams were traced from the Queensland mountains, holding a south-westerly course to Lake Eyre in South Australia; the Flinders, the Gilbert, the Gregory, and other northern rivers watering the country towards the Gulf of Carpentaria were also explored. These valuable additions to Australian geography were gained through humane efforts to relieve the lost explorers. The bodies of Burke and Wills were recovered and brought to Melbourne for a solemn public funeral, and a noble monument has been erected to their honor.

Mr. Stuart, in 1862, made his third and final attempt to traverse the continent from Adelaide along a central line, which, inclining a little westward, reaches the north coast of Arnhem Land, opposite Melville Island. He started in January, and on April 7 reached the farthest northern point, near S. lat. 17°, where he had turned back in May of the preceding year. He then pushed on, through a very thick forest, with scarcely any water, till he came to the streams which supply the Roper, a river flowing into the western part of the Gulf of Carpentaria. Having crossed a table-land of sandstone which divides these streams from those running to the western shores of Arnhem Land, Mr. Stuart, in the month of July, passed down what is called the Adelaide River of North Australia. Thus he came at length to stand on the verge of the Indian Ocean; "gazing upon it," a writer has said, "with as much delight as Balboa, when he had crossed the Isthmus of Darien from the Atlantic to the Pacific." The line crossing Australia which was thus explored has since been occupied by the electric telegraph connecting Adelaide, Melbourne, Sydney, and other Australian cities with London.

A third part, at least, of the interior of the whole continent, between the central line of Stuart and the known parts of West Australia, from about 120° to 134° E. long., an extent of half a million square miles, still remained a blank in the map. But the two expeditions of 1873, conducted by Mr. Gosse and Colonel Egerton Warburton, have made a beginning in the exploration of this *terra incognita* west of the central telegraph route. That line of more than 1800 miles, having its southern extremity at the head of Spencer Gulf, its northern at Port Darwin, in Arnhem Land, passes Central Mount Stuart, in the middle of the continent, S. lat. 22°, E. long. 134°. Mr. Gosse, with men and horses provided by the South Australian Government, started on April 21 from the telegraph station fifty miles south of Central Mount Stuart, to strike into West Australia. He passed the Reynolds range and Lake Amadeus in that direction, but was compelled to turn south, where he found a tract of well-watered grassy land. A singular rock of conglomerate, 2 miles long, 1 mile wide, and 1100 feet high, with a spring of water in its centre, struck his attention. The country was mostly poor and barren, sandy hillocks, with scanty growth of spinifex. Mr. Gosse, having travelled about 600 miles, and getting to 26° 32′ S. lat. and 127° E. long., two degrees within the West Australian boundary, was forced to return. Meanwhile a more successful attempt to reach the western coast from the centre of Australia has been made by Colonel Warburton, with thirty camels, provided by Mr. T. Elder, M.L.C., of South Australia. Leaving the telegraph line at Alice Springs (23° 40′ S. lat., 133° 14′ E. long.), 1120 miles north of Adelaide City, Warburton succeeded in making his way to the De Grey River, West Australia. Overland routes have now been found possible, though scarcely convenient for traffic, between all the widely separated Australian provinces. In Northern Queensland, also, there have been several recent explorations, with results of some interest. That performed by Mr. W. Hann, with Messrs. Warner, Tate, and Taylor, in 1873, related to the country north of the Kirchmer range, watered by the Lynd, the Mitchell, the Walsh, and the Palmer Rivers, on the east side of the Gulf of Carpentaria. The coasting expedition of Mr. G. Elphinstone Dalrymple, with Messrs. Hill and Johnstone, finishing in December 1873, effected a valuable survey of the inlets and navigable rivers in the Cape York peninsula. The Endeavor River in S. lat. 16°, which was visited by Captain Cook a hundred years ago, seems capable of being used for communication with the country inland. A newly discovered river, the Johnstone or Gladys, is said to flow through a very rich land, producing the finest cedars, with groves of bananas, nutmeg, ginger, and other tropical plants. The colonial geologists predict that the north-east corner of Australia will be found to possess great mineral treasures. At the opposite extremity of the continent, its south-west corner, a tour lately made by Mr. A. Forrest, Government surveyor, from the Swan River eastward, and thence down to the south coast, has shown the poorness of that region. The vast superiority of eastern Australia to all the rest is the most important practical lesson taught by the land-exploring labors of the last half century.

Physical Description.—The continent of Australia, with a circumference of nearly 8000 miles, presents a contour wonderfully devoid of inlets from the sea, except upon its northern shores, where the coast line is largely indented. The Gulf of Carpentaria, situated in the north, is enclosed on the east by the projection of Cape York, and on the west by Arnhem Land, and forms the principal bay on the whole coast, measuring about 6° of long. by 6° of lat. Further to the west, Van Diemen's Gulf, though much smaller, forms a better protected bay, having Melville Island between it

and the ocean; while beyond this Queen's Channel and Cambridge Gulf form inlets about S. lat. 14° 50′. On the north-west of the continent the coast line is much broken, the chief indentations being Admiralty Gulf, Collier Bay, and King Sound, on the shores of Tasman Land. Western Australia, again, is not favored with many inlets, — Exmouth Gulf and Shark Bay being the only bays of any size. The same remark may be made of the rest of the sea-board; for, with the exception of Spencer Gulf, the Gulf of St. Vincent, and Port Philip, on the south, and Moreton Bay, Hervey Bay, and Broad Sound, in the east, the coast line is singularly uniform.

The conformation of the interior of Australia is very peculiar, and may perhaps be explained by the theory of the land having been, at a comparatively recent period, the bed of an ocean. The mountain ranges parallel to the east and west coasts would then have existed as the cliffs and uplands of many groups of islands, in widely scattered archipelagoes resembling those in the Pacific. The singular positions and courses of some of the rivers lend force to this supposition. The Murray and its tributaries, the Murrumbidgee, the Lachlan, and the Darling, rising from the mountains on the east coast, flow inwards so far that they were at one time supposed to issue in a central sea. They do, in fact, spend their waters in a shallow lake; but this is not far from the south coast, and is provided with an outlet to the ocean. The Macquarie and the Lachlan merge in extensive swamps, and their beds in the dry season become a mere chain of ponds. This agrees with the idea that the whole country was a sea-bottom, which has scarcely yet assumed the character of permanent dry land, while another proof consists in the thinness and sterility of the soil in the low lands.

Along the entire line of the east coast there extends a succession of mountain ranges from Portland, in Victoria to Cape York in the extreme north, called in different parts the Australian Grampians, the Australian Alps, the Blue Mountains, the Liverpool Range, and other names. These constitute, like the Andes of South America, a regular Cordillera, stretching from north to south 1700 miles in length, with an average height of 1500 feet above the sea. The rivers flowing down the eastern slope, having but short courses before they reach the sea, are of a more determined character than those which take a westerly and inland direction. They cut their way through the sandstone rocks in deep ravines; but from their tortuous and violent course, and from the insufficient volume of water, they are unfit for navigation.

Minerals.— The useful and precious metals exist in considerable quantities in each of the five provinces of Australia. New South Wales has abundance of gold, copper, iron, and coal, as well as silver, lead, and tin. The mineral riches of Victoria, though almost confined to gold, have been the main cause of her rapid progress. South Australia possesses the most valuable copper mines. Queensland ranks next to the last-named province for copper, and excels her neighbors in the production of tin, while gold, iron, and coal are also found in considerable quantities. In Western Australia mines of lead, silver, and copper have been opened; and there is much ironstone.

The discovery of gold in New South Wales and Victoria took place in 1851, and during the next twenty years Victoria exported 40,750,000 oz. of the precious metal, while New South Wales, from 1851 to 1871, exported nearly 10,000,000 ounces. The Queensland gold mines, since 1860, have displayed increasing promise; up to the end of 1872 they had yielded rather less than 1,000,000 ounces; but much was expected, at a more recent date, from the Palmer River and other districts of the north. The yearly value of the aggregate gold exports of Australia, on the average of fifteen years, has been £10,000,000. Victoria alone has produced gold to the value of £170,000,000. The alluvial gold-fields, in which the early diggers, with the simplest tools, obtained for a short time large quantities of the coveted ore, seem now to be mostly exhausted. It is in the quartz formations of the mountain ranges, or in those at a great depth underground, reached by the sinking of shafts and regular mining operations, that Australian gold is henceforth to be chiefly procured. There are mines in Victoria 1000 feet deep, as at Clunes, and many others from 300 to 600 feet deep.

The copper mines of Burra Burra, in South Australia, proved very profitable some twenty-five years ago, yielding in a twelvemonth ore to the value of £350,000, and the Moonta mines, in 1872, were scarcely less productive. The province of South Australia, in that year, exported copper to the amount of £800,000. Queensland, in 1873, produced one-fourth that quantity. Tin, an article of great mercantile interest, is divided between Queensland and New South Wales in a frontier district, two-thirds of the extent of which belongs to the Darling Downs, within the last-mentioned province. There is a little tin, also, in some parts of Victoria. Lead, silver, and cinnabar have been obtained not only in New South Wales, but likewise in Western Australia.

The abundance of good iron ore, in convenient vicinity to thick beds of excellent coal, ensures a future career of manufacturing prosperity to New South Wales, and not less to Queensland. The country north and south of Sydney, and west of that city 100 miles inland to the dividing range of mountains, is all of Carboniferous formation. At the mouth of the Hunter River, from the port and town of Newcastle, coal was exported in 1873 to the value of £1,000,000 sterling. The collieries there taken up have an extent of 35,000 acres, but the area of the coal-field is officially estimated at 10,000,000 acres, and the seams are 9 feet to 11 feet thick. The quality of this coal is said to be equal to that of Great Britain for most furnace purposes, and it is generally used by steamships in the Pacific and Chinese navigation. Next in importance are the Wollongong collieries, south of Sydney, and those of Hartley, Maitland, and Berrima, now connected by railway with the capital.

In each of the places above named there is iron of a superior quality, the working of which to advantage cannot be long delayed. On the Illawarra coast it is found close to the finest bituminous coal, and to limestone. The iron of New South Wales is mostly hæmatite, and the ironstone contains from 60 to 70 per cent. of ore.

Among other mineral products of the same region are cannel coal and shale yielding kerosene oil. This is a recognised article of export from New South Wales to the other colonies. It is hardly worth while to speak of diamonds, opals, and precious stones, but they are often picked up, though of small size, along the Mudgee and Abercrombie Rivers, and at Beechworth and Daylesford, in Victoria.

Climate.— The Australian continent, extending over 28° of latitude, might be expected to show a considerable diversity of climate. In reality, however, it experiences fewer climatic variations than the other great continents, owing to its distance (28°) from the Antarctic circle and 11° from the equator. There is, besides, a powerful determining cause in the uniform character and undivided extent of its dry interior plain.

With regard to the temperature, the northern regions of the continent being situated within the tropic of Capri-

corn, resemble the parts of South America and South Africa, that are situated in the corresponding latitudes. The seaward districts of New South Wales seem in this respect to be like Southern Europe. The mean annual temperature of Sydney is 62° 4′ Fahr., almost equal to that of Lisbon in Portugal.

In winter, in New South Wales, the prevalent winds blow from the west, with occasional storms of wind and rain from the eastward, while the autumn months have much cloudy weather, not accompanied by rain. January and February are the hottest months of summer, and July the coldest month of winter.

The amount of humidity in the air is liable to great and rapid variations in the summer months. It is sometimes reduced as much as 60 per cent. within a few hours, by the effect of hot dry winds. But this is compensated by an access of moisture upon a change of wind. The annual average rainfall at Melbourne, which for thirty years is stated at 25.66 inches, does not seem less than that of places in similar latitudes in other parts of the world. Yet it proves inadequate, because of the great amount of evaporation, estimated by Professor Neumayer at 42 inches.

The spring season in Victoria, consisting of the months of September, October, and November, is genial and pleasant, with some rain. The summer — December, January, and February — is generally hot and dry, though its first month is sometimes broken by storms of cold wind and heavy rain. In February the north winds assume the character of siroccos, and bush-fires often devastate the grassy plains and forests of the inland country. The autumn months — March, April, and May — are, in general, the most agreeable; and at this season vegetable life is refreshed, and puts forth a growth equal to that of the spring. The winter is June, July, and August, with strong, dry, cold winds from the north, alternating with frequent rain from the opposite quarter; there is little ice or snow, except in the mountain districts.

Botany. — A probable computation of the whole number of distinct vegetable species indigenous to Australia and Tasmania has been made by Baron Ferdinand von Müller, the Government botanist at Melbourne. He believes that, omitting the minute fungi, there will not be found above 10,000 species of Australian plants.

The eastern parts of this continent, New South Wales and Queensland, are very much richer, both in their botany and their zoology, than any other parts of Australia. Much was done here for the former science, half a century ago, by Mr. Allan Cunningham, whose monumental obelisk fitly stands in the Botanic Garden at Sydney. In general the growth of trees on the north and north-west coasts is wanting in size and regularity, compared with their growth in eastern Australia.

From the extreme aridity of the climate in most parts of northern Australia, there is a singular absence of mosses and lichens. North-west Australia possesses, in the *Adansonia Gregorii*, or gouty-stem tree, a counterpart of the West African baobab, or monkey-bread tree. It is worthy of remark that, with but few exceptions, the Australian trees are evergreens. They also show a peculiar reverted position of their leaves, which hang vertically, turning their edges instead of their sides towards the sun; and the eucalypti have the peculiarity of shedding their bark annually instead of their leaves. In Australia the native species of lily, tulip, and honeysuckle appear as standard trees of considerable size. The native grasses do not form a continuous and even greensward, as in Europe, but grow in detached clumps or tufts. None of the cereal plants are indigenous, and very few of the fruits or roots that supply human food; but many Australian plants are likely to be valuable for medicinal or chemical manufactures.

This continent, as might be expected, has some of the same botanical families that occupy South Africa, Polynesia, and South America.

Animals. — The zoology of Australia and Tasmania presents a very conspicuous point of difference from that of other regions of the globe, in the prevalence of non-placental mammalia. The vast majority of the mammalia are provided with an organ in the uterus, by which, before the birth of their young, a vascular connection is maintained between the embryo and the parent animal. There are two orders, the Marsupialia and the Monotremata, which do not possess this organ. Both these are found in Australia, to which region indeed they are not absolutely confined; but the marsupials alone constitute two-thirds of all the Australian species of mammals. It is the well-known peculiarity of this order that the female has a pouch or fold of skin upon her abdomen, in which she can place the young for suckling within reach of her teats. The opossum of America is the only species out of Australasia which is thus provided. Australia is inhabited by at least 110 different species of marsupials, which have been arranged in five tribes, according to the food they eat, viz., the root-eaters (wombats), the fruit-eaters (phalangers), the grass-eaters (kangaroos), the insect-eaters (bandicoots), and the flesh-eaters (native cats and rats).

The kangaroo (Macropus) and most of its congeners show an extraordinary disposition of the hind limbs to the fore part of the body. The rock wallabies again have short tarsi of the hind legs, with a long pliable tail for climbing, like that of the tree kangaroo of New Guinea, or that of the jerboa. Of the larger kangaroos, which attain a weight of 200 lb. and more, eight species are named, only one of which is found in West Australia. There are some twenty smaller species in Australia and Tasmania, besides the rock wallabies and the hare kangaroos; these last are wonderfully swift, making clear jumps eight or ten feet high. To this agility they owe their preservation from the prairie fires, which are so destructive in the interior during seasons of drought. In the rat kangaroo there is not the same disproportion of the limbs; it approaches more nearly to the bandicoot, of which seven species exist, from the size of a rat to that of a rabbit. The carnivorous tribe of marsupials, the larger species at any rate, belong more to Tasmania, which has its "tiger" and its "devil." But the native cat, or dasyurus, is common to every part of Australia. Several different species of pouched rats and mice, one or two living in trees, are reckoned among the flesh-eaters. Fossil bones of extinct kangaroo species are met with, which must have been of enormous size, twice or thrice that of any species now living.

We pass on to the other curious order of non-placental mammals, that of the Monotremata, so called from the structure of their organs of evacuation with a single orifice, as in birds. Their abdominal bones are like those of the marsupials; and they are furnished with pouches for their young, but have no teats, the milk being distilled into their pouches from the mammary glands. Australia and Tasmania possess two animals of this order, — the echidna, or spiny ant-eater (hairy in Tasmania), and the *Platypus anatinus*, the duck-billed water-mole, otherwise named the *Ornithorhynchus paradoxus*. This odd animal is provided with a bill or beak, which is not, like that of a bird, affixed to the skeleton, but is merely attached to the skin and muscles.

Australia has no apes, monkeys, or baboons, and no ruminant beasts. The comparatively few indigenous

placental mammals, besides the dingo, or wild dog — which, however, may have come from the islands north of this continent — are of the bat tribe and of the rodent or rat tribe. There are four species of large fruit-eating bats, called flying foxes, twenty of insect-eating bats, above twenty of land-rats, and five of water-rats. The sea produces three different seals, which often ascend rivers from the coast, and can live in lagoons of fresh water; many cetaceans, besides the "right whale" and sperm whale; and the dugong, found on the northern shores, which yields a valuable medicinal oil.

The birds of Australia in their number and variety of species (reckoned at 960) may be deemed some compensation for its poverty of mammals; yet it will not stand comparison in this respect with regions of Africa and South America in the same latitudes. The black swan of West Australia was thought remarkable when discovered as belying an old Latin proverb. There is also a white eagle. The vulture is wanting. Sixty species of parrots, some of them very handsome, are found in Australia. The emu, a large bird of the order Cursores, or runners, corresponds with the African and Arabian ostrich, the rhea of South America, and the cassowary of the Moluccas and New Guinea.

The ornithology of New South Wales and Queensland is more varied and interesting than that of the other provinces.

As for reptiles, Australia has a few tortoises, all of one family and not of great size. The "leathery turtle," which is herbivorous, and yields abundance of oil, has been caught at sea off the Illawarra coast so large as 9 feet in length. The saurians or lizards are numerous, chiefly on dry sandy or rocky ground in the tropical region. The great crocodile of Queensland is 30 feet long; there is a smaller one, 6 feet long, to be met with in shallow lagoons of the interior. The monitor, or fork-tongued lizard, which burrows in the earth, climbs, and swims, is said to grow to a length of 8 or 9 feet. This species, and many others do not extend to Tasmania.

The snakes are reckoned at sixty-three species, of which forty-two are venomous, but only five dangerous. North Queensland has many harmless pythons. There are forty or fifty different sorts of frogs; the commonest is distinguished by its blue legs and bronze or gold back; the largest is bright green; while the tree-frog has a loud shrill voice, always heard during rain.

The Australian seas and rivers are inhabited by many fishes of the same genera as exist in the southern parts of Asia and Africa. Of those peculiar to Australian waters may be mentioned the arripis, represented by what is called among the colonists a salmon trout. A very fine fresh-water fish is Murray cod, which sometimes weighs 100 lb.; and the golden perch, found in the same river, has rare beauty of color. Among the sea fish, the snapper is of great value as an article of food, and its weight comes up to 50 lb. This is the *Pagrus unicolor*, of the family of Sparidæ, which includes also the bream. Its colors are beautiful, pink and red with a silvery gloss; but the male as it grows older takes on a singular deformity of the head, with a swelling in the shape of a monstrous human-like nose.

Aborigines.—The Papuan, Melanesian, or Australasian aborigines exhibit certain peculiarities which are not found in the African negro, to which they otherwise present some similarity. In the Australasian the forehead is higher, the under jaw less projecting, the nose, though flat and extended compared with that of the European, is less depressed than in the African. His lips are thick, but not protuberant; and the eyes are sunken, large, and black. The color of his skin is lighter — of a dusky hue — than that of the Negro. In stature he equals the average European, but tall men are rare, except in North Queensland; his body and limbs are well shaped, strongly jointed, and highly muscular. The hind parts are not, as in the African, excessively raised; and while the calf of the leg is deficient, the heel is straight. The natives of Papua have woolly spirally-twisted hair. Those of Tasmania, now exterminated, had the same peculiarity. But the natives of the Australian continent have straight or curly black hair. The men wear short beards and whiskers.

Their mental faculties, though probably inferior to those of the Polynesian copper-colored race, are not contemptible. They have much acuteness of perception for the relations of individual objects, but little power of generalisation. No word exists in their language for the general terms tree, bird, or fish; yet they have invented a name for every species of vegetable and animal they know. The grammatical structure of some North Australian languages has a considerable degree of refinement. The verb presents a variety of conjugations, expressing nearly all the moods and tenses of the Greek. There is a dual, as well as a plural form in the declension of verbs, nouns, pronouns, and adjectives. The distinction of genders is not marked, except in proper names of men and women. All parts of speech, except adverbs, are declined by terminational inflections. There are words for the elementary numbers, one, two, three; but "four" is usually expressed by "two-two;" then "five" by "two-three," and so on. They have no idea of decimals. The number and diversity of separate languages, not mere dialects, is truly bewildering. Tribes of a few hundred people, living within a few miles of each other, have often scarcely a phrase in common. This is more especially observed in New South Wales, a country much intersected by dividing mountain ranges. But one language is spoken all along the Rivers Murray and Darling, while the next neighbors of the Murray tribes, on both sides, are unable to converse with them.

It is, nevertheless, tolerably certain that all the natives of Australia belong to one stock. There appears reason to believe that their progenitors originally landed on the north-west coast, that of Cambridge Gulf or Arnhem Land, in canoes drifting from the island of Timor. They seem then to have advanced over the continent in three separate directions. From a comparison of their languages, the diversities of which have been already referred to, it appears that little aid is to be expected from them in ethnological grouping.

The natives of the north-eastern quarter — a tropical region of diversified surface, with many rivers and thick forests, as well as open highlands — are far superior in body, mind and social habits to those of the rest of Australia. They bear, in fact, most resemblance to their neighbors and kindred in the island of New Guinea, but are still below these in many important respects.

If a general view be taken of the tribes of Australia, and the state in which they existed independently of recent European intercourse, two or three extraordinary defects exhibit themselves. They never, in any situation, cultivated the soil for any kind of food-crop. They never reared any kind of cattle, or kept any domesticated animal except the dog, which probably came over with them in their canoes. They have nowhere built permanent dwellings, but contented themselves with mere hovels for temporary shelter. They have neither manufactured nor possessed any chattels beyond such articles of clothing, weapons, ornaments, and utensils as they might carry on their persons, or in the family store-bag for daily use. Their want of ingenuity and contrivance has, however, undoubtedly been promoted

by the natural poverty of the land in which the race settled.

The sole dress of both sexes in their aboriginal state is a cloak of skin or matting, fastened with a skewer, but opened on the right hand side. No headgear is worn, except sometimes a net to confine the hair, a bunch of feathers, or the tails of small animals. The bosom or back is usually tattoed, or rather scored with rows of hideous raised scars, produced by deep gashes at the age when youth comes to manhood or womanhood. Their dwellings, for the most part, are either bowers, formed of the branches of trees, or hovels of piled logs, loosely covered with grass or bark, which they can erect in an hour, wherever they encamp. But some huts of a more commodious and substantial form were seen by Flinders on the south-east coast in 1799, and by Captain King and Sir J. Mitchell on the north-east, where they no longer appear. The ingenuity of the race is mostly to be recognised in the manufacture of weapons of warfare and the chase. While the use of the bow and arrow does not seem to have occurred to them the spear and axe are in general use, commonly made of hard-wood; the hatchets of stone, and the javelins pointed with stone or bone. The peculiar weapon of the Australian is the boomerang, a curved blade of wood, of such remarkable construction, that it swerves from its direct course, sometimes returning so as to hit an object behind the thrower. Their nets, made by women, either of the tendons of animals or the fibres of plants, will catch and hold the strong kangaroo or the emu, or the very large fish of Australian rivers. Canoes of bent bark, for the inland waters, are hastily prepared at need; but the inlets and straits of the north-eastern sea-coast are navigated by larger canoes and rafts of a better construction.

The numbers of the native Australians are steadily diminishing. A remnant of the race exists in each of the provinces, while a few tribes still wander over the interior. Altogether it is computed that not more than about 80,000 aborigines remain on the continent.

Colonial History.—Of the five Australian provinces, that of New South Wales may be reckoned the oldest. It was in 1788, eighteen years after Captain Cook explored the east coast, that Port Jackson was founded as a penal station for criminals from England; and the settlement retained that character, more or less, during the subsequent fifty years, transportation being virtually suspended in 1839. The colony, however, from 1821 had made a fair start in free industrial progress.

By this time, too, several of the other provinces had come into existence. Van Diemen's Land, now called Tasmania, had been occupied as early as 1803. It was an auxiliary penal station under New South Wales, till in 1825 it became a separate province. From this island, ten years later, parties crossed Bass's Straits to Port Phillip, where a new settlement was shortly established, forming till 1851 a part of New South Wales, but now the richer and more populous colony of Victoria. In 1827 and 1829, an English company endeavored to plant a settlement at the Swan River, and this, added to a small convict station established in 1825 at King George's Sound, constituted Western Australia. On the shores of the Gulf St. Vincent, again, from 1835 to 1837, South Australia was created by another joint-stock company, as an experiment in the Wakefield scheme of colonisation.

Such were the political component parts of British Australia up to 1839. The earlier history, therefore, of New South Wales is peculiar to itself. Unlike the other mainland provinces, it was at first held and used chiefly for the reception of British convicts. When that system was abolished, the social conditions of New South Wales, Victoria, and South Australia became more equal. Previous to the gold discoveries of 1851 they may be included, from 1839, in a general summary view.

The first British governors at Sydney, from 1788, ruled with despotic power. They were naval or military officers in command of the garrison, the convicts, and the few free settlers. The duty was performed by such men as Capta.. Arthur Phillip, Captain Hunter, and others. In the twelve years' rule of General Macquarie, closing with 1821, the colony made a substantial advance. By means of convict labor roads and bridges were constructed, and a route opened into the interior beyond the Blue Mountains. A population of 30,000, three-fourths of them convicts, formed the infant commonwealth, whose attention was soon directed to the profitable trade of rearing fine wool sheep, first commenced by Mr. John M'Arthur in 1803.

During the next ten years, 1821–31, Sir Thomas Brisbane and Sir Ralph Darling, two generals of the army, being successively governors, the colony increased, and eventually succeeded in obtaining the advantages of a representative institution, by means of a legislative council. Then came General Sir Richard Bourke, whose wise and liberal administration proved most beneficial. New South Wales became prosperous and attractive to emigrants with capital. Its enterprising ambition was encouraged by taking fresh country north and south. In the latter direction, explored by Mitchell in 1834 and 1836, lay Australia Felix, now Victoria, including the well-watered, thickly-wooded country of Gipps' Land.

This district, then called Port Phillip, in the time of Governor Sir George Gipps, 1838 to 1846, was growing fast into a position claiming independence. Melbourne, which began with a few huts on the banks of the Yarra-Yarra in 1835, was in 1840 a busy town of 6000 inhabitants, the population of the whole district, with the towns of Geelong and Portland, reaching 12,850; while its import trade amounted to £204,000, and its exports to £138,000. Such was the growth of infant Victoria in five years; that of Adelaide or South Australia, in the same period, was nearly equal to it. At Melbourne there was a deputy governor, Mr. Latrobe, under Sir George Gipps at Sydney. Adelaide had its own governors, first Captain Hindmarsh, next Colonel Gawler, and then Captain George Grey. Western Australia progressed but slowly, with less than 4000 inhabitants altogether, under Governors Stirling and Hutt.

The general advancement of Australia, to the era of the gold-mining, had been satisfactory, in spite of a severe commercial crisis, from 1841 to 1843, caused by extravagant land speculations and inflated prices. Victoria produced already more wool than New South Wales, the aggregate produce of Australia in 1852 being 45,000,000 lb.; and South Australia, between 1842 and this date, had opened most valuable mines of copper. The population of New South Wales in 1851 was 190,000; that of Victoria, 77,000; and that of South Australia about the same.

At Summerhill Creek, 20 miles north of Bathurst, in the Macquarie plains, gold was discovered, in February 1851, by Mr. E. Hargraves, a gold-miner from California. The intelligence was made known in April or May; and then began a rush of thousands,—men leaving their former employments in the bush or in the towns to search for the ore so greatly coveted in all ages. In August it was found at Anderson's Creek, near Melbourne; a few weeks later the great Ballarat gold-field, 80 miles west of that city, was opened; and after that, Bendigo, now called Sandhurst, to the north

Not only in these lucky provinces, New South Wales and Victoria, where the auriferous deposits were revealed, but in every British colony of Australasia, all ordinary industry was left for the one exciting pursuit. The copper mines of South Australia were for the time deserted, while Tasmania and New Zealand lost many inhabitants, who emigrated to the more promising country. The disturbance of social, industrial, and commercial affairs, during the first two or three years of the gold era, was very great. Immigrants from Europe, and to some extent from North America and China, poured into Melbourne, where the arrivals in 1852 averaged 2000 persons in a week. The population of Victoria was doubled in the first twelvemonth of the gold fever, and the value of imports and exports was multiplied tenfold between 1851 and 1853.

The colony of Victoria was constituted a separate province in July 1851, Mr. Latrobe being appointed governor, followed by Sir Charles Hotham and Sir Henry Barkly in succession. The more rapid increase of Victoria since that time, in wealth and number of inhabitants, has gained it a pre-eminence in the esteem of emigrants; but the varied resources of New South Wales, and its greater extent of territory, may in some degree tend to redress the balance, if not to restore the character of superior importance to the older colony.

The separation of the northern part of eastern Australia, under the name of Queensland, from the original province of New South Wales, took place in 1859. At that time the district contained about 25,000 inhabitants; and in the first six years (as Sir George Bowen, the first governor, observed in 1865) its population was quadrupled and its trade trebled.

It appears, from a general view of Australian progress in the last twenty years, that the provinces less rich in gold than Victoria have been enabled to advance in prosperity by other means. Wool continues the great staple of Australia. But New South Wales, possessing both coal and iron, is becoming a seat of manufactures; while Queensland is also favored with much mineral wealth, including tin. The semi-tropical climate of the latter colony is suitable for the culture of particular crops, needing only a supply of other than European labor. Meantime South Australia, besides its production of copper and a fair share of wool, has become the great wheat-growing province of the continent.

AUSTRIA, or more strictly AUSTRIA-HUNGARY (Ger. *Oesterreich* and *Oesterreich-Ungarn*), is an extensive country in the southern portion of Central Europe. It extends through 17 degrees of longitude and 9 degrees of latitude, and has an area of about 240,000 English square miles. With the exception of the islands in the Adriatic, and the narrow projecting tract of Dalmatia, it forms a compact region of country, but of an irregular shape. It is surrounded on all sides by other countries, except where it borders upon the Adriatic, which is about one-fifth of the entire extent of its boundaries. Of the rest, about one-third on the W. and N. is formed by the German empire (Bavaria, Saxony, and Prussia), a third on the S. and E. by the Turkish empire and the Danubian Principalities, and the remaining third by Russia on the N.E. and Switzerland and Italy on the S.W. The boundaries are formed in some parts by river courses, in others by mountain ranges, and sometimes they extend through an open country. As compared with France, Austria has a form nearly as compact, but its frontiers are by no means so well defined or so strongly protected by natural barriers. It ranks third in extent among the countries of Europe (after Russia and Sweden), and fourth in point of population (after Russia, the German empire and France).

Austria is, after Switzerland, the most mountainous country of Europe, and about four-fifths of its entire area is more than 600 feet above the level of the sea. The mountains are frequently covered with vegetation to a great elevation. At the base are found vines and maize; on the lower slopes are green pastures, or wheat, barley, and other kinds of corn; above are often forests of oak, ash, elm, &c.; and still higher the yew and the fir may be seen braving the fury of the tempest. Corn grows to between 3400 and 4500 feet above the level of the sea, the forests extend to 5600 or 6400 feet, and the line of perpetual snow is from 7800 to 8200 feet. In some parts, however, particularly in Tyrol, Styria, Carinthia, and Carniola, the mountains appear in wild confusion, with rugged peaks and bare precipitous sides, forcibly reminding the traveller of Switzerland. Tyrol in particular has, like that country, its cascades. its glaciers, its perpetual snows, and its avalanches.

The Alps occupy the south-west portion of the country, and form its highest lands. They are distinguished by various names, as the Rhætian, Noric, Carnic, Julian, and Dinaric Alps. The Rhætian or Tyrolese Alps enter Tyrol from the Swiss canton of the Grisons, and are the loftiest range in the country, a number of the summits rising to the height of 12,000 feet, and the highest, the Orteler Spitze, attaining a height of 12,814 feet above the level of the sea. They divide into three principal chains, the most southern of which occupies the southern portion of Tyrol, and contains the Orteler Spitze, and others of the loftiest points in the country. The middle or principal chain extends in an easterly direction to the borders of Salzburg and Carinthia, and has many of its peaks covered with perpetual snow. The northern chain is inferior in elevation to the others, and few of its most elevated points reach the snow line. The Noric Alps are a continuation of the Rhætian eastward, passing through Salzburg, Styria, Carinthia north of the Drave, Lower and Upper Austria, to Hungary, where they gradually sink into the plains. They comprise three chains, a main chain and two lesser chains proceeding northward — the one the Salzburg, the other the Styria-Austrian Alps. The main chain, the Noric Alps in a stricter sense, traverses Salzburg, Carinthia, and Styria, and has a length of about 170 miles, some of its peaks rising to the height of 12,000 feet. The Carnic or Carinthian Alps are also an offshoot of the Rhætian Alps eastward, occupying the south-east of Tyrol, Carinthia, and the north of Carniola. They form several branches, and some of the summits are over 9,000 feet high. The Julian or Carniolan Alps extend in a south-easterly direction through Carniola and Croatia. They present little of an Alpine character, and with one or two exceptions nowhere rise to the height of 5000 feet. They are for the most part bare and rugged. The Dinaric Alps are a continuation of the preceding, extending through Croatia and Dalmatia, and resemble them in character. The highest point, Mount Dinara, from which they take their name, is 5956 feet above the level of the sea.

After the Alps, the most important mountain system of Austria is the Carpathians, which occupy its eastern and north-eastern portions, and stretch in the form of an arch through Silesia, Moravia, Galicia, Hungary, and Transylvania. They have an extent of about 650 miles, and are divided into three principal groups — the Hungarian Carpathians, the Carpathian Waldgebirge or Forest Mountains, and the Transylvanian Highlands. The Hungarian Carpathians stretch from west to east, through Hungary, Moravia, Silesia, and Galicia for about 200 miles, and comprise various smaller groups, among which are the Beskides, the Little Carpathians,

and the Central Carpathians or the Tatra Mountains. This last group constitutes the highest portion of the Carpathians, having an average elevation of over 6000 feet, and its two principal summits, the Eisthaler Thurm and the Lomnitzer Spitze, having a height of 8378 and 8222 feet respectively. In character it resembles the Alps more than the Carpathians, having rugged precipitous sides, deep chasms, snows, glaciers, cascades, &c. The Waldgebirge, or Forest Mountains, are a series of moderate elevations, for the most part wooded, and stretching for about 160 miles through Hungary, Galicia, and Buckowina, with an average breadth of about 45 miles. They are in general from 3000 to 6000 feet in elevation, the highest point, Pietrozza, rising to 7086 feet. The Transylvanian Highlands extend over Transylvania, a part of Hungary, and the Military Frontier, into Moldavia and Wallachia. They have a length of about 350 miles, and breadth of from 30 to 90. Several of the summits rise to the height of 8000 feet. The sides of the Carpathian mountains are generally covered with forests to a considerable height.

The Hercynian mountain system spreads itself over Bohemia, Silesia, Moravia, and the middle and northern portions of Upper and Lower Austria. It includes the lesser systems of the Bohemian Forest, the Erzgebirge, the Riesengebirge, and the Sudetes. The Bohemian Forest is a series of wooded heights on the confines of Bohemia and Bavaria, and extending south from the Eger to the Danube. Its highest point is 4610 feet above the sea. The Erzgebirge, or Ore Mountains, commence on the left bank of the Elbe, run eastward between Bohemia and Saxony, and terminate near the sources of the White Elster. None of the summits rise to the height of 4000 feet. The Risengebirge or Giant Mountains are on the confines of Bohemia towards Prussian Silesia, and have their highest point, Schneekoppe or Riesenkoppe, 5330 feet above the sea. The Sudetes is a name sometimes given to all the mountains of Northern Bohemia, but it more properly belongs to that range which runs between Moravia and Prussian Silesia, from the March to the Oder. The highest summit, the Spieglitzer Schneeberg, is 4774 feet high.

As the highlands of Austria form part of the great water-shed of Europe which divides the waters flowing northward into the North Sea or the Baltic, from those flowing southward or eastward into the Mediterranean or the Black Sea, its rivers flow in three different directions—northward, southward, and eastward. With the exception of the small streams belonging to it which fall into the Adriatic, all its rivers have their mouths in other countries, and its principal river, the Danube, has also its source in another country. This, which after the Volga is the largest river in Europe, rises in the grand duchy of Baden, flows through Würtemberg and Bavaria, and is already navigable when it enters Austria, on the borders of which it receives the Inn, a river which has as large a body of water as itself. It has a course of about 820 miles within the country, which is about 48 per cent. of its entire length. Where it enters it is 898 feet above the level of the sea, and where it leaves only 132 feet. It has thus a fall within the country of 766 feet, and is at first a very rapid stream, but latterly a very slow one. Its affluents, after the Inn, are at first generally small, the principal being the Traun, the Enns, and the March. In Hungary it receives from the Carpathians the Waag, Neutra, Gran, and Eipel; and from the Alps the Drave, the Mur, and the Save. But the principal affluent of the Danube is the Theiss, which rises in the Carpathians, and drains nearly the whole of the eastern half of Hungary. The country drained by the Danube is formed into several basins by the mountains approaching its banks on either side. The principal of these are the Lins and Krems basins, the Vienna basin, and the little and great Hungarian basins. Between this last and the plains of Wallachia, it passes through the narrow rocky channels of Islach, Kasan, and the Iron Door, where the fall is about 41 feet in less than half a mile. The Dniester, which, like the Danube, flows into the Black Sea, has its source in the Carpathians in Eastern Galicia, and pursues a very winding course towards the south-east. It receives its principal affluents from the Carpathians, and drains in Austria a territory of upwards of 12,000 English square miles. It is navigable for about 300 miles. The Vistula and the Oder both fall into the Baltic. The former rises in Moravia, flows first north through Austrian Silesia, then takes an easterly direction along the borders of Prussian Silesia, and afterwards a north-easterly, separating Galicia from Russian Poland, and leaving Austria not far from Sandomir. Its course in Austria is 240 miles, draining an area of 15,500 square miles. It is navigable for nearly 200 miles, and its principal affluents are the Save and the Bug. The Oder has also its source in Moravia, flows first east, and then north-east through Austrian Silesia into Prussia. Its length within the Austrian territory is only about 55 miles, no part of which is navigable. The only river of this country which flows into the North Sea is the Elbe. It has its source in the Riesengebirge, not far from the Schneekoppe, flows first south, then east, and afterwards north-east through Bohemia, and then enters Saxony. Its principal affluents are the Adler, Iser, and Eger, and, most important of all, the Moldau. The last, from the length of its course, and the quantity of water which it brings down, is entitled to be considered the main stream. It has a course of 260 miles, and is navigable for 190. The Elbe itself has a course within the Austrian dominions of 185 miles, for about 65 of which it is navigable. It drains an area of upwards of 21,000 square miles. The Rhine, though scarcely to be reckoned a river of the country, flows for about 25 miles of its course between it and Switzerland. The principal river of Austria which falls into the Adriatic is the Adige. It rises in the mountains of Tyrol, flows south, then east, and afterwards south, into the plains of Lombardy. Its principal affluent is the Eisack. Of the streams which have their course entirely within the country, and which fall into the Adriatic, the principal is the Isonzo, 75 miles in length, but navigable only for a short distance from its mouth.

The lakes and marshes of Austria are very numerous, and some of them are of great extent. The lakes lie principally in the valleys among the Alps, and the marshes are frequent along the courses of the rivers. The largest lake of Austria is the Balaton, in Hungary, which is about 46 miles in length by 18 in breadth, and, including the swamps in connection with it, covers an area of 500 square miles. The Neusiedler, also in Hungary, is 18 miles in length, by from 4 to 7 in breadth, and covers an area of 106 square miles. Among the many smaller ones the principal are the Traunsee, Attersee, Wörthersee, Mondsee, &c. No other European country equals Austria in the number and value of its mineral springs. No fewer than 1500 of these are reckoned, and they occur principally in Bohemia and Hungary. In the former are Karlsbad, Marienbad, Franzenbad, Teplitz, Püllna, and Seidlitz.

The climate of Austria, in consequence of its great extent, and the great differences in the elevation of its surface, is very various. It is usual to divide it into three distinct zones. The most southern extends to 46° N. lat., and includes Dalmatia and the country along the coast, together with the southern portions of Tyrol

and Carinthia, Croatia, Slavonia, and the most southern part of Hungary. Here the seasons are mild and equable, the winters are short (snow seldom falling), and the summers last for five months. The vine and maize are everywhere cultivated, as well as olives and other southern products. In the south of Dalmatia tropical plants flourish in open air. The central zone lies between 46° and 49° N. lat., and includes Lower and Upper Austria, Salzburg, Styria, Carinthia, Carniola, Central and Northern Tyrol, Southern Moravia, a part of Bohemia, the main portion of Hungary, and Transylvania. The seasons are more marked here than in the preceding. The winters are longer and more severe, and the summers are hotter. The vine and maize are cultivated in favorable situations, and wheat and other kinds of grain are generally grown. The northern zone embraces the territory lying north of 49° N. lat., comprising Bohemia, Northern Moravia, Selesia, and Galicia. The winters are here long and cold; the vine and maize are no longer cultivated, the principal crop being wheat, barley, oats, rye, hemp, and flax. The mean annual temperature ranges from about 59° in the south to 48° in the north. In some parts of the country, however, it is as low as 46° 40′ and even 36°. In Vienna the average annual temperature is 50°, the highest temperature being 94°, the lowest 2° Fahr. In general the eastern part of the country receives less rain than the western. In the south the rains prevail chiefly in spring and autumn, and in the north and central parts during summer. Storms are frequent in the region of the South Alps and along the coast. In some parts in the vicinity of the Alps the rainfall is excessive, sometimes exceeding 60 inches. It is less among the Carpathians, where it usually varies from 30 to 40 inches. In other parts the rainfall usually averages from 20 to 24 inches, but in the plains of Hungary it is as low as 26.

From the varied character of its climate and soil the vegetable productions of Austria are very various. It has floras of the plains, the hills, and the mountains; an alpine flora, and an arctic flora; a flora of marshes, and a flora of steppes; floras peculiar to the clay, the chalk, the sandstone, and the slate formations. The number of different species is estimated at 12,000, of which one-third are phanerogamous, or flowering plants, and two-thirds cryptogamous, or flowerless. The crown-land of Lower Austria far surpasses in this respect the other divisions of the country, having about four-ninths of the whole, and not less than 1700 species of flowering plants. Hungary, Bohemia, Moravia, and Gálicia are the principal corn-growing reigons of the country; and Tyrol, Salzburg, and Upper Styria are the principal pastoral regions.

The animal kingdom embraces, besides the usual domestic animals (as horses, cattle, sheep, swine, goats, asses, &c.), wild boars, deer, wild goats, hares, &c.; also bears, wolves, lynxes, foxes, wild cats, jackals, otters, beavers, polecats, martins, weasles, and the like. Eagles and hawks are common, and many kinds of singing birds. The rivers and lakes abound in different kinds of fish, which are also plentiful on the sea-coast. Among insects the bee and the silkworm are the most useful. The leech forms an article of trade. In all there are 90 different species of mammals, 248 species of birds, 377 of fishes, and more than 13,000 of insects.

Austria comprises five countries, each bearing the name of kingdom—viz., Hungary, Bohemia, Galicia. Illryia, and Dalmatia; one archduchy, Austria; one principality, Transylvania; one duchy, Styria; one margraviate, Moravia; and one county, Tyrol. These are now divided into provinces, which are called *crown-lands*, and of which at present there are 18, 14 being in Austria Proper, and 4 in Hungary. These various countries, while under the rule of one sovereign, have nothing else in common, and their union is only a political one; and it is not too much to say that nationalism, in its ordinary sense, does not exist. This will be evident when we consider the various races included.

The population of Austria is made up of a number of distinct races, differing from each other in manners, customs, language and religion, and united together only by living under the same government. The most numerous race is the German, amounting to 9,000,000, and forming 25 per cent. of the entire population. They are found more or less in all the crown-lands, but are most numerous in Lower and Upper Austria, Salzburg, Styria, Carinthia, and Northern Tyrol. The different Slavonic races number together 16,540,000, or 46 per cent. The principal Slavonic races are,—in the north, the Czechs and Moravians (4,480,000), who, together with the Slovacks in the Western Carpathians (1,940,000), form 18 per cent. of the entire population, and the Poles (2,370,000) and the Ruthens (3,360,000), occupying Galicia; and in the south, the Slovens (1,220-000), the Croats (1,520,000), and the Serbians (1,651,000). The Northern Slavonians are found chiefly in Bohemia, Moravia, Galicia, and the north of Hungary; the southern in Carniola, Dalmatia, Croatia, Slavonia, and the Military Frontier. The Maygars or Hungarians occupy chiefly Hungary and Transylvania, and number 5,590,-000, or 16 per cent. of the whole population. The Rumäni or Wallachians number 2,940,000, or over 8 per cent.; the Jews, 1,105,000, or 3 per cent.; the Italians, 515,000, or 1.4 per cent.; and the gipsies, 140.000. The rest consists of Armenians, Bulgarians, Albanians, Greeks, &c.

Austria has always remained strongly attached to the Roman Catholic Church. Her sovereigns, however, have in general resisted the temporal pretensions of the popes, and reserved to themselves certain important rights, such as the imposing of taxes on church property the nomination of bishops and archbishops, and the option of restricting, or even prohibiting, the circulation of Papal bulls. About two-thirds of the people, or nearly 24,000,000, profess the Roman Catholic religion. If, however, we deduct the kingdom of Hungary and Galicia, where less than one-half of the people are Roman Catholics, the proportion in the rest of the country is much increased. In some parts the proportion to the entire population is as high as 90 to 98 per cent. The Greek Catholics number in Austria Proper 2,342,168 (almost all in Galicia), and in Hungary 1,599,-628. The Eastern Greek Church numbers 461,511 adherents in Austria, and 2,589,319 in Hungary. Of the Protestant denominations, the Lutherans are more numerous in the western half of the empire, the Calvinists in the eastern. The numbers are — in Austria Proper, Lutherans, 252,327, and Calvinists, 111,935; in Hungary, Lutherans, 1,365,835, Calvinists, 2,143,178. The principal other religions are the Jewish, 1,375,861 (nearly half of them in Galicia); Armenian, 10,133; Unitarian, 55,079 (nearly all in Transylvania). The Catholic Church (including the Greek and Armenian Catholics) has 11 archbishops, 24 suffragan bishops, 2 vicariate bishops, and 1 military bishop, in Austria Proper, and 5 archbishops and 23 bishops in Hungary. Altogether there are about 34,000 ecclesiastics, and 950 convents, with 8500 monks and 5700 nuns. The Oriental Greek Church has, in Austria Proper, 3 bishops (1 in Buckowina and 2 in Dalmatia), and in Hungary, the patriarch of Karlowitz, the archbishop of Herrmannstadt, and 8 bishops, with, in all, 4000 priests, and 40 convents, with 300 monks.

Previous to 1848 Austria was very far behind in the matter of education; but since that time great improvements have been effected, and an entire change has taken place. This subject now receives the greatest attention; schools of all kinds have been established throughout the country, improved systems of teaching have been introduced, and instruction is open to all without regard to class or creed at a very small cost, or even gratuitously. It still continues, however, to be in great measure under the control of the priests, and many of the teachers are ecclesiastics. The Roman Catholic religion forms an essential part of the instruction in all schools, except those for special subjects. The Oriental Greek and Protestant Churches have, as a rule, their own common schools, and where this is not the case, they have to send their children to the Catholic schools. The Jews also, in places where they have no special schools, are obliged to send their children to Christian schools.

The majority of the people of Austria are engaged in agricultural pursuits or in connection with the forests, the proportion varying in different parts from 50 to 80 per cent. of the entire population.

Austria is distinguished for the number and superiority of its horses, for the improvement of which numerous studs exist over the country. The breeding of horses is more or less extensively carried on in all the crown-lands, but more especially in Hungary, Transylvania, Buckowina, Galicia, Styria, Bohemia, Moravia, and Upper and Lower Austria.

Austria cannot be said to be remarkable as a cattle-rearing country. Indeed, except in certain districts, particularly among the Alps, it must be considered to be much behind in this branch of industry. The finest cattle are to be found in the Alpine regions; in other parts the breeds are generally very inferior. The Hungarian crown-lands, however, have of late years been improving in this respect.

Bees are extensively kept, particularly in the crown-lands of Lower Austria, Hungary, Galicia, and Transylvania.

In the extent and variety of its mineral resources Austria ranks among the first countries of Europe. Besides the noble metals, gold and silver, it abounds in ores of more or less richness of iron, copper, lead, and tin; while in less abundance are found zinc, antimony, arsenic, cobalt, nickel, manganese, bismuth, chromium, uranium, tellurium, sulphur, graphite, asphalt, rock-salt, coal, and petroleum.

The manufactures of Austria have made great progress during the last twenty years, and now some of them are extensively carried on. They include cotton, flax, hemp, woollen and silk stuffs; gold, silver, iron, lead, copper, tin, and zinc articles; leather, paper, beer, brandy, and sugar; porcelain and earthenware; chemical stuffs; scientific and musical instruments, &c. The manufactures are principally carried on in the western crown-lands, and more particularly in Bohemia, Moravia, Silesia, and Lower Austria.

The *cotton* manufacture has made very rapid progress, and is now one of the most extensive and flourishing in the country.

The *flax* and *hemp* manufacture is one of the oldest in the country, and was long the most important. In consequence, however, of the rapid advancement of the cotton manufacture it is no longer of the same importance as formerly; yet it still affords employment to a great number of persons, and is very generally extended over the country.

The *woollen* manufacture is also an old established branch of industry, and is actively carried on.

The *iron* and *steel* manufactures form one of the most important branches of industry, and afford employment to a great number of persons. They are more or less extensively carried on in all the crown-lands, except in the Maritime District, Dalmatia, Croatia, and Slavonia; but their principal seats are in Lower and Upper Austria, Bohemia, Moravia, Styria, and Carinthia.

The principal *copper*-works are at Brixlegg and other places in Tyrol, and in Galicia, Buckowina, and Hungary.

The manufacture of mathematical, optical, and surgical instruments, and of physical and chemical apparatus, has of late years risen rapidly into importance, particularly in Vienna and Prague, and now these are to be found among the exports to other countries, Austria is also distinguished for the manufacture of musical instruments, particularly pianos and organs, and also for other stringed and wind instruments. Clock or watch making is not very extensively carried on.

Austria is noted for its *beer*, particularly that of Vienna and Bohemia.

The manufacture of *sugar* from beet-root is in a very flourishing state, and is rapidly extending.

The manufacture as well as the growth of *tobacco* is a government monopoly. There are 22 establishments for the manufacture of tobacco and cigars, employing about 20,000 work people.

Austria is not favorably situated for commerce on account of its inland position, its small extent of sea-coast, and the mountainous character of much of its surface. Its trade was also formerly very much hampered by high duties, and restrictions of various kinds. These, however, have now been very much modified or removed, and its trade has in consequence rapidly improved. Much has been done, too, in the way of making and improving the roads, opening mountain passes, constructing railways, and establishing lines of steamers.

The principal seaports of Austria are Trieste and Fiume, at the head of the Adriatic, the former in the Maritime crown-land, the latter in that of Croatia.

The head of the Austro-Hungarian monarchy is the emperor and king, who is also the head of the army and of the executive. The succession is hereditary, in the order of primogeniture, in the male line of the house of Hapsburg-Lothringen, or Lorraine; and failing this, in the female line. The monarchy comprises two distinct states — a German or Cisleithan, commonly called Austria, and a Magyar or Transleithan, usually termed Hungary. Each of these has its own parliament, ministers, and government; while the army and navy and foreign relations are common. These are under the direction of a controlling body known as the Delegations, consisting of sixty members for each state, two-thirds being elected by the Lower House, and one-third by the Upper House of each of the parliamentary bodies. They usually sit and vote in two chambers — one for Austria, the other for Hungary; but in the event of disagreement on any question, they meet together, and without further deliberation give their final vote, and the decision thus arrived at is binding on the whole empire. Their resolutions require neither the approval nor the confirmation of the representative assemblies by which they are chosen, but only imperial assent. The executive is vested in three departments — (1), A ministry of foreign affairs; (2), a ministry of war; and (3), a ministry of finance. These are responsible to the Delegations. The Reichsrath, or Parliament of Austria, consists of an Upper and a Lower House. The former, the House of Lords is composed — (1), of princes of the imperial house who are of age to serve; (2), of the heads of noble houses of high rank, in whom the dignity is hereditary (66); (3), of the archbishops (10) and of bishops with the rank of princes (7); and (4) of life members nomin-

ated by the emperor on account of distinguished services (102). The Lower House, or House of Representatives, is composed of 353 members, elected to represent the different crown-lands by all citizens who are of age and possessed of a small property qualification. The emperor annually convokes the Reichsrath, and nominates the presidents and vice-presidents of each division out of the members. The business of the Reichsrath embraces all matters of legislation relating to laws, duties, and interest, except such as are specially excluded as belonging to other departments. It also takes up matters connected with trade, commerce, and finance, the post-office, railways, telegraphs, customs, the mint, raising of new loans, imposing of new taxes, budgets, matters relating to military service, &c. The members of either House have the right to propose new laws on matters within their province; but the consent of both Houses, as well as the sanction of the emperor, is required to render them valid. The executive is vested in the president and ministries of the interior, religion and education, finance, commerce, agriculture, national defence, and justice. The ministers form also the Ministerial Council, which is presided over by the emperor or a minister-president.

In addition to the Reichsrath, there are seventeen provincial diets established in different districts of the country for the direction and regulation of local matters, taxation, education, religion, public works, charitable institutions, industry, trade, &c. Each diet is composed of the archbishops and bishops of the Roman Catholic and Greek Catholic Churches, of the rectors of the universities, and of representatives of the great landed estates, of the towns, of chambers of industry and commerce, and of rural communes. The number of members varies according to the size and importance of the districts — from 20 or 30 up to 100 for Moravia, 151 for Galicia, and 241 for Bohemia.

The Hungarian Parliament or Reichstag consists of an Upper and a Lower House,—the former known as the House of Magnates, the latter as the House of Representatives. The Upper House is composed of 3 princes of the reigning house, having estates in the kingdom, 31 archbishops and bishops of the Roman Catholic and Greek Churches, and 381 high officials and peers of the kingdom. The Lower House is composed of representatives elected for three years by citizens of age who pay a certain amount of direct taxes. The number of representatives, in 1890, was 444, of whom 334 represented the counties, rural districts, and towns of Hungary; 75 represented Transylvania; and 35 Croatia and Slavonia. The president and vice-president of the House of Magnates are nominated by the king from among the members; and the president and two vice-presidents of the House of Representatives are elected by the members. The sovereign, though emperor of Austria, is styled "king" in all public documents. The executive is vested in a president and ministries of national defence, the court, finance, interior, religion and education, justice, public works, agriculture, industry and commerce, and for Croatia and Slavonia.

The revenue and expenditure are presented in three distinct budgets:—(1), That of the Delegations for the whole empire; (2), that of the Austrian Reichsrath for Austria; and (3), that of the Hungarian Reichstag for Hungary. By an arrangement of 1868 Austria pays 70 per cent., and Hungary 30 per cent., towards the common expenditure of the empire.

The present empire of Austria took its rise in a margraviate founded by Charlemagne, toward the close of the 8th century, in that fertile tract of country lying along the southern bank of the Danube to the east of the River Enns, now included in Lower Austria. It was called *Ostreich* or *Oesterreich*, the eastern country, from its position relative to the rest of Germany. It continued to be ruled by margraves (Ger. *Markgraf*, lord of the marches) for several centuries, down to the year 1156, when the territory west of the Enns was added to it, and it was raised to a duchy. It subsequently received further accessions of territory, and in 1453 was made an archduchy.

The country of the present archduchy of Austria was in early times inhabited by the Taurisci, a Celtic race, who were afterwards better known as the Norici. They were conquered by the Romans in 14 B.C.; and thereafter a portion of what is now Lower Austria and Styria, together with the municipal city of *Vindobona*, now Vienna, and even then a place of considerable importance, was formed into the province of Pannonia; and the rest of Lower Australia and Styria, together with Carinthia and a part of Carniola, into that of Noricum. Tyrol was included in Rhætia, while north of the Danube, and extending to the borders of Bohemia and Moravia, were the territories of the Marcomanni and the Quadi. These were not unfrequently troublesome to the Romans; and during the greater part of the reign of Marcus Aurelius, from 169 to 180 A.D., they maintained with varying success a harassing war against them. In 174 the Roman army was so nearly cut off by the Quadi that its safety was attributed to a miracle. The emperor died at Vindobona when on an expedition against those troublesome neighbors, and his successor, Commodus, was glad to make peace with them. On the decline of the imperial power these Roman provinces became a prey to the incursions of barbaric tribes. During the 5th and 6th centuries the country was successively occupied by the Boii, Vandals, Heruli, Rugii, Goths, Huns, Lombards, and Avari. About 568, after the Lombards had settled in Upper Italy, the River Enns became the boundary between the Bajuvarii, a people of German origin, and the Avari, who had come from the east. In 788 the Avari crossed the Enns and attacked Bavari, but were subsequently driven back by Charlemagne, and forced to retreat as far as the Raab, their country from the Enns to that river being then made a part of Germany. It was taken by the Hungarians in 900, but was again annexed to Germany in 955 by Otho I. In 983 the emperor appointed Leopold I., of Babenberg or Bamberg, margrave of Austria, and his dynasty ruled the country for 263 years. He died in 994, and was succeeded by his son, Henry I., who governed till 1018. In 1156 Austria received an accession of territory west of the Enns, and was raised to a duchy by the Emperor Frederick I. The first duke was Henry Jasomirgott, who took part in the second crusade. He removed the ducal residence to Vienna, and began the building of St. Stephen's cathedral. His successor, Leopold V., in 1192, obtained Styria as an addition to his territory, and Frederick II. received possession of Carniola. Frederick, in the latter years of his life, contemplated the erection of Austria into a kingdom, but his sudden death in a battle against the Magyars, in 1246, put an end to the project, and with him the line became extinct.

The Emperor Frederick II. now declared Austria and Styria to have lapsed to the imperial crown, and appointed a lieutenant to govern them on the part of the empire. But claims to the succession were brought forward by descendants of the female branch of the Babenburg line; and after various contests Ottocar, son of the king of Bohemia, gained possession about 1252 of the duchies of Austria and Styria. In 1269 he succeeded to Carinthia, a part of Carniola and Friuli; but he lost all by refusing to acknowledge the Emperor Ru-

dolph of Hapsburg, and eventually fell in battle in an attempt to recover them in 1278.

The emperor now took possession of the country, and appointed his eldest son governor; but subsequently, in 1282, having obtained the sanction of the electors of the empire to act, he conferred the duchies of Austria and Styria, with the province of Carinthia, on his sons Albert and Rudolph, and thus introduced the Hapsburg dynasty. The brothers transferred Carinthia to Meinhard, count of Tyrol; and in 1283 Albert became sole possessor of Austria, Styria, and Carniola. He increased his possession considerably by wars with his neighbors, but was murdered at Rheinfelden in 1308, when on an expedition against the Swiss, by his nephew, John of Swabia, whom he had deprived of his hereditary possessions. He was succeeded by his five sons, Frederick, Leopold, Henry, Albert, and Otto. In 1314 Frederick, the eldest, was set up by a party as emperor in opposition to Louis, duke of Bavaria, but was defeated and taken prisoner by his rival in 1322. In 1315 Duke Leopold was defeated in an attempt to recover the forest towns of Switzerland which had revolted from his father. Leopold died in 1326, Henry in 1327, and Frederick in 1330. The two surviving brothers then made peace with the Emperor Louis, and in 1335 they acquired Carinthia by inheritance. On the death of Otto in 1339 Albert became sole ruler. He died in 1358. His son and successor, Rudolph II., finished the church of St. Stephen's and founded the university of Vienna, dying childless in 1365. He was succeeded by his two brothers, Albert III. and Leopold III., who in 1379 divided their possessions between them, the former taking the duchy of Austria, the latter Styria and other parts. Leopold fell at Sempach in 1386, but his descendants continued to rule in Styria. Albert acquired Tyrol and some other districts, and died in 1395. He was succeeded by his son, Albert IV., who was poisoned at Znaim in 1404, when on an expedition against Procopius, count of Moravia. Albert V. succeeded his father, and having married the daughter of the Emperor Sigismund, he obtained the thrones of Hungary and Bohemia, and became emperor (Albert II.) in 1438. He died the following year, and was succeeded by his posthumous son Ladislaus, who died without issue in 1457. The Austrian branch of the family thus became extinct, and was succeeded by that of Styria. The crowns of Hungary and Bohemia passed for a time into other hands.

The possession of Austria, which in 1453 had been raised to an archduchy, was for some years a subject of dispute between the Emperor Frederick III. and his brothers, but at length, on the death of Albert in 1463, the emperor obtained sole possession. His son Maximilian, by marrying the daughter of Charles the Bold, acquired the Netherlands in 1477, but on the death of his father in 1493 he succeeded him as emperor, and transferred the government of the Netherlands to his son Philip. He added Tyrol and some parts of Bavaria to his paternal possessions, and made some advances towards the recovery of Hungary and Bohemia. His son Philip, by his marriage with Johanna, daughter of Ferdinand and Isabella, acquired a right to the crown of Spain, but died in 1506. Maximilian died in 1519, and was succeeded by his grandson Charles (son of Philip), who two years before had obtained the Spanish crown, and was now made emperor under the title of Charles V. By treaties dated 1521 and 1524, Charles resigned all his hereditary possessions in Germany, except the Netherlands, to his brother Ferdinand. The latter, by his marriage with Anna, sister of the king of Hungary, acquired right to the kingdoms of Hungary and Bohemia, together with Moravia, Silesia and Lausatia. His right to Hungary, however, was contested by John Zapolya, waywode of Transylvania, who was elected by a party of the nobles, and was crowned king in 1527. Being unable to cope single-handed with Ferdinand, John sought the aid of the sultan, Soliman II., who in 1529 advanced with a large army to the very gates of Vienna; but after several ineffectual attempts to take the city he raised the siege and returned to Buda. At length, in 1535 an agreement was come to, in terms of which John was allowed to retain the title of king, together with half of Hungary, but his descendants were to be entitled to Transylvania only. John died in 1540, but the people of Lower Hungary were opposed to Ferdinand, and set up the son of their late king against him. In the struggle which ensued the aid of the Turks was again invoked, and the result was that Ferdinand had to agree to pay an annual sum of 30,000 ducats to the sultan for this part of Hungary. Ferdinand was also under the necessity of surrendering Würtemberg to Duke Ulrich, on condition of its remaining a fief of Austria and reverting to that country on the extinction of the male line. Notwithstanding this, the possessions of the German line of the house of Austria at this time are estimated at 114,000 square miles. On the abdication of Charles V. in 1556, Ferdinand succeeded to the imperial throne. He died in 1564, leaving directions for the division of his possessions among his three sons. The eldest, Maximilian II., received the imperial crown, together with Austria, Hungary, and Bohemia; the second, Ferdinand, obtained Tyrol and Lower Austria; and the third, Charles, was made master of Styria, Carinthia, Carnolia, and Görtz. In 1556 the sultan Soliman again marched at the head of a great army into Hungary, but met with a very determined resistance at Szigeth, before which town he was suddenly cut off by apoplexy. Peace was concluded with his successor, and in 1572 Maximilian caused his eldest son Rudolph to be crowned king of Hungary. He was afterwards crowned king of Bohemia, and was also elected king of the Romans. Maximilian died in 1576, and was succeeded by Rudolph on the imperial throne. This monarch was little fitted to rule, and left the management of affairs very much to others. He was entirely under the power of the Jesuits, set at nought the ancient laws of the country, and persecuted the Protestants. The latter, under Bocskay, revolted in 1604, and having secured the aid of the sultan, gained repeated victories over the imperial troops, compelling Rudolph to give them terms of peace in 1606. During this reign the possessions of the Archduke Ferdinand of Tyrol reverted to the two other lines; while in 1608 Rudolph was compelled to cede Hungary, and in 1611 Bohemia and Austria, to his brother Matthias, who on the death of Rudolph in 1612 was crowned emperor. His reign was full of promise, but unfortunately it was only of short duration. Being an old man and childless, he chose as his successor his cousin Ferdinand, archduke of Styria, whom he caused to be crowned king of Bohemia in 1616, and of Hungary in 1618. He died the following year, when Ferdinand became emperor.

Before the death of Matthias, the memorable struggle between Roman Catholicism and Protestantism, known as the *Thirty Years' War* (1618 to 1648), had commenced. It originated in an insurrection of the Protestants of Bohemia, who renounced their allegiance to Ferdinand and chose for their king the elector palatine Frederick V. Frederick was supported by all the Protestant princes except the elector of Saxony, while Ferdinand was assisted by the king of Spain and the other Catholic princes. At first success attended the arms of the insurgents, who repeatedly routed the imperial troops, and even laid siege to Vienna. But the

Duke Maximilian of Bavaria, coming to the assistance of the imperialists at the head of a well-appointed army, totally defeated Frederick at the White Hill near Prague (8th November 1620). The following day Prague opened its gates to the conqueror, and in a short time the whole country was reduced to subjection, and the territories of the elector palatine divided among the allies. The war might have ended here had Ferdinand adopted a conciliatory policy, but impelled by revenge and fanatical zeal he adopted an opposite course, and instituted against the Protestants a severe persecution. They were thus again compelled to take up arms, and in 1625 Christian IV., king of Denmark, supported by subsidies from England, put himself at their head. He was subsequently joined by Count Mansfield and Christian of Brunswick, while opposed to him were Wallenstein and Tilly at the head of two powerful armies. In April 1626 Mansfield was defeated by Wallenstein at Dessau, and a few months later Tilly vanquished the Danish king at Lutter. The victorious armies afterwards marched into Denmark, and the king was compelled to conclude a humiliating peace at Lübeck in 1629. The Protestants were now awed into submission, and Ferdinand was emboldened to carry out to still greater lengths, his policy of suppression. Aiming at the total extirpation of Protestant doctrines throughout his dominions, he revoked all the privileges that had formerly been granted, even such as had previously received his approval. By the so-called *Edict of Restitution*, dated 6th March 1629, he enjoined the restitution of all ecclesiastical property secularised since the peace of Passau, and ordered the Protestants to relinquish to the Catholics all benefices which they had appropriated contrary to the peace of Passau and the Ecclesiastical Reservation.

The Catholic princes themselves were now becoming alarmed at the enormous power which they had contributed to place in the hands of the emperor. They therefore demanded a reduction of the army and the dismissal of Wallenstein, and with these demands the emperor felt himself obliged to comply. But a new champion of the Protestant cause now appeared in the north, in the person of Gustavus Adolphus, king of Sweden. This valiant prince, having received promises of aid from France as well as from England and the United Provinces, suddenly landed an army of 15,000 men at Usedom in June 1630. Pomerania and Mecklenburg were soon conquered by him and a great part of Brandenburg was overrun by his army. He was unable, however, to relieve the town of Magdeburg, which was besieged by Tilly and taken by assault 20th May 1631, when the most barbarous atrocities were perpetrated upon the unfortunate inhabitants. The elector of Brandenburg and afterwards the elector of Saxony joined Gustavus, and the combined army met the imperialists under Tilly at Breitenfeld, near Leipsic, and defeated them with great slaughter (7th September 1631). The victor now rapidly regained all that had been lost. Again Tilly was beaten at the passage of the River Lech on 5th April 1632, and the following day he died of his wounds. Wallenstein was now recalled and placed at the head of the imperial troops. His name inspired fresh ardor among the soldiery, men flocked to his standard, and he speedily found himself at the head of a very large army. He drove the Saxons out of Bohemia, and afterwards marched to Nuremberg, where Gustavus was entrenched in a strong position. The two armies watched each other for eight weeks, when the king directed an attack against the imperialists, but after a fierce struggle was repulsed. A fortnight later Gustavus moved in the direction of Bavaria, but Wallenstein, instead of following him, marched into Saxony, and thus obliged him to suspend his operations in Bavaria and to set out in pursuit of his opponent. The two armies met at Lützen, where a battle took place on 16th November 1632. The greatest skill and bravery were displayed on both sides, and the issue was long doubtful, but at length victory declared in favor of the Swedes, though dearly purchased with the loss of their brave commander, who fell mortally wounded.

The death of Gustavus was an irreparable loss to the Protestants in Germany. Wallenstein, however, made but little use of the advantages he now possessed, and has even been accused of treacherous designs against the empire. Be this as it may, his enemies at court and in the army were numerous and powerful, and he was at length assassinated by some of his own officers, 25th February 1634. The Protestant cause met with another disaster in the defeat of Bernard of Weimar at Nordlingen on 6th September. On 30th May 1635 Saxony concluded at Prague a treaty of peace with the emperor, in terms of which the Lutherans were freed from the operation of the Edict of Restitution. The other Lutheran princes soon after accepted the like terms; but the Calvinists, who were disliked by both parties, were left to their fate.

Sweden, no longer able to carry on the war as she had done, entered into a treaty with France, resigning the direction of operations to that power, a position of which Richelieu gladly availed himself, as according with his ambitious designs. The war now assumed a new phase, France and Sweden being allied against the empire and the Lutheran states of Germany, aided by Spain. Richelieu's efforts were in great measure directed to humbling the latter power. He sent an army into Spain, and entered into leagues with the dukes of Savoy and Parma and the United Provinces for attacking the Spanish power in Italy and the Netherlands. These projects did not meet with success, and the war was for a time carried into the French territories. In the meantime the Swedes, under General Baner, gained a brilliant victory over the Saxons and imperialists at Wittstock (4th October 1636). The emperor died on the 15th February 1637, and was succeeded by his son Ferdinand III. The war was carried on for eleven years longer, and the success which at first was with the imperialists, after a time came round to their adversaries, till at length the emperor, pressed on all sides and deserted by his allies, was glad to agree to terms of peace. By the peace of Westphalia, signed 24th October 1648, France acquired Alsace; Sweden got Upper Pomerania, the Isle of Rugen, and some other territory; the sovereignty and independence of the different states was recognised; the Calvinists were placed on the same footing as the Lutherans; and the independence of the United Provinces and the Swiss Confederation was acknowledged.

Ferdinand III. died in 1657, and was succeeded by his son Leopold I. This prince, by his harsh treatment of the Hungarians, drove that people into revolt; and they, being unable to cope with the power of the empire single-handed, called in the aid of the Turks, who, under Kara Mustapha in 1683, besieged Vienna, which was only saved by an army of Poles and Germans under John Sobieski. The imperial army then reduced the whole of Hungary into subjection, and united to it Transylvania, which had been hitherto governed by its own princes, and the whole was declared to be a hereditary kingdom. In 1699 Turkey, after being defeated in several sanguinary engagements by the celebrated general Prince Eugene, was compelled by the peace of Carlowitz to cede to Hungary the country lying between the Danube and the Theiss. Previous to his troubles with Hungary and Turkey,

Leopold had lent his aid in 1672 to the Dutch in their struggle against the ambitious designs of France. This was brought to a close by the peace of Nimeguen in 1678; but the conflict broke out afresh the following year, when the English also came forward and contributed largely both in troops and money. The chief scenes of warfare were the Netherlands and the banks of the Rhine. At last, in 1697, came the peace of Ryswick, which left the contending parties in nearly the same relative positions as at the beginning of the contest. The allies had, however, the satisfaction of having compelled the French king to stop short in his schemes of aggrandisement.

The death of Charles II. of Spain in 1700, without leaving issue, led to what is known as the *War of the Succession*. Louis XIV. had married the eldest sister of the late king, but she had by solemn covenant renounced her right to the Spanish crown. The second sister had married the Emperor Leopold, and she had made no such renunciation, but her daughter had, who was married to the elector of Bavaria. Leopold had two sons by a second marriage, and now claimed the crown for the younger of these, on the ground of his mother being an aunt of the deceased king. Intrigues had been carried on by the several parties concerned for some time before the king's death, and he had been induced to make a secret will, in which he named Philip, duke of Anjou, grandson of Louis XIV., as his successor. Leopold, however, was by no means inclined to depart from what he considered his rights, and the other states of Europe looked on with jealousy on the prospect of a union of France and Spain under a Bourbon dynasty. An alliance was accordingly formed by Austria with England and Holland against France, with which power on the other hand Bavaria allied herself. The emperor dispatched an army into Italy under Prince Eugene, to take possession of the Spanish territories in that country; while the English and Dutch united their forces under Marlborough. The former experienced a good deal of hard fighting, but effected little of consequence, while the latter busied himself in taking one after another of the French strongholds in the Netherlands. At length the two generals combined their forces and met the united army of the enemies at Blenheim. The latter numbered about 56,000 men and occupied a strong position, while the number of the former was about 52,000. The fight commenced by Marlborough leading the right wing against the French, while Eugene with the left wing advanced against the Bavarians. The battle was long and fierce, the assailants being repeatedly driven back by a most terrible fire from the enemy's artillery. At length victory declared for the allied English and Austrian armies (13th August 1704). About 10,000 of the French and Bavarians fell on the field, and nearly 13,000 were made prisoners, among whom was the commander of the French army, Marshal Tallard. The elector of Bavaria was compelled to cross the Rhine with the French, and his territory was occupied by the imperialists. The following year the emperor died, and was succeeded by his eldest son, Joseph. The war was continued with vigor, but for a time nothing of importance was anywhere effected. France now directed her chief attention to the conquest of the Netherlands, and sent into that country a magnificent army under the command of Marshal Villeroi. But this general was no match for Marlborough; and in the battle of Ramillies (23d May 1706) he was totally defeated with a loss of about 13,000 men. Prince Eugene's efforts in Italy were also this year crowned with much success. After a memorable march of more than 200 miles, he suddenly appeared before Turin, which was then closely besieged by the enemy. Having effected a junction with the duke of Savoy, he attacked the French lines (7th September), and though repeatedly driven back, at length succeeded in totally routing the enemy. The French general, Count Marson, was wounded, taken prisoner, and died the following day. The French power in Northern Italy was thus shattered, and soon after both French and Spaniards were driven out of the country. The like success attended the efforts of Marlborough in the Netherlands, where he took possession of every place of note. After Eugene had settled affairs in Italy, he again formed a junction with Marlborough in the Netherlands, and on 11th June 1708 they attacked and routed the French under Vendôme at Oudenarde. France now made overtures for peace; but these being rejected, she sent a new army into the field, under the command of Marshal Villars. He was attacked by the two victorious generals in his entrenchments at Malplaques (11th September 1709) and totally defeated. France again made proposals for peace, but these meeting with no better success, the war was continued. The emperor died on 17th April 1711, and his successor being his brother, the Archduke Charles, who laid claim to the Spanish crown, this event contributed not a little to restore peace. The prospect of the union on one head of the crowns of Austria and Spain did not accord with the views of those who had been hitherto supporting the claims of Austria, and the transfer of Spain to a grandson of Louis XIV. appeared to them the less dangerous alternative of the two. This, joined to the change of ministry in England, and the removal of Marlborough from the command altogether, with the impatience of the Dutch under so long and so burdensome a war, led to the peace of Utrecht, which was signed 11th April 1713. Austria continued the war for some time longer, but the next year agreed to substantially the same terms at Baden. By this treaty France engaged that the crowns of France and Spain should never be united, and that no part of the Spanish Netherlands should ever be transferred to her; she also ceded to England Nova Scotia, Newfoundland, Hudson's Bay, and St. Kitt's, and agreed to destroy the fortifications of Dunkirk; Spain gave up her possessions in the Netherlands and in Italy to Austria (who, on her part, renounced her claim to the Spanish succession) and ceded Gibraltar and Minorca to England; the Dutch received a small accession of territory; and the duke of Savoy obtained Sicily, with the title of king — afterwards (1720) exchanged for the island of Sardinia. The Austrian monarchy now embraced about 190,000 square miles of territory, with nearly 29,000,000 of inhabitants. Its annual revenue was between 13,000,000 and 14,000,000 florins, and its army consisted of 130,000 men.

Austria next became involved in a war with the Turks, and in 1716 Prince Eugene set out at the head of an army against them. The result was a series of splendid successes, which led to a peace signed at Passarowitz (1718), by which Austria received a considerable accession of territory. Disaffection still continued to subsist between Spain and Austria, which led to repeated negotiations on the part of the other powers to preserve peace. Charles being without heirs-male, was desirous of securing the succession to his eldest daughter, Maria Theresa, and with this view he framed the celebrated Pragmatic Sanction, and it became his great object to get the assent of the other powers to this arrangement. England and almost all the other powers, except France, Spain, and Sardinia, acceded to it in 1731. In 1733 the emperor became involved in a war with France on behalf of Augustus III. of Saxony, who had been elected king of Poland. France supported the claims of Stanislaus Leszczinski, and received the aid of Spain and Sardinia.

The war was carried on principally in Italy, where Austria was driven out of most of her possessions, and was glad to sue for peace. By this treaty Augustus was confirmed on the throne of Poland; but Austria was obliged to cede to Stanislaus the duchies of Lorraine and Bar, to be afterwards transferred to France; Don Carlos was placed on the throne of the Two Sicilies, and the grand duchy of Tuscany was bestowed on the duke of Lorraine, the emperor receiving as compensation Parma and Placentia; and France, and afterwards Spain and Sardinia, acceded to the Pragmatic Sanction. War again broke out with the Turks, and Prince Eugene being now no more, the Austrians were repeatedly beaten and expelled from one stronghold after another, till, by the peace of Belgrade (1739), the emperor was compelled to yield up almost all that the arms of Eugene had formerly gained for him. The emperor died on the 20th October 1740, and his eldest daughter, Maria Theresa, who was married to the duke of Lorraine or Lothringen (afterwards archduke of Tuscany), assumed the government. Immediately counter-claims were advanced on all sides. The elector of Bavaria claimed to be rightful heir to the kingdom of Bohemia; the elector of Saxony and king of Poland, and also the king of Spain, claimed the entire succession; the king of Sardinia laid claim to the duchy of Milan, and Frederick II. of Prussia to the province of Silesia. France espoused the cause of Bavaria, while England alone came forward to the assistance of the queen, and the Hungarians, now united and loyal, willingly recruited her armies. Aided by France and Saxony, the elector of Bavaria, took possession of Bohemia, and was proclaimed king in 1741, and the following year he was elected emperor under the title of Charles VII. The king of Prussia marched suddenly into Silesia and took possession of that country. The elector of Bavaria, aided by French troops, next invaded Austria, and even threatened Vienna. The queen fled to Presburg and convoked the Hungarian diet. She appeared in the midst of the assembly with her infant son Joseph in her arms, and appealed to them for protection and help. A burst of enthusiasm followed, and a powerful Hungarian army was speedily at her service. The French and Bavarians were soon driven out of the archduchy. A battle was fought between the Austrians under the prince of Lorraine and the Prussians under Frederick, at Czaslau (17th May 1742), in which the former were defeated, and this was followed by the peace of Breslau (11th June), by which Prussia acquired possession of Upper and Lower Silesia (excepting the towns of Troppau and Jägerndorf, and the mountains of Silesia) and the county of Glatz. Austria now turned her arms against the French and Bavarians, the former of whom were driven out of the country. In 1744 the king of Prussia, jealous of the success attending the Austrians, again took the field against them in support of the emperor. He marched into Bohemia and took Prague, but subsequently was forced to retreat; and the death of the emperor Charles on 20th January 1745 changed the aspect of affairs. Maria Theresa's husband was in September elected emperor under the title of Francis I., and after some more fighting, a peace was concluded with Prussia at Dresden, by which the king was confirmed in the possession of Silesia. The war with France was prosecuted for some time longer in the Netherlands and in Italy, with varying success, but ultimately peace was concluded at Aix-la-Chapelle, in October 1748. Austria gave up the duchies of Parma, Placentia, and Guastalla to Don Philip, son of the king of Spain, and several districts of Milan to Sardinia; Prussia was confirmed in the possession of Silesia and Gletz; while Maria Theresa was recognised as rightful monarch of Austria. After having acquired peace, and been thus confirmed in her possessions, her great desire was to recover Silesia from Frederick, whose conduct towards her had sunk deep into her heart. She directed her attention to strengthening and improving her army, and to forming alliances with the other states against the Prussian king, particularly with Russia and Saxony. In 1755 war broke out in North America between France and England, and in view of its becoming more general England solicited the aid of Austria, but without success. This naturally led to a union between England and Prussia, while France allied herself with Austria and Russia.

In July 1756, Frederick despatched a messenger to Vienna to ascertain the meaning of the large forces assembled in Bohemia and Moravia. Receiving an evasive answer, he at once marched an army of 60,000 men into Saxony, took Dresden, and made himself master of the country, the Saxon army of only about 17,000 men being shut up in a strong position, but ill provisioned, between Pirna and Königstein. An Austrian army, under the command of Marshal Browne, advanced from Bohemia to the relief of Saxony, but was met by Frederick. A battle took place at Lowositz (1st October), which, though not decisive, ended in the retreat of the Austrians; and the famished Saxon army, after an ineffectual attempt to effect a retreat to Bohemia, laid down their arms. This ended the first campaign, and both sides did their utmost to prepare for renewing hostilities the following year. The empress strengthened her forces in Bohemia, and the imperial diet conceded an army of 60,000 men to assist her. France engaged to send an army of 80,000 or 100,000 men into Germany, and Russia set in motion an army of 100,000 men against Prussia. In all, the allies were estimated to muster about 500,000 men, while Fredrick could scarcely raise 200,000 of his own, his auxiliaries (English, Hanoverians, &c.) probably amounting to about 40,000 more. Frederick renewed the war by marching an army into Bohemia, where, on 6th May, he gained a victory over the Austrians, under Prince Charles of Lorraine, in the neighborhood of Prague, and then laid siege to that city. General Daun, at the head of an Austrian army, advanced to the relief of the city, and the king set out to meet him. The encounter took place at Kolin (18th June), and the Prussians, being much inferior in numbers, were beaten with great slaughter. Frederick was compelled at once to raise the seige and to evacuate Bohemia. In honor of this victory the empress instituted the military order of Maria Theresa. It had also the effect of inspiring the allies with fresh courage. The Russians invaded the kingdom of Prussia; the Swedes entered Pomerania; and two French armies crossed the Rhine in order to attack Hesse and Hanover and then march into Prussia. One of these armies under the command of Prince Soubise, advanced towards Thuringia, in order to form a junction with the imperial forces under the prince of Hildburghausen, while Marshal d'Estrées, who commanded the larger French army, entered Hanover, and through the incapacity of his opponent, gained an easy victory over the Anglo-Germanic army, under the duke of Cumberland, near Hastenback, on the Weser (26th July). The duke afterwards completed his disgrace by agreeing to disband his troops and give up Hanover, Hesse, Brunswick, and the whole country between the Weser and the Rhine, to the French. The other French army effected a union with the imperial troops of Thuringia, and made preparations for driving the Prussians out of Saxony. Frederick, however, determined to meet them, and after a series of marches and countermarches the two armies came together near Rossbach. The Prussian army amounted to about

22,000 men, while that of the French and Austrians numbered nearly 60,000. Frederick's troops were encamped upon a height, and the allies, when they advanced to the attack, were suddenly met by such a tremendous fire that they were thrown into confusion and unable to recover themselves. In less than half an hour the day was decided (5th November 1757). The allies had 1200 killed and more than 7000 taken prisoners, while the loss of the Prussians scarcely exceeded 500 in killed and wounded. At this time the imperialists had entered Silesia and there gained several advantages over the Prussians, who were at length driven to the walls of Breslau. Here a battle was fought (22d November) in which the Austrians were victorious, and the city itself soon after surrendered to the conquerors. Frederick now made what haste he could to retrieve his fortunes in this quarter, and met the Austrian army, under Prince Charles of Lorraine, in a plain near the village of Leuthen. The Austrians numbered about 80,000 men, while the Prussians did not exceed 30,000, yet by the skilful disposal of his troops and the celerity of his movements Frederick again gained a complete victory (5th December). The field was covered with slain, and it is estimated that about 20,000 surrendered themselves prisoners. Breslau was speedily retaken, and the Austrians driven out of Silesia.

The English were very indignant at the treaty entered into by the duke of Cumberland, and another army was speedily raised and placed under the command of Duke Ferdinand of Brunswick, who commenced the campaign of 1758 by suddenly attacking the French in their winter quarters. In a few weeks he succeeded in driving them out of the country, pursued them across the Rhine, and attacked them furiously at Crefeld, where they were completely routed.

While Field-Marshal Daun. who had received the command of the Austrian army, was waiting the attack of Frederick in Bohemia, the latter, by forced marches, entered Moravia and laid siege to Olmütz. The town, however, defended itself with the greatest bravery, and the Prussians were compelled to raise the seige. By this time, Daun having blocked up Frederick's retreat into Silesia, the Prussian army was marched suddenly northward into Bohemia, and attacked the Russians who had invaded Brandenburg. After a desperate battle the latter were defeated with great slaughter at Zorndorf (26th August), and compelled to retreat into Poland. Frederick now entered Saxony, where his brother Prince Henry was hard pressed by the Austrians. Thereupon Daun retired to a strong position in Lusatia, and Frederick took up a position near him, little thinking that Daun would attack him. Early in the morning of the 14th of October, however, the Austrians suddenly fell upon him at the village of Hochkirchen, and in the confusion and darkness the slaughter was terrible. Frederick lost several of his best generals, including Prince Francis of Brunswick, Prince Maurice of Dessau, and Field-Marshal Keith, with about 9000 of his soldiers. His camp, baggage, and ammunition also fell into the hands of the Austrians. The victory, however, was productive of little material results; Frederick retreated into Silesia, while the Austrians, after ineffectual attempts on Leipsic, Torgau, and Dresden, retired to Bohemia for the winter. The Austrian army was again largely reinforced, and every preparation made for renewing hostilities with vigor. The following year (1759) Duke Ferdinand found himself hard pressed by two French armies under the Duke de Broglie and the Marshal de Contades. He sustained a defeat at Bergen (12th April), but afterwards gained a signal victory at Minden (1st August), and compelled the French to retreat. Daun, waiting the approach of the Russians, did not take the field till the beginning of May, when, on their advance towards the Oder, he moved into Lusatia. In June, Dohna, who was sent to check the advance of the Russians, was forced to retreat, and, on the 23d July, Wedel, who succeeded him in the command, was totally routed near Züllichau. The Russians then marched on to Frankfort-on-the-Oder, where they were joined by 18,000 Austrians under Marshal Loudon. Frederick hastened with what troops he could collect to give battle to the combined army. The latter took up a strong position on the heights near Kunersdorf, and there they were attacked early on the 12th of August by the king. The Prussians numbered about 50,000, while the Russians and Austrians amounted to 90,000. The battle raged long and furiously, and the issue was long doubtful, but at length the Russians were giving way on all sides, and victory was about to be declared for the Prussians, when unexpectedly the Austrians made a furious attack upon them, threw them into confusion, and in a short time drove them from the field. Frederick lost in this action 20,000 of his bravest troops, and the loss on the side of the allies was not less than 24,000 men killed and wounded. In the meantime the Austrians overran Saxony, took Torgau, Wittenberg, and Leipsic, and invested Dresden, which, after a spirited defence, surrendered when an army of relief was close at hand. But Frederick was speedily in the field again at the head of a new army, and, by dint of skilful manœuvring and cutting off supplies, he succeeded in harassing the two armies, and compelled the Russians again to retire into Poland. An army of 13,000 men, under General Fink, attacked the rear of the Austrian army near Maxen, but after a brief but sanguinary conflict they were defeated and taken prisoners. Daun took up his winter quarters in Saxony, notwithstanding every effort of Frederick to dispossess him.

The imperial troops had been very successful during the last campaign, and were in good condition to renew the fight, while the Prussians had sustained great losses, were dispirited, and could only muster about 80,000 fighting men, and these no longer veterans, but in great measure raw recruits. In the campaign of 1760 Frederick was himself to conduct the war in Saxony, Prince Henry was to protect the marches against the Russians, and General Fouquet was to defend Silesia against the Austrians under Loudon. On 23d June, 8000 Prussians, under Fouquet, were surrounded and attacked on all sides by 30,000 Austrians at Landshut, and, after defending themselves long with great bravery, were obliged to yield. The king, after an ineffectual attack upon Dresden, marched into Silesia followed by the Austrians. At Liegnitz he found himself between three armies, under Generals Daun, Lacy, and Loudon, numbering about 90,000 men, while his own army amounted to only about 30,000. On the night preceding the 15th of August, Frederick took up a position on the neighboring heights of Pfaffendorf. Scarcely had he done so when the Austrian army, under Loudon, made its appearance, it having also intended to occupy the same position, and then fall upon the Prussians. The Austrians were greatly astonished to find the enemy before them; nevertheless, they fought for three hours with great bravery, returning again and again to the attack, but were at length compelled to retreat with a loss of 4000 killed and 6000 wounded. Daun afterwards came up and made an attack upon the Prussians, but, learning what had happened to Loudon, he withdrew. Frederick now directed his march on Breslau; and meanwhile the Russians effected a junction with the Austrians, and marched on Berlin, which surrendered to them (3d October). A week later, hearing that the

king was advancing against them, they left the city and retired into Saxony. Daun had likewise arrived in Saxony, and taken up a very strong position near Torgau. Here the Prussians attacked him with great fury on 3d November. The battle lasted till night without being decisive, and the carnage on both sides was fearful. The Prussians prepared to renew the attack next day, but the Austrians retreated during the night. They lost about 12,000 men killed and wounded, and 8000 prisoners. By this battle Frederick reconquered the greater part of Saxony, and accordingly he fixed his winter quarters there, establishing his headquarters at Leipsic. In 1761 Frederic employed every stratagem to prevent the junction of the Russian army under Buturlin with the Austrian under Loudon. The two armies, however, at length came together in the environs of Strigau (12th August), the combined force amounting to 130,000 men, while the Prussians numbered only about 50,000. The leaders, however, could not agree to a common course of proceeding, and the two armies separated without affecting anything of consequence. The Austrians surprised and took Schweidnitz (1st October), and the Prussians, after a four month's siege, took possession of Colberg (13th December). In Saxony Prince Henry had to retreat before Daun; but the latter gained no great advantages, and Frederic settled in Breslau for the winter. It seemed as if Prussia must at last yield to her assailants, but this was as far as ever from the king's mind. To add to his difficulties, the subsidies from England were stopped by the earl of Bute after the death of George II. But by the death of the Czarina Elizabeth (5th January 1762) he was freed from one of the most powerful of his enemies; and her successor, Peter III., not only recalled the army, but delivered up all the Prussian prisoners, and even entered into an alliance with the king. Sweden also retired from the contest, and entered into terms of peace. Frederick was therefore in a better condition to carry on the war vigorously against Austria, and the seventh campaign was marked by a series of disasters to that power. He attacked and overthrew Daun's right wing at Burkersdorf (21st July), gained a victory at Reichenbach (16th August), and took Schweidnitz after a very gallant defence (9th October). Prince Henry was also victorious at Freiberg (29th October). In the meantime Duke Ferdinand had been during the last three years successfully maintaining the war with the French. Fresh reinforcements and new generals were brought against him, but he could not be crushed; and, by the victories of Wilhelmsthal (24th June) and Lutternburg (23d July), France was brought to agree to peace. Thus Austria and Prussia were left to carry on the war alone; and the former, though amply provided with troops, was without money to furnish the necessary supplies, while Frederick was ever ready to come to terms on having the possession of Silesia secured to him. Austria found herself obliged to yield this point, and peace was at last agreed to. The treaty was signed at the castle of Hubertsburg, in Saxony, 15th February 1763, and thus ended the Seven Years' War, — a war disasterous to all concerned, and which is estimated to have cost in actual fighting men 853,000. It effected no territorial change in any of the countries, but through it Prussia rose to be one of the great powers of Europe. Austria, on her part, had carried on the conflict with remarkable vigor and determination; her soldiers had displayed great bravery, and some of her generals had shown a military genius not greatly inferior to that of Frederick himself.

Maria Theresa now zealously devoted herself to improving the condition of her people and country. She established schools, removed feudal hardships, improved the condition of the serfs, reformed ecclesiastical abuses, and fostered industry and commerce. The Emperor Francis died 18th August 1765, and was succeeded by his son, Joseph II., who the previous year had been elected king of the Romans. He also became joint-regent with his mother of the hereditary states. Maria established two collateral branches of her house in the persons of her two younger sons, the Archduke Leopold in Tuscany, and the Archduke Ferdinand, who married the heiress of Este, in Modena. By the first partition of Poland (1772) Austria acquired Galicia and Lodomeria, and in 1777 Buckowina was ceded by the Porte. On the death of the elector of Bavaria without issue, the Emperor Joseph laid claim to his dominions. To this Frederick was opposed, and again took the field against Austria. The dispute, however, was settled without war (1779), Austria being content with the cession by Bavaria of the frontier district called the quarter of the Inn, and one or two others. The empress died 29th November 1780, in the sixty-fourth year of her age and the forty-first of her reign. She was a woman of many and great virtues, with few weaknesses, and effected more for Austria than any of her predecessors. Mr. Carlyle says that she was "most brave, high and pious minded; beautiful, too, and radiant with good nature, though of a temper that will easily catch fire; there is, perhaps, no nobler woman then living." At her death the monarchy comprised 234,500 square miles, with a population estimated at 24,000,000, and a public debt of 160,000,000 florins, or £16,000,000.

The Emperor Joseph II., whose zeal for reform had in great measure been kept in check during the lifetime of his mother, now felt himself at liberty to give it full scope. He attempted a number of changes, of which several were praiseworthy in their objects, but abrupt and premature in their operation, so that in the end they were productive of evil consequences. He sought to establish a system of central government and uniformity of legislation throughout his dominions; enjoined the exclusive use of the German language in all schools, courts of justice, &c.; granted free and unreserved toleration to all sects of Christians; abolished numerous convents and monasteries; dismantled various fortresses; and did away with primogeniture and feudal vassalage. Had his people been ripe for these changes he would probably have been hailed as a reformer of abuses; but the Austrians were attached to their old usages, and were little inclined for change, while the arbitrary manner in which the improvements were introduced could not fail to provoke discontent. General uneasiness, therefore, began to prevail, which in the Netherlands broke out into open revolt in 1789. This, together with an unsuccessful war in which he had engaged with Russia against Turkey, is understood to have preyed upon his over-sensitive mind, and caused his death on 20th February 1790. He was, says Mr. Carlyle, "a man of very high qualities, and much too conscious of them; a man of ambition without bounds; one of those fatal men — fatal to themselves first of all — who mistake half genius for whole; and rush on the second step without having made the first."

He was succeeded by his brother Leopold, grand duke of Tuscany, who by his moderation and firmness was successful in restoring peace to the country, and in quelling the insurrection in the Netherlands. He also made peace with the Porte. The misfortunes of his sister Maria Antoinette and her husband, Louis XVI., of France, led him to enter into an alliance with Prussia against the Revolutionists, but he died before the war broke out (1st March 1792). He was succeeded by his son, Francis II., who had hardly ascended the throne when he found himself involved in a war with France.

Hostilities commenced on 28th April with an attempted invasion of Flanders by the French, but their undisciplined troops were speedily routed and put to flight. A combined army of 50,000 Prussians, under the command of the duke of Brunswick, and 15,000 Austrians under General Clairfait, besides about 20,000 French, soon after crossed the French frontier, took Longwy and Verdun, and marched on Paris. In the meantime Dumouriez was actively engaged in collecting an army, and soon found himself in a condition to meet them. A series of engagements took place without any decided result, beyond checking the advance of the allied troops, who were now also suffering very severely from sickness and famine. It was therefore deemed prudent to retire, and Verdun and Longwy were soon after retaken. Dumouriez next invaded the Netherlands with an army of 100,000 men, to oppose which the Austrian army only amounted to 40,000. A battle took place at Jemappes on the 6th of November, in which the Austrians fought with heroic bravery, and the contest was long doubtful, but the superior numbers of the French carried the day. The loss on both sides was very great; and soon after the whole of the Austrian Netherlands, with the exception of Luxemburg, was in the hands of the French. The commencement of the campaign of 1793 was distinguished by a series of brilliant victories gained by the allies in the Netherlands. Dumouriez was defeated at Aldenhoven, and again in a great battle at Neerwinden (18th March). Soon after, afraid of falling into the hands of the Jacobians in Paris, he passed over to the allies. His successor, General Dampierre, was defeated and slain on the plains of Famars, and the allies became masters of Valenciennes and Condé. Towards the end of the campaign, however, the republican troops were successful in a number of engagements. At the commencement of the year 1794, the Austrians, Dutch, English, and Hanoverians united their forces in the Netherlands under the command of the prince of Coburg, and the Emperor Francis himself joined the camp, in order by his presence to encourage the troops. In April the allies were successful at Cateau and at Landrecies, and took that town; but their good fortune then forsook them. Clairfait was attacked singly at Kortryk by Pichegru, and forced to yield to superior numbers; and the allies under the prince of Coburg were attacked by him at Tournay (22d May), when an extremely long and bloody, but undecisive, battle was fought. The Austrian troops were now greatly dispirited; and, on the 26th June they were defeated by General Jourdan at Fleurus. This was followed by other disasters, so that all Flanders was soon in the hands of the French. Pichegru, pursuing his victorious career, next invaded Holland, which, before the end of the year, was transformed into a republic. In the beginning of 1795 Prussia abandoned the cause of the allies, and concluded a treaty of peace with the French republic at Basle (5th April), and was joined therein by Hanover and Hesse Cassel, so that Austria and England were left alone to prosecute the war. For some months a cessation of hostilities took place between the contending parties; but on the 6th of September the French army under Jourdan suddenly crossed the Rhine near Düsseldorf, invested that town, and drove the Austrians before it over the Maine. Clairfait, however, reassembled his troops behind the latter river, and attacked the French at Höchst near Frankfort, and completely defeated them (11th October), so that they were obliged to recross the Rhine. In the meantime Pichegru had crossed the river with another army, near Mannheim, and took possession of that town. Wurmser, who was sent for its relief, arrived too late for that purpose, but attacked the French army near it, put them to flight, and compelled them to recross the Rhine, leaving a garrison of 8000 men to defend the town, which, after a vigorous siege, surrended to the Austrians. The French, undismayed by these failures, were only stimulated to greater efforts; and the following year they sent out three armies against Austria, one under Jourdan towards the Lower Rhine, another under Moreau towards the Upper Rhine, and a third into Italy. In the end of May the French army under Jourdan crossed the Lower Rhine, and gained some successes, but was afterwards attacked by the Archduke Charles (16th June), and forced to recross the river. Moreau soon after effected his passage over the Upper Rhine at Strasburg, defeated the Austrians in several partial engagements, and reduced the circle of Swabia to subjection. Jourdan again pushed forward his troops, and took Frankfort by bombardment, but was defeated with great loss by the archduke at Amberg (24th August), and again at Wurzburg (3d September). Moreau had in the meantime continued his advance into Bavaria, but was ultimately obliged to effect a retreat, which he carried out with great skill, suffering comparatively little loss, and recrossing the Rhine on 20th October. But a different fate was attending the army in Italy, under the command of a young officer, who afterwards became world-famous for his generalship, namely, Bonaparte. By the promptitude of his movements, and the suddenness of his attacks, he completely overcame and separated the army of the Sardinians from that of the Austrians, and forced the Sardinian king to sign a treaty of peace. He then turned his arms against the Austrians, defeated them in several engagements and made himself master of the whole of Lombardy, except Mantua. Wurmser was now summoned from Germany with an army of 30,000 men, which raised the Austrian force to about 60,000; while opposed to them were about 55,000 French. Instead, however, of advancing in one body, the Austrians were divided into two columns, which advanced by different routes, a mistake of which Bonaparte did not fail to take advantage. One division of 20,000 men was attacked and compelled to retreat towards the mountains, while Wurmser with the other division entered Mantua. Leaving that city he sustained a double defeat at Lonato and Castiglione (3d August); and, being again severely beaten at Medola (5th August), he was forced to seek shelter in the mountains of Tyrol. Having received reinforcements, however, he again advanced in divided columns, one of which was defeated at Roveredo, the other, under himself, near Bassano. He took the road to Mantua with the remains of his army, and reached that town after a brilliant victory over a body of French troops that had been sent to intercept him. Meanwhile the Austrians collected another army of 40,000 men under Alvinzi, who after a series of successes, gained a decided victory over Bonaparte at Caldiero (11th November). Four days later the Austrians were again attacked by the French near the village of Arcola, and after three days' desperate fighting on both sides the Austrians at length retreated. Alvinzi received reinforcements, and again set out to attack the French, but suffered a severe defeat at Rivoli on 14th January 1797. A fortnight later Mantua capitulated, and the French became undisputed masters of the country. Speaking of the perseverance and patriotic spirit of the Austrians in this struggle in Italy, Sir A. Alison says, "It is impossible to contemplate without admiration the vast armies which they successively sent into the field and the unconquerable courage with which these returned to a contest where so many thousands of their countrymen had perished before them. Had they been guided by greater or opposed by less ability they unquestionably would have

been successful, and even against the soldiers of the army of Italy and the genius of Napoleon, the scales of fortune repeatedly hung equal."—(*History of Europe.*) The Archduke Charles was now recalled from the Rhine to oppose Bonaparte. The latter set out on his journey northward on the 10th of March, with the view of crossing the Alps and so reaching Vienna. The Austrians attempted to oppose his progress at the river Tagliamento, but without success; and a desperate struggle took place for the possession of the Col de Tarvis, which ended in favor of Napoleon, so that in twenty days after the campaign opened the army of the archduke was driven over the Julian Alps, and the victorious French army of 45,000 strong was on the northern declivity of the Alps, within 60 leagues of Vienna. Napoleon, still pressing on, took possession of Klagenfurt, and advanced as far as Judenburg on the River Mur; but finding his position very insecure, and dangers thickening upon him, he despaired of carrying out his intention of dictating peace under the walls of Vienna. He therefore offered terms of accommodation to the Austrians, which they deemed it prudent to accept. Preliminaries were agreed to at Leoben (18th of April), and a formal treaty of peace was signed at Campo Formio, 17th October 1797. By this treaty Austria ceded to France Flanders and her Italian possessions, and received in return Venice and its dependent provinces. It, however, contained certain secret articles, by one of which Austria consented to surrender the whole of the left bank of the Rhine to France; and a convention was appointed to meet at Rastadt to provide equivalents on the right bank for the princes dispossessed on the left, and otherwise to settle the affairs of the empire. The terms were not particularly hard as regards Austria. The ceded territories contained about 3,500,000 souls, and those acquired about 3,400,000. But the taking away of the independence of Venice, which had been maintained for 1400 years, was an act of rapacity which excited the indignation of Europe, and Austria's share in it must ever remain a stain on her annals.

This peace was not of long duration. As the business of a convention which met at Rastadt advanced, and the bearing of the secret articles became known, a great sensation was created in Germany. The high-handed manner in which the French conducted their negotiations, and the insolence and contempt with which they treated the empire, led to the recall of the Austrian ambassador from the convention in the beginning of 1799, and on the 13th of March France again declared war against Austria. In the meantime the latter power had entered into an alliance with England and Russia against the former. In Germany the Archduke Charles defeated Jourdan at Stockach (26th March), and in several other encounters, and drove him out of the country; and he afterwards reconquered the whole of the western portion of Switzerland to beyond Zurich from Massena. In Italy Scherer was defeated by the Austrian general Kray at Verona and at Magnano, and then resigned the command into the hands of Moreau. The Russian army, under Suwaroff, now formed a junction with the Austrian, and the French were again beaten near Cassano (27th April). This was followed by other successes, so that in less than three months the French standards were driven back to the summit of the Alps, and the whole plain of Lombardy, with the exception of a few of its strongest fortresses, was recovered. After this the Russian general marched against Macdonald, who was advancing with a French army from Naples. A desperate conflict took place on the banks of the Trebbia, which was maintained with consummate bravery and skill for three days (17–19 June), until victory deciared for the Russians. Out of 36,000 men in the field the French lost above 12,000 in killed and wounded, and the allies nearly as many. One place after another now fell into the hands of the allies; but mutual jealousies and divisions breaking out among them, the Russian and Austrian forces were eventually separated. This led to the most disastrous results. The Russians were to prosecute the war in Switzerland, while the Austrians remained to carry it on in Italy. In the meantime another French army had been collected under General Joubert; and, on the 15th of August he was attacked by the allies at Novi. The battle was long and obstinate, but at length the allies were victorious. The French lost their general, who fell mortally wounded, besides about 1500 killed, 5500 wounded, and 3000 prisoners. The loss of the allies was 1800 killed, 5200 wounded, and 1200 prisoners. The Russian general now directed his march towards the Alps, forced the St. Gotthard, and descended into the valley of the Urseren, driving the French before him with great slaughter. With great difficulty and loss he effected a passage through the horrible defile of the Shächenthal, between Altdorf and Mutten; but, at the latter place, instead of meeting the allied troops, as he had expected, he found himself in the midst of the enemy. Before this time Massena had so beset the Russian general Korsakoff at Zürich, that he was compelled to fight, and with difficulty made his escape with the remains of his army, while the Austrian forces under Hotze had also been beaten by Soult. Nothing remained for Suwaroff but retreat, a course which he adopted with extreme reluctance, making his way with incredible resolution and perseverance over the rugged Alps into Glarus and the Grisons, and at length reaching the valley of the Rhine (10th October). Disagreements having taken place between the Austrian and Russian generals regarding their future proceedings, the latter withdrew to winter quarters in Bavaria; and soon after this the capricious czar of Russia, Paul, withdrew from the alliance and recalled his troops.

Bonaparte, who had now returned from his Egyptian campaign, made proposals for peace, which were rejected, and both sides prepared to renew the contest in 1800. A numerous and well appointed French army was collected at Dijon, at the head of which the first consul suddenly put himself, and set out for Italy across the Great St. Bernard. The passage was effected with great skill and determination in spite of every obstacle, and he arrived in Lombardy before Melas, the Austrian general there, had been informed of the expedition. On the 14th of June a great battle took place near the village of Marengo, the most obstinate and sanguinary that had up to this time been fought. The Austrian army numbered at least 21,000 foot and 7,000 horse, while opposed to them was an army of 22,000 men. The battle was maintained with great spirit and obstinacy on both sides; but at length, after repeated charges, the French were compelled to give way, and the retreat became general. At this moment, however, a fresh body of French troops under Desaix arriving on the field the contest was renewed, and after a final struggle the Austrians were compelled to yield. They lost about 7000 men in killed and wounded, and 3000 prisoners; while the French lost about the same number in killed and wounded, and 1000 prisoners, taken in the early part of the day. Their retreat being cut off, the Austrians capitulated to the conqueror, who thus again acquired possession of the whole of Italy. In the meantime Moreau had invaded Germany, and defeated Kray in several engagements, particularly at Stockah and Möskirch, and again at Biberach and Hochstädt; he also took Munich, and laid Bavaria and Swabia under contribution. An armistice was now agreed to (Pars-

dorf, 15th July), and overtures were made for peace, but without success. Hostilities were resumed in the end of November, and at first the Austrians gained some advantages, but on the 3d of December they sustained a crushing defeat at Hohenlinden. The fight was long and obstinate; the French lost on that and the preceding days 9000 men, while the loss of the Austrians was nearly twice as great. The moral effects of the defeat were most disastrous. Moreau now advanced by hasty marches, crossed the Inn, took Salzburg and pressed on towards Vienna. But an armistice was agreed to on 25th December. In Italy the Austrian forces sustained a severe defeat at the passage of the Mincio (26th December). Suffering under these disasters Austria was glad to agree to terms, which were concluded at Luneville, 9th February 1801.

By this treaty the whole of the left bank of the Rhine was again ceded to France, and the Adige was declared to be the boundary of Austria in Italy; the grand duke of Tuscany, on the promise of an indemnity in Germany, renounced his dukedom in favor of the infant duke of Parma, created king of Etruria; the duke of Modena received the margraviate of Breisgau in exchange for his territory; and the independence of the Batavian, Helvetic, Cisalpine, and Ligurian republics was recognised and guaranteed. A convention was to be again summoned for the regulation and adjustment of the rights of all concerned. In order to provide indemnities for the despoiled princes, a large proportion of the ecclesiastical sovereignties of the empire was *secularised*, or, in other words, confiscated; and all the free imperial cities were deprived of their privileges with the exception of six. To the share of Prussia fell the bishopries of Hildesheim and Paderborn, the city of Munster, and other cities and abbacies, to the amount of more than four times what she had lost on the left bank of the Rhine. Thus was she rewarded for her discreditable neutrality and impolitic desertion of the European alliance, though she subsequently suffered for this at Jena and by the treaty of Tilsit. The grand duke of Tuscany received the archbishopric of Salzburg, the Bishopric of Eichstadt, and part of that of Passau, in exchange for his hereditary possessions. Austria received the Tyrolese archbishoprics of Trent and Brixen. She had also received, in 1795, Western Galicia as her share in the third division of Poland, so that now her territory comprised over 254,000 square miles, her public debt amounting to 1,220,000,000 florins, or £122,000,000.

Austria now enjoyed a short period of peace, and employed it in silently repairing the breaches in her army and finances which had been produced by the late wars. After Napoleon had assumed the title of emperor of the French, the Emperor Francis took for himself and his successors that of emperor of Austria (11th August 1804). On 11th April 1805, an alliance was formed between England and Russia for resisting the encroachments of France, and some months later Austria and Sweden likewise joined it. Prussia held aloof, in the hope of receiving Hanover as a reward for her neutrality; while Baden, Würtemberg, and Bavaria sided with France. Deceived by the efforts that Napoleon was ostensibly making for the invasion of England, the Austrians (9th September) crossed the Inn, invaded Bavaria, and took up a position in the Black Forest. Meanwhile the French troops were in full march from the shores of the Channel to the banks of the Rhine; and the force in Hanover, under Bernadotte, was ordered to cross the Prussian territory without asking permission, and form a junction with the Bavarians in the rear of the Austrians, while other corps were at the same time directed by circuitous routes upon their flanks. The Austrian general, Mock, on the first intelligence of the approach of the French, had concentrated his forces at Ulm, Memmingen, and Stockach, contemplating an attack only in front. Great was his consternation, therefore, when he found that there was also an army on his rear. After several partial engagements, in which the Austrians were defeated, the Archduke Ferdinand, at the head of a body of cavalry, succeeded in making his way through the enemy, and in reaching Bohemia; while Mack, with the rest of the army, shut himself up in Ulm, which, with 30,000 men, he was forced to surrender (20th October). After this, Napoleon, with his usual rapidity, marched with the main body of his troops upon Vienna, and on the 5th of November established his headquarters at Linz, the capital of Upper Austria. The Russian and Austrian troops made various attempts to obstruct his farther progress (particularly at Dürrenstein, where a desperate engagement took place), but without success; and, on the 13th November, Vienna was in the hands of the conqueror, who made his headquarters at Schönbrunn. In the meantime the Archduke Charles was with the army in Italy, where, on 29th October, he was attacked with great fury on the heights of Caldiero, by the French under Massena. A terrible conflict ensued, and continued till night parted the combatants. It was renewed the following day, when at length victory declared for the Austrians. The archduke, however, was unable to avail himself of his success, for, hearing of the unfortunate state of matters in Germany, he set out with his army for the defence of the capital, and conducted it with great skill over the mountains, so that it suffered no serious loss. Marshal Ney, who had been sent with a body of troops into Tyrol, succeeded in taking the mountain barrier of Scharnitz by storm, and in making himself master of Innsbruck. Two bodies of Austrian troops had been so hard pressed that they were obliged to capitulate — one under General Jellachich at Feldkirch, and another under the Prince de Rohan at Castel-Franco in Italy.

After the loss of Vienna the allied forces collected themselves in Moravia, whither they were followed by Napoleon. At length the two armies came in sight of each other at Austerlitz, and both sides prepared for battle, which it was felt must be a most momentous one, and was to be witnessed by three emperors (those of France, Austria, and Russia). The allied forces numbered fully 80,000 men, of whom 15,000 were cavalry, while the French had 90,000 men in the field. The army of the allies was not well generaled, while on the side of the French were Soult, Bernadotte, Davoust, Murat, Lannes, Oudinot, Bessières, &c. The battle commenced on the morning of the 2d December, and continued till night. Both sides displayed the greatest skill and bravery; at one part of the field the allies would be victorious, at another the French; at one time victory would incline to the French, and again to the allies. At length, however, towards evening, the allies came to be beaten at all points, and the route soon became general. Numbers sought to save themselves by crossing the frozen lake of Satschan; but shots from the French batteries on the heights above broke the ice in all directions, and about 2000 men perished. The allies lost about 30,000 men, killed, wounded, or made prisoners, while the French lost about 12,000 in killed and wounded. This was the most glorious of all Napoleon's victories; but he was still in a very dangerous position. The archduke Charles, with an army of 80,000 men, was now approaching Vienna; Hungary was rising *en masse* against him; Russian reserves were advancing; and Prussia was at length preparing to declare war, on account of the unauthorised passage of French troops

through her territories. From these difficulties, however he was freed by the desire of the Emperor Francis for peace. An armistice was agreed to, and finally a treaty of peace was drawn up and signed at Presburg (25th December 1805) By this treaty Austria ceded to Bavaria, now erected into a kingdom, the whole of the Tyrol, Vorarlberg, Lindau, Burgau, Passau, Eichstädt, Trent, and Brixen, besides several petty lordships; to Würtemberg, now also become a kingdom, the bordering Austrian dominions in Swabia; and to Baden the Breisgau, the Ortenau, and the town of Constance. She also yielded up her Venetian possessions, and agreed to pay a war contribution of £1,600,000. In exchange for all these sacrifices she merely received the small electorate of Salzburg, and the possessions of the Teutonic Order. In all, Austria lost about 28,000 square miles of territory, with a population of 2,700,000, and a revenue of 14,175,000 florins. It was evidently not the intention of Napoleon to overthrow the Austrian monarchy, but rather to throw its strength to the eastward, and to impose a barrier of subordinate kingdoms between it and France, so as to prevent its interference with his schemes of aggrandisement in Germany and Italy.

A blow was inflicted upon the constitution of the German empire by Napoleon, in the formation of the Confederation of the Rhine. Representatives of the different powers concerned assembled at Paris in the beginning of July 1806; and, on the 12th of that month, an Act was signed whereby the kings of Bavaria and Würtemberg, the elector of Baden, and thirteen other princes of Western Germany, separated themselves from the German empire, and formed a confederation under the protection of the emperor of the French. 16,000,000 men were thus, by a single stroke, transferred from the empire to a foreign alliance. Wisely yielding to what he could not prevent, the Emperor Francis, by solemn deed, renounced the title of emperor of the Romans, and declared himself the first of the emperors of Austria.

The peace of Presburg was quickly followed by the war between France and Prussia, in which the latter suffered terrible retribution for her selfish policy in leaving Austria to struggle unaided against the common foe of Europe. Great efforts were made to induce Austria to take part in this war, but she prudently remained neutral, contenting herself with making every effort to strengthen and improve her army, and increase her warlike resources. During the whole of 1806 and 1807 the efforts of the war department, under the guidance of the Archduke Charles, were incessant to restore the losses that had been sustained in the late war. The army was also remodelled upon the system adopted by Napoleon. The transfer of a large portion of the French army in Germany to the Peninsula on the breaking out of war there, emboldened the Austrian Government to issue a decree (9th June 1808), instituting a landwehr or militia to be raised by conscription, which soon amounted to 300,000 men, in addition to a regular standing army of 350,000. On hearing of this, Napoleon addressed strong remonstrances to the court at Vienna, which made loud professions of pacific intentions, but did not cease its warlike preparations. In the spring of 1809 the armies on both sides took the field, and, on 8th April, Austrian troops crossed the frontiers at once in Bohemia, on the Inn, in the Tyrol, and in Italy. In the meantime France was bringing together her forces from all quarters towards the valley of the Danube, where at length she had an army, including the troops of the German Confederation, of about 200,000 men, and Berthier was despatched to take the command till the arrival of the emperor. The Archduke Charles had crossed the Inn with upwards of 120,000 men, and on the 16th they had advanced as far as the Isar, which they crossed. Berthier, instead of concentrating his troops, was separating them, so that they were in the utmost danger, when the arrival of Napoleon at once changed the aspect of affairs. On the 19th an action took place at Thann, between a body of about 20,000 French and a like number of Austrians, without any decisive result; and the following day the main body of the Austrians, over 50,000 strong, was suddenly attacked and defeated after a feeble resistance at Abensberg, by a French army of 65,000 men. The same day the Austrians attacked and took Ratisbon, and secured the bridge over the Danube there. Both sides now prepared for a general engagement, which took place at Eckmühl on the 22d of April. The battle was bravely contested; but at length the French were victorious, the loss to the Austrians being 5000 killed and wounded, and 7000 prisoners. The archduke retired during the night to recruit his army in Bohemia, and Ratisbon was taken by storm. In other parts, particularly in Italy, success was attending the Austrian arms.

Napoleon now lost no time in again marching on to Vienna, and no great attempt was made to impede his progress except at Ebersberg, where Hiller with about 30,000 Austrians took his stand to defend the wooden bridge over the Traun. He was gallantly attacked by a body of French troops under Massena, and a fearful struggle took place; but at length the French prevailed, and Hiller withdrew his troops. Each side lost about 6000 men on this occasion. On the 10th of May the French eagles appeared before the walls of Vienna, and, after an ineffectual attempt at defence, the city surrendered on the 13th. The Archduke Charles was hastening to the relief of the town, but arrived too late. The two armies therefore prepared for battle, the one on the north bank of the Danube, the other on the south. On the night of the 19th the French prepared to cross the river at the island of Lobau, and by daybreak on the 21st they had 40,000 men landed on the northern side. The Austrians now resolved upon an attack, and by two o'clock, when the fight began, the French force amounted to about 50,000 men, while the Austrians had 80,000 to oppose them. The scene of action was near the villages of Aspern and Essling, and the struggle was maintained with the most desperate courage on both sides till night parted the combatants. The Austrians had everywhere the advantage, but both sides prepared to renew the contest the next day. During the night, and early in the morning, French troops were still passing over, so that, notwithstanding his losses, Napoleon had fully 70,000 men to renew the fight. It commenced early in the morning, and continued the greater part of the day; but at length the French were beaten on all sides, and compelled to retreat to the island of Lobau. In these two days they lost upwards of 30,000 men, and the Austrians not less than 20,000. The victory produced a great impression on the mind of Europe, and dissipated in a great degree the charm of Napoleon's invincibility.

He, however, made every preparation for renewing the contest. He summoned troops from different parts, and fortified his position on the island of Lobau, connecting it also by several bridges with the south bank of the river. On the evening of the 4th July he assembled his troops on the island, amounting to 150,000 infantry and 30,000 cavalry, with 750 pieces of cannon. During the night several bridges, which had been secretly prepared, were thrown over to the northern bank at a point where they were not looked for, and by six o'clock the following morning the whole body had passed over. In the afternoon the French made a vehement attack upon the Austrians, but were repulsed

with great slaughter. Early on the morning of the 6th the Austrians began the attack. There numbers were then about 115,000 infantry and 25,000 cavalry; but they were in hourly expectation of the arrival of an additional body of 30,000 under the Archduke John, which was known to be not far off. The battle was contested with the utmost determination and bravery on both sides. The Austrian right wing succeeded in overthrowing and putting to flight the left wing of the enemy. On the other wing the contest was long and doubtful; but two divisions of troops having at length succeeded in turning the extreme flank of the Austrians, the latter, after a gallant defence, were compelled to abandon their position. In these circumstances, Napoleon collected all his disposable forces and brought them to bear upon the centre of the Austrians, which was their weak point, the archduke having thrown his strength chiefly into the two wings. After repeated charges, which were repulsed with great bravery, the French succeeded in forcing their line, and the archduke, despairing of maintaining his position, ordered a retreat, which was effected in good order and with little loss. The French were so exhausted that they displayed little vigor in the pursuit, and neither guns nor prisoners were taken. The Archduke John came up in the afternoon, but too late to be of any service. Had he made his appearance sooner there can be no doubt that the result would have been different. As it was, the Austrians succeeded in making a most gallant stand against a greater number of the best troops of France, led by Napoleon and some of his greatest generals. This battle of Wagram was one of the greatest and most obstinately contested fights in the whole war, and is perhaps the most glorious in the annals of Austria. The loss on both sides was immense, amounting to about 25,000 on each, including killed and wounded. The Archduke Charles retreated towards Bohemia without any serious molestation from the enemy. A battle was fought at Znaim (11th July) between the Austrians and a French army under Massena which was following them, but before it was decided news of an armistice arrived. This was followed by the peace of Vienna (14th October). "The campaign of Aspern and Wagram," says Sir A. Alison, "is the most glorious in the Austrian annals,—one of the most memorable example of patriotic resistance recorded in the history of the world. . . . Other empires have almost invariably succumbed upon the capture of the capital. . . . Austria is the only state recorded in history which (without the aid of a rigorous climate like Moscow) fought two desperate battles in defence of its independence after its capital had fallen."—(*History of Europe*). By the peace of Vienna Austria was compelled to cede Salzburg, Berchtesgaden, the Innviertel, and the Hausruckviertel, to Bavaria; portions of Galicia to Russia and the grand duke of Warsaw; and Carniola, Trieste, the greater part of Croatia, Istria, the circle of Villach, &c., to Italy, In all she lost about 42,000 square miles of territory and 3,500,000 inhabitants, together with more than 11,000,000 florins of revenue. The emperor also agreed to reduce his army to not more than 150,000 men; and a war contribution of £3,400,000 was imposed on the provinces occupied by the French troops. Before leaving the Austrian capital Napoleon caused the fortifications to be blown up.

Soon after this Napoleon obtained a divorce from his wife Josephine, and offered his hand to Maria Louisa, daughter of the emperor of Austria, and was accepted. The marriage was celebrated with great pomp at Vienna on the 11th March 1810. In 1812 Austria was obliged to enter into an alliance with France against Russia, and to furnish an auxiliary force of 30,000 men for the invasion of the latter country. The disastrous result of that expedition to the invaders showed Germany that the fortunate moment had now arrived for regaining her independence. Prussia was the first to form an alliance with Russia, and declared war against France (17th March 1813). Great efforts were made to induce Austria to join this alliance, but without success. She directed her attention to raising her military strength, and making other preparations to enable her to take an important part in the coming struggle, on the one side or the other. After the defeat of the allies at Lützen and Bautzen, and the conclusion of an armistice at Pleswitz, Austria, came forward as a mediator, with a view of affecting a peace between the parties, and not without the view, also, of gaining some material advantage for herself. In fact, she now held in her hand the balance between the contending parties. Her army of 150,000 or 200,000, which she had collected in Bohemia, would bring victory to whatever side she joined. Metternich, who at that period had the direction of the cabinet of Vienna, was too clear-headed not to perceive the advantages of the position, and he determined to avail himself of them, in order if possible to restore to Austria her lost possessions. He had openly avowed, that if Napoleon would accede to the terms which he proposed Austria would throw her whole 200,000 men into the scale in his favor. At first it seemed doubtful to which side she would attach herself; but it would appear that the allies had reason to believe that she was favorable to them, and that Napoleon had also reason for suspecting the strength of her attachment to him. It is evident that she would have more to expect from the allies than from Napoleon, but at the same time it was doubtful how far she would be influenced by the existing matrimonial alliance. While things were in this doubtful state news arrived of the battle of Vitoria, by which the death-blow was given to the power of France in the Peninsula, and after this there was little hope of peace on either side. Austria, whatever her previous intentions, doubtless now felt that there was little to be gained from attaching herself to a sinking empire and a falling cause, and she agreed, in the event of Napoleon not accepting the terms proposed, to join the allies. They could have had little hope that the terms would be accepted; they included the cession to Austria of all the Illyrian provinces, with Trieste, the reinstatement of Prussia in her ancient possessions, with a frontier on the Elbe, and the dissolution of the grand duchy of Warsaw, to be divided between Russia, Austria, and Prussia. These terms not being acceded to, both parties prepared for war. Austria agreed to furnish 200,000 to the allied forces, stipulating in return that she should be restored to the condition in which she was in 1803, or, at any rate, at the peace of Presburg.

By gigantic efforts Napoleon was able to raise his army to 400,000 men, of whom nearly 350,000 were effective and he resolved to make Dresden the pivot on which all his operations should turn. To oppose him the allies mustered about 400,000 men, so that the two forces were pretty nearly equal. Of the latter, a grand army of 220,000 men, chiefly Austrians, under Prince Schwarzenberg, was stationed in Bohemia; Blücher, with 95,000 men, was to protect Silesia; while Bernadotte, the crown prince of Sweden, who had joined the allies with 28,000 troops, was to protect Berlin and Brandenburg with an army of 90,000. Napoleon resolved to march with the main body of his troops into Silesia against Blücher, having despatched an army of 80,000 men under Oudinot against Berlin, and sending a force of 30,000 to keep the passes from Bohemia to

Dresden. Blücher judiciously retreated before the French troops, and while Napoleon was following him, the allied army in Bohemia came down upon Dresden. In place, however, of at once beginning the attack, it was delayed till Bonaparte, who had been informed of their movements, had time to arrive. The attack was commenced on 28th August, and kept up with great fury during the day; but in the evening a series of sallies were made from the town, which took the besiegers completely by surprise, and compelled them to withdraw. Napoleon had now received sufficient reinforcements to enable him to give battle, which he did the next day. He was then able to muster 130,000 men, while the allies numbered about 160,000. The fight was maintained for some time with great bravery on both sides, but at length a body of French troops under Murat succeeded in turning the flank of the allied left wing, and then attacking them suddenly on flank and rear; they were thus thrown into confusion, and the great body of them killed or made prisoners. The allies lost on this occasion about 26,000 men, of whom about 13,000 were prisoners. A French force under Vandamme had been sent to cut off the retreat of the allies, but this was engaged near Culm (29th August) by a body of Russians under Osterman, and a desperate struggle took place, which was renewed the next day, and only ended by the appearance in the rear of the French of a large body of Prussians, when the leader and most of his troops were made prisoners. The French lost in the two days 18000 men, of whom 7000 were prisoners.

Napoleon, on quitting Silesia, had left Macdonald with an army of 80,000 men to oppose Blücher. The latter suddenly attacked them with great fury on the Katzbach (26th August), and defeated them with great slaughter. The fight was several times renewed during the three following days when the allies were in pursuit, and in all the French lost about 7000 men in killed and wounded, and 18,000 prisoners. Nor was the French army under Oudinot more successful, for it sustained a severe defeat at Gross Beeren (23d August), and in that and subsequent engagements lost about 4000 in killed and wounded, and an equal number of prisoners. Napoleon was strongly affected by these reverses, the more so that they were quite unexpected. He gave the command of the army in the north to Ney, and set out himself against Blücher. Ney engaged the allied army at Dennewitz, and a desperate battle was fought (6th September), in which the French were at length beaten and put to flight with a loss of 13,000 men, of whom one-half were prisoners. The army in Bohemia now again resumed the offensive, and was preparing to fall upon Dresden, when Napoleon suddenly returned and drove them back. He again marched against Blücher, but returned to Dresden without effecting anything. He then resolved to enter Prussia and take Berlin, but was obliged to give up this project on learning that Bavaria had joined the allies (8th October). Now fearing that his retreat might be cut off, he directed his march toward the Rhine, and reached Leipsic on the 15th of October. Here the combined allied armies under Schwarzenberg, Blücher, and Bernadotte assembled, and on the 16th an indecisive battle was fought, which to the French was equivalent to a defeat, and the same evening Napoleon made proposals for peace, but no answer was returned. The battle was renewed on the 18th. The French army numbered about 175,000 men, while the allied forces amounted to about 290,000. The French strength was also weakened by two Saxon brigades of foot and one of cavalry passing over to the enemy during the engagement. Notwithstanding these disadvantages the French fought with great bravery and determination, but were at length beaten on every side. Next day they were in full retreat, and Leipsic was taken by the allies after a gallant defence. The total loss of the French during these four days exceeded 60,000 men. The emperor reached Erfurt on the 23d October, and there collected the scattered remains of his army. The Bavarians, under Wrede, attempted to intercept his retreat at Hanau, but though aided by some of the allied troops, they were defeated with great slaughter (30th October). The Rhine was crossed on 1st November, and on the 9th Napoleon arrived in Paris. Thus Germany regained its independence, and the Confederation of the Rhine was dissolved. Austria, as we have seen, had a principal share in bringing this about; but the Emperor Francis was opposed to the adoption of extreme measures against Napoleon, being desirous that the sceptre of France should continue in the hands of his daughter and her descendants. Other views, however, prevailed. The war was carried into the enemy's country, and at length, not without a good deal of fighting, the allies entered Paris on 31st March 1814. On 11th April Napoleon resigned the imperial crown.

In the end of September following a congress was assembled at Vienna to adjust the claims and the mutual relations of the several states. This, however, was found to be a matter of no small difficulty. Russia demanded the whole of Poland, and Prussia laid claim to Saxony. Austria, France, and England were opposed to these claims, and determined to resist them, so that at one time it appeared as if war was again to break out; but more peaceful views began to prevail, and when the news arrived that Napoleon had secretly quitted Elba, all minor differences were forgotten in the presence of this pressing danger. They at once declared him an enemy and a disturber of the peace of the world, and prepared to bring against him an army of upwards of half a million of men. But before these had all been collected, Wellington and Blücher had brought the military career of Bonaparte to a close on the field of Waterloo. In the new partition of Europe, which was fixed by the Congress of Vienna (1815), Austria received Lombardy and Venice, the Illyrian provinces, Dalmatia, the Tyrol, Vorarlberg, Salzburg, the Innviertel, and Hausruckviertel, together with the part of Galicia formerly ceded by her, making in all about 3,200 square miles of territory.

The emperors of Austria and Russia and the king of Prussia also entered into a "Holy Alliance," by which they bound themselves to remain united in the bands of true and brotherly love, to mutually help and assist each other, to govern their people like fathers of families, and to maintain religion, peace, and justice in their dominions. This alliance, beautiful in theory, was made, in fact, the means of maintaining absolute power in the hands of the rulers, and of suppressing free institutions and almost every form of liberty among the people. This was particularly the case in Austria, under the direction of Metternich, who did everything in his power to carry out these principles. A strict censorship of the press was established, not only to overlook the home press, but also to superintend the introduction of foreign publications. A system of secret police was also organised to observe and report what was said and done by the people in private. Besides this, Austria was ever ready to aid in the suppression of revolutionary movements in other states. In the construction of the German Confederation she used her influence to suppress the popular voice in all matters of government; her armies were employed in quelling the popular insurrections in Naples and Piedmont in 1822; and by diplomacy she aided in the sup-

pression of the popular movement in Spain in 1823. During the insurrection in Greece the influence of Austria was exerted against it; and when Greece was established as a kingdom (1827), under the protection of England, France, and Russia, she kept aloof. When, however, Russia invaded Turkey in 1828, Austria joined with England in interfering to prevent the fall of Constantinople, and in bringing about peace.

The commotions that followed the French revolution of July 1830 in different parts of Europe considerably affected Austria. This manifested itself chiefly in Lombardy, where the presence of 30,000 troops was required to maintain the imperial authority. In Parma and Modena the people suddenly rose in insurrection and expelled their rulers, and Austrian troops were employed to restore them. An insurrection also broke out in the Papal States, and the Pope invoked the aid of Austria, whose troops entered Bologna and established themselves there (January 1832). Upon this the French sent a force to occupy Ancona, and at one time it seemed as if France and Austria were again to cross swords on Italian soil, but this danger was at length averted. In the minor states of Germany the cry for popular institutions was raised, and in many cases the rulers were obliged for a time to comply with them, but after the danger appeared to pass away, Austria, acting in concert with Prussia, succeeded in bringing back the old state of things in the confederation. The Poles, tired of Russian rule, and hoping to be supported by France, took up arms to regain their independence (1831). Although Austria professed a strict neutrality in the struggle, a Polish corps that was driven into her territories was disarmed and detained, while a body of Russian troops under the same circumstances was allowed to continue its operations against Poland. During the remainder of the reign of Francis I. no public event of importance occurred. He died on the 2d of March 1835, in the sixty-seventh year of his age and the forty-third of his reign. He was one of those well-meaning but weak-minded men, who unfortunately adopt the wrong means for effecting the good which they intend. He wished to make his people contented and happy, but he sought to do so by repressing all independence in thought or action, and keeping them in most abject subjection. He earnestly strove for their advancement, but it was by strenuously endeavoring to keep things as they were, and opposing every form of change. The transition from an old to a new state of things was in his mind always associated with the utmost danger, and to be by all means avoided. He did much in the way of establishing elementary schools throughout the country, but said that he wished to have no learned men, only good loyal citizens. He was thoroughly conscientious and correct in his conduct, but at the same time narrow-minded, suspicious, and bigoted. He was most assiduous in his attention to the business of the state, but occupied himself chiefly with small matters and minor details, while more important concerns were entirely overlooked and neglected. His good qualities, however, commended him to the affections of his people, and this doubtless did much to repress among his subjects the insurrectionary spirit which subsequently manifested itself.

He was succeeded by his eldest son, Ferdinand I., an amiable but weak-minded prince, who left the government very much in the hands of his prime minister, Metternich. The various signs of discontent which had been manifested during the former reign soon became stronger and more marked. Baron Pillersdorf, the successor of Metternich, speaking of this period, says, "Circumstances permitted an uninterrupted enjoyment of peace, but the necessity for internal ameliorations became by so long a delay more urgent, the demand for them more sensible, whilst, owing to the procrastinations of the Government, faith and confidence were diminished. It is true that the prosperity of the provinces generally did not decline; on the contrary, many branches of commerce manifested an increase in their development; but in spite of this the situation of the whole empire inspired in different respects serious apprehensions arising from the disordered state of the economy of finance, the yearly augmentation of the public debt, the inefficiency of the measures adopted, and still more from the oppressed disposition of mind of the clear-sighted and intelligent classes of the population."—(*The Political Movement in Austria during* 1848–49.) The people saw growing up in the nations around them freer institutions and more liberal modes of government, and they could not help contrasting those with their own system. Austria, too, was made up of a number of different nationalities, and the Government attempted to strengthen its position by working upon their national prejudices and antipathies, setting race against race, and creed against creed. In particular, the German element was favored at the expense of the nationalities; and the Germanising measures of the Government excited great discontent among the other races. It has been remarked that the aversion of Austria to the development of the Slavonic element in her population was greatly owing to jealousy of Russia, which power she regarded as desirous of attaching all the Slavonic races to itself. Hence Austria has always been opposed to the encroachments of Russia in Turkey, and in favor of maintaining the integrity of the latter, so that, when war broke out in 1839 between the Sublime Porte and the Pasha of Egypt, she readily joined England in support of the former.

The court of Vienna was first frightened from its sense of security by an insurrection in Galicia in 1846. This having been suppressed, Austria, in conjunction with the other two powers which had dismembered Poland, determined to lay hold on Cracow, and thus extinguish the last remnant of Polish independence. This step being contrary to the treaty of Vienna, was strongly remonstrated against both by England and France; but these remonstrances were unheeded, and the republic was incorporated in the Austrian empire. The French revolution of 1848, which convulsed almost the whole of continental Europe, caused the Austrian empire to totter to its foundations. Scarcely had the news of the fall of Louis Philippe reached Vienna when the whole city was in a state of open rebellion (13th March). The populace, headed by the students, and forcing the magistracy along with them, made their way into the imperial palace, and loudly demanded from the emperor the dismissal of his old counsellors, and the immediate grant of a new constitution. Alarmed at these demonstrations Prince Metternich resigned, and was soon after on his way to London; and an imperial proclamation was issued, declaring the abolition of the censorship of the press, the establishment of a national guard, and the convocation of a national assembly. These measures, however, as well as the nomination of a new ministry, were far from sufficing to arrest the popular movement, encouraged and led on by the students and other members of the university. The national guard just called into being, along with the academic legion, formed themselves into a permanent committee, and dictated laws to the Government. On the 17th of May, Ferdinand, accompanied by the empress and the members of his family, secretly quitted the palace, and fled to Innsbruck. An attempt to dissolve the academic legion caused an outbreak on the 25th, and the streets were barricaded; but no fighting took place, for the ministers yielded to the demands of the rioters, and gave

up their design. A committee of citizens, national guards, and students, which was formed for the preservation of peace and order, was legalised by the prime minister, and assumed the authority of the Government. In the meantime the revolutionary spirit was manifesting itself in other parts of the empire. In Italy the inhabitants of Milan and Venice rose against their rulers, and expelled the Austrian troops. This was followed by a general rising throughout Lombardy and Venice. The insurgents found an ally in Charles Albert, king of Sardinia, who came with an army to their assistance, and declared war against the empire. At first he succeeded in driving the Austrians back to the northern frontier of Italy; but General Radetzky, having received reinforcements, vanquished him in several engagements, and compelled him to flee to his own dominions, and conclude a truce with the victors. This was followed by the reconquest of Milan and the whole of Lombardy. Venice withstood the besieging army of the Austrians for some months, but was at length obliged to surrender. In Bohemia the Czechs or Slavonic party determined to obtain redress against the Germanising measures of the Government, and forwarded a petition to the emperor, demanding a united and independent national assembly for Bohemia and Moravia, independent municipal institutions, and an equal share in public offices with the German part of the population. An evasive answer was returned, and the citizens of the capital rose in insurrection. A national assembly of delegates of the Slavonians in all parts of the empire was summoned to meet at Prague. Three hundred made their appearance, and the assembly was opened in the beginning of June. The efforts of the military to maintain peace excited the enmity of the citizens, and they petitioned for the removal of the commander, Prince Windischgrätz. Meanwhile a collision took place between the Slavonic militia and the regular troops. The Germans joined with the military, and the insurrection raged for five days; the town was bombarded and taken, and the leaders dispersed or taken prisoners.

In Hungary the National Diet had passed measures in favor of a responsible ministry, a perfect equality of civil rights, religious toleration, the formation of a national guard, and the abolition of the censorship of the press. The emperor gave his consent to these measures; but a strong Austrian party in the country, chiefly Slavonians, was opposed to them, and, instigated and supported by the Austrian Government, they broke out in open revolt. Jellachich, the ban or governor of Croatia, was the leader of the insurgents, and collecting an army of 65,000 men, he marched on towards Pesth. An army was speedily raised by the Hungarians to meet him, and a battle was fought within 25 miles of the capital on 29th September, in which Jellachich was beaten. The emperor now openly declared against the Hungarians, annulled the decrees of the Diet, suspended the civil authorities, and appointed Jellachich commander of the army. The Diet, denying the authority of the emperor, organised a committee of safety, and elected Kossuth president. This was equivalent to a declaration of war, and an Austrian army was ordered out against them. The people of Vienna, sympathising with the Hungarians, rose in arms, when the garrison of that city departed for Hungary (6th October). A deputation waited on the minister of war, Latour, demanding their recall, and on his refusal they took the arsenal by storm and murdered him. The National Diet, which had met on the 22d of July, now declared its sittings permanent, and elected a committee of public safety. It sent an address to the emperor asking for a new ministry, the revocation of the edict against the Hungarians, the dismissal of Jellachich, and an amnesty for the rioters. The emperor, who had returned from Innsbruck to Vienna in June, returned an evasive answer, and fled to Olmütz. The people in the capital armed themselves under the leadership of General Bem, and prepared to resist the impending attack of the army. The garrison, after having retired outside the limits of the city, was joined by Jellachich's horde of Croatians and by the army of Windischgrätz. On 23d October, an army of 100,000 men appeared before Vienna, and the city was summoned to surrender. This the people refused to do, and the attack was commenced on the 28th, when the city was set on fire in many places. The next day a part of the suburbs was taken, and the leaders began to think of surrendering when the news of a Hungarian army hastening to their relief inspired them with fresh courage. This force, however, was attacked and put to flight by Jellachich (30th October), and the next day the city was taken by storm, after a desperate struggle, which was attended with immense slaughter. On 22d November a new ministry was formed, of which Prince Schwarzenberg was president; and on 2d December the Emperor Ferdinand was induced to abdicate the throne. His brother, Francis Charles, who was his legal successor, likewise renounced his right in favor of his son, Francis Joseph, who was proclaimed emperor under the title of Francis Joseph I.

The war in Hungary was renewed by Windischgrätz, who crossed the Leitha, and after several successful engagements entered the capital of that country (January 1849), the Hungarian Government and one division of the army having departed eastward to Debreczins while the other under Görgei retired northward toward Waitzen. The Austrian general, instead of pursuing them, remained inactive for seven weeks at Pesth, and thus afforded them time to organise. In Transylvania General Bem gained a decisive victory over the Austrians in that territory, and also defeated and put to flight a Russian force that had come to their assistance. At length Windischgrätz moved forward towards Debreczin, and met the Hungarins at Kapolna, where an obstinate and bloody but indecisive battle was fought (26th February). Next day the Austrians, having received reinforcements, renewed the fight, and the Hungarians were obliged to retire. The latter having recruited their forces, another obstinate battle was fought near Gödölö (5th April), in which the Austrians were defeated, as they were in several subsequent engagements, so that they were compelled to abandon the capital and recross the Danube, leaving a small garrison at Buda, which afterwards surrendered. Had the victorious army now marched on to Vienna they would doubtless have succeeded in bringing the Austrians to terms; but disputes among the rulers and dissensions among the generals prevented such a course. In June Prince Paskewitch crossed the Galician frontier at the head of a Russian army of 130,000 men; and General Haynau, who now had the command of the Austrian troops, was joined by a Russian corps under General Palutin. The Hungarians were unable to contend against these forces, and had again to leave their capital, the seat of the Government being transferred to Szegedin. Driven from this place, the army made a stand at Temesvar, but were defeated with great slaughter (9th August), and again, two days later, at Arad. On 13th August the Hungarian general, Görgei, who had been named dictator, surrendered to the Russians. Hungary was now treated as a conquered country, and the greatest cruelties were practised against the people by the Austrian general, Haynau. The military and parliamentary leaders were shot or hanged, and the prisons filled with unhappy vic-

tims. In the meantime the war in Italy was renewed by the king of Sardinia. He was, however, defeated at Mortara (21st March) by the Austrian general, Radetzky, and again at Novara (23d March), when he abdicated in favor of his son, Victor Emmanuel, with whom a peace was concluded. Venice held out against the Austrians till 23d August, when it was forced to surrender.

The congress which, since the final struggle in Vienna, had been adjourned to Kremsier, was dissolved (March 4, 1849), and a constitution promulgated by the free will of the emperor. At this time efforts were made in the German National Assembly at Frankfort to form Germany into one integral empire, excluding Austria, the imperial crown being offered to the king of Prussia. This was violently opposed by the Austrian Government, and though the king of Prussia did not venture in the face of this opposition to accept the imperial crown, he concluded a treaty with the kings of Saxony and Hanover (May 1849), with the view of forming a strict union with the different states of the German confederacy to the exclusion of Austria. To this treaty the majority of the lesser states afterwards acceded, and a diet was convened at Erfurt (May 1852), under the presidency of Prussia, for the reorganisation of Germany. Austria, to counteract the efforts of her rival, invited the different states to send their representatives to Frankfort, where she assumed the lead. The legality of the assembly was at once acknowledged by Bavaria, and Saxony and Hanover were subsequently gained over to it. While matters were in this state disturbances arose in Hesse-Cassel. The margrave invoked the assistance of Austria, while the people looked for aid to Prussia. Having received the authority of the diet at Frankfort, Austria sent an army into Hesse, where they were confronted by another army from Prussia, and an immediate commencement of hostilities was looked for, but this was averted by a conference held at Olmütz, when Prussia acknowledged the right of Austria to enter Hesse. Soon after this Austria and Prussia convoked a congress of all the states at Dresden, where it was agreed that the final settlement of the affairs of the confederacy should be submitted to the decision of the diet at Frankfort. Austria now proposed to the diet that all her provinces, including Hungary and Lombardo-Venetia, should be included in the German confederacy, but this bold proposal failed of acceptance.

Austria now made strenuous efforts to develop the resources of the monarchy by encouraging agriculture, industry, and commerce. The land was freed from the burdens of feudalism, taxes were removed, new roads were formed, and railways were constructed. A new tariff was adopted (July 1851), and negotiations were entered into with the other German states for a complete customs' union with the Zollverein, but this was strongly opposed by Prussia and several of the other states in the union. A commercial treaty, however, was, after considerable negotiation, concluded between Austria and the Zollverein (19th February 1853). The liberal concessions that had been made by the Government were rapidly disappearing, a rigorous military system of rule was being introduced, and centralisation was taking the place of the old provincial system. On the 1st of January 1852 it was announced that the constitution and fundamental rights were abolished, the ministers were declared responsible only to the emperor, trial by jury was set aside, the censorship of the press was again in operation. The influence of the Roman Catholic clergy and the Jesuits was also re-established. A popular outbreak occurred in Milan (6th February 1853), when a number of the military were killed, but it was speedily suppressed. An attempt was made to assassinate the emperor in Vienna by a young Hungarian (18th February). In the quarrel between the Montenegrins and the Porte, Austria sided with the former, and Count Leiningen was sent to Constantinople (February 1853) to demand the redress of their grievances, which was granted. About this time Russia demanded the protectorate of the Greek Christians in Turkey, and this being denied, her troops crossed the Pruth and occupied the principalities of Moldavia and Wallachia (July 1853). Austria took a leading part, along with France and England, in condemning these proceedings and in endeavoring to bring about peace. She also gave the Western powers to believe that she would actively co-operate with them in the defence of Turkey, but afterwards fell back upon vague promises, and on April 20, 1854, entered into an alliance with Prussia, by which the two powers guaranteed each other's dominions from attack, and pledged themselves only to take an active part in the war when the interests of Germany appeared to be endangered. On June 14th Austria agreed with Turkey to occupy the Danubian principalities with an armed force, and by the end of August she had a large army there, which virtually brought the war on the Danube to an end. Austria still continued to use her exertions to bring about peace, and with this view a conference was opened at Vienna in March 1855, but the representatives of the several powers were unable to agree upon a basis. After the fall of Sebastapol she again renewed her efforts, and having ascertained the terms on which the Western powers would be prepared to treat, she sent Count Esterhazy to St. Petersburg to lay them before the czar, by whom they were accepted, and a treaty of peace was signed at Paris, 31st March 1856.

In August 1855 the emperor signed a concordat with the Pope, giving the church greater power in the country than it had ever possessed before. The clergy were to have unlimited control over all ecclesiastical matters and matters connected with education, and were to enjoy free communication with Rome without the intervention of the civil power. The Government now seemed desirous of relaxing somewhat their restrictions, and of making the people forget the troubles of 1848 and 1849. The military rule was made less strict, and a general amnesty was proclaimed for political offences (12th July 1856). The emperor visited Italy in the end of 1856 and Hungary in May 1857, but the remembrance of past wrongs was still alive in the minds of the people, and he was everywhere received with the greatest coolness. Austria was opposed to the union of the Danubian principalities, and for some time refused to evacuate them, but at length (March 1857) her troops were recalled.

Sardinia had frequently remonstrated with Austria concerning her policy in Italy, while Austria, on the other hand, complained of the attacks made upon her by the Sardinian press. A growing coolness had also sprung up between Austria and France on this subject, which reached its climax when the French emperor said to the Austrian minister, M. Hübner, at the levee on the 1st of January 1859, "I regret that our relations with your Government are not so good as they were; but I request you to tell the emperor that my personal feelings for him have not changed." The preparations for war were carried on with the greatest activity by Austria, France, and Sardinia. England sent Lord Cowley to Vienna to endeavor to arrange differences, but without success. Russia proposed a congress of the five great powers, and this was agreed to, but Austria demanded the disarmament of Sardinia previous to the congress, which the latter declined to agree to, and both sides prepared for war. Austrian troops poured into Italy, France was concentrating her forces at Toulon, and Garibaldi was

organising a corps of Italian volunteers. The Austrians crossed the Ticino (April 26), and the French troops were marched into Italy. Napoleon left Paris on the 10th of May, and reached Genoa on the 12th, where he was the next day joined by Victor Emmanuel. The first serious encounter took place at Montebello (May 20), when a strong body of Austrians was, after a desperate resistance, defeated and put to flight by a body of French troops. The Austrians again suffered a severe defeat at Palestro (May 31.) On 4th June the battle of Magenta was fought, in which the Austrians were, after a long and desperate conflict, defeated and put to flight by the combined army of the French and Sardinians, under the command of the Emperor Napoleon in person. The Austrians fought with great bravery and determination, but were not well officered, and the arrival of General M'Mahon with his troops at an opportune moment decided the battle against them. They had about 75,000 men in the field, while the allies numbered about 55,000. The latter lost about 4000 men in killed and wounded, the former about 10,000, besides 7000 prisoners. Next day the inhabitants of Milan rose in insurrection, and the garrison fled. Pavia was evacuated on the 7th, and on the 8th the fortified position of Melegnano was taken after three hours' hard fighting. The same day the allied monarchs made their triumphal entry into Milan. One stronghold after another now fell into the hands of the conquerers. The defeated army retreated to the further bank of the Mincio, where it was reorganised, and the emperor himself assumed the command. It then recrossed the Mincio, and took up a position near the village of Solferino. Here the allies came up to it, and both sides prepared for battle. The Austrian army numbered about 170,000 men, while the allied troops were not less than 150,000. The battle commenced early in the morning of the 24th June, and continued till late in the afternoon. The Austrian line extended for nearly 12 miles. The right and left wings of the Austrians were for some time successful, while Napoleon was using every effort to break their centre. In this he was at length successful, and the wings were then obliged to retire in order that they might not be overflanked. The French lost in killed and wounded 12,000 men, the Sardinians 5000, and the Austrians 20,000, besides 7000 prisoners. The Austrians now abandoned the line of the Mincio, and fell back upon Verona. The allies crossed the Mincio, Peschiera was invested, and great preparations were made on both sides for renewing the contest. While all Europe was in the expectation of another great battle, news arrived that an armistice for five weeks had been agreed to; and on 11th July the two emperors met at Villafranca, and agreed to terms of peace. A conference was afterwards held at Zürich, and a treaty drawn up and signed (10th November 1859). By it Austria gave up Lombardy, with the exception of the fortresses of Mantua and Peschiera, to Napoleon, who was to hand it over to the king of Sardinia; Italy was to be formed into a confederation under the presidency of the Pope, and Austria was to be a member on account of Venetia; and the princes of Tuscany and Modena were to have their possessions restored to them.

In March 1860 the emperor, by patent, enlarged the number and powers of the Reichsrath or council of the empire, and on 21st October promulgated a new constitution, in which he declared the right to issue, alter, and abolish laws, to be exercised by him and his successors only with the co-operation of the lawfully assembled diets and of the Reichsrath. The things to be settled with the co-operation of the Reichsrath were all legislative matters relating to the rights, duties, and interests of the several kingdoms and countries, such as the laws connected with the coinage, currency, public credit, customs, and commercial matters. This was followed by proposals of similar changes for Hungary; and, on 27th February following, it was decreed that their former constitutions should be restored to Hungary, Croatia, Salvonia, and Transylvania. At last-mentioned date a fundamental law was also promulgated for the representation of the empire by a Reichsrath, composed of two bodies, a house of peers and a house of deputies, and declaring the constitution and functions of each. It was declared to be the earnest wish of the Government that hyper-centralisation should be avoided. On 1st May the new Reichsrath was formally opened by the emperor at Vienna, when he declared his conviction "that liberal institutions, with the conscientious introduction and maintenance of the principles of equal rights of all the nationalities of his empire, of the equality of all his subjects in the eye of the law, and of the participation of the representatives of the people in the legislation, would lead to a salutary transformation of the whole monarchy." Hungary, Croatia, Slavonia, and Transylvania declined to send representatives, claiming to have constitutions and rights distinct from the empire. The Reichsrath sat till the close of 1862, occupying itself chiefly with ecclesiastical affairs, the state of education, personal liberty, and the laws relating to the press, commerce, feudal tenures, &c. In 1863 the emperor of Austria invited the different potentates of Germany to meet him at Frankfort, in order to determine upon a scheme of reform for their common country. They almost all responded to the invitation except the king of Prussia, and the congress was opened (August 16) by a speech from the emperor. The proceedings, however, did not result in any important change, owing in great measure to the want of sympathy from Prussia.

The death of Ferdinand VII., king of Denmark (15th November 1863), gave rise to a general ferment in Germany on the subject of the duchies Schleswig, Holstein, and Lauenburg. To the Germans a united fatherland had long been a favorite idea, and they now saw a step towards its accomplishment. Notwithstanding the treaty of London (8th May 1852), which fixed the succession to the Danish crown, and was signed by Austria and Prussia, they denied the right of the new king, Christian IX., to the duchies, and laid claim to them as part of Germany. To enforce their claim the diet determined that they should be occupied by an armed force, and Saxony and Hanover were directed to enter and take possession of Holstein. This was done without their coming into hostile collision with the Danish troops, who retired to Schleswig (December 1863). Soon after this, however, Austria and Prussia gave notice that they, as the chief powers in Germany, intended to take upon themselves the carrying on of the war. Hostilities commenced (1st February 1864) when Austrian and Prussian troops crossed the Schleswig frontier. Denmark had trusted to England and France coming forward to maintain the conditions of the treaty of 1852; but these powers remained passive, and the Danes, after a short but heroic stand, were forced to succumb. An armistice was concluded (1st August), and a treaty of peace was eventually signed at Vienna (30th October), by which Denmark made over Schleswig, Holstein,, and Lauenburg to Austria and Prussia.

But Austria speedily suffered terrible retribution for the part she had taken in this affair. By inducing Austria to with join her, Prussia succeeded in removing part of the odium of the proceeding from herself, and she also succeeded in obtaining the aid of a rival power to secure territories which she had previously determined

to appropriate as her own. The acquired territory naturally lay very convenient for Prussia, and Austria would have willingly enough given up her claim on it if Prussia had agreed to grant her a territorial equivalent in some other quarter of her dominions. This the latter power declined to do, but would readily have consented to a pecuniary compensation. A convention was therefore held at Gastein (August 1865), which brought about a temporary understanding. Prussia was to receive Lauenburg on payment of a sum of 1,500,000 thalers, while Austria was to have the administration of affairs in Holstein, and Prussia in Schleswig. Austria, however, was desirous of the formation of the duchies into a separate state, and supported the claims of the duke of Augustenburg to them. This was strenuously opposed by Prussia, who regarded the public meetings that were permitted to be held in Holstein in support of this as a breach of agreement. Austria referred the question to the Frankfort diet, which decided in favor of the duke. Matters were now approaching a crisis. Prussia had long looked with jealousy upon the power of Austria, and considered a war with that country for the supremacy of Germany as sooner or later a necessity. The German people had for some time felt that there was not room for two great powers,—each too great to submit to the other,—one or other must give way before the country could obtain its proper place and influence in Europe. While both powers were professing the utmost desire for peace, each was actively preparing for war. Prussia entered into an alliance with Victor Emanuel (27th March 1866), the latter undertaking to declare war against Austria as soon as Prussia commenced hostilities, while the former engaged to secure Venetia for her Italian ally. In the beginning of May orders were issued by the emperor of Austria for putting the whole army upon a war footing, and for concentrating a portion of it upon the Bohemian and Silesian frontiers; and about the same time the Prussian cabinet issued orders to fill up to the war strength the different branches of the service. On 7th June the Prussian troops entered Holstein, and compelled the Austrians to retire, which they did without bloodshed.

Austria was in an unprepared state when the war actually broke out, but the Prussian forces, on the other hand, were thoroughly equipped. The Austrian army in the north amounted to 247,000 men, besides the Saxon army at Dresden of 24,000, in all 271,000. The Prussian force consisted of three armies: the first, under the command of Prince Frederick Charles, consisted of 93,000 men and was destined for Saxony and Bohemia; and second, under the crown prince, numbered 115,000 men, and was to operate in Silesia; while the third, or army of the Elbe, under General Herwarth, consisting of 46,000 men, was to march on the right flank of the first army, making in all 254,000 men, besides reserve corps of 24,300 men stationed at Berlin. General Benedek was appointed commander-in-chief of the Austrian army, and his forces were distributed along the frontier that separates Moravia from Saxony and Silesia. On the 16th of June the Prussians entered Saxony, and marched upon Dresden, the Saxon army retiring to join the Austrians. On the 18th the Austrians entered Silesia, and the same day the Prussians took possession of Dresden. The three Prussian armies now advanced into Bohemia, and endeavored to concentrate in the direction of Gitschin. On June 26th an engagement took place between some companies of the first army and a body of Austrians at Podol, in which the latter were defeated, while, at Hühnerwasser, the advanced guard of the Elbe army attacked some Austrian troops and drove them back towards Münchengrätz. Here, on the 28th, a severe struggle took place between the Prussians and the Austrians, supported by the Saxons, but the latter were ultimately driven back in the direction of Gitschin. In the meantime the second army, under the crown prince, had to march through the long and narrow passes of the mountains lying between Silesia and Bohemia. On the 27th one of the corps of this army, under General Steinmetz, engaged an Austrian force under General Ramming, and after a severe contest began to give way, but the crown prince coming up, the Austrians were driven back. The same day another corps of this army took possession of Trautenau, but were attacked by the Austrians under General Gablenz, and sustained a repulse. Both sides having received reinforcements, the action was renewed next day at Soor, when victory ultimately declared for the Prussians. At Skalitz, on the 28th, the Prussians, under Steinmetz, were attacked by the Austrians under Archduke Leopold, but the latter were defeated, and the town taken by storm. It is said that on this occasion the archduke had disobeyed positive orders, which were on no account to make an attack. On the 29th, two divisions of the first army, under Generals Tümpling and Werder defeated the Austrians under Count Clam Gallas, at Gitschin, and took the town. The count, who occupied a strong position here, had orders not to attack the enemy, but these he had disobeyed, and the consequence was that Benedek, who had taken up a strong position at Dubenets to oppose the army of the crown prince, found himself at once in a most dangerous situation, and was obliged to retreat towards Königgrätz. On the same day bodies of Austrians were defeated at Königinhof and Schweinschädel. In these various engagements the Austrians lost in all from 30,000 to 40,000 men. Both sides now concentrated their forces in the direction of Königgrätz, and prepared for a general engagement. On June 30 the king of Prussia joined the army, and the battle of Königgrätz, or Sadowa, was fought on the 3d of July. The Austrians numbered about 220,000, and the Prussians probably about 240,000. The battle was long and well contested, both sides fighting with the greatest determination and bravery; but at length the Austrians were broken, and obliged to retire. The Prussians lost 359 officers and 8794 men, while the Austrians and Saxons lost in all about 44,200 men, of whom 19,800 were prisoners. This terminated what has been sometimes called the *Seven Days' War*. The Austrians retreated to Zwittau and afterwards to Olmütz. A portion of the Prussians went in pursuit, but the king, with an army of upwards of 100,000 men, marched on towards Vienna, and reached Nikulsburg, July 18. After the battle of Königgrätz, the emperor, seeing the disastrous state of his affairs, resolved to cede Venetia to the Emperor Napoleon, so as to be able to bring his army in Italy against the Prussians, and he also expressed his willingness to accept the mediation of the latter to bring about a peace. The Archduke Albert, who had the command of the army in Italy, with which he had inflicted a severe defeat on the Italians at Custozza, was recalled to take the chief command in place of Benedek. An armistice, however, was agreed upon through the mediation of France (22d July). The preliminaries of peace were signed at Nikolsburg (26th July), and negotiations were afterwards carried on at Prague, where a treaty was signed (23d August). By this treaty Austria gave up to the kingdom of Italy Venetia and the fortresses of the quadrilateral, namely, Peschiera, Mantua, Verona, and Legnano; recognised the dissolution of the late German Confederation, and consented to a new formation of Germany, in which she should have no part; gave up all claim to the duchies of Holstein and Schleswig; and agreed to pay a

war indemnity of 40,000,000 thalers, less 20,000,000 allowed her on account of the duchies.

Having thus obtained peace, the emperor now turned his attention to home affairs. Hungary was still in a very troubled and dissatisfied state. We have seen that she declined to send representatives to the Reichsrath, insisting on her right to self-government, and refusing to have anything else. The plan of opposition she adopted was that of passive resistance, by the non-payment of taxes. At length, at the opening of the Hungarian diet at Pesth by the emperor in person, on December 14, 1865, he recognised the necessity of self-government for Hungary so far as it did not affect the unity of the empire and the position of Austria as a great European power. He also recognised the Pragmatic Sanction as the basis on which a settlement of their difficulties was to be sought. At the opening of the diet on 19th November 1866, an imperial rescript, signed by the emperor, was read, in which he promised, by the appointment of a responsible ministry and the restoration of municipal self-government, to do justice to the constitutional demands of the Hungarians. In the end of 1866, Baron Beust, who had previously been prime minister of Saxony, and was not only a foreigner but a Protestant, was made foreign minister. He subsequently became prime minister and chancellor of the empire. In the spring of 1867 the emperor summoned the Reichsrath to assemble at Vienna to deliberate upon various important measures. It was opened by the emperor in person on May 22, and in his speech on the occasion he earnestly recommended to their attention these subjects. On June 8 the emperor and empress were crowned king and queen of Hungary at Pesth amid great public rejoicings, on which occasion full pardon was given for all past political offenses, and full liberty to all offenders residing in foreign countries to return. Many important and liberal measures were discussed and carried in the Reichsrath; in particular, marriage was made a civil contract, and the perfect equality of believers of different creeds was recognized. On May 25, 1868, the civil marriage bill received imperial assent, and on July 30, 1870, the concordat with Rome was declared to be suspended in consequence of the promulgation of the doctrine of Papal infallibility. This last measure introduced a very beneficial change in the relations between Austria and the kingdom of Italy.

For some years the Government had much difficulty in settling the law of elections so as to secure the due representation of the different races and classes of the people in the Reichsrath. On March 6, 1873, a reform bill was passed by the lower house, taking the election of members of the Reichsrath out of the hands of the provincial diets and transferring it to the body of the electors in the several provinces, thus substituting direct for indirect election. In April it passed the upper house and received the imperial assent. This measure was hailed with great satisfaction, and has established the government upon a much broader and more secure basis. The session of the new Reichsrath was opened by the emperor in person on November 5. In the same year a great exhibition of the industries of all nations was held at Vienna. It was opened on May 1 by the emperor, and attracted to the capital, among others, the prince of Wales, the czar of Russia, the emperor and empress of Germany, the king of Italy, and the shah of Persia. On December 2 the twenty-fifth anniversary of the emperor's accession to the throne was celebrated amid great rejoicing in Vienna, having been celebrated three days before in Pesth. The emperor and empress were present on both occasions, and everywhere met with an enthusiastic reception. In the spring of 1874 a bill for the abolition of the concordat was introduced by the Government, and measures for restricting the powers of the clergy passed both houses. In 1878 Bosnia and Herzegovina were placed under the protection of Austria.

AUSTRIA, ARCHDUCHY OF, the cradle and nucleus of the Austrian Empire, lies on both sides of the Danube, from the mouth of the Inn to Presburg, on the borders of Hungary, and embraces an area of 18,052 square miles, with a population of nearly 3,300,000. It now forms three of the crown-lands, or administrative provinces of the empire—viz.: Lower and Upper Austria (*i. e.*, Austria below and Austria above the Ens), and the duchy of Salzburg. The population is mostly German Catholic. The chief towns, besides Vienna, are Wiener-Neustadt, Salzburg, Steyer, Linz, and Ischl.

AUTEUIL, formerly a country village at the entrance of the Bois de Boulogne, now inclosed within the fortifications of Paris. It is known as the residence of famous literary men—such as Boileau and Molière.

AUTOCRACY (Gr., sole mastery, ruling by one's self) signifies that form of government in which the sovereign unites in himself the legislative and the executive power of the State, and thus rules uncontrolled. Such a sovereign is therefore called an autocrat. Nearly all eastern Governments are of this form.

AUTOCHTHONES, in *Greek Mythology*, the first human beings who appeared in the world, and who, as their name implies, were believed to have sprung from the earth itself. Instead of one pair as the first parents of the whole race, each district of Greece had its own autochthones, who, according to the prominent physical features of the neighborhood, were supposed to have been produced from trees, rocks, or marshy places, the most peculiar, and apparently the most widely-spread belief being that which traced the origin of mankind to the otherwise unproductive rocks.

AUTO-DA-FÉ (*Act of Faith*), a public solemnity of the Inquisition in Spain and Portugal, at which the sentences of the court were read; those who were declared innocent were formally absolved, and the condemned were handed over to the secular power for punishment. The day chosen was usually some Sunday between Trinity and Advent. The first auto-da-fe was held by Torquemada at Seville in 1481; the last was probably that mentioned by Llorente, the historian of the Inquisition, as having been solemnised in Mexico in 1815. See INQUISITION.

AUTOGRAPH, that which is written with a person's own hand, an original manuscript as opposed to an *apograph* or copy, is used to designate either a whole document (*e.g.*, a letter) or a signature only.

AUTOLYCUS of PITANE, in Æolis, was one of the earliest Greek writers on mathematics and astronomy. As he is said to have given instruction to Arcesilaus, he probably flourished about the middle of the 4th century B.C.

AUTOMATON (from self, and to seize), a self-moving machine, or one in which the principle of motion is contained within the mechanism itself. According to this description, clocks, watches, and all machines of a similar kind, are automata, but the word is generally applied to contrivances which simulate for a time the motions of animal life. If the human figure and actions be represented, the automaton has sometimes been called specially an *androides*. We have very early notices of the construction of automata *e.g.*, the tripods of Vulcan, and the moving figures of Dædalus. 400 years B.C., Archytas of Tarentum is said to have made a wooden pigeon that could fly; and during the Middle Ages numerous instances of the construction of automata are recorded. Regiomontanus is said to have

made an iron fly, which would flutter round the room and return to his hand, and also an eagle, which flew before the Emperor Maximilian when he was entering Nuremberg. Roger Bacon is said to have forged a brazen head which spoke, and Albertus Magnus to have had an androides, which acted as doorkeeper, and was broken to pieces by Aquinas. Of these, as of some later instances, *e.g.*, the figure constructed by Descartes and the automata exhibited by Dr. Camus, not much is accurately known. But in the 18th century, Vaucanson, the celebrated mechanician, exhibited three admirable figures, — the flute-player, the tambourine-player, and the duck, which was capable of eating, drinking, and imitating exactly the natural voice of that fowl. No notice of automata can be complete without at least a reference to Kempelen's famous chess player, which for many years astonished and puzzled Europe. This figure, however, was no true automaton, although the mechanical contrivances for concealing the real performer and giving effect to his desired movements were exceedingly ingenious.

AUTOPSY (Gr. seeing for one's self), eye-witnessing, a direct observation; but generally used of a post-mortem examination or dissection of the dead body.

AUTOTYPE. In this process a sheet of paper coated with a film of bichromatized gelatine, in which lampblack or other permanent pigment has been held in solution or suspension, is exposed to the action of light in a printing-frame, beneath an ordinary photograph negative. In proportion as the light is admitted to the gelatine film, or "tissue," through the negative, it becomes hardened and insoluble in water. The print is afterward treated by washing away the unaltered portions of the film, and the result is a permanent print of the object photographed. The process is admirably adapted for the reproduction of oil-paintings.

AUTUMN, the third season of the year, between summer and winter. Astronomically, in the Northern Hemisphere, it begins at the autumnal equinox, when the sun enters Libra, September 22, and ends at the winter solstice, when the sun enters Capricorn, December 21. According to Webster, in North America it includes the months of September, October and November. In the Southern Hemisphere it corresponds in time to the northern spring.

AUTUN, the capital of an arondissement of the same name in the department of Saône and Loire, in France, is picturesquely situated on the declivity of a hill, at the foot of which flows the Arroux. It is one of the most ancient towns of France; and when Cæsar invaded Gaul it was the most important of the Ædui. Its name was then Bibracte, but being afterward much improved and embellished by Augustus it took that of Augustodunum. Population, 12,682.

AUVERGNE, a district, and formerly a province, of France, corresponding to the departments of Cantal and Puy-de-Dôme, with the arrondissement of Brioude in Haute-Loire. It is divided into Lower and Upper by the River Rue, the distinction between the two portions being well marked. Population (1890) 54,000.

AUXENTIUS of CAPPADOCIA was an Arian theologian of some eminence. When Constantine deposed the orthodox bishops who resisted, Auxentius was installed into the seat of Dionysius, bishop of Milan, and came to be regarded as the great opponent of the Nicene doctrine in the West.

AUXERRE (the ancient *Autissiodurum*), a town of France, in the department of Yonne, situated on the banks of the Yonne, in a wine-producing district, and built in an antique fashion. Population, 18,390.

AUXONNE (formerly *Assonium*, *i. e.*, *ad Sonam*, from its position on the Saône), a city of France, in the arrondissement of Dijon and department of Côte d'Or. It is strongly fortified, and possesses an old castle, an arsenal, and a school of artillery. Population, 5,000.

AVA, the former capital of the Burman empire, is situated on the Irawadi, which is here 3,282 feet broad, and which, making a bend out of its ordinary course, flows past the city on the north. On the east it has the river Myt-nge, a rapid stream 450 feet broad, which flows into the Irawadi close under its walls.

This former capital of the Burman dominions comprehends, according to the political divisions of that empire, the town of Sagaing, on the opposite shore of the Irawdi, and the town of Amarapura, four miles to the east. To each of the towns of Ava, Sagaing, and Amarapura, are attached districts, the two former of which extend twelve miles along the river, and are of equal breadth. The district of Amarapura is of equal size, so that Ava must be considered as not only the name of the former capital, but of a large district, which includes an area of 288 miles, containing, according to the most accurate estimate, 354,200 inhabitants; but the city of Ava is not supposed to contain more than 50,000 inhabitants.

AVALANCHES (Fr., from *avaler*, to descend) are masses of snow or ice that slide or roll down the declivities of high mountains, and often occasion great devastation. Ice avalanches are those that are seen and heard in summer thundering down the steeps of the Alps. They consist of masses of ice that detach themselves from the glaciers in the upper regions. They are most common in July, August, and September. Nine great Alpine avalanches, which cost 447 lives, are on record between 1518 and 1879, the most destructive being one of 1827, which swept away half the village of Biel, in the Upper Valais, with eighty-eight inhabitants. Sudden avalanches, larger or smaller, constitute one of the special dangers of Alpine climbing.

AVALLON, a town of France, in the department of Yonne, finely situated on a granite rock, at the foot of which flows the river Voisin or Cousin. Pop., 6,100.

AVATAR (Sanskrit, *avatâra*) signifies primarily a descent, but is specially applied to the descent of a Hindu deity upon the earth in a manifest shape, either for beneficent or for retributive ends.

AVATCHA, one of the numerous volcanoes of Kamchatka. It rises to a height of nearly 9,000 feet (Mr. Kennan says 11,000), and has an extensive crater at the summit and another on the side. It was in active eruption in 1827, 1837, and 1855.

AVEBURY, a village of England, in the county of Wilts, six miles west of Marlborough. It occupies the site of one of the most remarkable megalithic structures in England. This consisted of a large outer circle formed of 100 stones of from fifteen to seventeen feet in height and about forty feet in circumference, enclosing an area of about 1,000 feet in diameter. This circle was surrounded by a broad ditch and lofty rampart. Within its area were two smaller circles, 350 and 325 feet in diameter respectively, each consisting of a double concentric row of stones.

AVEIRO, a town in Portugal, province of Beira, the seat of a bishopric and college. Population, 7,167.

AVELLA, a town of Italy, in the province of Principato Ulteriore, a fine situation, and commanding most extensive prospects. Pop., 3,714.

AVELLINO, a fortified city of Italy, in the province of Principato Ulteriore, at the foot of Mount Vergine, and twenty-eight miles east of Naples. Pop., 16,376.

AVEMPACE. ABU BEKR MOHAMMED IBN JAHYA, surnamed Ibn Badja or Ibn Sayeg (*i.e.* son of the goldsmith), whose name has been corrupted by the Latins into Avempace, Avenpace, or Aben Pace, was the ear-

liest and one of the most distinguished of the Arab philosophers in Spain. Almost nothing is known in the events of his life; he was born, probably at Saragossa, toward the close of the eleventh century, and died at Fez in 1148 at a not very advanced age.

AVENBRUGGER, or AUENBRUGGER, LEOPOLD, a physician of Vienna, the discoverer of the important mode of investigating diseases of the chest and abdomen by AUSCULTATION. (*q.v.*) His method was to apply the ear to the chest, and to note the sounds it afforded on percussion by the hand, or what is called *immediate auscultation*.

AVENTINUS (JOHANN THURMAYR), author of the *Annals of Bavaria*, was born in the year 1466 at Abensberg, and died in 1534.

AVENZOAR [ABU MERWAN ABDAMALEC IBN ZOHR], an eminent Arabian physician, who flourished about the end of the 11th or beginning of the 12th century, was born at Seville, where he exercised his profession with great reputation. His ancestors had been celebrated as physicians for several generations, and his son was afterwards held by the Arabians to be even more eminent in his profession than Avenzoar himself. He was contemporary with Averroes, who, according to Leo Africanus, heard his lectures and learned physic of him. This seems probable, because Averroes more than once gives Avenzoar very high and partly deserved praise, calling him admirable, glorious, the treasure of all knowledge, and the most supreme in physic from the time of Galen to his own. He wrote a book entitled *The Method of Preparing Medicines and Diet*, which was translated into Hebrew in the year 1280, and thence into Latin by Paravicius, whose version, first printed at Venice 1490, has passed through several editions.

AVERAGE, a term used in maritime commerce to signify damages or expenses resulting from the accidents of navigation. Average is either *general* or *particular*. General average arises when sacrifices have been made, or expenditures incurred, for the preservation of the ship, cargo, and freight, from some peril of the sea, or from its effects. It implies a subsequent contribution, from all the parties concerned, rateably to the values of their respective interests, to make good the loss thus occasioned. Particular average signifies the damage or partial loss happening to the ship, goods, or freight by some fortuitous or unavoidable accident. It is borne by the parties to whose property the misfortune happens, or by their insurers.

Although nothing can be more simple than the fundamental principle of general average, that a loss incurred for the advantage of all the coadventurers should be made good by them all in equitable proportion to their stakes in the adventure, the application of this principle to the varied and complicated cases which occur in the course of maritime commerce has given rise to many diversities of usage at different periods and in different countries. It is soon discovered that the principle cannot be applied in any settled or consistent manner unless by the aid of rules of a technical and sometimes of a seemingly arbitrary character. The distinctions on which these rules turn are often very refined indeed. This is the chief reason why no real progress has yet been made toward an international system of general average, notwithstanding repeated conferences and other efforts by most competent representatives from different countries, seeking to arrive at a common understanding as a preliminary basis for such a system.

The subject of general average is only incidentally connected with that of marine insurance, being itself a distinct branch of maritime law. But the subject of particular average arises directly out of the contract of insurance, and will therefore be best considered in connection with it. (See INSURANCE.)

AVERNUS, a lake of Campania in Italy, near Baiæ, occupying the crater of an extinct volcano, and about a mile and a half in circumference. From the gloomy horror of its surroundings, and the mephitic character of its exhalations, it was regarded by ancient superstition as an entrance to the infernal regions. It was especially dedicated to Proserpine, and an oracle was maintained on the spot. Originally there seems to have been no outlet to the lake, but Agrippa opened a passage to the Lucrine, and turned this "mouth of hell" into a harbor for ships. The channel, however, appears to have become obstructed at a later period. The *Lago d'Averno* is now greatly frequented by foreign tourists, who are shown what pass for the Sibyl's Grotto, the Sibyl's Bath, and the entrance to the infernal regions, as well as the tunnel from Cumæ, and ruins variously identified as belonging to a temple or a bathing-place.

AVERROES, known among his own people as Abûl-Walid Mohammed Ibn-Ahmed Ibn-Mohammed IBN-ROSHD, the kâdi, was born as Cordova in 1126, and died at Marocco in 1198. His early life was occupied in mastering the curriculum of theology, jurisprudence, mathematics, medicine, and philosophy, under the approved teachers of the time. The years of his prime were a disastrous era for Mahometan Spain, where almost every city had its own petty king, whilst the Christian princes swept the land in constant inroads. But with the advent of the Almohades, the enthusiasm which the desert tribes had awakened, whilst it revived religious life and intensified the observance of the holy law within the realm, served at the same time to reunite the forces of Andalusia, and inflicted decisive defeats on the chiefs of the Christian North. For the last time before its final extinction the Moslem caliphate in Spain displayed a splendor which seemed to rival the ancient glories of the Ommiade court. Great mosques arose; schools and colleges were founded; hospitals, and other useful and beneficent constructions, proceeded from the public zeal of the sovereign; and under the patronage of two liberal rulers, Jusuf and Jakûb, science and philosophy flourished apace. It was Ibn-Tofail (Abubacer), the philosophic vizier of Jusuf, who introduced Averroes to that prince, and Avenzoar (Ibn-Zohr), the greatest of Moslem physicians, was his friend. Averroes, who was versed in the Malekite system of law, was made kâdi of Seville (1169), and in similar appointments the next twenty-five years of his life were passed. We find him at different periods in Seville, Cordova, and Marocco, probably following the court of Jusuf Almansur, who took pleasure in engaging him in discussions on the theories of philosophy and their bearings on the faith of Islam. But science and free thought then, as now, in Islam, depended almost solely on the tastes of the wealthy and the favor of the monarch. The ignorant fanaticism of the multitude viewed speculative studies with deep dislike and distrust, and deemed any one a Zendik (infidel) who did not rest content with the natural science of the Koran. These smouldering hatreds burst into open flame about the year 1195. Whether, as one story ran, he had failed in conversation and in his writings to pay the customary deference to the emir, or a court intrigue had changed the policy of the moment, at any event Averroes was accused of heretical opinions and pursuits, stripped of his honors, and banished to a place near Cordova, where his actions were closely watched. Tales have been told of the insults he had to suffer from a bigoted populace. At the same time efforts were made to stamp out all liberal culture in Andalusia, so far as it went beyond the little medicine, arithmetic, and astronomy required for practical

life. But the storm soon passed, when the transient passion of the people had been satisfied, and Averroes for a brief period survived his restoration to honor. He died in the year before his patron Almansur, with whom (in 1199) the political power of the Moslems came to an end, as did the culture of liberal science with Averroes.

For Aristotle the reverence of Averroes was unbounded, and to expound him was his chosen task. The uncritical receptivity of his age, the defects of the Arabic versions, the emphatic theism of his creed, and the rationalising mysticism of some Oriental thought, may have sometimes led him astray, and given prominence to the less obvious features of Aristotelianism. But in his conception of the relation between philosophy and religion, Averroes had a light which the Latins were without. Averroes maintains that a return must be made to the words and teaching of the prophet; that science must not expend itself in dogmatising on the metaphysical consequences of fragments of doctrine for popular acceptance, but must proceed to reflect upon and examine the existing things of the world. Averroes, at the same time, condemns the attempts of those who tried to give demonstrative science where the mind was not capable of more than rhetoric; they harm religion by their mere negations, destroying an old sensuous creed, but cannot build up a higher and intellectual faith.

Averroes, rejected by his Moslem countrymen, found a hearing among the Jews, to whom Maimonides had shown the free paths of Greek speculation. In the cities of Languedoc and Provence, to which they had been driven by Spanish fanaticism, the Jews no longer used the learned Arabic, and translations of the works of Averroes became necessary. His writings became the text-book of Levi ben Gerson at Perpignan, and of Moses of Narbonne. Meanwhile, before 1250, Averroes became accessible to the Latin Schoolmen by means of versions, accredited by the names of Michael Scot and others. William of Auvergne is the first Schoolman who criticises the doctrines of Averroes, not, however, by name. Albertus Magnus and St. Thomas devoted special treatises to an examination of the Averroist theory of the unity of intellect, which they labor to confute in order to establish the othodoxy of Aristotle. But as early as Ægidius Romanus (1247-1316), Averroes had been stamped as the patron of indifference to theological dogmas and credited with the emancipation which was equally due to wider experience and the lessons of the Crusades. There had never been an absence of protest against the hierarchical doctrine. Berengar had struggled in that interest, and with Abelard, in the 12th century, the revolt against authority in belief grew loud. The dialogue between a Christian, a Jew, and a philosopher suggested a comparative estimate of religions, and placed the natural religion of the moral law above all positive revelations. Nihilists and naturalists, who deified logic and science at the expense of faith, were not unknown at Paris in the days of John of Salisbury. In such a critical generation the words of Averroism found willing ears, and pupils who outran their teacher. Paris became the centre of a sceptical society, which the decrees of bishops and councils, and the enthusiasm of the orthodox doctors and knight-errants of Catholicism, were powerless to extinguish. At Oxford Averroes told more as the great commentator. In the days of Roger Bacon he had become an authority. Bacon, placing him beside Aristotle and Avicenna, recommends the study of Arabic as the only way of getting the knowledge which bad versions made almost hopeless; and the student of the present day might echo his remark.

Meanwhile Averroism had, in the eye of the great Dominican school, come to be regarded as the archenemy of the truth. When Frederick II. consulted a Moslem free-thinker on the mysteries of the faith, when the phrase or legend of the "Three Impostors" presented in its most offensive form the scientific survey of the three laws of Moses, Christ, and Mahomet, and when characteristic doctrines of Averroes were misunderstood, it soon followed that his name became the badge of the scoffer and the sceptic.

It was in the universities of North Italy that Averroism finally settled, and there for three centuries it continued as a stronghold of Scholasticism to resist the efforts of revived antiquity and of advanced science. Padua became the seat of Averroist Aristotelianism; and, when Padua was conquered by Venice in 1405, the printers of the republic spread abroad the teaching of the professors in the university. As early as 1300 at Padua, Petrus Aponensis, a notable expositor of medical theories, had betrayed a heterodoxy in faith; and John of Jandun, one of the pamphleteers on the side of Louis of Bavaria, was a keen follower of Averroes, whom he styles a "perfect and most glorious phycicist."

With Pomponatius, in 1495, a brilliant epoch began for the school of Padua. Questions of permanent and present interest took the place of outworn scholastic problems. The disputants ranged themselves under the rival commentators, Alexander and Averroes; and the immortality of the soul became the battle-ground of the two parties. Pomponatius defended the Alexandrist doctrine of the utter mortality of the soul, whilst Augustinus Niphus, the Averroist, was entrusted by Leo X. with the task of defending the Catholic doctrine.

Meantime, in 1497, Aristotle was for the first time expounded in Greek at Padua. Plato had long been the favorite study at Florence; and Humanists, like Erasmus, Ludovicus Vives, and Nizolius, enamored of the popular philosophy of Cicero and Quintilian, poured out the vials of their contempt on scholastic barbarism with its "impious and thrice-accursed Averroes." The editors of Averroes complain that the popular taste had forsaken them for the Greek. Nevertheless, while Fallopius, Vesalius, and Galileo were claiming attention to their discoveries, the Professors Zabarella, Piccolomini, Pendasio and Cremonini continued the traditions of Averroism, not without changes and additions. Cremonini, the last of them, died in 1631, after lecturing twelve years at Ferrara, and forty at Padua. The legend which tells that he laid aside his telescope rather than see Jupiter's moons, which Galileo had discovered, is a parable of the fall of scholastic Averroism. Mediævalism, with its misconstruction of Averroes, perished because it would not see that the interpretation of the past calls for the ripest knowledge of all discoveries in the present.

AVERSA, a town of Italy, province of Terra di Lavoro, situated in a beautiful plain covered with orange-groves and vineyards, about midway between Naples and Capua. It is the seat of a wealthy bishopric, and its foundling hospital and lunatic asylum, the latter founded by Murat, are very celebrated. Aversa owed its origin to the Normans, and dates from 1030, the people of the ancient city of Atella being transported thither. Population, 21,176.

AVESNES, a town of France, in the department of Nord, situated on the Greater Helpe. Pop., 4,000.

AVEYRON, a department in the S. of France, bounded on the N. by Cantal, E. by Lozère, S. Hérault and Tarn, and W. by Tarn-et-Garonne and Lot, containing an area of 3429 square miles. It corresponds to a large portion of the ancient district of Rouergue in Guienne, which formerly gave its name to a family of counts. Its earliest inhabitants known to us were the Rutheni, whose capital was Segodunum, identified

with the modern Rodez. The department is rich in prehistoric antiquities, such as the dolmens at Taurines, Laumières, Grailhe, etc. Pop., 410,000.

AVEZZANO, a town of Italy, in Abruzzo Ulteriore II., containing a castle, which was built in 1499 by Virgilio Orsini, afterward belonged to the family of the Colonnas, and is now in possession of the Barberinis. Population about 5,900.

AVIARY, a place for keeping birds. Amongst the Romans, the name *aviarium* was sometimes used of a place for keeping and fattening birds meant to be killed for food.

AVICEBRON. The writer referred to by the scholastics of the 13th century under this name was supposed by them to be an Arabian philosopher, and was accordingly classed along with Avempace, Abubacer, and others. Recent researches have shown that this is an error, and that this author, about whom so little was known, is identical with Salomon ben Gebirol, a Jewish writer, several of whose religious poems are still celebrated among the Jews. Few details are known regarding the life of Gebirol. He was born at Malaga, and received his education at Saragossa, where, in 1045, he wrote a small treatise on morals, which has been several times reprinted. He died in 1070 at Valencia.

AVICENNA (in Arabic, Abû Ali el-Hosein Ibn-Abdallah Ibn-Sina) was born about the year 980 A.D. at Afshena, one of the many hamlets in the district of Bokhara. His mother was a native of the place; his father, a Persian from Balkh, filled the post of tax-collector in the neighboring town of Harmaitin, under Nûh ibn Mansir, the Samanide emir of Bokhara. On the birth of Avicenna's younger brother the family migrated to the capital, then one of the chief cities of the Moslem world, and famous for a culture which was older than its conquest by the Saracens. Avicenna was put in charge of a tutor, and his precocity soon made him the marvel of his neighbors,—as a boy of ten who knew by rote the Koran and much Arabic poetry besides. Under him Avicenna read the *Isagoge* of Porphyry, and the first propositions of Euclid. But the pupil soon found his teacher to be but a charlatan, and betook himself, aided by commentaries, to master logic, geometry, and the Almagest. Before he was sixteen he not merely knew medical theory, but by gratuitous attendance on the sick had, according to his own account, discovered new methods of treatment. For the next year and a half he worked at the higher philosophy, in which he encountered greater obstacles. In such moments of baffled inquiry he would leave his books, perform the requisite ablutions, then hie to the mosque, and continue in prayer till light broke on his difficulties. Deep into the night he would continue his studies, stimulating his senses by occasional cups of wine, and even in his dreams problems would pursue him and work out their solution. Forty times, it is said, he read through the metaphysics of Aristotle, till the words were imprinted on his memory; but their meaning was hopelessly obscure, until one day they found illumination from the little commentary by Alfarabius, which he bought at a bookstall for the small sum of three drachmæ. So great was his joy at the discovery, thus made by help of a work from which he expected only mystery, that he hastened to return thanks to God, and bestowed an alms upon the poor. Thus, by the end of his seventeenth year, he had gone the round of the learning of his time; his apprenticeship of study was concluded, and he went forth a master to find a market for his accomplishments.

His first appointment was that of physician to the emir, whom the fame of the youthful prodigy had reached, and who owed him his recovery from a dangerous illness. Avicenna's chief reward for this service was access to the royal library, contained in several rooms, each with its chests of manuscripts in some branch of learning. The Samanides were well-known patrons of scholarship and scholars, and stood conspicuous amid the fashion of the period, which made a library and a learned retinue an indispensable accompaniment of an emir, even in the days of campaign. In such a library Avicenna could inspect works of great rarity, and study the progress of science. When the library was destroyed by fire not long thereafter, the enemies of Avicenna accused him of burning it, in order for ever to conceal the sources of his knowledge. Meanwhile, he assisted his father in his financial labors, but still found time to write some of his earliest works for two wealthy patrons, whose absolute property they became. Among them was the *Collectio*, one of those short synopses of knowledge which an author threw off for different patrons.

At the age of twenty-two Avicenna lost his father. The Samanide dynasty, which for ten years had been hard pressed between the Turkish Khan of Kashgar on the north and the rulers of Ghazni on the south, came to its end in December 1004. Avicenna seems to have declined the offers of Mahmud the Ghaznevide (who, like his compeers, was rapidly gathering a brilliant cortege of savants, including the astronomer Albiruni), and proceeded westwards to the city of Urdjensh in the modern district of Khiva, where the vizier, regarded as a friend of scholars, gave him a small monthly stipend. But the pay was small, and Avicenna wandered from place to place through the districts of Nishapur and Merv to the borders of Khorasan, seeking an opening for his talents. In the restless change which threw the several cities of Iran from hand to hand among those feudal emirs of the Buide family, who disputed for the fragments of the caliphate, the interests of letters and science were not likely to be regarded. Shems al-Maâli Kabûs, the generous ruler of Deilem, himself a poet and a scholar, with whom he had expected to find an asylum, was about that date (1013) starved to death by his own revolted soldiery. Avicenna himself was at this season stricken down by a severe illness. Finally at Jorjân, near the Caspian, he met with a friend, who bought near his own house a dwelling in which Avicenna lectured on logic and astronomy. For this patron several of his treatises were written; and the commencement of his *Canon of Medicine* also dates from his stay in Hyrcania.

He subsequently settled at Rai, in the vicinity of the modern Teheran, where a son of the last emir, Medj Addaula, was nominal ruler, under the regency of his mother. At Rai about thirty of his shorter works are said to have been composed. But the constant feuds which raged between the regent and her second son, Shems Addaula, compelled the scholar to quit the place, and after a brief sojourn at Kaswîn, he passed southwards to Hamadân, where that prince had established himself. At first he entered into the service of a high-born lady; but ere long the emir, hearing of his arrival, called him in as medical attendant, and sent him back with presents to his dwelling. Avicenna was even raised to the office of vizier; but the turbulent soldiery, composed of Koords and Turks, mutinied against their nominal sovereign, and demanded that the new vizier should be put to death. Shems Addaula consented that he should be banished from the country. Avicenna, however, remained hidden for forty days in a sheikh's house, till a fresh attack of illness induced the emir to restore him to his post. Even during this perturbed time he prosecuted his studies and teaching. Every

evening extracts from his great works, the *Canon* and the *Sanatio*, were dictated and explained to his pupils; among whom, when the lesson was over, he spent the rest of the night in festive enjoyment with a band of singers and players. On the death of the emir Avicenna ceased to be vizier, and hid himself in the house of an apothecary, where, with intense assiduity, he continued the composition of his works. Meanwhile, he had written to Abu Jaafar, the prefect of Ispahan, offering his services; but the new emir of Hamadân getting to hear of this correspondence, and discovering the place of Avicenna's concealment, incarcerated him in a fortress. War meanwhile continued between the rulers of Ispahan and Hamadân; in 1024 the former captured Hamadân and its towns, and expelled the Turkish mercenaries. When the storm had passed Avicenna returned with the emir to Hamadân, and carried on his literary labors; but at length, accompanied by his brother, a favorite pupil, and two slaves, made his escape out of the city in the dress of a Sufite ascetic. After a perilous journey they reached Ispahan, and received an honorable welcome from the prince. The remaining ten or twelve years of Avicenna's life were spent in the service of Abu Jaafar Ala Addaula, whom he accompanied as physician and general literary and scientific adviser, even in his numerous campaigns. During these years he began to study literary matters and philology, instigated, it is asserted, by criticisms on his style. But amid his restless study Avicenna never forgot his love of enjoyment. Unusual bodily vigor enabled him to combine severe devotion to work with facile indulgence in sensual pleasures. His passion for wine and women was almost as well known as his learning. With much gaiety of heart, and great powers of understanding, he showed at the same time the spirit of an Aristippus more than that of an Aristotle at the courts of the wealthy. Versatile, light-hearted, boastful, and pleasure-loving, he contrasts with the nobler and more intellectual character of Averroes. His bouts of pleasure gradually weakened his constitution; a severe colic, which seized him on the march of the army against Hamadân, was checked by remedies so violent that Avicenna could scarcely stand. On a similar occasion the disease returned; with difficulty he reached Hamadân, where, finding the disease gaining ground, he refused to keep up the regimen imposed, and resigned himself to his fate. On his deathbed remorse seized him; he bestowed his goods on the poor, restored unjust gains, freed his slaves, and every third day till his death listened to the reading of the Koran. He died in June 1037, in his 58th year, and was buried among the palm-trees by the Kiblah of Hamadân.

The rank of Avicenna in the mediæval world as a philosopher was far beneath his fame as a physician. Still, the logic of Albertus Magnus and succeeding doctors was largely indebted to him for its formulæ.

The place of Avicenna amongst Moslem philosophers is seen in the fact that Shahrastani takes him as the tpye of all, and that Algazali's attack against philosophy is in reality almost entirely directed against Avicenna. His system is in the main a codification of Aristotle modified by fundamental views of Neo-Platonist origin, and it tends to be a compromise with theology. In order, for example, to maintain the necessity of creation, he taught that all things except God were admissible or possible in their own nature, but that certain of them were rendered necessary by the act of the creative first agent,—in other words, that the possible could be transformed into the necessary. Avicenna's theory of the process of knowledge is an interesting part of his doctrine. Man has a rational soul, one face of which is turned towards the body, and, by the help of the higher aspect, acts as practical understanding; the other face lies open to the reception and acquisition of the intelligible forms, and its aim is to become a reasonable world, reproducing the forms of the universe and their intelligible order. In man there is only the susceptibility to reason, which is sustained and helped by the light of the active intellect. Man may prepare himself for this influx by removing the obstacles which prevent the union of the intellect with the human vessel destined for its reception.

Upwards of 100 treatises are ascribed to Avicenna. Some of them are tracts of a few pages, others are works extending through several volumes. The best-known amongst them, and that to which Avicenna owed his European reputation, is the *Canon of Medicine;* an Arabic edition of it appeared at Rome 1593, and a Hebrew version at Naples in 1491.

AVIENUS, Rufus Festus, a Latin poet, who appears to have flourished in the latter half of the 4th century, but of whom nothing definite is known.

AVIGLIANO, a towo of Italy, in the province of Basilicata, eleven miles north-northwest of Potenza. A peculiar kind of pottery produced here toward the end of the 18th century is still sought after by collectors. The surrounding country is said to produce the finest cattle in the kingdom. Population (1890), 16,000.

AVIGNON, the chief town of the department of Vaucluse in France, situated in a beautiful plain, on the left bank of the Rhone, not far from the entrance of the Durance. It is surrounded by its ancient crenellated walls, which are in a state of remarkable preservation, and, on the outside, by a line of pleasant boulevards planted with trees. A precipitous rock rises from the river's edge; and from its summit the cathedral of *Nôtre Dame des Domes*, a building of the 12th century, looks down on the city, but is almost thrown into insignificance by the Palace of the Popes, which rises by its side, and stretches in sombre grandeur along the southern slope. This building, or congeries of buildings, was commenced by Benedict XII. in 1336, and continued by successive popes for sixty years. It covers an area of rather more than 1¼ acres. The paintings with which it was profusely adorned are in a great measure destroyed, and even the grandeur of its dismantled interiors was for a long time broken in upon by the carpentry and plaster-work of French barracks. A restoration has, however, been for some time in progress; and the building will again be appropriated for ecclesiastical and civic purposes. The churches of St. Agricol, St. Didier, and St. Pierre may be mentioned as of some importance; also the papal mint, now known as a music academy; the town-hall, built in 1862; the Calvet museum, rich in Roman remains; the Requien museum of natural history; and the Hôtel des Invalides. From 1309, when Clement V. took up his abode in the city, to 1377, when Gregory XI. returned to Rome, Avignon was the seat of the papal court, and it continued from 1378 to 1418 to be the seat of French anti-popes. In 1348 it was purchased by Pope Clement VI. from Joanna of Sicily for the sum of 80,000 florins, and it remained in possession of the popes till the French Revolution. Population, 38,196.

AVILA, a province of Spain, one of the modern divisions of the kingdom of Old Castile. It is bounded on the N. by Valladolid, E. by Segovia and Madrid, S. by Toledo and Caceres, and W. by Salamanca. The area is 2570 square miles; population, 176,769. It naturally divides itself into two sections, differing completely in soil, climate, productions, and social economy. The northern portion is generally level; the soil is of indifferent quality, strong and marly in a few places, but rocky in all the valleys of the Sierra de Avila; and

the climate alternates from severe cold in winter to extreme heat in summer. The population of this part is agricultural. The southern division is one mass of rugged granitic *sierras*, interspersed, however, with sheltered and well-watered valleys, abounding with rich vegetation. The winter here, especially in the elevated region of the Paramera and the waste lands of Avila, is long and severe, but the climate is not unhealthy. The inhabitants are occupied in the rearing of cattle.

AVILA (the ancient *Abula*), a city of Spain, the capital of the above province, is situated on the right bank of the Adaja, about 3,000 feet above the sea level, at the termination of the Guadarrama mountains.

AVILA, GIL GONZALEZ D', a Spanish biographer and antiquary, was born at Avila about the year 1577, and died there in 1658.

AVILA Y ZUNIGA, LUIS D', author of a Spanish history of the wars of Charles V. Nothing is known as to the place or date either of his birth or of his death.

AVILES, SAN NICOLAS DE (the Latin *Flavionavia*), a town of Spain, in the province of Oviedo, about a league from the sea-coast. It has considerable trade by means of its port, which affords good anchorage for all classes of vessels. Population, 3,299.

AVLONA, or VALONA, a town and seaport of Albania, in the eyalet of Yanina. It stands on an eminence near the Gulf of Avlona, an inlet of the Adriatic, almost surrounded by mountains. In 1464 it was taken by the Ottomans, and after being in Venetian possession in 1690, was restored to them in 1691. In 1851 it suffered severely from an earthquake.

AVOCA, or OVOCA (Celt. meeting of the waters), a small river in the southeast of County Wicklow, formed by the union of the Avonmore and Avonbeg, which rise in the hills of the center of the county. The Avoca runs through a very picturesque vale only a quarter of a mile broad, with wooded banks 300 to 500 feet high, and after a course of nine miles reaches the sea at Arklow. The "sweet vale" is celebrated in one of Moore's *Irish Melodies*. At Avondale, on the Avonmore, was born Mr. C. S. Parnell.

AVOCET (*Recurvirostra*), a genus of birds which, although having the feet webbed nearly to the end of the toes, is usually ranked among the Grallæ, or Grallatores, on account of the length of the legs, the half-naked thighs, the long, slender, elastic bill, and the general snipe-like habit. They scoop through the mud with the bill, first to one side and then to the other, in quest of worms and other small animals; although Audubon also observed the American avocet taking insects which were swimming on the surface of the water, and expertly catching them in the air, running after them with partially expanded wings. The avocets are found in most parts of the globe. The American avocet (*R. americana*) has the bill less recurved than the common avocet.

AVOIRDUPOIS, or AVERDUPOIS, the name of a system of weights, commonly supposed to be derived from the French *avoir du pois*, to have weight. The suggested derivation from *averer*, to verify, seems, however, more probable, *averdupois* being the earlier form of the word. Avoirdupois weight is used for all commodities except the precious metals, gems and medicines. The pound avoirdupois, which is equal to 7,000 grains troy, or 453.54 grammes, is divided into 16 ounces, and the ounce into 16 drams. See WEIGHTS AND MEASURES.

AVOLA, a city on the coast of Sicily, in the province of Syracuse, with 11,912 inhabitants.

AVON, the name of several rivers in England, Scotland and France. The word is Celtic, appearing in Welsh, as *afon*, in Manx as *aon*, and in Gaelic as *abhuinn* (pronounced *avain*), and is radically identical with the Sanskirt *ap*, water, and the Latin *aqua* and *amnis*. Of the principal English rivers of this name in its full form three belong to the basin of the Severn. The Upper, or Shakespearean Avon, rising in Northamptonshire, near the battlefield of Naseby, flows through Warwickshire, Worcester, and Gloucester, past Rugby, Warwick, Stratford and Evesham, and joins the larger river at Tewkesbury; while the Lower Avon has its sources on the borders of Wiltshire, and enters the estuary of the Severn at King's Roads, after passing Malmesbury, Bath and Bristol.

AVRANCHES (ancient *Abrincatæ*, or *Ingena*) a town of France, in the department of Manche. It was an important military station of the Romans, and has in more modern times sustained several sieges, the most noticeable of which was the result of its opposition to Henry IV. Avranches was formerly a bishop's see, and its cathedral, destroyed as insecure in the time of the first French Revolution, was the finest in Normandy. Its site is now occupied by an open *place*, called after the celebrated Huet, bishop of Avranches; and one stone remains with an inscription marking it out as the spot where Henry II. received absolution for the murder of A' Becket. Population (1890), 8,500.

AWN (*Arista*), in the flowers of grasses, a solitary pointed bristle, growing either from a glume or a palea. The flowers of some grasses are entirely *awnless;* in many the glumes alone are *awned*, or only one of them; in others the glumes are awnless, and the paleæ, or one palea awned. In barley it is known as the "beard."

AXE, an instrument, usually of iron, edged with steel, for hewing timber and chopping wood. The haft or handle is of a length and size suitable for wielding with both hands, and is fitted into a head with an arching edge in the plane of the sweep of the tool—the axe differing in this last respect from the adze, which is found in use amongst some uncivilized people that do not use axes at all. Similar instruments of smaller size, for use with one hand, are called hatchets (Fr. *hachette*, diminutive of *hache*, an axe). Within historic times the axe has recovered its early importance with the progress of colonization, and its importance to settlers has led to the invention of the American axe, which effects speedier results with the smallest expenditure of strength.

AXEL, see ABSALON, Vol. 1, p. 18.

AXESTONE, a variety of the mineral Jade or Nephrite. It is of greenish, grayish or grayish-white color, is more or less translucent, hard, tough and not easily broken. It occurs in Silesia, in Central Asia and China, and in New Zealand and other islands of the Southern Pacific.

AXIL (*axilla*), in Botany, the angle between the upper side of a leaf and the stem or branch from which it grows. (2) In anatomical terminology, the axilla is the armpit.

AXHOLM, or AXELHOLM, an island in the northwest part of Lincolnshire, England, formed by the rivers Trent, Idle and Don. Area, 47,000 acres.

AXIOM is a word of great import both in general philosophy and in special science; it also has passed into the language of common life, being applied to any assertion of the truth of which the speaker happens to have a strong conviction, or which is put forward as beyond question. The scientific use of the word is most familiar in mathematics, where it is customary to lay down under the name of axioms, a number of propositions of which no proof is given or considered necessary, though the reason for such procedure may not be the same in every case, and in the same case may be variously understood by different minds.

AXIS, a genus of deer, abundant on the banks of the Ganges, but found throughout India and in many islands

of the Eastern archipelago. One of its Indian names is Chittra or Cheetal, and by British sportsmen in India it is often called the Spotted Hog-deer, though that name is also given to a rarer species. The axis has a great resemblance in size and coloring to the European fallow deer.

AXIS, in Geometry. The axis of a curved line is formed by a right line dividing the curve into two symmetrical parts, so that the part on one side exactly corresponds with that on the other; as in the parabola, the ellipse and the hyperbola. The axis of any geometrical solid is the right line which passes through the center of all the corresponding parallel sections of it; in this sense, we speak of the axis of a cylinder, a globe or a spheroid. In physical science, the axis of a *lens* is the right line passing through it in such a manner as to be perpendicular to both sides of it; and the axis of a telescope is the right line which passes through the center of all the glasses in the tube. The axis of the *eye* is the right line passing through the centers of the pupil and the crystalline lens.

AXIS, in Botany, a term applied to the central portion of the higher plants (higher cryptograms as well as phanerogams), which bears the appendages or lateral members arranged upon it. Those plants in which no distinction of axis and appendages can be made out are termed *Thallophytes*, and include algæ, litchens and fungi. The stem is called the *ascending axis*; the root, the *descending axis*. (2) In human anatomy the axis is the second vertebra of the neck.

AXMINSTER, a market-town of England, in the county of Devon, 147 miles from London, and 24 from Exeter. It takes its name from the river Axe, on which it stands. Population (1890), 3,000.

AXOLOTL (the Aztec word), an amphibian form occurring abundantly in some Mexican lakes, and found widely distributed in the western United States. It used to rank among the forms which permanently retain their gills (*Perennibranchiata*), but more complete observation has shown that it develops into a gill-less adult form (*Amblystoma*) like a salamander.

AXUM, an ancient city of Abyssinia, eighty-five miles northwest of Antalo, still remarkable for its ruins. It was for a long time the capital of a great Shemitic people, who extended their sway over a large part of Abyssinia; and the language spoken there at the time of the introduction of Christianity has continued to be the ecclesiastical language ever since. The chronicles of Abyssinia were preserved in the church, and are frequently referred to as the *Books of Axum*. The most interesting of the monuments still extant are the obelisk and the so-called coronation-room, both constructed of granite, and the latter containing some valuable bilingual inscriptions.

AYACUCHO, formerly Huamanga or Guamanga, a town in the Peruvian department of the same name, 220 miles east-southeast of Lima. Founded by Pizarro in 1539, it is now a handsome and thriving town. Here, on December 9, 1824, the combined forces of Peru and Colombia—the latter then comprising Ecuador, New Granada and Venezuela—totally defeated the last Spanish army that ever set foot on the continent. Population, 9,387. The department of Ayacucho has an area of 24,213 square miles, and a population of 142,000.

AYAMONTE, a fortified city of Spain, in the province of Huelva, on the left bank of the Guadiana, about two miles from it mouth. Population, 6,000.

AYE-AYE (*Cheiromys madagascariensis*) a rare and aberrant member of the Lemur family. It inhabits the woods of Madagascar, and was first noted in 1780 by Sonnerat, who was said to have given it the name aye-aye in reference to the astonished exclamation of some natives when they saw the first specimen of the curious creature caught by a European. It was long a puzzle to zoölogists; Buffon placed it beside squirrels, and Cuvier was also inclined to regard it as a rodent. It was carefully described by Owen in the *Transactions* of the Zoölogical Society, 1866, and since the publication of this beautiful and exhaustive memoir, there has been no doubt as to the position of the aye-aye as an aberrant lemur.

AYESHAH (also *Aysha* or *Aïsha*), the favorite wife of Mohammed, and daughter of Abu-Bekr, was born at Medina about 610 A. D., and was only nine years of age when the prophet married her. She was the only one of Mohammed's wives who accompanied him in his campaigns. Although Ayeshah bore no children to Mohammed, she was tenderly beloved by him. She was accused of adultery, but Mohammed produced a revelation from heaven (now in the Koran) to the effect that she was innocent. Mohammed expired in her arms (632). She died in 677.

AYLESBURY, a market town, parliamentary borough and railway junction, in the county of Buckingham, thirty-nine miles northwest of London. Population of parliamentary borough, 28,760.

AYLESFORD, a village of England, in the county of Kent, three and one-half miles from Maidstone, and thirty-two from London. Population of parish in 1889, 2,400.

AYLMER, John, Bishop of London in the reign of Queen Elizabeth, was born in the year 1521 at Aylmerhall, in the parish of Tilney, in the county of Norfolk. He seems to have been a man of harsh and violent temper, coarse and avaricious, and with few redeeming qualities. He is said to have been an able scholar, but he has left nothing which could prove this. He died in 1594.

AYR, County of, or Ayrshire, a Scottish county, bounded by Wigtownshire and the stewartry of Kirkcudbright on the south; by Kirkcudbright, Dumfries, and Lanark on the east, and by Renfrewshire on the north. On the west it has a coast line extending to seventy miles on the Irish Sea and the Firth of Clyde. The county contains 1,149 square miles, or 735,262 acres. The middle part, which is the broadest, is about twenty-six miles across. There are six rivers of some note in Ayrshire—Stinchar, Girvan, Doon, Ayr, Irvine and Garnock. Of these the Ayr, from which the county and country town take their name, is the largest. It rises at Glenbuck, on the border of Lanarkshire, and, after a course of thirty-three miles, falls into the Firth of Clyde at the county town. The scenery along its banks from Sorn downward—passing Catrine, Ballochmyle, Barskimming, Sundrum, Auchencruive and Craigie—is varied and beautiful. The lesser streams are numerous; and there are many fresh-water lochs, the largest of which is Loch Doon, the source of the river Doon. The southern and eastern parts of the county are hilly, but none of the peaks reaches a height of 2,000 feet.

The manufactures of Ayrshire have attained considerable importance. The cotton works at Catrine are extensive, and have been a long time established. The site was chosen with the view of utilizing the water power of the river Ayr, and steam is still merely an auxiliary. At Kilmarnock and Ayr there are extensive engineering establishments, and large carpet works; and other fabrics are manufactured in those towns and at Dalry, Kilbirnie, Beith and Stewarton.

The iron trade at Ayrshire has risen to great importance. The manufacture has long been carried on at Muirkirk, although the iron had to be carted long distances to Ayr and Glasgow before the introduction of

railways. Immense fields of ironstone have been opened up within the last quarter of a century; and there are now thirty-three furnaces in blast within the county, producing about 330,000 tons per annum. Ayrshire is well supplied with railways.

The rural population of Ayrshire is decreasing, but the mining population has increased, and the towns are growing.

AYR, the capital of the above county, is situated at the mouth of the river of the same name, and about forty miles south-southwest from Glasgow. The spot has probably been inhabited from a remote antiquity. Nothing, however, is known of its history till the close of the thirteenth century, when it was made a royal residence, and soon afterward a royal burgh, by William the Lion. On better authority, the records of the burgh, it is known that early in the sixteenth century Ayr was a place of considerable influence and trade. The liberality of William the Lion had bestowed upon the corporation an extensive grant of lands; while in addition to the well-endowed church of St. John's, it had two monasteries, each possessed of a fair revenue. When Scotland was overrun by Cromwell, Ayr was selected as the site of one of those forts which he built to command the country. This fortification, termed the citadel, enclosed an area of ten or twelve acres, and included within its limits the church of St. John's, in which the Scottish Parliament on one occasion met, and confirmed the title of Robert Bruce to the throne. Ayr proper lies on the south bank of the river, and is connected with Newton and Wallacetown on the north by two bridges, the old and the new, the "twa Brigs" of Burns. Of late years the town has extended greatly on the Ayr side of the stream. Ayr possesses several good streets and a number of elegant public buildings. Population, 20,000.

AYRER, JACOB, one of the earliest dramatists of Germany, was born in 1560, probably at Nuremberg, —at least he resided there when a mere boy. His first occupation was keeping an iron-store, which he did with considerable success. After studying law for some time at Bamberg, where he attained a good position as a lawyer, he returned to Nuremberg, and continued to practice there, acquiring the freedom of the city in 1594, and ultimately becoming an imperial notary. He died 26th March 1605.

AYTON, SIR ROBERT (1570–1638), a Scottish lyrical poet, the second son of Andrew Ayton of Kinaldie in Fifeshire, was educated at the University of St. Andrews, and seems afterwards to have resided for several years in France, where he gained considerable reputation as a poet and scholar. On the accession of James VI. in 1603, Ayton published a very elegant Latin panegyric, which at once brought him into notice and favor at court.

AYTOUN, WILLIAM EDMONSTOUNE, a Scottish poet, humorist, and miscellaneous writer, was born at Edinburgh, 21st June 1813. He was the only son of Roger Aytoun, a writer to the Signet, and the family was of the same stock as Sir Robert Ayton noticed above. In 1836 he made his earliest contributions to *Blackwood's Magazine*, in translations from Uhland; and from 1839 till his death he remained on the staff of *Blackwood's*. About 1841 he became acquainted with Mr. Theodore Martin, and in association with him wrote a series of light humorous papers on the tastes and follies of the day, in which were interspersed the verses which afterwards became popular as the *Bon Gualtier Ballads*. The work on which his reputation as a poet chiefly rests is the *Lays of the Scottish Cavaliers*. The first of these appeared in *Blackwood's Magazine* in April 1843, and the whole were published in a collected edition in 1848. They became very popular, and have passed through nineteen editions, the last of which has spirited and beautiful illustrations by Sir J. Noel Paton and W. H. Paton. In 1860 Aytoun was elected honorary president of the Associated Societies of Edinburgh University. The death of his mother took place in November 1861, and his own health was failing. In December 1863 he married Miss Kinnear, and health and happiness for a time revived; but his malady recurred, and he died at Blackhills, near Elgin, 4th August 1865.

AZAIS, PIERRE HYACINTHE, a brilliant French writer on philosophy, was born at Sorrèze in 1766, and died at Paris in 1845. He was educated at the college in his native town; and at the age of 17 joined a religious body with the view of afterwards entering the church. He remained only a year in this society, and then accepted an appointment as teacher in the college at Tarbes. The duties of this office proved most uncongenial to him, and he gladly entered the service of the bishop of Olèron, to whom he acted as secretary. He afterward acted as tutor to the Count de Bosc's sons, with whom he remained till the outbreak of the Revolution. Azais, at first an ardent admirer of that great movement, was struck with dismay at the atrocities that were perpetrated, and published a vehement pamphlet on the subject. He was denounced, and had to seek safety in flight. For eighteen months he found refuge in the hospital of the Sisters of Charity at Tarbes; and it was not till 1806 that he was able to settle at Paris. There, three years later, he published his treatise *Des Compensations dans les Destinées Humaines*, in which he sought to show that happiness and misery were fairly balanced in this world, and that consequently it was the duty of citizens to submit quietly to a fixed government. This doctrine was not displeasing to Napoleon, who made its author professor at St. Cyr. After the removal of that college, he obtained, in 1811, the post of inspector of the public library at Avignon, and from 1812 to 1815 he held a similar office at Nancy.

AZARA, DON FELIX DE, a Spanish naturalist, was born 18th May 1746, and died in 1811. He studied first at the university of Huesca, and afterwards at the military academy of Barcelona. In 1764 he entered the army as a cadet, and in 1767 obtained an ensigncy in the engineer corps. In 1781 he was appointed, with the rank of lieutenant-colonel of engineers and captain in the navy, on a commission to lay down the line of demarcation between the Spanish and Portuguese territories in South America. There he spent many years, observing and collecting specimens of the various interesting objects of natural history that abound in those wide and little-known regions.

AZARA, DON JOSE NICHOLAS D', the elder brother of the naturalist, born in 1731, was appointed in 1765 Spanish agent and procurator-general, and in 1785, ambassador at Rome. During his long residence there he distinguished himself as a collector of Italian antiquities and as a patron of art.

AZEGLIO, MASSIMO TAPARELLI, MARQUIS D', an eminent Italian author and statesman, was born in October 1798, at Turin. He was descended from an ancient and noble family of Piedmont, and was the son of a military officer, who, when the subject of this notice was in his fifteenth year, was appointed ambassador to Rome. The boy went with him, and, being thus introduced to the magnificent works of art for which the Eternal City is famous, contracted a love for painting, as well as for music. He desired to become a painter, and, although his studies were for a time interrupted by his receiving a commission in a Piedmontese cavalry regiment, and by a subsequent illness, brought on by the severity of his scientific investigations and resulting in

his quitting the service, he eventually returned to Rome, and, with some difficulty, obtained his father's permission to devote himself to art. He remained at the Papal capital eight years, and acquired great skill and some fame as a landscape-painter. At the close of that period events directed his mind into other channels. His father died in 1830, and the younger Azeglio then removed to Milan, where he became acquainted with Alessandro Manzoni, the poet and novelist, whose daughter he married. In this way his thoughts were turned towards literature and politics. At that time, Italy was profoundly agitated by the views of the national and liberal party. The country was divided into several distinct states, of which the greater number, even of those that were nominally independent, were under the influence of Austria. Lombardy and Venetia formed parts of the Austrian dominions. The petty monarchies of the north were little better than vassals to the house of Hapsburg; the Papacy, in the centre, was opposed to all national aspirations; and the kingdom of the Two Sicilies, in the south, was a despotism, which for cruelty and mental darkness could not have been exceeded in Asia itself. The French revolution of July 1830 gave additional force to the movements of the Italian liberal party, and the young men of the day threw themselves with fervor into the crusade against old abuses and foreign domination. Mazzini was just beginning his career as an agitator, and the whole air was surcharged with revolutionary enthusiasm. This was especially the case in the north of Italy, where Massimo d'Azeglio was now settled. Art was abandoned by him for literature, and literature was practised with a view to stimulating the sense of national independence and unity. In 1833, M. d'Azeglio published a novel called *Ettore Fieramosca*, which was followed in 1841 by another, entitled *Niccolo di Lapi.* Both had a political tendency, and between the two dates at which they appeared, M. d'Azeglio visited various parts of Italy, diffusing those liberal principles which he saw were the only hope of the future. His views, however, were very different from those of the republican party. He was a constitutional monarchist, and strongly opposed to the insurrections and secret conspiracies which Mazzini and others so frequently fostered at that time, and which always resulted in failure and renewed oppression. His treatise *Degli Ultimi Casi di Romagna* (Of the Last Events in the Romagna), published in 1846, before the death of Pope Gregory XVI., was at once a satire on the Papal Government, a denunciation of the republican attempts at insurrection, and an exhortation to the Italian princes to adopt a national policy. M. d'Azeglio returned to Rome in 1846, after the death of Pope Gregory, in June, and, it is thought, had considerable influence in persuading the new Pope (Pius IX.) to conduct his government in accordance with liberal principles. He supported measures relating to the freedom of the press, the reform of the Papacy, and the emancipation of the Jews. In 1848 he accompanied the Papal army of observation sent from Rome to watch the insurgent forces in Lombardy and Venetia, which had temporarily discomfited the Austrians, and were being supported by Charles Albert, king of Sardinia. General Durando, who had the command of the Papal army, actively assisted the rebels, in defiance, it is said, of his instructions; and Azeglio was severely wounded in the leg at the battle of Vicenza, where he commanded a legion. In the same year (1848) he published a work on the *Austrian Assassinations in Lombardy;* and on the opening of the first Sardinian parliament he was chosen a member of the chamber of deputies. After the crushing defeat of the Sardinians at Novara, March 23, 1849,—a defeat which brought the second of the two brief wars with Austria to a disastrous close,—D'Azeglio was made president of the cabinet by Victor Emmanuel, in whose favor his father, Charles Albert, had just resigned. In this position the marquis used his high powers with great advantage to the progress and consolidation of the Sardinian kingdom. His occupation of the office lasted from the 11th of May 1849 to the 20th of October 1852, when he was replaced by Count Cavour. At the termination of the war of 1859, when a large portion of the States of the Church shook off the dominion of the Pope, and declared for annexation to the kingdom of Northern Italy, Azeglio was appointed general and commissioner-extraordinary, purely military, for the Roman States — a temporary office, which he administered in a conciliatory and sagacious spirit. He died on the 11th of January 1866, leaving a reputation for probity and wisdom, which his countrymen will not forget to cherish. His writings, chiefly of a polemical character were numerous. In addition to those already mentioned, the most noteworthy was a work on *The Court of Rome and the Gospels*, of which an English translation, with a preface by Dr. Layard appeared in 1859. A volume of personal recollections was issued, in 1867, after M. d'Azeglio's death.

AZERBIJAN (so called, according to Sir William Ouseley, from a fire-temple, a province of Persia, corresponding to the ancient Atropatene. It is separated from a division of the Russian Empire on the N. by the River Araxes, and from Irak on the S. by the Kizil-Uzen, or Golden Stream, while it has the Caspian Sea and Ghilan on the E., and Asiatic Turkey on the W. Its area is estimated at 25,280 square miles. The country is superior in fertility to the southern provinces of Persia. It differs entirely from the provinces of Fars and Irak, as it consists of a regular succession of undulating eminences, partly cultivated, and opening into extensive plains such as Anjan, Tabreez, and Urumiyah or Van. Near the centre of the province the mountains of Sahend or Serhund rise in an accumulated mass to the height of 9000 feet above the sea. The highest point, Mount Sevellan, towards its eastern frontier, attains a height of about 12,000 feet, according to some authorities, but according to Khanikoff, it is 15,400; and the Talish Mountains, which run from N. to S. parallel to, and at no great distance from, the Caspian, have an altitude of 7000 feet. Except the boundary rivers already mentioned, there are none of any great extent; but these both receive a number of tributaries from the province, and several streams of considerable volume, such as the Jughutu, the Agi, and the Shar, belong to the basin of the Lake Urumiyah. This lake is about 300 miles in circumference, and 4200 feet above the sea. Its waters are more intensely salt than the sea, and it is "supposed to contain no living creature except a kind of polype;" but it is the resort of great flocks of the flamingo. The country to the N. and W., namely, the districts of Urumiyah and Selmart, is the most picturesque and prosperous part of Azerbijan; yet even here the traveller from the more civilised regions of Europe laments the want of enterprise among the inhabitants. Azerbijan is on the whole, however, reckoned one of the most productive provinces of Persia, and the villages have a more pleasing appearance than those of Irak. The Persian army is largely composed of natives of Azerbijan, who make excellent soldiers; they are subject to compulsory enlistment. The province is under the government of the heir-apparent to the Persian throne.

AZIMGARH, a district and city in the Benares division of British India, and under the jurisdiction of the Lieutenant-Governor of the North-Western Provinces

It is bounded on the N. by the river Ghagrá, separating it from Gorakhpur district; on the E. by Gházípur district and the river Ganges; on the S. by the districts of Jaunpur and Gházípur; and on the W. by Jaunpur and the Oudh district or Faizábád. Its area in 1872 was returned at 2494 square miles, of which 1268 square miles are under cultivation, 344 square miles are cultivable waste, and the remaining 882 square miles are barren and uncultivable. The population of the district in 1865 was 1,385,872 souls, of whom 1,184,689 were Hindus, and 201,183 Mahometans. The pressure of the population on the soil averaged 555 per square mile. The soil is fertile and very highly cultivated, bearing magnificent crops of rice, sugar-cane, and indigo. The principal industries of the district are cotton and silk manufactures, the total value of which in 1872 amounted to £109,081.

AZIMGARH CITY, the principal place in the district of the same name, is situated on the river Tons. The city is said to have been founded about 1620 by a powerful landholder named Azím Khán, who owned large estates in this part of the country.

AZO, a distinguished professor of civil law in the university of Bologna, and a native of that city. He was the pupil of Joannes Bassianus, who taught at Bologna towards the end of the 12th century, and who was the author of the famous *Arbor Actionum*. Azo, whose name is sometimes written Azzo and Azzolenus, and who is sometimes described as Azo Soldanus from the surname of his father, occupied a very important position amongst the gloss-writers, and his *Readings* (*Lectura*) *on the Code*, which were collected by his pupil, Alexander de Sancto Ægidio, are considered by Savigny, a most competent judge, to be the most valuable of the works of that school which have come down to us.

AZOFF, or Asov (in Turkish, *Asak*), a town on the left bank of the southern arm of the Don, about 20 miles from its mouth. Peter the Great obtained possession of it after a protracted siege in 1696, and did a great deal for the security and prosperity of the town. At the peace of 1711, however, he had to restore it to the Turks; and it was not till 1774 that it was finally united to the Russian empire.

AZOFF, THE SEA OF, an inland sea of Southern Europe, communicating with the Black Sea by the Strait of Yenikale, the ancient *Bosphorus Cimmerius*. To the Romans it was known as the *Palus Mœotis*, from the name of the neighboring people, who called it in their native language *Temarenda*, or Mother of Waters. Possibly to account for the outward current into the Black Sea, it was long supposed to possess direct communication with the Northern Ocean, and, when it was discovered that there was no visible channel, recourse was had to a "secret sluice;" there being, it was thought, but a comparatively narrow isthmus to be crossed. In some prehistoric time, according to Pallas and Murchison, a connection with the Caspian Sea seems to have existed; but no great change has taken place in regard to the character or relations of the Sea of Azoff since our earliest records.

AZORES, THE, or WESTERN ISLANDS, are situated in the Atlantic Ocean, and extend in an oblique line from N. W. to S.E. They are generally considered as pertaining to Europe, though separated by a distance of 800 miles from the coast of Portugal. They are divided into three distinct groups; the south-eastern consisting of Saõ Miguel, or St. Michael's, and Sta. Maria; the central and largest, of Fayal, Pico, Saõ Jorge, Terceira, and Graciosa; and the north-western, of Flores and Corvo.

It does not appear that the ancient Greeks and Romans had any knowledge of the Azores, but from the number of Carthaginian coins discovered at Corvo it has been supposed that the islands must have been visited by that adventurous people. The Arabian geographers, Edrisi in the 12th century, and Ibn-al-Wardi in the 14th, describe, after the Canaries, nine other islands in the Western Ocean, which are in all probability the Azores. This identification is supported by various considerations. The number of islands is the same; the climate under which they are placed by the Arabians makes them north of the Canaries; and special mention is made of the hawks or buzzards, which were sufficiently numerous at a later period to give rise to the present name (Port. *Açor*, a hawk.) The Arabian writers represent them as having been populous, and as having contained cities of some magnitude; but they state that the inhabitants had been greatly reduced by intestine warfare. The Azores are first found distinctly marked in a map of 1351, the southern group being named the Goat Islands (*Cabreras*); the middle group, the Wind or Dove Islands; and the western, the Brazil Island (*De Brasi*) — the word Brazil at that time being employed for any red dye-stuff. It has been conjectured that the discoverers were Genoese, but of this there is not sufficient evidence. It is plain, however, that the so-called Flemish discovery by Van der Berg is only worthy of the name in a very secondary sense. According to the usual account, he was driven on the islands in 1432, and the news excited considerable interest at the court of Lisbon. The navigator, Gonzalo Velho Cabral — not to be confounded with his greater namesake, Pedro Alvarez Cabral — was sent to prosecute the discovery. Another version relates that Don Henry of Portugal had in his possession a map in which the islands were laid down, and that he sent out Cabral through confidence in its accuracy. The map had been presented to him by his brother, Don Pedro, who had travelled as far as Babylon. Be this as it may, Cabral reached the island, which he named Santa Maria, in 1432, and in 1444 took possession of St. Michael's. The other islands were all discovered by 1457. Colonisation had meanwhile been going on prosperously; and in 1466 the Azores were presented by Alphonso V. to his aunt, Isabella, the duchess of Burgundy. An influx of Flemish settlers followed, and the islands became known for a time as the Flemish Islands. From 1580 to 1640 they were subject to Spain like the rest of the Portuguese kingdom, of which they now form a province. At that time the Azores were the grand rendezvous for the fleets on their voyage home from the Indies; and hence they became a theatre of that maritime warfare which was carried on by the English under Queen Elizabeth against the Peninsular powers. The connection with England has long since been of a more peaceful description; no other country affording such a ready market for Azorean productions.

The islands are now divided into three administrative districts, which take their names from the chief towns of Angra in Terceira, Horta in Fayal, and Ponta-Delgada in St. Michael's — the first of the three being also the capital of the islands. The most of the inhabitants are of Portuguese origin, but there is a mixture not only of Flemish but Moorish blood. Negroes, Mulattoes, English, Scotch, and Irish immigrants are present in considerable numbers, especially in San Miguel and Fayal. Education is in a very backward state, the great proportion of the lower classes being unable to read or write. Progress, however, is being made in this as well as other respects.

Under the active administration of Pombal, considerable efforts were made for the improvement of the Azores, but the stupid and bigoted Government which

followed rather tended to destroy these benefits, and to create a retrograde course. Towards the beginning of the present century, the possession of the islands was contested by the claimants for the crown of Portugal. The adherents of the constitution, who supported against Miguel the rights of Maria da Gloria, obtained possession of Terceira in 1829, where they succeeded in maintaining themselves, and after various struggles, Queen Maria's authority was established over all the islands. She resided at Angra from 1830 to 1833.

The aspect of all the islands is very similar in general characteristics, presenting an elevated and undulating outline, with little or no table-land, and rising into peaks, of which the lowest (that of Sta. Maria) is 1889 feet, and the highest (that of Pico) 7613 feet above the level of the sea. Their lines of sea-coast are, with few exceptions, high and precipitous, with bases of accumulated masses of fallen rock, in which open bays, or scarcely more enclosed inlets, form the harbors of the trading towns. The volcanic character of the whole archipelago is very obvious, and has been abundantly confirmed by the numerous earthquakes and eruptions which have taken place since its discovery. Hitherto the western group of Flores and Corvo has been quite exempt, Graciosa has been equally undisturbed, and Fayal has only suffered from one eruption, in 1672. The centre of activity has for the most part been St. Michael's, while the neighboring island of Santa Maria has altogether escaped. In 1444–45 there was a great eruption at St. Michael's, of which, however, the accounts that have been preserved exaggerate the importance. In 1522 the town of Villa Franca, at that time the capital of the island, was buried, with all its 6000 inhabitants, during a violent convulsion. In 1572 an eruption took place in the island of Pico; in 1580 St. George was the scene of numerous outbursts; and in 1614 a little town in Terceira was destroyed. In 1630, 1652, 1656, 1755, 1852, &c., St Michael's has been visited with successive eruptions and earthquakes, several of them of great violence. On various occasions, as in 1638, 172c, 1811, and 1867, subterranean eruptions have taken place, which have sometimes been accompanied by the appearance of temporary islands. Of these the most remarkable was thrown up in June 1811, about half a league from the western extremity of St. Michael's. It was called Sabrina by the commander of the British man-of-war of that name, who witnessed the phenomenon. Details will be found in a valuable chapter of Hartung's *Die Azoren*, p. 99, and in the 23d vol. of the *Philosophical Transactions*.

The climate is particularly temperate and equable, the extremes of sensible heat and cold being, however, increased by the humidity of the atmosphere. This is so great that paper-hangings will not adhere to the walls, and the veneering of furniture strips off. The range of the thermometer is from 45° Fahr,. the lowest known extreme, or 48°, the ordinary lowest extreme of January, to 82°, the ordinary, or 86°, the highest known extreme of July, near the level of the sea. Between these two points (both taken in the shade) there is from month to month a pretty regular gradation of increase or decrease, amounting to somewhat less than four degrees (*Geographical Journal*, vol. xv.) In winter the prevailing winds are from the north-west, west, and south; while in summer the most frequent are the north, north-east, and east. The weather is often extremely stormy, and the winds from the west and south-west render the navigation of the coasts very dangerous.

The general character of the flora is decidedly European, no fewer than 400 out of the 478 species generally considered as indigenous belonging likewise to that continent, while only four are found in America, and forty are peculiar to the archipelago. Vegetation in most of the islands is remarkably rich, especially in grasses, mosses, and ferns, heath, juniper, and a variety of shrubs.

The mammalia of the Azores are limited to the rabbit, weasel, ferret, rat (brown and black), mouse, and bat, in addition to domestic animals. Among the fish caught off the coast may be mentioned the mullet, the tunny, the bonito. The numbers of birds are so remarkable that in St. Michael's, where a reward is given for the destruction of the blackbird, the bullfinch, the redbreast, the chaffinch, and the canary, the sum paid annually represents a deathlist of 420,000. The game includes the woodcock, red partridge (introduced in the 16th century), quail and snipe.

St Michael's the largest and most populous of the islands, has an area of 224 square miles, and 105,404 inhabitants. The east end rises from a bluff cliff, from 1200 to 1400 feet high, to a lofty inland peak, whence a central range, varying in height from 2000 to 2500 feet, runs to the westward, terminating in the Serra de Agoa de Paõ, 3060 feet above the sea. The sea-coast gradually declines in approaching the last point, where it is not more than about 100 feet high. The middle part of the island is lower, and more undulating; its western extremity being marked by the conspicuous Serra Gorda, 1574 feet above the sea; its shores on both sides are low, broken, and rocky. The aspect of the western portion of the island is that of a vast truncated cone, irregularly cut off at an elevation of about 800 feet, and falling on the N., S., and W. sides to a perpendicular coast of between 300 and 800 feet high. In the higher parts an undergrowth of shrubs gives the mountains a rich and wooded appearance. Like all volcanic countries, the face of the island is uneven and irregular, being deeply excavated by numerous ravines, and roughened by streams of semi-vitrified and scoriaceous lava, that resist all atmospheric influences and repel vegetation. Heavy rains falling on the mountains afford a constant supply of water to four lakes at the bottom of extinct craters, and a number of minor reservoirs, and through them to small streams running rapidly down on all sides into the sea (*Geographical Journal*, vol. xv.)

Hot springs abound in many parts of the island, and from almost every crevice vapor is seen issuing. But the most remarkable phenomena are the Caldeiras or boiling fountains, which rise chiefly from a valley called the Furnas, near the western extremity of the island. The water ascends in columns to the height of 12 feet, after which it dissolves in clouds of vapor. The ground in the immediate vicinity is entirely covered with native sulphur, like hoar frost.

The plains are fertile, producing wheat, barley, and Indian corn; whilst vines and oranges grow luxuriantly on the sides of the mountains. The plants are made to spring even from the interstices of the volcanic rocks, which are sometimes blasted to receive them. Raised in this manner, these fruits are said to be of superior quality; but the expense of such a mode of cultivation necessarily restricts it. The western part of the island yields hemp, which might be raised to a considerable extent. The exports consist of wine, fruit, and provisions, the most important trade being in oranges. Foreign intercourse was at one time confined rigorously to Lisbon; but the inhabitants now trade directly with England, America, and other countries. The exports during 1872 at the port of St. Michael's were of the value of £85,279, and the imports amounted to £91,943.

The principal town in the island is Ponta-Delgada, which contains 15,520 inhabitants.

St. Mary is a small island immediately adjacent to St. Michael's, through the medium of which its trade is conducted, as it has no good harbors of its own. It has an area of 36 square miles, and produces wheat in abundance, of which a considerable quantity is exported.

Terceira (so called as being the third in order of discovery) is smaller than St. Michael's, but being placed in a more central position with respect to the other islands, has been chosen as the seat of government. The port of Angra, protected by Mt. Brazil, is also superior to any of those in St. Michael's.

Fayal (so called from the extreme abundance of the *faya*, an indigenous shrub) is the most frequented of all the Azores, after St. Michael's, as it has one of the best harbors in the islands, and lies directly in the track of vessels that are crossing the Atlantic in any direction. Its principal town is Villa de Horta. Population 26,264.

A considerable quantity of wine used to be exported from Fayal under the name of Fayal wine, which was really the produce of Pico, one of the most remarkable of the Azores. This island is composed of an immense conical mountain, rising to the height of 7613 feet, and bearing every trace of volcanic formation. The soil consists entirely of pulverised lava. All the lower parts of the mountain used to be in the highest state of cultivation, and covered with vine and orange plantations. But in 1852 the vines were attacked by the *Oidium* fungus and completely destroyed, while the orange-trees suffered almost as much from the *Coccus Hesperidum*. The people were consequently reduced to want, and forced to emigrate in great numbers. The planting of fig-trees and apricots alleviated the evil, and after a time many of the emigrants returned. Pico also produces a valuable species of wood resembling, and equal in quality to, mahogany. Population, 24,000.

Graciosa and St. George are two small islands, situated between Fayal and Terceira. The chief town of St. George is Velas, and the population 18,000.

The two small islands of Corvo and Flores seem but imperfectly to belong to the group. They lie also out of the usual track of navigators; but to those who, missing their course, are led thither, Flores affords good shelter in its numerous bays. Its poultry is excellent; and the cattle are numerous, but small. It derives its name for the abundance of the flowers that find shelter in its deep ravines. Population of Corvo, 1000 and of Flores, 10,508.

AZOTUS, the name given by Greek and Roman writers to Ashdod, or Eshdod, an ancient city of Palestine, now represented by a few remains in the little village of Esdud, in the pashalik of Acre. It was situated a short distance inland from the Mediterranean, on the usual military route between Syria and Egypt, about 18 geographical miles N.E, of Gaza. As one of the five chief cities of the Philistines, and the seat of the worship of Dagon, it maintained, down even to the days of the Maccabees, a vigorous, though somewhat intermittent independence against the power of the Israelites, by whom it was nominally assigned to the territory of Judah. In spite of its being dismantled by Uzziah, and somewhat later, in 731 B.C., captured by the Assyrians, it was strong enough in the next century to resist the assaults of Psammetichus for twenty-nine years. Restored by the Roman Gabinius from the ruins in which it had been left by the Jewish wars, it was presented by Augustus to Salome, the sister of Herod. It became the seat of a bishop early in the Christian era, but seems never to have attained any importance as a town.

AZPEITIA, a town of Spain, in the province of Guipuzcoa, on the left bank of the Urola, 15 miles S. W. of San Sebastian. The neighboring country is fertile, and quarries of marble are wrought in the mountains. During the Carlist movement in 1870–74, Azpeitia was the seat of the Guipuzcoan *Diputacion*, or court for the management of the war; and gunpowder, cartridges, and cannon were manufactured in the town. The famous monastery of San Ignacio, dedicated to Loyola, about a mile distant, was also appropriated for military purposes. Population stated at 2335.

AZTECS, the native name of one of the tribes that occupied the table-land of Mexico on the arrival of the Spaniards in America. It has been very frequently employed as equivalent to the collective national title of Nahuatlecas, or Mexicans. The Aztecs came, according to native tradition, from a country to which they gave the name of Aztlan, usually supposed to lie towards the N.W., but the satisfactory localisation of it is one of the greatest difficulties in Mexican history. The date of the exodus from Aztlan is equally undetermined, being fixed by various authorities in the 11th and by others in the 12th century. One Mexican manuscript gives a date equivalent to 1164 A.D. They gradually increased their influence among other tribes, until, by union with the Toltecs, who occupied the table-land before them, they extended their empire to an area of from 18,000 to 20,000 square leagues. The researches of Humboldt gave the first clear insight into the early periods of their history. See MEXICO.

AZUNI, DOMENICO ALBERTO, a distinguished jurist and writer on international law, was born at Sassari; in Sardinia, in 1749. He studied law at Sassari and Turin, and in 1782 was made judge of the consulate at Nice. In 1786-88 he published his *Dizionario Universale Ragionato della Giurisprudenza Mercantile*. In 1795 appeared his systematic work on the maritime law of Europe, *Sistema Universale dei Principii del Diritto Maritimo dell' Europa*, of which a second edition was demanded in the following year. A French translation by Digeon was published in 1798, and in 1805 Azuni recast the work, and translated it into French. In 1806 he was appointed one of the French commission engaged in drawing up a general code of commercial law, and in the following year he proceeded to Genoa as president of the court of appeal. After the fall of Napoleon in 1814, Azuni lived for a time in retirement at Genoa, till he was invited to Sardinia by Victor Emmanuel I., and appointed judge of the consulate at Cagliari, and director of the university library. He resided at Cagliari till his death in 1827.

B.

B is the second symbol of all European alphabets, except those derived from the Cyrillic original (see ALPHABET), such as the Russian. In these a modified form, in which only the top of the upper loop appears, stands as the second letter, with the value of the originl sound *b;* whilst the old symbol B comes third with the phonetic value *v* or *w*. In Egypt this letter was originally a hieroglyph for a crane, and afterwards represented also the sound *b*. The symbol and its phonetic value were borrowed by the Phœnicians, but not its name, as we infer from finding it called in Hebrew *beth*, *i. e.*, a house. In its oldest known Phœnician form the upper loop only exists in a more or less rounded shape. In different alphabets even the upper loop was gradually opened, so that in the square Hebrew the original form can no longer be detected. The Greeks, when they borrowed it from the Phœnicians, closed up the lower loop, as well as the upper, for convenience of writing. Sometimes the loops were angular, but more generally they were rounded. There is little variation of the form, except in the old alphabets of Corinth and Corcyra, where the original is harldly recognisable. In old Latin both the rounded and the pointed loops appear.

The original sound which this symbol represented, and which it still represents in most European languages, is a closed labial, *i.e.*, one in which perfect closure of the lips is necessary, the sound being heard as the lips open.

In the earliest stage to which we can trace back the language spoken by the forefathers of the Indo-European nations, it cannot be certainly proved that the sound *b* was ever heard at the beginning of a word. Perhaps in this position it may have been sounded indistinctly as a labial *v*.

BAADER, FRANZ XAVER VON, an eminent German philosopher and theologian, born 27th March 1765 at Munich, was the third son of F. P. Baader, court physician to the elector of Bavaria. His two elder brothers were both distinguished, the eldest, Clemens, as an author, the second, Joseph, as an engineer. Franz when young was extremely delicate, and from his seventh to his eleventh year was afflicted with a species of mental weakness, which singularly enough disappeared entirely when he was introduced for the first time to the mathematical diagrams of Euclid. His progress thenceforth was very rapid. At the age of sixteen he entered the university of Ingolstädt, where he studied medicine, and graduated in 1782. He then spent two years at Vienna, and returning home, for a short time assisted his father in his extensive practice. This life he soon found unsuited for him, and he decided on becoming a mining engineer. He studied under Werner at Frieburg, traveled through several of the mining districts in North Germany, and for four years, 1792–1796, resided in England. There he became acquainted with the works of Jakob Böhme, and at the same time was brought into contact with the rationalistic 18th-century ideas of Hume, Hartley, and Godwin, which were extremely distasteful to him. For Baader throughout his whole life had the deepest sense of the *reality* of religious truths, and could find no satisfaction in mere reason or philosophy. "God is my witness," he writes in his journal of 1786, "how heartily and how often I say with Pascal, that with all our speculation and demonstration we remain without God in the world." Modern philosophy he thought essentially atheistic in its tendencies, and he soon grew to be dissatisfied with the Kantian system, by which he had been at first attracted. Particularly displeasing to him was the ethical autonomy, or the position that man had in himself a rule of action, that duty contained no necessary reference to God. This Baader called "a morality for devils," and passionately declared that if Satan could again come upon earth, he would assume the garb of a professor of moral philosophy. The mystical, but profoundly religious, speculations of Eckhart, St. Martin, and above all of Böhme, were more in harmony with his mode of thought, and to them he devoted himself. In 1796 he returned from England, and in his passage through Hamburg became acquainted with Jacobi, the *Faith* philosopher, with whom he was for many years on terms of close friendship. He now for the first time learned something of Schelling, and the works he published during this period were manifestly influenced by that philosopher. Yet Baader is no disciple of Schelling, and probably, in the way of affecting the future course of Schelling's thought, gave out more than he received. Their personal friendship continued till about the year 1822, when Baader's vehement denunciation of modern philosophy in his letter to the Czar of Russia entirely alienated Schelling.

While prosecuting his philosophical researches, Baader had continued to apply himself diligently to his profession of engineer. He gained a prize of 12,000 gulden (about £1000) for his new method of employing Glauber's salts instead of potash in the making of glass. From 1817 to 1820 he held the post of superintendent of mines, and was raised to the rank of nobility for his services. He retired from business in 1820, and soon after published one of the best of his works, *Fermenta Cognitionis*, 6 pts., 1822–25, in which he combats modern philosophy, and recommends the study of J. Böhme. In 1826, when the new university was opened at Munich, he was appointed professor of philosophy and speculative theology. Some of the lectures delivered there he published under the title, *Spekulative Dogmatik*, 4 pts., 1827–1836. In 1838 he opposed the interference in civil matters of the Roman

Catholic Church, to which he belonged, and in consequence was, during the last three years of his life, interdicted from lecturing on the philosophy of religion. He died 23d May 1841.

Baader is, without doubt, the greatest speculative theologian of modern Catholicism, and his influence has extended itself even beyond the precincts of his own church.

BAAL is a Semitic word, which primarily signifies *lord* or *owner*, and then, in accordance with the Semitic way of looking at family and religious relations is specially appropriated to express the relation of a *husband* to his wife, and of the *deity* to his worshipper. In the latter usage, which does not occur among the Arabian Semites, the word Baal seems at first to have been a mere title of deity and not a proper name. In the Old Testament it is regularly written with the article — "the Baal;" and the Baals of different tribes or sanctuaries were not necessarily conceived as identical, so that we find frequent mention of Baalim, or rather "the Baalim," in the plural. There is even reason to believe that at an early date the Israelites applied the title of Baal to Jehovah himself, for one of Saul's sons is named Esh-baal, while everything we know of Saul makes it most unlikely that he was ever an idolater. Afterwards, when the name Baal was exclusively appropriated to idolatrous worship, abhorence for the unholy word was marked by writing *Bosheth* (shameful thing) for Baal in compound proper names, and thus we get the usual forms Ishbosheth, Mephibosheth.

The great difficulty which has been felt by investigators in determining the character and attributes of the god Baal mainly arises from the originally appellative sense of the word, and many obscure points become clear if we remember that when the title became a proper name it might be appropriated by different nations to quite distinct deities, while traces of the wider use of the word as a title for any god, might very well survive even after one god had come to be known as Baal *par excellence*. That Baal is not always one and the same god was known even to the ancient mythologists, who were very much disposed to fuse together distinct deities; for they distinguish an "old" Baal or Belitan (Bel êthan) from a younger Baal, who is sometimes viewed as the son of the other. The "old" Baal has sometimes been identified with the planet Saturn, but it is more likely that he is the Baal (in Assyrian pronunciation Bil) of the first triad of the Babylonian Pantheon, that is the Bel. as distinct from the Baal, of the Old Testament. This Assyrian and Babylonian Bel is no mere solar or planetary god, but is represented in Chaldean cosmogony as the shaper of heaven and earth, the creator of men and beasts, and of the luminaries of heaven. At the same time, we find that the inscriptions give the title of Bel to other and inferior gods, especially to Merodach or the planet Jupiter. This planet was, we know, the Baal (Bâl, Bêl) of the heathen Mesopotamians (Sabians) of later times, and of the Babylonian Mendeans.

The Baal of the Syrians, Phœnicians, and heathen Hebrews is a much less elevated conception than the Babylonian Bel. He is properly the sun-god, Baal Shamem, Baal (lord) of the heavens, the highest of the heavenly bodies, but still a mere power of nature, born like the other luminaries from the primitive chaos. As the sun-god he is conceived as the male principle of life and reproduction in nature, and thus in some forms of his worship is the patron of the grossest sensuality, and even of systematic prostitution. An example of this is found in the worship of Baal-Peor, and in general in the Canaanitish high places, where Baal, the male principle, was worshipped in association with the unchaste goddess Ashera, the female principle of nature. The frequent references to this form of religion in the Old Testament are obscured in the English version by the rendering "grove" for the word Ashera, which sometimes denotes the goddess, sometimes the tree or post which was her symbol. Baal himself was represented on the high places not by an image, but by obelisks or pillars sometimes called sun-pillars, a name which is to be compared with the title Baal-chamman, frequently given to the god on Phœnician inscriptions. There is reason to believe that these symbols, in their earliest form of the sacred tree and the sacred stone, were not specially appropriated to Baal worship, but were the mark of any sanctuary, memorials of a place where the worshipper had found God, while the stone pillar was also a primitive altar. Gradually, however, they came to be looked upon as phallic symbols, appropriate only to sensual nature worship, and as such were attacked by the prophets, and destroyed by such orthodox kings as Josiah. The worship of Baal among the Hebrews has two distinct periods — one before the time of Samuel, and a second from the introduction of the Tyrian worship of Baal by Ahab, who married a Phœnician princess. The ritual of this new Baal, with his long train of priests and prophets, his temple and sacred vestments, was plainly much more splendid than the older Canaanitish worship. Of the worship of the Tyrian Baal, who is also called Melkart (king of the city), and is often identified with the Greek Heracles, but sometimes with the Olympian Zeus, we may have many accounts in ancient writers, from Herodotus downwards. He had a magnificent temple in insular Tyre, founded by Hiram, to which gifts streamed from all countries, especially at the great feasts. The solar character of this deity appears especially in the annual feast of his awakening shortly after the winter solstice (Joseph., *Ant.*, viii. 5). At Tyre, as among the Hebrews, Baal had his symbolical pillars, one of gold and one of smaragdus, which, transported by phantasy to the Farthest West, are still familiar to us as the pillars of Hercules. The worship of the Tyrian Baal was carried to all the Phœnician colonies. His name occurs as an element in Carthaginian proper names (Hanni*bal*, Asdru*bal*, &c.), and a tablet found at Marseilles still remains to inform us of the charges made by the priests of the temple of Baal for offering sacrifices.

Finally, we may mention as a special form of Baal the Philistine Baal-zebub, or "Baal of flies," a conception which has more than one analogy in Greek religion. The use of the word Beelzebub, or rather, with a slight change, Beelzebul, by the later Jews, to denote the prince of the devils, is easily understood on the principle laid down in 1 Cor. x. 20.

BAALBEC, or BA'ALBAK, an ancient city of Syria, celebrated for the magnificence of its ruins, which, with the exception of those at Palmyra, are the most extensive in that region.

The origin of Baalbec is lost in remote antiquity, and the historical notices of it are very scanty. The silence of the classical writers respecting it would seem to imply that previously it had existed under another name, and various attempts have been made to identify it with certain places mentioned in the Bible. In the absence of more positive information, we can only conjecture that its situation on the high road of commerce between Tyre and Palmyra and the farther East rendered it at an early period a seat of wealth and splendor.

From the accounts of Oriental writers, Baalbec seems to have continued a place of importance down to the time of the Moslem invasion of Syria. They describe it as one of the most splendid of Syrian cities, enriched with stately palaces, adorned with monuments of ancient

times, and abounding with trees, fountains, and whatever contributes to luxurious enjoyment. After the capture of Damascus it was regularly invested by the Moslems, and after a courageous defence, at length capitulated. The ransom exacted by the conquerors was 2000 ounces of gold, 4000 ounces of silver, 2000 silk vests, and 1000 swords, together with the arms of the garrison. The city afterwards became the mart for the rich pillage of Syria; but its prosperity soon received a fatal blow from the caliph of Damascus, by whom it was sacked and dismantled, and the principal inhabitants put to the sword (748 A.D.) It continued, however, to be a place of military importance, and was frequently an object of contest between the caliphs of Egypt and the various Syrian dynasties. In 1090 it passed into the hands of the Seljuk princes of Aleppo and Damascus, who in 1134 were disputing its possession among themselves, and had to yield in 1139 to the power of Genghis Khan. He held the city till 1145, when it reverted to Damascus, and continued mostly, from that time, to follow the fortunes of that city. During the course of the century it suffered severely from one or more of the earthquakes that visited the district in 1139, 1157, 1170. In 1260 it was taken by the forces of Hulagu, who destroyed the fortifications; but, in the 14th century, it is again described by Abulfeda as enclosed by a wall with a large and strong fortress. Whether it was Baalbec, or, as others say, Cairo, that was, in 1367, the birthplace of Takkieddin Ahmed, the Arabic historian, he appears to have derived the name by which he is best known, El-Makrizi, from one of the quarters of the city. In 1400 it was pillaged by Timur in his progress to Damascus; and afterwards it fell into the hands of the Metaweli, a barbarous predatory tribe, who were nearly exterminated when Djezzar Pacha permanently subjected the whole district to Turkish supremacy.

The ancient walls of the city are about 4 miles in compass, but the present town is, with the exception of some portions of its Saracenic fortifications and its two mosques, a cluster of mean-looking buildings, which serve only to bring out into greater prominence the grandeur of the neighboring ruins. These consist of three temples, usually known as the Great Temple (and it well deserves the name), the Temple of Jupiter, Apollo, or the Sun, and the Circular Temple.

The ruins of Baalbec have awakened the admiration of European travellers from the 16th century down to the present day. Baumgarten visited them in 1507, Belon in 1548, Thevet in 1550, Melchior von Seydlitz in 1557, Radzivil in 1583, Quaresmius in 1620, Monconys in 1647, De la Roque in 1688, and Maundrell in 1699. In the 18th century Pococke gave a sketch of the ruins, which was followed by the magnificent work of Wood and Dawkins (1751), to this day one of our principal authorities, and Volney, in 1784, supplied a graphic description. During the present century the number of travellers who have visited Baalbec has enormously increased; it may be sufficient to mention Richardson, Addison, Lindsay, Wilson, the Duke of Ragusa, Lamartine, De Saulcy, Chesney, and Robinson.

BABATAG, or BABADAG, a city of Turkey in Europe, in the government of Bulgaria and sanjak of Silistria. It stands on the lake or estuary Rasein, which communicates with the Black Sea, and is surrounded by mountains covered with woods. It used to be the winter headquarters of the Turkish army during their wars with Russia; and, in 1854, it was bombarded by the Russians. The population of 10,000 includes many Jews Armenians, Tatars, and Greeks. Babatag was founded by Bajazet.

BABBAGE, CHARLES, a distinguished English mathematician and mechanician, was born, 20th December 1792, at Teignmouth in Devonshire. He was educated at a private school, and afterwards entered Trinity College, Cambridge, where he graduated in 1814. Though he did not compete in the mathematical tripos, he acquired a great reputation at the university. In the year after his graduation he contributed a paper on the "Calculus of Functions" to the *Philosophical Transactions*, and in 1816 was made a fellow of the Royal Society. Along with Herschel and Peacock he labored to raise the standard of mathematical instruction in England, and specially endeavored to supersede the Newtonian by the Leibnitzian notation in the Calculus. With this object the three friends translated, in 1816, Lacroix's *Treatise on the Differential and Integral Calculus*, and added, in 1820, two volumes of examples. During the later years of his life he resided in London, and surrounded by his workshops, still continued to devote himself to the construction of machines capable of performing arithmetical and even algebraical calculations. He died at London, 20th October 1871.

BABEL was the native name of the city called Babylon by the Greeks. It means "gate of god," or "gate of the gods," and was the Semitic translation of the original Accadian designation Ca-dimirra. According to Gen. xi. 1-9, mankind, after the deluge, travelled from the mountain of the East (or Elwand), where the ark had rested, and settled in Shinar, (Sumir, or the north-west of Chaldea.) Here they attempted to build a city and a tower whose top might reach unto heaven, but were miraculously prevented by their language being confounded. In this way the diversity of human speech was accounted for; and an etymology was found for the name of Babylon in the Hebrew verb *balbel*, "to confound." According to Alexander Polyhistor and Abydenus, the tower was overthrown by the winds. The native version of the story has recently been discovered among the cuneiform tablets in the British Museum. It is fuller and more complete than the account in Genesis, and formed part of a collection of Babylonian legends older, probably, than 2000 B.C. We learn from it that the tower was erected under the supervision of a semi-divine being called Etanna. The tower has been identified with the temple or tomb of Belus, which Strabo stated with some exaggeration to have been a stade (606 feet) high, but without sufficient reason. It is most probably represented by the modern *Birs Nimrud*, the ruined remains of the "Temple of the Seven Lights of the Earth," at Borsippa, a suburb of Babylon, which was dedicated to Nebo. The temple had been begun by "a former king," and built to the height of 42 cubits, but it lay an uncompleted ruin for many centuries, and was not finished till the reign of Nebuchadnezzar. Dr. Schrader believes that the state of wreck in which it so long remained caused "the legend of the confusion of tongues" to be attached to it.

BAB-EL-MANDEB, that is, the Gate of Tears, is the strait between Arabia and Abyssinia which connects the Red Sea with the Indian Ocean. It derives its name from the dangers attending its navigation, or, according to an Arabic legend, from the numbers who were drowned by the earthquake which separated Asia and Africa. The distance across is about 20 miles, from Ras Menheli on the Arabian coast to Ras Seyan on the African. In the end of the 18th century (1799) the island of Perim was taken possession of by the British and held as a military outpost, so to speak, of the Indian empire. They again asserted their right to it in 1857, and in 1861 a lighthouse was built at Straits Point, at the eastern extremity of the island. The harbor is accessible and commodious and the position gives complete command of the Red Sea.

BABER. ZEHIR-ED-DÎN MAHOMET, surnamed Ba-

ber, or the Tiger, the famous conqueror of India and founder of the so-called Moghul dynasty, was born on the 14th February 1483. He was a descendant of Genghis Khan and Timur, and his father, Omar Sheikh, was king of Farghana, a district of Transoxiana, lying east of Samarcand. Omar died in 1495, and Baber, though only twelve years of age, succeeded to the throne. An attempt made by his uncles to dislodge him proved unsuccessful, and no sooner was the young sovereign firmly settled than he began to meditate an extension of his own dominions. In 1497 he attacked and gained possession of Samarcand, to which he always seems to have thought he had a natural and hereditary right. A rebellion among his nobles robbed him of his native kingdom, and while marching to recover it, his troops deserted him, and he lost Samarcand also. After some reverses he regained both these places, but in 1501 his most formidable enemy, Schaibani Khan, ruler of the Usbeks, defeated him in a great engagement, and drove him from Samarcand. For three years he wandered about trying in vain to recover his lost possessions; at last, in 1504, he gathered some troops, and crossing the snowy Hundu Kush, besieged and captured the strong city of Cabul. By this dexterous stroke he gained a new and wealthy kingdom, and completely re-established his fortunes. In the following year he united with Hussian Mirza of Herat against Schaibani. The death of Hussian put a stop to this expedition, but Baber spent a year at Herat, enjoying the pleasures of that capital. He returned to Cabul in time to quell a formidable rebellion, but two years later a revolt among some of the leading Moghuls drove him from his city. He was compelled to take to flight, with very few companions, but his great personal courage and daring struck the army of his opponents with such dismay that they again returned to their allegiance, and Baber regained his kingdom. Once again, in 1510, after the death of Schaibani, he endeavored to obtain possession of his native country. He received considerable aid from Shah Ismael of Persia, and in 1511 made a triumphal entry into Samarcand. But in 1514 he was utterly defeated by the Usbeks, and with difficulty reached Cabul. He seems now to have resigned all hopes of recovering Farghana, and as he at the same time dreaded an invasion of the Usbeks from the west, his attention was more and more drawn towards India. Several preliminary incursions had been already made, when in 1521 an opportunity presented itself for a more extended expedition. Ibrahim, emperor of Delhi, had made himself detested, even by his Afghan nobles, several of whom called upon Baber for assistance. He at once assembled his forces, 12,000 strong, with some pieces of artillery, and marched into India. Ibrahim, with 100,000 soldiers and numerous elephants, advanced against him. The great battle was fought at Paniput, 21st April 1526, when Ibrahim was slain and his army routed. Baber at once took possession of Arga. A still more formidable enemy awaited him; the Rana Sanga of Mewar collected the enormous force of 210,000 men, with which he moved against the invaders. On all sides there was danger and revolt, even Baber's own soldiers, worn out with the heat of this new climate, longed for Cabul. By vigorous measures and inspiriting speeches he restored their courage, though his own heart was nearly failing him, and in his distress he abjured the use of wine, to which he had been addicted. At Kanweh, on the 10th March 1527, he won a great victory, and made himself absolute master of India. The remaining years of his life he spent in arranging the affairs and revenues of his new empire and in improving his capital, Agra. He died 26th December 1530, in his forty-eighth year. Baber was above the middle height, of great strength, and an admirable archer and swordsman. His mind was as well cultivated as his bodily powers; he wrote well, and his observations are generally acute and accurate; he was brave, kindly and generous.

BABEUF, FRANÇOIS-NOEL, surnamed by himself *Gracchus* Babeuf, the earliest of the French socialists, was born in 1762, in the department of Aisne. From his father, a major in the Austrian army, he received special instruction in mathematics, but was deprived of him by death at the age of sixteen. Established as a land-surveyor at Roye, in the Somme department, he became a fervid advocate of the Revolution, and wrote articles in the *Correspondant Picard*, for which he was prosecuted in 1790. He was acquitted on that occasion, and was afterwards elected an administrator of the department; but a charge of forgery being brought against him, he was condemned by the Somme tribunal to twenty years' imprisonment in 1793. Escaping to Paris, he became secretary to the Relief Committee of the Commune, and joined Garin in his denunciation of the Committee of Public Safety. This led to his incarceration, ostensibly under the former sentence. This was, however, annulled by the Court of Cassation; and he was also discharged by the Aisne tribunal (18th July 1794), to which he had been remitted. Returning to Paris, he entered on a violent crusade against the remains of the Robespierre party, and started the *Journal de la Liberté de la Presse* to maintain his views. In the following year (1795) the Girondists acquired supremacy in the Convention; Babeuf's journal was suspended, and himself imprisoned — first in Paris and then at Arras. Thrown into the society of certain partisans of Robespierre, he was won over by them, and was ready, on his release, to become the indiscriminating defender of the very men whom he had previously attacked (No. 34 of the *Tribun*, as he now called his journal). In April 1796 Babeuf, Lepelletier, and others constituted themselves a "Secret Directory of Public Safety," and took the title of the "Equals;" while another association of self-styled "Conventionals" and "Patriots" met at the house of Amar. The latter party aimed at the re-establishment of the revolutionary government, while Babeuf and his friends wanted besides to realise their schemes for the organisation of common happiness. Disputes naturally arose; and to reconcile the Equals and the Patriots, it was agreed, first, to re-establish the constitution of 1793; and secondly, to prepare for the adoption of true equality by the destruction of the Government. Everything was ready by the beginning of May 1796, and the number of adherents in Paris was reckoned at 17,000; but on the 10th the Government succeeded in arresting the main leaders of the plot. The army protected the Government, and the people of Paris looked on. The trial was opened at Vendôme on Feb. 2, 1797, and lasted three months. Babeuf and Darthé were sentenced to death; Germain, Buonarroti, and five others, to transportation; Amar Vadier, Duplay, and the remaining fifty-three, were acquitted. On the announcement of the sentence, Babeuf and Darthé stabbed themselves, but the wounds were not mortal. They passed a frightful night, and next morning were borne bleeding to the scaffold. Ardent and generous, heroic and self-sacrificing, Babeuf had neither solid knowledge nor steadiness of judgment. "The aim of society is happiness, and happiness consists in equality," is the centre of his doctrine.

BÂBI, or BÂBY, the appellation of a remarkable modern sect in Persia, is derived from the title (*bâb*, *i. e.*, gate) assumed by its founder, Seyed Mohammed Ali, born at Shiraz about 1824, according to Count Gobineau, but ten years earlier according to Kasem Beg.

Persia, as is well known, is the least strictly Mahometan of all Mahometan countries, the prophet himself occupying an almost secondary place in the popular estimation to his successor Ali, and the latter's sons, Hassan and Hosein. The cause of this heterodoxy is, no doubt, to be sought in ethnological distinctions, the Aryan Persians never having been able to thoroughly accommodate themselves to the creed of their Semitic conquerors. Their dissatisfaction has found vent partly in the universal homage paid to Ali, and the rejection of the Sunna or great mass of orthodox Mahometan tradition, partly in violent occasional outbreaks, most characteristically of all in the mystical philosophy and poetry of the Sufis, which, under the guise of a profound respect for the externals of Mahometanism, dissolves its rigid Monotheism into Pantheism. Bâbism is essentially one of the innumerable schools of Sufism, directed into a more practical channel by its founder's keen perception of the evils of his times. The doctrines of Bâbism are contained in an Arabic treatise, entitled *Biyan* (the Exposition), written by the Bâb himself. It is essentially a system of Pantheism, with additions from Gnostic, Cabbalistic, and even Buddhistic sources. The prophetic character of Moses, Christ, and Mahomet is acknowledged, but they are considered as mere precursors of the Bâb. The morality of the sect is pure and cheerful, and it manifests an important advance upon all previous Oriental systems in its treatment of woman. Polygamy and concubinage are forbidden, the veil is disused, and the equality of the sexes so thoroughly recognised that one at least of the nineteen sovereign prophets must always be a female. The other chief precepts of Bâbism inculcate hospitality, charity, and generous living, tempered by abstinence from intoxicating liquors and drugs. Asceticism is entirely discountenanced, and mendicancy, being regarded as a form of it, is strictly prohibited.

BABOON, the popular name of apes belonging to the genus *Cynocephalus* of the family *Simiadæ*. See APE.

BABRIUS, or BABRIAS, or GABRIAS (the original name being possibly Oriental), a Greek fabulist, who wrote, according to Sir G. C. Lewis, shortly before the Augustan age, though dates have been assigned to him from 250 B.C. to 250 A. D.

BABYLON (the modern *Hillah*) is the Greek form of Babel or Bab-ili, "the gate of god" (or, as it is sometimes written, "of the gods"), which, again, is the Semitic rendering of *Ca-dimirra*, the ancient name of the city in the Turanian language of the primitive Accadian population of the country. It is doubtful whether the god meant was Merodach or Anu, Merodach being the patron divinity of Babylon in the Semitic period, and Su-Anna, "the valley of Anu" (Anammelech), being one of its oldest names. Another synonym of the place was *E-ci*, "the hollow," in reference to its situation, and it was also known, down to the latest times, as Din-Tir, "the house of the jungle," though this seems properly to have been the designation of the town on the left bank of the Euphrates. Under the Cassite dynasty of Khammuragas, it received the title of Gan-Duniyas or Gun-Duni, "the Fortress of Duniyas," which was afterwards made to include the neighboring territory, so that the whole of Babylonia came to be called this name. Sir H. Rawlinson has suggested that it was the origin of the Biblical Gan Eden, or "Garden of Eden," to which a popular etmology has given a Hebrew form. However this may be, Babylon figures in the antediluvian history of Berosus, the first of his mythical monarchs, Alorus, being a native of it. The national epic of the Babylonians, which grouped various old myths round the adventures of a solar hero, knows of four cities only -- Babylon, Erech, Nipur (*Niffer*) or Calneh, and Surippac or Larankha, and, according to Genesis x., Babylon was a member of the tetrapolis of Shinar or Sumir, where the Semite invaders of the Accadians first obtained permanent settlement and power. It seems, however, to have ranked below its three sister-cities, among which Erech took the lead until conquered by the Accadian sovereigns of Ur. It was not until the conquest of Khammuragas that Babylon became a capital, a position, however, which it never afterwards lost, except during the Assyrian supremacy. But it suffered severely at the hands of its northern neighbors. Tiglath-Adar drove the Cassi from it, and established an Assyrian dynasty in their place; and after being captured by Tiglath-Pileser I. (1130 B.C.) and Shalmaneser (851 B.C.) it became a dependency of the Assyrian empire in the reign of the son of the latter. The decline of the first Assyrian empire restored Babylon to independence; but it had soon afterwards to submit to the Caldai, and from the reign of Tiglath-Pileser II. to the death of Assurbanipal, it was a mere provincial town of Assyria, breaking now and then into fierce revolt under the leadership of the Caldai, and repeatedly taken and plundered by Sargon, Sennacherib, and Assur-bani-pal. Sennacherib, indeed, razed the city to its foundations. After the defeat of Suzub (690 B.C.), he tells us that he "pulled down, dug up, and burned with fire the town and the palaces, root and branch, destroyed the fortress and the double wall, the temples of the gods and the towers of brick, and threw the rubbish into the Araxes," the river of Babylon. After this destruction it is not likely that much will ever be discovered on the site of Babylon older than the buildings of Essar-haddon and Nebuchadnezzar. It was under the latter monarch and his successors that Babylon became the huge metropolis whose ruins still astonish the traveller, and which was described by Greek writers. Of the older city we can know but little. The Babylon of Nebuchadnezzar and his father, Nabopolassar, must have suffered when taken by Cyrus; but two sieges in the reign of Darius Hystaspes, and one in the reign of Xerxes, brought about the destruction of the defences, while the monotheistic rule of Persia allowed the temples to fall into decay. Alexander found the great temple of Bel a shapeless ruin, and the rise of Seleucia in its neighborhood drew away its population and completed its material decay. The buildings became a quarry, first for Seleucia and then for Ctesiphon, Al Modain, Baghdad, Kufa, Kerbelah, Hillah, and other towns, and our only cause for wonder is that the remains of the great capital of Babylon are still so extensive.

The principal of these lie on the left bank of the Euphrates, and consist of three vast mounds — the *Babil* or *Mujellib*, the *Kasr*, and the *Amrám*, which run from north to south; two parallel lines of rampart east and west of them; and an isolated mass, together with a series of elevations separated by the river westward of the *Kasr*, — the whole being surrounded by a triangulur rampart. Our two chief authorities for the ancient topography of the city are Herodotus and Ctesias; and though both were eye-witnesses, their statements differ considerably. The city was built, we are told, on both sides of the river, in the form of a square, and enclosed within a double row of high walls. Ctesias adds a third wall, but the inscriptions refer only to two, the inner *enceinte*, called Imgur-Bel, and its *salkhu* or outwork, called Nimitti-Bel. Ctesias makes the outermost wall 360 stades (42 miles) in circumference, while according to Herodotus it measured 480 stades (56 wiles), which would include an area of about 200 square miles! Pliny follows Herodotus in his figures,

but Strabo with his 385 stades, Qu. Curtius with his 368 stades and Clitarchus with 365 stades agree sufficiently closely with Ctesias. Even the estimate of Ctesias, however, would make Babylon cover a space of about 100 square miles, nearly twice the size of London. Such an area could not have been occupied by houses, especially as these were three or four stories high. Indeed Q. Curtius asserts that even in the most flourishing times, nine-tenths of it consisted of gardens, parks, fields, and orchards. According to Herodotus, the height of the walls was about 335 feet, and their width 85 feet; while Ctesias makes the height about 300 feet. Later writers give smaller dimensions, but it is clear that they have merely tried to soften down the estimates of Herodotus (and Ctesias); and we seem bound, therefore, to accept the statements of the two oldest eye-witnesses, astonishing as it is. But we may remember that the ruined wall of Nineveh was 150 feet high, even in Xenophon's time, while the spaces between the 250 towers irregularly disposed along the wall of Babylon were broad enough to allow a four-horse chariot to turn. The clay dug from the moat had served for the bricks of the wall, which was pierced with 100 gates, all of brass, with brazen lintels and posts. The two inner enclosures were faced with colored brick, and represented hunting-scenes. Two other walls ran along the banks of the Euphrates and the quays with which it was lined, each containing 25 gates, which answered to the number of the streets they led into. Ferry-boats plied between the landing-places of the gates; and a movable drawbridge (30 feet broad), supported on stone piers, joined the two parts of the city together. At each end of the bridge was a palace; the great palace of Nebuchadnezzar on the eastern side (the modern *Kasr*), which Herodotus incorrectly transfers to the western bank, being the more magnificent of the two. It was surrounded, according to Diodorus, by three walls, the outermost being 60 stades (7 miles) in circuit. The inner walls were decorated with hunting-scenes painted on brick, fragments of which have been discovered by modern explorers. Two of its gates were of brass, and had to be opened and shut by machine; and Mr. Smith has found traces of two libraries among its ruins. The palace, called "the Admiration of Mankind" by Nebuchadnezzar, and commenced by Nabopolassar, overlooked the Ai-ipursabu, the great reservoir of Babylon, and stretched from this to the Euphrates on the one side, and from the Imgur-Bel, or inner wall, to the Libil, or eastern canal, on the other. Within its precincts rose the Hanging Gardens, consisting of a garden of trees and flowers on the topmost of a series of arches at least 75 feet high, and built in the form of a square, each side measuring 400 Greek feet. Water was raised from the Euphrates by means, it is said, of a screw. Some of the materials for the construction of this building may have been obtained from the old ruined palace of the early kings, now represented by the adjoining Amrám mound. The lesser palace in the western division of the city belonged to Neriglissar, and contained a number of bronze statues.

The most remarkable edifice in Babylon was the temple of Bel, now marked by the *Babil*, on the north-east. It was a pyramid of eight square stages, the basement stage being over 200 yards each way. A winding ascent led to the summit and the shrine, in which stood a golden image of Bel 40 feet high, two other statues of gold, a golden table 40 feet long and 15 feet broad, and many other colossal objects of the same precious material. At the base of the tower was a second shrine, with a table and two images of solid gold. Two altars were placed outside the chapel, the smaller one being of the same metal. A similar temple, represented by the modern *Birs Nimrud*, stood at Borsippa, the suburb of Babylon. It consisted of seven stages, each ornamented with one of the seven planetary colors, the azure tint of the sixth, the sphere of Mercury, being produced by the vitrifaction of the bricks after the stage had been completed. The lowest stage was a square, 272 feet each way, its four corners exactly corresponding to the four cardinal points, as in all other Chaldean temples, and each of the square stages raised upon it being placed nearer the south-western than the north-eastern edge of the underlying one. It had been partly built by an ancient monarch, but, after lying unfinished for many years, like the Biblical tower of Babel, was finally completed by Nebuchadnezzar.

The amount of labor bestowed upon these brick edifices must have been enormous, and gives some idea of the human force at the disposal of the monarch. If any further illustration of this fact were needed, it would be found in the statement made by Nebuchadnezzar in one of his inscriptions (and quoted also from Berosus), that he had finished the Imgur-Bel in fifteen days. The same monarch also continued the embankment of the Euphrates for a considerable distance beyond the limits of Babylon, and cut some canals to carry off the overflow of that river into the Tigris. The great reservoir, 40 miles square, on the west of Borsippa, which had been excavated to receive the waters of the Euphrates while the bed of its channel was being lined with brick, was also used for a similar purpose. The reservoir seems to have been entered by the Arakhtu or Araxes, "the river of Babylon," which flowed through a deep wady into the heart of Northern Arabia. Various nomad tribes, such as the Nabathæans or the Pekod, pitched their tents on its banks; but, although it is not unfrequently mentioned in early Babylonian history, we hear no more of it after the time of Nebuchadnezzar. It is possible, therefore, that it was drained by the western reservoir.

BABYLONIA AND ASSYRIA. Geographically, as well as ethnologically and historically, the whole district enclosed between the two great rivers of Western Asia, the Tigris and Euphrates, forms but one country. The writers of antiquity clearly recognized this fact, speaking of the whole under the general name of Assyria, though Babylon, as will be seen, would have been a more accurate designation. It naturally falls into two divisions, the northern being more or less mountainous, while the southern is flat and marshy; and the near approach of the two rivers to one another, at a spot where the undulating plateau of the north sinks suddenly into the Babylonian alluvium, tends still more completely to separate them. In the earliest times of which we have any record, the northern portion was comprehended under the vague title of Gutium (the *Goyim* of Gen. xiv. 1), which stretched from the Euphrates on the west to the mountains of Media on the east; but it was definitely marked off as Assyria after the rise of that monarchy in the 16th century B.C. Aram Naharaim, or Mesopotamia, however, though claimed by the Assyrian kings, and from time to time overrun by them, did not form an integral part of the kingdom until the 9th century B.C., while the region on the left bank of the Tigris, between that river and the Greater Zab, was not only included in Assyria, but contained the chief capitals of the empire. In this respect the monarchy of the Tigris resembled Chaldea, where some of the most important cities were situated on the Arabian side of the Euphrates. The reason of this preference for the eastern bank of the Tigris was due to its abundant supply of water, whereas the great Mesopotamian plain on the western side had to depend upon the streams which flowed into the Euphrates. This vast

flat, the modern El-Jezireh, is about 250 miles in length, interrupted only by a single limestone range, rising abruptly out of the plain, and branching off from the Zagros mountains under the names of *Sarazûr*, *Hamrin*, and *Sinjar*. The numerous remains of old habitations show how thickly this level tract must once have been peopled, though now for the most part a wilderness. North of the plateau rises a well-watered and undulating belt of country, into which run low ranges of limestone hills, sometimes arid, sometimes covered with dwarf-oak, and often shutting in, between their northern and north-eastern flank and the main mountain-line from which they detach themselves, rich plains and fertile valleys. Behind them tower the massive ridges of the Niphates and Gargos ranges, where the Tigris and Euphrates take their rise, and which cut off Assyria from Armenia and Kurdistan. The name Assyria itself originally denoted the small territory immediately surrounding the primitive capital "the city of Asur" (*al Asur*, the Ellasar of Genesis), which was built, like the other chief cities of the country, by Turanian tribes, in whose language the word signified "water meadow." It stood on the right bank of the Tigris, midway between the Greater and the Lesser Zab, and is represented by the modern *Kalah Sherghat*. It remained the capital long after the Assyrians had become the dominant power in Western Asia, but was finally supplanted by Calah (*Nimrûd*), Nineveh (*Nebi Yunus* and *Kouyunjik*), and Dur-Sargina (*Khorsabad*), some 60 miles further north. See NINEVEH.

In contrast with the arid plateau of Mesopotamia, stretched the rich alluvial plain of Chaldea, formed by the deposits of the two great rivers by which it was enclosed. The soil was extremely fertile, and teemed with an industrious population. Eastward rose the mountains of Elam, southward were the sea-marshes and the ancient kingdom of Nituk or Dilvun (the modern Bender-Dilvun), while on the west the civilisation of Babylonia encroached beyond the banks of the Euphrates, upon the territory of the Semitic nomades (or Suti). Here stood Ur (now *Mugheir*), the earliest capital of the country; and Babylon, with its suburb, Borsippa (*Birs Nimrûd*), as well as the two Sipparas (the Sepharvaim of Scripture, now *Mosaib*), occupied both the Arabian and Chaldean side of the river. (See BABYLON.) The Araxes, or "River of Babylon," was conducted through a deep valley into the heart of Arabia, irrigating the land through which it passed; and to the south of it lay the great inland fresh-water sea of *Nedjef*, surrounded by the red sandstone cliffs of considerable height, 40 miles in length and 35 in breadth in the widest part. Above and below this sea, from Borsippa to Kufa, extend the famous Chaldean marshes, where Alexander was nearly lost; but these depend upon the state of the Hindiyah canal, disappearing altogether when it is closed. Between the sea of *Nedjef* and Ur, but on the left side of the Euphrates, was Erech (now *Warka*), which with Nipur or Calneh (now *Niffer*), Surippac (*Senkereh?*), and Babylon (now *Hillah*), formed the tetrapolis of Sumis and Shinar. This north-western part of Chaldea was also called Gan-duniyas or Gun-duni after the accession of the Cassite dynasty. South-eastern Chaldea, on the other hand, was termed Accad, though the name came also to be applied to the whole of Babylonia. The Caldai, or Chaldeans, are first met with in the 9th century B.C. as a small tribe on the Persian Gulf, whence they slowly moved northwards, until under Merodach-Baladan they made themselves masters of Babylon, and henceforth formed so important an element in the population of the country, as in later days to give their name to the whole of it. In the inscriptions, however, Chaldea represents the marshes of the sea-coast, and Teredon was one of their ports. The whole territory was thickly studded with towns; but among all this "vast number of great cities," to use the words of Herodotus, Cuthah, or Tiggaba (now *Ibrahim*), Chilmad (*Kalwadah*), Is (*Hit*), and Dur-aba (*Akkerkuf*) alone need be mentioned. The cultivation of the country was regulated by canals, the three chief of which carried off the waters of the Euphrates towards the Tigris above Babylon,—the "Royal River," or Ar-Malcha, entering the Tigris a little below Baghdad, the Nahr-Malcha running across to the site of Seleucia, and the Nahr-Kutha passing through Ibrahim. The Pallacopas, on the other side of the Euphrates, supplied an immense lake in the neighborhood of Borsippa. So great was the fertility of the soil that, according to Herodotus, grain commonly returned two hundredfold to the sower, and occasionally three hundredfold. Pliny, too (*H. N.*, xviii. 17), says that wheat was cut twice, and afterwards was good keep for sheep; and Berosus remarked that wheat, barley, sesame, ochrys, palms, apples, and many kinds of shelled fruit grew wild, as wheat still does in the neighborhood of Anah. A Persian poem celebrated the 360 uses of the palm, and Ammianus Marcellinus states that from the point reached by Julian's army to the shores of the Persian Gulf was one continuous forest of verdure.

Such a country was well fitted to be one of the primeval seats of civilisation. Where brick lay ready to hand, and climate and soil needed only settled life and moderate labor to produce all that man required, it was natural that the great civilising power of Western Asia should take its rise. The history of the origin and development of this civilisation, interesting and important as it is, has but recently been made known to us by the decipherment of the native monuments. The scanty notices and conflicting statements of classical writers have been replaced by the evidence of contemporaneous documents; and though the materials are still but a tithe of what we may hope hereafter to obtain, we can sketch the outlines of the history, the art, and the science of the powerful nations of the Tigris and Euphrates. Before doing so, however, it would be well to say a few words in regard to our classical sources of information, the only ones hitherto available. The principal of these is Berosus, the Manetho of Babylonia, who flourished at the time of Alexander's conquests. He was priest of Bel, and translated the records and astronomy of his nation into Greek. His works have unfortunately perished, but the second and third hand quotations from them, which we have in Eusebius and other writers, have been strikingly verified by inscriptions so far as regards their main facts. The story of the flood, taken from Berosus, for instance, is almost identical with the one preserved on the cuneiform tablets. Numerical figures, however, as might be expected, are untrustworthy. According to Berosus, ten kings reigned before the Deluge for 120 *saroi*, or 432,000 years, beginning with Alorus of Babylon, and ending with Otiartes (Opartes) of Larankha, and his son Sisuthrus, the hero of the flood. Then came eight dynasties, which are given as follows:—

(1.)	86	Chaldean kings	34,080	years.
(2.)	8	Median "	224	"
(3.)	11	(Chaldean) "	*	
(4.)	49	Chaldean "	458	"
(5.)	9	Arabian "	245	"
(6.)	45	Assyrian "	526	"
(7.)	*	(Assyrian) "	*	
(8.)	6	Chaldean "	87	"

Ptolemy's canon (in the *Almagest*) gives the seventh dynasty in full—

(1.) Nabonassar (747 B.C.)..... .....14 years.

(2.) Nadios	2	years.
(3.) Khinziros and Poros (Pul)	5	"
(4.) Iluæos	5	"
(5.) Mardokempados (Merodach-Baladan)	12	"
(6.) Arkeanos (Sargon)	5	"
(7.) Interregnum	2	"
(8.) Hagisa	1	month.
(9.) Belibos (702 B.C.)	3	years.
(10.) Assaranadios (Assur-nadin-sum)	6	"
(11.) Rêgebelos	1	"
(12.) Mesêsimordakos	4	"
(13.) Interregnum	8	"
(14.) Asaridinos (Essar-haddon)	13	"
(15.) Saosdukhinos (Savul-sum-yucin)	20	"
(16.) Sinêladanos (Assur-bani-pal)	22	"

Next to Berosus, the authority of Herodotus ranks highest. His information, however, is scanty, and he had to trust to the doubtful statements of *ciceroni*. Herodotus was controverted by Ctesias of Cnidus, the physician of Artaxerxes Mnemon. But Ctesias mistook mythology for history, and the Ninus and Semiramis, the Ninyas and Sardanapalus, of Greek romance were in great measure his creations. We may yet construct an Assyrian epopee, like the Shahnameh of Firdusi, out of his pages, but we must not look to them for history. Other historical notices of Assyria and Babylonia, of more or less questionable value, are to be gathered from Diodorus and one or two more writers, but beyond Berosus and, to a limited extent, Herodotus, our only ancient authority of much value upon this subject is the Old Testament.

Ethnology and History.—The primitive population of Babylonia, the builders of its cities, the originators of its culture, and the inventors of the cuneiform system of writing, or rather of the hieroglyphics out of which it gradually developed, belonged to the Turanian or Ural-Altaic family. Their language was highly agglutinative, approaching the modern Mongolian idioms in the simplicity of its grammatical machinery, but otherwise more nearly related to the Ugro-Bulgaric division of the Finnic group; and its speakers were mentally in no way inferior to the Hungarians and Turks of the present day. The country was divided into two halves, the Sumir (Sungir, or Shinar) in the north-west, and the Accad in the south-east, corresponding most remarkably to the Suomi and Akkara-k, into which the Finnic race believed itself to have been separated in its first mountain home. Like Suomi, Sumir signified "(the people) of the rivers," and just as Finnic tradition makes Kemi a district of the Suomi, so Came was another name of the Babylonian Sumir. The Accadai, or Accad, were "the highlanders" who had descended from the mountainous region of Elam on the east, and it was to them that the Assyrians ascribed the origin of Chaldean civilisation and writing. They were, at all events, the dominant people in Babylonia at the time to which our earliest contemporaneous records reach back, although the Sumir, or "the people of the home language," as they are sometimes termed, were named first in the royal titles out of respect to their prior settlement in the country. A survey of the syllabary has led to the conclusion that the first attempts at writing were made before the Accad had descended into the plains and exchanged papyrus as a writing material for clay; other considerations, however, go to show that although the system of writing may have been invented before they had entered Babylonia, it was not completed until after they had done so. In harmony with this, we find Berosus ascribing the culture of "the mixed population of Chaldea" to Oannes and other similar creatures from the Persian Gulf. So far as we can judge, the civilisation of Elam is at least coeval with that of Babylonia, and the capture of Babylon by the Medes, with whom the historical dynasties of Berosus are commonly supposed to begin, must be explained by an Elamite conquest. Media was the Accadian *Mada*, "the land" *par excellence;* and Accadian tradition looked back upon the mountainous district to the south-west of the Caspian as the cradle of their race. Among these "mountains of the east," and in the land of Nisir (the furthermost division of Gutium beyond the Lesser Zab), rose "the mountain of the world," the Turanian Olympus, on which the ark of the Chaldean Noah was believed to have rested. From this centre Turanian tribes spread in all directions, meeting Alarodians on the north, and the Semites on the south-west. The Aryans had not yet penetrated across the great Sagartian desert. The numerous tribes of Susiana, both civilised and uncivilised, spoke languages more closely Ugrian than even that of the Accadians; the oldest towns of Northern Syria, where the Semite afterwards reigned supreme, bore Accadian names, and as in the case of Haran, were mythologically connected with Babylon; while the chief cities of Assyria were founded by Accadians, were denoted by Accadian symbols, and were ruled by Accadian princes, in strict accordance with the statement of Genesis that out of Babylonia "went forth Ashur." An Elamite conqueror of Chaldea, like Chedorlaomer (Gen. xiv. 1), imposed his authority, not only over Shinar, but over Assyria and Gutium as well. The earliest geographical lists know only of Nuvva, or Elam, on the east, the Khani on the west, Martu, the land of "the path of the setting sun," Subarti, or Syria, with its four races, and Gutium, which stretched across Mesopotamia from the Euphrates on the one side to the mountains of Media on the other. To these must be added Anzan, or southern Elam, with its capital Susa, Dilvun, or Nituk, on the Persian Gulf, and, at a considerably later date, the Hittites, with their chief city Carchemish.

The first monarchs whose monumental records we possess had their seats at Ur, on the right bank of the Euphrates. Ur, in Accadian, signified "the city" *par excellence*, and so bore testimony to the supremacy claimed by its rulers over the rest of Babylonia. The great temple of the Moon-god there was one of the oldest buildings in the country, and its erection was due to a prince who claimed sovereignty over the whole of Babylonia, and adorned Erech, Nipur, Larsa, and other cities with temples of vast size, dedicated to the sun, to Istar, and to Bel. He seems to have been the first great Babylonian builder; and this would imply that it was under him that Ur rose to its prominent position, and united the numerous principalities of Chaldea under one head. The enormous brick structures were cemented with bitumen in the place of lime mortar; but the use of the buttress, of drains, and of external ornamentation, shows that architectural knowledge was already advanced. The cuneiform system of writing had attained its full development, signet stones were carved with artistic skill, and the amount of human force at the disposal of the monarch may be estimated from the fact that the Bowariyeh mound at Warka, on the site of the temple of the Sun-god, is 200 feet square and 100 feet high, so that above 30,000,000 bricks must have been employed upon its construction. The vicinity of Ur to the Semitic tribes of Arabia implies that the Accadian sovereigns had been turning their attention in that direction, and we find nothing surprising therefore in the Scriptural account of Abraham's migration from this place, or the Phœnician tradition of the original home of the Canaanitish race on the shores of the Persian Gulf (Strab. i. 2, 35, xvi. 3, 4, 27; Justin, xviii. 3, 2; Pliny, *N. H.*, iv. 36). Indeed, we have clear evidence that Semitic was spoken in Ur itself at this remote epoch. Although the

ruling caste were Accadian, and generally wrote their inscriptions in that language, Dungi, one of their earliest monarchs, in spite of his Turanian name, has left us a short legend in Semitic; and it is more than probable that the imperial title of "Sumir and Accad" was soon to be assumed to mark a linguistic as well as a geographical distinction. The brick legends of the various viceroys who governed the cities of Chaldea under this dynasty are all, however in Accadian.

The supremacy of Ur had been disputed by its more ancient rival Erech, but had finally to give way before the rise of Nisin or Karrak, a city whose site is uncertain, and Karrak in its turn was succeeded by Larsa. Elamite conquest seems to have something to do with these transferences of the seat of power. In 2280 B.C. —the date is fixed by an inscription of Assur-bani-pal's —Cudur-nankhundi, the Elamite, conquered Chaldea at a time when princes with Semitic names appear to have been already reigning there, and Cudur-mabug not only overran "the west," or Palestine, but established a line of monarchs in Babylonia. His son and successor took an Accadian name, and extended his sway over the whole country. Twice did the Elamite tribe of Cassi or Kossæans furnish Chaldea with a succession of kings. At a very early period we find one of these Kossæan dynasties claiming homage from Syria, Gutium, and Northern Arabia, and rededicating the images of native Babylonian gods, which had been carried away in war, with great splendor and expense. The other Cassite dynasty was founded by Khammuragas, who established his capital at Babylon, which henceforth continued to be the seat of empire in the south. The dynasty is probably to be identified with that called Arabian by Berosus, and it was during its domination that Semitic came gradually to supersede Accadian as the language of the country. Khammuragas himself assumed a Semitic name, and a Semitic inscription of his is now in the Louvre. A large number of canals were constructed during his reign, more especially the famous Nahr-Malcha, and an embankment built along the banks of the Tigris. The king's attention seems to have been turned to the subject of irrigation by a flood which overwhelmed the important city of Mullias. His first conquests were in the north of Babylonia, and from this base of operations he succeeded in overthrowing Naram-Sin (or Rim-Acu?) in the south and making himself master of the whole of Chaldea. Naram-Sin and a queen had been the last representatives of a dynasty which had attained a high degree of glory both in arms and in literature. Naram-Sin and his father Sargon had not only subdued the rival princes of Babylonia, but had successfully invaded Syria, Palestine, and even, as it would seem, Egypt. At Agane, a suburb of Sippara, Sargon had founded a library, especially famous for its works on astrology and astronomy, copies of which were made in later times for the libraries of Assyria. Indeed, so prominent a place did Sargon take in the early history of Babylonia, that his person became surrounded with an atmosphere of myth. Not only was he regarded as a sort of eponymous hero of literature, a Babylonian Solomon, whose title was "the deviser of law and prosperity," popular legends told of his mysterious birth, how, like Romulus and Arthur, he knew no father, but was born in secrecy, and placed by his mother in an ark of reeds and bitumen, and left to the care of the river; how, moreover, this second Moses was carried by the stream to the dwelling of a ferryman, who reared him as his own son, until at last the time came that his rank should be discovered, and Sargon, "the constituted king," for such is the meaning of his name, took his seat upon the throne of his ancestors. It was while the Cassite sovereigns were reigning in the south, and probably in consequence of reverses that they suffered at the hands of the Egyptians, who, under the monarchs of the 18th dynasty, were pushing eastward, that the kingdom of Assyria took its rise. Its princes soon began to treat with their southern neighbors on equal terms; the boundaries of the two kingdoms were settled, and inter-marriages between the royal families took place, which led more than once to an interference on the part of the Assyrians in the affairs of Babylonia. Finally, in the 14th century B.C., Tiglath-Adar of Assyria captured Babylon, and established a Semitic line of sovereigns there, which continued until the days of the later Assyrian empire. From this time down to the destruction of Nineveh, Assyria remained the leading power of Western Asia. Occasionally, it is true, a king of Babylon succeeded in defeating his aggressive rival and invading Assyria; but the contrary was more usually the case, and the Assyrians grew more and more powerful at the expense of the weaker state, until at last Babylonia was reduced to a mere apanage of Assyria.

We possess an almost continuous list of Assyrian kings; and, as from the beginning of the 9th century downwards there exists a native canon, in which each year is dated by the *limmu* or *archon eponymous*, whose name it bears, as well as a portion of a larger canon which records the chief events of each eponymy, it is evident that our chronology of the later period of Assyrian history is at once full and trustworthy. Similar chronological lists once existed for the earlier period also, since an inscription of a king of the 14th century B.C. is dated by one of these eponymies; and the precise dates given in the inscriptions for occurrences which took place in the reigns of older monarchs cannot otherwise be accounted for. How far back an accurate chronological record extended it is impossible to say; but astronomical observations were made in Babylonia from a remote period, and the era of Cudur-nankhundi was known, as we have seen, more than 1600 years afterward; while in Assyria not only can Sennacherib state at Bavian that Tiglath-Pileser I. was defeated by the Babylonians 418 years before his own invasion of that country, but the same Tiglath-Pileser can fix 701 years as the exact interval between his restoration of the temple of Anu and Rimmon at Kalah Sherghat and its foundation by the dependent viceroys of the city of Assur.

This Tiglath-Pileser, in spite of his subsequent defeat by the Babylonians, was one of the most eminent of the sovereigns of the first Assyrian empire. He carried his arms far and wide, subjugating the Moschians, Comagenians, Trumians, and other tribes of the north, the Syrians and Hittites in the west, and the Babylonians (including their capital) in the south. His empire, accordingly, stretched from the Mediterranean on the one side to the Caspian and the Persian Gulf on the other; but, founded as it was on conquest, and centralised in the person of a single individual, it fell to pieces at the least touch. With the death of Tiglath-Pileser, Assyria seems to have been reduced to comparative powerlessness, and when next its claims to empire are realised, it is under Assur-natsir-pal, whose reign lasted from 883 to 858 B.C. The boundaries of his empire exceeded those of his predecessor, and the splendid palaces, temples, and other buildings raised by him, with their elaborate sculptures and rich painting, bear witness to a high development of wealth and art and luxury. Calah, which had been founded by Shalmaneser I. some four or five centuries previously, but had fallen into decay, became his favorite residence, and was raised to the rank of a capital. His son Shalmaneser had a long reign of 35 years, during which he

largely extended the empire he had received from his father. Armenia and the Parthians paid him tribute; and under the pretext of restoring the legitimate monarch he entered Babylon, and reduced the country to a state of vassalage. It is at this time that we first hear of the Caldai or Chaldeans,—carefully to be distinguished from the *Casdim* or Semitic "conquerors" of Scripture,—who formed a small but independent principality on the sea-coast. In the west Shalmaneser succeeded in defeating in 854 B.C. a dangerous confederacy, headed by Rimmon-idri or Ben-hadad of Damascus and including Ahab of Israel and several Phœnician kings. Later on in his reign he again annihilated the forces of Hazael, Ben-hadad's successor, and extorted tribute from the princes of Palestine, among others from Jehu of Samaria, whose servants are depicted on the black obelisk. The last few years of his life, however, were troubled by the rebellion of his eldest son, which well-nigh proved fatal to the old king. Assur, Arbela, and other places joined the pretender, and the revolt was with difficulty put down by Shalmaneser's second son, Samas-Rimmon, who shortly after succeeded him. Samas-Rimmon (824–811) and Rimmon-nirari (811–782) preserved the empire of Assyria undiminished; but their principal exploits were in Babylonia, which they wasted with fire and sword, and converted into an Assyrian province.

The first Assyrian empire came to an end in 744, when the old dynasty was overthrown by a usurper, Tiglath-Pileser, after a struggle of three or four years. Once settled on the throne, however, Tiglath-Pileser proceeded to restore and reorganise the empire. Babylonia was first attacked; the Assyrian monarch offered sacrifices and set up his court in its chief cities; and the multitudinous Arab tribes who encamped along the banks of the Euphrates were reduced to subjection. The Caldai in the south alone held out, and to them belonged the first four kings given in Ptolemy's canon. Indeed, it may be said that from the invasion of Tiglath-Pileser to the revolt of Nabopolassar, Babylonia ceased to have any separate existence. It was governed by Assyrian kings or the viceroys they appointed, and the only attempts to recover independence were made under the leadership of the "Caldean" chiefs. It becomes nothing more than an important province of Assyria.

The second Assyrian empire differed from the first in its greater consolidation. The conquered provinces were no longer loosely attached to the central power by the payment of tribute, and ready to refuse it as soon as the Assyrian armies were out of sight; they were changed into satrapies, each with its fixed taxes and military contingent. Assyrian viceroys were nominated wherever possible, and a turbulent population was deported to some distant locality. This will explain the condition in which Babylonia found itself, as well as the special attention which was paid to the countries on the Mediterranean coast. The possession of the barbarous and half-deserted districts on the east was of little profit; the inhabitants were hardy mountaineers, difficult to subdue, and without wealth; and although Tiglath Pileser penetrated into Sagartia, Ariana, and Aracosia, and even to the confines of India, the expedition was little more than a display of power. The rich and civilised regions of the west, on the contrary, offered attractions which the politicians of Nineveh were keen to discover. Tiglath-Pileser overthrew the ancient kingdoms of Damascus and Hamath, with its nineteen districts, and after receiving tribute from Menahem (which a false reading in the Old Testament ascribes to a non-existent Pul) in 740, placed his vassal Hoshea on the throne of Samaria in 730 in the room of Pekah. Hamath had been aided by Uzziah of Judah; and, on the overthrow of the Syrian city, Judah had to become the tributary of Assyria. Tiglath-Pileser seems to have met with a usurper's fate, and to have fallen in a struggle with another claimant of the throne, Shalmaneser. The chief event of Shalmaneser's reign (727–722) was the campaign against Samaria. The capture of that city, however, was reserved for his successor, Sargon, in 720, who succeeded in founding a new dynasty. Sargon's reign of seventeen years forms an era in later Assyrian history. At the very commencement of it he met and defeated the forces of Elam, and so prepared the way for the future conquest of that once predominant monarchy. He came into conflict, also, with the kingdoms of Ararat and Van in the north; and the policy of the countries beyond the Zagros was henceforth influenced by the wishes of the Assyrian court. But it was in the west that the power of Nineveh was chiefly felt. Syria and Palestine were reduced to a condition of vassalage, Hamath was depopulated, and Egypt, then governed by Ethiopian princes, first came into collision with Assyria. The battle of Raphia in 719, in which the Egyptians and their Philistine allies were defeated, was an omen of the future; and from this time onward the destinies of civilised Asia were fought out between the two great powers of the ancient world. As the one rose the other fell; and just as the climax of Assyrian glory is marked by the complete subjugation of Egypt, so the revolt of Egypt was the first signal of the decline of Assyria. The struggle between the representative states of the East led, as was natural, to the appearance of the Greek upon the stage of history. Sargon claims the conquest of Cyprus as well as Phœnicia, and his effigy, found at Idalium, remains to this day a witness of the fact. Babylonia, however, was the point of weakness in the empire. It was too like, and yet too unlike, Assyria to be otherwise than a dangerous dependency; and its inhabitants could never forget that they had once been the dominant nation. New blood had been infused into them by the arrival of the Caldai, whose leader, Merodach-Baladan, the son of Yacin, called Mardokempados in Ptolemy's canon, had taken advantage of the troubles which closed the life of Tiglath-Pileser to possess himself of Babylonia; and for twelve years he continued master of the country, until in 710 Sargon drove him from the province, and crowned himself king of Babylon. Merodach-Baladan had foreseen the attack, and endeavored to meet it by forming alliances with Egypt and the principalities of Palestine. The confederacy, however, was broken up in a single campaign by the Assyrian monarch; Judea was overrun, and Ashdod razed to the ground. Sargon, who now styled himself king of Assyria and Babylon, of Sumir and Accad, like Tiglath-Pileser before him, spent the latter part of his reign in internal reforms and extensive building. A new town, called after his name, was founded to the north of Nineveh (at the modern Kouyunjik), and a magnificent palace was erected there. The library of Calah was restored and enlarged, in imitation of his semi-mythical namesake of Agane, whose astrological works were re-edited, while special attention was given to legislation. In the midst of these labors Sargon was murdered, and his son, Sennacherib, ascended the throne on the 12th of Ab 705 B.C. Sennacherib is a typical representative of the great warriors and builders of the second Assyrian empire, and is familiar to the readers of the Old Testament from his invasion of Judah, which the native monuments assign to the year 701. The check he received at Eltakeh, where he was met by the forces of Egypt and Ethiopia, saved the Jewish king, not, however, before his towns had been ravaged, a heavy tribute laid upon the capital, and his allies in Ascalon and Akron severely punished.

At the commencement of this campaign Sennacherib had reduced Tyre and Sidon, and the overthrow of these centres of commerce, caused a transfer of trade to Carchemish. Babylonia had shaken off the yoke of Assyria at the death of Sargon under Merodach-Baladan, who had escaped from his captivity at Nineveh, but was soon reduced to obedience again, and placed under the government of the Assyrian viceroy Belibus. In 700, however, the year after the Judæan war, Babylon rebelled once more under the indomitable Merodach-Baladan, and Suzub, another Chaldean. Sennacherib was occupied with a naval war — the first ever engaged in by the Assyrians — against a body of Chaldeans who had taken refuge in Susiana, and the revolt in his rear was stirred up by the Susianian king. But the insurgents were totally defeated; Assur-nadin-sum, Sennacherib's eldest son, was appointed viceroy of the southern kingdom; and the Assyrian monarch felt himself strong enough to carry the war into the heart of Elam, wasting the country with fire and sword. A last attempt, made by the Susianians and the Chaldeans of Babylonia, to oppose the power of Assyria was shattered in the hardly-contested battle of Khaluli. The interregnum, however, which marks the last eight years of Sennacherib's rule in Ptolemy's canon, shows that Chaldea still continued to give trouble and resist the Assyrian yoke.

Meanwhile Sennacherib had been constructing canals and aqueducts, embanking the Tigris, and building himself a palace at Nineveh on a grander scale than had ever been attempted before. His works were interrupted by his murder, in 681, by his two sons, who, however, soon found themselves confronted by the veteran army of Essar-haddon, their father's younger and favorite son. Essar-haddon had been engaged in Armenia; but in January 680 he defeated them at Khanirabbat, and was proclaimed king. Soon afterwards he established his court at Babylon, where he governed in person during the whole of his reign. After settling the affairs of Chaldea his first campaign was directed against Syria, where Sidon was destroyed and its inhabitants removed to Assyria, an event which exercised a profound influence upon Asiatic trade. The most remarkable expedition of his reign was into the heart of Arabia, to the kingdoms of Huz and Buz, 980 miles distant from Nineveh, 280 miles of the march being through arid desert. The Assyrian army accomplished a feat never since exceeded. In the north, also, it penetrated equally far, subjugating the tribes of the Caucasus, receiving the submission of Teispes the Cimmerian, and taking possession of the copper-mines on the most remote frontiers of Media. All this part of the country was now in the hands of Aryan settlers, and each small town had its independent chief, like the states of Greece. In fact, on two sides, on both north and west, the Assyrian empire was in contact with an Aryan population, and among the twenty-two kings who sent materials for Essar-haddon's palace at Nineveh were Cyprian princes with Greek names. But the most important work of Essar-haddon's reign was the conquest of Egypt, which left the ancient world under the rule of a single power for some twenty years, and by fusing the nations of Western Asia together, broke down their differences, spread an equalised civilisation, and first struck out the idea of universal empire. In 672 B.C. the land of the Pharaohs was invaded, Tirhakah, the Ethiopian, driven beyond its borders, and the country divided into twenty governments. Vain efforts to shake off the Assyrian supremacy were made from time to time; but just as Babylon had to look to the foreign Caldai for the championship of its independence, so Egypt found its leaders in Ethiopian princes. In 669 Essar-haddon fell ill, and on the 12th day of Iyyar in the following year he associated his son, Assur-bani-pal, with him in the kingdom. On his death at Babylon in 667, Assur-bani-pal was left sole king. One of his first acts was to appoint his brother Savul-sum-yucin (Sammughes) governor of Babylonia.

Assur-bani-pal, the Sardanapalus of the Greeks, was the "grand monarque" of ancient Assyria. The empire on his accession was at the height of its glory and magnitude; the treasures and products of the world flowed into Nineveh, and its name was feared from the frontiers of India to the shores of the Ægean. Constant wars asserted the superiority of the Assyrian troops, though they drained the empire of money and men; and the luxury, which had come in like a flood, was sapping the foundations of the national strength. Assur-bani-pal, in spite of his victories, his buildings, and his patronage of literature, left a diminished inheritance to his son; and the military expeditions, formerly conducted by the king in person, were now entrusted to his generals. His first work was to check the southward advance of the Cimmerians, who were thus driven upon Asia Minor, and to quell a revolt that had broken out in Egypt. Two campaigns were requisite to effect this, and meanwhile Gyges of Lydia had sent tribute to the formidable Assyrian monarch. War had also broken out with Elam, which ended, after a long and hard struggle, with the complete conquest of the country. It was divided into two states, each ruled by Assyrian vassals. But soon after this (in 652) the first blow was struck which eventually led to the downfall of the empire. A general insurrection suddenly took place, headed by Assur-bani-pal's own brother, the viceroy of Babylonia. Elam, Arabia, Egypt, and Palestine made common cause against the oppressor. Egypt alone, however, under the guidance of Psammitichus, and with the help of Gyges, succeeded in recovering her independence; the wandering tribes of Northern Arabia, Kedar, Zobah, Nabathæa, &c., were chastised, and summary vengeance taken on Babylonia and Elam. Babylon and Cuthah were reduced by famine (649), Sammughes was captured and burnt to death, and fire and sword were carried through Elam. After a protracted war, in which Assur-bani-pal was aided by internal dissensions, Shushan was plundered and razed, and the whole of Susiana reduced to a wilderness. This happened in 643.

Assur-bani-pal's buildings were unrivalled for size and grandeur. Assyrian culture reached its culminating point in his reign, and his palaces glittered with the precious metals, and were adorned with the richest sculpture. The library which he formed at Nineveh far surpassed any that had ever existed before; literary works were collected from all sides; the study of the dead language of Accad was encouraged, grammars and dictionaries were compiled, and learned men of all nations were attracted to the court. Patron of the arts as he was, however, Assur-baní-pal's character was stained by cruelty and sensuality. Under his second name of Sin-inadina-pal, he appears as king of Babylon in Ptolemy's list; and the complete amalgamation of Assyria and Babylonia in the later years of his rule is shown by the appearance of a prefect of Babylon among the Assyrian eponyms. He was succeeded in 625 by his son Assur-ebil-ili. His death was the signal for a general revolt. Nabopolassar, the viceroy of Babylonia, made himself independent; and Assyria, shorn of its empire, was left to struggle for bare existence, until, under Saracus its last monarch, Nineveh was taken and burnt by the Babylonians and Medes.

The seat of empire was now transferred to the southern kingdom. Nabopolassar was followed in 604 by his son Nebuchadnezzar, whose long reign of forty-three

years made Babylon the mistress of the world. The whole East was overrun by the armies of Chaldea, Egypt was invaded, and the city of the Euphrates left without a rival. Until systematic explorations are carried on in Babylonia, however, our knowledge of the history of Nebuchadnezzar's empire must be confined to the notices of ancient writers, although we possess numerous inscriptions which record the restoration or construction of temples, palaces, and other public buildings during its continuance. One of these bears out the boast of Nebuchadnezzar, mentioned by Berosus, that he had built the wall of Babylon in fifteen days. Evil-Merodach succeeded his father in 561, but he was murdered two years after, and the crown seized by his brother-in-law, Nergal-sharazer, who calls himself son of Belsumaiscun, "king of Babylon." Nergal-sharezer reigned four years, and was succeeded by his son, a mere boy, who was put to death after nine months of sovereignty (555 B.C.). The power now passed from the house of Nabopolassar, Nabu-nahid, who was raised to the throne, being of another family. Nebuchadnezzar's empire already began to show signs of decay, and a new enemy threatened it in the person of Cyrus the Persian. The Lydian monarchy, which had extended its sway over Asia Minor and the Greek islands, had some time before come into hostile collision with the Babylonians, but the famous eclipse foretold by Thales had parted the combatants and brought about peace. Crœsus of Lydia and Nabu-nahid of Babylonia now formed an alliance against the common foe, who had subjected Media to his rule, and preparations were made for checking the Persian advance. The rashness of Crœsus, however, in meeting Cyrus before his allies had joined him, brought about his overthrow; Sardis was taken, and the Persian leader occupied the next fourteen years in consolidating his power in the north. This respite was employed by Nabu-nahid in fortifying Babylon, and in constructing those wonderful walls and hydraulic works which Herodotus ascribes to Queen Nitocris. At last, however, the attack was made; and after spending a winter in draining the Gyndes, Cyrus appeared in the neighborhood of Babylon. Belshazzar, Nabu-nahid's eldest son, as we learn from an inscription, was left in charge of the city, while his father took the field against the invader. But the Jews, who saw in the Persians monotheists and deliverers, formed a considerable element of the population and army; and Nabu-nahid found himself defeated and compelled to take refuge in Borsippa. By diverting the channel of the Euphrates the Persians contrived to march along the dry river-bed, and enter the city through an unguarded gate. Babylon was taken, and Nabu-nahid shortly afterwards submitted to the conqueror, receiving in return pardon and a residence in Carmania. He probably died before the end of Cyrus's reign; at all events, when Babylon tried to recover its independence during the troubles that followed the death of Cambyses, it was under impostors who claimed to be "Nebuchadnezzar, the son of Nabu-nahid."

Art, Science, and Literature.—Although in art, as in other things, Assyria was but the pupil and imitator of Babylonia, there was yet a marked difference between its development in the two countries, due partly to natural causes. While the Assyrians had stone in abundance, the Babylonians were obliged to import it from a distance. Brick-clay, on the contrary, lay ready at hand, and architecture among them, consequently, took the forms imposed upon it by the use of bricks instead of stone. Where the Assyrians employed sculptured alabaster to ornament their buildings, the Babylonians contented themselves with enamelled bricks and painted plaster. It is a curious proof of the servile dependence of the northern upon the southern kingdom in artistic matters, that the Assyrians continued to make large use of brick up to the downfall of the empire, in spite of the accessibility of stone and the rapid decay of their palaces caused by the employment of the more fragile material. Still, though Assyrian art clung thus unaccountably to the building materials of another country, it did not dispense with its native stone altogether; and speaking broadly, we may say that the architecture of Nineveh is characterised by the use of stone in contradistinction to the brickwork of Babylonia. Sculpture was naturally developed by the one, just as painting was by the other; and the ornamentation which could be lavished on the exterior in Assyria had to be confined to the interior in Chaldea.

Another distinction between the art of the two monarchies arose from the character of their respective populations. Babylonia was essentially a religious country, and its art, therefore, was primarily religious. Nearly all the great edifices, whose ruins still attract the traveller, were temples, and the inscriptions we possess of the Babylonian princes relate almost wholly to the worship of the gods. In Assyria, on the other hand, the temple was but an appendage of the palace, the king among "these Romans of Asia," as Prof. Rawlinson calls them, being the central object of reverence. While the Chaldean temple, with its huge masses of brickwork, rose stage upon stage, each tier smaller than the lower, differently colored, and surmounted at the top by a chamber which served at once as a shrine and an observatory, the Assyrian palace was erected upon a mound of rubble, with open courts and imposing entrances, though never more than one or two stories high.

Closely connected with this difference in the religious feelings of the two nations was the greater care and attention paid to burial in Babylonia. As yet not a single tomb had been found in Assyria, while sepulchral remains abound in Chaldea. The vast necropolis of Erech astonishes us by the number of its graves, and the potters of Babylonia were largely employed in making clay coffins. The character of the Assyrian art being thus secular, and that of Babylonia sacred and sepulchral, necessarily led to a different application and development of it in the two countries.

We must regard Assyrian art as parallel with later Babylonian, both having branched off from Accadian. In Assyrian we may trace two or even three periods of development; but our want of materials makes it impossible to do this in the case of later Babylonian. Among neither people, however, did art altogether escape from the swathing-bands of its nursery, although it was never crystallised as in ancient Egypt. The oldest monuments of Accad already display it in all its forms, rude and rudimentary though they may be. The terraced temples of Ur, Erech, and other places, mount back to the earliest times of Chaldean history, and we find them already adorned with enamelled bricks, which were first colored, then glazed, and finally baked in the fire. Terra-cotta cones of various hues, embedded in plaster, were used for external ornamentation, and at Warka (Erech) colored half-columns are employed for the same purpose, — an ornamentation which recurs in Sargon's palace at Khorsabad, and was the germ of the many kinds of pillars met with in Assyria. The internal walls of the shrine were bright with paint and bronze and gilding; but the brilliant coloring of the Chaldeans was not reproduced in the northern monarchy where more sombre tints were preferred. The huge structures themselves, of burnt and unburnt brick, were supported by buttresses, and the rain was carried off by elaborately-constructed drains, some of which afford us the earliest examples of the arch. A leaded pipe for the same object was found by Mr. Loftus at Mugheir (Ur).

Stone, on account of its scarcity, was highly prized, and used only for sculpture and carving. Fragments of the statue of an Accadian king have been brought from Hammám, and a portrait of Merodach-iddin-akhi, the successful opponent of Tiglath-Pileser I. (1120 B.C.), is cut in low relief on a stone now in the British Museum. Like all other Babylonian stone relics, they are of small size, and of hard black granite, and the royal portrait is interesting not only as being one of the few specimens we possess of Babylonian sculpture, but as showing the marked contrast of the Babylonian face to the typically Jewish features of the Assyrians. If larger stones were rare, however, the same cannot be said of the smaller ones, which were used as signets and talismans. These were always incised, and though the figures are frequently rude, and still more often grotesque, they are always clearly cut and vigorous. Indeed, it is clear that emery must have been used for the purpose, while many of the carvings are so minute as to suggest the employment of a magnifying glass. This, however, seems to be out of the question at so early a date as that to which many of the gems belong, although a crystal lens was discovered by Mr. Layard at Nimrúd. The design on the signet-cylinder of the earliest king of Ur of whom we have any knowledge is of a high order of merit.

Next to gem-cutting, pottery was carried to a considerable perfection by the Accadians. Some of their vases and lamps exhibit great beauty of form, and bear evidence of the potter's wheel; though the large majority are made by the hand, and extremely rude. Spirited bas-reliefs in terra-cotta, however, have been exhumed at Senkereh, and some small terra-cotta figures may also be assigned to this early period. Metallurgy was more backward. Stone implements were still in use, although weapons and ornaments of bronze and copper are met with in abundance; and even iron was not unknown. Bronze bowls occur in almost every tomb, sometimes wrought with considerable skill. Metallurgic art, however, attained its highest point in the manufacture of gold objects like ear-rings and fillets. The latter may be compared with the gold head-dresses found by Dr. Schliemann in the Troad. This backward state of metallurgy is somewhat remarkable when we consider the skill displayed in the making of textile fabrics. The oldest gems portray the most richly embroidered robes, and it is probable that the muslins and carpets for which Babylonia was afterwards so famous were already a branch of industry.

Art in Assyria developed chiefly, as has been said, on the side of architecture and sculpture. Its first period is best represented by the reign of Assur-natsir-pal, in whose palaces we obtain excellent illustrations of its excellencies and defects. The period is characterised by a simplicity and vigor which shows itself in the bas-reliefs, where the figures, more especially the animal forms, are spirited and natural beyond anything that we meet with at a later time. Nothing, for instance, can be bolder and more life-like than the lion-hunt depicted on the slabs of Assurnatsir-pal. There is a freedom in the attitude of the animals which evidences a remarkable grandeur of conception. On the other hand, the execution is somewhat heavy, the perspective is worse even than in later works, and the outlines are reproduced with too servile an exactitude. A background, again, is entirely wanting, the attention of the artist being concentrated upon the principal group. In the second period, which extends from the beginning of the second empire to the reign of Essarhaddon, the freshness and boldness of the preceding stage have passed away. The care once exclusively bestowed upon the chief figures is now shared with an elaborate background, and a pre-Raffaellite minuteness prevails throughout the whole. This, added to a total want of perspective, causes too obtrusive a realism. Still, what is lost in vigor is gained in delicacy and finish, and the general effect of such rich and intricate grouping could not but have been effective. The reign of Assur-bani-pal marks the third and last period of Assyrian art. Drawing has made a rapid advance, and the sculptures furnish several instances of successful foreshortening. The art of this period is distinguished by great softness and chasteness; vegetable forms are represented with admirable skill, and the overcrowding of the preceding stage is avoided by recurring to the plain backgrounds of the first period, or introducing merely the main outlines of a landscape. At the same time, it is clear that Assyrian art is beginning to decline; the freedom and boldness that once marked it tend to disappear, and it is prevaded by a spirit of effeminacy which is well exemplified by the subjects portrayed. For the first time scenes are taken from the harem; the king lies, with his wife seated beside him, banqueting under the shade of the vine; and the lions that Assur-natsir-pal hunted in the open field at the risk of life are now tame creatures, kept in cages, and let out for a royal *battue*, where they have to be whipped into activity.

The effect of this Assyrian bas-relief sculpture was heightened by judicious coloring. Red, blue, black, and white — none of them, however, of very great brilliancy — were laid upon certain parts of the picture, such as the eyes, hair, and fringes of the garments. This partial coloring was also adopted by the Greeks, and it is extremely probable that they borrowed it from Assyria. The beginning of Greek art coincides with the decadence of Assyrian; and the objects found by M. Cesnola and others in Cyprus show us the transition of the one into the other. While the remains found by Dr. Schlieman in the Troad do not exhibit any Assyrian influence, the oldest works of art in Greece itself are thoroughly Assyrian in character. Indeed, we can trace the lion-sculpture at Mycenæ through the similar rock-carving at Kumbet, in Phrygia, back to the artists of Nineveh. The lions themselves are Assyrian in all their details, and the pillar against which they rest reappears in the monuments of Assur-bani-pal. Columnar architecture, in fact, obtained a more extensive development in the empire of the Tigris than has ever been the case elsewhere. The half columns of ancient Chaldea germinated into a wonderful variety of elaborate forms. The most peculiar are those which rest with circular pedestals upon the backs of lions, dogs, and winged bulls. The chasteness of Hellenic taste preserved it from this Eastern fantasticness, but the Doric and Ionic pillars had their first home on the banks of the Tigris. There was something in the round firm column which was congenial to the mind of the Assyrian.

Indeed, it may be said that solidity and realism underlie all Assyrian art. Muscular strength and power of an intensely earthly and human nature is expressed in their bas-reliefs and the colossal bulls that guarded the palace from the entrance of evil spirits. Nowhere else in the world can we find such an embodiment of brute force and unimaginative energy. Not only is Assyrian art valuable as disclosing the genesis of Hellenic, but yet more so as filling up a vacant chapter in the history of æsthetics. The divine calm and mysterious immensity of Egyptian sculpture was not more foreign to the Greek than the stiff unspirituality and coarse vigor of the Assyrians, which found in the lion an appropriate symbol. But the Assyrian artists did not confine themselves to architecture and bas-reliefs. Gem-cutting was carried to high perfection, and even sitting statues of "the great king" were attempted. These, however,

were not so successful as the terra-cotta models, some of which are of great beauty. Indeed, the potters' work of Nineveh can quite vie with that of ancient Greece, and their lamps seem to be prototypes of those which we find in the tombs of Athens or Syracuse. Besides porcelain, glass was also manufactured, and though transparent glass does not appear to have been known before the reign of Sargon, colored glass, with all the tints that we admire in Venetian ware, had long been an article of trade. Metallurgy, again, was a branch of industry in which the Assyrians particularly excelled. Their gold ear-rings and bracelets are admirable both in design and workmanship; their bronze casts are free from the narrowness of their sculptures in stone; and so well were they acquainted with the art of inlaying one metal with another, that our modern artists have been content to learn from them the method of covering iron with bronze. Household furniture, too, gives us a high idea of Assyrian skill. Like gem-cutting, it brought out the Chinese minuteness and accuracy of the people, and the profuse, though tasteful ornamentation of the seats is especially to be noticed.

It is unfortunate that our knowledge of the development of art in the sister kingdom is still so imperfect. As has been said, however, it is characterised by painting rather than sculpture, and the use of brick instead of stone. The few bas-reliefs that exist are small and inferior in execution; but brilliant coloring and a lavish use of the metals made up for this want. The walls were covered with the most costly materials, and "images portrayed with vermilion" excited the admiration of the stranger. The love of bright colors, in contrast with the sober hues of the Assyrian palaces, led also to the cultivation of gardens, and the hanging gardens of Babylon, raised upon tiers of arches, were one of the wonders of the world. The Babylonian had, too, a strong sense of humor. In the engraved gems and metal work of the southern empire, we miss the finish and minute care of the sister-kingdom, but they are replaced by a spirit of grotesqueness and serio-comedy. In pottery and the manufacture of textile fabrics the Babylonians particularly excelled; their carpets and variegated dresses were highly prized, while their fondness for music was much celebrated. The history of the latter art, however, both in Babylonia and Assyria, has yet to be traced.

The science of Assyria, like most things else, was derived from Accad. A large number of its technical terms were borrowed from the Turanian, and continued to the last an enduring monument of the debt owed by the Semite to his predecessor. At the same time, he did not remain a mere imitator; science received a development in his hands, which might have been looked for in vain from a Turanian race. First and foremost comes the astronomy, for which Babylonia was so famous in the ancient world. Its beginning goes back to the time when the Accadai had not yet descended from their mountain fastnesses. The zenith was fixed above Elam, and not above Babylonia, and "the mountain of the East," the primitive home of the race, was supposed to support the firmament. The shrines on the topmost terraces of the temples were used also as observatories. Ur had its royal observatory, and so probably had the other cities of Chaldea; in Assyria they existed at Assur, Nineveh, and Arbela, and the astronomers-royal had to send in their reports to the king twice a month. At an early date the stars were numbered and named; but the most important astronomical work of the Accadians was the formation of a calendar. This came after the division of the heavens into degrees, since the twelve months (of 30 days each) were named after the zodiacal signs, and would seem to belong to about 2200 B.C. Somewhat strangely, the Accadian calendar appears to have passed to the Assyrians (and through them to the Jews) through the medium of the Aramæans. The year being roughly made to consist of 360 days, intercalary months had to be added, one of them being regularly inserted every six years, and two others being counted in by the priests when necessary. The *soss* of 60 years, the *ner* of 600, and the *sar* of 3600, were merely cycles dependent upon the general mathematical system of the Babylonians, which made 60 the unit, and then multiplied it by the factors of itself. The week of 7 days was in use from an early period; indeed, the names which we still give to the days can be traced to ancient Babylonia; and the seventh day was one of *sulum* or "rest." The night was divided into three watches; but this was afterward superseded by the more accurate division of the day into 12 *casbu* (of 2 hours each), corresponding to the divisions of the equator, each *casbu* being further subdivided into 60 minutes, and these again into 60 seconds. The sections of the equator contained 30 degrees each — a degree being 60 sosses or minutes; but since an astrolabe, now in the Museum, divides each of the 12 sections in the outer circle into 20 degrees, and those in the inner circle into 10 degrees, it is plain that a different system was adopted for astrological purposes. Eclipses were carefully recorded from a very remote epoch, and since some of these are said to have happened "according to calculation," and others "contrary to calculation," their recurrence after a cycle of eighteen years must have been roughly determined. One of the Assyrian reports states that a watch was kept for an eclipse of the sun on the three last days of the month, but that, contrary to expectation, the eclipse did not take place, and we possess notices of eclipses which have been verified by modern astronomers, though antecedent to the era of Nabonassar, with whom, so far as Ptolemy knew, the first record of them began. The chief work on astronomy was one compiled for the library of Sargon of Agane in seventy tablets or books, which went through many editions, one of the latest being now in the British Museum. It was called "The Illumination of Bel," and was translated into Greek by Berosus. The catalogue of its contents includes observations on comets, on the pole star, the conjunction of the sun and moon, and the motions of Venus and Mars. The main purpose, however, of all these Babylonian astronomical observations was an astrological one; to cast a horoscope, or predict the weather, was the chief business of the Chaldean astronomer. Indeed, the patient minuteness of the meteorological observations is most curious, and it was believed that the same weather recurred after a definite number of years. In the later Assyrian period the study became more scientific, and the observatory reports have something of the precision of modern times. But from a much earlier era we obtain interesting tables of lunar longitudes and numerical equivalents of the daily increase and decrease of the moon. As is implied by the attention given to astronomy, mathematics was fairly advanced. The unit was 60, a very convenient number, especially when used as the denominator of a fraction. A tablet found at Senkereh gives a table of squares and cubes, correctly calculated, from 1 to 60; and a people who were acquainted with the sun dial, the clepsydra; the lever, and the pulley, must have had no mean knowledge of mechanics. The lens, too, discovered at Nineveh, explains the minuteness of the cuneform writing on so many of the tablets, and suggests the possibility of artificial aids to the observation of the heavens.

Assyria possessed but little native literature. It was essentially a land of soldiers, and the more peaceful pur-

suits had their home in Babylonia, where the universities of Erech and Borsippa were renowned down to classical times. It was not until the reign of Assur-bani-pal that any attempt was made to rival Babylon in learning; then for the first time original compositions came from the pens of Assyrian scholars, and works were even written in the dead language of Accad. Syllabaries, together with grammars, dictionaries, and reading-books of Assyrian and Accadian, were drawn up, besides lists of Semitic synonyms. In these grammars and vocabularies lay the germ of comparative philology, and they are otherwise valuable as affording us the earliest native analysis of Semitic speech. But before this closing period of the empire, the Assyrians had been chiefly content to translate the ancient Accadian literature, or re-edit the contents of Babylonian libraries; and the cramping influence of a dead language, in which all the precedents of law and the first principles of science were locked up, could not but make itself felt. Every great city of Chaldea had at least one library, and it was in imitation of this that the royal libraries at Calah, Nineveh, Assur, and elsewhere, were founded. The larger part of the literature was in clay, stamped in minute characters upon baked bricks, *laterculæ coctiles* as Pliny calls them; but papyrus was also used, though none of this fragile material has been preserved to our day. In fact, the use of papyrus seems to have preceded that of clay, which was not employed until after the settlement of the Accadians in the plains. The clay tablets or books were arranged in order; and we learn from the catalogue of Sargon's library at Agane (about 2000 B.C.) that each was numbered, so that the student had only to write down the number of the tablet he wanted and the librarian thereupon handed it to him. The subjects of Accadian literary composition were multifarious. Among the most interesting are the hymns to the gods, some of which strikingly resemble the Hebrew psalms in substance as well as in form. Indeed, the parallelism of Hebrew and Assyrian poetry seems to have been borrowed from the Accadians. But the similarity of expression and feeling is no less remarkable. Thus we read in one—(1.) "May god, my creator, take mine hands. (2.) Guide thou the breath of my mouth: guide thou mine hands; (3.) O lord of light!" and in another—(1.) "In heaven who is high? Thou alone, thou art high. (2.) In earth who is high? Thou alone, thou art high. (3.) As for thee, thy word in heaven is declared: the gods bow their faces to the ground. (4.) As for thee, thy word in earth is declared: the spirits of earth kiss the ground;" or in a third—(1.) "O Lord, my transgressions are many: great are my sins. (2.) The Lord in the anger of his heart: has confounded me. (3.) God in the strength of his heart set himself against me." A collection was afterwards made of these hymns, which was used for ritualistic purposes, and regarded as an inspired volume, and has been aptly compared by M. Lenormant with the Rig-Veda of the Hindus. Of an older date is the collection of magic formulæ and charms, chiefly intended to counteract the effects of sorcery and demoniac possession, which go back to the Shamanistic period of Accadian religion. Later than the hymns, but still prior to the second millennium B.C. and the formation of the calendar, are the mythological poems which grew out of the development of a solar worship and the personification of the attributes of the gods. Two of these poems we possess intact,—on the Deluge and the descent of Istar into Hades,—and part of a third which describes the war of the seven evil spirits against the moon. The first two form the sixth and eleventh books of a very remarkable epic which centred round the adventures of a solar hero, older and originally independent lays being woven into it as episodes. The epic was divided into twelve books, each book dealing with a legend appropriate to the name of the corresponding zodiacal sign. This astronomical basis of the national epic shows how thoroughly the study had penetrated the mind of the people; and the clearness with which we can trace the growth and formation of the whole work throws great light on the history of epic literature generally, and adds one more confirmation to the theory of Wolf. The Assyrians also had their epic, in imitation of the Accadians, and M. Lenormant has pointed out that the Semiramis and Nannarus of the Greeks and the other personages of Ctesias were really figures of this mythical epopee. The historical and chronological works that have been preserved are of purely Assyrian origin, though there is every reason to suppose that when the libraries of Accad come to be excavated similar compositions will be found in them. The legal literature of the Accadians was certainly very extensive, and a collection of fables, one a dialogue between the ox and the horse, and another between the eagle and the sun has been met with.

Language and Trade.—As above stated, the language of the primitive Sumirian and Accadian population of Assyria and Babylonia belonged to the Turanian or Ural-Altaic family of speech. The Semitic tribes, who first possessed themselves of the tetrapolis of Sumir or Shinar, and then gradually spread over the whole of Assyria and Babylonia, borrowed many words from their more civilised predecessors, and lent them a few others in return. The so-called Assyrian language is sub-divided into the two dialects of Assyria and Babylonia, the latter dialect being characterised by a preference for the softer sounds, and a fuller use of the vowels. Literature and the influence of a dead language stereotyped it to such an extent that it underwent comparatively little change during the 1500 years during which we can watch its career; at least this is the case with the literary dialect. The closest affinities are with Hebrew and Phœnician; it shares their peculiarities in phonology, grammar, and vocabulary; and some obscure points in Hebrew etymology have already been cleared up by its help. Next to Hebrew, it shows perhaps the greatest resemblance to Arabic; differing most widely, on the other hand, from Aramaic. Aramaic, however, from becoming the *lingua franca* of trade and diplomacy after the fall of Tyre and Sidon, ended (like Arabic in later times) in superseding its sister idioms; but in Babylonia this did not happen until after the Persian conquest.

The earliest Semitic settlements in Babylonia seem to have been mainly for commercial purposes, and their career there may be compared with that of the English in India. In the 12th century B.C. the trading spirit had so thoroughly pervaded them that not only were objects of utility and art a marketable commodity, but we find Tiglath-Pileser I. bringing trees from the countries he had overrun, and acclimatising them in Assyria. The fullest development of business and commerce, however, does not show itself until the 8th and 7th centuries B.C., when Nineveh was a busy centre of trade. Sidon and Tyre had been ruined by the Assyrian kings—indeed, it is very possible that the obstinate wars with the Phœnician cities had their origin in commercial jealousy, and trade had accordingly transferred itself to Carchemish, which was conveniently situated on the Euphrates. The maneh of Carchemish became the standard of weight, and Aramaic the common language of trade. The interest upon money was usually at 4 per cent.; but sometimes, more especially when objects like iron were borrowed at

3 per cent. Payment might still be made in kind; but more ordinarily in bars of the three chief metals, which were weighed, though mention of coined money also occurs. Houses could be let on lease, and the deeds which conveyed them give a careful inventory of the property and its appurtenances. Commercial relations extended from India on the one side, whence came ivory and the teak found at Mugheir, which Sennacherib probably means by "wood of Sinda," to the tin islands of Cornwall on the other.

Religion and Mythology.— The earliest religion of Accad was a Shamanism resembling that of the Siberian or Samoyed tribes of to-day. Every object had its spirit, good or bad; and the power of controlling these spirits was in the hands of priests and sorcerers. The world swarmed with them, especially with the demons, and there was scarcely an action which did not risk demoniac possession. Diseases were regarded as caused in this way, and the cherubs, bulls, and other composite creatures which guarded the entrance to a house, were believed to protect it from mischief. In course of time certain spirits (or rather deified powers of nature) were elevated above the rest into the position of gods; and at the head of all stood the Triad of Na or Anna, "the sky," Ea, "the earth," and Mulge, "the lord of the underworld." The old Shamanism gradually became transformed into a religion with a host of subordinate semi-divine beings; but so strong a hold had it upon the mind, that the new gods were still addressed by their spirits. The religion now entered upon a new phase; the various epithets applied to the same deity were crystallised into fresh divinities, and the sun-god under a multitude of forms became the central object of worship. This inevitably led to a mythology, the numerous personified attributes passing into demi-gods and heroes. A large part of the Accadian mythology was solar, and the transparency of its proper names which, as in other agglutinative languages, never disguise their primitive meaning, makes it valuable in verifying the so-called "solar theory" of compaartive mythology. At this stage of development, however, an important change passed over the old faith. The Semitic settlers in Sumir had adopted the Accadian pantheon and belief, and after a conflict between the discordant religious conceptions of the two races, a great sacerdotal "reform" took place analogous to that of Brahmanism, and the official religion fused them into one whole. The magicians were taken into the priestly body, and the hierachy of divine beings was determined. The old triad of Na, Ea, and Mulge became the trinity of Anu, Ea, and Bel the Demiurge, all children of Zicu or Zicara, "the sky" Ea, "the god of life and knowledge," "the lord of the abyss," "the king of rivers and the garden," the husband of Bahu (the Bohu of Gen. i. 2), whose spirit pervades the universe, being made the father of Bel-Merodach, the tutelary divinity of Babylon. In accordance with the genius of the sex-denoting Semitic idioms, each deity was furnished with a female principle, and "The god" in Babylonia, and the personified city of Assur, with his wife Seruá, in Assyria, were placed at the head of the Pantheon. Below these four supreme divinities came a second trinity of the Moon-god, Sun-god, and Air-god, and the seven together formed "the seven magnificent deities." After these were arranged "the fifty great gods," and then the 300 spirits of heaven, and the 600 spirits of earth, among whom was found a place for the primeval divinities of Accad as well as for the many local deities of Chaldea. The most dreaded of "the spirits of earth" were "the seven spirits" who were born "without father and mother" in the encircling abyss of ocean, and carried plague and evil over the earth. An old myth told of their war against the moon, which was deputed to watch over the interests of mankind.

Along with the establishment of the Babylonian official religion, an astro-theology was created by the introduction of astronomy into the religious sphere. The "spirits" of the various stars were identified with the gods of the new creed, Merodach, for instance, properly one of the forms of the sun-god, being identified with the planet Jupiter, and the five planetary deities were added to the seven magnificent gods, making up altogether "the twelve chiefs of the gods." The elaboration of this astro-theology was also accompanied by the formation of a cosmogony. The details of the latter are to be found in the fragments of Berosus and Nicolaus Damascenus, whose statements are confirmed by the inscriptions, and they show a remarkable resemblance to the cosmogonies of Genesis and Phœnicians. It must be remembered that both Phœnicians and Hebrews profess to have migrated from Chaldea.

The resemblance is still more striking when we examine the Babylonian mythology. The sacred tree of Babylonia, with its guardian "cherubs" — a word, by the way, which seems of Accadian origin — as well as the flaming sword or thunderbolt of fifty points and seven heads, recall Biblical analogies, while the Noachian deluge differs but slightly from the Chaldean one. Indeed, the Jehovistic version of the flood story in Genesis agrees not only in details, but even in phraseology with that which forms the eleventh lay of the great Babylonian epic. The hero of the latter is Tam-zi or Tammuz, "the sun of life," the son of Ubaratutu, "the glow of sunset," and denotes the revivifying luminary of day, who sails upon his "ark" behind the clouds of winter to reappear when the rainy season is past. He is called Sisuthrus by Berosus, that is, Susru "the founder," a synonym of Na "the sky." The mountain on which his ark rested was placed, as already noticed, in Nisir, south-west of Lake Urumiyeh. Its peak, whereon the first altar was built after the deluge, was the legendary model after which the *zigurats* or towers of the Babylonian temples were erected. Besides the account of the flood, fragments have been met with of stories resembling those of the tower of Babel or Babylon, of the creation, of the fall, and of the sacrifice of Isaac,— the latter by the way, forming probably the first lay of the great epic. The sixth lay we possess in full. It describes the descent of Istar into Hades in pursuit of her dead husband Dū-zi, "the offspring," the Babylonian Adonis. Dū-zi is but another form of Tam-zi, and denotes the sun when obscured by night and winter. At each of the seven gates of Hades the goddess left some portion of her apparel, until she at last reached the abode of the dead, dark and joyless, where dust alone is the food of the unhappy shades. In the midst rose the golden throne of the spirits of earth, beneath which welled "the waters of life," and here, too, was the seat of Bahu. Bahu, as queen of the underworld, smote Istar with many diseases, and confined her in Hades until her brother the Sun-god complained to the Moon-god and Ea, who sent a sphinx to pour the waters of life upon the imprisoned goddess and restore her to the light of day. This myth gives a good idea of the Chaldean conception of the next world. Certain favored individuals, however, might look forward to a happier state of existence. A psalm which invokes blessings upon the king wishes him everlasting life in "the land of the silver sky," where the gods feast and know no evil. It will be observed that the Babylonian Hades (like the Hebrew Sheol) is not very dissimilar to the Homeric one; and the possibility of borrowing on the part of the Greeks is suggested by the fact, that the seven-headed

serpent of Hindu legend is of foreign origin, being taken from the seven-headed serpent of the Accadians, "which lashes the waves of the sea," while the story of Andromeda came through Phœnician hands from a Chaldean myth which forms the subject of one of the lays of the great epic. So, too, the Oceanus of Homer finds its prototype in the encircling abysmal waters of Accadian geography, and the *fravashis* and *mithras* of Mazdaism were introduced by the Magian (or Turanian) population found in Media by the Arvan invaders.

But the old Shamanistic ideas survived also in Assyria and Babylonia, and so were handed on to the Jews. An elaborate system of augury flourished down to the last days of the empire, and omens were drawn from every event that could possibly happen. Magic formulæ for warding off the attacks of demons were extensively used, and the bronze bowls found by Mr. Layard, as well as the part played by charms and demons in the Talmud, show how strongly the belief had seized upon the Jewish mind.

BABYLONISH CAPTIVITY, the deportation, under Nebuchadnezzar, of a large portion of the principal inhabitants of Judah, after the fall of Jerusalem, 586 B. C. It must be carefully distinguished from the carrying into Assyria of a large number of the inhabitants of the northern kingdom—the ten tribes—by Sargon, the successor of Shalmaneser, as early as 721. A large number of the inhabitants of Judah had been already carried off to Babylon in 597, when Zedekiah had become King over the remainder. It was not long before these excited the anger of the powerful Chaldean king, and the second capture of the city and captivity of the inhabitants put an end to the kingdom of Judah. They were allowed the free exercise of their religion, and here Ezekiel and the unknown author of the last part of the book of Isaiah gave hope to the spiritual aspirations of the despondent people.

BACCARAT (Fr. *Baccara*) is one of the most widespread French games of chance, played for money between a banker and several punters.

BACCARAT, a town of France, in the department of Meurthe and arrondissement of Lunéville.

BACCHIGLIONE, a river of north-eastern Italy, which, rising in the mountains eastward of Trent, passes by Vicenza, and Padua, and, after a course of 90 miles, falls into the lagune of Venice, south of Chioggia.

BACCHUS, the Latin name of Dionysus, the god of wine. See DIONYSUS.

BACCHYLIDES, a famous Greek lyric poet, born at Iulis in Ceos, was the nephew of Simonides, and flourished about 470 years before Christ.

BACCIO DELLA PORTA, called FRA BARTOLOMMEO DI S. MARCO, a celebrated historical and portrait painter, was born at Savignano, near Florence, in 1469, and died in 1517.

BACH, JOHANN-SEBASTIAN, was born at Eisenach in Thuringia, on March 21, 1685, the same year which gave birth to his great contemporary Handel. His father held a musical appointment from the town council, being himself descended from a musician. The family of the Bachs, like those of some of the great Italian painters, may be cited as one of the most striking instances of hereditary artistic genius. Through four consecutive generations they followed the same calling, counting among their number no less than fifty musicians of more or less remarkable gifts. Johann-Sebastian's parents died before he had reached his tenth year, and he was left to the care of his elder brother, an organist at Ohrdruf, from whom he received his rudimentary musical education. In 1698 his brother died, and Bach, at the age of fourteen, saw himself thrown on his own resources for his further means of support. He went to Lüneburg, where his beautiful soprano voice obtained him an appointment as chorister at the school of St. Michael. In this manner he became practically acquainted with the principal works of vocal music, continuing at the same time his practice on the organ and pianaforte. A special teacher of any of these instruments, or, indeed, of the theory of music, Bach seems never to have had, at least not to our knowledge, and his style shows little affinity to the modes of expression in use before him.

At the age of eighteen Bach returned to Thuringia, where his executive skill on the organ and pianoforte attracted universal attention, and even obtained him various musical appointments, of which we mention as the most important that of court organist to the duke of Weimar. One, and not the least welcome, of his official duties was the composition of sacred music. One of his most beautiful sacred cantatas, *Ich hatte viel Bekümmerniss*, was composed during his stay at Weimar. In 1723 he removed to Leipsic, where the position of cantor at the celebrated "Thomasschule," combined with that of organist at the two principal churches of Leipsic, was offered to him. It was here that the greater part of his works were composed, mostly for the immediate requirements of the moment. Several of them he engraved himself, with the assistance of his favorite son, Friedemann. The further course of his life ran smoothly, only occasionally ruffled by his altercations with his employers, the town-councilors of Leipsic, who, it is said, were shocked by the "unclerical" style of Bach's compositions, and by his independent bearing generally. He was married twice, and had by his two wives a family of eleven sons and nine daughters. In 1747 Bach made a journey to Potsdam by the invitation of Frederick the Great, who, himself a musical amateur, received the master with distinguished marks of regard. He had to play on the numerous pianofortes of the king, and also to try the organs of the churches of Potsdam. Two years after this event his sight began to fail, and before long he became perfectly blind, a circumstance which again coincides with the fate of his great contemporary, Handel. Bach died of apoplexy on the 28th July 1750. His loss was deplored as that of one of the greatest organists and pianoforte players of his time. Particularly his powers of improvisation are described as unrivalled by any of his contemporaries. Of his compositions comparatively little was known. His MS. works were at his death divided amongst his sons, and many of them have been lost in the course of time; only about one-half of his greater works were recovered, when, after the lapse of nearly a century, the verdict of his neglectful contemporaries was reversed by an admiring posterity.

The history of this Bach revival is closely connected with the name of Mendelssohn, who was amongst the first to proclaim by word and deed the powers of a genius almost too gigantic to be grasped by the receptivity of one generation. By the enthusiastic endeavours of Mendelssohn, Schumann, and others, the circle of Bach's worshippers has increased rapidly. In 1850, a century after his death, a society was started for the correct publication of all of Bach's remaining works, to which music owes the rescue from oblivion of some of its sublimest emanations. Amongst those who have vastly contributed to establish the *rapport* between our master's genius and modern lovers of art, we also mention Dr Robert Franz, himself one of Germany's greatest lyrical composers, who has edited and adapted to the resources of the modern orchestra several of Bach's most beautiful works. It remains to add a few words about Bach's position in the

history of musical development. By Marx, a well-known critical writer, he has been called the "Founder and Father of German Music;" and it cannot be denied that no other German composer before him had attained a specifically national type of musical utterance as distinguished from that of other nations. This applies both to matter and manner. Bach has frequently founded his grandest conceptions on the simplest tune of old chorales, that is, of purely popular effusions of pious fervor, such as had survived in the living memory of the nation from the time of Luther and his great revival of religious feeling. Sometimes these tunes were adapted for religious purposes from still older songs of a secular character, being thus thoroughly interwoven with the inmost feeling of the German people. In raising these simple creations of popular growth to the higher sphere of art, Bach has established his claim to the name of the creator of the *Germanic* as opposed to the *Romance* phase of musical art. This spirit of German, or to speak more accurately, North German nationality, thoughtful yet *naïve*, earnest yet tender, has also reacted on the form of Bach's creations. Bach's counterpoint, compared with the polyphonous splendour of Palestrina or Orlando di Lasso, is as it were, of a more intense, more immediately personal kind. In his sacred cantatas the alternate exclamations of the voices sometimes rise to an almost passionate fervor of devotion, such as is known only to the more individualised conception of human relations to the Deity peculiar to Protestant worship, — applying that term in a purely emotional, that is, entirely unsectarian sense. It is thus that Bach has vivified the rigid forms of the fugue with the fire of individual passion. About the peculiarities of his style, from a technical point of view, we can speak no further. How his style and his genius, neglected by his contemporaries, and obscured by other masters, like Hayden and Mozart, starting from a different basis and imbued with a different spirit, have ultimately been destined to exercise a potent spell on modern art, we have indicated already.

BACH, KARL PHILIPP EMMANUEL, second son of the above, was born at Weimar on the 14th March 1714, and died at Hamburg on the 14th September 1788. He was perhaps the most highly gifted musician of the eleven brothers, and his influence on the development of certain musical forms gives him a prominent place in the history of the art. He studied at the Thomasschule and afterwards at the university of Leipsic, devoting himself, like several of his brothers, to jurisprudence. In 1738 he took up his residence in Berlin, where he was soon afterwards appointed chamber musician to Frederick the Great. In 1767 he was allowed, after considerable negotiation, to relinquish his situation at court in order to accept the post of kapellmeister at Hamburg, where he passed the last twenty-one years of his life.

BACHE, ALEXANDER DALLAS, a distinguished American physicist, who has gained a wide reputation as superintendent of the great American Coast Survey, was a great-grandson of Benjamin Franklin, and was born at Philadelphia, 19th July 1806. In 1821 he entered the military academy at West Point, and graduated there with the highest honors in 1825. For some time he acted as assistant professor in the academy, holding at the same time a commission as lieutenant of engineers, in which capacity he was engaged for a year or two in the erection of coast fortifications. He occupied the post of professor of mathematics in the university of Pennsylvania from 1827 to 1836, and was then made president of the newly-instituted Girard College. In this capacity he undertook a journey through some of the principal countries of Europe, in order to examine their systems of education, and on his return published a very valuable report. In 1843, on the death of Professor Hassler, he was appointed by Government to the office of superintendent of the coast survey. He succeeded in impressing Congress with a sense of the great value of this work, and by means of the liberal aid it granted, he carried out a singularly comprehensive plan with great ability and most satisfactory results. By a skillful division of labor, and by the erection of numerous observing stations, the mapping out of the whole coast proceeded simultaneously under the eye of the general director. Nor were the observations confined to mere description of the coast-line; the several stations were well supplied with instruments, and a vast mass of magnetic and meteorological observations was collected, such as must infallibly prove of infinite service in the future progress of physical science. The annual reports issued by the superintendent were admirable specimens of such summaries, and secured for him a high reputation among European savants. Professor Bache contributed numerous papers to scientific journals and transactions, and labored earnestly to raise the position of physical science in America. For some months before his death, which took place at Newport, 17th February 1867, he was afflicted with softening of the brain, caused, perhaps, by intense and long-continued mental exertion.

BACHELOR, a word of various meaning, and of exceedingly obscure origin. In modern times the most common significations of it are — (1), an unmarried person; (2), one who has taken the lowest degree in any of the faculties at a university. At various times, however, it has signified either a young man in general, from which the first of the modern meanings was easily developed; or a knight who was unable to lead a body of retainers in the field, *i.e.*, to use the technical phrase, was not able *lever bannière;* or, finally, an ecclesiastic at the lowest stage of his course of training. It has also been pointed out that *bacheleria*, which meant the body of aspirants to knighthood, came to be used as synonymous with *gentry*.

Bachelors, or unmarried persons have in many countries been subjected to penal laws. The best-known examples of such legislation are those of Sparta and Rome. At Sparta, citizens who remained unmarried after a certain age were subjected to a species of *ἀτιμία*. They were not allowed to witness the gymnastic exercise of the maidens; and during winter they were compelled to march naked round the market place, singing a song composed against themselves, and expressing the justice of their punishment. The usual respect of the young to the old was not paid to bachelors.

BACHIAN, one of the East Indian islands belonging to the group of the northern Moluccas, situated immediately south of the equator. It is of an irregular form, consisting of two distinct mountainous parts, united by a low isthmus, which a slight subsidence would submerge. The area is estimated at 600 geographical square miles.

BACKGAMMON, a game played with dice, said to have been invented about the 10th century.

Backgammon is played by two persons, having between them a *backgammon board*. The board is divided into *tables*, each table being marked with six *points*, colored alternately white and black. The inner and outer tables are separated from each other by a projecting *bar*.

Two *dice* boxes are required, one for each player, and a pair of dice, which are used by both players. The dice are marked with numbers on each face from one to six, number one being called *ace;* two, *deuce;* three, *trois* (pronounced threy); four, *quatre* (katre); five, *cinque;* and six, *six* (size).

The board being arranged, each player throws one die; the one who throws the higher number has the right of playing first; and he may either adopt the throw originally made by the two players, each throwing one die; or he may throw again, using both dice.

Each player moves his own men from point to point, the moves being determined by throws of the dice made by the players alternately. A player may move any of his men a number of points corresponding to the numbers thrown by him, provided the board is not *blocked* by two or more of his adversary's men occupying the point to which he wishes to move. Thus, suppose white throws cinque, six, he may move one of his men from the left-hand corner of the black's inner table to the left-hand corner of black's outer table for six; he may, again, move the same man five points further on, viz., to the right-hand point of the same table for five, when his move is completed; or he may leave the man first moved six, and move any other man five points, where the board is open. But white cannot move a man for five from the ace point in black's inner table, because the six point in that table (*i.e.*, the fifth point from where white moves) is blocked by the black men. Any part of the throw which cannot be moved is of no effect; but it is compulsory for a player to move the whole throw if he can. Thus, if the men were differently placed, and white could move a six, and having done so could not move a five, his move is completed. If, however, by moving the five first, he can afterwards move a six, he may be required to make the move in that manner. All white's moves must be in the direction indicated, viz., from black's inner table to black's outer, and from this to white's outer table, and so on to white's inner table; and all black's moves must be in the contrary direction. Of course, where men are originally placed part of the way home, they only have to traverse the remainder of the distance.

A player in moving must not skip a point which is blocked by his adversary's men. Thus, suppose white's first throw is fives, he cannot move a man from the ace point of black's inner table to the cinque point of black's outer, although that is free; because in moving the first cinque he comes to a point which is occupied by black.

When two similar numbers are thrown (called *doublets*), the player has a double move. Thus, if he throws aces he has to move four aces instead of two, and so on for the other numbers.

When a player moves his men so as to occupy a point with two men, it is called *making a point*. Thus, if ace, trois are thrown and white moves one man from the three in his outer table to the cinque point in his inner table, for trois, and then moves a man from the six point to the cinque point of his inner table, for ace, he makes a point there.

If a player leaves only a single man on a point, or places a single man on an unoccupied point, it is called *leaving a blot*. Thus, if the first throw is six, cinque, and white carries a man from black's inner table as far as he will go, white leaves a blot on the ace point of his opponent's home table.

When a blot is left the man may be taken up, or the blot may be *hit*, if, while it remains, the adversary throws a number which will enable him to place a man on that point. For example, if a blot is left on black's ace point, as in the case previously supposed, and black throws a five, or numbers that make up five, he can hit the blot from his six point; or similarly, if he throws seven, or numbers that make up seven, he can hit the blot from the three men posted in his outer table. The man hit is placed on the bar, and has to *enter* black's inner table again at white's next throw.

It will be observed that black in taking up white leaves a blot himself, which subjects him to be taken up if white enters with an ace. If this should occur, black's man is placed on the bar, and has at his next throw to enter white's inner table, whence he has to start his journey home. Suppose white to have a blot as before on black's ace point, and black to throw sixes, black could then move two men from white's outer table to his own bar point (so called because it is close to the bar), and thence again to his own ace point, when he would hit white without leaving a blot.

The point in which a man is entered must not be blocked by two or more men belonging to the adversary. Thus, to carry on the illustration, if white now throws aces, or sixes, or six ace, he cannot enter at all. He is not allowed to move any man while he has one to enter; consequently his throw is null and void, and black throws again. It sometimes happens that one player has a man up, and that his adversary occupies all the points on his own home table with two or more men (called having his table *made up*). In this case, the player with a man up cannot enter; and as it is useless for him to throw, his adversary continues throwing until he is obliged to open a point on his inner table.

Two blots may be taken up at once if the adversary throws numbers that will hit them both. It is possible with doublets to take up four blots at once, but this could scarcely happen in a game between players of any proficiency.

The game proceeds by moving the men round towards home, or by hitting blots and sending them back, until one of the players gets all his men into his inner table or home. As soon as this stage is reached, the player who has accomplished it begins to take his men off the board or to *bear* them. Thus, suppose he has several men on every point of his table, and throws six, quatre; he bears one man from his six point, and one from his quatre point. If his six point is unoccupied, he can bear a six from his cinque point, or from the highest point which is occupied, and so on with smaller numbers, provided the numbers thrown are higher than the points occupied; if lower, the throw must be moved. A player has the option of moving a man when he can, instead of bearing it. Thus, in the case originally given the six must be borne, because a six cannot be moved; but the quatre may be moved if preferred, by moving a man from the six point to the deuce point, or from cinque point to the ace point. Doublets entitled to bear or move four men in accordance with the previous rules. The adversary similarly bears his men as soon as he gets them all home. If, after a player has commenced bearing his men, he should be hit on a blot, he must enter on his adversary's inner table, and must bring the man taken up into his own inner table before he can bear any more.

Whoever first bears all his men wins the game:—a single game or *hit* if his adversary has borne any of his men; a double game or *gammon* if the adversary has not borne a man; and a triple game or *backgammon*, if, at the time the winner bears his last man, his adversary, not having borne a man, has one in the winner's inner table.

When a series of games is played, the winner of a hit has the first throw in the succeeding game; but if a gammon is won, the players each throw a single die to determine the first move of the next game.

BACON, Francis, Baron Verulam, Viscount St. Alban, was born at York House in the Strand, London, on the 22d January 1561. He was the youngest son of Sir Nicholas Bacon, the celebrated lawyer and statesman, who for twenty years of Elizabeth's reign held the seals as lord keeper. His mother, the second wife of Sir Nicholas, was a daughter of Sir

Anthony Cooke, formerly tutor to Edward VI. She was a woman of considerable culture, well skilled in the classical studies of the period, and a warm adherent of the Reformed or Puritan Church. In April 1573 he was entered at Trinity College, Cambridge, where for three years he resided with his brother Anthony. Our information with regard to these important years is singularly scanty. We know only that Bacon at Cambridge, like Descartes at La Flêche, applied himself diligently to the several sciences as then taught, and came to the conclusion that the methods employed and the results attained were alike worthless and erroneous. Although he preserved a reverence for Aristotle (of whom, however, he seems to have known but little), he learned to despise the Aristotelian philosophy. It yielded no fruit, was serviceable only for disputation, and the end it proposed to itself was a mistaken one. Philosophy must be taught its true business, and to attain its new aim a new method must be devised. With the first germs of this great conception in his mind, Bacon left the university in 1576.

In the same year he and his brother Anthony were entered *de societate magistrorum* at Gray's Inn, and a few months later he was sent abroad with Sir Amyas Paulet, the English ambassador at Paris. He spent some time in that city, and travelled through several of the French provinces. The disturbed state of government and society in France at that time must have afforded him much valuable political instruction; and it has been commonly supposed that certain *Notes on the State of Christendom*, usually printed in his works, contain the results of his observations. But Mr. Spedding has shown that there is no reason for ascribing these "Notes" to him, and that they may be attributed with more probability to one of his brother Anthony's correspondents.

The sudden death of his father in February 1579 necessitated Bacon's return to England, and exercised a very serious influence on his fortunes. A considerable sum of money had been laid up by Sir Nicholas in order to purchase an estate for his youngest son, the only one otherwise unprovided for. Owing to his sudden death, this intention was not carried out, and but a fifth part of the money descended to Francis, who thus began his career in comparative poverty. It was one of the gravest misfortunes of his life; he started with insufficient means, acquired a habit of borrowing, and was never afterwards out of debt. As it had become absolutely necessary that he should adopt some profession by which an adequate income would be yielded, he selected that of law, and took up his residence at Gray's Inn in 1579.

Nothing throws so clear a light on the career of any great man as a knowledge of his character and aims when he made the first step into the world. We learn from this how he himself desired to shape his course, and at every point can see how far his actions correspond to the end he had placed before him. His grand and comprehensive aim, the production of good to the human race through the discovery of truth, was combined in him with the more practical desire to be of service to his country, service for which he felt himself by birth and education eminently fitted. He purposed, therefore, to obtain, if possible, some honorable post in the state which would give him the means of realising, so far as in him lay, these two great projects, and would at the same time enable him to do somewhat for the church, the third of the objects whose good he had at heart. The constant striving after these three ends is the key to Bacon's life. His qualifications for accomplishing the task he thus set before him were not small. His intellect was far-seeing and acute, quick and yet cautious, meditative, methodical, and free from prejudice. If we add to this account what Bacon himself does not tell us — that he seems to have been of an unusually sweet temper and amiable disposition — we shall have a fairly complete picture of his mental character at the critical period of his entry into the world.

In 1580 he appears to have taken the first step in his projected career by applying, through his uncle, Burghley, for some post at court. His suit, though well received by the queen and the lord treasurer, was unsuccessful: the particulars of it are totally unknown. For two years after this disappointment he worked quietly at Gray's Inn, and in 1582 was admitted an outer barrister. In 1584 he took his seat in Parliament for Melcombe in Dorsetshire, but the notes for the session do not disclose what part he took or what reputation he gained. About the same time he made another application to Burghley, apparently with a view to expediting his progress at the bar. His uncle, who appears to have "taken his zeal for ambition," wrote him a severe letter, taking him to task for arrogance and pride, qualities which Bacon vehemently disclaimed. It is uncertain what success attended this suit; but as his advancement at the bar was unusually rapid, his uncle's influence may not improbably have been exerted in his behalf. Some years later, in 1589, he received the first substantial piece of patronage from his powerful kinsman, the reversion of the clerkship of the Star Chamber being granted to him. The office was valuable, worth about £1600 a year; but it did not become vacant for nearly twenty years, and was thus, as Bacon used to say, "like another man's ground buttailing upon his house, which might mend his prospect, but did not fill his barn." A considerable period of his life had thus slipped away, and his affairs had not prospered. He had written on the condition of parties in the church; he had set down his thoughts on philosophical reform in the lost tract, *Temporus Partus Maximus;* but he had failed in obtaining the position which he looked upon as an indispensable condition of success. A long and eloquent letter to Burghley, written under these circumstances, gives a vivid picture of his mental state, throws additional light upon his character and aims, and at the same time gives a slight hint as to the cause of his uncle's slackness in promoting him.

Some time before this, perhaps as early as 1588, Bacon appears to have become acquainted with Essex, the impetuous and headstrong favorite of Elizabeth's later years. At the close of 1591 he was acting as the earl's confidential adviser, and in the following year Anthony Bacon, returning from the Continent, was also introduced to the young nobleman, and the two brothers exerted themselves diligently in his service. In Feb. 1593 Parliament was called, and Bacon took his seat as member for Middlesex. The special occasion for which the House had been summoned was the discovery of one of the numerous Popish plots that distracted Elizabeth's reign. The conspiracy seemed to be formidable, and Government felt the necessity for increased supplies. As Bacon's conduct in this emergency seriously affected his fortunes, and has been much misunderstood, it is necessary to state, as briefly as possible, the whole facts of the case. The House having been duly informed of the state necessities, assented to a double subsidy, and appointed a committee to draw up the requisite articles. Before this was completed, a message arrived from the House of Lords requesting a conference, which was granted. The committee of the Commons were then informed that the crisis demanded a triple subsidy to be collected in a shorter time than usual, that the Lords could not assent to less than this, and that they desired to confer on the matter. This proposal of the Lords

to discuss supply infringed upon the privileges of the Commons; accordingly, when the report of committee was read to the lower House, Bacon stood up and spoke against the proposed conference, pointing out at the same time that a communication from the Lords might be received, but that the actual deliberation on it must be taken by themselves alone. His motion, after some delay, was carried, and the conference was rejected. The Lords upon this lowered their demands, and desired merely to make a communication, which, being legitimate, was at once assented to. The House had then before them the proposal for a triple subsidy, to be collected in three, or, as the motion ultimately was shaped, in four years, instead of in six, as the ordinary custom would have been. Bacon, who approved of the increased subsidy, was opposed to the short period in which it was proposed to be raised. He suggested that it would be difficult or impossible for the people to meet such heavy demands, that discontent and trouble would arise, and that the better method of procedure was to raise money by levy or imposition. His motion appears to have received no support, and the four years' subsidy was passed unanimously. Bacon, as it turned out, had been mistaken in thinking that the country would be unable to meet the increased taxation, and his conduct, though prompted by a pure desire to be of service to the queen, gave deep and well-nigh ineradicable offence. He was accused of seeking popularity, and was for a time excluded from the court. His letter to Burghley, who had told him of the queen's displeasure with his speech, offers no apology for what he had said, but expresses regret that his motives should have been misunderstood, and that any offence should have been taken. He soon felt that the queen's anger was not to be appeased by such a justification. The attorney-generalship had fallen vacant, and Bacon became a candidate for the office, his most formidable rival being his life-long antagonist, Coke, who was then solicitor. Essex warmly espoused Bacon's cause, and earnestly pressed his claims upon the queen; but his impetuous, pettish pleading tended rather to retard than advance the cause. Burghley, on the other hand, in no way promoted his nephew's interest; he would recommend him for the solicitorship, but not for the attorney-generalship; and it is not improbable that Sir Robert Cecil secretly used his influence against his cousin. The queen delayed the appointment, and Bacon's fortunes, as they then stood, could ill brook delay. He was harassed with debt, and at times so disheartened that he contemplated retirement from public life and devotion to abstract studies. In March 1594 it was at last understood that Coke was to be attorney-general. Essex though bitterly mortified, at once threw all his energies into the endeavor to procure for Bacon the solicitorship; but in this case also, his method of dealing, which was wholly opposed to Bacon's advice, seemed to irritate, instead of conciliating the queen. The old offence was not yet forgiven, and after a tedious delay, the office was given, in Oct. 1595, to Sergeant Fleming. Burghley and Puckering seem to have assisted Bacon honestly, if not overwarmly, in this second application; but the conduct of Cecil had roused suspicions which were not perhaps without foundation. Essex, to compensate in some degree for Bacon's disappointment, insisted upon presenting him with a piece of land, worth about £1800, and situated probably near Twickenham Park. Nor did his kindness cease there; before sailing on the expedition to Cadiz, in the beginning of 1596, he addressed letters to Buckhurst, Fortescue, and Egerton, earnestly requesting them to use their influence toward procuring for Bacon the vacant office of master of the rolls. Before anything came of this application, the Cadiz expedition had resulted in a brilliant success, and Essex became the idol of the army and the people. Bacon saw clearly that such a reputation would assuredly alienate the affections of the queen, who loved not to have a subject too powerful or too popular. He therefore addressed an eloquent and imploring letter to the earl, pointing out the dangers of his position, and urging upon him what he judged to be the only safe course of action, to seek and secure the favor of the queen alone; above all things dissuading him from the appearance of military popularity. His advice, however, was unpalatable and proved ineffectual. The earl still continued his usual course of dealing with the queen, depending solely upon her supposed affection for him, and insanely jealous of any other whom she might seem to favor. His unskilful and unlucky management of the sea expedition to Ferrol and the Azores in no way lowered his popularity with the people, but undoubtedly weakened his influence with the queen.

Bacon's affairs in the meantime had not been prospering. He had increased his reputation by the publication, in 1597, of his *Essays*, along with which were the *Colors of Good and Evil* and the *Meditationes Sacræ*; but his private fortunes were in a bad condition. No public office apparently could be found for him; he failed in the endeavor to retrieve his position by marriage with the wealthy widow, Lady Hatton, and in 1598 he was arrested for debt. He seems, however, to have been growing in favor with the queen. Some years previously (perhaps about 1594), he had begun to be employed by her in crown affairs, and he gradually acquired the standing of one of the learned counsel, though he held no commission or warrant, and received no salary. At the same time he was no longer on the former friendly terms with Essex, a certain estrangement having sprung up between them, caused no doubt by the earl finding his friend's advice distasteful. The earl's affairs were then at a somewhat critical stage, and as our judgment upon a most important episode in Bacon's life depends upon our knowledge of the events of the ensuing year, it will be requisite to enter more minutely than would otherwise be necessary into proceedings with which Bacon himself had nothing to do.

Ireland was then in a rebellious and discontented condition, and it was somewhat difficult for the English Government to decide either on a definite course of policy with regard to it, or on a leader by whom that policy might be carried out. Upon this subject a violent quarrel took place between the queen and Essex, who for some months retired from court, and refused to be reconciled. At last he came forth from his seclusion, and it was soon understood that he was in person to undertake the subjugation of the rebels in Ireland, with a larger force than had ever before been sent into that country. Into the obscure details of this unhappy campaign it is unnecessary to enter; one fact stands out clearly, that Essex endeavored to carry out a treasonable design. His jealousy and ill temper had been so roused that the only course open to him seemed to be the obtaining a powerful military force, the possession of which would compel the queen to reinstate him in her favor. Whether or not this plan was in contemplation before he undertook the Irish expedition is not evident, though even outsiders at that time entertained some suspicions, but there can be no doubt of the treasonable character of the negotiations carried on in Ireland. His plans, probably not very definite, were disturbed by an imperative message from the queen, ordering him not to return to England without her permission. He at once set off, and, trusting apparently to her affection for him, presented himself suddenly before her. He was, for the moment, received kindly, but

was soon afterwards ordered to keep his chamber, and was then given into the custody of the lord keeper at York House, where he remained till March 1600. His great popularity, and the general ignorance of the reasons for his imprisonment, stirred up a strong feeling against the queen, who was reported to be influenced by Bacon, and such indignation was raised against the latter, that his friends feared his life would be in danger. The groundless character of this accusation shows how little confidence should be reposed in popular versions of obscure occurrences. It was at last felt necessary that the queen should in some way vindicate her proceedings, and this she at first did, contrary to Bacon's advice, by a declaration from the Star Chamber. This, however, gave little or no satisfaction, and it was found expedient to do what Bacon had always recommended, to have a fair trial, yet not one in which the sentence must needs be damaging to the earl. The trial accordingly took place before a body of her majesty's councillors, and Bacon had a subordinate and unimportant part in the accusation. Essex does not seem to have been at all hurt by his action in this matter, and shortly after his release they were again on friendly terms, Bacon drawing up letters as if to or from the earl with the design of having them brought before the queen. But Bacon did not know the true character of the transactions in which Essex had been engaged. The latter had been released from all custody in August, but in the meantime he had been busily engaged in treasonable correspondence with James of Scotland, and was counting on the Irish army under his ally, Montjoy, the new deputy. But Montjoy had apparently come to see how useless the attempt would be to force upon the queen a settlement of the succession, and declined to go further in the matter. Essex was thus thrown upon his own resources, and his anger against the queen being aroused afresh by the refusal to renew his monopoly of sweet wines, he formed the desperate project of seizing her person and compelling her to dismiss from her council his enemies Raleigh, Cobham, and Cecil. As some pretext, he intended to affirm that his life was in danger from these men, who were in league with the Spaniards. The plot was forced on prematurely by the suspicions excited at court, and the rash attempt to rouse the city of London (8th February 1601) proved a complete *fiasco*. The leaders were arrested that night and thrown into prison. Although the actual rising might have appeared a mere outburst of frantic passion, the private examinations of the most prominent conspirators disclosed to the Government a plot so widely spread, and involving so many of the highest in the land, that it would have been perilous to have pressed home accusations against all who might be implicated. Essex was tried along with the young earl of Southampton, and Bacon, as one of her majesty's counsel, was present on the occasion. Coke, who was principal spokesman, managed the case with great want of skill, incessantly allowing the thread of the evidence to escape, and giving the prisoners opportunity to indulge in irrelevant justifications and protestations which were not ineffectual in distracting attention from the real question at issue. On the first opportunity Bacon rose and briefly pointed out that the earl's plea of having done nothing save what was absolutely necessary to defend his life from the machinations of his enemies was weak and worthless, inasmuch as these enemies were purely imaginary; and he compared his case to that of Pisistratus, who had made use of a somewhat similar stratagem to cloak his real designs upon the city of Athens. He was thereupon interrupted by the earl, who proceeded to defend himself, by declaring that in one of the letters drawn up by Bacon, and purporting to be from the earl to Anthony Bacon the existence of these rumors, and the dangers to be apprehended from them, had been admitted; and he continued, "If these reasons were then just and true, not counterfeit, how can it be that now my pretences are false and injurious?" To this Bacon replied, that "the letters, if they were there, would not blush to be seen for anything contained in them, and that he had spent more time in vain in studying how to make the earl a good servant to the queen than he had done in anything else." It seems to be forgotten in the general accounts of this matter, not only that Bacon's letters bear out what he said, but that the earl's excuses *were* false. A second time Bacon was compelled to interfere in the course of the trial, and to recall to the minds of those present the real question at issue. He animadverted strongly upon the puerile nature of the defence, and in answer to a remark by Essex, that if he had wished to stir up a rebellion he would have had a larger company with him, pointed out that his dependence was upon the people of London, and compared his attempt to that of the duke of Guise at Paris. To this the earl made little or no reply. Bacon's use of this illustration, and of the former one of Pisistatus, has been much commented on, and in general it seems to have been thought that had it not been for his speeches Essex might have escaped, or, at all events, have been afterwards pardoned. But this view of the matter depends on the supposition that Essex was guilty only of a rash outbreak. That this was not the case was well known to the queen and her council. Unfortunately, prudential motives hindered the publication of the whole evidence; the people, consequently, were still ignorant of the magnitude of the crime, and, till recently, biographers of Bacon have been in like ignorance. The earl himself, before execution, confessed his guilt and the thorough justice of his sentence, while, with singular lack of magnanimity, he incriminated several against whom accusations had not been brought, among others his sister Lady Rich. After his execution it was thought necessary that some account of the facts should be drawn up and circulated, in order to remove the prejudice against the queen's action in the matter. This was intrusted to Bacon, who drew up a *Declaration of the Practices and Treasons attempted and committed by Robert, late Earl of Essex*, his first draft being extensively altered and corrected by the queen and council. Nothing is known with certainty of the reception given to this official explanation, but the ill feeling against Bacon was not wholly removed, and some years later, in 1604, he published, in the form of a letter to Montjoy, an *Apology* for his action in the case. This *Apology* gives a most fair and temperate history of the relations between Bacon and Essex, shows how the prudent counsel of the one had been rejected by the other, and brings out very clearly what we conceive to be the true explanation of the matter. Everything that Bacon could do was done by him, until the real nature of Essex's design was made apparent, and then, as he had repeatedly told the earl, his devotion and respect were for the queen and state, not for any subject; friendship could never take rank above loyalty. Those who blame Bacon must acquit Essex of all wrong-doing.

Bacon's private fortunes, during the period after the death of Essex, were not in a flourishing condition. He had obtained a grant of £1200 from the fines imposed on Catesby, one of the conspirators, but his debts were sufficient to swallow up this and much more. And, though he was trusted by Elizabeth, and on good terms with her, he seems to have seen that he had no chance of advancement. But her death in 1603, followed by the undisputed succession of James, gave him

new hopes; to use his own expression, he found himself "as one awaked out of sleep." It appeared to him that at length the abilities he was conscious of possessing would obtain recognition; he thought that "the canvassing world" had gone, and the "deserving world" had come. He used every means in his power to bring himself under James' notice, writing to all his friends at the Scottish court and to the king himself. He managed to obtain a personal interview with the king but does not seem to have been much satisfied with it. In fact, while the king confirmed in their situations, those who had held crown offices under Elizabeth, Bacon, not holding his post by warrant, was practically omitted. He was, however, continued, by special order of the king, as learned counsel extraordinary, but little or no law business appears to have been intrusted to him. He procured, through his cousin Cecil, the dignity of knighthood, which, contrary to his inclination, he received along with about 300 others, on the 23d July 1603. Between this time and the opening of James' first Parliament he was engaged in literary work, and sent to the king two pamphlets — one on the Union, the other on measures for the pacification of the church. What opinion was formed of them by James is unknown. Shortly after he published his *Apology;* the reception it met with is equally uncertain. In March 1604 Parliament met, and during their short session Bacon's hands seem to have been full of work, It was a busy and stirring time, and events occurred during it which carried within them the seeds of much future dissension. Prerogative and privilege came more than once into collision, the abuses of purveyance and wardship were made matters of conference, though the thorough discussion of them was deferred to a succeeding session; while James' temper was irritated by the objections brought against his favorite scheme of the Union, and by the attitude taken up by the House with regard to religious affairs. The records are barely full enough to enable us to judge very accurately of the share taken by Bacon in these discussions; his name generally appears as the reporter of the committees on special subjects. We can occasionally, however, discern traces of his tact and remarkable prudence; and, on the whole, his attitude, particularly with regard to the Union question, recommended him to James. He was shortly afterwards formally installed as learned counsel, receiving the salary of £40, and at the same time a pension of £60 yearly. He was also appointed one of the commission to treat of the conditions necessary for the Union; and the admirable manner in which the duties of that body were discharged must be attributed mainly to his influence and his complete mastery of the subject. During the recess he published his *Advancement of Learning*, dedicated to the king.

He was now fairly brought into relations with James, and his prospects began to look a little brighter. It is important for us to know what were his ideas upon government, upon parliaments, prerogative, and so forth, since a knowledge of this will clear up much that would seem inexplicable in his life. It seems quite evident that Bacon, from position, early training, and, one might almost think, natural inclination, held as his ideal of government the Elizabethan system. The king was the supreme power, the centre of law and justice, and his prerogative must not be infringed. Parliament was merely a body called to consult with the king on emergencies (*circa ardua regni*) and to grant supplies. King and parliament together make up the state, but the former is first in nature and importance. The duty of a statesman was, therefore, to carry out the royal will in as prudent a manner as possible; he was the servant of the king, and stood or fell according to his pleasure. It is hard to put ourselves at this point of view, and we can with difficulty understand how such a man as Bacon held a theory which seems now so inadequate. But he was not singular in his opinions, and he was undoubtedly sincere; and it is only by keeping them constantly in mind that we can understand his after relations with the king.

In the second Parliament there was not so much scope for the exercise of his powers. The Gunpowder Plot had aroused in the Commons warmer feelings towards the king; they passed severe laws against recusants, and granted a triple subsidy. At the same time they continued the collection of the grievances concerning which they were to move. In the course of this session Bacon married Alice Barnham, "the alderman's daughter, an handsome maiden, to my liking," of whom he had written some years before to his cousin Cecil. Little or nothing is known of their married life.

The third Parliament was chiefly occupied with the commercial and legal questions rising out of the proposed Union, in particular, with the dispute as to the naturalisation of the *Post Nati*. Bacon argued ably in favor of this measure, but the general feeling was against it. The House would only pass a bill abolishing hostile laws between the kingdoms; but the case of the *Post Nati*, being brought before the law courts, was settled as the king wished. Bacon's services were rewarded in June 1607 by the office of solicitor; he had at last gained a step upon the ladder of advancement. His promotion, however, was not rapid; several years passed before he gained another step. Meantime, though circumstances had thrown him too much into active life, he had not forgotten his cherished project of reorganising science. A survey of the ground had been made in the *Advancement*, and some short pieces not published at the time were probably written in the subsequent two or three years. Towards the close of 1607 he sent to his friends a small tract, entitled *Cogitata et Visa*, probably the first draft of what we have under that title. In 1609 he wrote the noble panegyric, *In felicem memoriam Elizabethæ*, and the curiously learned and ingenious work *De Sapientia Veterum;* and completed what seems to have been the *Redargutio Philosophiarum*, or treatise on the idols of the theatre.

In 1610 the famous fourth Parliament of James met. It is not possible to enter minutely into the important occurrences of this short session. Prerogative, despite Bacon's advice and efforts, clashed more than once with liberty; Salisbury's bold schemes for relieving the embarrassment caused by the reckless extravagance of the king proved abortive, and the House was dissolved in February 1611. Bacon took a considerable share in the debates, consistently upheld the prerogative, and seemed yet to possess the confidence of the Commons. The death of Salisbury, occurring soon after, opened a position in which Bacon thought his great political skill and sagacity might be made more immediately available for the king's service. How far he directly offered himself for the post of secretary is uncertain, but we know that his hopes were disappointed, the king himself undertaking the duties of the office. About the same time he made two ineffectual applications for the mastership of the wards; the first, on Salisbury's death, when it was given to Sir George Carey; the second, on the death of Carey. It is somewhat hard to understand why so little favor was shown by the king to one who had proved himself able and willing to do good service, and who, in spite of his disappointments, still continued zealously to offer advice and assistance. At last, in 1613, a fair opportunity for promotion occurred. The death of Sir Thomas Fleming made a vacancy in the chief-justice-

ship of the King's Bench, and Bacon, after some deliberation, proposed to the King that Coke should be removed from his place in the Court of Common Pleas and transferred to the King's Bench. He gives several reasons for this in his letter to the king, but in all probability his chief motive was that pointed out by Mr. Spedding, that in the Court of King's Bench there would be less danger of Coke coming into collision with the king on questions of prerogative, in handling which Bacon was always very circumspect and tender. The vacancy caused by Coke's promotion was then filled up by Hobart, and Bacon, finally, stepped into the place of attorney-general. The fact of this advice being offered and followed in all essentials, illustrates very clearly the close relations between the king and Bacon, who had become a confidential adviser on most occasions of difficulty. That his adherence to the royal party was already noticed and commented on appears from the significant remark of Chamberlain, who, after mentioning the recent changes among the law officials, says, "There is a strong apprehension that little good is to be expected by this change, and that Bacon may prove a dangerous instrument."

Further light is thrown upon Bacon's relations with James, and upon his political sympathies, by the letter to the king advocating the calling of a parliament, and by the two papers of notes on which his letter was founded. These documents, even after due weight is given to all considerations urged in their favor, seem to confirm the view already taken of Bacon's theory of government, and at the same time to show that his sympathies with the royal party tended to blind him to the true character of certain courses of action, which can only be justified by a straining of political ethics. The advice he offered, in all sincerity, was most prudent and sagacious, and *might* have been successfully carried out by a man of Bacon's tact and skill; but it was intensely one-sided, and exhibited a curious want of appreciation of what was even then beginning to be looked on as the true relation of king, parliament, and people. Unfortunately for James, he could neither adopt nor carry out Bacon's policy. The Parliament which met in April 1614 and was dissolved in June, after a stormy session, was by no means in a frame of mind suitable for the king's purposes. The House was enraged at the supposed project (then much misunderstood) of the "Undertakers;" objection was taken to Bacon being elected or serving as a member while holding office as attorney-general; and, though an exception was made in his favor, it was resolved that no attorney-general should in the future be eligible for a seat in Parliament. No supply was granted, and the king's necessities were increased instead of diminished. The emergency suggested to some of the bishops the idea of a voluntary contribution, which was eagerly taken up by the noblemen and crown officials. The scheme was afterwards extended so as to take in the whole kingdom, but lost something of its voluntary character, and the means taken to raise the money, which were not what Bacon would have recommended, were calculated to stir up discontent. The general dissatisfaction received a somewhat unguarded and intemperate expression in a letter sent to the justices of Marlborough by a gentleman of the neighborhood, named St. John, in which he denounced the attempt to raise funds in this way as contrary to law, reason, and religion, as constituting in the king personally an act of perjury, involving in the same crime those who contributed, and thereby subjecting all parties to the curses levelled by the church at such offences. St. John was summoned before the Star Chamber for slander and treasonable language, and Bacon, *ex officio*, acted as public prosecutor. The sentence pronounced (a fine of £5000 and imprisonment for life) was severe, but it was not actually inflicted, and probably was not intended to be carried out, the success of the prosecution being all that was desired. St. John remained a short time in prison, and was then released, after making a full apology and submission. The fine was remitted. It seems incredible that Bacon's conduct on this occasion should have been censured by his biographers. The offence was clear; the law was undoubted; no particular sympathy was excited for the culprit; the sentence was not carried out; and Bacon did only what any one in his place would naturally and necessarily have done. The nature of his office involved him in several trials for treason occurring about the same time, and one of these is of interest sufficient to repay a somewhat longer examination. Edmund Peacham, a clergyman in Somersetshire, had been committed to custody for a libel on his superior, the bishop of Bath and Wells. In searching his house for certain papers, the officers came upon some loose sheets stitched together in the form of a sermon, the contents of which were of such a nature that it was judged right to lay them before the council. As it was at first suspected that the writing of this book had been prompted by some disaffected persons, Peacham was interrogated, and after he had declined to give any information, was subjected to torture. Bacon, as one of the learned counsel, was ordered by council to take part in this examination, which was undoubtedly warranted by precedent, whatever may now be thought of it. Nothing, however, was extracted from Peacham in this way, and it was resolved to proceed against him for treason. Now, in the excited state of popular feeling at that period, the failure of Government to substantiate an accusation of treason would have been a serious matter. The king, with whom the council agreed, seems therefore to have thought it desirable to obtain beforehand the opinions of the four chief judges as to whether the alleged offence amounted to treason. In this there was nothing unusual or illegal, and no objection would at that time have been made to it, but James introduced a certain innovation; he proposed that the opinions of the four judges should be given separately and in private. It may be reasonably inferred that his motive for this was the suspicion, or it may be the knowledge, that Coke did not consider the matter treasonable. At all events when Coke, who as a councillor already knew the facts of the case, was spoken with regarding the new proposal of the king, he at once objected to it, saying that "this particular and auricular taking of opinions" was "new and dangerous," and "not according to the custom of the realm." He at last reluctantly assented, and proposed that Bacon should consult with him, while the other law officers addressed themselves to the three puisne judges. By Bacon's directions, the proposal to the three judges to give their opinions separately was made suddenly and confidently, and any scruples they might have felt were easily overcome. The first step was thus gained, and it was hoped that if "infusion" could be avoided, if the papers bearing on the case were presented to the judges quickly, and before their minds could be swayed by extraneous influence, their decision on the case would be the same as that of the king. It is clear that the extraneous influence to be feared was Coke, who, on being addressed by Bacon, again objected to giving his opinion separately, and even seemed to hope that his brother judges after they had seen the papers would withdraw their assent to giving their decisions privately. Even after the discussion of the case with Bacon, he would not give his opinion until the others had handed in theirs. What the other judges thought is not definitely known, but Bacon

appears to have been unable to put in operation the plan he had devised for swaying Coke's judgment, by putting him in some dark manner in doubt that he should be left alone; or if he did attempt this, he was unsuccessful, for Coke finally gave an opinion consistent with what he seems to have held at first, that the book was not treasonable, as it did not disable the king's title. Although the opinions of the judges were not made public, yet as we learn, not only from Bacon, but from a sentence in one of Carleton's letters, a rumor had got about that there was doubt as to the book being treasonable. Under these circumstances, Bacon, who feared that such a report might incite other people to attempt a similar offence, proposed to the king that a second rumor should be circulated in order to destroy the impression caused by the first. "I do not think it necessary," he says, "that because we live in an age in which no counsel is kept, and that it is true there is some bruit abroad that the judges of the King's Bench do doubt of the case that it should not be treason, that it be given out constantly, and yet as it were in secret, and so a fame to slide, that the doubt was only upon the publication, in that it was never published. For that (if your majesty marketh it) taketh away or at least qualifieth the danger of the example; for that will be no man's case." Bacon's conduct in this matter has been curiously misrepresented. He has been accused of torturing the prisoner, and of tampering with the judges by consulting them before the trial; nay, he is even represented as selecting this poor clergyman to serve for an example to terrify the disaffected, as breaking into his study and finding there a sermon never intended to be preached, which merely encouraged the people to resist tyranny. All this lavish condemnation is wide of the mark, and rests on a complete misconception of the case. If any blame attaches to him, it must arise either from his endeavor to force Coke to a favorable decision, in which he was in all probability prompted by a feeling, not uncommon with him, that a matter of state policy was in danger of being sacrificed to some senseless legal quibble or precedent, or from his advice to the king that a rumor should be set afloat which was not strictly true. We do not imagine that in any other politician either of these actions would meet with very severe condemnation.

Meanwhile, his great rival Coke, whose constant tendency to limit the prerogative by law and precedent had made him an object of particular dislike to James, had on two points come into open collision with the king's rights. The first case was an action of *præmunire* against the Court of Chancery, evidently instigated by him, but brought at the instance of certain parties whose adversaries had obtained redress in the chancellor's court after the cause had been tried in the Court of King's Bench. With all his learning and ingenuity, Coke failed in inducing or even forcing the jury to bring in a bill against the Court of Chancery, and it seems fairly certain that on the technical point of law involved he was wrong. Although his motive was, in great measure, a feeling of personal dislike toward Ellesmere, yet it is not improbable that he was influenced by the desire to restrict in every possible way the jurisdiction of a court which was the direct exponent of the king's wishes. The other case, that of *commendamus*, was more important in itself and in the circumstances connected with it. The general question involved in a special instance was whether or not the king's prerogative included the right of granting at pleasure livings *in commendam*, *i. e.*, to be enjoyed by one who was not the incumbent. Bacon, as attorney-general, delivered a speech, which has not been reported, but the king was informed that the arguments on the other side had not been limited to the special case, but had directly impugned the general prerogative right of granting livings. It was necessary for James, as a party interested, at once to take measures to see that the decision of the judges should not be given on the general question without due consultation. He accordingly wrote to Bacon, directing him to intimate to the judges his pleasure that they should delay judgment until after discussion of the matter with himself. Bacon communicated first with Coke, who in reply desired that similar notice should be given the other judges. This was done by Bacon, though he seems to hint that in so doing he was going a little beyond his instructions. The judges took no notice of the intimation, proceeded at once to give judgment, and sent a letter in their united names to the king, announcing what they had done, and declaring that it was contrary to law and to their oath for them to pay any attention to a request that their decision should be delayed. The king was indignant at this encroachment, and acting partly on the advice of Bacon, held a council on the 6th June 1616, at which the judges attended. James then entered at great length into the case, censuring the judges for the offensive form of their letter, and for not having delayed judgment upon his demand, which had been made solely because he was himself a party concerned. The judges, at the conclusion of his speech, fell on their knees, and implored pardon for the manner of their letter; but Coke attempted to justify the matter contained in it, saying that the delay required by his majesty was contrary to law. The point of law was argued by Bacon, and decided by the chancellor in favor of the king, who put the question to the judges individually, "Whether, if at any time, in a case depending before the judges, which his majesty conceived to concern him either in power or profit, and thereupon required to consult with them, and that they should stay proceedings in the meantime, they ought not to stay accordingly?" To this all gave assent except Coke, who said that "when the case should be, he would do that should be fit for a judge to do." No notice was taken by the king of this famous, though somewhat evasive, reply, but the judges were again asked what course they would take in the special case now before them. They all declared that they would not decide the matter upon general grounds affecting the prerogative, but upon special circumstances incident to the case; and with this answer they were dismissed. Bacon's conduct throughout the affair has been blamed, but apparently on wrong grounds. As attorney he was merely fulfilling his duty in obeying the command of the king; and in laying down the law on the disputed point, he was, we may be sure, speaking his own convictions. Censure might more reasonably be bestowed on him, because he deliberately advised a course of action than which nothing can be conceived better calculated to strengthen the hands of an absolute monarch. This appeared to Bacon justifiable and right, because the prerogative would be defended and preserved intact. Coke certainly stands out in better light, not so much for his answer, which was rather indefinite, and the force of which is much weakened by his assent to the second question of the king, but for the general spirit of resistance to encroachment exhibited by him. He was undeniably troublesome to the king, and it is no matter for wonder that James resolved to remove him from a position where he could do so much harm. On the 26th June he was called before the council to answer certain charges, one of which was his conduct in the *præmunire* question. He acknowledged his error on that head, and made little defence. On the 30th he was suspended from council and bench, and ordered to employ his leisure in revising certain obnoxious opinions in his

reports. He did not perform the task to the king's satisfaction, and a few months later he was dismissed from office.

Bacon's services to the king's cause had been most important; and as he had, at the same time, acquired great favor with Villiers, his prospects looked brighter than before. According to his custom, he strove earnestly to guide by his advice the conduct of the young favorite. His letters, in which he analyses the various relations in which such a man must stand, and prescribes the course of action suitable for each, are valuable and deserving of attention. Very striking, in view of future events, are the words in which he gives him counsel as to his dealing with judges: "By no means be you persuaded to interpose yourself by word or letter in any cause depending, or like to be depending, in any court of justice, nor suffer any man to do it where you can hinder it; and by all means dissuade the king himself from it, upon the importunity of any, either for their friends or themselves. If it should prevail, it perverts justice; but if the judge be so just, and of so undaunted a courage (as he ought to be) as not to be inclined thereby, yet it always leaves a taint of suspicions and prejudice behind it." It is probable that Villiers at this time had really a sense of the duties attaching to his position, and was willing to be guided by a man of approved wisdom. It was not long before an opportunity occurred for showing his gratitude and favor. Ellesmere resigned the chancellorship on the 5th March 1617, and on the 7th the great seal was bestowed upon Bacon, with the title of Lord Keeper. Two months later he took his seat with great pomp in the Chancery Court, and delivered a weighty and impressive opening discourse. He entered with great vigor on his new labors, and in less than a month he was able to report to Buckingham that he had cleared off all outstanding Chancery cases. He seemed now to have reached the height of his ambition; he was the first law officer in the kingdom, the accredited minister of his sovereign, and on the best terms with the king and his favorite. His course seemed perfectly prosperous and secure, when a slight storm arising opened his eyes to the frailty of the tenure by which he held his position.

Coke was in disgrace but not in despair; there seemed to be a way whereby he could reconcile himself to Buckingham, through the marriage of his daughter, who had an ample fortune, to Sir John Villiers, brother of the marquis, who was penniless or nearly so. The match was distasteful to Lady Hatton and to her daughter; a violent quarrel was the consequence, and Bacon, who thought the proposed marriage most unsuitable, took Lady Hatton's part. His reasons for disapproval he explained to the king and Buckingham, but found to his surprise that their indignation was strongly roused against him. He received from both bitter letters of reproof; it was rumored that he would be disgraced, and Buckingham was said to have compared his present conduct to his previous unfaithfulness to Essex. Bacon, who seems to have acted from a simple desire to do the best for Buckingham's own interests, at once changed his course, advanced the match by every means in his power, and by a humble apology appeased the indignation that had been excited against him. It had been a sharp lesson, but things seemed to go on smoothly after it, and Bacon's affairs prospered. In January 1618 he received the higher title Lord Chancellor; in July of the same year he was made Baron Verulam; and in January 1621 he was created Viscount St. Alban. His fame, too, had been increased by the publication in 1620 of his most celebrated work, the *Novum Organum*. He seemed at length to have made satisfactory progress towards the realisation of his cherished aims; the method essential for his Instauration was partially completed; and he had attained as high a rank in the state as he had ever contemplated. But history too clearly tell us that his actions in that position were not calculated to promote the good of his country.

Connected with the years during which he held office is one of the weightiest charges against his character. Buckingham, notwithstanding the advice he had received from Bacon himself, was in the habit of addressing letters to him recommending the causes of suitors. In many cases these seem nothing more than letters of courtesy, and from the general tone, it might fairly be concluded that there was no intention to sway the opinion of the judge illegally, and that Bacon did not understand the letters in that sense. This view is supported by consideration of the few answers to them which are extant. One outstanding case, however, that of Dr. Steward, casts some suspicion on all the others. The terms of Buckingham's note concerning it might easily have aroused doubts; and we find that the further course of the action was to all appearances exactly accommodated to Dr. Stewart, who had been so strongly recommended. It is, of course, dangerous to form an extreme judgment on an isolated and partially understood case, of which also we have no explanation from Bacon himself, but if the interpretation given by Mr. Heath be the true one, Bacon certainly suffered his first, and so far as we can see, just judgment on the case to be set aside, and the whole matter to be reopened in obedience to a request from Buckingham.

It is somewhat hard to understand Bacon's position with regard to the king during these years. He was the first officer of the crown, the most able man in the kingdom, prudent, sagacious, and devoted to the royal party. Yet his advice was followed only when it chimed in with James's own will; his influence was of a merely secondary kind; and his great practical skill was employed simply in carrying out the measures of the king in the best mode possible. We know indeed that he sympathised cordially with the home policy of the Government; he had no objection to such monopolies or patents as seemed advantageous to the country, and for this he is certainly not to be blamed. The opinion was common at the time, and the error was merely ignorance of the true principles of political economy. But we know also that the patents were so numerous as to be oppressive, and we can scarcely avoid inferring that Bacon more readily saw the advantages to the Government than the disadvantages to the people. In November, 1620, when a new parliament was summoned to meet on January following, he earnestly pressed that the most obnoxious patents, those of alehouses and inns, and the monopoly of gold and silver thread, should be given up, and wrote to Buckingham, whose brothers were interested, advising him to withdraw them from the impending storm. This prudent advice was unfortunately rejected. But while he went cordially with the king in domestic affairs, he was not quite in harmony with him on questions of foreign policy. Not only was he personally in favor of a war with Spain for the recovery of the Palatinate, but he foresaw in such a course of action the means of drawing together more closely the king and his Parliament. He believed that the royal difficulties would be removed if a policy were adopted with which the people could heartily sympathise, and if the king placed himself at the head of his Parliament and led them on. But his advice was neglected by the vacillating and peace-loving monarch, his proffered proclamation was put aside, and a weak, featureless production substituted in its place. Nevertheless the new Parliament seemed at first more responsive than might have been looked for. A double subsidy was granted, which was expressly

stated to be "not on any consideration or condition for, or concerning the Palatinate." The session, however, was not far advanced when the question of patents was brought up; a determined attack was made upon the very ones of which Bacon had been in dread, and it was even proposed to proceed against the referees (Bacon and Montagu) who had certified that there was no objection to them in point of law. This proposal, though pressed by Coke, was allowed to drop; while the king and Buckingham, acting under the advice of Williams, afterwards lord keeper, agreed to give up the monopolies. It was evident, however, that a determined attack was about to be made upon Bacon, and that the proceeding against the referees was really directed against him. It is probable that this charge was dropped because a more powerful weapon had in the meantime been placed in his enemies' hands. This was the accusation of bribery and corrupt dealings in Chancery suits, an accusation apparently wholly unexpected by Bacon, and the possibility of which he seems never to have contemplated until it was actually brought against him. At the beginning of the session a committee had been appointed for inquiring into abuses in the courts of justice. Some illegal practices of certain Chancery officials had been detected and punished by the court itself, and generally there was a disposition to overhaul its affairs, while Coke and Cranfield directly attacked some parts of the chancellor's administration. But on March 14th one Aubrey appeared at the bar of the House, and charged Bacon with having received from him a sum of money while his suit was going on, and with having afterwards decided against him. Bacon's letter on this occasion is worthy of serious attention; he evidently thought the charge was but part of the deliberate scheme to ruin him which had already been in progress. A second accusation (Egerton's case) followed immediately after, and was investigated by the House, who, satisfied that they had just matter for reprehension, appointed the 19th for a conference with the Lords. On that day Bacon, as he had feared, was too ill to attend. He wrote to the Lords excusing his absence, requesting them to appoint a convenient time for his defense and cross-examination of witnesses, and imploring them not to allow their minds to be prejudiced against him, at the same time declaring that he would not "trick up an innocency with cavilations, but plainly and ingenuously declare what he knew or remembered." The charges rapidly accumulated, but Bacon still looked upon them as party moves, and was in hopes of defending himself. Nor did he seem to have lost his courage, if we are to believe the common reports of the day, though certainly they do not appear worthy of very much credit.

The notes bearing upon the interview which he obtained with the king, show that he had begun to see more clearly the nature and extent of the offences with which he was charged, that he now felt it impossible altogether to exculpate himself, and that his hopes were directed towards obtaining some mitigation of his sentence. The long roll of charges made upon the 19th April finally decided him; he gave up all idea of defence, and wrote to the king begging him to show him favor in this emergency. The next day he sent in a general confession to the Lords, trusting that this would be considered satisfactory. The Lords, however, decided that it was not sufficient as a ground for their censure, and demanded a detailed and particular confession. A list of twenty-eight charges was then sent him, to which an answer by letter was required. On the 30th April his "confession and humble submission" was handed in. In it, after going over the several instances, he says, "I do again confess, that on the points charged upon me, although they should be taken as myself have declared them, there is a great deal of corruption and neglect; for which I am heartily and penitently sorry, and submit myself to the judgment, grace, and mercy of the court." On the 3d May after considerable discussion, the Lords decided upon the sentence, which was, That he should undergo fine and ransom of £40,000; that he should be imprisoned in the tower during the king's pleasure; that he should be for ever incapable of any office, place, or employment in the state or commonwealth; that he should never sit in parliament; or come within the verge of the court. This heavy sentence was only partially executed. The fine was in effect remitted by the king; imprisonment in the tower lasted for about four days; a general pardon (not of course covering the parliamentary censure) was made out, and though delayed at the seal for a time by Lord Keeper Williams, was passed probably in November 1621. The cause of the delay seems to have lain with Buckingham, whose friendship had cooled, and who had taken offence at the fallen chancellor's unwillingness to part with York House. This difference was finally smoothed over, and it was probably through his influence that Bacon received the much-desired permission to come within the verge of the court. He never again set in parliament.

So ends this painful episode, which has given rise to the most severe condemnation of Bacon, and which still presents great and perhaps insuperable difficulties. On the whole, the tendency of the most recent and thorough researches has been towards the opinion that Bacon's own account of the matter (from which, indeed, our knowledge of it is chiefly drawn) is substantially correct. He distinguishes three ways in which bribes may be given, and ingenuously confesses that his own acts amounted to corruption and were worthy of condemnation. Now, corruption strictly interpreted would imply the deliberate sale of justice, and this Bacon explicitly denies, affirming that he never "had bribe or reward in his eye or thought when he pronounced any sentence or order." When we analyse the specific charges against him, with his answers to them, we find many that are really of little weight. The twenty-eighth and last, that of negligence in looking after his servants, though it did him much harm, may fairly be said to imply no moral blame. The majority of the others are instances of gratuities given after the decision, and it is to be regretted that the judgment of the peers gives us no means of determining how such gifts were looked upon, whether or not the acceptance of them was regarded as a "corrupt" practice. In four cases specifically, and in some others by implication, Bacon confesses that he had received bribes from suitors *pendente lite*. Yet he affirms, as we said before, that his intention was never swayed by a bribe; and so far as any of these cases can be traced, his decisions, often given in conjunction with some other official, are to all appearance thoroughly just. In several cases his judgment appears to have been given against the party bestowing the bribe, and in at least one instance, that of Lady Wharton, it seems impossible to doubt that he must have known when accepting the present that his opinion would be adverse to her cause. Although, then, he felt that these practices were really corrupt, and even rejoiced that his own fall would tend to purify the courts from them, he did not feel that he was guilty of perverting justice for the sake of reward. How far, then, is such defence or explanation admissible and satisfactory? It is clear that two things are to be considered: the one the guilt of taking bribes or presents on any consideration, the other the moral guilt depending upon the wilful perversion of justice.

The attempt has sometimes been made to defend the whole of Bacon's conduct on the ground that he did nothing that was not done by many of his contemporaries. Bacon himself disclaims a defence of this nature, and we really have no direct evidence which shows to what extent the offering and receiving of such bribes then prevailed. That the practice was common is indeed implied by the terms in which Bacon speaks of it, and it is not improbable that the fact of these gifts being taken by officials was a thing fairly well known, although all were aware of their illegal character, and it was plain that any public exposure of such dealings would be fatal to the individual against whom the charge was made out. Bacon knew all this; he was well aware that the practice was in itself indefensible, and that his conduct was therefore corrupt and deserving of censure. So far, then, as the mere taking of bribes is concerned, he would permit no defence, and his own confession and judgment on his actions contain as severe a condemnation as has ever been passed upon him. Yet in the face of this he does not hesitate to call himself "the justest chancellor that hath been in the five changes since Sir Nicholas Bacon's time"; and this on the plea that his intentions had always been pure, and had never been affected by the presents he received. His justification has been set aside by modern critics, not on the ground that the evidence demonstrates its falsity, but because it is inconceivable or unnatural that any man should receive a present from another, and not suffer his judgment to be swayed thereby. It need hardly be said that such an *a priori* conviction is not a sufficient basis on which to found a sweeping condemnation of Bacon's integrity as an administrator of justice. On the other hand, even if it be admitted to be possible and conceivable that a present should be given by a suitor simply as seeking favorable consideration of his cause, and not as desirous of obtaining an unjust decree, and should be accepted by the judge on the same understanding, this would not entitle one absolutely to accept Bacon's statement. Further evidence is necessary in order to give foundation to a definite judgment either way; and it is extremely improbable, nay, almost impossible, that such can ever be produced. In these circumstances, due weight should be given to Bacon's own assertions of his perfect innocence and purity of intention; they ought not to be put out of court unless found in actual contradiction to the facts; and the reverse of this is the case, so far as has yet appeared.

The remainder of his life, though still harassed by want of means, for James was not liberal, was spent in work far more valuable to the world than anything he had accomplished in his high office. In March 1622 he presented to Prince Charles his *History of Henry VII.;* and immediately, with unwearied industry, set to work to complete some portions of his great work. In November 1622 appeared the *Historia Ventorum;* in January 1623, the *Historia Vitæ et Mortis;* and in October of the same year, the *De Augmentis Scientiarum*, a Latin translation, with many additions of the *Advancement*. Finally, in December 1624, he published his *Apophthegms*, and *Translations of some of the Psalms;* and, in 1625, a third and enlarged edition of the *Essays*.

Busily occupied by these labors, his life now drew rapidly to a close. In March 1626 he came to London, and when driving one day near Highgate, was taken with a desire to discover whether snow would act as an antiseptic. He stopped his carriage, got out at a cottage, purchased a fowl, and with his own hands assisted to stuff it with snow. He was seized with a sudden chill, and became so seriously unwell that he had to be conveyed to Lord Arundel's house, which was near at hand. Here his illness increased, the cold and chill brought on bronchitis and he died, after a few days' suffering, on the 9th April 1626.

Bacon's Works and Philosophy.

A complete survey of Bacon's works and an estimate of his place in literature and philosophy are matters for a volume.

An attempt has been made to substantiate the opinion held by some that Bacon was the author of the works ascribed to Shakespeare. The strongest writer on the subject, Ignatius Donnelly (Minnesota) claims to have discovered a cypher running through the poems which prove their Baconian origin. Mr. Donnelly is certainly ingenious and daring in his conception and argument.

Putting aside the letters and occasional writings, we may conveniently distribute the other works into three classes, *Professional*, *Literary*, *Philosophical*. Of the Professional works, which include the *Reading on the Statute of Uses*, the *Maxims of Law*, and the treatise (possibly spurious) on the *Use of the Law*, only experts can speak with confidence; and their opinion, so far as it has yet been given, coincides to some extent with Bacon's own estimate of his powers as a lawyer. "I am in good hope," he says, "that when Sir Edward Coke's reports and my rules and decisions shall come to posterity, there will be (whatsoever is now thought) question who was the greater lawyer." If Coke's reports show completer mastery of technical details, greater knowledge of precedent, and more of the dogged grasp of the letter than do Bacon's legal writings, there can be no dispute that the latter exhibit an infinitely more comprehensive intelligence of the abstract principles of jurisprudence, with a richness and ethical fulness that more than compensate for their lack of dry legal detail. Bacon seems indeed to have been a lawyer of the first order, with a keen scientific insight into the bearings of isolated facts, and a power of generalisation which admirably fitted him for the self-imposed task, unfortunately never completed, of digesting or codifying the chaotic mass of English law.

Among the literary works are included all that he himself designated moral and historical pieces, and to these may be added some theological and minor writings, such as the *Apophthegms*. Of the moral works the most valuable are the *Essays*. It is impossible to praise too highly writings which have been so widely read and universally admired. The matter is of the familiar practical kind, that "comes home to men's bosoms." The thoughts are weighty, and even when not original, have acquired a peculiar and unique tone or cast by passing through the crucible of Bacon's mind. A sentence from the *Essays* can rarely be mistaken for the production of any other writer. The short, pithy sayings:

> "Jewels, five words long,
> That on the stretched forefinger of all time,
> Sparkle for ever,"

have become popular mottoes and household words. The style is quaint, original, abounding in allusions and witicisms, and rich, even to gorgeousness, with piled-up analogies and metaphors. The first edition contained only ten essays, but the number was increased in 1612 to thirty-eight, and in 1625 to fifty-eight. The short tract, *Colors of Good and Evil*, which with the *Meditationes Sacræ* originally accompanied the *Essays*, was afterwards incorporated with the *De Augmentis*. Along with these works may be classed the curiously learned piece, *De Sapientia Veterum*, in which he works out a favorite idea, that the mythological fables of the Greeks were allegorical and concealed the deepest truths of their philosophy. As a scientific explanation

of the myths the theory is of no value, but it affords fine scope for the exercise of Bacon's unrivalled power of detecting analogies in things apparently most dissimilar. The *Apophthegms*, though hardly deserving Macaulay's praise of being the best collection of jests in the world, contain a number of those significant anecdotes which Bacon used with such effect in his other writings. Of the historical works, besides a few fragments of the projected history of Britain, there remains the *History of Henry VII.*, a valuable work, giving a clear and animated narrative of the reign, and characterising Henry with great skill. The style is in harmony with the matter, vigorous and flowing, but naturally with less of the quaintness and richness suitable to more thoughtful and original writings. The series of the literary works is completed by the minor treatises on theological or ecclesiastical questions. Some of the latter, included among the occasional works, are admirably sagacious and prudent, and deserve careful study. Of the former, the principal specimens are the *Meditationes Sacræ* and the *Confession of Faith*. The *Paradoxes* (Characters of a believing Christian in paradoxes, and seeming contradictions), which was often and justly suspected, has been conclusively proved by Mr. Grosart not to be the work of Bacon.

Philosophical Works.— The great mass of Bacon's writings consists of treatises or fragments, which either formed integral parts of his grand comprehensive scheme, or were closely connected with it. More exactly they may be classified, as is done by the most recent editors, under three heads: — A. Writings which actually formed part of the *Instauratio Magna;* B. Writings originally intended to form parts of the *Instauratio*, but which were afterwards superseded or thrown aside; C. Works connected with the *Instauratio*, but not directly included in its plan.

To begin with the second of these classes, we have under it some important tracts, which certainly contain little, if anything, that is not afterwards taken up and expanded in the more elaborate works, but which are not undeserving of attention, from the difference in the point of view and method of treatment. The most valuable of them are: — (1.) The *Advancement of Learning*, of which no account need be given, as it is completely worked up into the *De Augmentis*, and takes its place at the first part of the *Instauratio.* (2.) *Valerius Terminus*, a very remarkable piece, composed probably about 1603, though perhaps retouched at a later period. It contains a brief and somewhat obscure outline of the first two parts in the *Instauratio*, and is of importance as affording us some insight into the gradual development of the system in Bacon's own mind. (3.) *Temporis Partus Masculus*, another curious fragment, remarkable not only from its contents, but from its style, which is arrogant and offensive, in this respect unlike any other writings of Bacon's. The adjective *masculus* points to the power of bringing forth fruit possessed by the new philosophy, and perhaps indicates that all previous births of time were to be looked upon as feminine or imperfect; it is used in a somewhat similar sense in *Letters and Life*, vi. 183, "*In verbis masculis*, no flourishing or painted words, but such words as are fit to go before deeds." (4.) *Redargutio Philosophiarum*, a highly finished piece in the form of an oration, composed probably about 1608 or 1609, containing in pretty full detail much of what afterwards appears in connection with the *Idola Theatri* in book i. of the *Novum Organum.* (5.) *Cogitata et Visa*, perhaps the most important of the minor philosophical writings, dating from 1607 (though possibly the tract in its present form may have been to some extent altered), and containing in weighty and sonorous Latin the substance of the first book of the *Organum.* (6.) The *Descriptio Globi Intellectualis*, which is to some extent intermediate between the *Advancement* and the *De Augmentis*, goes over in detail the general classification of the sciences, and enters particularly some points of minor interest. (7.) The brief tract *De Interpretatione Naturæ Sententiæ Duodecim* is evidently a first sketch of part of the *Novum Organum*, and in phraseology is almost identical with it. (8.) A few smaller pieces, such as the *Inquisitio de Motu*, the *Calor et Frigus*, the *Historia Soni et Auditus*, and the *Phænomena Universi*, are early specimens of his *Natural History*, and exhibit the first tentative applications of the new method.

The third great division of the philosophical works consists of treatises of subjects connected with the *Instauratio*, but not forming part of it. It is not necessary to characterise these at any length. The most interesting, and in many respects the most remarkable, is the philosophic romance, the *New Atlantis*, a description of an ideal state in which the principles of the new philosophy are carried out by political machinery, and under state guidance, and where many of the results contemplated by Bacon are in imagination attained. The work was to have been completed by the addition of a second part, treating of the laws of a model commonwealth, which was never written. Another important tract is the *De Principiis atque Originibus secundum Fabulas Cupidinis et Cœli*, where, under the disguise of two old mythological stories, he (in the manner of the *Sapientia Veterum*) finds the deepest truths concealed. The tract is unusually interesting, for in it he discusses at some length the limits of science, the origin of things, and the nature of primitive matter, giving at the same time full notices of Democritus among the ancient philosophers and of Telesius among the modern. Deserving of attention are also the *Cogitationes de Natura Rerum*, probably written early, perhaps in 1605, and the treatise on the theory of the tides, *De Fluxu et Refluxu Maris*, written probably about 1616.

The philosophical works which form part of the *Instauratio* must of course be classed according to the positions which they respectively hold in that scheme of the sciences. Before entering on an account of Bacon's object and method, it is necessary to give the general outline of his arrangement.

The great work, the reorganisation of the sciences, and the restoration of man to that command over nature which he had lost by the fall, consisted in its final form of six divisions.

I. *Partitiones Scientiarum*, a survey of the sciences, either such as then existed or such as required to be constructed afresh — in fact, an inventory of all the possessions of the human mind. The famous classification on which this survey proceeds is based upon an analysis of the faculties and objects of human knowledge. This division is represented by *De Augmentis Scientiarum.*

II. *Interpretatio Naturæ.*— After the survey of all that has yet been done in the way of discovery or invention, comes the new method, by which the mind of man is to be trained and directed in its progress towards the renovation of science. This division is represented, though only imperfectly, by the *Novum Organum*, particularly book ii.

III. *Historia Naturalis et Experimentalis.*— The new method is valueless, because inapplicable, unless it be supplied with materials duly collected and presented — in fact, unless there be formed a competent natural history of the *Phænomena Universi.* A short introductory sketch of the requisites of such a natural his-

tory, which, according to Bacon, is essentially necessary, the *basis totius negotii*, is given in the tract *Parasceve*, appended to the *Novum Organum*. The principal works intended to form portions of the history, and either published by himself or left in manuscript, are *Historia Ventorum*, *Historia Vitæ et Mortis*, *Historia Densi et Rari*, and the extensive collection of facts and observations entitled *Sylva Sylvarum*.

IV. *Scala Intellectus*.—It might have been supposed that the new philosophy could now be inaugurated. Materials had been supplied, along with a new method by which they were to be treated, and naturally the next step would be the finished result. But for practical purposes Bacon interposed two divisions between the preliminaries and the philosophy itself. The first was intended to consist of types or examples of investigations conducted by the new method, serviceable for keeping the whole process vividly before the mind, or as the title indicates, such that the mind could run rapidly up and down the several steps or grades in the process. Of this division there seems to be only one small fragment, the *Filum Labyrinthi*, consisting of but two or three pages.

V. *Prodromi*, forerunners of the new philosophy. This part, strictly speaking, is quite extraneous to the general design. According to the *Distributio Operis*, it was to contain certain speculations of Bacon's own, not formed by the new method, but by the unassisted use of his understanding. These, therefore, form temporary or uncertain anticipations of the new philosophy. There is extant a short preface to this division of the work, and according to Mr. Spedding, some of the miscellaneous treatises, such as *De Principiis*, *De Fluxu et Refluxu*, *Cogitationes de Natura Rerum*, may probably have been intended to be included under this head. This supposition receives some support from the manner in which the fifth part is spoken of in the *Novum Organum*, i. 116.

VI. The new philosophy, which is the work of future ages, and the result of the new method.

BACON, John, who may be considered the founder of the British school of sculpture, was born Nov. 24, 1740. He was the son of Thomas Bacon, cloth-worker in Southwark, whose forefathers possessed a considerable estate in Somersetshire. At the age of fourteen he was bound apprentice in Mr. Crispe's manufactory of porcelain at Lambeth, where he was at first employed in painting the small ornamental pieces of china, but by his great skill in moulding he soon attained the distinction of being modeller to the work. The produce of his labor he devoted to the support of his parents, then in somewhat straitened circumstances. While engaged in the porcelain works he had an opportunity of seeing the models executed by different sculptors of eminence, which were sent to be burned at an adjoining pottery. An observation of these productions appears to have immediately determined the direction of his genius; he devoted himself to the imitation of them with so much success, that in 1758 a small figure sent by him to the Society for the Encouragement of Arts received a prize, and the highest premiums given by that society were adjudged to him nine times between the years 1763 and 1776. During his apprenticeship he also improved the method of working statues in artificial stone, an art which he afterwards carried to perfection. Bacon first attempted working in marble about the year 1763, and, during the course of his early efforts in this art, was led to improve the method of transferring the form of the model to the marble (technically called *getting out the points*), by the invention of a more perfect instrument for the purpose, which has since been adopted by many sculptors both in England and other countries. This instrument possesses many advantages above those formerly employed; it is more exact, takes a correct measurement in every direction, is contained in a small compass, and can be used upon either the model or the marble. In the year 1769 he was adjudged the first gold medal given by the Royal Academy, and in 1770 was made an associate of that body. He shortly afterwards exhibited a figure of Mars, which gained him considerable reputation, and he was then engaged to execute a bust of George III., intended for Christ Church College. He secured the king's favor, and retained it throughout life. His great celebrity now procured him numerous commissions, and it is said, that of sixteen different competitions in which he was engaged with other artists, he was unsuccessful in one case only. Considerable jealousy was entertained against him by other sculptors, and he was commonly charged with ignorance of classic style. This charge he repelled by the execution of a noble head of Jupiter Tonans, and many of his emblematical figures are in perfect classical taste. On the 4th of August 1799 he was suddenly attacked with inflammation, which occasioned his death in little more than two days, in the 59th year of his age. He left a widow, his second wife, and a family of six sons and three daughters. On his merit as a sculptor, the universal reputation of his works affords decisive proof, and his various productions which adorn St. Paul's Cathedral, London, Christ Church and Pembroke Colleges, Oxford, the Abbey Church, Bath, and Bristol Cathedral, give ample testimony to his powers. Perhaps his best works are to be found among the monuments in Westminster Abbey. (See *Memoir of the late John Bacon, R.A.*, by the Rev. Richard Cecil: London, 1811.)

BACON, Sir Nicholas, lord keeper of the great seal in the reign of Queen Elizabeth, was born at Chislehurst in Kent in 1510, and educated at the university of Cambridge, after which he traveled in France, and made some stay at Paris. Very early in the reign of Elizabeth he was knighted; and in 1558 he succeeded Nicholas Heath, archbishop of York, as keeper of the great seal of England; he was at the same time made one of the queen's privy council. As a statesman, he was remarkable for the clearness of his views and the wisdom of his counsels, and he had a considerable share in the settling of ecclesiastical questions. That he was not unduly elated by his preferments, appears from the answer he gave to Queen Elizabeth when she told him his house at Redgrave was too little for him, "Not so, madam," returned he, "but your majesty has made me too great for my house." He died on the 26th of February 1579, having held the great seal more than twenty years, and was buried in St. Paul's, London, where a monument, destroyed by the great fire of London in 1666, was erected to his memory.

BACON, Roger. The 13th century, an age peculiarly rich in great men, produced few, if any, who can take higher rank than Roger Bacon. He is in every way worthy to be placed beside such thinkers as Albertus Magnus, Bonaventura, and Thomas Aquinas. These had an infinite wider renown in their day, while he was ignored by his contemporaries and neglected by his successors; but modern criticism has restored the balance in his favor, and is even in danger of going equally far in the opposite direction. Bacon, it is now said, was not appreciated by his age because he was so completely in advance of it; he is a 16th or 17th century philosopher, whose lot has been by some accident cast in the 13th century; he is no schoolman, but a modern thinker, whose conceptions of science are more just and clear than are even those of his more celebrated namesake. In this view there is certainly a

considerable share of truth, but it is much exaggerated. As a general rule, no man can be completely dissevered from his national antecedents and surroundings, and Bacon is not an exception. Those who take up such an extreme position regarding his merits have known too little of the state of contemporary science, and have limited their comparison to the works of the scholastic theologians. We never find in Bacon himself any consciousness of originality; he has no fresh creative thought or method to introduce whereby the face of science may be changed; he is rather a keen and systematic thinker, who is working in a well-beaten track, from which his contemporaries were being drawn by the superior attractions of theology and metaphysics.

Roger Bacon was born in 1214, near Ilchester, in Somersetshire. His family appears to have been in good circumstances, for he speaks of his brother as wealthy, and he himself expended considerable sums on books and instruments; but in the stormy reign of Henry III. they suffered severely, their property was despoiled, and several members of the family were driven into exile. Roger completed his studies at Oxford, though not, as current traditions assert, at Merton or at Brazenose, neither of these colleges having then been founded. His great abilities were speedily recognised by his contemporaries, and he came to be on terms of close intimacy with some of the most independent thinkers of the time. Of these the most prominent were Adam de Marisco and Robert Grosseteste (*Cupito*), afterwards bishop of Lincoln, a man of liberal mind and wide attainments, who had especially devoted himself to mathematics and experimental science.

The scientific training which Bacon had received, partly by instruction, but more from the study of the Arab writers, made patent to his eyes the manifold defects in the imposing systems reared by these doctors. It disgusted him to hear from all around him that philosophy was now at length complete, that it had been reduced into compact order, and was being set forth by a certain professor at Paris. Even the great authority on which they reposed, Aristotle, was known but in part, and that part was rendered well-nigh unintelligible through the vileness of the translations; yet not one of those professors would learn Greek so that they might arrive at a real knowledge of their philosopher. The Scriptures, if read at all in the schools, were read in the erroneous versions; but even these were being deserted for the *Sentences* of Peter Lombard. Physical science, if there was anything deserving that name, was cultivated, not by experiment in the true Aristotelian way, but by discussion and by arguments deduced from premises resting on authority or custom. Everywhere there was a show of knowledge covering and concealing fundamental ignorance. Bacon, accordingly, who knew what true science was, and who had glimpses of a scientific method, withdrew from the usual scholastic routine, and devoted himself to languages and experimental researches. Among all the instructors with whom he came in contact in Paris, only one gained his esteem and respect; this was an unknown individual, Petrus de Maharncuria Picardus, or of Picardy. The contrast between the obscurity of such a man and the fame enjoyed by the fluent young doctors of the schools seems to have roused Bacon's indignation.

It is probable that Bacon, during his stay in Paris, acquired considerable renown. He took the degree of doctor of theology, and seems to have received from his contemporaries the complimentary title of *doctor mirabilis*. In 1250 he was again at Oxford, and probably about this time, though the exact date cannot be fixed, he entered the Franciscan order. His fame spread very rapidly at Oxford, though it was mingled with suspicions of his dealings in magic and the black arts, and with some doubts of his orthodoxy. About 1257, Bonaventura, general of the order, interdicted his lectures at Oxford, and commanded him to leave that town and pleace himself under the superintendence of the body at Paris. Here for ten years he remained under constant supervision, suffering great privations, and strictly prohibited from writing anything which might be published. But during the time he had been at Oxford his fame had reached the ears of the Papal legate in England, Guy de Foulques, a man of culture and scientific tastes, who in 1265 was raised to the papal chair as Clement IV. In the following year he wrote to Bacon, who had been already in communication with him, ordering him, notwithstanding any injunctions from his superiors, to write out and send to him a treatise on the sciences which he had already asked of him when papal legate. Bacon, who in despair of being ever able to communicate his results to the world, had neglected to compose anything, and whose previous writings had been mostly scattered tracts, *capitula quædam*, took fresh courage from this command of the Pope. Relying on his powerful protection, he sat at naught the many obstacles thrown in his way by the jealousy of his superiors and brother friars, and despite the want of funds, instruments, materials for copying, and skilled copyists, completed in about eighteen months three large treatises, the *Opus Majus*, *Opus Minus*, and *Opus Tertium*, which, with some other tracts, were despatched to the Pope by the hands of one Joannes, a young man trained and educated with great care by Bacon himself.

The composition of such extensive works in so short a time is a marvellous feat. We do not know what opinion Clement formed of them, but before his death he seems to have bestirred himself on Bacon's behalf, for in 1268 the latter was released and permitted to return to Oxford. Here he continued his labors in experimental science, and also in the composition of complete treatises. The works sent to Clement he regarded as mere preliminaries, laying down principles which were afterwards to be applied to the several sciences. The first part of an encyclopædic work probably remains to us in the *Compendium Studii Philosophiæ*, belonging to the year 1271. In this work Bacon makes a vehement attack upon the ignorance and vices of the clergy and monks, and generally upon the insufficiency of the existing studies. In 1278 he underwent the punishment which seems to have then been the natural consequence of outspoken opinions. His books were condemned by Jerome de Ascoli, general of the Franciscans, a gloomy bigot, who afterwards became Pope, and the unfortunate philosopher was thrown into prison, where he remained for fourteen years. During this time, it is said, he wrote the small tract *De Retardandis Senectutis Accidentibus*, but this is merely a tradition. In 1292, as appears from what is probably his latest composition, the *Compendium Studii Theologiæ*, he was again at liberty. The exact time of his death cannot be determined; 1294 is probably as accurate a date as can be fixed upon.

BACONTHORPE, or BACON, JOHN, called The Resolute Doctor, a learned monk, born toward the end of the thirteenth century, at Baconthorpe, a village in Norfolk. He died in London in 1346.

BACSANYI, JANOS, a Hungarian poet, was born at Tapoleza, May 11, 1763, and died at Linz, May 12, 1845.

BACTERIA (plural of the late Lat. *bacterium*, Gr. *bakterion*, dimin. of *baktron*, stick, staff,) microscopic infusoria which generate in stagnant water. These bacteria multiply with extraordinary rapidity by cross division. Whenever organic matter is in process of decomposition, in infusion as above indicated, or in disease or death, or within the living and healthy organism,

there these bacteria are to be found. So abundant are they, that in spite of their minuteness they did not escape the enthusiastic observation of the early workers with the microscope. Not much progress was made however, till about 1838, when Ehrenberg and Dujardin included bacteria in their investigation of minute organisms. They referred the forms which they described to the animal series among Infusorians, and united a large number under the general title *Vibrionia*. To Cohn (1853) is due the merit of having established, on grounds of structure and life-history (morphology and development), the fact that bacteria are plants, and all succeeding research has confirmed his conclusion, which Nägeli (1857) corrected in detail, however, by referring the bacteria or schizomycetes not to algæ, but to the parallel class of fungi.

Bacteria are found practically everywhere, but especially where there is disease, death, or decomposition. To speak of the "omnipresent bacillus" is hardly an exaggeration.

Even pure water contains many bacteria, and always more than occur in air. The minimum occurs in condensed water-vapor (900 to the litre), the maximum (80 millions per litre, 1¾ pint), of course, in sewer water, especially if there be the least stagnation.

Nor is soil free from bacteria. Spring-water fresh from the source carries a cargo of these micro-organisms. Pasteur found that the germ of splenic fever (*Bacillus anthracis*) occurred in great abundance in the earth round about the pits in which diseased cattle had been buried.

The rancidity of butter, the putrefaction of cheese, the game-flavor and high odor of meat, the yellowness and blueness of milk kept in imperfectly scalded vessels, the excessive staleness of bread, and a crowd of other unhealthy conditions in food, are largely due to the presence of bacteria. Bloody stains on bread, meat, paste, etc., have also been traced to the presence of a brightly-colored micrococcus. In the same way the bitterness, ropiness, etc., of bad wine are due to the same organisms.

A large number of bacteria are known to occur in direct association with pathological processes of decomposition in plants and animals, without apparently having any direct connection with the decomposition. These are saprophytes, like fungi generally. Others, however, have been proved in many cases to be the causes of pathological conditions in men and animals, a profound fact fundamental to the germ theory of disease.

As regards the shape of the individual units, four principal forms may be distinguished—viz., spherical, elliptical, rod-like, and spirally curved.

BACTRIA, or BACTRIANA, an ancient country of Central Asia, lying to the south of the river Oxus, and reaching to the western part of the Paropamisan range, or Hindu Kush. It was sometimes regarded as including the district of Margiana, or Merv, which was more frequently considered as distinct.

BACUP, a town of England, in Lancashire, twenty miles north from Manchester. It is situated in a beautiful valley on the River Speddon, and is a station on the East Lancashire railway. It is chiefly important for its factories, foundries, and mills, as well as for the coal-mines in the neighborhood. Population (1890), about 20,000.

BADAJOS, a province of Spain, forming, by the division of 1833, the southern half of the old province of Estremadura, or what is generally called Lower Estremadura. It is bounded on the north by Caceres, east by Ciudad Real, south and southeast by Cordova, Seville, and Huelva, and west by Portugal, embracing an area of 8,687 square miles. Population (1891) 520,000.

BADAJOS, the capital of the above province, is a fortified city, and the see of a bishop. It is is situated about five miles from the Portuguese frontier, on a slight elevation near the left bank of the Guadiana, and is one of the principal stations on the railway between Madrid and Lisbon. The population (1890) is estimated at 23,000.

BADAKHSHAN, a country of Central Asia, situated in the upper valley of the Kokcha river, one of the principal head streams of the Oxus. Its extent from east to west is about 200 miles, and from north to south about 150 miles. On the north it is bounded by Kulab and Darwaz; on the east by the lofty table-land of Pamir; on the south by the Hindu Kush range and on the west by Kunduz.

Badakhshan was visited by Hwen Thsang in 630 and 644. The Arabian geographers of the 10th century speak of its mines of ruby and azure, and give notices of the flourishing commerce and large towns of Waksh and Khotl, regions which appear either to have in part corresponded with or to have lain close to Badakhshan. In 1272–73 Marco Polo and his companions stayed for a time in Badakhshan. During this and the following centuries the country was governed by kings who claimed to be descendants of Alexander the Great. The last of these kings was Shah Mahomet, who died in the middle of the 15th century, leaving only his married daughters to represent the royal line. Early in the middle of the 16th century the Uzbeks obtained possession of Badakhshan, but were soon expelled, and then the country was generally governed by descendants of the old royal dynasty by the female line. About the middle of the 18th century the present dynasty of Mírs established its footing in place of the old one which had become extinct. In 1765 the country was invaded and ravaged by the ruler of Cabul. During the first three decades of the present century it was overrun and depopulated by Kokan Beg and his son Murad Beg, chiefs of the Kataghan Uzbeks of Kundus. The country was still suffering from the disasters when Wood visited it in 1837. When Murad Beg died, the power passed into the hands of another Uzbek, Mahomet Amir Khan. In 1859 the Kataghan Uzbeks were expelled; and Mír Jahander Shah, the representative of the modern royal line, was reinstated at Faizábád under the supremacy of the Afghans. In 1867 he was expelled by the Afghans and replaced by the present ruler, Mír Mahomet Shah, and other representatives of the same family. According to the latest accounts the country was reviving from its past misfortunes, and the towns were again rising.

BADALOCCHIO, SISTO, surnamed ROSA, a painter and engraver, was born at Parma in 1581, and died in 1641 or 1647.

BADEN, THE GRAND DUCHY OF, is situated in the S.W. of Germany. It is bounded on the N. by Bavaria and Hesse-Darmstadt; W. by Rhenish Bavaria, Alsace, and Lorraine; S. by Switzerland; E. by Würtemberg and part of Bavaria. At the commencement of the present century Baden was only a margraviate, with an area little exceeding 1300 square miles, and a population of 210,000. Since then it has from time to time acquired additional territory, so that its area now amounts to upwards of 5800 square miles, and its population to 1,601,255 (1890).

It consists of a considerable portion of the eastern half of the fertile valley of the Rhine, and of the mountains which form its boundary. The mountainous part is by far the most extensive, forming, indeed, nearly 80 per cent of the whole area. From the Lake of Constance in the south to the River Neckar is a portion of the so-called Black Forest or *Schwarzwald*, which is divided by the valley of the Kinzig into two districts of

different elevation. To the south of the Kinzig the mean height is 3100 feet, and the loftiest summit, the Feldberg, reaches about 4780 feet; while to the north the mean height is only 2100 feet, and the Belchen, the culminating point of the whole, does not exceed 4480. To the north of the Neckar is the Odenwald range, with a mean of 1440 feet, and, in the Kàtzenbuckel, an extreme of 1980. Lying between the Rhine and the Dreisam is the Kaiserstuhl, an independent volcanic group, nearly 10 miles in length and 5 in breadth, the highest point of which is 1760 feet.

The greater part of Baden belongs to the basin of the Rhine, which receives upwards of twenty tributaries from the highlands of the duchy alone; a portion of the territory is also watered by the Main and the Neckar. A part, however, of the eastern slope of the Black Forest belongs to the basin of the Danube, which there takes its rise in a number of mountain streams. Among the numerous lakes which belong to the duchy are the Mummel, Wilder, Nonnenmattweiher, Titti, Eichener, Schluch, &c., but none of them are of any size. The Lake of Constance, or Boden See, belongs partly to Bavaria and Switzerland.

From 1819 to 1832 Baden was divided into six circles, which were reduced in the latter year to the four following:—The Lake Circle or Constance, the Upper Rhine or Freiburg, the Middle Rhine or Carlsruhe, and the Lower Rhine or Manheim. This division, though still employed, has been legally supplanted by one into the eleven circles of Constance, Villingen, Waldshut, Freiburg, Lörrach, Offenburg, Baden, Carlsruhe, Manheim, Heidelberg, and Mosbach. The capital of the duchy is Carlsruhe, which in 1889 had a population of 61,074; the other principal towns are Manheim (39,614), Freiburg (24,599), Heidelberg (19,988), Pforzheim (19,801), Rastadt (11,559), Baden (10,083), Constance (10,052), Bruchsal (9786), and Lahr (6710). The population is most thickly clustered in the north and in the neighborhood of the Swiss town of Basel.

The inhabitants of Baden are of various origin,—those to the N. of the Murg being descended from the Alemanni, and those to the S. from the Franks, while the Swabian plateau derives its name and its population from another race. This distinction is still marked in the manners, the language, and the dress of the different districts. The majority of the people are engaged in agricultural and pastoral pursuits, for which much of the country is well adapted. In the valleys the soil is particularly fertile, yielding luxuriant crops of wheat, maize, barley, spelt, beans, potatoes, flax, hemp, hops, beet-root, and tobacco; and even in the more mountainous parts rye, wheat, and oats are extensively cultivated. There is a considerable extent of pasture land, and the rearing of cattle, sheep, pigs, and goats is largely attended to. The culture of the vine has recently been increasing, and the wines, which are characterised by a mildness of flavor, are in good demand. The gardens and orchards supply abundance of fruits, especially almonds and walnuts; and the keeping of bees is common throughout the country. A greater proportion of Baden than of any other of the South German states is occupied by forests. In these the predominant species are the fir and pine, but many others, such as the chestnut are well represented. A third, at least, of the annual supply of timber is exported, the chief consumer being Holland, though of late years Paris has derived a considerable supply from this source.

The exports of Baden, which coincide largely with the industries just mentioned, are of considerable importance, but the bulk of its trade consists in the transit of goods. The country is well furnished with roads and railways, the greater proportion of the latter being in the hands of the state. A line runs the whole length of the land, for the most part parallel with the Rhine, while branches cross obliquely from east to west.

The educational institutions of Baden are numerous and flourishing, and public instruction is largely subsidised by the Government. There are two universities, the Protestant one at Heidelberg, founded in 1386, and the Catholic one at Freiburg, founded in 1457. The library at Heidelberg numbers 150,000 volumes, and that at Freiburg 100,000, while there is another of almost equal size at Carlsruhe. There are also lyceums at Carlsruhe, Constance, Freiburg, Heidelberg, Manheim, Rastadt and Wertheim; several gymnasiums; normal schools at Carlsruhe, Ettlingen, and Meersburg, besides upwards of 2000 common schools established throughout the country. There is an institution in Pforzheim for the deaf and dumb, and one in Freiburg for the blind. The polytechnic school at Carlsruhe is among the most efficient institutions of the kind in Germany. The preparatory course extends over three years, and includes French, German, English, special history, mathematics, drawing, modelling, chemistry, mineralogy and geology, mechanics, &c. The special courses are engineering, architecture, forestry, chemistry, mechanics, commerce, and post-office service, and extend over from one to four years. The ducal family of Baden belong to the Protestant section of the Church, but the majority of the population are Roman Catholics. The returns of the census of 1889 are as follows:—Catholics, 942,560; Protestants, 491,008; other sects, 2265; and Jews, 25,703. The district where the Roman Catholic preponderance was greatest was Constance, while the Protestants were slightly more numerous in the district of Manheim.

The government of Baden is an hereditary monarchy, with the executive power vested in the grand duke, and the legislative authority in a Parliament consisting of two Chambers. The upper Chamber is composed of all the princes of the reigning line who are of age, the chiefs of ten noble families, the possessors of hereditary landed estates worth £25,000, the Roman Catholic archbishop of Freiburg, the president of the Protestant Church, a deputy from each of the universities, and eight nominees of the duke. The lower Chamber consists of 63 representatives, of whom 22 are elected by the burgesses of certain towns, and 41 by the inhabitants of the bailiwicks. The parliamentary candidate must possess tax-paying property of the value of 10,000 florins (£833), or derive a salary of at least £125 from a public office. Every citizen, if neither criminal nor pauper, has the right of voting, but only in the choice of deputy-electors, by whom the real election of the representatives is decided. The members of the lower House are elected for eight years, and meetings of Parliament must take place every two years.

By the treaty of Lunéville in 1801, Baden acquired a considerable addition of territory; in 1803 the margrave received the title of Elector; and by the treaty of Presburg in 1805 his domains were still further increased by the accession of Breisgau. On the dissolution of the empire in 1806, the elector joined the Confederation of the Rhine, and received the title of Grand Duke, with 1950 square miles of additional territory. In 1821 the union of the two Protestant churches in Baden was brought about. Other questions of importance, such as trial by jury, freedom of the press, abolition of tithes, and extension of education, became subjects of interest and debate; but unfortunately, the influence of the French revolution of 1830 led the democratic party to excesses, which the Government met with acts of ill-advised repression. Matters were beginning to readjust themselves when the Revolution of 1848 again aroused

the opposing forces. In 1849 the duke was constrained to flee, and Bretano, the democratic leader, took possession of Carlsruhe in the name of the national committee. By the 25th of June, however, the Prussian forces, after several severe engagements with the revolutionists, effected the restoration of the duke, who returned to his capital on 18th August; and it was not long before the country began to recover from the effects of the outbreak. Not, indeed, that it became quiescent; for Baden has had its full share in the political and ecclesiastical disputes that have been so rife throughout Germany during recent years. The Roman Catholic clergy, with the bishop of Freiburg at their head, have maintained an obstinate struggle with the Liberal party, which is now predominant. The separation of church and state has been established; the Jews have been admitted to full civic rights; freedom of trade has been promulgated, and a number of minor reforms successfully carried through. In the German war of 1866 Baden sided against Prussia; but in 1870 it joined in the formation of the new German empire, and its troops are incorporated in the 14th corps of the imperial army.

BADEN (or BADEN-BADEN, to distinguish it from other places of the name), a town and celebrated watering-place of Germany, in the grand duchy of Baden. It stands on the side of a hill, near the Oos or Oel, in a beautiful valley of the Black Forest, 18 miles S.W. of Carlsruhe; and it is connected by a branch with the Manheim and Basel railway. The superiority of its situation, its extensive pleasure-grounds, gardens, and promenades, and the brilliancy of the life that is led during the season, have for a long series of years continued to attract crowds of visitors from all parts of the world. The resident population amounts to about 10,000, but that number is frequently augmented fourfold. The prevailing nationality is, or rather was, the French, but Americans, Russians, and English are all numerously represented. The hot springs, which are among the earliest attractions of the place, are twenty-nine in number, and vary in temperature from 37° to 54° R., *i.e.*, from 115° to 153° Fahr. They flow from the castle rock at the rate of 90 gallons per minute, and the water is conveyed through the town in pipes to supply the different baths. The town proper is on the right bank of the Oos, but the principal resorts of the adventitious population are on the other side. A *Conversationshaus* and a *Trinkhalle* or pump-room (1842), a theatre (1861), and a picture-gallery, are among the chief fashionable buildings, to which may be added the library and reading-room. The gaming-tables, which for so many years were a striking feature of Baden-Baden, are now abolished. The only building of much antiquarian interest, with the exception of the castles, is the parish church, which dates from the 15th century, and contains the tombs of several of the margraves. There is a Protestant church a short distance to the east of Leopoldsplatz, and not far off a small Episcopalian church; while on the Michaelsberg is the Greek chapel, with its gilded dome, which was erected over the tomb of the Roumanian prince, Michael Stroudza, who died at Baden in 1863.

BADEN, Switzerland, a small town in the canton of Aargau, on the Limmat, fourteen miles northwest of Zurich. It is much frequented on account of its warm medicinal springs, which are about twenty in number, and vary in temperature from 98° to 126° Fahr. About 15,000 persons visit the place annually. Tacitus, in the first book of his *Histories*, incidentally speaks of it, and numerous remains of pillars and inscriptions, coins, and other antiquities confirm his description

BADEN, the chief town of a circle in Lower Austria, about 12 miles S. of Vienna on the railway to Gratz. It is beautifully situated at the mouth of the romantic *Helenenthal*, near the banks of the Schwachat, a rapid stream with several waterfalls, and has become a favorite summer resort with the inhabitants of the neighboring capital. The warm baths, which give name to the town, are thirteen in number, and vary in temperature from 72° to 97° Fahr. Population, 6,500.

BADGER (*Meles*), a family of Plantigrade Carnivora, possessing greatly elongated bodies and short limbs, each of the latter furnished with five toes, provided at their extremities with long, powerful claws, by means of which they form deep burrows in the earth. The carnassial tooth, which in the bears is wholly tuberculate, is in the badgers provided also with a cutting edge, their whole dentition being specially adapted to the partly vegetable, partly animal diet on which they subsist. The badger differs from all other mammals in having the lower jaw so articulated to the upper, by means of a transverse condyle firmly locked into a long cavity of the cranium, that dislocation of the jaw is all but impossible, and this enables those creatures to maintain their hold with the utmost tenacity. The European badger (*Meles Taxus*) may be taken as typical of the entire family. It is nowhere abundant, but is found over the entire northern parts of Europe and Asia. It is a quiet, inoffensive animal, nocturnal and solitary in its habits, sleeping by day in its burrow, and issuing forth at night to feed on roots, beech-mast, fruits, the eggs of birds, some of the smaller quadrupeds, frogs, and insects. It is said also to dig up the nests of wasps in order to eat the larvæ, as the ratel — a closely allied South African form — is said to rob the bees of their honey. The male and female are seldom seen together, and are supposed to trace each other by means of the odor of the secretion contained in a glandular pouch beneath the tail. Although the badger does not seek to attack, yet, when driven to bay, its great muscular power and tough hide renders it a formidable antagonist, as was often seen in the days, now happily gone by, when badger-baiting was a favorite amusement of the English peasantry.

BADIA Y LEBLICH, DOMINGO, a celebrated Spanish traveller, better known under his assumed name of Ali Bey, was born in Biscay in the year 1766. Under the name of Ali Bey and in Mussulman costume, he visited Egypt, Marocco, Tripoli, Arabia, and Syria, and was received as a person of high rank wherever he appeared. On his return to Europe in 1807 he declared himself a Bonapartist, and was made Intendant, first of Segovia, and afterwards of Cordova. When the French were driven from Spain, Badia was compelled to take refuge in France, and there, in 1814, published an account of his travels. A few years later he set out again for Syria, under the assumed name of Ali Othman and, it is said, accredited as a political agent by the French Government. He only reached Aleppo, and there died, 30th August 1818, not without suspicion of having been poisoned.

BADIUS, JODOCUS or JOSSE, sometimes called BADIUS ASCENSIUS, from the village of Asche, near Brussels, where he was born in 1462, was an eminent printer at Paris, whose establishment was celebrated under the name of *Prelum Ascensianum*. He died in 1535.

BADMINTON, a game of recent introduction. It may be played in or out of doors, by any number of persons from two to eight. It is played with battledores and shuttlecocks.

BADRINATH, a town and celebrated temple in Hindustán, in the British district of Garhwal, situate on the right bank of the Vishnugangá, a tributary of the Alaknandá River, in the middle of a valley nearly 4 miles in length and 1 in breadth. The town is small

containing only twenty or thirty huts, in which reside the Bráhmans and the attendants on the temple. The building, however, which is considered a place of high sanctity, by no means corresponds to its great celebrity.

BAENA, a town of Spain, in the province of Cordova, 8 leagues S.E. of the city. It is picturesquely situated, near the River Marbello, on the slope of a hill crowned with a castle, which formerly belonged to Gonsalo de Cordova, and is now the property of the Altamira family.

BAEZA (ancient *Beatia*), a city of Spain, in the province of Jaen. It stands on a considerable elevation, about 3 miles from the right bank of the Guadalquivir.

BAFFIN, WILLIAM, an able and enterprising English seaman, born in 1584. Nothing is known of his early life, and his fame rests entirely on the voyages undertaken by him during the years 1612 to 1616. In 1612 he accompanied Captain James Hall on his fourth voyage in search of the north-west passage, and in 1613 he commanded one of the English vessels engaged in the Greenland fisheries. In 1615 and 1616 Baffin made two voyages in the "Discovery" under Bylot, and on the second of them explored the large inlet, afterwards called Baffin's Bay.

BAFFIN'S BAY, or BAFFIN'S SEA, is properly neither a bay nor a sea, but part of the long strait or inlet which separates Greenland from the N.E. coast of America.

BAGATELLE is an indoor game, probably derived from the old English shovel-board, described by Cotton in his *Compleat Gamester* (1674), though many consider that its invention is due to the French. Like billiards, chess, and draughts, its origin is not certainly known; but whatever its genesis, its name is undoubtedly French. Bagatelle games are played on the oblong board, usually from six to ten feet in length, by a foot and a half to three feet in width. The bed of the table, which is ordinarily of slate or mahogany, is covered with fine green cloth; and at the upper end, which is rounded, there are nine holes or cups, numbered from 1 to 9.

Into these holes ivory balls are driven by a cue in all respects similar to the instrument used in BILLIARDS, which see. The sides and circular end of the table are furnished with elastic cushions; and in some of the newer tables there is also a pocket on each side. Nine balls — eight white, and one red or black (sometimes four white, four red, and one black) — are used in the most popular of the several bagatelle games.

BAGGESEN, JENS EMMANUEL, the most prominent literary figure in Denmark during the latter part of last century, was born on the 15th of February 1765, at Korsör. His parents were very poor, and before he was twelve he was sent to copy documents at the office of the clerk of the district. By dint of indomitable perseverance, he managed to gain an education, and in 1782 entered the university of Copenhagen. His success as a writer was coeval with his earliest publication; his *Comical Tales* in verse, poems that recall the *Broad Grins* that Colman the younger brought out a decade later, took the town by storm, and the struggling young poet found himself a popular favorite at twenty-one. He then tried serious lyrical writing, and his tact, elegance of manner, and versatility, gained him a place in the best society. This sudden success received a blow in 1788, when a very poor opera he had produced was received with mockery, and a reaction against him set in. He left Denmark in a rage, and spent the next years in Germany, France, and Switzerland. In the country last mentioned he married, began to write in German, and published in that language his next poem, *Alpenlied*. In 1790 he returned to his mother-country, bringing with him as a peace-offering his fine descriptive poem, the *Labyrinth*, in Danish, and was received with unbounded homage. The next twenty years were spent in incessant restless wanderings over the north of Europe, Paris latterly becoming his nominal home. He continued to publish volumes alternately in Danish and German. In 1811 he returned to Copenhagen to find the young Ohlenschläger installed as the great poet of the day, and he himself beginning to lose his previously unbounded popularity. Until 1820 he resided in Copenhagen, in almost unceasing literary feud with some one or other, abusing and being abused, the most important feature of the whole being Baggesen's determination not to allow Ohlenschläger to be considered a greater poet than himself. He then went back to his beloved Paris, where he lost his wife and youngest child, and fell at last into a state of hopeless melancholy madness. In 1826, having slightly recovered, he wished to see Denmark once more, but died at Hamburg on his way, on the 3d of October, and was buried at Kiel.

BAGHDAD, a Turkish pashalic or government of Asia, computed to have an area of above 100,000 square miles. It stretches in a N.W. direction, from the mouth of the Shatt-el-Arab at Bussorah, to Merdin, situated near the source of the Tigris; and from the confines of Persia to the banks of the Khabour, which separates it from the pashalic of Diarbekir. Its general boundaries are the Euphrates and the Arabian desert of Nejd to the W. and S., Kusistan and Mount Zagros to the E., the pashalic of Diarbekir to the N.W., and Armenia with the territories of the Kurdish chief of Julamerick to the N. This great tract comprehends ancient Babylonia and the greatest part of Assyria proper. The first includes the space enclosed by the Tigris and the Euphrates, which is also known under the general appellation of Mesopotamia; and the second, that which is beyond the Tigris, commonly called Lower Kurdistan. This tract of country is an extensive and very fertile plain, and is watered by the Tigris and Euphrates, which at Baghdad approach within 25 miles of each other, and afford an inexhaustible supply of the finest water. Only some parts of these fertile districts, however, are cultivated, as the population consists in many places of wandering Arabs, who are averse to agriculture, and who, in their vagrant life of idleness and rapine, neglect all the natural advantages of the country. The most productive portion of the pashalic is on the banks of the Shatt-el-Arab, in the neighborhood of Bussorah. This tract, for upward of 30 miles below that city, is well cultivated and yields vast quantities of dates, wheat, barley, and various kinds of fruits. The banks of the Euphrates produce abundant crops of dry grain. Higher up the Euphrates, the country which is possessed by the Arabs is a low marshy tract, formed by the expansion of the Euphrates, and is famed for plentiful crops of rice. Among the mountainous districts of the Upper Euphrates the country is highly picturesque and beautiful; it is watered by the River Mygdonius (the Gozan of Scripture), and is in a tolerable state of cultivation. It produces in abundance the finest fruits, such as grapes, olives, figs, pomegranates, which are considered the most delicious in the east; apples, pears, apricots of an inferior quality; and the finest dates, on which the inhabitants, as in other parts of Asia, depend in many cases for subsistence. The domestic animals are, the horse, for which the country has long been famed, the ass, camel, dromedary, buffalo and mule. Of the wild animals, the lion, the hyena, the jackal, the wolf, and the wild boar, are common; and antelopes are very numerous. Hares are plentiful, but foxes are seldom seen. All sorts of poultry are bred except the

turkey. On the cultivated lands, and on the borders of the rivers, the black partridge is met with in great numbers. Snipes and almost every species of wild fowl may be found in the marshes, and pelicans on the banks of the Euphrates and Tigris. In addition to these two rivers the country is watered by the Khabour or Chaboras, formed by the junction of several small streams about ten miles to the S.W. of Merdin, and by the Mygdonius, or Gozan, the Hermas of the Arabs, which used formerly to discharge a part of its waters into the Euphrates through the Khabour, and a part into the Tigris through the Thirthar, passing by Hatra, but which is now entirely lost in a salt marsh at the foot of the Singar hills.

In ancient times the plain of Mesopotamia was occupied by the great and wealthy cities of Nineveh, Babylon, Seleucia, Ctesiphon, &c., and was in a high state of cultivation. It was intersected by many well-constructed canals and other works, which, in dispersing over the country the superfluous waters of the Tigris and Euphrates, proved extremely useful to agriculture. These works are now all ruined, and not a vestige remains of many of the canals, while the course of others can only be faintly traced in their imperfect remains. One canal, however, called El-Hye, still exists; it connects the Euphrates and the Tigris exactly half-way between Bussorah and Baghdad, and is navigable in spring for large boats.

BAGHDAD, a city of Asia, formerly the capital of the empire of the caliph, and long renowned for its commerce and its wealth, is situated on an extensive and desert plain, which has scarcely a tree or village throughout its whole extent; and though it is intersected by the Tigris, it stands mostly on its eastern bank, close to the water's edge. The town has been built without the slightest regard to regularity. The streets are even more intricate and winding than those in most other Eastern towns; and, with the exception of the bazaars and some open squares, the interior is little else than a labyrinth of alleys and passages. The streets are unpaved, and in many places so narrow that two horsemen can scarcely pass each other; and as it is seldom that the houses have windows facing the great public thoroughfares, and the doors are small and mean, they present on both sides the gloomy appearance of dead walls. All the buildings, both public and private, are constructed of furnace-burnt bricks, of a yellowish-red color, taken chiefly from the ruins of other edifices, as their rounded angles evidently show.

The principal public buildings in Baghdad are the mosques, the khans or caravanserais, and the serai or palace of the pasha. The palace, which is situated in the north-western quarter of the town, not far from the Tigris, is distinguished rather for extent than grandeur. It is a comparatively modern structure, built at different periods, and forming a large and confused pile, without proportion, beauty, or strength. There are no remains of the ancient palace of the caliphs.

In all Mahometan cities the mosques are conspicuous objects. The number in Baghdad is above 100; but of these not more than thirty are distinguished by the characteristic minarets or steeples, the rest being merely chapels and venerated places of prayer. The most ancient of these mosques was erected in the year of the Hegira 633, or 1235 of the Christian era, by the Caliph Mustansir.

There are about thirty khans or caravanserais in Baghdad, all of the inferior construction to those in the other large towns of Turkey. The only remarkable building of this class is called *Khan-el-Aourtmeh*, and adjoins the Merjaneeah mosque, to which it formerly belonged.

The only other Mahometan remains which it is necessary to mention are — 1. The Tekiych, or shrine of the Bektash dervishes, on the western bank of the river. The shrine is in ruins, but it contains a fine Cufic inscription now mutilated, which bears the date of 333 A.H. (or 944 A.D.) 2. The tomb of the famous Maaruf-el-Kerkhi, in the immediate vicinity, dating from 1215 A.D. 3. In Eastern or New Baghdad the college of Mustansir, near the bridge, now in ruins, but bearing a fine inscription dated 630 A.H. (or 1233 A.D.) 4. The shrine of the famous Saint Abdel Kadir, which is visited by pilgrims from all parts of the Mahometan world.

Baghdad has much declined from its ancient importance. It was formerly a great emporium of Eastern commerce; and it still receives, by way of Bussorah, from Bengal the manufactures and produce of India, which are distributed over Arabia, Syria, Kurdistan, Armenia, and Asia Minor. At the same time the inland trade from Persia and the East has fallen off. The productions and manufactures of Persia, which were intended for the Syrian, Armenian, and Turkish markets, and were sent to Baghdad as a central depôt, now reach Constantinople by the more direct route of Erzeroum and Tocat. Wealth, indeed, appears to be deficient among all classes, and Baghdad has many symptoms of a decayed city.

The population is a mixture of nations from various quarters of the East. The chief officers of Government, whether civil or military, are of the families of Constantinoplian Turks, though they are mostly natives of the city; the merchants and traders are almost all of Persian or Arabian descent; while the lower classes consist of Turks, Arabs, Persians, and Indians.

Baghdad is governed by a pasha, assisted by a council. He was formerly chosen from the ranks of the Georgian Mamelukes, but is now always selected from among the highest officers of the Constantinople court, his term of office being usually for four or five years. He is also governor-general of Irak, and possesses supreme authority from Diarbekir to Bahrein, though he does not under ordinary circumstances interfere with the subordinate governments of Mosul and Kurdistan.

The East India Company used to maintain a resident in Baghdad with a large establishment, and his post is now replaced by that of a consul-general and political agent. A French consul is also regularly appointed.

Until recently Baghdad was supposed to be entirely a Mahometan city, dating from the time of Al Mansúr; but Sir H. Rawlinson discovered in 1848, during an unusually dry season, when the rivers had fallen six feet below the ordinary low-water mark, that the western bank of the Tigris was lined with an embankment of solid brick-work, dating from the time of Nebuchadnezzar, as the bricks were each stamped with his name and titles; and it has been since remarked that in the Assyrian geographical catalogues of the time of Sardanapalus, one of the Babylonian cities bears the name of *Bagdad*, and may thus very possibly represent the after site of the capital of the caliphs. According to the Arabian writers, however, there were no traces of former habitation when Al Mansúr laid the foundation of the new city. It was adorned with many noble and stately edifices by the magnificence of the renowned Haroun al Raschid, who also built on the eastern side of the river, connecting the two quarters of the town by a bridge of boats. Under the auspices of Zobeide, the wife of that prince, and Jaffer the Barmecide, his favorite, the city may be said to have attained its greatest splendor. It continued to flourish and increase, and to be the seat of elegance and learning, until the 656th year of the Hegira (1277 A.D.), when Hulaku the Tatar,

the grandson of Genghis Khan, took it by storm, and extinguished the dynasty of the Abassides.

BAGHERMI, or BAGIRMI, a district or kingdom of Central Africa, lying to the S. of Lake Chad and S.W. of Bornu. It extends about 240 miles from N. to S., and has a breadth of barely 150 miles. The surface is almost flat, with a slight inclination to the N., and the general elevation is about 950 feet above sea-level. The Shari, a large and always navigable river, forms the western boundary, and throws out an important effluent called the Bachikam, which passes through the heart of the country. The soil consists partly of lime and partly of sand, and is by no means unfertile. In many parts not a stone is to be seen. Negra-millet, sesamum, and sorghum are the principal grains in cultivation, but rice grows wild, and several kinds of grass or *poa* are used as food by the natives. Cotton and indigo are grown to a considerable extent, especially by Bornu immigrants. Among the trees the most important are the tamarind, the deleb-palm, the dum-palm, the hajilij or *Balanites ægyptiaca*, the sycamore, and the cornel. The country often suffers from drought, and is greatly plagued with worms and insects, especially ants of all kinds, red, black, and white.

BAGHMATI, a river of Hindustán, which has its source in the hills to the north of Kátmandu, the capital of Nepál, whence it flows in a southerly direction through the district of Tirhut in the province of Behar, and, receiving the waters of the Buchiá on its north bank, and of Burá Gandak on its south bank, joins the Ganges, after a course of 285 miles.

BAGLIVI, GIORGIO, an illustrious Italian physician, descended from a poor persecuted Armenian family, was born at Ragusa in 1769, and assumed the name of his adoptive father, Pietro Angelo Baglivi, a wealthy physician of Lecce. He studied successively at the universities of Salerno, Padua, and Bologna; and after travelling over Italy, he went in 1602 to Rome, where, through the influence of the celebrated Malpighi, he was elected professor of anatomy in the college of Sapienza. He died at Rome in 1707, at the early age of thirty-eight.

BAGNACAVALLO, BARTOLOMMEO, an Italian painter, who flourished about the beginning of the sixteenth century and died in 1542.

BAGNÈRES-DE-BIGORRE (the *Vicus Aquensis* of the Romans), the capital of an arrondissement in the department of Hautes-Pyrénées, is situated on the left bank of the Adour, 13 miles S.E. of Tarbes. It is one of the principal watering-places in France, and is much admired for its picturesque situation and the beauty of its environs, particularly the valley of Campan, which abounds with beautiful gardens and handsome villas. Population, 10,000.

BAGNÈRES-DE-LUCHON, a small well-built town of France, department of Haute-Garonne, pleasantly situated in the valley of the Luchon, at the foot of the Pyrenees. It is celebrated for its sulphurous thermal springs, which vary in temperature from 88° to 180° Fahr. Resident population, 4,000.

BAGPIPE, a musical instrument of unknown antiquity which seems to have been at one time or other in common use among all the nations of Europe, and still retains its place in many Highland districts, such as Calabria, the Tyrol, and the Highlands of Scotland. The wind is generally supplied by a blowpipe, though in some cases bellows are used. These, and other slight variations, however, involve no essential difference in character or construction, and a description of the great bagpipe of the Highlands of Scotland will serve to indicate the leading features of the instrument in all its forms. It consists of a large wind-bag made of greased leather covered with woolen cloth; a mouth-tube, valved, by which the bag is inflated with the player's breath; three reed drones; and a reed chanter with finger-holes, on which the tunes are played. Of the three drones, one is long and two are short. The longest is tuned to A, an octave below the lowest A of the chanter, and the two shorter drones are tuned each an octave above the A of the longest drone; or, in other words, in unison with the lowest A of the chanter. The scale of the chanter has a compass of nine notes, all natural, extending from G on the second line of the treble stave up to A in alt.

BAGRATION, PETER, PRINCE, a distinguished Russian general, descended from the noble Georgian family of the Bagratides, was born in 1765. In 1782 he entered the Russian army and served for some years in the Caucasus. In 1788 he was engaged in the siege of Oczacow, and afterwards accompanied Suwaroff, by whom he was highly esteemed, through all his Italian and Swiss campaigns. He particularly distinguished himself in 1799 by the capture of the town of Brescia. He was mortally wounded in the bloody battle of Borodino, 7th Sept. 1812, and died one month later.

BAHAMAS, or LUCAYAS, a very numerous group of islands, cays, rocks, and reefs, comprising an area of 3021 square miles, lying between 21° 42′ and 27° 34′ N. lat. and 72° 40′ and 79° 5′ W. long. They encircle and almost enclose the Gulf of Mexico, stretching more than 600 miles from the eastern coast of Florida to the northern coast of St. Domingo, and are traversed by only three navigable channels — 1st, the Florida Channel to the N., which runs along the coast of the United States and lies to the westward of the whole Bahama group; 2d, the Providence Channels, passing through the group to the N., and separating the Great and Little Banks; and 3d, the old Bahama Channel, which passes to the S. of the Great Bahama Bank, between it and Cuba. The islands lie for the most part on the windward edge of the Great and Little Banks, or of the ocean sounds or tongues which pierce them. The total number of islands is 29, while the cays are reckoned at 661, and the rocks at 2387. The principal islands are New Providence (which contains the capital Nassau), Abaco, Harbor Island, Eleuthera, Inagua, Mayaguana, St. Salvador, Andros Island, Great Bahama, Ragged Island, Rum Cay, Exuma, Long Island, Crooked Island, Acklin Island, Long Cay, Watling Island, the Berry Islands, and the Biminis. Turk's Island and the Caicos, which belong geographically to the Bahama group, were separated politically in 1848. The formation of all the islands is the same, — calcareous rocks of coral and shell hardened into limestone, honeycombed and perforated with innumerable cavities, without a trace of primitive or volcanic rock; the surface is as hard as flint, but underneath it gradually softens and furnishes an admirable stone for building, which can be sawn into blocks of any size, these hardening on exposure to the atmosphere. The shores are generally low, the highest hill in the whole range of the islands being only 230 feet high. The soil, although very thin, is very fertile. On Andros Island and on Abaco there is much large timber, including mahogany, mastic, lignum vitæ, iron, and bullet woods, and many others. Unfortunately the want both of labor and of roads renders it impossible to turn this valuable timber to useful account. The fruits and spices of the Bahamas are very numerous, — the fruit equalling any in the world. The produce of the islands includes tamarinds, olives, oranges, lemons, limes, citrons, pomegranates, pine-apples, figs, sapodillas, bananas, sowersops, melons, yams, potatoes, gourds, cucumbers, pepper, cassava, prickly pears, sugar cane, ginger, coffee, indigo, Guinea corn and pease. Tobacco and cascarilla

bark also flourish; and cotton is indigenous, and was woven into cloth by the aborigines.

It is a remarkable fact that except in the island of Andros, no streams of running water are to be found in the whole group. The inhabitants derive their water supply from wells, the rain-water in which appears to have some connection with the sea, as the contents of the wells rise and fall with the tide upon the neighboring shore. The Bahamas are far poorer in their fauna than in their flora. It is said that the aborigines had a breed of dogs which did not bark, and a small coney is also mentioned. The guana also is indigenous to the islands. Oxen, sheep, horses, and other live stock introduced from Europe, thrive well, but of late years very little attention has been paid to stock rearing, and Nassau has been dependent upon Cuba for its beef, and on the United States or Nova Scotia for its mutton. There are many varieties of birds to be found in the woods of the Bahamas; they include flamingoes and the beautiful humming-bird, as well as wild geese, ducks, pigeons, hawks, green parrots, and doves. The waters of the Bahamas swarm with fish, and the turtle procured here is particularly fine. In the southerly islands there are salt ponds of great value.

The story of the Bahamas is a singular one, and bears principally upon the fortunes of New Providence, which, from the fact that it alone possesses a perfectly safe harbor for vessels drawing more than 9 feet, has always been the seat of Government, when it was not the headquarters of lawless villainy. St. Salvador (Cat Island, or as some suppose, Watling Island), however, claims historical precedence as the landfall of Columbus on his memorable voyage. He passed through the islands, and in one of his letters to Ferdinand and Isabella he said, "This country excels all others as far as the day surpasses the night in splendor; the natives love their neighbors as themselves; their conversation is the sweetest imaginable; their faces always smiling; and so gentle and so affectionate are they, that I swear to your highness there is not a better people in the world." But the natives, innocent as they appeared, were doomed to utter destruction. Ovando, the governor of Hispaniola, who had exhausted the labor of that island, turned his thoughts to the Bahamas, and in 1509 Ferdinand authorised him to procure laborers from these islands. It is said that reverence and love for their departed relatives was a marked feature in the character of the aborigines, and that the Spaniards made use of this as a bait to trap the unhappy natives. They promised to convey the ignorant savages in their ships to the "heavenly shores," where their departed friends now dwelt, and about 40,000 were transported to Hispaniola to perish miserably in the mines. From that date until after colonisation of New Providence by the English, there is no record of a Spanish visit to the Bahamas, with the exception of the extraordinary cruise of Juan Ponce de Leon, the conqueror of Porto Rico, who passed months searching the islands for "Bimini," which was reported to contain the miraculous "Fountain of Youth."

The deserted islands were first visited by the English in 1629, and a settlement formed in New Providence, which they held till 1641, when the Spaniards expelled them but made no attempt to settle there themselves. The English again took possession in 1667, and in 1680 Charles II. made a grant of the islands to George, Duke of Albemarle; William, Lord Craven; Sir George Carteret; John, Lord Berkeley; Anthony, Lord Ashley: and Ser Peter Colleton. Governors were appointed by the lords proprietors, and there are very copious records in the state papers of the attempts made to develop the resources of the island; but the repeated attacks of the Spaniards, and the tyranny and mismanagement of the governors, proved great obstacles to success. In July 1703 the French and Spaniards made a descent on New Providence, blew up the fort, spiked the guns, burnt the church, and carried off the governor, with the principal inhabitants, to the Havannah; and in October the Spaniards made a second descent, and completed the work of destruction. It is said that when the last of the governors appointed by the lords proprietors, in ignorance of the Spanish raid, arrived in New Providence, he found the island without an inhabitant. It soon, however, became the resort of pirates, and the names of many of the worst of these ruffians is associated with New Providence, the notorious Blackbeard being chief among the number. At last matters became so intolerable that the merchants of London and Bristol petitioned the Crown to take possession and restore order, and Captain Woods Rogers was sent out as the first Crown governor, and arrived at New Providence in 1718. Many families of good character now settled at the Bahamas, and some progress was made in developing the resources of the colony, although this was interrupted by the tyrannical conduct of some of the governors who succeeded Captain Woods Rogers. At this time the pine-apple was introduced as an article of cultivation at Eleuthera; and a few years subsequently, during the American war of independence, colonists arrived in great numbers, bringing with them wealth and also slave labor. Cotton cultivation was now attempted on a large scale. In 1783, at Long Island, 800 slaves were at work, and nearly 4000 acres of land under cultivation. But the usual bad luck of the Bahamas prevailed; the red bug destroyed the cotton crops in 1788, and again in 1794, and by the year 1800 cotton cultivation was almost abandoned, There were also other causes that tended to retard the progress of the colony. In 1776 Commodore Hopkins, of the American navy, took the island of New Providence; he soon, however, abandoned it as untenable, but in 1782 it was retaken by the Spanish governor of Cuba. The Spaniards retained nominal possession of the Bahamas until 1783, but before peace was notified New Providence was recaptured by a loyalist, Colonel Devaux, of the South Carolina militia, in June 1783. In 1787, the descendants of the old lords proprietors received each a grant of £2000 in satisfaction of their claims, and the islands were formally reconveyed to the Crown. The Bahamas began again to make a little progress, until the separation of Turks and Caicos Islands in 1848, which had been hitherto the most productive of the salt-producing islands, unfavorably affected the finances. Probably the abolition of the slave trade in 1834 was not without its effect upon the fortunes of the landed proprietors.

The next event of importance in the history of the Bahamas was the rise of the blockade-running trade, consequent on the closing of the southern ports of America by the federals in 1861. At the commencement of 1865 this trade was at its highest point. In January and February 1865 no less than 20 steamers arrived at Nassau, importing 14,182 bales of cotton, valued at £554,675. The extraordinary difference between the normal trade of the islands and that due to blockade-running, will be seen by comparing the imports and exports before the closing of the southern ports in 1860 with those of 1864. In the former year the imports were £234,029, and the exports £157,350, while in the latter year the imports were £5,346,112, and the exports, £4,672,398. The excitement, extravagance, and waste existing at Nassau during the days of blockade-running exceed belief. Individuals may have profited largely, but the Bahamas probably benefited little The Government managed to pay its debt amounting to

£43,786, but crime increased, and sickness became very prevalent. The cessation of the trade was marked, however, by hardly any disturbance; there were no local failures, and in a few months the steamers and their crews departed, and New Providence subsided into its usual state of quietude. This, however, was not fated to last long, for in October 1866 a most violent hurricane passed over the island, injuring the orchards, destroying the fruit-trees, and damaging the sponges, which had proved hitherto a source of profit. The hurricane, too, was followed by repeated droughts, and the inhabitants of the out-islands were reduced to indigence and want. There was an increase, however, in the production of salt. The exports as a whole fell off. The rainfall is heavy from May to October. During the winter months it is small, and from the month of November up to April the climate of New Providence is most agreeable. Advantage has been taken of this for many years by the inhabitants of the mainland of America, who can escape by a four days' voyage from the icy winter of New York to the perpetual summer of the Bahamas. New Providence has gained a name as a resort for the consumptive, and perhaps justly so far as the Anglo-Saxon race is concerned, but the Africans and colored races suffer greatly from diseases of the lungs, and the black troops stationed at Nassau have always been notorious for the proportion of men invalided. Population, 40,000.

BAHAWALPUR, capital of an Indian native State in political connection with the Punjab, lies near the left bank of the Sutlej. Population (1881), 13,635. The great majority of the inhabitants are Mohammedans.

BAHIA, a province of the Brazilian empire, situated on the S.E. coast, and extending from the Rio Grande do Belmonte in the S. to the Rio Real in the N. It is bounded by Sergipe and Pernambuco on the N., by Piauhi on the N.W., by Goyaz on the W., and on the S. by Minas Geraes and Espirito Santo. It has an area of 202,272 square miles, and its population is stated at 1,450,000. Bahia sends 14 deputies to the general assembly of the empire, and 7 senators to the upper house, while its own legislative assembly consists of 36 members. Besides Bahia the capital, Olivença, Branca, Jacobina, and Joazeira are important towns. A chain of mountains, broken into numerous sierras, runs from N. to S. through the province at the distance of 200 miles from the coast, while the intermediate district gradually rises in successive terraces. The maritime region, the so-called *Reconcavo*, is remarkably fertile, and is studded with thriving towns and villages, but the interior is often very dry and barren, and is only thinly peopled in many places with wandering Botacudos. The main sources of wealth of the province are cotton, coffee, sugar, and tobacco, all of which are cultivated with the greatest success. Mandioc, rice, beans, and maize are grown; also jalap, ipecacuanha, and saffron, as well as oranges, mangoes, and various other fruits. A large portion is still covered with primeval forest, but the woodman is rapidly diminishing the extent. The mineral wealth of the province is but partially explored and still more partially utilized. In 1844 diamond mines were discovered to the N. of the River Peraguass, and, till the deposits near the Cape of Good Hope were brought to light, afforded employment to a large number of *garimpeiros* or "washers."

BAHIA, or, in full, SAN SALVADOR DA BAHIA DE TODOS OS SANTOS, a large city, and, till 1763, the capital of Brazil, is situated on the S.E. coast on the Bay of All Saints, from which it takes its name, in 13° S. lat., and 38° 20′ W. long. Built partly along the foot and partly on the top of a steep hill, it consists of an upper and lower town, communication between the two being effected by large flights of steps, and since 1873 by a powerful hydraulic elevator. The carrying of goods and passengers up and down these stairway-streets affords employment to a large number of negro porters and chairmen. The lower town, or Praya, consists mainly of one long and narrow street, with still narrower and more tortuous lanes. The houses are built of stone, and many of them are several stories high. This is the business part of the city, where are situated the quays, docks, warehouses, custom-houses, exchange, and arsenal; and here the sailors, porters, and lower classes generally reside. The church of *Nostra Señora da Praya* is remarkable as having been built of stones that were hewn in Lisbon and shipped across the ocean. The upper city has wide and well-paved streets, open squares, and pleasant promenades, adorned with orange trees and bananas. The most important is the *Passeio Publico*, which was open in 1814, and overlooks the beautiful bay. There is no city in Brazil that can vie with Bahia in the number and splendor of its ecclesiastical buildings, among which the Jesuits' college, now used as a hospital, and the cathedral, which is built of marble, are pre-eminent. There are likewise numerous educational institutions, including a lyceum (in which Latin, Greek, French, and English, mathematics, philosophy, &c., are taught), a theological seminary, and a medical academy, which is supported by the imperial Government, and has about 400 students. The museum and public library also deserve mention. Among the buildings connected with the civic and commercial activity of the city are the government-house, the court-house, the mint, and the town-house; also the *Alfandega*, where all foreign importations have to be entered, and the *Consolado*, where all native productions are registered for exportation. There are likewise a number of banks and commercial associations of various kinds. Bahia has long been a place of great traffic.

Bahia was visited in 1503 by Amerigo Vespucci. The first settlement was founded and called San Salvador by Diego Alvarez Correa, who had been shipwrecked on the coast; but the Portuguese governor who gave formal existence to the city was Thomas de Souza, who landed in 1549. It owed its increase to the Jesuits, who defended it against the English in 1588. In 1623 it fell into the hands of the Dutch, who held it for two years. In 1823 it was surrended by the Portuguese to the Brazilian nationality. A revolution, which broke out in the city in 1837, was suppressed by the imperial government. The first printing-press was introduced in 1811, and the first sugar-mill in 1823. In 1858 railway communication was established to Joazeiro.

BAHRDT, KARL FRIEDRICH, a German theologian, distinguished for his extreme rationalism and his erratic life, was born in 1741 at Bischofswerda, of which place his father, afterwards professor of theology at Leipsic, was for some time pastor. His numerous works, including a translation of the New Testament, are comparatively worthless, and are written in an offensive tone. He has been well called by Herzog a caricature of the rationalism of the 18th century.

BAHREIN, the principal island of a cluster in the Persian Gulf, in an indentation of the Arabian coast. It is about 70 miles long and nearly 25 broad, and is very flat and low except towards the east, where a range of hills attain an elevation of 800 or 900 feet. The climate is mild, but humid, and rather unhealthy. The soil is for the most part fertile, and produces rice, pot herbs, and fruits, of which the citrons are especially good. Water is abundant, but frequently brackish. Fish of all kinds abound off the coast, and are very cheap in the markets. The inhabitants are a mixed race of Arab, Omanite, and Persian blood, slender

and small in their physical appearance; they possess great activity and intelligence, and are known in all the ports of the Persian Gulf for their commercial and industrial ability.

BAIÆ, an ancient town of Campania, Italy, situated between the promontory of Misenum and Puteoli, on the Sinus Baianus, and famous for its warm springs and baths, which served the wealthier Romans for the purposes both of health and pleasure. The variety of these baths, the mildness of the climate, and the beauty of the landscape, captivated the minds of the opulent nobles. It flourished till the days of Theodoric the Goth; but its destruction followed quickly upon the irruption of the northern conquerors. When the guardian hand of man was withdrawn, the sea reclaimed its old domain; moles and buttresses were washed away; and promontories, with the proud towers that once crowned their brows, were undermined and tumbled into the deep. Innumerable ruins, heaps of marble, mosaics, and other relics of the past, attest the ancient splendor of the city.

BAIBURT, a town of Asiatic Turkey, in the pashalic of Erzeroum, and 65 miles W.N.W. from that city. Population of town about 6000.

BAÏF, JEAN ANTOINE DE, poet of the French Renaissance and member of the Pleiad, was the natural son of Lazare de Baïf and an Italian girl. He was born in 1532 at Venice, where his father was residing as French ambassador. Thanks, perhaps, to the surroundings of his childhood, he grew up a fanatic for the fine arts, and surpassed in zeal all the leaders of the Renaissance in France. Besides writing an immense number of short poems of an amorous or congratulatory kind, he translated or paraphrased various pieces from Bion, Moschus, Theocritus, Anacreon, Catullus, and Martial. He resided in Paris, enjoyed the continued favor of the court, and founded the Académie Royale de Musique; his house became famous for the charming concerts which he gave, entertainments at which Charles IX. and Henry III. frequently flattered him with their presence. He was a dear friend of Ronsard and the other members of the Pleiad.

BAIKAL (*i.e.*, *Baïakhal*, or Abundant Water), a great fresh-water lake of Siberia, in the government of Irkutsk, 397 miles in length from S.W. to N.E., and from 13 to 54 miles in breadth, with an area of about 12,500 square miles. This vast reservoir is situated 1360 feet above the level of the sea, in the midst of steep mountain ranges, that often rise sheer from the water's edge in lofty walls of syenite, gneiss, or conglomerate, while elsewhere their sloping flanks are thickly clad with dark forests of coniferous trees. The lake is fed by several rivers,— the Upper Angara, the Selenga, which descends from the basin of Lake Kossogol, the Barguzin, and others; while the only visible outlet is by the Lower Angara, a tributary of the Yenisei. The water is excellent, and is extremely clear, so that the bottom can be seen at the depth of 8 fathoms. The depth of the lake varies from 22 to upwards of 300 fathoms. It yields abundance of salmon, and there is a profitable fishery of seals on its shores during the whole summer. The climate is extremely severe; and the lake, which is frozen over from November to May, is almost perpetually swept by the wind. It facilitates, however, the Russian trade with China, and that between Irkutsk and Dauria. It is navigated by the Russians in summer, and in winter they cross it on the ice.

BAIKIE, WILLIAM BALFOUR, M.D., eldest son of Captain John Baikie, R.N., was born at Kirkwall, Orkney, on the 21st August 1824. He studied at Edinburgh, and, on obtaining his degree, joined the royal navy. He early attracted the notice of Sir Roderick Murchison, through whom he was appointed surgeon and naturalist to the Niger Expedition of 1854. The death of the senior officer occurring at Fernando Po, Dr. Baikie succeeded to the command. The results of the voyage are given in his own and other narratives. Ascending the river about 250 miles beyond the point reached by former explorers, the little steamer *Pleiad* returned and reached the mouth after a voyage of 118 days without the loss of a single man. The second expedition started in March 1857. After two years passed in exploring, the navigating vessel was wrecked in passing through some of the rapids of the river, and Dr. Baikie was unable longer to keep his party together. All returned home but himself; no way daunted, he determined single-handed to carry out the purposes of the expedition. Landing from a small boat with one or two native followers at the confluence of the Quorra and Benue, he here chose the old model farm ground as the base of his future operations — a spot memorable from the disasters of the exploring party of 1841. After purchasing the site, and concluding a treaty with the native chief, he proceeded to clear the ground, build houses, form enclosures, and pave the way for a future city. Numbers flocked to him from all parts round, and in his settlement were representatives of almost all the tribes of Central Africa. To the motley commonwealth thus formed he acted not merely as ruler, but also as physician, teacher and priest. Before five years he had opened up the navigation of the Niger, made roads, and established a market, to which the native produce was brought for sale and barter. He had also collected vocabularies of nearly fifty African dialects, and translated portions of the Bible and prayer-book into Housa. Once only during his residence had he to employ armed force against the surrounding tribes. He died on his way home, at Sierra Leone, in November 1863, aged thirty-nine years. An appropriate monument has been erected to his memory within the nave of the ancient cathedral of St. Magnus.

BAIL (*Ballium*) is used in common law for the freeing or setting at liberty of one arrested or imprisoned upon any action, either civil or criminal, on surety taken for his appearance on a certain day or place.

BAILEN, a town of Spain, in the province of Jaen, 24 miles N.N.W. of Jaen. It seems to correspond to the ancient Bæcula, where Scipio gained signal victories over Hasbrubal, 209 B.C., and over Mago and Masinissa, 206 B.C. In the neighborhood also, in 1212, was fought the great battle of Navas de Tolosa, where Alphonso VIII. is said to have left 200,000 Moors dead on the field, with the loss of only 25 Christians. Here again, on the 23d of July 1808, the French general Dupont, after a bloody contest of several days, signed the capitulation of Bailen. Population, 8,000.

BAILEY, or BAILY, NATHANAEL or NATHAN, an eminent English philologist and lexicographer, whose *Etymological English Dictionary*, published apparently in 1721, was a great improvement on all previous vocabularies, and really formed the basis of Johnson's great work. Bailey died in 1742.

BAILEY, PHILIP JAMES, poet, was born at Basford, England, April 22, 1816. *Festus*, the poem by which he is best known, was published in 1839.

BAILEY, SAMUEL, an able writer on philosophical and literary subjects, was born at Sheffield in 1791. In 1852 he published *Discourses on various Subjects;* and finally summed up his philosophic views in the *Letters on the Philosophy of the Human Mind* (three series, 1855, 1858, 1863), which is at once the most considerable and the most valuable of his contributions to mental science.

The *Letters* contain, in clear and lively language, a

very fresh discussion of many of the principal problems in philosophy, or rather in psychology. Bailey can hardly be classed as belonging either to the strictly empirical or to the idealist school, but his general tendency is toward the former. He died in 1870.

BAILIFF (Scotch *bailie*, Fr. *bailli*, Ital. *balio;* all from late Lat. *bajulivus*, an adj. from *bajulus*, a carrier, then a manager), an officer with public authority in a certain district. In the United States the term bailiff is seldom used except sometimes to designate a sheriff's deputy or constable, or a party liable to account to another for the rents and profits of real estate, as in some cases a tenant in common who receives more than his share. The duties of a bailiff are performed by a deputy-sheriff, constable or tipstaff, who are officers acting under the orders of the sheriff or magistrate, or under the immediate supervision of the court.

BAILIWICK legally means the county or district within which the sheriff, as bailiff of the king, may exercise jurisdiction. It is often applied by English writers to foreign towns or districts under a *vogt* or *bailli.*

BAILLET, ADRIEN, a French writer and critic, was born in June, 1649, at the village of Neuville, near Beauvais, in Picardy, and died in January, 1706.

BAILLEUL, an ancient town of France, in the department of Nord, near the Belgian frontier, situated on a rising ground to the north of the River Lys. It was formerly a place of great strength, and is now a busy industrial town, with manufactures of lace, thread black soap, pottery, woolen stuffs and ribbons, brandy leather, and cheese. Population, 12,896.

BAILLIE, JOANNA, poet and dramatist, was born at the manse of Bothwell, on the banks of the Clyde (Scotland), in 1762. She and her sister were left a small competence by their uncle, Dr. William Hunter, and took up their residence at Hampstead, on the outskirts of London, where they passed the remainder of their lives. Miss Baillie died February 23, 1851, at the advanced age of eighty-nine, her faculties remaining unimpaired to the last. Her gentleness and sweetness of disposition made her a universal favorite, and her little cottage at Hampstead was the centre of a brilliant literray society. Miss Baillie had received an excellent education, and probably cultivated very early her faculty of poetical composition, but it was not till 1798 that she published the first volume of her *Plays on the Passions.* The success of the first volume was very considerable, and a second edition was soon called for. A second volume followed in 1802, a third in 1812, and three more in 1836. Some miscellaneous dramas were published in 1804, and the *Family Legend* appeared in 1810. Miss Baillie herself intended her plays not for the closet but for the stage. The *Family Legend*, brought out at Edinburgh under the enthusiastic patronage of Sir Walter Scott, had a brief though brilliant success: *De Monfort* had a short run in London, mainly through the acting of Kemble and Mrs. Siddons; *Henriquez* and *The Separation* were coldly received.

BAILLIE, DR. MATTHEW, anatomist and physician, was born in Lanarkshire, Scotland, in 1761. He came of a highly gifted family; his father, the Rev. James Baillie, was successively clergyman of the parishes of Shotts, Bothwell, and Hamilton, in Lanarkshire, and afterward professor of divinity in the university of Glasgow; his mother was Dorothea, sister of the celebrated William and John Hunter; and his sister Joanna was the poet. Dr. Baillie was for several years a student in the university of Glasgow, where he heard the lectures of Dr. Reid on moral philosophy. His professional career was determined by the advice of his uncle, Dr. William Hunter, who undertook to superintend his education. Dr. Hunter, at his death, bequeathed the use of his magnificent collections to his nephew, together with the lecture-rooms in Windmill Street, an annuity of $600 a year, and a small family estate in Scotland. In 1795 he published his *Morbid Anatomy*, a work which was speedily translated into French, Italian, and German. Dr. Baillie died in 1823.

BAILLIE, ROBERT, a prominent Scotch Presbyterian of the seventeenth century, was born at Glasgow in 1602. He graduated in 1620 at the university of that town, and then applied himself to the study of divinity. In 1638 he was a member of the famous Glasgow Assembly, and soon after he accompanied Leslie and the Scotch army as chaplain or preacher. He continued to take an active part in all the minor disputes of the church, and in 1661, after the ejection of Gillespie, he was made principal of the Glasgow University. He died in August of the following year,—his death being probably hastened by his mortification at the apparently firm establishment of Episcopacy in Scotland. Baillie was a man of learning and ability.

BAILLY, JEAN SYLVAIN, a French astronomer and orator, was born at Paris on September 15, 1736. His acquaintance and friendship with the celebrated mathematician Lacaille, and perhaps the example of his brilliant young contemporary Clairaut, decided the direction of his studies, which were then entirely devoted to science and scientific investigation. The first of his labors was a calculation of the comet which appeared in the year 1759. In 1763 he was admitted a member of the Academy of Sciences; and in the same year he published a reduction of the observations made by Lacaille in 1760 and 1761 on the zodiacal stars, a compilation of great labor and utility. In 1764 he competed for the prize offered by the Academy for a dissertation on the theory of Jupiter's satellites. Lagrange, who was a complete master of the most powerful analysis, was the successful competitor; but Bailly's memoir, which was published in an expanded form in 1766, showed great ability, and at once established the author's reputation as a physical astronomer. He followed up his dissertation in 1771 with an able and important memoir on the *Light of the Satellites*, in which he expounded some novel and elegant methods of observation.

In the year 1775 he published the first volume of his most extensive work, *History of Astronomy*, which contained the history from its origin down to the foundation of the Alexandrian school. This was followed by three volumes on *Modern Astronomy*, published between 1776 and 1783.

The quiet course of Bailly's life, hitherto devoted to literature and science, was now broken in upon by that great convulsion, the French Revolution, of which he was one of the first and most zealous promoters. In the part which he acted, he has had the singular good fortune to be well spoken of by opposite factions, and has never been charged either with want of integrity or with selfish designs. When the states-general of France were assembled in 1789, he was elected a deputy to the *tiers-état*, of which he was afterwards chosen president; and when the national assembly had been constituted, he continued in the chair, and officiated as president at the time the king's proclamation was issued ordering that body to disperse. During the struggle which took place between the national assembly and the court, Bailly was amongst the most forward in asserting those popular rights which were then new in France; and it was he who dictated the famous oath to the members of the *tiers-état*, by which they pledged themselves "to resist tyrants and tyranny, and never to separate till they had obtained a free constitution." On the 14th of July following, the day on which the Bastille was stormed and taken by the people, he was by universal consent appointed

mayor of Paris. In this high office he is allowed to have acted with great integrity, courage, and moderation, and to have discharged its arduous and sometimes perilous duties in a highly honorable manner, and during its course he was instrumental in promoting the various measures by which the popular party at length prevailed over that of the court; for which, as well as for his conduct in other respects, he obtained a high degree of popularity. But the multitude, newly unshackled from the fetters of despotism, greedy of novelty, fired with enthusiastic and unsettled notions of freedom, and daily panting for change, would brook no opposition to their wild schemes. Bailly, who probably saw too late the general disposition of the people to anarchy, still wished the laws to be respected, and hoped by the vigorous enforcement of them to restore and maintain tranquility. He ordered some deputies from the military insurgents of Nancy to be arrested, and firmly opposed the rash proceedings of Murat and Hebert; he ceased to be a member of the Jacobin club; and he exerted himself strongly to persuade the populace to permit the king and royal family to depart to St. Cloud. By these measures, which were very distasteful to the fickle and infuriated people, he lost their confidence and favor; and his popularity was finally destroyed by his conduct on the occasion of the tumultuous meeting of the populace on the 17th of July 1791, to demand the abolition of monarchy; for, when called on by the national assembly to disperse the mob, who had assaulted the soldiery, he ordered the latter to fire, by which means 40 persons were killed and above 100 wounded. Finding himself after this an object of hatred and suspicion to the people, whom he had faithfully served, he resigned his office at the dissolution of the constituent assembly in the end of the year 1791, and retired to Nantes. From there he wrote to Laplace, who was residing at Melun, and proposed, if it were safe, to join him. Laplace, finding that a detachment of revolutionary troups had been ordered to Melun, advised Bailly not to venture, but his advise was neglected. The ex-mayor was recognised by one of the soldiers, arrested, and thrown into prison. Arraigned on 10th November 1793 before a sanguinary tribunal, he was on the 11th condemned to death as a conspirator, and executed the day following, near the spot where he had given the order for the military to fire on the people. He met his death with the greatest calmness and courage.

BAILY, EDWARD HODGES, a distinguished sculptor, was born at Bristol, 10th March 1788, and died at London 22d May 1867.

BAILY, FRANCIS, an English astronomer, was born in Berkshire in the year 1774, and for many years carried on business as a stockbroker in London. While amassing a large fortune by his business, he applied the profound mathematical knowledge for which he was distinguished to the doctrine of probabilities, and published several interesting works on that subject. Baily was extremely patient and methodical, and these qualities enabled him to effect, in the last twenty years of his career, a greater number of researches than most other philosophers have accomplished during a whole lifetime. He died August 30, 1844.

BAINBRIDGE, DR. JOHN, physician and astronomer, was born at Ashby-de-la-Zouche, in Leicestershire, in the year 1582. He taught a grammar school for some years, and practised physic, employing his leisure hours in astronomy, which was his favorite study. After removing to London he was admitted a Fellow of the College of Physicians, and gained considerable reputation by his description of the comet in 1618. The next year Sir Henry Saville appointed Bainbridge his first professor of astronomy at Oxford; and the masters and fellows of Merton College made him first junior, and then superior reader of Linacre's lecture. He died in 1643.

BAINES, EDWARD, for many years proprietor and editor of the *Leeds Mercury*, and M.P. for Leeds from 1834 to 1841, was born in 1774 at Walton-le-Dale, a village distant a little way from Preston, in Lancashire. In 1801 the assistance of friends enabled him to purchase the copyright of the *Leeds Mercury*. Provincial newspapers did not at that time possess much influence; the editorial province was not extended to the composition of what are now called leading articles, and the system of reporting was defective. In both respects Baines made a complete change in the *Mercury*. The ability of his political articles gradually caused the paper to be looked upon as the organ of Liberal opinion in Leeds, and it contributed not a little to the spread of sound doctrines on practical questions in the north of England. He strongly advocated the separation of church and state, and opposed Government interference in national education. His letters to Lord John Russell on the latter question (1846) had a powerful influence in determining the action of the Government. He died in 1848.

BAINES, MATTHEW TALBOT, eldest son of the above, was born in 1799, and died in 1860. He was educated at Cambridge, and entered the bar.

BAINI, GIUSEPPE, a learned musical critic and composer of church music, was born at Rome in 1775, and died there in 1844.

BAIRAM, a Turkish or Persian word meaning *feast*, is the name applied to the two great Mahometan festivals. The first of these, called generally, though, according to some authorities, incorrectly, the Greater Bairam, is the day following the Ramadan, or Month of fasting. It lasts strictly for only one day, though the common people generally extend it to three, and is a period of great animation and enjoyment. What is called commonly the Lesser Bairam follows the first at an interval of sixty days. It is the feast of sacrifices, at which all Mahometans imitate the offerings of animals which are then being made at Mecca to commemorate Abraham's offering of Isaac. It lasts for four days, and is not of so sacred a character as the first Bairam.

BAIRD, GENERAL SIR DAVID, Bart., was born at Newbyth in Aberdeenshire, in December 1757. He entered the British army in 1773, and was sent to India with the 73d Highlanders in 1779. In the following year he had the misfortune to fall into the hands of Hyder Ali, in the Mysore chief's perfidious attack on a handful of British troops at Perambucum. The prisoners, were most barbarously treated. Baird survived his captivity; and on his release, visited his native country, but returned to India in 1791 as a lieutenant-colonel. In 1804 he was knighted, and in the following year commanded the expedition against the Cape of Good Hope, and captured Cape Town; but here again his usual ill-luck attended him, for he was recalled before he had organised his conquest, for having sanctioned the expedition of Sir Home Popham against Buenos Ayres. He served again in 1807 in the expedition against Copenhagen, and in the following year commanded the considerable force which was sent to Spain to co-operate with Sir John Moore. In the battle of Coruña, where, after the death of Moore, he held supreme command, a grape-shot shattered his left arm, so that it had to be amputated at the shoulder-joint. He again obtained the thanks of Parliament for his gallant services, and was rewarded with the decoration of the order of the Bath, and the rank of a baronet. He died on the 18th August 1829. (See Hook's *Life of Sir David Baird.*)

BAIREUTH, or BAYREUTH, the capital of the circle of Upper Franconia, in Bavaria, is pleasantly situated in a valley on the left bank of the Red Maine, 40 miles N.N.E. of Nuremberg. It is well built, with broad, regular, and well-paved streets, and is partially surrounded by old walls. The river is crossed here by two bridges. Most of the buildings are of comparatively modern date, the city having suffered severely from the Hussites in 1430, and from a conflagration in 1621. Baireuth has been chosen by Richard Wagner as the scene of his musical festivals, and a theatre has been erected for his special use. Population, 17,841.

BAJA, a market-town of Hungary, in the county of Bacs, on the left bank of the Danube, 90 miles S. of Pesth. It was burned down in 1807, but has since been well built. Population, 18,110.

BAJAZET I., sultan of the Turks, commenced to reign in 1389, and died in 1403. The well-known story of the iron cage, in which this monarch was said to have been carried about by his conqueror Timur, has no authority, and probably originated in a mistake as to the word for a *litter*, in which Bajazet was carried.

BAJAZET II., son of Mahomet II., succeeded his father as sultan in 1481, and died in 1512, at the age of 66 years.

BAJUS, or DE BAY, MICHAEL, a celebrated theologian, was born in Hainaut in 1513, and died in 1589.

BAJZA, ANTON, a distinguished Hungarian poet and critic, was born at Szücsi in 1804. His earliest contributions were made to Kisfaludy's *Aurora*, a literary paper of which he was editor from 1830 to 1837. He also wrote largely in the *Kritische Blätter*, the *Athenæum*, and the *Figyelmező*, or *Observer*. His criticisms on dramatic art were considered the best of these miscellaneous writings. He died in 1858.

BÁKARGANJ, a district of British India in the Dacca division, under the Lieutenant-Governor of Bengal, is bounded on the N. by the districts of Dacca and Farídpur, from which it is separated by the Padmá and Mainákátíkhál ; on the E. by the Meghná and Sháhbázpur rivers, and by the Bay of Bengal, which separates it from Noákháli and Tipperah; on the S. by the Bay of Bengal; and on the W. by Jessor and Farídpur districts. Area, 4935 square miles ; population, 2,377,433. The general aspect of the district is that of a flat even country, dotted with clusters of bamboos and betel-nut trees, and intersected by a perfect network of dark-colored and sluggish streams. There is not a hill or hillock in the whole district, but it derives a certain picturesque beauty from its wide expanses of cultivation, and the greenness and freshness of the vegetation. This is especially conspicuous in the rains, but at no time of the year does the district present a dried or burnt-up appearance. The villages, which are always walled round by groves of bamboos and betel-nut palms, have often a very striking appearance ; and Bákarganj has many beauties of detail which strike a traveller in passing through the country. The level of the country is low, forming as it does a part of the great Gangetic Delta; and the rivers, streams, and water-courses are so numerous that it is very difficult to travel except by boat at any season of the year. Every natural hollow is full of water, around the margin of which long grasses, reeds, and other aquatic plants grow in the greatest profusion, often making it difficult to say where the land ends and where the water begins. Towards the north-west the country is very marshy, and nothing is to be seen for miles but tracts of unreclaimed swamps and rice lands, with a few huts scattered here and there, and raised on mounds of earth. In the south of the district, along the sea face of the Bay of Bengal, lie the forest tracts of the Sundarbans, the habitation of tigers, leopards, and other wild beasts.

BAKER CITY, the county seat of Baker county, Ore., is situated on the Powder river, 300 miles east of Salem, the capital of the State. It contains several churches and schools and an academy, and has some trade. Population, 4,500.

BAKER, HENRY, a distinguished naturalist, was born in London in 1698, and died in 1774.

BAKER, SIR RICHARD, author of the *Chronicle of the Kings of England*, was born at Sissinghurst, in Kent, about the year 1568. He was educated at Oxford, took the degree of Master of Arts, and in 1603 received the honor of knighthood. In 1620 he was made high sheriff of Oxfordshire; but having engaged to pay some debts of his wife's family, he was reduced to poverty, and obliged to betake himself for shelter to the Fleet prison, where he died, February 18, 1645. During his confinement he composed numerous works, historical, poetical, and miscellaneous.

BAKER, THOMAS, a learned antiquary, descended from an ancient family distinguished by its loyalty, was born in England in 1656, and died in 1740.

BAKEWELL, a market town in Derbyshire, on the River Wye, 152 miles from London. Its fine old church contains monuments of the families of Vernon and Manners. The inhabitants are supported by the working of the coal, lead, and zinc mines, and the stone and marble quarries in the neighborhood. Population, 3,000.

BAKHCHISARAI (Turkish, *the Garden Palace*), a town of Russia in the government of Taurus, situated in a narrow gorge on the banks of a small stream called the Chiryuk-Su, about 10 miles S.S.W. of Simpheropol. Of unknown origin, it became towards the close of the 15th century the residence of the Tatar khans; and its chief objects of interest are the remains of its splendor under the Tartar dynasty. The population still consists for the most part of Tatars, Catherine II. in 1783 having granted them the exclusive right of habitation in the city. The remainder consists of Russians, Greeks, Armenians, and Jews, 10,000 in all.

BAKHMUT, a town of Russia in the government of Ekaterinoslav, near the river from which it derives its name. Population, 17,000.

BAKING. The art of baking consists in heating anything in an oven or fire so as to harden it, and in this sense the term is used when applied to the manufacture of bread, porcelain, pottery, and bricks. It is also applied to certain modes of dressing or cooking animal food; thus we speak of baked meats, pies, &c. In the present article the baking of flour or meal for use as human food will alone be treated of.

The origin of baking, as of most arts of primary importance, precedes the period of history, and is involved in the obscurity of the early ages of the human race. Excavations conducted on the site of some of the numerous lake dwellings of Switzerland have resulted in the discovery of abundant evidence that the art of making bread was practised by our prehistoric ancestors as early as the Stone Period. Not only have stones for grinding meal and baking bread been discovered, but bread itself in large quantities has been disinterred, preserved by being carbonised in the fires which frequently destroyed the pile-dwellings of the primitive inhabitants of the world. At Robenhausen, Meisskomer discovered 8 pounds of bread, a weight which would correspond with about 40 pounds of newly-baked bread. At Wangen there has been discovered "actual baked bread or cake made of the crushed corn, precisely similar to that found about the same time by Mr. Meisskomer at Robenhausen. Of course, it has been burned or charred, and thus these interesting specimens have been preserved to the present day. The form of these cakes is somewhat round, and about an inch to an inch

and a half in diameter. The dough did not consist of meal, but of grains of corn more or less crushed. In some specimens the halves of grains of barley are plainly discernible. The under side of these cakes is sometimes flat, sometimes concave, and there appears no doubt that the mass of dough was baked by being laid on hot stones and covered over with glowing ashes."

The very early mention of bread in written history further bears out the great antiquity of the art of baking. Bread is first specifically mentioned in Genesis xviii. 5, when Abraham, wishing to entertain the three angels on the plains of Mamre, offered to "fetch a morsel of bread;" and the operation of baking is immediately thereafter alluded to in the instructions to Sarah to "make ready quickly three measures of fine meal, knead it, and make cakes upon the hearth." At the same time, when, in the city of Sodom, Lot entertained two angels, "he made them a feast, and did bake unleavened bread, and they did eat" (Genesis xix. 3). It may be inferred from the mention of unleavened bread that, in those patriarchal times, the two great classes of bread were known and used. At a period little later the art of baking was carried to a high perfection in Egypt, which then took the lead in the arts of civilised life. The Egyptians baked cakes and loaves of many varieties and shapes, in which they employed several kinds of flour, and they flavored their bread with various aromatic ingredients. The chief baker of Pharaoh, who was in prison along with Joseph, doubtless pursued his craft in its essential features in the same way as bakers do at the present day.

From ancient Egypt excellence in the art of baking travelled with the march of civilisation into Greece, and the allusion to bread in the works of classic authors are very numerous. In *The Deipnosophists* of Athenæus mention is made of no less than sixty-two varieties of bread as known among the ancient Greeks, and minute descriptions of many of them are given. We learn from Pliny (*Nat. Hist.*, xviii. 28) that professional bakers were first introduced into Rome at the close of the war with Perseus, king of Macedon. By the practical Romans the baking trade was formed into a kind of incorporation or guild, with special privileges and immunities attached to the calling. Public bakeries were distributed throughout the city, to which slaves were assigned for performing the heavier and more disagreeable tasks connected with the occupation. Grain was delivered into public granaries by enrolled *Saccarii*, and it was distributed to the bakers by a corporation called the *Catabolenses*. No separate mills for grinding corn then existed, the grain being pounded and sifted in the bakeries, and hence the Roman bakers were known as *Pistores*. A special magistrate was appointed to take cognisance of every matter connected with the management of public bakeries.

The calling of the baker during the Middle Ages was considered to be one so closely affecting the interests of the public that it was put under strict regulation and supervision, and these special restrictions continued to affect the trade down to very recent times. In England, an Act of Parliament was passed in 1266 for regulating the price of bread by a public assize, and that system continued in operation till 1822 in the case of the city of London, and till 1836 for the rest of the country. The price of bread was determined by adding a certain sum to the price of every quarter of flour, in the name of the baker's expenses and profit; and for the sum so arrived at tradesmen were required to bake and sell eighty quartern loaves, or a like proportion of other sizes, which it was reckoned each quarter or flour ought to yield.

The art of making bread made its way northwards very slowly; and even at present, in the northern countries of Europe and Asia, loaves of bread are seldom used except by the higher classes of inhabitants. In Sweden, for example, rolls are frequently seen in the towns, but loaves rarely. Towards the end of 1812 the captain of an English packet ordered a Gothenburg baker to bake for him a quantity of bread, to the value of £1 sterling. The baker was confounded at so large an order, and refused to comply till the captain gave him security that he would carry off and pay for the loaves, declaring that he could never dispose of so great a quantity of bread in Gothenburg if it were left upon his hands. In the country part of Sweden no bread is made but rye-cakes, nearly as hard as flint, which are only baked twice a year. About a century ago loaf-bread was almost as rare in the rural districts of Scotland, *barley bannocks* and *oaten cakes* then constituting the universal substitutes among almost all ranks. In many parts of England it is the custom for private families to bake their own bread. This is particularly the case in Kent, and in some parts of Lancashire. In the year 1804 the town of Manchester, with a population of 90,000 persons, did not contain a single public baker.

As compared with wheat-flour all other materials used for making bread are of comparative insignificance. Oatcakes still form a staple article of food in many rural districts of Scotland, and are occasionally used in other countries. They are made by mixing up oatmeal, warm water, and salt, sometimes with the addition of butter or fat, into a very stiff paste, and kneading this out into a thin cake, which is first fired on a hot plate or "girdle," and finished in front of an open fire. Scones of barley-flour, sweet and tough, were formerly largely used in Scotland, but have now given place to a similar preparation of wheaten flour. Rye bread, both fermented and unfermented, is largely consumed by the inhabitants of the northern parts of Europe in the poor and backward districts. Cakes of maize meal, baked like oat cakes, are consumed in many parts of the United States. The meal of various species of millet is used in Southern Europe to form bread; and in India and China, durra (*Sorghum vulgare*) and other cereal grains are baked for food. Of non-cereal flours, the principal used for bread-making is buckwheat, *Fagopyrum esculentum*, extensively employed in Russia and Holland. The flour of pease, beans, and other leguminous seeds, are also baked into cakes; and cavassa cakes are made from the meal of the tapioca plant, *Jatropha Manihot*, in South America. Excepting rye, none of these substances is used for making vesiculated or fermented bread.

The grain of wheat consists of an outer husk or covering, an embryo or germ, and a central mass of farinaceous material. The outer husk is composed of several distinct layers of ligneous tissue, closely adhering to the seed, and very hard in texture. In grinding, this is detached in scales, and constitutes the chief proportion of the bran. The inner portion of the envelope is softer, and contains an active nitrogenous principle, termed cerealin, and is besides rich in fat and salts. This portion goes with the pollard or parings in the dressing of wheat flour. Towards the centre of the grain the substance becomes whiter in color and more friable in texture, so that, in grinding, the finest flour in consistence is always the whitest in appearance. By agriculturists several hundred varieties of wheat and a number of distinct species are recognised; but in commerce the grain is distinguished as white and red, or as hard and soft wheats. There is a considerable range of difference in the proportions of their proximate constituents, hard wheats as a rule being much more nitrogenous than the soft varieties; and similarly, wheats grown in hot climates are also usually richest in nitrogen-

The following analyses of two typical varieties of wheat are taken from Payen's tables, water being neglected:—

	Hard Wheat. Taganrog.	Soft Wheat. Touzelle.
Nitrogenous matter	20.00	12.65
Starch	63.80	74.51
Dextrin	8.00	6.05
Cellulose	3.10	2.80
Fatty matter	2.25	1.87
Mineral matter	2.85	2.12

When wheat is ground it is sifted or dressed into a series of mill products, ranging from fine flour to bran, according to the size of the ground particles.

It is a disputed point whether dextrin or sugar exists in flour of the best quality; but the action of heat and moisture in the baking process quickly transforms a portion of the starch into the soluble condition. In flour of inferior quality a large percentage of dextrin is usually found — a circumstance very detrimental to its bread-making qualities. A table of the percentage of gluten, obtained by Messrs. Lawes and Gilbert from a large number of flours, shows a variation from 8.9 to 14.9 per cent. This gluten itself (the insoluble nitrogenous substance in flour) is a compound body, composed of three or four distinct substances; but its physical conditions of elasticity, tenacity, and color are of much greater importance to the baker than either its chemical constitution or its amount.

The varieties of wheaten bread are divisible into two great classes — *Unvesiculated* and *Vesiculated* Bread. Under the first head are included such products of the art as are fired or baked without first being raised or rendered spongy by the development of carbonic acid gas within the mass, either by fermentation or otherwise. Vesiculated bread is produced when carbonic acid is either developed in or introduced into the dough, so as to permeate the mass with an infinite number of minute cavities, which render the product light and spongiform.

Unvesiculated Bread.— The simplest form of bread, and the rudest baking, are seen in the Australian "Damper," a cake made from dough composed of flour, salt, and water, baked in the dying embers of a wood fire. The dough is laid on a flat stone, covered with a tin plate, and the hot ashes heaped around and over it, care being taken not to expose it to a heat of more than 212° Fahr. Passover cakes, scones and "bannocks" are prepared from a similar dough, and fired on hot plates or in ovens, and form an agreeable and nutritious food. When such dough is exposed to a high heat, so that the resulting cake is hard, dry, and resonant, biscuits (*bis cuit*, twice baked) are formed.

Biscuit Manufacture.— Biscuit making is a branch of trade distinct from ordinary baking, conducted under different conditions, and requiring machinery and processes peculiar to itself. Biscuits are made by a rapid and continuous process; they can be preserved a long time, and in proportion to their price they occupy little space, so that it is practicable to sell them in markets remote from the place of manufacture. The manufacture of biscuits is now conducted on a very large scale, ingenious and complicated machinery is employed in the various processes, and a large export trade in biscuits has grown up.

There is an endless variety in the form and composition of plain and fancy biscuits.

The richest class of biscuits, the dough for which is necessarily soft, are cut out by hand labor, and fired on trays in common ovens. The dough for rout biscuits is placed in a strong metal box or chamber in which a piston is tightly fitted. The piston is moved forward by a screw, and it pushes the dough through a series of holes or dies. The dough is received on a sliding board, and is cut into proper lengths by a knife. Cracknels are made without either milk or water being used to mix the dough, eggs alone being employed for this purpose. Certain proportions of butter, sugar, and sesqui-carbonate of ammonia are added to the mixture of flour and eggs, and the dough is baked in the usual way. The cracknels, when cut out, are thrown into a boiler of boiling water, and in about two minutes they float to the top. They are then fished out and thrown into cold water, and then drained on cloths, panned, and fired in an ordinary oven at a high heat. In the firing, the ammonia carbonate, being very volatile, is driven off, and the cracknell thus assumes its spongy structure. Many other varieties of biscuits are rendered light and spongiform by the use of the sesqui-carbonate of ammonia, or of carbonate of soda, in conjunction with sour milk. In the firing of biscuits, not only the moisture of the dough is driven off, but a certain proportion of the water held by the flour in its apparently dry state, so that from 10 lb of flour only about 9 lb of water biscuits are obtained.

Vesiculated Bread.— Under this head is included such bread as is rendered spongiform in structure by the action of carbonic acid within the dough, and which is not baked hard and dry as in the case of biscuits. It includes ordinary loaf bread, pan loaves, French or Paris loaves, cottage loaves, bricks, rolls, buns, and many varieties of fancy bread distinguished by local names and minor differences of form and composition. Vesiculated bread is made in three different ways:—

1*st*, By the development of carbonic acid within the dough through fermentation of the flour. This is the ordinary and principal method of bread-making.

2*d*, By mixing the dough with water previously aerated with carbonic acid. The aerated bread made under the patent of the late Dr. Dauglish is thus manufactured.

3*d*, By the disengagement of carbonic acid from chemical agents introduced in the dough. Dodson's patent unfermented bread comes under this head, and the "baking powders" and "yeast powders" extensively sold consist generally of carbonate of soda or ammonia and citric or tartaric acid, which evolve carbonic acid in presence of water.

Fermented Bread.— The manufacture of fermented or leavened bread is, as has already been hinted, of very great antiquity, and it is still by the fermentation process that bread is chiefly made. In ancient times leaven was employed to induce fermentation in dough ("a little leaven leaveneth the whole lump,"Gal. v. 9), and to this day Parisian bakers, who excel all others in the quality of the bread they produce, chiefly use the same ferment. Leaven is simply a portion of dough, put aside from a previous baking, in which the fermentative action has reached an advanced stage of activity. Yeast, however, has been used as a ferment from an early period, and it appears that it was first so employed in France. Pliny says (*Nat. Hist.*, xviii. 12), "Galliæ et Hispaniæ frumento in potum resoluto, spuma ita concreta pro fermento utuntur; qua de causa levior illis quam cæteris panis est." The use of yeast appears to have died out in France, but was revived again towards the end of the 17th century, when its reintroduction was violently opposed by the Faculty of medicine of Paris. Yeast is now used by Parisan bakers for fancy bread and pastry only.

The baking of fermented bread involves three distinct operations, which are technically denominated "setting the sponge," making the dough or kneading, and baking or firing. It will be convenient first to describe these processes as they are conducted in a Lon-

don bakehouse. The first duty of the baker is to mix a ferment, which consists of a mixture of potatoes, yeast, and flour. The potatoes, in the proportion of 6 lb to a sack of flour, are boiled and mashed in a tub, and water is stirred in, till the mixture is reduced to a temperature of from 70° to 90° Fahr. About 2½ pints of yeast and 12 lb of flour scalded in boiling water are then added, and the whole forming a thin uniform paste is set aside for several hours, during which it undergoes an active fermentation. Setting the sponge consists in mixing the ferment in a large trough with flour and water sufficient to make the whole into a rather stiff paste. The flour used at this stage, when "full sponge" is made, should be about one-half the entire quantity intended to be used in the "batch," and the ingredients have to be thoroughly incorporated by the workman stirring them laboriously together with his arms. The operation occupies from twenty minutes to half an hour, and when ready the sponge is covered over and allowed to rest for several hours according to the temperature at which it is maintained. Generally in from four to five hours the sponge "rises;" fermentation has been going on, and carbonic acid steadily accumulating within the tenacious mass till it has assumed a puffed out appearance. By degrees the sponge gives off the gas in puffs, and the mass begins to collapse, till what was a swollen convex surface assumes a somewhat concave form, the centre being depressed while the sides adhere to the edges of the trough. The workman judges by the amount of collapse the time the sponge is ready to be taken in hand for kneading or making the dough.

A loaf ready for going into the oven has about half the bulk it attains during the process of firing. Batches of cottage and household loaves are packed close side by side on the sole of the oven, the sides of each loaf being rubbed with butter to prevent them from adhering to each other, and they are consequently crusted on the top and bottom only. Pan loaves are baked each in separate tinned pans of the form of the loaf, and Parisian loaves are baked end to end in long tinned pans. The firing of bread in the oven occupies from 1 to 1½ hours, the temperature at the beginning of the process being 550° to 600° Fahr. The baker can ascertain if the oven is at a proper temperature by throwing a little flour on the sole of the oven, which ought to turn to a light brown color. Ovens in London are usually built of brick, with a sole only 2½ inches thick; in Scotland stone is used, the sole being from 10 to 12 inches thick, and the oven consequently retains heat much more effectually.

Sound flour yields from 90 to 94 4-lb loaves per bag of 280 lb, some "strong" flours giving even a greater quantity of bread.

The bakers' standard of excellence of flour, apart from the question of color, is the weight of bread it will produce of a proper dryness and texture. The "strength" of flour in this respect appears to depend much more on its condition than on the absolute percentage of its constituents.

Panary Fermentation.—It would be altogether out of place in this paper to refer to the conflicting theories as to the cause of fermentation in organic substances. The so-called panary fermentation in bread-making is a true alcoholic fermentation, and whether induced by yeast or leaven the result is precisely the same. The gluten of the flour is the fermenting agent, and it is stirred into activity by contact with a glutinous body already in an active condition, which may be either yeast or leaven. In this condition it exerts a fermentative influence over the sugar which may either have existed previously in flour, or which is at least immediately developed in it by the influence of moisture. The active gluten splits up each molecule of sugar into two of alcohol, two of carbonic acid, and one of water, and consequently an infinite number of minute air bubbles are developed throughout the fermenting mass.

As the evolution of carbonic acid and alcohol proceeds, the sponge gradually swells, the little bubbles coalesce and enlarge, rising through the tenacious mass till the surface is reached, and then the carbonic acid bursts out and the dough begins to fall. This process would go on a considerable time, but the alcoholic fermentation would soon pass into an acetous fermentation, and the sponge would become sour. When acetous fermentation ensues, as not unfrequently happens in baking, it may be remedied to some extent by the addition of bicarbonate of soda to the sponge. The late master of the mint, Dr. Thomas Graham, was the first to demonstrate the presence of alcohol in fermented dough, and he thus describes his experiment. "To avoid the use of yeast, which might introduce alcohol, a small quantity of flour was kneaded and allowed to ferment in the usual way to serve as leaven. By means of the leaven a considerable quantity of flour was fermented, and when the fermentation had arrived at the proper point, formed into a loaf. The loaf was carefully enclosed in a distillatory apparatus, and subjected for a considerable time to the baking temperature. Upon examining the distilled liquid the taste and smell of alcohol were quite perceptible, and by repeatedly rectifying it, a small quantity of alcohol was obtained, of strength sufficient to burn and to ignite gunpowder by its combustion. The experiment was frequently repeated, and in different bakings the amount of the spirit obtained of the above strength was found to vary from 0.3 to 1 per cent. of the flour employed." Although the temperature of the oven drives off that amount of the spirit, fermented bread is yet found to retain a proportion of alcohol, as much as from 0.221 to 0.401 per cent. having been found in different specimens of baked bread. Speaking in 1858, Dr. Odling estimated the amount of alcohol thrown out into the atmosphere from the bread baked in London as equal to 300,000 gallons of spirits annually. Many years ago a patent was secured by a Mr. Hicks for collecting and condensing the alcoholic fumes from bakers' ovens, and a company was formed for working the invention. After an expenditure of £20,000 the attempt had to be abandoned, not from any failure to obtain the spirit, but because the bread baked in the process was dry, unpalatable and unsalable.

When what is termed "whole wheaten flour"—that is, the entire substance of the grain, excepting only the outer bran—is baked, it is known that the resulting loaf is of a dark brown color, sweetish in taste, and liable to be somewhat heavy and sodden. The brown color was at one time supposed to be due to the presence of bran particles in the flour, and in 1846 an American, Mr. Bentz, invented a process for removing the outer cuticle of wheat before grinding, it being supposed that the flour so prepared would yield a loaf of white color, while utilising a larger proportion of the substance of the grain than is commonly used. To the astonishment of experimenters, however, the bread made from such flour was found to have the color and other chacteristics of whole wheaten bread. The subject was investigated by an eminent French chemist, M. Mège Mouriès, who found that the peculiar action of whole wheaten flour was due to the presence in the outer part of the seed of a peculiar nitrogenous body, to which he gave the name cerealin, and which is closely allied in composition and action to the diastase of malt. Cerealin exerts a peculiarly energetic influence on starch, transforming it into a brown adhesive mixture of dextrin and sugar. He showed that when the fermentative

action of gluten preponderates, the result is the formation of the products desired by the baker — carbonic acid and alcohol; but when the influence of cerealin prevails, lactic fermentation ensues, and dextrin, sugar, and acid substances are formed, which it is the object of the baker to avoid. Several methods of avoiding this deteriorating influence of cerealin, and at the same time securing the use of the maximum of flour, have been put in operation by M. Mège Mouriès. The process now in use at the Boulangerie Centrale de l'Assistance Publique (the Scipion) in Paris, for the preparation of the flour and baking white bread with the whole of the mill products excepting the bran, he thus describes: — "The corn is moistened with from 2 to 5 per cent. of water saturated with sea-salt, and at the end of some hours the exterior coverings only become moist and tender. The grain is then thrown between nearly closed millstones, and 70 per cent. of flour is obtained without cerealin, plus 10 to 14 per cent. of meal. This is bruised between light stones, and separated by winnowing from the greater part of the husk remnants. To prepare the bread, all the leaven is made with flour at 70 per cent., and the meal is added to the soft dough last of all; as, in spite of the small amount of cerealin which it still contains, it will not produce brown bread, because at that time the length of incubation is not sufficient to change it into a leaven. Thus white bread is produced containing all the farinaceous part of the wheat."

It not unfrequently happens that flour of good color, and unexceptionable chemical composition, fails to yield a dough which will rise by fermentation, and the loaf from which is sweet, solid, sodden, and adhesive. Wheat that has been badly harvested, or which in any way has been allowed to sprout, has part of the gluten changed into the form of diastase, which, like cerealin, changes starch into dextrin and sugar. The gluten of flour which has been dried at a too high temperature, and of flour which has been kept in a damp situation, is modified and acts in the same manner. If dough is made with an infusion of malt, it yields a result exactly the same as that above described. It is to guard the starch of inferior flour against this deteriorative influence that a proportion of alum is used by many bakers of second-class bread. Alum has the power of preserving starch to a large extent from the metamorphic action of altered gluten, diastase, or cerealin, and of producing from an inferior flour a loaf of good texture and color. The use of alum is regarded as an adulteration, and heavy penalties have been imposed on its detection; but its estimation in bread is a process of the greatest difficulty, and authorities are by no means agreed as to its deleterious influence. Other mineral salts have a similar protective power on the starch of inferior wheat, and lime-water has been successfully employed in place of alum. To this also it is objected by some that the addition of lime renders the valuable phosphatic salts of flour insoluble by transforming them into phosphate of lime.

Aerated Bread.—When carbonic acid, instead of being generated by fermentation within dough, is separately prepared and incorporated with flour and water, aerated bread is produced. The system by which this is effected was invented by the late Dr. Dauglish, and aerated bread has been manufactured under his patent since March 1859. The system is now in operation in all the principal towns in the United Kingdom, and it appears to be steadily gaining in public favor.

Unfermented Bread.—Under this head is included such bread as is vesiculated by means of carbonic acid evolved from chemical substances introduced in the making of the dough. About 1842 Mr. Henry Dodson commenced to manufacture bread on this system, and obtained a patent for his process. He used hydrochloric acid and bicarbonate of soda in such proportions that while, by their re-action, they liberated sufficient carbonic acid to aerate the dough, they formed chloride of sodium or common salt enough for the bread. Liebig, in his *Familiar Letters*, says regarding this system: — "Chemists, generally speaking, should never recommend the use of chemicals for culinary preparations, for chemicals are seldom met with in commerce in a state of purity. Thus, for example, the muriatic [hydrochloric] acid which it has been proposed to mix with carbonate of soda in bread is always very impure, and very often contains arsenic." The sesqui-carbonate of ammonia is also used as a source of carbonic acid in vesiculating bread, and it, on account of its highly volatile nature, is entirely driven off in the process of baking. A great amount of private or domestic baking is conducted on the same principle, butter-milk and bicarbonate of soda being used for mixing the dough in making "scones." In this case the lactic acid of the milk combines with the soda, liberating carbonic acid. The baking powders and yeast powders which are sold, and the so-called self-raising flour, all depend for their action on the mixture of bicarbonate of soda with some organic acid, such as tartaric or citric acid.

The art of baking, although it is the most important of all industries connected with the preparation of human food, is one which is still carried on in the most rude and primitive manner. While modern inventions and the progress of improvement have changed the conditions under which nearly all arts and manufactures are conducted, the baking of bread is still conducted as it was during the palmy days of ancient Greece. The nature of the processes necessary for the preparation of bread, the limited time it will keep, and the consequent impossibility of storing the product or sending it any considerable distance, tend to keep the trade in the position of a limited and local handicraft. It is, therefore, not a pursuit which attracts capitalists, and master bakers are mostly in the position of small tradesmen, without either the inclination or ability to invest money in expensive machinery and fittings. In the case of biscuit-baking the conditions are quite different, and it, as has been seen, has developed into a great manufacture, with elaborate and complex machinery and the most perfect mechanical appliances. Many forms of machine have been proposed as substitutes for the rude and laborious manual labor — always unfavorable to health, and sometimes not very clean — involved in baking. Many of these machines admittedly produce better bread than can be made by handwork, and that at no inconsiderable saving of material and time, but the necessity of either steam or water power for their effective working greatly restricts their use.

The two processes to which machinery has been successfully adapted, are the mixing of the sponge and the kneading of the dough. Attempts have been made to mould loaves by machinery, but these have hitherto failed; nor has the endeavor to fire bread in traveling ovens yet been practically successful. A great variety of kneading machines have been suggested and used, since the first trial of such an implement in Paris upwards of a century ago.

Much thought and skill have been expended in the endeavor to effect improvements in the ordinary form of a baker's oven, but hitherto no plan has been devised which produces bread of a quality superior to that fired in the oven which is commonly used. A baker's oven of the common description is a low, vaulted chamber, about 10 feet long, by 8 feet wide, and 30 inches high. It is built and floored of stone or brick, and has a small door in front by which the moulded dough is put in and the loaves withdrawn. At one side of this door, in the

extreme corner, are placed the furnace and fire-grate, opening into the oven, and at the opposite corner, the smoke flue by which smoke escapes from the interior. The heat is by this arrangement carried throughout the entire oven, and when the temperature is sufficient the fire is withdrawn, the flue shut, and the dough is quickly introduced on a "peel," or long wooden shovel. Various efforts have been made to effect the heating of ovens by fire external to the chamber itself, but they fail to produce that radiation of heat which is found essential to good baking. Perkin's hot-water oven for some time met with favor in Great Britain, and a modification of it was employed in France. On this system the oven is heated by superheated water, conveyed from a stove through closed pipes, which are coiled around the entire interior of the oven. This oven has the recommendation of perfect cleanness, and the temperature in it is easily regulated; but it is costly in construction, and the method has not commended itself in practice. Among ovens heated from the exterior, that of M. Rolland takes a high place for ingenuity and novelty of construction. Its characteristic peculiarity consists in the possession of a revolving sole, which not only allows the easy introduction and withdrawal of the bread, but the bringing of the different parts regularly and uniformly under the influence of the heat applied. The revolution of the sole is accomplished by a handle worked from the front of the oven; and besides this rotatory motion the sole can also be raised or lowered so as to bring either the upper or under side of the bread close to the heat as desired. The heating of M. Rolland's oven is effected by means of flues, which pass radially under and over the revolving sole. The chief objection urged against this form of oven is, that the air within it becomes too dry, which detracts from the flavor of the loaves fired in it. The use of the Vienna oven is general in Germany, and is extending in Paris for the baking of small or Vienna bread. It is egg-shaped in form, with an inclined sole, a very small aperture, and a low roof. Its average internal dimensions are 12 feet in depth, 10 feet wide, and 18 inches high. In the best of these ovens glazed tiles are used for the sole. The inclination of the sole facilitates the filling and emptying of the oven; and the confined space of the interior retains a large proportion of moisture, which gives a fine color to the crust and flavor to the crumb of the bread.

Qualities of Bread.—The process of baking changes the structure of the crust or outer part of a loaf, and, according to Reichenbach, developes in it a substance termed *Assamar*, which he says has an influence in retarding the waste of tissue. It does not alter the starch of the crumb or internal part, but only swells the granules, and by the induced sponginess of the mass renders it readily digestible. Well-baked bread should have a yellowish-brown crust; the crumb should be uniform in texture, permeated with minute cavities, and without "eyes" or large air-cells.

BAKING POWDER is essentially a mixture of tartaric acid and bicarbonate of soda. These are carefully dried and sifted together, some flour being usually mixed with them to dilute the strength. When added to flour in the manufacture of bread or biscuits, carbonic acid gas is liberated by the action of the water which is used, and this blows or puffs up the doughy mass, giving it the requisite lightness.

BAKSHISH. The ordinary meaning of this word, in Persian, is a present; but in the East, in modern times, it has acquired the special signification of gratuity. (Fr. *pourboire*, Ger. *Trinkgeld*, Eng. *tip*.)

BAKU, or BADKU, the chief town of the government of the same name, in the Russian province of Transcaucasia (Daghestan), situated in the peninsula of Apsheron, on the west coast of the Caspian, and possessing one of the most spacious and convenient ports in that sea. It is built in the form of an obtuse triangle, on the slope of an arid hill, and is defended by a double wall and ditch constructed during the reign of Peter the Great. The general appearance of the town is decidedly Oriental, with its flat-roofed houses rising one behind the other, often in so close proximity that the top of the one forms the courtyard of the next. The whole soil around Baku is impregnated with petroleum, which, monopolized till 1872, now forms the staple branch of its industry. Some of the fountains ignite spontaneously, and this natural phenomenon has caused Baku to be esteemed as a holy city by the Parsees or fire-worshipers. There is evidence that petroleum has been flowing from the Apsheron Peninsula for 2,000 years. Of the 500 petroleum wells at Baku, most are situated on the Balakhani Peninsula, eight or nine miles to the north of the town. Lines of pipe carry the oil into the "black town" of Baku, which is full of oil refineries emitting vast volumes of smoke, black and greasy buildings, and pools of oil refuse. One prolific well, tapped in September, 1886, began to spout oil with extraordinary force, deluging the whole district. Nothing could be done to stop the outflow, which on the eighth day had reached a daily rate of 11,000 tuns, or more than the entire produce of the world at the time. Another gigantic naphtha fountain burst out in March, 1887, rising to a height of 350 feet, and after forming an extensive petroleum lake, forced its way into the sea. The production of crude petroleum in 1885 exceeded 420,000,000 gallons, and 120 firms now have oil refineries there. Population about 20,000. Baku is capital of a government of Russian Transcaucasia, with an area of 15,516 square miles, and a population (1883), of 569,992.

BALA, a market-town of Wales, county of Merioneth, and hundred of Penllyn, at the northern extremity of the lake of the same name, 17 miles N.E. of Dolgelly.

BALAAM, or rather BILEAM, the son of Beor, belonging to Pethor, by the River Euphrates in Aram, is represented in Scripture as a seer who possessed the power of blessing and cursing effectually. According to the narrative in Numbers xxii.–xxiv., he was invited by Balak, king of Moab, to come and curse Israel, in order to ensure the latter's defeat. Jehovah, however, forbade him to go as he was requested, and therefore he refused to accompany the deputation of elders, who had been sent to invite him, "with the rewards of divination in their hand." After the arrival of a second embassy more imposing than the first, he received divine permission to go, but only on condition that he should adhere strictly to what Jehovah should tell him. He set out accordingly, and in his journey experienced the anger of the Lord, an angel being sent to stop his progress, who was perceived only by the ass on which the prophet was riding. After Balaam's eyes had been opened he saw the angel, and declared his willingness to go back, but received permission to continue his journey on condition of saying nothing but what was suggested to him by God. His reception by Balak was honorable and imposing, yet he continued faithful to Jehovah, and told the king he would only announce what Jehovah revealed. Standing on the height of Baal-Bamoth, and surveying the tents of Israel, he declared his inability to curse a people so peculiar and righteous. Brought next to the top of Pisgah, and beholding thence a part of the Israelite camp, he announced that Jehovah saw no iniquity or perverseness in Jacob; that He was with them; that they were therefore strong and victorious. Conducted afterwards to the top of Peor, he surveyed

the army of Israel, and predicted their future, their goodly dwellings in Canaan, and their successful wars against the nations down to Saul's time. Though Balak was angry and interrupted him, Balaam continued his prophecy, announcing Israel's valiant deeds, from David down to Hezekiah. Upon this he returned to his home.

Another account of Balaam appears in Numbers xxxi. 8–16, Joshua xiii. 22, where we learn that he advised the Midianite women to seduce the Israelites to the licentious worship of Baal, and that he was slain in a war with the Midianites.

The character given to Balaam in the first account is a favorable one. He is a worshipper of Jehovah the true God, receives divine revelations, and repeatedly declares that he will not go beyond or against them. Faithful to his calling, he steadfastly resists temptations sufficiently powerful, and therefore God communicates His Spirit to him, enabling him to predict the future of Israel.

The second account is unfavorable. In it he appears as a diviner, a heathen seer, who tempted the worshippers of the true God to idolatry. Instead of being a prophet of Jehovah, receiving visions and revelations, a man to whom the Almighty came by night, giving him instructions what to do, he is an immoral soothsayer. Of the two accounts, the latter, brief as it is, seems entitled to greater consideration. The former is elaborate and artificial, the theme being the glorification of the chosen people by the mouth of one of their enemies. An inspired seer from the far distant land of Aram is called in to bless the Israelites. He does so reluctantly, but like a true prophet, announcing nothing but what came to pass. The way in which he is taught the high destiny of the chosen people is instructive. Ignorant at first of Israel's relation to the true God, and thinking they were like others, he was disposed to curse them, but is enlightened, and forcibly impelled to follow the divine revelations. From a heathen *mantis* he is converted into a true prophet by revelations and visions which he cannot resist. The seer is taken to three places in succession, whence he surveys Israel, and utters oracular sayings concerning them. Three times the angel of the Lord stands in the way, and three times the ass is smitten by Balaam. There are four prophetic announcements — xxiii. 7–10, 18–24; xxiv. 3–9, 15–24. The first refers to the separate condition of Israel, their numbers, and their worship of the true God amid the idolatry of the surrounding nations. The second declares that God blesses Israel because there is no iniquity or perverseness in them, that He dwells among them, reveals himself to them, and makes them powerful and victorious. Both these refer to Mosaic times, or at least to times not later than Joshua. But the third announcement has the character of prediction, and refers to future events. Hence Balaam is introduced as a man whose eyes are opened, who hears the words of God, and sees visions of the Almighty. The condition of the people down to the time of Saul is glanced at, their secure settlement in Canaan, and victorious wars with the native races. The fourth prophecy apparently carries down the history to the time of Hezekiah; and a future ruler is distinguished as the star out of Jacob, the sceptre out of Israel, the conqueror of the Moabites and Edomites. The mention of the Kenites and Assyria in ver. 22, the former of whom were allies of Edom, shows, in the opinion of some recent critics, that the writer was acquainted with the Edomite wars under Amaziah and Uzziah, and hoped that the latter power would permanently subjugate the restless Edomites. This would bring the composition down to the first half of the 8th century. Verses 23 and 24 are obscure, but probably refer to no event later than Hezekiah. A fleet from the Phœnician Cyprians seems to have attacked the Canaanitish and Phœnician coasts, threatening the Syrians farther north.

The writer of Num. xxxi. 8, 16, Joshua xiii. 22, is the Elohist, whose account is very brief. Meagre, however, as it is, it is probably historical. A heathen soothsayer, connected with the Midianites, perished in one of their battles with Israel. The writer of Numbers xxii.–xxiv. is, in this view, the Jehovist, who, under the name of Balaam, gives expression to his ideas and hopes in the elevated diction of an inspired prophet. As Jacob and Moses had pronounced blessings on Israel under the immediate inspiration of the Almighty, so Balaam is summoned from a distant land to eulogize the same people.

BÁLÁGHÁT, a British district in the Central Provinces of India, situated between 21° and 23° N. lat. and 80° and 81° E. long.; bounded on the N. by the district of Mandlá; on the E. by the district of Chhattisgarh; on the S. by Chhattisgarh and Bhandárá; and on the W. by the district of Seoní. Bálághát forms the eastern portion of the central plateau which divides the province from east to west. These highlands, formerly known as the Ráigrh Bichhiá tract, remained desolate and neglected until 1866, when the district of Bálághát was formed, and the country opened to the industrious and enterprising peasantry of the Wainangá valley. Geographically the district is divided into three distinct parts:—(1.) The southern lowlands, a slightly undulating plain, comparatively well cultivated, and drained by the Waingangá, Bágh, Deo, Ghisrí, and Son rivers. (2.) The long narrow valley, known as the Mau Táluká, lying between the hills and the Waingangá river, and comprising a long, narrow, irregular-shaped lowland tract, intersected by hill ranges and peaks covered with dense jungle, and running generally from north to south. (3.) The lofty plateau, in which is situated the Ráigárh Bichhiá tract, comprising irregular ranges of hills, broken into numerous valleys, and generally running from east to west.

Since 1867 considerable encouragement has been given to the cultivating tribes of Fonwárs, Kunbis, Marárs, etc., of the low country to immigrate, and take up lands in the upland tracts. By this means a large quantity of jungle land has lately come under cultivation.

BALAKLAVA, a small Greek fishing village with 700 inhabitants, in the Crimea, eight miles southeast of Sebastopol. From September, 1854, to June, 1856, it was the British headquarters during the Crimean war, and the famous charge of the Six Hundred (October 25, 1854), has made the name historic.

BALANCE. For the measurement of the "*mass*" of (*i.e.*, of the quantity of matter contained in) a given body we possess only *one* method, which, being independent of any supposition regarding the nature of the matter to be measured, is of perfectly general adaptability. The method — to give it at once in its customary form — consists in this, that after having fixed upon a *unit mass*, and procured a sufficiently complete set of bodies representing each a known number of mass-units (a "set of weights"), we determine the ratio of the *weight* of the body under examination to the *weight* of the unit piece of the set, and identify this ratio with the ratio of the *masses*. Machines constructed for this particular *modus* of weighing are called *balances*. Evidently the weight of a body as determined by means of a balance — and it is in this sense that the term is always used in everyday life, and also in certain sciences, as, for instance, in chemistry — is independent of the magnitude of the force of gravity; what the merchant (or chemist)

calls, say, a "pound" of gold is the same at the bottom as it is at the top of Mont Blanc, although its real weight, *i.e.*, the force with which it tends to fall, is greater in the former than it is in the latter case.

To any person acquainted with the elements of mechanics, numerous ideal contrivances for ascertaining which of two bodies is the heavier, and for even determining the ratio of their weights, will readily suggest themselves; but there would be no use in our noticing any of these many conceivable balances, except those which have been actually realised and successfully employed.

Spring Balances.—The general principle of this class of balances is that when an elastic body is acted upon by a weight suspended from it, it undergoes a change of form, which is the greater the greater the weight. The simplest form of the spring balance is a straight spiral of hard steel (or other kind of elastic) wire, suspended by its upper end from a fixed point, and having its lower end bent into a hook, from which, by means of another hook crossing the first, the body to be weighed is suspended,—matters being arranged so that even in the empty instrument the axis of the spiral is a plumb-line. Spring balances are very extensively used for the weighing of the cheaper articles of commerce and other purposes, where a high degree of precision is not required. In this class of instruments, to combine compactness with relatively considerable range, the spring is generally made rather strong; and sometimes the exactitude of the reading is increased by inserting, between the index and that point the displacement of which serves to measure the weight, a system of levers or toothed wheels, constructed so as to magnify into convenient visibility the displacement corresponding to the least difference of weight to be determined. Attempts to convert the spring balance into a precision instrument have scarcely ever been made; the only case in point known to the writer is that of an elegant little instrument constructed by Professor Jolly, of Munich, for the determination of the specific gravity of solids by immersion, which consists of a long steel-wire spiral, suspended in front of a vertical strip of silvered glass bearing a millimetre scale. To read off the position of equilibrium of the index on the scale, the observing eye is placed in such a position that the eye, its image in the glass, and the index are in a line, and the point on the scale noted down with which the index apparently coincides.

The *Precision Balance* being quite identical in principle with the ordinary "pair of scales," there is no sharp line of demarcation between it and what is usually called "a common balance," and it is equally impossible to name the inventor of the more perfect form of the instrument. But taking the precision balance in what is now considered its most perfected form, we may safely say that all which distinguishes it from the common balance proper is, in the main, the invention of the late Mr. Robinson of London. In Robinson's, as in most modern precision balances, the beam consists of a perforated flat rhombus or isosceles triangle, made in one piece out of gun-metal or hard-hammered brass. The substitution for either of those materials of *hard steel* would greatly increase the relative inflexibility of the beam, but, unfortunately, steel is given to rusting, and, besides, is apt to become magnetic, and has therefore been almost entirely abandoned. The perforations in the beam are an important feature, as they considerably diminish its weight (as compared with what that would be if the perforations were filled up) without to any great extent reducing its relative solidity. In fact, the loss of carrying power which a solid rhombus suffers in consequence of the middle portions being cut out, is so slight that a very insignificant increase in the size of the minor diagonal is sufficient to compensate for it. *Why* a balance beam should be made as light as possible is easily seen; the object (and it is well here to say at once, the *only* object) is to diminish the influence of the unavoidable imperfections of the central pivot. To reduce these imperfections to a minimum, the beam in all modern balances is supported on a polished horizontal plane of *agate* or *hard steel* fixed to the stand, by means of a perfectly straight "*knife edge*," ground to a prism, of hard steel or agate, which is firmly connected with the beam, so that the edge coincides with the intended axis of rotation. In the best instruments the bearing plane is continuous, and the edge rests on it along its entire length; in less expensive instruments the bearing consists of two separate parts, of which the one supports the front end, the other the hind end of the edge. Every complete balance is provided with an "arrestment," one of the objects of which is, as the name indicates, to enable one to arrest the beam, and, if desired, to bring it back to its normal position; but the most important function of it is to secure to *every point of the central edge* a perfectly fixed position on its bearing. In Robinson's, and in the best modern balances, the beam is provided at its two extremities with two knife-edges similar to the central one (except that they are turned upwards), which, in intention at least, are parallel to, and in the same plane as the central edge; on each knife-edge rests a plane agate or steel bearing with which is firmly connected a bent wire or stirrup, provided at its lower end with a circular hook, the plane of which stands perpendicular to the corresponding knife-edge; and from this hook the pan is suspended by means of a second hook crossing the first, matters being arranged so that, supposing both end-bearings to be in their proper places and to lie horizontally, the working points of the two hook-and-eye arrangements are vertically below the intended point-pivots on the edges. In this construction it is an important function of the arrestment to assign to each of the two terminal bearings a *perfectly constant* position on its knife-edge.

Compound Lever Balances.—Of these numerous inventions—in all of which a high degree of practical convenience is obtained at the expense of precision—we must content ourselves with noticing two which, on account of their extensive use, cannot be passed over. We here allude, in the first place, to that particular kind of equal-armed level balances, in which the pans are situated above the beam, and which are known as "*Roberval's balances;*" and secondly, to those peculiar complex *steel-yards* which are used for the weighing of heavy loads by means of comparatively small weights.

The ordinary *Decimal Balance* is a combination of levers purporting to weigh heavy masses with comparatively light weights.

Torsion Balances.—Of the several instruments bearing this name, the majority are no balances at all, but machines for measuring horizontal forces (electric, magnetic, &c.), by the extent to which they are able to distort an elastic wire vertically suspended and fixed at its upper end. In the torsion *balances* proper the wire is stretched out horizontally, and supports a beam so fixed to it that the wire passes through its centre of gravity. Hence the elasticity of the wire here plays the same part as the weight of the beam does in the common balance. An instrument of this sort was invented by Ritchie for the measurement of very small weights, and for this purpose it may offer certain advantages; but, clearly, if it were ever to be used for measuring larger weights, the beam would have to be supported by knife-edges and bearings, and in regard to such application therefore (*i.e.*, as a means for serious

gravimetric work), it has no *raison d'être*. See ELECTRICITY and MAGNETISM.

For *Hydrostatic weighing machines* see the article HYDROMETER.

BALANCE OF POWER. The theory of the Balance of Power may be said to have exercised a preponderating influence over the policy of European statesmen for more than two hundred years, that is, from the Treaty of Westphalia until the middle of the present century; and to have been the principal element in the political combinations, negotiations, and wars which marked that long and eventful period of modern history. It deserves, therefore, the attentive consideration of the historical student, and, indeed, the motive cause of many of the greatest occurrences would be unintelligible without a due estimate of its effects. Even down to our own times it has not been without an important influence; for the Crimean War of 1854 was undertaken by England and France for no other object than to maintain the balance of power in Eastern Europe, and to prevent the aggrandisement of Russia by the dismemberment of the Ottoman empire and the conquest of Constantinople. Nevertheless there is, perhaps, no principle of political science, long and universally accepted by the wisest statesmen, on which modern opinion has, within the last twenty years, undergone a greater change; and this change of opinion is not merely speculative, it has regulated and controlled the policy of the most powerful states, and of none more than of Great Britain, in her dealings with the continent of Europe.

The theory of the balance of power rested on several assumptions. It was held, more especially from the time of Grotius, in the early part of the 17th century, that the states of Europe formed one grand community or federal league, of which the fundamental principle and condition was the preservation of the balance of power; that by this balance was to be understood such a disposition of things, as that no one potentate or state shall be able absolutely to predominate and prescribe laws to the others; that all were equally interested in maintaining this common settlement, and that it was the interest, the right, and the duty of every power to interfere, even by force of arms, when any of the conditions of this settlement were infringed or assailed by any other member of the community. In this respect all neighboring nations, trading with each other, form one great body and a sort of community. Thus, Christendom is a kind of universal republic, which has its interests, its fears, and its precautions to be taken. All the members of this great body owe it to one another for the common good, and owe it to themselves for the security of their country, to prevent the progress of any other members who should seek to overthrow this balance, which would turn to the certain ruin of all the other members of the same body. Whatever changes or affects this general system of Europe is too dangerous, and draws after it infinite mischief. Whatever may be the value of these philanthropic principles, history reminds us that when they were most loudly professed they were most frequently violated, and that no cause of war seems to have been so frequent or so fatal as the spurious pretext of restoring peace and defending the general tranquillity of the world. Thus, it was to balance the power of the house of Austria that Cardinal Richelieu flung France into the quarrels of Germany in the Thirty Years' War, and even lent her aid to the Protestant cause. It was to balance the encroaching and aggressive power of Louis XIV. that numerous combinations were formed between England, Austria, and Holland, which, after nearly half a century of almost uninterrupted contests and bloodshed, ended in the peace of Utrecht. The pretext of Frederick II., when he was meditating some act of rapine, generally was that he believed some hostile combination had been formed against him, which it was wise to anticipate. In short, no cause of war has been more frequently alleged and acted upon, than that a proper consideration for the balance of power rendered it necessary to take forcible measures to avert some remote or hypothetical danger.

The ablest and most eloquent champion of the system of equipoise in the present century was the Chevalier von Gentz, who published his *Fragments upon the Balance of Power in Europe* in 1806, under the influence of the catastrophe which had subjugated the Continent, and who subsequently took an active part at the Congress of Vienna in the attempts to constitute a a new system of European policy. Gentz defines the balance of power as "a constitution subsisting between neighboring states more or less connected with one another, by virtue of which no one among them can injure the independence or essential rights of another, without meeting with effectual resistance on some side, and consequently exposing itself to danger." And he rests this constitution on four propositions: — (1.) That no state must ever become so powerful as to coerce all the rest; (2.) That every state which infringes the conditions is liable to be coerced by others; (3.) That the fear of coercion should keep all within the bounds of moderation; and (4.) That a state having attained a degree of power to defy the union should be treated as a common enemy. To determine the true character and limits of the balance of power, we must have recourse, not to vague general principles, but to positive law, framed in the shape of international contracts, which are termed treaties, and which have been sanctioned at different epochs of modern history by a congress of states. This historical treatment of the subject leads us to more tangible and solid ground; and it will be seen that on these occasions more especially attempts have been made to establish a balance of power in Europe upon the basis of general treaties; and that these attempts have been rewarded by considerable, though not by permanent, success in the 17th, 18th and 19th centuries.

The first idea of a general congress, to put an end to the horrors of the Thirty Years' War, and to adjust the conflicting claims of rival creeds and hostile princes, appears to have originated with the emperor of Germany in 1640. The attempt to restore peace by the authority of the Germanic Diet had failed. It became necessary to have recourse to mediating powers, and after a protracted preliminary negotiation, the Congress of Münster or Westphalia opened on the 11th July 1643, — the Catholic and Protestant belligerents being represented on the one hand, and the mediating powers, France, Sweden, Venice, and the Pope, on the other. We do not propose in this place to follow the train of these complicated negotiations. It is enough for our present purpose to remark that the great treaty which resulted from them, and was signed on the 24th October 1648, became the basis of the public law of Europe, and the first official recognition of the existence of a European balance of power. The conditions established in Germany left the Catholic, the Lutheran, and the Reformed Churches in possession of their respective independence, whilst they relieved the minor princes from their strict dependence on the empire; but, above all, they conferred on France and Sweden, as mediating powers, the right of intervention for the purpose of upholding the provisions of the treaty. In other words, the balance which had been established between the states of Central Europe was regulated by external weights, which could be brought to bear upon it. The result of this combination, due mainly to Cardinal Mazarian, was certainly

injurious to the unity and independence of Germany, and it tended to aid the aggressive and dictatorial power of Louis XIV. Nevertheless, the fundamental principles of the Treaty of Westphalia were recognized and renewed as the conditions of the general peace of Europe down to the French Revolution; they were not wholly absent from the minds of the negotiators at Vienna in 1815; and they only received their death-blow from the hand of the Prussian Government in 1866 and 1870. Whatever might be the merits of the Treaty of Westphalia, it had not that of securing to Europe an unbroken or durable peace; and even the territorial relations of France and Germany were altered within thirty years of that time by the conquest of Franche Comté and Alsace. But the wars of Louis XIV. were not general wars, until he engaged in the fatal attempt to place his grandson on the throne of Spain, and to unite the two crowns in the house of Bourbon. Efforts had been made, in view of the approaching extinction of the Spanish branch of the house of Austria, to preserve the balance of power by a timely partition of the vast dominions of the Spanish empire — a remarkable example of an attempt to prevent a formidable catastrophe by an equitable arrangement. But it may be doubted whether any arrangement in which so little account was taken of the wishes and traditions of nations could possibly have succeeded; and it unquestionably failed, because Louis XIV. did not hesitate to repudiate the treaties he had signed, and to avail himself of the last will and testament of Charles II., which had been extorted from the Spanish court by his intrigues. That event raised again the whole question of the balance of power in Europe. It was received as a doctrine of political faith that the union of the French and Spanish crowns in one family must be fatal to the independence of all other states; that it would replace the Stuarts upon the throne of England, and establish the ascendency of France and the Catholic party over Europe. It was therefore resisted by a coalition, of which England, Austria, and Holland were the principal members. France was at length reduced to the lowest point of humiliation, and in 1709 peace might have been obtained on every point but one. Louis refused to turn his arms against his own grandson, and the war continued till 1715. Philip V. retained the Spanish crown, and the relations of all the European states were once more adjusted with legal nicety at Utrecht. Great pains were taken to provide, by a system of renunciations, against the possibility of the union of the crowns of France and Spain on the same head, because it was held that such a contingency would be fatal to the balance of power in Europe. But these precautions did not prevent the conclusion, at a later period, of the family compact between the two branches of the house of Bourbon, which was regarded as a lasting danger to other countries, and was opposed by the whole strength of Britain and the genius of Chatham. The peace of Utrecht was denounced by Parliament and detested by the nations as an inglorious termination of a glorious war, and its authors were consigned to obloquy and exile; but it secured the peace of Europe for thirty years; it reduced the power of France; and had it not been for the German dominions of the house of Hanover, it might have been still longer before England was drawn into another war.

Hitherto the political system of Europe had comprised little more than the states of France, Austria, Spain, Sweden, and Holland, with the occasional intervention of Great Britain, more for the defence of the interests of others than of her own. But the 18th century witnessed a total change in the politics of the world. A new empire, Russia, arose in the north, under the genius of Peter and of Catherine; the ambition and military skill of Frederick II. raised Prussia from a secondary member of the German empire to a powerful and independent kingdom; the colonial empires of Spain, France, and Britain had extended their territorial interests to the continents of Asia and America, and to the eastern and the western isles, insomuch that wars, begun in Europe, soon raged on the banks of the Ganges and the St. Lawrence; and the declaration of independence of the United States of America called into being a new and powerful people of the future. The partition of Poland, which was commenced in 1772, marked a new era of aggressive revolutionary policy; it was a gross invasion of the principle of the balance of power, effected by three powers, jealous of their respective strength, but indifferent to the rights of an independent nation and to the opinion of Europe. That lawless act was the prelude to more violent attacks on the sovereignty and nationality of many countries, for before the century closed the French Revolution, and the wars that followed it, crushed to atoms the ancient fabric of Europe. Whilst events of this magnitude were occurring in the world, it is obvious that the theory of the balance of power was entirely displaced and dislocated. New elements were at work over a far wider area, new sources of power and influence were opened of far more importance than those territorial and dynastic questions which occupied the statesmen of Münster and of Utrecht; ancient land-marks were swept away; minor states were annihilated; and the temporary domination of Napoleon over a great portion of the continent of Europe seemed to have overthrown the balance of power for ever. In those dark and evil days public writers like Gentz and Mackintosh still maintained the principle that peace could only be restored by a due recognition of the rights and independence of every nation, and England adhered inflexibly to the policy of combining the scattered elements of Europe against the common enemy. Half a dozen times over these coalitions failed; but they succeeded at last, and England had the glory of playing no inconsiderable part in the restoration of the liberties of all other nations against foreign aggression.

Upon the fall of Napoleon in 1814 it became the common interest, and the universal desire, of all the sovereigns and nations of Europe to restore peace upon a settled basis, to re-establish the authority of public law, to reinstate the rightful owners in the possessions and dominions they had been forcibly deprived of, to reduce the military establishments which weighed so heavily on the finances and on the population of Europe, and to create anew a balance of power between the states of Europe, by which the greatest of them might be restrained and the least of them protected. A secret article had been annexed to the Treaty of Paris, declaring that "the allied powers had agreed among themselves on the bases which were to be given to the future system of equilibrium;" though what the nature of that agreement and of those bases was, has never been made clearly apparent. But the matter was unquestionably referred to the congress then about to open at Vienna, where the most powerful sovereigns and the most distinguished ministers of all the European states met for the first time in council. That congress was certainly the most complete, and in its action the most important, assemblage of independent political powers and their representatives which ever took place in the world. Its decisions were not all of them just, or wise, or disinterested. The broad general principles of pacification which had been laid down were more than once traversed and thwarted by particular interests and ambitions. The theory of the rights of legitimate sovereigns over their subjects was carried to an extravagant point, pregnant with danger for the future. Genoa was transferred to

Sardinia, Venice to Austria, Norway to Sweden, Poland to Russia, part of Saxony to Prussia, and the sacred hopes and pledges of freedom which had animated the nations in the contest were forgotten by the leading courts of Europe in the division of the spoil. But in spite of these shortcomings and abuses, we cannot concur with writers who, like Hardenberg, denounce the Congress of Vienna as an auction of nations and an orgy of kings. It was said that every one withdrew from the Congress of Vienna disappointed, no one having obtained as much as he expected; but if so, that would suggest the inference that the general interest of Europe, prevailed over the pretensions of each particular state. From the point of view we are now considering, which is the restoration of the balance of power, it cannot be denied that the Treaties of Vienna secured forty years of peace to Europe. They stood the brunt of two fresh convulsions in France in 1830 and 1848, and their main provisions, though modified with respect to the Low Countries in 1832, and abrogated in Italy by the campaign of 1859, were not seriously impaired until the dissolution of the Germanic body in 1866, and the Franco-German War of 1870. During the whole of this period the warlike ambition of France, and the disposition of Russia to overawe Central Europe, were successfully held in check. At Vienna itself, and during the congress, the struggle was close and sometimes doubtful. Russia was resolved to retain the whole of Poland, which she occupied with her armies, and Prussia claimed the whole of Saxony as a compensation for her share of the Polish provinces. To counteract this combination of Russia and Prussia, an alliance was signed on the 3d January 1815 between Austria, England, and France, which might have led to hostilities between those powers and their recent allies. Perhaps it was fortunate that the return of Napoleon from Elba broke up the congress, and reminded all the powers that union and mutual concessions were the first duties of those who had devoted themselves to the cause of law, order, and peace. It was a sign of the wisdom of the congress, and of its respect for sound principles, that although France was the vanquished power and the author of the calamities ot Europe, she was treated at Vienna with as much consideration as any other state. Her ambassador, M. de Talleyrand, had his full weight in the congress; and no attempt was made in 1814 to curtail her ancient territorial possessions or to lower her rank in Europe. On the contrary, the just influence of France was recognised as an essential condition of the balance of power.

For the first time, then, by this general act of the Congress of Vienna, the territorial possessions and frontiers of the Continental states were defined in one document, to which all the Governments of Europe were parties; the constitution of the Germanic body was incorporated in the same instrument, and the neutrality and independence of the smallest cities and commonwealths were established and guaranteed. Every state in Europe had therefore an equal right and interest to invoke the authority of the treaty, and to claim the execution of all its conditions. A complete fabric of European policy, such as had never existed before, was thus literally established by mutual contract; and every infraction of it might justly be brought under the consideration of the high contracting parties, or might even have been the ground of a declaration of war. In several instances this controlling power was wisely and beneficially exercised, and more than one burning question was adjusted by the conferences which met from time to time, always on the basis of the treaties of 1815. This certainly was the nearest approach ever made to a practical balance of power; and we owe to it, as we have seen, a long period of mutual confidence, respect for public law, and peace, which contributed enormously to the progress, prosperity, and happiness of the world.

But there are darker shades to the picture. The comprehensive interest which every state was thus held to have acquired in maintaining the general settlement might be held, and was held, to justify a dangerous and mischievous degree of intervention in the internal affairs of every other country, and this right was too often exercised in a manner injurious to liberty and independence. The northern powers, not content with the terms of the general alliance and the Treaties of Vienna, proceeded to connect themselves more closely by the mystic ties of the Holy Alliance, which provided that they were to act together on all subjects, and to regard their interests as one and indivisible. The construction they put upon the system recently established in Europe was that it gave the allied powers a right to interfere, not only for the prevention of quarrels, aggressions, and war, but in the internal government of states, for the purpose of preventing changes which they chose to regard as injurious to their own security and eventually to the balance of power. At the congresses and conferences of Troppau, Carlsbad, Aix-la-Chapelle, and Verona, these doctrines were avowed and acted upon to their furthest extent, and under pretence of maintaining and defending the common interests of Europe, the popular movements and constitutional progress of Italy were crushed, a French army entered Spain in 1823 to restore the authority of Ferdinand VII. against the Cortes, and even the independence of the South American colonies was represented as a blow to the peace and security of Europe. The British Government had early perceived that the interpretation thus given to the theory of the balance of power, and to what was termed the federal system in Europe, was only another name for an intolerable oppression, and that the right of intervention in the internal affairs of other countries was claimed and exercised under false and dangerous pretexts. The duke of Wellington, who represented Great Britain at the Congress of Verona, under instructions framed by Lord Castlereagh, was the first to declare that England could be no party to such an application of the theory of the alliance, and that that country preferred isolation to any such system of combined policy. That was the germ of the modern doctrine of non-intervention. But as long as the Treaties of Vienna lasted, it was her duty and her right to endeavor to support their authority, and to vindicate the rights established by a compact to which that country was a party. She declined in 1852 to join with Prussia in enforcing the declaration made by the allied powers in 1815, which excluded any member of the family of Bonaparte from the throne of France; but she sought, in conjunction with France, to protest against the annihilation of the kingdom of Poland, the incorporation of Cracow, the admission of non-German provinces into the confederation, and the invasion of Schleswig; and she opposed the annexation of Savoy and Nice to France, but alone without effect. The compact of Vienna was gradually set aside and violated in the course of years by those who were most interested in maintaining it; and when the Emperor Napoleon III. proposed, in 1863, a new congress for the purpose of revising and re-establishing the balance of power in Europe, under the name of an International Council, England refused to be a party to the negotiation, and rejected the scheme. Lord Russell replied, "There being no supreme authority in such an assembly to enforce the decision of the majority, the congress would probably separate, leaving many of its

members on worse terms with each other than they had been before." This was the last attempt made to bring the authority of a congress, representing the collective authority of Europe, to bear on questions affecting the general peace. When this point was reached it was apparent that the whole theory of the confederated system in Europe had become, for a time at least, obsolete; that the treaties and mutual guarantees on which that system rested had lost their power; and that there was no controlling force to resist the ambitious or warlike designs of any state capable of giving effect to them. The Italian campaign of 1859 had considerably altered the condition of Southern Europe, and weakened Austria. Possibly, Prussia, in withholding her assistance at that time from her federal ally, foresaw in the defeat of Austria an event favorable to her own future pretensions. At any rate, for the first time, a war seriously affecting the balance of power was begun and ended by the two principal belligerents alone, and even the price paid by the house of Sardinia for the services of France — the cession of Savoy and Nice — was tacitly acquiesced in by Europe. Twenty years before, it would have been thought impossible that the doctrine of non-intervention should have acquired so great an ascendency.

But the consequences of this novel state of affairs soon became manifest in the increasing disintegration of Europe. No state could have a greater claim than Denmark to the protection of the principles of the balance of power, for, as late as 1852, all the great powers had pledged themselves by treaty to maintain the integrity of her dominions, the unity of the monarchy, and the order of succession to the crown which was then established. Yet in 1864 the German powers proceeded to what was termed a Federal Execution against her; Holstein, Lauenberg, and, eventually, Schleswig were torn from her by Prussia, Austria acting a subordinate part. England in vain appealed by her diplomacy to the terms of the agreement of 1852, but France and Russia stood aloof, and the greatest injustice the world had witnessed since the partition of Poland was consummated. As every event in political life is closely connected, Prussia now proceeded to ally herself with the crown of Italy against Austria, and to execute her grand design of the overthrow of the Germanic Confederation and the expulsion of Austria from that body, which had been regarded as the centre of gravity of the European system. As long as that body subsisted, war was impossible between its respective members, and France was incapable of attacking their united forces. The success of Prussia in the campaign of 1866 was rapid and complete, and Austria ceased to form part of the Germanic Confederation. The power of Prussia was further increased by the military conventions, which gave her the absolute command over the armies of the minor German states. This was undoubtedly the severest blow which had yet been inflicted on the balance of power in Europe; and the Emperor Napoleon III., who had recently given vent to his dissatisfaction with the treaties of 1815, now found himself confronted by an enemy infinitely more powerful and dangerous. The results of Sadowa were as fatal to the influence and security of France as if she herself had lost a campaign. The French nation, however, failed to understand the magnitude of the danger, though they were irritated by the approach of it. War was, on more than one occasion, on the point of breaking out; and at length France plunged into it with a recklessness and incapacity only to be equalled by the tremendous calamities that war caused her to endure. Again, no third state was drawn by political considerations into the conflict. The terms of peace were settled between the vanquished and the conquerors without reference to the general interests of other nations; and no attempt has been made to place these arrangements under the sanction of the public law of Europe. Russia took advantage of the agitated condition of Western Europe to abrogate, by her own will and pleasure, an important stipulation of the Treaty of Peace of 1856, and Europe again submitted to this breach of covenant.

The general result is that, at the present time, the military power of the German empire far surpasses that of any other state, and could only be resisted by a general combination of all the rest. Where the reign of law ends, the reign of force begins, and we trace the inevitable consequence of this dissolution of legal international ties in the enormous augmentation of military establishments, which is the curse and the disgrace of the present age. Every state appears to feel that its security depends on arming the whole virile population, and maintaining in what is called a state of peace all the burdens of a complete armament; indeed, in the most barbarous ages and the most sanguinary wars there were, doubtless, fewer men under arms, and less money was spent in arming them, than at the present day.

BALANCE OF TRADE. The theories connected with the balance of trade arose out of the "mercantile system" of political economy. In the mercantile system, which looked upon the possession of gold as the grand aim, it not unnaturally came to be a maxim that a nation becomes richer in proportion as the money-value of its exports exceeds that of its imports; the excess being paid in gold, was thought to be just so much added to the national wealth. Now, the difference between the money-value of the exports and imports of a State is called the "balance of its trade;" and by the adherents of the mercantile system, this balance was said to be "in favor" of the country or "against" it, according as the exports or imports showed the excess. As a practical result of this theory, every sort of device was adopted in order to bring out a favorable balance. Laws were enacted prohibiting importation of foreign manufactures, or imposing high duties upon them, and giving premiums and other protective encouragements to exportation. The aim of commercial legislation, in short, was to promote the flow of the precious metals to one's own country, and to keep them there. The fallacies of the balance of trade were obviously due to a mistaken conception of the nature of wealth, and must, therefore, be traced to the errors of the mercantile system.

BALANOGLOSSUS, a worm-like animal of much zoölogical interest as a connecting link between invertebrates and vertebrates. The genus, which includes at least four species, occupies so unique a position, that it is regarded as representative of a distinct class of Enteropneusta (gut-breathers). The animals live in fine sand, which they appear to saturate with lime.

BALASINOR, a tributary State of India, in the Province of Guzerat, Bombay. Area about 150 square miles; pop., 42,000. The chief town, Balasinor, is fifty-one miles north of Baroda. Pop., 9,000.

BALASOR, a district of British India in the Orissa division, under the Lieutenant-Governor of Bengal, is bounded on the N. by the district of Midnapur; on the S. by Cattack district, from which it is separated by the Baiteraní river; on the W. by the tributary states of Keunjhar, Nígiri, and Morbhanj; and on the E. by the Bay of Bengal. Balasor district forms a strip of alluvial land between the hills and sea, varying from about 9 to 34 miles in breadth; area, 2066 sq. miles. The hill country rises from the western boundary line. The district naturally divides itself into three well-defined tracts — (1.) The Salt Tract, along the coast; (2.)

The Arable Tract, or rice country; and (3.) The Submontane Tract, or jungle lands. The Salt Tract runs the whole way down the coast, and forms a desolate strip of a few miles broad. Towards the beach it rises into sandy ridges, from 50 to 80 feet high, sloping inland, and covered with a vegetation of low scrub jungle. Sluggish brackish streams creep along between banks of fœtid black mud. The sand hills on the verge of the ocean are carpeted with creepers and the wild convolvulas. Inland, it spreads out into prairies of coarse long grass and scrub jungle, which harbor wild animals in plenty; but throughout this vast region there is scarcely a hamlet, and only patches of rice cultivation at long intervals. From any part of the Salt Tract one may see the boundary of the inner arable part of the district, fringed with long lines of trees, from which every morning the villagers drive their cattle out into the saliferous plains to graze. The Salt Tract is purely alluvial, and appears to be of recent date. Towards the coast the soil has a distinctly saline taste.

The Arable Tract lies beyond the salt lands, and embraces the chief part of the district. It is a long dead level of rich fields, with a soil lighter in color than that of Bengal or Behar; much more friable, and apt to split up into small cubes with a rectangular cleavage. A peculiar feature of the Arable Tract is the *Páts*, literally the Cups, or depressed lands near the river banks. They were probably marshes that have partially silted up by the yearly overflow of the streams. These Cup-lands bear the finest crops. As a whole, the Arable Tract is a treeless region, except around the villages, which are encircled by fine mango, *pipal*, banyan, and tamarind trees, and intersected with green shady lanes of bamboo. A few palmyras, date palms, and screw pines (a sort of aloe, whose leaves are armed with formidable triple rows of hook-shaped thorns) dot the expanse, or run in straight lines between the fields. The Submontane Tract is an undulating country with a red soil, much broken up into ravines along the foot of the hills. Masses of laterite, buried in hard ferruginous clay, crop up as rocks or slabs. At Kopári, in Kila Ambohatá, about 2 square miles are almost paved with such slabs, dark red in color, perfectly flat, and polished like plates of iron. A thousand mountain torrents have scooped out for themselves picturesque ravines, clothed with an ever-fresh verdure of prickly thorns, stunted gnarled shrubs, and here and there a noble forest tree.

BALASOR, the principal town and administrative headquarters of the above district, situated on the River Burábalang, about eight miles from the sea-coast as the crow flies, and sixteen by the river. The population of Balasor is estimated at 800,000, nearly all Hindus.

BALBI, ADRIAN, an eminent geographer, was born at Venice in 1782, and died in 1848.

BALBO, CESARE, a noted Italian writer and statesman, was born at Turin, November 21, 1789, and died in 1853.

BALBOA, VASCO NUNEZ DE, one of the bravest and most successful of the Spanish discoverers of America, was born at Xeres de los Caballeros, in Estremadura, about the year 1475. He was by birth a *hidalgo*, or gentleman, but was in poor circumstances. Little is known of his life till the year 1501, when he was one of the company of adventurers who followed Roderigo de Bastidas in his voyage of discovery to the western seas. He appears to have settled in Hispaniola, and took to cultivating land in the neighborhood of Salvatierra, but with no great success, as his debts soon became oppressive. In 1509 the famous Ojeda sailed from San Domingo with an expedition, and founded the settlement of San Sebastian. He had left orders with Enciso, an adventurous lawyer of the town, to fit out two ships and convey provisions to the new settlement. Enciso set sail in 1510, and Balboa, whose debts made the town unpleasant to him, managed to accompany him, by concealing himself in a cask which was conveyed from his farm to the ship as if containing provisions. The expedition, after various adventures, reached San Sebastian to find Ojeda gone and the settlement in ruins. While Enciso was undecided how to act, Vasco Nuñez proposed that they should sail for Darien, on the Gulf of Uraba, where he had touched when with Bastidas. His proposal was at once accepted and carried out. The new town was named Sta. Maria de la Antigua del Darien. Bitter quarrels broke out among the adventurers, caused chiefly by Enciso prohibiting all private interchange for gold with the natives. Enciso was deposed from the office of authority which he had assumed, but it was found no easy matter to elect a successor. Nicuesa, in whose province they were, was proposed by several, and was brought from Nombre de Dios by a ship which had been sent out to bring assistance to him. The inhabitants of Darien, however, would not receive him, and, in their wrath, seized him and placed him, with seventeen companions, in a crazy bark with which to find his way back to Hispaniola. The party of Vasco Nuñez grew strong; Enciso was thrown into prison, and finally sent off to Spain along with Vasco's ally, the alcalde Zamudio. Being thus left in authority, Balboa began to make excursions into the surrounding country, and by his bravery and conciliatory manners gained the friendship of several native chiefs. On one of these excursions he heard for the first time of the great ocean that lay on the other side of the mountains, and of the wondrous land of gold, afterward called Peru. Soon after his return to Darien he received letters from Zamudio, informing him that Enciso had complained to the king, and had obtained a sentence condemning Balboa and summoning him to Spain. In his despair at this message Vasco resolved to attempt some great enterprise, the success of which he trusted would conciliate his sovereign. On the 1st September 1513, he set out with about 190 men, well armed, and sailed to Coyba, where he left half his forces to guard the canoes and ships. With the remainder he started on his perilous journey across the isthmus. On the 26th September they reached the summit of the range of mountains, and the glorious expanse of the Pacific was displayed to them. Three days later they began to descend the mountains on the western side, and Vasco, arriving at the sea-shore, formally took possession of the ocean in the name of the Spanish monarch. He remained on the coast for some time, heard again of Peru, had the Pearl Islands pointed out to him, and set out for Darien. On the 18th January 1514 he reached the town, and was received with the utmost joy. He at once sent messengers to Spain bearing presents, to give an account of his discoveries; but, unfortunately, these did not arrive till an expedition had sailed from Spain, under Don Pedro Arias de Avila (generally called Pedrarias, or Davila), to replace Vasco Nuñez, and to take possession of the colony. For some time after Pedrarias reached Darien Vasco was in great straits, but at length letters came from the king, announcing to him his satisfaction with his exploits, and naming him *Adelantado*, or admiral. Pedrarias was prevailed upon to be reconciled with Vasco, and gave him one of his daughters in marriage. Vasco then resolved to accomplish his grand project of exploring the western sea. With infinite labor materials for building ships were conveyed across the isthmus, and two brigantines were constructed. With these the adventurers took possession of the Pearl Islands, and, had it not been for the weather, would have reached the coast of Peru. This

career of discovery was stopped by the jealousy of Pedrarias, who feared that Balboa would throw off his allegiance, and who enticed him to Acla by a crafty message. As soon as he had him in his power, he threw him into prison, had him tried for treason, and forced the judge to condemn him to death. The sentence, to the grief of all the inhabitants, was carried into execution on the public square of Acla in 1517.

BALBRIGGAN, a seaport of Ireland, in the county of Dublin and parish of Balrotherv 18½ miles N.N.E. of the capital. Population, 2,400.

BALCONY (till about 1825 BALCO'NY; Ital. *balcone*), a projecting gallery in front of a window or of several windows, with a balustrade or parapet at its outer edge, and supported by consoles, or brackets fixed in the wall, or by pillars resting on the ground below. The balcony was unknown in Greek and Roman architecture, the earliest examples of it occurring in Italy, to the climate of which country it is peculiarly adapted.

BALDACHIN (Ital. *baldacchino*), a canopy of the form of a tent or umbrella, made of costly materials and richly adorned, which is either supported on pillars or fastened to the roof over a throne or couch, or over a pulpit, an altar, or other sacred object. One of the most celebrated is the baldachin in the Church of St. Peter's in Rome, cast in bronze by Bernini, which is supported on four large twisted columns.

BALDE, JAKOB, a modern Latin poet of considerable repute, was born at Ensisheim in Alsace in 1603, and died in 1668.

BALDI, BERNARDINO, a distinguished mathematician and miscellaneous writer, was descended of a noble family at Urbino, in which city he was born on the 6th of June, 1533. Baldi died at Urbino on the 12th of October, 1617. He was, perhaps, the most universal genius of his age, and is said to have written upward of a hundred different works, the chief part of which have remained unpublished. His various works give satisfactory evidence of his abilities as a theologian, mathematician, geographer, antiquary, historian and poet.

BALDNESS (Gr. *alopecia*, fox-mange). Congenital baldness (complete absence of hair at birth) is sometimes met with; but in most cases is only temporary, and gives place in a few years to a natural growth of hair. Occasionally, however, it persists through life.

Senile baldness (calvities) is one of the most familiar signs of old age. It is more common in men than women. A precisely similar condition occurs not unfrequently at an earlier age (presenile baldness). Great loss of hair frequently follows severe illness or other causes which produce general debility. As health returns, the hair usually returns with it; its growth may be promoted by the use of lotions containing cantharides, ammonia, or some other stimulating agent. Baths containing common salt, and brisk rubbing, are also useful.

BALDRIC is a belt or sash worn partly as a military and partly as a heraldic symbol.

BALDUNG, HANS, called also Hans Grün, a German painter and engraver, contemporary with Albert Durer, to whom, in expression, coloring, and finish, he was little inferior. He was born at Gmünd, in Swabia, about 1476, and died at Strasburg in 1545.

BALDINGER, ERNEST GOTTFRIED, a German physician of considerable eminence, and the author of a great number of medical publications, was born near Erfurt, 13th of May, 1738. In 1768 he became professor of medicine at Jena, whence he removed, in 1773, to Göttingen, and in 1785 to Marburg, where he died of apoplexy on the 21st of January, 1804.

BALDINUCCI, FILLIPPO, a distinguished Italian writer of the history of the arts, was born at Florence about 1624, and died in 1696.

BALDOVINETTI, ALESSIO, was a distinguished painter of Florence in the 15th century, whose works have now become very scarce. Hogarth takes him as a type of those obscure artists to whom the affected amateurs of his time were wont to ascribe old paintings—"'Tis a fine piece of Alessio Baldovinetti, in his third manner."

BALDUINUS, JACOBUS, a distinguished professor of civil law in the university of Bologna. He died at Bologna in 1225, and has left behind him some treatises on Procedure, which have the merit of being the earliest of their kind.

BALDUR, one of the most interesting figures of the Scandinavian mythology, was the son of Odin and Frigg. His name (from *baldr*, the foremost or pre-eminent one) denoted his supreme excellence and beauty. The wonderful legend of his death is first dimly recorded in the *Voluspa*, the grandest and most ancient of Eddaic poems, and more fully in the younger Edda. Baldur was visited by evil dreams, and felt his life to be in danger. His mother, Frigg, took oath of all things in the world, animal, vegetable, and mineral, that they should not slay her son. The gods being then secure, found pastime in setting the good Baldur in their midst, and in shooting or hurling stones at his invulnerable body. Then Loki, the evil god, took on him the form of a woman and went to Frigg in Fensal. From Frigg he learned that of all things in the earth but one could injure Baldur, and that was a little tree westward from Valhal, that was too young to take the oath. Thither went Loki and found the plant; it was the mistletoe. He plucked it up, fashioned it into an arrow, and went back to the Æsir. They were still in a circle, shooting at Baldur; and outside the ring stood the blind god Höder, of whom Loki asked wherefore he did not shoot. When Höder had excused himself because of his blindness, Loki offered to aim for him, and Höder shooting the arrow of mistletoe, Baldur suddenly fell, pierced and dead. No such misfortune had ever yet befallen gods or men; there was long silence in heaven, and then with one accord there broke out a loud noise of weeping. The Æsir dared not revenge the deed, because the place was holy, but Frigg, rushing into their midst, besought them to send one to Hel to fetch him back. Hel promised to let him go if all things in heaven and earth were unanimous in wishing it to be so; but when inquiry was made, a creature called Thökt was found in the cleft of a rock that said, "Let Hel keep its booty." This was Loki, and so Baldur came not back to Valhal.

BALDUS, an eminent professor of the civil law, and also of the canon law, in the university of Perugia. He came of the noble family of the Ubaldi; and his two brothers, Angelus de Ubaldis and Petrus de Ubaldis, were almost of equal eminence with himself as jurists. He was born in 1327, and studied civil law under Bartolus at Perugia, where he was admitted to the degree of doctor of civil law at the early age of seventeen in 1344.

BALDWIN I., King of Jerusalem, 1100–18, was born in 1058. He was the youngest brother of Godfrey de Bouillon, with whom he took part in the first Crusade. After the death of his brother Godfrey, in 1100, he became Protector of the Holy Sepulchre, and Baron of Jerusalem, and immediately assumed the regal title, which his brother had refused. He died in 1118.—BALDWIN II., cousin and successor of Baldwin I., reigned from 1118-31. During his reign Tyre was taken and the order of the Templars was instituted. He died in 1131.—BALDWIN III., King of Jerusalem, 1143-62, the son and successor of Foulques of Anjou, was born in 1129. He died in 1162, and with his death the Christian power in the East began to decline. He was suc-

ceeded in the government by his brother Amalric, who died in 1173.—BALDWIN IV., the son and successor of Amalric, surnamed the Leper, reigned till 1184, when he caused BALDWIN V., a child six years old, the son of his sister Sybilla, to be crowned. The child died in 1186.

BALDWIN I., the first Latin Emperor of Constantinople, was born in 1171 A.D., and succeeded his father as Count of Hainault and Flanders in 1195. In 1200 he joined the fourth Crusade, and assisted in the recapture of Constantinople for the Emperor Isaac II. Alexis having been murdered by a rising of the citizens, Baldwin was chosen Emperor, and crowned in 1204. But, defeated and taken prisoner by the Bulgarian king, he died (1206) in captivity.

BALDWIN II., Emperor of Constantinople, was born in 1217. He was but eleven years old when, by the death of his brother Robert, he succeeded to the throne. In 1261 his capital was taken by one of the generals of Michael Palæologus, and Baldwin fled to Italy. With him terminated the Latin Empire in the East, after it had lasted fifty-seven years. He died in 1273.

BALDWIN, THOMAS, a celebrated English prelate of the twelfth century.

BALE, JOHN, Bishop of Ossory, in Ireland, was born at Cove, in Suffolk, in November, 1495, and died in 1563.

BALEARIC ISLANDS, a remarkable group in the western part of the Mediterranean Sea, lying to the south and east of Spain. The name, as now employed, includes not only the ancient *Insulæ Baleares* (*Major* and *Minor*), but also the *Pityusæ* or Pine Islands, as the two more western were called. The origin of the name Baleares is a mere matter of conjecture, and the reader may choose any of the derivations usually offered with about an equal chance of not being right.

Majorca is the largest island of the group, having an area of 1,430 square miles. It shape is that of a trapezoid, with the angles directed to the cardinal points; and its diagonal, from Cape Grozer in the west to Cape Pare in the east, is about sixty miles. On the northwest the coast is highly precipitous, but on the other side it is low and sloping. On the northeast there are several considerable bays, of which the chief are those of Alcuda and Pollenza, while on the southwest is the still more important bay of Palma. No fewer than twelve ports or harbors are enumerated round the island, of which may be mentioned Andraix, Soller and Porto Colom. In the northwest Majorca is traversed by a chain of mountains running parallel with the coast, and attaining its highest elevation in Silla de Totillas, 4,600 feet above the sea. Besides the towns already mentioned, Lluchmayor and Campos are places of considerable size; and the castle of Belbez near Palma, which was the former residence of the kings, is worthy of notice. Population of the island, 204,000.

Minorca, the second of the group in size, is situated twenty-seven miles east-northeast of Majorca. It has an area of 260 square miles, and extends about thirty-five miles in length. The coast is deeply indented, especially on the north, with numerous creeks and bays,—that of Port Mahon being one of the finest in the Mediterranean, if not the best o them all. "June, July, August, and Port Mahon are the best harbors of the Mediterranean." The surface of the island is uneven, flat in the south, and rising irregularly toward the centre, where the mountain El Toro has an altitude of 5,250 feet.

Iviça, Ivissza, or in Spanish, Ibiza, the *Ebusus* of the ancients, lies fifty miles southwest of Majorca, and about sixty from Cape San Martin on the coast of Spain, between 38° 50′ and 39° 8′ N. lat., and between 1° 14′ and 1° 38′ E. long. Its greatest length from northeast to southwest is about twenty-five miles, and its greatest breadth about thirteen. The coast is indented by numerous small bays, the principal of which are those of San Antonio on the northwest and of Iviza on the southeast coast. Of all the Balearic group, Iviza is the most varied in its scenery and the most fruitful. The population of the island is about 21,000, of whom 5,500 are resident in the capital.

South of Iviza lies the smaller and more irregular island of Formentera, which is said to derive its name from the production of wheat. With Iviza it agrees both in general appearance and in the character of its productions, but it is altogether destitute of streams.

Of the origin of the early inhabitants of the Balearic Islands nothing is certainly known, though Greek and Roman writers refer to Bœotian and Rhodian settlements. According to general tradition the natives, from whatever quarter derived, were a strange and savage people till they received some tincture of civilization from the Carthaginians, who early took possession of the islands, and built themselves cities on their coasts. Of these cities, Mahon, the most important, still retains the name which it derived from the family of Mago. About twenty-three years after the destruction of Carthage the Romans accused the people of the islands with piracy, and sent against them Q. Cæcilius Metellus, who soon reduced them to obedience, settled amongst them 3,000 Roman and Spanish colonists, founded the cities of Palma and Pollentia, and introduced the cultivation of the olive. Besides valuable contingents of the celebrated Balearic slingers the Romans derived from their new conquests mules (from Minorca), edible snails, *sinope*, and pitch. Of their occupation numerous traces still exist—the most remarkable being the aqueduct at Pollentia.

BALES, PETER, a famous caligraphist, and one of the first inventors of short-hand writing. He was born in 1547, and is described by Anthony Wood as a "most dexterous person in his profession, to the great wonder of scholars and others." He died in 1610.

BALFE, MICHAEL WILLIAM, musician and composer, was born, in 1808, at Limerick, in Ireland. Musical knowledge of a higher kind he never possessed, nor did he supply this want by the natural impulses of a truly refined nature. To speak of Balfe as an artist is either to misuse the word or to permit its meaning to depend on temporary successes, no matter how acquired, indeed less on the intrinsic merits of his works than on their undoubted success; and, most of all, on the fact of his being one of the few composers of British birth whose names are known beyond the island. He died in 1870.

BALFOUR, SIR JAMES, of Pittendreich, at one time lord president of the Supreme Court in Scotland, an active and unscrupulous politician during the stormy period of the reign of Mary. He died in 1583.

BALFOUR, SIR JAMES, Bart., of Denmylne and Kinnaird, an eminent annalist and antiquary, was born about 1600, and died in 1657.

BALFOUR, ROBERT, a learned Scotchman, born about the year 1550, and was for many years principal of the Guienne College at Bordeaux.

BALFROOSH, or BAKFURUSH, a large commercial town of Persia, province of Mazanderan, on the River Bhawal, which is here crossed by a bridge of nine arches, about twelve miles distant from the southern shore of the Caspian Sea, where the small town of Meshed-i-Sir serves as a kind of port.

BALGUY, JOHN, an eminent English theologian and moral philosopher, was born at Sheffield, August 12, 1686. He entered St. John's College, Cambridge, in 1702, graduated Bachelor of Arts in 1706, was ordained to the ministry in 1710, and soon after obtained

the small living of Lamesly and Tanfield in the county Durham. He died at Harrowgate, September 21, 1748.

BALI, or LITTLE JAVA, one of the Sunda Islands, in the Eastern Seas, separated from Java by the straits of the same name, which are a mile and a half wide. It is seventy-five miles in length; its greatest breadth is fifty miles. A chain of mountains crosses the island in a direction east and west, and terminates on the east in the volcanic peak Gunungagung, 12,379 feet above the sea-level. The climate and soil are the same as in Java; it has mountains of proportionate height, several lakes of great depth, and streams well fitted for the purposes of irrigation. Rice is produced in great quantities, and is even exported to Madura, Celebes, Timor, and Java. The other productions are tobacco, maize, pulses, oil, and salt; also cotton of an excellent quality. Coffee is now grown with great success; in the district of Teja Kulo alone, 150,000 trees were planted in the first four months of 1873. The inhabitants (estimated at about 800,000), though originally sprung from the same stock as those of Java, exceed them in stature and muscular power, as well as in activity and enterprising habits.

BALIOL, or BALLIOL, SIR JOHN DE, an English baron, after whom Balliol College in Oxford has been named, was the son of Hugh Baliol, of Bernard's Castle, in the diocese of Durham. His great wealth and power raised him to a prominent position in the kingdom, and he rendered good service to Henry III. in his contest with De Montfort and the revolted barons. In 1263 he endowed several scholarships at Oxford, and formed the intention of founding a college. This he did not accomplish, but after his death in 1269, his widow, Devorgille or Devorguill, carried out his design, and the foundation received the name of Balliol College. Sir John's son was the well-known John Baliol, the competitor with Bruce for the throne of Scotland.

BALISTES, or FILE FISH, a genus of bony fishes of the order of Plectognathi of Cuvier. The type of a large family, Balistidæ, the species of which are almost all inhabitants of tropical and subtropical seas, frequent rocky coasts and coral reefs.

BALKAN (the ancient *Hæmus*), a mountain range that separates the waters of the Lower Danube from those that flow into the Archipelago; or, in the more extended application of the name, the whole mountain system from the Adriatic to the Euxine. The main chain has a mean elevation of 4,000 to 5,000 feet, and rises in various parts to a height of 7,000 or 8,000. Mount Scardus attains a height of 9,700 feet.

BALKAN PENINSULA is the peninsula in south-eastern Europe running southward between the Adriatic and the Ægean. The northern boundary is the Save and the Lower Danube, though historically and politically Roumania, and some parts of the Austrian dominions are closely associated with the regions south of the Danube. Greece is a peninsula upon a peninsula, but is not usually accounted one of the Balkan States. In a general way, the Balkan Peninsula and the Balkan States cover the area of Turkey in Europe and the non-Turkish States either now or lately under Turkish suzerainty, with the exception of Roumania and Greece. The Balkans proper (ancient *Hæmus*) form the boundary between Bulgaria and Eastern Roumelia. They are highest in the west, where the mean height is 6,500 feet. The ridge is crossed by some thirty passes, of which the Skipka, between Kezanlik and Tirnova, and 4,290 feet high, is the most noted in history—especially as the scene of severe fighting in the Russo-Turkish war of 1877-78.

The following table, compiled from official returns, gives the area and population of the different parts of the Balkan Peninsula:

POLITICAL DIVISIONS.	Area in Sq. Miles.	Population.
Immediate Possessions of Turkey in Europe	63,875	4,500,000
Bulgaria (tributary principality)	24,699	2,007,919
Eastern Roumelia (autonomous province)	13,861	976,100
Bosnia, Herzegovina (in the occupation of Austro-Hungary)	23,577	1,336,091
Novi-Bazar (in the occupation of Austro-Hungary)		168,000
Total, Turkey in Europe	126,012	8,988,110
Servia (kingdom)	18,757	1,902,409
Montenegro (principality)	3,486	250,000
Total, Balkan Peninsula	148,225	11,140,529

Greece, with the aid of the Great Powers, obtained her independence in 1836, as also did Servia in 1830-67. Walachia and Moldavia (now united in the kingdom of Roumania) were made tributary principalities by the Peace of Paris, 1856. Roumania and Servia obtained their complete independence by the Berlin treaty of 1878—the former receiving the Dobrudja in exchange for a portion of Bessarabia, which was restored to Russia, the latter having its area enlarged. The same treaty handed over to Austro-Hungary the administration of Bosnia and Herzegovina.

BALKH, the ancient *Bactra* or *Zariaspa*, was formerly a great city, but is now for the most part a mass of ruins, situated on the right bank of the Adirsiah or Balkh river, in a large and fertile plain 1,800 feet above the sea. The modern name is, according to Vámbéry, the Turkish *balik*, or *balikh*, a city. The ruins, which occupy a space of about twenty miles in circuit, consist chiefly of fallen mosques and decayed buildings of sun-burnt brick. No monuments of pre-Mahometan date have been pointed out, if we except the bricks with cuneiform inscriptions which Ferrier asserts he observed; but nothing like a proper investigation of the site has yet been effected. The antiquity and greatness of the place are recognized by the native populations, who speak of it as the *Mother of Cities*. In 1220 Genghis Khan sacked Balkh, butchered its inhabitants, and leveled all the buildings capable of defense,—treatment to which it was again subjected in the fourteenth century by Timur.

BALKHASH (Kirghiz *Tingis;* Chinese *Sihai*) a great inland lake near the eastern borders of Russian Central Asia, between 44° and 47° N. latitude, and 73° and 79° E. longitude. Lying 780 feet above sea-level, it extends 323 miles west-southwest; its breadth at the west is fifty miles, at the east from nine to four miles; the area is 8,400 square miles.

BALL, JOHN, a priest who was one of the leaders in the rebellion of Wat Tyler in England in 1381.

BALL, JOHN, a Puritan divine, of whom Baxter speaks in very high terms, was born, in 1585, at Cassington, or Chessington, near Woodstock, and died in 1640.

BALL, SIR ROBERT STAWELL, LL.D., F. R. S., astronomer, was born in Dublin, July 1, 1840, and studied at Trinity College. He was appointed Lord Rosse's astronomer at Parsonstown in 1865, professor of Applied Mathematics and Mechanics at the Royal Irish College of Science in 1873; and in 1874 professor of Astronomy at Dublin, and Astronomer Royal for Ireland.

BALLADS. The word ballad is derived from the Old French *baller*, to dance, and originally meant a song sung to the rhythmic movement of a dancing chorus. Later, the word became the technical term for a particular form of old-fashioned French poetry, remarkable for its involved and recurring rhymes.

In England the term has usually been applied to any simple tale, told in simple verse, though attempts have been made to confine it to the subject of this paper,

namely, Popular Songs. By popular songs we underderstand what the Germans call *Volks-lieder*, that is, songs composed by the people, for the people, handed down by oral tradition, and in style, taste, and even incident, common to the people in all European countries. The beauty of these purely popular ballads, their directness and freshness, has made them admired even by the artificial critics of the most artificial periods in literature. Addison devoted two articles in the *Spectator* to a critique of the same poem. Montaigne praised the *naïvété* of the village carols; and Malherbe preferred a rustic *chansonette* to all the poems of Ronsard. These, however, are rare instances of the taste for popular poetry, and though the Danish ballads were collected and printed in the middle of the 16th century, and some Scotch collections date from the beginning of the 18th, it was not till the publication of Allan Ramsay's *Evergreen* and *Tea Table Miscellany*, and of Bishop Percy's *Reliques*, that a serious effort was made to recover Scotch and English folk-songs from the recitation of the old people who still knew them by heart. At the time when Percy was editing the *Reliques*, Madame de Chénier, the mother of the celebrated French poet of that name, composed an essay on the ballads of her native land, modern Greece; and later, Herder and Grimm and Goethe, in Germany, did for the songs of their country what Scott did for those of Liddesdale and the Forest. It was fortunate, perhaps, for poetry, though unlucky for the scientific study of the ballads, that they were mainly regarded from the literary point of view. The influence of their artless melody and straightforward diction may be felt in the lyrics of Goethe and of Coleridge, of Wordsworth, of Heine, and of André Chénier. Chénier, in the most affected age even of French poetry, translated some of the Romaic ballads; one, as it chanced, being identical with that which Shakspeare borrowed from some English reciter, and put into the mouth of the mad Ophelia. The beauty of the ballads and the interest they excited led to numerous forgeries. It is probable that Hogg was as great a culprit in Scotland as Prosper Mérimée with his *Guzla*, or collection of Servian imitations, in France. Editors could not resist the temptation to interpolate, to restore, and to improve the fragments that came in their way.

The vexed and dull controversy as to the origin of Scottish folk-songs was due to ignorance of the comparative method, and of the ballad literature of Europe in general. The result of the discussion was to leave a vague impression that the native ballads were perhaps as old as the time of Dunbar, and were the production of a class of professional minstrels. These minstrels are a stumbling-block in the way of the student of the growth of ballads. The domestic annals of Scotland show that her kings used to keep court-bards, and also that strollers, *jongleurs*, as they were called, went about singing at the doors of farm-houses and in the streets of towns. Here were two sets of minstrels who had apparently left no poetry; and, on the other side, there was a number of ballads that claimed no author. It was the easiest and most satisfactory inference that the courtly minstrels made the verses, which the wandering crowders imitated or corrupted. But this theory fails to account, among other things, for the universal sameness of tone, of incident, of legend, of primitive poetical formulæ, which the Scotch ballad possesses, in common with the ballads of Greece, of France, of Provence, of Portugal, of Denmark, and of Italy. The object, therefore, of this article is to prove that what has long been acknowledged of nursery tales, of what the Germans call *Märchen*, namely, that they are the immemorial inheritance at least of all European peoples, is true also of ballads. The main incidents and plots of the fairy tales of Celts, and Germans, and Slavonic and Indian peoples, their unknown antiquity and mysterious origin, are universally recognised. No one any longer attributes them to this or that author, or to this or that date. The attempt to find date or author for a genuine popular song is as futile as a similar search in the case of a *Märchen*.

There can scarcely be a better guide in the examination of the *notes* or marks of popular poetry than the instructions which M. Ampère gave to the committee appointed in 1852–53 to search for the remains of ballads in France. M. Ampère bade the collectors look for the following characteristics:—"The use of assonance in place of rhyme, the brusque character of the recital, the textual repetition, as in Homer, of the speeches of the persons, the constant use of certain numbers,—as three and seven,—and the representation of the commonest objects of every-day life as being made of gold and silver." M. Ampère might have added that French ballads would probably employ a "bird-chorus," the use of talking-birds as messengers; that they would repeat the plots current in other countries, and display the same non-Christian idea of death and of the future world, the same ghostly superstitions and stories of metamorphosis, and the same belief in elves and fairies, as are found in the ballads of Greece, of Provence, of Brittany, Denmark, and Scotland. We shall now examine these supposed common notes of all genuine popular song, supplying a few out of the many instances of curious identity. As to brusqueness of recital, and use of assonance instead of rhyme, as well as the aid to memory given by reproducing speeches verbally, these are almost unavoidable in all simple poetry preserved by oral tradition. Then there is "the league, the league, the league, but barely three," of Scotch ballads; and the τριὰ πουλακιὰ three golden birds, which sing the prelude to Greek folk-songs, and so on. A more curious note of primitive poetry is the lavish and reckless use of gold and silver. M. Tozer, in his account of ballads in the *Highlands of Turkey*, remarks on this fact, and attributes it to Eastern influences. But the horses' shoes of silver, the knives of fine gold, the talking "birds with gold on their wings," as in Aristophanes, are common to all folk-song. Everything almost is gold in the *Kalevala*, an epic formed by putting into juxtaposition all the popular songs of Finland. Gold is used as freely in the ballads, real or spurious, which M. Verkovitch has had collected in the wilds of Mount Rhodope.

Next as to talking-birds. These are not so common as in *Märchen*, but still are very general, and cause no surprise to their human listeners. The omniscient popinjay, who "up and spoke" in the Border minstrelsy, is of the same family of birds as those that, according to Talvj, pervade Servian song; as the τριὰ πουλακιὰ which introduce the story in the Romaic ballads; as the wise birds whose speech is still understood by exceptionally gifted Zulus; as the wicked dove that whispers temptation in the sweet French folk-song; as the "bird that came out of a bush, on water for to dine," in the *Water o' Wearies Well*.

In the matter identity of plot and incident in the ballads of various lands, it is to be regretted that no such comparative tables exist as Von Hahn tried, not very exhaustively, to make of the "story-roots" of *Märchen*. A common plot is the story of the faithful leman, whose lord brings home "a braw new bride," and who recovers his affection at the eleventh hour. In Scotland this is the ballad of Lord Thomas, and Fair Annie; in Danish it is Skiaen Anna. It occurs twice in M. Fauriel's collection of Romaic songs. Again, there is the familiar ballad about a girl who pretends to be dead, that she may be borne on a bier to meet her

lover. This occurs not only in Scotland, but in the popular songs of Provence (collected by Damase Arbaud) and in those of Metz (Puymaigre), and in both countries an incongruous sequel tells how the lover tried to murder his bride, and how she was too cunning, and drowned him. Another example of a very wide-spread theme brings us to the ideas of the state of the dead revealed in folk-songs. *The Night Journey*, in M. Fauriel's Romaic collection, tells how a dead brother, wakened from his sleep of death by the longing of love, bore his living sister on his saddle-bow, in one night, from Baghdad to Constantinople. In Scotland this it the story of Proud Lady Margaret; in Germany it is the song which Burger converted into Lenore; in Denmark it is Aagé und Elsé; in Brittany the dead foster-brother carries his sister to the apple close of the Celtic paradise (*Barzaz Breiz*). Only in Brittany do the sad-hearted people think of the land of death as an island of Avalon, with the eternal sunset lingering behind the flowering apple trees, and gleaming on the fountain of forgetfulness. In Scotland the chankering worm doth chide even the souls that come from where, "beside the gate of Paradise, the birk grows fair enough." The Romaic idea of the place of the dead, the garden of Charon, whence "neither in spring or summer, nor when grapes are gleaned in autumn, can warrior or maiden escape," is likewise pre-Christian.

It would not be difficult to multiply instances of resemblance between the different folk-songs of Europe; but enough has, perhaps, been said to support the position that they are popular and primitive in the same sense as *Märchen*. They date from times, and are composed by peoples who find, in a natural improvisation, a natural utterance of modulated and rythmic speech, the appropriate relief of their emotions, in moments of high-wrought feeling or on solemn occasions. Ballads sprang from the very heart of the people, and flit from age to age, from lip to lip of shepherds, peasants, nurses, of all the class that continues nearest to the state of natural men. They make music with the plash of the fisherman's oars and the hum of the spinning-wheel, and keep time with the step of the ploughman as he drives his team. The country seems to have aided man in their making; the bird's note rings in them, the tree has lent her whispers, the stream its murmur, the village-bell its tinkling tune. The whole soul of the peasant class breathes in their burdens, as the great sea resounds in the shells cast up on the shores. Ballads are a voice from secret places, from silent peoples, and old times long dead; and as such they stir us in a strangely intimate fashion to which artistic verse can never attain.

BALLANCHE, Pierre Simon, a distinguished French philosopher of the theocratic school, was born at Lyons in 1776, and died in 1847.

It is almost impossible to give a connected view of Ballanche's fundamental ideas. He belonged to the theocratic school, who, in opposition to the rationalism of the preceeding age, emphasised the principle of authority, placing revelation above individual reason, order above freedom and progress. But Ballanche made a sincere endeavor to unite in one system what was valuable in the opposed modes of thinking. He held with the theocratists that individualism was an impracticable view; man, according to him, exists only in and through society. He agreed further with them that the origin of society was to be explained, not by human desire and efforts, but by a direct revelation from God. Lastly, with De Bonald, he reduced the problem of the origin of society to that of the origin of language, and held that language was a divine gift. But at this point he parts company with the theocratists, and in this very revelation of language finds a germ of progress. Originally, in the primitive state of man, speech and thought are identical; but gradually the two separate; language is no longer only spoken, it is also written, and finally is printed. Thus the primitive unity is broken up; the original social order which co-existed with, and was dependant on it, breaks up also. New institutions spring up, upon which thought acts, and in and through which it even draws nearer to a final unity, a rehabilitation, a *palingenesis*. The volition of primitive man was one with that of God, but it becomes broken up into separate volitions which oppose themselves to the divine will, and through the oppositions and trials of this world work onward to a second and completer harmony. The history of humanity is therefore comprised in the fall from the perfect state, and in the return, after repeated trials, to a similar condition. In the dim, shadowy records of mythical times may be traced the obscure outlines of primitive society and of its fall; and this is attempted in the *Orphée*. Actual history exhibits the conflict of two great principles, which may be said to be realised in the patricians and plebeians of Rome. Such a distinction of caste is regarded by Ballanche as the original state of historical society; and history, as a whole, he considers to have followed the same course as that taken by the Roman plebs in its gradual and successful attempts to attain equality with the patriciate. On the future events through which the human race shall achieve its destiny Ballanche gives few intelligent hints. The sudden flash which disclosed to the eyes of Hebal the whole epic of humanity cannot be reproduced in language trammelled by time and space. Scattered throughout the works of Ballanche are many valuable ideas on the connection of events which makes possible a philosophy of history; but his own theory, so far as it can be understood and judged, does not seem likely to find more favor than it has already met with.

BALLARAT, or Ballaarat, a thriving Australian town, next in importance to Melbourne, in the province of Victoria. It is situated about 58 miles northwest of Geelong. It owes its rise to the discovery of the gold fields there in June, 1851, being the oldest of the considerable gold fields of Victoria. The "Welcome Nugget," the largest ever found, was discovered in 1858 at Bakery Hill. It weighed 2,217 oz. 16 dwt. The "Lady Hotham," found near Canadian Gully, weighed 1,158 oz. 2 dwt. In 1880 about 7,000 men were employed at the gold fields, 1,000 of whom were Chinese. Population (1881) Ballarat, 22,411; Ballarat East, 14,894, total, 37,260. The combined cities contain 56 churches, 477 hotels, 10,000 dwellings, 11 banks, 8 iron foundries, 13 breweries and distilleries, 3 flour-mills, a free public library, a mechanics' institute, a hospital, a "benevolent institution," a theatre and a public garden, while about sixty miles of water-mains and fifty of gas-mains have been laid down.

BALLĀRĪ [Bellary], a district in the Madras Presidency, is bounded on the N. by the Nizám's territory, from which it is separated by the Tungbhadrá river; on the E. by the districts of Kadapa and Karnul; on the S. by the Mysore country; and on the W. by Mysore, and the Bombay district of Dharwar. Its extreme length from north to south is 170 miles, and its breadth from east to west about 120 miles. The area of the district, including 145 square miles of the Sandúr State, is estimated at about 11,496 square miles; according to other returns the area is 10,857 square miles (excluding Sandúr), of which 1004 consist of barren soil, sites of villages, beds of water-courses, &c., and 9852 of lands either actually cultivated or capable of cultivation. The census of 1885 returned the population at 1,752,069, of whom 94 per cent were Hindus. It is estimated that

941,712, or 71.8 per cent. of the population, live by agriculture. The general aspect of the district is that of an extensive plateau between the Eastern and Western Ghâts, of an average height of from 800 to 1,000 feet above the sea-level. The most elevated tracts are on the west, where the surface rises toward the culminating range of hills, and on the south, where it rises to the elevated table-land of Mysore. Toward the center the surface of the plain presents a mountainous aspect, being almost treeless.

Little is known of the early history of the district. It appears to have been a portion of the ancient kingdom of Vijayanagaram, and on the overthrow of that state in 1564 A.D. by the Mahometans, the tract now forming the district of Ballári was split up into a number of military holdings, held by chiefs called Poligárs. In 1635 the Carnatic was annexed to the Bijápur dominions, from which again it was wrested in 1680 by Sivaji, the founder of the Marhattá power. It was then included in the dominions of Nizám-ul-mulk, the nominal viceroy of the Great Mughul in the Dakhin, from whom again it was subsequently conquered by Haidar Ali of Mysore. At the close of the war with Tipu Sultán, 1792, the territories which now form the Ballári district fell to the share of the Nizám of Haidarábád, by whom it was ceded to the British in 1800, in return for a force of English troops to be stationed at his capital. In 1818 the district of Ballári was constituted as it at present remains.

BALLARI, the principal town of the above district, is the chief seat of the judicial and revenue establishments, and the headquarters of the military force in the ceded districts. Population, 60,000.

BALLAST is a heavy substance employed to give a ship sufficient immersion in the water to insure her safe sailing with spread canvas, when her cargo and equipment are too light. The amount of ballast required by a ship depends not only on her size and cargo, but also on her build; some forms of construction requiring more ballast than others. The substances used as ballast are various—chiefly iron, stone, gravel, sand and water. In ships of any considerable size, or engaged in any service of importance, iron has long superseded stone, gravel, or other variety of dry ballast, but within recent years the adoption of water ballast has become very general in almost all classes of vessels. The practice of fitting vessels with double bottoms, divided into cellular spaces by continuous longitudinal keelsons and transverse bracket floors—of which the *Great Eastern* is an early and notable example—had been instituted by Mr. Scott Russell between 1850-58. The object then in view, however, was that of enhanced structural strength, but about 1874-78 several vessels were built on the north-east coast of England on the cellular-bottom system, the end in view being chiefly the carriage of water-ballast.

BALLATER, a village of Aberdeenshire, Scotland, on the river Dee, forty-two miles west from Aberdeen. In its vicinity are the medicinal wells of Pannanich, Balmoral Castle (a summer residence of Queen Victoria) and Ballatrich Farm, where Byron spent a part of his boyhood. Ballatrich is a short distance from "Lachin-y-Gair" (Lochnagar), one of the loftiest of the Grampian range, and the subject of one of Byron's most beautiful poems.

BALLENSTEDT, a city in the duchy of Anhalt-Bernburg. It is situated on the Getel in the Harz Forest, in a most picturesque district, and consists of an old and a new town. Population, 5,000.

BALLET is a word, the signification of which depends upon the century in which we find it employed. Originally derived from the Greek "to dance," it has passed through the mediæval Latin *ballare* (with *ballator* as synonymous with *saltator*) to the Italian *ballare* and *ballata*, to the French *ballet*, to the old English word *ballette*, and to *ballad*. In old French, according to Rousseau, *ballet* signifies "to dance, to sing, to rejoice;" and thus it incorporates three distinct modern words, "ballet, ball, and ballad." Through the gradual changes in the amusements of different ages, the meaning of the first two words has at length become limited to dancing, and the third is now confined to singing. But, although ballads are no longer the vocal accompaniments to dances round the maypole, our old ballads are still sung to dance tunes. The present acceptation of the word *ballet* is—a theatrical representation in which a story is told only by gesture, accompanied by music which should be characterised by stronger emphasis than would be employed with the voice. The dancing should be connected with the story, but is more commonly incidental. The French word was found to be so comprehensive as to require further definition, and thus the above-described would be distinguished as the *ballet d'action* or pantomime ballet, while a single scene, such as that of a village festival with its dances, would now be termed a *divertissement*.

The *ballet d'action*, to which the changed meaning of the word is to be ascribed, and therewith the introduction of modern ballet, has been generally attributed to the 16th century. Novelty of entertainment was then sought for in the splendid courts of Italy, in order to celebrate events which were thought great in their time, such as the marriages of princes, or the triumphs of their arms. Invention was on the rack for novelty, and the skill of the machinist was taxed to the utmost. It has been supposed that the art of the old Roman *pantomimi* was then revived, to add to the attractions of court-dances. Under the Roman empire the *pantomimi* had represented either a mythological story, or perhaps a scene from a Greek tragedy, by mute gestures, while a chorus, placed in the background, sang *cantica* to narrate the fable, or to describe the action of the scene. The question is whether mute pantomimic action, which is the essence of modern ballet, was carried through those court entertainments, in which kings, queens, princes, and princesses took parts with the courtiers; or whether it is of later growth, and derived from professional dancers upon the stage. The former is the general opinion, but an analysis of the only ballet which is known to have been printed in a complete form during the 16th century, would lead to the inference that the court entertainments of Italy and France were masques, or masks, which included declamation and song, like those of Ben Jonson with Inigo Jones for the court of James I.

The introduction of the Italian style of ballet into France was on the occasion of the marriage of the Duc de Joyeuse with Mdlle. de Vaudemont, sister to the queen. This was in 1581; and the ballet was printed in 1582, in a small folio of eighty-two leaves, with music, dialogue, engravings of the scene and of the fancy dresses, and full details of the plot. One lady of the court sang a song, two others a duet, and, again, others a chorus. Jupiter and Mercury each sang a song, but Circe and the rest spoke poetry. The king's musicians, as tritons, were the mainstays of the music; the ladies and gentlemen of the court appeared in splendid fancy dresses, and danced the entrées. The inventor of the ballet was Baltazarini Belgioioso, who had assumed the name of Baltasar de Beaujoyeux upon his appointment as first musician to Catherine de Medicis, queen dowager of France. The disuse of dialogue and of vocal music in ballet seems to have been arrived at only by degrees. At length the opinion gained ground that, in stage representations, the ac-

tions, feelings, and passions could be more faithfully, gracefully, and intelligibly expressed to the eye by pantomimic action, than it would be possible to do to the ear. The art of dramatic expression then became a greater object of study; and, perhaps, from about the middle of the last century, or in the time of Noverre, the spectators have been prepared only by a short printed summary of the story which was to be represented.

BALLINA, a seaport and market-town of Ireland, county of Mayo, 18 miles N.N.E. of Castlebar, situated on the River Moy, which is here crossed by two bridges. Population in 1871, 5551.

BALLINASLOE, a town of Ireland, province of Connaught, 91 miles W.S.W. of Dublin. The River Suck, an affluent of the Shannon, divides it into two parts; the western being in the county of Galway, the eastern in the county of Roscommon.

BALLOON. See AERONAUTICS.

BALLOT, or secret voting, has been employed in political, legislative, and judicial assemblies, and also in the proceedings of private clubs and corporations. At Athens, the dicasts, in giving their verdict, generally used balls of stone *(psephi)* or of metal *(sponduli)*. Those pierced in the centre, or black in color, signified condemnation; those unpierced, or white, signified acquittal. The boxes were variously arranged; but generally a brass box received both classes of votes, and a wooden box received the unused balls. In the assembly, cases of *privilegia*, such as ostracism, the naturalisation of foreigners, or the release of state-debtors, were decided by secret voting. The petalism, or voting by words on olive-leaves, practiced at Syracuse, may also be mentioned. At Rome the ballot was introduced to the comitia by the *Leges Tabellariae*, of which the *Lex Gabiana* (139 B.C.) relates to the election of magistrates, the *Lex Cassia* (137 B.C.) to *judicia populi*, and the *Lex Papiria* (131 B.C.) to the enactment and repeal of laws. The wooden *tabellae*, placed in the *cista*, or wicker box, were marked U. R. *(uti rogas)* and A. *(antiquo)* in the case of a proposed law; L. *(libero)* and D. *(damno)* in the case of a public trial; in the case of an election, *puncta* were made opposite the names or initials of the candidates. *Tabellae* were also used by the Roman judices, who expressed their verdict or judgment by the letters A. *(absolvo)*, C. *(condemno)*, and N. L. *(non liquet)*.

In Great Britain the ballot was suggested for use in Parliament by a political tract of the time of Charles II. It was actually used by the Scots Parliament of 1662 in proceeding on the "Billeting Act," a measure proposed by Middleton to secure the ostracism of Lauderdale and other political opponents who were by secret vote declared incapable of public office. The plan followed was this: each member of Parliament wrote, in a disguised hand, on a piece of paper, the names of twelve suspected persons; the billets were put in a bag held by the registrar; the bag was then sealed, and was afterwards opened and its contents ascertained in the Exchequer Chamber, where the billets were immediately burned, and the names of the ostracised concealed on oath. The Billeting Act was repudiated by the king, and the ballot was not again heard of till 1705, when Fletcher of Saltoun, in his measure for a provisional government of Scotland by annual Parliaments in the event of Queen Anne's death, proposed secret voting to protect members from court influence. The gradual emancipation of the British Parliament from the power of the Crown, and the adoption of a strictly representative system of election, have not only destroyed whatever reason may once have existed for the ballot in deliberative voting, but have rendered it essential that such voting should be open. It was in the agitations for parliamentary reform at the beginning of the 19th century that the demand for the ballot in parliamentary elections was first seriously made. The Benthamites advocated the system in 1817. At the Peterloo Massacre (1819) several banners were inscribed with the ballot. O'Connell introduced a bill on the subject in 1830; and the original draft of Lord John Russell's Reform Bill, probably on the suggestion of Lords Durham and Duncannon, provided for its introduction. Later on Mr. Grote became its chief supporter in the House of Commons; and from 1833 to 1839, in spite of the ridicule cast by Sydney Smith on the "mouse-trap," and on Mr. Grote's "dagger-box, in which you stab the card of your favorite candidate with a dagger," the minority for the ballot increased from 106 to 217. In 1838 the ballot was the fourth point of the People's Charter. In the same year the abolition of the land qualification introduced rich commercial candidates to the constituencies. Lord Melbourne's cabinet declared the question open. The cause, upheld by Macaulay, Ward, Hume (in his resolutions, 1848), and Berkeley, was strengthened by the Report of Lord Hartington's Select Committee (15th March 1870), to the effect that corruption, treating, and intimidation by priests and landlords took place to a large extent at both parliamentary and municipal elections in England and Ireland; and that the ballot, if adopted, would probably not only promote tranquillity at elections, but protect voters from undue influence, and introduce greater freedom and purity in voting, provided secrecy was made inviolable, except in cases where a voter was found guilty of bribery, or where an invalid vote had been given. At Manchester and Stafford in 1869, test ballots had taken place on the Australian principle as practised in Victoria — the voting cards containing the names of all the candidates, printed in different colors (for the benefit of illiterate voters), and the voter being directed to score out the names of those he did not support, and then to place the card (covered by an official envelope) in the box. It was found at Manchester that the voting was considerably more rapid, and therefore less expensive, than under the old system; that only 80 cards out of 11,475 were rejected as informal; and that, the representatives of candidates being present to check false statements of identity, and the public outside being debarred from receiving information what voters had voted, the ballot rather decreased the risk of personation. At Manchester the cards were not numbered consecutively, as is done in Victoria, so that (assuming the officials to be free from corruption) no scrutiny could have detected by whom particular votes were given. At Stafford the returning officer stamped each card before giving it to the voter, the die of the stamp having been finished only on the morning of the election. By this means the possibility was excluded of what was known in the colonies as "the Tasmanian Dodge," by which a corrupt voter gave to the returning officer, or placed in the box, a blank non-official ticket, and carried out from the booth his official card, which a corrupt agent then marked for his candidate, and gave, so marked, to corrupt voter No. 2 (before he entered the booth), on condition that he also would bring out his official card, and so on *ad libitum;* the agent thus obtaining security for his bribe, unless the corrupt voter chose to disfranchise himself by making further marks on the card.

At the close of 1870 the ballot was employed in the election of members for the London School Board, under the Education Act of that year.

In 1872 Mr. Foster's Ballot Act (35 and 36 Vict. c. 33) introduced the ballot in all parliamentary and municipal elections, except parliamentary elections for uni-

versities; and the code of procedure prescribed by the Act was adopted by the Scotch Education Board in the first School Board election (1873), under "The Education (Scotland) Act, 1872."

The ballot is used very largely in the British Colonies, and on the Continent. In South Australia, under the Constitution Act of 1856 and the Electorial Act of 1858, both the Legislative Council and the House of Assembly are elected by manhood suffrage under the ballot, the returning officer *putting his initials* on the voting card, which the voter is directed, under pain of nullity, to fold so that the officer may not see the vote which is indicated by a cross. The cards are destroyed when the poll is announced; and thus personation, though proved against certain voters for the purpose of punishing them, would not void an election, for there can be no scrutiny before the Court of Disputed Returns. Canvassing has almost disappeared. In Victoria, under the Electoral Act of 1865, both the Legislative Council and the Legislative Assembly are elected practically by manhood suffrage under the ballot, which was introduced in 1856. The officer adds to his initials a number corresponding to the voter's number on the register, and the cards are preserved till after the time for petitioning the Committee of Elections and Qualifications has expired, so that a scrutiny may take place of challenged votes. The important Road Boards under the Local Government Consolidation Act of 1869 are also elected by ballot. In Tasmania the chief peculiarity is that (as in South Australia) the card is not put directly by the voter into the box, but handed to the officer who puts it there (this being thought a security against double voting or voting with a non-official card, and also against the voter carrying away his card); here also the cards are destroyed immediately, while in New South Wales, where, as in Victoria, the voting is by scoring out and not by a cross, the cards are kept for five years. The vigorous municipal boards of these colonies are also elected by ballot, which has diminished expense and undue influence very greatly, but has not produced complete secrecy of voting.

In France, where from 1840 to 1845 the ballot, or *scrutin*, had been used for deliberative voting in the Chamber of Deputies, its use in elections to the Corps Législatif was carefully regulated at the beginning of the Second Empire by the Organic Decree of 2d February 1852. Under this law the voting was superintended by a bureau consisting of the deputy returning officer (called president of the section), four unpaid assessors selected from the constituency, and a secretary. Each voter presents a polling card, with his designation, date of birth, and *signature* (to secure identity), which he has previously got at the *Mairie*. This the president mutilates, and the vote is then recorded by a "bulletin," which is not official, but is generally printed with a candidate's name, and given to the voter by an agent outside, the only conditions being that the bulletin shall be "sur papier blanc, sans signes extérieurs, et préparé en dehors de l'assemblée." The total number of votes given (there being only one member in each electoral district) is checked by reference to "la feuille *d'appel* et inscription des votants," the law still supposing that each voter is publicly called on to vote. If the voter, when challenged, cannot sign his polling card, he may call a witness to sign for him. The following classes of bulletins are rejected: —"illisibles, blancs, ne contenant pas une désignation suffisante; sur lesquels les votants se sont fait connaître; contenant le nom d'une personne n'ayant pas prêté le serment prescrit" (*i.e.*, of a person not nominated). Only the votes pronounced bad by the bureau in presence of representative scrutineers are preserved, in case these should be called for during the "Session pour vérification des Pouvoirs." Practically the French ballot did not afford secrecy, for you might observe what bulletin the voter took from the agent, and follow him up the *queue* into the polling-place; but the determined voter might conceal his vote even from the undue influence of Government by scratching out the printed matter and writing his vote. This was always a good vote, and scrutiny of good votes was impossible. The ballot is still used in the elections to the National Assembly, but in the Assembly itself only in special cases, as, *e.g.*, in the election of a "rapporteur." Under the law of 10th August 1871, the conseils généraux (departmental councils) are elected by ballot. In Piedmont the ballot formed part of the free constitutional government introduced by Charles Albert in March 1848; it was extended to Italy in 1861. Voting for the Italian Chamber of Deputies takes place under the law of 20th November 1859, and in public halls (not booths), to which admission is gained by showing a certificate of inscription, issued by the mayor to each qualified voter. A stamped blue official paper, with a memorandum of the law printed on the back (*bolletino spiegato*), is then issued to the elector; on this he writes the name of a candidate (there being equal electoral colleges), or, in certain exceptional cases, gets a confidential friend to do so, and hands the paper folded up to the president of the bureau, who puts it in the box (*urna*), and who afterwards presides at the public "squittinio dei suffragi." No scrutiny is possible; canvassing and bribery are rare; and Cavour thought the ballot had quite nullified the clerical power, at least in Piedmont. Greece is the only European country in which the ball ballot is used. The voting takes place in the churches, each candidate has a box, on which is his name. Each box has two compartments —"Yes" and "No"—into one of which the voter drops his ball.

In the United States the ballot system has frequently been changed to meet the exigencies of the case. In a country where the ballot *is* the government, where the suffrages of the citizen cannot be dispensed with without dispensing with the organic law, the voter wishes to precisely know, before depositing his ballot, what for and for whom he has voted. To cover this point, and at the same time to absolutely secure an uninfluenced and secret ballot, what is known as the Australian, or, commonly, the "Kangaroo," ballot was invented. The origin of it seems to have been the locality indicated by the name. So great has been the desire to influence voters, to know beforehand that a given scheme would be decided upon, or a certain man elected, that the usual manipulators of elections, not including the average citizen, would have prevented, and would now if possible prevent, the adoption of any plan to frustrate that which in innumerable instances, was a means of livelihood.

But State Legislatures may not so easily withstand a public sentiment never by any means generally controlled by the professional small politician, and the sentiment in favor of the new system grew as it came to be understood until at this writing the States are adopting it one after the other, with modifications in details it is true, but leaving its essential features, which are well understood, unchanged.

To make the features and advantages of a balloting system like the Australian clear, it is necessary to understand something of the evils designed to be prevented. A custom, concealed, but well known and prevalent, was to offer the unscrupulous voter such inducements as would control his ballot. This can still be done. Men can still be induced to cast a vote for certain considerations. But it is necessary for the vote-purchaser to know that the agreement for which

the inducement or reward has been given, generally in advance, should be carried out. To this end often the ballot was prepared, the voter was accompanied to the polling-place, and it was seen that the folded ballot, and no other, was duly deposited. When this essential step in the proceedings is prevented; when it cannot be known whether the voter has actually deposited the ballot agreed upon or not, the manipulation is practically impossible among those who deal in the unreliability of a class, and with whom want of conviction or purpose, mendacity, and poverty are the recognized stock in trade.

To prevent these under-mining influences the Australian Ballot was invented. As stated, its details vary by States, but its general features remain so far as yet adopted, often with safeguards not included in the original, and it may be generally described. The ballot to be used by every voter is in custody of one of the judges of election at the polling place, and is not procurable outside, not to be found in the hands of "peddlers," and each one must be accounted for, used and unused, when the election is over.

There is but one ticket, which is printed under supervision of law, and furnished in form by the State. No other must exist under penalty. This authorized printed ticket contains in distinct order and arrangement, all names or subjects or questions to be voted for, with directions printed upon the ticket, verbally and publicly explained by the proper person when explanations are asked for.

Registration is required as a preliminary step. When the intending voter appears he must give his name and residence verbally, and his registration is then verified before he receives his ticket. Only one is given him, and with it he retires *alone* to a booth to prepare it in accordance with his intentions.

The booth is a small inclosure. The specific details of it are non-essential, so that it be private, inclosed, and contain only one voter at a time. There are in this booth to be found a writing-board or desk, a pen, ink and blotting-pad, and nothing else. The printed slip, or ticket, which the voter carries with him to this booth, is usually printed so that there is a small oval, or circle, blank in the center, at the head of each party-list. If a simple X be made within this little circle, that list of names is counted as having been voted for. If, however, the prescribed sign is not made at the head of the list, any name printed there may be marked as described, in which case that name is voted for. If the sign be made at the head of a list, and then the pen be run through a name, or names, in the list below, the list is voted for *with the exception of the names so marked*. As this, if so left, would deprive the voter of his suffrage in regard to other candidates for the same offices whom he may prefer, he is authorized to mark with the sign of approval the name of any other candidate on the list *corresponding to the ones he has marked out*.

It will be seen that thus any citizen of sufficient intelligence to read, may in a few moments cut or "split" his ticket to suit himself. He must, as he should, exercise care. His rule is that he cannot vote for two candidates for the same place, and must not, unless he desires that his vote shall be thrown out, commit this error in the marking of his ballot.

When, through mistake, the voter has spoiled his ticket, he must not attempt to correct. But he may leave his booth and return with the ballot given him to the person from whom he had it, and exchange it for a new one to be again carried to a booth and correctly made. If, however, he renders his ballot unintelligible or illegal without knowing he has done so, and so places it in the ballot-box, it must necessarily be thrown out at the final count.

These, in general terms, are the essential features of the Australian ballot, and so long as they are adhered to in statutes now in force or yet to be passed, all old and accustomed forms of fraud and pre-manipulation would seem to be almost impossible.

BALLSTON SPA, the capital of Saratoga county, N. Y., is situated six miles southwest of Saratoga Springs and thirty-two miles from Albany. It contains two national banks, two newspaper offices, and manufactures of paper, cotton and woolen goods, sash, doors and blinds, axes and scythes. The town has several mineral springs, much patronized by visitors in the season, when the population increases to over 5,000.

BALLYCASTLE, a seaport town of Ireland, county Antrim, situated on a bay opposite Rathlin island. The town is well built, consisting of two parts, about a quarter of a mile asunder, and connected by a fine avenue. Towards the close of the 18th century, one of the Boyd family devoted himself to the extension and improvement of the town, establishing manufactures, endowing charities, and building churches, and succeeded in producing a temporary vitality. Upwards of £150,000 is said to have been expended upon the pier and harbor; but the violence of the sea overthrew the former, and the latter has been filled with sand.

BALLYSHANNON, a seaport and market-town of Ireland, county of Donegal, situated at the mouth of the Erne. The river is here crossed by a bridge of fourteen arches, which connects the town with the suburb of Purt. Below the bridge the river forms a beautiful cascade, 150 yards wide, with a fall at low water of 16 feet. The harbor is a small creek of Donegal Bay, about 600 yards long and 350 yards broad, and is only accessible to small vessels. Population, 3,000.

BALMEZ, JAIME LUCIEN, a Spanish ecclesiastic, eminent as a political writer and a philosopher, was born at Vich in Catalonia, on the 28th August 1810, and died there on the 9th July 1848.

BALMORAL CASTLE, a residence of her Majesty Queen Victoria, on the right bank of the River Dee, about 9 miles above Ballater and 50 miles from Aberdeen. The property, which now consists of upward of 10,000 acres, besides a large tract of hill ground, belonged in its original extent to the Farquharsons of Inverey, by whom it was sold to the Earl of Fife. In 1848 it was leased by the late Prince Consort, and in 1852 was finally purchased for a sum of £32,000. The castle, which was erected at Prince Albert's private expense, is of the Scotch baronial style of architecture.

BALNAVES, HENRY, a Scottish Protestant, born at Kirkcaldy in Fife, in the reign of James V., and educated at the university of St. Andrews. There is some doubt both as to the exact date of his birth, which has been fixed as 1520, and as to the rank in society to which he belonged. He completed his studies on the Continent, and, returning to Scotland, entered the family of the Earl of Arran, who at that time was regent; but in the year 1542 the earl dismissed him for embracing the Protestant religion. In 1546 he was implicated in the murder of Cardinal Beaton, at least he is known to have taken refuge with the conspirators in the castle of St. Andrews; and when they were at last obliged to surrender to the French, he was sent with the rest of the garrison as a prisoner to France. During his confinement at Rouen he wrote the work entitled *Confession of Faith*, to which Knox added marginal notes and a preface; but it was not published till 1584, five years after his death. He returned to Scotland about the year 1559, where he died (in the city of Edinburgh) in 1579.

BALSAM, an oleo-resin or natural compound of resin and essential oil, in such proportions that the substance is in a viscous or semi-fluid condition. The gradations from a solid resin to a limpid essential oil are insensible, and most resins have a balsamic consistency on their exudation, only hardening by exposure to air. It has been proposed to limit the name balsam to such substances as contain cinnamic or an analogous acid in addition to the volatile oil and resin which turpentines contain alone; but this distinction has not been carried out.

The fragrant balsams which contain cinnamic or benzoic acid may, however, be regarded as a distinct class, allied to each other by their composition, properties, and uses. Those of this class found in commerce are the balsam of Peru, balsam of Tolu, liquid storax, and liquidambar. *Balsam of Peru* is the produce of a lofty leguminous tree, *Myrospermum peruiferum*, growing within a limited area in San Salvador, Central America, but now introduced into Ceylon. It is a thick, viscid oleo-resin of a deep brown or black color and a fragrant balsamic odor. It has been analysed by Kachler, who thus states its percentage composition,—cinnamic acid 46, resin 32, benzylic alcohol 20. It is used in perfumery, and in medicine as a stimulant application to indolent sores, as well as internally for asthma and pectoral complaints. *Balsam of Tolu* is likewise produced from a species of *Myrospermum*, *M. toluiferum*. It is of a brown color, thicker than Peru balsam, and attains a considerable degree of solidity on keeping. It also is a product of equatorial America, but is found over a much wider area than is the balsam of Peru. Tolu balsam consists of a combination of inodorous resin with cinnamic acid, no benzoic acid being present in it. It is used in perfumery and as a constituent in cough syrups and lozenges. *Liquid storax* is a balsam yielded by *Liquidambar orientalis*, a native of Asia Minor. It is a soft resinous substance, with a pleasing balsamic odor, especially after it has been kept for some time. It contains a principle — styrol or cinnamene — to which it owes its peculiar odor, besides cinnamic acid, stryacin, and a resin. Liquid storax is used in medicine as an external application in skin diseases, and internally as an expectorant. An analogous substance is derived from *Liquidambar Altingia* in Java., *Liquidambar balsam* is derived from *Liquidambar styraciflua*, a tree found in the United States and Mexico. It contains cinnamic acid, but is destitute of benzoic acid.

Of balsams entirely destitute of cinnamic and benzoic constituents the following are found in commerce:— *Mecca Balsam* or *Balm of Gilead*, yielded by the *Balsamodendron Berryi* (*B. gileadense* of De Candolle), a tree growing in Arabia and Abyssinia, is supposed to be the balm of Scripture and the *βάλσαμον* of Theophrastus. When fresh it is a viscid fluid, with a penetrating odor, but it solidifies with age. It was regarded with the utmost esteem among the nations of antiquity, and to the present day it is peculiarly prized among the people of the East. *Balsam of Copaiba* or *Capivi* is a fluid oleo-resin of a pale brown or straw color, produced from several trees of the genus *Copaifera*, growing in tropical America. It possesses a peculiar odor and a nauseous persistent tarry taste.

Canada Balsam.—The oleo-resins obtained from coniferous trees are usually termed turpentines, but that yielded by *Abies balsamea* is known in commerce as Balsam of Canada. It is a very transparent substance, somewhat fluid when first run, but thickening considerably with age, possessed of a delicate yellow color, and a mild terebinthous odor. According to Flückiger and Hanbury it contains 24 per cent. of essential oil, 60 per cent. of resin soluble in alcohol, and 16 per cent. of resin soluble only in ether. It has been used for the same purposes as copaiba, but its chief uses are for mounting preparations for the microscope and as a varnish.

BALTA, the chief town of a circle of the same name in the Russian government of Podolia. Population, 25,000.

BALTARD, Louis Pierre, a distinguished French architect and engraver, was born at Paris in 1765, and died in 1846.

BALTIC PROVINCES (in Russia). This term, in a wider sense, comprehends the five Russian governments bordering on the Baltic, viz., Courland, Livonia, Esthonia, Petersburg, and Finland; in a restricted sense it often designates the first three. The Baltic provinces once belonged to Sweden, except Courland, which was a dependency of Poland. They came into the possession of Russia partly in the beginning of the eighteenth century, through the conquests of Peter the Great, partly under Alexander in 1809. The three Baltic governments strictly so called have an area of 36,500 square miles, and (1889) a population estimated at 2,225,000.

BALTIC SEA. The name by which this inland sea is commonly designated is first found in the 11th century, in the work of Adam of Bremen, entitled *Cherographia Scandinaviæ*. The derivation of the word is uncertain. It seems probable that, whatever may be the etymology of the name *Baltic*, that of the Great and Little *Belts* is the same. The Swedes, Danes, and Germans call it the *Ossee* or East Sea.

The Baltic is enclosed by Sweden, Russia, the German empire, and Denmark; and it communicates with the North Sea, by the winding channel which lies between the southern part of the Scandinavian peninsula and the northern peninsula of Schleswig and Jutland. The first part of this channel is in great measure blocked by the islands of Zealand and Fünen, so as to form the three narrow passages which are known as the Sound (between Sweden and Zealand), the Great Belt (between Zealand and Fünen), and the Little Belt (between Fünen and Jutland). Each of these forms a distinct communication between the Baltic and the Cattegat, which is the open portion of the channel lying between the coast of Sweden and the eastern side of Jutland; while the Cattegat opens freely into the Skager Rack, which is the continuation of same open channel, between the southern end of Norway and the north-west coast of Jutland, into the North Sea.

The length of the Baltic Sea, from Swinemünde in the S. to Tornea in the N., is nearly 900 miles; and its greatest width, between Karlscrona and Memel, exceeds 200 miles. Its whole area, including the Gulfs of Bothnia and Finland, is about 160,000 geographical square miles. It runs first in an easterly direction as far as Memel, a distance of 300 miles, and then northwards a distance of 350 miles, at which point it separates into two great gulfs. One of these, the Gulf of Finland, runs nearly due E.; the other, the Gulf of Bothnia, almost N. The Gulf of Bothnia is 400 miles in length, with an extreme breadth of 120 miles, but where narrowest it does not exceed 40 miles. The archipelago of Aland lies at its entrance. The Gulf of Finland is 280 miles in length, with a mean breadth of 60 or 70 miles.

The depth of the Baltic rarely exceeds 100 fathoms — being greatest between the island of Bornholm and the coast of Sweden, where it reaches 115 fathoms, and least in the neighborhood of the mouths of large rivers, which bring down a great quantity of earthy matter, especially in the spring, so that in many parts the bot-

tom is being so rapidly raised by its deposit that the mouths of rivers formerly navigable are now inaccessible. This is especially the case in the northern part of the Gulf of Bothnia, above Quarken, where several tracts are now dry land which were once water; and also in the neighborhood of Tornea, where meadows now take the place of waters which were traversed in boats by the French Academicians, when they were measuring an arc of the meridian. Along the southern coast the shallowness of the harbors is a great obstacle to navigation, especially since they are closed by ice for nearly one-third of the year. On the western side it is not more than 15 fathoms deep; and, in general, it is only from 8 to 10 fathoms. On the S. it nowhere exceeds 50 fathoms. The Gulf of Finland suddenly shallows from 50 or 60 fathoms to 5, or even less. The average depth of the Gulf of Bothnia is not greater than that of the rest of the sea. Numerous rocky islands and reefs, many of them level with the water, render the navigation of this sea extremely dangerous.

The shore of the Baltic is generally low. Along the southern coast it is for the most part sandy,—with sand-banks outside, and sand-hills and plains inland. Where streams come down, there are often fresh-water lakes termed *haffs*, which are separated from the sea by narrow spits called *nehrungs*. Two of these *haffs* are of great extent; one of them, termed the Frische Haff, lies between Danzig and Königsberg, which last town is situated on the part of it most remote from the sea; the other, termed the Kurische Haff, lies between Königsberg and Memel, the latter town being situated on the channel connecting the haff with the sea. Near the entrance to the Gulf of Finland the coast becomes rocky, and continues to be so for the most part around the gulfs both of Finland and Bothnia, except towards the head of each; the rocks, however, are never high. The shores of the southern part of the Swedish peninsula are mostly high, but not rocky; at Stockholm, however, there is an archipelago of rocky islands, on some of which the town is partly built.

Drainage Area.— The Baltic may be considered as the estuary of a great number of rivers, none of them individually of great size, but collectively draining a very large area, which is estimated at about 717,000 square miles, or nearly one-fifth of the entire area of Europe. This great drainage area is remarkable for the small proportion of its boundary that is formed by mountains or high table-lands,—its greater part consisting of land of no considerable elevation, which slopes down very gradually to its coast-line, and of which a large proportion is covered by lakes. This is especially the character of the drainage area of the Neva, whose waters are immediately derived from the large shallow Lake Ladoga, which receives the contributions of numerous other lakes, Onega being the largest, though Lake Saima in Finland, with its irregular prolongations, is scarcely less extensive. The entire surface drained by the Neva is estimated at about 100,000 square miles, or nearly twenty times that of the drainage area of the Thames. Through Lake Onega, the Neva is connected with the Dwina and the Volga by canals, through which small vessels can pass from the Baltic into either the White Sea or the Caspian. The Duna or South Dwina, which discharges itself into the Gulf of Riga, is another important river, draining an area of about 35,000 miles in West Russia, and having a length of 520 miles, of which 405 miles are navigable. The drainage area of the Niemen, which enters the Baltic at Memel, is conterminous with that of the Duna, and is of about the same extent; the river is navigable for more than 400 miles from its outlet, and communicates with the Dnieper by a canal through which vessels can pass from the Baltic to the Black Sea. The Vistula, which receives the waters of the whole area of Russian and Prussian Poland, flowing past Warsaw into the Baltic at Dantzig, is a very large and important river, having a length of 520 miles, of which 430 are navigable, and a drainage area of 72,000 square miles. And the Oder, rising in the hill districts of Silesia, drains the extensive level areas of Brandenberg and Pomerania, and discharges into an estuary, that may be said to begin from Stettin, the water drawn from an area of 45,000 square miles. Numerous rivers discharge themselves into the Gulf of Bothnia, bringing down water from the mountain ranges of Sweden and Norway; but their course is comparatively short and direct, with few tributaries, so that, individually, they do not attain any great size. The drainage of the more level southern portion of Sweden is for the most part collected by the great lakes of Wener, Wetter, and Mälar, of which the first pours its waters into the North Sea, and the others into the Baltic. By means of a canal joining Lakes Wener and Wetter vessels can pass directly from the Cattegat into the Baltic.

Climate.— It is not only, however, the extent of its drainage area, but the large proportion borne by the rain and snow which fall upon that area to the amount dissipated by evaporation from its surface, that goes to swell the aggregate of fresh water poured into the basin of the Baltic; for there is probably no inhabited region of the whole globe over which so large a quantity of snow falls, in proportion to its area, as it does in the countries round this basin. They receive, direct from the Atlantic, a vast amount of moisture brought by its west and south-west winds; and even the winds which have already passed over the low plains of Jutland and Northern Germany will have parted with little of their moisture before reaching the Baltic provinces of Russia. When these vapor-laden west and south-west winds meet the cold dry east and north-east winds of Siberia, their moisture is precipitated, in summer as rain, and in winter as snow; and owing to the prevalence of a low atmospheric temperature through a large part of the year, the proportion lost by evaporation is extremely small as compared with what passes off from other inland seas. The large excess of the amount of fresh water discharged into the basin, over that which passes off by evaporation from its surface, is indicated by its low salinity, which, however, varies considerably in its different parts and at different seasons of the year. The temperature of the Baltic is remarkable for its *range*, which is rather that of a terrestrial than of a marine area — this being doubtless owing in great degree to the fact that its shallowness and the low salinity of its water allow a large part of its surface to be frozen during the winter. Nearly the whole of the Gulf of Bothnia, with the land enclosing it on both sides, lies between the January isotherms of 10° and 20° — the former crossing it near its head, and the latter near its junction with the Baltic proper; and the whole of the Baltic proper, with the land enclosing it on the east, south, and west, lies between the January isotherms of 20° and 30°. On the other hand, the July isotherm of 60°, which crosses England near the parallel of 54° passes across the Gulf of Bothnia near the Walgrund Islands, almost 9° further north; and the whole of the Baltic proper, with the Gulf of Finland and the southern part of the Gulf of Bothnia, lies between the July isotherms of 60° and 65°. Thus the range between the *mean summer* and *mean winter* temperatures, which is only about 20° in the British Islands, is about 40° over the Baltic area. The *mean annual* temperature of the Gulf of Bothnia ranges between 30° at its northern extremity and 40° at its southern, while that of the Baltic

ranges from 40° at its northern boundary to about 46° at its southern.

Formation and Transportation of Ice.— The greater part of the Gulfs of Bothnia and Finland is usually frozen over during the winter, the formation of ice beginning at the head and extending downwards. Masses of ice, conveyed by the currents into the Baltic proper, freeze together as the winter advances, and form vast fields, generally extending on the east side as far south as the islands of Dagö and Oesel, and on the west to the south of Stockholm. It happens sometimes, though rarely, that large portions of the Baltic proper are continuously frozen over; but navigation is usually interrupted by the blocking up of its bays and harbors with ice, from the latter part of December to the beginning of April. The freezing of the Gulfs of Bothnia and Finland begins earlier and ends later.

The curious phenomenon of *the formation of bottom-ice*, and its rise to the surface, is more frequently seen in the Baltic and the Cattegat than in the open ocean,— chiefly, it seems probable, on account of the shallowness of these seas. It has been particularly observed by Prof. Nilsson in the Cattegat, off Kullen Point, near the southern extremity of Sweden; but according to Chydenius it is very common in various parts of the Baltic, having been especially noticed by the fishermen off the Aland Islands. In calm winter weather, water of from 4 to 8 feet deep is often covered in a very short time with small plates of ice, mostly circular in form, varying in diameter from 1 to 5 inches, and having a uniform thickness which never exceeds two lines. These plates can be seen coming up from below, rising edgeways towards the surface, often with such force as to lift themselves three or four inches out of the water. When they come up in great numbers they are often piled one upon another, and are then usually soon broken, by the action either of waves or of currents, into small pieces, which unite again by regulation so as to form irregular cakes of ice; and these, as soon as the water becomes tolerably still, cohere into a continuous rough sheet. But it sometimes happens that if the plates come up more sparsely, and the weather is very still and cold, they remain unbroken, and the diameter of each increases, sometimes to two feet or even more. When fishermen notice these ice-plates coming up from below in large quantities, they at once make for land, as they know they might otherwise be soon completely ice-bound. The same thing appears to happen in polar seas in the shallow water near land.

It does not seem very clear in what way this formation of bottom-ice is to be accounted for. Bottom-ice has often been noticed in fresh-water lakes and streams; and large plates have been seen to rise to the surface, sometimes with force enough to bring up stones of considerable size,— in one instance a heavy iron chain. In these cases it would seem that the motion of the bottom-water over roughened surfaces contributes to its congelation. And in the shallow water near the sea-shore, stones and sea-weeds may be seen covered with ice, like the hoar-frost on trees, before any ice forms on the surface. It is to be remembered that *sea*-water increases in density down to its freezing point, so that the water cooled at the surface will always go down, the deepest stratum being thus the coldest. And thus, although no lower temperature can be carried down by the water than that to which it has been subjected at the surface, the water that does not freeze at (say) — 2° 5 C. when lying upon water, changes into ice when it comes in contact with the irregular solid bottom, perhaps on account of the more ready dissipation, under the latter circumstances, of the heat set free in the act of congelation.

When ice forms over the shallow bottoms which border parts of the Gulfs of Bothnia and Finland, large blocks of stone are frequently frozen into it; and these, being lifted when the water rises in the early summer, are often transported by currents to considerable distances, finally subsiding again to the bottom when the ice melts. In this manner a deposit of rocky fragments, some of them 6 or 8 feet across, is being formed at the bottom of the Baltic outlets; as is known from the fact, that sunken ships which have been visited by divers in the Sound and in Copenhagen roads have been found covered with such blocks within no very long period. It not unfrequently happens, moreover, that sheets of ice with included boulders are driven up on the coast during storms, and are thus carried some way inland, being sometimes packed to a height of even 50 feet. The diminution which has been noticed from time to time in the depth of the channels, and the appearance above water of what were formerly regarded as sunken rocks or reefs, have been regarded as concurring with other evidence to prove that a general rise of land is now going on over this area. But it seems probable, from what has now been stated, that the increase of height and dimensions which has been observed in the reefs and inlets of the skär during the last half century, may be adequately accounted for by the action of ice, which has piled up (generally on a basis of *fixed* rock) accumulations of transported *débris*.

Early in the last century the Swedish physicist Celsius (to whom we owe the invention of the centigrade scale) formed the opinion that the waters both of the Baltic and of the North Sea were gradually subsiding; and this opinion, though controverted by other authorities, was embraced by Linnæus. It is now clear that many of the facts by which it was supported are explicable by the transporting agency of rivers and of ice, as already explained; and it was pointed out by Playfair in 1802, that even admitting the proofs on which Celsius relied, they would rather show that the land is rising, than that the water is receding. During the present century a great deal of attention has been given to this question, on account of its geological interest, by many very able observers; and the results may be briefly summarised as follows: — (1.) An elevation of the whole of Norway, from the North Cape to the Naze, has taken place within a comparatively recent period, — as is evidenced by the numbers of raised beaches containing existing shells, which are found at different points along the western coast, frequently at a height of 200 feet above the present sea-level, and in some spots at a height of more than 600 feet. As these beaches, where one lies above another, are not always parallel, it appears that the elevatory action did not take place equally over the whole area; and the movements were probably intermittent, with long pauses between. (2.) At various points along the coast of the Baltic and the Gulf of Bothnia, alike in Sweden and in Finland, similar collections of shells have been found, belonging to species now inhabiting the basin, and characterised by the peculiar *facies* to be presently noticed as distinguishing its molluscan fauna from that of the ocean. Such deposits have been found very far inland, and at a height of 230 feet above the sea. Hence it appears that before this upheaval took place, the Baltic must have been separated, as now, from the North Sea by the mountain ridge of Norway, although it extended over a considerably larger area of what is at present low-lying land. (3.) Notwithstanding the numerous observations which have been made with a view to ascertain whether any change of level is now going on, the question must be regarded as still undetermined. Little reliance can be placed on occasional comparisons of the height of marks made upon rocks above the sea-level, since,

although there are no tides, the height of the water in the basin is subject to considerable variations, from causes to be presently explained. (4.) There is a good deal of evidence, on the other hand, that, towards the southern extremity of Sweden there has been a *depression* of the land since the historic period. In this portion, known as Scania, no elevated beds of recent marine shells have been met with; in its seaport towns there are streets now at or even below the level of the water, which must have been above it when first built; and a large stone whose distance from the sea was measured by Linnæus, in 1749, was found 100 feet nearer the water's edge when its distance was again measured in 1836. Near Stockholm, again, a fishing-hut, with remains of boats of every antique form and construction, was found, in 1819, at a depth of 60 feet, covered over with gravel and shell-marl; and it was considered by Sir C. Lyell to be impossible to explain the position of this hut without imagining first a subsidence to the depth of more than 60 feet, and then a re-elevation. On the whole, it appears clear that oscillations of level, not uniform either in direction or degree, have taken place in various parts of the Scandinavian peninsula within a recent period, whilst in regard to the continuance of any such changes at the present time we have no certain knowledge, though it is considered probable by many of the most distinguished *savans* both of Sweden and Norway.

The fauna of the Baltic may be regarded as that of a large estuary, having a narrow communication with the sea,—its marine inhabitants being such as can adapt themselves to considerable variations in the salinity of its water. Whales rarely enter the Baltic; but porpoises frequent the neighborhood of the Danish islands. Seals are obtained in considerable numbers at the breaking up of the ice around Gottland and the Aland Isles. The salmon is among the most abundant fishes of the Baltic proper, ascending its rivers from April to June; and salmon-trout are caught in some of its bays.

BALTIMORE, in Maryland, the seventh largest and one of the most flourishing cities in the United States, is situated on the north side of the Patapsco River or Bay, 14 miles above its entrance into the Chesapeake, 37 miles N. E. of Washington, and 100 S. W. of Philadelphia. The natural advantages of this position were long overlooked by the settlers in the vicinity of the Chesapeake; and it was only in 1729 that they directed their attention to the place, and laid out a plan of the town. At that time a part of it was under cultivation as a farm, but all the rest was a wilderness. For some years its growth was by no means rapid, as it had to contend with all the obstacles that could be thrown in its way by the jealousy of older rivals. From an authentic sketch of Baltimore made in the year 1752, it appears that it then contained about twenty-five houses, only four of which were built of brick, the rest being of a more primitive structure. In 1768 it became the county town; and in 1775, according to a census then taken, it contained 564 houses, and 5934 inhabitants. From this time it rose rapidly into importance; and in 1780 became a port of entry, when a custom-house was opened. Previous to this all vessels trading to and from the port had to be entered, cleared and registered at Annapolis. In December 1796 it obtained an act of incorporation. By the census of 1890 Baltimore contained 434,151 inhabitants.

The city is splendidly situated on slightly undulating ground, and extends about 4½ miles from E. to W., and 3½ from N. to S., covering an area of 10,000 acres. It is divided into two nearly equal parts by a small stream called Jones's Falls, crossed by a number of bridges. The division east of the falls is nominally subdivided into two parts—Fell's Point and Old Town. The former, the most easterly part of the town, is the principal resort of seamen, and is the place where the shipbuilding and manufactures are principally carried on. The Old Town lies to the N. and W. of this. The portion west of the Falls is likewise divided into two parts, the city proper and Spring Garden. The former is the centre of trade, and the residence of the more wealthy inhabitants; while the latter, which is the extreme south-western quarter, and the lowest and most unhealthy portion of the city, is inhabited by the poorer classes. Baltimore contains about 200 churches, and has three universities, several colleges, 122 public schools, a state normal school, a manual labor school, besides numerous private schools and academies, an academy of art and science, an infirmary, hospitals, asylums, dispensaries, &c., three theatres, an opera-house, a museum, and many fine public buildings. The most imposing building in the city is the new city hall, one of the finest structures of the kind in the country. It occupies an entire square of ground, an area of about 26,000 square feet, near the centre of the city, and contains the various municipal offices. The style of architecture is the Renaissance, of which it is a fine specimen. The entire outer facing of the walls, the portico, and all the ornamental work, are of white Maryland marble; the inner walls and floors are of brick, and are fire-proof. It is four stories high, surmounted by a Mansard roof of iron and slate, with a dome and tower of iron on a marble base, rising to the height of 240 feet. The interior is very finely finished. It was begun in 1867, and cost about $2,600,000. Another important public building is that of the Peabody Institute, founded by the late George Peabody, Esq. of London, and endowed by him to the amount of $1,400,000. It has provisions for a public library, a gallery of art, and a conservatory of music, also for lectures and musical performances. It was incorporated in 1857. One wing of the building, which is immediately contiguous to the Washington monument, is completed, and the remainder is in progress. The completed wing is faced and ornamented with white marble, in a simple but massive and imposing style, and contains the library of over 56,000 volumes (1875), and a hall for lectures, concerts, &c. The new postoffice is a splendid structure, built of granite, and recently completed. The Johns Hopkins University is another imposing edifice, built by the legacy of the late Johns Hopkins. There are also several grain and coal elevators, and numerous magnificent hotels. Baltimore has several splendid monuments, which have acquired for it the name of "the Monumental City." The largest of these, erected to the memory of Washington, stands on an eminence of 150 feet, and has, with its base, an altitude of 200 feet. It is of white marble; the base is 50 feet square, and 24 feet in height, surmounted by a Doric column 25 feet in diameter at the base, with a spiral staircase in its interior, and on the summit is a statue of Washington, 13 feet high. The "Battle Monument," also of white marble, was erected by public subscription in 1815, to the memory of those who had fallen in defence of the city in the previous year. It is 52 feet high; the base is of Egyptian architecture; the column is in the form of a bundle of Roman faces, upon the bands of which are inscribed the names of those whom it commemorates; and the whole is surmounted by a female figure, the emblematical genius of the city. The city is supplied with water from Lake Roland, an artificial lake about 8 miles north of the city, of a capacity of 500,000,000 gallons, and from three other reservoirs, with an aggregate storage capacity of about 580,000,000 gallons, the common source of supply being Jones's Falls. There are also

numerous public springs and fountains throughout the town. Baltimore has a number of parks and public squares, chief of which is Druid Hill Park, a tract of 700 acres on the extreme north-west of the city, possessing more natural beauties than any other in the United States.

The manufactures and commerce of Baltimore are very extensive and flourishing. There is scarcely a branch of industry that is not prosecuted to some extent in the city or its vicinity. Among these are shipbuilding, iron and copper works, woolen and cotton manufactures, pottery, sugar-refining, petroleum refining, distilling, saddlery, agricultural implement-making, cabinet, tanning, &c. In the vicinity of Baltimore is found the finest brick clay in the world, of which more than 100,000,000 bricks are made annually. The Abbot Iron Works in the eastern part of the city has one of the largest rolling mills in the United States. An industry peculiar to Baltimore is the packing of oysters in air-tight cans for shipment to all parts of the world. The oysters are taken in Chesapeake Bay. Fruits and vegetables are also packed in the same way, the entire trade consuming from twenty to thirty million cans annually. This city is one of the greatest flour markets in the Union, and has a large export trade in tobacco. There are twenty-six banks, and seven savings-banks; seventeen fire and marine and three life insurance companies, besides many agencies for other companies. The harbor, which consists of three parts, is excellent. Its entrance, between Fort M'Henry and the lazaretto, is about 600 yards wide, with 23 feet of water. This depth is continued with an increased width for a mile and a quarter to near Fell's Point. The entrance to the second harbor is opposite Fell's Point, where the width is contracted to one-fourth of a mile, with a depth of 16 feet. Above this entrance it widens to an ellipse of a mile long, half a mile broad, and 15 feet deep. The third, or inner harbor, has a depth of 14 feet, and penetrates to near the centre of the city. Vessels of the largest class can lie at the wharves near Fell's Point, Locust Point, and Canton, and those of 500 tons can come into the inner harbor. The harbor is defended by Fort M'Henry. Opposite Fort M'Henry is Fort Carroll, a solid masonry structure, designed to aid in defense of the harbor, but which was abandoned on account of the sinking of the foundation.

A dozen important lines of railroad center at Baltimore, notable among which is the Baltimore and Ohio railroad, the oldest in the country. The city has also a very extensive coastwise trade. Intramural communication is afforded by numerous lines of street railroads. Baltimore is of considerable historic interest. It was incorporated as a city almost a century ago. In the war of 1814 the British bombarded Fort McHenry, and made an attempt to capture the city, but were defeated, and their commander, General Ross, was killed. It was on this occasion that Key wrote the "Star Spangled Banner."

At the outbreak of the Civil war there was considerable doubt as to which side Maryland would cast her fortunes with. Being a slave State, and having its social and commercial connections chiefly with the South, the presumption was that it would join the Confederacy. Baltimore contained in those days, like most busy seaports, a class of loafers and thugs, known locally as "plug-uglies." Impelled possibly by their Southern proclivities, but more probably by their inborn desire for deviltry, a mob of this class attacked a Massachusetts regiment which, in April, 1861, was passing through Baltimore on its way to Washington. The volunteers replied with volleys of musketry, and some of the rioters were killed. A few days later General Butler occupied the city, and Maryland remained in the Union.

BALUCHISTAN, a maritime country of Asia, whose coast is continuous with that of the northwestern part of the Indian Peninsula. It is bounded on the N. by Afghanistan, on the E. by Sindh, on the S. by the Arabian Sea, and on the W. by Persia. Baluchistan has an area of 106,500 sq. miles, its extreme length from E. to W. being 500 miles, and its breadth 370.

The outline of the sea-coast is in general remarkably regular, running nearly due E. and W., a little N. from Cape Monze, on the border of Sindh, to Cape Jewnee, on the River Dustee. It is for the most part craggy, but not remarkably elevated, and has in some places, for considerable distance, a low sandy shore, though almost everywhere the surface becomes much higher inland. The principal headlands, proceeding from E. to W., are Cape of Monze or Ras Moarree, which is the eastern headland of Sonmeanee Bay; Goorab Sing; Ras Arubah; Ras Noo, forming the western headland of Gwadel Bay, Ras Jewnee, forming the eastern point of Gwadur Bay, and Cape Zegin at its western extremity. There is no good harbor along the coast, though it extends about 600 miles; but there are several roadsteads with good holding-ground, and sheltered on several points. Of these the best are Sonmeanee Bay, Homara, and Gwadur. On the latter are situated a small town and a fort of the same name, and also a telegraph station of the Indo-European line.

Of the early history of this portion of the Asiatic continent little or nothing is known. The poverty and natural strength of the country, combined with the ferocious habits of the natives, seem to have equally repelled the friendly visits of inquisitive strangers and the hostile incursions of invading armies. The first distinct account which we have is from Arrian, who, with his usual brevity and severe veracity, narrates the march of Alexander through this region, which he calls the country of Oritæ and Gadrosii.

The country derives its name from the Baluches, but the Brahoes are considered the dominant race, from which the ruler of the country is always selected. From whatever quarter these may have arrived, they eventually expelled, under their leader Kumbur, the Hindu dynasty, which at that time governed the country, and conquered Baluchistan for themselves. The Baluches are a quite distinct race, and must have arrived in this country at a subsequent period, probably in small bodies, some of which may have come from Syria or from Arabia; in proof of this the Kyheree, for instance, possess a remarkably handsome breed of horses showing unmistakable Arab blood. Anyhow, so marked is the social distinction between Baluch and Brahoe, that when the khan assembles his forces for war the latter tribes demand, as their right, wheaten flour as a portion of their daily rations, while the Baluch tribes are only entitled to receive that made from a coarse grain called jowar. There is also a Persian colony known as the Deliwars; and a considerable number of Hindus, who appear to have been the first settlers in the Brahoe mountains on their expulsion from Sindh, Lus, Mekran by the caliphs of Baghdad.

Taking a general view on the subject of the original inhabitants of Baluchistan, we may conclude that they have, from a very early date, been reinforced by emigration from other countries, and from stragglers dropped from the hosts of the numerous conquerors, from Alexander to Nadir Shah, who have passed and repassed through Baluchistan or its neighborhood on their way to and from India. Thus we find the Saka tribe located on the plains of Gressia, on the borders of Mekran, the ancient Gedrosia, and still further to the west, the Dahoe. These tribes are on the direct line of Alexander's march; and we know that tribes of this name from

the shores of the Caspian accompanied his army. In Sarawan we find the Sirperra, and Pliny tells us that a tribe called Saraparæ resided near the Oxus. Further, on the Dushti-be-doulets, a plain at the northern entrance of the Bolan Pass, we find the Kurds, a name, again, familiar as that of the celebrated and ancient nation. The names of numerous other tribes might be cited to support this view, but it would require too much space to follow up the subject. Both Brahoes and Baluches are Mahometans of the Suni persuasion.

The precise period at which the Brahoes gained the mastery cannot be accurately ascertained; but it was probably about two centuries ago. The last rajah of the Hindu dynasty found himself compelled to call for the assistance of the mountain shepherds, with their leader, Kumbur, in order to check the encroachments of a horde of depredators, headed by an Afghan chief, who infested the country, and even threatened to attack the seat of government. Kumbur successfully performed the service for which he had been engaged; but having in a few years quelled the robbers, against whom he had been called in, and finding himself at the head of the only military tribe in the country, he formally deposed the rajah and assumed the government.

The history of the country after the accession of Kumbur is as obscure as during the Hindu dynasty. It would appear, however, that the sceptre was quietly transmitted to Abdulla Khan, the fourth in descent from Kumbur, who, being an intrepid and ambitious soldier, turned his thoughts toward the conquest of Cutch-Gundava, then held by different petty chiefs, under the authority of the Nawabs of Sindh.

After various success, the Kumburanees at length possessed themselves of the sovereignty of a considerable portion of that fruitful plain, including the chief town, Gundava. It was during this contest that the famous Nadir Shah advanced from Persia to the invasion of Hindustan; and while at Kandahar, he despatched several detachments into Baluchistan, and established his authority in that province. Abdulla Khan, however, was continued in the government of the country by Nadir's orders; but he was soon after killed in a battle with the forces of the Nawabs of Sindh. He was succeeded by his eldest son, Hajee Mohummud Khan, who abandoned himself to the most tyrannical and licentious way of life, and alienated his subjects by oppressive taxation. In these circumstances Nusseer Khan, the second son of Abdulla Khan, who had accompanied the victorious Nadir to Delhi, and acquired the favor and confidence of that monarch, returned to Khelat, and was hailed by the whole population as their deliverer. Finding that expostulation had no effect upon his brother, he one day entered his apartment and stabbed him to the heart. As soon as the tyrant was dead, Nusseer Khan mounted the *musnud*, amid the universal joy of his subjects; and immediately transmitted a report of the events which had taken place to Nadir Shah, who was then encamped near Kandahar. The shah received the intelligence with satisfaction, and despatched a firman, by return of the messenger, appointing Nusseer Khan beglerbey of all Baluchistan. This event took place in the year 1739.

Nusseer Khan proved an active, politic, and warlike prince. He took great pains to re-establish the internal government of all the provinces in his dominions, and improved and fortified the city of Khelat. On the death of Nadir Shah in 1747, he acknowledged the title of the king of Cabul, Ahmed Shah Abdulla. In 1758 he declared himself entirely independent; upon which Ahmed Shah despatched a force against him, under one of his ministers. The khan, however, raised an army and totally routed the Afghan army. On receiving intelligence of this discomfiture, the king himself marched with strong reinforcements, and a pitched battle was fought, in which Nusseer Khan was worsted. He retired in good order to Khelat, whither he was followed by the victor, who invested the place with his whole army. The khan made a vigorous defence; and, after the royal troops had been foiled in their attempts to take the city by storm or surprise, a negotiation was proposed by the king, which terminated in a treaty of peace. By this treaty it was stipulated that the king was to receive the cousin of Nusseer Khan in marriage; and that the khan was to pay tribute, but only, when called upon, to furnish troops to assist the armies, for which he was to receive an allowance in cash equal to half their pay. The khan frequently distinguished himself in the subseqent wars of Cabul; and, as a reward for his services, the king bestowed upon him several districts in perpetual and entire sovereignty. Having succeeded in quelling a dangerous rebellion, headed by his cousin Beheram Kahn, this able prince at length died in extreme old age, in the month of June 1795, leaving three sons and five daughters. He was succeeded by his eldest son Muhmood Khan, then a boy of about fourteen years. During the reign of this prince, who has been described as a very humane and indolent man, the country was distracted by sanguinary broils; the governors of several provinces and districts withdrew their allegiance; and the dominions of the khans of Khelat gradually so diminished, that they now comprehend only a small portion of the provinces formerly subject to Nusseer Khan.

In 1839, when the British army advanced through the Bolan Pass towards Afghanistan, the conduct of Mehrab Khan, the ruler of Baluchistan, was considered so treacherous and dangerous, as to require "the exaction of retribution from that chieftain," and "the execution of such arrangements as would establish future security in that quarter." General Willshire was accordingly detached from the army of the Indus with 1050 men to assault Khelat. A gate was knocked in by the field-pieces, and the town and citadel were stormed in a few minutes. Above 400 Baluches were slain, among them Mehrab Khan himself; and 2000 prisoners were taken. Subsequent inquiries have, however, proved that the treachery towards the British was not on the part of Mehrab Khan, but on that of his vizier, Mahomed Hassein, and certain chiefs with whom he was in league, and at whose instigation the British convoys were plundered in their passage through Cutch-Gundava and in the Bolan Pass. The treacherous vizier, however, made our too credulous political officers believe that Mehrab Khan was to blame,—his object being to bring his master to ruin and to obtain for himself all power in the state, knowing that Mehrab's successor was only a child. How far he succeeded in his object history has shown. In the following year Khelat changed hands, the governor established by the British, together with a feeble garrison, being overpowered. At the close of the same year it was reoccupied by the British under General Nott. In 1841, Nusseer Khan, the youthful son of the slain Mehrab Khan, was recognized by the British, who soon after evacuated the country.

From the conquest of Sindh by the British troops under the command of the late General Sir Charles Napier in 1843 up to 1854, no diplomatic intercourse occurred worthy of note between the British and Baluch states. In the latter year, however, under the governor-generalship of the late marquis of Dalhousie, the late General John Jacob, C.B., at the time political superintendent and commandant on the Sindh frontier, was deputed to arrange and conclude a treaty between the Khelat state, then under the chieftainship of Meer Nusseer Khan, and the British Government. This

treaty was executed on the 14th of May 1854, and was to the following effect:—

"That the former offensive and defensive treaty, concluded in 1841 by Major Outram between the British Government and Meer Nusseer Khan, chief of Khelat, was to be annulled.

"That Meer Nusseer Khan, his heirs and successors, bound themselves to oppose to the utmost all the enemies of the British Government, and in all cases to act in subordinate co operation with that Government, and to enter into no negotiations with other states without its consent.

"That should it be deemed necessary to station British troops in any part of the territory of Khelat, they shall occupy such positions as may be thought advisable by the British authorities.

"That the Baluch chief was to prevent all plundering on the part of his subjects within, or in the neighborhood of, British territory.

"That he was further to protect all merchants passing through his territory, and only to exact from them a transit duty, fixed by schedule attached to the treaty; and that, on condition of a faithful performance of these duties, he was to receive from the British Government an annual subsidy of 50,000 rupees (£5000)."

The provisions of the above treaty were most royally performed by Meer Nusseer Khan up to the time of his death in 1856. He was succeeded by his brother, Meer Khodadad Khan, the present ruler, a youth of twelve years of age, who, however, did not obtain his position before he had put down by force a rebellion on the part of his turbulent chiefs, who had first elected him, but not receiving what they considered an adequate reward from his treasury, sought to depose him in favor of his cousin Shere dil Khan. In the latter part of 1857, the Indian rebellion being at its height, and the city of Delhi still in the hands of the rebels, a British officer (Major Henry Green) was deputed, on the part of the British Government, to reside, as political agent, with the khan at Khelat, and to assist him by his advice in maintaining control over his turbulent tribes. This duty was successfully performed until 1863, when, during the temporary absence of Major Malcomb Green, the then political agent, Khodadad Khan was, at the instigation of some of his principal chiefs, attacked, while out riding, by his cousin, Shere dil Khan, and severely wounded. Khodadad fled in safety to a residence close to the British border, and Shere dil Khan was elected and proclaimed khan. His rule was, however a short one, for, early in 1864, when proceeding to Khelat, he was murdered in the Gundava Pass; and Khodadad was again elected chief by the very men who had only the previous year caused his overthrow, and who had lately been accomplices to the murder of his cousin. Since the above events Khodadad has maintained his precarious position with great difficulty; but owing to his inability to govern his unruly subjects without material assistance from the British Government, which they are not disposed to give, his country has gradually fallen into the greatest anarchy; and, consequently, some of the provisions of the treaty of 1854 having been broken, diplomatic relations having been discontinued with the Khelat state since the end of 1874.

The territories of Baluchistan are now comprised under the following divisions — Jalawan, Sarawan, Khelat, Mekran, Lus, Cutch-Gundava, and Kohistan.

The climate of Baluchistan is extremely various in the different provinces. The soil in general is exceedingly stony. In the province of Cutch-Gundava, however, it is rich and loamy, and so very productive, that, it is said, were it all properly cultivated, the crops would be more than sufficient for the supply of the whole of Baluchistan. Gold, silver, lead, iron, tin, antimony, brimstone, alum, sal-ammoniac, and many kinds of mineral salts, and saltpetre, are found in various parts of the country. The precious metals have only been discovered in working for iron and lead, in mines near the town of Nal, about 150 miles S.S.W. of Khelat. The different other minerals above enumerated are very plentiful. The gardens of Khelat produce many sorts of fruit, which are sold at a very moderate rate, such as apricots, peaches, grapes, almonds, pistachio-nuts, apples, pears, plums, currants, cherries, quinces, figs, pomegranates, mulberries, plantains, melons, guavas, &c. All kinds of grain known in India are cultivated in the different provinces of Baluchistan, and there is abundance of vegetables. Madder, cotton and indigo are also produced; and the latter is considered superior to that of Bengal. Great attention is given to the culture of the date fruit in the province of Mekran. The domestic animals of Baluchistan are horses, mules, asses, camels, buffaloes, black-cattle, sheep, goats, dogs, and cats, besides fowls and pigeons, but there are neither geese, turkeys nor ducks. The wild animals are tigers, leopards, hyenas, wolves, jackals, tiger-cats, wild dogs, foxes, hares, mangooses, mountain goats, antelopes, elks, red and moose deer, wild asses, &c. Of birds they have almost every species to be met with either in Europe or India.

The principal towns in Buluchistan are as follows:— KHELAT is the capital of the whole country; *Mustoong*, of the province of Sarawan; *Kozdar*, of Jalawan; *Beyla*, of Beyla; *Kej*, of Mekran; *Bagh*, of Cutch-Gundava; and Dadur and Gundava are towns in the last-mentioned province.

The capital stands on an elevated site 7000 feet above the sea, on the western side of a well-cultivated plain or valley, about eight miles long and two or three broad, a great part of which is laid out in gardens and other enclosures. The town is built in an oblong form, and on three sides is defended by a mud wall, 18 or 20 feet high, flanked, at intervals of 250 yards, by bastions, which, as well as the wall itself, are pierced with numerous loopholes for matchlock-men. The defence of the fourth side of the city has been formed by cutting away perpendicularly the western face of the hill on which it is partly built. On the summit of this eminence stands the palace, commanding a distinct view of the town and adjacent country.

We have no data from which we can form an accurate computation of the population of Baluchistan, but it may be estimated at about 400,000. The two great races of Baluch and Brahoe, each subdivided into an infinite number of tribes, are clearly distinguished from each other by their language and appearance.

The Baluches are a handsome, active race of men, not possessing great physical strength, but inured to changes of climate and season, and capable of enduring every species of fatigue. In their habits they are pastoral and much addicted to predatory warfare, in the course of which they do not hesitate to commit every kind of outrage and cruelty. Notwithstanding their predatory habits, however, they are considered to be a hospitable people.

The common dress of the Brahoes is a coarse white or blue calico shirt, buttoned round the neck, and reaching below the knee; their trousers are made of the same cloth, or of a kind of striped stuff called soosee, and puckered around the ankles. On their heads they wear a small silk or cotton quilted cap, fitted to the shape of the skull, and a *kummurbund* or sash, of the same color, round their waists. The Baluches wear a similar dress, but a turban on the head and wide trousers unconfined at the ankle. In winter the chiefs and their relatives

appear in a tunic of chintz, lined and stuffed with cotton; and the poorer classes, when out of doors, wrap themselves up in a surtout made of cloth, manufactured from a mixture of goats' hair and sheep's wool. The women's dress is very similar to that of the men; their trousers are preposterously wide, and made of silk, or a mixture of silk and cotton.

BALUE, JEAN, a French cardinal, who raised himself from a very mean station to dignity and honors. He was born of very humble parentage at Angle in Poitou, in 1421, and was first patronised by the bishop of Poitiers. He eventually became almoner to Louis XI., and managed to secure a considerable share in the government; but being detected in treasonable correspondence with the duke of Bourgogne, he was confined by Louis in an iron cage 8 feet square. On his release, however, eleven years afterwards, he was loaded with honors by Sixtus IV., was sent as legate to France, and received the bishopric of Albano. He died at Ancona in 1491.

BALUZE, ETIENNE, a celebrated French scholar, was born at Tulle on the 24th of December 1630, and died in July 1718. His reputation and his mastery of French law and antiquities obtained for him in 1670 the professorship of canon law in the royal college, a chair founded expressly for him. On the fall of the Cardinal de Bouillon in 1710, Baluze, who had attached himself to his party, was removed by a *lettre de cachet* from Paris, and transferred from Rouen to Blois, Tours, and Orleans in succession. He obtained his recall in 1813, though he never recovered his professorship. Of Baluze's numerous works the best known is the *Capitularia Regum Francorum*, which is of considerable historical value.

BALZAC, HONORÉ DE, perhaps the greatest name in the post-Revolutionary literature of France, was born at Tours in 1799, and died in 1858. His date thus corresponds with the whole period of the rise, the acme, and the decline of the Romantic school, to which he can scarcely, however, be said to have belonged. It is true that he was inspired by many of the influences that animated Victor Hugo and his followers. Like them he was much occupied by the study of the fantastic element in mediæval art, so strongly opposed to the calm and limit of classical literature, like them he reproduced the remoter phases of life and passion, and thought that few subjects were so base or obscure as to be unworthy of artistic treatment. But there is something in the powerful personality of Balzac indicated by the colossal body, by the strong and sensual face, somewhat resembling the profile of the Emperor Nero, which preserved him from the mannerism of any school. He was never successful in reproducing the existence of the past, he was essentially the man of his own day, and *La Comédie Humaine* is as much the picture of the 19th, as the *Divina Commedia* is of the 13th century. The passions that move his characters are the intense desire of boundless wealth, of luxury, of social distinction; and though here and there his financiers, his journalists, his political intriguers, his sordid peasantry, are relieved by the introduction of some pure figure like that of Eugénie Grandet, of David, or of Eve, there are only too many elaborate studies of creatures sunk below the surface of humanity, the embodiments of infinite meanness and nameless sin. He was merely "the secretary of society," he said, and "drew up the inventory of vices and virtues." His ambition was "by infinite patience and courage, to compose for the France of the 19th century that history of morals which the old civilisations of Rome, Athens, Memphis, and India have left untold." The consequence of this ambition is, that Balzac's voluminous romances have too often the air of a minute and tedious chronicle, and that the contemporary reader is wearied with a mass of details about domestic architecture, about the stock exchange, and about law, which will prove invaluable to posterity.

Balzac's private history, which may be traced through many passages of his novels, was a strange and not a happy one. He was early sent from his home in Tours to the college of Vendôme, where he neglected the studies and sports of childhood to bury himself in mystic books and mystic reveries. He has told the story of his school life in *Louis Lambert*, how he composed a *théorie de la volonté*, a theory which was to complete the works of Mesmer, Lavater, Gall, and Bichat. This promising treatise was burned by one of the masters of the school; and Balzac, falling into bad health, returned home. The next stage in his education was a course of study at the Sorbonne, and of lectures on law. In the offices of attorneys and notaries he picked up his knowledge of the by ways of chicanery,—knowledge which he uses only too freely in his romances. Nature did not mean Balzac for an advocate; he was constant in the belief in his own genius, a belief which for many years he had all to himself, and his family left him to work and starve, on the scantiest pittance, in a garret of the Rue Lesdiguières. There followed ten years of hard toil, poverty, experiments in this and that way of getting a living. These struggles are described in *Facino Cane*, in the *Peau de Chagrin*, and in a series of letters to the author's sister, Madame de Surville. Balzac found "three sous for bread, two for milk, and three for firing" suffice to keep him alive, while he devoured books in the library of the Arsenal, copied out his notes at night, and then wandered for hours among the scenes of nocturnal Paris. "Your brother," he writes to Madame de Surville, "is already nourished like a great man,—he is dying of hunger." He tried to make money by scribbling many volumes of novels without promise, and borrowed funds to speculate in the business of printing. Ideas which have since made other men's fortunes failed in Balzac's hands, and he laid the foundations of those famous debts which in later life were his torment and his occupation. At length appreciation came, and with appreciation what ought to have been wealth. Balzac was unfortunately as prodigal of money as of labor; he would shut himself up for months, and see no one but his printer; and then for months he would disappear and dissipate his gains in some mysterious hiding-place of his own, or in hurried travelling to Venice, Vienna, or St. Petersburg. As a child he had been a man in thought and learning; as a man he was a child in caprice and extravagance. His imagination, the intense power with which he constructed new combinations of the literal facts which he observed, was like the demon which tormented the magician with incessant demands for more tasks to do. When he was not working at *La Comédie Humaine*, his fancy was still busy with its characters; he existed in an ideal world, where some accident was always to put him in possession of riches beyond the dreams of avarice. Meantime he squandered all the money that could be rescued from his creditors on sumptuous apparel, jewels, porcelain, pictures. His excesses of labor, his sleepless nights, his abuse of coffee undermined his seemingly indestructible health. At length a mysterious passion for a Russian lady was crowned by marriage; the famous debts were paid, the visionary house was built and furnished, and then, "when the house was ready, death entered." Balzac died at the culmination of his fame, and at the beginning, as it seemed, of the period of rest to which he had always looked forward.

BALZAC, JEAN LOUIS GUEZ DE, a celebrated French writer, was born at Angoulême in 1594, and died at

Paris in 1654. His fame rests entirely upon the *Letters*, which, though empty, bombastic, and affected in matter, are written with great skill, and show a real mastery over the language. They introduced a new style; and Balzac has thus the credit of being the first reformer of French prose, as his contemporary Malherbe was the first reformer of French poetry.

BAMBA, a province of Congo, on the western coast of Africa, lying to the S. of the River Ambriz. This district is fertile, abounds in gold, silver, copper, salt, &c., and is said to be thickly populated. Its chief town, which bears the same name, was formerly of considerable importance, the climate being remarkably healthy for that region of Africa.

BAMBARRA, a country of inner Africa, on the Joliba or Upper Niger. The principal towns are Segor, Sansading, Jamima, Mursha, Jabbi, Sai, Kullikoro, Maraca-Duba, and Damba, in many of which the Mahometans have mosques. For further particulars see AFRICA.

BAMBARRA, a town of western Africa on a backwater of the Niger, of considerable commercial importance, and situated in a fertile plain, 115 miles S.S.W. of Timbuctoo.

BAMBERG, a town of Bavaria, in the circle of Upper Franconia, on the River Regnitz, 3 miles above its junction with the Maine, and 33 miles N. of Nuremberg, with which it is connected by railway. It was founded in 1004 by the Emperor Henry II., and finished in 1012, but was afterwards partially burnt, and rebuilt in 1110. It contains the tombs of the founder and his empress Cunigunde, Conrad III., Pope Clement II., &c., and numerous monuments and paintings by eminent masters. Bamberg was formerly the capital of an independent bishopric, which was secularised in 1801, and assigned to Bavaria in 1803. Population 25,738.

BAMBOCCIO. See LAER, PETER VAN.

BAMBOO, a genus (*Bambusa*) of arborescent grasses very generally distributed throughout the tropical lands of the globe, but found and cultivated especially in India, China, and the East Indian Archipelago. There is a large number of species enumerated; but, as is the case with most plants under cultivation, much difficulty is found in distinguishing species from varieties produced by artificial selection. *Bambusa arundinacea* is the species most commonly referred to. It is a tree-like plant, rising to a height of 40, 60, or even 80 feet, with a hollow stem, shining as if varnished. The stem is extremely slender, not exceeding the thickness of 5 inches in some which are 50 feet high, and in others reaching 15 or 18 inches in diameter. The whole is divided into joints or septa called knots or internodes, the intervals between which in the case of some of the larger stems is several feet. These joints or divisions are formed by the crossing of the vascular bundles of fibres. They produce alternate lateral buds, which form small alternate branchlets springing from the base to the top, and, together with the narrow-pointed leaves issuing from them, give the plant an elegant feathered appearance as it waves in the wind. The rapidity of its growth is surprising. It attains its full height in a few months, and Mr. Fortune records the observation of a growth of from 2 to 2½ feet in a single day. In Malabar it is said to bear fruit when fifteen years old, and then to die.

The bamboo is cultivated with great care in regular plantations by the Chinese. The plant is propagated by shoots or suckers deposited in pits 18 inches or 2 feet deep at the close of autumn or the beginning of winter. Various expedients are followed to obtain good bamboos; one of the most usual being to take a vigorous root and transplant it, leaving only four or five inches above the joint next the ground. The cavity is then filled with a mixture of horse-litter and sulphur. According to the vigor of the root, the shoots will be more or less numerous; they are destroyed at an early stage during three successive years; and those springing in the fourth resemble the parent tree. The uses to which all the parts and products of the bamboo are applied in Oriental countries are almost endless. The soft and succulent shoots, when just beginning to spring, are cut over and served up at table like asparagus. Like that vegetable, also, they are earthed over to keep them longer fit for consumption; and they afford a continuous supply during the whole year, though it is more abundant in autumn. They are also salted and eaten with rice, prepared in the form of pickles, or candied and preserved in sugar. As the plant grows older, a species of fluid is secreted in the hollow joints, in which a concrete substance, highly valued in the East for its medicinal qualities, called *tabaxir* or *tabascheer*, is gradually developed. This substance, which has been found to be a purely siliceous concretion, is possessed of peculiar optical properties. The grains of the bamboo are available for food, and the Chinese have a proverb that it produces seed more abundantly in years when the rice crop fails, which means, probably, that in times of dearth the natives look more after such a source of food. The Hindus eat it mixed with honey as a delicacy, equal quantities being put into a hollow joint, coated externally with clay, and thus roasted over a fire. It is, however, the stem of the bamboo which is applied to the greatest variety of uses. Joints of sufficient size form water buckets; smaller ones are used as bottles, and among the Dyaks of Borneo they are employed as cooking vessels. Bamboo is extensively used as a timber wood, and houses are frequently made entirely out of the product of the plant; complete sections of the stem form posts or columns; split up, it serves for floors or rafters; and, interwoven in lattice-work, it is employed for the sides of rooms, admitting light and air. The roof is sometimes of bamboo solely, and when split, which is accomplished with the greatest ease, it can be formed into laths or planks. It is employed in shipping of all kinds; some of the strongest plants are selected for masts of boats of moderate size, and the masts of larger vessels are sometimes formed by the union of several bamboos built up and joined together.

The bamboo is employed in the construction of all kinds of agricultural and domestic implements, and in the materials and implements required in fishery. Bows are made of it by the union of two pieces with many bands; and, the septa being bored out and the lengths joined together, it is employed, as we use leaden pipes, in transmitting water to reservoirs or gardens. From the light and slender stalks shafts for arrows are obtained; and in the south-west of Asia there is a certain species of equally slender growth, from which writing-pens or reeds are made. A joint forms a holder for paper or pens, and it was in a joint of bamboo that silk-worm eggs were carried from China to Constantinople during the reign of Justinian. The outer cuticle of Oriental species is so hard that it forms a sharp and durable cutting edge, and it is so siliceous that it can be used as a whetstone. This outer cuticle, cut into thin strips, is one of the most durable and beautiful materials for basket-making, and both in China and Japan it is largely so employed. Strips are also woven into cages, chairs, beds, and other articles of furniture, Oriental wicker-work in bamboo being unequalled for beauty and neatness of workmanship. In China the interior portions of the stem are beaten into a pulp, and used for the manufacture of the finer varieties of paper. Bamboos are imported to a considerable extent into Europe for the use of basket-makers, and for umbrella and walk-

ing-sticks. In short, the purposes to which the bamboo is applicable are almost endless, and well justify the opinion that "it is one of the most wonderful and most beautiful productions of the tropics, and one of Nature's most valuable gifts to uncivilized man."

BAMBOROUGH, a village in Northumberland, on the sea-coast, 14 miles N. of Alnwick.

BAMBOUK, a country in the interior of Western Africa, situated between the Senegal and its tributary the Faleme. It is traversed from N.W. to S.E. by the steep and wall-like range of the Tamba-Ura Mountains. The soil in a large part of the country is of remarkable fertility; rice, maize, millet, melons, manioc, grapes, bananas, and other fruits, grow almost without cultivation; the forests are rich in a variety of valuable trees; and extensive stretches are covered with abundant pasturage of the long guinea grass. As a natural consequence there is great profusion of animal life. The inhabitants, a branch of the Mandingo race, have made but little progress in civilisation. The one product of their country which really excites them to labor is gold; and even it is so common and accessible that the rudest methods of collection are deemed sufficient. The most remarkable deposit is at Natakoo, where a considerable hill seems to be wholly composed of auriferous strata. There is also a good mine at Kenieba. In exchange for the gold, cloth, ornaments, and salt—the last a most valuable article—are imported. The usual beast of burden is the ass, the horse being only possessed by the very wealthiest in the country. Sheep and cattle are both pretty numerous. Unfortunately, the climate is very unhealthy, especially in the rainy season, which lasts for about four months, from July or August. The chief towns are Bambouk, Salaba, and Konkuba. The Portuguese early penetrated into Bambouk, and were even for some time masters of the country; but the inhabitants made a general rising and completely drove them out. Remains of their buildings, however, are still to be seen. The French, soon after they had formed their settlement on the Senegal, turned their attention to this land of gold. It was not till 1716, however, that Compagon, under the auspices of De la Brue, the governor of Senegal, succeeded, by great address, and not without risk, in visiting various parts of the auriferous region; and his explorations were followed up by David, Levens, and others. Raffenel visited the country in 1844, and Pascal, a naval lieutenant, was there in 1859. A few commercial stations or *comptoirs* have recently been established.

BÁMIÁN, a once renowned city in the territory now subject to the Afghans. Its remains lie in a valley of the Hazara country, on the chief road from Kábul towards Turkestán, and immediately at the northern foot of that prolongation of the Indian Caucasus now called Koh-i-Baba.

That the idols of Bámián, about which so many conjectures have been uttered, were Buddhist figures, is ascertained from the narrative of the Chinese pilgrim, Hwen Thsang, who saw them in their splendor in 630 A.D. His description of the position of the city and images corresponds accurately with modern reports. He assigns to the greater image, which was gilt (the object, probably, of the plaster coating), a height of 140 or 150 feet, and to the second 100. The latter would seem from his account to have been sheathed with copper. Still vaster than these was a recumbent figure, 2 miles east of Bámián, representing Sakya Buddha entering *Nirvána*, *i.e.*, in act of death. This was "about 1000 feet in length." No traces of this are alluded to by modern travellers, but in all likelihood it was only formed of rubble plastered (as is the case still with such *Nirvána* figures in Indo-China), and of no durability. For a city so notable Bámián has a very obscure history. It does not seem possible to identify it with any city in classical geography: *Alexandria ad Caucasum* it certainly was not.

BAMPTON, Rev. John, founder of the series of divinity lectures at Oxford known as the *Bampton Lectures*, appears to have been born in 1689 and to have died in 1751. He was a member of Trinity College, Oxford, and for some time canon of Salisbury.

BANANA (*Musa sapientum*), a gigantic herbaceous plant belonging to the natural order *Musaceæ*, originally a native of the tropical parts of the East, but now cultivated in all tropical and sub-tropical climates. It forms a spurious kind of stem, rising 15 or 20 feet by the sheathing basis of the leaves, the blades of which sometimes measure as much as 10 feet in length by 2 feet across. The stem bears several clusters of fruit, which somewhat resemble cucumbers in size and form; it dies down after maturing the fruit. The weight of the produce of a single cluster is sometimes as much as 80 lb, and it was calculated by Humboldt that the productiveness of the banana as compared with wheat is as 133 to 1, and as against potatoes 44 to 1. The varieties of banana cultivated in the tropics are as numerous as the varieties of apples in temperate regions, and the best authorities now agree that no specific difference exists between it and the plantain. The fruit is extensively used as food; and in many of the Pacific islands it is the staple on which the natives depend. In its immature condition it contains much starch, which on ripening changes into sugar; and as a ripe fruit it has a sweet but somewhat flavorless taste. From the unripe fruit, dried in the sun, a useful and nutritious flour is prepared. The following represents the percentage composition of the pulp of the ripe fruit:—Nitrogenous matter, 4.820; sugar, pectin, &c., 19.657; fatty matter, 0.632; cellulose, 0.200; saline matter, 0.791; water, 73.900. An analysis of the flour by Dr. Murray Thompson yielded the following results:—Water, 12.33; starch, 71.60; gum and sugar, 6.82; nitrogenous matter, 2.01; cellulose, 5.99; oil, 0.50; salts, 0.64.

BANAT, a district in the south-east of Hungary, consisting of the three counties of Thorontal, Temeswar, and Krasso, which has strangely acquired this title, though it was never governed by a "ban." It is bounded by the Theiss, the Maros, and the Danube, forming almost a regular parallelogram. The soil is in many parts a remarkably rich alluvial deposit. Under the Turkish yoke it was allowed to lie almost desolate in marsh and heath and forest; but Joseph II. determined to render it, if possible, a populous and prosperous district. He accordingly offered land, at a very low rate, to all who were willing to settle within its borders. Germans, Greeks, Turks, Servians, Italians, and Frenchmen responded to his call, and soon developed the agricultural resources of the region. Canals were formed at great expense of labor; marshes and forests were cleared; and now the Banat is one of the most highly cultivated parts of the Austrian empire.

BANBRIDGE, a town of Ireland, county of Down, on the Bann, 23 miles S. W. of Belfast, standing on the summit of an eminence. To facilitate access, a central carriage-way, 200 yards long, has been cut through the main street to a depth of 15 feet, the opposite terraces being connected by a bridge.

BANBURY, a market-town, municipal and parliamentary borough, and railway junction, in the county of Oxford, 71 miles from London, and a little to the west of the River Cherwell and the Oxford and Birmingham canal.

BANCA, Banka, or Bangka, an island off the east

coast of Sumatra, and separated from it by the Strait of Banca. It varies from 8 to 20 miles in breadth, and has an area of 5000 English square miles. Its mines of tin, which were discovered in 1710, are remarkably productive, and in 1872 yielded no less than 68,148 piculs, the average yield during the previous ten years being 73,961 piculs. The washing is almost wholly carried on by Chinese, and a large part of the metal finds its way to their country. Iron, copper, lead, silver, and arsenic are also found in the island. The soil is generally dry and stony, and the greater part of the surface is covered with forests, in which the logwood tree especially abounds.

BANCROFT, RICHARD, Archbishop of Canterbury in the reign of James I., distinguished as an inflexible opponent of Puritanism, was born at Farnworth in Lancashire in 1544. He was educated at Cambridge University, studying first at Christ's College, and afterwards at Jesus College. He took his degree of B.A. in 1567, and that of M.A. in 1570. Ordained about that time, he was named chaplain to Dr. Cox, then bishop of Ely, and in 1575 was presented to the rectory of Teversham in Cambridgeshire. The next year he was one of the preachers to the university, and in 1584 was presented to the rectory of St. Andrew's, Holborn. His unquestionable abilities, and his zeal as a champion of the church in those unsettled times, secured him rapid promotion, and at length the highest ecclesiastical position in the land. He graduated B.D. in 1580, and D.D. five years later. In 1585 he was appointed treasurer of St. Paul's Cathedral, London. On February 9, 1589, he preached at Paul's Cross a sermon on 1 John iv. 1, the substance of which was a passionate attack on the Puritans. He described their speeches and proceedings, caricatured their motives, denounced the exercise of the right of private judgment, and set forth the divine right of bishops in such strong language that one of the queen's councillors held it to amount to a threat against the supremacy of the Crown. Sixteen days after the publication of this ecclesiastical manifesto, Bancroft was made a prebendary of St. Paul's. Within a few years he was advanced to the same dignity in the collegiate church of Westminster, and in the cathedral church of Canterbury. He was chaplain successively to Lord Chancellor Hatton and Archbishop Whitgift. In May 1597 he was consecrated bishop of London; and from this time, in consequence of the age and incapacity for business of Archbishop Whitgift, he was virtually invested with the power of primate, and had the sole management of ecclesiastical affairs. Among the more noteworthy cases which fell under his direction were the proceedings against Martin Mar-Prelate, Cartwright and his friends, and the pious Henry, whose "seditious writings" he caused to be intercepted and given up to the Lord Keeper. In 1600 he was sent on an embassy, with others, to Embden, for the purpose of settling certain matters in dispute between the English and the Danes. This mission, however, failed. Bishop Bancroft was present at the death of Queen Elizabeth. He took a prominent part in the famous conference of the prelates and the Presbyterian divines held at Hampton Court in 1604. By the king's desire he undertook the vindication of the practices of confirmation, absolution, private baptism, and lay excommunication; he urged, but in vain, the reinforcement of an ancient canon, "that schismatics are not to be heard against bishops;" and in opposition to the Puritans' demand of certain alterations in doctrine and discipline, he besought the king that care might be taken for a *praying clergy*; and that, till men of learning and sufficiency could be found godly homilies might be read and their numbers increased. In the capacity of a commissioner for ecclesiastical causes (1603), he advocated severe measures for the suppression of "heresy and schism" treating books against Episcopacy as acts of sedition, and persecuting their authors as enemies of the state. In March 1604, Bancroft, in consequence of the death of the primate, was appointed by royal writ president of Convocation then assembled; and he there presented for adoption a book of canons collected by himself. In the following November he was elected successor to Whitgift in the see of Canterbury. In 1608 he was chosen chancellor of the University of Oxford. He died at Lambeth Palace, November 2d, 1610.

BANDA, a district of British India, in the Alláhábád division, under the Lieutenant-Governor of the North-Western Provinces. It is bounded on the N. by the district of Fathipur, from which it is separated by the River Jamná; on the N.E. by the districts of Fathipur and Alláhábád; on the S.E, by the native state of Riwá; on the S. and S.W. by some of the petty states Bundelkhand; and on the W. and N.W. by the district of Hamírpur. Area, 3030 square miles, of which 1390 are under cultivation, 846 cultivable, but not cultivated, 108 revenue free, and 688 uncultivable waste. The census of 1872 took the area at 2908.68 square miles, and returned the district population at 697,610 souls,—viz., Hindus, 657,107; Mahometans, 40,497; Christains, 6. Average density, 230 persons to the square mile. Of the population in 1872, 2897 were landed proprietors, 42,230 agriculturists, and 63,644 non-agriculturists. In some parts the district rises into irregular uplands and elevated plains, interspersed with detached rocks of granite; in others it sinks into marshy lowlands, which frequently remain under water during the rainy season. The sloping country on the bank of the Jamná is full of ravines. To the S.E. the Vindhya chain of hills takes its origin in a low range not exceeding 500 feet in height, and forming a natural boundary of the district in that direction. The principal river of the district is the Jamná, which flows from north-west to south-east, along the N.E. boundary of the district for 125 miles. Its most important tributaries within the district are the Ken, Bágain, Paisuní, and Ohán, all of which take their rise in the Vindhya hills. The principal towns and market villages in the district are Mau, Májhgáon or Rájápur, Markâ, Samgará, Augásí, Chillá, and Barágáon, all situated on the bank of the Jamná.

BANDA ISLANDS, a group in the East Indian Archipelago, lying to the S. of Ceram. They are ten or twelve in number, and have an area of about 7150 square miles. Their volcanic origin is distinctly marked. Banda Lantoir, which derives its name from the *lontar* or Palmyra palm, is the largest of the group. The principal articles of commerce in the Banda group are nutmegs and mace. The native population having been cleared off by the Dutch, the plantations were worked by slaves and convicts till the emancipation of 1860. The introduction of Malay and Chinese laborers has since taken place. The plantations or *perken* can neither be sold nor divided. About 700,000 lb or upwards of nutmegs are obtained in a year, with a proportionate quantity of mace. The imports are provisions, cloth, and iron-ware from Batavia, and various native productions from the Aru Islands, Ceram, &c.

The Banda Islands were discovered and annexed by the Portuguese Abreus about 1511; but in the beginning of the 17th century his countrymen were expelled by the Dutch. In 1608 the English built a factory on Pulo Way, which was demolished by the Dutch as soon as the English vessel left. Shortly after, however, Banda Neira and Lantoir were resigned by the natives to the English, and in 1620 Pulo Roon and Pulo Way were

added to their dominions; but, in spite of treaties into which they had entered, the Dutch attacked and expelled their British rivals. In 1654 they were compelled by Cromwell to restore Pulo Roon, and to make satisfaction for the massacre of Amboyna; but the English settlers not being adequately supported from home, the island was retaken by the Dutch in 1664. They retained undisturbed possession of their conquests in this quarter of the globe until the year 1796, when the Banda Islands, along with all the other Dutch colonies, were conquered by the British. They were restored by the treaty of Amiens in the year 1800, again captured, and finally restored by the treaty of Paris concluded in 1814. In the Presidency of Banda there are 111,194 inhabitants, of whom 6000 belong to Neira.

BANDANA, a kind of printed handkerchief of Indian origin, usually of cotton. The cloth is first dyed Turkey red, and the pattern is made by discharging the color with bleaching liquor in a powerful Bramah press.

BANDELLO, MATTEO, an Italian novelist, was born at Castelnuovo, near Tortona, about the year 1480. Bandello wrote a number of poems, but his fame rests entirely upon his extensive collection of *Novelle*, or tales, which have been extremely popular. They belong to that species of literature of which Boccaccio's *Decameron* and the queen of Navarre's *Heptameron* are, perhaps, the best. He died in 1562.

BAND-FISH *(Cepola)*, a genus in the family Cepolidæ in the blenny-form division of Acanthopterygious Fishes. The body is much elongated and laterally compressed and is covered by very small scales. The dorsal fin is very long, and consists like the anal of soft rays. The tail vertebræ are very numerous, and the whole structure of the body exhibits unusual delicacy.

BANDICOOT *(Perameles)*, a genus of small marsupials, occupying in the fauna of Australia a place somewhat analogous to that of the much higher shrews in Europe. The fur is short and rough. The long head forms a pointed snout, the tail is rather short, the marsupial pouch is complete and opens backward. They keep to the ground, making nests in the hollows. Their movements and habits are like those of hares or rabbits. Numerous species occur in Australia and New Guinea.

BANDICOOT RAT, MALABAR RAT, or PIG-RAT *(Mus giganteus)*, the largest known species of rat. The name is a corruption of the Telinga *pandikoku*, literally meaning pig-rat. The animal inhabits many parts of India, and is plentiful in Ceylon. It attains the weight of two or three pounds, and is twenty-four to thirty inches long, including the tail, which at the base is two and one-half inches in circumference.

BANDINELLI, BARTOLOMMEO or BACCIO, a Florentine sculptor, was born in 1487, and died in 1559. His best works are the marble colossal group of Hercules and Cacus in the Piazza del Gran Duco; his group of Adam and Eve; his exquisite *bassi-rilievi* in the choir of the cathedral of Florence; his copy of the Laocoon; and the figures of Christ and Nicodemus on his own tomb.

BANDINI, ANGELO MARIA, an Italian author, was born at Florence in 1726, and died in 1800.

BANDOLINE is a mucilaginous substance used for stiffening hair, and keeping it in shape or form.

BANDON, or BANDONBRIDGE, an inland town and parliamentary borough of Ireland, in the county of Cork, and twenty miles by rail from the county town, is situated on both sides of the River Bandon, which is here crossed by a bridge of six arches. Population, 6,500.

BANFF, the county town of Banffshire, is a place of great antiquity; according to tradition it was at times the residence of Malcolm Canmore. It was visited by David I. and his son Henry; and there is a charter of Malcolm IV., signed at Banff the eleventh year of his reign, which corresponds with 1163. Population, 4,000.

BANFFSHIRE, a maritime county in the northeast of Scotland, bounded on the north by the Moray Firth, east and south by Aberdeenshire, and west by Morayshire and part of Inverness-shire. It has an area of 686 square miles, or 439,219 statute acres, its extent from north to south being fifty miles, and from east to west thirty-two miles,—its average breadth not exceeding fourteen miles. Population, 63,000.

Some interesting minerals have been found in Banffshire. Among them may be mentioned magnetite, chromite, and asbestos at Portsoy; fluorite near Boharm, at Keith, and on the Avon; also cyanite and chiastolite in clayslate at Boharm. Attempts were made many years ago to work a vein of sulphuret of antimony near Keith; and more recently mines of hæmatite were opened near Arndilly on the Spey.

The manufactures of Banffshire are very unimportant, the inhabitants being principally engaged in agriculture and the rearing of cattle. The salmon-fishery is actively prosecuted on the rivers, and herring and other fisheries on the coast. Distilling is largely carried on in Glenlivet and other places; and there is a woollen factory at Keith.

Banffshire was the scene of many bloody conflicts between the Scots and their Danish invaders. From 1624 to 1645 it was the theatre of almost incessant struggles, and the Covenanting troubles of that period, combined with the frequent conflicts of the clans, were productive of serious evils. Several remains of antiquity are pointed out in different parts of the country, such as the sculptured stone at Mortlach, and the churches of Cullen and Fordyce. Ruins of castles and traces of encampments are often to be met with, and a great number of cairns and tumuli are also found. Among the distinguished men whom Banffshire has produced, the following may be mentioned:—Archbishop Sharp of St. Andrews; George Baird, distinguished for his services as sheriff of the county during the time of the Covenanters; Thomas Ruddiman, the grammarian; Walter Goodall, the defender of Mary Queen of Scots; Dr. Alexander Geddes; and James Ferguson, the astronomer.

BANGALORE, the administrative capital and most important town of the chief commissionership of Mysore, also a large military cantonment, is now one of the handsomest English stations in India, with noble public buildings, spacious and artistically laid out gardens, broad smooth roads, well-supervised bazaars, and a good water supply. The markets display almost every sort of English and Indian fruit or vegetable. Bangalore forms the residence of the chief commissioner of Mysore and the principal officers of his administration, and is well worthy of its place as the political and military capital of the province. Population (1890), 200,000.

BANGKOK, a city of Siam, which was raised to the rank of capital in 1769. It is situated on both sides of the River Menam, about 20 miles from the sea. The river is navigable to the city for vessels of 350 tons, but there is a bar at its mouth, which at the lowest ebbs has only six feet of water, and at no time has more than fourteen. The general appearance of Bangkok is very striking, alike from its extent, the strange architecture of its more important buildings, and the luxuriant greenness of the trees with which it is profusely interspersed. The streets are in many cases traversed by canals, and the houses raised on piles, while a large part of the population dwell in floating houses moored along the river sides in tiers three or four deep. The nucleus of the city on the eastern bank is surrounded by a wall 30

feet high, and 10 or 12 feet thick, relieved by numerous towers and bastions ; but the rest of the city stretches irregularly for full seven miles along each side of the river, and in some places attains nearly as great a breadth,— the Menam itself being about a quarter of a mile across. In all there are upwards of a hundred temples in the city and suburbs. The palace of the "First King" is inclosed in high white walls, which are about a mile in circumference. It consists of a large number of different buildings for various purposes — temples, public offices, seraglios, the stalls for the sacred elephant, and accommodation for thousands of soldiers, cavalry, artillery, and war elephants, an arsenal, a theatre, &c. The hall of audience, in which the throne of the king stands, is situated in the middle of the principal court. The temples are of great richness, floored with mats of silver, and stored with monuments and relics. In one of them is a famous jasper statue of Buddha. The population of the city is of various nationalities,— Burmese, Peguans, Cambodians, Cochin-Chinese, Malays, Indo-Portuguese, and others, besides the two predominant classes, the Chinese and Siamese. There is great commercial activity, the principal articles of trade being sugar, pepper, and rice. The population is said to amount to 400,000.

BANGOR, a parliamentary borough and market-town of Carnarvonshire, North Wales, nine miles N.E. of Carnarvon, to which it is a contributory borough. Population of burgh in 1889, 11,000.

BANGOR, a seaport and market-town of Ireland, county Down, on the south side of Belfast Lough, twelve miles east-northeast of Belfast. Population, 2,560.

BANGOR, a seaport-town in the State of Maine, and the county seat of the county of Penobscot, on the river of that name, at its junction with the Kenduskeag, 60 miles from the sea. It was incorporated as a town in 1791, and raised to the rank of a city in 1834. The harbor is spacious, and affords anchorage for the largest vessels at high tide. The chief article of trade is timber, which employs about 2000 ships annually; and there are saw-mills, planing-mills, ship-yards, foundries, and manufactories of furniture. There are numerous good schools arranged on a graduated scale, and churches of about ten different denominations. A theological seminary belonging to the Congregationalists was founded in 1816. A library, instituted in 1843, has upward of 11,000 volumes. Population in 1890, 19,090.

BANGWEOLO (also called Bemba), a great Central African lake, discovered by Livingstone in 1868, which is 150 miles long by 75 in width, and 3,700 feet above the sea.

BANIALUKA, a town and fortress of Turkey, in the eyalet of Bosnia, situated on the Verbas or Verbitza, a navigable tributary of the Save. Its warm baths, for which it is still known, would seem, from the antiquities discovered on the spot, to have been frequented by the Romans. There are upwards of forty mosques in th town, and one of them is regarded as the finest in Turkey. In 1688 it was captured for the Austrians by Louis of Baden. Population, 15,000.

BANIM, JOHN, an Irish novelist of great power and ability, was born at Kilkenny in 1798. He received a good education, and at a very early age gave evidence of remarkable genius. In his thirteenth year he entered Kilkenny College. He published a poem, *The Celt's Paradise*, and had some success as a writer for the stage. During a short visit to Kilkenny he married, and at the same time planned, in conjunction with his brother Michael (born 1796), a series of tales illustrative of Irish life. He then set out for London, the great centre of literary activity, and supported himself by writing for magazines and for the stage. A volume of miscellaneous essays was published anonymously in 1824, called *Revelations of the Dead Alive*. In April, 1825, appeared the first series of *Tales of the O'Hara Family*, which achieved immediate and decided success. One of the most powerful of them, *Crohoore of the Bill Hook*, was by Michael Banim. In 1826 a second series was published, containing what is decidedly one of the best Irish novels, *The Nowlans*. His last piece of literary work was the novel entitled *Father Connell*. He died in July, 1842, aged 44. Banim's true place in literature is to be estimated from the merits of the *O'Hara Tales;* his later works, though of considerable ability, are not unfrequently prolix, and are marked by too evident an imitation of the *Waverly Novels*. The *Tales*, however, show him at his best; they are masterpieces of faithful delineation. The strong passions, the lights and shadows of Irish peasant character, have rarely been so ably and truly depicted. The prevailing quality is a wonderful vehemence, combined with gloominess.

BANJARMASSIN, a district in the south-east of Borneo, which was incorporated by the Dutch in consequence of the war of 1860, in regard to the succession in the sultanate, which had been under their protection since 1787. It is watered by the river system of the Banjar, and traversed by a chain of mountains that in some places reaches the height of 3000 feet. The district has been divided by the Dutch into the residency of Kween and the sub-residencies of Amuntal and Martapura. The town of Martapura was the seat of the sultan from 1771. The principal productions of the district are gold, diamonds, coal, pepper and other spices, drugs, edible birds' nests, gum, wax, rattans, &c. The inland portion is covered with forest, while the flat and swampy seaboard is largely occupied by rice-fields. The inhabitants, who are for the most part Dayaks, are roughly estimated from 300,000 to 600,000.

BENJARMASSIN, the chief town of the above district, also known as Fort Tatas, is situated about 15 miles from the mouth of the Banjar. Population, 30,000.

BANJO (originally a mere negro mispronunciation of *bandore*, derived through the medium of Spanish or Portuguese, from Lat. *pandura*, Gr. *pandoura*, a three-stringed musical instrument), an instrument of the guitar kind, played with the fingers, but without frets to guide the stopping.

BANKING. A bank, in its simplest form, is an institution where money may be deposited for safe keeping; but banks are usually established to lend as well as to receive money; and the profits of a banker are commonly derived from the excess of the interest he receives from those indebted to him over the interest he allows, so far as he allows any to those who have deposited money with him. Early denunciations of usury (Exod. xxii. 25) show the antiquity of the practice of lending money at interest; but this must have long preceded the origin of the business of both borrowing and lending money. When this first appeared it was not, at least in modern Europe, a distinct profession, but was undertaken by goldsmiths and dealers in precious metals. In the progress of the separation of employments, which is a characteristic of an advancing society, banking became a business of its own, which has again been subdivided into many branches independently pursued. It was, for example, formerly generally allowed to be part of the business of a banker to borrow money by issuing promissory notes payable to bearer, which passed from hand to hand as money, within the sphere of the operations of the banks, and banks thus borrowing money were called *Banks of Issue;* but it has been contended of late years that the function of issuing notes passing by delivery as money

should be reserved for the state, or for some institution controlled and directed by the state; and we shall have hereafter to notice the controversy that has arisen on this point, and the steps that have been taken in consequence of it. An explanation of the different species of banks will also properly be deferred till a later stage, but it will be convenient here to give a general sketch of the nature of the business of an ordinary banker. We have said he receives and lends money; he may receive money either on a deposit or on a current or drawing account. When money is received on deposit it is commonly repayable to the depositor alone, to whom a deposit note or receipt is given; but it may also be paid to any one to whom the depositor gives an order on the bank either endorsed on the deposit note or receipt or accompanying it. If the banker undertakes to pay interest on deposits, the rate varies according to the length of the notice the depositor agrees to give before withdrawing the money, the ability of the banker to deal with it being, of course, dependent upon the time he may rely upon keeping it. When money is received on a current or drawing account, the customer of the banker draws it out, as he requires, by means of orders, to which the specific name cheques is given; and partly for convenience and partly by way of security against fraud, bankers are in the habit of giving their customers books of forms of cheques consecutively numbered. Cheques are generally payable to the person in whose favor they are drawn (the payee) or bearer, though they are sometimes payable to the payee or order, in which case endorsement by the payee is necessary before the money can be received.

Bankers lend money by opening credits in their books, against which their favored customers may draw to the extent of the credits opened; by discounting bills; by the purchase of securities; or by advancing money on securities, &c., &c. It will have been gathered that they also undertake the business of collecting the money for cheques, for bills, and for other securities as they mature, which they may have received from their customers. The labor of collection is much facilitated in England by the fact that bills of exchange are almost invariably made payable in London, and that every country banker has a correspondent among the London bankers who collects for him and pays for him; and the London bankers again maintain an establishment called the Clearing-house, where their clerks meet to effect their interchanges.

Banking appears to have reached a high state of development among the ancients. The bankers of Greece and Rome exercised nearly the same functions as those of the present day, except that they do not appear to have issued notes. They received money on deposit, to be repaid on demands made by cheques or orders, or at some stipulated period, sometimes paying interest for it, and sometimes not. Their profits arose from their lending the balance at their disposal at higher rates of interest than they allowed the depositors. They were also extensively employed in valuing and exchanging foreign moneys for those of Athens, Corinth, Rome, &c., and in negotiating bills of exchange. In general they were highly esteemed, and great confidence was placed in their integrity. The rate of interest charged by the bankers was sometimes very high, but that was not a consequence, as has been alleged, of their rapacity, but of the defective state of the law, which, as it gave every facility to debtors disposed to evade payment of their debts, obliged the bankers to guarantee themselves by charging a proportionately high rate of interest. Banking reappeared in Italy upon the revival of civilisation. The bank of Venice is reputed the first in date in the history of modern Europe; but it did not become a bank, as we understand the term, till long after its foundation. Historians inform us that the republic being hard pressed for money, was obliged, upon three different occasions, in 1156, 1480, and 1510, to levy forced contributions upon the citizens, giving them in return perpetual annuities at certain rates per cent. The annuities due under the forced loan of 1156 were, however, finally extinguished in the 16th century; and the offices for the payment of the annuities due under the other two loans having been consolidated, eventually became the bank of Venice. This might be effected as follows:—The interest on the loan to Government being paid punctually, every claim registered in the books of the office would be considered as a productive capital; and these claims, the right of receiving the annuity accruing thereon, must soon have been transferred, by demise or cession, from one person to another. This practice would naturally suggest to holders of stock the simple and easy method of discharging their mutual debts by transfers on the office books, and as soon as they became sensible of the advantages to be derived from this method of accounting, bank-money was invented. It will, however, be seen that the establishment thus described was at first no more than the transfer office of a National Debt, transfers of which were accepted at par in discharge of private debts, and it is indeed said that the funded debt transferred sometimes commanded an agio or premium above the current money of the republic. This establishment was ruined, after passing through many changes, by the invasion of the French in 1797.

The origin of modern banking may be traced to the money-dealers of Florence, who were in high repute as receivers on deposit and lenders of money in the 14th century; and banking was indeed practised at Florence in the 13th if not in the 12th century.

The business of banking was not introduced into England till the 17th century, when it began to be undertaken by goldsmiths in London, who appear to have borrowed it from Holland. It was attacked, as innovations commonly are.

The Bank of England, which has long been the principal bank of deposit and circulation in Great Britain, and indeed in Europe, was founded in 1694. Its principal projector, Mr. William Paterson, an intelligent Scotch gentleman, was afterwards engaged in the ill-fated Darien enterprise. Government being at the time much distressed for want of money, partly from the defects and abuses in the system of taxation, and partly from the difficulty of borrowing because of the supposed instability of the Revolutionary establishment, the bank grew out of a loan of £1,200,000 for the public service. The subscribers, besides receiving 8 per cent. on the sum advanced as interest, and £4000 a year as the expense of management, in all £100,000 a year, were incorporated into a society denominated the Governor and Company of the Bank of England. The charter is dated the 27th of July 1694. It declares, amongst other things, that they shall "be capable, in law, to purchase, enjoy, and retain to them and their successors, any moneys, lands, rents, tenements, and possessions whatsoever; and to purchase and acquire all sorts of goods and chattels whatsoever, wherein they are not restrained by Act of Parliment; and also to grant, demise, and dispose of the same.

"That the management and government of the corporation be committed to the governor and twenty-four directors, who shall be elected between the 25th of March and the 25th day of April each year, from among the members of the company duly qualified.

"That no dividend shall at any time be made by the said governor and company, save only out of the interest,

profit, or produce arising by or out of the said capital, stock, or fund, or by such dealing as is allowed by Act of Parliament.

"They must be natural-born subjects of England, or naturalised subjects; they shall have in their own name, and for their own use, severally, viz., the governor at least £4000, the deputy governor £3000, and each director £2000, of the capital stock of the said corporation.

"That thirteen or more of the said governors and directors (of which the governor or deputy-governor must be always one) shall constitute a court of directors, for the management of the affairs of the company, and for the appointment of all agents and servants which may be necessary, paying them such salaries as they may consider reasonable.

"Every elector must have, in his own name and for his own use, £500 or more capital stock, and can only give one vote. He must, if required by any member present, take the oath of stock, or the declaration of stock in case he may be one of the people called Quakers.

"Four general courts shall be held in every year, in the months of September, December, April, and July. A general court may be summoned at any time, upon the requisition of nine proprietors duly qualified as electors. The majority of electors in general courts have the power to make and constitute bye-laws and ordinances for the government of the corporation, provided that such bye-laws and ordinances be not repugnant to the laws of the kingdom, and be confirmed and approved according to the statutes in such case made and provided."

The corporation is prohibited from engaging in any sort of commercial undertaking other than dealing in bills of exchange, and in gold and silver. It is authorised to advance money upon the security of goods or merchandise pledged to it, and to sell by public auction such goods as are not redeemed within a specified time.

It was also enacted, in the same year in which the bank was established, by statute 6 William and Mary, c. 20, that the bank "shall not deal in any goods, wares, or merchandise (except bullion), or purchase any lands or revenues belonging to the Crown, or advance or lend to their majesties, their heirs or successors, any sum or sums of money, by way of loan or anticipation on any part or parts, branch or branches, fund or funds of the revenue, now granted or belonging, or hereafter to be granted, to their majesties, their heirs and successors, other than such fund or funds, part or parts, branch or branches of the said revenue only on which a credit of loan is or shall be granted by Parliament." And in 1697 it was enacted, that the "common capital or principal stock, and also the real fund, of the governor and company, or any profit or produce to be made thereof, or arising thereby, shall be exempted from any rates, taxes, assessments, or impositions whatsoever during the continuance of the bank; that all the profit, benefit, and advantage from time to time arising out of the management of the said corporation, shall be applied to the uses of all the members of the said association of the governor and company of the Bank of England, rateably and in proportion to each member's part, share, and interest in the common capital and principal stock of the said governor and company hereby established."

In 1696, during the great recoinage, the bank was involved in great difficulties and was even compelled to suspend payment of its notes, which were at a heavy discount. Owing, however, to the judicious conduct of the directors, and the assistance of the Government, the bank got over the crisis. But it was at the same time judged expedient, in order to place it in a situation the better to withstand any adverse circumstances that might afterwards occur, to increase the capital from £1,200,000 to £2,201,171. In 1708 the directors undertook to pay off and cancel one million and a half of exchequer bills they had circulating two years before, at 4½ per cent., with the interest upon them, amounting in all to £1,775,028, which increased the permanent debt due by the public to the bank, including £400,000 then advanced in consideration of the renewal of the charter, to £3,375,028, for which they were allowed 6 per cent. The bank capital was then also doubled or increased to £4,402,342. But the year 1708, is chiefly memorable in the history of the bank, for the Act previously alluded to, which declared, that during the continuance of the corporation of the Bank of England, "it should not be lawful for any body politic, erected or to be erected, other than the said governor and company of the Bank of England, or of any other persons whatsoever, united or to be united in covenants or partnership, exceeding the number of six persons, in that part of Great Britain called England, to borrow, owe, or take up any sum or sums of money on their bills or notes payable on demand, or in any less time than six months from the borrowing thereof." This proviso is said to have been elicited by the Mine Adventurers Company having commenced banking business and begun to issue notes. It will be seen on examination that the proviso did not prohibit the formation of associations for general banking business; it simple forbade the issue of notes by associations of more than six partners; but the issue of notes was regarded as so essential to the business of banking, that it came to be believed that joint-stock banking associations were absolutely prohibited in England, and no such association was founded until after the legislation of 1826 which expressly permitted them to be established. The charter of the Bank of England, when first granted, was to continue for eleven years certain, or till a year's notice after the 1st of August 1705. The charter was further prolonged in 1697. In 1708, the bank, having advanced £400,000 for the public service, without interest, the exclusive privileges of the corporation were prolonged till 1733. And in consequence of various advances made at different times, the exclusive privileges of the bank were continued by successive renewals till the 1st August, 1855, with the proviso that they might be cancelled on a year's notice to that effect being given after the said 1st of August 1855.

The capital of the bank on which dividends are paid has never exactly coincided with, though it has seldom differed very materially from, the permanent advance by the bank to the public. We have already seen that it amounted in 1708 to £4,402,342. Between that year and 1727 it had increased to near £9,000,000. In 1746 it amounted to £10,780,000. From this period it underwent no change till 1782, when it was increased 8 per cent., amounting to £11,642,400. It continued stationary at this sum down to 1816, when it was raised to £14,553,000, by an addition of 25 per cent. from the profits of the bank, under the provisions of the Act 56 Geo. III. c. 96. The act for the renewal of the charter 3 and 4 Will. IV. c. 98, directed that the sum of £3,671,700, being the fourth part of the debt due by the public to the bank, should be paid to the latter, giving the bank the option of deducting it from its capital. But that has not been done; and after sundry changes, the capital of the bank amounts, as formerly, to £14,553,000.

The Bank of England has been frequently affected by panics amongst the holders of her notes. In 1745 the alarm occasioned by the advance of the Highlanders, under the Pretender, as far as Derby, led to a run upon

the bank; and in order to gain time to effect measures for averting the run, the directors adopted the device of paying in shillings and sixpences! But they derived a more effectual relief from the retreat of the Highlanders, and from a resolution agreed to at a meeting of the principal merchants and traders of the city, and very numerously signed, declaring the willingness of the subscribers to receive bank-notes in payment of any sum that might be due to them, and pledging themselves to use their utmost endeavors to make all their payments in the same medium.

During the tremendous riots in June 1780, the bank incurred considerable danger. Had the mob attacked the establishment at the commencement of the riots, the consequences might have proved fatal. But they delayed their attack till time had been afforded for providing a force sufficient to insure its safety. Since that period a considerable military force occupies the bank every night as a protection in any emergency that may occur.

Different Species of Banks — The Clearing-house — Authorisation of Banks with Limited Liabilities.

We have elsewhere hinted at the subdivision of the business of banking which has accompanied the development of commerce. A banker borrows and lends money, but the conditions under which money is borrowed or lent may be extremely various, and the different classes of bankers are distinguished from one another by differences in the rules which they observe in borrowing or lending. Bankers may borrow money on call, at deposit, on debentures, at interest, or without interest, and they may lend on open credits, by discounting bills, by advances on mortgage repayable in instalments or otherwise, &c., &c.

Banks of Deposit.—These banks receive money on deposit, that is to say, on conditions that a certain prescribed notice shall be given of the time of withdrawal. They allow interest, and they usually lend a large proportion of their money on securities which are not at any moment immediately capable of being realised.

Land Mortgage Banks may be classed with banks of deposit, but they are also accustomed to borrow on debentures repayable at the end of one, two, three, or a larger number of years, at rates of interest varying with the period of the debenture. These institutions were first started for the purpose of granting facilities to the mortgagers of land. The money received on debentures was lent out again to proprietors and purchasers of land, who repaid their debts by annual instalments. It was in this way that the legislation of Stein was facilitated in Germany; the peasant being able to obtain at once from the Land Mortgage Bank the capital necessary to redeem the feudal rights of his lord, a debt which he repaid by a series of annual payments often corresponding to what he had previously paid as rent, until he became an absolute unincumbered owner of the fields he cultivated.

Credit Companies, such as the *Crédit Foncier*, the *Crédit Mobilier*, &c., &c., are strictly analogous to land mortgage banks, except that they invest their funds in loans on the security of general industrial undertakings, to which business they have added the function of negotiators of direct loans between companies formed for the conduct of such undertakings and the capitalist public.

Discount Banks and *Discount Agencies* borrow money on call or deposit, and lend it exclusively in the discount of bills and negotiable securities, which they often rediscount with capitalists desirous of investing their money in forms capable of being speedily realised.

Trust Associations borrow money on debentures and invest it in the loans of foreign states or similar securities,—the principle of such an association being that the original investor can be secured against the default of any one borrower by the receipt of a high average rate of interest and the general solvency of the rest.

Savings-Banks are institutions established for the receipt of the smaller savings of the poor. As at present existing they are divided into two classes, the Trustees' Savings-banks and the Post Office Savings-banks; but it seems probable that some rearrangement of their machinery will be made in the next session of Parliament. For further particulars see SAVINGS-BANKS.

Allusion has already been made to the Clearing-house. This institution was established, just a century ago, as a place where the clerks of the bankers in the City of London could assemble daily to exchange with one another the cheques drawn upon and bills payable at their respective houses. Before the Clearing-house existed, each banker had to send a clerk to to the places of business of all the other bankers in London to collect the sums payable by them in respect of cheques and bills; and it is obvious that much time was consumed by this process, which involved also the use of an unnecessary quantity of money and corresponding risks of safe carriage. In 1775 the common centre of exchange was agreed upon. Its use was confined to the bankers,—at that time and long afterward exclusively private bankers,—doing business within the city, and the bankers in the west end of the metropolis used some one or other of the city banks as their agent in clearing, a practice which still continues. When the joint-stock banks were first established the jealousy of the existing banks was powerful enough to exclude them altogether from the use of the Clearing-house; and some years elapsed before this feeling was removed so as to allow them to be admitted.

At first the Clearing-house was simply a place of meeting, but it came to be perceived that the sorting and distribution of cheques and bills could be more expeditiously conducted by the appointment of two or three common clerks, to whom each banker's clerk could give all the instruments of exchange he wished to collect, and from whom he could receive all those payable at his own house. The payment of the balance settled the transaction, and the analysis of the statistics of the Clearing-house by the late Mr. Babbage (*Journ. Statist. Soc.*, March, 1856), shows that the amount of cash that passed was often less than 4 per cent. of the total sums cleared. Latterly, however, the arrangements of the Clearing-house have been further perfected, so that neither notes nor coin are now required. The Clearing-house, as well as each banker using it, has an account at the Bank of England; and the balances due at the close of each day's transactions are settled by transfers from one account to another at the bank.

The use of the Clearing-house was still further extended in 1858, so as to include the settlement of exchanges between the country bankers of England. Before that time each country banker receiving cheques on other country bankers sent them to those other bankers by post (supposing they were not carrying on business in the same place), and requested that the amount should be paid by the London agent of the banker on whom the cheques were drawn to the London agent of the banker remitting them. Cheques were thus collected by correspondence, and each remittance involved a separate payment in London. In 1858 it was proposed to set up a country clearing-house in London; but it was suggested by Sir John Lubbock that the existing establishment could accomplish what was desired, and this was eventually done. A country banker now sends cheques on other country banks to his London correspondent, who exchanges them at the Clearing-house

with the correspondents of the bankers on whom they are drawn. (Sir John Lubbock, *Jour. Statist. Soc.*, Sept. 1865.) It will be easily understood that an extraordinary economy in the use of coin has resulted from these arrangements; and in the paper by Sir John Lubbock to which we have referred, he gives statistics showing that out of the sum of a million paid into the bank in which he is a partner, only £21,500 consists of bank notes and £6,210 of coin. An ordinary weekly clearing varies from 100 to 130 millions; in 1868 the weekly average was, however, no more than £65,397,075, from which it rose continuously to an average of £116,254,717 in 1873. There was a little falling off in 1874, which is now being recovered.

Up to the year 1858 banking companies could not be constituted with limited liability of partners except by way of privilege under special Acts of Parliament, Royal Charters, or Letters Patent; and although the Bank of England, and the three oldest established banks in Scotland, were thus favored without any consequent deterioration in the character of their management, abundant arguments were adduced in depreciation of a general law in the subject. In 1858, however, an Act was passed authorising the formation and registration of banking companies with limited liability, and also enabling existing unlimited companies to register as associations with a limited liability of partners, subject to a proviso that, if the bank was a bank of issues, the liability of its partners should remain unlimited in respect of such issue. Several banks have been established and registered under this law, and no evil results have been observed to follow.

Present Management of the Bank of England.

When the charter was renewed in 1833, the notes of the Bank of England were made legal tender everywhere in England except at the bank. Of the wisdom of this regulation no doubt can be entertained. Bank-notes are necessarily always equivalent to bullion; and by making them substitutes for coin at country banks, the demand for the latter during periods of alarm or runs is materially diminished, and the stability of the bank and of the pecuniary system of the country proportionally increased.

Since 1826 the bank has established branches in some of the great commercial towns.

The Bank of England transacts the whole business of Government. "She acts not only," says Adam Smith, "as an ordinary bank, but as a great engine of state. She receives and pays the greater part of the annuities which are due to the creditors of the public; she circulates Exchequer bills; and she advances to the Government the annual amount of the land and malt taxes, which are frequently not paid till some years thereafter."

The Bank of England rarely discounts bills that have more than two, or at most three months to run, and it were well were this rule generally observed by other establishments. The discounting of bills at long dates is a powerful stimulus to unsafe speculation. When individuals obtain loans which they are not to be called upon to pay for six, twelve, or perhaps, eighteen months, they are tempted to adventure in speculations which are not expected to be wound up till some proportionally distant period; and as these not unfrequently fail, the consequence is that, when the bills become due, there is commonly little or no provision made for their payment. In such case the discounters to avoid an imminent loss, sometimes consent to renew the bills. But, while a proceeding of this sort is rarely productive of ultimate advantage to either party, the fact of its having taken place makes other adventurers reckon that, in the event of their speculation proving less successful than they anticipated, their bills will be treated in the same manner, and thus agravates and extends the evil.

In other respects, too, the discount of bills at long dates, or their renewal, or the making of permanent loans, is altogether inconsistent with sound banking principles, for it prevents the bankers from having that command over their resources which is advantageous at all times, and indispensable in periods of difficulty or distress.

In the discounting of bills, a great deal of stress is usually laid, or pretended to be laid, on the distinction between those that arise out of real transactions and those that are fictitious or that are intended for accommodation purposes. The former are said to be legitimate, while the latter are stigmatised as illegitimate. But Mr. Thornton has shown that the difference is neither so well marked nor so wide as many suppose. A notion seems to be generally entertained that all real bills are drawn against produce of one sort or other, which (or its value) is supposed to form a fund for their payment. Such, however, is not always, nor even most commonly, the case. A, for example, sells to B certain produce, for which he draws a bill at sixty days' date. But prices are rising, trade is brisk, or a spirit of speculation is afloat, and, in a week or two (sometimes much less), B sells the produce at an advance to C, who thereafter sells it to D, and so on. Hence it may, and, in fact, frequently does happen, that bills amounting to four, five, or even ten times the value of a quantity of merchandise, have grown out of its successive sales, before the first bill of the series has become due. And not only this, but bills are themselves very frequently rediscounted; and in this case the credit of the last indorser is generally the only thing looked to; and there is not, perhaps, one case in ten in which any inquiries are made in regard to the origin and history of the bills, though they are often of the most questionable description.

On the whole, therefore, it would seem that the real or presumed solvency of the parties signing a bill, and responsible for its payment, is the only safe criterion by which to judge whether it should or should not be discounted. But the fact of a merchant or other trader offering accommodation bills for discount ought unquestionably to excite a suspicion that he is trading beyond his capital. Inquiries of the most searching description should forthwith be instituted; and unless satisfactory explanations are given, his paper should be rejected. On the same principle, the offering of bills for rediscount ought to awaken suspicions of the bankers and others who resort to so questionable a mode of carrying on business. But, except in so far as a feeling of distrust may be thus very properly excited, there does not appear to be anything in an accommodation bill *per se* to hinder it from coming within the pale of negotiability. It is a mode of obtaining a loan from a bank; and when the character of the bill is known to the banker, or is openly declared, it does not appear to be an objectionable mode.

Besides bills avowedly intended for accommodation purposes, another and a different variety of such bills is drawn by parties at a distance from each other, often men of straw, and made to appear as if they were bottomed on real transactions. Bills of this sort are, it is greatly to be regretted, always current, and often to a large extent. Of course no person of respectability can be knowingly connected with such bills, which are almost always put in motion either to bolster up some bankrupt concern, or to cheat and defraud the public. But despite the mischief of which they are productive, it appears to be pretty generally supposed that the currency of these bills is an evil which cannot be prevented. There can, however, be no real doubt that it may, at all

events, be very greatly diminished; and this desirable result would be effected were it enacted that all bills shall henceforth bear upon their face what they really are; that those that are intended for accommodation purposes shall have at their head the words "*Accommodation bill;*" and that those only shall bear to be for "value received" that has grown out of *bona fide* transfers of property. An enactment of this sort could not be felt as a grievance by any one unless he had a fraudulent purpose in view. And were the impressing of a false character on a bill made a criminal offence, punishable by several years' imprisonment, there is every probability that a formidable check would be given to the issue of spurious bills, and to the manifold abuses to which the practice gives rise.

Bill-discounters who have got fictitious paper on their hands and attempt to get rid of it by concealing its character or representing it in a favorable light make themselves parties to the fraud. Such conduct is so very flagitious, that when it can be fairly brought home to the parties it should subject them to the severest penalties.

The Bank of England does not allow, either at the head office in London, or at its branches, any interest on deposits, and many plausible reasons have been advanced in defence of this rule.

Previously to 1786 the bank received an allowance for paying the dividends, superintending the transfer of the stock, &c., of the national debt, at the rate of £562, 10s. a million on its amount. In 1786 this allowance was reduced to £450 a million, the bank being, at the same time, entitled to a considerable allowance for its trouble in receiving contributions on loans, lotteries, &c. This, though long regarded as a very improvident arrangement on the part of the public, was acquiesced in till 1808, when the allowance on account of management was reduced to £300 per million on £600,000,000 of the public debt, and to £300 per million on all that it exceeded that sum, exclusive of some separate allowances for annuities, &c. The impression, however, was still entertained that the allowances for management should be further reduced, and this has been effected in the interim.

Exclusive of its functions as public banker and manager of the public debt, the Bank of England is connected with Government through the circulation. It is entitled to issue the sum of £15,000,000 upon securities, that is, on the credit of the funds lent to Government. But for these the bank receives about 3 per cent. interest, and such being the case, the public is clearly entitled to a portion, if not to the whole amount of the profits realised by the bank on the issue of these £15,000,000. It is difficult to say how much this ought to be. The issue department of the bank seldom re-issues notes, but for the most part destroys them as soon as they are returned to it. This practice is said to be necessary to enable the bank to obviate fraud, by keeping a proper account of the numbers of the notes afloat. An opinion is, however, pretty generally entertained that this might be effected by a less expensive process than that which is now resorted to. And certainly, it seems to be a very wasteful proceeding, that a quantity of newly manufactured notes issued by the bank in the forenoon, and returned to her in the afternoon, should not be re-issued, but consigned to the flames. The Scotch banks are justly censurable for keeping their notes too long afloat, but this is running with a vengeance into the opposite extreme.

In 1861 a fresh arrangement was made between the Government and the bank, to endure for 25 years. Under this agreement the bank receives £300 per million on £600,000,000, and £150 per million on the amount of debt above that sum; but from these allowances are deducted £60,000 for exemption from stamp duties and the whole allowance out of profit of issue, making together nearly £200,000.

It should be observed that the responsibility and expense incurred by the bank, in managing the public debt, are very great. The temptation to the commission of fraud, in transferring stock from one individual to another, and in the payment of the dividends, is well known; and notwithstanding the skilfully devised system of checks adopted by the bank for preventing this, it has frequently sustained very great losses by forgery and otherwise. In 1803 the bank lost, through a fraud committed by one of the principal cashiers, Mr. Astlett, no less than £340,000; and the forgeries of Fauntleroy, the banker, cost it a still larger sum. At an average of the ten years ending with 1831, the bank lost, through forgeries on the public funds, £40,204 a year.—*Report on Bank Charter, Appen.* p. 165.

Besides the transactions alluded to, the bank entered, on the 20th of March 1823, into an engagement with Government with respect to the public pensions and annuities, or, as they have been more commonly termed, the *dead weight.* At the end of the war, the naval and military pensions, superannuated allowances, &c., amounted to above £5,000,000 a year. They would, of course, have been gradually lessened, and ultimately extinguished, by the death of the parties; but it was resolved in 1822 to attempt to spread the burden equally over the whole period of *forty-five* years, during which it was calculated the annuities would continue to decrease. To effect this purpose, it was supposed that, upon Government offering to pay £2,800,000 a year for forty-five years, capitalists would be found who would undertake to pay the entire annuities, according to a graduated scale previously determined upon, making the first year a payment of £4,900,000, and gradually decreasing the payments until the forty-fifth and last year, when they were to amount to only £300,000. This supposition was not, however, realised. No capitalists were found willing to enter into such distant engagements. But in 1823, the bank agreed, on condition of receiving an annuity of £585,740 for *forty-four* years, commencing on the 5th of April 1823, to pay, on account of the pensions, &c., at different specified periods, between the years 1823 and 1828, both inclusive, the sum of £13,089,419.—(4 Geo. IV. c. 22.) This annuity has, in due course of time, expired.

Formerly the business transacted at the bank was so much encumbered with forms and conditions, that the generality of merchants and ordinary people rarely thought of employing it to keep their money or make their payments. But in this respect an entire change has been effected. Cheques, the minimum amount of which was formerly £10, may now be drawn of any amount, great or small; and all sorts of banking business is conducted with facility and despatch, and, it may be added, with perfect security.

The bank opens banking accounts, or, as they are called, "drawing accounts," for the safe custody, and the receipt and payment of cash, not only with merchants and traders, but with all persons who choose to keep their money at a banker's and to draw cheques against it. The bank also takes charge of its customers' bills of exchange, Exchequer bills, and other securities, and does all that is needful either in the collection of bills of exchange, the exchange of Exchequer bills, the receipt of dividends, and so forth, free of any charge. Plate chests, and deed and security boxes, may be deposited free of expense, by customers, for safe custody. The bank looks to the average balance of cash on each account to compensate for the trouble and expense of

keeping it, and in this respect the requirements of the bank are certainly not greater than those of ordinary bankers. No particular sum is required to be lodged on opening an account; it is only necessary that the party should be known as respectable, and in a condition to require a banking account. But the bank receives and holds sums of money for safe custody for parties who have no current accounts.

Scotch Banks.

The Act of 1708, preventing more than six individuals from entering into a partnership for carrying on the business of banking, did not extend to Scotland. In consequence of this exemption, several banking companies, with numerous bodies of partners, have existed, for a lengthened period, in that part of the empire.

The Bank of Scotland was projected by Mr. John Holland, merchant, of London, and was established by Act of the Scotch Parliament in 1695, by the name of the Governor and Company of the Bank of Scotland. Its original capital was £1,200,000 Scotch, or £100,000 sterling, distributed in shares of £1000 Scotch, or £83, 6s. 8d. sterling, each. The Act exempted the capital of the bank from all public burdens, and gave it the exclusive privilege of banking in Scotland for twenty-one years. The objects for which the bank was instituted, and its mode of management, were intended to be, and have been, in most respects, similar to those of the Bank of England. The responsibility of the shareholders is limited to the amount of their shares. The capital of the bank was increased to £200,000 in 1774, and was enlarged by subsequent Acts of Parliament, the last of which (44 Geo. III. c. 23) was passed in 1804, to £1,500,000, its present amount. Of this sum £1,000,000 has been paid up. The last-mentioned Act directed that all sums relating to the affairs of the bank should henceforth be rated in sterling money; that the former mode of dividing bank stock by shares should be discontinued; and that, for the future, it should be transferable in sums or parcels of any amount. On the union of the two kingdoms in 1707, the Bank of Scotland undertook the recoinage, and effected the exchange of the currency in Scotland. It was also the organ of Government in the issue of the new silver coinage in 1817.

The Bank of Scotland is the only Scotch bank constituted by Act of Parliament. It began to establish branches in 1696, and issued notes for one pound as early as 1704. The bank also began, at a very early period, to receive deposits on interest, and to grant credit on cash accounts, a minute of the directors with respect to the mode of keeping the latter being dated as far back as 1729. It is, therefore, entitled to the credit of having introduced and set on foot the distinctive principles of the Scotch banking system, which, whatever may be its defects, is perhaps superior to most other systems hitherto established. Generally speaking, the Bank of Scotland has been cautiously and skillfully conducted; and there can be no doubt that it has been productive, both directly and as an example to other banking establishments, of much public utility and advantage.

It may be worth mentioning, that the Act of Will. III. establishing the Bank of Scotland, declared that all foreigners who became partners in the bank should by doing so become, to all intents and purposes, naturalised Scotchmen. After being for a long time forgotten, this clause was taken advantage of in 1818, when several aliens acquired property in the bank in order to secure the benefit of naturalisation. But after being suspended, the privilege was finally cancelled in 1822.

The *Royal Bank of Scotland* was established in 1727. Its original capital of £151,000 has been increased to £2,000,000.

The *British Linen Company* was incorporated in 1746, for the purpose, as its name implies, of undertaking the manufacture of linen. But the views in which it originated were speedily abandoned, and it became a banking company only. Its capital amounts to £1,000,000.

None of the other banking companies established in Scotland are chartered associations with limited responsibility, the partners being liable, to the whole extent of their fortunes, for the debts of the firms. The number of partners is in every case considerable. The affairs of the banks are uniformly conducted by a board of directors, annually chosen by the shareholders.

The Bank of Scotland began, as already stated, to issue £1 notes so early as 1704, and their issue has since been continued without interruption. "In Scotland," to use the statement given in the Report of the Committee of the House of Commons of 1826 on the Promissory Notes of Scotland and Ireland, "the issue of promissory notes payable to the bearer on demand, for a sum not less than 20s., has been at all times permitted by law; nor has any Act been passed limiting the period for which such issue shall continue legal in that country."

All the Scotch banks receive deposits of as low a value as £10, and often lower, and allow interest upon them.

The interest allowed by the banks upon deposits varies, from time to time, according to the variations in the current rate of interest. The aggregate amount of the sums deposited with the Scotch banks in 1874–5 is stated to be £78,401,070.

A witness, connected for many years with different banks in Scotland, and who had experience of their concerns at Stirling, Edinburgh, Perth, Aberdeen and Glasgow, being examined by the Commons' Committee of 1826, stated that more than half the deposits in the banks with which he had been connected were in sums from £10 to £200. Being asked what class of the community it is that makes the small deposits, he gave the following answer,— from which it appears that the mode of conducting this branch of the bank business in Scotland has long given to that country most part of the benefits derivable from the establishment of savings-banks:—

Answer.— They are generally the laboring classes in towns like Glasgow; in country places like Perth and Aberdeen, it is from servants and fishermen, and that class of the community who save small sums from their earnings, till they come to be a bank deposit. There is now a facility for their placing money in the Provident Banks, which receive money till the deposit amounts to £10. When it comes to £10 it is equal to the minimum of a bank deposit. The system of banking in Scotland is an extension of the Provident Bank system.

The loans or advances made by the Scotch banks are either in the shape of discounts, or upon cash-credits, or, as they are more commonly termed, *cash accounts.*

A cash-credit is a credit given to an individual by a banking company for a limited sum, seldom under £100 or £200, upon his own security, and that of two or three individuals approved by the bank, who become sureties for its payment. The individual who has obtained such a credit is enabled to draw the whole sum, or any part of it, when he pleases, replacing it, or portions of it, according as he finds it convenient, interest being charged upon such part only as he draws out. "If a man borrows £5000 from a private hand, besides that it is not always to be found when required, he pays interest for

it whether he be using it or not. His bank credit costs him nothing, except during the moment it is of service to him, and this circumstance is of equal advantage as if he had borrowed money at a much lower rate of interest" (Hume's *Essay on Balance of Trade*). This, then, is plainly one of the most commodious forms in which advances can be made. Cash-credits are not, however, intended to be *dead loans;* and they are not granted except to persons in business, or to those who are frequently drawing out and paying in money.

The system of cash-credits has been very well described in the Report of the Lords' Committee of 1826 on Scotch and Irish Banking.

The expense of a bond for a cash-credit of £500 is 12s. 6d. stamp duty, and a charge of from 5s. to 10s. 6d. per cent. for preparing it.

There have been, on the whole, comparatively few failures among the Scotch banks. In 1793 and 1825, when so many of the English banks were swept off, there was not a single establishment in Scotland that gave way. This superior solidity appears to have been owing to various causes,—partly to the banks having, for the most part, large bodies of partners, who, being conjointly and individually bound for the debts of the companies to which they belong, go far to render their ultimate security all but unquestionable, and partly to the facility afforded by the law of Scotland of attaching a debtor's property, whether it consists of land or movables, and making it available for the payment of his debts.

But, on the whole, we are inclined to think that the long familiarity of the inhabitants with banks and paper money, and the less risk that has attended the business of banking in Scotland, have been the principal causes of the greater stability of the Scotch banks. This stability was not, however, everywhere exhibited in the crisis of 1857, when two of the principal Scotch banks, the headquarters of which were in Glasgow, were compelled to stop payments.

A complaint has been often raised that the Act of 1845 gave the existing Scotch banks a practical monopoly of the business of banking in North Britain, and it must be admitted to be the fact, that only one new bank has been established in Scotland since the passing of the Act, and that bank carried on business for a short time only. It is, however, true that legislation precisely the same has not prevented the establishment of new banks in Ireland, and it is doubtful whether the observed fact is rightly attributed to the cause assigned to it. With the exception of London, and some of the larger provincial towns, there have been very few banks established in England since 1836, eight years before the Bank Charter Act; and of the banks established in 1835 and 1836, very many were formed by the conversion of pre-existing private banks into joint-stock associations. The truth appears to be that the natural obstacles to the establishment of a new bank in a district already occupied by banks and bankers are almost insuperable. A bank cannot be successful unless it commands credit; and those who want a place of safe keeping for their money select establishments that have been tried and tested through long years. Hence it appears that, though private banks of long standing continue in esteem, the attempts to set up new private banks are most rare; and, unless the wealth and prosperity of a neighborhood have rapidly developed, so that capitalists have risen to prominence in it who are not connected as shareholders or directors with existing banks, it is not easy to form joint stock associations of weight enough to compete with the institutions in possession of the field. It is not necessary to refer the absence of new banking companies in Scotland or elsewhere to the legislation of Sir Robert Peel. Though he allowed the Scotch banks to increase indefinitely the issue of their notes, it was upon condition of keeping in hand cash to represent every note above fixed limits; so that the amount of profit derivable from their issues is not capable of increase, and the value of their privileges will have been strictly included in the selling price of shares in these banks since 1845. As far as the privilege of issue goes capitalists preparing to start a new banking association in Scotland would be in the same position as in buying shares in an established company; and if they do not start an association of their own, it is from the difficulty of attracting confidence, rather than because they would not enjoy the profits of a privileged circulation for which they would have to pay a full value. It must also be observed that the competition among the existing banks is sufficiently active to have caused them to increase the number of their branches 40 per cent. since 1845.

Another question has been raised in relation to Scotch banks, which was the subject of a keen parliamentary discussion during the past session (1875). It has been mentioned that English joint-stock banks of issue are debarred from setting up branches in London, or within sixty-five miles of it, a prohibition originally imposed on them in the interest of the Bank of England as a bank of issue. There is no such prohibition affecting Scotch and Irish banks, which can set up offices in London, or elsewhere in England subject to the single condition affecting all banking establishments set up in England since 1844, that notes other than Bank of England notes are not issued at such offices; and it is obvious that a Scotch or Irish banking company establishing a head office in London would be able to give it at once a large agency business, and would be able to feed it continuously with new connections owing to the flow of immigration from Scotland and Ireland to London. Accordingly, the Directors of the National Bank of Ireland began to conduct the general business of banking at their head office in London in 1854, and they have subsequently set up seven or eight branches in the metropolis, each of which is understood to be the centre of much business. This example was so far followed, that the National Bank of Scotland started an office in London in 1864; the Bank of Scotland did the same in 1867; and the Royal Bank in 1874, having attained a private act for the purpose. The Clydesdale Bank also opened three branches in Cumberland in 1874. In consequence of this action Mr. Goschen brought into Parliament a bill, the object of which was to disable Scotch banks from coming into England, as English joint-stock banks of issue are disabled from coming to London. The bill did not extend to Irish banks, as they were held too firmly settled in the metropolis to be expelled from it. Two arguments were advanced in favor of this measure: the first, that it was hard that Scotch banks should be permitted to do that which is denied to English joint-stock banks; but it is an easy, and, it would seem, a conclusive answer to this argument, that English joint-stock banks of issue should be freed from the disability now imposed upon them. Now that an increase in its issue is not a measure of profit to the Bank of England, there is no reason why these country banks of England should not be allowed to set up head offices in London, subject to the law forbidding the issue of their notes in London. The second argument in favor of Mr. Goschen's measure was, that something ought to be done to hasten that unification of issues which Sir Robert Peel contemplated; and if the Scotch banks had come to Parliament asking for a liberty they did not possess, there would have been some plausibility in this argument. It

is to be feared that the whole strength of the support to Mr. Goschen's bill sprang from the jealousy of the existing bankers of London of any intrusion into their domain. Unworthy as this source of opposition was, it prevailed so far as to cause the appointment of a Select Committee of the House of Commons to consider the law and practice of banking, and this Committee's report appeared in August, 1875, and has formed the basis of subsequent legislation.

Banking in Ireland.

"In no country, perhaps," says Sir Henry Parnell, "has the issuing of paper money been carried to such an injurious excess as in Ireland. A national bank was established in 1783, with similar privileges to those of the Bank of England in respect to the restriction of more than six partners in a bank, and the injury that Ireland has sustained from the repeated failure of banks may be mainly attributed to this defective regulation. Had the trade of banking been left as free in Ireland as in Scotland, the want of paper money that would have arisen with the progress of trade would in all probability have been supplied by joint-stock companies, supported with large capitals and governed by wise and effectual rules.

"In 1797, when the Bank of England suspended its payments, the same privilege was extended to Ireland; and after this period the issues of the Bank of Ireland were rapidly increased. In 1797 the amount of the notes of the Bank of Ireland in circulation was £621,917; in 1810, £2,266,471; and in 1814, £2,986,999.

"These increased issues led to corresponding increased issues by the private banks, of which the number was fifty in 1804. The consequence of this increase of paper was its great depreciation; the price of bullion and guineas arose to 10 per cent. above the mint price; and the exchange with London became as high as 18 per cent., the par being 8⅓. This unfavorable exchange was afterwards corrected, not by any reduction in the issues of the Bank of Ireland, but by the depreciation of the British currency in the year 1810, when the exchange between London and Dublin settled again at about par.

"The loss that Ireland has sustained by the failure of banks may be described in a few words. It appears, by the Report of the Committee on Irish Exchanges in 1804, that there were, at that time, in Ireland fifty registered banks. Since that year a great many more have been established, but the whole have failed, one after the other, involving the country from time to time in immense distress, with the following exceptions—First, a few that withdrew from business; secondly, four banks in Dublin; thirdly, three at Belfast; and, lastly, one at Mallow. These eight banks, with the new Provincial Bank and the Bank of Ireland, are the only banks now (1827) existing in Ireland."

Since Sir Henry Parnell published the pamphlet from which we have taken the foregoing extract, several joint-stock banking companies have been founded in Ireland. The Provincial Bank, to which Sir Henry alludes, has a paid up capital of £540,000, and has been well and profitably managed. But others have been less fortunate. The Agricultural and Commercial Bank of Ireland, established in 1834, with 2170 partners, a paid up capital of £352,790, and many branches, stopped payment during the pressure in November 1836, and by doing so involved many persons in great distress. It appears to have been extremely ill-managed. The auditors appointed to examine into its affairs reported—"Its book-keeping has been found to be so faulty, that we are convinced no accurate balance-sheet could at any time have been constructed." And they significantly added—"the personal accounts at the head office require a diligent and searching revision."

The Tipperary Joint-Stock Bank, which was established in 1839, and stopped payments in 1855, appears to have been little, if at all, better than a mere swindling engine. Luckily it did not issue notes; and the sphere of its operations was not very extensive. But, so far as influence went, nothing could be worse, being ruinous alike to the majority of its partners and to the public.

We have in the previous section on Scotch banks mentioned the fact of the establishment by the National Bank of Ireland of a head office and of several branches in London. This example has been so far followed by the Provincial Bank that it has also set up a head office in London, without, however, competing for general business in the metropolis. An addition was made to the number of Irish banks in 1864 by the establishment of the Munster Bank (Limited), having its head office in Cork. It has established upwards of 40 branches, and pays a dividend of 12 per cent. to its shareholders.

Bank of Amsterdam.

The Bank of Amsterdám was founded in 1609, on strictly commercial principles and views, and not to afford any assistance, or to intermeddle with the finances of the state. Amsterdam was then the great entrepôt of the commerce of the world, and of course the coins of all Europe passed current in it. Many of them, however, were so worn and defaced as to reduce their general average value to about 9 per cent. less than their mint value; and, in consequence, the new coins were immediately melted down and exported. The currency of the city was thus exposed to great fluctuations; and it was chiefly to remedy this inconvience and to fix the value or par of the current money of the country, that the merchants of Amsterdam established a "bank," on the model of that of Venice. Its first capital was formed of Spanish ducats or ducatoons, a silver coin which Spain had struck in the war with Holland, and with which the tide of commerce had enriched the country it was formed to overthrow. The bank afterwards accepted the coins of all countries, worn or new, at their intrinsic value, and made its own bank-money payable in standard coin of the country, of full weight, deducting a "brassage" for the expense of coinage, and giving a credit on its books, or "bank-money," for the deposits.

The Bank of Amsterdam professed not to lend out any part of the specie entrusted to its keeping, but to retain in its coffers all that was inscribed on its books. In 1672, when Louis XIV. penetrated to Utrecht, almost every one who had an account with the bank demanded his deposit, and these were paid off so readily that no suspicion could exist as to the fidelity of the administration. Many of the coins then brought forth bore marks of the conflagration which happened at the Hôtel de Ville, soon after the establishment of the bank. This good faith was maintained till about the middle of last century, when the managers secretly lent part of their bullion to the East India Company and Government. The usual "oaths of office" were taken by a religious magistracy, or rather by the magistracy of a religious community, that all was safe, and the good people of Holland believed, as an article of their creed, that every florin which circulated as bank-money had its metallic constituent in the treasury of the bank, sealed up, and secured by oaths, honesty, and good policy. This blind confidence was dissipated in December 1790, by a declaration that the bank would retain 10 per cent. of all deposits, and would return none of a less amount than 2500 florins.

Even this was submitted to and forgiven. But, four

years afterwards, on the invasion of the French, the bank was obliged to declare that it had advanced to the States of Holland and West Friesland, and the East India Company, more than 10,500,000 florins, which sum it was, of course, unable to make up to the depositors, to whom, however, it assigned its claims on the states and the company. Bank-money, which previously bore an agio of 5 per cent. immediately fell to 16 per cent. below current money.

This epoch marked the fall of an institution which had long enjoyed an unlimited credit and had rendered the greatest services. The amount of treasure in the vaults of the bank, in 1775, was estimated by Mr. Hope at 33,000,000 florins.

The Bank of France.

This bank, second in magnitude and importance to the Bank of England only, was originally founded in 1800, but was not placed on a solid and well-defined basis till 1806. Its capital, which was originally fixed at 45,000,000 fr., was raised in the last-mentioned year to 90,000,000 fr., divided into 90,000 shares or *actions*, of 1000 fr. each. Of these shares, 67,900 have passed into the hands of the public; the remaining 22,100, having been purchased up by the bank out of its surplus profits, were subsequently cancelled. Hence its capital amounted, down to 1848, to 67,900,000 fr. (£2,716,000), with a reserve fund, first of 10,000,000 fr., and more recently of 12,980,750 fr. Since 1806 the bank has enjoyed the privilege of being the only institution in Paris entitled to issue notes payable on demand; and, as will be afterwards seen, it is now the only authorized issuer of such paper in France. Its charter and exclusive privileges have been prolonged and varied by laws passed at different periods.

The bank has established, at different periods since 1817, offices or branches (*succursales*) in different parts of the country. They are managed nearly in the same way as the parent establishment; but their operations were long on a comparatively small scale. These are exclusive of the departmental banks united, as will be immediately seen, to the bank in 1848.

Notwithstanding the skill and caution with which its affairs have generally been conducted, the revolution of 1848 brought the bank into a situation of extreme danger. It had to make large advances to the Provisional Government and the city of Paris. And these circumstances, combined with the distrust that was universally prevalent, occasioned so severe a drain upon the bank for gold, that to prevent the total exhaustion of its coffers, it was authorized, by a decree of the 16th March 1848, to suspend cash payments, its notes being at the same time made legal tender. But to prevent the abuse that might otherwise have taken place under the suspension, the maximum amount of its issues was fixed at 350 millions. The bank was then also authorized to reduce the value of its notes from 500 fr. to 200 and 100 fr.

Previously to 1848, joint-stock banks, on the model of that of Paris, and issuing notes, had been established in Lyons, Marseilles, Bordeaux, Rouen, and other large cities. And it was then determined that these banks should be incorporated with the Bank of France, and made branches of the latter. This was effected by decrees issued on the 27th April and 2d May 1848, by which the shareholders of the banks referred to (nine in number) were allowed, for every 1000 fr. nominal value of their shares, a share of 1000 fr. nominal value of the stock of the Bank of France. And, in consequence of this measure, 23,351 new shares, representing a capital of 23,351,000 fr., were added to the stock of the Bank of France, making the latter consist of 91,250 fr divided into 91,250 shares. In 1851 the bank resumed specie payments.

The suppression of the local issues of the departmental banks was, no doubt, a judicious measure, and was indispensable, indeed, to secure the equal value of the paper circulating in different parts of the country. This, however, might have been effected by the mere stoppage of the issues of the departmental banks, without consolidating them with the Bank of France. The latter measure is one of which the policy is very questionable; and there are, as already seen, good grounds for thinking that the banking business of the departments would have been more likely to be well conducted by local associations, than by branches of the Bank of France. Constant additions have been made to the number of branches, which now exceeds seventy.

Owing to the war with Russia, and still more to the rage for speculation, and the drain for silver to the East that followed it, the Bank of France became exposed to considerable difficulties. And in the view of strengthening its position, and also, it may be presumed, of providing a loan for Government, a law was passed (9th June 1857), by which the capital of the bank was increased from 91,250 shares of 1000 fr. each to 182,500 shares of 1000 fr. each. The new shares were assigned to the existing proprietors at the rate of 1100 fr. per share, producing a total sum of 100,375,000 fr., of which 100 millions were lent to Government at 3 per cent. Hence the measure, though it added to the credit and security of the bank, made no addition to the means directly at its disposal.

Down to the passing of this law, the bank could not raise the rate of interest on loans and discounts above 6 per cent. But this impolitic restriction was removed, and the bank authorized to charge any rate of interest which she reckoned expedient, except upon advances to Government, the maximum interest on which was limited to 3 per cent. The bank was further authorized to issue notes of the value of 50 fr., to make advances on railway shares, &c., and the charter was extended to 1897.

The management of the Bank of France was severely tried in the latter part of 1864 by the occurrence of a financial crisis at Paris; and in January 1865 a commission of inquiry was appointed to examine into the principles and practice of banking. There was, however, nothing mysterious or exceptional in the experience of 1864. Speculation had been much stimulated in France by the establishment of companies (Crédit Foncier, Crédit Mobilier, &c.,|&c.) for the undertaking of public works, and much capital was locked up and more pledged towards the completion of enterprises supposed at first to be highly profitable, but in reality offering a distant and doubtful promise of remuneration. The crisis of 1864 was the dissipation of these delusions, and the voluminous publication of evidence and opinion by the commission of inquiry produced no practical consequences.

The war of 1870-71 could not but have an important influence on the operations of the bank. Successive Governments resorted to it for assistance, which was obtained by increasing the issue of its notes and by giving them a forced currency. The rate of interest, which had been 2½ per cent. from May 1867, rapidly rose to 6 and 6½, at which it remained with scarcely any variation from 9th August 1870 till late in the year 1872. The rate would probably have risen much higher, but on the 13th August a law was approved suspending the liability of the acceptors of bills current to meet them at maturity, and this suspension was renewed until it was finally withdrawn in July 1871. The amount of unpaid bills held by the bank reached a maximum of 368 millions of francs, but the ultimate loss was extremely

small. On the 23d June 1870 the metallic reserve at the bank was 1318½ millions of francs, which was reduced to a minimum of 505 millions on the 24th December of the same year. The notes in circulation before the war had been about 1400 millions of francs; but before the end of the year 1870 their volume had increased to 1700 millions; and this again rose to 2000 millions before July 1871, and to 2400 millions before the end of 1871. A law of the 29th December 1871 fixed the maximum at 2800 millions, which was finally raised on 15th July 1872 to a maximum of 3200 millions. The debt of the state to the bank increased concurrently with this increase of issues, which was, indeed, authorized for the purpose of enabling the bank to assist the treasury. On the 26th December 1870 the bank held treasury "bons" to the extent of 174,800,000 francs only, but on the 30th November 1871 it held 1,193,600,000 of these "bons," and in August 1872 the amount reached 1,363,100,000 francs. A law of the 21st June 1871, followed by an agreement between the bank and the Government, provided for the repayment of this debt in annual payments of 200 millions, but up to this time (August 1875) the income of the state has never been large enough to provide the whole of this sinking fund. The bank has, however, been able to increase its metallic reserve through the liquidation of securities and the accumulation of deposits; so that, after having been reduced, as we have said, to 505 millions in December 1870, and not attaining to more than 634 millions in December 1871, it rose in the same month of 1872 to 793 millions, in 1873 to 820 millions, and in 1874 to 1331, or just the amount at which it stood before the declaration of war. Its volume has, however, continued to increase, and on the 25th March of this year (1875) it stood at 1528 millions; and the forced currency of the notes of the bank might be at any time withdrawn. It must be admitted that the management of the bank throughout these years of difficulty has been eminently prudent and successful.

The bank is obliged to open a *compte courant* for any one who requires it, and performs services, for those who have such accounts, similar to those performed for their customers by the banks in London. The bank does not charge any commission on current accounts, so that its only remuneration arises from the use of the money placed in its hands by the individuals whose payments it makes. It is probable, therefore, as has been alleged, that this part of the business is but little profitable. The bank also discounts bills with three signatures at variable dates, but not having more than three months or ninety days to run. Besides discounting bills, the bank makes advances on stocks and pledges of various kinds, and undertakes the care of valuable articles, such as plate, jewels, title-deeds, &c., at a charge of ⅛ per cent. on the value of the deposit for every period of six months and under.

The administration of the bank is vested in a council of twenty-one members, viz., a governor and two sub-governors, nominated by the chief of the state, and fifteen directors and three censors, nominated by the shareholders. The bank has a large surplus capital or rest. In 1848 the dividends only amounted to 75 fr. per share. In 1855 and 1856 they were 200 and 272 fr. on each share. In 1870 they fell to 114 fr., but rose again to 300 fr. in 1871, and to 320 fr. in 1872. In July 1856 the 1000 fr. share of bank-stock was worth 4075 fr.; in July 1857 it had sunk to 2880 fr.

Banking in the United States.

Before the late Civil War it had been the uniform practice of the different States of the Union to allow banks to be established for the issue of notes, payable in specie on demand. In cases where the liability of shareholders in banks was to be limited to the amount of their shares, they had, previously to 1838, to be established by Acts of the local legislatures; but, in general, these were easily obtained, and it may be said that banking was quite free, and that, practically, all individuals or associations might issue notes, provided they abided by the rules laid down for their guidance, and engaged to pay them when presented.

Under this system the changes in the amount and value of the paper currency of the United States were greater than in any other country, and it produced an unprecedented amount of bankruptcy and ruin.

Between 1811 and 1820, about 195 banks, in different parts of the Union, became bankrupt; and it is said, in a report by the Secretary of the Treasury of the United States, dated 12th May 1820, that these failures, which mostly happened in 1814 and 1819, produced a state of distress so general and severe that few examples of the like had then occurred.

But bad as this instance was, it was nothing to that which took place subsequently to 1834. The accounts of the aggregate issues of the banks differ a little, but the following statement is believed to be very nearly accurate, viz:—

Years.	Notes.
1830	$ 66,628,898
1834	94,839,570
1835	103,692,495
1836	140,310,638
1837	149,185,890

Now observe, that this sudden and enormous increase took place under the obligation which we are told is quite enough to prevent all abuse of paying notes on demand. The result was what most men of sense must have anticipated, viz., that a revulsion took place, and that every bank within the Union, without, it is believed, a single exception, stopped payment in 1837.

In 1838 such of the banks as had been best managed and had the largest capitals resumed payment in specie. But in 1839 and 1840 a farther crash took place; and the bank-notes afloat, which, as has been seen, amounted to $149,185,890 in 1837, sunk to $83,734,000 in 1842, and to $58,563,000 in 1843. It is supposed that in this latter crash nearly 180 banks, including the Bank of the United States, were totally destroyed. And the loss occasioned, by the depreciation which it caused in the value of stock of all kinds and of all sorts of property, was quite enormous. And yet, vast as the loss was, it was really trifling, as a writer in the *American Almanack* has stated, compared with "the injury resulting to society from the upheaving it occasioned of the elements of social order, and the utter demoralization of men by the irresistible temptation to speculation which it afforded, ending in swindling to retain ill-gotten riches."

The evils of the American system were aggravated by the lowness of the notes which most banks issued. This brought them into the hands of retail traders, laborers, and others in the humbler walks of life, who always suffer severely by the failure of a bank.

After 1838 and 1842 various measures were taken in nearly all the States, but principally in New York, to restrain the free action of the banks, and to prevent a repetition of the calamities referred to.

In New York, for example, banks were divided into two great classes—the incorporated and the free banks. The former, incorporated by the State law, had to conform to certain regulations, and to contribute a half per cent. annually upon their capital to a security fund, which was devoted to the payment of the notes of de-

faulting banks. But this was a most objectionable plan; for, in the first place, it did not prevent bankruptcies, and in the second place, it compelled the well-managed banks to contribute to a fund which went to pay the debts of those that were mismanaged. It consequently declined in favor, and soon became rarely acted upon.

In the other or free banking system, all individuals or associations who chose to deposit securities (minimum amount, $100,000) for their payment were allowed to issue an equal amount of notes. And this was certainly by far the more efficient as well as the more popular of the two plans. It was, however, not free from objection; because, 1*st*, A longer or shorter, but always a considerable, period necessarily elapses after a bank stops before its notes can be retired; and, 2*d*, The securities lodged for the notes were necessarily at all times of uncertain and fluctuating value, while, in periods of panic or general distrust, they became all but inconvertible. The Sub-Secretary of the Treasury of the United States animadverted as follows on this plan, in a letter dated 27th Nov. 1854:—

"The policy of many of the State Governments has of late years consisted in encouraging the issue of small notes, by sanctioning the establishment of what are popularly called 'free banks,' with deposits of stocks and mortgages for the 'ultimate' security of their issues. This 'ultimate' security is, it may be admitted, better than no security at all. The mischief is, that it is least available when most wanted. The very causes which prevent the banks from redeeming their issues promptly, cause a fall in the value of the stocks and mortgages on 'the ultimate security' of which their notes have been issued. The 'ultimate' security may avail something to the broker who buys them at a discount, and can hold them for months or years; but the laboring man who has notes of these 'State security banks' in his possession, finds, when they stop payment, that 'the ultimate security' for their redemption does not prevent his losing twenty-five cents, fifty cents, or even seventy-five cents in the dollar.

"In a circulating medium we want something more than 'ultimate security.' We want also 'immediate' security; we want security that is good to-day, and will be good to-morrow, and the next day, and for ever thereafter. This security is found in gold and silver, and in these only."

The Report of the Superintendent of Banking for the State of New York for 1856 showed that the securities he then held in trust amounted to $39,359,071, which were almost wholly lodged by banking associations and individual bankers.

During the year the securities held in trust for the undermentioned banks that had become insolvent in 1855 were disposed of. But the sums realized by their sale did not in any case suffice to pay the notes at par; while a period, varying from two to four years, would have to elapse before the affairs of the insolvent banks were finally settled.

This statement set the defective nature of the security system, as administered in New York, in the clearest point of view. It might, no doubt, have been improved by increasing the proportion of securities to notes. But, owing to the variety of securities that were taken (viz., all manner of bonds and mortgages, state, canal, and railway stocks, &c., &c.), and the uncertainty of their value, a great deal of risk was always incurred in accepting them, and they could never form a proper foundation on which to issue notes.

In 1857 another crash took place, and *all* the banks in the Union, from the Gulf of Mexico to the frontiers of Canada, again stopped payments.

There had been a rapid increase of discounts since 1851, and that increase was especially great in 1856, and went on augmenting down to August 1857. On the 8th of that month the discounts and advances by the New York banks amounted to $122,077,252, the deposits in their possession being, at the same time, $94,436,417. This was the maximum of both. On the 24th of August the Ohio Life and Trust Company, which carried on an extensive banking business in New York, stopped payments, and by so doing gave a severe shock to credit and confidence, which the suspension of two or three more banks turned into a panic. Notes being in a certain degree secured, the run upon the banks was principally for deposits. And to meet it they so reduced their discounts and advances, that, on the 17th October, they amounted to only $97,245,826. This sudden and violent contraction necessarily occasioned the suspension of many of those mercantile houses that had depended on the banks for discounts. And it did this without stopping the drain for deposits, which had sunk, on the 17th October, to $52,894,623, being a decrease of $41,546,784 in about two months. The universal stoppage of the banks was a consequence of these proceedings.

The Civil War had as one of its consequences the introduction of a general banking law in the United States, conformable in many respects to the principles of what we have described as the free banking law of New York. At the beginning of the war in 1861, the amount of paper money in circulation was about $200,000,000, of which $150,000,000 had been issued in the loyal States; and the coin in circulation was estimated at $275,000,000. The necessities of the Treasury very soon compelled the Government to borrow from the associated banks of New York, Philadelphia, and Boston, and to issue demand notes to the extent of $50,000,000,—which, however, were not at first made legal tender. In February 1862 an Act was passed by Congress authorizing the issue of $150,000,000, in Treasury notes of not less than $5 each, out of which, however, $50,000,000 were in lieu of the notes already issued; and this issue was declared to be legal tender except in the discharge of customs, duties, and of the payment of interest by the United States on the national debt. It will be easily understood that coin went out of circulation, and a premium on gold was established, which increased as the amount of the Treasury notes was increased by successive legislation and as national bank-notes came to be issued in pursuance of the law we must proceed to describe. This is the Banking Law of the 25th February 1863, which, as amended by the Act of the 3d June 1864, now continues in force. By this law a Currency Bureau and Comptroller of Currency were appointed in the Treasury Department, with the power to authorize banking associations of not less than five persons subscribing, except in very small towns, a minimum capital of $100,000, 50 per cent. to be paid up at once, and the remainder within six months. It was enacted that any such association, before commencing business, must transfer to the Treasurer of the United States any United States interest-bearing bonds not less than one-third of the capital stock, and should thereupon receive from the Comptroller of the Currency circulating notes of different denominations in blank, registered and countersigned, equal in amount to 90 per cent. of the current market value of the bonds so transferred, but not exceeding their par value. The whole amount of notes thus issued was not to exceed $300,000,000, one-half to be apportioned among the States according to their representative population, and the other half to be apportioned with regard to the existing banking capital, resources, and business of the States

The banks already existing in the several States were rapidly transformed into national banks under the operation of this law, and their previous notes withdrawn in exchange for the new national bank issue. The currency of the Union thus came to consist of the demand-notes of the Treasury, which rose in 1865 to about $450,000,000, and of the notes of the national banks, which rapidly approached the limit of $300,000,000,—the latter notes passing throughout the Union, whatever the bank through which they were issued, as freely as the former, since the ultimate payment of them was secured by the deposit under the law we have stated, of an adequate amount in United States' bonds at the Treasury. It is not our purpose to trace the subsequent financial history of the States, but the experience of 1873 must be referred to for the instruction it affords. As no sufficient steps were taken after the termination of the war to reduce the swollen value of the currency, gold remained out of circulation, though with the growth of business the premium on it declined to an average rate of 12 per cent.; but no inconvenience was felt from the existence of a pure paper circulation, and the opinion, in fact, arose that the currency thus established was a sure preventive of recurring panics and exaggerated rates of discount. But in September 1873 the financial house of Jay, Cooke, & Co., having locked up a large amount of capital in railway enterprises not immediately if ever likely to be productive, suspended payments; other financial houses were forced to take the same step, several banks closed their doors, and a severe panic set in. The holders of the notes in circulation of the banks that failed were protected by the deposit of bonds at the Treasury, and the notes were never discredited ; but the financial distress throughout the Union was excessive, and continued for many months. It was practically demonstrated that the national bank law protected the holders of national bank-notes from loss, but afforded no immunity against the occurrence of financial crises. See article on UNITED STATES.

BANKRUPTCY. When a person is unable to pay his debts in full, the law of civilized countries adopts some means of satisfying the creditors, as far as they can be satisfied, out of the debtor's estate, and relieving the debtor himself from pressure which, by his own efforts, he would not be likely to overcome. The debtor having been declared a bankrupt, his property vests in his creditors for the purpose of being ratably divided among them, and he thereupon starts a new man, entirely relieved from the obligations thus partially satisfied. Such, in general terms, is the process of bankruptcy as observed in modern societies, slowly evolved out of the criminal code in answer to the necessities of a widely-spread industrial life. The slow development of the law, and the practical difficulties with which each new adjustment was met, are copiously illustrated by the history of bankruptcy legislation in England. The first English statute on bankruptcy was directed against *fraudulent debtors*, and gave power to the lord chancellor and other high officers to seize their estates and divide them among the creditors.

Since that time there have been a great many revisions of the bankruptcy laws. The most important changes made were the abolition of the distinction between bankruptcy and insolvency and of imprisonment for debt.

In the United States, Congress alone has power to pass a bankruptcy law which shall have authority throughout the country. The several states may enact such statutes when there is no law of Congress in operation, but these statutes will fully bind only the citizens of the state which enacts them. There is no power to obtain effectual control of property without its limits so as to prevent local preferences; nor can the state laws discharge contracts due to non-residents. The general government has made so little use of the power confided to it, that many of the states were obliged to pass bankruptcy laws, notwithstanding the imperfection of their operation in some cases, and those, often, the most important of the interests involved. Massachusetts had an excellent system, established in 1838, which is especially mentioned because the act of Congress was largely drawn from this source. All state laws on the subject were suspended while a general law of bankruptcy was in force.

The first general Bankrupt Act was passed in 1800, and repealed in 1803. In 1841 another law was put in operation, with a special view of meeting the urgent needs of debtors who had been ruined by the commercial revulsion of 1837-38, and who could receive no effectual relief from the local laws. The act was repealed in thirteen months; but in the meantime a very large number of cases had been disposed of, amounting, for example, to 3,250 in Massachusetts alone. The law last in operation took effect June 1, 1867. It was hoped by its authors that it would form a permanent addition to the commercial jurisprudence of the country, but in 1878 it was repealed. We append a synopsis of the insolvency and assignment laws of all the states and territories.

Alabama.—Every general assignment made by a debtor, by which a preference or priority of payment is given to one or more creditors over the remaining creditors of the grantor, shall be and inure to the benefit of all the creditors of the grantor equally. All assignments by a debtor made with intent to hinder, delay, or defraud creditors, is void.

Arizona.—A general assignment by insolvent debtor must be recorded, have annexed an inventory, under oath, of all creditors, their residence, sum and consideration due each, how evidenced, with statement of debtors' entire estate, giving values. Insolvent may make assignments for benefit of such creditors only as will accept their *pro rata* in discharge of all liability.

Arkansas.—Assignments for the benefit of creditors may be made with or without preference. Assignee must give bond in double the amount of property assigned, and must sell within 120 days, at auction, all the property assigned to him for the payment of debts. Proof of fraud on the part of assignor is sufficient to invalidate the assignment, whether the assignee knew of it or not.

California.—No assignment of an insolvent debtor is valid except in conformity with the Civil Code sections 3,449-73, as amended in 1889.

Colorado.—A general assignment may be made for benefit of creditors. Deed of assignment to be recorded where assignor resides. Deed of non-resident to be recorded where principal business is carried on. Assignor to attach inventory under oath, giving name of creditors and the amount of their respective demands. Deed for benefit of all creditors, whose consent will be presumed.

Connecticut.—Voluntary assignments in insolvency can be made by any debtor to a trustee of his own selection, subject to the substitution of another by the probate court, if deemed proper. Assigning debtor must lodge with court of probate, within five days after assignment, a list verified under oath of his creditors and schedule of his property. A creditor for over $100, having brought suit and finding no property to attach, may apply to the probate court for the appointment of a trustee in insolvency of the debtor's estate. A hearing is had, and, if the petition is granted, trustee takes all debtor's estate not exempt; and all incomplete levies or

attachments on mesne process commenced within sixty days previous are dissolved.

Delaware.—There is a domestic insolvent law, providing for full surrender and equal distribution of all property, but it is very seldom used, and there is no provision in the act for the discharge of the debtor upon his making an assignment. The assignee must file a schedule of property assigned within thirty days, and two appraisers are then appointed by the chancellor. Assignments must be for the benefit of all creditors alike.

District of Columbia.—There is no insolvent law in force. Debtors may assign their property for the benefit of creditors, with or without preferences. No bond is required of the assignee, and no provision is made for the discharge of an insolvent debtor unless the debt are paid in full. No exception is made in favor of employes or servant for salaries or wages due them.

Florida.—Assignments by insolvents are provided for by law. Preferences are not allowed. All property, except that which is exempt, must be surrendered to the assignee. Assignee gives bond and winds up estate. The assignment releases debtor from all debts made prior to the assignment.

Georgia.—A debtor may prefer one creditor to another, and may create a *bona fide* lien, by mortgage or other legal means, may sell in payment of the debt, or transfer papers as collateral security. But every assignment made by a debtor insolvent at the time, either in trust or in behalf of creditors, is fraudulent and null and void, when any trust or benefit is reserved to the assignor, or any person for him. There is no imprisonment for debt.

Idaho.—An insolvent debtor may be discharged of his debts by executing an assignment of all his property, real and personal, which, with a sworn inventory of property, and schedule of creditors, must be filed in court. At a creditors' meeting, held after thirty days' notice given, one or more assignees, not exceeding three, are appointed, and claims proved. Court will set aside property exempt, and issue order for direct payment of money, where no mortgage or pledge had been given, or where such security, if given, has been rendered nugatory by act of defendant.

Illinois.—The county court has jurisdiction in cases of voluntary assignment for the benefit of creditors, which assignment must be duly acknowledged and recorded in the county where the assignor resides, or where the business has been carried on, and in the county or counties where land embraced in the assignment is situate. Assignee must file bond, inventory and valuation, and send notice by mail to creditors of whom he shall be informed, to present claims under oath, within three months from publication of notice. Claims not so presented do not participate in dividends until after the payment in full of all claims properly presented and allowed. Assignee is required to make equal dividends among creditors at the first term of court after the three months allowed, and to render a final account within one year.

Indiana.—Any debtor in embarrassed or failing circumstances, may make a general assignment of all property in trust for benefit of all *bona fide* creditors. To be valid this must be by indenture duly signed and acknowledged, and filed with the recorder of the county in which assignor resides, for record within ten days after the execution thereof. Indenture to contain full description of real estate and be accompanied by schedule of personal property, and assignor to make oath that the indenture and schedule contains a full statement of all his property, etc. Trustee makes oath and files bond in circuit court, and must file copy of assignment, etc., in office of clerk of that court within fifteen days after execution of indenture. Trustee named failing to act, court may appoint a substitute upon petition.

Indian Territory.—There is no provision.

Iowa.—No insolvent law. Assignments not valid unless for benefit of all creditors, when assent of creditors is presumed. Debtor must furnish sworn inventory and list of creditors; and the assignment, which vests in the assignee title to all property of the debtor, must be recorded. Assignee must give bonds, prepare an inventory and valuation, and notify creditors by mail to file claims within three months. All claims not filed within three months after notice published can not be paid until all claims filed within said three months are paid.

Kansas.—Assignments must be for benefit of all creditors, and do not discharge the debtor. Must be executed and recorded like conveyances of real property. Creditors (above ten dollars) are notified by clerk of district court, and at the meeting held for choice of assignee a majority of such creditors must be present, otherwise appointment rests with the court. Creditors who fail to appear are precluded.

Kentucky.—There are two statutory provisions on the subject of insolvency. First. Any assignment, mortgage sale, judgment, or other device resorted to by a debtor in contemplation of insolvency and with a design to prefer one or more creditors, if assailed by petition, filed within six months after the transfer is recorded, shall inure as a general assignment of all the debtor's effects for the equal benefit of all creditors. Second. Assignees must give bond with surety, make an inventory within sixty days, and a report of sales within two years.

Louisiana.—Under the state laws insolvent debtor may make surrender of property to creditors, or an involuntary surrender may be forced by any creditor who shall have issued an execution which is returned unsatisfied. Surrender vests all property of debtor in creditors, and stops all legal proceedings against him. Debtor must file sworn schedules of assets and liabilities. Creditors elect a syndic, who gives bond and manages the estate.

Maine.—Insolvent law applies to residents where debts not less than $300; is voluntary, and where one or more creditors holding one-fourth of provable claims, involuntary; applies also to absconding debtors within six months; assignees elected subject to approval of court, who dispose of property, pay expenses and divide assets, and may be authorized to carry on business. No assignment law; assignment for creditor valid, as at common law, unless avoided by proceedings in insolvency.

Maryland.—A debtor may be declared insolvent upon his own application or upon a petition filed by one or more creditors, the aggregate of whose debts amount to the sum of $250—alleging some of the causes specified in the statute. No preferences are allowed except to employes for wages contracted not more than three months anterior to deed or application in insolvency.

Massachusetts.—The insolvent law is in many respects similar to the United States bankruptcy law repealed in 1878, and has no jurisdiction over debts contracted outside the state, unless the same are proved in the insolvency proceedings. But an assignment to trustee to divide property among creditors can not be avoided by attaching creditor, and only by assignee in insolvency. Any person owing $100 or more may obtain relief; and any creditor may apply within ninety days after commission of act of insolvency for seizure and distribution of estate. Assignee is chosen by majority in value, and may be required to give bond.

Michigan.—Assignments for the benefit of creditors

may be made by any debtor, without preference, and must be of all property of assignor not exempt from execution. Assignee must give approved bond in double the amount of property assigned. The bond, the instrument of assignment, or a duplicate thereof, inventory of the assigned property, and a list of the creditors of the assignor, must be filed with the clerk of the circuit court in the county where the assignor resides, or, if he is not a resident of this state, then in the county where the assignee resides, and if neither are residents of this state, then in the county where the assigned property is principally located. No assignment shall be effectual until such bond shall be executed and filed as above stated and approved by said clerk. No attachment or execution levied upon assigned property after the assignment and before the expiration of the time for filing bond shall be valid.

Minnesota.—Assignments must be in writing, subscribed by debtor or debtors and acknowledged and filed with the Clerk of the District Court in the proper county, within ten days of the levy of an attachment, garnishment, etc. Debtor must file inventory of all property within ten days after filing assignment. Assignee must give bond with two or more sureties to be approved by Judge of District Court in double the amount of property inventoried. Claim must be verified by oath of the party, except claims of the United States or State of Minnesota. Conveyances and payments made by an insolvent debtor within ninety days of insolvency, in contemplation of insolvency, to parties having reasonable cause to believe the debtor to be insolvent, are void, and may be rescinded by the assignee or receiver.

Mississippi.—No insolvent law. Debtor may make assignments to secure creditors and may prefer one creditor over the remainder, but this must be *bona fide.* There is no provision for the discharge of a debtor or his making an assignment.

Missouri.—An insolvent may make a voluntary assignment for the benefit of all creditors, which must contain a statement of the value of his property and his liabilities. Circuit court has supervision of all assignment proceedings, and may appoint an assignee in case of a vacancy in the trust. Debtor is not discharged from his liabilities except by consent of creditors.

Montana.—There is no law relating to assignment or insolvency, except that the wages of miners, mechanics, salesmen, servants, clerks, or laborers, for services rendered within sixty days immediately previous to such assignment, not to exceed $200 for each person, are preferred claims.

Nebraska.—There is no insolvent law. Assignments for benefit of creditors are regulated by act of Feb. 26, 1833. Full authority and jurisdiction is conferred on County Courts to execute and carry out the provisions of the Act. Sheriff of county where assignor resides to be first assignee. Assignment to be filed with County Clerk for record within twenty-four hours after its execution. Within ten days after such assignment, assignor shall file with County Judge a sworn inventory. County Judge to fix a day, not more than fifteen days after receiving such inventory, for meeting of creditors, at his office, to choose assignee to succeed Sheriff.

Nevada.—Insolvent debtors may be discharged from their debts by complying with provisions of insolvent laws. An assignment of insolvent debtor, not in compliance with insolvent laws, is void as to creditors.

New Hampshire.—Assignments for benefit of creditors to be filed in the Probate Court of the county in which debtor resides. Debtor, within ten days thereafter, shall file list of creditors, verified by oath, and within fifteen days a schedule of his property. Wages of clerks, domestics, and other laborers to be paid in full. Debtor given a full discharge from all his debts upon the written approval of three-quarters of his creditors in number and amount, and without such approval upon paying seventy per cent. of his debts.

New Jersey.—The insolvent laws provide for the discharge of a person under arrest for debt or damages on his delivering up all his real and personal property to his creditors. Assignments by debtors for the benefit of creditors must be without preference, and all others are void. Debtor must annex sworn inventory. Wages of clerks, servants and laborers up to $300 each are preferred claims. Assignee must file list of creditors at the end of three months, and make dividends at the next term of court. Creditor not presenting claim does not share in the dividend, but retains his right of action against the debtor.

New Mexico.—Voluntary general assignments may be made for the benefit of creditors. Deed of assignment and inventory must be promptly recorded in the county or counties where the assignor or assignors reside.

New York.—Statutory provisions exist regulating the making of general assignments in trust for the benefit of creditors. Preferences are allowed for the wages or salaries of employés, and to the amount of one-third in value of the assigned estate after deducting such wages or salaries and the cost and expenses of executing the trust. Also, regulating and filing of inventory, the giving of bonds and accounting by the assignee.

North Carolina.—An insolvent debtor may be discharged by filing petition and making assignment of property to a trustee for benefit of all creditors. But his subsequently acquired property (not exempt) is liable for the satisfaction of his debts. No creditor not having received notice is bound by the discharge. Any creditor may suggest fraud, and on fraud or concealment being found by jury, judgment will be that debtor be imprisoned until a full and fair disclosure of all his money, property or effects be made. Voluntary assignments are only good against creditors from registration. A debtor may in an assignment prefer one creditor to another.

North Dakota.—Same as SOUTH DAKOTA. (*q.v.*)

Ohio.—An insolvent debtor may make an assignment in trust for the benefit of creditors. Assignee must, within ten days after delivery of assignment to him, produce the original assignment, or copy thereof, in the Probate Court, file same and enter into a bond in such sum and with such sureties as court shall approve. Assignment made in contemplation of insolvency, with intent to prefer one or more creditors, inures to the benefit of all creditors. Assignment made with intent to hinder, delay or defraud creditors, shall be declared void at the suit of any creditor, and such assignment, after having been declared void, or a preferred assignment, is cause for the appointment of trustee. No assignment shall be construed to include property exempt, unless the exemption is expressly waived.

Oregon.—There is no insolvent law. There is an act governing assignments. No general assignment by an insolvent, or in contemplation of insolvency, for the benefit of all creditors, is valid unless made for the benefit of all creditors in proportion to the amount of their respective claims. The assent of creditors is presumed. The debtor selects his assignee.

Pennsylvania.—A debtor may make a voluntary assignment in trust for the benefit of all creditors, which must be recorded in thirty days. The assignment does not relieve the debtor from the debt. The insolvent laws in cases where imprisonment is still permitted allow a person to be discharged from prison, but do not relieve him from debt.

Rhode Island.—There is no general insolvent law. Assignments for equal benefit of all creditors are allowed; all preferences are void. Any resident debtor whose property, real or personal, is attached may dissolve the attachment by a general assignment for the equal benefit of his creditors.

South Carolina.—An embarrassed debtor may assign his property for the benefit of creditors, who have the right to appoint an agent or agents equal to the number of assignees. The assignment of all his property by a debtor under arrest effects his discharge from such arrest. Only the claims of creditors participating in dividends are affected by these assignments. The debtor, however, can make no preferences or priorities other than as to debts due the public and to such creditors as shall release under the assignment, and all transactions within ninety days before assignment, with a view to give fraudulent preferences, are null and void.

South Dakota.—Insolvent debtor may in good faith make assignment in trust for benefit of creditors which may provide for any subsisting liability of the assignor, whether absolute or contingent. Such assignment is subject to provisions of the code relative to trusts and fraudulent transfers. Any debtor may make assignment without preference of creditors, but is not relieved from liability for any unpaid balance to his creditors.

Tennessee.—No insolvent law. No preferences allowed. Insertion of such clause does not render a general assignment invalid, but *that* clause is nugatory, and all the creditors shall share ratably. General assignment must be accompanied by sworn schedule of assets and liabilities; if not, it is fraudulent and void. A general assignment nullifies all mortgages, etc., of a portion of debtor's property made within three months.

Texas.—A general assignment, by insolvent debtor, must be recorded; have annexed an inventory, under oath, of all creditors; their residence; sum and consideration due each; how evidenced; place created; collateral securities held by creditors; with statement of debtor's entire estate, giving value.

Utah.—Has no statutes on the subject of insolvency or assignments and is governed by the common law.

Vermont.—There is an insolvent law (passed in 1876), but its provisions are of no effect as regards nonresident creditors. The Probate Courts have jurisdiction in insolvency. All assignments must be for the benefit of all creditors.

Virginia.—Has no insolvent laws and no statutory provisions concerning assignments. An insolvent debtor may make a voluntary assignment to a trustee for the benefit of creditors, and may prefer certain creditors to others. Such assignments do not operate as a release.

Washington.—Insolvent debtor may be discharged from debts upon executing an assignment of all his property for benefit of his creditors, if done in good faith and without fraud.

West Virginia.—No insolvent law and no statute regulating assignments in trust for benefit of creditors. Such assignments are sometimes made, but do not operate as a discharge.

Wisconsin.—Assignments for benefit of creditors may be made by an insolvent debtor to such person as the elects, who must give bond in double the nominal value of assets.

Wyoming.—An insolvent debtor may make an assignment in good faith to one or more assignees for satisfaction of creditors. No preference of creditors or payment of false or fraudulent claims is allowed.

BANKS, Sir Joseph, for upward of forty years president of the Royal Society of London, was born in Argyle street, London, February 13, 1743. After taking an honorary degree he left Oxford, and at the age of twenty-one he found himself possessed of ample means, his father having died in 1761. Three years later he made his first scientific expedition to Newfoundland and Labrador, and brought back a rich collection of plants and insects. Shortly after his return, Government resolved to send out Captain Cook to observe the transit of Venus in the Pacific Ocean, and Banks, through the influence of his friend, Lord Sandwich, obtained leave to join the expedition. The voyage occupied three years and many hardships had to be undergone; but the rich harvest of discovery—many natural phenomena being for the first time brought to light—was more than adequate compensation. Banks was equally anxious to join Cook's second expedition, and expended large sums in engaging assistants and furnishing the necessary equipment; but, owing to ill-feeling on the part of some government officials, he was compelled to relinquish his purpose. He, however, employed the assistants and materials he had collected in a voyage to Iceland, returning to the Hebrides and Staffa, the geological formation of which he was the first to describe. In 1778 Banks was elected president of the Royal Society, of which he had been a fellow from 1766. He died March 19, 1820.

BANKURA, a district of British India, within the Bardwan division, under the Lieutenant-Governor of Bengal, bounded on the north and east by Bardwán district; on the south by Midnapur district, and on the west by Mánbhum district. Population, 600,000.

Bankura, the principal town of the district of the same name, stands on the left bank of the river Dhalkisor. It has a bázár, a spacious building for the accommodation of travelers, and the district courts, schools, jail, postoffice, etc. In 1889 the population amounted to 20,000.

BANN, a considerable river of Ireland, which rises in the Mourne Mountains, County Down, and falls into Lough Neagh. The salmon and eel fisheries are of considerable value. Measured in a direct line, the Upper Bann is about thirty-five miles long, and the Lower thirty miles.

BANNERETS. In the early days of chivalry there were two kinds of knights, called respectively *Bachelors* and *Bannerets*. The former carried pennons terminating in a point or points; the latter, banners—that is to say, pennons rendered square by having the points cut off. This process of converting the pennon into the banner was done by the sovereign himself on the field of battle, standing beneath his own royal standard displayed.

BANNOCKBURN, a village of Scotland, on the Bannock, where Bruce defeated the English June 24, 1314.

BANQUETTE, in Fortification, is a raised ledge or step inside the parapet of a rampart, of such a height that musketeers, when standing on it, may be able to fire over the crest of the parapet without too much exposure to the enemy.

BANSHEE, in the folklore of the Irish and Western Highlanders of Scotland, a female fairy who makes herself known by wailings and shrieks, before a death in a family over which she exercises a kind of guardianship. This notion is woven into many folk-tales of rare pathos and beauty. A guardian spirit of the same kind occurs frequently in the folklore of Brittany. The name is supposed to be a phonetic spelling of the Irish *bean sidhe*, old Irish *ben side*, "woman of the fairies."

BANSWARA (literally the forest country), a Rájput feudatory state under the Mewár agency in Rájputáná, borders on Gujarát and is bounded on the north by the native states of Nungarpur and Udaipur or Mewár; on the northeast and east by Pratábgarh; on the south by

the dominions of Holkár and the state of Jubuá, and on the west by the state of Riwákánta. Bánswárá State is about forty-five miles in length from north to south, and 33 miles in breadth from east to west, and has an area of 1,440 square miles, with an estimated population of 144,000 souls. The Mahi is the only river in the state, and great scarcity of water occurs in the dry seasons.

BANTAM, a decayed town of Java, formerly capital of a district of the same name, at the northwestern extremity of the island, situated on the Bay of Bantam, near the mouth of a river which falls into the bay.

BANTRY, a small seaport situated on Bantry Bay, on the southwest coast of Ireland, in the county of Cork.

BANTRY BAY, a deep inlet in the southwestern extremity of Ireland, in County Cork. It is twenty-five miles long, with a breadth of four to six miles. It is one of the finest harbors in Europe, affording safe and commodious anchorage for ships of all sizes. Here a French force attempted to land in 1796.

BANTU (people), a native word applied by Friedrich Müller as an ethnographical name to a large group of African languages and to the people speaking the same. The Bantu races occupy most of Africa from 20° S. latitude to 6° N. latitude northward, and are broadly distinguished from the Negritos and Hottentots to the south and the Soudanese negroes to the north.

BANU, a district of British India, under the Lieutenant-Governor of the Panjáb. Population, 287,547.

BANVILLE, THEODORE DE, a French poet and prose-writer, was born in 1820. His first volume, *Les Caryatides*, issued in 1841, gave him a standing as a poet among the younger members of the Romantic school. He is one of the most musical and sparkling of lyrists; one of the gayest and wittiest of parodists.

BANYAN TREE (*Ficus indica*, Linn., *Urostigma benghalense*, Gaspar.) is a native of several parts of the East Indies and Ceylon. It has a woody stem, branching to a great height and vast extent, with heart-shaped entire leaves terminating in acute points. Every branch from the main body throws out its own roots, at first in small tender fibres, several yards from the ground; but these continually grow thicker until they reach the surface, when they strike in, increase to large trunks, and become parent trees, shooting out new branches from the top, which again in time suspend their roots, and these, swelling into trunks, produce other branches, the growth continuing so long as the earth contributes her sustenance.

BAOBAB (*Adansoniæ digitata*), a magnificent tree belonging to the natural order Sterculiaceæ, also called the Monkey-bread Tree, is a native of tropical Western Africa, but now introduced into the East and West Indies. It is one of the very largest trees—not rising to a great height, but exceeding almost all other trees in the thickness of its trunk (20-30 feet). Even its branches (60-70 feet long) are often as thick as the stems of large trees, and they form a hemispherical head of 120-150 feet in diameter; their outermost boughs drooping to the ground, with large horse-chestnut-like leaves, and huge, white, solitary drooping flowers. The fruit (Monkey-bread) is of the size of a citron.

BAPHOMET, the imaginary symbol or idol which the Knights Templars were accused of worshipping in their secret rites. The term is supposed to be a corruption of *Mahomet*, who in several mediæval Latin poems seems to be called by this name.

BAPTISM. Christian baptism is the sacrament by which a person is initiated into the Christian Church. The word is derived from the Greek, to dip or wash, which is the term used in the New Testament when the sacrament is described. In discussing what is meant by baptism, three things have to be inquired into—(1) the origin of the rite, (2) its meaning, or the doctrine of baptism, and (3) the form of the rite itself.

1. *The Origin of Baptism.*—Christian theologians do not require to go further back than to the New Testament, for there, in the record of our Lord's life, and in the writings of His apostles, they find all that is required to form a basis for their doctrines. But while theologians do not require to go beyond the New Testament for the origin and meaning of baptism, historical investigation cannot help trying to trace analogies to the rite in the Old Testament and even in Pagan history. In the New Testament itself there are two distinct kinds of baptism spoken of—the baptism of John and Christian baptism. Treatises on Jewish antiquities speak of the baptism of proselytes; and St. Paul applies the term baptism to describe certain Old Testament events, and we find in use among Pagan tribes rites resembling Christian baptism. The question arises, what is the relation of Christian baptism to these?

Writers on the antiquities of the Christian church were accustomed to find the source of Christian baptism in the baptism of John, and to assert that John's baptism was simply a universal and symbolical use of the well known ceremony of the baptism of proselytes, and they connected this Jewish rite with Old Testament and even with Pagan lustrations. But this mode of explanation must now be abandoned. It is very difficult to show any real connection between the baptism of John and Christian baptism further than the general relation which all the actions of the forerunner must have had to the Messiah.

The connection between the baptism of John and the Jewish baptism of proselytes, of which a great deal has been made, is also founded on assumptions which cannot be proved. This very plausible theory first assumes that proselytes were baptized from an early time in the Jewish Church, although the Old Testament tells us nothing about it, and then supposes that John simply made use of this ordinary Jewish rite for the purpose of declaring symbolically that the whole Jewish nation were disfranchised, and had to be re-admitted into the spiritual Israel by means of the same ceremony which gave entrance to members of heathen nations. But the subject of the baptism of proselytes is one of the most hopelessly obscure in the whole round of Jewish antiquities, and can never be safely assumed in any argument; and the general results of investigation seem to prove that the baptism of proselytes was not one of the Jewish ceremonies until long after the coming of Christ, while there is much to suggest that this Jewish rite owes its origin to Christian baptism. Others again, find the historical basis of baptism in the lustrations or sprinklings with water so often mentioned in the Old Testament, in such symbolical acts as Naaman's bathing in the Jordan, and in various prophecies where purification from sin is denoted by sprinkling, *e.g.*, Ezek. xxxvi. 25–30, Zech. xiii. 1, &c.; but such anticipations can scarcely be called the historical origin of the rite. Many modern writers connect baptism with certain Pagan rites, and point to the lustrations in use in religious initiation among the Egyptians, Persians, and especially the Hindus, but very little can be made of such far-fetched analogies. Perhaps the most curious instance of this kind is to be found in the double baptism,—the one Pagan and civil, and the other religious and Christian,—which existed side by side with each other in Norway and Iceland. The Pagan rite was called "ansa vatri," while the name for Christian baptism was "skéro." The Pagan rite was much older than the introduction of Christianity, and was connected with the savage custom of exposing infants who

were not to be brought up. The newly-born infant was presented to the father, who was to decide whether the child was to be reared or not; if he decided to rear it, then water was poured over the child and the father gave it a name; if it was to be exposed, then the ceremony was not gone through. The point to be observed is that, if the child was exposed by any one after the ceremony had been gone through, it was a case of murder, whereas it was not thought a crime if the child was made away with before water had been poured over it and it had been named. The analogy lies in the use of water, the bestowal of the name, and the entrance into civil life through the rite.

II. *The Doctrine of Baptism.*—Among the Greek Fathers, for it is there we must look for the beginning of the doctrine, baptism was called by various names, all of which referred to the spiritual effects which were supposed to accompany the rite. For example, a common term for baptism was *regeneration* — for every Christian was supposed to be born again by the waters of baptism. The *great circumcision*, because it was held to succeed in the room of circumcision, the *gift of the Lord*, because it had Christ for its author, and not man; sometimes by way of eminence simply the gift, the *consecration* and *consummation*, because it gave men the perfection of Christians, and a right to partake of the Lord's Supper. In studying the statements made by the early Fathers upon baptism, we find not so much a distinct and definite doctrine as gropings toward a doctrine, and it is not until we come to St. Augustine that we can find any strict and scientific theory of the nature and effects of the sacrament. The earlier theologians sometimes make statements which imply the most extreme view of the magical effects of the sacrament, and at other times explain its results in a purely ethical way. It should never be forgotten that the abundant use of metaphorical language by the Greek Fathers, and the want of anything like a strictly theological terminology, prevent our finding anything like the precise doctrinal statements which became familiar in the Western Church; while the prevalence of curious Greek physical speculations, which taught the creative power of water, mingled with and distorted the ideas about the effects of the water in baptism. It was St. Augustine, the great theologian of the Western Church, who first gave expression to exact dogmatic statements about the nature and meaning of baptism. The real difficulty to be explained was the connection between the outward rite and the inward spiritual change; or to put it more precisely, the relation between the water used and the Holy Spirit who can alone regenerate. The Greek theologians had shirked rather than faced the difficulty, and used terms at one time exaggerating the magical value of the element, at another insisting on the purely ethical and spiritual nature of the rite; but they never attempted to show in what precise relation the external rite stood to the inward change of heart. It is true that one or two theologians had almost anticipated Augustine's view, but the anticipation was more apparent than real, for the theology of the Greek Church in this, as in most other doctrines, is greatly hampered by the mystical tendency to represent regeneration and kindred doctrines much more as a species of chemical change of nature than as a change in the relations of the will. Augustine insisted strongly on the distinction between the sacrament itself and what he called the "res sacramenti," between the inward and spiritual and the outward and material, and by doing so Augustine became the founder of both the modern Roman Catholic and the modern orthodox Protestant views. Apart from certain modifying influences, it would not be difficult for the orthodox Protestant to subscribe to most of Augustine's views upon baptism, for he insists strongly on the uselessness of the external sign without the inward blessing of the Spirit. But in this doctrine, as in most others, Augustine's doctrine of the Church so interfered as to make practically inoperative his more spiritual views of baptism. The Church, Augustine thought, was the body of Christ, and that in a peculiarly external and physical way, and just as the soul of man cannot, so far as we know, exert any influence save upon and through the body, so the Spirit of Christ dispenses His gracious and regenerating influences only through the body of Christ, *i. e.*, the Church. But the Church, Augustine thought, was no invisible spiritual communion. It was the visible kingdom of God, the visible "civitas Dei in peregrinatione per terras," and so entrance into the Church, and the right and possibility of participating in the spiritual benefits which members of the Church can alone enjoy was only possible by means of a visible entrance into this visible kingdom. Thus while Augustine in theory always laid great stress upon the work of the Holy Spirit and upon the spiritual side of baptism, he practically gave the impulse to that view of the sacrament which made the external rite of primary importance. It was the Holy Spirit who alone imparted spiritual gifts to the children of God. But the one way by which the benefits of this Spirit could be shared was in the first place through baptism. Baptism was thought to be necessary to salvation, and all who were unbaptized were unsaved. In this way Augustine, while recognizing the spiritual nature of the sacrament, held views about the importance of the rite which were as strong as those of any Greek theologian who had mingled confusedly in his mind Christian doctrines and the maxims of Pagan philosophy about the creative power of the element of water. Of course such a doctrine of the importance of the baptism with water had to be modified to some extent. There were cases of Christian martyrs who had never been baptized, and yet had confessed Christ and died to confess Him: for their sakes the idea of a baptism of blood was brought forward; they were baptized not with water, but in their own blood. And the same desire to widen the circle of the baptized led the way to the recognition of the baptism of heretics, laymen, and nurses. It was the Augustinian doctrine of baptism which was developed by the Schoolmen, and which now is the substance of modern Roman Catholic teaching. The Schoolmen, whose whole theology was dominated by the Augustinian conception of the Church, simply took over and made somewhat more mechanical and less spiritual Augustine's doctrine. They were enabled to give the doctrine a more precise and definite shape by accommodating it to the terms of the Aristotelian philosophy. They began by distinguishing between the matter and the form of baptism. Had Augustine had this distinction before him he would probably have called the water the matter, and the action of the Holy Spirit the form which verified and gave shape to the matter; but the whole idea of the Schoolmen was much more mechanical, the magical idea of the sacrament came much more into prominence, and the spiritual and ethical fell much more into the background, and with them, while water was the *materia sacramenti*, the *forma sacramenti* was the words of the rite,—"I baptize thee," &c., &c. Thus insensibly the distinction between the external rite and the work of the Holy Spirit, which Augustine had clearly before him in theory at least, was driven back into its original obscurity, and while it was always held theoretically that the grace conferred in baptism was conferred by the Holy Spirit, still the action of the Spirit was so in-

separably connected with the mechanical performance of the rite, that the external ceremony was held to be full warrant for the inward spiritual presence and power, and it was held that in baptism grace was conferred "by the action performed." The actual benefits which were supposed to come in this way were, freedom from original sin and forgiveness of it and all actual sins committed up to the time of baptism, and the implanting of the new spiritual life — a life which could only be slain by a deadly sin. The Scholastic doctrine of baptism is the doctrine of the Roman Catholic Church, and the restatements made by Möhler on the one hand, and Jesuit theologians on the other, do not do more than give a poetical coloring to the doctrine, or bring out more thoroughly the magical and mechanical nature of the rite.

The Protestant doctrine of baptism, like the Scholastic or Roman Catholic, is to be traced back to Augustine and his distinction between the sign and the thing signified, and may be looked at as a legitimate development of the Augustinian doctrine, just as that must be considered to be an advance on the doctrine of the early Church Fathers. The early Fathers had confused the sign with the thing signified, — the water with the action of the Holy Spirit, — and could only mark their half-conscious recognition of the distinction by an alternating series of strong statements made now on the one side and now on the other. Augustine distinguished the two with great clearness, but connected them in an *external* way by means of his conception of the visible Church and of baptism as the door leading into it, and this led his followers to pay exclusive attention to the external side, until the thing signified became lost in the sign. The Protestant theologians connected the two in an *internal* way by means of the spiritual conception of faith, and so were able always to keep the sign in due subordination to the thing signified. It is faith — not faith in the sense of imperfect knowledge, or assent to intellectual propositions, but faith in the sense of personal trust in a personal Savior, or "fiducia," as the 17th century theologians called it — which so connects the water with the presence and power of the Spirit that the one is the means which the other uses to impart His spiritual grace. In this way baptism is looked upon as one of the means of grace, and grace is imparted through it as through the other means — the Lord's Supper, the Word of God, prayer, &c. Just as the dead letters and sounds of the Word of God are but the signs of the presence and power of His Spirit, and become at His touch the living revelation of the Lord, so in baptism, the outward rite, worthless in itself, becomes the sign and pledge of the presence and power of the Spirit of God; and as, in the case of the Word of God, it is faith or "fiducia" that on the human side connects the external signs with the inward power of the Spirit, so, in baptism, it is the same faith which unites the water and the Spirit. So far all orthodox Protestants are agreed, but in order to show the historical evolution of the doctrine, it is necessary to notice in a sentence the difference between the Lutheran and Calvinist doctrines. Luther's own doctrine of baptism changed very much; in the second stage — the stage represented by the tract, *De Babyl. Capt. Eccl.* — it is not different, in germ at least, from the Calvinist view; but he afterwards drew back and adopted views much nearer to the Scholastic theory. He was evidently afraid that, if he went too far from the Scholastic doctrine, and insisted too strongly on the importance of faith, he might be led on to reject the baptism of infants; and his later theories are a recoil from that. The question which Luther had to face and answer here was, What is meant by faith, the faith which connects the symbol with the reality, and so appropriates the gifts of God's grace in the sacrament? Is it a faith which begins and ends in the individual act of faith at work in the person that is baptized? or is it a much wider thing with a more universal significance? Luther did not face this question thoroughly, but his recoil from the Reformed theory of baptism seems to show that he would have taken the former answer. Nor did Calvin face the question; but his doctrine of baptism implies that he would have taken the latter answer. The faith which a man has in Christ, the faith which appropriates, is not the individual's only, but extends far beyond him and his small circle. It is awakened by the Holy Spirit, it comes into being within the sphere of God's saving purpose. Its very existence indicates a *solidarité* between the individual believer and the whole Church of God. Hence on the Reformed doctrine, while faith is essential to the right appropriation of the blessing in the rite, there is no need for thoroughly developed faith in those who are baptized. If they are infants, then they are baptized because of the faith of their parents or near relations, or of the congregation before whom the baptism is performed; only those who are the sponsors for the child bind themselves before God to train up the child to know that it has been baptized, and to appropriate in conscious individual faith the benefits of the ordinance. Such is the Reformed theory of baptism; and it rests upon the ideas of the *solidarité* of believers, of the prior existence of the Church to the individual believer's, and of the ethical unity of the Church. On the other hand, those who hold that the Church is simply the sum of individual men and women, and that it is increased not by the silent widening of the influence of God's saving purpose within mankind, but by individual conversions and by individuals joining the Church, cannot help regarding infant baptism as a mere mockery. Hence the doctrines of the Anabaptists, Baptists, Mennonites, &c. (see BAPTISTS), who reject infant baptism altogether, and maintain that there can be no valid baptism without the conscious appropriation by an act of faith of the benefits symbolized by the rite. It is to be noticed that the tendency of those who reject infant baptism is to regard the sacrament not so much as a means of grace, but simply as an act symbolical of entrance into the Church, and to approach in this way the views of the Socinians and Remonstrants. Quakers reject baptism altogether along with the sacrament of the Supper.

III. *Baptismal Rites.*— In the Apostolic and immediately post-Apostolic Church, there was no stated time or place for baptism. Philip baptized the Ethiopian eunuch by the roadside, as soon as he had declared his faith. The early Church, like most of the Reformation Churches, condemned private baptism.

In the Apostolic Church the baptismal rite seems to have been a very simple one. "Repent and be baptised, every one of you," was all that Peter thought it necessary to say to those whom he invited to join the Christian Church; but soon after the Apostolic times baptism became a very elaborate ceremonial. No one could be baptized unless he had submitted to a long and elaborate course of instruction as a catechumen; and in order to be made a catechumen a ceremony of some length had to be gone through. In the baptismal ceremony the minister first consecrated the water by prayer, and the catechumen was then baptized in the name of the Father, the Son, and the Holy Ghost. The usual mode of performing the ceremony was by immersion. In the case of sick persons the minister was allowed to baptize by pouring water upon the head or by sprinkling. In the early church "clinical" baptism, as it was called, was only permitted in cases of necessity, but the practice

of baptism by sprinkling gradually came in in spite of the opposition of councils and hostile decrees. The Council of Ravenna, in 1311, was the first council of the Church which legalized baptism by sprinkling, by leaving it to the choice of the officiating minister. The custom was to immerse three times, once at the name of each of the persons in the Trinity, but latterly the threefold immersion was abolished, because it was thought to go against the unity of the Trinity. The words used in baptising always embodied the formula in the last chapter of St. Matthew. But the mode of uttering them varied.

The present form of administering baptism in the Church of Rome is as follows: — When a child is to be baptized, the persons who bring it wait at the door of the church for the priest, who comes thither in his surplice and his purple stole, surrounded by his clerks. He begins by questioning the godfathers, whether they promise in the child's name to live and die in the true Catholic and Apostolic faith; and what name they would give to the child. Then follows an exhortation to the sponsors, after which the priest, calling the child by its name, asks, "What dost thou demand of the Church?" The godfather answers, "Eternal life." The priest proceeds, "If thou art desirous of obtaining eternal life, keep God's commandments, — Thou shalt love the Lord thy God," &c.; after which he breathes three times in the child's face, saying, "Come out of this child, thou evil spirit, and make room for the Holy Ghost." Then he makes the sign of the cross on the child's forehead and breast, saying, "Receive the sign of the cross on thy forehead and in thy heart;" upon which, taking off his cap, he repeats a short prayer, and, laying his hand gently on the child's head, repeats a second prayer; then he blesses some salt, and putting a little of it into the child's mouth, he says, "Receive the salt of wisdom." All this is performed at the church door. Afterwards, the priest, with the godfathers and godmothers, come into the church, and advancing towards the font, repeat the Apostles' Creed and the Lord's Prayer. Arrived at the font, the priest again exorcises the evil spirit, and taking a little of his own spittle, with the thumb of his right hand rubs it on the child's ears and nostrils, repeating as he touches the right ear, the same word *Ephphatha*, "be thou opened," which our Saviour made use of to the man born deaf and dumb. Lastly, they pull off its swaddling-clothes, or strip it below the shoulders, during which the priest prepares the oil. The sponsors then hold the child directly over the font, observing to turn it due east and west; whereupon the priest asks the child whether he renounces the devil and all his works, and the godfather having answered in the affirmative, the priest anoints the child between the shoulders in the form of a cross; then taking some of the consecrated water, he pours part of it thrice on the child's head, at each perfusion calling on one of the persons of the Holy Trinity. The priest concludes the ceremony of baptism with an exhortation. It may be added that the Roman Church allows midwives, in cases of danger, to baptize a child before the birth is completed. A still-born child thus baptized may be buried in consecrated ground.

Baptism of the dead seems to have been founded on the opinion that when men had neglected to receive baptism in their life time, some compensation might be made for this default by their receiving it after death, or by another being baptised for them. This practice was chiefly in use among various heretical sects.

Hypothetical Baptism was that administered in certain doubtful cases, with the formula, "If thou art baptized, I do not rebaptize; if thou art not, I baptize thee in the name of the Father," &c.

Solemn Baptism was that conferred at stated seasons. Such in the ancient Church were the Paschal baptism and that at Whitsuntide. This is sometimes also called general baptism.

Lay Baptism we find to have been permitted both by the Common Prayer Book of King Edward, and by that of Queen Elizabeth, when an infant is in immediate danger of death, and a lawful minister cannot be had; but afterwards, in a convocation held in the year 1575, it was unanimously resolved, that even private baptism, in a case of necessity, was only to be administered by a lawful minister. The Scotch Reformed Church also prohibited private baptism by lay persons, but ordained that when any had been thus baptized, the rite was not to be repeated.

The name *baptism* has been applied to certain ceremonies used in giving names to things inanimate. The ancients knew nothing of the custom of giving baptism to inanimate things, such as bells, ships, and the like. The first notice we have of this is in the capitulars of Charles the Great, where it is mentioned with censure; but afterwards it crept by degrees into the Roman offices. Baronius carries its antiquity no higher than the year 968, when the great bell of the church of Lateran was christened by Pope John III. At last it grew to such a height as to form a ground of complaint in the *Centum Gravamina* of the German nation, drawn up at the diet of Nuremberg in 1581, where the ceremony of baptizing a bell, with godfathers, &c., to make it capable of driving away tempests and devils, was declared to be a superstitious practice, contrary to the Christian religion, and a mere seduction of the simple people.

BAPTISTERY (*Baptisterium*) was a hall or chapel in which the catechumens were instructed and the sacrament of baptism administered. It was commonly a circular building, although sometimes it had eight and sometimes twelve sides, and consisted of an ante-room where the catechumens were instructed, and where before baptism they made their confession of faith, and an inner apartment where the sacrament was administered.

BAPTISTS, a denomination of Christians, distinguished, as their name imports, from other denominations by the views they hold respecting the ordinance of baptism.

The early history of the Baptists, both in England and on the Continent, is very obscure. In the great awakening of religious thought and feeling which characterized the beginning of the 16th century, it was inevitable that amongst those who burst the fetters which bound them to the see of Rome some should be willing to retain as much of the ancient doctrine and practice as they could with a safe conscience, whilst others, rejoicing in their new-found liberty, would desire to cast aside every remnant of what they regarded as superstition, and to advance as far as possible in the path of what they deemed Christian liberty; nor is it at all to be wondered at that strange and wild theories on matters even remotely connected with religion should spring into life. But amidst all the diversities of opinion that existed, it was constantly held by Protestants that "holy Scripture containeth all things necessary to salvation, so that whatsoever is neither read therein nor may be proved thereby, although it be sometime received of the faithful as godly and profitable for an order and comeliness, yet no man ought to be constrained to believe it as an article of faith or repute it requisite to the necessity of salvation." We must not be surprised that the right of private judgment, which is involved in the principle thus broadly laid down, was nevertheless far from being conceded to the extent that was desired by those who departed farthest from

the Church of Rome. In fact, each separate section of Protestants claimed for itself to stand on the ground of holy Scripture, and was prepared to resist alike the tyranny of Rome and what is considered the licence of other bodies of Protestants. Thus it happened that the Baptists, or as their opponents called them, the Anabaptists (or, as Zwingli names them, Catabaptists), were strenuously opposed by all other sections of the Christian Church, and it was regarded by almost all the early reformers to be the duty of the civil magistrate to punish them with fine and imprisonment, and even with death. There was, no doubt, some justification for this severity in the fact that the fanaticism which burst forth in the early times of the Reformation frequently led to insurrection and revolt, and in particular that the leader of the "peasant war" in Saxony, Thomas Münzer, and probably many of his followers, were "Anabaptists." One result of this severity is, that the records of the early history of the Anabaptists both on the Continent and in England are very few and meagre. Almost all that is currently known of them comes to us from their opponents. There is, however, much valuable information, together with detailed accounts of their sufferings, in the Dutch Martyrology of Van Braght, himself a Baptist, which bears the title *Martelaers Spiegel der Doops-gesinde* an English translation of the latter half of which was published by Dr. Underhill, now secretary of the Baptist Missionary Society. Probably the earliest confession of faith of any Baptist community is that given by Zwingli in the second part of his *Elenchus contra Catabaptistas*, published in 1527. Zwingli professes to give it entire, translating it, as he says, *ad verbum* into Latin. He upbraids his opponents with not having published these articles, but declares that there is scarcely any one of them that has not a written (*descriptum*) copy of these laws which have been so well concealed. These articles are in all seven. The first, which we give in full, relates to baptism:—

"Baptism ought to be given to all who have been taught repentance and change of life, and who in truth believe that through Christ their sins are blotted out (*abolita*), and the sins of all who are willing to walk in the resurrection of Jesus Christ, and who are willing to be buried with him into death, that they may rise again with him. To all, therefore, who in this manner seek baptism, and of themselves ask us, we will give it. By this rule are excluded all baptisms of infants, the great abomination of the Roman pontiff. For this article we have the testimony and strength of Scripture, we have also the practice of the apostles; which things we simply and also steadfastly will observe, for we are assured of them."

The second article relates to withdrawment or excommunication, and declares that all who have given themselves to the Lord and have been baptized into the one body of Christ should, if they lapse or fall into sin, be excommunicated. The third article relates to the breaking of bread; in this it is declared that they who break the one bread in commemoration of the broken body of Christ, and drink of the one cup in commemoration of his blood poured out, must first be united together into the one body of Christ, that is, into the church of God. The fourth article asserts the duty of separation from the world and its abominations, amongst which are included all papistical and semi-papistical works. The fifth relates to pastors of the church. They assert that the pastor should be some one of the flock who has a good report from those who are without. "His office is to read, admonish, teach, learn, exhort, correct, or excommunicate in the church, and to preside well over all the brethren and sisters both in prayer and in the breaking of bread; and in all things that relate to the body of Christ, to watch that it may be established and increased so that the name of God may by us be glorified and praised, and that the mouth of blasphemers may be stopped." The sixth article relates to the power of the sword. "The sword," they say, "is the ordinance of God outside the perfection of Christ, by which the bad is punished and slain and the good is defended." They further declare that a Christian ought not to decide or give sentence in secular matters, and that he ought not to exercise the office of magistrate. The seventh article relates to oaths, which they declare are forbidden by Christ.

However much we may differ from the points maintained in these articles, we cannot but be astonished at the vehemence with which they were opposed, and the epithets of abuse which were heaped upon the unfortunate sect that maintained them. Zwingli, through whom they come down to us, and who gives them, as he says, that the world may see that they are "fanatical, stolid, audacious, impious," can scarcely be acquitted of unfairness in joining together two of them,—the fourth and fifth,—thus making the article treat "of the avoiding of abominable pastors in the church" though there is nothing about pastors in the fourth article, and nothing about abominations in the fifth, and though in a marginal note he himself explains that the first two copies that were sent him read as he does, but the other copies make two articles, as in fact they evidently are. To us at the present day it appears not merely strange but shocking, that the Protestant Council of Zürich, which had scarcely won its own liberty, and was still in dread of the persecution of the Romanists, should pass a decree ordering, as Zwingli himself reports, that any person who administered anabaptism should be drowned; and still more shocking that, at the time when Zwingli wrote, this cruel decree should have been carried into effect against one of the leaders of the Anabaptists, Felix Mantz, who had himself been associated with Zwingli, not only as a student, but also at the commencement of the work of Reformation. No doubt the wild fanaticism of some of the opponents of infant baptism seemed to the Reformers to justify their severity. In 1537 Menno Simonis joined himself to the Anabaptists and became their leader. His moderation and piety, according to Mosheim, held in check the turbulence of the more fanatical amongst them. He died in 1561, after a life passed amidst continual dangers and conflicts. His name remains as the designation of the Mennonites, who eventually settled in the Netherlands under the protection of William the Silent, Prince of Orange.

About the beginning of the 17th century the severe laws against the Puritans led many dissenters to emigrate to Holland. Some of these were Baptists, and an English Baptist Church was formed in Amsterdam about the year 1609. In 1611 this church published "a declaration of faith of English people remaining at Amsterdam in Holland." The article relating to baptism is as follows:—"That every church is to receive in all their members by baptism upon the confession of their faith and sins, wrought by the preaching of the gospel according to the primitive institution and practice. And therefore churches constituted after any other manner, or of any other persons, are not according to Christ's testament. That baptism or washing with water is the outward manifestation of dying unto sin and walking in newness of life; and therefore in no wise appertaineth to infants." They hold "that no church ought to challenge any prerogative over any other; "that magistracy is a holy ordinance of God;"

"that it is lawful in a just cause for the deciding of strife to take an oath by the name of the Lord."

The last execution for heresy in England by burning alive took place at Lichfield, April 11, 1612. The condemned person, Edward Wightman, was a Baptist.

With the Revolution of 1688, and the passing of the Act of Toleration in 1689, the history of the persecution of Baptists, as well as of other Protestant dissenters, ends. The removal of the remaining disabilities, such as those imposed by the Test and Corporation Acts repealed in 1828, has no special bearing on Baptists more than any other nonconformists. The ministers of the "three denominations of dissenters,"— Presbyterians, Independents, and Baptists,—resident in London and the neighborhood, had the privilege accorded to them of presenting on proper occasions an address to the sovereign in state, a privilege which they still enjoy.

The Baptists were early divided into two sections,—those who in accordance with Arminian views held the doctrine of "General Redemption," and those who, agreeing with the Calvinistic theory, held the doctrine of "Particular Redemption;" and hence they assumed respectively the names of General Baptists and Particular Baptists. In the last century many of the General Baptists had gradually adopted the Arian, or, perhaps the Socinian theory; whilst, on the other hand, the Calvanism of the Particular Baptists had in many of the churches become more rigid, and approached or actually became Antinomianism. In 1770 the orthodox portion of the General Baptists formed themselves into a separate association under the name of the General Baptist New Connection, since which time the "Old Connection" has gradually merged into the Unitarian denomination. Somewhat later many of the Particular Baptist churches became more moderate in their Calvinism, a result largely attributable to the writings of Andrew Fuller. Up to this time the great majority of the Baptists admitted none either to membership or communion who were not baptized, the principal exception being the churches in Bedfordshire and Hertfordshire, founded or influenced by Bunyan, who maintained that difference of opinion in respect to water baptism was no bar to communion. At the beginning of the present century this question was the occasion of great and long-continued discussion, in which the celebrated Robert Hall took a principal part. The practice of mixed communion gradually spread in the denomination. Still more recently many Baptist churches have considered it right to admit to full membership persons professing faith in Christ, who do not agree with them respecting the ordinance of baptism. Such churches justify their practice on the ground that they ought to grant to all their fellow Christians the same right of private judgment as they claim for themselves. It may not be out of place here to correct the mistake, which is by no means uncommon, that the terms Particular and General as applied to Baptist congregations are intended to express this difference in their practice, whereas these terms relate, as has been already said, to the difference in their doctrinal views. The difference now under consideration is expressed by the terms "strict" and "open," according as communion (or membership) is or is not confined to persons who, according to their view, are baptized.

The Baptists early felt the necessity of providing an educated ministry for their congregations. Some of their leading pastors had been educated in one or other of the English universities. Others had by their own efforts obtained a large amount of learning, amongst whom Dr. John Gill was eminent for his knowledge of Hebrew. He is said to have assisted Bishop Walton in the preparation of his Polyglot. Mr. Edward Terrill, from whose *Records* we have already quoted, and who died in 1685, left a considerable part of his estate for the instruction of young men for the ministry, under the superintendence of the pastor of the church now meeting in Broadmead, Bristol, of which he was a member. Other bequests for the same purpose were made, and from the year 1720 the Baptist Academy, as it was then called, received young men as students for the ministry amongst the Baptists. Fifty years later, in 1770, a society, called the Bristol Education Society, was formed to enlarge this academy; and it was still further enlarged by the erection of the present Bristol Baptist College about the year 1811. In the North of England a similar Education Society was formed in 1804 at Bradford, Yorkshire, which has since been removed to Rawdon near Leeds. In the metropolis a college was formed in 1810 at Stepney, and was removed to Regent's Park in 1856. The Pastors' College, in connection with the Metropolitan Tabernacle was instituted in 1856. Besides these, the General Baptists have maintained a college since 1797 which at present is carried on at Chilwell, near Nottingham. A theological institution, intended to promote the views of the "Strict" Baptists, has lately been established at Manchester. There is also a Baptist theological institution in Scotland, and there are three colleges in Wales. The total number of students in these institutions may be reckoned to be about 200.

The Baptists were the first denomination of British Christians that undertook the work of missions to the heathen, which has become so prominent a feature in the religious activity of the present century. As early as the year 1784, the Northamptonshire Association of Baptist churches resolved to recommend that the first Monday of every month should be set apart for prayer for the spread of the gospel, a practice which has since, as a German writer remarks, extended over all Protestant Christendom, and we may add over all Protestant Missions. Six years later, in 1792, the Baptist Missionary Society was formed at Kettering in Northamptonshire, after a sermon on Isaiah lii. 2, 3, preached by the afterwards celebrated William Carey, the prime mover in the work, in which he urged two points: "Expect great things from God; attempt great things for God." In the course of the following year Carey sailed for India, where he was joined a few years later by Marshman and Ward, and the mission was established at Serampore. The great work of Dr. Carey's life was the translation of the Bible into the various languages and dialects of India. The society's operations are now carried on, not only in the East, but in the West Indies, Africa and Europe.

In regard to church government, the Baptists agree with the Independents that each separate church is complete in itself, and has, therefore, power to choose its own ministers, and to make such regulations as it deems to be most in accordance with the purpose of its existence, that is, the advancement of the religion of Christ. A comparatively small section of the denomination maintain that a "plurality of elders" or pastors is required for the complete organization of every separate church.

Some of the English settlers in all parts of the world have carried with them the principles and practice of the Baptists. The introduction of Baptist views in America was due to Roger Williams, who emigrated to Boston, Massachusetts, in 1630. Driven from Massachusetts on account of his denying the power of the civil magistrate in matters of religion, he formed a settlement and founded a state in Rhode Island, and having become a Baptist he formed, in 1639, the first Baptist church in America, of which he was also for a short time the pastor. It is impossible here to trace the his-

tory of the Baptists in the United States. In 1889 there are reported, churches, 46,624; ministers, 32,017; members, 4,078,589. The great majority of the churches practice "strict" communion.

BAR, in Hydrography, is a bank of sand, silt, etc., opposite the mouth of a river, which obstructs or bars the entrance of vessels. The bar is formed where the rush of the stream is arrested by the water of the sea, as the mud and sand suspended in the river-water are thus allowed to be deposited.

BAR, in Law. This word has several legal meanings; thus, it is the term used to signify an inclosure or fixed place in a court of justice where lawyers may plead. The dock, or inclosed space where persons accused of felonies and other offenses stand or sit during their trial, is also called the bar.

BAR, in Music, is a line drawn across the stave to divide the music into small portions of equal duration; and to indicate the accent, each of these small portions, called *measures*, are also commonly termed bars.

BAR, a town of Russian Poland, in the government of Podolia, fifty miles from Kaminetz. Pop., 8,077.

BARABOO, the capital of Sauk county, Wis., is situated on the Baraboo river, thirty-seven miles northwest of Madison. It is a banking and railroad town, and has considerable manufactures of carriages and woolen goods, a foundry, grist-mills, saw-mills, planing-mills and other diversified industries. There is a graded school system and seven churches. Population, 4,602.

BAR-HEBRÆUS. See ABULFARAGIUS, vol. i. p. 19.

BAR-LE-DUC, or BAR-SUR-ORNAIN, the chief town of the department of Meuse in France. It occupies the declivity and base of a hill, on the river Ornain, a tributary of the Marne, 125 miles E. of Paris, and consists of an upper and lower town, the latter being the more modern and respectable of the two. It is a railway station on the Paris and Strasburg line, and has a population of 16,000.

BAR-SUR-AUBE, the chief town of an arrondissement in the department of Aube, in France. It is a station on the Paris-and-Mulhouse line, and is situated on the right bank of the River Aube, at the foot of Sainte Germaine, in a picturesque district, the wine of which is much esteemed. It is a pretty little town, with a few remains of its ancient fortifications. Pop. 4500.

BAR-SUR-SEINE, the chief town of an arrondissement in the department of the Aube, in France. In the Middle Ages Bar-sur-Seine was a place of considerable importance, and, according to Froissart, contained no fewer than 900 "hôtels" or mansions. Pop. 3000.

BÁRA BÁNKÍ, a district of British India under the jurisdiction of the Chief Commissioner of Oudh. It is bounded on the N.W. by the district of Sítápur; on the N. by Bharáich; on the N.E. by Gondá; on the E. by Faizábád; on the S. by Sultánpur and Rai Barelí; and on the W. by Lucknow. The district stretches out in a level plain interspersed with numerous *jhils* or marshes. In the upper part of the district the soil is sandy, while in the lower part it is clayey, and produces finer crops. The principal rivers are the Ghagrà (*Gogra*), forming the northern boundary, and the Gúmtí. Area, 1735 square miles; pop. 1,110,000.

BARAGUAY D'HILLIERS, LOUIS, general, was born at Paris in 1764, and, receiving an appointment in the army of Italy, from Napoleon, shared all the successes of the campaigns of 1796–97. Made a general of division and commandant of Venice, in 1798, he accompanied the expedition to Egypt; and afterward successively held appointments on the Rhine, in the Tyrol; and at Catalonia. He died in 1813.—ACHILLE, his son, was born in Paris in 1795, and entering the army in 1812, next year lost his left hand at the battle of Leipzic. He held a number of appointments up to 1854, when he received the command of the Baltic expedition; and on the capture of Bomarsund, he was made a marshal. In the Italian campaign of 1859 he distinguished himself at Solferino, and during 1870 he was for a brief time commander of Paris. He died at Amélie-les-Bains, June 6, 1878.

BARAHAT, a town of northern Hindustán, situated in the Himálayas, and within the native state of Garhwál. The town was almost destroyed in 1803 by an earthquake — a calamity greatly aggravated by the houses having been built of large stones, with slated roofs.

BARANTE, AMABLE GUILLAUME PROSPER, Baron de Brugière, an eminent French statesman, and the learned historian of the dukes of Burgundy, was the son of an advocate, and was born at Riom, June 10, 1782. At the age of sixteen he entered the Ecole Polytechnique at Paris, and at twenty obtained his first appointment in the civil service. His abilities secured him rapid promotion, and in 1806 the post of auditor to the council of state was given to him. After being employed in several political missions in Germany, Poland, and Spain, during the next two years, he became prefect of Vienne. At the time of the return of Napoleon I. he held the prefecture of Nantes, and this post he immediately resigned. About this period he married. On the second restoration of the Bourbons he was named councillor of state and Secretary-general of the Ministry of the Interior. About the same time he was elected to the Chamber of Deputies for the two departments of Puy-de-Dôme and Loire Inférieure; but in the following year, in consequence of being under the legal age of a deputy, as required by a new law, he lost his seat. After filling for several years the post of Director-general of Indirect Taxes, he was created, in 1819, a peer of France, and took an active and prominent part as a member of the opposition in the debates of the Upper Chamber. As a scholar his *opus magnum* is the *Histoire des Ducs de Bourgogne de la Maison de Valois*, which appeared in a series of volumes between 1824 and 1828. It procured him immediate admission among the Forty of the French Academy; and its great qualities of scholarship, impartiality, accuracy, and purity of style, have given him a place among the greatest French historians. He died in 1866.

BARANYA, a province in the kingdom of Hungary, extending over 1960 square miles. It lies in the angle formed at the junction of the Danube and the Drave, is traversed by offshoots of the Styrian Alps, and contains one city, 13 market-towns, and 341 villages. The inhabitants number about 283,500, and consist of Magyars, Germans, Croatians, and Servians, a large proportion being Roman Catholics.

BARANZANO, JEAN ANTOINE, surnamed *Redemptus*, an eminent natural philosopher and mathematician, was born in Piedmont in 1590, and died at Montargis in 1622.

BÁRÁSAT, a subdivisional town in the district of the 24 Parganás, under the jurisdiction of the Lieutenant-Governor of Bengal. Population, 12,000.

BARATIERE, or BARETTIER, JOHN PHILIP, a very remarkable instance of precocious genius, was born at Schwabach near Nuremberg on the 10th January 1721. His early education was most carefully conducted by his father, Francis Baratière, pastor of the French church at Schwabach, and so rapid was his progress that by the time he was five years of age he could speak French, Latin, and Dutch with ease, and read Greek fluently. He then engaged in the study of Hebrew, and in three years was able to translate the Hebrew Bible into Latin or French, or to retranslate these versions into the orig-

inal Hebrew. From his reading he collected materials for a dictionary of rare and difficult Hebrew words, with critical and philological observations; and when he was about eleven years old translated from the Hebrew Tudela's *Itinerarium*. In his fourteenth year he was admitted Master of Arts at Halle, and received into the Royal Academy at Berlin. The last years of his short life he devoted to the study of history and antiquities, and had collected materials for histories of the Thirty Years' War and of Antitrinitarianism, and for an *Inquiry Concerning Egyptian Antiquities*. His health, which had always been weak, gave way completely under these labors, and he died on the 5th October 1740, aged 19 years and 8 months. He had published eleven separate works, and left a great quantity of manuscript materials.

BARATYNSKI, JEWGENIJ ABRAMOVITCH, a distinguished Russian poet, was born in 1792. He was educated at the royal school at St. Petersburg, and then entered the army. He served for eight years in Finland, and appears to have got into disgrace on account of some foolish pranks which he had played. During these years he composed his first poem, *Eva*, which bears very manifest traces of his residence in Finland. Through the interest of friends he obtained leave from the Czar to retire from the army, and settled near Moscow. There, so far as his broken health would allow him, he devoted his time to poetry, and completed his chief work, *The Gipsy*, which has been spoken of by critics as the best poem of its kind in the Russian language, and as fully equal, if not superior, to the finest productions of Pouschkin. This was his only work of any extent; his health gave way completely, and he died in 1844 at Naples, whither he had gone for the sake of the milder climate.

BARBACENA, a town of Brazil, in the province of Minas-Geraes, situated at the height of about 3500 feet above the sea, in the Sierra Mantiqueira, 150 miles N. W. of Rio de Janeiro. It has low houses and broad streets, and contains a town-hall, a prison, a hospital, founded in 1852 by Antonio Ferreira Armond, and a "school of intermediate instruction," in which French history and geometry are taught. The trade is principally in gold-dust, cotton, and coffee. Population of town and district, 14,000.

BARBADOS, or BARBADOES, the most windward of the Caribbean Islands, 78 miles E. of St. Vincent, the island nearest to it in the Caribbean chain. It lies in the track of vessels, and is well adapted to be an *entrepôt* of commerce. It has nearly the size and proportions of the Isle of Wight, being 21 miles in length, and about 14½ miles in its broadest part. It has a superficial area of 106,470 acres, or about 166 square miles,—70,000 acres (besides grass land) are under cultivation, and nearly 30,000 acres of sugar cane are annually cut. The island is almost encircled by coral reefs, which in some parts extend seaward nearly three miles. There are two lighthouses, one on the south point and another on the south-east coast. A harbor light has also been placed on Needham's Point. The harbor Carlisle Bay, is a large open roadstead. The inner harbor, or careenage, for small vessels, is protected by a breakwater called the Molehead. Barbados presents every variety of scenery,—hill and valley, smooth table-land and rugged rocks. From one point of view the land rises in a succession of limestone and coral terraces, which indicate different periods of upheaval from the sea. From another there is nothing to be seen but a mass of abruptly rising rocks. The rainfall is caused, apart from elevation, by the exposure of the land to those winds laden with moisture which strike the island at different periods of the year.

The N.E. trade-wind blows for three-fourths of the year, and most of the rain comes from the same quarter. March is the driest of the months, and October the wettest; the average rainfall for the former being 1½ inch, and for the latter 9 inches. Leprosy is not uncommon among the negroes, and elephantiasis is so frequent as to be known by the name of "Barbados leg."

Bridgetown is the capital and port of the island, and the centre of business activity. It contains about 23,000 inhabitants. Over the creek which received the waters from the heights around the Indians had built a rude bridge. This was known for a long time after the British settlement as the Indian Bridge, but as the settlement grew, and after the old bridge had been replaced by a more solid structure, the place received the name of Bridgetown. The town was destroyed by fire in 1666, and rebuilt, principally of stone, upon a larger scale. It suffered again from fire in 1766 and 1845.

The first settlers cultivated maize, sweet potatoes, plantains, and yams for their own consumption, and indigo, cotton wool, tobacco, ginger, and aloes for export. Quantities of logwood, fustic, and lignum vitæ were also shipped. But the adaptability of the soil for cane becoming known, and the necessary knowledge for the manufacture of sugar being obtained, this article at once became the great staple of the colony. The value of property very largely increased. The half of an estate of 500 acres, 200 under cane, with buildings and appurtenances, was sold for £7000 about the year 1650, the laborers being slaves from Africa.

It was while the rapid progress of the colony was attracting especial attention, and many persons of family and means, adherents of the royal cause, were finding it a refuge from the troubles at home, that Francis Lord Willoughby of Parham went out as governor, with the consent of King Charles II., who had been proclaimed in Barbados as soon as the news of the execution of Charles I. had arrived. Lord Carlisle had died, and his heir had been entrusted with the duty of paying his debts out of the revenue from the island. Lord Willoughby agreed to take a lease from the new earl of the profits of the colony for twenty-one years, to pay Lord Carlisle one-half, and to accept the governorship, including that of the other islands in the Carlisle grant. Upon his arrival in 1650, notwithstanding the active opposition of a party headed by Colonel Walrond, he procured the passing of an Act acknowledging the king's sovereignty, the proprietary rights of the earl of Carlisle, and his own interest derived from the latter. But the Parliament despatched Sir George Ayscue with a squadron and considerable land forces, to reduce the island to submission to its authority. About the same time the famous Navigation Law was enacted, by which foreign ships were probibited from trading with British colonies, and imports into England and the dependencies were not allowed in foreign bottoms. This restriction had a great effect upon Barbados, which depended upon foreign importation for a great deal of its provisions. Sir G. Ayscue's expedition appeared off Barbados in October 1651. After one unsuccessful attempt, a landing was effected, and Lord Willoughby's force was routed. The counsels of a moderate party in the island, however, prevailed, and a compromise was effected. A treaty was made declaring the authority of the Parliament, but containing provisions not at all unfavorable to the inhabitants, and reserving even to Lord Willoughby his rights in the island. During the Commonwealth prisoners of war were sometimes sent to Barbados. The expedition of 1655 against St. Domingo and Jamaica under Penn and Venables was reinforced by a troop of horse and 3500 vol-

unteers from Barbados. At the Restoration Lord Willoughby went out once more to Barbados and resumed his office. Several of the faithful adherents of the royal cause in the island were made baronets and knights, but the restrictions upon commercial intercourse which had been imposed by the Parliament were made more stringent. Then doubts began to arise in the minds of the planters as to the title by which they held their estates. They had created by their exertions a very valuable property, and the bare possibility of the earl of Carlisle stepping in and dispossessing them caused much discontent. The death of Lord Carlisle brought matters to a crisis. An arrangement was made in 1663 by which the different claimants were satisfied, the proprietary or patent interest was dissolved, and the Crown exercised directly its rights, and undertook the government, although it was not till 1672 that the nomination of the council was taken into the hands of the king. A duty of 4½ per cent. upon the produce of the island was levied in 1663 to satisfy the claims and defray the government expenses. Lord Willoughby received a new commission, and the only practical change effected in the constitution was that all laws were thenceforward made subject to a confirmation by the king. In 1665 the colony successfully resisted an attack by the Dutch; but in conducting an expedition against the French in Guadaloupe in 1666, Lord Wilioughby was lost in a hurricane, and an eventful and occasionally brilliant career was thus prematurely ended. He was succeeded in the government by his brother, Lord William Willoughby, during whose governorship the division of the Caribbean Islands into Windward and Leeward was made. The hurricane of 1675 gave a serious check to the prosperity of the colony. An unsuccessful application was made to the home Government, to remit, on account of the distress that prevailed, the 4½ per cent. duty, which pressed very heavily upon the planters. The island had scarcely recovered from the effects of the hurricane when the supply of labor was restricted and its expense increased by the Royal African Company, at the head of which was the duke of York, receiving a charter for the exclusive supply of slaves of the West India Islands. This company had great influence in the appointment of governors; and in consequence of oppressive proceedings and depreciation of the value of property, many families left the island. A number of persons implicated in the duke of Monmouth's rebellion were sent to Barbados and treated harshly. Duties upon sugar were imposed by the mother country, which were increased at the accession of James the II., to 2s. 4d. per cwt. on Muscovado, and to 7s. upon all sugars for common use. From the survey made by governor Sir Richard Dutton in 1683–4, it appears that the population consisted of 17,187 free, 2381 unfree and servants (prisoners of war and persons brought from England under engagements for terms of years), and 46,602 slaves. The number of acres in useful possession was 90,517, and of sugar works 358. These figures show how rapidly, in spite of all difficulties, the colony had grown in sixty years.

The wars in Europe were reproduced upon a smaller scale, though with equal if not greater intensity, among the different nationalities in the West Indies. In such times the seas swarmed with privateers; and freights were so high as to induce the island Legislature to make a vain attempt to regulate them by law. The news of the peace of Ryswick was received with great joy, and matters remained quiet until the declaration of war against France and Spain in 1702 revived privateering in West Indian waters. Events in the first half of the 18th century do not call for detailed description. It was the custom of the assembly to supplement the salary of the governor (which was paid by the Crown out of the 4½ per cent. duty) by special grants, sometimes of large amount. But this did not prevent many constitutional conflicts between the assembly and the executive. During the war which commenced between England and France in 1756, the West Indies witnessed much fighting, with its attendant suffering. In 1761 a determined attempt was made to break the power of France in the archipelago. Barbados entered with enthusiasm into the project. Guadaloupe had been taken in 1759, and the principal effort now, under Admiral Rodney and General Monck ton, was directed against Martinique. In 1762 that island surrendered. Barbados spent £24,000 in raising and equipping her proportion of men in the attacking forces; and in 1765 the House of Commons voted £10,000 as compensation for the expense incurred. By the Treaty of 1763, however, both these islands were restored to France. The constant wars had naturally an injurious effect upon Barbados. During the governorship of the Hon. Edward Hay, who was appointed in 1773, differences of opinion arose as to the state of the island. When the war between England and the American colonies began, the supply of provisions, upon which Barbados depended, necessarily stopped. The assembly addressed a petition to the king, praying for relief; through the interposition of the governor the relief was not immediately granted; but in 1778, when the island was in a very depressed state, the British ministry sent a quantity of provisions for sale at prime cost. With the advent of General Cunninghame as governor another series of contentious years began. In the midst of disputes as to the right of the governor to exact certain fees without the consent of the assembly, a hurricane visited the island and caused much destruction of property. Parliament in 1782 granted £80,000 for relief, but an attempt to obtain the repeal of the 4½ per cent. duty was again unsuccessful. The French were regaining their ascendency in the archipelago, and had it not been for the great naval victory won by Sir George Rodney, Barbados and the remaining British colonies might have fallen to the enemy. As the 18th century closed, the prospect of the great final struggle with France overshadowed the colonies. The Barbadians energetically put themselves in a state of defence, and at the same time voted and privately subscribed money to assist his Majesty to carry on the war. The peace of Amiens, in 1802, relieved anxiety for a brief interval, but hostilities were soon renewed. When in 1805 Napoleon sent a squadron to the archipelago, with 4000 soldiers, the crisis put Barbados on her mettle. The French fleet was successful in exacting large sums of money from adjacent colonies. Admiral Villeneuve, too, was on his way with a still larger fleet and stronger force. But when Admiral Cochrane arrived off Barbados the safety of the island was secured. Even amid the intense excitement of these events constitutional questions were not forgotten. The governor could only establish martial law when the enemy's fleet was in sight. A premature declaration drew forth a protest from the assembly, and the controversy was only ended when the Home Government asserted the full prerogative of the Crown to impose martial law when necessary for the safety of the island. The most memorable event in 1805 was a flying visit from Lord Nelson in search of a French fleet. In October of the same year the battle of Trafalgar was won, and Bridgetown soon after had its Trafalgar Square and its Nelson statue. In 1809 an expedition sailed from Barbados, under Governor Beckwith, against the French in Martinique. After a bombardment of five days that place was taken. Twelve months later Beckwith similarly attacked Guadaloupe;

and when that island was conquered, after some hard fighting, the power of the French in the archipelago was again reduced to its lowest ebb. When the war ended in 1810 in the West Indies, the British were supreme in that region. But danger was threatened from another source. The rupture between Great Britain and the United States in 1812 caused privateering to be resumed to an extent that almost destroyed the commerce of the island, until the abdication of Napoleon and the peace with America in 1814 again brought relief to the colonies. The military history of Barbados ceased at the close of the Peninsular War.

In the meantime Barbadian affairs had attracted notice in Parliament. In 1812 a motion was made in the House of Commons that the 4½ per cent. duty should be applied exclusively to local purposes. A considerable amount of this revenue had been devoted to pensions to persons entirely unconnected with the colony, and it was stated in the House of Commons that part of the money had been appropriated to the king's household in the reign of William III. Nor were the Barbadians themselves backward in stating their grievances. In 1813 they protested against the importation of East Indian sugars into Great Britain, and also against the system of patent offices, by which non-resident officials were able to draw large sums from the island for services which they never performed. By Act of the Parliament 6 Geo. IV. c. 114, 1825, foreign commodities were admitted into the British possessions at moderate rates of duty if the countries sending those articles would give similar privileges to British ships. As the United States refused reciprocity, the West Indian ports were closed against their vessels, and the United States retaliated by prohibiting all intercourse with British colonies. From the operation of the above-mentioned Act an important constitutional question arose. These duties, levied in the name of the king, were to be paid into the local treasury for the uses of the colony, but the customs officers, of course appointed from home, received instructions to retain their own salaries from the revenue. This was denounced by the assembly as illegal, and after a long controversy it was agreed, in 1832, that 10 per cent. should be deducted to defray the expense of collecting the tax. Another question arose which illustrates the relations between England and the colony. By an island Act of 1773, a 2s. 6d. tonnage duty was imposed, but small vessels belonging to residents were only to pay on three voyages a year. By an Act of Parliament in 1832 this exemption was abolished. The assembly protested and denied the right of Parliament to tax colonies which had no representative institutions; but Lord Stanley, in 1833, declared that this right existed, although its exercise was a matter of expediency. After the hurricane of 1831, which was perhaps the severest the island had ever experienced, causing 1591 deaths and a destruction of property estimated at more than a million and a half sterling, another urgent appeal was made for the remission of the 4½ per cent. duty, but without effect, although £100,000 was granted by Parliament in 1832 for the relief of the islands which had suffered from the visitation; of this sum Barbados took half. By an Act of Parliament passed in 1838, the 4½ per cent. duty was at length removed, after having been in existence for 175 years.

But a social revolution had begun which was destined to change not so much the prosperity of the colony, as the conditions under which that prosperity arose. From the first settlement, of course, the one great want was labor. As the labor supply increased and became more certain the cultivation expanded, wealth was created, and the importance of the colony grew. In the early days white labor was employed, assisted by Indians obtained from other islands and the mainland of South America, but when the sugar-cane began to be cultivated, negro slaves were imported from Africa. This slave trade, mostly conducted by companies or persons in England, continued until the year 1806, when it was stopped by Act of Parliament. In that year there were 60,000 negroes in the island. This measure was, of course, the first step to the abolition of slavery itself. On the 1st of August 1834, the great Act of Emancipation came into force, and four years of apprenticeship began. Out of the 20 millions granted for compensation, Barbados received £1,720,345, being an average payment of £20, 14s. on 83,176 slaves. In consequence of the large population and small extent of uncultivated land, emancipation had not in Barbados such a relaxing effect upon the industry of the negroes as it had in the more thinly-populated colonies. An efficient system of town and rural police was, however, essential. From the time of emancipation the negroes multiplied rapidly. In 1844, out of a total population of 122,198, at least 90,000 were negroes, among whom females were largely in excess. The density of the population in 1871 was therefore 966 to the square mile.

BARBAROSSA, meaning *red-beard*, the name of two celebrated Turkish corsairs of the 16th century. They were the sons of a Roumelian sipahi who had settled in Mitylene after the capture of that island by Mahomet II., and who appears to have embraced Islamism. The elder of the two is generally called Aruch, Horuk, or Ouradjh; the name of the younger was Khizr, but he was afterwards called by the Sultan *Khair-ed-deen*, meaning "one good in the faith," which was corrupted by the Christians into Hayraddin. The brothers early betook themselves to piracy; and after various successes and reverses, they acquired sufficient wealth and renown to enable them to fit out a small fleet with which they ravaged the shores of the Mediterranean, and became the pests of that sea. A richly laden vessel which they presented to the sultan at Constantinople procured for them honorary caftans and recognition of their services. About the year 1516, after having been for some time in the service of the bey of Tunis, they began to acquire considerable possessions on the coast of Africa. Hayraddin seized the island of Shershel, and Aruch gained a footing in Algiers. The latter began to extend his conquests into the district of Telmessan or Tlemcen, and was resisted by the Arabs, who summoned the Spaniards of Oran to their assistance. Aruch fell in battle in 1518, and was succeeded at Algiers by Hayraddin, who, after the reigning prince, Selim, was removed (in what way is somewhat doubtful), consolidated his power by placing himself under the Sublime Porte. Solyman, who was delighted at obtaining so much territory at such a small cost, conferred upon Hayraddin the title of *Begler-beg* of Algiers. The power of the pirates rapidly increased; Algeciras, a small island opposite Algiers, was taken from the Spaniards after an obstinate resistance, and was united to the mainland by a mole. The coasts of the Mediterranean were completely at the mercy of Barbarossa, who carried off immense numbers of slaves. In 1533, when Solyman was about to make war upon his grea rival, Charles V., Hayraddin joined him with a number of ships. He was received with great honor, and made admiral (*capitan-pasha*) of the fleet. His greatest exploit was the capture of Tunis, in which he obtained a footing by adopting the cause of a rival prince. As soon as he had deposed Muley Hassan, the reigning sovereign, he seized the town for himself and held it despite the resistance of the people. Charles V., however, sent out a great fleet, under Andrea Doria, who retook the town after a protracted siege. Barbarossa escaped to Algiers, collected his fleet, and

again swept the seas. He plundered the coasts of Italy, captured Castelnuova, and inflicted a severe defeat on Doria. He died at Constantinople 4th July 1546. (See Von Hammer, *Geschichte des Osmanischen Reiches*, iii. 164, *seq.*; also *Blackwood's Magazine*, vol. lii.) The Emperor Frederick I. is very frequently designated by surname Barbarossa.

BARBARY, the general designation of that part of Northern Africa which is bounded on the E. by Egypt, W. by the Atlantic, S. by the Sahara, and N. by the Mediterranean, and comprises the states of Marocco, Algeria, Tunis, and Tripoli. The name is derived from the *Berbers*, one of the most remarkable races in the region. (See AFRICA, ALGERIA, MAROCCO, TRIPOLI, TUNIS.)

BARBASTRO, a fortified city of Spain, in the province of Huesca, on the River Vero, near its junction with the Cinca.

BARBAULD, MRS. ANNA LETITIA, distinguished pedagogue and author, was born at Kibworth-Harcourt, in Leicestershire, on the 20th June 1743, and died on the 9th March 1825. A collected edition of her works, with Memoir, was published by her neice, Miss Lucy Aikin.

BARBER, one whose occupation is to shave or trim beards. In former times the barber's craft was dignified with the title of a profession, being conjoined with the art of surgery. In France the barber-surgeons were separated from the perruquiers, and incorporated as a distinct body in the reign of Louis XIV. In England barbers first received incorporation from Edward IV. in 1461. By 32 Henry VIII. c. 42, they were united with the company of surgeons, it being enacted that the barbers should confine themselves to the minor operations of blood-letting and drawing teeth, while the surgeons were prohibited from "barbery or shaving." In 1745 barbers and surgeons were separated into distinct corporations by 18 George II. c. 15. The barber's shop was a favorite resort of idle persons; and in addition to its attraction as a focus of news, a lute, viol, or some such musical instrument, was always kept for the entertainment of waiting customers. The barber's sign consisted of a striped pole, from which was suspended a basin, symbols the use of which is still preserved. The fillet round the pole indicated the ribbon for bandaging the arm in bleeding, and the basin the vessel to receive the blood.

BARBERINI, the title of a powerful family, originally of Tuscan extraction, who settled in Florence during the early part of the 11th century. They acquired great wealth and influence, and in 1623 Maffeo Barberini was raised to the papal throne as Urban VIII. He made his brother, Antonio, and two nephews, cardinals, and gave to a third nephew, Taddeo, the principality of Palestrina.

BARBEYRAC, JEAN, an able writer on the principles of natural law, was the nephew of Charles Barbeyrac, a distinguished physician of Montpellier, and was born at Béziers in Lower Languedoc, in 1674.

BARBIERI, GIOVANNI FRANCESCO (otherwise called GUERCINO, from his squinting), an eminent historical painter, was born at Cento, a village not far from Bologna, in 1590. His most famous piece is thought to be the Sta. Petronilla, which was painted at Rome for Gregory XV. and is now in the Capitol. Guercino continued to paint and teach up to the time of his death in 1666. He had amassed a handsome fortune by his labors.

BARBIERI, PAOLO ANTONIO, a celebrated painter of still life and animals, the brother of Guercino, was born at Cento in 1596. He chose for his subjects fruits, flowers, insects, and animals, which he painted after nature with a lively tint of color, great tenderness of pencil, and a strong character of truth and life. He died in 1640.

BARBOUR, JOHN, the author of the great Scottish national poem *The Bruce*, was born, probably in Aberdeenshire, about the beginning of the 14th century. He was a contemporary of Chaucer and Gower; but so little is known of his life, that the very date of his birth can be only approximately given as about 1316. In 1357, as we learn from a safe-conduct permitting him to visit Oxford for the purpose of study, he held the position of archdeacon of Aberdeen. In 1364 he was again permitted to enter England for a similar purpose, and in 1368 he received letters of safe-conduct authorizing him to pass through England on his way to France, whither, it may be conjectured, he was proceeding in order to visit the famous university of Paris. From this date to his death, which took place probably in March 1395, notices of him are slightly more numerous. In 1373 he is described as holding the office of clerk of audit of the king's household. About the same time he must have been busily engaged in the composition of his great work, for, as he himself tells us, his poem was more than half finished in 1375.

A sum of ten pounds, which was paid to the poet by the king's orders in 1377, was in all probability a royal gift on the completion of the work. Barbour seems indeed to have been well treated by his sovereign; he received a perpetual annuity of twenty shillings, which he bequeathed to the dean and chapter of Aberdeen as payment of a yearly mass to be said for his soul), tithes of the parish of Rayne in the Garioch, and a crown wardship, always a lucrative office in these times. A further bounty of ten pounds a year during life, granted in 1388, was probably a reward on the completion of the poet's second large work, *The Bruce*. The cessation of payment of this annuity enables us to fix with some accuracy the date of Barbour's death.

The Bruce, which is Barbour's principal poem, although it is almost the sole authority for the events of the period, is not to be considered as merely a rhyming chronicle. His theme was freedom and the liberation of his country from the dominion of a foreign people. The age of Bruce was the age of Scottish chivalry, and the king himself presented the most perfect model of a valiant knight. With such a crisis and such a hero, therefore, it is not surprising that Barbour should have achieved a work of lasting fame.

The poem begins with an account of the succession to the Scottish crown after the death of Alexander III. In this part of his poem Barbour has made a slight anachronism. He makes his hero compete with John Baliol for the crown of Scotland, while it was his grandfather, the Lord of Annandale, who unsuccessfully contested the right. Then follows a lamentable account of the desolation of the country and the oppression of the people by the English. Bruce's energetic actions to free his country, and his romantic adventures, which form so interesting an episode in Scottish history, are narrated with great minuteness, down to the battle of Bannockburn, which is described with all its interesting details. At this point the national epic properly ends; but Barbour further relates the expedition of Bruce to Ireland, and the exploits of Douglas and Randolph on the borders, and concludes with an account of the deaths of King Robert and his gallant knights.

BARBUDA, one of the lesser Antilles or Caribbean islands, is 10 miles in length by about 8 in breadth, presenting a very flat surface, covered to a great extent with woods, in which deer abound. Many varieties of shell-fish and other fish are found on the coast, which is also frequented by large flocks of water-fowl. The part

of the island under cultivation is fertile; corn, cotton, sugar, tobacco, and indigo are grown; and the rearing of cattle is one of the principal occupations. So salubrious is the climate that Barbuda serves as a kind of *sanitarium* for the adjacent islands. The inhabitants, who number less than 2000, are mainly negroes. The island was annexed to Britain in 1628, and was bestowed in 1680 on the Codrington family, in whose possession it still remains. The north point is in lat. 17° 33′ N. and long. 61° 43′ W.

BARCA, a maritime district of Northern Africa, which formerly belonged to Tripoli, but was raised in 1869 to be a separate province immediately dependent on Constantinople. It extends from the Gulf of Sert (the ancient Syrtes) to the Egyptian frontier, and has an area of about 60,700 square miles. This territory is traversed from east to west by a mountain chain varying in height from 400 or 500 to upward of 1800 feet. A great part of Barca, particularly toward the coast, is very fertile, abounding with excellent pasturage, and producing large supplies of corn. The chief town is Bengazi.

BARCA, an ancient city in Cyrenaica, and within the above district, to which it gave name. Its ruins are now known as *El-Medinah*. It was situated between Cyrene (now *Grennah*) and Hesperides (now *Bengazi*), about 11 miles distant from the sea, on the top of the rising ground that overlooks the Syrtes. It was founded about 554 B.C. by a colony from Cyrene, who fled from the ill-treatment of Arcesilaus II., and obtained the co-operation of a number of Libyans.

BARCELONA, formerly the capital of the kingdom of Catalonia, and now the chief town of the Spanish province to which it gives its name, is a flourishing city and seaport on the shore of the Mediterranean, between the rivers Bésos (*Bætulo*) on the north and the Llobregat (*Rubricatus*) on the south. It stands on the sloping edge of a small but fertile plain now covered with villas and gardens.

The educational institutions of Barcelona have from an early period been numerous and important. The university (*Universidad Literaria*) was originally founded in 1430 by the magistracy of the city, and received a bull of confirmation from Pope Nicholas V. in 1450, possessing at that time four faculties and thirty-one chairs, all endowed by the corporation. It was suppressed in 1714, but restored in 1841, and now occupies an extensive building in the new town. There are, besides, an academy of natural sciences, a college of medicine and surgery,—confirmed by a bull of Benedict XIII. in 1400,—an academy of fine arts, a normal school, a theological seminary, an upper industrial school, an institution for the education of deaf-mutes, a school of navigation, and many minor establishments. Gratuitous instruction of a very high order is afforded by the Board of Trade to upwards of two thousand pupils.

The inhabitants of Barcelona are not only an intelligent and industrious, but a gay and pleasure-loving people. Means of public recreation are abundantly supplied. There are no fewer than fourteen theatres of more or less pretension, the two most important being the Teatro Principal and the Teatro del Liceo.

Barcelona has long been the industrial and commercial centre of Eastern Spain—a pre-eminence which dates from the 12th and 13th centuries. It was the rival of Genoa and Venice, and in renown its hardy mariners were second to none. The origin of the famous code of maritime laws known as the *Consolado del mar* is usually, though not with absolute certainty, ascribed to its merchants; and it is pretty well established that they were the first to employ the method of marine insurance. We find them at an early period trading, not only with the ports of the Mediterranean, but with the Low Countries and England, on the one hand, and with Constantinople and Damascus, Egypt and Armenia, on the other,—entering into treaties with kings and magistracies, and establishing in all important places consuls to look after their interests. The prosperity so deeply rooted continued through numerous vicissitudes till the emancipation of the Spanish American colonies, when a comparative decline set in. This, however, proved only temporary, and, in spite of the disastrous consequences of the French invasion, and the various revolutions of the country since then, Barcelona has no need to look back with regret to the past. A great variety of industries are now carried on—the most important being the spinning and weaving of wool, cotton, and silk. Of the numerous guilds that were anciently formed in the city an interesting list is to be found in Capmany. It carries on a large shipping trade.

According to traditions preserved by the Roman writers, Barcelona owed its origin, or at least its first importance, to the Carthaginians under Hamilcar Barca, after whom it was called *Barcino*. It received a Roman colony, and was known by the name of *Faventia*. After having shared in the various vicissitudes of the barbaric invasions, it became the capital of a dukedom under Louis the Pious, and not long after began to give the title of count to a family that soon made itself independent. In 985 the city was captured by the Moors, but not long after it was recovered by Count Borell. In 1151 Raymund Berenguer married the daughter of Ramiro II. of Aragon, and thus the countship of Barcelona, was united to that kingdom by his son. From the successive princes of the line the city received many privileges. In 1640 Barcelona was the centre of the Catalonian rebellion against Philip IV., and threw itself under French protection. In 1652 it returned to its allegiance, but was captured by the duke of Vendôme in 1697. At the peace of Ryswick, in the same year, it was restored to the Spanish monarchy. During the War of the Sucession Barcelona adhered to the house of Austria. The seizure of Montjuich in 1705 and the subsequent capture of the city by the earl of Peterborough formed one of his most brilliant achievements. In 1714 it was taken after an obstinate resistance by the duke of Berwick in the interests of Louis XIV., and at the close of the war was reluctantly reconciled to the Bourbon dynasty. At the commencement of Bonaparte's attempt on the liberty of Spain, the French troops obtained possession of the fortress, and kept the city in subjection. Since then it has shared in most of the revolutionary movements that have swept over Spain, and has frequently been distinguished by the violence of its civic commotions.

BARCLAY, ALEXANDER, an English poet, was born probably about 1476. His nationality has been matter of much literary dispute, but the evidence on the whole seems to point to the conclusion that, though he spent the greater part of his life in England, he was a native of Scotland. The place of his education is equally doubtful; he studied at one of the great English universities, but at which has not yet been settled by his biographers. He received a benefice from the provost of Oriel College, Oxford, and it might therefore be inferred that he had been a student at that place. But Oxford is nowhere referred to in his writings, whereas Cambridge is mentioned once. He appears to have travelled on the Continent after completing his university course, and on his return received an appointment as chaplain in the collegiate church at Ottery St. Mary in Devonshire. He afterwards became a Benedictine

monk of the monastery of Ely, and at length assumed the habit of St. Francis at Canterbury. Having survived the dissolution of the monasteries, he became successively vicar of Much-Badew in Essex, and, in 1546, of Wokey in Somersetshire; and a few months before his death he was presented by the dean and chapter of Canterbury to the rectory of All-Saints in Lombard Street. As he retained some of his preferments in the reign of Edward VI., it is presumed that he must have complied with the changes of the times. He died at an advanced age in the year 1552, and was interred at Croydon. Barclay wrote at a period when the standard of English poetry was extremely low; and, as excellence is always comparative, this circumstance may partly enable us to account for the high reputation which he enjoyed among his contemporaries. At the same time his best work, being a comprehensive and easily understood satire on the manners of the times, naturally acquired a wide popularity, and was extensively read. The title given to it was the *Ship of Fooles*, and it was first printed by Pinson in 1509.

BARCLAY, JOHN, a distinguished scholar and writer, was born, January 28, 1582, at Pont-à-Mousson, where his father William Barclay (see below) was professor of civil law. Educated at the Jesuits' college, he gave evidence of remarkable ability at an early age, and was only nineteen when he published a commentary upon the *Thebais* of Statius. The Jesuits were naturally desirous that he should enter their order, but to this both himself and his father were averse. The jealous enmity of the order was roused against them in consequence of this refusal, and in 1603 both left France and crossed over to England. In 1610 he edited an important treatise left by his father, *De Potestate Papæ*, which involved him in controversy with the famous Cardinal Bellarmin. In 1614 appeared the wittiest and most interesting part of the *Satyricon*, entitled *Icon Animorum*, which gives a critical survey of the varied manners and characteristics of the several European nations. It has been frequently reprinted. In 1616, after a short stay in Paris, he proceeded to Rome, where he continued to reside till his death on 12th August 1621. The *Argenis*, his last work, a long Latin romance, sometimes looked on as a political allegory, was very popular. It is said to have been warmly admired by Richelieu and Leibnitz, while Cowper, Disraeli, and Coleridge speak of it in terms of high admiration.

BARCLAY, JOHN, M.D., an eminent anatomist, was born in Perthshire in 1760, and died at Edinburgh in 1826.

BARCLAY, JOHN, founder of a small sect in the Scotch Church called Bereans or Barclayites, was born in Perthshire in 1734, and died at Edinburgh in 1798. Neither his writings, which were collected in three volumes, nor the sect formed by him, are of much importance. His adherents were called Bereans, because they regulated their conduct as the inhabitants of Berea are said to have done, by diligently searching the Scriptures.

BARCLAY, ROBERT, one of the most eminent writers belonging to the Society of Friends, or Quakers, was born in 1648 at Gordonstown in Morayshire. He was sent to finish his education in Paris, and it appears he was at one time inclined to accept the Roman Catholic faith. In 1667, however, he followed the example of his father, Colonel Barclay of Urie, and joined the recently formed Society of Friends. He was an ardent theological student, a man of warm feelings and considerable mental power, and he soon came prominently forward as a leading apologist of the new doctrine. He died in 1690 at the early age of forty-two. His *Apology* is still the most important manifesto of the Quaker society. Translations of it into foreign language have also appeared.

BARCLAY, WILLIAM, LL.D., a writer on civil law, was born in Aberdeenshire in the year 1541. He was a man of considerable ability, and his legal writings are still valued. In his political opinions he was directly opposed to his illustrious countryman Buchanan, and was a strenuous defender of the rights of kings; his own speculations on the principles of government are best known to some from an incidental confutation by Locke, in his *Treatises on Government*.

BARCLAY DE TOLLY, MICHAEL, a Russian prince and general, highly distinguished in the wars with Napoleon, was born in Livonia in 1759. He was a descendant of the old Scotch family of Barclay, a branch of whom had settled in Russia in the 17th century. He was adopted by General Vermoulen, and entered a Russian cuirassier regiment when very young. In 1788 and 1789 he served against the Turks, and in the following years against the Swedes and Poles. In 1806, when Russia took up arms against Napoleon, he commanded the advanced guard at the battle of Pultusk. At Eylau he lost an arm, and was promoted to the rank of lieutenant-general. In 1808 he commanded against the Swedes, and in 1809 by a rapid and daring march for two days over the ice he surprised and seized Umeo. In 1810 he was made minister of war, and retained the post till 1813. There was keen opposition to the appointment of a foreigner as commander-in-chief, and after the defeat of Smolensk, the outcry was so great that he resigned his office and took a subordinate place under the veteran Kutusoff. On the death of the latter he was reappointed to the supreme command, and fought at the battles of Bautzen, Dresden, and Leipsic. He was unable to bring up his forces in time for the battle of Waterloo, but marched into France and took part in the occupation of Paris. He was rewarded for his services by being made prince and field-marshal. He died in 1818 at Insterburg, in Prussia, while on his way to the Bohemian baths.

BAR-COCHEBAS, or BAR-COCHAB (*Son of a Star*), a celebrated Jewish leader in the insurrection against Hadrian, 131–135 A.D., whose real name was Simeon. The events of his life belong to the history of the Jews.

BARD, from the Welsh *bardd*, is the name applied to the ancient Celtic poets, though the word is sometimes loosely used as synonymous with poet in general. So far as can be ascertained, the title *bards*, and some of the privileges peculiar to that class of poets, are to be found only among Celtic peoples. The name itself is not used by Cæsar in his account of the manners and customs of Gaul and Britain, but he appears to ascribe the functions of the bards to a section of the Druids, with which class they seem to have been closely connected. Later Latin authors used the term *Bardi* as the recognized title of the national poets or singers among the peoples of Gaul and Britain. In Gaul, however, the institution soon disappeared; the purely Celtic peoples were swept back by the waves of Latin and Teutonic conquest, and finally settled in Wales, Ireland, Brittany, and the north of Scotland. There is clear evidence of the existence of bards in all these places, though the known relics belong almost entirely to Wales and Ireland, where the institution was more distinctively national. In Wales they formed an organized society, with hereditary rights and privileges. They were treated with the utmost respect, and were exempt from taxes or military service. Their special duties were to celebrate the victories of their people, and to sing hymns of praise

to God. In Ireland also the bards were a distinct class with peculiar and hereditary privileges. They appear to have been divided into three great sections: the first celebrated victories and sang hymns of praise; the second chanted the laws of the nation; the third gave poetic genealogies and family histories. The Irish bards were held in high repute, and frequently were brought over to Wales to give instruction to the singers of that country.

BARDESANES, or BAR DEISAN, a celebrated Gnostic, was a native of Edessa in Mesopotamia, and appears to have flourished during the reign of Marcus Aurelius. Very little is known of his life. He is said to have held a disputation with Apollonius, a philosopher in the train of Lucius Verus, and he is known to have written against the Marcionite and other heresies. There is considerable doubt whether he was ever a disciple of Valentinus, but it is acknowledged that he never ceased to belong to the Christian church. However seriously his principles, if rigidly interpreted, might conflict with the doctrines of Christianity, he did not regard himself as opposed to that faith, and he was generally considered one of its best defenders. He was especially famed for his hymns, fragments of which are still extant. Of his other works there seems to remain only a treatise *On Fate*, a portion of which was preserved by Eusebius, while the whole has been printed from a Syriac MS. with English translation by Cureton (*Spicilegium Syriacum*, Lond. 1855).

BARDILI, CHRISTOPH GOTTFRIED, a German metaphysician, distinguished by his opposition to the system of Kant, was born at Blaubeuren in Würtemburg, in 1761, and died at Stuttgart in 1808.

BARDSEY (*i.e.*, Bard's Island), or in Welsh YNYS ENLLI, the Island of the Current. is situated at the northern extremity of Cardigan Bay.

BARDWAN (sometimes spelled Burdwan), a division or commissionership in India under the Lieutenant-Governor of Bengal, comprising the districts of Bardwán, Húglí, with Howrah, Midnapur, Bánkurá or West Bardwán, and Bírbhúm. It is bounded on the N. by the district of the Santál Parganás in the Bhágalpur division, and Murshidábád in the Rájsháhī division; on the E. by the Presidency districts of Nadiyá, and the 24 Parganás; on the S. by the Bay of Bengal, and on the W. by the native tributary state of Morbhanj, and the district of Mánbhúm in the Chhotá Nágpur division.

BARDWÁN, an important district in the division of the same name, under the Lieutenant-Governor of Bengal. It is bounded on the N. by the districts of Bírbhúm and Murshidábád, from which it is separated by the River Ajai; on the E. by the districts of Nadiyá and Húglí, the River Bhágirathí separating it from the former; on the S. by the districts of Húglí and Midnapur; and on the W. by the districts of Bánkurá and Mánbhúm.

BARDWÁN, the principal town of the district of the same name, situated on the route from Calcutta to Benares, and a station on the East Indian Railway. Jacquemont formerly described Bardwán town "as consisting of an assemblage of crowded suburbs, of wretched huts, with walls of mud, and covered with thatch, having no temples of striking aspect, and few handsome houses." At the present time Bardwán is a well-built, busy town, with commodious streets, dotted with large tanks, and surrounded by luxuriant gardens. The Mahárájá's palaces are handsome buildings, furnished in the English style, with elegant mirrors and nick-nacks from Paris, and some tolerable oil paintings. Bardwán forms the headquarters of the civil authorities of the division and district, consisting of the commissioner, the judge, magistrate, and collector, and their European and native assistants.

BARÈGES, a small town situated between two mountain chains in the department of Hautes Pyrénées in France, about 25 miles from Bagnères de Bigorre. It is celebrated for its warm sulphurous springs, first brought into notice by the visit of Madame du Maintenon in 1676, the temperature of which varies from 88° to 111° Fahr. The benefit of the waters is granted to the army at the expense of the Government, which erected a bath-house in 1864. During the winter the town is so exposed to avalanches that only a few of the residents remain. The town gives its name to a silk-fabric (barège) which is principally manufactured in Bagnères de Bigorre.

BARELÍ, or BAREILLY, a district of British India in the Rohilkhand division, under the jurisdiction of the Lt.-Governor of the North-Western Provinces. It is bounded on the N. by Kumáon district and the independent state of Nepál; on the E. by a portion of the district of Sháhjahánpur, and the district of Lakhimpur in Oudh; on the S. by the districts of Budáon and Sháhjahánpur; and on the W. by the native state of Rámpur and Budáon. Barelí is a level country, watered by many streams, the general slope being towards the south. The soil is fertile and highly cultivated, groves of noble trees abound, and the villages have a neat, prosperous look. A tract of forest jungle, called the *Tarái*, stretches along the extreme north of the district, and teems with large game, such as tigers, bears, deer, wild pigs, &c.

BARELÍ [*bareilly*], the principal place in the district of the same name, situated on the left bank of the Juá, a tributary of the Western Rámgangá, in N. lat. 28° 23′, E. long. 79° 28′. It is a large town, with a brisk and lucrative commerce, and manufactures consisting principally of house furnitures, such as chairs, tables, &c.

BARÈRE DE VIEUZAC, BERTRAND, one of the most notorious members of the French National Convention, was born at Tarbes in Gascony, September 10, 1755. He was brought up to the profession of the law, and was admitted advocate to the parliament of Toulouse. He wrote several trivial pieces, panegyrics of Louis XVI., Montesquieu, J. J. Rousseau, and others which obtained prizes from provincial academies, and a dissertation on a Latin inscription which procured him membership of the Academy of Floral Games of Toulouse. Such was the smooth beginning of a career which ultimately became unparalleled for meanness, cowardice, lying, and atrocious cruelty. At the age of thirty he married. Four years later, in 1789, he was elected deputy by his own province to the States-general, which met in May. He had made his first visit to Paris in the preceding year. His personal appearance, his manners, social qualities, and liberal opinions, gave him a good standing among the multitude of provincial wise-heads then thronging into Paris, eager to be the saviors of France, or at least of themselves. He took his place at first with the monarchical party; and his glib pen found occupation in the preparation of various reports, and in editing a journal, the *Point du Jour*, containing reports of the debates of the National Assembly. For a time he formed a connection with the House of Orleans, passing over soon to the republican party. Barère appears to have been wholly free from the restraints of conscience or any guiding principle; his conduct was regulated only by the determination to be on the side of the strongest. After the close of the National Assembly he was nominated one of the judges of the newly-instituted Court of Cassation. In 1792 he

was elected deputy to the National Convention for the department of the Hautes Pyrénées. At first he took part with the Girondists; but on the trial of the king he voted, with the Mountain, for the king's death "*sans appel et sans sursis.*" He closed his speech with a sentence which became memorable, "*L'arbre de la liberté ne saurait croître s'il n'était arrosé du sang des rois.*" As the Mountain became the strongest party Barère advanced with it, unscrupulously carrying out its extremest projects, and playing a prominent part in the Reign of Terror. The light-heartedness with which he acted in these awful scenes, the fluency and flippancy of his speeches and reports, procured him the title of the "Anacreon of the Guillotine." He supported Robespierre in his atrocious measure against the Girondists, crawled like a slave at the feet of the "incorruptible" Maximilian till the day of his fall, and then advocated his execution without a hearing. It was Barère who had proposed the decree that no quarter should be given to any English or Hanoverian soldier, which was unanimously adopted. This procured him admission by acclamation to the Jacobin Club, from which he had been previously excluded. The decree, however, remained a dead letter. A few months after the fall of the Convention, proceedings were taken against Barère and his colleagues of the Terror, Collot d'Herbois and Billaud-Varennes, and he was sent to the Isle of Oléron. He was removed to Saintes, and thence escaped to Bordeaux, where he lay in concealment for several years. In 1795 he was elected member of the Council of Five Hundred, but was not allowed to take his seat. When Napoleon Bonaparte was First Consul he was anxious to employ Barère, but Barère refused to overture. It was only for a while. The witling of the Terror became the hireling and the spy of the new Tyranny. On the fall of Napoleon, Barère played the part of royalist, but on the final restoration of the Bourbons in 1815 he was banished for life from France, and then withdrew into Belgium and temporary oblivion. After the Revolution of July 1830 he reappeared in France, was reduced by a series of lawsuits to extreme indigence, accepted a small pension assigned him by Louis Philippe (on whom he had heaped abuse and railing), and died, the last survivor of the Committee of Public Safety, January 15, 1841.

BARETTI, GIUSEPPE, an Italian critic of some distinction, was born at Turin in 1716, and died in May 1789.

BARFLEUR, called formerly Barbeflot, and in the Latin chroniclers *Barbatus Fluctus*, an ancient town of Normandy, in France, now in the department of Manche, 15 miles E. of Cherbourg. It was at one time the seat of an active trade across the Channel, but was ruined and had its harbor filled up by the English in 1346. Cape Barfleur has a lighthouse 271 feet above the sea, in long. 1° 16′ W., lat. 49° 40′ N.

BARHAM, RICHARD HARRIS, a celebrated humorist, better known by his *nom de plume* of THOMAS INGOLDSBY, was born at Canterbury, December 6, 1768. At seven years of age he lost his father, who left him a small estate, part of which was the manor of Tappington, so frequently mentioned in the *Legends*. At nine he was sent to St. Paul's school, but his studies were interrupted by an accident which shattered his arm and partially crippled it for life. Thus deprived of the power of bodily activity, he became a great reader and diligent student. In 1807 he entered Brasenose College, Oxford, intending at first to study for the profession of the law. Circumstances, however, induced him to change his mind and to enter the church. The choice seems surprising, for he had from childhood displayed that propensity to fun in the form of parody and punning which afterwards made him a reputation. In 1813 he was ordained and took a country curacy; he married in the following year, and in 1821 removed to London on obtaining the appointment of minor canon of St. Paul's Cathedral. Three years later he became one of the priests in ordinary of his Majesty's chapel royal. In 1826 he first contributed to *Blackwood's Magazine;* and on the establishment of *Bentley's Miscellany* in 1837 he began to furnish the series of grotesque metrical tales known as *The Ingoldsby Legends*. These became very popular, were published in a collected form, and have since passed through numerous editions. In variety and whimsicality of rhymes these verses have hardly a rival since the days of *Hudibras*. But beneath this obvious popular quality there lies a store of solid antiquarian learning, the fruit of patient enthusiastic research by the light of the midnight lamp, in out-of-the-way old books, which few readers who laugh over his pages detect. If it were of any avail we might regret that a more active faculty of veneration did not keep him from writing some objectional passages of the *Legends*. His life was grave, dignified, and highly honored. His sound judgment and his kind heart made him the trusted counsellor, the valued friend, and the frequent peacemaker; and he was intolerant of all that was mean, and base, and false. In politics he was a Tory of the old school; yet he was the life-long friend of the liberal Sydney Smith, whom in many respects he singularly resembled. Theodore Hook was one of his most intimate friends. Mr. Barham was a contributor to the *Edinburgh Review* and the *Literary Gazette;* published a novel in 3 vols., entitled *My Cousin Nicholas;* and, strange to tell, wrote nearly a third of the articles in Gorton's *Biographical Dictionary*. His life was not without such changes and sorrows as make men grave. He had nine children, and six of them died in his lifetime. But he retained vigor and freshness of heart and mind to the last, and his latest verses show no signs of decay. He died in London after a long, painful illness, June 17, 1845, leaving his beloved wife, two daughters, and a son, surviving him.

BARI, TERRA DI, a province of Italy, in the district of Apulia, bounded on the N. by the Adriatic, E. and S.E. by the province of Otranto, S.W. by Basilicata, and W. by Capitanata. It has an area of 1782 geographical square miles, and is divided into the three districts of Bari, Barletta, and Altamura. Except in the S. and S.W., where branches of the Apennines occur, the surface is generally level. The soil is for the most part calcareous, with a rich covering of loam. The climate is oppressively hot in summer, but very pleasant during the rest of the year. The only considerable river is the Ofanto, or *Aufidus*; but, in spite of the lack of irrigation, the province is among the best cultivated in the kingdom, producing abundance of grain, flax, tobacco, cotton, wine, oil, almonds, liquorice, &c. Swine, asses, goats, and sheep with a very fine wool, are numerous; and the salt and nitre works form important branches of industry. Among the more important towns beside the capital are Barletta, Trani, Bisceglie, Molfetta, Monopoli, and Fasano on the coast, and Andria Ruvo, Nola, Bitonto, and Conversano somewhat inland. The population, which is densest along the coast, was 604,540 in 1871.

BARI, the ancient *Barium*, capital of the above province and seat of an archbishop, is situated on a tongue of land projecting into the Adriatic. It is defended by various fortifications, among which the most important is the citadel, which is about a mile in circumference, and dates from the Norman possession. The general character of the older part of the town is gloomy and

irregular, but the newer portion has spacious streets, with handsome buildings. *Barium*, according to the evidence of its coins, was a place of importance in the third century, B.C., and had a decided Greek element in its culture; but it never acquired any great influence in the old Roman world, and all allusions to it in the classical authors are of an incidental description.

BARILLA, an impure carbonate of soda, produced from plants which grow in salt-marshes or other places near the sea; it forms a considerable article of commerce, being used in the manufacture of soap and of glass, and for other purposes in the arts. The greatest quantities of barilla are produced in Spain and the Balearic Islands; but the Canary Islands, Italy, and France also contribute a part. It is produced by burning the plants, much in the same way that seaweeds once were largely burned on the coasts of Scotland for kelp.

BARING. The firm of Baring Brothers & Co. was for many years one of the greatest financial and commercial houses in the world.

In November, 1890, the financial world was startled to learn that the great house of Barings, second only to the Rothschilds, was in distress, and in a few days it was announced that a syndicate representing the Bank of England, the Rothschilds, and other great English banks and bankers had assumed the liabilities of the firm and guaranteed to carry out its contracts. The cause of the entanglement was the attempt of Baring Brothers to carry an enormous loan for the Argentine Republic, this alone representing ten millions sterling, while the total liabilities were reported to be over £16,000,000. As the failure of such an important factor in the commercial world would have caused widespread disaster prompt measures were taken by leading financiers, the trouble was tided over and the firm continues in business for the time necessary in which to realize on securities and straighten out affairs.

BARING-GOULD, SABINE, an active littérateur in widely different fields, was born at Exeter in 1834. In early life he lived much in Germany and France. Educated at the Clare College, Cambridge, he was appointed incumbent of Dalton, Thirsk, in 1869; rector of East Mersea, Colchester, in 1871; and in 1881 rector of Lew Trenchard, Devonshire. He attained some notoriety by the production of various novels, which, though powerfully written, have not become popular.

BARITONE, that species of the human voice which lies between the bass and the tenor, but whose tone-character is more allied to the bass.

BARIUM (sym. Ba, eq. 137) is the metal present in heavy spar (sulphate of baryta) and baryta. It was regarded as a white metal, until the researches of Dr. Matthiessen demonstrated that it possesses a yellow color. As yet, the metal barium has not been obtained in mass, but only as a powder.

BARK. The hard outer covering of any stem is often popularly called bark, or by botanical writers, cortex. Botanists are accustomed to restrict the term bark to the outer portion of the dicotyledonous stem, and especially to that of woody and perennial stems.

The bark of many trees is capable of being used for tanning, but those kinds are usually preferred which are rich in tannin, although other properties besides the percentage of tannin determine the value of a bark for preparing leather. Oak bark from *Quercus robur* and *pedunculata* are used more than all other kinds in Europe, and contain from 7 to 11 per cent. of tannin; but the barks of willow, larch, Scotch fir, birch, and alder are likewise employed to a considerable extent. That of the chestnut (*Castanea vesca*) is much esteemed. From both bark and wood of this tree an extract is made in France which is largely used both in tanning and dyeing. In Spain tanners employ the inner layer of the bark of the cork oak. Three species of oak are used for tanning in the United States—namely, *Quercus tinctoria*, *prinus*, and *falcata*; the former two contain about 6 per cent., and the last 8.6 per cent. of tannin.

BARKING, a town of England, county of Essex, seven miles east-northeast of London, on the River Roding, not far from the Thames. It was celebrated for its nunnery, one of the oldest and richest in England.

BARLAAM AND JOSAPHAT, Saints. These two saints appear in both the Greek and the Roman Martyrology, in the former under August 26, in the latter under November 27. Their story is in the highest degree worthy of note, because it is, in fact, a Christianized version of the Indian legendary history of the Buddha Sakya Muni.

The outline of the Greek story is as follows: — St. Thomas had converted the people of India, and after the eremitic life originated in Egypt, many Indians adopted it. But a powerful pagan king arose who hated and persecuted the Christians, especially the ascetics. After this king, Abenner by name, had long been childless, a boy greatly desired, and matchless in beauty, was born to him, and received the name of Josaphat. The king, in his joy, summons astrologers to predict the child's destiny. They foretell glory and prosperity beyond those of all his predecessors. One sage, most learned of all, assents, but intimates that the scene of this glory will be, not the paternal kingdom, but another infinitely more exalted, and that the child will adopt the faith which his father persecutes.

The boy shows a thoughtful and devout turn. King Abenner, troubled by this and by the remembrance of the prediction, selects a secluded city, in which he causes a splendid palace to be built, where his son should abide, attended only by tutors and servants in the flower of youth and health. No stranger was to have access, and the boy was to be cognizant of none of the sorrows of humanity, such as poverty, disease, old age, or death, but only of what was pleasant, so that he should have no inducement to think of the future life; nor was he ever to hear a word of Christ and his religion.

Prince Josaphat grows up in this seclusion, acquires all kinds of knowledge, and exhibits singular endowments. At length, on his urgent prayer, the king reluctantly permits him to pass the limits of the palace, after having taken all precautions to keep painful objects out of sight. But through some neglect of orders, the prince one day encounters a leper and a blind man, and asks of his attendants with pain and astonishment what such a spectacle should mean. These, they tell him, are ills to which a man is liable. Shall all men have such ills? he asks. And in the end he returns home in deep depression. Another day he falls in with a decrepit old man, and, stricken with dismay at the sight, renews his questions, and hears for the first time of death.

At this time Barlaam, an eremite of great sanctity and knowledge, dwelling in the wilderness of Sennaritis, divinely warned, travels to India in the disguise of a merchant, and gains access to Prince Josaphat, to whom he imparts the Christian doctrine and commends the monastic life. Suspicion arises and Barlaam departs. But all attempts to shake the prince's convictions fail. As a last resource the king sends for Theudas, a magician, who removes the prince's attendants and substitutes seductive girls; but all their blandishments are resisted through prayer. The king abandons these efforts and associates his son in the government. The prince uses his power to promote religion, and everything prospers in his hands. At last Abenner himself yields to the faith, and after some years of penitence dies. Josaphat

surrenders the kingdom to a friend called Barachias, and departs for the wilderness. After two years of painful search, and much buffeting by demons, he finds Barlaam. The latter dies, and Josaphat survives as a hermit many years. King Barachias afterwards arrives, and transfers the bodies of the two saints to India, where they are the source of many miracles.

BARLETTA, the ancient *Bardulum*, called in the Middle Ages, *Barolum*, a fortified seaport town of Italy, the seat of an archbishop, in the province of Terri di Bari. Population, 30,000.

BARLEY (*Hordeum*), a most important genus of the cereal plants which belongs peculiarly to temperate regions. Four distinct species of barley, cultivated for the production of grain, are commonly enumerated,—1st, common or two-rowed barley, *Hordeum distichum;* 2d, Bere or Bigg, *H. vulgare;* 3d, six-rowed barley, *H. hextastichum;* and 4th, fan, spratt, or battledore barley, *H. zeocriton*. Of these species, but chiefly of the first two, very many varieties are recognized by cultivators, and new kinds are constantly being introduced. Barley is the most hardy of all cereal grains, its limit of cultivation extending further north than any other; and, at the same time, it can be profitably cultivated in sub-tropical countries. The opinion of Pliny, that it is the most ancient aliment of mankind, appears to be well founded, for no less than three varieties have been found in the lake dwellings of Switzerland, in deposits belonging to the Stone Period. According to Professor Heer these varieties are the common two-rowed (*H. distichum*), the large six-rowed (*H. hextastichum densum*), and the small six-rowed (*H. hextastichum sanctum*). The last variety is both the most ancient and the most commonly found, and is the sacred barley of antiquity, ears of which are frequently represented plaited in the hair of the goddess Ceres, besides being figured on ancient coins. The cultivation of barley in ancient Egypt is indicated in Exod. ix. 31. Till within recent times barley formed an important source of food in northern countries, and barley cakes are still to some extent eaten. Owing, however, to its poverty in that form of nitrogenous compound called gluten, so abundant in wheat, barley-flour cannot be baked into vesiculated bread.

BARLOW, JOEL, an American poet and politician, born in 1755 at Reading in Connecticut. In 1774, some years after his father's death, he was entered at Yale College, New Haven, where he soon began to manifest considerable taste for poetry and power of composition. A few small pieces published by him were received with some degree of public favor. During his vacations he had taken part with the colonists in several engagements against the British, and immediately after completing his course, he qualified himself for the church, and was appointed chaplain to a regiment. This post he held till the conclusion of peace between Britain and America, when he settled in the village of Hartford, and began to practise as a lawyer. He also conducted a newspaper, and about the same time published his best poem, the *Vision of Columbus*, a vigorous and spirited piece of writing. About the year 1788 he gave up his newspaper and his legal practice, and went to Europe as the agent for a land company. Having discovered that this company was merely a swindling concern, he severed his connection with it, but did not return to America. In London he became acquainted with some of the most advanced liberal thinkers, and published several political tracts of a decidedly revolutionary character. In 1793, after having been some time in France, he accompanied the Commission of the National Convention, which was sent to organize the newly-acquired territory in Savoy. During his residence in Paris he engaged in commercial transactions, by which he acquired considerable fortune and importance. In 1795 he was appointed American consul at Algiers, and efficiently discharged the duties of that office. In 1805 he returned to America and began to interest himself in the politics of his own country. A pamphlet of his, sketching a plan of national education, was received with great favor. In 1808 he published an enlarged edition of his great poem, under the title *Columbiad*. It was magnificently illustrated, but did not achieve the popularity of its predecessor. In 1811 he was appointed minister plenipotentiary to France, with the object mainly of negotiating a commercial treaty and of obtaining compensation for some American property that had been unjustly confiscated. To accomplish this he required a personal interview with Napoleon, and set out to meet the emperor, who was at Wilna. On his way he was attacked with inflammation of the lungs, and died at a Polish village near Cracow, on the 22d December 1812.

BARLOW, PETER, an able writer on pure and applied mathematics, was born in Norwich, England, in 1776, and died in 1862.

BARMECIDES, or descendants of Barmak, were a noble Persian family, who attained great power under the Abbaside caliphs. Barmak, the first of them, was a Ghebre, or Persian fire-worshipper, and is supposed to have been a native of the district of Khorassan. He was introduced to the caliph Abd-ul-Malik, and acquired great power under him. His family prospered, and his grandson, Yahya, was vizier to the caliph El Mahdy, and tutor of the famous prince Haroun-al-Raschid, celebrated in the *Thousand and One Nights*. Yahya's sons occupied high offices, one of them, Ja'afar (the Giafar of the *Arabian Nights*), being vizier and constant companion of Haroun. The caliph, however, conceived suspicions against the Barmecides, and in 802 beheaded Ja'afar with great cruelty, condemned the whole family to prison, and confiscated their property. The use of the expression *Barmecides' Feast*, to denote an imaginary banquet, is drawn from one of the tales in the *Arabian Nights*, where an entertainment of merely imaginary viands is served up to a hungry man by one of the Barmecides.

BARMEN, a town is Rhenish Prussia, in the government of Dusseldorf and circle of Elberfeld, on the Bergisch-Märkisch railway. It is formed by the combination of a large number of separate villages, which stretch along the northern valley of the Wupper for a distance of six miles in almost perfect continuity with Elberfeld. It is the chief seat of ribbon-weaving in braids, cotton, cloth, silk stuffs, steel wares, and plated goods. There are also numerous bleachfields, printfields, dyeworks,—famous for their Turkey-red,—soapworks, chemical-works, and potteries. Population, 75,000.

BARNABAS was the surname given by the apostles to Joses, "a Levite, of the country of Cyprus," who, though like Paul not of the twelve, was with him recognized among the number of the apostles.

BARNABAS, EPISTLE OF, and GOSPEL OF. See APOSTOLIC FATHERS and GOSPELS.

BARNACLE, a common crustacean, techinically known as Lepas, and belonging to the group of stalked Cirripedia. Like the closely-allied sessile acorn-shell, a barnacle may be said to be a crustacean fixed by its head, and kicking the food into its mouth by its legs. So much are they disguised, however, in their fixed state, that they were formerly referred to the class of molluscs.

BARNARD CASTLE, a market and manufacturing town and parish in the county of Durham, on the banks of the Tees, 246 miles from London.

BARNAUL, a town of Asiatic Russia, in the government of Tomsk, and capital of a circle to which it gives its name. It is situated in a wide plain which is bounded by offshoots of the Altai Mountains, and is built on both sides of the Barnaulka River at its confluence with the Ob. Population, 12,927.

BARNAVE, ANTOINE PIERRE JOSEPH MARIE, one of the greatest orators and noblest actors and victims of the first French Revolution, was born at Grenoble in Dauphiny, October 22, 1761. He was of a Protestant family. His father was an advocate to the parliament of Grenoble, and his mother was a woman of high birth, superior ability, and noble character. He was at once thoughtful and passionate, studious and social, handsome in person and graceful in manners. He was brought up to the law, and at the age of twenty-two made himself favorably known by a discourse pronounced before the local parliament on the division of political powers. Dauphiny was one of the first of the provinces to feel the excitement of the coming revolution; and Barnave was the foremost to give voice to the general feeling, in a pamphlet entitled *Esprit des édits enregistrés militairement le* 20 *Mai* 1788. He was immediately elected deputy, with his father, to the States of Dauphiny, and took a prominent part in their debates. A few months later he was transferred to a grander field of action. The States-general were convoked at Versailles for May 5, 1789, and Barnave was chosen deputy of the *Tiers État* for his native province. He soon made an impression on the Assembly, and became the friend of most of the leaders of the popular party. He took part in the conferences on the claims of the three orders, drew up the first address to the king, and supported the proposal of Sieyès that the Assembly should declare itself National. Though a passionate lover of liberty, he knew that excess is the ruin of liberty, and maintained the necessity for the individual and for the community of both freedom and restraint. He hoped to secure the freedom of France and her monarchy at the same time. But he was almost unawares borne away by the mighty currents of the time, and he took part in the attacks on the monarchy, on the clergy, on church property, and on the provincial parliaments. With the one exception of the mighty Mirabeau, Barnave was the most powerful orator of the Assembly. On several occasions he stood in opposition to Mirabeau. After the fall of the Bastile he wished to save the throne. He advocated the suspensive veto, the system of two chambers, and the establishment of trial by jury in civil causes. His conflict with Mirabeau on the question of assigning to the king the right to make peace or war was one of the most striking scenes in the Assembly. About this time, after a vehement debate, he fought a duel with Cazalès, in which the latter was slightly wounded. About the close of October 1790 Barnave was called to the presidency of the Assembly. On the death of Mirabeau a few months later, Barnave paid a high tribute to his worth and public services, designating him the Shakespeare of oratory. On the arrest of the king and the royal family at Varennes, while attempting to escape from France, Barnave was one of the three appointed to conduct them back to Paris. On the journey he was deeply affected by the mournful fate of these royal persons, and resolved to do what he could to alleviate their sufferings. In one of his most powerful speeches he maintained the inviolability of the king's person. His public career came to an end with the close of the Constituent Assembly, and he returned to Grenoble at the beginning of 1792. His sympathy and relations with the royal family, and his desire to check the downward progress of the Revolution, brought on him the suspicion and persecution of the more violent party. At the end of August 1792 he was arrested and imprisoned, and in November 1793 was transferred to Paris. The nobility of his character was proof against the assaults of suffering. "Better to suffer and to die," he said, "than lose one shade of my moral and political character." On November 28 he appeared before the Revolutionary Tribunal, in company with Duport-Dutertre, and two days later they both perished by the guillotine.

BARNES, ALBERT, a theologian of America, specially distinguished as a Biblical expositor, was born at Rome in the state of New York, 1st December 1798, and died at Philadelphia 24th December 1870. In 1820 he graduated at Hamilton College, and in the same year commenced his studies for the ministry at Princeton Theological Seminary. Soon after taking licence he was called to the Presbyterian church in Morristown, New Jersey, from which he was transferred to the pastoral charge of the first Presbyterian church of Philadelphia in 1830. In 1867 he was compelled to resign owing to failing health. Barnes held a prominent place in the New School branch of the Presbyterians, to which he had adhered on the division of the denomination. He was an eloquent preacher, but his widespread reputation rests chiefly on his expository works, which have probably had a larger circulation both in Europe and America than any others of their class. Of the well-known *Notes on the New Testament* it is said that more than a million volumes had been issued at the time of their author's death.

BARNES, JOSHUA, an English scholar, born in 1654. In 1695 he was chosen queen's professor in Greek, a language which he wrote and spoke with the utmost facility. He died in 1712.

BARNET, or CHIPPING BARNET, a market-town in the county of Hertford, 11 miles from London, on the great northern road. Near it, in 1471, was fought the decisive battle between the houses of York and Lancaster, in which the great earl of Warwick fell.

BARNEVELDT, JAN VAN OLDEN, Grand Pensionary of Holland, who played a great part and rendered the most signal services to his country in the long conflict with Philip II. of Spain, was born in 1547. He was a native of Amersfoot in the province of Utrecht, and could boast of a long line of noble ancestors. Endowed with superior abilities, he was educated for the profession of the law, and commenced practice as an advocate at the Hague in 1569. He sympathized deeply with his countrymen in their resolution to throw off the hated yoke of Spain, and served as a volunteer at the sieges of Haarlem and Leyden. In 1575 he married; and in the following year he was appointed to the honorable post of counsellor and chief-pensionary of Rotterdam. In 1585, when, in consequence of the assassination of the sagacious and resolute leader of the Dutch, and the general success of the Spaniards under the Prince of Parma, the cause of the patriots seemed almost hopeless, Barneveldt was chosen head of an embassy to Queen Elizabeth, to ask for her assistance and to offer her the sovereignty of the United Provinces. The queen agreed to give aid both in money and men, but refused to accept the sovereignty. An expedition was sent under the command of Dudley, earl of Leicester, on whom the Dutch conferred supreme and absolute authority. Barneveldt was then raised to the high office of advocate-general of Holland and West Friesland. Dissatisfied and indignant at Leicester's incompetence, arrogance, and mismanagement, he endeavored to limit his powers. For this purpose he succeeded in persuading the States to appoint Maurice of Nassau, the young son of the late Prince of Orange, stadtholder and captain-general of Holland

and Zealand, thus contributing to place in the highest position the man who was afterwards to become his great antagonist. Leicester was recalled at the close of 1586. In the course of a few years Barneveldt, by his prudence and energy in administration, succeeded in restoring order and materially improving the financial affairs of the States. He proposed to resign in 1592, but at the urgent entreaty of the States he retained his post. In 1598 he was sent on an embassy to Henry IV. of France, the object of which was to strengthen and maintain the friendship of France and the United Provinces. In 1603, on the accession of James I. to the throne, Barneveldt was again sent to England as head of an embassy, and in conjunction with the French ambassador, M. de Rosny, afterwards duke of Sully, negotiated an arrangement for further assistance against the Spaniards. In 1607, having first insisted on and obtained a recognition of the independence of the Provinces, he began negotiations with Spain with a view to establish a truce. He had to contend against the opposition of the stadtholder and the army, and to suffer from unmerited popular suspicions of taking bribes from the Spanish court. But he triumphed over all difficulties, and on April 9, 1609, the famous twelve years' truce was concluded. From this time Maurice was his sworn foe. The two men were leaders of two great political parties, and the struggle between them was embittered by the admixture of theological and ecclesiastical controversy. In the strife then going on between the Gomarites (the Calvanistic party) and the Arminians, Maurice sided with the former, while Barneveldt supported the latter. Maurice was aiming at the sovereign power; Barneveldt resolutely maintained the freedom of the republic. The clerical party, who looked up to Prince Maurice as their chief, were bent on getting the Calvinistic system established as the state religion, and on refusing to tolerate any other system; Barneveldt and the Arminians contended that each province should be free to adopt the form which it preferred. Barneveldt was the consistent champion of the supremacy of the civil authority, and "the prime minister of Protestantism" (Motley). The convocation of a National Synod was proposed by the party of the stadtholder and resisted by Barneveldt. When disturbances broke out against the Arminians, Maurice refused to suppress them, and disarmed the militia organized for the purpose by Barneveldt. The former now assumed the chief power. An interview took place on August 17, 1618, between the advocate and the stadtholder; each adhered resolutely to his own views, and the meeting remained fruitless. Barneveldt, with his friends Grotius and Hoogerbeets, was arrested and imprisoned on the 29th. In November following, in pursuance of the command of Prince Maurice, the famous Synod of Dort assembled. A few days later the trial of the prisoners began before a special commission. The proceedings were illegal; the accusations against Barneveldt were fully disproved, but he was unjustly found guilty and sentenced to death. This sentence was unscrupulously confirmed by the clerical synod. It was a foregone conclusion, and Barneveldt had seen clearly that there was no hope for him. On the 14th of May 1619, just five days after the closing of the synod, the venerable statesman and patriot, then in his seventy-first year, was beheaded at the Hague. He met his fate without a word of regret, without a sign of fear. His calm courage and his tenderness of heart are attested by a letter, still extant, written to his wife a few hours before his execution. Besides his wife, Maria van Utrecht, Barneveldt left two sons and two daughters. Four years after their father's death the sons took part in a plot against Prince Maurice; one of them made his escape and entered the service of Spain, the other was arrested and beheaded.

BARNSLEY, or BLACK BARNSLEY, mentioned in *Doomesday Book* as Bernesleye, a town and municipal borough in the West Riding of Yorkshire, 171 miles from London and about 11 north of Sheffield. It is situated on rising ground to the west of the River Dearne, in a district of considerable natural beauty. The manufacture of iron and steel, and the weaving of linen and other cloth, are the two principal industries; but there are also bleachfields, printfields, dyeworks, sawmills, cornmills, and malt-houses; and the manufacture of glass, needles, and wire is still carried on. Population in 1889, 32,000.

BARNSTABLE, a seaport town, and capital of the county of the same name, in the state of Massachusetts, North America. It is situated on the south side of a bay of the same name, which opens into Cape Cod Bay, and is 65 miles S.E. of Boston. The population, which is largely sea-faring, amounted in 1890 to 4,022.

BARNSTAPLE, a market and borough town of England, county of Devon, 40 miles N.W. of Exeter. It is situated on the River Taw, 6 miles from its mouth, but has always been considered a seaport. The stream, which is only navigable for small craft, is here crossed by an ancient stone bridge of 16 arches, and by a railway bridge on the Ilfracombe line. Pop., 12,282.

BAROCCHIO, or BAROZZI, GIACOMO DA VIGNOLA, architect, born at Vignola in the Modenese territory, in 1507, and died in 1573.

BAROCCI, or BAROCCIO, FEDERIGO, painter, was born in 1528 at Urbino, where the genius of Raphael inspired him. In his early youth he travelled to Rome, where he painted in fresco, and was warmly commended by Michael Angelo. He then returned to Urbino, where, with the exception of some short visits to Rome, he continued to reside till his death in 1612.

BARODÁ, a city of British India, the capital of the native state known as the Gaikwár's dominions, is situated near the River Biswamintri. The Government of Bombay exercises a political superintendence over the Gaikwár and a British political agent resides at Barodá. The town is fortified. Population, 105,000.

BAROMETER, the instrument by which the weight or pressure of the atmosphere is estimated. The barometer was invented by Torricelli, a pupil of Galileo, in 1643. It had shortly before been found, in attempting to raise water from a very deep well near Florence, that, in spite of all the pains taken in fitting the piston and valves, the water could by no effort be made to rise higher in the pump than about 32 feet. This remarkable phenomenon Torricelli accounted for by attributing pressure to the air. He reasoned that water will rise in a vacuum only to a certain height, so that the downward pressure or weight of the column of water will just balance the pressure of the atmosphere; and he further argued that if a fluid heavier than water be used it will not rise so high in the tube as the water. To prove this, he selected a glass tube about a quarter of an inch in diameter and 4 feet long, and hermetically sealed one of its ends; he then filled it with mercury and, applying his finger to the open end, inverted it in a basin containing mercury. The mercury instantly sank to nearly 30 inches above the surface of the mercury in the basin, leaving in the top of the tube an apparent vacuum, which is, indeed, one of the most perfect that can yet be produced, and is called after this great experimenter, the *Torricellian vacuum*. He next converted the mercurial column into a form suited for observation by bending the lower end of the tube, thus constructing what has since been called the siphon barometer. The fundamental principle of the barometer cannot be better illus-

trated than by his experiment. In truth, a scale is all that is required to render this simple apparatus a perfect barometer.

The heights of the columns of two fluids in equilibrium are inversely as their specific gravities; and as mercury is 10,784 times heavier than air, the height of the atmosphere would be 10,784 times 30 inches, or nearly five miles, if it were composed of layers equally dense throughout. But since air becomes less dense as we ascend, owing to its great elasticity and the diminished pressure, the real height of the atmosphere is very much greater. From observations of luminous meteors, it has been inferred that the height is at least 120 miles, and that, in an extremely attenuated form, it may even considerably exceed 200 miles.

Various fluids might be used in constructing barometers. If water were used, the barometric column would be about 35 feet long. The advantages, however, which *water barometers* might be supposed to possess in showing changes of atmospheric pressure on a large scale, are more than counter-balanced by a serious objection. The space in the tube above the column of water is far from being a vacuum, being filled with aqueous vapor, which presses on the column with a force varying with the temperature. At a temperature of 32° Fahr. the column would be depressed half an inch, and at 75° a foot. Since in mercurial barometers the space at the top of the column is one of the most perfect vacuums that can be produced, the best fluid for the construction of barometers is mercury. It is therefore the only fluid used where scientific accuracy is aimed at. Pure mercury must be used in filling the tubes of barometers; because if it be impure, the density will not be that of mercury, and, consequently, the length of the columns will not be the same as that of a column composed of pure mercury alone.

The best barometers are usually fitted with an *air-trap*, originally proposed by Gay-Lussac for the purpose of arresting the ascent to the Torricellian vacuum of any air that may have found its way into the column by the cistern. The air-trap is fitted into the tube somewhere between the scale and the cistern. Barometers furnished with an air-trap can be conveyed from place to place with more safety, and they remain longer in good working order.

There are two classes of barometers — *Siphon Barometers* and *Cistern Barometers*. The *Siphon Barometer* consists of a tube bent in the form of a siphon, and is of the same diameter throughout. A graduated scale passes along the whole length of the tube, and the height of the barometer is ascertained by taking the difference of the readings of the upper and lower limbs respectively. This instrument may also be read by bringing the zero-point of the graduated scale to the level of the surface of the lower limb by means of a screw, and reading off the height at once from the surface of the upper limb. This barometer requires no correction for errors of capillarity or capacity. Since, however, impurities are contracted by the mercury in the lower limb, which is usually in open contact with the air, the satisfactory working of the instrument comes soon to be seriously interfered with.

The *Cistern Barometer* is subject to two kinds of error, the one arising from capillarity, and the other from changes in the level of the surface of the cistern as the mercury rises and falls in the tube, the latter being technically called the *error of capacity*. If a glass tube of small bore be plunged into a vessel containing mercury, it will be observed that the level of the mercury in the tube is not in the line of that of the mercury in the vessel, but somewhat below it, and that the surface is convex. The capillary depression is inversely proportional to the diameter of the tube. If the diameter of the tube be 0.1 inch, the capillary depression of mercury in boiled tubes, or *error of capillarity*, is 0.070 inch; if 0.2 inch, the error is 0.029 inch; if 0.3 inch, it is 0.014 inch; and if 0.5 inch, it is only 0.003 inch. Since capillarity depresses the height of the column, cistern barometers require an addition to be made to the observed height, in order to give the true pressure, the amount depending, of course, on the diameter of the tube.

The error of capacity arises in this way. The height of the barometer is the perpendicular distance between the surface of the mercury in the cistern and the upper surface of the mercurial column. Now, when the barometer falls from 30 to 29 inches, an inch of mercury must flow out of the tube and pass into the cistern, thus raising the cistern level; and, on the other hand, when the barometer rises, mercury must flow out of the cistern into the tube, thus lowering the level of the mercury in the cistern. Since the scales of barometers are usually engraved on their brass cases, which are fixed (and, consequently, the zero-point from which the scale is graduated is also fixed), it follows that, from the incessant changes in the level of the cistern, the readings would be sometimes too high and sometimes too low, if no provision were made against this source of error.

A simple way of correcting the error of capacity is — to ascertain (1) the neutral point of the instrument, or that height at which the zero of the scale is exactly at the height of the surface of the cistern, and (2) the rate of error as the barometer rises or falls above this point, and then apply a correction proportional to this rate. In many of the barometers used on the Continent the surface area of the cistern is 100 times greater than that of the tube, in which case the error is small, and can, besides, be easily calculated. This is a good barometer for ordinary observers, inasmuch as no error arises in bringing the surface of the mercury of the cistern to the zero-point of the scale, which one requires to have some skill as a manipulator and good light to do correctly. Another way of getting rid of this error is effected by the *Board of Trade Barometer*, constructed originally by Adie of London. In this barometer the error of capillarity is allowed for in fixing the zero-point of the scale, and the error of capacity is obviated by making the scale-inches not true inches, but just so much less as exactly to counterbalance the error of capacity.

But the instrument in which the error of capacity is satisfactorily (indeed, entirely) got rid of is *Fortin's Barometer*. The cistern is formed of a glass cylinder, through which the level of the mercury may be seen. The bottom is made like a bag, of flexible leather, against which a screw works. At the top of the interior of the cistern is a small piece of ivory, the point of which coincides with the zero of the scale. By means of the screw, which acts on the flexible cistern bottom, the level of the mercury can be raised or depressed so as to bring the ivory point exactly to the surface of the mercury in the cistern. In some barometers the cistern is fixed, and the ivory point is brought to the level of the mercury in the cistern by raising or depressing the scale.

What is called the *Fitzroy Barometer* is only a modified form of the siphon barometer, with the lower limb blown into a moderately-sized bulb, resembling a cistern in some respects, and thus giving a larger range to the readings of the upper limb. It is only suited for popular, not for scientific purposes. The common *Wheel Barometer*, the common form of the *weather glass*, is also a modification of the siphon barometer. A small weight, glass or iron, floats on the mercury in the lower limb; to this weight a thread is attached, which is led

round a horizontal axis, a small weight being suspended at its free extremity to keep it tight. The float rises and falls with the fluctuations of the barometer, and a pointer fixed to a horizontal axis being turned by this means indicates the height of the barometer by figures on a dial. Since the mercury only rises or falls in the open end of the siphon to the extent of half the oscillation, a cistern is added to the top of the upper limb to increase the amount of the oscillation in the lower limb. This form of the barometer is only suited for very rough purposes, since large and uncertain errors arise from the shortening and lengthening of the thread with the varying dampness or dryness of the air, and from the friction of the different parts of the mechanism of the instrument.

Since in working out the great atmospheric problem of the force of the wind in its relation to the barometric gradient (*i.e.*, the differences of the pressures at different places, reduced to the same level) readings from about the hundredth of an inch (0.010), or even less, required to be observed and stated with great accuracy, the extreme importance of accurate sensitive barometers will be apparent,—instruments not only possessing a great range of scale, but a scale which will truly indicate the real atmospheric pressure at all times. The two barometers which best satisfy this requirement are *King's Barometer*, which has been in use for many years at the Liverpool Observatory, and *Howson's Barometer*.

The liability of the barometer to be broken in carriage is great. This risk is considerably lessened in the *Board of Trade Barometer*, which has the tube very much reduced in diameter for a part of its length, breakage from "pumping" being so much lessened thereby that the instrument may be sent as a parcel by rail, if only very ordinary care be taken in the carriage. This is essentially the principle of the *Marine Barometer*, which, however, has the tube still more contracted. For rougher modes of transit an ingeniously constructed iron barometer has been invented by Mr. T. Stevenson, C. E.

The *Aneroid Barometer* was invented by Vidi, and patented in England in 1844. Its action depends on the effect produced by the pressure of the atmosphere on a circular metallic chamber partially exhausted of air and hermetically sealed.

The instrument requires, however, to be repeatedly compared with a mercurial barometer, being liable to changes from the elasticity of the brass chamber changing, or from changes in the system of levers which work the pointer. Though aneroids are constructed showing great accuracy in their indications, yet none can lay any claim to the exactness of mercurial barometers. The mechanism is liable to get fouled and otherwise go out of order, so that they may change 0.300 inch in a few weeks, or even indicate pressure so inaccurately and so irregularly that no confidence can be placed in them for even a few days, if the means of comparing them with a mercurial barometer be not at hand.

Of the *self-registering barometers*, the best are those which accomplish this object by photography. This is done by concentrating the rays of a gas flame by means of a lens, so that they strike the top of the mercurial column. A sheet of prepared paper is attached to a frame placed behind a screen, with a narrow vertical slit in the line of the rays. The mercury being opaque throws a part of the paper in shade, while above the mercury the rays from the flame pass unobstructed to the paper. The paper being carried steadily round on a drum at a given rate per hour, the height of the column of mercury is photographed continuously on the paper. From the photograph the height of the barometer at any instance may be taken. *King's*, *Hardy's*, *Hough's*, *Hipp's* and *Thorell's self-registering barometers* may also be referred to as giving continuous records of the presure.

The height of the barometer is expressed in English inches in England and America. In France and most European countries, the height is given in millimètres, a millimètre being the thousandth part of a mètre, which equals 39.37079 English inches. Up to 1869 the barometer was given in half-lines in Russia, which, equalling the twentieth of an English inch, were readily reduced to English inches by dividing by 20. The metric barometric scale is now used in Russia. In a few countries on the Continent the French or Paris line, equalling 0.088814 inch, still continues to be used. Probably millimètre and English inch scales will soon be exclusively in use. The English measure of length being a standard at 62° Fahr., the old French measure at 61°.2, and the metric scale at 32°, it is necessary, before comparing observations made with the three barometers, to reduce them to the same temperature, so as to neutralize the inequalities arising from the expansion of the scales by heat.

The barometer is a valuable instrument as an indicator of coming weather, provided its readings be interpreted with intelligence. High pressures generally attend fine weather, but they not unfrequently accompany wet stormy weather; on the other hand, low pressures, which usually occur with wet and stormy weather, not unfrequently accompany fine mild weather, particularly in winter and in the northern parts of Great Britain. The truth is, the barometer merely indicates atmospheric pressure directly, whilst it indicates weather only inferentially. The chief points to be attended to are its fluctuations taken in connection with the wind and the state of the sky, but above all, the readings of the barometer as compared with those at neighboring places, since it is *difference* of pressure, or the amount of the barometric gradient, which determines the strength of the wind and the weather generally.

Barometrical Measurement of Heights.

The decisive experiment by which Pascal established the reality of atmospheric pressure suggested to him the method of measuring heights by means of the barometer. The first attempts to effect this were necessarily rude and inaccurate, since they went on the assumption that the lower mass of air is of uniform density. The discovery, however, of the actual relation subsisting between the density of air and its elasticity by Boyle in England, and about the same time by Mariotte in France, laid a sure foundation for this branch of atmospheric physics—the relation being that, at the same temperature, the pressure of a gas is exactly proportional to its density.

This law, however, only holds provided the temperature is the same. The familiar illustration of a bladder, partially filled with air, expanding on being placed near a fire, shows that if the pressure remains the same,—the pressure in this case being that of the atmosphere,—the gas will occupy a larger space if its temperature be raised. If the temperature be increased and the air be confined so as to occupy the same space, the pressure will be increased.

The relation between the temperature and pressure of gases was first discovered by Gay-Lussac; and more recently our knowledge of this branch of the subject has been greatly enlarged by the beautiful and accurate experiments of Regnault. From these experiments it has been concluded that the co-efficient which denotes increase of elasticity for 1° Fahr. of air whose volume is constant equals .002036; and that the co-efficient which denotes increase of volume for 1° Fahr. of air

whose elasticity is constant equals .002039. It may further be added that the co-efficient of expansion for carbonic acid gas, hydrogen, and all other gases, is as nearly as possible the same.

When a fluid is allowed to evaporate in the exhausted receiver of an air-pump, vapor arises from it until its pressure reaches a certain point, after which all further evaporation is arrested. This point depends on the nature of the fluid itself and on the temperature, and it indicates the greatest vapor pressure possible for the fluid at the particular temperature.

If gases of different densities be put into the same vessel it is found that they do not arrange themselves according to their densities, but are ultimately diffused through each other in the most intimate manner. Each gas tends to diffuse itself as in a vacuum, the effect of the presence of other gas being merely to retard the process of their mutual diffusion. As regards the atmosphere, evaporation goes on until the maximum vapor pressure for the temperature has been attained, at which point the air is said to be saturated, and whilst the temperature remains the same further evaporation is arrested. Thus, at a temperature of 50° evaporation goes on until the vapor pressure reaches 0.361 inch, but if the temperature were raised to 60° the process of evaporation would be renewed, and go on till the vapor pressure rose to 0.518 inch. If at a vapor pressure of 0.518 inch the temperature were to fall from 60° to 50°, the air would no longer be capable of retaining the whole of the aqueous vapor in suspension, but the surplus part would be condensed and fall as rain. In the change from the aeriform to the liquid state a quantity of latent heat is given out. The yet uncertain effect of these changes, particularly the change of form from the aeriform to the liquid state, on the pressure, temperature, and movements of the air, renders it peculiarly desirable that barometeric observations for the determination of heights should not be made when clouds are forming or rain is falling.

Dalton has shown that air charged with vapor is specifically lighter than when it wants the vapor; in other words, the more vapor any given quantity of air has in it the less is its specific gravity; and Sir William Thompson has shown that the condensation of vapor in ascending currents of air is the chief cause of the cooling effect being so much less than that which would be experienced by dry air. From these ascertained effects of aqueous vapor in modifying the pressure and temperature of the atmosphere, the importance in the barometric measurement of heights of full and accurate observations of the hygrometry of the atmosphere and of the weather will be apparent.

Since the equilibrium of the vapor atmosphere is being constantly disturbed by every instance of condensation, by the ceaseless process of evaporation, and by every change of temperature, and since the presence of oxygen and nitrogen greatly obstructs the free diffusion of the aqueous vapors, it follows that Dalton's law of the independent pressure of the vapor and the dry air does not absolutely hold good. From the constant effort of the vapor to attain to a state of equilibrium there is, however, a continual tendency to approach this state. Since the equal diffusion of the dry air and the vapor is never reached, observations can only indicate local humidity, and therefore as regards any considerable stratum of air can only be regarded as approximate. Though particular observations may often indicate a humidity wide of the mark, yet in long averages a close approximation is reached, except confined localities which are exceptionally damp or dry. Hence in observations for the determination of heights, the results of a long-continued series of observations should be employed, and those hours should be chosen whose mean is near the daily mean.

The most recent results arrived at by Regnault are the best, but it is to be regretted that the whole subject of hygrometry, both as regards the methods of observation and the methods of discussing the observations, is still in an unsatisfactory state. This consideration, taken in connection with our defective knowledge of the relation of aqueous vapor to radiant heat, of the mode of its diffusion both vertically and horizontally, and of the influence exerted by its condensation into cloud and rain, and with our ignorance of the merely mechanical effects of ascending, descending, and horizontal currents of air in increasing or diminishing barometric pressure, renders it evident that heights deduced from barometric observations can only be regarded as approximate. It is much to be desired, in stating results, that the limit of error were taken into account, and the nearest round number in accordance therewith should alone be given as the calculated result. Thus, it is a mistake to give as the height of a place 1999 feet when the calculation is based wholly on barometric observations, and the limit of error amounts to 30 feet or more. The height 2000 should be given as the result.

The correction for decrease of gravity at the higher station, as compared with the force of gravity at the lower station or at sea-level, must also be taken into account. Its amount is small, being, roughly speaking, only about 0.001 inch per 400 feet. Since the force of gravity is diminished in proportion to the square of the distance from the centre of gravity, the rate of its decrease with the height varies in different latitudes. Places at the equator being farther from the earth's centre than places at the poles, it follows that the force of gravity diminishes at a less rapid rate as we ascend at the equator than it does at the poles. Now, since at the equator gravity diminishes less rapidly with the height, the air at any given height will exert a higher pressure there than anywhere else on the globe at the same height as compared with what it does at the sea-level of the latitude. Hence a subtraction requires to be made at the equator, and the amount to be subtracted diminishes as we proceed into higher latitudes, till it falls to zero at latitude 45°, where the force of gravity is assumed to be the mean. For higher latitudes an addition is required which constantly increases till it reaches the maximum at the poles. This correction is also small, being for 1000 feet less than 0.001 inch in Great Britain, and less than 0.003 at the equator and the poles.

From their portability and handiness the aneroid barometer, and the thermometer for ascertaining the point at which water boils, are of great use in determining heights,—the thermometer, if properly managed, being the more accurate of the two. Since, owing to the sluggishness with which the aneroid often follows the changes of pressure, especially low pressures, its readings should not be recorded till it has hung for some hours at the place of observation, and if this be not possible, the time which elapsed from arriving at the place and making the observations should be stated. It may not be unnecessary to add that every opportunity which presents itself should be taken of comparing it with a standard mercurial barometer, owing to the variations, irregular or permanent, to which aneroids are subject, and that the instrument should always be read in one position, since the difference between the reading in a horizontal position and the reading in a vertical position is often considerable.

BARON. The origin and primary import of this term have been much contested. Menage derives it from the Latin *baro*, a word which we find used in classical Latin to signify "a simple" or "foolish man."

Another form of the same word appears to be *varo*, to which Lucilius gives the meaning "a stupid man," "a blockhead," Forcellini observing that its primary sense is "a block of tough, hard wood." But with greater probability Graff derives the word baron from the old German *Bar=Mann, freier Mann.* The word seems related to the Spanish *varon*, which means "a male," "a noble person," and its root may be found in the Sanskrit *vîra.* Like the Greek *aner* and the Latin *vir*, the word *baron* signifies man in general and also a *husband* — the old legal expression *baron* and *feme* being equivalent to our ordinary phrase "man and wife."

In modern English usage the term is particularly applied to a member of the lowest order of the peerage, but in ancient records the barony included all the (titular) nobility of England, because all noblemen were barons though they might possess a higher dignity also; and the great council of peers, in which were included dukes, marquesses, and earls, as well as barons, was styled simply the "Council de Baronage." In like manner we speak of the "barons' wars," and "the barons" who signed Magna Charta, although nobles of higher rank joined in both, and it is usual in summoning to the Upper House a peer's son in the lifetime of the father to give, for the occasion, a separate existence to the latter's barony. Thus Earl Fortescue sat in the House of Lords during his father's lifetime as baron of Castle Hill, county Devon — the barony held with his father's earldom. The fiction is still maintained when a commoner is raised directly to one of the higher grades of the peerage, as in the case of Admiral Jervis, who was created at the same time Baron Jervis and Earl St. Vincent.

Barons of the Exchequer, six judges (a chief baron and five puisne barons) to whom the administration of justice is committed in causes betwixt the king and his subjects relative to matters of revenue. Selden, in his *Titles of Honor*, conjectures that they were originally chosen from among the barons of the kingdom, and hence their name.

Barons of the Cinque Ports (originally Hastings, Dover, Hythe, Romney, and Sandwich) were (prior to 1831) members of the House of Commons, elected by the Cinque Ports, two for each port. Their right to the title is recognized in many old statutes, but in 1606 the use of the term in a message from the Lower House drew forth a protest from the peers, that "they would never acknowledge any man that sitteth in the Lower House to the right or title of a baron of parliament" (*Lords' Journals*). These ports are now under the jurisdiction of a *warden.*

Baron and Feme, in the *English Law*, a term used for husband and wife, in relation to each other, who are accounted as one person. Hence, by the old law of evidence the one party was excluded from being evidence for or against the other in civil questions, and a relic of it is still preserved in the criminal law.

Baron and Feme, in *Heraldry*, is when the coats-of-arms of a man and his wife are borne per pale in the same escutcheon,— the man's being always on the dexter side, and the woman's on the sinister. But in this case the woman is supposed not to be an heiress, for then her coat must be borne by the husband on an escutcheon of pretence.

See HERALDRY.

BARONET, a name originally given to the *lesser barons* mentioned in the preceding article, but now confined to the lowest grade of our hereditary nobility. The order was instituted by King James I. in 1611, at the suggestion of Sir Robert Cotton, to whom the plan had been submitted by Sir Thomas Sherley of Wiston, its actual inventor.

Baronets take precedence according to the dates of their patents, conformably to the terms of which no intermediate honor between baron and baronets can be established, and they rank above all knights except those of the Garter. The title or prefix of *Sir* is granted them by a peculiar clause in their patents, and until 1827 they could claim for themselves and the heirs male of their bodies the honor of knighthood. All baronets are entitled to bear in their coat-of-arms, either in a canton or an escutcheon at their choice, the arms of Ulster, viz., a bloody hand.

Baronets of Scotland, called also *Baronets of Nova Scotia.*—This order of knights-baronets was instituted by Charles I. in the year 1625, when the first person dignified with the title was Sir Robert Gordon of Gordonstone, a younger son of the earl of Sutherland.

After the Union with England in 1707 the baronets of Scotland charged their arms with the Ulster badge, being created as baronets of the United Kingdom.

Baronets of Ireland.—This order was likewise instituted by King James I. in the 18th year of his reign, for the same purpose and with the same privileges within the kingdom of Ireland as had been conferred on the analogous order in England; for which also the Irish baronets paid the same fees into the treasury of Ireland.

BARONIUS, CÆSAR, the great church historian, was born on the 31st October 1538 in the district of Naples. His parents, Camillo de Barono or Baronio and Porcia Trebonia, were of noble birth. He was educated at Veroli and Naples, where his favorite studies were theology and jurisprudence. In 1557 he accompanied his father to Rome, and found himself in the midst of the reactionary enthusiasm which did much to restore Italy, in spite of the efforts of her reformers, to the papal authority. There he was brought in contact with Philip Neri, a man who then and since has done much to reconcile the speculative student with the Church of Rome, and to provide for him work in her service to which he can give his whole heart. Neri had just founded the Italian Oratory, the model of many another, and he and his monks had vowed to devote themselves to student lives, and to dedicate their whole power of study to the Roman Catholic Church. Among the theological studies pursued in the oratory, church history and ecclesiastical biography held a prominent place, the greater part of every forenoon being set apart for these subjects. In this small congregation Baronius found a congenial home, and his superior, Philip Neri, soon saw that he had secured a coadjutor who would make his oratory all he had hoped it would become. The alarm caused by the first Protestant church history, the *Magdeburg Centuries*, gave his studies a special direction, and, as he told Pope Sixtus V., he was urged by his own desires, and the encouragement of Neri, to attempt to answer the Magdeburg divines. This was the origin of the *Annales Ecclesiastici*, his great work, which occupied thirty laborious years. These *Annales*, the first and in many respects the most important historical work which the Roman Catholic Church has produced, begin with the birth of Christ and end with the year 1198. The book is not properly history; it is annals rather, as everything is subordinated to chronology.

BARQUISMETO, a city of Venezuela, and since 1830 the capital of the province of Nueva Segovia, is situated on a confluent of the Portuguesa, which belongs to the northern part of the Orinoco system. The surrounding district is fertile, and produces excellent coffee, cocoa, and sugar; and the climate is healthy and pleasant. Barquisimeto was founded in 1522 by Juan de Villegas, principally for the exploration and working of gold-mines supposed to exist in the neigh-

borhood; and at first it received the name of Nueva Sagovia in honor of his native city. The commercial advantages of its situation soon raised it to considerable prosperity. In 1807 it had about 15,000 inhabitants; but on the 26th of March 1812, it was totally destroyed by an earthquake. It has since been regularly rebuilt, and, in spite of disastrous effects of the revolutionary wars, has recovered its position. Among its public buildings may be mentioned a college and several schools. The inhabitants are partly engaged in the rearing of horses and mules.

BARR, a town in Alsace, 18 miles S. W. of Strasburg, situated on the eastern slope of the Vosges, at the mouth of the Ulrichthal. Population 5651.

BARRA, or BAERAY (from the Scandinavian *Baraey*, isle of the ocean), one of the Hebrides or Western Isles of Scotland, forming part of Inverness-shire. It lies about five miles S.W. of South Uist, and is 8 miles in length by from 2 to 4 miles in breadth.

BARRACKPUR, a magisterial subdivision and town of British India, in the district of 24 Parganás, under the Lieutenant-Governor of Bengal.

BARRACKPUR TOWN and CANTONMENT, situated on the Húglí, 15 miles above Calcutta.

Barrackpur played an important part in the two Sepoy mutinies of 1824 and 1857, but the details of these belong to the general history of British rule in India.

BARRACKS are groups of buildings constructed for the accommodation of soldiers. The word, which was formerly spelt "baracks" or "baraques," is derived from the Spanish "barracas," meaning the little huts or cabins used by the fishermen on the sea-shore, or for soldiers in the field. The French call them "casernes," meaning lodgings for soldiers. Barracks of a temporary character, commonly called "huts," have ordinarily been constructed by troops on a campaign as winter quarters, or when for any length of time in "standing camp,"—they being accommodated when in the field under other circumstances in tents, or else, if not provided with tents, bivouacing without cover.

In time of peace barracks were formerly only provided for troops in fortified places termed "garrisons," soldiers elsewhere being provided with quarters by being billeted on public-houses. The apprehension of disturbances, and risk of the troops being too much mixed up with the populations of the localities in which they might be stationed, mainly led to the construction of barracks in or near towns in England about the year 1792. In the first instance the Deputy-adjutant-general was charged with the building and fitting up of barracks. In 1793 the same officer was appointed "Superintendent-general of barracks," and subsequently "Barrack-master-general." In 1806 the barrack establishment was placed under the direction of a board of four commissioners, of whom one was generally a military man. About the year 1825 the duke of Wellington arranged for the construction and maintenance of barracks to be given over to the corps of Royal Engineers. The custody and equipment of barracks, with the supply of fuel and light to the troops quartered in them, were then made and remained, until recently, the duty of the "barrack department," which consisted of barrack-masters and barrack-sergeants.

The arrangement and composition of barracks vary according to the arm of the service to be accommodated in them; thus for the cavalry, horse and field artillery, Royal Engineer train, and transport branch of the army service corps, stables are required; and it is usual to provide for the unmarried non-commissioned officers and men quarters over their horses, a troop of cavalry or a division of field artillery being placed in a separate block of two stories in height. Horse and field artillery also require gunsheds and workshops for artificers, such as collarmakers, wheelers, &c. All mounted troops require forage and shoeing accommodation as well as saddlers' shops. Garrison artillery and companies of Royal Engineers can be accommodated in similar barracks to those for infantry, but the latter require an ample provision of workshops for artificers, with store accommodation for materials, &c.

Not fifty years since, in the West Indies, men slept in barracks, in hammocks touching each other, only 23 inches of lateral space being allowed for each man. At the same time in England the men slept in wooden beds, with two tiers, like the berths of a ship, and not unfrequently each bed held four men. Now, each soldier has an iron bedstead which turns up in the middle, forming a seat for the day-time, and only two rows of beds are allowed in barrack-rooms, and the principle of providing one window for every two beds is carried out in all new barracks.

The best size of a barrack-room is now considered to be 60 or 62 feet long, by 20 feet wide, and about 12 feet high. The number of men each room is to contain is painted on the door; and in barracks of modern construction each barrack-room has attached to it:—

(1.) A small (single) sergeant's room, with fire-place, cupboard, and small window looking into the men's room.

(2.) An ablution room, with basins, water-taps, and a fixed pan in which the feet can be washed.

(3.) A night urinal, with water for flushing laid on.

Barracks are washed once a week, and on intermediate days the rooms are dry-scrubbed. The walls and ceilings are limewashed by the troops twice a year. The general periodical painting of all barrack buildings is performed twice externally and once interally in every eight years. Formerly, barrack buildings were placed on very limited areas, and even a whole regiment was lodged in one house built in the form of a square, with the quarters of the officers on one side for the better supervision of the men; but the Barrack and Hospital Improvement Commission recommended that the men should be divided in numerous detached buildings, so placed as to impede as little as possible the movement of air and the action of the sun's rays.

For barracks, as a general rule, buildings of two stories in height are preferred to those of three stories, but three-story buildings may be adopted where space is limited and land very costly. Buildings of two stories are less expensive than those of only one story in height, and the general arrangement, when the former mode of construction is adopted, is more compact. The selection of a site for a barrack requires great care and circumspection. This duty is performed in the first instance by the Commanding Royal Engineer of the district, or an officer appointed by him; but the ground proposed is also reported on by an Army medical officer as well as subsequently by the General Officer commanding the district, the final approval resting with the Secretary of State for War.

BARRAS, PAUL FRANÇOIS JEAN NICOLAS, COMTE DE, a distinguished actor in the great French Revolution, was born in June 1755. He was a descendant of a noble family in Provence, and at an early age entered the army. He was twice in India with his regiment, but retired from the service after attaining the rank of captain. Like many others, he saw in the Revolution a good opportunity for retrieving his fortunes, which had been ruined by his extravagance and dissipation; and his penetration enabled him to foresee the certain fall of the royalist party. He threw in his lot with the revolutionists, and speedily distinguished himself by his vigor and hardihood. When elected a member of the

National Convention, he gave an uncompromising vote for the king's death; and at the siege of Toulon, where for the first time he met Napoleon, his energetic measures contributed much to the success of the French arms. Robespierre, who hated Barras for his dissolute habits, and feared him for his boldness, endeavored to have his name included in one of his prescription lists, but, on the 9th Thermidor 1794 Barras completely overthrew his power. His success from this period was secured; after the 13th Vindémiaire 1795, he was nominated general-in-chief; and after the affair of the 18th Fructidor, 1797, in which Augereau played a prominent part, he was practically dictator. Bonaparte's *coup d'état* of the 18th Brumaire 1799 changed the whole aspect of affairs. Barras, seeing that resistance to his powerful protégé was useless, gave in his resignation, and retired to his country seat. His latter years were spent in various intrigues, in which he showed a strong leaning towards the royalist party. He died in 1829. The character of Barras has little in it that is worthy of admiration. He was dissolute in private life, and can scarcely be said to have had any definite public policy. At the same time he was courageous, prudent, and on occasions, an able speaker.

BARRHEAD, a town of Scotland, county of Renfrew, three miles S. of Paisley, and 8 miles S. W. of Glasgow on the Caledonian Railway line between that city and Kilmarnock. Population, 7,000.

BARRI, Girald de, commonly called *Giraldus Cambrensis*, an historian and ecclesiastic of the 12th and 13th centuries, was born at the castle of Maenor Pyrr near Pembroke, probably in 1147. By his mother he was descended from the princes of South Wales, and the De Barris were one of the most powerful Welsh families. Being a younger brother, and intended for the church, he was sent to St. David's, and educated in the family of his uncle, the bishop of that see. When about twenty years of age he was sent to the University of Paris, where he continued for some years, and, according to his own account, became an excellent rhetorician and lecturer. On his return in 1172 he entered holy orders, and was made archdeacon of Brecknock. Having observed with much concern that his countrymen the Welsh were very backward in paying tithes of wool and cheese, he applied to Richard, archbishop of Canterbury, and was appointed his legate in Wales for remedying this and other disorders. Barry excommunicated all, without distinction, who refused to compound matters with the church, and, in particular, delivered over bodily to the evil one those who withheld the tithes. Not satisfied with enriching, he also attempted to reform the clergy. He delated an aged archdeacon to the archbishop, for the unpardonable crime of matrimony; and on his refusing to put away his wife he was deprived of his archdeaconry, which was bestowed upon the zealous legate. On the death of his uncle, the bishop of St David's, in 1176, he was elected his successor by the chapter; but this choice having been made without the permission and against the will of Henry II., Girald prudently declined to insist upon it, and went again to Paris to prosecute his studies. He speaks with exultation of the prodigious fame which he acquired by his eloquent declamations in the schools, and of the crowded audiences who attended them. Having spent about four years at Paris, he returned to St. David's, where he found everything in confusion; and on the temporary retirement of the bishop, which took place soon after, he was appointed administrator by the advice of the archbishop of Canterbury, and governed the diocese in that capacity till 1184, when the bishop was restored. About the same time he was called to court by Henry II., appointed one of his chaplains and sent into Ireland with Prince John, by whom he was offered the united bishoprics of Fernes and Leighlin. He would not accept them, and employed his time in collecting materials for his *Topography of Ireland*, and his history of the conquest of that Island, which was completed in three books in 1187. In 1188 he attended Baldwin, archbishop of Canterbury, in his progress through Wales, preaching a crusade for the recovery of the Holy Land,—an employment in which he tells us, with his usual modesty, that he was far more successful than the primate, adding significantly, that the people were most affected with Latin sermons (which they did not understand), melting into tears, and coming in crowds to take the cross. On the accession of Richard I. in 1189 he was sent by that monarch into Wales to preserve the peace of that country, and was even joined in commission with William Longchamp, bishop of Ely, as one of the regents of the kingdom. He failed, however, to improve this favorable opportunity; and having fixed his heart on the see of St. David's, the bishop of which was very old and infirm, he refused the bishopric of Bangor in 1190, and that of Llandaff the year following. But in 1192 the state of public affairs became so unfavorable to Barri's interest at court that he determined to retire. He proceeded to Lincoln, where William de Monte read lectures in theology with great applause; and here he spent about six years in the study of divinity, and in composing several works. At last the see of St. Davids, which had long been the object of his ambition, became vacant, and he was unanimously elected by the chapter, but met with so powerful an adversary in Hubert, archbishop of Canterbury, that it involved him in a litigation which lasted five years. He died in 1220.

BARRIE, capital of Simcoe county, Ontario, Canada, is situated on Kempenfeldt Bay, Lake Simcoe, sixty miles northwest of Toronto. It contains two banks, several churches and schools, woolen factories, flour mills, two newspapers, and a population of 5,000.

BARRINGTON, John Shute, first Viscount, a nobleman distinguished for theological learning, was the youngest son of Benjamin Shute, merchant, and was born at Theobald, in Hertfordshire, in 1678. He died in 1734. Of his large family four were distinguished.

The eldest, William Wildman, second Viscount Barrington (born 1717, died 1793), held important Government offices.

The Hon. Daines Barrington, the third son, born in 1727, was a distinguished antiquary and naturalist. Among the most curious and ingenious of his papers, are his *Experiments and Observations on the Singing of Birds*, and his *Essay on the Language of Birds*. He died on the 14th March 1800, and was buried in the Temple church.

Samuel Barrington, the fourth son, was born in 1729, and died in 1800. He entered the navy at an early age, and in 1747 had worked his way to a post-captaincy. He was distinguished for his bravery and skill, and in 1778 attained the rank of rear-admiral. He held command for some time in the West Indies, and repulsed a superior French force at Sta Lucia.

Shute Barrington, the youngest son, was born in 1784, and died in 1826. He was educted at Eton and Oxford, and after holding some minor dignities, was made bishop of Llandaff in 1769.

BARRISTERS, in England, are the highest class of lawyers who have exclusive audience in all the superior courts. Every barrister must be a member of one of the four ancient societies called Inns of Court, viz., Lincoln's Inn, the Inner and Middle Temples, and Gray's Inn. The existence of these societies as schools can be traced back to the 13th century, and their rise is

attributed to the clause in Magna Charta, by which the Common Pleas were fixed at Westminster instead of following the king's court, and the professors of law were consequently brought together in London. Associations of lawyers acquired houses of their own in which students were educated in the common law, and the degrees of barrister (corresponding to apprentice or bachelor) and sergeant (corresponding to doctor) were conferred. The schools of law are now represented by the Inns of Court, which still enjoy the exclusive privilege of calling to the bar, and through their superior order of *benchers* control the discipline of the profession.

BARROW-IN-FURNESS, a borough, port, and parish in the hundred of Lonsdale, North-West Lancashire, situated opposite the island of Walney, at the extreme point of the peninsula of Furness, which lies between Morecambe Bay and the estuary of the Duddon. It is distant 35 miles from Lancaster and 91 from Carlisle. The area of the borough, which includes Walney and the islets at its south end, is 17,000 acres, of which 8155 are land, the rest being sand and water.

BARROW, Isaac, an eminent mathematician and divine, was the son of Thomas Barrow, a linen draper in London, where he was born in 1630. He was at first placed for two or three years at the Charter-house school. There, however, his conduct gave but little hopes of his ever succeeding as a scholar, for he was inattentive and extremely fond of fighting. But after his removal from this establishment, his disposition took a happier turn; and having soon made considerable progress in learning, he was in 1643 entered at St. Peter's College, and afterwards at Trinity College, Cambridge, where he applied himself with great diligence to the study of literature and science, especially of natural philosophy. He at first intended to adopt the medical profession, and made some progress in anatomy, botany, and chemistry, after which he studied chronology, geometry, and astronomy. He then travelled in France and Italy, and in a voyage from Leghorn to Smyrna gave proofs of great personal bravery; for the ship having been attacked by an Algerine pirate, Barrow remained upon deck, and fought with the utmost intrepidity, until the pirate, unprepared for the stout resistence made by the ship, sheered off and left her to pursue her voyage.

In July 1662 he was elected professor of geometry in Gresham College, on the recommendation of Dr. Wilkins, master of Trinity College, and afterwards bishop of Chester; and in May 1663 he was chosen a fellow of the Royal Society, at the first election made by the council after obtaining their charter. In 1669 he resigned his mathematical chair to his illustrious pupil Isaac Newton, having now determined to renounce the study of mathematics for that of divinity. In the year 1670 he was created doctor in divinity by mandate; and, upon the promotion of Dr. Pearson, master of Trinity College, to the see of Chester, he was appointed to succeed him by the king's patent, bearing date of 13th February 1672. In 1675 Dr. Barrow was chosen vice-chancellor of the university. He died on the 4th of May 1677, in the 47th year of his age, and was interred in Westminster Abbey, where a monument, surmounted by his bust, was soon after erected by the contributions of his friends. By his English contemporaries Barrow was considered a mathemetician second only to Newton. Continental writers do not place him so high, and their judgment is probably the more correct one.

BARROW, Sir John, Bart., was born near Ulverston, in Lancashire, June 19, 1764. His early opportunities of instruction were limited; but by self-education he matured those powers which eventually were turned to so good an account. He displayed at an early age a decided inclination for mathematical pursuits. He passed some years of his youth as superintending clerk of an iron foundry at Liverpool, and he afterwards taught mathematics at an academy in Greenwich. While in the latter situation he was fortunate in obtaining, through the interest of Sir George Staunton, a place in the first British embassy to China. He was thus enabled to put his foot on the first step of the ladder of ambition; but each step in his subsequent career may be fairly said to have been achieved by himself. The account of the embassy published by Sir George Staunton records many of Barrow's valuable contributions to literature and science connected with China. This work, together with his own subsequently published volume of travels, is ample evidence how well his time had been employed. Few persons could, within the space of a few months, overcome all the practical difficulties of such a language as the Chinese; but Barrow soon began to converse in it, and acquired a complete knowledge of its theory. His papers on the subject in the *Quarterly Review* (to which periodical he was for many years a very frequent contributor) contain a very admirable account of that singular lauguage.

He retired from public life in 1845, in consideration of his advanced years, although still in vigorous possession of all the mental and bodily powers required for the due discharge of the functions of his office.

BARROWS. The custom of constructing barrows, or mounds of stones or earth, over the remains of the dead was the most characteristic feature of the sepulchral systems of primitive times. Originating in the common sentiment of humanity, which desires by some visible memorial to honor and perpetuate the memory of the dead, it was practised alike by nations of high and of low development, and continued through all the stages of culture that preceded the introduction of Christianity. The primary idea of sepulture appears to have been the provision of a habitation for the dead; and thus, in its perfect form, the barrow included a chamber or chambers where the tenant was surrounded with all the prized possessions of his previous life. A common feature of the earlier barrows is the enclosing fence, which marked off the site from the surrounding ground. When the barrow was of earth, this was usually effected by an encircling trench or a low *vallum*. When the barrow was a stone structure, the enclosure was usually a circle of standing stones. Sometimes, instead of a chamber formed above ground, the barrow covered a pit excavated under the original surface, in which the interments had been made. In later times the mound itself was frequently dispensed with, and the interments made under the natural surface, within the enclosure of a trench, a *vallum*, or a circle of standing stones. Usually the great barrows occupy conspicuous sites; but in general the external form is no index to the internal construction, and gives no absolute indication of the nature of the sepulchral usages. Thus, while the long barrow is characteristic of the Stone Age it is impossible to tell without direct examination whether it may be chambered or unchambered, or whether the burials within it may be those of burnt or of unburnt bodies.

In England the long barrow usually contains a single chamber, entering by a passage underneath the higher and wider end of the mound. In Denmark the chambers are at irregular intervals along the body of the mound, and have no passages leading into them. The long barrows of Great Britain are often from 200 to 400 feet in length by 60 to 80 feet wide. Their chambers are rudely but strongly built, with dome-shaped roofs.

formed by overlapping the successive courses of the upper part of the side walls. In Scandinavia, on the other hand, such dome-shaped chambers are unknown, and the construction of the chambers as a rule is megalithic, five or six monoliths supporting a capstone of enormous size. Such chambers denuded of the covering mound, or over which no covering mound has been raised, are popularly known in England as "cromlechs" and in France as "dolmens." The prevailing mode of sepulture in all the different varieties of these structures is by the deposit of the body in a contracted position, accompanied by weapons and implements of stone, occasionally by ornaments of gold, jet, or amber. Vessels of clay, more or less ornate in character, which occur with these early interments of unburnt bodies, are regarded as food vessels and drinking cups, differing in character and purpose from the cinerary urns of the Cremation Period in which the ashes of the dead were deposited.

In the case of the long barrows, the traditional form of the circular chambered barrows was retained through various changes in the sepulchral customs of the people, and we find it used both in connection with burnt and with unburnt burials. It was the natural result of the practice of cremation, however, that it should induce a modification of the barrow structure. The chamber, no longer regarded as a habitation to be tenanted by the deceased, became simply a cist for the reception of the urn which held his ashes. The degradation of the chamber naturally produced a corresponding degradation of the mound which covered it, and the barrows of the Bronze Age, in which cremation was the rule, are smaller and less imposing than those of the Stone Age, but often surprisingly rich in the relics of the life and of the art workmanship of the time. In addition to the varied and beautiful forms of implements and weapons,—frequently ornamented with a high degree of artistic taste,—armlets, coronets, or diadems of solid gold and vases of elegant form and ornamentation in gold and bronze, are not uncommon. The barrows of the Bronze Period, like some of those of the Stone Age, appear to have been used as tribal or family cemeteries. In Denmark as many as seventy deposits of burnt interments have been observed in a single mound, indicating its use as a burying-place throughout a long succession of years.

In the early Iron Age there was a partial return to the more massive construction of the earlier periods. Sometimes chambers are found formed of timber instead of stones, in which the bodies were deposited unburnt, although the custom of cremation was largely continued. In Scandinavia both of these modes of sepulture lingered till the close of the Pagan time. One of the latest examples of the great timber-chambered barrow is that at Jellinge in Jutland, known as the barrow of Thyre Danebod, queen of King Gorm the Old, who died about the middle of the 10th century. It is a mound about 200 feet in diameter, and over 50 feet in height, containing a chamber 23 feet long, 8 feet wide, and 5 feet high, formed of massive slabs of oak. Though it had been entered and plundered in the Middle Ages, a few relics, overlocked by its original violaters, were found when it was recently reopened, among which were a silver cup, ornamented with the interlacing work characteristic of the time, and some personal ornaments. It is highly illustrative of the tenacity with which the ancient sepulchral usages were retained even after the introduction of Christianity that King Herald, son and successor of Gorm the Old, who is said to have Christianized all Denmark and Norway, followed the Pagan custom of erecting a chambered tumulus over the remains of his father, on the summit of which was placed a rude pillar-stone, bearing on one side the memorial inscription in Runes, and on the other a representation of the Savior of mankind distinguished by the crossed nimbus surrounding the head.

The Homeric account of the building of the barrow of Hector (*Il.* xxiv.) brings vividly before us the scene so often suggested by the examination of the tumuli of prehistoric times. During nine days wood was collected and brought, in carts drawn by oxen, to the sight of the funeral pyre. Then the pyre was built and the body laid upon it. After burning for twenty-four hours the smouldering embers were extinguished with libations of wine. The white and calcined bones were then picked out of the ashes by the friends and placed in a metallic urn, which was deposited in a hollow grave, or cyst, and covered over with large well-fitting stones. Finally, a barrow of great magnitude was heaped over the remains, and the funeral feast was celebrated. The obsequies of Achilles, as described in the *Odyssey*, were also celebrated with details which are strikingly similar to those observed in tumuli both of the Bronze and Iron Ages.

Herodotus, describing the funeral customs of the Scythians, states that, on the death of a chief, the body was placed upon a couch in a chamber sunk in the earth and covered with timber, in which were deposited all things needful for the comfort of the deceased in the other world. One of his wives was strangled and laid beside him, his cup-bearer, and other attendants, his charioteer, and his horses, were killed and placed in the tombs which was then filled up with earth, and an enormous mound raised high over all. The barrows which cover the plains of ancient Scythia attest the truth of this description. A Siberian barrow, described by Demidoff, contained three contiguous chambers of unhewn stone. In the central chamber lay the skeleton of the ancient chief, with his sword, his spear, his bow, and a quiver full of arrows. The skeleton reclined upon a sheet of pure gold, extending the whole length of the body, which had been wrapped in a mantle broidered with gold and studded with precious stones. Over it was extended another sheet of pure gold. In a smaller chamber at the chief's head lay the skeleton of a female, richly attired, extended upon a sheet of pure gold, and similarly covered with a sheet of the same metal. A golden chain adorned her neck, and her arms were encircled with bracelets of pure gold. In a third chamber, at the chief's feet, lay the skeleton of his favorite horse with saddle, bridle, and stirrups.

So curiously alike in their general features were the sepulchral usages connected with barrow-burial over the whole of Europe, that we find the Anglo-Saxon Saga of Beowulf describing the chambered tumulus with its gigantic masonry "held fast on props with vaults of stone," and the passage under the mound haunted by a dragon, the guardian of the treasures of heathen gold which it contained. Beowulf's own burial is minutely described in terms which have a strong resemblance to the parallel passage in the *Iliad* and *Odyssey*.

The pyramids of Egypt, the mausolea of the Lydian kings, the sepulchres of the Atreidæ at Mycenæ, and the Etruscan tombs at Cære and Volci, are lineally descended from the chambered barrows of prehistoric times, modified in construction according to the advancement of architectural art at the period of their erection. There is no country in Europe destitute of more or less abundant proofs of the almost universal prevalence of barrow-burials in early times. It can be traced on both sides of the basin of the Mediterranean, in Northern Africa, and in Asia Minor, across the plains of Mesopotamia, in the valley of Cabul, and throughout Western India. But more extended research in the archæology of these vast regions is needed to enable

us to correlate their ancient remains with those of the European continent.

In the New World, as well as in the Old, the same customs prevailed over vast areas from a very remote period. In the great plains of North America the dead were buried in barrows of enormous magnitude, which occasionally present a remarkable similarity to the long barrows of Great Britain. In these mounds cremation appears more frequently than inhumation; and both are accompanied by implements, weapons, and ornaments of stone and bone. The pottery accompanying the remains is often elaborately ornamented, and the mound builders were evidently possessed of a higher development of taste and skill than is evinced by any of the modern aboriginal races, by whom the mounds and their contents are regarded as utterly mysterious.

It is not to be wondered at that customs so widely spread and so deeply rooted as those connected with barrow-burial should have been difficult to eradicate. In fact, compliance with the Christian practice of inhumation in the cemeteries sanctioned by the church, was only enforced in Europe by capitularies denouncing the punishment of death on those who persisted in burying their dead after the Pagan fashion or in the Pagan mounds. Yet even in the Middle Ages kings were buried with their swords and spears, and queens with their spindles and ornaments; the bishop was laid in his grave with his crosier and comb, his chalice and vestments; and clay vessels filled with charcoal (answering to the urns of heathen times) are found with the interments in the churches of France and Denmark.

BARROW'S STRAITS, a portion of the channel which runs W. from Baffin's Bay through the islands of the Arctic archipelago to Melville Sound.

BARRY, Sir Charles, a distinguished English architect, was born at Westminster, May 23, 1795. His masterpiece, and perhaps, notwithstanding all unfavorable criticism, the masterpiece of English architecture of the 19th century, is the new palace at Westminster. After the destruction of the old houses of parliament by fire in October 1834, Barry was the successful competitor for erecting the new palace. The first stone was laid in the spring of 1840; the work was steadily carried on in the face of many difficulties, and through a maze of private dissensions and public complaints, and it was at length completed in 1860. Twenty years seemed long in passing, but once past the time assuredly will no more seem too long to have been employed in the erection, or, we might say, allowed for the growth of this stately and beautiful pile. Sir Charles Barry died in 1806.

BARRY, James, an eminent painter, was born at Cork on October 11, 1741, and died in 1806.

As an artist Barry is more distinguished for the strength of his conceptions, and for his resolute and persistent determination to apply himself only to great subjects, than for his skill in designing or for beauty in his coloring. His ideas were generally fine, but the realization of them was almost without exception unsuccessful. His drawing is rarely good, his coloring frequently wretched.

BARS, a province of Hungary, in the district watered by the Neutra, Gran and Zsitva, which belong to the northern part of the system of the Danube. It is for the most part mountainous and has great mineral wealth, especially in gold and silver. Population, 140,000.

BARTAN, a town in Asiatic Turkey, situated near the mouth of the Bartan-su, which was known to the Greeks as the *Parthenius*, and formed part of the boundary between Bithynia and Paphlagonia. Population, 6,000.

BARTAS, Guillaume de Salluste du, a French poet, was born in 1544, and died in 1590 of wounds received in the battle of Ivry.

BARTER, in commerce and political economy, a term used to express the exchange of one commodity for another, contrasted with the sale of commodities for money. It is simply a primitive form of exchange carried on in countries in which the use of money has not yet been introduced or is not prevalent.

BARTFELD, or Bartfa, a town in Hungary, county of Saros, on the River Tepla. Population, 500.

BARTH, Heinrich, a distinguished African explorer, was born at Hamburg in 1821, and died in 1865. He wrote several works on African explorations.

BARTH, or Bart, Jean, son of a fisherman of Dunkirk, was born in 1651 and died in 1702. He served, when young, in the Dutch navy, but when war broke out between Louis XIV. and Holland, he entered the French service. He gained great distinction in the Mediterranean, where he held an irregular sort of a commission, not being then able from his low birth to receive a command in the navy. His success was so great, however, that he was made a lieutenant. He rose rapidly to the rank of captain, and then to that of admiral. The peace of Ryswick put a close to his active service. Many anecdotes are narrated of the courage and bluntness of the uncultivated sailor, who became the popular hero of the French naval service.

BARTHÉLEMY, Auguste Marseille, a French satirical poet, was born at Marseilles in 1796, and died in 1867.

BARTHÉLEMY, Jean Jacques, a celebrated French writer, was born on the 20th January 1716, at Cassis, a little seaport on the shores of the Mediterranean. He was educated, first at the college of the Oratory in Marseilles, and afterwards at that of the Jesuits in the same city. While completing the course of study requisite for the church, which he intended to join, he devoted much attention to Oriental languages, in which he became very proficient. After assuming the ecclesiastical habit, he resided with his family at Aubagne, and during this period of his life was introduced by his friend, M. Cary of Marseilles, to the study of classical antiquities, particularly in the department of numismatics. In 1744 he repaired to Paris, carrying with him a letter of introduction to M. Gros de Boze, perpetual secretary of the Academy of Inscriptions and Belles Letters, and keeper of the medals. He became assistant to De Boze, and on the death of the latter in 1753, was appointed his successor. In the following year he was enabled to pay a visit to Italy, and spent some time in that country, inspecting its rich treasures of classical remains. While on his journey he made the acquaintance of the French ambassador, M. de Stainville, afterwards duc de Choiseul, and of his wife. The minister conceived a great regard for Barthélemy, and on his accession to power loaded the scholar with benefits. In 1759 he gave him a pension on the archbishopric of Albi; in 1765 he conferred on him the treasurership of St. Martin de Tours, and, in 1768, made him secretary-general to the Swiss guards. In 1789 he was elected to the academy, and died in 1795.

BARTHELEMY SAINT-HILAIRE, Jules, French savant and statesman, was born at Paris, August 19, 1805. At the *coup d' etat* he was imprisoned. On his release he resigned his chair, as he could not take the oath of allegiance to Napoleon III., and returned to his studies, especially Sanskrit and ancient Indian philosophy. Elected in 1871 to the Assembly at Bordeaux, he gave constant support to Thiers. In 1876 he was elected a Life-Senator by the Assembly; and he held the Portfolio of Foreign Affairs in Ferry's Ministry—1880-1881. He died January 27, 1889.

BARTHEZ, or BARTHES, PAUL JOSEPH, one of the most celebrated physicians of France, was born December 11, 1734, at Montpellier. He commenced the study of medicine at Montpellier in 1750, and in 1753, when he had only attained his nineteenth year, he received his doctor's degree. In 1761 he obtained a medical professorship at Montpellier. His *Traitement des Maladies Goutteuses*, in two vols. 8vo, appeared in 1802, and he afterward occupied himself in preparing for the press a new edition of his *Elemens de la Science de l' Homme*. He died October 15, 1806.

BARTHOLINUS, GASPARD, a learned Swede, born in 1585, at Malmoë. His precocity was extraordinary; at three years of age he was able to read, and in his thirteenth year he composed Greek and Latin orations, and delivered them in public. In 1613 he was chosen professor of medicine in the University of Copenhagen, and filled that office for eleven years, when, falling into a dangerous illness, he made a vow, that if it should please God to restore him, he would apply himself solely to the study of divinity. He recovered, observed his vow, and obtained the professorship of divinity, with the canonry of Rothschild. He died July 13, 1630.

BARTHOLINUS, THOMAS, a physician, son of the above, was born at Copenhagen in 1619, and died December 14, 1680.

BARTHOLOMEW, ST., one of the twelve apostles, supposed to be the same person as Nathanael. According to the traditional record of Eusobius, he carried Christianity into India. The church at Rome bearing his name claims to preserve his relics. The Roman church holds his festival August 24; the Greek, June 11.

BARTHOLOMEW, MASSACRE OF ST. (Fr. *La St. Barthelemy*), the appellation given to the massacre of the Huguenots in Paris on the night of St. Bartholomew's Day, August 24, 1572. After the death of Francis II. in 1560, Catharine de' Medici assumed the management of affairs, as regent for her son, Charles IX., and showed throughout a more than Italian craft and faithlessness, as well as a cruelty almost without parallel in modern history. In order to annoy the Catholic party of the Duke Francis of Guise, she granted an edict of toleration to the Reformed, at whose head was the Prince of Condé. Both parties took up arms, and there ensued a war which lasted for eight years, the cruelties of which, through mutual exasperation, are almost incredible. Guise was assassinated and Condé was taken prisoner in the battle of Jarnac and shot (1569). His nephew, young Henry, of Bearn, afterward Henry IV., then became leader of the Huguenots, along with Admiral Coligny. It was not till the strength of both sides was exhausted that the peace of St. Germain-en-laye was made in 1570, whereby the Huguenots obtained the free exercise of their religion. Catharine de' Medici now expressed much friendliness toward them, and even endeavored to lull them into negligence by the marriage of the youthful Henry of Bearn with her daughter Margaret, August 18, 1572. Admiral Coligny was drawn to Paris, and the king not only made him costly presents, but gave him an important office in the Council of State. When, by means of the marriage of Prince Henry, the most eminent of the Huguenots had been allured to Paris, Admiral Coligny was wounded by a shot from a window of the palace, August 22, 1572. The king, indeed, hastened to him and swore to avenge him; but, on the very same day the king was persuaded by his mother that the admiral sought his life. "By God's death!" he exclaimed, "let the admiral be slain, and not him only, but all the Huguenots, till not one remains that can give us trouble!" That night Catharine held a council, and appointed St. Bartholomew's Day for carrying into effect the long-contemplated massacre. After Coligny had been murdered a bell in the tower of the royal palace at the hour of midnight gave the signal to the assembled companies of citizens for a general massacre of the Huguenots, in which it is estimated that over 4,000 perished. The king himself is popularly represented as having fired from his palace upon those that were fleeing past, but of this there is no proof. The Prince of Condé and the King of Navarre only saved their lives by going to mass, and appearing to conform to the Catholic church. The pope celebrated the events of St. Bartholomew's Day by a procession to the Church of St. Louis, a grand *Te Deum*, the striking of a medal, and the proclamation of a year of jubilee.

BARTLETT, JOHN RUSSELL, American author, was born at Providence, R. I., October 23, 1805. He was employed by the United States government in 1850-53 as a commissioner for determining the Mexican boundary line, and in 1854 published an account of his explorations and adventures in that capacity. In 1855 he became secretary of state of Rhode Island and in 1861-62 was its acting governor. He died May 28, 1886.

BARTOLINI, LORENZO, an Italian sculptor, was born in 1777, of very humble parents, at Vernio in Tuscany. After various vicissitudes in his youth, during which he had acquired great skill and reputation as a modeller in alabaster, he came to Paris in 1797. His great patron, however, was Napoleon, for whom he executed a colossal bust, and who sent him to Carrara to found a school of sculpture. He remained in Carrara till after the fall of Napoleon, and then took up his residence in Florence, where he continued to reside till his death in 1850. His works, which include an immense number of busts, are numerous and varied.

BARTOLOZZI, FRANCESCO, a distinguished engraver, was born at Florence in 1725, or, according to some authorities, in 1730. For nearly forty years he resided in London, and produced an enormous number of engravings, the best being those of Clytie, after Annibale Carracci, and of the Virgin and Child, after Carlo Dolce. A great proportion of them are from the works of Cipriani and Angelica Kauffmann. Bartolozzi also contributed a number of plates to Boydell's *Shakespeare Gallery*. In 1802 he was invited to Lisbon to superintend a school of engraving in that city. He remained in Portugal till his death, at an advanced age, about the year 1816.

BARTOLUS, professor of the civil law at the University of Perugia, and the most famous master of the dialectical school of jurists, was born in 1314, at Sasso Ferrato, in the duchy of Urbino, and hence is generally styled Bartolus de Saxo Ferrato. His father was Franciscus Severi, and his mother was of the family of the Alfani. He studied the civil law first of all under Cinus at Perugia, and afterwards under Oldradus and Jacobus de Belvisio at Bologna, where he was promoted to the degree of doctor of civil law in 1334. His great reputation dates from his appointment to a chair of civil law in the University of Perugia, 1343, where he lectured for many years, raising the character of the law school of Perugia to a level with that of Bologna. He died in 1357 at Perugia, where a magnificent monument recorded the interment of his remains in the church of San Francisco, by the simple inscription of "Ossa Bartoli."

BARTON, BENJAMIN SMITH, M.D., an American naturalist, who was the first professor of botany and natural history in a college in the United States. He was born in Pennsylvania in 1766, studied for two years at Edinburgh, and afterwards graduated at Göttingen. He settled at Philadelphia, and soon obtained a considerable practice. In 1789 he was appointed to the professorship above mentioned in Philadelphia College; he

was made professor of materia medica in 1795, and on the death of Dr. Rush in 1813 he obtained the chair of practical medicine. In 1802 he was chosen president of the American Philosophical Society. Barton was the author of various works on natural history, botany, and materia medica. By his lectures and writings he may be said to have founded the American school of natural history. He died in 1815.

BARTON, ELIZABETH, the "Maid of Kent," belonged to the village of Aldington in Kent. She was a pious, nervous, and enthusiastic person, subject to epilepsy; and her enthusiasm, unfortunately for herself, took a political turn at a somewhat critical period in English history. When all England was excited with the attempts made by Henry VIII. to obtain a divorce from Queen Catherine, Elizabeth Barton saw visions and heard speeches, all of which related to the contemplated divorce. These she confided to her parish priest, Richard Masters, and he made them known to Dr. Bockling, a canon of Canterbury. Through these men they became widely known, and were everywhere proclaimed to be divine revelations. The chapel at Aldington became the centre of many pilgrimages, and the scene of many excited and tumultuous assemblies. Elizabeth Barton was commonly believed to be a prophetess, and was called the "holy maid of Kent." Meanwhile her visions continued; she saw letters written in characters of gold sent to her by Mary Magdalene, which contained both revelations and exhortations. Among other things she declared that it was revealed to her that if the contemplated divorce took place, the king would be a dead man within seven months. The principal agents for the Pope and for Queen Catherine lent themselves to fan the excitement. Even such men as bishops Fisher and Warham and Sir Thomas More corresponded with the Maid of Kent. At last the king's wrath was aroused. In 1533 Elizabeth with her principal supporters, Masters, Bockling, and several others, were examined before parliament, and sentenced to be executed. She was beheaded at Tyburn April 21, 1534.

BARUCH, son of Neriah, was the friend and amanuensis of the prophet Jeremiah. After the temple at Jerusalem had been plundered by Nebuchadnezzar, he wrote down Jeremiah's prophecies respecting the return of the Babylonians to destroy the state, and read them in the temple before the assembled people at the risk of his life. The roll having been burned by the king's command, Jeremiah dictated the same again. When the temple was destroyed, Baruch went to Egypt with Jeremiah, having been blamed as the prompter of the threatening prophecies uttered by the latter. Nothing certain is known as to his death,—some accounts representing him as dying in Egypt, others in Babylonia. The Talmud adopts the latter opinion, making him the instructor of Ezra, to whom he is said to have communicated the traditions he had received from Jeremiah.

The BOOK OF BARUCH belongs to the Apocrypha, according to Protestants, and to the deutero-canonical productions, according to Roman Catholics.

Much difference of opinion prevails regarding the original language. Some are for a Greek original, others for a Hebrew one; while Fritzsche and Ruetschi think that the first part was composed in Hebrew, the second in Greek. The original seems to have been Hebrew, though Jerome says that the Jews had not the book in that language; and Epiphanius asserts the same thing. The testimony of the former resolves itself into the fact that the original had been supplanted by the Greek; and that of the latter is not of much value, since he gives Baruch, along with Jeremiah and the Lamentations, in a second list of the canonical books. We rely on the statement that the work was meant to be publicly read in the temple (i. 14) as favorable to a Hebrew original, as well as on the number and nature of the Hebraisms, which are sometimes so peculiar that they cannot be resolved into the authorship of a Greek-speaking Jew. That the writer was a Palestinian appears from various passages, such as ii. 17, "For the dead that are in the graves, whose souls are taken from their bodies, will give unto the Lord neither praise nor righteousness;" "Hearken, O ye that dwell about Zion" (iv. 9); "Ye have forgotten the everlasting God that brought you up; and ye have grieved Jerusalem that nursed you" (iv. 8). Both the latter passages betray a Palestinian. Besides, the conception of Wisdom in iii. 12, &c., is Palestinian rather than Alexandrian; for the words in iii. 37 do not refer to the incarnation of the Logos, but to personified Wisdom, as in Sirach xxiv. 10. This points to a Hebrew original. The version seems to be free, especially in the latter part. Who was the translator? A comparison of the Septuagint translation of Jeremiah with that of Baruch will suggest the answer. The agreement between the two is remarkable. Constructions, phrases, and words are the same in them, so that we may conjecture with Ewald and Hitzig that the same translator appears.

Though Baruch professes to have written the book, a later writer speaks in his name. Jeremiah's faithful friend is said to have composed it at Babylon. This view is untenable on the following grounds: —

1. The work contains historical inaccuracies. Jeremiah was living in the fifth year after the destruction of Jerusalem, yet the epistle is dated that year at Babylon. It is unlikely that Baruch left Jeremiah, since the two friends were so united. According to Baruch i. 3, Jeconiah was present in the great assembly before which the epistle was read, whereas we learn from 2 Kings xxv. 27 that he was kept a prisoner as long as Nebuchadnezzar lived. Joakim is supposed to be high priest at Jerusalem (i. 7). But we learn from 1 Chron. vi. 15 that Jehozadak filled that office the fifth year after Jerusalem was destroyed. In i. 2 there is an error. The city was not burned when Jehoiachim was carried away. And if the allusion be to the destruction of the city by Nebuchadnezzar, the temple and its worship are supposed still to exist in i. 8–10. The particulars narrated are put into the fifth year of the exile; yet we read, "Thou art waxen old in a strange country" (iii. 10).

2. Supposing Baruch himself to have been the writer, books later than his time are used in the work. Nehemiah is followed, as in ii. 11 (comp. Nehem. ix. 10). But Eichhorn's language is too strong in calling the contents "a rhapsody composed of various writings belonging to Hebrew antiquity, especially Daniel and Nehemiah."

According to Jerome and Epiphanius, the Jews did not receive the book into their canon; nor is it in the lists given by Josephus, Melito, and others. It has been thought, however, that Origen considered it canonical, because in his catalogue of sacred books he gives Lamentations and "the epistle" along with Jeremiah; and Jeremiah's epistle formed a part of Baruch. The testimony of Origen on this point is perplexing; but it is conceivable that *some* Jews may have thought very highly of the book in his time, though its authority was not generally admitted among the co-religionists. From the position which the book occupied in the Septuagint, *i.e.*, either before or after Lamentations, it was often considered an appendix to Jeremiah by the early Christians, and was regarded in the same light, and of equal authority. Hence the words of it were often quoted as Jeremiah's by Irenæus, Clemens Alexandrinus, and Tertullian.

The versions are the two Latin, a Syriac, and an Arabic. The Latin one in the Vulgate belongs to a time prior to Jerome, and is tolerably literal.

Epistle of Jeremy.—An epistle of Jeremiah's is often appended to Baruch, forming the sixth chapter. According to the inscription, it was sent by the prophet by God's command to the Jews who were to be carried captive to Babylon. The writer describes the folly and absurdity of idolatry in a declamatory style, with repetitions somewhat like refrains. Thus, in verses 16, 23, 29, 65 occurs the sentence, "Whereby they are known not to be gods; therefore fear them not;" "How should a man then think and say that they are gods," in 40, 44, 56, 64, 69; "How then cannot men perceive that they be no gods," in 49, 52. These and other repetitions are unlike Jeremiah's. The concluding verse is abrupt.

BARYTES, or BARYTA, an oxide of the metal barium, usually prepared from the two most common ores of the substance, the sulphate and the carbonate of baryta. It is a highly caustic alkaline poisonous body, which with water forms a hydrate of baryta. On a commercial scale baryta is prepared from the native carbonate (Witherite) by exposing the mineral, mixed with one-tenth of its weight of lamp black, to a very high heat. It is now largely employed in the beet sugar manufacture for separating crystallized sugar from the molasses. A solution of the hydrated oxide, under the name of baryta-water, is of very great use in the chemical laboratory for precipitating metallic oxides, and on account of its sensitiveness to carbonic acid. Sulphate of baryta, or heavy spar, the cawk of miners, is a mineral of very high specific gravity, found abundantly in veins in the mountain limestone of England and frequently associated with metallic ores. When reduced to powder the white varieties are sometimes used as a pigment, but the powder is more frequently applied as an adulterant to white lead. Heavy spar is also used in the manufacture of pottery. The powdered carbonate of baryta is used to some extent in the manufacture of glass, taking the place of a part of the alkali in plate glass, and some portion of red-lead in flint glass. Cassel green, or Rosenstiehl's green, is a pigment manufactured from the calcined manganate of baryta. Both the nitrate and the chloride are of great value as chemical reagents. The nitrate and chlorate are also used to produce a green light in pyrotechny.

BASALT. Basalt rocks are of igneous origin, and are composed essentially of plagioclase feldspar, augite, olivine, and generally magnetic or titaniferous iron. They show all varieties of texture, from smooth compact up to coarsely crystalline; and vary in color from pale blue up to dark-grayish blue, brownish and black. The older basalt-rocks have frequently undergone some changes, owing to the chemical action of percolating water. There are volcanic masses of Tertiary age which occur in such regions as the Thüringer Wald, Erzgebirge, the Eifel, Italy, etc., which closely resemble basalt-rocks. Basalt rocks, especially the compact varieties, often assume a columnar structure. This structure, however, is not confined to basalt-rocks. The columns vary in the number of their angles from three to twelve, but they have most commonly from five to seven sides. In some cases they are more or less perfectly hexagonal. Two of the best known and finest examples of columnar structure in basalt-rocks are Fingal's Cave in the Island of Staffa, on the west coast of Scotland, and the Giant's Causeway.

BASE-BALL. The national game of America, is an evolution of the old English school-boy pastime known as "rounders." It was but a boy's game in this country prior to about 1860, but has been extended throughout the United States, and has secured a strong foothold in Canada. The game needs little introduction to the American reader. It is played on a level field of convenient size, upon which a space 90 feet square is marked out in the form of a diamond, as per diagram. Upon each angle of the diamond are marked the bases — home, first, second and third. The players, nine on each side, are as follows: Pitcher, catcher, first baseman, second baseman, third baseman, right-fielder, left-fielder, centre-fielder and shortstop. The first man to bat takes his position, and the pitcher of the opposite party delivers a ball. This, to be fair, must pass fairly over the home base, not lower than the batsman's knee nor higher than his shoulder. If three good balls are delivered he must strike or go out; if four unfair balls are pitched, he gets a base, and the second man comes in. If he strikes the ball, he must run to at least one base, and, if the hit will allow it, may make all four; thus achieving a home run. Supposing the first man to have reached first base, he

must run further on when his successor makes a strike, or he can steal a run to another base if the fielders are negligent. The pitcher's aim is to so deliver the balls as to bring them within the fair line and still to bother the batsman, which he does by putting a twist or curve upon the ball by a peculiar turn of the wrist, very difficult to attain, and answering to "side" or "English" at billiards, or to "inwick" or "outwick" in curling. But in this case the pitcher has only the resistance offered to the ball by the air to rely upon, supplemented of course by his own skill in giving it a rotary motion. If the batsman strikes the ball and the catcher can secure it before it grounds, the batsman is out; and, so, too, if it is taken by a fielder under similar circumstances. A ball hit behind the lines of the diamond is "foul," but the batsman may be caught out on such a ball, though

he cannot run upon it. The nine players go to bat in succession, but when three are caught out, struck out, or run out, the innings is over and the opposite side take their turn at the bat; the first team supplanting them in the field. Two men may be put out at once—*e.g.*, the batsman may be caught and the man on base may fail to reach the next stopping place. Nine innings are played by each side, the one securing the most runs winning the game. If there is a tie an additional inning or more is played. The bat used in League or Association matches must not be more than 42 inches long, nor have a greater diameter than 2½ inches. The ball is from 5 to 5¼ ounces in weight, and from 9 to 9¼ inches in circumference.

BASEDOW, JOHANN BERNHARD, a German author, born at Hamburg 11th September 1723, and died Magdeburg on the 25th July 1790.

BASEL, BÂLE, or BASLE (the first being the German, the others the French and Old French forms of the name), a canton in the N.W. of Switzerland, with an area of 184 English square miles. It is bounded on the N.W. by Alsace, N. by the grand-duchy of Baden, E. by the canton of Aargau, and S. and S.W. by those of Solothurn and Berne. The canton is traversed by the Jura chain, the highest peaks of which rise to from 4000 to 5000 feet. With the exception of the Rhine and its tributaries,—the Birse and the Ergolz,—there are no streams of any magnitude. The soil is for the most part fertile and well cultivated, the mountain sides affording excellent pasturage. The principal pursuits of the people are agricultural and pastoral, though here and there, as at Liestal, Sissach, and Münchenstein, coal-mining is carried on. The chief manufactures are ribbons, woollen, linen, and cotton goods, and iron and steel wares. Politically the canton consists of two divisions, one urban and the other rural (Basel-stadt and Basel-landschaft), each with its own constitution and laws. The former sends two members to the National Council; its legislative power is in the hands of a Great Council which consists of 134 members, chosen for six years, and its executive power belongs to a Lesser Council of 15 members. In the rural division the legislative body (or *Landrath*) is chosen for three years, and has the ultimate authority over all departments; the executive council consists of five members elected for the same period; it sends three members to the National Council. The prevailing language is German. Population of Basel-stadt 48,000, and of Basel-landschaft, 55,000.

BASEL, or BÂLE, the capital of the above canton, and next to Geneva, the largest city in Switzerland, is situated on both sides of the Rhine, 43 miles N. of Berne. Great Basel or the city proper, lies on the south side of the river, and is connected with Little Basel on the north side by a handsome bridge 800 feet long, which was originally erected in 1229. The city is generally well built, but there are fewer remarkable edifices than in many other Continental cities of similar size. The fine old Gothic cathedral, founded 1010, still stands, and contains a number of interesting monuments, besides the tombs of Erasmus Œcolampadius, and other eminent persons. A re-decoration was skilfully effected in 1852–1856. Among other ecclesiastical buildings of interest may be mentioned St. Martin's, restored in 1851; St. Alban's, formerly a monastery; the church of the Bare-footed Friars, which now serves as a store house; Elizabeth Church, of modern erection; and St. Clara's in Little Basel. The town-hall was built in 1508 and restored in 1826. A post-office, a new bank, and an hospital are of recent erection. Besides the university, which was founded by Pope Pius II. in 1459, and reorganized in 1817, Basel possesses a public library of 95,000 vols., with a valuable collection of MSS., a picture-gallery, a museum, a theological seminary for missionaries (established in 1816), a gymnasium, an industrial school, a botanical garden, an orphan-asylum, an institution for deaf-mutes, and various learned societies. Of these may be mentioned the Society for the Propagation of Useful Knowledge, founded in 1777 by Iselin, the Society of Natural History, the Society of National Antiquities, and the Bible Society, which dates from 1804 and was the first of the kind on the Continent. Basel is the seat of an active transit-trade between France, Germany, and Switzerland, and possesses important manufactures of silk, linen, and cotton, as well as dyeworks, bleach-fields, and iron-works, the most valuable of all being the ribbon-trade. Basel was the birthplace of Euler, Bernouilli, Iselin, and perhaps of Holbein; and the names of Erasmus, Œcolampadius, Grynæus, Merian, De Wette, Hagenbach, and Wacknernagel, are associated with the university. Population in 1880, 53,000.

Basel (*Basilia*) first appears in the 4th century as a Roman military post. On the decay of the neighboring city of *Augusta Rauracorum*, the site of which is still marked by the village of Augst, it began to rise into importance, and, after numerous vicissitudes, became a free city of the empire about the middle of the 10th century, and obtained a variety of privileges and rights. In 1356 the most of its buildings were destroyed by an earthquake.

BASEL, THE COUNCIL OF (1431–1443), was the last of the three great reforming councils of the 15th century, coming after the councils of Pisa (1409) and Constance (1414–18). In these three councils the aim of the majority was to reform the church by destroying the absolute supremacy of the Pope, and by curbing the rule of the Roman curia; and the acts of these councils were all designed to re-establish the power of the episcopate by asserting the supremacy of œcumenical councils. At Pisa these aims were only indicated; at Constance they were so far successful that schismatic popes were deposed, and the council practically showed its superiority to the Pope by bestowing the papal chair on Martin V.; and although the fathers of Constance were compelled to separate before they could do much else in the way of reform, they practically laid the foundation by insisting that councils should be held frequently, and by ordering a new council to be called at the end of five years. The council summoned in obedience to this command was the Council of Basel, but the results of its meeting were simply to show the helplessness of the episcopate and the power of the Roman curia. At Basel the labors of Pisa and Constance were undone, and after this council thoughtful men began to see that the church could not be reformed without destroying the Papacy.

The Council of Basel was summoned by Martin V. (1431). He first appointed it to meet at Pavia, then at Siena, but Basel was at last fixed upon. At the very beginning Martin died, but his successor, Eugenius IV., sanctioned all his decrees; and the council accordingly met at Basel on the 23d of July 1431, under the presidency of Cardinal Julian Cesarini. At first all went well. The bishops took care so to arrange the organization of the council and its method of procedure as to make it a true and fair representative of the whole Catholic Church. The members of the council were divided into four equal classes, each consisting of about the same number of cardinals, archbishops, bishops, abbots, &c., and each completely organized, with its president, secretaries, and other officers. This was done to neutralize the votes and prevent the intrigues of the Italian bishops, who were very numerous, and for the most part under the power of the Roman curia. To each of the four was assigned the investigation of a special

class of subjects. Each section met separately in its own hall thrice a week. Each section elected three of its number to form a committee of business. One-third of this committee was changed every month. All the business had to pass through this committee, and it sent down special subjects to be discussed in each of the sections. When the section had discussed the matter it sent its decision with the reasons of it to each of the other sections, who then discussed the matter and gave their opinion upon it. If three sections were agreed upon it, the subject was brought before the whole council for general discussion and a final decision.

The three subjects which were specially assigned to this council were the reunion of the Greek and Latin Churches, the reconciliation of the Bohemians, and the reform of the church according to the resolutions come to at Constance. Soon after the beginning of the council the Roman curia took alarm at the zeal and determination of the assembled bishops, and by intrigues compelled the Pope, who was really anxious for reform, to do all he could to hinder the work of the fathers at Basel. Eugenius twice tried to dissolve the council; but it resisted, maintaining that a council being superior to the Pope could not be dissolved, and the Pope yielded. The bishops refused to admit the Pope's legatees until they admitted the supremacy of the council and promised to obey its decrees.

The first business to which the members addressed themselves was to curb the power of the Pope and of the Roman curia. They tried to do this by attempting to stop the flow of money from all parts of Europe to Rome. They abolished the annates; they declared it illegal in a bishop to send the sum of money commonly presented on his investiture, &c.; and they passed many laws to restrain the luxury and vice of the clergy. These proceedings so alarmed Eugenius that he resolved either to bring the council within the reach of his influence or to dissolve it. The occasion for interference arose out of a debate which the subject of reunion with the Greek Church gave rise to. The Emperor John Palæologus, induced principally by fear of the Turks, had written both to the Pope and to the council on the subject of the reunion of Christendom, and both had entertained his proposals. The majority, however, of the bishops in the council maintained that this subject could not properly be discussed in Italy, and that the deliberations must take place in France, Savoy, or Basel, far from the influence of the Pope. To this Eugenius would not agree; and when the council decided against him, he resolved to assemble another council, which met first at Ferrara and afterwards at Florence.

The rest of the proceedings of the Council of Basel is simply a record of struggles with the Pope. In 1437 the council ordered the Pope to appear before them at Basel. The Pope replied by dissolving the council; the bishops, backed by the emperor and the king of France, continued their deliberations, and pronounced the Pope contumacious for not obeying them. When Eugenius tried to take away the authority of the council by summoning the opposition Council of Florence, the bishops at Basel deposed him. Eugenius replied by a severe bull, in which he excommunicated the bishops, and they answered by electing a new Pope, Amadeus, duke of Savoy, who assumed the name of Felix V. The greater part of the church adhered to Eugenius, but most of the universities acknowledged the authority of Felix and the Council of Basel. Notwithstanding the opposition of Eugenius and his adherents, the Council of Basel continued to pass laws and degrees until the year 1443; and when the bishops separated they declared publicly that they would reassemble at Basel, Lyons, or Lausanne. In 1447 Eugenius died and was succeeded by Nicholas V., who tried to bring about a reconciliation between the parties in the church. A compromise was effected, by which Felix resigned the pontificate, and the fathers of Basel having assembled at Lausanne, ratified the abdication of Felix, and directed the church to obey Nicholas, while Nicholas confirmed by his sanction the acts and decrees of the Council of Basel.

BASHAN, a country lying to the east side of the Jordan valley, towards its northern extremity, often mentioned in Jewish history. The name is understood to be derived from a root signifying *fertile*, or, according to some, *basaltic;* and in some of the ancient versions of the Old Testament it is occasionally rendered by a word indicating fertility. When we first hear of this region in the days of Abraham it is occupied by the Rephaim, whose chief city is Ashteroth Karnaim (Gen. xiv. 5). These Rephaim, with kindred tribes spread over the trans-Jordanic region, were in great part subdued and supplanted by the children of Lot (Deut. ii, 10, 11, 19–21), who in their turn were invaded and displaced by the Amorities (Num. xx. 26–30). By this people, at the time of the Exodus, the whole region north of the Arnon was occupied; and they formed two kingdoms, the most northerly embracing all Bashan and a part of Gilead (Deut. iii. 8, 13; Josh. xii. 4, 5). Og, who is described as a man of gigantic statue, belonging to the race of the Rephaim, was, at the time referred to, the ruler of this kingdom; and having come out against the Israelities, he was overthrown in battle at Edrei, one of his own cities. Subsequently, his country became the allotment of the half tribe of Manasseh (Josh. xiii. 29–31).

The history of Bashan, after its conquest by the Israelites, merges into the general history of that nation, and of Western Asia. It is last mentioned in the Old Testament, in 2 Kings x. 33, in connection with the attacks made by Hazael, the king of Damascus, upon the territory of Israel. Throughout the Psalms and the Prophets Bashan is celebrated for its fertility and luxuriance, its rich pastures, its strong bulls, its fatlings "of rams, of lambs, and of goats, of bullocks;" its oaks and its firs (Ps. xxii. 12; Amos iv. 1; Isa. ii. 13; Jer. l. 19; Ezek. xxxix. 18, xxvii. 6); and its extraordinary fertility is attested by the density of its population (Deut. iii. 4, 5, 14)—a density proved by the unparalleled abundance with which ruined towns and cities are now strewn over the whole country. In the disturbed period which followed the breaking up of the empire of Alexander, its possession was an object of continued contest. Idumæan princes, Nabathæan kings, Arab chiefs, ruled in their turn.

Both in its natural and its archæological aspects, the country of Bashan is full of interest. The Lejâh is one of the most remarkable regions on the earth's surface. It is, in fact a lava bed; a stone torrent poured out . . . over the ruddy yellow clay and the limestone floor of the Haurân valley, high raised by the ruins of repeated eruptions, broken up by the action of fumaroles or blow holes, and cracked and crevassed when cooling by earthquakes, and by the weathering of ages.

In regard to the architectural monuments of the Haurân, the striking feature, says Count de Vogué is the exclusive use of stone. The country produces no wood, and the only rock which can be obtained is a basalt, very hard and very difficult to work. The walls are formed of large blocks, carefully dressed, and laid together without cement, and often let into one another with a kind of dovetail. Roofs, doors, stairs, and windows, are all of stone. This, of course, imparts to the buildings great massiveness of appearance and great solidity, and in multitudes of cases the houses, though

"without inhabitants," are as perfect as when first reared. Since buildings so strong are apparently capable of enduring for any length of time, and since some of these are known, from the inscriptions upon them, to date from before the commencement of the Christian era, it is not unnatural to regard them as, in fact, the work of the earliest known inhabitants of the land, the Amorites of the Rephaim. This however, is contested, on the ground that the extant inscriptions and the architectural style point to a much later date, and must be regarded as at least unproved. Many inscriptions have been found in this region, — most of them composed in Greek, a considerable number in two forms of Shemitic writing (the Palmyrenian or Aramæan, and the Sinaitic or Nabathæan), and some in an unknown character, resembling the Himyaritic. Arabic inscriptions are numerous on buildings of more recent date. The oldest recognizable Greek record bears the name of Herod the Great; and the Nabathæan kings, of the dynasty of Aretas, who reigned from about 100 B.C. at Bozrah have also left memorials.

BASHKIRS, a people who inhabit the Russian governments of Orenburg, Perm, and Samar, and parts of Viatka, especially on the slopes and confines of the Ural, and in the neighboring plains. The Bashkirs are a Tatarized Finnish race, and are called Eestyak by the Kirghiz, in allusion to their origin from a mixture of Ostyaks and Tatars. The name Bashkir or Bash-kûrt appears for the first time in the beginning of the 10th century in the writings of Ibn-Foslan, who, describing his travels among the Volga-Bulgarians, mentions the Bashkirs, as a warlike and idolatrous race. The name was not used by the people themselves in the 10th century, but is a mere nickname. It probably points to the fact that the Bashkirs, then as now, were distinguished by their large, round, short, and, possibly, close-cropped heads. In 1556 they voluntarily recognized the supremacy of Russia, and, in consequence, the city of Upha was founded to defend them from the Kirghiz, and they were subjected to a fur-tax. In 1786 they were freed from taxes; and in 1798 an irregular army was formed from among them. They are now divided into thirteen cantons, and each canton into yûrts or districts, the whole being under the jurisdiction of the Orenburg governor-general. Almost their sole occupation is the rearing of cattle; and they attend to that in a very negligent manner, not collecting a sufficient store of winter fodder for all their herds, but allowing part of them to perish. The Bashkirs are usually very poor, and in winter live partly on a kind of gruel called yûryu, and badly prepared cheese named skûrt. They are hospitable but suspicious, apt to plunder, and to the last degree lazy. They have large heads, black hair, eyes narrow and flat, small fore-heads, ears always sticking out, and a swarthy skin. In general, they are strong and muscular, and capable of enduring all kinds of labor and privation. They profess Mahometanism, but are little acquainted with its doctrines. In intellectual development they do not stand high.

BASIL THE GREAT, an eminent ecclesiastic in the 4th century. He was a leader in the Arian controversy, a distinguished theologian, a liturgical reformer; and his letters to his friends, especially those to Gregory of Nazianzus, give a great amount of information about the stirring period in which he lived. Basil came of a somewhat famous family, which gave a number of distinguished supporters to the church of the 4th century. His eldest sister, Macrina, was celebrated for her saintly life; his second brother was the famous Gregory of Nyssa; his youngest was Peter, bishop of Sebaste; and his eldest brother was the famous Christian jurist Naucratius. It has been observed that there was in the whole family a tendency to ecstatic emotion and enthusiastic piety. Basil was born about 330, at Cæsarea in Cappadocia. While he was still a child, the family removed to Pontus; but he soon returned to Cappadocia to live with his mother's relations, and seems to have been brought up by his grandmother Macrina. It was at Cæsarea that he became acquainted with his life-long friend Gregory of Nazianzus, and it was there that he began that interesting correspondence to which reference has been made. Basil did not from the first devote himself to the church. He went to Constantinople in pursuit of learning, and spent four or five years there and at Athens. It was while at Athens that he seriously began to think of the church, and resolved to seek out the most famous hermit saints in Syria and Arabia, in order to learn from them how to attain to that enthusiastic piety in which he delighted, and how to keep his body under by maceration and other ascetic devices. After this we find him at the head of a convent near Arnesi in Pontus, in which his mother Emmilia, now a widow, his sister Macrina, and several other ladies, gave themselves to a pious life of prayer and charitable works. He was not ordained presbyter until 365, and his ordination was probably the result of the entreaties of his ecclesiastical superiors, who wished to use his talents against the Arians, who were numerous in that part of the country, and were favored by the Arian emperor, who then reigned in Constantinople. In 370 Eusebius, bishop of Cæsarea, died, and Basil was chosen to succeed him. It was then that his great powers were called into action. Cæsarea was an important diocese, and its bishop was, *ex officio*, exarch of the great diocese of Pontus. Basil was threatened with confiscation of property, banishment, and even death, if he did not relax his regulations against the Arians; but he refused to yield, and in the end triumphed. He died in 379. The principal theological writings of Basil are his *De Spiritu Sancti* and his three books against Eunomius. He was a famous preacher, and we possess at least seventeen homilies by him on the Psalms and on Isaiah. His principal efforts as a reformer were directed towards the improvement of the Liturgy (the *Liturgy of the Holy Basil*), and the reformation of the monastic orders of the East.

The name BASIL also belongs to several distinguished churchmen besides Basil the Great. (1.) Basil, bishop of Ancyra (336–360), a semi-Arian, highly favored by the Emperor Constantine, and a great polemical writer; none of his works are extant. (2.) Basil of Seleucia (fl. 448–458), a bishop who shifted sides continually in the Eutychian controversy, and who wrote extensively; his works were published in Paris in 1622. (3.) Basil of Ancyra, fl. 787; he opposed image worship at the second council of Nicæa, but afterwards retracted. (4.) Basil, the founder of a sect of mystics who appeared in the Greek Church in the 12th century (*cf.* Anna Comnena, *Alexiad*, bk. 15).

BASILICA, a term denoting (1) in civil architecture, a court of law, or merchants' exchange, and (2) in ecclesiastical architecture, a church of similar form and arrangement.

The name *basilica*, "a royal portico," or "hall," is evidence of a Greek origin. The portico at Athens in which the second archon, sat to adjudicate on matters touching religion, and in which the council of Areŏpagus sometimes met, was known as Basilike. From this circumstance the term appears to have gained currency as the designation of a law-court, in which sense it was adopted by the Romans. The introduction of *basilicæ* into Rome was not very early. Livy expressly tells us, when describing the conflagration of the city, 210 B.C., that there were none such then. The earliest named is

that erected by M. Porcius Cato, the censor, 183 B.C., and called after its founder *basilica Porcia*. When once introduced this form of building found favor with the Romans. As many as twenty basilicæ are recorded to have existed within the walls of Rome, erected at different periods, and bearing the names of their founders, *e.g.* — *Æmilia*, *Julia*, *Sempronia*, *Ulpia* or *Trajani*, &c. The basilicas were always placed in the most frequented quarter of the city, in the immediate vicinity of a forum, and on its sunniest and most sheltered side, that the merchants and others who resorted thither might not suffer from the severity of the weather. Originally, the bascilicas, like the Royal Exchange in London and the Bourse at Antwerp, were unroofed, consisting of a central area surrounded simply by covered porticoes, without side walls. Subsequently, side walls were erected and the central space was covered by a roof, which was generally of timber, the beams being concealed by an arched or covered ceiling, ornamented with *lacunaria*. Some baslicas (*e.g.* that of Maxentius or "the Temple of Peace") were vaulted.

In plan the basilicas were large rectangular halls, the length of which, according to the rules laid down by Vitruvius, was not to be more than three times or less than twice its width. In any cases where, from the necessity of the locality, the length exceeded these proportions, the excess was to be masked by the construction of small apartments at the further end, on both sides of the tribunal. On each side of the central area was one, or sometimes, as in the Ulpian and Æmilian basilicas, two rows of columns. These were returned at either end, cutting off a vestibule at one extremity, and the tribunal or court proper, forming a kind of transept, elevated above the nave, at the other. Above the aisles thus formed (*porticus*) were galleries, formed by a second row of columns supporting the roof, approached by external staircases, for the accommodation of the general public — men on one side, women on the other. They were guarded by a parapet wall between the columns, high enough to prevent those in the galleries from being seen by those below. Sometimes, as in Vitruvius's own basilica at Fanum, and in that at Pompeii, instead of a double there was only a single row of columns, the whole height of the building, on which the roof rested. In this case the galleries were supported by square piers behind the main columns. The building was lighted with windows in the side walls, and at the back of the galleries. In the centre of the end-wall were the seats of the judge and his assessors, generally occupying a semicircular apse, the prætor's curule chair standing in the centre of the curve. When the assessors were very numerous (according to Pliny *u.s.*, they sometimes amounted to one hundred and eighty), they sat in two or three concentric curves arranged like the seats of a theatre. The advocates and other officials filled the rest of the raised platform, divided from the rest of the building by a screen of lattice-work (*cancelli*). In the centre of the chord of the apse stood an altar on which the *judices* took an oath to administer true justice. The tribunal sometimes ended square instead of apsidally. This is so in the basilica at Pompeii, where the tribunal is parted from the body of the hall by a *podium* bearing a screen of six columns, and is flanked by staircases to the galleries and by the *chalcidica*. The larger and more magnificent basilicas were sometimes finished with an apse at each extremity.

The plans of Trajan's basilica usually give this arrangement.

The fragment of the ground-plan in the marble tablets preserved in the Capitol, usually called that of the Æmilian, but really, as Canina has shown, that of the Ulpian basilica, also shows an apse, designated (*Atrium*) *Libertatis*. This, we know from many ancient authorities, was the locality for the manumission of slaves; and, therefore, the tribunal must have been at the other end, and, doubtless, also apsidal. The basilica of Trajan was one of the largest and most magnificent in Rome. From its existing remains we learn that it was 174 feet in breadth, and more than twice as long as it was broad. The nave, 86 feet in breadth, was divided from the double aisles by rows of granite columns, 35 feet high. An upper row of columns in front of the galleries above the aisles supported a ceiling, covered with plates of gilt bronze. The total internal height was about 120 feet. The walls were cased with white marble from Luna. It was paved with giallo antico and purple breccia. A side court, which enclosed the well-known memorial column to Trajan, was flanked by libraries. The basilica of Maxentius (or of Constantine), usually known as the *Temple of Peace*, in the Forum at Rome, was on an entirely different plan from those already described. The internal colonnades were dispensed with, the central space being covered by a vast quadripartite brick vault, in three bays; and the aisles were roofed with three huge barrel vaults, each 72 feet in span. Columns were only used for ornament. The tribunal was apsidal. Its width was 195 feet, but it was 100 feet shorter than Trajan's basilica. A good example of a provincial basilica remains at Trèves. It is a plain hall, about 90 feet long, the walls, being 100 feet high, without aisles, and it has an apsidal tribunal elevated considerably above the floor. Under the empire, when architectural magnificence reached a hitherto unparalleled height *basilicæ* formed a part of the plan of the palaces erected by the emperors and nobles of Rome. A beautiful example on a small scale, the *Basilica Jovis*, has been recently excavated in the ruins of the palace of the Cæsars on the Palatine. Only the lower part of the walls remains, but the arrangements of the building are singularly perfect, even to the pierced marble *cancelli*, and throw the clearest light on the construction of these halls.

On the establishmen. of Christianity as the imperial religion, these vast halls furnished exactly what was wanted for the religious assemblies of the Christian community. The basilica was, in fact, a ready-made church, singularly adapted for its new purpose. The capacious nave accommodated the ordinary congregations, the galleries or aisles the females and the more dignified worshippers; while the raised tribunal formed the sanctuary, separated by lattice-work from the less sacred portion below, the bishop and his clergy occupying the semicircular apsis. The prætor's curule chair became the episcopal throne, the curved bench of his assessors the seat for the presbyters of the church. The inferior clergy, readers, and singers took the place of the advocates below the tribunal; while on the site of the heathen altar rose the holy table of the Eucharistic feast, divided from the nave by its protecting lattice-work screen, from which were suspended curtains guarding the sacred mysteries from the intrusive gaze of the profane.

The words of Ausonius to the Emperor Gratian, in which he speaks of "the basilicas once full of business, but now of prayers for the emperor's preservation," are a testimony to the general conversion of these civil basilicas into Christian churches. We know this to have been the case with the basilicas of St. Cross and St. Mary Major's at Rome, which were halls in the Sessorian and Liberian palaces respectively, granted by Constantine to the Christians. We may adduce also as evidence of the same practice a passage from the theological romance known as *The Recognitions of Clement*

(bk. x. ch. 71), probably dating from the early half of the 3d century, in which we are told that Theophilus of Antioch, on his conversion by St. Peter, made over "the basilica of his house" for a church. But however this may have been, with, perhaps, the single exception of St. Cross, the existing Christian basilicas were erected from the ground for their sacred purpose. At Rome the columns, friezes, and other materials of the desecrated temples and public buildings furnished abundant materials for their construction. The decadence of art is plainly shown by the absence of rudimentary architectural knowledge in these reconstructions. Not only are columns of various heights and diameters made to do duty in the same colonnade, but even different orders stand side by side; while pilasters assume a horizontal position, and serve as entablatures, as at St. Lawrence's. There being no such quarry of ready-worked materials at Ravenna, the noble basilicas of that city are free from these defects, and exhibit greater unity of design and harmony of proportions. In all cases, however, the type of the civil basilica, which had proved so suitable for the requirements of Christian congregations, was adhered to with remarkable uniformity.

An early Christian basilica may be thus described in its main features:— A porch supported on pillars (as at St. Clement) gave admission into an open court or *atrium*, surrounded by a colonnaded cloister (St. Clement, Old St. Peter's, St. Ambrose at Milan, Parenzo). In the centre of the court stood a cistern or fountain (*cantharus*, *phiale*), for drinking and ablutions. In close contiguity to the atrium, often to the west, was the baptistery, usually octagonal (Parenzo). The church was entered through a long narrow porch (*narthex*), beyond which penitents, or those under ecclesiastical censure, were forbidden to pass. The narthex was sometimes internal (St. Agnes), sometimes an external portico (St. Lawrence's, St. Paul's). Three or four lofty doorways, according to the number of the aisles, set in marble cases, gave admission to the church. The doors themselves were of rich wood, elaborately carved with scriptural subjects, or of bronze similarly adorned and often gilt. Magnificent curtains, frequently embroidered with sacred figures or scenes, closed the entrance, keeping out the heat of summer and the cold of winter.

The interior consisted of a long and wide nave, often 80 feet across, terminating in a semicircular apse, with one or sometimes (St. Paul's, Old St. Peter's, St. John Lateran) two aisles on each side, separated by colonnades of marble pillars supporting horizontal entablatures (Old St. Peter's, St. Mary Major's, St. Lawrence's) or arches (St. Paul's, St. Agnes, St. Clement, the two basilicas of St. Apollinaris at Ravenna). Above the pillars the clerestory wall rose to a great height, pierced in its upper part by a range of plain round-headed windows. The space between the windows and the colonnade (the later triforium-space) was usually decorated with a series of mosaic pictures in panels (Old St. Peter's, St. Paul's, St. Mary Major's, St. Apollinaris within the walls at Ravenna). The upper galleries of the secular basilicas were not usually adopted in the West, but we have examples of this arrangement at St. Agnes, St. Lawrence's, and the Quattro Santi Coronati. They are much more frequent in the East. The colonnades sometimes extended quite to the end of the church (St. Mary Major's), sometimes ceased some little distance from the end, thus forming a transverse aisle or transept (St. Paul's, Old St. Peter's, St. John Lateran). Where this transept occurred it was divided from the nave by a wide arch, the western face and soffit of which were richly decorated with mosaics. Over the crown of the arch we often find a bust of Christ or the holy lamb lying upon the altar, and, on either side, the evangelistic symbols, the seven candlesticks, and the twenty-four elders. Another arch spanned the semicircular apse, in which the church always terminated. This was designated the *arch of triumph*, from the mosaics that decorated it, representing the triumph of the Saviour and His church. The conch or semi-dome that covered the apse was always covered with mosaic pictures on a gold ground, usually paintings of our Lord, either seated or standing, with St. Peter and St. Paul, and other apostles and saints, on either hand. The beams of the roof were generally concealed by a flat ceiling, richly carved and gilt. The altar, standing in the centre of the chord of the apse on a raised platform, reached by a flight of steps, was rendered conspicuous by a lofty canopy supported by marble pillars (*Ciborium*, *baldacchino*), from which depended curtains of the richest materials. Beneath the altar was the *confessio*, a subterranean chapel, containing the body of the patron saint, and relics of other holy persons. This was approached by descending flights of steps from the naves or aisles. The *confessio* in some cases reproduced the original place of interment of the patron saint, either in a catacomb-chapel or in an ordinary grave, and thus formed the sacred nucleus around which the church arose. We have good examples of this arrangement at St. Peter's, St. Paul's, St. Pudenziana, and St. Lawrence. It was copied, as we will see hereafter, in the original Cathedral of Canterbury. The bishop or officiating presbyter advanced from his seat in the centre of the semicircle of the apse to the eastern side (ritually) of the altar, and celebrated the Eucharist with his face to the congregation below. At the foot of the altar steps a raised platform occupying the upper portion of the nave formed a choir for the singers, readers and other inferior clergy. This oblong space was separated from the aisles and from the western portion of the nave by low marble walls or railings. From these walls projected *ambones*, or pulpits with desks, also of marble, ascended by steps. That for the reader of the gospel was usually octagonal, with a double flight of steps westward and eastward. That for the reader of the epistle was square or oblong.

The exterior of the basilicas was usually of a repulsive plainness. The vast brick walls were unrelieved by ornament, without any compensating grace of outline or beauty of proportion. An exception was made for the west front, which was usually covered with plates of marble mosaices or painted stucco (Old St. Peter's, St. Lawrence's). This part was frequently crowned with a hollow projecting cornice (St. Lawrence's, Ara Cœli). But in spite of any decorations the external effect of a basilica must always have been heavy and unattractive.

To pass from general description to individual churches, the first place must be given, as the earliest and grandest examples of the type, to the world-famous Roman basilicas; those of St. Peter, St. Paul, and St. John Lateran. It is true that no one of these exists in its original form, Old St. Peter's having been entirely removed in the 16th century to make room for its magnificent successor; and both St. Paul's and St. John Lateran having been greatly injured by fire, and the last named being so completely modernized as to have lost all interest. Of the two former, however, we possess drawings, and plans, and minute descriptions, which give an accurate conception of the original buildings. As to St. Peter's, the church was entered through a vast colonnaded *atrium*, 212 feet by 235 feet, with a fountain in the centre,— the atrium being preceded by a porch mounted by a noble flight of steps. The church was 212 feet wide by 380 feet long; the nave,

80 feet in width, was six steps lower than the side aisles, of which there were two on each side. The four dividing colonnades were each of twenty-two Corinthian columns. Those next the nave supported horizontal entablatures. The inner colonnades bore arches, with a second clerestory. The main clerestory walls were divided into two rows of square panels containing mosaics, and had windows above. The transept projected beyond the body of the church,— a very unusual arrangement. The apse, of remarkably small dimensions, was screened off by a double row of twelve wreathed columns of Parian marble, of great antiquity, reported to have been brought from Greece, or from Solomon's Temple. The pontifical chair was placed in the centre of the curve of the apse, on a platform raised several steps above the presbytery. To the right and left the seats of the cardinals followed the line of the apse. At the centre of the chord stood the high altar beneath a ciborium, resting on four pillars of porphyry. Beneath the altar was the subterranean chapel, the centre of the devotion of so large a portion of the Christian world, believed to contain the remains of St. Peter; a vaulted crypt ran round the foundation wall of the apse in which many of the popes were burried. The roof showed its naked beams and rafters.

The cathedral on the island of Torcello near Venice, originally built in the 7th century, but largely repaired *circa* 1000 A.D., deserves special attention from the fact that it preserves, in a more perfect state than can be seen elsewhere, the arrangements of the seats in the apse.

Another very remarkable basilicia, less known than it deserves to be, is that of Parenzo in Istria, *circa* 542 A.D. Few basilicas have sustained so little alteration.

In the Eastern church, though the erection of St. Sophia at Constantinople introduced a new type which almost entirely superseded the old one, the basilican form, or as it was then termed *dromical*, from its shape being that of a race-course, was originally as much the rule as in the West. The earliest church of which we have any clear account, that of Paulinus at Tyre, 313–322 A.D., described by Eusebius, was evidently basilican, with galleries over the aisles, and had an atrium in front. That erected by Constantine at Jerusalem, on the site of the Holy Sepulchre, 333, followed the same plan, as did the original churches of St. Sophia and of the Apostles at Constantinople. Both these buildings have entirely passed away, but we have an excellent example of an Oriental basilica of the same date still standing in the church of the Nativity at Bethlehem, rebuilt by Justinian in the 6th century.

Constantinople still preserves a basilican church of the 5th century, that of St. John Studios, 463, now a mosque.

BASILICA, a code of law, drawn up in the Greek language, with a view to put an end to the uncertainty which prevailed throughout the empire of the East in the 9th century as to the authorized sources of law. This uncertainty had been brought about by the conflicting opinions of the jurists of the 6th century as to the proper interpretation to be given to the legislation of the Emperor Justinian, from which had resulted a system of teaching which had deprived that legislation of all authority, and the imperial judges at last were at a loss to know by what rules of law they were to regulate their decisions. An endeavor had been made by the Emperor Leo the Isaurian to remedy this evil, but his attempted reform of the law had been rather calculated to increase its uncertainty; and it was reserved for Basilius the Macedonian to show himself worthy of the throne, which he had usurped by purifying the administration of justice and once more reducing the law into an intelligible code. There has been considerable controversy as to the part which the Emperor Basilius took in framing the new code. There is, however, no doubt that he abrogated in a formal manner the ancient laws, which had fallen into desuetude, and the more probable opinion would seem to be, that he caused a revision to be made of the ancient laws which were to continue in force, and divided them into forty books, and that this code of laws was subsequently enlarged and distributed into sixty books by his son Leo the Philosopher. A further revision of this code is stated to have been made by Constantinus Porphyrogenitus, the son and successor of Leo, but this statement rests only on the authority of Theodorous Balsamon, a very learned canonist of the 12th century, who, in his preface to the *Nomocanon* of Patriarch Photius, cites passages from the Basilica, which differ from the text of the code as revised by the Emperor Leo. The weight of authority, however, is against any further revision of the code having been made after the formal revision which it underwent in the reign of the Emperor Leo, who appointed a commission of jurists under the presidency of Sympathius, the captain of the body-guard, to revise the work of his father, to which he makes allusion in the first of his *Novellæ*. This latter conclusion is the more probable from the circumstance, that the text of the code, as revised by the Emperor Leo, agrees with the citations from the Basilica which occur in the works of Michael Psellus and Michael Attaliates, both of them high dignitaries of the court of Constantinople, who lived a century before Balsamon, and who are silent as to any second revision of the code having taken place in the reign of Constantinus Porphyrogenitus, as well as with other citations from the Basilica, which are found in the writings of Mathæus Blastares and of Constantinus Hermenopulos, both of whom wrote shortly after Balsamon, and the latter of whom was far too learned a jurist and too accurate a lawyer to cite any but the official text of the code.

Authors are not agreed as to the origin of the term Basilica, by which the code of the Emperor Leo is now distinguished. The code itself appears to have been originally entitled *The Revision of the Ancient Laws.*

BASILICATA, or, as it is also called, POTENZA, a province of Italy, bounded on the N. by Capitanata, N.E. by Terra di Bari, E. by Otranto and the Gulf of Taranto, S. by Calabria Citra, S.W. by the Mediterranean, W. by Principato Citra, and N.W. by Principato Ultra. It has an area of 4120 English square miles, and is divided into the four districts of Lagonegro, Matera, Melfi, Potenza.

BASILIDES, one of the most celebrated of the Gnostics, flourished probably about 120 A.D. Extremely little is known of his life. He is said to have been born in Syria and to have studied at Alexandria, and this is probably correct. There is, to some extent, a corresponding uncertainty with regard to the precise doctrines held by him.

BASILISK,— of the Greeks, and Tsepha (cockatrice) of the Hebrews,— a name applied by the ancients to a horrid monster of their own imagination, to which they attributed the most malignant powers and an equally fiendish appearance. The term is now applied, owing to a certain fanciful resemblance, to a genus of Lizards belonging to the family *Iguanidæ*, the species of which are characterized by the presence of a membraneous bag on the crown of the head, which they can distend or contract at will, and of a fin-like ridge along the back and part of the tail. Both appendages are admirably adapted for aiding the basilisk in swimming, while they do not impede its movements on land,— its mode of life being partly aquatic, partly arboreal. The Mitred Basilisk occurs in Guiana, the Hooded Basilisk in Amboyna.

BASINGSTOKE, a market and borough town in the county of Hants, 45 miles from London.

BASKERVILLE, JOHN, a celebrated printer, and the introducer of many improvements in type-founding, was born at Wolverley in Worcestershire in 1706, and died in 1775.

BASKET, a utensil made of twigs, rushes, or strips of wood, as well as of a variety of other materials, interwoven together, and used for holding or carrying any commodity. Modern ingenuity has applied many substances before unthought of to the construction of baskets, such as iron and even glass. But wicker-work being the oldest as well as the most universal invention, it alone will be treated of in the present article. The process of interweaving twigs, seeds, or leaves, is practiced among the rudest nations of the world; and as it is one of the most universal of arts, so also does it rank among the most ancient industries, being probably the origin of all the textile arts of the world. A bundle of rushes spread out may be compared to the warp of a web, and the application of others across it to the woof, also an early discovery; for basket-work is literally a web of the coarsest materials. The ancient Britons appear to have excelled in the art of basket-making, and their baskets were highly prized in Rome as we learn from Martial. Among many uncivilized tribes at the present day baskets of a superior order are made and applied to various useful purposes. The North American Indians prepare strong water-tight "Wattape" baskets from the roots of a species of *Abies*, and these they frequently adorn with very pretty patterns made from the dyed quills of their native porcupine. The Indians of South America weave baskets equally useful from the fronds of the Carnahuba and other palms. The Kaffres and Hottentots of South Africa are similarly skillful in using the Ilala reed and the roots of plants; while the tribes of central Africa and the Abyssinians display great adroitness in the art of basket-weaving.

Basket-making, however, has by no means been confined to the fabrication of those simple and useful utensils, from which its name is derived. Of old, the shields of soldiers were fashioned of wicker-work, either plain or covered with hides; and the like has been witnessed among modern savages. In Britain, the shields of the ancient warriors, and also their huts, even up to the so-called palaces of the Saxon monarchs, were made of wicker-work; and their boats of the same material, covered with the skins of animals, attracted the notice of the Romans. Herodotus mentions boats of this kind on the Tigris and Euphrates, but with this difference, that the former seem to have been of the ordinary figure of a boat, whereas the latter were round and were covered with bitumen. Boats of this shape, about 71 feet in diameter, are used at the present day on these rivers and boats of analogous construction are employed in crossing the rivers of India which have not a rapid current. Nothing can be more expeditious or more simple than the fabrication and materials of these vessels, if they merit that name. One may be made by six men in as many hours — only two substances, hides and bamboo, almost always accessible, being used. Window screens, perambulators, chairs, &c., are now largely made of basket-work, and the light pony basket carriages in general use are the representatives of the Continental Holstein wagon of the early part of the century, which was a two-horse basket carriage of considerable size. In Berlin and Kiel there now exist large factories of basket furniture, devoted to the manufacture of basket-work, chairs, tables, stands, frames, screens, &c., and the use of this description of furniture is very general in Continental houses.

The materials which are actually employed in the construction of basket-work are numerous and varied, and to the principal of these allusion will be made below. As it is, however, from various species of willow that the largest supply of basket-making materials is produced, we shall first confine our attention to this source. Willows for basket-work are extensively grown in Holland, Belgium, France, and Germany, whence large quantities are exported to Great Britain and even to the United States. The willows of France are highly esteemed by basket-makers as firm, clean rods; and the Dutch produce are lowest in value, being soft and pithy. No Continental rods equal those of English growth for their tough and leathery texture, and the finest of all basket-making willows are now cultivated in large quantities in the valleys of the Thames and the Trent.

The genus *Salix*, to which all willows and osiers belong, is extremely complex in its botanical characters, and the species and varieties, as systematically arranged, are very numerous.

It was long supposed that willows flourish nowhere but with abundance of water. Undoubtedly the osier class thrive well with a considerable degree of humidity, but a dry well-drained soil is best suited for all hard-wooded varieties. For the laying out of a willow holt, the land should be well drained, cleared and tilled to a depth of about one foot. Willows are propagated solely from cuttings, which retain their vitality long, and strike with great facility. The cuttings are made about 9 inches long, and two or three may be obtained from a single rod. They should be planted in rows from 16 to 18 inches apart, the plants in each row being placed at intervals of from 8 to 12 inches according to the size of the willow under cultivation; and the entire length of the cutting should be pushed into the ground. The planting may be done at any time from late autumn to early spring during the period of plant rest, when the ground is free from frost. At the end of each year the shoots are to be cut down close to the ground, manure is laid on between the rows and ploughed in, and the soil should be kept as open and free from weeds as arable land. The produce of the first year will, as a rule, be of little value; nevertheless, in Mr. Scaling's opinion, it is of consequence that the rods should be cut down. The second year's crop should yield a good return; in the third year the plants are at their best, and for the ten following years they should exhibit undiminished productiveness, after which they gradually decline in strength.

The rods intended for basket-making are either taken entire, cut from the root, split asunder, or stripped of their bark, according to the work to be produced; but in all cases they are previously soaked in water, and indeed sometimes boiled. The stripping is performed by drawing the willows through a bifurcated iron implement called a brake, which removes the bark, and the willows are then cleaned, as far as necessary, by manual operation with a knife. When they are boiled previous to peeling a very nice light brown color is developed in the wood by the action of the tannin contained in the bark, and rods thus prepared are much more durable than those peeled white. Next they are exposed to the sun and air, and afterwards placed in a dry situation. But it is not the less necessary to preserve willows with their bark in the same manner; for nothing can be more injurious than the humidity inherent in the plant; and previous to use they must be soaked some days in water also. The barked or white osier is then divided into bundles or faggots according to the size; the larger being reserved to form the strong work in the skeleton of the basket, and the smaller for weaving the

bottom and sides. Should the latter be applied to ordinary work, they are taken whole; but for implements of slight and finer texture, each osier is divided into splits and skains of different degrees of size. Splits are osiers cleft into four parts, by means of an implement employed for that purpose called a cleaver, which is a wedge-shaped tool inserted at the point or top end of the rod and run down through its entire length. These are next drawn through an implement resembling the common spoke-shave, keeping the grain of the split next the iron or stock of the shave, while the pith is presented to the steel edge of the instrument, which is set in an oblique direction to the wood; and in order to bring the split into a shape still more regular, it is passed through another implement called an upright, consisting of a flat piece of steel, each end of which is fashioned into a cutting edge, like that of an ordinary chisel. The flat is bent round, so that the two edges approach each other at a greater or less interval by means of regulating screws, and the whole is fixed into a handle. By passing the splits between the two edges they are reduced to skains, the thickness of which is determined by the interval between the edges of the tool.

The implements required by a basket-maker are few and simple. They consist, besides the preceding, of knives, bodkins, leads for keeping the work steady while in process; and where the willows are worked as rods a heavy piece of iron called a beater is employed to beat them close as they are woven in. On the Continent, where fancy baskets are made, blocks are required on which the webs of wicker-work are set to particular shapes.

From the simplicity of this manufacture, a great many individuals, independent of professed basket-makers, are occupied in it; and it affords suitable employment to the blind in the several asylums and workshops established for their reception in this and other countries.

In addition to willows, a large variety of other materials is employed in the fabrication of wicker-work. Among the most important of these are splits of various species of bamboo, with which the Japanese and Chinese manufacture baskets of unequalled beauty and finish. The bamboo wicker-work with which the Japanese sometimes encase their delicate egg-shell porcelain is a marvellous example of manipulation, and they and the Chinese excel in the application of bamboo wicker-work to furniture. The "canes" or rattans of commerce, stems of species of *Calamus* and *Dæmonorops* are scarcely less important as a source of basket materials. In India "Cajan" baskets are extensively made from the fronds of the Palmyra palm, *Borassus flabelliformis;* and this manufacture has in recent years been established in the Black Forest of Germany, where it is now an important and characteristic staple.

BASNAGE, JACQUES, pastor of the Walloon Church at the Hague, was born at Rouen in Normandy on the 8th of August 1653. He was the son of Henri Basnage, one of the ablest advocates in the parliament of Normandy. At the age of seventeen, having acquired a good knowledge of the Greek and Latin authors, as well as of the English, Spanish, and Italian languages, he went to Geneva, where he began his theological studies under Mestrezat, Turretin, and Tronchin; he completed them at Sedan, under the professors Jurieu and Leblanc de Beaulieu. He then returned to Rouen, where he was received as pastor in September 1676; and in this capacity he remained till the year 1685, when, the exercise of the Protestant religion being suppressed at Rouen, he obtained leave of the king to retire to Holland. He settled at Rotterdam, and continued a minister pensionary there till 1691, when he was chosen pastor of the Walloon Church of that city. In 1709, the pensionary Heinsius secured his election as one of the pastors of the Walloon Church at the Hague, intending to employ him not only in religious but also in civil affairs. Accordingly he was engaged in a secret negotiation with Marshal d'Uxelles, plenipotentiary of France at the congress of Utrecht,—a service which he executed with so much success, that he was afterwards instrusted with several important commissions, all of which he discharged with such ability and address that Voltaire said of him that he was fitter to be a minister of state than the minister of a parish. The Abbé Dubois, who represented France at the Hague in 1716, in negotiating a defensive alliance between France, England, and the States-General, received instructions to consult with Basnage; they accordingly acted in concert, and the alliance was concluded in January 1717. He died on the 22d September 1723.

BASQUE PROVINCES (*Provincias Vascongadas*). The three Spanish provinces known by this name, which are distinguished from all the other divisions of Spain by the character, language, and manners of the inhabitants, and by the enjoyment of political privileges which make the form of their government nearly republican, are Biscay (Vizcaya), Guipuzcoa, and Alava. The territory occupied by them is in the form of a triangle, bounded on the N. by the Bay of Biscay, S. by Soria, E. by Navarra and part of France, and W. by Santander and Burgos. It comprises an area of 2958 square miles; population in 1857, 414,146. These three provinces are more particularly described under their respective heads. The French Basque provinces now form the arrondissements of Bayonne and Mauleon. The Basque language which is also prevalent in Navarre, is still spoken by about 600,000 Spaniards and French. Its native name is *Eskuara*. It cannot be classed with any Indo-European or Semitic tongue, and appears to be of earlier origin, presenting some grammatical analoligies with Mongol, North American, and certain East African languages. No written Basque is known of earlier date than the 15th century, and little genuine literature exists; the orthography is therefore arbitrary, and the earliest writings are difficult to interpret. All that has yet been noticed regarding manners, customs, institutions, and legends may be paralled by those of other Pyrenean peoples, or traced to foreign influences. But, through their moral qualities, physical situation, and historical circumstances the Basques have built up and preserved a body of customs and institutions highly original in the mass. Each province is governed by a parliament composed of representatives selected partly by election, partly by lot, among the householders of each country parish or town. A deputation named by the parliament, ensures the strict observance of the special laws and customs of the province, and negotiates with the representatives of the Spanish crown. Delegates from the three parliaments meet annually to consider the common interests of the provinces; they employ a seal representing three interlaced hands, with the motto *Iruracbat*, "the three are one" but no written federal pact exisits. Much speculation regarding the origin of the Basques has been indulged in without sufficient special knowledge. The belief that they originally occupied great part of Spain and Southern France, founded on the apparently Basque character of certain local names, is very generally accepted.

BASS ROCK, an islet of greenstone and trap tuff, about a mile in circumference, on the coast of East Lothian near the entrance to the Firth of Forth.

BASS'S STRAITS, the channel which separates Tasmania from Victoria. It is about 180 miles in length from E. to W., and about 140 from N. to S.

BASSÁHIR, a Rájput hill state in Hindustán, under the political superintendence of the Lieutenant-Governor of the Panjáb, is bounded on the N. by the Spiti valley, on the E. by Chinese Tartary, on the S. by the district of Garhwál, and on the W. by several small hill states.

BASSANO, a city in Italy in the province of Vincenza. It stands on the river Brenta, over which there is a bridge 180 feet in length, built by Palladio. It is surrounded with walls, and has six gates, one of which, also by Palladio, is very much admired. Population, 13,254.

BASSANO, GIACOMO DA PONTE, a Venetian painter, born in 1510 at Bassano. His compositions, though they have not much eloquence or grandeur, have abundance of force and truth; the local colors are well observed, the carnations are fresh and brilliant, and his chiaroscuro and perspective are unexceptionable. He is said to have finished a great number of pictures; but his genuine works are somewhat rare and valuable,—many of those which are called originals being copies either by the sons of Bassano, or by others. He died in 1592, aged eighty-two.

BASSE-TERRE, the capital of St. Christopher's, one of the British West India Islands. Population, 8500. See SAINT CHRISTOPHER'S

BASSE-TERRE, formerly the capital of Guadeloupe, one of the French West India Islands. Population, 9480. See GUADELOUPE.

BASSEIN, a British district on the eastern coast of the Bay of Bengal, under the jurisdiction of the Chief Commissioner of Burmah, is bounded on the N. by the districts of Kyouk Phoo and Myanoung, on the E. by the district of Rangoon, and on the S. and W. by the Bay of Bengal.

BASSEIN, the principal place of the district of the same name, on the eastern bank of the Bassein River, one of the main arteries by which the waters of the Irawadi discharge themselves into the sea. It forms an important seat of the rice trade, and has great capabilities both from a mercantile and a military point of view, as it commands the great outlet of the Irawadi. It fell before the British arms, in May 1852, during the second Burmese war.

BASSELIN, OLIVIER, an old French poet or writer of verses, was born in the Val-de-Vire in Normandy about the middle of the 14th century, and died about 1418 or 1419.

BASSI, LAURA MARIA CATERINA, an Italian lady, eminently distinguished for her learning, was born at Bologna in 1711. On account of her extraordinary attainments she received a doctor's degree, and was appointed professor in the philosophical college, where she delivered public lectures on experimental philosophy till the time of her death. She was elected member of many literary societies, and carried on an extensive correspondence with the most eminent European men of letters. She was well acquainted with classical literature, as well as with that of France and Italy. In 1738 she married Giuseppe Verrati, a physician, and left several children. She died in 1778.

BASSIANUS, JOANNES, a distinguished professor in the law school of Bologna, the pupil of Bulgarus and the master of Azo.

BASSOON, a musical wind instrument of the reed order, made of wood, and played through a bent mouthpiece of metal.

BASSO-RILIEVO. See SCULPTURE, page 5305, Vol. IX.

BASTAR, a feudatory state in the Central Provinces of British India, bounded on the N. by the Kanker zamíndárí and Ráipur district; on the E. by the Bendrá Nawágarh zamíndárí and Ráipur, Jaipur state and Sabarí River; on the S. by the Sironchá district; and on the W. by the Indrávatí River and the Aherí zamíndárí.

BASTARD is a person born out of lawful wedlock, *i.e.*, whose parents have not been married previous to his birth. The rules by which legitimacy is determined vary chiefly as to the effect to be assigned to the subsequent marriage of the bastard's parents. The law of Scotland, and of most Continental countries, following the rules of the civil and canon law, legitimizes the bastard whose parents afterwards marry. The same principle was at one time advocated by the clergy in England, but summarily rejected by the famous statute of Merton. The English law, however, takes no account of the interval between the marriage and the birth; provided the birth happens after the marriage, the offspring is legitimate. The presumption of law is in favor of the legitimacy of the child of a married woman, and at one time it was so strong that Lord Coke held that "if the husband be within the four seas, *i.e.*, within the jurisdiction of the king of England, and the wife hath issue, no proof shall be admitted to prove the child a bastard unless the husband hath an apparent impossibility of procreation." It is now settled, however, that the presumption of legitimacy may be rebutted by evidence showing non-access on the part of the husband, or any other circumstance showing that the husband could not in the course of nature have been the father of his wife's child. If the husband had access, or the access be not clearly negatived, and others at the same time were carrying on a criminal intercourse with the wife, a child born under such circumstances is legitimate. If the husband had access intercourse must be presumed, unless there is irresistible evidence to the contrary. Neither husband nor wife will be permitted to prove the non-access directly or indirectly. Children born after a divorce *a mensa et thoro* will be presumed to be bastards unless access be proved. A child born so long after the death of a husband that he could not in the ordinary course of nature have been its father is illegitimate. The period of gestation is presumed to be *about* nine calendar months; and if there were any circumstances from which an unusually long or short period of gestation could be inferred, special medical testimony would be required. A marriage between persons within the prohibited degrees of affinity was before 1835 not void, but only voidable, and the ecclesiastical courts were restrained from bastardizing the issue after the death of either of the parents. Lord Lyndhurst's Act declared all such existing marriages valid, but all future marriages between persons within the prohibited degrees of consanguinity or affinity were made null and void, and the issue illegitimate. (See MARRIAGE.)

The incapacities attaching to a bastard consist principally in this, that he cannot be heir to any one; for being *nullius filius*, he is therefore of kin to nobody, and has no ancestor from whom an inheritable blood can be derived. Therefore, if there be no other claimant upon an inheritance than such an illegitimate child, it escheats to the lord. And as bastards cannot be heirs themselves, so neither can they have any heirs but those of their own bodies; for as all collateral kindred consists in being derived from the same common ancestor, and as a bastard has no legal ancestor, he can have no collateral kindred, and consequently no legal heirs, except such as claim by a lineal descent from himself. And hence, if a bastard purchase land, and die seised thereof without issue and intestate, the land escheats to the lord of the fee. Originally a bastard was deemed incapable of holy orders, and disqualified by the fact of his birth from holding any dignity in the church;

but this doctrine is now obsolete, and in all other respects there is no distinction between a bastard and another man.

BASTÍ, a district of British India, in the Benares division, under the jurisdiction of the Lieutenant-Governor of the N. W. Provinces. It is bounded on the N. by the independent state of Nepál, on the E. by the district of Gorakhpur, on the S. by the Ghagrá River, and on the W. by the district of Gondá in Oudh.

BASTIA, a fortified town and seaport on the eastern coast of the island of Corsica, and the capital of an arrondissement. It occupies a very picturesque situation, rising from the sea in the form of an amphitheatre; but the town itself is ill-built, and the streets are narrow and crooked. The harbor, which is defended by a citadel, has a narrow and difficult entrance. Bastia is the seat of a royal court for the island, and of tribunals of commerce and primary jurisdiction, and has a theatre, a military and a civil hospital, a communal college, a model school, a museum, and a library of 30,000 volumes.

BASTIAT, FREDERICK, the son of a merchant of Bayonne, was born in that town on the 19th of June 1801. After being educated at the colleges of Saint-Sever and of Soréze, he entered in 1818 the counting-house of his uncle at Bayonne. Here his intensely active mind soon began to interest itself in the study of the principles of commerce, but he felt no enjoyment in the practical routine of mercantile life, and in 1825 retired to a property at Mugron, of which he became posssessor on the death of his grandfather. Thus withdrawn from society, he devoted himself with eagerness to meditation and study, mastering the English and Italian languages and literatures, speculating on the problems of philosophy and religion, digesting the doctrines of Adam Smith and Say, of Charles Compte and Dunoyer, cultivating music, experimenting in farming, and talking over all that he read, thought and desired, with his able, dearly loved, and life-long friend, M. Felix Coudroy. He welcomed with enthusiasm the Revolution of 1830.

In 1845 he came to Paris in order to superintend the publication of his *Cobden et la Ligue, ou l'agitation Anglaise pour la liberté des échanges*, and was very cordially received by the economists of the capital; from Paris he went to London and Manchester, and made the personal acquaintance of Cobden, Bright, and other leaders of the league. When he returned to France he found that his writings had been exerting a powerful influence; and in 1846 he assisted in organizing at Bordeaux the first French Free Trade Association.

He wrote in rapid succession a series of brilliant and effective pamphlets and essays, showing how socialism was connected with protection, and exposing the delusions on which it rested. While thus occupied he was meditating the composition of a great constructive work, meant to renovate economical science by basing it on the principle that "interests, left to themselves, tend to harmonious combinations, and to the progressive preponderance of the general good." The first volume of this work *Les Harmonies Économiques* was published in the beginning of 1850. In the autumn of that year, when working on the second volume, the increase of his malady compelled him to repair to Italy. After lingering at Pisa and Florence he reached Rome, but only to die there on the 24th of December 1850, in the fiftieth year of his age. An affecting account of the last days of this illustrious martyr to the cause of economical science and political justice was published by his friend, M. Paillottet.

The life-work of Bastiat, in order to be fairly appreciated, requires to be considered in three aspects. (1.) He was the advocate of free trade, the opponent of protection. The general theory of free trade had, of course, been clearly stated and solidly established before he was born, and his desire to see its principles acted on in France was quickened and confirmed by the agitation of the Anti-Corn-Law League for their realization in England, but as no one denies it to have been a great merit in Cobden to have seen so distinctly and comprehensively the bearing of economical truths which he did not discover, no one should deny it to have been also a great merit in Bastiat. He did far more than merely restate the already familiar truths of free trade. He showed as no one before him had done how they were applicable in the various spheres of French agriculture, trade, and commerce. Now, the abstract theory of free trade is of comparatively little value; its elaboration so as to cover details, its concrete application, and its varied illustration are equally essential. And in these respects it owes more, perhaps, to Bastiat than to any other economist. In the *Sophismes Économiques* we have the completest and most effective, the wisest and the wittiest exposure of protectionism in its principles, reasonings, and consequences which exists in any language. (2.) He was the opponent of socialism. In this respect also he had no equal among the economists of France. He alone fought socialism hand to hand, body to body, as it were, not caricaturing it, not denouncing it, not criticzing under its name some merely abstract theory, but taking it as actually presented by its most popular representatives, considering patientiy their proposals and arguments, and proving conclusively that they proceed on false principles, reasoned badly, and sought to realize generous aims by foolish and harmful means. Nowhere will reason find a richer armory of weapons available against socialism than in the pamphlets published by Bastiat between 1848 and 1850. These pamphlets will live, it is to be hoped, at least as long as the errors which they expose. (3). He attempted to expound in an original and independent manner political economy as a science. In combating, first, the Protectionists, and, afterwards, the Socialists, there gradually rose on his mind a conception which seemed to him to shed a flood of light over the whole of economical doctrine, and, indeed, over the whole theory of society, viz., the harmony of the essential tendencies of human nature. The radical error, he became always more convinced, both of protectionism and socialism, was the assumption that human interests, if left to themselves, would inevitably prove antagonistic and anti-social, capital robbing labor, manufactures ruining agriculture, the foreigner injurying the native, the consumer the producer, &c.; and the chief weakness of the various schools of political economy, he believed he had discovered in their imperfect apprehension of the truth that human interests, when left to themselves, when not arbitrarily and forcibly interfered with, tend to harmonious combination, to the general good. Such was the point of view from which Bastiat sought to expound the whole of economical science. The sphere of that science he limited to exchange, and he drew a sharp distinction between utility and value. Political economy he defined as the theory of value, and value as "the relation of two services exchanged." The latter definition he deemed of supreme importance. It appeared to him to correct what was defective or erroneous in the conflicting definitions of value given by Adam Smith, Say, Ricardo, Senior, Storch, &c., to preserve and combine what was true in them, and to afford a basis for a more consistent and developed economical theory than had previously been presented. It has, however, found little acceptance, and Roscher, Cairnes, and others seem to have shown it to be ambiguous and misleading. A consequence of it on which he

laid great stress was that the gratuitous gifts of nature, whatever be their utility, are incapable of acquiring value,—what is gratuitous for man in an isolated state remaining gratuitous in a social condition. Thus, land, according to Bastiat, is as gratuitous to men at the present day as to their first parents, the rent which is paid for it—its so-called value—being merely the return for the labor and capital which have been expended on its improvement. In the general opinion of economists he has failed to establish this doctrine, failed to show that the properties and forces of nature cannot be so appropriated as to acquire value. His theory of rent is nearly the same as Mr. Carey's, *i. e.*, decidedly anti-Ricardian. His views on the growth of capital and interest, on landed property, competition, consumption, wages, and population, are independent, and, if not unqualifiedly true, at least richly suggestive.

BASTILLE (from *bastir*, now *bâtir*, to build), in the earlier use of the word, was any fortified building forming part of a system of defence or attack; and the name was especially applied to several of the principal points in the ancient fortifications of Paris. In the reign of king John, or even earlier, the gate of Saint Antoine was flanked by two towers; and in 1369 Hugues Aubriot, at the command of Charles V., changed it into a regular bastille or fort by the addition of six others of massive structure, the whole united by thick walls and surrounded by a ditch 25 feet wide. Various extensions and alterations were afterwards effected; but the building remained substantially what it was made by the vigorous provost, a strong and gloomy structure, with eight stern towers. As the ancient fortifications of the city were superseded, the use of the word bastille as a general designation gradually died out, and it became restricted to the castle of Saint Antoine, the political importance of which made it practically, long before it was actually, the only bastille of Paris. The building had originally a military purpose, and it appears as a fortress on several occasions in French history. When Charles VII. retook Paris from the English in 1436, all his opponents in the city took refuge in the Bastille, which they were prepared to defend with vigor, but the want of provisions obliged them to capitulate. In 1588 the duke of Guise took possession of the Bastille, gave the command of it to Bussy-Leclerc, and soon afterwards shut up the whole parliament within its walls, for having refused their adherence to the League. When Henri IV. became master of Paris he committed the command of the Bastille to Sully, and there he deposited his treasures, which at the time of his death amounted to the sum of 1,870,000 livres. On the 11th of January 1649, the Bastille was invested by the forces of the Fronde, and, after a short cannonade, capitulated on the 13th of that month. The garrison consisted of only twenty-two men. The Frondeurs concluded a peace with the court on the 11th of March; but it was stipulated by treaty that they should retain possession of the Bastille, which, in fact, was not restored to the king till the 21st of October 1651. In that year took place the famous fight of the Porte St. Antoine between Condé and Turenne, on which occasion the forces of Condé owed their safe retreat into Paris to the cannon of the Bastille.

At a very early period, however, the Bastille was employed for the custody of state prisoners, and it was ultimately much more of a prison than a fortress. According to the usual account, which one is tempted to ascribe to the popular love of poetical justice, the first who was incarcerated within its walls was the builder himself, Hugues Aubriot. Be this as it may, the duke of Nemours spent thirteen years there in one of those iron cages which Louis XI. called his *fillettes* and Jacques d'Armagnac, Poyet, and Chabot were successively prisoners. It was not till the reign of Louis XIII. that it became recognized as a regular place of confinement; but from that time till its destruction it was frequently filled to embarrassment with men and women of every age and condition.

Of the treatment of prisoners in the Bastille very various accounts have been given even by those who speak from personal experience, for the simple reason that it varied greatly in different cases. The prisoners were divided into two main classes, those who were detained on grounds of precaution or by way of admonitory correction, and those who lay under presumption or proof of guilt. The former were subject to no investigation or judgment, and the length of their imprisonment depended on the will of the king: the latter were brought to trial in the ordinary courts or before special tribunals, such as that of the Arsénal,—though even in their case the interval between their arrest and their trial was determined solely by the royal decree, and it was quite possible for a man to grow old in the prison without having the opportunity of having his fate decided. Until guilt was established, the prisoner was registered in the king's name, and—except in the case of state prisoners of importance, who were kept with greater strictness and often in absolute isolation—he enjoyed a certain degree of comfort and freedom. Visitors were admitted under restrictions; games were allowed; and, for a long time, at least, exercise was permitted in open parts of the interior. Food was both abundant and good, at least for the better class of prisoners; and instances were not unknown of people living below their allowance and, by arrangement with the governor, saving the surplus. When the criminality of the prisoner was established, his name was transferred to the register of the "commission," and he became exposed to numerous hardships and even barbarities, which, however, belonged not so much to the special organization of the Bastille as to the general system of criminal justice then in force.

At the breaking out of the Revolution the Bastille was attacked by the Parisians, taken and razed to the ground on the 14th July 1789. At the time of its capture only seven prisoners were found in it. A very striking account of the siege will be found in Carlyle's *French Revolution*, vol. i. The site of the building is now marked by a lofty column of bronze, dedicated to the memory of the patriots of July 1789 and 1830. It is crowned by a gilded figure of Mercury spreading his pinions in the act of flight.

BASTROP, the capital of the county of the same name, in central Texas, is situated on the left bank of the Colorado river, thirty-six miles below Austin, and is an important shipping point for cotton. It contains a cotton mill and other factories, six churches, a number of schools, and a newspaper office, and has a population of 5,500.

BASTWICK, Dr. John, born at Writtle, in Essex, in 1593, was a physician at Colchester, whose celebrity rests on his strong opposition to the Roman Catholic ceremonial. He died in 1646.

BAT, the common name of a well marked group of Mammals forming the order *Cheiroptera* (*i.e.*, wing-handed), distinguished from all other members of their class by the possession of true organs of flight. These consist of a delicate membrane stretching from limb to limb on both sides of the body, enclosing the greatly elongated digits of the hand, and in many cases extending beyond the posterior limbs so as to include the tail. Their whole structure bears evidence of special adaptation to the purpose of sustained flight, while their mode of progression on the ground is as awkward as

their aerial movements are graceful. The eyes of the bat are usually small, but the organs of the other senses in most cases attain extraordinary development. The external ear is generally large, as in the Long-eared Bat of Britain (*Plecotus auritus*), in which it is equal to the entire length of the body. In the group to which the Horse-shoe Bats (*Rhinolophus ferrum equinum*) belong, the nose is surrounded with leaf-like appendages, the purpose of which is by no means well determined, but which, probably, are as useful to the organ of smelling as is the greatly elongated auricle to that of hearing. In all bats the wing-membrane affords a vast expansion of the sense of touch, which is of such exquisite delicacy that bats which have been deprived of their sight, and as far as possible of hearing and smelling, are yet able by it alone to fly about in perfect security, avoiding, with apparent ease, all the obstacles that may be placed in their way.

BATAVIA, a flourishing post village in Claremont county, O., 24 miles east of Cincinnati. It has five churches, a national bank and three newspapers, besides several industries of growing importance.

BATAVIA, a town of Kane county, Ill., on the Fox river, thirty-six miles west of Chicago, with which it has direct railroad communication. It possesses valuable water-power, which is utilized for paper-mills, wind-mill factories, and other manufactures. The surrounding country is one of the richest agricultural and grazing portions of the State, and extensive dairy interests are carried on, most of the products of which find a ready market at Chicago. Batavia has a national bank, a newspaper, eight churches and good schools, and a population (1890) of 3,613.

BATAVIA, the capital of Genesee county, N. Y., is situated on Tonawanda creek, thirty-two miles southwest of Rochester, and thirty-six miles northeast of Buffalo, and enjoys superior railroad accommodations. It contains two national and two other banks, three newspaper offices, nine churches, a public library, a convent and ample school accommodation. It is the seat of the State Arsenal, of the New York State Institute for the Blind, and of the Union School. It has important manufactures of plows and agricultural implements, steam-engines, sash and blinds, and other products, and a population (1890) of 7,200.

BATAVIA, a large city and seaport on the north coast of the island of Java, and the capital of all the Dutch settlements in the East. It is situated on both sides of the river Jacatra or Tjiliwong, in a swampy plain at the head of a capacious bay. The streets are for the most part straight and regular, and many of them have a breadth of from 100 to 200 feet. In several cases there is a canal in the centre lined with stone, and defended by low parapets or banks, while almost every street and square is fringed with trees. The old town has greatly changed from what it was in the 18th century. It was then surrounded by strong fortifications, and contained a number of important buildings, such as the town-house (built in 1652 and restored in 1706), the exchange, the infirmary and orphan asylum, and the European churches. But the ramparts were long ago demolished.

The population of Batavia is very varied,— the Dutch residents being a comparatively small class, and greatly intermixed with Portuguese and Malays. Here are found members of the different Indian nations, originally slaves; Moors and Arabs, who are principally engaged in navigation, but also inhabit the Rua Malacoa district, and trade in gold and precious stones; Javanese, who are cultivators; and Malays, chiefly boatmen and sailors, and adherents of Mahometanism. But, perhaps, the most important Asiatic element is the Chinese, who are both numerous and industrious.

Batavia is still a great commercial depôt, though it has had to contend against the rivalry of Singapore. The bay is rendered secure by a number of islands at its mouth, and is capacious enough for a much larger traffic than it has ever seen; but it unfortunately grows very shallow towards the shore. Ships of 300 or 400 tons anchor about a mile and a half out; the river is navigable a couple of miles inland for vessels of 30 or 40 tons, but the entrance is narrow, and requires continual attention to keep it open.

The exports from Batavia to the other islands of the archipelago, and to the ports in the Malayan peninsula, are rice, sago, coffee, sugar, salt, oil, tobacco, teak timber and planks, Java cloths, brass wares, &c., and European, Indian, and Chinese goods. The produce of the Eastern Islands is also collected at its ports for re-exportation to India, China, and Europe,— namely, gold-dust, diamonds, camphor, benzoin, and other drugs; edible bird-nests, trepang, rattans, bees' wax, tortoise-shell, and dyeing woods from Borneo and Sumatra; tin from Banca; spices from the Moluccas; fine cloths from Celebes and Bali; and pepper from Sumatra. From Bengal are imported opium, drugs, and cloths; from China, teas, raw silk, silk piece-goods, varnished umbrellas, coarse China wares, nankeen, paper, and innumerable smaller articles for the Chinese settlers. British manufactures also are largely introduced. The number of British ships that entered in 1870 was 103, with a tonnage of nearly 31,000 tons, the total number of vessels of all nationalities being 783, with a tonnage of nearly 194,000.

Almost the only manufactures of any importance are the distillation of arrack, which is principally carried on by Chinese, the burning of lime and bricks, and the baking of pottery; and even the brick-making is in a decaying condition.

Batavia owes its origin to the Dutch general John Petersen Coen, who, in 1619, took the town of Jacatra (which had been built on the ruins of the old Javanese town of Sunda Calappa), destroyed it, and founded in its stead the present city, which soon acquired a flourishing trade and increased in importance. The ruins of Jacatra are to be found between Batavia and Anjol. In 1699 Batavia was visited by a terrible earthquake, and the streams were choked by the mud from the volcano of Gunong Salak (7244 feet high), by which the climate was so affected that the city became notorious for its unhealthiness, and was in great danger of being altogether abandoned. In the twenty-two years from 1730 to 1752, 1,100,000 deaths are said to have been recorded. General Daendals, who was governor from 1808 to 1811, caused the ramparts of the town to be demolished, and began to form a nucleus of a new city at Weltevreden. By 1816 nearly all the Europeans had left the old town. In 1811 a British armament was sent against the Dutch settlements in Java, which had been incorporated by France, and to this force Batavia surrendered on the 8th of August. It was restored, however, to the Dutch by the treaty of 1814. Population, 100,000.

BATES, WILLIAM, D.D., an eminent Nonconformist divine, born in November 1625, and died in July 1699, in the 74th year of his age.

BATH, the chief town of Somersetshire, and, from the elegance of its buildings and the beauty of its situation, one of the finest cities in England, is situated mainly on the right bank of the river Avon, though a considerable extension has also taken place on the left.

According to the legend to which the inhabitants adhered till the middle of the 18th century, Bath was

founded by the British king Bladud; but its origin cannot be historically traced to an earlier date than the 1st century, when the Romans established here the city of *Aquæ Solis*, numerous remains of which have at various times been discovered. During the Saxon period the chief events in its annals are the foundation of an abbey by Offa in 775, and the coronation of Edgar in 973. In the reign of William Rufus the city was reduced to ashes, but it soon recovered its prosperity under its abbot John of Villula, and his successors. Richard Cœur de Lion granted its first charter as a free borough, and about the same time the foundations were laid of its wool manufactures. In 1297 the city was first represented in parliament; in 1447 it obtained a charter from Henry VI., and one from Queen Elizabeth in 1590. In the 18th century it became the most fashionable watering-place in England, and was greatly extended under the direction of the architect Wood. Population, 60,000.

BATH, a city and port of the United States, being the chief town of the county of Sagadahock, in Maine. It is situated on the west bank of the Kennebec, about twelve miles from the sea, and forms a station on the branch railway from Brunswick to Rockland. The prosperity of the town depends almost entirely on its shipping and fisheries; and its manufacturing industries are nearly all auxiliary to the one department, shipbuilding, in which it competes with the chief American centres of the trade. It has a fine custom-house built of granite. The city was settled in 1756, incorporated in 1780, and raised to the rank of a city in 1850. Population (1890 census), 8,713.

BATH, the county seat of Steuben county, N. Y., is situated on Conhocton creek, thirty-seven miles north-west of Elmira, and on the Rochester division of the Erie railroad. It contains one national and two other banks, carriage factories and other industrial enterprises, five churches, a Union school, an orphan asylum, and the New York State Soldiers' Home, and has a population (1890) of 5,200.

BATH, KNIGHTS OF THE. See HERALDRY and KNIGHTHOOD.

BATHGATE, a town of Scotland, in the county of Linlithgow, 19 miles from Edinburgh, and 26 from Glasgow, with both of which it has direct communication by railway.

BATHS. In the ordinary acceptation of the word a bath is the immersion of the body in a medium different from the ordinary one of atmospheric air.

Ancient Baths.— Bathing, as serving both for cleanliness and for pleasure, has been almost instinctively practiced by nearly every people. The most ancient records mention bathing in the rivers Nile and Ganges. From an early period the Jews bathed in running water, used both hot and cold baths, and employed oils and ointments. So also did the Greeks; their earliest and commonest form of bathing was swimming in rivers, and bathing in them was practiced by both sexes. Warm baths were, according to Homer, used after fatigue or exercise. The Athenians appear for a long time only to have had private baths, but afterwards they had public ones: the latter seem to have originated among the Lacedæmonians, who invented the hot-air bath, at least the form of it called after them, the *Laconicum*. Although the baths of the Greeks were not so luxurious as those of some other nations, yet effeminate people were accused among them of using warm baths in excess; and the bath servants appear to have been rogues and thieves, as in later and larger establishments. The Persians must have had handsomely equipped baths, for Alexander the Great admired the luxury of the baths of Darius.

But the baths of the Greeks, and probably of all Eastern nations, were on a small scale as compared with those which eventually sprung up among the Romans. In early times the Romans used after exercise to throw themselves into the Tiber. Next, when ample supplies of water were brought into the city, large cold swimming baths were constructed, the earliest of which appear to have been the *piscina publica* (312 B.C.), near the Circus Maximus, supplied by the Appian aqueduct, the *lavacrum* of Agrippina, and a bath at the end of the Clivus Capitolinus. Next, small public as well as private baths were built; and with the empire more luxurious forms of bathing were introduced, and warm became far more popular than cold baths.

Public baths or *balneæ* were first built in Rome after Clodius brought in the supply of water from Præneste. After that date baths began to be common both in Rome and in other Italian cities; and private baths, which gradually came into use, were attached to the villas of the wealthy citizens. Mæcenas was one of the first who built public baths at his own expense. After his time each emperor, as he wished to ingratiate himself with the people, lavished the revenues of the state in the construction of enormous buildings, which not only contained suites of bathing apartments, but included gymnasia, and sometimes even theatres and libraries. Such enormous establishments went by the name of *thermæ*. The principal thermæ were those of Agrippa 21 B.C., of Nero 65 A.D., of Titus 81, of Domitian 95, of Commodus 185, of Caracalla 217, and still later those of Diocletian 302, and of Constantine. The technical skill displayed by the Romans in rendering their walls and the sides of reservoirs impervious to moisture, in conveying and heating water, and in constructing flues for the conveyance of hot air through the walls, was of the highest order.

The Roman baths contained swimming baths, warm baths, baths of hot air, and vapor baths.

The water was heated ingeniously. Close to the furnace, about 4 inches off, was placed the *calidarium*, the copper (*ahenum*) for boiling water, near which, with the same interval between them, was the copper for warm water, the *tepidarium*, and at the distance of 2 feet from this was the receptacle for cold water, or the *frigidarium*, often a plastered reservoir. A constant communication was kept up between these vessels, so that as fast as hot water was drawn off from the calidarium a supply was obtained from the tepidarium, which, being already heated, but slightly reduced the temperature of the hotter boiler. The tepidarium, again, was supplied from the frigidarium, and that from an aqueduct. In this way the heat which was not taken up by the first boiler passed on to the second, and instead of being wasted, helped to heat the second — a principle which has only lately been introduced into modern furnaces. In the case of the large thermæ the water of an aqueduct was brought to the *castellum*, or top of the building, and was allowed to descend into chambers over the hypocaustum, where it was heated and transmitted in pipes to the central buildings. Remains of this arrangement are to be seen in the baths of Caracalla.

The arrangements of the *thermæ* were mainly those of the balance on a larger scale. Some idea of their size may be gathered from such facts as these, that in the baths of Diocletian one room has been transmuted into a church of most imposing proportions, and that the outside walls of the baths of Caracalla extend about a quarter of a mile on each of the four sides. A visit to the remains of the baths of Titus, of Diocletian, or of Caracalla impresses the mind strongly with a sense of the vast scale on which they were erected, and Ammianus's designation of them as provinces appears scarcely

exaggerated. It is said that the baths of Caracalla contained 1600, and those of Diocletian 3200 marble seats for the use of the bathers. In the largest of the thermæ there was a stadium for the games of the young men, with raised seats for the spectators. There were open colonnades and seats for philosophers and literary men to sit and discourse or read their productions aloud, or for others to discuss the latest news. Near the porticoes, in the interior open space, rows of trees were planted. There was a *sphæristerium*, or place for playing ball, which was often over the apodyterium; but it must be confessed that the purposes of many portions of these large edifices have not been made out in as satisfactory a way as those of smaller baths.

The magnificence of many of the thermæ and their luxurious arrangements were such that some writers, as Seneca, are quite lost in their descriptions of them. The piscinæ were often of immense size,—that of Diocletian being 200 feet long,—and were adorned with beautiful marbles. The halls were crowded with magnificent columns, and were ornamented with the finest pieces of statuary. The walls, it has been said, were covered with exquisite mosaics that imitated the art of the painter in their elegance of design and variety of color. The Egyptian syenite was encrusted with the precious green marbles of Numidia. The rooms contained the works of Phidias and Praxiteles. A perpetual stream of water was poured into capacious basins through the wide mouths of lions of bright and polished silver; water issued from silver, and was received on silver. "To such a pitch of luxury have we reached," says Seneca, "that we are dissatisfied if we do not tread on gems in our baths."

The richer Romans used every variety of oils and pomades (*smegmata*); they scarcely had true soaps. The poorer class had to be content with the flour of lentils, an article used at this day for the same purpose by Orientals. The most important bath utensil was the strigillus, a curved instrument made of metal, with which the skin was scraped and all sordes removed.

The bath servants assisted in anointing, in using the strigillus, and in various other menial offices. The poorer classes had to use their strigils themselves. The various processes of the aliptæ seem to have been carried on very systematically.

The hot baths appear to have been open from 1 P.M. till dark. It was only one of the later emperors that had them lighted up at night. When the hot baths were ready (for, doubtless, the plunge baths were available at an earlier hour,) a bell was rung for the information of the people. Among the Greeks and Romans the eighth hour, or 1 o'clock, before their dinner, was the commonest hour for bathing. The bath was supposed to promote appetite, and some voluptuaries had one or more baths after dinner, to enable them to begin eating again; but such excesses, as Juvenal tells us, occasionally proved fatal. Some of the most effeminate of the emperors are said to have bathed seven or eight times in the course of a day. In early times there was delicacy of feeling about the sexes bathing together; even a father could not bathe with his sons, but latterly, under most of the emperors, men and women often used the same baths. There frequently were separate baths for the women, as we see at Pompeii, or at Badenweiler; but although respectable matrons would not go to public baths, promiscuous bathing was common during the empire.

The public baths and thermæ were under the more immediate superintendence of the ædiles. The charge made at a public bath was only a quadrons or quarter of an as, about half a farthing. Yet cheap though this was, the emperors used to ingratiate themselves with the populace, by making the baths at times gratuitous.

Wherever the Romans settled, they built public baths; and wherever they found hot springs or natural stufæ, they made use of them, thus saving the expense of heating, as at the *myrteta* of Baiæ, or the *aquæ solis* of Bath. In the cities there appear to have been private baths for hire, as well as the public baths; and every rich citizen had a set of baths attached to his villa, the fullest account of which is given in the *Letters* of Pliny, or in Ansonius's *Account of a Villa on the Moselle*, or in Statius's *De Balneo Etrusco.* Although the Romans never wholly gave up cold bathing, and that practice was revived under Augustus by Antonius Musa, and again under Nero by Charmis (at which later time bathing in the open sea became common), yet they chiefly practiced warm bathing (*calida lavatio*). This is the most luxurious kind of bathing, and when indulged to excess, is enervating. The women were particularly fond of these baths, and were accused, at all events in some provincial cities, of drunkenness in them.

The unbounded licence of the public baths, and their connection with modes of amusement that were condemned, led to their being to a considerable extent proscribed by the early Christians. The early fathers wrote that bathing might be practiced for the sake of cleanliness or of health, but not of pleasure; and Gregory the Great saw no objection to baths being used on Sunday. About the 5th century many of the large thermæ in Rome fell into decay. The cutting off of the aqueducts by the Huns, and the gradual decrease of the population, contributed to this. Still it is doubtful whether bathing was ever disused to the extent that is usually represented. It was certainly kept up in the East in full vigor at Alexandria and at Brusa. Hot bathing, and especially hot air and vapor baths, were adopted by the Mahometans; and the Arabs brought them with them into Spain. The Turks, at a later time, carried them high up the Danube, and the Mahometans spread or, it may be more correct to say, revived their use in Persia and Hindustan. The Crusaders also contributed to the spread of baths in Europe, and hot vapor baths were specially recommended for the leprosy so prevalent in those days. After the commencement of the 13th century there were few large cities in Europe without hot vapor baths. We have full accounts of their regulations,—how the Jews were only allowed to visit them once a week, and how there were separate baths for lepers. In England they were called hothouses. Erasmus, at the date of the Reformation, spoke of them as common in France, Germany, and Belgium; he gives a lively account of the mixture of all classes of people to be found in them, and would imply that they were a common adjunct to inns. They seem after a time to have become less common, though Montaigne mentions them as being still in Rome in his day. In England the next revival of baths was at the close of the 17th century, under the Eastern name of Hummuns, or the Italian name of Bagnios. As these, like more recent revivals of them, were avowedly on the principle of the Turkish baths, that species of bath must be briefly noticed. But before doing so, we must observe that there were several considerable epochs in the history of baths, one in the commencement of the 18th century, when Floyer and others recalled attention to cold bathing, of which the virtues had long been overlooked. In the middle of the century also, Russell and others revived sea-bathing in England, and were followed by others on the Continent, until the value of sea-bathing became fully appreciated. Later in the same century the experiments of Currie on the action of complete or partial baths on the

system in disease attracted attention; and though forgotten for a while, they have borne abundant fruit in more recent times.

Modern Baths.—It is uncertain how far the Turkish and Egyptian and even the Russian baths are to be regarded merely as successors of the Roman baths, because the principle of vapor baths has been known to many nations in a very early period of civilization. Thus the Mexicans and Indians were found using small vapor baths. The ancient inhabitants of Ireland and of Scotland had some notion of their use, and the large vapor baths of Japan, now so extensively employed, are probably of independent origin.

Turkish baths have, with various modifications, become popular in Europe. The Russian baths were introduced into most German towns about half a century ago. They had a certain limited amount of popularity, but did not take firm root. Another class practically owes its origin to Dr. Barter and Mr. Urquhart. It professed to be founded on the Turkish bath, but in reality it was much more of a hot air bath, *i.e.*, more devoid of vapor than either Roman or Turkish baths ever were, for it is doubtful whether in any case the air of the laconicum was free from vapor. These baths, with their various modifications, have become extremely popular in Great Britain, in Germany, and in Northern Europe, but have, curiously enough, never been used extensively in France, notwithstanding the familiarity of the French with Turkish baths in Algiers.

In England hot air baths are now employed very extensively. They are often associated with Turkish and electric baths, and with the usual processes of hydropathic treatment.

Bathing among the ancients was practised in various forms. It was sometimes a simple bath in cold or in tepid water; but at least, in the case of the higher orders, it usually included a hot air or vapor bath, and was followed by affusion of cold or warm water, and generally by a plunge into the piscina. In like manner the order varies in which the different processes are gone through in Turkish baths in modern Europe. Thus in the new baths in Vienna, the process begins by immersion in a large basin of warm water. Sudation is repeatedly interrupted by cold douches at the will of the bathers, and after the bath they are satisfied with a short stay in the cooling-room, where they have only a simple sheet rolled round them. In Copenhagen and in Stockholm the Oriental baths have been considerably modified by their association with hydropathic practices.

This leads us to notice the introduction of hydropathy. Although cold baths were in vogue for a time in Rome, warm baths were always more popular. Floyer, as we have seen, did something to revive their use in England; but it was nearly a century and a half afterwards that a Silesian peasant, Priessnitz, introduced with wonderful success, a variety of operations with cold water, the most important of which was the packing the patient in a wet sheet, a process which after a time is followed by a profuse sudation. Large establishments for carrying out this mode of bathing and its modifications have within the last thirty years been erected in many places on the Continent and in Great Britain, and have enjoyed a large share of popularity.

But the greatest and most important development of ordinary baths in modern times has taken place in England, and has been extending gradually to the Continent. The English had long used affusion and swimming baths freely in India. Cold and hot baths and shower baths have been introduced into private houses to an extent never known before; and from 1842 downwards, public swimming baths, besides separate baths, have been supplied to the public at very moderate rates, and in some cases associated with wash houses for the poorer classes. Their number has increased rapidly in London and in the principal continental cities. Floating baths in rivers, always known in some German towns, have become common wherever there are flowing streams. The better supply of most European cities with water has aided in this movement. Ample enclosed swimming baths have of late years been erected at many sea-side places. When required, the water, if not heated in a boiler, is raised to a sufficient temperature by the aid of hot water pipes or of steam; and gas has been utilized for heating small quantities of water for baths in private houses. As to separate baths, they used to be of wood, painted; they are now most frequently of metal, painted or lined with porcelain enamel. The swimming baths are lined with cement, tiles, or marble and porcelain slabs; and in some of the newest baths a good deal of ornamentation and painting of the walls and ceiling of the apartments, in imitation of the ancients, has been attempted.

We have thus traced in outline the history of baths through successive ages down to the present time. The medium of the baths spoken of thus far has been water, vapor, or dry hot air. But baths of more complex nature, and of the greatest variety, have been in use from the earliest ages. The best known media are the various mineral waters and sea-water. These, and baths impregnated with their gases, cannot here be considered in detail; we can do little more than enumerate a few of the artificial baths. Of baths of *mineral* substances, those of sand are the oldest and best known; the practice of *arenation* or of burying the body in the sand of the seashore, or in heated sand near some hot spring, is very ancient, as also that of applying heated sand to various parts of the body. Within the last few years establishments have been introduced into various European cities where hot dry sand is methodically applied. Baths of *peat* earth are of comparatively recent origin, and are little used out of Germany. The peat earth is carefully prepared and pulverized, and then worked up with water into a pasty consistence, of which the temperature can be regulated before the patient immerses himself in it.

There are various baths that may be termed *chemical*, in which chlorine or nitromuriatic acid is added to the water of the bath, or where fumes of sulphur are made to rise and envelop the body.

Of *vegetable* baths the number is very large. Leys of wine, in a state of fermentation, have been employed. An immense variety of aromatic herbs have been used to impregnate water with. Of late years fuci or seaweed have been added to baths, under the idea of conveying into the system the iodine which they contain; but by far the most popular of all vegetable baths are those made with an extract got by distilling certain varieties of pine leaves. They are pleasant and stimulating.

The strangeness of the baths of *animal* substances, that have been at various times in use, is such that their employment seems scarcely credible. That baths of milk or of whey might not be unpopular is not surprising, but baths of blood, in some cases even of human blood, have been used.

Electrical or *galvanic* baths have been popular of late years, in which galvanic action is communicated to the patient while in baths.

Baths also of *compressed air*, in which the patient is subjected to the pressure of two or three atmospheres, have been in use at certain places for some years.

A *sun* bath, exposing the body to the sun, the head being covered, was a favorite practice among the Greeks and Romans. This list of artificial baths might be readily increased.

We have hitherto spoken of general baths, but there are many varieties of local ones, the use of which has become somewhat more definite than it used to be, before the principles of hydropathy were understood. Some of these are affusion, half-bath, full bath, sitz baths, wave baths, local baths, shower and spray baths, douches, fomentations, injections, wrapping up in the wet sheet. Some of these processes, though by no means of novel origin, require a few words of explanation.

Douches were used by the ancients, and have always been an important mode of applying water to a circumscribed portion of the body. They are, in fact, spouts of water, varying in size and temperature, applied with more or less force for a longer or shorter time against particular parts. A douche exercises a certain amount of friction, and a continued impulse on the spot to which it is applied, which stimulate the skin and the parts beneath it, quicken the circulation of the capillaries, and thus favor the absorption of abnormal deposits. It wakes up the slumbering activity of the tissues and helps to remove congestions from the deeper seated organs. The effects of the douche are so powerful that it cannot be applied for a long time continuously. After every two or three minutes there should be an interval in its use. It is obvious that a douche is capable of many local applications, on the description of which it is here impossible to enter. Nor need we say that the douche must be used with great care in the case of nervous and excitable people, and better not at all when any irritation or inflammation is present. Douches are invaluable in old neuralgias, in the sequelæ of rheumatism, and in thickened joints.

The alternation of hot and cold douches, which for some unknown reason has got the name of *Ecossaise*, is a very powerful remedy from the strong action and reaction which it produces, and is one of very great value. The shower bath may be regarded as a union of an immense number of fine douches projected on the head and shoulders. It has been long in use in England, and produces a strong effect on the nervous system. An ingenious contrivance for giving circular spray baths, by which water is propelled laterally in fine streams against every portion of the surface of the body, is now found in most establishments.

To all these modes of acting on the cutaneous surface and circulation must be added dry rubbing, as practiced by the patient with the flesh glove, but much more thoroughly by the bath attendants, if properly instructed.

Action of Baths on the Human System.—We shall now inquire shortly into the theory of the operation of the baths and of the bathing processes, of which we have briefly traced the history.

The primary operation of baths is the action of heat and cold on the cutaneous surfaces through the medium of water.

The first purpose of baths is simply that of abstersion and cleanliness, to remove any foreign impurity from the surface, and to prevent the pores from being clogged by their own secretions or by desquamations of cuticle. It need scarcely be said that such objects are greatly promoted by the action of alkali of soaps and by friction; that the use of warm water, owing to its immediate stimulation of the skin, promotes the separation of sordes; and that the vapor of water is still more efficient than water itself.

It has been supposed that water acts on the system by being absorbed through the skin. The question has been frequently discussed; but the great majority of observers believe that, under ordinary circumstances, no water is absorbed, or if any, so minute a quantity that it is not worth considering. And further, as we have alluded to medicated baths, it is proper to say that, according to the latest authorities, no foreign bodies, under the ordinary circumstances of a bath, are absorbed into the system; although when a portion of skin has been entirely cleared of its sebaceous secretion, it is possible that a strong solution of salts may be partially absorbed. In the case of medicated baths we therefore only look (in addition to the action of heat and cold, or more properly to the abstraction or communication and retention of heat) to any stimulant action on the skin which the ingredients of the bath may possess.

The powerful influence of water on the capillaries of the skin, and the mode and extent of that operation, depend primarily on the temperature of the fluid; for the influence of the mechanical pressure on the body of the water of a bath, which has been calculated at nearly one pound on each square inch of the surface, has never been accurately determined. Baths have therefore to be considered according to their temperature; and the effects of cold and of hot baths have to be studied. But we may as well first point out one or two general facts. The human system bears changes of temperature of the air much better than changes of the temperature of water. While the temperature of the air at 75° is perhaps too warm for the feelings of many people, a continued bath at that temperature is felt to be cold and depressing. Again, a bath at 98° to 102° acts far more excitingly than air of the same temperature, both because, being a better conductor, water brings more heat to the body, and because it suppresses the perspiration, which is greatly augmented by air of that temperature. Further, a temperature a few degrees below blood heat is that of indifferent baths, which can be borne longest without natural disturbance of the system.

Cold baths act by refrigeration, and their effects vary according to the degree of temperature. The effects of a cold bath, the temperature not being below 50°, are these: — there is a diminution of the temperature of the skin and of the subjacent tissues; the blood at first rises in temperature nearly 4°, but soon subsides again, this diminution of temperature of the blood usually not taking place in the bath, but shortly after leaving it. There is a certain feeling of shock diffused over the whole surface, and if the cold is intense it induces a slight feeling of numbness in the skin. It becomes pale and its capillaries contract. The further action of cold bath reaches the central nervous system, the heart and the lungs, as manifested by the tremor of the limbs it produces, along with a certain degree of oppression of the chest and a gasping for air, while the pulse becomes small and sinks. After a time reaction takes place, and brings redness to the skin and an increase of temperature.

The colder the water is, and the more powerful and depressing its effects, the quicker and more active is the reaction. Very cold baths, anything below 50°, cannot be borne long. Lowering of the temperature of the skin may be borne down to 9°, but a further reduction may prove fatal. The diminution of temperature is much more rapid when the water is in motion, or when the bather moves about; because, if the water is still, the layer of it in immediate contact with the body gets warmed to a certain degree.

The effects of *hydropathy* depend on the power of abstracting heat from the body, and of stimulating it by the application of cold water. The action is depressing or exciting, according as the withdrawal of heat or the stimulation predominates.

A great deal depends on the form of the bath; thus one may have — (1.) Its depressing operation,— with a loss of heat, retardation of the circulation, and feeling of

weariness, when the same water remains in contact with the skin, and there is continuous withdrawal of heat without fresh stimulation. This occurs with full or sitz baths, with partial or complete wrapping up the body in a wet sheet which remains unchanged, and with frictions practiced without removing the wet sheets. (2.) Its exciting operation,—with quickening of the action of the heart and lungs, and feeling of glow and of nervous excitement and of increased muscular power. These sensations are produced when the layer of water next the body and heated by it is removed, and fresh cold water causes fresh stimulus. These effects are produced by full baths with the water in motion used only for a short time, by frictions when the wet sheet is removed from the body, by douches, shower baths, bathing in rivers, &c. The depressing operation comes on much earlier in very cold water than in warmer; and in the same way the exciting operation comes on faster with the colder than with the warmer water. The short duration of the bath makes both its depressing and its exciting action less; its longer duration increases them; and if the baths be continued too long, the protracted abstraction of animal heat may prove very depressing.

We shall not attempt to give more than those few hints about hydropathic processes, and shall merely remark that, under them the system is subjected to alternate periods of excitement and of rest. There is persistent lowering of the temperature of the body, with contraction of the capillaries and local anæmia. This is succeeded by the reverse, or by local hyperæmia. There is powerful excitement of the vascular and nervous systems. The processes of absorption and of excretion are stimulated. There is a great increase of perspiration. The transformation of tissue is materially quickened.

We must next consider the operation of warm baths of different temperatures.

Tepid, 85° *to* 95°.—The effects of a bath of this temperature are confined to the peripheral extremities of the nerves, and are so slight that they do not reach the central system. There is no reaction, and the animal temperature remains unchanged. Baths of this kind can be borne for hours with impunity.

Warm baths from 96° *to* 104°.—In these the action of the heat on the peripheral surface is propagated to the central system, and causes reaction. which manifests itself in moderately increased flow of the circulating fluids to the surface, and in an increased frequency of pulse. It appears to supply a slight stimulus to the renewal of tissue.

With a *hot bath* from 102° up to 110° the central nervous and circulating systems are more affected. The frequency of the pulse increases rapidly, the respiration becomes quickened, and is interrupted by deep inspirations. The skin is congested, and the retained animal heat bursts out, causing a profuse perspiration.

Very hot bath.—Everything above 110° feels very hot; anything above 120° almost scalding. Baths of from 119° to 126° have caused a rise of 2° to 4½° in the temperature of the blood. Such a bath can only be borne for a few minutes. It causes violent reflex action on the heart and the arterial system, excessive congestion of the skin, and violent perspiration.

In the use of hot baths a certain amount of vapor reaches the parts of the body not covered by the water, and is also inhaled.

Vapor baths produce profuse perspiration, and act in cleansing the skin, as powerful hot water baths do. Vapor, owing to its smaller specific heat, does not act so fast as water on the body. A vapor bath can be borne for a much longer time when the vapor is not inhaled. Vapor baths can be borne hotter than water baths, but cannot be continued so long, a vapor, being a bad conductor, prevents radiation of heat from the body. A higher heat than 122° is not borne comfortably. The vapor bath, though falling considerably short of the temperature of the hot air bath, heats the blood considerably more.

Hot air baths differ from vapor baths in not impeding the respiration as the latter do, by depositing moisture in the bronchial tubes. The lungs, instead of having to heat the inspired air, are subjected to a temperature above their own. Hot air baths, say of 135°, produce more profuse perspiration than vapor baths. If very hot, they raise the temperature of the body by several degrees.

Vapor baths, hot air baths, and many hydropathic processes agree in producing violent sudation, and also frequently in subjecting the body, while in a state of perspiration, to the action of water of a comparatively low temperature. Of perspiration we shall only say, that it is sensible and insensible: 30 oz. may be considered to be about its average amount in the twenty-four hours; of this, which is chiefly water, about ⅓ of an oz. consists of urea and of other peculiar substances. A man has been known to lose 3 pounds in a Russian bath; some think more may be lost. As perspiration eliminates water and effete matter from the system, and also aids in respiration, it is obvious that its regulation must have an important effect on the economy.

In comparing the general effects of hot and cold baths, it may be said that while the former tend to check cutaneous transpiration, the latter favor it. It is supposed, but is scarcely proved, that cold baths, by the stimulus they give, increase the reaction of the gastric and other fluids of the stomach, and of the alimentary canal, and that warm baths rather serve to retard it. Either hot or cold baths, but especially the latter, favor the secretion of urine. Whether warm or cold baths, like the breathing of hot or cold air, have any effect on the exhalation of carbonic acid has not been determined.

The warm bath causes swelling and congestion of the capillaries of the surface in the first instance; when the stimulus of heat is withdrawn their contraction ensues. A cold bath, again, first causes a contraction of the capillaries of the surface, which is followed by their expansion when reaction sets in. A warm bath elevates the temperature of the body, both by bringing a supply of heat to it and by preventing the radiation of heat from it. It can be borne longer than a cold bath. It draws blood to the surface, while a cold bath favors internal congestions. There is in both cases increased oxidation or waste of the tissues; but with the warm bath there is less call made on the system, as oxidation depends chiefly on increased heat, which in the case of the warm baths is artificially supplied. The reason why a man when much exhausted feels a hot bath refreshing, while he cannot bear a cold one, may be that the increased heat conveyed to him by the warm bath helps the process of oxidation, and thus relieves his system. Cold refreshes by exciting the functions, heat by physically relieving their action; a hot bath calms by reducing the loss of heat, and by supplying a certain amount of it. Very hot baths, it is true, act like cold baths, as stimulants to the heart and nervous centres; but they do it more gradually and with less shock to the system than cold baths. The general result of this comparison would show that warm are a milder remedy than cold baths, and are applicable often when the system does not possess power of reaction sufficient to make the use of the latter expedient.

As regards the use of baths simply for the promotion of health, it follows, from what has been stated, that

warm baths are best suited for the delicate, for the very young, and for the old; cold baths for the strong and active, in whom the powers of reaction are unimpaired. It would be out of place to say much here about the use of baths in medicine. Warm baths according to their degree of heat are of great value in relaxing spasms, in calming the nervous system, and in neuralgias, chronic rheumatism, and gout. Turkish baths are useful in these last affections, and wherever it is of importance that there should be free action of the skin. Cold baths, again, are more useful when the system requires tonics, and when it can bear the shock of cold affusion; when diseases of the system, especially of the nervous system, are more functional than organic. It is obvious that the cold-water cure, including, as it does, copious sudation, combines in a certain degree the effects of both kinds of baths.

But baths often produce injurious effects when used injudiciously. Long continued warm baths are soporific, and have owing to this action often caused death by drowning. The effects of very hot baths are swimming in the head, vomiting, fainting, congestion of the brain, and, in some instances, apoplexy.

The symptoms seem to point to paralysis of the action of the heart. It is therefore very evident how cautious those should be, in the use of hot baths, who have weak hearts or any obstruction to the circulation. Fat men, and those who are full-blooded or predisposed to epilepsy, should avoid them. Protracted indulgence in warm baths is relaxing, and has been esteemed a sign of effeminacy in all ages. Sleepiness, though it will not follow the first immersion in a cold bath, is one of the effects of protracted cold baths; depression of the temperature of the surface that exceeds 9° becomes dangerous. The risk in cold baths is congestion of the internal organs, as often indicated by the lips getting blue. Extremely cold baths are, therefore, very unsafe wherever there is a tendency to internal congestion; and they are always dangerous when the system is exhausted by fatigue.

We shall conclude with a few words of advice about ordinary bathing for hygienic purposes:—Whenever it is practicable, bathing should be over before 1 p.m. It is not to be thought of when the stomach is loaded, or after much wine. The shorter the bath is, especially if the water be cold, and the bather cannot swim, the better,—say five minutes. He should swim if possible, and then a quarter of an hour is long enough. Bathing should not be practiced more than once a day. When one is over-heated, but not exhausted, it is advisable to bathe at once, without waiting to cool. After hot air or vapor baths care must be taken that cold be not caught, although the more enthusiastic advocates of such baths declare that there is no risk of this.

BATHURST, a town of New South Wales, on the Macquarie River, 122 miles W.S.W. of Sydney, with which it is connected by railway. Population, 10,000.

BATHURST, ALLEN BATHURST, EARL OF, a distinguished statesman in Queen Anne's reign, was born in the year 1684. He died after a few days' illness, at his seat near Cirencester, September 16, 1775, in the ninety-first year of his age.

BATHURST, RALPH, uncle of the preceding, was born in the year 1620. He died June 24, 1704, in his eighty-fourth year.

BATHYCLES, a Greek sculptor, born at Magnesia on the Mæander, known for his sculptures on the throne of the statue of Apollo at Amyclæ near Sparta, which Pausanias saw and describes (iii. 18, 6). His date is uncertain, but cannot well be later than between 563–549 B.C.

BATON-ROUGE, a town in the southeastern part of Louisiana, situated on a bluff on the left bank of the Mississippi, 120 miles above New Orleans. It has a court house, state penitentiary, national arsenal and barracks, military hospital, deaf and dumb asylum, and state university. Baton-Rouge was one of the first settlements of the French. In 1849 it was the State capital, and has recently superseded New Orleans as the seat of government. Occupied by the Federal troops after the capture of that city, it was defended in 1862 by General Williams against the attack of the Confederates under Breckinridge. Population, 10,397.

BATONI, POMPEO GIROLAMO, a native of Lucca, who was regarded in Italy as a great painter in the 18th century, and who unquestionably did much to rescue the art from the intense mannerism into which it had fallen during the century preceding. He was born in 1708, and died at Rome in 1787.

BATRACHIA. See AMPHIBIA, vol. i. p. 292.

BATRACHUS, according to Pliny, the name of a Greek architect who, along with Sauras (both natives of Sparta), was employed by Metellus in the construction of certain temples in Rome.

BATTALION is the tactical unit of infantry. It is the term applied to the most numerous body of dismounted men which one commanding officer can personally superintend. It consists of from four to ten companies, is always commanded by a field officer, and has a normal war strength of about 1000 men. Two or more battalions constitute a regiment; two or more regiments a brigade; two or more brigades a division; two or more divisions a *corps d'armée;* and two or more *corps d'armée* an army. See ARMY.

BATTAS, a people in the northern portion of Sumatra, which regards itself as the oldest in the island, and is distinguished by a pertinacious adherence to ancient customs. The Batta is of middle height, his color is a light brown, and his hair is black and is worn long. He is dirty in his dress and dwelling, and eats any kind of food that presents itself, though he lives chiefly on rice. Cannibalism is practiced.

Batta or Batak Language.—Up to the publication of Dr. H. N. van der Tuuk's essay *Ovar schrift en uitspraak der Tobasche taal* (1855), the first fruits of an eight years' residence amongst the Battas, our knowledge of the Batak language was confined to lists of words more or less complete, chiefly to be found in Marsden's *Miscellaneous Works*. By his exhaustive works that eminent Dutch savant has made the Batak language the most accessible of the various tongues spoken in Sumatra. According to him the Batak language is nearest akin to the Old Japanese and Tagal, whereas a recent writer has endeavored to prove its closer affinity with the Malay proper. Like most languages spoken by less civilized tribes, the Batak is poor in general terms, but abounds in terms for special objects.

BATTERING RAM (*Aries*), a military engine used before the invention of gunpowder, for beating down the walls of besieged fortresses.

BATTERY is the tactical unit of artillery. It is the term applied to the largest number of fully equipped mobile guns which can be personally superintended by one man. Batteries may be divided into four classes of *horse*, *field*, *mountain*, and *position* artillery batteries. In England, France, and Germany batteries consist of six guns; in Austria and Russia of eight guns each. The guns of horse field artillery are drawn by from four to eight horses, the usual number being six. Each battery has a certain number of men told off for the service of the gun called *gunners*, and others to manage the draught called *drivers*. In the horse artillery the gun-

ners are mounted on horses, in field batteries they are carried on the limbers and wagons, in mountain and position batteries both gunners and drivers usually walk. Both horse and field batteries are recognized tactical units of an army, and are maintained in an efficient state in time of peace. Position batteries are organized generally in time of war, are possessed of the heaviest guns consistent with mobility, and are useful in certain special cases, such as the attack or defence of a fortified position, the bombardment of a town, &c. Mountain batteries consist usually of light guns mounted on the backs of mules, and are adapted solely for warfare in the mountainous countries. See ARTILLERY.

BATTERY, as a law term, is the unlawful beating of another. See ASSAULT.

BATTEAUX, CHARLES, a French writer on philosophy and the principals of literature, was born near Vouziers in 1713, and died in 1780.

BATTICALOA, the chief town of a district in the Eastern Province of Ceylon, situated on an island. It is of importance for its haven and the adjacent salt lagoons.

BATTLE, an engagement between two armies, as distinguished from the skirmishes, or minor actions, fought between their smaller sections. A battle is said to be general, where the whole, or the greater part, of each army is brought into action; and partial, where only brigades, divisions, or some corps d'armée out of several upon the ground, are engaged. However the numbers may vary, the great principles to be applied in delivering battle are at root in all ages the same. It is no doubt true that, in the circumstances under which battles are fought, there is nothing invariable; on the contrary, it is scarcely possible to suppose two cases alike in every particular, or even resembling each other in all their leading features. From the very nature of things, the minor data of the problem are variable; but the grand principles — those which depend on moral elements — continue immutably the same. On the other hand, the material elements which enter into the calculations of a general are constantly changing; and it is this circumstance which affords scope for the exercise of his genius, his sagacity, and his military science. But it would be manifestly absurd to maintain that, because the lesser conditions are so frequently altered, the great principles of the art are changed with them. The issue of a battle is indeed always uncertain, — because the calculations of the general may be defective, his combinations unscientific, his foresight limited, or his temperament rash and impetuous; and because, even where none of these causes of failure exist, events which no human sagacity could have divined or provided against may occur to defeat the wisest plans. But all this implies that if every contingency could have been foreseen and properly met, the result would not have been doubtful, and that the grand chances are always on the side of him who, being provided with sufficient means for his end, forms his plan with the greatest sagacity, and executes it with corresponding vigor and ability. For, variable as the results of battles appear, decisive success has in all ages followed the combinations of great commanders; and victory in the long-run has seldom failed to pay homage to science. And this is because those principles which science has established as universally applicable depend on certain fixed laws in human nature, which ages have not changed since history was first written. The undisciplined forces, for example, are easily shaken by panic arising out of any such sudden disaster as the fall of their general, was as true in the day when Ahab, for this reason, disguised himself at Ramoth-Gilead as it is now. That infantry, thoroughly broken up and exposed on open ground, may be taken or destroyed by a very inferior number of cavalry, was illustrated no less by Hannibal at Cannæ than by Murat's charge round the allied right at Dresden. The feeling that there was no safe retreat open in case of disaster was as fatal to the Persians at Marathon as to the French at Leipsic. The crushing effect of heavy columns pressing against a line (which, as only the outer part of the column can act, is purely moral) was quite as conspicuous in the victory of Epaminondas at Mantinea as when Napoleon cut his enemy's centre through at Austerlitz. Above all, military history, from the earliest times, proves two facts of prime importance to commanders in every action: the one, that the best troops become unsteady when their flank is gained. just as a single man in a struggle desires to face fairly the adversary about to rush on him; the other, that a comparatively small body coming fresh into action with troops exhausted by the exertions and nervous tension of a battle, has an advantage over much larger numbers. And being thus fixed, these principles obviously yield certain general rules, to which every prudent commander of any age strives to conform. Circumstances may lead him to violate them, but the examples of Leipsic and Waterloo are there to prove that, even with the greatest of generals, the result may be ruinous. In the first case, the French were forced to fight with their backs to a river; in the second, by a combination they were not prepared, for their flank was struck by the Prussians when they were fully engaged with Wellington in front; and total defeat ensued in both.

A battle is not only the most imposing, but also the most important event in war. It is the consummation to which all previous combinations necessarily tend; it is that grand act which may decide the fate of empires as well as armies. The highest and dearest interests of nations, nay, even of humanity itself, may be involved in its issue. It cannot, therefore, be uninstructive to look briefly at the theory of those received principles by the skilful application of which the fate of battles has in all ages been determined.

All the methods in which a battle can be fought may be reduced to three for abstract purposes, each governed by a distinct principle. The first, the purely defensive, consists in waiting for the enemy, in a position chosen for the purpose, the object being simply that of maintaining it successfully against him. Theorists almost universally condemn this, and that with good apparent reason; for there is something peculiarly trying to the moral endurance of even the best troops in feeling that they are pinned to one spot to await the assaults of the enemy without any prospect of retaliation. But the rule is not without exceptions, as is plainly proved by comparing the two great examples of purely defensive actions fought during the campaigns of 1862–63 in America,— Fredericksburg and Gettysburg. The defender in each case was perfectly successful, beating off his assailant with tremendous loss; but the results were very opposite. Lee's victory at Fredericksburg stopped, indeed, the advance upon Richmond for the time, but did not seriously affect the course of the war. Meade, on the other hand, by beating the Confederates off at Gettysburg, completely turned the tide of the campaign, and compelled Lee to abandon all idea of invading the North and commence a difficult retreat to Virginia; while thenceforth Washington was saved from all danger of being separated from the states that supported the union. This was because the position maintained at Fredericksburg was no more than one point on a single line of advance direct upon Richmond, whereas that of Gettysburg was so completely the key to the whole of the campaign of Maryland, that, whilst it was held by Meade, it was im-

possible for Lee to advance beyond it or any part of the north-eastern states. The failure to carry it therefore paralyzed the whole scheme of the Confederates for transferring the burden of the struggle to hostile soil. And from a comparison of the varying consequences of these actions, so similar in their course, it will be seen that the defensive battle is justified only when the position to be maintained is one of vital consequence for the enemy to seize in order to carry on further operations with success. Lee has been fairly condemned by even friendly critics for not turning his defensive attitude at Fredericksburg into an offensive on the repulse of the enemy's attack. No one blames Meade for the like conduct at Gettysburg, because his holding his ground fully accomplished all that it was necessary for him to do. But such an instance as this last, it should be added, can but rarely occur.

The second system is the entirely offensive,—in plain words, the attacking the enemy wherever found, with all force available. As it carries with it the moral power which in all ages is found to accompany, until some decided check occurs, bodies of disciplined men moving freely forward to the assault, and as it gives the leader the power of choosing the weaker points of his adversary's line on which to concentrate his blows, so it has ever been the favorite with bold and skilful generals leading good troops. Frederick and Napoleon alike preferred it, and won some of their chiefest victories by using it freely. Wellington employed it with marked success in the latest phases of the Peninsular War in 1813–14. Grant adopted it avowedly in his great struggle with Lee in Virginia in 1864. And the Prussians fought on this principle throughout the two great wars of 1866 and 1870–71. History, however, shows that it is only fully justified when the attacking general has a force decidedly superior either in numbers or in moral power; or when, as in the famous case of Frederick at Leuthen, he possesses such extraordinary skill in manœuvering as to give him all the advantages of long odds, although engaged against superior numbers. It has the serious defect that if the defence prove more successful than was expected, the assailant may have to bring up successively and exhaust all his forces, and thus leave himself without any reserve to meet a sudden onset from the opposite side. In such case defeat probably entails the complete wreck of the hitherto offensive army, and with it possibly the loss of the campaign.

It is for this reason that prudent commanders are wont, where the choice lies with them, to select the third mode, the defensive-offensive, or a combination of the two preceding. This consists in taking up a position with the design of awaiting the adversary's attack on it, but also of watching the opportunity afforded by the exhaustion of his army in its assaults, or by his extending it too widely in choosing the best points from which to make them, in order to pass suddenly to the offensive. Wellington is justly famous for the success with which he employed this form of action. But it is one of the highest tests of generalship to know exactly when most fitly to use either. And as Napoleon won three at least of his most striking victories,—Marengo, Austerlitz, and Dresden,—by passing at the right moment suddenly from an apparently passive attitude of defence to a vigorious offensive, so Wellington, after all the world had come to regard him as great only on the defensive used the strictly offensive form, with the like success, at Vitoria, Orthez, and Toulouse, the last of these three actions being one of such apparent temerity as can hardly be paralleled in modern history, and yet perfectly justified by his instinctive knowledge of the demoralized state of the enemy whose position he undertook to force. Marlborough, who as a fighter of great battles has never been surpassed, and who, like Wellington, led a mixed army of English and allies, appears to have always had a decided preference for the offensive;—so little does nationality supply any just rule for selecting either. Marlborough's choice, in all probability, was adopted from the comparatively passive attitude of his various adversaries at Blenheim, Ramillies, and Malplaquet, which tempted a bold offensive on his part. Lee, though certainly addicted to the strictly defensive, which was suited to his inferiority of numbers and to the strong nature of the ground he usually occupied, had the true instinct (as was especially shown in his great victory at Chancellorsville) of seizing any special opportunity offered by the carelessness of an adversary who brought against him apparently overwhelming forces. And in the late war, although the German generals elsewhere continually took that bold offensive which was justified at first by superior numbers, and later by the increasingly high spirits of their troops, yet in the most important and bloodiest action of the whole, Mars-la-Tour, they were content, after it had been well begun by their own attack, to pass to the completely defensive,—it being evident that by merely maintaining the position they had taken up across the French line of retreat from Metz, all the immediate advantage possible from victory would be won.

On the whole, therefore, it may be affirmed that no theory is sound which prescribes or forbids the use of any of the three methods, or lays down strict rules for the application of any of them. Defence is, however, the natural attitude of the weaker party, as Clausewitz, the greatest of all theoretical writers on war, has carefully pointed out under what conditions it is to be accepted, or how long adhered to when once assumed, are problems which it requires true genius to grapple with successfully; for they can only be solved rightly according to the circumstances of the hour, perhaps of the moment. To see a crucial instance illustrated by a failure, we may look at Gravelotte. There Bazaine was forced by the case to fight on the defensive. An opportunity occurred in the day, on the decided repulse of the German right-wing under Steinmetz, of striking such a counterblow as, from Napoleon's hand, would probably have forced a victory over even the great odds possessed by the German commander. But Bazaine had no spark of the instinctive genius needed. He lost the opportunity, and with it the battle,—the loss entailing the last hope of rescuing his host from the dangerous and indeed ignominious position in which previous errors of judgment had placed it.

In conclusion, in order to demonstrate the undying truth of the main principle of battle, which is that, the the general conditions being equal, the moral advantage is invariably at the outset with the offensive rather than the defensive,—with the army that feels itself moving forward rather than that which stands still,—it is well to refer to the recent discussion on the effect of breech-loading arms. It was almost universally assumed by theorists, especially by those of Prussia herself, when she first put the needle-gun into her soldiers' hands, that the power of the new weapon would be most perceptible in defense, for which its more rapid fire seemed so specially adapted. The Prussian instructions, drawn up before 1866, avowedly followed this view. Those who compiled them overlooked the fact that the moral power of the weapon would of itself tend to carry those who bore it forward, and add an additional advantage to those the assailant had before in his greater show of vigor and activity, and his power of searching out the weaker parts of his enemy's position and throwing his troops in force upon them. History has reversed the Prussian theory, and proved afresh how powerful for

victory is the moral element in the soldiers' character. For, out of the opening events of 1866, and the vast encouragement the Prussians experienced in their first collisions with Benedek's army, has been evolved the most audacious and aggressive series of actions any nation ever fought. Certain Prussian writers have since the war of 1870–71 gone almost to the opposite extreme, and claimed absolute superiority for the offensive under all circumstances, forgetting that, against a stronger army, or even one perfectly equal in all other respects and well posted, it must inevitably be as dangerous as it proved when confidently tried by Napoleon's marshals against British troops under Wellington.

The various so-called "orders of battle" of which theoretical writers treat, believing that they see a close similarity in the dispositions of well-led armies from the days of the Grecians down to our own, are, so far as such similarity really exists, founded entirely on one or other of the moral elements already mentioned, above all, on the desire to gain the enemy's flank. The late General Winfield Scott, one of the few commanders who could boast that he had more than once seen the back of English infantry in fair fight, declared that this desire is so instinctive that it is impossible to array two bodies of disciplined troops against each other without one at least soon striving for this advantage. But so far as this and other like universal principles are applied to the actual drawing up of an army at any period in a special order of battle, the arrangements must in practice vary with the arms and discipline.

BATTLE CREEK, a city of Michigan, in Calhoun county, 45 miles southwest of Lansing and 163 miles east-northeast of Chicago. It is situated on the Kalamazoo river at the mouth of the creek for which it is named, and from which it derives extensive and valuable water power. The principal manufactures are of threshing machines and agricultural implements, furniture and carriages, and the town is an important shipping point. It has several flour and grist mills, iron foundries and machine shops. There is an opera house, several hotels, nine churches, a high school and a full complement of graded schools. One daily and four weekly newspapers are published here. Population (1890), 13,090.

BATTLE, a market-town in the county of Sussex, on the South-Eastern Railway, 56 miles from London. It derives its name from the great battle of Senlac (or Hastings), fought October 14, 1066, between the Saxon king Harold and William, duke of Normandy.

BATTUS, the founder of the Greek colony of Cyrene in Libya, whither he had been directed by the oracle at Delphi (about 650 B.C.). The Greeks who accompanied him were, like himself, natives of Thera (Santorin), and partly descended from the race of the Minyæ.

BATU, a thickly-wooded island lying off the north-western coast of Sumatra, 40 miles in length by 10 in average breadth, almost immediately under the equinox.

BATUM, a seaport town of Asiatic Turkey, in the pashalic of Trebizond, and 110 miles N. E. of the city of that name. It is situated on the Black Sea, not far from the mouth of the Chorak, and the harbor is the safest and most important on the eastern coast. Pop., 2,000.

BAUDELAIRE, CHARLES, who would have been pleased to be considered as a master in the French Satanic school of poetry, was born at Paris in April 1821, and died in 1867 at the age of forty-six. He will possibly be best remembered for his translation of the works of Edgar Allen Poe, one of the most accurate and brilliant translations in literature.

BAUHIN, GASPARD, the son of an eminent French physician, who had to leave his native country on becoming a convert to Protestantism, was born at Basel in 1560. In 1582 he was appointed to the Greek professorship in the university of that city, and in 1588 to the chair of anatomy and botany. He was afterwards made city physician, professor of the practice of medicine, rector of the university, and dean of his faculty. He published several works relative to botany, of which the most valuable is his *Pinax Theatri Botanici*. The confusion that began to rise at this time from botanical writers describing the same plant under different names rendered such a task highly necessary; and though there are many defects in the execution, the *Pinax* of Bauhin is still a useful key to all the writers before his time. He died in 1624.
