[VOL. XLVII.]

ONE-HUNDRED-AND-FORTY-FIFTH SESSION, 1898-9.

COUNCIL.

H.R.H. THE PRINCE OF WALES, K.G., *President of the Society.*

SIR JOHN WOLFE BARRY, K.C.B., F.R.S., M.Inst.C.E., *Chairman of the Council.*

H.R.H. THE DUKE OF SAXE COBURG GOTHA, K.G., *Vice-Pres.*

H.R.H. THE DUKE OF YORK, K.G., *Vice-Pres.*

SIR FREDERICK ABEL, Bart., K.C.B., D.C.L., D.Sc., F.R.S.,
Vice-Pres.

DUKE OF ABERCORN, K.G., C.B., *Vice-Pres.*

CAPTAIN W. DE W. ABNEY, R.E., C.B., D.C.L., F.R.S.,
Vice-Pres.

THE ATTORNEY-GENERAL, G.C.M.G., M.P., *Vice-Pres.*

SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E.

LORD BELHAVEN AND STENTON, *Vice-Pres.*

SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D.,
Vice-Pres.

SIR EDWARD BIRKBECK, Bart., *Vice-Pres.*

SIR FREDERICK BRAMWELL, Bart., D.C.L., F.R.S., *Vice-Pres.*

MAJOR-GENERAL SIR OWEN TUDOR BURNE, G.C.I.E.,
K.C.S.I., *Vice-Pres.*

MICHAEL CARTEIGHE.

R. BRUDENELL CARTER, F.R.C.S., *Vice-Pres.*

B. FRANCIS COBB, *Treasurer.*

RIGHT HON. VISCOUNT CROSS, G.C.B., *Vice-Pres.*

LORD CURZON OF KEDLESTON, *Vice-Pres.*

LEWIS FOREMAN DAY.

MAJOR-GEN. SIR JOHN F. D. DONNELLY, K.C.B., *Vice-Pres.*

SIR JOHN EVANS, K.C.B., F.R.S., *Vice-Pres.*

HON. SIR CHARLES W. FREMANTLE, K.C.B., *Vice-Pres.*

SIR DOUGLAS GALTON, K.C.B., D.C.L., F.R.S., *Vice-Pres.*

JOSEPH G. GORDON.

HENRY GRAHAM HARRIS.

SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B., *Vice-Pres.*

SIR VILLIERS LISTER, K.C.M.G., *Vice-Pres.*

JAMES SEWELL NEVILLE.

SIR WESTBY B. PERCEVAL, K.C.M.G.

SIR WALTER S. PRIDEAUX.

SIR OWEN ROBERTS, M.A., D.C.L., F.S.A., *Treasurer.*

PROF. WILLIAM CHANDLER ROBERTS-AUSTEN, C.B., F.R.S.,
Vice-Pres.

ALEXANDER SIEMENS.

LORD STRATHCONA AND MOUNT ROYAL, G.C.M.G., LL.D.,
Vice-Pres.

SIR THOMAS SUTHERLAND, G.C.M.G., M.P., *Vice-Pres.*

WILLIAM LUSON THOMAS.

PROFESSOR JOHN MILLAR THOMSON, LL.D., F.R.S.

SECRETARY.

SIR HENRY TRUEMAN WOOD, M.A.

ASSISTANT-SECRETARY.

HENRY B. WHEATLEY, F.S.A.

ACCOUNTANT.

HOWARD H. ROOM.

AUDITOR.

ANDREW D. CHADWICK, F.C.A.

SESSIONAL ARRANGEMENTS.

The Opening Meeting of the One-Hundred-and-Forty-Fifth Session was held on Wednesday evening, the 16th of November, when an Address was delivered by SIR JOHN WOLFE BARRY, K.C.B., M.Inst.C.E., F.R.S., Chairman of the Council.

The following arrangements have been made for the four meetings before Christmas :—

NOVEMBER 23.—PROF. GEORGE FORBES, F.R.S., “Long Distance Transmission of Electric Power.” SIR JOHN WOLFE BARRY, K.C.B., M.Inst.C.E., F.R.S., Chairman of the Council, will preside.

,, 30.—C. H. BOTHAMLEY, F.C.S., “Photographic Developers and Development.” COL. J. WATERHOUSE, Hon. Sec. Royal Photographic Society, will preside.

DECEMBER 7.—W. T. MAUD, “Egypt and the Soudan, in 1897 and 1898.” Major-General SIR OWEN TUDOR BURNE, G.C.I.E., K.C.S.I., will preside.

,, 14.—SIR ALBERT ROLLIT, LL.D., M.P., “Commercial Education.”

FOREIGN AND COLONIAL SECTION.

TUESDAY, DECEMBER 6, AT 4.30 P.M.—ARCHIBALD LITTLE, F.R.G.S., of Chungking, “The Yangtse Basin and the British Sphere.” THE RIGHT HON. SIR RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., will preside.

Papers for meetings after Christmas :—

- PHILIP DAWSON, "Electric Traction and its Application to Railway Work."
 L. F. VERNON-HARCOURT, M.A., "Canals and Inland Navigation in the United Kingdom."
 S. B. BOULTON, "Preservation of Timber."
 T. FORSTER BROWN, "Coal Supplies."
 W. H. PREECE, C.B., F.R.S., "Wireless Telegraphy."
 WILTON P. RIX, "Leadless Glazes."
 W. HUNTING, "Tuberculosis in Animals."
-

INDIAN SECTION.

The meetings of this Section will take place on the following Thursday Afternoons, at 4.30 o'clock :—

January 19, February 9, March 9, April 13, May 11, 25.

FOREIGN AND COLONIAL SECTION.

The meetings of this Section will take place on the following Tuesday Afternoons, at 4.30 o'clock :—

December 6, February 28, March 21, April 25.

APPLIED ART SECTION.

The meetings of this Section will take place on the following Tuesday Evenings, at 8 o'clock :—

January 31, February 21, March 14, April 18, May 2, 30.

CANTOR LECTURES.

Monday Evenings, at 8 o'clock :—

PROF. VIVIAN B. LEWES, "Acetylene." Four Lectures.

LECTURE I.—NOVEMBER 21.—The history of acetylene—Methods of formation—The chemistry of acetylene—The part played by acetylene in ordinary luminous flames.

LECTURE II.—NOVEMBER 28.—The commercial production of acetylene—Calcic carbide and its properties—The electric furnace and the various modifications in use for carbide manufacture—Carbide without electrical power—Carriage and storage of carbide.

LECTURE III.—DECEMBER 5.—The commercial generation of acetylene—The types of generator in use—The actions taking place in acetylene generators, and the effect upon the gas produced—The purification of acetylene for domestic consumption.

LECTURE IV.—DECEMBER 12.—The combustion of acetylene—Acetylene burners—Smoking and Carbonising of burners—Burners for heating—Acetylene for gas engines—Diluted acetylene and its applications.

DR. SAMUEL RIDEAL, "Bacterial Purification of Sewage." Four Lectures.

January 16, 23, 30, February 6.

ARCHIBALD SHARP, A.M.Inst.C.E., "Cycle Construction and Design." Four Lectures.

February 20, 27, March 6, 13.

PROF. HENRY R. PROCTER, "Leather Manufacture." Four Lectures.

April 10, 17, 24, May 1.

JUVENILE LECTURES.

Two Lectures, available for a Juvenile audience, will be delivered on Wednesday Evenings, January 4 and 11, at Seven o'clock.

CONVERSAZIONE.

The Annual *Conversazione* of the Society will be held on Wednesday, June 21. Each member receives a card for himself, and one for a lady.

PROCEEDINGS OF THE SOCIETY.

CHARTER.—THE SOCIETY OF ARTS was founded in 1754, and incorporated by Royal Charter in 1847, for “The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom; and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department or science in connection with the Arts, Manufactures, and Commerce of this country.”

THE SESSION.—The Session commences in November, and ends in June. The number of Meetings held during the Session amounts to between 70 and 80.

ORDINARY MEETINGS.—At the Wednesday Evening Meetings during the Session, papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed.

INDIAN SECTION.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session, three of which during the Session 1898-9 will be at the Imperial Institute.

FOREIGN AND COLONIAL SECTION.—This Section was formed in 1874 under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged in 1879, so as to include the consideration of subjects connected with our Colonies and Dependencies, and with Foreign Countries. Four Meetings will be held during the Session.

APPLIED ART SECTION.—This Section was formed in 1886, for the discussion of subjects connected with the industrial applications of the Fine Arts. Six or more Meetings are held during the Session.

CANTOR LECTURES.—These Lectures originated in 1863, with a bequest by the late Dr. Cantor. There are several Courses every Session, and each course consists generally of two or more Lectures.

ADDITIONAL LECTURES.—Special Courses of Lectures are occasionally given.

JUVENILE LECTURES.—A Short Course of Lectures, suited for a Juvenile audience is delivered to the Children of Members during the Christmas Holidays.

ADMISSION TO MEETINGS.—Members have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor and other Lectures. Books of tickets for the purpose are supplied to the Members, but admission can be obtained on the personal introduction of a Member. For the Juvenile Lectures special tickets are issued.

JOURNAL OF THE SOCIETY OF ARTS.—The *Journal*, which is sent free to Members, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce.

EXAMINATIONS.—Examinations, founded in 1853, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal divisions of a Commercial Education, Domestic Economy, and Music. A Programme, containing detailed information about the Examinations, can be had on application to the Secretary.

LIBRARY AND READING-ROOM.—The Library and Reading-room are open to Members, who are also entitled to borrow books.

CONVERSAZIONI are held, to which Members are invited, each Member receiving a card for himself and a lady.

MEMBERSHIP.

The Society numbers at present between three and four thousand Members. The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid.

Every Member whose subscription is not in arrear is entitled:—

To be present at the Evening Meetings of the Society, and to introduce two visitors at such meetings, subject to such special arrangements as the Council may deem necessary to be made from time to time.

To be present and vote at all General Meetings of the Society.

To be present at the Cantor and other Lectures, and to introduce one visitor.

To have personal free admission to all Exhibitions held by the Society at its house in the Adelphi.

To be present at all the Society's *Conversazioni*.

To receive a copy of the weekly *Journal* published by the Society.

To the use of the Library and Reading-room.

Candidates for Membership are proposed by Three Members, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

All subscriptions should be paid to the Secretary, Sir Henry Trueman Wood, and all Cheques or Post-office Orders should be crossed "Coutts and Company," and forwarded to him at the Society's House, John-street, Adelphi, London, W.C.

HENRY TRUEMAN WOOD. *Secretary.*

CALENDAR FOR THE SESSION.

The following is the Calendar for the Session 1898-99. It is issued subject to any necessary alterations:—

31	F	GOOD FRIDAY				31	W	Ordinary Meeting			

The Chair will be taken at Eight o'clock at each of the Ordinary Meetings, the Cantor Lectures, and the Meetings of the Applied Art Section.

The Meetings of the Indian Section and the Foreign and Colonial Section will commence at either Half-past Four or Eight o'clock, as may be announced from time to time.

The Annual General Meeting will be held at Four o'clock.

The Juvenile Lectures will be given at Seven o'clock.

Proceedings of the Society.

FIRST ORDINARY MEETING.

Wednesday, November 16, 1898; SIR JOHN WOLFE BARRY, K.C.B., F.R.S., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society :—

Acland, Sir C. Thomas Dyke, Bart., Killerton, Devon.
Anear, Joseph Henry, Morwell-cottage, West-street, Harwich.

Bannerman, William Bruce, The Lindens, Sydenham-road, Croydon.

Bhumgara, Jamsetjee S., 135, London-wall, E.C., and 8, Loudoun-road, N.W.

Boulton, Wilfrid Swanwick, Sudbury, Beechcroft-road, Upper Tooting, S.W.

Boyd, William Christopher, The Grange, Waltham-cross, Herts.

Brickwood, John, Ortageny, Southsea, Hants.

Brown, Alfred Charles, Eastern Telegraph Company, Winchester-house, Old Broad-street, E.C., and 129, Algernon-road, Lewisham, S.E.

Burrell, Arthur William, M.D., 5, Baker-street, W.

Byrne, Rev. Father, Catholic Presbytery, Court-road, Barry Dock, Glamorganshire.

Carey, Alfred Edward, 39, Trinity-square, Tower-hill, E.C.

Cawson, James, 8, Alfred-place, Bedford-square, W.C.

Cheesley, Robert Godwin, Westrop-villas, 16, Canonbury-street, N.

Corner, Walter William, 115, Fellows-road, South Hampstead, N.W., and City Liberal Club, Walbrook, E.C.

Coventry, Henry G., Worsley, near Manchester.

Coventry, Walter Bulkeley, Burgate-house, Fording-bridge, Salisbury.

DeBrath, Stanley, Grande Roque, Guernsey.

Dodds, John Brauburne, Stotes hall, Jesmond, Newcastle-on-Tyne.

Duncan, Harold M., Hyde-park-court, Albert-gate, S.W.

Duncanson, Edward Ford, Nutwood, Bickley, Kent.

Edgcombe, Kenelm, 33, Tedworth-square, S.W.

Elworthy, Thomas, London-road, St. Leonard's-on-Sea.

Erskine, Captain William Charles Chitty, New Club, Princes-street, Edinburgh.

Finny, Commander T. G. R., R.I.M., Royal Bombay Yacht Club-chambers, Bombay.

Gadsby, Charles Herbert, Donington-house, Norfolk-street, Strand, W.C.

Gibb, Alexander, 23, Chapter-road, Willesden-green, N.W.

Gibson, William Augustus, 4, Queen Victoria-street, E.C.

Girtin, George Wyndham Hog, 125A, Highbury New-park, N.

Gordon, William Gordon, Knowlesly, Port of Spain Trinidad.

Gould, Henry, 1, Matthew's-lane, Kingston, Jamaica.

Hamong, Count de, 180, New Bond-street, W.

Harding, Josiah, 51, Hill-lane, Southampton.

Hay, Walter Robert, 20, Abchurch-lane, E.C.

Holah, Ernest, 5, Crown-court, Cheapside, E.C., and Sun Trap, Radcliffe-road, Croydon.

Howard, Henry Lionel, 38, St. George's-road, S.W.

Humphreys, Henry Howard, 6, Stanley-gardens, Willesden-green, N.W.

Jones, Walter Lindley, 21, St. Helen's-place, E.C.

Kimmins, C. W., M.A., D.Sc., Bermondsey Settlement-lodge, Farncombe-street, S.E.

Langdon, William, Oakfields, Kingsbury, N.W.

Lugard, Cecil Edward, 97, Sinclair-road, West Kensington, W.

Mackenzie, Sir Alexander, K.C.S.I., 71, Lancaster-gate, W.

Mair, George John, Millom, Cumberland.

Marshall, Charles H., The Poplars, Howard-street, York.

May, Cornelius, Oxford-street, Freetown, Sierra Leone.

O'Dwyer, Arthur Williamson, Duketown, Old Calabar, Niger Coast Protectorate, West Africa.

Ormerod, John, 62, Chorley New-road, Bolton.

Osman, Constant Edward, 132, Commercial-street, E.

Oulton, William, J.P. (Lord Mayor of Liverpool), Hillside, Gateacre, Liverpool.

Park, C. J., 23, Mutley-plain, Plymouth.

Parkinson, John, 251, Camden-road, N.

Pentheny-O'Kelly, Captain Edmund de, Sierra Leone, West Africa, and Badminton Club, 100, Piccadilly, W.

Pickering, Robert Young, Railway Wagon Works, Wishaw, N.B.

Plant, Edmund H. T., Charters Towers, North Queensland.

Reed, Frederick Richard Cowper, M.A., The Limes, Oxford-road, Cambridge.

Rollin, Charles, B.Sc., 1, Queen's-road, Jesmond, Newcastle-on-Tyne.

Ross, Alexander, Great Northern Railway, King's-cross Station, N.

Rundell, T. W., 25, Castle-street, Liverpool.

Sam, Thomas Birch Freeman, Cape Coast Castle, West Africa.

Sayer, Henry, 10, Nottingham-terrace, N.W.

Schattner, Ernest B., 78, Mill Hill-road, Norwich.

Scott, Sir John, K.C.M.G., M.A., Malabar-house, St. Albans, and 1, Adam-street, Adelphi, W.C.

Sheer, John, 13, King's College-road, South Hampstead, N.W.

Skilbeck, George Thornton, Clonard, Harrow Weald, Middlesex.

Stevens, Charles Cecil, C.S.I., Fair View, Church-hill, Honiton.

Swan, Edward Arthur, 74, Culverden-park-road, Tunbridge Wells.

Vaughan, J. C., Wraxall, near Bristol.
 Walker, Thomas Speck, J.P., Stafford-villa, Thornaby-on-Tees.
 Ware, Captain F. Webb, I.C.S., Quetta, Baluchistan, India.
 Wilson, Norman James, 70 Waterloo Road, N., Wolverhampton.
 Woollan, Benjamin Minors, Fairfield-lodge, 6, Addison-road, W.

The CHAIRMAN delivered the following

ADDRESS.

I have to express my thanks to the Council for the honour which they have done me in electing me to the Chair of this important Society, and to bespeak the forbearance of its members in respect of any shortcomings on my part in the fulfilment of the duties of the post. In following so many distinguished men who have been Chairmen of the Council, and in the contemplation of the multifarious labours which attach to the position, I cannot but feel much misgiving as to my ability to adequately fill the position. But having served for some time on the Council, I know the loyal support which it has always accorded to its Chairman, and I am aware also of the assistance which the experience and devotion of the Secretary and staff have uniformly extended to the Chairman and Council. I feel certain that I may rely on these advantages myself, and in that confidence I will only say that I will do my utmost to uphold with the help of the Council, the great interests which the Society of Arts represents.

In selecting a subject for my opening address, I have thought that there is one which touches all our interests, and with which I happen to have been brought in connection for many years. It will oblige me to allude to some of the many aspects of modern London, as the particular question which I propose to consider is that of the means of communication of its inhabitants with each other by means of its streets and thoroughfares. I take this to be one of the pressing matters of the present time, not only in respect of the existing state of things, but still more in view of the future requirements of our ever growing population.

If I can succeed in bringing before you sufficient information and such a view of the questions involved as to induce some systematic consideration of this great subject, I shall feel that my labour has not been thrown away. I feel sure that nowhere will the subject find more adequate recognition than in this theatre, in which so many problems for the

amelioration of our physical conditions have been discussed and forwarded.

Before we approach the detailed consideration of my topic we must realise its extent and boundaries, and the first question which arises is—What is to be understood as London? and in particular what is the London which we have in our mind when we speak of its streets.

If we take London as defined by the jurisdiction of the Metropolitan and City Police, we have an area of 688 square miles, and a population of nearly 6,000,000. If we deal with Postal London we have an area of 243 square miles, and a population of perhaps from five to five-and-a-quarter millions. And if we reckon as London, the County of London and City of London controlled for municipal purposes by the London County Council and the Corporation, we are dealing with an area of 115 square miles, and a population of upwards of 4,500,000.

In the consideration for our purposes of the County of London there should be added the southern portion of West Ham, which district is not included in it for administrative purposes, and we thus arrive at an area nearly oval in shape, having a major axis, east and west, of 12 miles, and a minor axis, north and south, of 11 miles. This area would contain about 122 square miles, and a population of nearly 5,000,000. It is the region as last defined which we may denominate as London with its environs as distinguished from Greater London, under which term I include the much larger area within the police boundaries.

Once more we must recognise that London and its environs, with its 5,000,000 of inhabitants, may be roughly divided into urban and suburban portions, and without attempting a precise division I think that we may take it that the parts continuously built upon and covered with streets and houses as distinguished from roads and lanes, villas and cottages, have an area of about 95 square miles and a population of perhaps 4,000,000. This area we may distinguish as Urban London.

The last-mentioned estimate can only be a rough approximation, for everywhere things are in a state of transition, and roads and villas are continually giving place to continuous streets and houses.

We talk glibly of millions, but it is difficult for the human mind to realise what a million means. Perhaps the following illustration may help us. A person counting aloud can in a minute count from 140 to 180, depending

on his power of enunciation. If we adopt an average of 150 per minute, and I assume that he will not repeat the complicated numbers, but will count up to 100 and then a second 100 and so on, 7,000 minutes will be required in which to count one million. Seven thousand minutes amount approximately to 10 days of 12 hours each. Thus, if a man could perform such a feat of endurance, and could count as rapidly as 150 per minute, he would be occupied for twelve hours a day, from the 1st of December to the 29th of January, in counting the present population of Greater London.

So far as the effects of population are concerned, it is necessary to take careful note of the 6,000,000 of Greater London as well as of the inhabitants of the more immediate suburbs of London, because the question of intercommunication in Urban London is intimately bound up with matters which are brought into prominence by the existence and growth of the whole area. It may confidently be said that the inhabitants of the whole of the 688 square miles, and those from a still larger area, are more or less constantly passing in and out of the strictly urban portions, thronging the streets with pedestrian and wheeled traffic of all descriptions. An active circulation is kept up, as in the human body, from all parts to and from the central heart of the system. We must keep this fact prominently before us in the consideration of the streets and thoroughfares of Urban London.

Some years ago (in 1891) the daily influx and efflux of traffic as to and from the City only was enumerated and found to amount to a total of 1,186,000 individuals. To these must be added the ebb and flow of traffic in other business centres, such as Westminster, the Strand, Oxford-street, the Temple, and its neighbourhood; but, as far as I know, no systematic counting has ever been made except in the City itself.

Again, in the middle of the day there are the numberless ladies and others who come for their shopping or visits to the western and central parts of the town, and we have also in the evenings the theatre-going and amusement-seeking public. Both these classes come from the suburbs and return there in great and increasing numbers.

In this connection we may note the great augmentation in the number of theatres and other places of amusement within the last thirty or forty years. These, though chiefly situated in the most central parts of London, undoubtedly rely greatly, if not mainly, on the patronage of

those who live in the suburbs or of those who are staying in town as visitors from remoter parts. The same may be said of the great retail shops, warehouses, and stores. Both have increased greatly in neighbourhoods in which the resident population is either stationary in numbers or diminishing, indicating clearly enough that the choice of position is independent of the number of neighbouring inhabitants.

To a large extent this great circulation of traffic in and out of Central London is the creation of the last thirty or forty years, and it has added enormously to the demands on our street accommodation, as compared with the requirements of that volume of traffic which existed when the streets were mainly used by those who dwelt within perhaps two or three miles of Charing-cross; and when it was said the "Tide of Life is seen at Charing Cross."

Forty years will take us back to a date anterior to the opening of the Metropolitan and District Railways; and it will be interesting to note in a general way what has been done by railway companies in the endeavour to keep pace with the growth of suburban traffic within, for example, 20 miles of London. Afterwards we may profitably consider what has been undertaken during the same period by municipal bodies towards improving the streets.

Forty years ago none of our main lines had more than two tracks of rails into London—now all have at least four; and it is common knowledge that the necessity for widening our railways into London has been mainly occasioned by the rapid and continuous growth of suburban traffic. The Charing-cross line, with Cannon-street Station, was but thought of. Victoria, Broad-street, Liverpool-street, Fenchurch-street stations, all of which are chiefly occupied by suburban traffic, either did not exist or had been too recently opened to have produced their full effect, and the Midland Railway had not reached London.

The Joint Committee of Parliament which sat in 1864 on the various schemes which were then promoted in order to endeavour to grapple with the ebb and flow of traffic and its distribution, had very much in view the crowded state of the streets, and the hope was general that a circular railway touching the chief terminal stations of the main lines together with a line under the Thames through the old Thames Tunnel, and another line of underground railways from north to south through the centre of London, would effectually relieve the traffic of the streets.

The lines thus recommended by the Joint Committee resulted in the Inner Circle line, with extensions east and west and junctions with most of the main lines; in the East London Railway, utilising the Thames Tunnel for access to South London; and in the St. John's-wood line, giving access to its northern suburbs. In addition to these the northern and southern districts have been connected by the West London Railway and by the junction at Ludgate-hill between the Chatham and Dover and Metropolitan Railways and the Midland; the Great Western, the Great Northern, and the North-Western systems have been brought into the heart of the City. Another useful line recommended, but not yet made, would have joined the South-Eastern and North-Western Companies' systems by a route from Charing-cross-bridge to Camden-town.

We have lately seen the construction of the City and South London and of the Waterloo and City Railways, and the highly-important Central London Railway from Shepherd's-bush to the heart of the City is rapidly approaching completion.

I roughly estimate that in the widenings of the railways above mentioned and in the various metropolitan and suburban lines constructed since 1858, an expenditure has been made or incurred of not less than £60,000,000 sterling, of which more than half has been incurred during the past 20 years.

The result, so far as the public streets are concerned, has certainly not answered the expectations which were formed by Parliament. Not only have the Metropolitan and District Railways, as well as the other railways alluded to, developed an enormous additional suburban traffic of their own, which has been thrown into inner London, but the facilities afforded by the various metropolitan lines have increased the amount of travelling from one part to another of the central parts of London itself, thus adding greatly to the movement of those inhabiting the town itself, and using the public thoroughfares.

I have tried to estimate the daily number of persons entering and leaving urban London daily by railways only, from and to the suburbs, and I arrive at the large number of 960,000. This amount of traffic, which is to a great extent new since 1858, is all thrown on the streets either in the form of pedestrian or omnibus or cab traffic to and from the railway stations and the destination of the travellers.

After the railways, consider the increase of

omnibus traffic. In 1871 there were 1,268 of those vehicles which the police call "metropolitan stage carriages" and the ordinary man knows as omnibuses, and now there are 3,170, and 1,000 tramcars. Thus the number of these vehicles has more than trebled.

If a man stands in Cheapside, he will in an hour count 384 omnibuses as passing him; if in the Strand, 444; if in Piccadilly, 423; if in Tottenham-court-road, 487, or an average of from 6 to 8 omnibuses in every minute.

As to cabs (which the police equally mysteriously denominate "hackney carriages"), in 1871 there were 7,341, and now there are no less than 11,034, and this great increase has occurred in spite of the establishment of late years of railway omnibuses.

Another means of transit remains to be alluded to, namely, the river steamboats. This subject introduces some interesting considerations. When I was a boy the steamboat service was better and much more used than at present. There were two independent lines of steamers, one of which ran only between Westminster to the City, while the other started from Chelsea or higher up the river and ended the journey at London-bridge; some were express steamers stopping once on the journey, and others at every pier. I think a steamer was available every five minutes from one end or the other of Westminster-bridge, and they travelled at a good speed. In addition, the means of access by steamboat were very good from Putney on the west, and from Woolwich on the east, to London-bridge.

These facilities have largely disappeared, and though several efforts have been made to improve the service and attract traffic, they have not been very successful. I think the reason is to be found in those facts of suburban dispersion to which I have alluded, added to the comparatively low rate of average speed on a river with a strong tide, as compared with the speed even of metropolitan railways, and to some extent in the character of accommodation on the London steamers; still more in the inconvenient situation of the City piers; and lastly in the competition of the quicker mode of transport by railways.

Though steamboat travelling might easily be made more attractive, I question whether there is much scope for further development in it, and certainly not to the extent of its being of great value in grappling with the continued demand for circulation in urban London. Nevertheless there are very considerable numbers of

persons still conveyed by the river steamers. The Thames Steamboat Company have 35 steamers running during the summer, and none during the winter months.

As to cart and waggon traffic, the numbers are continually growing. In 1858 there were but few railway vans—now there are 6,000, and the increase in the number of other carts, postal vehicles, and waggons can only be marked as most considerable without the possibility of actual enumeration. The traffic of carts and waggons bringing produce into London, especially from the market gardens, and returning with manure or empty, is almost continuous, and scarcely ceases for more than an hour or two during each 24 hours. As London grows in numbers, there is more and more pressure on the central districts in which are situated the markets and places of distribution for the whole of the urban and most of the suburban retail trade.

Lastly, we have the bicycles, at present in their stage of infancy or early growth, the numbers of which are only kept down in the metropolis by the dangers which their riders encounter in our streets. This mode of travelling, which will yearly grow in importance and that very rapidly throughout the whole civilised world, is one upon which I shall have more to say later on. It is a mode of conveyance which should not be undervalued or lost sight of, but which is, practically speaking, impossible at present in Urban London.

To sum up, in the endeavour to give some idea of the results of these various modes of discharging traffic upon the streets, I have had observations taken, and find that the total numbers of vehicles and foot-passengers passing the spots, alluded to above, in a busy hour, are as follows:—

	Vehicles.	Pedestrians.
Cheapside.....	992	6,358
The Strand.....	1,228	5,660
Piccadilly.....	1,497	3,910
Tottenham-court-road ..	661	5,586

The great traffic which I have endeavoured to describe is most wonderfully controlled by the police, but no one who has lived in London can doubt that the pressure on the streets is getting yearly heavier and heavier, and becoming more and more unmanageable. I think, that it must continue to increase for reasons apart from the mere increase of

population, and to these causes I will presently allude.

The increase of population is, of course, a most important consideration, and I do not at all wish to lose sight of it, and the following figures indicate some remarkable results:—

In 1851 the population of what is now the County of London was 2,330,000, and it is now 4,500,000, but in the consideration of this increase as a whole, it is a noteworthy fact that in many of the the central districts of London, not only has there been no increase of resident population, but, on the contrary, a serious diminution of numbers.

For example, as between 1851 and 1896, we note the following decreases:—

In the City.....	127,000	to	31,000
„ Holborn.....	47,000	„	31,000
„ Marylebone.....	158,000	„	141,000
„ St. Giles.....	54,000	„	38,000
„ St. James.....	36,000	„	23,000
„ St. Martin.....	25,000	„	13,000
„ Strand.....	44,000	„	24,000
„ Westminster.....	65,000	„	53,000

Being a decrease in these districts alone of 202,000, or 36 per cent.

Others of the central districts are nearly stationary in numbers, and it may be safely said, that the great growth in the numbers of residents is almost entirely in the immediate suburbs of the Urban London of 1851.

Contrasted with these figures the increase of population between 1851 and 1896, in the undermentioned districts, not to mention others has been as follows:—

Battersea.....	from	11,000	to	165,000
Camberwell....	„	55,000	„	253,000
Fulham.....	„	12,000	„	114,000
Greenwich.....	„	67,000	„	176,000
Hackney.....	„	54,000	„	213,000
Hammersmith..	„	18,000	„	104,000
Hampstead....	„	12,000	„	75,000
Islington.....	„	95,000	„	337,000
Kensington....	„	44,000	„	170,000
Lambeth.....	„	139,000	„	295,000
Lewisham.....	„	16,000	„	104,000
West Ham....	„	19,000	„	270,000

Being an increase in the districts mentioned of 1,734,000, or over 300 per cent.

These are all districts within the outskirts of what I have called Urban London. If we extend our view to the suburbs of Greater London, such as Bromley, Enfield, Harrow, Willesden, Ealing, Staines, Richmond, Twickenham, Kingston, and Croydon, it

appears that the increase between 1851 and 1896 is no less than 3,200,000, or 125 per cent.

The ratio in the decennial growth of population in London, including its suburbs, shows some slight sign of diminution by the last census, it is still sufficiently startling to find that during the past decade the average increase is nearly 100,000 per annum, equivalent to the population of a town like Huddersfield being added yearly to the numbers of the metropolis.

The late Royal Commission on the Water Supply of London tells us what we are to expect in the future. After careful study of the question they came to the conclusion that in 1931 Greater London would contain a minimum population of $8\frac{1}{2}$ millions with a maximum of nearly 12 millions, depending on the present and former ratios of annual increase.

As I have said, the striking feature of the condition of modern London is the continual stream of traffic between the extremities and the central parts. Now I take it that the rapid increase in the population of the suburbs, as compared with the strictly urban parts of the metropolis, is due to three prominent causes.

First, the increased wealth of the middle and labouring classes.

Second, the modern development of cheap transport.

Third, the extreme value of the sites in Central London, and the desire of all for more accommodation in their houses and their surroundings.

(1.) With regard to the first and second of these causes, we find that the rateable value of the County of London (excluding the City) per inhabitant in 1871 was £5 9s. 2d, and is now £7 2s. 4d. Apart from this test, we know that wages and salaries have increased in a larger proportion. The augmentation of wages of artisans and labourers cannot be less than 35 per cent. in the last 30 years, while, with the exception of house-rent, all the necessities and luxuries of life are conspicuously cheaper. Thus there is a much larger margin for that travelling which not only enables many to live at a considerable distance from their work, but permits them to move in and out of London in connection with entertainments and pleasures of various kinds.

(2.) I have already indicated what railway companies have done in providing physical means of access to the suburbs, by widenings of their lines and by extensions of their systems. These improvements have resulted in cheap fares, season tickets, and workmen's tickets at prices unknown in former times. Thus a third-class season ticket for a year will

enable a man to perform 600 journeys for a distance of, say, 12 miles for 3'8d. per journey; while workmen's tickets enable their holders to come to and from, say, Enfield, a distance of 22 miles at 2d. per journey. Omnibus fares again, since 1851, have been reduced by about 50 per cent., and the introduction of the penny fare has immensely increased the short distance journeys. Again, as tramways have been introduced within the same period, the fares paid, in proportion to distances, have been still further diminished within the period under review.

If, as has been the case in Glasgow, half-penny fares by tramcars and omnibuses are introduced, we shall doubtless see an enormous increase in the number of these vehicles and a greater crowding of our streets than can be easily realised.

Apart from suburban developments, it is to be observed with regard to railways in connection with the country at large, that the great concession to third-class travellers inaugurated by the Midland Railway, by the enlightened advice of the late Sir James Allport, under which third-class carriages are attached to all trains, has caused an immense and even startling increase of travelling throughout the whole country, and naturally the metropolis has experienced a very large amount of that increase, as it attracts visitors to itself in far larger numbers than formerly was possible, from all parts of the kingdom far outside the limit of Greater London.

(3.) The other cause of suburban development which I mentioned, viz., the rise in value of land in central situations since 1851, is most remarkable. It is one of the great difficulties which the London County Council have found in dealing with the important matter of housing the working-classes, of which problem the gravity and magnitude are frankly recognised by the Council.

The Chairman of the County Council recently stated that, in the case of the proposed street from Holborn to the Strand, the value of sites in the immediate neighbourhood of the improvement was so high that the use of the land for housing the working-classes, who would be dispossessed, would mean a loss to the Council of £260 per person apart from the value of the buildings to be constructed for the purpose, whereas on a site only $1\frac{1}{2}$ miles distance the cost for land would be but £9 per head. Of course, still further afield it would be still more reduced.

These facts, which are more or less applic

able in other schemes for accommodating the working-classes in central stations, are potent reasons, apart from all other considerations, why easy, speedy, and cheap locomotion are vital questions for the welfare of London, and why the volume of traffic in our streets indicates continuous increase, keeping pace with and in many places overtaking the means of accommodating it.

These appear to me to be some salient points of the necessities of the case, which produce the congestion of our streets, and tend to rapidly add to that congestion. I have to some extent described, however briefly, some of the means to meet them which have been provided by private enterprise, such as by railway, omnibus, tramway, and steamboat companies, and commercial enterprise in general, as distinguished from Government and municipal efforts.

I leave aside such questions as the acquisition of tramway lines by the County Council, which only very indirectly touch the subject, being a mere change of ownership and management, possibly though not certainly resulting in cheaper fares.

I propose now to consider the new streets and widenings of streets which have been effected in the last 50 years with a view of facilitating the constantly growing streams of traffic.

In comparison with the large expenditure by railway and tramway companies we cannot but be struck with the smallness of the mileage of streets made and of the capital expended.

The following are the most prominent of the street improvements executed within the last 40 years, exclusive of the Thames-embankments:—

Date.	Length. Furlongs.	Cost. £
1854. Cannon-street	3½	500,000
1864. Southwark-street.	5	366,000
1870. Holborn-viaduct and streets connected with it	6	2,552,000
1871. Hamilton-place.	1	111,000
1871. Queen Victoria-street.	5	1,076,000
1876. Northumbertand-avenue.	1½	711,000
1882. Tooley-street.	6	405,000
1883. Hyde-park-corner	1	11,000
1884. Eastcheap	1¼	600,000
1886. Shaftesbury-avenue.	5	779,000
1887. Charing Cross-road.	4	584,000

Totals. 4 m. 7¼ f. £7,695,000

This total amount, small as it is for the metropolis during nearly 40 years, is really an

over-statement, as it takes no account of the recoupment by sale of surplus property, improved rents, or the like. On the other hand, there are no doubt many street improvements which I have not noticed which are of less prominence. But in the aggregate, and when all are recognised, the amount of expenditure in so long a period cannot but appear very small.

In the matter of street improvements in London also, one cannot but notice an almost entire absence of grasp of a large subject. We can, no doubt, record some useful and even fine undertakings, but in the history of the past 40 years, we look in vain for any new arterial thoroughfares traversing Inner London from end to end, and proportioned in width to the demands upon them at different parts of their route. On the contrary, we find in the new streets, as in the old ones, that the nearer they are to the heaviest of the traffic, the narrower they are in absolute dimensions.

Cheapside, Fleet-street, Piccadilly, the Strand, Oxford-street, Marylebone and Euston-roads remain very much as they were 50 years ago, when the traffic was a mere fraction of what it is now, and there has been, practically speaking, no attempt at improvement in these most important thoroughfares. In the case of the Strand, no doubt some relief has been found from the Thames-embankment, promoted, though it was only in a minor degree, as a thoroughfare, but the monstrous condition of the Strand at crowded hours of the day and night shows that the embankment roadway, which has been opened 28 years, has failed altogether to afford the necessary relief. At such times, one can say, in the words of Hood, that there is

“No road, no street, no t’other side the way.”

I desire to speak with all respect of those who years ago conceived and executed the idea of Regent-street. I believe we have to thank Nash the architect and the Prince Regent for having made an improvement in the arterial line from north to south in a large-minded way and with some conception of the requirements of that time, and of provision for the future.

If we can imagine that in 1813, when Regent-street was designed, the four east and west routes by Pall-mall, Piccadilly, Oxford-street, and the New road were adequate for the east and west traffic, we can see that Nash’s wide Waterloo-place and Regent-street with its circuses at Piccadilly and Oxford-street,

and joining the only 100 feet street in Mid-London, Portland-place, except Whitehall which is 125 feet wide, was a work conceived in a large-minded way, and was a real effort to deal with the requirements of the traffic north and south at the western end of London.

When, however, we come to consider more modern street improvements, most of them at least seem piecemeal and patchwork enterprises narrowed to the very least dimensions which would pass muster, and without any but the most meagre provision for the future, or, except in the case of Regent-street, the slightest attempt at systematic artistic treatment of the question. In fact there has been and is now a hitherto incurable *petitesse* in dealing with such matters in London, which is a great contrast to what we see in foreign cities of far less importance and of far less wealth than those of the English metropolis.

For example, when Queen Victoria-street was made—a highly useful and costly undertaking—not only was the inadequate width of 65 feet adopted for a street with shops and warehouses on both sides, which is in prolongation of the 110 feet of the Victoria-embankment, which has no buildings upon it at which vehicles stop to load and unload, but where Queen Victoria-street crosses Cannon-street, a street (New Earl-street) made in former years, which had only a width of 50 feet, was allowed to remain and form part of the new Queen Victoria-street.

Again, where the new street was to reach the Mansion House no provision was made by any widening of existing thoroughfares to carry forward the traffic, and as Queen Victoria-street in the nature of things was only a means to an end, viz., for traffic to reach the heart of the city, the congestion at the Mansion House could not be relieved by it, and we daily see this highly expensive street blocked by traffic at Cannon-street and at the Poultry, and the confusion at the Mansion House worse confounded.

In the instance too, of the important widenings of Eastcheap and Tower-street, made—only some 15 years ago—at the joint expense of the Metropolitan Board of Works, the City, and the Metropolitan and District Railway Companies, a width of only 60 feet was adopted, though I remember the late Colonel Haywood, the experienced engineer of the Commissioners of Sewers stating that even 80 feet would soon be found inadequate. His prophecy has been already fulfilled. The widen-

ing of Ludgate-hill, but very recently completed, only leaves this most important approach 59 feet wide, crowded with shops on both sides, and Fleet-street remains untouched with a width of 45 feet.

The highly useful and well-designed Holborn Viaduct improvement was a local and not an arterial improvement, for it left Newgate-street and Cheapside unaltered, and was the means of facilitating the bringing of traffic to another point of congestion.

In more modern improvements the width of 60 feet has been adopted for Shaftesbury-avenue, and the Charing-cross-road, and one can even now easily see that in a few years they will be found much too narrow, though the north and south traffic does not probably call for such widths as does that from west to east.

Even in the case of Northumberland-avenue one cannot but notice the same fatal parsimony. If ever there was a case for a fine street, as approaching the Thames-embankment, this surely was one, and at the time at which it was made, urgent remonstrances were made in favour of a width of 100 feet. But it was in vain, some not very important banking house would have been required, and to save this the line of the avenue was altered, and a width of 80 feet adopted as an approach to the embankment roadway which is 110 feet wide.

Now of course it must be admitted that a street 80 feet or 100 feet wide will cost more than one 60 feet wide, but it will not cost proportionally more, and this is specially the case when a street is widened and not cut transversely to existing streets.

If one assumes a street of 60 feet from house to house, about 12 feet on each side must be devoted to footways, leaving 36 feet for vehicular traffic. One must deduct about 9 feet on each side for drays and carts standing at the houses, and all that remains is 18 feet, which is only adequate to two or at most three lines of moving vehicles.

But when one criticises these dimensions, what is to be said of the Strand (50 feet wide constricted at one of the busiest parts to 40 feet) and Piccadilly from Sackville-street to Regent-street (55 feet wide), or Cheapside (50 feet wide), except that they are ludicrously inadequate to the demands of a great city flooded daily with an enormous influx from a closely populated area of 688 square miles.

What do we find in continental cities? In Paris, the old Boulevards have a width of 100 feet or over, the Rue de Rivoli (made 60 years ago) of 80 feet, the new Boulevards, a

width of 80 to 130 feet. In Vienna, the Ring-strasse has a width of 175 feet, in Buda-Pesth the Andrassy Strasse must be 140 feet wide, and in New York the principal Avenues have widths of 80 to 150 feet.

If we take Paris alone by way of contrast with our metropolis, we find that in about 40 years the following important street improvements have been effected, besides many others :—

Completion of	Length. (miles.)	Width. (feet.)
Rue de Rivoli.....	1·4	80
Boulevard Sebastopol	2·5	95
„ Strasbourg	2·5	95
„ Haussman	1·7	95
„ Malesherbes	1·7	125
„ du Palais	0·2	130
„ St. Michel	1·1	80
„ St. Germain	2·0	125
„ Magenta	1·2	90
„ Voltaire	2·0	95
Avenue de l'Opera	0·5	95
Rue de quatre Septembre.....	0·6	80
Avenues leading to the Champs Elysées	3·5	100
Total..	18·4	miles.

As in my reference to the principal street improvements of London, so in the case of Paris, there must be a large number of less prominent works the aggregate of which must be very considerable, and more in proportion than the London improvements not included in my list.

It is to be carefully borne in mind that the want of accommodation for the traffic in the streets of London is not merely a question of grumbling of those who suffer from it, but involves many other considerations. In the first place there is daily and hourly loss of much money in the delays to men of business or in professions, and to the operative classes. We must add loss of time to vehicles and horses, the practical impossibility of introducing cheaper and more expeditious means of transit, such as by electric tramways, and great want of free circulation of air.

I may here refer to the extremely valuable and interesting report on City improvements, written by Colonel Haywood to the City Commissioners of Sewers as long ago as 1867, in which he points out the immense loss of money daily occasioned by inadequate streets, and recommends various modes of relieving the recognised congestion of the City. Some of these recommendations, such as the Hol-

born-viaduct and the Tower-bridge, have been carried out; but we look in vain for the great arterial street, recommended in the same report, extending from Newgate, on the west, to the Commercial-road, on the east.

As to one aspect of the financial returns of improved streets and gradients, I find in Colonel Haywood's report that, about 1847, it was stated before a Parliamentary Committee that the annual loss incurred in carriage traffic alone on Holborn and Ludgate hills amounted to £100,000. And again, on the same subject, he remarks :—

“Thus, inadequate thoroughfares are not only inconvenient but are expensive to the public; lead to police regulations which impede the free and natural course of the traffic and business of a community; and are repugnant to the spirit of the age. Evidence may, at the present time, be adduced in support of these views, by reference to the Traffic Bill now [1867] before the Houses of Parliament. By it the hours during which coals can be delivered are to be much restricted, and it is computed by one who has unusual opportunities of forming a sound opinion on the subject, that it will result in the price of coals being increased to the consumer as much as 2s. 6d. per ton, involving a total loss to the metropolitan inhabitants of between £400,000 and £500,000 annually.”

I mention such figures not as any attempt to estimate the whole effect, but as illustrations of the great influence on the trade generally in a great city of adequate or inadequate thoroughfares.

In the consideration again of wide and narrow streets, we can recognise that, apart from the circulation of air, the ground on each side cannot be so well utilised by lofty buildings in the narrower thoroughfare. It is rightly a regulation in London that an angle of 45° at the pavement should be subtended by the opposite side of a new street. Thus a street 60 feet wide will permit of 40 feet less in height on each side of a street being devoted to additional stories as compared with a street 100 feet wide. Consequently, three stories on each side of the street are lost by the narrower street. In these days of rapidly moving lifts, which give value to the upper stories, such a consideration ought to be at least a great help towards the extra cost of the land required for the wider street.

Again, one broad continuous thoroughfare is, so far as the circulation of air is concerned, a vastly different thing to the same width cut up into two narrow streets, and would tend to improved health and sanitation.

Apart from time saved and the benefits to health the question of accidents to life and limb, which might be avoided by less crowding of vehicular traffic, should not be lost sight of. At present no less than 150 persons per year, or an average of nearly one person every second day, lose their life by street accidents in London, and the number of those injured amounts to 8,000 per year.

My plea is then that to meet the requirements of the traffic of London what is wanted is not so much additional railways, underground or overground, traversing the town and connected with the suburbs, but wide arterial improvements of the streets themselves. Railways which are strictly urban, or rather I should say trains which only traverse the town itself through carrying immense numbers of passengers, have not dealt with the question and will not produce the desired result in relieving the streets; on the contrary they tend to add to the congestion from the point of view of both urban movement and suburban influx.

It is an open secret that if the underground railways could only rely on strictly urban passengers, they would be nearly bankrupt. A reason for this is not far to seek. The urban journey is generally a short one, and when the little losses of time necessary to reach a station, catch a train, and to go from the station to one's destination are all reckoned, the omnibus which carries a man directly from one door to the other, at fares which are frequently cheaper than even a third-class ticket, is found the preferable mode of transport. The Metropolitan and the District Railways alone between them carry about 140,000,000 of passengers annually, but the bulk of this great traffic is not urban, but is of suburban origin, deposited in urban localities. Moreover we must take note of the fact that third-class traffic is in numbers 78 per cent. of the whole traffic on the underground lines. This indicates that the great travelling public is one which scrutinises expenditure narrowly, and the fact implies that so long as omnibuses can carry people for penny fares, and still more if the halfpenny fares of Glasgow are introduced in the metropolis, the vehicular traffic of the streets will show more and more increase as compared with the journeys made from one part of the town to another by railways. But apart from these considerations, the extension of the underground railways into the suburbs more than counterbalances what relief they afford to the traffic of the streets by carrying strictly urban passengers.

I do not lose sight of the fact that the new Central London Railway, now nearly approaching completion, will be made under the existing thoroughfares of Oxford-street, Holborn, and Cheapside, but I do not think, from reasons already given, that any underground line can do very much to relieve the ever-growing traffic of the streets. No doubt the new railway will carry multitudes of people, but in the first place it will create a new urban and suburban traffic of its own, and, secondly, the experience of the Metropolitan and District lines is that surface transit for short distances continues to increase, in spite of the competition of the underground railways, even if it be not fostered by them.

I had written the above remarks as to the influence of railways before I read Col. Haywood's Report of 1867. I am pleased to see that his views entirely coincide with mine in this as indeed in other particulars.

In my judgment, the question of street improvements in London should be considered as a whole and in a large-minded way, unless we are to be doomed to perpetual disappointment. We should endeavour to enlarge our views of present requirements, and provide for our successors. A scheme of new main thoroughfares of adequate width for present and future traffic should be laid down, and this should be realised as time and finance will permit. It should be a scheme worthy of London, and such as that which was laid down by Sir Christopher Wren and published in 1666 for the renovation of the City after the fire of London, but unhappily laid aside; or as was designed for the improvement of Westminster, presented to the public by my father, Sir Charles Barry, in 1857, and published in the memoir of his life.

There should be continuity of effort towards radical amelioration, by the construction of great main lines of through communication as distinguished from merely local improvements; and all local improvements should, as we have seen in Paris and other foreign cities, be so devised as to form parts of a harmonious whole. Thus I venture to think that the first thing to be done by our municipal rulers, is to realise what is wanted, and to employ the highest and most experienced talent of the age to lay down the best lines for arterial thoroughfares.

Much has to be done without delay, but it is not necessary to urge that the whole expenditure should be immediately or concurrently undertaken. The vital point is to endeavour to realise requirements and to make every

improvement which can be put in hand subserve the purposes of a thorough conception of the problem of how best to deal with the traffic of London in the great streams from east to west and from north to south.

Apart from wide streets, a matter which has been too much lost sight of, is the provision of means for allowing the north and south traffic to cross the east and west traffic with the least possible confusion. With the exceptions of the north approach of London-bridge crossing Thames-street, of the famous Highgate Archway, of the Holborn-viaduct improvement undertaken by the Corporation of London, and of the arches which carry the south approaches of Waterloo, Blackfriars, and Southwark Bridges over a road which closely adjoins the river bank, there are no means of such crossings in London otherwise than on the level. The Holborn-viaduct, and the streets leading to it, form collectively a very fine and creditable work, and they have been an enormous benefit to Londoners. The value of the undertaking can only be appreciated by those who remember the steep slopes of Holborn-hill and the continual congestion of traffic, in consequence of the level crossing of Holborn and Farringdon-street.

A very easy and obvious improvement of this nature, on a small scale, could be readily effected by passing the north approach to Southwark-bridge over the crowded thoroughfare of Upper Thames-street.

If some means could be devised for the crossing of north and south traffic over or under the east and west traffic at such places as Hyde-park-corner, Piccadilly-circus, Ludgate-hill, the south end of Tottenham-court-road, and Wellington-street (Strand), the relief to the main thoroughfares at the spots in question would be enormous.

For example, a scheme is now being promoted for a new street from the Strand to Holborn, in a line, or nearly so, with Waterloo-bridge; but its utility, great as it may be in itself, will be to a great extent marred if no means are provided for dealing with the traffic from the south of the Thames by Waterloo-bridge, and crossing the Strand, or coming from the north, and crossing Holborn, otherwise than interjecting it athwart the east and west traffic in those crowded thoroughfares.

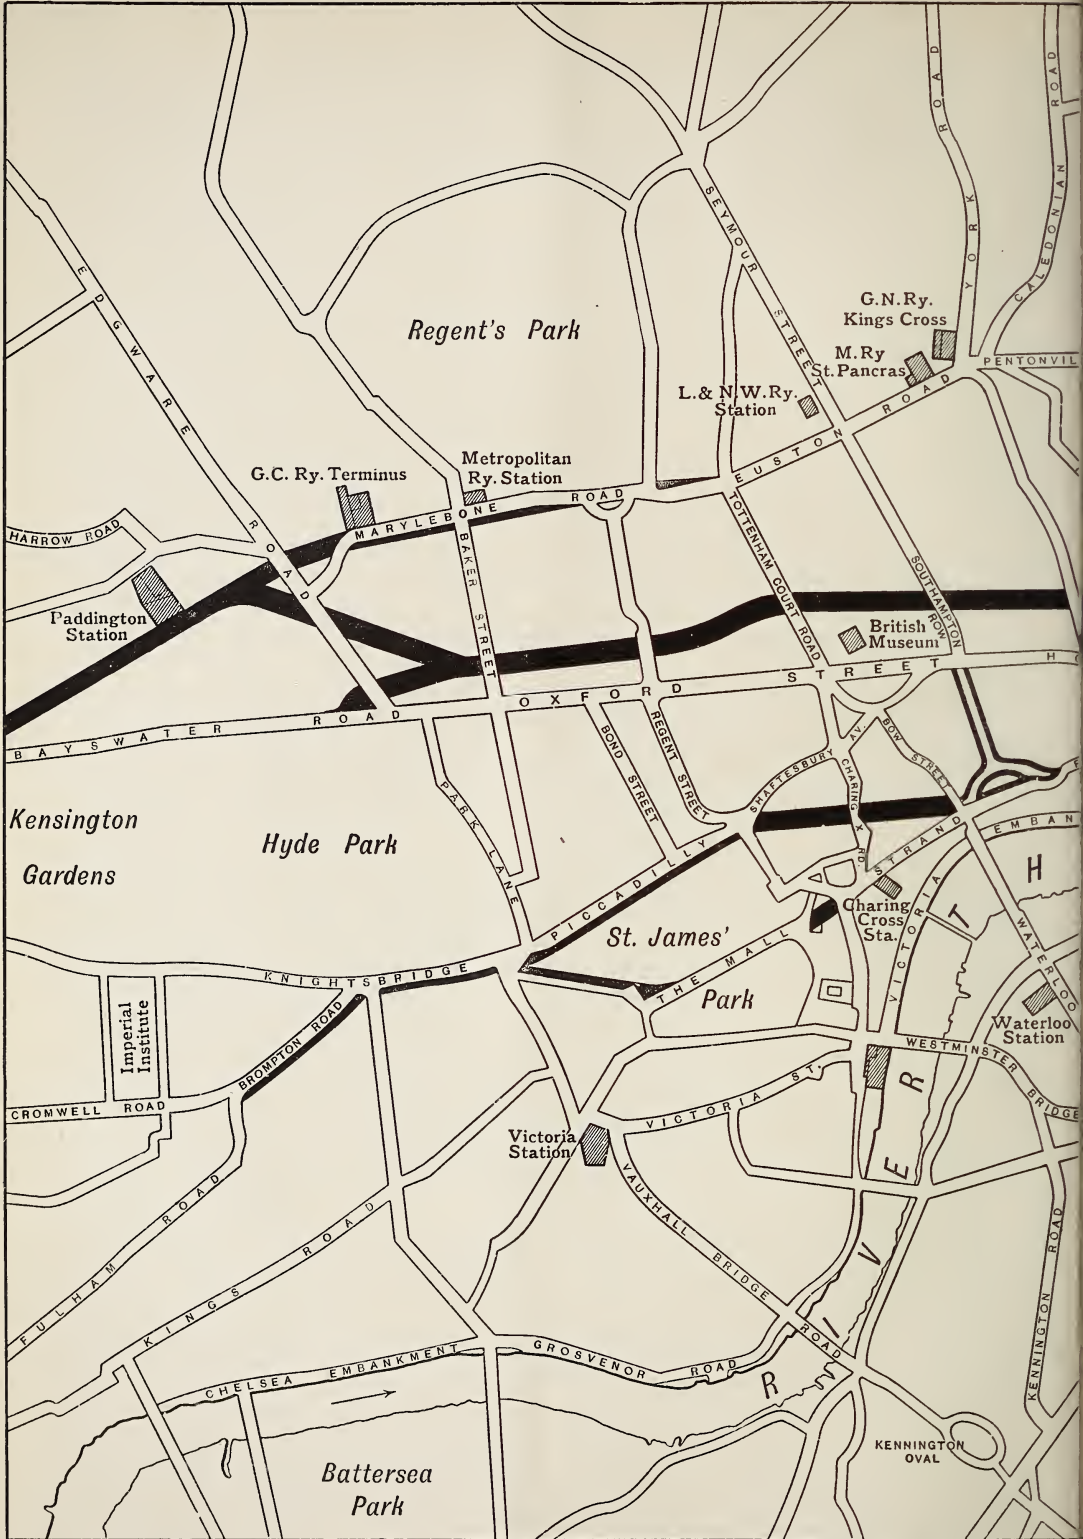

Of course, all such works would be very costly, for they involve not merely the crossing itself of leading thoroughfares by means of bridges and viaducts with approaches of about

1 in 40, but the connection of the streets on the level must, of course, be also maintained, so that traffic desiring to join the streets at right angles on the level might be able to do so. The results would, however, be well worth the expenditure, heavy as it might be, and I venture to contend that as in the case of the provision of wide arterial streets, the improvements of right-angled level crossings by means of sunken or raised roads and bridges ought not to be put aside as impracticable because they involve the same difficulty of cost. In this they would be as efficacious in their way of systematically meeting the wants of London as the other more obvious work of widened thoroughfares, while they possess this advantage, that they could be put in hand at once without waiting for the completion of the great through routes. There is no reason whatever why such works should be unsightly; on the contrary, they might be made highly artistic, and be architectural embellishments of London. When we contemplate what has been voluntarily spent by railway companies in getting rid of junctions on the level for similar advantages to their main lines of traffic, and when we remember the expenditure which is properly laid upon them by Parliament when they carry their lines across public streets, the outlay necessary for providing over or under crossings for the enormous vehicular and pedestrian traffic of London ought not in itself to be considered prohibitory.

The mode of executing such works would require much study, and different crossings would have to be dealt with in different ways. I have given some consideration to the subject at the points above mentioned, and I can say that there is nothing impracticable in the suggestion, and I feel confident that such improvements would be really worth their cost.

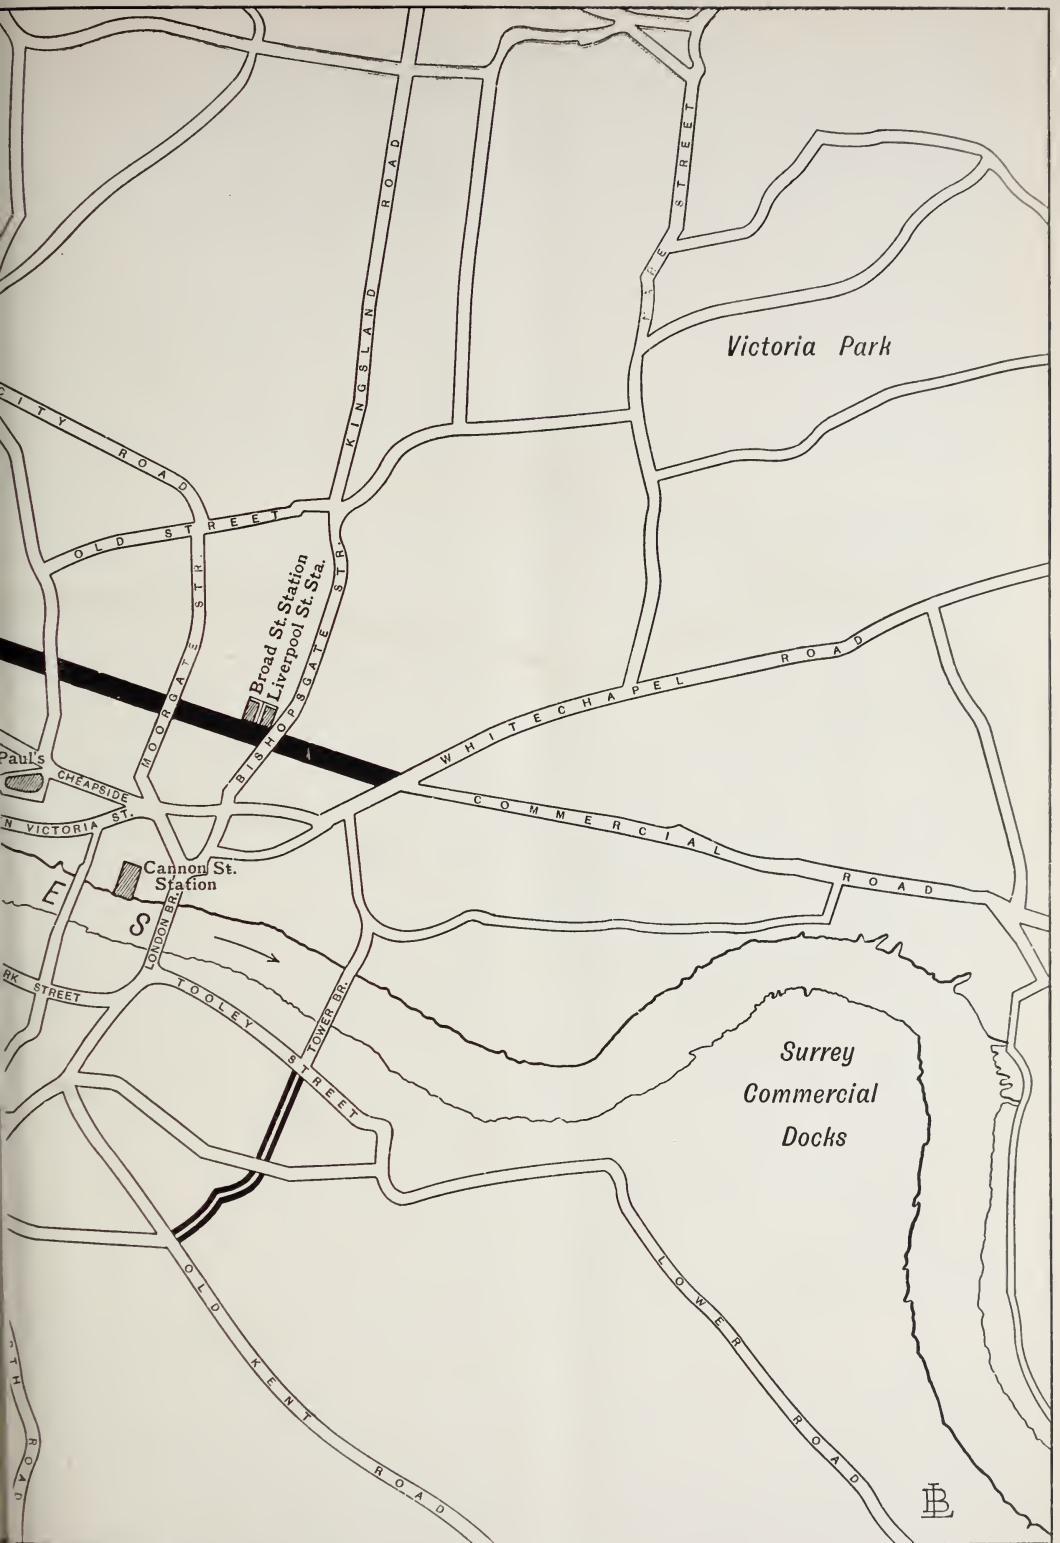

Approaching now the question of improved arterial streets, I cannot but feel that to lay down any good plan for dealing with the main lines of traffic of London must involve much study. I should be rash to do more than roughly indicate what I think should be aimed at.

There are three main lines of east and west traffic on the north side of the Thames, viz., those of Euston-road, Oxford-street, and Piccadilly, together with the Strand, all of which urgently call for remedial measures of a drastic character, but before discussing the north side of the river I should like to say a few words on the

Suggested New Streets and Improvements in solid black lines.

New Streets proposed by the London County Council thus: -..... 

Map to illustrate suggested New Thoroughfare and Street Improvements.

Scale of Miles

thoroughfares of the south side of the Thames. They certainly merit full attention, though, as a matter of fact, I think that the general urgency there apart from one or two special points is not at present so great as on the north side.

Dealing, then, with Lambeth, Southwark, and Bermondsey, we notice that, owing to the great bend of the Thames between Vauxhall and Bermondsey, the direction of the main lines of traffic on the south side of the river is radial, with a southernly trend, as distinguished from the chief lines of traffic on the north side of the river, of which we know the main direction is east and west.

Owing also to the fact that the bridges of London have, with the exception of London-bridge, been all built within the last 150 years, the roads leading to them are wider, and more adequate to modern requirements than the older streets of the north side. Again, in consequence of the roads being, as I have said, radial, there is no such pressure of traffic on the south side along two or three routes as we see on the north side of the river, except where three of the bridge roads bring their traffic more or less to one point near the "Elephant and Castle," from which it again disperses.

At this spot the congestion is frequently serious, and it will doubtless become worse. No doubt some improvement is required near the "Elephant and Castle," which should have for its object the separation of the at present converging streams of traffic before they reach the present point of concentration.

Although, as I have said, the chief lines of traffic are radial, it is right to remember that there is a very considerable stream of traffic to be accommodated on the south side of the Thames, which passes generally east and west, though following the bending course of the river. To deal with this traffic brought into London by the Wandsworth and Stockwell roads we have, starting from the west, the Albert-embankment, 85 feet wide, made by the Metropolitan Board of Works at a cost of £1,014,000, the old streets of the York-road and Stamford-street, 60 feet wide; Southwark-street, a comparatively new work, 70 feet wide, made in 1864 by the Metropolitan Board of Works at a cost of £366,000, ending in the overcharged thoroughfare of the Borough.

When all these streets are considered, we cannot but see again the inevitable blots of piecemeal undertakings. We find that the widths are designed in a haphazard

way, that where the route ought to be wide, as at the access to Waterloo Station, it is narrow, that the eastern end of Southwark-street is only connected with Tooley-street, by which the route is continued further eastward by narrow and tortuous lanes, or by the alternative route of a nearly double right-angled corner, involving also very steep gradients up to and from the south end of London-bridge and to Duke-street. Added to these disadvantages, the east and west stream of traffic has to cross on the level all the routes north and south from Vauxhall, Westminster, Waterloo, Blackfriars, Southwark, and London bridges.

Anyone who knows the Westminster-bridge-road and York-road and Waterloo-bridge-road, on a busy day at Waterloo station, when the traffic is blocked as far back as Parliament-street, or is acquainted with the continual and vexatious stoppages which occur at the crossings of Blackfriars-road and at the Borough, will recognise, first, that the east and west routes on the south side of the Thames have been laid out from time to time as merely local improvements, and without any grasp of the necessity for a main trade route approximately parallel to the river bank, and, secondly, that before long these imperfect means to an end must be extended, straightened, and widened on a more adequate basis.

Leaving the southern side, I will now refer to what I recognise as of more importance and urgency, viz., the north bank of the Thames and the three main lines of east and west traffic. There are the Euston-road (in which term I include Praed-street, Chapel-street at the west, and the Pentonville and City roads at the east); Oxford-street (in which term I include Uxbridge-road, Bayswater-road, Holorn, Newgate-street, and Cheapside); and Piccadilly, with the Strand (including Fleet-street, Ludgate-hill, Cheapside, and Cannon-street). I venture to submit that all these are almost ludicrously inadequate to what is wanted.

The Euston-road route is less glaring in its shortcomings than is Oxford-street, and the Oxford-street route is better than the Piccadilly and Strand route. It appears to me that in respect of all three routes there can only be a choice between greatly widening the routes themselves or making parallel streets.

In the case of the Euston-road, the widenings and improvements which would be necessary are less long and involve less serious consequences than in the other

thoroughfares, and one would think that if a bold widening of Praed-street and Chapel-street, a connection of Junction-road by a wide direct street with the Bayswater-road, near Victoria-gate, some considerable widening from Chapel-street to beyond Baker-street, so as to include the two important railway stations of the Great Central and Metropolitan companies, if another bold widening were made from Albany-street to Gower-street, an avoiding parallel street from Chalton-street to Rodney-street, so as to leave the existing road as an access to the Midland and Great Northern Stations, and if at the east end of the line a more convenient connection were made with Old-street, this northern line of communication east and west through London might serve for some years to come. I am purposely leaving out here allusion to the crossings of the north and south streams of traffic, which subject I have already discussed at some length.

When we turn to the Oxford-street route, we are face to face with a more important line of traffic and one more crowded than the Euston-road route. Coming from the west, we may, I think, say that with the exception of some narrow places near Notting-hill-gate Station, and to the confused crossing of Edgware-road and Park-lane, the Oxford-street route is fairly adequate as far east as Edgware-road, having regard merely to the present traffic on the portions in question. But from that point a radical improvement, either by means of important widenings or by a new street, is wanted which should be carried through the City so as to connect at its eastern end with the Mile-end-road, and form a wide thoroughfare through the very heart of London on the north side of the Thames. Such a street, so far as the City itself was concerned, was proposed by Colonel Haywood in 1867, who stated that he limited his design to the City because of the conditions of his appointment being confined to its jurisdiction.

It appears to me that electric tramways on the surface of the ground are what will be wanted in the near future of London, on at least one great through route east and west, and on two, or perhaps three routes north and south. We have, I think rightly, in view of the narrowness of our streets, stopped the tramways south of the Thames and at the Euston-road, but it cannot be doubted that this necessity is most unfortunate for the welfare of the poorer classes of the metropolis.

It is also obvious that any such accommodation, however desirable, cannot be afforded by

any street of the width of the present Oxford-street and Holborn.

Another want also which is beginning to be pressing, is a route for bicycle traffic. One cannot but recognise that the bicycle, as a means of rapid and cheap locomotion, is a new endowment to mankind, and it is difficult to realise what an advantage it would be to the bulk of Londoners if they could travel safely and at perhaps eight or ten miles an hour, on their bicycles from their homes to their work and back again.

Apart from the almost universal use of bicycles for general traffic, we see already, in country districts, artisans going to their work and returning homewards on their bicycles, covering by this means distances which were but a few years ago prohibitory. We ought not to be content that Londoners, and especially the working-classes, should be debarred from these facilities.

Two years ago I said in an address to the Institution of Civil Engineers that I looked forward to a time when bicycles would be as much part of a man's—and, doubtless, also of a woman's—equipment as a pair of boots, and from the progress which has already come about, I think that this was scarcely an exaggerated anticipation.

The present price of bicycles will not, I suppose, rule very long, and we shall see these admirable machines made at prices which seem now unattainably cheap. The proper application of machinery in the making of bicycles will result in the same reduction as it has occasioned in the manufacture of watches. The weight of a bicycle is so small that the value of the material (except the india-rubber tyres) cannot be serious. And if all the parts of a good machine-made watch can be manufactured and put together and sold for less than £1, the manufacture and putting together of a bicycle ought not to cost much more. If we add the cost of the steel and the india-rubber, it surely seems not too sanguine an estimate to suppose that a few years hence bicycles will be sold at about a fourth of their present price.

When this takes place, are Londoners to be debarred from their use by the fact that the streets are so crowded with vehicular traffic as to be too dangerous for bicycles? This will seem hereafter to be as absurd as a proposition that foot passengers ought not now to be accommodated in the streets because of the requirements of the vehicular traffic.

If these views of the future requirements of

London are correct, we want, in my opinion, one new and spacious thoroughfare east and west, about 120 feet wide, that is to say, as wide as Whitehall, opposite the Horse Guards. It might follow approximately the route indicated on the map, leaving the Bayswater-road near Westbourne-terrace, following the line of Wigmore-street to Russell-square behind the British Museum, thence to near Broad-street Station, and ending at the Commercial and Whitechapel-roads, as proposed by Colonel Haywood. In addition to this east and west artery, there should be two or three thoroughfares north and south, slightly less in width, which should be carried over the east and west route, by bridges at the points of their intersection, and all these new routes should have a raised or sunken road throughout for bicycles, so that they should not mix either with vehicular or pedestrian traffic. Communication between the streets and the sunken roads could be given by ramps at selected spots for bicycle access, and by steps, and stables for the bicycles could be provided at the level of the sunken road by excavations and enlargements similar to those of the admirable underground lavatories of modern construction, which are so great a boon to Londoners.

When one contemplates the cost of such a work as an arterial street 120 feet wide through the length and breadth of London, the prospect is, no doubt, somewhat alarming. A street of this kind four or five miles long, with side accesses and the works of construction, must mean many millions of money, though the recoupment from the frontages of such a new street would be very important. Such, however, is the kind of undertaking required for the London of the future, and if Paris can undertake the great streets to which I have referred, why should we take such niggardly views of what is really important for the public good of London?

Whether it would be cheaper to cut such a new street through the property north or south of Oxford-street and Holborn, or to widen those thoroughfares, would require much more study than could be given to the subject in such an address as this. My impression is that in the case of the central line of traffic, east and west, money would best be laid out in a grand new street, similar to one of the great Boulevards of Paris, rather than in any widening of such trading thoroughfares as Oxford-street and Holborn, Newgate-street or Cheapside, for in making an entirely new street the property to be acquired would have less present trading

value, there would be much less disturbance of commerce than in widening an existing street, and the frontages to the new street would be of immense value hereafter.

We have discussed two out of the three east and west thoroughfares, and we come naturally now to that of the Strand, Fleet-street, and Piccadilly. In this case it seems to me that systematic widening of all these three thoroughfares is probably the only course to be adopted, together with a broad diagonal street from Piccadilly - circus, *viâ* Coventry - street, to join the widened Strand near the south end of Wellington-street, so as to avoid the right-angled bend up Waterloo-place and its steep ascent. In addition, some equivalent for the diagonal street from the Strand, near Waterloo - bridge, to the Thames-embankment, proposed in 1868 by the Metropolitan Board of Works, and laid aside from exaggerated reverence to the somewhat obscure Chapel of the Savoy, should certainly be made. It would be of the greatest use in relieving the western parts of the Strand. The new street, so long talked of, to connect the Mall with Charing-cross, and afford a direct route from Charing-cross to Buckingham-palace-road, and to Hyde-park-corner, *viâ* Constitution - hill, is another pressing necessity, and could very easily be put in hand.

Constitution-hill again urgently calls for widening, which could readily be done by the inclusion of the present bridle path on its east side. The bridle path could be moved a few yards into the Green-park, in which position it would be a very attractive feature of the park—a sort of miniature Rotton-row. The present bridle path is so narrow as to be dangerous, not only to equestrians, but also, in the London season, to the vehicular traffic of Constitution-hill. This improvement could be carried out without disturbing any of the trees, and it would form a fine and stately approach to Buckingham Palace from Hyde-park.

I fear that in the street improvements which I have sketched I shall be thought to have extravagant and utopian views, but when one contemplates the vast sums spent by railway and public companies to bring traffic to London, or realizes what has been done by continental nations to improve their means of transit in their capitals and to embellish them, I cannot see that Londoners should consider the cost of such measures in the metropolis of the kingdom and may I not say of the Greater Britain as prohibitory. I have above given an

indication that a wise and liberal expenditure on street improvements brings with it an immediate return in public convenience, though it does not appear in the same direct way as do fares paid to public companies for the use of their means of locomotion.

One difference attending continental improvements, as compared with those of this country, is that they are largely paid for by indirect taxation of octroi duties, while our only system, since the short-sighted repeal of the coal and wine duties, is that of direct rating. The money equally comes out of the pockets of the inhabitants, but our present system undoubtedly tends to cramp the views of our administrators. No doubt it is right that those who pay should have a directly preponderating voice in the expenditure. This they have here, and no doubt the electors narrowly scrutinise the rates, but I should not despair of educating the public of London to an appreciation of the value of good arterial means of communication so that those who favour them would not run the risk, which our local representatives so much dread, of being accused of extravagance when the day of re-election comes. Expenditure may be wise or foolish, and it is foolish expenditure on ill-considered schemes and piecemeal projects which should really be deprecated. At any rate let the subject have its due attention and let the best minds devote themselves to the problem which is urgent now and becoming intolerable.

All roads were said to lead to Rome. How much more do they now lead to London from every part of the civilised world. London is *par excellence* the city of Europe, Asia, Africa, and America. England is the home of our fellow subjects from every colony, and I think I may say also of many of our American Cousins. London is the richest city ever known and the most populous, but when this is acknowledged we have to admit that its streets are getting day by day, in spite of the improved means of transit afforded by underground lines, more and more impassable, and to look more and more mean, while we must further remember that in 33 years we shall be face to face with a population of at least 8½ millions in Greater London.

Is it not time then to approach the subject of its streets in a large-minded and systematic way, laying down the great principles to be carried out and working steadily towards a great result?

The expenditure involved, heavy as it no doubt would be, should not affright us. It would be repaid by the increased facilities both for trade and pleasure. London would be more attractive than it now can be. The stress of life would be lightened, and the saving of time to the millions using our streets would be enormous, though, as I have said, a money value to that saving cannot possibly be appraised. That saving would accrue to the poor even more than to the rich, for to the poor man who has nothing to sell but his labour time is of cardinal importance. The crowding together of our labouring classes would be diminished as better facilities of easy and cheap locomotion enabled them to reside in the outer ring of London, increasing their means of inhabiting healthy homes and adding greatly to the happiness of themselves and their families.

My ideas of what is wanted may be erroneous or imperfect—and I do not pretend to their being more than suggestive—but be that as it may, I cannot but think that the relief of the present congestion of our streets by a systematic and well-considered enlargement of the arteries of London, is a subject which must commend itself as of primary importance to the whole city—nay more, to the whole nation, and that it is one worthy of the fullest consideration by those who would devote themselves to no peddling treatment, but to such a large-minded plan of a remodelled town as was made by the great architect of the 17th century in respect of the City of London after the great fire; and as has been carried out so successfully in Paris, where I suppose the cost of land and of construction differ but little from similar values in London.

In conclusion, I have to acknowledge a great deal of assistance which has been rendered me in various quarters. The Foreign Office very kindly caused enquires to be made in several foreign cities, and have supplied me with much valuable information. Similar statistics have also been kindly provided by the Mayors of New York and Boston, to whom direct application was made. As there was a good deal more information than I could readily utilise in the course of this address, I have handed the papers over to the Editor of the *Journal*, in order that the statistics they contain may be published in form in the *Journal* at a later date.

The General Managers of the following rail-

way companies have been most obliging in furnishing me with statistics of their past and present traffic :—District, Great Eastern, Great Northern, Great Western, London, Brighton and South Coast, London, Chatham and Dover, London and North Western, London and South Western, London, Tilbury and Southend, Metropolitan, Midland, North London, and South Eastern. The Labour Department of the Board of Trade, the Commissioner of Police, the Public Health Department of the City of London, the Statistical Department, and the Engineers' Department of the London County Council, have indicated sources of information and furnished me with extracts from their official records. The Secretary of the London General Omnibus Company gave me some interesting particulars as to the past and present working of the Company. The Thames Steamboat Company have answered some inquiries as to the river traffic.

These and many others, have supplied me with much valuable material, some of which I have been able to utilise, but more I have been obliged to omit, having regard to the necessary limit in length of this address, and to my desire not to overburden it with dry statistics.

After the delivery of his Address the CHAIRMAN presented the Society's medals which have been awarded during the last Session.

For papers at the Ordinary Meetings :—

To PROF. JAMES DOUGLAS, for his paper on the "Progress of Metallurgy and Metal Mining in America during the last Half Century."

To SAMUEL RIDEAL, D.Sc., for his paper on "The Purification of Sewage by Bacteria."

To CAPTAIN B. F. S. BADEN-POWELL, for his paper on "Kites: their Theory and Practice."

To PROF. J. A. EWING, F.R.S., for his paper on "Linde's Method of Producing Extreme Cold and Liquefying Air."

To PROF. SILVANUS P. THOMPSON, F.R.S., for his paper on "Telegraphy Across Space."

To MISS CLIVE-BAYLEY, for her paper on "The Revival of Hand-loom Weaving."

To J. K. STARLEY, for his paper on "The Evolution of the Cycle."

In the Indian Section :—

To HERBERT MILLS BIRDWOOD, C.S.I., M.A., LL.D., for his paper on "The Plague in Bombay."

To HENRY LUTTMAN-JOHNSON, I.C.S., for his paper on "The Earthquake in Assam."

To SIR ALFRED COMYNS LYALL, G.C.I.E., K.C.B., D.C.L., for his paper on "Chartered Companies and Colonisation."

In the Foreign and Colonial Section :—

To NEVILLE LUBBOCK, for his paper on "The West Indies and Sugar Bounties."

In the Applied Art Section :—

To J. HUNGERFORD POLLEN, for his paper on "Renaissance Woodwork in England."

To SIR E. MAUNDE THOMPSON, K.C.B., for his paper on "English Art in Illuminated MSS."

Sir OWEN TUDOR BURNE, G.C.I.E., K.C.S.I., said he had much pleasure in asking the members to join him in a cordial vote of thanks to Sir John Wolfe Barry for his very instructive and interesting address. Many of the observations and recommendations had filled him with admiration, and some of the statistics had filled him with surprise, but the remarks with regard to the bicycle had filled him with terror. However, as they were precluded by the rules of the Society from raising any discussion on the address, he could only assure the Chairman that they all appreciated the valuable information he had given with regard to the metropolis; and he should like to add that he was sure they would all concur in the opinion that both the Council and the Society at large were proud of having so distinguished a man to preside over their deliberations.

Sir FREDERICK J. BRAMWELL, Bart., D.C.L., F.R.S., as senior past chairman of the Council present, had much pleasure in seconding the vote of thanks. He could not say much upon it, because Sir John Wolfe Barry was too great and too old a friend to allow him to form an unprejudiced opinion on the address, but if he had not known anything of him before that evening he should have cordially congratulated the Society on having at the head of its Council for the ensuing year, a man with so large a grasp of so important a subject.

The vote of thanks having been passed unanimously,

Sir J. WOLFE BARRY, in responding, said he had devoted a good deal of trouble to the preparation of the address, which he feared had occupied more than the usual time, and if it had been more than usually tedious he must apologise. He thought he might reassure Sir Owen Burne by saying that if his views of what was wanted in London were ever carried out, Sir Owen would be relieved from the dangers of bicycles, unless he took to riding one himself, because he (the Chairman) was not quite so mad as to propose that vast numbers of bicycles should be sent careering through the crowded streets of London. He thanked the members for their cordial reception, and hoped they would have a successful session.

Miscellaneous.

THE COLONIES AND PROTECTORATES OF FRANCE.

The colonies that are under French rule have an area of 1,887,991 square miles and a population of 51,615,427. Their special trade with the mother country, *i.e.*, imports from home consumption and exports of domestic produce, amounts in value, according to the *Dépêche Coloniale*, to £30,300,000, made up as follows: Imports into France from the colonies, £15,972,000, and exports from France thereto £14,328,000. These figures are for the year 1897. The following statistics show the population, area, and annual foreign trade (imports for home consumption and exports of domestic produce) of the colonies and protectorates. The area of Algeria is 226,184 square miles, and the population numbers 4,429,421. The productions of this colony consist of cereals, flax, seed, vegetable fibre, iron ore, oranges, essences, red and white wine. The trade between France and Algeria for the year 1897 amounted in value to £18,164,000—£9,516,000 imports into France and £8,648,000 exports from France. The general trade with other nations aggregates £4,000,000, of which £1,700,000 represents exports from, and £2,300,000 imports into, Algeria. The largest article of importation into France from Algeria was wine, the value being £4,000,000. Among the exports from France to Algeria, the values are in the order given: Tissues, trimmings, and cotton ribbons, £1,200,000; tools, £340,000; furniture and objects in wood, £300,000, and woollens, £275,000. Algeria is composed of three departments, and the population is as follows: Algiers, 1,526,667; Constantine, 1,874,506, and Oran, 1,028,248. The area of Madagascar, with its dependencies, is estimated at 375,000 square miles, with a population of 6,000,000. The commercial exchanges between France and Madagascar were valued at £632,000—£108,000 in imports into France and £524,000 in exports from France. The articles exported from Madagascar to the mother country consist chiefly of rubber and raw gutta percha, phormium tenax, and vegetable fibres, and raw hides. The exports from France to Madagascar are composed principally of wines, machinery, tissues, ribbons, tools, and other metal wares, hides, and leather, brushes, buttons, and fancy goods. The area of Réunion is 1,600 square miles, and the population numbers 169,493. The trade with France amounted in 1897 to £976,000—£636,000 imports into France and £340,000 exports from France. The articles imported into Réunion consist principally of tissues, wines, fish, and metal wares, and the goods exported are principally sugar, vanilla, sago, jalep, and exotic fecula. The area of Tunis is 52,903 square miles, and population

1,600,000. The trade between France and Tunis in 1897 was valued at £2,116,000—£1,140,000 imports into the mother country, and £976,000 exports therefrom. The principal articles exported from Tunis are cereals, olive oil, wine, and sponges and those imported are cereals, hides and leather clothing, toys, fancy goods, tissues, machinery, and apparatus. Senegal has a population of 1,800,000. The trade with France amounts in value to £1,608,000—£792,000 imports into France from Senegal, and £816,000 exports thereto. The principal articles exported from the colony are earth nuts, gums, rubber and gutta-percha, and the imports are chiefly tissues, wines, clothing, and metal wares. The area of the Kongo is 418,750 square miles, with a population of 12,000,000 to 15,000,000. Soudan has a population of 300,000. Dahomey and dependencies—area 7,500 square miles; population, 22,000. The area of Guadeloupe is 687 square miles, and the population is estimated at 167,099. The commercial exchange between this colony and the mother country in 1897 were valued at £960,000—£548,000 imports into France, and £412,000 exports therefrom. The principal articles exported from Guadeloupe are sugar, coffee, dye-stuffs, and rum and tafia. The imports are chiefly wines, tissues, leather and leather wares, ready-made clothing, metal wares, and fish (dried, salted, or smoked). Martinique has an area of 381 square miles, and a population of 181,599. The trade with the mother country was valued at £1,232,000—752,000 imports into France, and £480,000 exports therefrom. The principal articles exported from Martinique are sugar, molasses, brandy, cocoa and chocolate, and woods; while those imported are wines, tissues, clothing, hides, fish (dried, salted, or smoked), fancy goods, and metal articles. French Guiana has a population of 26,839. The trade with the mother country was valued at £460,000—£68,000 imports into France, and £392,000 exports therefrom. The principal articles imported into this colony are wines, leather goods, tissues, salted meats, and manufactures of metals. The colony of St. Pierre et Miquelon has an area of 94 square miles and a population of 6,300. This number is doubled during the fishing season. The exchanges between France and St. Pierre et Miquelon were £1,312,000—£1,076,000 imports into France, and £236,000 exports therefrom. Exports from St. Pierre consist chiefly of fish (dry, salted, and smoked) and fish oil. Cochin China has an area of 37,375 square miles, and a population of 2,034,453; Tonquin, an area of 56,250 square miles, and a population of 15,000,000. Annam has an area of 162,500 square miles, and a population of 6,000,000. Cambodia has an area of 75,000 square miles, and a population of 1,500,000. The commercial exchanges between France and Indo-China are valued at £2,104,000—imports into France £876,000; exports therefrom, £1,228,000. The principal exports from Indo-China are composed of rice, pepper, raw hides, exotic resins, cocoa, waste silk, volatile oil or essences, and albumen. French

possessions in India have an area of 196 square miles, with a population of 283,053. The exchanges between France and French India in 1897 were valued at £40,000—imports into France, £4,000; exports therefrom, £36,000. New Caledonia and its dependencies have an area of 8,117 square miles, with a population of 62,752. Tahiti has an area of 402 square miles, and a population of 24,418.

IMPROVEMENTS IN BRONZE CASTING.

At a meeting of the Société des Ingénieurs Civils de France, M. E. Maglin made a communication on the casting of bronze statues, in which he sketched the art of working in bronze from the earliest ages, while dwelling more particularly on the method of moulding known as the waste-wax process (*moulage à cire perdue*). In recent times, he observed, several inventors had endeavoured to make moulds of gelatine, the results of which were not encouraging; but it was given to a French sculptor—M. Le Bourg—to devise a method perfect as regards the results obtained, and also the saving in labour.

The process in question depends upon the fact that gelatine, with the addition of glycerine and glucose, preserves a constant elasticity even when exposed to the atmosphere; and by its means a statue may be moulded in its entirety, being surrounded by an envelope, or covering, in two parts, which are detached with great facility, while producing moulds of remarkable sharpness. In this manner a wax (*une cire*) is obtained by a single pouring, the seam of the mould joint being easily removed, since it is upon soft wax that the retouching has to be effected. This done—by the ordinary methods of the waste-wax process—the statue to be reproduced is covered with slip (*barbotine*); the wax is melted out; and the bronze is run into the mould after the jets and vents have been arranged. The specially original point about this method is that, while affording a considerable number of copies, absolutely identical, it is independent alike of the sculptor, the chaser (*ciseleur*), and the bronze mounter.

M. Maglin also observed that M. Le Bourg had made other improvements, some for preventing cracks in the wax, and others for producing various patinas in a dry manner by oxidation. At the same time he showed a series of models in different stages of progress, for illustrating the details of the successive operations.

The president, M. Edouard Lippmann, asked if the method that had been described was public property, and if not, whether it was applicable to the same compositions of metal as those for other methods of moulding, to which M. Maglin replied that the method was not public property, and that it was applicable to the mixtures of metal usually employed, but the bronze could be cast at a greater heat.

To a question by M. J. Gaudry, whether the

method was suitable for large statues, the author replied that, as the chief object of the method was to afford a considerable number of copies, it had chiefly been applied to statues of ordinary dimensions, although it had also been employed for others of greater size, while in theory there was no limit in this respect.

M. Périssé mentioned the case of a large equestrian statue which, instead of being cast in several pieces, and afterwards united by internal sockets (*manchons*), was formed of one single cast piece, although the casting was effected in several jets or pourings. This was the statue of Etienne Marce', intended for the Paris Hôtel de Ville, and shown—rough as it left the mould from the atelier of MM. Thiébaud Frères—in the wide central gallery of the 1889 Paris Exhibition, where it attracted great attention from connoisseurs. The method of producing this statue consisted in casting separately the ten parts, which could not have been cast all together in the ordinary manner without liability to fracture during contraction—viz., the four legs of the horse; the two arms, head, and legs of its rider; and also the horse's tail; and then in putting these ten parts in their proper places in the general mould in such a manner as to obtain, thanks to certain precautions, an intimate union of the metal, advantage being taken of the heat in the last bronze run for effecting the "firing on."

This method, which greatly simplifies the moulding while ensuring a better casting, had already been adopted with success for parts of existing statues that required changing; but, for the operation to succeed, it was necessary that the molten metal should circulate in sufficient quantity over the parts to be connected by fusion, for which object pockets, or jets, were arranged, the excess of metal being received outside the mould. Such precautions were taken for the equestrian statue above mentioned, in which case, however, there was this exceptional difficulty, that the frings-on or fusions, had to be effected at ten different points simultaneously. Indeed, the sockets (*manchons*) for each of these ten parts had been cast previously; and, above each socket, there had been arranged, in the general mould, a feeding pocket, which had furnished metal in excess for fusing the extremities of the ten parts. It is thus that the eleven parts of this equestrian statue only formed a single whole, which formed such a prominent figure at the last Paris Exhibition, although it is not this identical statue which was erected in front of the Hôtel de Ville, because the Paris Municipality insisted on strict observance of a certain clause in the contract.

In connection with an observation by M. Roget, that M. Le Bourg's method produced works of art differing widely from those to which the public are accustomed, and that perhaps a little educating up will be required before its delicacy is appreciated, M. Maglin expressed the hope that, inasmuch as reproductions by this method had already received the sanction of artists, they would eventually be

appreciated generally, and also raise the tone of public taste—to which one circumstance greatly contributed, viz., that perfect replicas could be obtained at a lower rate than heretofore.

In reply to a question by M. E. Badois, M. Maglin added that about one hundred reproductions might be made with one and the same mould, but that when the gelatine process was used such moulds only lasted for five or six castings.

ORANGES IN PARAGUAY.

Oranges are of prolific growth in Paraguay, being found everywhere, many growing wild. They are cultivated, however, on farms. The seed will bear five years after being planted. The orange flourishes all the year round except in January, February, and March, and a tree seven years old bears about 1,000 oranges. According to the American Consul at Ascencion the orange is one of the most generally used articles of food in Paraguay, forming a staple article for the poor, particularly in the country districts. Hogs are fattened on them, and orange-fed pork is stated to be very good. The exportation commences about the end of May and lasts till November. The boats are loaded all along the river, women with flat baskets on their heads carrying them on board. Most of the fruit is sent to Buenos Ayres and Monte Video. During the season an average of 300,000 oranges are exported. The orange is usually about three inches in diameter and is very sweet. There are three classes, which might be mentioned, the ordinary Paraguayan orange, the mandarin, and the bitter orange. The first kind is described above; the second (mandarin) is very small and not as sweet as the first, but its pungency makes it popular. The sale of this orange is brisk and the price is remunerative. The third class is the sour, or bitter orange, from whose skin marmalade is made. There is also an extract made from its blossoms, and some Frenchmen are engaged in this business in Paraguay, which is said to be very remunerative.

THE TRADE OF THE CANARY ISLANDS.

The commercial movement of the Canaries has progressed in the last ten years at the rate of from £80,000 to £120,000 a year. From £720,000 in 1888, imports rose to £1,720,000. In these totals, however, the importation of coal is included; without coal the total in 1895 was £700,000. The economic development of the Canaries depends solely on the number of boats stopping at the ports, which promotes a larger importation of coal and a more extended sale of meat, poultry, vegetables, fruit, wines, &c. The exportation of early fruits and vegetables has been of importance in the last six years. Cochineal formed at one time the sole wealth of the Canaries. In 1889, its exportation amounted to £800,000; since that time the quantity has greatly diminished.

The early fruits and vegetables from the Canaries are sent almost entirely to London and Liverpool. Tomatoes are exported in boxes of different sizes. As regards cultivation, the seeds are imported from England, sown in the months of August and September, and transplanted a month later into well-irrigated land. About 9,300 plants can be put in a fanagada or 1½ acres. The potato crop is ready in December or January. Many landowners plant a second crop, which is ready for market in March or April. From October to May, two harvests can always be counted on, whatever may be the product cultivated. Both potatoes and tomatoes are remunerative, but the banana, when it is of good quality, gives the greatest profit. The ground yields eighteen months after planting; there are usually about 1,000 to 1,200 plants to the acre, and 150 bananas to the plant, with two harvests a year. There are seven sugar refineries, operated by steam, in Grand Canary Island, one at Teneriffe, and two on the Island of Palma. The vines produce well, and the wines, when made with care, rival the best known. The Canaries are famous as a health resort, from 2,000 to 3,000 visitors wintering in the islands.

MEETINGS FOR THE ENSUING WEEK.

- MONDAY, NOV. 21...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. Vivian Lewes, "Acetylene." (Lecture I.)
 Chemical Industry (London Section), Burlington-house, W., 8 p.m.
 Imperial Institute, South Kensington, 8½ p.m.
 Mr. F. Lambert, "The Stalactite Caves of New South Wales."
 British Architects, 9, Conduit-street, W., 8 p.m.
 Mr. Francis Bond, "The Comparative Value of Documentary and Architectural Evidence in Establishing the Chronology of English Cathedrals."
 London Institution, Finsbury-circus, E.C., 5 p.m.
 Mr. W. Carruthers, "The Plant Friends and Foes of the Farmer."
- TUESDAY, NOV. 22...Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. William Beedie Esson, "Electrical Transmission of Power in Mining."
- WEDNESDAY, NOV. 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Prof. Forbes, "Long Distance Transmission of Electric Power."
 Sanitary Institute, 74A, Margaret-street, W., 8 p.m.
 Mr. Charles Jones, "Scavenging—Disposal of House Refuse."
 Japan Society, 20, Hanover-square, W., 8½ p.m.
 Prof. Sakuye Takahashi, "The Art of Flower Arrangement in Japan."
- THURSDAY, NOV. 24...London Institution, Finsbury-circus, E.C., 6 p.m. Rev. Canon Benham, "Richard Porson."
 Electrical Engineers, 25, Great George-street, S.W., 8½ p.m. Adjoined discussion on Professor Thompson's paper, "Rotatory Converters."
- FRIDAY, NOV. 25...Sanitary Institute, 74A, Margaret-street, W., 8 p.m. Prof. Henry Robinson, "Sewerage and Sewage Disposal."
 Physical, Chemical Society's Rooms, Burlington-house, W., 5 p.m. 1. Mr. R. A. Lehfeldt, "The Properties of Liquid Mixtures." 2. Mr. L. N. G. Filon, "Certain Diffraction Fringes as applied to Micrometric Observations."

Journal of the Society of Arts.

No. 2,401. VOL. XLVII.

FRIDAY, NOVEMBER 25, 1898.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be given on Wednesday evenings, January 4 and 11, 1899, at 7 o'clock, by Professor F. JEFFREY BELL, M.A. (of the Department of Zoology, British Museum). The first lecture will be on "Hands and Feet," and the second lecture on "Some Ways in which Animals Breathe." The lectures will be fully illustrated with lantern slides.

Due notice will be given when the tickets for the lectures are ready for issue.

A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received. Subject to these conditions each member is entitled to a ticket admitting two children and an adult.

CANTOR LECTURES.

On Monday evening, 21st inst., Professor VIVIAN B. LEWES delivered the first lecture of his course on "Acetylene." The lectures will be published in the *Journal* during the Christmas recess.

FOREIGN & COLONIAL SECTION.

A meeting of the Committee of the Foreign and Colonial Section was held on Thursday afternoon, 17th inst. Present:—Sir Charles Malcolm Kennedy, K.C.M.G., C.B. (chairman); B. Francis Cobb, Sir Villiers Lister, K.C.M.G., Sir Westby B. Perceval, K.C.M.G., Hon. Sir David Tennant, K.C.M.G., with Sir Henry Trueman Wood, Secretary to the Society, and S. Digby, Secretary to the Committee. The arrangements for the new Session were considered.

Proceedings of the Society.

SECOND ORDINARY MEETING.

Wednesday, November 23, 1898; SIR JOHN WOLFE BARRY, K.C.B., M.Inst.C.E., F.R.S., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

- Aström, Carl A., 83, Cannon-street, E.C.
 Baylor, Armistead Keith, 23, Cadogan-gardens, S.W.
 Cole, Philip Henry, 20, Lessing-street, Honor Oak-park, S.E.
 Courtney, Charles Frederick, Central Mine, Broken-hill, New South Wales.
 Leach, Herbert Louis, 28, Leigham-court-road West, Streatham, S.W.
 Magnus, Sir Philip, 16, Gloucester-terrace, Hyde-park, W.
 Spencer, John W., Newbiggin-house, Kenton, Northumberland.
 Strutt, Denner John, The Firs, Strawberry-hill, Middlesex.
 Thomas, Richard Beaumont, J.P., Denzel-hill, Tidenham, Gloucestershire.
 Van Raalte, Jacques, Holland-house, Broadwater Down, Tunbridge Wells.

The paper read was—

LONG DISTANCE TRANSMISSION OF ELECTRIC POWER.

BY PROF. GEORGE FORBES, F.R.S.,
M.Inst. C.E.

This subject has been much talked about, but little has been done, and even at this moment there are few people who realise what a vast field there is in this way for investment of capital on a sound commercial basis. Hitherto people have been appalled at the capital required for copper conductors.

In the present paper I bring forward nothing new. I use the methods which have been used for shorter distances; and I do not propose to suggest the use of electric pressures which have hitherto been considered unattainable. In all cases it is assumed that the power is generated by a waterfall driving a turbine which rotates a dynamo machine. The electric pressure may be raised by transformers. It is then carried by bare copper conductors to a point perhaps hundreds of miles distant; the pressure may there be lowered. The current is then passed through an electric motor which drives stamps, or mills, or pumps, or hoists, &c.

In this paper there is no time to devote to consideration of different systems or kinds of machinery, or of replacing copper by aluminium. It is a plain unvarnished tale of the ordinary methods in use, extended to somewhat greater distances.

During the progress of the electric works at Niagara Falls, attention was much given to the economic problems involved in the transmission of electric energy to a distance. But in that case clearly the following financial conclusion ruled the conditions:—It is always more profitable to bring the works requiring power to the electric source of power than to transmit the power to a distance *provided*—and in most schemes this is a large IF—you can find consumers to come to your locality. At Niagara this seemed likely, and, consequently, distance transmission beyond 25 miles was considered undesirable in the first instance.

I am here as an advocate of very distant transmission in all cases where it pays, and I know that it will yield a splendid return in many cases that have come under my notice. In all cases it would pay if there were a demand for the power at suitably high rates.

TO GOLD MINERS AND OTHER USERS OF POWER.

Of all industries to which it is applicable, gold-mining is the one which has come mostly to my notice as wanting a continuous supply of power day and night, and often without any economical means of getting it except by electric transmission. In these cases it will often be profitable to the gold miner to pay a high price for his power.

The distances with which I have had to deal go up to 250 miles in India, New Zealand, and Egypt, and if the Rhodesia mines show generally such returns as the Geelong and Selukwe mines have done, I have shown that the power of the Victoria Falls may be economically transmitted in some cases to 500 miles, and pay well.

Waterfalls will be valuable assets in the future. At present the difficulty of using their power generally lies in the fact that there is no demand for power in the neighbourhood. Some industries, like those connected with aluminium and carbide of calcium, are ready to go considerably out of their way to plant their works near a source of power. There are not many such industries.

In 1893, I sat on a committee appointed by the Indian Government to see whether the water-power, incidentally created by the

Periyar irrigation works, could be used for making aluminium electrically out of the corundum found in the neighbourhood, and for other purposes. We found that power could be generated very cheaply, but that the corundum was not suitable, and no other important demands for power were brought to our notice. Years afterwards, I found that the Mysore, Kolar, and other gold mines could easily be reached by the power, and save great cost in coal. Here we have a transmission of 250 miles which will pay well if the mines are likely to continue producing gold as they have done.

Another specially favourable case of gold mines is in New Zealand in the North Island. The Waihi mines already work their mills by electrical and water power, but there is no adequate supply of water in summer. At many of the other mines there are no roads, and power cannot be obtained. In 1896, I was asked to explore the Waikato River, in order to find the best site for developing power to be transmitted to all the gold mines on the Coromandel Peninsula near Auckland. I finally settled on the Haka Falls, near the centre of the island, with a transmission line of from 180 to 250 miles, 20,000 horse-power being generated to supply not only all the gold mines but every freezing works and factory on the North Island. I spent six weeks on the survey of sites for the works, and furnished plans which would already be executed, except for what I must call the dog-in-the-manger policy of the Government. The site was peculiarly favourable.

To take another case of gold-mining. I was engaged in 1895-6 on a project without water-power and a transmission of 300 miles as a maximum. The Coolgardie gold-fields are so far from a port that coal is very expensive, and water for the boilers could hardly be obtained. I found that it was actually more economical to generate power by steam-engines at the coast, where coal and water were available, and to transmit power all the distance electrically, rather than to transport coal which was otherwise a necessity in all cases as well as water in many cases. In this case the miners were prepared to pay as much as £180 per annum for the horse-power.

In 1894, before I had completed the first electric works at Niagara, I was asked by letter from Johannesburg whether it would be possible to transmit power from the Victoria Falls, on the Zambesi, to all the gold mines in Rhodesia, varying from 350 to 500 miles dis-

tance. At first I was inclined to throw the letter into the waste-paper basket. No one, up to that date, had, to my knowledge, seriously considered the financial aspects of so distant a transmission of electric power. But the letter required an answer; so I sat down to work out and quote some figures which should show the absurdity of the scheme. I had been supplied with maps and costs of fuel, &c., and in a short time I found, to my astonishment, that if the facts were as stated, the scheme was financially and electrically a sound one. I was assured that at least 10,000 horse-power would be required at the mines, and that from £70 to £100 per annum would readily be paid for the horse-power. Upon this I was asked to go to South Africa to negotiate with Mr. Cecil Rhodes and Dr. Jameson for a concession. They both appreciated the value of the enterprise to the country, and prepared a draft of the concession, which was only awaiting the sanction of the Chartered Company's Board when the Jameson raid and the Matabele rising closed negotiations. Here is a case where, if there be really good gold mines, it will pay handsomely to transmit electric energy a distance of 500 miles, provided the surveys of the Falls prove as satisfactory as the photographs do, and provided the fever is not an insurmountable obstacle.

At this stage let me point out to those unacquainted with the difficulty of obtaining power at some gold mines, that £100 per annum for each horse-power continuously delivered would readily be paid in many cases. Broadly speaking, the power required for rock breakers, stamps, &c., may be taken as being such that 1 horse-power mills 1 ton of ore per day—the value of the gold is, say, £3 or more per ton in a rich mine. I am not speaking of soft conglomerate like the Rand ore, where 1 horse-power mills two or three tons per day, but hard quartz. Now, when I speak of £100 per annum for a horse-power, this, at the rate of 1 ton a day means 5s. 5d. per ton of ore for milling expenses. There are plenty of places where they would pay double this.

You have now heard of a number of cases where gold mining can be assisted by long distance transmission of electric power, for which I have worked out plans and estimates. There are hundreds of other cases about which I could not speak with the same authority.

But while I expect that gold mining is the principal industry to be benefited, there are many others, the chief requisite being a continuous demand for power day and night.

This is met by electro-metallurgical processes, but these can generally be brought to the power. It also includes irrigation, which in some countries wants power day and night, and, to a certain extent, throughout the year. The quantity of water pumped does not need to be perfectly constant, and this enables intermittent demands for lighting, railways, and factories, to be met by slight variations in the pumping. Thus the plant is always fully work and earning its dividend.

In speaking these words I am naturally thinking of the utilisation of the Nile cataracts, upon which I have been engaged during the years 1897-8. My report on this subject is in the hands of the Egyptian Government, and is their property; but I am not divulging secrets when I tell you that the electric lighting of Cairo could be done cheaper by power generated at the First Cataract than by steam-engines at Cairo. The distance is 400 miles as the crow flies. Do not imagine that I propose lighting Cairo immediately in this way. The Government has far more important uses for the power, not only in the irrigation of the country as it is, but still more for the perennial irrigation which will be so much extended when the great reservoir designed by Mr. Willcocks, Sir William Garstin, and Sir Benjamin Baker shall be completed by Mr. John Aird. You may take it as certain that before long the cataracts will be harnessed and forced to assist in developing not only Egypt proper but the Sudan, and specially the Dongola province up to the Fourth Cataract, which, with efficient irrigation, may become the most fertile country in the world.

Higher up the Nile, I have not travelled or made surveys, but I notice that Sir William Garstin is undertaking a journey to Khartum and the Blue and White Niles to determine the value of the country there. A time will doubtless come when the Murchison and Ripon Falls will also be turned to account.

I trust that I have said enough to lead the users of power in certain industries, and specially gold miners, to see that it is well worth their while to look into the relative costs of steam and electro-hydraulic works, even when the transmission is for a distance of many hundreds of miles; and it will be seen that many a gold mine hitherto considered worthless because of the cost of power, will be valuable if there be water-power available within a few hundred miles.

I will now speak to the financiers who may think of taking up electric transmission.

TO FINANCIAL MEN.

The financiers in the City of London or elsewhere, who enable the projects of engineers to be carried out, even when they possess no technical knowledge, have a wonderful instinct by which they know the important points to be certain about before supporting a scheme with their money. Erroneous opinions on the engineering points may for a time prevail, but not for long.

Many examples of this insight might be given, but let us confine the matter to long distance electric transmission. I will give you four objections which are always raised:—

1. "Has electric power ever been carried to such distances as you speak of?" The answer is "No." But electrical practice is advancing by strides. In 1882, at Munich, Marcel Desprez earned great credit for transmitting electric power 35 miles and getting a return of 25 per cent. But, in 1891, 70 per cent. efficiency was obtained between Lanffen and Frankfort, the distance being 108 miles.

2. "Are you sure that no new electric difficulties will arise when you go beyond the 108 miles of transmission, which has been accomplished?" The answer is, "We are sure of this from the tests made at Frankfort." [Only one difference between short transmissions and the 108 miles from Lanffen to Frankfort was found to exist and it had been anticipated by me in preparing the Niagara works. In 1892, I laid it down as essential for the works at Niagara, in order to be prepared for long distance work and for other reasons, that the frequency of the alternations should be as low as the construction of a good dynamo would warrant. In 1894, the tests at Lanffen-Frankfort were published, showing that without this low frequency no good efficiency could be got from the long distance power transmission owing to the great self-induction of the line.]

3. The financier again asks, "Are not the losses by leakage on a long line insurmountable?" The answer is, "There is hardly any loss by leakage. There is loss of power used up only in warming the transmission lines." But this loss can be calculated accurately, and in those cases where the wasted power costs little enough, we are glad enough to waste it if it saves copper, which is the great cost.

4. The business man then asks, "Well, but if you allow a great loss of current in transmission, do you not require an enormous quantity of copper to carry the extra current

which you have to generate?" The answer is that this is perfectly true if you allow the losses to be too great, but up to a loss of 50 per cent. on the transmission line you are always saving copper by having greater losses on the way. In fact, every engineer who has made a serious study of long distance transmission will bear me out when I say that the cases in which electric transmission will pay can be clearly differentiated from those which will not pay, and the whole question is principally one of £ s. d. Also, that all engineers will agree as to what is the principal item of expenditure, viz., the cost of copper under the conditions of existing practice. Improvements may reduce this cost, but cannot increase it; hence the financier may be very sure of the data of expense, and if he can be equally well assured of the data of revenue, he has before him everything required for forming a sound judgment. Let us take three cases.

1. Suppose a water-power is utilised for distant transmission of 200 miles to a gold mine where transport is difficult and the ore rich. Suppose that the miners are ready to pay £100 per annum for each horse-power delivered continuously to the stamps, &c.—I am taking what may be looked on by some as an extreme case, but there are many such places in the world—suppose that it is a gold field employing only 1,000 horse-power continuously, the gross income is then £100,000 per annum. This is a large sum, and will warrant a very large capital expenditure.

Now if it is a case in which 20,000 volts of electric pressure may be used, less than 900 tons of copper is required, after 50 per cent. has been added for self-induction, giving an inefficiency (inverse of efficiency) of only 1·4. Thus 1,400 horse-power will have to be generated at the waterfall end of the transmission line for 1,000 horse-power delivered at the other end—the gold mine. The hydraulic and electric machinery are not likely in a favourable case, even with costly transport, to exceed £14,000. The working expenses are small, and clearly the great thing to be considered is the cost of copper. This might amount to £80 per ton of copper laid, or £72,000. Very likely the whole cost would be under £100,000, which, with a maximum possible annual expenditure of £20,000, would produce a revenue of £80,000 per annum or 80 per cent. I am sure that actual cases exist where this might be done.

2. If the distance were 400 miles, all other things remaining the same, the only serious

difference is in the cost of copper, which rises to £288,000; and taking £32,000 for the other expenses, the capital expenditure is £320,000. If the annual expenses were £20,000, which seems impossible, the nett income is £80,000 or 25 per cent.

3. Suppose the distance still 400 miles, and all other things remaining the same, but only £50 being paid per annum for the horse-power; here we have still £320,000 of capital expenditure, and a nett income of £30,000 for 1,000 horse-power delivered, or 9 per cent.

Of course, it is understood that while cases can occur where these figures apply, each case must be examined on its merits.

Looking at the last case quoted, the delivery of 1,000 horse-power at 400 miles, using 20,000 volts (or 200 miles with 10,000 volts), the financier would say 9 per cent. was not good enough for such a venture. I will now show how he may get 40 per cent., using the same machinery, the same copper, and the same annual expenses. This leads me to say a few words to the great copper companies.

TO COPPER MERCHANTS.

I have now the pleasure to lay before you a simple financial transaction which copper merchants or others would willingly make, and which may avoid the huge capital hitherto required by those who would transmit the power, and will increase the dividends on money spent on the transmission. What I propose is to divide the capital account into two parts, ordinary stock which may be looked upon as speculative, and bonds on the copper which would be as sound an investment as could be desired.

Taking the last case mentioned, the capital charges are—

3,600 tons of copper at the extreme value of £75 a ton	£	270,000	£
Putting it in place at £5 a ton		18,000	
			288,000
Hydraulic and electric machinery, &c.		32,000	
Total capital required			320,000

Most of this capital is required for copper which may be taken away if the Company fails, and is an absolutely safe security.

The value of the copper is	£	270,000
Cost of removal [uncalled capital]		18,000

On the £270,000 a mortgage may be raised, and 4 per cent. ought to cover the chances of a change of market value. Thus we have—

Annual payment on mortgage	£	10,800
----------------------------	---	--------

All we have done is to raise a mortgage on the best possible security. This might be done by the copper companies, who often have too much material in stock not paying interest, or the money could easily be obtained from independent capitalists. Let us now see what difference this has made upon the balance-sheet. The capital charges are—

	£
Putting copper in place	18,000
Hydraulic and electric machinery	32,000
	50,000
Annual gross receipts—1,000 horse-power at £50	50,000
Less annual expenses	20,000
Mortgage on copper	10,800
	30,800
Annual net receipts	19,200

or almost 40 per cent.

By this simple transaction we reduce the total capital required by the transmitters of power from £320,000 to £50,000 for 1,000 horse-power delivered, and we have increased the rate of interest from 9 per cent. to 40 per cent., which ought to satisfy most people.

This scheme I have laid before the manager of one of our largest copper companies, and he entirely approved of the general lines.

Before leaving this part of the subject, I wish to make it quite clear that none of the figures which I have given up to the present must be taken as applicable to every case that may arise; the cost of developing the power at a waterfall depends so much upon the height of the fall, accessibility, &c., that no kind of an idea can be given of the cost without some data to go upon. The costs used in the above calculation are over the mark for the most favourable cases, and the cost of copper is also too high. Another factor is the size of the works. The larger the scale the smaller is the relative cost of works.

All that I have tried to make clear is that if there be a large and continuous demand for the power, and if the value of the mechanical power to the gold miner or others is great, the distance to which it can be transmitted with financial success is not limited to one or two hundred miles.

TO ENGINEERS.

Up to the present date, financial men have not realised the value of long distance transmission. Engineers, too, have been so much engaged with electric lighting and traction that few have

devoted much time to its study. The last nine years of my life have been devoted almost entirely to electric transmission and the last four years to very distant transmission.

At present, there exist no printed tables for facilitating calculations, such as civil engineers possess in other branches of the profession. In the case of electric transmission, every engineer must prepare his own sets of tables and curves to work from. I have been compelled to work these out for myself in various units. In England, we use miles, tons, and pounds sterling. In America, the units are

efficiency and cost of transmission lines. It is so simple in its present form through a gradual evolution that I cannot help thinking that it may be of use to others.

In transmission schemes the cost of copper becomes so all-important, when dealing with long distances, that it helps more than I can tell you to have simple means for estimating even roughly the cost and efficiency under various conditions.

I feel some diffidence in laying before you these methods because there is nothing new in the results, and all the results can be ob-

FIG. 1.

ELECTRIC TRANSMISSION CURVE FOR 100 MILES AT 10,000 VOLTS CONTINUOUS CURRENT

1,000 feet, the pound avoirdupois, and the dollar. In Egypt, the metric system prevails. The flow of water, too, must be taken in cubic feet per minute, gallons per day, metres per second, the Californian "miner's inch," or the New Zealander's unit, which is called a "head."

You will believe then that I possess a mass of tables and curves, and these might be worth publishing if the time had arrived, which is not perhaps yet. During these years, however, my methods have gradually become so simplified that I venture to bring to your notice one curve in relation to the one special question of

tained by the ordinary methods. They have, however, been invaluable to myself. These methods are particularly useful for getting out preliminary estimates quickly.

Here let me say that in all preliminary work on the cost of long conductor lines, I never take notice of the resistance of the conductor, nor of the value of the current. I deal only with the current density, and loss of volts. It is the same thing under a different name. But it is what you want.

Again, I never use, in calculations for my own use, the efficiency of the conductor system. It is far more convenient to use the in-

efficiency, or the reciprocal of the efficiency, which is also the horse-power put into the generating end of the line to deliver one horse-power at the other end.

I give you these suggestions for what they may be worth as the result of long experience.

I suppose everyone present is aware of the fact that if you had a case where the power cost absolutely nothing, you would use the least copper and have the cheapest arrangement, with an inefficiency of 2, *i.e.*, an efficiency of 50 per cent., or 2 horse-power generated

density until the efficiency is 50 per cent., and then rises. This figure shows the weight of copper required per horse-power delivered at a distance of 100 miles at 10,000 volts. It is drawn for the simplest case of continuous current, to which corrections only for temperature and sag have to be made. It is equally applicable to a single phase or two phase alternating transmission to 100 miles at 10,000 effective volts; or at 5,000 effective volts from any wire to the middle of the electric system, or to three phase transmission to 100 miles at 5,000 effective volts

FIG. 2.

for each horse-power delivered. If you make the current density either greater or less than what is required to produce this inefficiency, then you have to use more copper to deliver the same quantity of power.

This is a point which in a general way is appreciated by the business man who is not an electrician, as has been already stated.

Fig. 1 shows this very well, and a study of it is interesting. We see that the copper required to transmit 1 horse-power 100 miles, at an initial pressure of 10,000 volts, with continuous current, falls with the increase of

from any wire to the middle of the electric system. But with alternating current corrections must be made for self-induction and capacity.

The same remarks apply to the meaning of the voltage of the line in all the curves and tables referred to. They are worked out for continuous current, and for any other system the engineer must add the usual corrections.

Another curve may be drawn showing the inefficiency at each current density. This curve constantly rises, *i.e.*, the greater

the current density, the greater is the inefficiency.

Now from these two curves we can deduce a third curve, which is the one which I find gives one in a few minutes all the main facts one wants for any horse-power to be delivered to any distance at any initial volts.

This curve gives the tons of copper per horse-power delivered at 100 miles with 10,000 volts, continuous current, in terms of the horse-power generated per horse-power delivered.

Measuring along a horizontal line you get the inefficiency, *i.e.*, the horse-power generated for each horse-power delivered; and measuring vertically you get the corresponding tons of copper required for each horse-power delivered, at a distance of 100 miles.

The curve is also marked with figures to show the current density, in amperes per square inch section of copper.

I never travel a day without this curve in my pocket.

This curve is correct for 100 miles and 10,000 volts, or for any other case where the volts = 100 times the miles. The curve shows you, for example, that for an inefficiency of $1\frac{1}{2}$ you require a current density of 387 amperes per square inch, and .55 tons of copper. And thus current density and weight of copper per horse-power is the same, whether you use 10,000 volts at 100 miles or 100 volts at 1 mile.

For any other volts and distance in miles, V and M, you divide the volts by the miles and get $\frac{V}{M}$; then $\frac{V}{100M} = D$, the multiplier

for the current density, and $\left[\frac{V}{100M} \right]^2 = T$ the divisor, for the tons of copper per horse-power.

As an example, 15,000 volts and 300 miles. Here $D = \frac{15,000}{100 \times 300} = \frac{1}{2}$. Hence for an inefficiency as above of $1\frac{1}{2}$, the current density will be $\frac{1}{2} \times 387 = 198$. The tons of copper per horse-power will be $\frac{.55}{(\frac{1}{2})^2} = 2.20$ tons.

Now let me show another use of the curve. Suppose we capitalise the cost of running the generating station, and add to it the cost of the generating works, and divide by the horse-power, we have then the capitalised value of 1 horse-power generated;

I will call it for short the value of 1 horse-power generated. We also know the cost of one ton of copper. Divide the value of the horse-power by the value of the ton of copper, and draw a line across the axes so that it cuts the axes in that ratio. Draw a line parallel to this and touching the curve. This gives you, according to Lord Kelvin's law (as modified by Ayrton and Perry) the point of maximum economy giving directly the inefficiency, the tons of copper per horse-power and the current density. Thus on the curve two examples are shown, one where the value of 1 horse-power is four times that of a ton of copper. In this case the greatest economy is got by an inefficiency of 1.18, a current density of 180 amperes per square inch, and 0.91 tons of copper per horse-power delivered at 100 miles distance, the initial pressure being 10,000 volts.

Another example is shown on the curve where the horse-power is $\frac{1}{4}$ th of the cost of a ton of copper. The resulting values are seen directly to be—Inefficiency = 1.58; current density = 420; copper = 0.51 tons.

To do this for other values of T $\left[T = \left[\frac{100M}{V} \right]^2 \right]$ you must divide the value of the horse-power by T. Measure this distance vertically by the unit on the vertical scale or by fractions of these units, and measure the cost of a ton of copper horizontally by the unit on the horizontal scale or by the same fraction as before of that unit. Join the two points by a line and draw a parallel line touching the curve at the point of maximum economy.

You will see now how valuable such a curve must be for obtaining the very information that an engineer requires in his first examination of any project. But we can do more than this. Divide the tons of copper per horse-power by eighteen times the distance in miles, and you get the sectional area in square inches of the conductors (go and return) per horse-power. Multiply this by the total horse-power to be delivered, and you get the size of your conductors.

N.B.—Remember that this is all worked out for continuous current, and must be corrected for other systems as well as for temperature and sag.

Some people prefer to work by tables instead of by curves, so I will put down the readings of the curve which we have just been discussing. For ordinary work the following is sufficient:—

Inefficiency.	Tons Copper per horse-power.	Current Density.
1·20	·86	190
1·30	·66	266
1·40	·58	330
1·50	·55	387
1·60	·51	432
1·70	·49	475
1·80	·48	510
1·90	·472	545
2·00	·470	574

In most practical cases, however, the economical inefficiency for long distance transmission, lies between 1·20 and 1·50. The following Table gives closer values over this range:—

Inefficiency.	Tons.	Density.
1·20	0·86	190
1·22	0·80	207
1·24	0·76	221
1·26	0·72	236
1·28	0·69	250
1·30	0·66	266
1·32	0·64	279
1·34	0·62	292
1·36	0·60	306
1·38	0·59	319
1·40	0·58	330
1·42	0·57	342
1·44	0·56	354
1·46	0·55	365
1·48	0·54	376
1·50	0·53	387

From either of these Tables, having given the inefficiency, to get the density for any volts and distance, multiply the above value

by $\frac{V}{100M}$, and to get the tons of copper, divide

the above value by $\left[\frac{V}{100M} \right]^2$

This little Table enables us then, with a very simple piece of arithmetic, to get the result for any case that may arise, sufficiently close.

But in actual practice I find it far more useful to have the Table extended in such a way that an approximate result may be arrived at without any calculation.

Three Tables are here given. The first gives a reference letter for any volts and distance. In the second and third Tables the results we want are found under that reference letter. The second Table gives the tons of copper per horse-power delivered, and the third gives the current density for any inefficiency that we may select.

RULES FOR USING THE TABLES.

Rule I.—To find the reference letter.—In Table I., in the column referring to the volts generated, find the approximate distance of transmission in miles. The capital letter at the beginning of the line in which this is found is the reference letter.

Rule II.—To find the tons of copper per horse-power delivered.—Look along the row in Table II. referring to the reference number, and tons of copper are there given for each inefficiency. The inefficiency being the horse-power generated to deliver the horse-power at the distant point.

Rule III.—To find the current density.—Table III. gives this in amperes per square inch in the row corresponding to the reference number, and in the column corresponding to the inefficiency chosen.

Rule IV.—To find the economical conditions of working (Kelvin's law).—Divide the capitalised value of one horse-power by the cost of 1 ton of copper. Divide this by 10 and call it *g*. In Table II. look along the row corresponding to the reference letter until the difference between successive numbers is approximately *g*. The number at the head of that column is the economical inefficiency, the tons are also then given, and the current density is obtained directly in Table III.

Rule V.—To find the total section (go and return) of all the transmission conductors.—Multiply the tons per horse-power by the total horse-power, and divide by 18 times the distance in miles. This is the result in square inches. Dividing this by the number of conductors gives the sectional area of each.

TABLE I.—DISTANCE OF VOLTS.

I trust that I have not wearied you with these arithmetical conundrums. All I can say is that I have found them of the greatest use, and I shall be very pleased if some of you do so also.

I trust that all here present who are not engineers realise now that the cost of transmission of electric power to a distance is a pure question of balancing expenditure and profits. By the methods now described, or by the ordinary methods, there can be no question as to the cost of the work. The only point in fact affecting the cost which has been left to the choice of the engineer is the electric pressure to be used, and every engineer in reporting on a scheme generally gives his reasons for selecting the pressure. In old days the highest pressure for which we could get a guarantee from contractors was used. But the expense of insulation increased so much with increase of pressure that now, as at Rheinfelden, we work to that pressure which is the most economical. Manufacturers will

now guarantee any pressure if you will pay for it.

Having now determined with sufficient accuracy the cost of the works and their maintenance, annual expenses and interests on mortgage; the next thing is to see (or perhaps this ought to be the first matter attended to) what return can be obtained for the power delivered to a distance. It is then for the purely financial men to say whether the profits to be derived are worth the venture.

It has been my object to-night to put before engineers some useful rapid methods for arriving, on the ordinary lines of working, at the data for any special case of long distance transmission of power. It has also been my object to show that those who carry out such schemes do not require to be handicapped by the enormous capital which has hitherto been generally considered necessary. Incidentally it would appear that whenever gold mines exist which can afford to pay 5s. or 6s. per ton of ore milled, and if there be good water-power within

400 miles of the mines, it is most probable that it will pay well to transmit the power electrically.

If I have convinced any doubters that simply in my limited experience I have found many cases where it will pay well to transmit power to distances of several hundred miles, then my purpose is served, and I shall be glad that I have brought this subject to your notice.

DISCUSSION.

THE CHAIRMAN said there were two matters of which there could be no doubt—first, that Professor Forbes had brought forward a most suggestive and valuable paper upon a subject which was pressing on the minds of many people in all parts of the world; and secondly, that engineering was a most delightful profession. He was sure all those who belonged to it would agree with him, and those who did not belong to it, after hearing this paper, would be more envious than ever of those who did. The profession of the civil engineer had been defined as that of one who directed the great forces of Nature for the use and convenience of man, and engineers were brought into contact with so many interesting subjects, localities, and people, that they were all happy to belong to such a profession. One of the matters which pressed on the mind of the engineer was the conservation of energy. It might take the form of capturing the power which existed in and came from the clouds in the form of rain, and was found in rivers or stored in reservoirs; it might harness the winds, and make them serve the use of man; proposals had even been made to capture the force running to waste in the waves; and there was the very seductive proposal of directly capturing the electricity in the air, due to terrestrial magnetism or electricity. All these subjects were germane to the interesting question brought forward that evening, because in so many cases the conservation of energy was not of much use unless there were also the power to transmit it to the place where it could be used. For instance, in Scotland, the valley of Ben Nevis had a rainfall of 10 feet per annum, which represented an enormous force at present unused. If that could be captured at a reasonable cost for storage, and transmitted to a distance, what a great future seemed to lie before future generations. It was rather startling to hear of £100 being paid per horse-power, but figures had been given showing that gold mining could afford to pay even that figure. In England one expected to get horse-power at £5 or £6 per annum by the storage of water, but he would not go into those details, nor yet into the financial question, except to suggest that the idea of a mortgage at 4 per cent. on copper, which was spread over 400 miles in Central Africa, seemed to him rather hypothetical. No doubt the value of the copper was there, but whether capitalists would be

ready to lend money on it at 4 per cent. under those circumstances he had some doubt about it. He was not an electrician, and would not attempt to follow the figures and diagrams, but they seemed to be of the greatest possible value to those who had to deal practically with this subject, and they must all be grateful to Professor Forbes for giving them such means of forming a judgment on the problem which was at first sight so intricate, as that of the transmission of electric force for distances of 400 or 500 miles.

Colonel GOURAUD expressed his regret that there was not as large an audience to hear this paper as thronged the room and its approaches some years ago when he read a paper on the Phonograph, and said he thought the present subject, if not at first sight so fascinating, had more money in it, and it was a great pity the hall was not filled with capitalists and financiers. He was glad to be again in England, after an absence of some years, and he well remembered, about four years ago, meeting Professor Forbes at Niagara Falls amidst a crowd of the greatest men of science and finance of both hemispheres gathered together in connection with the great scheme of utilising that enormous water-power for the creation of electric energy to be transmitted at a distance of 25 miles to Buffalo. Three years later he found himself again—*one Sunday evening*—at Buffalo, and heard as a secret that that night the long-looked for transmission of power was to take place. He at once telegraphed to Niagara for permission to be present, but it was not accorded, and he then cabled over to *The Times*, got authority from the editor to represent the paper on the occasion, and ultimately, after some difficulty, got admission to the works, saw the first motion of the machinery, and a few minutes after eleven sent off his message to *The Times*, which was published in London before the news was printed in the Buffalo papers. He was much struck with the proposal as to the division of capital, having, in times past, had a good deal to do with the financing of electric companies. He well remembered one company with a very long name, of which he was vice-chairman, which had a capital of a million, the object being to advance money to people who had central station schemes, this being at the time of the boom, just after the electric light exhibition in Paris and at the Crystal Palace. For about a year the board met nearly every week, but their two managing directors who examined the schemes which were sent in, were not able to report favourably of any of them, and at the end of the time the capital was returned to the subscribers. With regard to mortgages on copper in the centre of Africa or Australia, he did not think there was much of a market for it there, but even adding the cost of transportation it might be a good investment.

MR. G. L. ADDENBROOKE said this was a subject to which he had paid a good deal of attention during

the last few years, but the form in which it was presented almost took one's breath away. He did not wish, however, to say anything derogatory of the view put forward, for which they were much indebted to Professor Forbes. There were no doubt many large sources of water-power in various parts of the world, and in time they might be utilised, but he might point out that for many purposes the cost of electric power was much the same whether generated by steam or water-power. If these great waterfalls were used in this way, it might lead to an enormous shifting of population, and some of the great centres of industry at present might be destroyed. The question was whether there was any danger of this, and whether anything could be done to enable existing manufactories and populations to remain where they were. What Professor Forbes said was perfectly feasible. He thought that Englishmen who had not travelled or specially studied the subject had little notion of what had been done in this way abroad. Nothing struck him more at Geneva and one or two other places than the confidence with which capitalists put immense sums into these water-power transmission schemes, especially considering the difference between them and steam-power installations. In the latter case you could start on a small scale; put down, say, 1,000 horse-power and see if there was likely to be a return; but in the case of water-power it was essential to begin on a large scale. At Rheinfelden they put down a plant and obtained 22,000 horse-power, of which perhaps not more than one-fourth was as yet utilised. But they erected immense works, brought in sidings, built a bridge over the Rhine, bought up all the land in the neighbourhood, and advertised that they would sell sites to manufacturers; so that there was an immense amount of capital locked up which could not be immediately remunerative; but they had sufficient confidence in the thing to wait until it was. What had been done there could no doubt be carried out in other places, such as Professor Forbes had mentioned. The only one with which he had any acquaintance was Western Australia, for while Professor Forbes was considering the scheme to which he had referred, he (Mr. Addenbrooke) was acting for some people who had a concession for lighting Coolgardie, and had to consider what they should do with it, and whether they would not be swamped by power transmitted from the coast. He came to the conclusion that there was not very much risk of it. Having spent some time in the country, he was fairly conversant with the local circumstances, and ascertained from some large shipping people at what price they could land coal at the nearest port. He also found there were coal fields within 500 miles which the Government were developing, and which had since been placed in communication by rail. The railways were in the hands of the Government, who were willing to carry coal at $\frac{1}{2}$ d. per ton per mile, and he found that they could get coal delivered in Coolgardie at 45s. a ton or less, and at that price

he did not think it would pay to generate power on the coast and transmit it. It would be better to generate it on the spot as they were doing on the Rand, and distributing it up to distances of 20 miles. There the price charged per horse-power was about £45. He mentioned that to show that one of the elements which capitalists would have to consider was the chance of coal being found in the neighbourhood, which might alter the whole of the conditions. At the same time there would be many places where this method of transmitting power would be valuable.

Mr. L. GASTER said that he had visited some institutions in Switzerland, and had seen a steam-engine factory where a current of 5,000 volts was transmitted from a river $12\frac{1}{2}$ miles away with an efficiency of 77 per cent., and it was used for all the purposes of the factory. Some time ago Mr. Wallace read a paper at the Society of Chemical Industry on the utilisation of water-power, in which he said that by that means power could be supplied at a profit for £4 per annum per horse-power, which was cheaper than steam. The one requisite was to have a very large central station, as in that way it was produced more economically. For long distances the way to reduce the charge for copper was to increase the voltage. From Laufen to Frankfort, a distance of 108 miles, a high voltage transmission (although double transformation was used) gave an efficiency at Frankfort of 73 per cent. Large works always produced power more cheaply than small ones, and small manufacturers did better by obtaining their power from such sources than by working independently. Professor Forbes had shown that long distances were no obstacle, and there was every reason to believe that the time was not far off when this method would be very largely adopted. If England had no great amount of water-power she had cheap coal, and if large central stations were established near the coal pits it would be a great benefit to the people at large.

Mr. W. M. MORDEY emphasised the very great technical advances of recent years, which justified the reader of the paper in treating these bold engineering proposals entirely from the commercial standpoint. What will it cost to transmit the power? And what can be got for it? The Chairman had given them two propositions. He ventured to give them a third: If you can make the mouths of capitalists water by showing how to make big profits, you produce a water-power of the greatest value. He congratulated Professor Forbes on having done much to start that power.

Professor FORBES said he had very little to reply to; and perhaps what he had put forward would be like seed sown in the ground, which in due time might yield a valuable return. He did not think the objections raised were really very serious, not even what the Chairman had been good enough to point out, for all the places referred to were not in Central Africa. That question had been fully discussed by himself and

the business men before whom he had put the proposition. It was perfectly obvious that something must be laid by for the removal of the copper, and there were many other points which he might have mentioned; for instance, it would be essential that those who held the bonds should have some representative on the spot to see how much copper was put down, and that the value remained, and many other precautions would have to be taken, but these were matters of detail, with which he did not think it necessary to burden the paper. He trusted the view put forward by Mr. Mordey would be generally adopted, that they really had no differences to settle in this matter; at any rate, none worth talking about. The estimates which could be made were like those for building a bridge or any other work; it was purely a question for business men whether it was worth venturing. He thought the scheme of dividing the capital into a speculative and a solid investment was a sound proposition. He should be glad to be able to get 4 per cent. on such a safe investment as this seemed to him to be, and, as for the speculative side, he thought 40 per cent. ought to make even a large capitalist's mouth water.

The CHAIRMAN then proposed a cordial vote of thanks to Professor Forbes, which was carried unanimously.

Miscellaneous.

EXHIBITION OF LITHOGRAPHS.

Several exhibitions have been held abroad in honour of the centenary of the invention of lithography, more particularly those at Paris, New York, and Düsseldorf; but we have the inventor's own authority for the fact that the real art of lithography, as subsequently practised (or chemical printing, as he himself called it), was not invented until 1798. The invention of 1796 was something quite different. On the frontispiece to the German edition of the inventor's Complete Course of Lithography—*Lehrbuch der Stein-druckerey*, 1818, appears the following:—"Der Steindruck erfunden zu München von Aloys Senefelder, 1796. Durch ihn zur chemischen Druckerey erhoben, 1798." This book is now exhibited at South Kensington.

The Society of Arts proposed to organise an Exhibition of Artistic Lithography in the present year, but the Council, finding that they could not provide sufficient space in the Society's rooms, asked the Department of Science and Art to carry out the scheme at the South Kensington Museum. The Lords of the Committee of Council on Education having given their sanction to this, a Loan Exhibition has been formed, which was opened to the public on Monday last. The Exhibition consists of over 2,250

articles, and presents a larger number of artistic lithographs (both historical and modern) than has ever been publicly shown before.

The practice of lithography appears to have been introduced into England almost immediately after its invention, and some specimens of the work of Richard Corbould, Richard Cooper, William Delamotte, and R. L. West, were published by the Polyautographic Society in 1802.

The gold medal of the Society of Arts was not awarded to Senefelder until 1819, or the year after the publication of his work on Lithography. In this same year a silver medal was awarded to C. Hullmandel for a lithographic drawing, and the silver Isis medal to D. Redman for a lithographic drawing on English stone.

The Exhibition at South Kensington shows very clearly the vast capabilities of the art, and the beautiful pictures which have been produced both by artists in the past, and during the remarkable revival of the last twenty years. An exhibition such as this, which is thoroughly international in its scope, cannot but have a considerable effect upon public opinion. Hitherto these fine works have only been known to the few, now the public are enabled to see what has been done in the past and what is being done in the present by artists who know what a matchless medium lithography is for the reproduction of their drawings.

A very large number of the fine old historical lithographs are contributed from the National Art Library, and the possessors of other collections have come forward willingly to help in the formation of a really representative exhibition. In the division apportioned to the English school are early lithographs, published by the Polyautographic Society, of 9, Buckingham-place, Fitzroy-square, previously referred to, Rowney and Forster's Lithographic Press, Rathbone-place, and Ackermann's Lithographic Press, 412, Strand. Fine examples of the work of Samuel Prout, J. S. Prout, Joseph Nash, J. D. Harding, Richard James Lane, Frederick Tayler, Thomas Barker, of Bath, George Scharf, F. W. Hulme, John Linnell, jun., and C. J. Hullmandel are shown. There is a large amount of Louis Haghe's work, some of it reproductions of David Roberts's drawings. Here is Thomas Bewick's only attempt at lithography (Man on Horseback in Rain, 1823, No. 250), and a design of Alfred Stevens, lithographed by himself. Of living artists of the older school, Mr. William Simpson, Mr. John A. Vinter, and others may be noted.

The new school of lithographic artists, headed by Mr. Whistler, are well represented. The names of Messrs. Abbey, Oliver Hall, Legros, McCulloch, Pennell, Rothenstein, Shannon, F. Short, and T. R. Way may be specially mentioned.

A collection of over 800 lithographs of the artists of France are shown, and among these works of old of Charlet, Daumiér, Decamps, Delacroix, Gavarni, Gericault, Isabey, Laurens, Raffet, the two Vernets, and M. Fantin-Latour figure prominently.

Germany contributes 153 lithographs, and the works by Piloty and Menzel are conspicuous in this collection.

The United States, Holland, Belgium, Switzerland, Italy, Russia, and Spain are all represented in the Exhibition. Amongst the specimens from the latter country are three very fine lithographs by Goya, lent by Mr. Philip Norman. One of the curiosities of the Exhibition is a portrait of the Queen, by C. Fuhr ($73 \times 46\frac{1}{2}$) which is said to have been printed from the largest stone ever used.

With the increased use of lithography it may, in the future, become a question whether the supply of Solenhofen stone is likely to fail. Other materials have been tried, and attempts have been made to find a stone which might be used as a substitute for the original stone. T. Barker tried Bath stone; a Spanish stone from the quarries of Salsadella also has been used with success. Senefelder himself said that English, French, and Italian stones had been found serviceable. The Society of Arts offered many years ago a gold medal for the best specimen of lithography "executed on stone, the produce of the United Kingdom or its colonies," and as above mentioned the medal was awarded to D. Redman in 1819.

Zinc plates have been largely used, but principally for commercial purposes, and at the present time experiments are being made in the use of aluminium with fairly good results, as may be seen in the present Exhibition.

Obituary.

SIR JOHN FOWLER, BART., K.C.M.G.—Sir John Fowler, the distinguished civil engineer, who died on Sunday, 20th inst., was a member of the Society of Arts of fifty years standing, having been elected in 1848. He was born in 1817, at Wadsley-hall, Sheffield, and at the age of 17 became a pupil of Mr. J. T. Leather, hydraulic engineer, and was associated with many of the engineering schemes which were at that time carried out for the water supply of Yorkshire and the surrounding districts. When only 26 years of age, he was engineer, manager, and locomotive superintendent of the Stockton and Hartlepool Railway. Amongst the principal works executed by Sir John Fowler were the original "Underground" or Metropolitan Railway, the District Railway, the St. John's-wood Railway, the Victoria Station and Pimlico Railway, on which occurred the first railway bridge built over the river Thames at London, and many other railway works all over the country. He was consulting engineer to several of the great railway companies, and also to the Government of Egypt. In 1888, he was made a K.C.M.G. in recognition of important service

rendered in connection with the Soudan campaign. On the completion of that great work—the building of the Forth Bridge, which he carried out in conjunction with Sir Benjamin Baker—he was created a baronet. Sir John Fowler was President of the Institution of Civil Engineers in 1866, and received the honorary degree of LL.D. from the University of Edinburgh in 1890.

SIR STUART KNILL, BART.—The death of Alderman Sir Stuart Knill occurred at Blackheath on 19th inst., after an illness of about a month's duration. Sir Stuart was elected a member of the Society of Arts in 1861, and he filled the office of Vice-President from 1893 to 1896, during which time he was a constant attendant at the Council and at the evening meetings. He was born in 1824, and succeeded his father as head of the firm of Messrs. John Knill and Co., wharfingers and warehouse keepers. It was not until 1885 that he became officially connected with the Corporation of London. He was then elected Alderman of the Ward of Bridge Within in succession to Sir Charles Whetham. He served the office of Sheriff in 1889, and was elected Lord Mayor in 1892. He was created a baronet in celebration of the marriage of the Duke and Duchess of York. In 1897, Sir Stuart accepted the sinecure aldermanship of the Ward of Bridge Without, and he had the satisfaction of seeing his son, Mr. John Knill (his successor in the baronetcy) succeed him as Alderman of Bridge Within.

General Notes.

PROVINCIAL EXHIBITION AT GHENT.—The Provincial Exhibition of East Flanders, which is to be held at Ghent during the summer of 1899, will, says the United States Consul there, be opened on June 14th. While the principal exhibits will naturally be made by residents of the province there will be a department for foreign exhibitors. There will be exhibits in fine arts, industrial arts, hygienic life-saving apparatus, instruction and science, literature (Flemish and French), woman's work, alimentation, horticulture, agriculture, apiculture, lighting, heating and ventilating apparatus, sporting goods, arts, export trade and colonial products. Inquiries with reference to this Exhibition are to be addressed to the executive committee, 47, Boulevard Leopold, Ghent.

THE IVORY TRADE.—The greater part of the ivory imported into Europe comes from different regions of Africa; British India and Ceylon furnish a comparatively small quantity. Africa, according to the *Moniteur Officiel du Commerce*, contributes about 1,764,000 pounds of ivory annually distributed among the different centres of exportation as follows:—From Zanzibar, 441,000 pounds; Mozambique,

220,000; Gaboon, Cameroons, Lagos, 165,000; Niger Territories, 166,000; Loanda, Benguela, 221,000; Cape Colony, 110,000; Egypt, 331,000; and the Red Sea Coast, 110,000 pounds. The principal markets for ivory are London, Liverpool, and Antwerp. Hamburg also carries on an important trade, but a great part of it has first passed through the London market. Of the work imported at Antwerp, the larger part is from the Congo Free State. As regards the uses to which ivory is put, France, England, Germany, and the United States manufacture the four principal articles in ivory, viz., billiard balls, piano keys, comb and knife handles; in addition France makes a specialty of brushes, fancy articles, handles of umbrellas, and carved goods. Spain manufactures a considerable quantity of billiard balls; Italy and Turkey, combs; Austria, billiard balls and keys; Holland, a very few balls, and Belgium some fancy and carved goods.

COACHBUILDING.—The Company of Coach Makers and Coach-Harness Makers of London offer the following prizes for competition among British subjects generally, resident in the United Kingdom of Great Britain or Ireland:—Competition No. 1—Prizes are offered to competitors, under the age of 22 years, for sets of three drawings of (1) a square sociable, (2) a victoria (both vehicles on elliptic springs), and (3) a lady's pony vehicle (any pattern) hung on two wheels; scale, one inch to the foot; 1st prize, £3; 2nd, £2; 3rd, £1. No. 2—Prizes are offered to competitors, under the age of 25 years, for perspective designs of a lady's pony vehicle of any description; scale, one inch to the foot; 1st prize, £3; 2nd, £2; 3rd, £1. No. 3—Prizes are offered to competitors, under the age of 21 years, for working drawings of an elegant cab-body one-horse victoria, on elliptic springs, side elevation, half back and half plan and looking from the bottom; scale, two inches to the foot; 1st prize, £3; 2nd, £2; 3rd, £1. No. 4—Prizes are offered to competitors, under the age of 35 years, for perspective drawings of a skeleton double cab-shaped sociable on elliptic springs, with driving seat supported on elegant open iron-work; hood down, with dotted lines shewing it up; drawings to be tinted or shaded in grey colour; scale, six inches to the foot, on one piece of paper, 8 feet by 4 feet; 1st prize, the Company's silver medal and £6; 2nd, the Company's bronze medal and £4; 3rd, the Company's certificate and £2. No. 5—Mr. George Edwards (the master of the Company) offers £10 10s., to be divided as follows among competitors, under the age of 30 years, for essays on road carriage axles of all sorts, including ball-bearing axles, their manufacture, uses, advantages and disadvantages, and suitability for use in all parts of the world; 1st prize, £6 6s.; 2nd, £4 4s. No. 6—For a short descriptive statement and working drawings of a public conveyance to carry passengers for excursions or pic-nic parties. Particular and special attention to be given to the con-

struction of the vehicle to ensure safety and avoid upsetting; scale of drawings, two inches to the foot; prize, £10. The above prizes will be accompanied by the certificate of the Company. The prize winner in any of the competitions showing the greatest merit, if not already free of the Company, may have the Honorary Freedom conferred upon him should his drawing or essay in the opinion of the judges deserve it. Drawings and essays to be delivered free at the hall of the Company, Noble-street, St. Martin's-le-Grand, London, on or before April 10, 1899.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

NOVEMBER 30.—“Photographic Developers and Development.” By C. H. BOTHAMLEY, F.C.S. COL. J. WATERHOUSE, Hon. Sec., Royal Photographic Society, will preside.

DECEMBER 7.—“Egypt and the Soudan, in 1897 and 1898.” By W. T. MAUD, Artist and Correspondent to *The Graphic*.

DECEMBER 14.—“Commercial Education.” By SIR ALBERT ROLLIT, LL.D., M.P.

Papers for meetings after Christmas:—

- “Tuberculosis in Animals.” By W. HUNTING.
 “Canals and Inland Navigation in the United Kingdom.” By L. F. VERNON-HARCOURT, M.A.
 “Preservation of Timber.” By S. B. BOULTON.
 “Electric Traction and its Application to Railway Work.” By PHILIP DAWSON.
 “Coal Supplies.” By T. FORSTER BROWN.
 “Wireless Telegraphy.” By W. H. PREECE, C.B., F.R.S.
 “Leadless Glazes.” By WILTON P. RIX.

INDIAN SECTION.

The meetings of this Section will take place on the following Thursday afternoons, at 4.30 o'clock:—

January 19, February 9, March 9, April 13, May 11, 25.

FOREIGN AND COLONIAL SECTION.

The meetings of this Section will take place on the following Tuesday afternoons, at 4.30 o'clock:—

December 6, January 24, February 28, April 25.

At the meeting before Christmas the following paper will be read:—

TUESDAY, DECEMBER 6.—“The Yangtze Basin and the British Sphere.” By ARCHIBALD LITTLE, F.R.G.S., of Chungking. The Right Hon. SIR RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., will preside.

* * Numerous lantern slides of the Upper Yangtze and beyond will be shown and described by Mrs. LITTLE.

APPLIED ART SECTION.

The meetings of this Section will take place on the following Tuesday evenings at 8 o'clock :—

January 31, February 21, March 14, April 18, May 2, 30.

CANTOR LECTURES.

The following courses of Cantor lectures will be delivered on Monday evenings, at 8 o'clock :—

PROF. VIVIAN B. LEWES, “Acetylene.” Four Lectures.

LECTURE II.—NOVEMBER 28.

The commercial production of acetylene—Calcium carbide and its properties—The electric furnace and the various modifications in use for carbide manufacture—Carbide without electrical power—Carriage and storage of carbide.

LECTURE III.—DECEMBER 5.

The commercial generation of acetylene—The types of generator in use—The actions taking place in acetylene generators, and the effect upon the gas produced—The purification of acetylene for domestic consumption.

LECTURE IV.—DECEMBER 12.

The combustion of acetylene—Acetylene burners—Smoking and carbonising of burners—Burners for heating—Acetylene for gas engines—Diluted Acetylene and its applications.

DR. SAMUEL RIDEAL, “Bacterial Purification of Sewage.” Four Lectures.

January 16, 23, 30, February 6.

ARCHIBALD SHARP, A.M.Inst.C.E., “Cycle Construction and Design.” Four Lectures.

February 20, 27, March 6, 13.

PROF. HENRY R. PROCTER, “Leather Manufacture.” Four Lectures.

April 10, 17, 24, May 1.

JUVENILE LECTURES.

Two Lectures, suitable for a Juvenile audience, will be delivered on Wednesday evenings, the 4th and 11th of January, at Seven p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. Vivian Lewes, “Acetylene.” (Lecture II.)

Scottish Society of Arts, 117, George-street, Edinburgh, 8 p.m. Mr. Gilbert Thomson, “A Suggested Standard for Drain Testing.”

Imperial Institute, South Kensington, 8½ p.m. Mr. Ernest Lidgley, “Gold-mining in Victoria.”

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Actuaries, Staples-inn-hall, Holborn, 7 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Sir Wyke Bayliss, “Art—Contra the World, the Flesh, and the Devil.”

TUESDAY, Nov. 29...Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Stanley Robert Kay, “The Effect of Subsidence due to Coal-Workings upon Bridges and other Structures.”

Zoological, 3, Hanover-square, W., 8½ p.m. 1. Dr. E. A. Goeldi, “Further Notes on the Amazonian *Lepidosiren*.” 2. Mr. F. G. Parsons, “The Anatomy of Adult and Fœtal Specimens of *Pedetes capifer* as compared with that of the *Dipodops*.” 3. Mr. F. O. Pickard-Cambridge, “New Species of Spiders from Trinidad, West Indies.”

WEDNESDAY, Nov. 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. C. H. Bothamley, “Photographic Developers and Development.”

British Astronomical, Sion College, Victoria-embankment, W.C., 5 p.m.

Royal, Burlington-house, W., 4 p.m. Annual Meeting.

THURSDAY, Dec. 1. Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. R. H. Biffen, “The Biology of *Agaricus velutipes*.” Curt. 2. Mr. Jas. Johnstone, “The Gastric Glands of the *Marsupialia*.”

Chemical, Burlington-house, W., 8 p.m. 1. Messrs. H. J. H. Fenton and H. Jackson, “The Oxidation of Polyhydric Alcohols in Presence of Iron.” 2. Ballot for the Election of Fellows.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Eric T. Bruce, “Some Experiments in Persistence of Vision.”

FRIDAY, Dec. 2...Royal Institution, Abemarle-street, W., 9 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. Charles Benjamin Saner, “The Sunlight Gold-bearing Reef, Lynd-nburg, Transvaal.”

Geologists' Association, University College, W.C., 8 p.m. Mr. A. M. Davies, “Contributions to the Geology of the Thame Valley.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Journal of the Society of Arts.

No. 2,402. VOL. XLVII.

FRIDAY, DECEMBER 2, 1898.

*All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.***Notices.****JUVENILE LECTURES.**

The usual short course of lectures adapted for a juvenile audience will be given on Wednesday evenings, January 4 and 11, 1899, at 7 o'clock, by Professor F. JEFFREY BELL, M.A. (of the Department of Zoology, British Museum). The first lecture will be on "Hands and Feet," and the second lecture on "Some Ways in which Animals Breathe." The lectures will be fully illustrated with lantern slides.

Due notice will be given when the tickets for the lectures are ready for issue.

A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received. Subject to these conditions each member is entitled to a ticket admitting two children and an adult.

CANTOR LECTURES.

Professor VIVIAN B. LEWES delivered the second lecture of his course on "Acetylene," on Monday evening, 28th ult. The lectures will be published in the *Journal* during the Christmas recess.

APPLIED ART SECTION.

A meeting of the Committee of the Applied Art Section was held on Wednesday afternoon, 30th November. Present:—Sir George Birdwood, K.C.I.E., C.S.I. (chairman); C. Purdon Clarke, C.I.E., Alan S. Cole, I. Hunter Donaldson, J. Starkie Gardner, W. Gowland, Sir Villiers Lister, K.C.M.G., T. Buxton Morrish, J. Hungerford Pollen, Sir Walter S. Prideaux, J. Sparkes, and Sir Thomas Wardle, with Sir Henry Trucman Wood, Secretary to the Society, and Henry B. Wheatley, Secretary to the Section. The arrangements for the new session were considered.

Proceedings of the Society.**THIRD ORDINARY MEETING.**

Wednesday, November 30, 1898; Colonel J. WATERHOUSE, Hon. Secretary of the Royal Photographic Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Agnew, Sir William, Bart., 11, Great Stanhope-street, W.

Gardiner, Henry Nathaniel, 30, Finsbury-circus, E.C. Gibb, George S., North Eastern Railway, York.

Hayles, George Edward, 12, Northampton-park, Canonbury, N.

Jacob, Augustus Hamilton, M.A., 26, Maberley-road, Upper Norwood, S.E.

Rayner, Arthur B., 56, Paddington-street, W., and 68, Oakfield-road, Finsbury-park, N.

Sears, Arthur Holroyd, Cae Glas, Llandrindod Wells Radnorshire.

Townsend, John Walter, Wendreda, Lancaster-road, Wimbledon, S.W.

Walker, Arthur Tannett, Messrs. Tannett, Walker and Co., Leeds.

The following candidates were balloted for and duly elected members of the Society:—

Acland, Sir C. Thomas Dyke, Bart., Killerton, Devon. Annear, Joseph Henry, Morwell-cottage, West-street, Harwich.

Bannerman, William Bruce, The Lindens, Sydenham-road, Croydon.

Bhumgara, Jamsetjee S., 135, London-wall, E.C., and 8, Loudoun-road, N.W.

Boult, Wilfrid Swanwick, Sudbury, Beechcroft-road, Upper Tooting, S.W.

Boyd, William Christopher, The Grange, Waltham-cross, Herts.

Brickwood, John, Ortageny, Southsea, Hants.

Brown, Alfred Charles, Eastern Telegraph Company, Winchester-house, Old Broad-street, E.C., and 129, Algernon-road, Lewisham, S.E.

Burrell, Arthur William, M.D., 5, Baker-street, W.

Byrne, Rev. Father, Catholic Presbytery, Court-road, Bary Dock, Glamorganshire.

Carey, Alfred Edward, 39, Trinity-sq., Tower-hill, E.C.

Cawson, James, 8, Alfred-place, Bedford-square, W.C.

Cheesley, Robert Godwin, 16, Canonbury-street, N.

Corner, Walter William, 115, Fellows-road, South Hampstead, N.W., and City Liberal Club, Walbrook, E.C.

Coventry, Henry G., Worsley, near Manchester.

Coventry, Walter Bulkeley, Burgate-house, Fording-bridge, Salisbury.

DeBrath, Stanley, Grande Roque, Guernsey.

Dodds, John Bradburne, Stotes hall, Jesmond, Newcastle-on-Tyne.

Duncan, Harold M., Hyde-park-court, Albert-gate, S.W.

Duncanson, Edward Ford, Nutwood, Bickley, Kent.

- Edgcombe, Kenelm, 33, Tedworth-square, S.W.
 Elworthy, Thomas, London-road, St. Leonard's-on-Sea.
 Erskine, Captain William Charles Chitty, New Club, Princes-street, Edinburgh.
 Finny, Commander T. G. R., R.I.M., Royal Bombay Yacht Club-chambers, Bombay.
 Gadsby, Charles Herbert, Donington-house, Norfolk-street, Strand, W.C.
 Gibb, Alexander, 23, Chapter-road, Willesden-green, N.W.
 Gibson, William Augustus, 4, Queen Victoria-street, E.C.
 Girtin, George Wyndham Hog, 125A, Highbury New-park, N.
 Gordon, William Gordon, Knowlesly, Port of Spain, Trinidad.
 Gould, Henry, 1, Matthew's-lane, Kingston, Jamaica.
 Hamong, Count de, 180, New Bond-street, W.
 Harding, Josiah, 51, Hill-lane, Southampton.
 Hay, Walter Robert, 20, Abchurch-lane, E.C.
 Holah, Ernest, 5, Crown-court, Cheap-side, E.C., and Sun Trap, Radcliffe-road, Croydon.
 Howard, Henry Lionel, 38, St. George's-road, S.W.
 Humphreys, Henry Howard, 6, Stanley-gardens, Willesden-green, N.W.
 Jones, Walter Lindley, 21, St. Helen's-place, E.C.
 Kimmins, C. W., M.A., D.Sc., Bermondsey Settlement-lodge, Farncombe street, S.E.
 Langdon, William, Oakfields, Kingsbury, N.W.
 Lugard, Cecil Edward, 97, Sinclair-road, West Kensington, W.
 Mackenzie, Sir Alexander, K.C.S.I., 71, Lancaster-gate, W.
 Mair, George John, Millom, Cumberland.
 Marshall, Charles H., The Poplars, Howard-street, York.
 May, Cornelius, Oxford-street, Freetown, Sierra Leone.
 O'Dwyer, Arthur Williamson, Duketown, Old Calabar, Niger Coast Protectorate, West Africa.
 Ormerod, John, 62, Chorley New-road, Bolton.
 Osman, Constant Edward, 132, Commercial-street, E. Oulton, William, J.P. (Lord Mayor of Liverpool), Hillside, Gateacre, Liverpool.
 Park, C. J., 23, Mutley-plain, Plymouth.
 Parkinson, John, 251, Camden-road, N.
 Penhenty-O Kelly, Captain Edmund de, Sierra Leone, West Africa, and Badminton Club, 100, Piccadilly, W.
 Pickering, Robert Young, Railway Wagon Works, Wishaw, N.B.
 Plant, Edmund H. T., Charters Towers, North Queensland.
 Reed, Frederick Richard Cowper, M.A., The Limes, Oxford-road, Cambridge.
 Rollin, Charles, B.Sc., 1, Queen's-road, Jesmond, Newcastle-on-Tyne.
 Ross, Alexander, Great Northern Railway, King's-cross Station, N.
 Rundell, T. W., 25, Castle-street, Liverpool.
 Sam, Thomas Birch Freeman, Cape Coast Castle, West Africa.
 Sayer, Harry, 10, Nottingham-terrace, N.W.
 Schattner, Ernest B., 78, Mill Hill-road, Norwich.
 Scott, Sir John, K.C.M.G., M.A., Malabar-house, St. Albans, and 1, Adam-street, Adelphi, W.C.
 Sheer, John, 13, King's College-road, South Hampstead, N.W.
 Skilbeck, George Thornton, Clonard, Harrow Weald, Middlesex.
 Stevens, Charles Cecil, C.S.I., Fair View, Church-hill, Honiton.
 Swan, Edward Arthur, 74, Culverden-park-road, Tunbridge Wells.
 Vaughan, John C., Wraxall, near Bristol.
 Ware, Captain F. Webb, I.C.S., Quetta, Baluchistan, India.
 Wilson, Norman James, 70, Waterloo-road, N., Wolverhampton.
 Woollan, Benjamin Minors, Fairfield-lodge, 6, Addison-road, W.

The paper read was—

PHOTOGRAPHIC DEVELOPERS AND DEVELOPMENT.

By C. H. BOTHAMLEY, F.I.C., F.C.S.

Photographic developers are many, and the phenomena of development are complex and often obscure. It is impossible in the time at my disposal to deal with more than a comparatively small part of such a wide subject, and I propose, therefore, to consider developers rather than the operation of development, though the latter must naturally be dealt with incidentally.

It is a noteworthy fact that with the exception of ferrous oxalate and ferrous citro-oxalate all the substances that have been found to be of any practical value as developers for gelatinobromide plates, are carbon compounds, and with one exception are derivatives, and comparatively simple derivatives, of one and the same parent substance, the hydrocarbon benzene.

For some time pyrogallic acid or pyrogallol, which had been used as a developer in the collodion process, was the only carbon compound applied as a developer for gelatinobromide plates. In 1880, however, Captain Abney, to whom photography owes so much, showed that hydroquinone or, to use its systematic name, quinol, not only may be used as a developer but has properties that distinguish it from pyrogallol and make it especially useful for particular purposes. In the same year Eder and Toth recognised that pyrocatechin,

or, again to be systematic, catechol, which is very closely related, and in many ways very similar to quinol, likewise has strongly marked developing power. Up to the present time, however, this compound has been but little used, partly because until quite recently it has been comparatively costly. Some years later an α -amido- β -naphthol- β -sulphonic acid, which was described by Meldola in 1881, was recognised by Dr. Andresen as a photographic developer of considerable power, and its sodium salt was placed on the market under the trade name of eikonogen. For a time it was distinctly popular, but it is doubtful whether it is used to any large extent now, not because of any special demerits, but because photography, and especially amateur photography, is peculiarly subject to fashions, and for a time at least eikonogen seems to have been displaced by later novelties, such as paramidophenol, amidol, and metol.

Since 1890 new developers have appeared in even greater numbers than minor planets, and to-day there are at least twelve distinct developing agents in the market: pyrogallol, catechol, quinol, eikonogen, metol, paramidophenol, amidol, glycin, ortol, diamidodoresorcin, diphenal, and diogen. Perhaps to these may be added reducin, and if we were to include all the substances that have been patented as developers, the total number would not fall far short of a hundred. This embarrassment of riches, for such the average photographer finds it to be, is mainly due to two German chemists, Dr. J. Hauff, of Feuerbach, and Dr. M. Andresen, of Berlin, who have inquired into the developing properties of a very large number of benzene and naphthalene derivatives. Their investigations have not only resulted in a number of patents, but what is very much more important, have paved the way for the recognition of certain relations between the constitution of benzene derivatives and their power of acting as photographic developers. The establishment of these relations is valuable, not only because they reduce chaos to at least a semblance of order, but also because they indicate the directions in which further investigations may be made with the greatest promise of useful results.

The broad general principles were first definitely enunciated independently by Dr. Andresen and by Messieurs A. and L. Lumière, of Lyons, in July, 1891, and a summary of the position to which they have brought the matter will probably be of interest, premising at the outset that in some

points of detail they are not quite in agreement even as to matters of fact.

All the benzene derivatives that are known to act as photographic developers, with one or two partial exceptions, to be referred to hereafter, contain hydroxyl groups (OH) or amido groups (NH_2) that have been substituted for hydrogen, and moreover contain at least two such groups, which may be either both hydroxyls, or both amido groups or one hydroxyl and one amido group. Phenol and aniline and their homologues are not developers.

Chemists are familiar with the fact that the bisubstitution derivatives of benzene, in which two out of the six atoms of hydrogen originally in the hydrocarbon have been displaced by either elementary or compound radicles, are capable of existing in three distinct modifications or isomerides, which have the same composition, but differ from one another in physical properties, such as crystalline form, melting point, and solubility, and also in chemical behaviour, more especially as regards their aptitude to enter into chemical reactions, the character of the reactions in which they will take part, and the nature of the products that they yield under similar conditions, and notably when treated with oxidising agents. The three modifications are known respectively as the ortho-derivatives, para-derivatives, and meta-derivatives, and the differences between are believed to be due to differences in the arrangement of the atoms within the molecule, and in particular to the relative positions of of the elements or groups that have been substituted for hydrogen. Adopting the usual plan of representing benzene by means of a hexagon with a carbon atom and a hydrogen atom at each of the six angles, the three dihydroxy derivatives of benzene, in which two hydrogen atoms have been displaced by two hydrogen groups (OH), are represented by the formulæ on page 44.

A similar plan is adopted for all other bisubstitution derivatives. In the ortho-derivatives the two substituted radicles are supposed to be adjacent; in the para-derivatives they are directly opposite; in the meta-derivatives they are neither adjacent nor directly opposite, or, in other words, they cannot be represented as lying at the opposite extremities of any side or diagonal of the hexagon.

Now it is found that whilst the ortho and para-derivatives are developers, the meta-derivative has no developing power. Ortho-dihydroxybenzene is catechol, or pyrocatechin, to which reference has already been made,

whilst paradihydroxybenzene is quinol, or hydroquinone, which is well known and widely used as a developer.

The metadihydroxybenzene is also well known under the name of resorcin, or resorcinol, and is of great practical importance from other points of view, but it has no power of developing the latent image on an exposed gelatino-bromide plate.

Similarly, the ortho and paradiamidobenzines (phenylene diamines), have developing power, but metadiamidobenzene (metaphenylene diamine) has none or extremely little.

The same law holds good when the amido-group and the hydroxyl group occur together; orthoamidophenol and paramidophenol are developers, but metamidophenol is not. One of these, paramidophenol, is now tolerably well known, and is sufficiently in vogue as a developer to be included amongst those put up by Burroughs and Welcome in the convenient form of tabloids; it is also the active constituent of the developing solution sold as "Rodinal." The constitution of these three groups is shown in the following Table:—

	Developers.		Non-developers.
Dihydroxy-benzenes	$\begin{array}{c} \text{Ortho.} \\ \text{C.OH} \\ \text{HC} \diagdown \quad \diagup \text{C.OH} \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{CH} \\ \text{CH} \\ \text{Catechol.} \end{array}$	$\begin{array}{c} \text{Para.} \\ \text{C.OH} \\ \text{HC} \diagdown \quad \diagup \text{CH} \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{CH} \\ \text{C.OH} \\ \text{Quinol.} \end{array}$	$\begin{array}{c} \text{Meta.} \\ \text{C.OH} \\ \text{HC} \diagdown \quad \diagup \text{CH} \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{C.OH} \\ \text{CH} \\ \text{Resorcinol.} \end{array}$
Diamido-benzenes (Phenylene diamines)	$\begin{array}{c} \text{C.NH}_2 \\ \text{HC} \diagdown \quad \diagup \text{C.NH}_2 \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{CH} \\ \text{CH} \end{array}$	$\begin{array}{c} \text{C.NH}_2 \\ \text{HC} \diagdown \quad \diagup \text{CH} \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{CH} \\ \text{C.NH}_2 \end{array}$	$\begin{array}{c} \text{C.NH}_2 \\ \text{HC} \diagdown \quad \diagup \text{CH} \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{C.NH}_2 \\ \text{CH} \end{array}$
Amido-hydroxy-benzenes.... (Amidophenols)	$\begin{array}{c} \text{C.OH} \\ \text{HC} \diagdown \quad \diagup \text{C.NH}_2 \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{CH} \\ \text{CH} \end{array}$	$\begin{array}{c} \text{C.OH} \\ \text{HC} \diagdown \quad \diagup \text{HC} \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{HC} \\ \text{C.NH}_2 \\ \text{Paramidophenol} \end{array}$	$\begin{array}{c} \text{C.NH}_2 \\ \text{HC} \diagdown \quad \diagup \text{CH} \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{C.NH}_2 \\ \text{CH} \end{array}$
Methamido-hydroxy-benzenes	$\begin{array}{c} \text{C.OH} \\ \text{HC} \diagdown \quad \diagup \text{C.NH.CH}_3 \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{CH} \\ \text{CH} \\ \text{Ortol.} \end{array}$	$\begin{array}{c} \text{C.OH} \\ \text{HC} \diagdown \quad \diagup \text{CH} \\ \quad \\ \text{HC} \diagup \quad \diagdown \text{CH} \\ \text{C.NH.CH}_3 \\ \text{Metol (Andresen).} \end{array}$	

In the case of derivatives of diphenyl, C_6H_5 , C_6H_3 , which is formed by the union of two benzene nuclei, the two amido or hydroxyl groups must be in the same benzene nucleus.

Benzidine, or diamidodiphenyl, $\text{NH}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{NH}_2$, is not a developer because the two amido groups are in different benzene nuclei, but hydroxydiamido-diphenyl, $\text{NH}_2\text{C}_6\text{H}_4\text{C}_6\text{H}_3(\text{OH})(\text{NH}_2)$,

is a developer, because one amido group and one hydroxyl group are associated in the same benzene nucleus in the para-position. Hydroxy-diamidodiphenyl is the active constituent of the developer diphenal.

Naphthalene derivatives, to be developers, must also contain at least two hydroxyl groups, or two amido groups, or one hydroxyl and one amido group, but it would seem that in this case the two groups need not both be in the same benzene nucleus, and it is not quite definitely ascertained whether the rule with regard to meta-derivatives holds good. The association of two benzene nuclei to form a naphthalene molecule is of a very intimate character, different from that which obtains in the case of diphenyl, and the various derivatives show certain relations and differences that are not observed in the case of benzene derivatives. As illustrations of the main general law however, it may be stated that the naphthols and the naphthylamines are not developers, but most of the dihydroxynaphthalenes and the amidonaphthols are developers in a greater or less degree.

Returning to the benzene derivatives, it is well-known that the hydrogen of the hydroxyl group, or the amido group, can be displaced by alkyl radicles such as *methyl* CH₃ or *ethyl* C₂H₅, and also by other radicles, and the results are of some practical importance. In the case of a developing compound that contains two hydroxyl groups or one hydroxyl and one amido group, the substitution of a radicle for the hydrogen of an hydroxyl group destroys the developing power; for example, methylcatechol, commonly known as guaiac, has no developing power when quite pure (Lumière).

On the other hand, when a similar substitution takes place in the amido group the results are quite different, and some of the products are already important developers.

Methylorthoamidophenol is the chief constituent of the valuable developer "ortol;" whilst methylparamidophenol is Andresen's "metol," and its homologue, methylparamidometacresol, is Hauff's metol. The constitution of the first two compounds is shown in the Table already given. Both "metols" act practically in the same way, and this seems to be true also of the parent substances, paramidophenol and

paramidocresol, so far as the behaviour of the latter has been examined.

The chief advantages gained by the introduction of an alkyl group in place of the hydrogen in the amido group are increased solubility in water and a slight increase in developing power. An apparent exception to the latter statement, however, is "glycin,"

which is parahydroxyphenylglycin, or is paramidophenol, in which one of the hydrogen atoms of the amido group has been displaced by the group CH₂.COOH. It is, however, more properly regarded as glycin, NH₂.CH₂.COOH, in which an atom of hydrogen has been displaced by the hydroxyphenyl group, C₆H₄.OH.

It may be convenient to state here the broad general distinction between developers which owe their power to hydroxyl groups and those which owe it to amido groups. Dr. Eder has pointed out that all the developers in use may be broadly divided into two groups, according to the manner of their action on those parts of the sensitive film that have received different exposures. The members of the first group develop the image gradually and step by step, the high lights of the subject first making their appearance, and being followed by the other parts of the image in the order of their relative brightness. The members of the second group act differently; all the details of the image appear almost simultaneously, whether they represent dark parts or bright parts of the object, and afterwards the various parts gradually acquire opacities that represent their relative brightness. In the first group Eder places pyrogallol, catechol, and quinol; and in the second group amidol, eikonogen, metol, and paramidophenol. The first group contains developers that are suitable for normal exposures and over-exposures; the second contains those that are suitable for normal exposures or under-exposures, such as are frequently given in hand-camera work. It is clear that with one and the same exposure the two groups of developers would give negatives of very different characters, especially if development were not pushed to its limit; and this is well shown by the example thrown on the screen. One half of the plate was developed with pyro-soda, and the other half with metol-soda, and it is evident that the

gradations of the two halves are markedly different.

The fact to which I wish especially to draw attention, is that all the members of Eder's first group owe their developing power to hydroxyl groups only; whereas those in the second group contain both amido and hydroxyl groups. It is a noteworthy fact that no developer containing amido groups without a hydroxyl group has yet been adopted for practical purposes. Other compounds, such as ortho-methylamidophenol may be added to Eder's second group, and it would seem that we must attribute to the amido group the peculiar property of developing and making visible those parts of the image where the action of light has been smallest, with practically the same rapidity as those parts where the action of light has been greatest. This view is supported by the fact that this peculiarity is more marked when more than one amido group is present. In any case

there can be no doubt that the property of developing in this way makes the group of developers especially valuable when dealing with subjects that have great extremes of light and shade, particularly where circumstances are such that only a minimum exposure has been or can be given.

It is, however, necessary to point out that there is no hard and fast line between the two groups of developers, and even the mode of action of one and the same developer depends on the manner in which it is used.

With the tri-substitution derivatives, *i.e.*, those in which three hydrogen atoms of the benzene have been displaced by hydroxyl or amido groups, or partly by one and partly by the other; the same general law holds good. The ortho- and para-derivatives are developers, whilst the meta-derivatives are not. As examples we may take the three trihydroxy-benzenes, the ortho-derivative being pyrogallol.

And also some of the diamidophenols, of which there are six altogether.

In these cases the effects of substitution in the hydroxyl or amido groups themselves are similar to those observed with the bi-substitution derivatives, making due allowance, of course, for the fact that, where three hydroxyl groups are present, displacement of the hydrogen of one of them only will not destroy the developing power if the two that are left are in the ortho or para positions.

Other points concerning the relation between chemical constitution and developing power have received attention, and notably the influence of the carboxyl group COOH and the sulphonic group HSO₃, but at present no very definite conclusions can be drawn, and the results do not seem to be of much practical importance. Generally speaking, it would seem that the introduction of either of these

groups into the molecule reduces the developing power of the compound, and in some cases destroys it altogether. Here again the naphthalene derivatives show differences from the benzene derivatives.

Since the developing power of carbon compounds is traceable to the presence of hydroxyl and amido groups, it becomes a question of some interest whether these groups show developing power when they are in one free state as hydrogen peroxide (dihydroxyl HO.OH) and hydrazene (diamide or amidogen H₂N.NH₂) unassociated with a benzene nucleus, and this interest extends to hydroxylene NH₂.OH, which may be regarded as a compound of both groups.

It was stated a few years ago by Le Roy that hydrogen peroxide in strongly alkaline

solution will develop the latent image on gelatinobromide plates, and that alkali peroxides behave similarly. This statement I am able to confirm, and I show some examples. The developing power of hydrogen peroxide is comparatively feeble, but that of alkali peroxide is much stronger, and it is not greatly inferior in energy to some of the organic developers. The evolution of oxygen that accompanies the reduction, causes the gelatine to swell up in innumerable small blisters. Hydrazine, in presence of an alkali, has also considerable developing power (examples shown), whilst hydroxylamine is still more efficient, and may, in fact rank with the ordinary organic developers. The power of hydroxylamine was recognised in 1884 by Egli and A. Spiller, and probably the only cause that has prevented its general adoption is the fact that the nitrogen liberated in the reaction produces small bubbles or blisters in the gelatine. The same phenomenon is observed in a greater degree with hydrazine.

The developing power of hydrazine and hydroxylamine is found to exist also in derivatives that do not strictly conform to the general laws previously stated. That phenylhydrazine, $C_6H_5.HN.NH_2$, is a somewhat powerful developer was recognised so long ago as 1887, by E. Jacobsen, who also found that its homologues and naphthylhydrazine behave in a similar way. Phenylhydrazine has the same composition as phenylene diamine, but in the one case the nitrogen atoms are in direct union with one another, whilst in the other they are not, but are associated with different carbon atoms. In the one case the phenyl group has been substituted for one of the hydrogen atoms in the hydrazine molecule $H_2N.NH_2$, whilst in the other two amido groups have been substituted for two hydrogen atoms of the benzene molecule.

Phenylhydroxylamine $C_6H_5.NH.OH$ and its homologues also have developing power, and it is noteworthy that the relation between phenylhydroxylamine and amidophenol is very similar to that between phenylhydrazine and phenylenediamine.

All photographers are aware that these various developers will not act by themselves, but have to be mixed with an alkali, or in some cases with an alkali sulphite only, in order to bring their developing powers into play. They are potential developers rather than actual developers. Very generally too when an alkali carbonate or hydroxide is used an alkali sulphite is also added, as recommended by Berkley

in 1882, mainly for the purpose of preventing the discolouration of the developer and the consequent staining of the film. In view of these facts it is customary to speak of the organic developers as "alkaline developers," but the question at once arises, what do we mean by "alkaline" in this connection? Chemists recognise different degrees of alkalinity, as shown by different indicators, and these different degrees have a different significance. There is alkalinity or acidity to phenolphthalein, and there is alkalinity or acidity to methyl orange, which are by no means the same thing, and there is also alkalinity or acidity to the familiar litmus, which is less definite in its significance than the other two. When we speak of alkaline developers, which degree of alkalinity do we mean?

Many years ago Abney showed that pyrogallol will develop an image when simply mixed with an alkali sulphite, and this result has been confirmed, and it has further been shown that the same result is obtained when special care is taken, that the sulphite contains no alkali carbonate. It is then not alkaline to phenolphthalein, but is alkaline to litmus. It has been stated that quinol and catechol do not develop when mixed with a sulphite only, but I find that as a matter of fact development does take place under these conditions, though very slowly, in complete absence of an alkali carbonate or hydroxide. It requires 30 hours at a temperature of about 50° Fahr. to reach a moderate degree of opacity.

Again, pyrogallol will develop an image completely in presence of an alkali bicarbonate, and in these cases also the solutions are alkaline to litmus but are not alkaline to phenolphthalein. Development is naturally slower than with the normal carbonate, but the method can be applied with distinct practical advantages to plates that have been much over-exposed or that show a marked tendency to general fog if treated in the ordinary way.

Further, paramidophenol, methylorthoamidophenol, metol, amidol, and diamidoresorcin, all develop when mixed with an alkali sulphite free from carbonate or hydroxide.

It follows, therefore, that the minimum *active alkalinity*, if I may use the expression, is alkalinity to litmus. It must, however, be understood that with this degree of alkalinity development is usually very slow, too slow in fact to be of practical value except in special cases. Amidol (diamidophenol) diamidoresorcinol, triamidophenol, and probably

other derivatives that contain at least two amido groups with a hydroxyl group are exceptions to the general rule, since they give a workable rate of development when mixed with normal sodium sulphite alone.

As a rule, however, a normal alkali carbonate or an alkali hydroxide must be added; that is to say, the liquid must be made alkaline to phenolphthalein, and, with the exceptions just mentioned, this degree of alkalinity must be regarded as the working alkalinity.

In most cases sodium carbonate or potassium carbonate is the alkali used; sodium and potassium hydroxide have to be employed with great care, and ammonia gives satisfactory results only with pyrogallol, and that only with comparatively few of the various brands of gelatine bromide plates at present on the market. The great drawback to the use of alkali hydroxides (caustic alkalies) is that unless the proportion is kept very low the developer becomes too energetic, and produces general fog, or, in other words, reduces silver bromide that has not been exposed to light instead of attacking only that which has been exposed.

Unfortunately at the present time we are almost entirely without exact information as to the relative effects of sodium and potassium carbonate. It is generally believed that potassium carbonate is the more energetic of the two, and this is probably the case, but so far as I am aware no really careful comparison has ever been made. It may serve as an example of the loose kind of experimenting from which exact photography suffers so much if I point out that in a number of such comparisons as have been made, a given weight of anhydrous potassium carbonate has been compared with the same weight of soda crystals, that is, hydrated sodium carbonate containing very nearly two-thirds of their weight of water. It is scarcely to be wondered at that when compared in this way potassium carbonate was found to be more energetic than sodium carbonate.

There are a few exceptions to the general rule that solutions must be at least alkaline to litmus in order to obtain developing power. In this respect also naphthalene derivatives seem to provide exceptions. Eikonogen when dissolved in water yields a solution that is decidedly acid to litmus, and I find that such a solution will develop image on an exposed plate, although the action is very slow, even when the plate has received many times the

normal exposure; a period of about 48 hours being required to obtain a satisfactory opaque image with a 2 per cent. solution of eikonogen. Given sufficient time, however, enough and more than enough opacity can be obtained, and I think development in this way is worthy the attention of anyone who has to develop plates that in ordinary phraseology are known to be "hopelessly over-exposed." It was recognised some years ago that eikonogen will develop very fairly well with no addition except sodium sulphite, but I have not been able to find any previous definite evidence that it will develop in a solution acid to litmus. So far as my own experience goes, eikonogen is in this respect unique amongst all the ordinary developers. Amidol and diaminodoresorcinol do not develop in solutions acid to litmus, even when allowed to act for so long as 76 hours on plates that had much more than a normal exposure, though the addition of some sodium sulphite at the end of this time sets the developing action going at once. Probably other naphthalene derivatives analogous to eikonogen will behave in the same way as it does.

Phenylhydrazine is also an exception in that it will develop with some energy in a solution that is neutral to litmus, but I have not been able to obtain any developing action when the solution was acid to litmus. Hydrazine and hydroxylamine also will not develop if the solutions are acid to litmus.

Referring once more to the action of sodium sulphite, it is obvious that as all the ordinary developers will act in presence of the sulphite alone, this substance not only keeps the liquid from becoming discoloured, but also has a weak accelerating action of its own. Since, however, the rate of development in presence of an alkali sulphite is very much lower than when an alkali is added, it follows that in the operation as usually carried out, the accelerating effect of the sulphite is a practically negligible quantity. At the same time it ought not to be forgotten that sodium sulphite in moderately concentrated solutions has a distinct solvent action on silver bromide, and it is conceivable that this action may play some part in the process. At present, however, there is no direct evidence that this is the case.

In order to avoid the inconveniences attending the use of alkalis, and notably of caustic alkalis, Messieurs Lumière have proposed the use of tribasic sodium phosphate, Na_3PO_4 , a salt which is fairly stable. When dissolved in

water it splits up into the ordinary sodium phosphate (disodium hydrogen phosphate) and caustic soda, to an extent depending on the degree of dilution. Its effect is consequently the same as that of caustic soda, but the variations in the proportion of caustic soda present, that result merely from different degrees of dilution, introduce complications that are not without influence on the result.

Another novel and very interesting method of providing the necessary alkali has been devised by Messieurs Lumière. It is based on the well-known fact that aldehydes and acetones unite with acid sodium sulphite to form crystalline compounds. If to a solution of normal sodium sulphite containing pyrogallol or quinol, a small quantity of formaldehyde, or ordinary aldehyde, or acetone is added, interaction seems to take place with formation of aldehyde sodium bisulphite or acetone sodium bisulphite and the sodium salt of the pyrogallol or quinol. The change may be represented in this way—

(Acetone)

At any rate the addition of the acetone or aldehyde confers on the solution powerful developing properties, the rate of action depending to a considerable extent on the proportion of aldehyde or acetone added.

The most satisfactory results for general purposes seem to be obtained with pyrogallol and acetone. A solution is prepared containing pyrogallol one part, sodium sulphite five parts, water 100 parts, and to this acetone is added up to an amount not exceeding ten parts. The developer works regularly but fairly rapidly; the method has some distinct advantages, and seems likely to become of considerable practical importance. Some examples are shown on the screen. Quinol and sodium sulphite, and formaldehyde are said to yield a developer very useful where negatives with strong contrasts are desired, and paramidophenol also develops in presence of sulphites when an aldehyde or acetone is added.

The only other substance commonly added to developers is a soluble alkali bromide, the action of which varies according to the nature of the particular developer. It generally lowers the rate of development, but within certain limits as to the proportion added, its only other effect on the final result, when development is allowed to proceed to its limit, is, according to my experience, to reduce or prevent general

fog. When development is not pushed to its limit, the bromide, if in sufficient quantity, has a materially influence on the character of the negative, as photographers have long believed, and as the later experiments of Hurter and Driffield seem clearly to prove. Broadly speaking the effect is the same as if the plate were somewhat slower, or had received a shorter exposure, but the matter requires further investigation.

Concerning the chemical changes that go on during development I propose to say very little, and, indeed, there is very little definitely to say. It is recognised in a general way that a developer is a reducing agent, and that the operation of development is a process of reduction. It is important not to forget that in its ideal form at any rate it is a process of *selective* reduction, and the ideal developer is one that will not reduce silver gelatinobromide that has not previously been exposed to light. In this case, as in so many others the real is often very different from the ideal, but the ideal is not unattainable even under ordinary working conditions, though it must be confessed that in the desire to obtain high sensitiveness the silver bromide in many gelatinobromide plates is brought into such a highly unstable condition that it is attacked by the developer even without any preliminary action of light.

It is also recognised that the developer undergoes oxidation, but no definite oxidation products have yet been satisfactorily isolated. The matter is especially difficult to investigate because only a small part of the change in the developer is due to its action on the photographic plate; the greater part is due to the action of the air on the developer.

Three chief hypotheses have been propounded concerning the nature of the change in the silver bromide. There is the view expounded by Abney that the undeveloped image consists of a minute quantity of silver sub-bromide, which is reduced by the developer to metallic silver; the silver thus liberated unites with the silver bromide that is in contact with it to form more sub-bromide, which in its turn is reduced yielding still more silver, and this in the same way forms more sub-bromide, which is again reduced, and so on. Secondly, there is the view that the reduction of the silver bromide is to be regarded as a process of electrolysis initiated by the minute quantity of silver that results from the action of the developer on the material forming the latent image. Lastly, there is the view of Hurter and

Driffield that every particle of silver forming the developed image is represented in the undeveloped or latent image by a corresponding particle of silver bromide that has been affected by light, and has thereby been thrown into a state of such unstable equilibrium that it is reduced by the developer; they accept neither the sub-bromide hypothesis nor the hypothesis of electrolytic action.

In considering the question, I think it is important to bear in mind that the chemistry of development is a chemistry of dilute solutions. An ordinary developer on an average contains 5 parts of the developing agent in 1,000 parts of solution, or a gram molecule in 22 litres. It is possible, however, to develop a normally exposed plate in a solution containing only 1 part of pyrogallol in 10,000 parts of solution, *i.e.*, a gram molecule in 1,260 litres, or a degree of dilution far beyond that which obtains in ordinary chemical operations. The first example exhibited was developed for 2 hours in a solution containing 1 part of pyrogallol in 5,000. The second was developed for 100 minutes in a solution containing 1 part of pyrogallol in 10,000. In explaining these phenomena it may be necessary to take into account the special properties of very dilute solutions.

The main reaction, whatever its mechanism, is of course the separation of bromine from silver, the metal remaining to form the image, whilst the bromine dissolves in the form of an alkali bromide. At the same time the developer is oxidised, apparently at the expense of the water that is present. The reaction does not seem to me to be one that can properly be represented by an ordinary equation; many attractions are at work tending to keep the system in its original configuration, whilst many counter-attractions are tending to bring about a change of configuration, that is, a re-arrangement of the atoms with the production of new substances. Under proper conditions the occurrence of any change at all is dependent on the initial change produced by the action of light. When a change does take place the reaction is not a reversible one, but nevertheless the relative masses of the reacting substances have a distinct influence; the change is accelerated within certain limits by an increase in the relative masses of the reducing agent and the alkali, but on the other hand it is retarded by an increase in the mass of alkali bromide, which is one of the products of the reaction. In some cases also it seems to be retarded by the product of the alteration

of the developing agent. The whole question has been the object of much speculation—and a little experiment—but many of the problems that it includes have still to be solved.

DISCUSSION.

The Rev. F. C. LAMBERT said one of the most interesting points mentioned was the developing power of hydrogen-peroxide. Most present would be aware probably of the interesting experiments recently made by Dr. Russell on so-called photography in the dark. He understood him to say in a recent lecture at the Royal Photographic Society that he was tending to the opinion that all these curious actions could be traced to the elimination or production of hydrogen-peroxide, that the substances which acted on the photographic plate in the dark were those which gave off hydrogen-peroxide.

Sir H. TRUEMAN WOOD said this subject required for its discussion much greater knowledge of organic chemistry than most people possessed, and he rather regretted that the paper had been fixed for that evening, when many chemists who might otherwise have been present were enjoying themselves elsewhere at the annual dinner of the Royal Society. The average photographer would probably look at the paper in three different ways. First of all he would be struck by the clear and brilliant way in which Mr. Bothamley had treated a subject of great difficulty and complexity; next he would be led to hope these researches would throw some light on the very abstruse phenomena of photographic development; and lastly, he might be tempted to despair on finding how little was really known of those phenomena, and how empirical was the knowledge which had been gained. Seeing that three or four theories had been put forward as to the nature of development itself, how could they expect to know the action of the various substances which were used as developers. The practical question which would occur to many of them would be what was the good of having so many developers, and were any of them any better than their old friend pyrogallol? The practical man would say that the results produced by these newer agents were not very different from those produced by the older ones, and that although metol, for instance, might give you the power of bringing out more easily an image which had been very slightly exposed, the actual benefit derived from the additions to the list was not very great. There was, of course, a great advantage in having for certain purposes, developers which did not stain. Perhaps Mr. Bothamley could tell them why pyrogallol stained the plate or paper more than metol or hydroquinone or some of the other substances, whether the more rapid oxidation of the pyro produced a dye which stained any material to which it came in contact, or for one would like to know. H

oped some practical photographers would give their opinion as to benefit derived by having so many different materials placed at their command, but he fancied that nine-tenths of the work was still done with pyrogallol, and that those newer developers were, to a large extent, used by amateurs and experimentalists.

Mr. W. BROOKS said he had used acetone pyro for the last six months, and found that it would do all that alkaline pyro would do, and a great deal more. It had rather a tendency to soften the film, which he did not like, but it had the great advantage that it did not stain the hands, which made it very suitable for ladies. He had also used glycin, which was superior to anything he knew of, from the point of view of gradation. Some time ago he had to photograph the memorial plate to a Lord High Admiral (Lord Howard of Effingham) in the church at Reigate, the colour of the plate being that of burnt sienna, and the letters black, and he thought it was almost a hopeless case, but to his surprise all the letters came out like an engraving. Amidol was another developer which he had found useful. Many people thought glycin was only suitable for line work, but he found it gave the most delicate details possible. With regard to Dr. Russell's experiments with metals, he might say that he worked on that subject, at the latter part of the sixties and beginning of the seventies, and he thought Dr. Russell would find that the effect depended on the distances at which the elements were placed in front of the plate; there was a sort of photosphere produced which caused the action, which did not take place when there was actual contact. With zinc the distance might be $\frac{1}{4}$ inch, and with iron $\frac{1}{2}$ inch, but with each metal there was one plane in which the action was most marked.

Mr. KROHN asked whether precautions had been taken in the case of the acetone experiment, to see that the sulphite was pure and contained no carbonate. A friend of his some time ago experimented in this direction though he was not able to conclude his researches. As far as he remembered he tried both acetone and formalin, and in both cases obtained development, but on neutralising or adding sulphurous acid to the sulphite, so as to get rid of all traces of carbonate, the action was reduced, if not altogether stopped. This was a point frequently ignored, but commercial sulphite sometimes contained as much as 25 per cent. of carbonate.

The CHAIRMAN said he could not follow the chemistry of the paper in detail, but Mr. Bothamley had done a great service to photographers in preparing it, and it would afford a valuable basis for further research. He had tried most of these developers in a more or less experimental way, but could not say much about them; after all he thought the old friend pyro was the real stand-by of the photographer, though a good word

might also be said for ferrous oxalate. This had one advantage over organic developers, that you knew exactly what you were working with; the others, especially in tropical climates, were liable to decompose. In India the great difficulty was to keep things fresh; sometimes the pyro looked nice and white, but when put into water it gave a dark-brown or almost black solution. Eikonogen, which he had also used, sometimes appeared as a brilliant purple blue powder. Ferrous oxalate for a long time was the favourite on the Continent, and was largely used there, but was not much used in England. Glycin was valuable when you knew how to use it, and he liked it very well for certain purposes though it was said to be slow. With regard to guaiacol, it showed how easy it was to mistake the action of an impurity for that of the substance with which it was mixed. When he was working with guaiacol it was not so commonly used as now for medical purposes and was not so pure. Lumière showed that *pure* guaiacol had no developing power, and it seemed likely that the developing action was due to minute traces of pyrocatechin, which he had found by experiment had considerable developing power, even when reduced to $\frac{1}{50000}$ inch, and 1 per cent. solution of caustic potash. Carbolic acid or phenol was another case in point. The pure phenol was not a developer, but samples of carbolic acid, that had been kept for some time and turned red, had considerable developing power. Cresol, paracresol, and phlorol had also some power of development. Hydroxylamine hydro-chlorate was also an exceedingly valuable developer if you could use it, but the difficulty was to prevent the little bubbles and blisters; this defect had prevented its use. He had lately used pyro-acetone, which gave good density and tone and freedom from stains, but he found it had a tendency to frill and reticulate, at any rate in the summer. One of the nicest developers was paramidophenol hydro-chlorate; it was something like rodinal, but he preferred the salt itself. It was very good for office use, because you could put your plate in, go away and attend to visitors, and come back and find the plate all ready. It had also great keeping powers, and was always ready for use. Eikonogen was also useful for ordinary work and in making reversals. He thought it was a good thing to have a large choice of developers, because one would serve best for one purpose and another for another, but it required experience and skill in making a selection. Metol had become popular because it was a snapshot developer, which could be used after very short exposures, or in places where the light was weak.

Mr. BOTHAMLEY, in reply, said as far as he could form an opinion, Dr. Russell had practically proved that the pseudo-photographic effects he had noticed were due to the action of hydrogen-peroxide in very small quantities on the plate. It was well known to be

formed in almost all cases where a metal, or anything else—varnish, for instance—was oxidised in the presence of air. He had himself repeated some of Dr. Russell's results and found that very small quantities of hydrogen-peroxide would produce very dense latent images; that is to say, latent images which, when developed, showed considerable opacity. It had also been shown long ago by Captain Abney, that hydrogen-peroxide, in solution, would destroy the latent image if it were allowed to act on the photographic plate. In a paper read at the British Association he (Mr. Bothamley) had shown, not only that hydrogen-peroxide vapour, if allowed to go on acting, would, in time, destroy the image that it had first produced, but that turpentine and one or two other substances would do the same thing. Hydrogen-peroxide would produce a latent image, destroy it, and develop it, according to the conditions under which it acted. Years ago it was shown by Brodie that hydrogen-peroxide would act sometimes as a reducer, and sometimes as an oxidiser, and in one and the same liquid it would be reducing and oxidising at the same time. With regard to the practical result of researches of this kind he thought they were distinctly useful, mainly because they showed in what direction to look for new developers. Metol, which was to a certain extent the outcome of this work, was a distinct gain, as it was very useful for special classes of work, difficult interiors, and the like. It was a great advantage to have substances which did not stain, such as metol, paramidophenol, and others. They gave images on a gelatine bromide plate, which had always practically the same colour, which was not the case with pyrogallol; there the colour was more or less brown, but it varied a great deal. With metol and other substances the colour of the image was almost always the same; it was only the degree of opacity which varied. Why some developers produced stains and others did not, was a difficult question. Why one dye would dye wool and another cotton, and why some would dye gelatine and others would not, were questions which he doubted if any chemist could answer at present. Some years ago, when making experiments in orthochromatic photography, he observed frequently that some of the eosin dyes would readily stain gelatine a deep colour, and certain others would not, rhodamine for example. There was no doubt that many of these new developers, like metol, were not acted on by the oxygen of the air to anything like the same extent as pyro and some others. A solution of metol or of catechol, with a very little sulphite in it, might be left exposed to the air for a long time without showing any marked colour. Amidol, though it produced a deep colouring matter by the action of the air, did not apparently stain gelatine, nor did it stain the fingers. Ortol, which he used largely for lantern slides and bromide prints, was also remarkable for its freedom from stains. Probably the great majority of negatives were still developed with pyrogallol. When Dr. Paul Liesegang was last in England he told him that

he believed in Germany they had gone back to pyrogallol acid for all practical purposes, except in those cases where they still used ferrous oxalate. His own opinion was that metol, ortol, amidol, and paramidophenol were all distinct practical gains, and glycin also was very useful. With regard to the acetone experiments, the sulphite contained no carbonate. Although the solution was not alkaline to phenolphthalein, to make quite sure he added a small quantity of metabisulphite of potassium, a strongly acid salt, and still the development went on very rapidly, even with a small quantity of acetone. It was a new thing, and wanted working out, but he thought under proper conditions it might be very useful. It was much more convenient to have a small bottle of acetone than a big bottle of soda solution, and you escaped all the unpleasantness of using a caustic alkali. There was no difficulty now in obtaining at a moderate price, under 1s. per pound, sodium sulphite, which contained only a small trace of carbonate. Of course you must be careful where you obtain it because he knew that some of the so-called commercial sulphites were the greatest rubbish. He thought it probable that the guaiacol used by the Chairman was a vegetable product, because at that time synthetic guaiacol was not readily obtainable; it was probably far purer than the natural product.

Mr. HOWARD asked why metol acted on the fingers, and if anything could be done to prevent it.

Mr. BOTHAMLEY said he believed it was a question of idiosyncrasy. He had found no ill effects himself from using it; but, on the other hand, he knew that some few people did experience serious skin trouble from it.

The CHAIRMAN then proposed a cordial vote of thanks to Mr. Bothamley, which was carried unanimously, and the meeting adjourned.

Miscellaneous.

A TALLOW LAMP FOR GLASS-BLOWING, AND OTHER BLOWPIPE WORK.

BY THOMAS BOLAS, F.C.S. F.I.C.

Before coal gas came into use, glass blowers used a lamp containing tallow or other fatty fuel, and after a long period of almost complete disuse such lamps are once more becoming important; electric lighting having replaced gas in so many houses and public buildings.

The chief disadvantages of the old forms of tallow lamp having one large wick of soft cotton are as follows:—I. A flame with a very

large hollow is obtained, and the partially vaporised and decomposed tallow contained in the large hollow tends to blow out sideways, and give a ragged reducing flame. 2. There is a rapid burning away of the wick at the edges; this necessitating trimming and involving considerable and troublesome variations in the character of the flame. 3. The flame cannot be regulated rapidly, especially as to its fitness to furnish a small or large blowpipe flame as required.

The above disadvantages of the tallow lamp all disappear in the case of the form described below. The new form gives a blowpipe flame fully equal to the best gas blowpipe flame; and the lamp being once adjusted to the character of the flame required will remain constant for half an hour or more.

The new tallow lamp consists merely of a tin-plate tray open at the top, 1 inch deep, $1\frac{5}{8}$ inches wide, and $3\frac{1}{2}$ inches long, through the bottom of which 5 lat air-shafts $\frac{1}{8} \times \frac{3}{8}$ inch rise, and these air-shafts terminate level with the top of the tray; so that if one looks downwards on the lamp it appears as shown by Fig. I. The tray being filled with tallow (or any fat oil may be used) pieces of the compact cotton wick used for mineral oil lamps and cut to a length of 1 inch, are placed between the air shafts and lighted. Naturally one large flame is formed; but the air rising through the shafts so breaks up the central hollow, and so far brings the combustion into a smaller area, that little difficulty is found in so adjusting the air jet or blast as to obtain a good blowpipe flame, and the hard wicks, being well within the flame, scarcely suffer after many hours use. The soft wick ordinary found to be essential for use with the tallow lamp is undesirable in this case.

Fig. I.

Fig. II.

Fig. II. shows the approximate position of the six wicks (1 inch wide) and air-jet which are used when we require the largest blowpipe flame which can be maintained by one person's blowing: the

air jet in this case being nearly a quarter of an inch in diameter; but for smaller flames fewer and narrower wicks should be used. For example, an air-jet one twenty-fifth of an inch in diameter will require three wicks, each wick being one-fourth of an inch wide. The spaces between the air-shafts are so wide, as to allow the wick—as ordinarily used for mineral oil lamps—to be easily removed or changed by a small pair of tweezers, but so close as hinder any tendency to shift and disturb the adjustment. A slight adjustment of one wick or more can be made with the tweezers instantly and while the blast is maintained, so the adaptation of the fuel to the air becomes almost as easy as with coal-gas and a stopcock. It will be remarked that the lamp-body which I recommend is very small, and this necessitates the frequent dropping of fresh lumps of fuel into the open ends of the lamp-body, a matter of no inconvenience when solid paraffin or wax is used and the material is at hand in small lumps. Tallow is ideal as far as the character of flame is concerned, but it is messy to handle, and productive of smoke and smell. Paraffin-wax and white bees-wax are open to neither of these objections, and can be used in any house, or even drawing-room, without inconvenience.

The lamp, as I have made it, stands in an outer tin-plate tray about a foot square, and the bottom of the lamp is an inch-and-a-half or so above the tray. The front of the tray carries the air-jet with universal motions for adjustment, and a plain cover fitting loosely over the lamp, serves not only as a general extinguisher, but also to extinguish any burning wicks which may be taken out of the lamp and laid on the tray. I find it convenient never to trim the wicks, but to soak the stock of wick in paraffin-wax, and then cut it into 1-inch lengths; replacement of an old wick by a new one being far quicker and more convenient than trimming. As before mentioned, the wicks last a long time, and in practice they are more often changed (one at a time, and while the lamp is burning) to suit a new air-jet, than because hardened or charred at the top; and the wick material is so cheap that it is scarcely worth while to put back a wick that has been once used.

For flames considerably inclined upwards or downwards, the lamp may be trunnioned at the ends; but a tilt of about 15 degrees is the utmost practicable, as in this case the highest wick would be at least half out of the liquid fuel. Longitudinal division at the second and fourth air-shafts will make the tilted lamp like a canal divided into three locks, and now a tilt of over 45 degrees can be given without inconvenience. Adaptations of this kind are so obvious as scarcely to require mention.

Paraffin wax of low melting is better than the more expensive kinds which melt at a high temperature, and in practice it is often convenient to purchase the cheapest paraffin candles, to split them longitudinally, tear out the wicks, and to break the material into lengths of about an inch.

THE ITALIAN HEMP INDUSTRY.

It is unquestionable that hemp is the most remunerative of the agricultural products of Italy, partly on account of its own value and partly because the large amount of residuary matter is subsequently of great value to the farmer. Wherever land is suitable for its cultivation we are therefore sure to find it, and the Government statistics calculate the annual yield at 70,000 to 75,000 tons. That this calculation very much under-estimates the quantity grown seems tolerably certain, for the returns from the province of Emilia show 40,000 tons; Naples and Caserta, 18,400, which would only leave 11,600 for the provinces of Bologna and Ferrara, which are notoriously the chief producers of the article. Consul Neville-Rolfe, of Naples, says that to take those statistics which concern his consular district the sum of 18,400 tons of produce is manifestly too small, for the export trade alone shows an average of 16,000 tons, which would only leave 2,400 tons to supply the large factories of Sarno and other places as well as the considerable quantities consumed by local rope walks and other small industries. The hemp of Bologna is especially noted for its great length of fibre, which is due to the unusual height (13 feet) to which the plant grows in that region. It possesses particular strong and tenacious properties. The Naples hemp coming from lower but thicker plants is more delicate, has the merit of greater fineness, and is particularly in request for the whiteness of its fibre. In fact the different classifications, which are called, according to quality, "homespun extra 1 and 2" and "cordage 1 and 2," are made up specially according to their colour, and naturally also according to the fineness of their fibre. Heavy rain when the crop is cut and lying out to dry is one of the most serious misfortunes which can befall the farmer, as his produce loses whiteness of colour, and hence falls in quality. There are a certain number of varieties of hemp all easily propagated and crossed, as the plant bears male flowers producing the pollen or fertilising powder, and the female, from which the seed eventually comes. Hence in a region where cultivation of hemp is carried on on a large scale, the seed of one variety may easily become fertilised by the pollen of another. This leads to the crossing and fusion of all kinds. In the Naples district, whether the hemp of Carmagnola, of Bologna, of Ordei, or Pilosella, or any other kind, is sown, the plants, after two or three generations, lose their characteristic qualities, and it becomes necessary to import fresh seed from a district where only one kind is grown. Agriculturists divide the varieties of hemp into two groups, "La Gigante" (the Giantess) of tough fibre, and the "Dwarf" Nana or Ortichina (small nettle) which is lacking in fibre, and whose seed is specially used for the production of oil. But the difference between these two varieties soon disappears when they are subjected to a different cultivation from that which they have been accustomed, and this without taking into considera-

tion the effect of propagation and crossing by pollen. In practice it is most difficult to distinguish one variety from another, judging by the seed alone, and *à propos* of this, Dr. Todaro of the Agrarian Station of Modena, observes in a recent publication, that not even from the weight of the seed, or from the best sample of fruit, can one arrive at a sure conclusion, seeing that from experiments made by him on various samples in the average weight of 100 seeds of the giant hemp and 100 seeds of the dwarf hemp the difference was hardly perceptible. He cites a series of minute marks in which the two varieties differ from each other after the germination of the seed, and at the end notes how the dwarf hemp when sown in a pot and kept in a place purposely heated, flowers much sooner than the giant variety, and on an average within a month of being sown. Special experiments should be made to test the difference in richness of oil obtainable from the different varieties, in order to make quite sure that the dwarf hemp is in reality a better oil producer than the giant variety. Foreign demand for Italian hemp has been regularly on the increase, although the price since 1875 has been regularly on the decline. The cause of the fall in price is the ever increasing competition of jute hemp, largely cultivated in the East Indies, the hemp called manilla manufactured from the *Musa Textilis*, and the fibre textures of the ramine or *Boehmeria nivea* of China. Besides this, the diminution in sailing vessels, and the consequent decrease in the demand for canvas and rope, gave a great blow to the demand for hemp, although nothing up to the present has been found that can take its place in the manufacture of strong linen or running gear, for no plant surpasses it in the production of fibre of great length and tenacity. In spite of this, the export of hemp has always been on the increase, and since 1892 the exports from Italy have increased considerably. During the past ten years the cultivation of hemp has been gradually extended in the province of Terra di Lavoro to such an extent that at the present time the land between Capua and the sea, formerly given up to pasture and growing of corn, is now under hemp cultivation; the same applies to the land to the right of Volturno, where not many years ago the names of the towns of Capua and Teano were almost unknown as hemp-producing districts. In the districts of Bologna and Ferrara, and in the frontier provinces of Emilia and Rome, as well as in the lower part of Venice, the great increase in grants for reclaiming ground has transformed thousands of acres of marshes into arable land, of which a great part has been given up to the cultivation of hemp, and this increase of acreage is enough to account for the increased production. Italian hemp is said to be now taking the place of the Russian article on the different European markets simply on account of its great superiority in quality. Consul Neville-Rolfe says that one regrettable result of the increased cultivation of hemp has been the large increase of malaria in the districts where it is

grown. The hemp is cut, its leaves stripped off it, and then it is placed in ponds and weighted with large stones. These ponds give out miasmatic exhalations to such an extent as to make their neighbourhood uninhabitable. Indeed, the plant has in all conditions a poisonous effluvium, for at the end of the last century, when the British and Neapolitan armies were besieging the French at San Elmo, severe sickness broke out among the British troops, which was clearly traced to the fact that they had built their huts of hemp from the adjoining fields.

THE PINE-APPLE INDUSTRY OF THE BAHAMAS.

After sponge, the most important productions of the Bahamas are pine-apples, of which no less than nearly 5,000,000 were shipped to the United States in 1897. The report of the Acting Colonial Secretary states that they are chiefly grown in the islands of Eleuthera, San Salvador, and Long Island; but nearly every island of considerable size possesses soil which is suited to the cultivation of pine-apples. The species produced is known as the "scarlet" or "red Spanish," and is of inferior quality. It is, however, a good traveller, and four-fifths of the output of these islands go to the canning factories of Baltimore. The methods of cultivation are exceedingly primitive. As many as 20,000 plants are crammed into an acre of more or less rocky ground, and it is only during the last three or four years that chemical fertilizers have been used in these fields. In most cases the pine-apples are grown on the *metayer* system, the owners of the large tracts of land sharing with the cultivators the crop of fruit. These proprietors make advances in cash or provisions to the labourers until the reaping of a crop, and the cultivator is precluded, under an agreement, from selling his share to any other than the landlord. The price to be paid for the fruit varies from 1s. to 1s. 6d. per dozen, according to the date of production; and as the cultivator does not receive more for a fruit weighing six pounds than he does for one that is only half the size quantity and not quality is the object of his labours. From eighteen months to two years must elapse between the planting and the reaping of a crop of pine-apples, and in that interval the cultivator will have required so many advances in cash and provisions for the maintenance of his family that his account with the landlord in the shipping season is very often on the wrong side. This system is open to much objection. Apart from the unsatisfactory transactions in truck, the method acts as a bar to any improvement in cultivation, and tends to the elimination of any independence on the part of the labourer. When ripe the pine-apples are cut and carried on the heads of men and women to the beach nearest the plantation, where they are shipped in large American sailing vessels. The Acting Colonial Secretary says it will hardly be credited that in most cases the fruit

is shipped in bulk in the ship's hold, and as a large schooner will carry from 75,000 to 150,000 pine-apples, the condition of the fruit in the lowest layers, when it arrives in Baltimore, after a 10 days' passage, may be better imagined than described. In spite, however, of these intensely primitive methods, the pine-apple cultivation in the Bahamas is one of considerable profit and importance to the colony; but there is every reason to believe, if more care were taken, and a superior grade of fruit cultivated, the results would be manifestly more profitable to every one concerned. Tentative efforts are now being made to encourage the cultivation of the finer varieties of pine-apples, and there seems to be no reason why the London market, which is now principally supplied by the Azores and the Canary Islands, should not provide a profitable outlet for Bahamas fruit of a superior grade. Factories for the canning of pine-apples have lately been established in Nassau and in Eleuthera, and in 1897 they shipped more than 20,000 cases of preserved fruit.

General Notes.

MOTOR-CAR SERVICE IN FRANCE.—The first goods and passenger service by automotor cars has been established between the Montmedy and Stenay stations in the French department of La Meuse, a distance of 19 kilometres (12 miles). The pace is not to exceed 20 kilometres (12½ miles) per hour; and there are to be three departures in each direction daily. The passenger fares must not be more than 10 centimes per kilometre (1½d. per mile); and passengers taken up on the way will be charged from the last stopping place, while those so getting down will be charged to the next stopping place. Luggage will be carried free up to 30 kilogrammes (66 lb.) for every ticket of 60 centimes (6d.) and upwards, while excess will be charged at the rate of 1 franc per ton per kilometre, with a minimum of 40 centimes (4d.).

MEEINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

DECEMBER 7.—"Egypt and the Soudan, in 1897 and 1898." By W. T. MAUD, Artist and Correspondent to *The Graphic*. MAJOR-GEN. SIR OWEN TUDOR BURNE, G.C.I.E., K.C.S.I., will preside.

DECEMBER 14.—"Commercial Education." By SIR ALBERT ROLLIT, LL.D., M.P.

Papers for meetings after Christmas:—

"Tuberculosis in Animals." By W. HUNTING.

"Canals and Inland Navigation in the United Kingdom." By L. F. VERNON-HARCOURT, M.A.

"Preservation of Timber." By S. B. BOULTON.

"Electric Traction and its Application to Railway Work." By PHILIP DAWSON.
 "Coal Supplies." By T. FORSTER BROWN.
 "Wireless Telegraphy." By W. H. PREECE, C.B., F.R.S.
 "Leadless Glazes." By WILTON P. RIX.

FOREIGN AND COLONIAL SECTION.

The meetings of this Section will take place on the following Tuesday afternoons, at 4.30 o'clock :—

December 6, January 24, February 28, April 25.

At the meeting before Christmas the following paper will be read :—

TUESDAY, DECEMBER 6.—"The Yangtse Basin and the British Sphere." By ARCHIBALD LITTLE, F.R.G.S., of Chungking. The Right Hon. SIR RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., will preside.

** Numerous lantern slides of the Upper Yangtse and beyond will be shown and described by Mrs. LITTLE.

CANTOR LECTURES.

Monday Evenings, at 8 o'clock :—

PROF. VIVIAN B. LEWES, "Acetylene." Four Lectures.

LECTURE III.—DECEMBER 5.

The commercial generation of acetylene—The types of generator in use—The actions taking place in acetylene generators, and the effect upon the gas produced—The purification of acetylene for domestic consumption.

LECTURE IV.—DECEMBER 12.

The combustion of acetylene—Acetylene burners—Smoking and carbonising of burners—Burners for heating—Acetylene for gas engines—Diluted Acetylene and its applications.

DR. SAMUEL RIDEAL, "Bacterial Purification of Sewage." Four Lectures.

January 16, 23, 30, February 6.

ARCHIBALD SHARP, A.M.Inst.C.E., "Cycle Construction and Design." Four Lectures.

February 20, 27, March 6, 13.

PROF. HENRY R. PROCTER, "Leather Manufacture." Four Lectures.

April 10, 17, 24, May 1.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 5...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. Vivian Lewes, "Acetylene." (Lecture III.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. George Thudichum, "Bacterial Treatment of Sewage."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Colonel W. J. Engleclue, "Oxone and its Commercial Applications." 2. Mr. Arthur Marshall, (a) "An Improved Apparatus for the Estimation of Carbonic Acid in Minerals, &c.;" (b) "The Preparation of Standard Solutions of Sulphuric Acid."

Imperial Institute, South Kensington, 8½ p.m. Sir J. Benjamin Stone, "A National Photographic Record."

Surveyors, 12, Great George-street, S.W., 8 p.m. Adjourned discussion on the paper by Mr. H. T. Eve, "Compensation Values of Cattle Foods—Chemist *versus* Valuer," will be resumed.

British Architects, 9, Conduit-street, W., 8 p.m. Japan Society, 20, Hanover-square, W., 8 p.m. Mr. S. Kajima, "The Art of Flower Arrangement in Japan."

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Mr. Theo. G. Pinches, "Recent Discoveries on Babylonian Tablets."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. H. A. Kennedy, "The Story of Canada."

TUESDAY, DEC. 6...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Foreign and Colonial Section.) Mr. Archibald Little, "The Yangtse Basin and the British Sphere."

Civil Engineers, 25, Great George-street, S.W., 8 p.m.

Pathological, 20, Hanover-square, W., 8½ p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m.

Biblical Archaeology, 37, Great Russell-street, W.C., 8 p.m.

Colonial Inst., Whitehall-rooms, Whitehall-place, S.W., 8 p.m. Dr. Alfred P. Hillier, "The Native Races of South Africa."

WEDNESDAY, DEC. 7...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. T. Maud, "Egypt and the Soudan, in 1897 and 1898."

Geological, Burlington-house, W., 8 p.m.

Entomological, 11, Chandos-street, W., 7 p.m.

Archæological Association, 32, Sackville-street, W., 8 p.m.

Obstetrical, 20, Hanover-square, W., 8 p.m.

THURSDAY, DEC. 8...Royal, Burlington-house, W., 4½ p.m. Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Josiah Booth, "Humour in Classical Music."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Prof. Oliver Lodge, "Improvements in Magnetic Space Telegraphy;" and if time permits—Mr. Sydney Evershed, "Telegraphy by Magnetic Induction."

Mathematical, 22, Albemarle-street, W., 8 p.m.

FRIDAY, DEC. 9...Astronomical, Burlington-house, W., 8 p.m.

Junior Engineering, Westminster Palace Hotel, S.W., 8 p.m. Mr. E. A. Heath, "British Cable Tramways and their Construction."

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Chemical Society's Rooms, Burlington-house, W., 5 p.m. 1. Dr. C. Chree, "Longitudinal Vibrations in Solid and Hollow Cylinders." 2. Mr. J. Rose-Innes and Dr. Sydney Young "The Thermal Properties of Normal Pentane."

SATURDAY, DEC. 10...Botanic, Inner Circle, Regent's-park, N.W., 3¼ p.m.

Journal of the Society of Arts.

No. 2,493. VOL. XLVII.

FRIDAY, DECEMBER 9, 1898.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be given on Wednesday evenings, January 4 and 11, 1899, at 7 o'clock, by Professor F. JEFFREY BELL, M.A. (of the Department of Zoology, British Museum). The first lecture will be on "Hands and Feet," and the second lecture on "Some Ways in which Animals Breathe." The lectures will be fully illustrated with lantern slides.

A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received. Subject to these conditions each member is entitled to a ticket admitting two children and an adult.

The tickets for the lectures are now ready, and can be had by members on application.

CANTOR LECTURES.

On Monday evening, 5th inst., Professor VIVIAN B. LEWES delivered the third lecture of his course on "Acetylene." The lectures will be published in the *Journal* during the Christmas recess.

FOREIGN & COLONIAL SECTION.

Tuesday afternoon, Dec. 6, 1898; The Right Hon. Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., in the chair. The paper read was "The Yangtse Basin and the British Sphere," by ARCHIBALD LITTLE, F.R.G.S., of Chang-king.

Numerous slides of the Upper Yangtse and beyond were shown and described by Mrs. Little.

The paper will be published in a future number of the *Journal*.

Proceedings of the Society.

FOURTH ORDINARY MEETING.

Wednesday, December 7, 1898; Major-Gen. Sir OWEN TUDOR BURNE, G.C.I.E., K.C.S.I., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Granger, Arthur Otis, Girard-building, Philadelphia, U.S.A.

Johnson, Alexander Banks, Bringewood, Mulgrave-road, Sutton, Surrey.

Kitching, Henry, J.P., The Grange, Great Ayton, Yorkshire.

Lutwyche, Stanley, 3, Chichester-terrace, Brighton.

Stevens, Charles, 10, Wemyss-road, Blackheath, S.E.

Winch, Richard, Morden-grange, Kidbrook, Blackheath, S.E.

The following candidates were balloted for and duly elected members of the Society:—

Aström, Carl A., 83, Cannon-street, E.C.

Baylor, Armistead Keith, 23, Cadogan-gardens, S.W.

Cole, Philip Henry, 20, Lessing-street, Honor Oak-park, S.E.

Courtney, Charles Frederick, Central Mine, Broken Hill, New South Wales.

Leach, Herbert Louis, 28, Leigham-court-road West, Streatham, S.W.

Magnus, Sir Philip, 16, Gloucester-terrace, Hyde-park, W.

Spencer, John W., Newbiggin-house, Kenton, Northumberland.

Strutt, Denner John, The Firs, Strawberry-hill, Middlesex.

Thomas, Richard Beaumont, J.P., Dannel-hill, Tidenham, Gloucestershire.

Van Raalte, Jacques, Holland-house, Broadwater Down, Tunbridge Wells.

The CHAIRMAN, in introducing Mr. Maud, said that although still young, he had already been as special war correspondent and artist of *The Graphic* through something like seven campaigns. He was in Constantinople at the time of the Armenian sacrifices, he was in the Greek War, twice in the Soudan operations, and in the expedition on the North-West Frontier, so that he would be listened to with a great deal of interest.

The paper read was—

EGYPT AND THE SOUDAN IN 1897-98.

By W. T. MAUD.

The battle of Omdurman is still fresh in our memories, it will stay with us until our dying day, it will adorn for ever one of the brightest pages in the history of the British Empire. It stands by itself as a great and glorious fight.

Yet, in reality, it is nothing more than the brilliant climax of a grand drama: the supreme moment that is only attained after a series of acts which, taken separately, are not remarkable for exciting scenes or stirring incidents. The acts to which I refer are the campaigns of 1895, 1896, 1897, 1898. Each one is the sequence of its predecessor, each one is stamped with the same characteristic feature—progress. The period of defeat, dishonour, and retreat was ended, and a new era had dawned in the dark history of the Soudan.

The comprehensive treatment of so vast a subject as the overthrow of Mahdism is a manifest impossibility within the limits of a single lecture—I might even say within the limits of twenty lectures. Therefore I propose to-night to deal more particularly with the picturesque features of the final campaign in the Soudan, and of that which immediately preceded it.

It was in the month of July, 1897, that I left London for the Soudan to take part in the advance on Omdurman. I was filled with enthusiasm at the prospect of a campaign in that land of battlefields, and of marching side by side with British officers, so many of whom had already earned high reputations for their qualities of fighting, keenness, and organisation. The prospect was made the more pleasurable to me by the fact that only six weeks previously I had witnessed all the disasters that had befallen the Greek army in Thessaly, an army in which those soldierly qualities I have just mentioned were so conspicuously absent.

My first glimpse of the Egyptian army was gained in the workshops of the Citadel at Cairo. This ancient fortress crowns the crest of a bare rock hill to the eastward of the city, and the view from its battlements is one of the grandest in the world. At one's feet lies Cairo, a glittering mass of masonry, beautified throughout its broad extent by the golden domes of the mosques, the tall and graceful minarets, and countless gorgeous palaces. In the distance the grand old Nile rolls up from the South, and beyond the dark line of palm trees on its banks, rise the wondrous Pyramids of Gizeh, floating like phantoms in the heat-haze of the desert.

Within the Citadel lie stored a host of interesting relics of past magnificence; indeed, each stone of the crumbling wall has a history of its own; but these things are beyond my province altogether. I went there to see the Arsenal, the cradle of Egypt's young army,

and I found it amidst the ruins of her ancient power. The dry bones had received the breath of life once more, and every workshop rang with the busy hum of toil, as it did in the days of Mehemet Ali. This great work of resuscitation was inaugurated four years ago by Major S. Gordon, R.E., the nephew of the great General Gordon, and it is under his careful supervision that the Arsenal has developed into a complex and efficient machine, thoroughly up to date and in full working order.

In passing through the various departments, one is struck by the fact that economy, and economy of the very strictest kind, is enforced throughout the establishment. For instance, here one sees the old brass Martini cartridge cases being melted down and the metal made to do new service in various ways. In one of the workshops I saw two or three men repairing bugles, and the means employed by them most certainly possessed the virtue of simplicity. The workman took up a broken and crumpled trumpet which had once been used in Arabi's army, and into the mouth of it he dropped a number of bullets, each slightly bigger than the preceding one. He then began to shake the trumpet up and down until first one and then another of the balls was forced through the dent by the weight of those behind them, and in this manner the tube became gradually straightened out. Close by these workmen a little boy squatted on the ground and manipulated a goatskin bellows, which communicated with a charcoal fire laid inside an old water-bucket. This primitive apparatus served as a forge for the trumpet menders, who thus heated their soldering irons. There were several of these bugles mended and polished hanging on the wall ready to be sent to a battalion, and no one but an expert could have told they were not brand new. The next department I went into was also a sample of economy. Martini rifles that had been worn at the muzzle by the cleaning rod were being cut down and converted into carbines. The director of the armoury told me that their shooting qualities remained excellent up to 500 yards, which is of course an extreme range for cavalry. The old and new fashioned methods of constructing war material are clearly demonstrated when one passes from the small arm factory with its trim and neat machines into the old gun foundry used by Mehemet Ali. The place is lofty, dark, and picturesquely tumble-down, but the huge beams and ponderous wheels with which the guns were bored and moved about

still stand as they were left by the old warrior. In his day the motive power was supplied by buffaloes harnessed to a wheel, but now steam and oil engines set every kind of machinery in motion. In the Citadel there are many workshops and departments, but they are not in themselves of any great importance, though each one plays its part, however humble it may be, in the reconquest of the Soudan. With a visit to the Citadel, one may say that the military interests of the city are exhausted, for with the exception of a British battalion at the Kase-el-hil Barracks, and the Khedive's body-guard, there are no soldiers to be seen in Cairo. The Egyptian army is concentrated in the Soudan, one day fighting the Dervishes, the next building railways, hospitals, and barracks in the reconquered territory, and establishing civil government. We will therefore pass at once from Cairo to Wady Halfa, which is, or rather was in 1897, by far the most important town upon the Nile. Wady Halfa is the most unpretentious city in the world, but it is, nevertheless, a most remarkable one. It marks the highest point reached by the wave of Mahdism, which rose in Central Africa and swept northwards to Egypt, carrying all before it. Here the Dervishes surged around the loop-holed fortifications which surround the town, and after many vain attacks, they retired to Dongola. Wady Halfa then had rest, and its aspect began to change. From being nothing more than a frontier fortress, it developed into a railway depot. Lord Kitchener was then Sirdar, and he initiated the grand principle of fighting the Dervishes by railway. He had been with Lord Wolseley in 1884-5, and he had seen the disastrous results which were brought about by lack of adequate transport. He had seen that the necessities of a civilised army, sufficiently powerful to reconquer the Soudan, could never be brought to it over the burning desert by camels alone. He, therefore, commenced to build the railway which now ends at Kerma, and which enabled him in 1896 to reconquer the province of Dongola. Dongola taken, the Sirdar then set out from Halfa with another railway for Abu Hamed, on the south side of the Nubian desert. Abu Hamed at that time was in the hands of the Khalifa, but that fact made no difference to the plans of the Sirdar. With sublime self-confidence he set himself the Herculean task of crossing 225 miles of sandy wilderness. It was a huge fight against the forces of nature, but the Sirdar won it, and thereby saved us many battles against the Dervishes

When I arrived at Wady Halfa the rail-head had already eaten its way 100 miles into the desert. One day in the Sapper's Mess I heard that water had just been found at No. 4 station. The young subalterns of Engineers, who built this line, were jubilant at the result of their well-sinking, for every one, including the indigenous Arab, had laughed to scorn the notion of finding water in the heart of the desert. I received an invitation to run out to railhead and inspect the workings, and this opportunity I eagerly embraced. From the time that the train steamed out of Halfa until it rolled into the railway battalion camp, there was always something to wonder at and admire. Three colleagues and myself embarked in a carriage marked "saloon," attached to the end of a long train laden with every kind of railway plant. Our "saloon" had no cushioned seats or chairs, it would not be accepted in England as a third-class carriage, but it was roomy and airy, which is all that a traveller wants in the Soudan. The engine which drew our train was a new machine, built on the "bogey" system. It had lately come out from England in small pieces, and it had been fitted together in the workshops at Halfa. It weighed over sixty tons, and it was capable of pulling 300 tons. The gauge of the permanent way is 3 ft. 6 in., exactly the same as that of the Cape railways, which it is destined some day to meet. Next to the engine came five bogey trucks, each one bearing an enormous iron water-tank. Behind them was attached the remainder of the train, which was made up of trucks filled with sleepers, rails, telegraph poles, and food for the railway battalion. It will give some idea of the enormous difficulties which beset the construction of this desert railway, when I say that each of the 3,000 men who were always at work upon it consumed three gallons of water a day—that is, 9,000 gallons a day. The engine which runs out from Halfa and back had to take sufficient water for a 30 hours' run, and another engine, which was permanently working at railhead had also to be supplied with water. In addition to this the 3,000 men had to be fed, and every day one mile of rails and 2,000 sleepers had also to be brought out. Then again, precautions had to be taken against the possibility of a breakdown, for had this occurred, the railway battalion would have been cut off from their water, and the lack of water in the desert means death. This stern fact accounted for the ponderous iron

tanks, which were the most remarkable features of the train which conveyed us into the desert. We correspondents were particularly fortunate on this occasion, for we had as travelling companion Lieut. Girouard, R.E., D.S.O., the director of the Soudan Military Railway (this brilliant young officer has since been promoted to the rank of Major in the Royal Engineers, and he is now the Director of Egyptian Railways, with a salary of £2,000 a year).

We left Halfa in the afternoon, and early the next morning a long line of tents appeared upon the horizon. This was Railhead Camp, and here we left the train and were welcomed by the Sapper officers, who had prepared an excellent breakfast. While the meal was in progress we gathered some interesting items with regard to the building of the railway. There are two railway battalions, made up of both Egyptians and Soudanese. They are civilians, but they receive soldier's pay and rations. Amongst them are a great number of Soudanese who were taken prisoners at Firket and Dongola in 1896. The black man is always light-hearted, and ready to laugh at any time and any place. Nothing seems to depress him, and no amount of toil to tire him. Imagine these men working out in the desert, a hundred miles from anywhere, month after month, from sunrise to sunset, in a choking cloud of dust, with the thermometer at 120° in the shade; yet in spite of all these adverse circumstances, the railhead gang was one of the merriest set of men in the world.

When the material train steamed into camp from the workings, the men scrambled out of the trucks laughing and chaffing and playing jokes upon one another like a lot of boys let out of school.

There was one very remarkable individual in the camp, called Samit. He was taken prisoner at Dongola, and he had fought against us at Hafir. He was a wonderful mimic and contortionist, and his *repertoire* consisted chiefly of imitations of the different Dervish leaders under whom he had served. Wad-el-Bishara was taken off by this savage comedian in the most beautiful manner. We saw how the Dervish leader crouched behind the fortifications and trembled with fear when our shells flew screaming over his head. But the most marvellous of all his performances was the rather gruesome imitation of a man being hanged. Samit in this was perfect and horrible. The protruding eyeballs, the spasmodic jerk of the limbs, the quivering tongue,

all these were imitated with wonderful fidelity. The gestures of a special artist making rapid sketches did not escape the watchful eyes of Samit. It was not long after my arrival in the camp that he was seen on the top of a truck in an exaggerated posture sketching his comrades amidst roars of laughter.

By the time breakfast was over, the material train was loaded up with more rails and sleepers, and a start was made for the workings, about five miles out of camp, and here we saw exactly how the line was being built. The surveying party were on ahead, measuring, taking levels, and deciding the course of the railway. Behind them came the "bankers," who built a bank or dug a cutting, according to the nature of the ground. Then the material train arrived, creeping slowly along to the end of the rails already laid and there stopped. Immediately the workers jumped down from the trucks, and so admirably were they drilled that without any confusion the men at once fell into their appointed places. The first thing was to unload the sleepers and lay them down along the track in front of the engine. When this was done the rails followed, and were placed in position and held there temporarily by iron spikes. When a hundred yards or so were ready, the engine crept forward again, and halted only to disgorge more sleepers and more rails. It was a magnificent sight. We watched the work go on spellbound. The engine, the material train, and the workmen were enveloped in a cloud of sandy dust, every form became indistinct. Under the blazing tropical sun the component parts became merged into a fiery mass; it was no longer a machine and men working like machines: it was an irresistible monster taming the savage pitiless desert.

The construction of the Abu Hamed Railway was undoubtedly the chief feature of the campaign of 1897. It was vastly more important in its results than the battle of Abu Hamed, for without that railway the British flag would never have been hoisted at Khartoum on the 3rd of September last. The Khalifa's army, encumbered by an enormous transport, would still have been creeping slowly southwards along the Nile to Omdurman. Abu Hamed was bound to fall into our hands sooner or later, though that event came upon us as a surprise. The reason for General Hunter's sudden dash upon that place was the result of information brought to Merawi Camp by the friendly Arabs, to the effect that the Khalifa was sending troops from Berber to reinforce it. The strength of it

garrison was known to the Sirdar, so he decided to seize it before the reinforcements could arrive. With Abu Hamed taken, Berber became untenable to the Dervishes, who evacuated it, and retired upon Metemneh.

With Abu Hamed taken, the Sirdar at once pushed on his troops to Berber, and occupied it, and when this important city fell into our hands, the whole question of the Soudan became much less complicated. By the fact of its falling, the Khalifa lost the use of a very powerful limb. The Eastern Soudan, where for so many years the wily Osman Digma reigned supreme, was no longer an element of menace to our advance, and the pacification of the tribes which inhabit the country between the Nile and the Red Sea became a very simple thing. The battle of Abu Hamed, and the occupation of Berber, took place before my colleagues and myself had reached Merawi, which was the point from whence the Sirdar struck this blow. There appeared to be no prospect of immediate fighting, and the great question in camp was whether a British expedition would be sent out or not. There was nothing for us to do but wait for further developments, so we proceeded to make ourselves as "comfortable as possible," which is a watchword of the Egyptian army in the Soudan. Our position, as war correspondents, was really an unenviable one. We had travelled nearly 4,000 miles from London to record the military operations of the Egyptian army, and the first thing we learnt on arrival at headquarters was that the fighting was all over for the present. For us there would be no riding immense distances with exciting news, no smoke and roar of battle, no moving pictures of an army on the march. We strove to attain unto the philosophy of the Orient, which enables a man to preserve his equanimity under the most adverse circumstances, to cast from his mind all troublesome and disquieting thoughts, to find eternal consolation in the utterance of that all-embracing word "Mahlesh," which means "It is a small thing," "It does not matter," "Do not worry about it," &c. &c. I cannot say that we succeeded greatly in our efforts to assume this sublime attitude—the intense heat and choking dust storms interfered too frequently with our labours—and life at Merawi would have been unendurable but for the genial and untiring hospitality which we received from the officers of the Egyptian army.

While there I made a very enjoyable ex-

pedition from the camp to the pyramids of Napata, which are situated on the opposite bank of the Nile. These pyramids lie clustered together on the western side of Gebel Barkal mountain, a huge mass of sandstone rock which rises majestically out of the desert. It was my great privilege to have as a companion on this occasion Dr. Wallis Budge, the Keeper of the Egyptian Section of the British Museum. He had been sent out by the Government to make excavations among these interesting and little-known relics of the past. His presence at Merawi was not officially made known; in fact, we correspondents were requested not to mention his name publicly, because the Sirdar had received so many applications from Egyptologists all over the world, asking for permission to excavate, a permission which it was impossible to grant them at that time. I learn that Dr. Budge is on the point of bringing out a book upon his discoveries at Merawi, therefore I feel myself at liberty to refer to him now. He and I had arranged to go on board our giasseh and cross the river at midday, but the "reis" and his crew did not put in an appearance until four o'clock in the afternoon. It was a good opportunity for the use of the word "Mahlesh," but I fear we expressed our feelings to the "reis" in more forcible English. This delay meant that we should not reach our destination until long after nightfall, because there was no wind for sailing, and the muddy waters of the Nile at this season of the year run down at the rate of eight miles an hour. The width of the river at Merawi is nearly a mile, and by the time we reached the opposite bank our boat had drifted a mile or more down stream. Then the crew got out and commenced to tow us up the river. It was a very tedious and slow means of progression, for every hundred yards or so we came across a "sakeyeh," one of those ponderous water-wheels which are so characteristic of the Nile, and which groan day and night while they feed the tall date palms and green dhurra fields around them. These pumps, though indispensable to cultivation, are an unmitigated nuisance to the river-side traffic, because the tree trunks which support them just out far into the deep water, and a lot of time is wasted in passing the tow rope round the outside of them. We negotiated thirty or forty of the sakeyehs before sunset, and the reis then came to say that he would not be able to bring us to our destination. The prospect of passing the night in his ramshackle boat did not appeal to us at all, so we told him we

would make it our business to get him dismissed from the Government service on our return to Merawi. (I should say that at that time every boat on the Nile between Halfa and Berber was impressed into the service for the transport of military stores.) This threat, coupled with that of "no back-sheesh," had the desired effect, and he swam ashore to join his men at hauling the boat along; and about eight o'clock we reached Gebel Barkal, where we were carried ashore in the stalwart arms of the boatmen. We groped our way across some small fields and irrigation channels until we reached the Sheik's house in the village, where our quarters were to be. Here a frugal meal of sardines and bully beef awaited us, spread out beneath the palm trees; and when dinner was over, we retired to our "augureets" or native beds, for the night. It was so hot and close, that I got my servant to move the bed out into the open ground away from the trees.

The following morning I awoke to find myself in the centre of a small lake, with the water half way up the legs of the bed. It then dawned upon me that my augureet had been placed in a dhurra field, which the owner had commenced to irrigate during the night. There was nothing for it but to wade through the mud and water to dry land and finish my toilet surrounded by a laughing circle of Arabs and their wives. After breakfast, donkeys were brought round and Dr. Budge and I started for the pyramids. We rode for a mile or more over splendid soil that had once been cultivated, but which, under Dervish rule, had returned to its original desert state, and produced nothing but the poisonous Sodam apple. Here were thousands and thousands of acres of rich ground ready to yield two rich crops every year, if only the irrigation channels could once more be filled with water. But the owners of the soil had long since been looted of all their cattle and able-bodied men, and the result was desolation.

The pyramids are six in number and, with one exception, they are all in a wonderful perfect state of preservation. None of them, however, are of such vast dimensions as the pyramids of Gizeh; the largest does not exceed sixty feet in height. They appear to have been built in groups of three, placed at right angles to one another. The stones which form the outer facing are small, not more than 3 feet long by $1\frac{1}{2}$ in depth, and they are not fitted closely to one another. In places where these have fallen away, one sees that the interior is

built of small stones and rubble, indicating a late period in Egyptian history, and the decadence of its architecture. A gang of Arabs, who were employed by Dr. Budge, were sinking a shaft under the foundations of the central pyramid, where it was hoped that the passage would be found which communicates with the interior of the pyramid. Whilst watching these men digging away the earth and levering up huge blocks of stone, I began to feel the excitement of the explorer. History has no record that these ancient tombs have ever been opened, and who could tell what priceless treasures might be concealed beneath this mass of masonry, what rare inscriptions might adorn the walls of its sepulchral chambers?

Not far away from the pyramids stands the remains of the temples of Napata. The hand of time and man has turned with terrible effect against these glories of a departed age, and the place to-day is truly an "abomination of desolation." Here and there a sphinx's head, minus the nose or the chin, peeps at you round the corner of a carved and polished block of granite. Of the hundred or more columns which still raise their heads above this broad expanse of ruin, not more than two retain their capitals, and both are in a tottering condition. Quite close to them there is a small temple, carved out of the sheer up-cliff of Gebel Barkal. It contains three chambers, the central one being the largest, with two smaller ones on either side of it. In every case the walls are richly decorated with hieroglyphics, and in some places the original colouring remains. It is, however, extremely difficult to trace the details of the carvings, for the wild bees have found them convenient projections on which to build their little nests.

Gebel Barkal, as it is now called, was once the capital of Ethiopia. In the unsettled times which followed the death of Ramses II. the Ethiopians saw that the power of Egypt to retain her supremacy abroad was becoming less and less. For many years they paid the customary tribute to the feeble successors of Ramses, but at the same time they looked forward to the day when they could cast off the yoke of Egypt. They had adopted Egyptian civilisation, the hieroglyphic form of writing language, and also the religion of Egypt. They seemed to have wished to make a second Egypt in Ethiopia. During the reigns of the kings of the twenty-first and twenty-second dynasties the power of Egypt continued to decrease, and the Ethiopians boldly resolved to

found a kingdom of their own, and they chose Napata as the site of their capital. The founder of the kingdom was one of the descendants of the priest kings of the 21st dynasty. Early in the 8th century, B.C., Piauchi was king of Napata. In the 21st year of his reign he marched northwards and defeated the army of Tafuecht, Prince of Sais and Memphis, first at Thebes, then at Hermopolis, and finally at Memphis. The rebel princes came in one by one and tendered their submission to the Ethiopians, and thus Piauchi became master of Egypt. All this and more is written large in hieroglyphics on the rock walls of these ruined temples and the broken fragments of the columns which block up the entrance to them.

A few days after my visit to the pyramids permission arrived from the Sirdar for the correspondents to proceed to Berber, so we lost no time in striking our tents and bidding farewell to Merawi. We followed the line of march taken by General Hunter when he advanced on Abu Hamed, and we reached that place in ten days. There were no exciting incidents to break the monotony of this long march, one day was exactly like another, and with the exception of Hebba there was not a single place of interest to visit by the way. It will be remembered that it was at Hebba that Colonel Stewart and his companions came to an untimely end. He was sent down by Gordon from Khartoum in the steamer *Abbas*, with full details of that gallant man's desperate position. Through the treachery of the "reis," the steamer was run upon the rocks in a narrow channel of the rapids, where she stuck fast. Seeing that the boat was of no further use, Colonel Stewart and his party landed at Hebba, where they were received with every mark of hospitality by the Sheikh Fakri Wad Osman. He told them he would afford them all the aid he could, at the same time sending off a messenger to Sheikh Sulieman Wad Gamr to tell him to come with all his people, for he had the "infidels" at his mercy. Poor Stewart trusted his host, even so far as to enter his house unarmed, and when the reinforcements had arrived from Wad Gamr, there ensued a brutal butchery which only ended when all but the native interpreter had been cut to pieces. This is an outline of the tragedy of the *Abbas*, and it was not without a feeling of depression that we saw, as we gained the last eminence overlooking the river, the remains of the steamer lying wedged between the ugly rocks, a grim relic of a terrible disaster.

The people of Hebba belong to the Monasir

tribe, which is well known throughout the Soudan for inhospitality. In travelling through their villages we had remarked upon their sullen demeanour towards us. They had been punished in 1885, for the murder of Stewart, by the River Column, under General Brackenbury, and a good many of their villages were destroyed. The present village of Hebba is immediately opposite to the island with the wrecked *Abbas* upon it. The channel was not more than 100 yards wide, but the water was broken and decidedly swift. However, a colleague and myself could not resist the opportunity of a closer inspection of the wreck, so we swam across. Our servants produced water-skins, which they inflated, and they tried to instruct us in the art of swimming with them, but they were so unsteady that we discarded them. The current was very swift, but by dint of hard swimming we got into the slack water at the tail of the island, and waded ashore. I put my sketch-book inside my helmet, and in this way carried it across without wetting it. We found that there was very little left of the ill-fated steamer, when we got alongside of her; her peak stuck up out of the heavy sand, and the only thing wholly visible was her boiler, which seemed to be quite sound. Part of her bulwarks still remained, scored with many bullet marks, and the bulky pieces of her machinery lay half buried in the sand, but all the wood work and light iron had been carried away by the natives. We searched about for any relic that might remain, but found nothing, so we plunged once again into the river, and regained the opposite bank.

We left Hebba the following morning and arrived at Abu Hamed two days later. Abu Hamed is only important now as being one of our victorious battle-fields in the Soudan. It is difficult to judge of what the place appeared formerly, since the greater part of it has been destroyed to make way for the new railway line which was only a few miles out in the desert when we passed through. It had been our intention to stay at Abu Hamed some days and rest our weary horses and camels, but finding that the Sirdar had taken up his residence at Berber, we determined to take the road again. Just before we left we were informed that a party of Dervish horsemen had swooped down upon the village of Abaddia, only seven miles north of Berber, and had killed and mutilated eleven of the inhabitants, at the same time carrying off a number of women and the Sirdar's mail, which happened to be halting there. An avenging force, consisting

of a company of the Camel Corps under Captain King, and Abdul Azzim Bey's Ababdeh irregulars, was sent out in pursuit, but the Dervishes did not wait to try conclusions, and in their haste to get away they dropped all their loot, including the mail bags. There was great excitement at Abu Hamed over this event, and the likelihood of our coming across a raiding party, added a zest to the journey. Our caravan numbered twenty-three persons, but all of us were armed, so we felt fairly confident of being able to resist any attack. However, we were not molested, and reached Berber without any exciting incident, making the 125 miles in five days. At Abu Dom, a small village at the head of the 5th Cataract, we halted for a few hours at mid-day, and the Sheikh showed us the boat in which Slatin Pasha crossed the Nile during his memorable escape from Omdurman. It was a curious ramshackle kind of craft, made of three baulks of hollowed-out palm trees, lashed together with bits of rope grass.

On arrival at Berber, after a thirty-five mile march, we reported ourselves at once to Colonel Wingate, the head of the Intelligence Department, and he did everything to make us comfortable. I shall never forget his kindness in sending us not only blankets and bedding, but his own cook and servants, and an excellent dinner to boot. The following morning we were presented to the Sirdar by Colonel Wingate. It would be superfluous on my part to give you at this time a description of Lord Kitchener, so I will merely say that he received us with that courtesy which is so characteristic of him. He told us frankly that the campaign was over, that he would not advance until the Nile rose again, and that he did not anticipate being attacked by the Dervishes. Under these circumstances he recommended us to return home, and he offered us the option of doing so either by the Abu Hamed railway, or across the desert to Suakim.* He told us that the latter route was practically safe for caravans, especially at that particular time, because General Hunter was away with a brigade scouring the country between Berber and the Athara, and he would cut off any raiding bands of Dervish cavalry.

The prospect of the journey was a most fascinating one, and it is needless to say that we eagerly accepted this opportunity

of seeing practically a new country, and of having the honour of opening the road from Berber to Suakim. The next few days were given up entirely to preparation for the journey. The difficulty of getting a guide was solved for us by Colonel Wingate, who gave us a fine-looking Bisbarin, named Osman, whose relatives in the old days had been "Sheikhs of the Post" between Suakim and Berber. We were deep in the bustle of preparation, when the arrival of Major Sparkes, commanding the 4th Egyptian Battalion from Suakim, with an armed patrol, aroused our keenest interest. His arrival was quite unexpected, and for us it was an added guarantee of the safety of the road. As soon as possible I went off to see the first British officer who had crossed the desert since the rise of Mahdism. His information about the road was of the utmost value to us. We learnt from him one most important fact, which was that the wells at Obak afforded no water for camels, and this news was far from cheering. Obak lies about half way between Berber and Ariab Wells, distant 112 miles, and we had calculated on being able to water our camels there. There were wells six miles out of Berber, but that was all, and we had before us 106 miles to cover without water.

To those who have read the books of our boyhood, when the camel did all sorts of wonderful things, and kept a kind of reservoir of cool crystal water in one of his seven stomachs, the distance we had to travel seemed nothing, but the plain truth about it is that the camel cannot go for four days without water, unless he is trained for it beforehand. The camel has, first of all, to be deprived of water for two days, then for three, and the start must take place just after he has drunk enough for four. We, however, were obliged to start before this process could be gone through, so it was once more a case of "Mahlesh," and we decided to leave Berber on the 30th October, and trust to our luck. Our examination of the camels that were to convey us over the 245 miles of desert was not encouraging. There were 20 of them, all wretchedly thin, and covered with half-healed sores, and we cursed our guide, Osman, for supplying such useless looking animals. He only smiled an Oriental smile, and assured us that they were some of the finest examples of their race to be found in the Soudan, and that all of them were in wonderfully hard condition. For once he certainly spoke the truth, for there was not a soft lump of fat to be found on one of

* This journey from Berber to Suakim was described by Mr. Frederic Villiers, one of the party, in his paper read before the Foreign and Colonial Section of the Society, on the 18th January last.

them. However, the camels were there and we had to start, so we ordered him to put on the loads and proceed to Mahobeh Wells, where we would overtake him. Major Walter and the officers of the 9th Soudanese kindly gave us a farewell dinner, and about nine o'clock we mounted our camels and rode out of Berber, heading due east. Gradually the silver streak made by the moon across the hill became smaller and smaller, and finally disappeared altogether as we dipped down over a small ridge. Thenceforward we should see no welcome stretch of water until we came in sight of the dancing waves of the Red Sea. About eleven we arrived at Mahobeh, where our servants and the camels were waiting for us. Our original intention had been to start at daybreak the following morning, but in the East plans are made to be disarranged. We awoke to find the rest of the party, except ourselves, fast asleep, although we had given them orders to be ready at daybreak. A shout or two brought them all to their feet, and we ordered them at once to "shid," *i.e.*, load up. There was a look of astonishment on their faces. "But we must wait for Osman," they said. "Osman, why, isn't he here?" "Oh, no, he had not arrived from Berber yet." Our feelings with regard to Osman can be more easily imagined than described. Not content with getting us the most decrepit camels he could find, he had actually stayed behind, and was keeping the whole caravan waiting. "But why is he staying behind," we asked indignantly. "Ah! sir, he must say good-bye to his wife;" and this was all the answer we could get. However, we made them water the camels and get the loads ready. Most of the animals drank eagerly enough, but one of them absolutely refused to touch the water, so the camel man grasped it by the upper and lower lips and twisted them round like a pig's tail, while another man emptied three or four water skins down his throat. Amongst our animals we had two cow camels, with young ones running at their heels. One was about two months old, but the other was only seventeen days, and it was one of the prettiest creatures imaginable. It was covered with dark brown curly hair of great softness, and it kept frolicking around like a kitten. Towards the end of our long waterless march we noticed that the little fellow became very subdued, and showed every sign of great fatigue. By the time everything was ready for a start the sun was high in the heavens, and our guide, Osman, had not arrived.

However, we had in our company two young Arabs, the sons of two Sheikhs of the region through which we should pass. Their fathers had been taken to Berber by Major Sparks, and were kept there by the Sirdar as hostages for our safety. The young men knew the way, so we set out upon our long ride across the desert, leaving word at the well for Osman to come and catch us up, which he did in the course of the day.

To describe the journey from Berber to Suakim in detail would be wearisome; the desert is always the same, no matter if you ride one mile or one hundred. Once embarked on this sea of sand, your only object is to get across it as quickly as possible. You know that there are wells at certain points, generally far apart, and your only anxiety is to find them. If you fail in this, you die of thirst, which is one of the most awful deaths in the world. These reflections were forced upon us when we reached Obak Wells. We saw that some of the camels were already beginning to feel the effects of two days without water, and the last half-day's march had been made through loose drifted sand, into which the camels' broad feet sank above the fetlocks. Obak Wells consisted of three little holes in the sand, and around each of these sat stolidly a group of women. These ghouls had filled up the holes with sand, and there was no chance of the water forcing its way through for a long time to come.

The people who inhabit the small patch of fertile land around the wells belong to the Bisharin tribe, and their Sheikh was with the Dervishes, and it was for this reason that we were unable to procure water. (Since our ride across the desert these and many other wells have been greatly improved and placed by the Sirdar in the hands of responsible people.) An inspection of our camels resulted in a decision to push on as rapidly as possible to Ariab, where we knew there was plenty of water, so we started the following morning at dawn. From Obak we commenced to draw upon our reserve of drinking water, which had assumed a dark brown inky colour, the result of being kept for three days in the half-cured goat skins. The taste of it also was terribly bitter, but we all had a thirst that made light of such trifles. We travelled as much as possible at night in order to save the camels, for under the burning rays of the mid-day sun they perspired freely. This night marching robbed us of our sleep, for it is too hot for a white man to sleep in the Soudan when the sun is up, but Ariab was two long

days' marches from Obak, and there was nothing else to be done. Washing was another necessity which had to be foregone, and the dirt accumulated thick upon our hands and faces. One of my colleagues' camel became utterly done up, and fell with him three or four times. Whenever this occurred it meant a considerable delay, for it was only after a lot of pushing, heaving, and beating that the wretched brute would hoist itself on to its legs again. Our last march into Ariab was 14½ hours without a single halt, and men and animals, thoroughly tired and worn out, lay down under the shade of a big mimosa tree near the deep well. A Hadendowa, a typical Fuzzy Wuzzy, was guarding it, with a spear in his hand and a shield slung over his shoulder. With a rope he let down a skin and filled it with deliciously cool and clean water.

We emptied that skin again and again. What a glorious drink it was! We all agreed that it was the very best we ever had in our lives. We halted at Ariab two days to rest camels, and we filled up the time by working at our note books and shooting gazelles, which were plentiful in the neighbourhood.

The remainder of the journey to Suakim was devoid of any such hardships as we had already endured. The flat desert we had hitherto passed over gave way to a mountainous country, and nearly all the "khors" in the valleys held water. This we obtained by scraping a hole in the shingley ground, into which the water percolated slowly. At Kokreb, two days march east of Ariab, we passed through what had been the toll-bar gate of the desert. At the foot of some rising ground was the abandoned camp of Osman Digma's brother, Abdullah Abu Bekr, who commanded a large force of Hadendowas. His duties were to collect the tolls from passing caravans, and send the money to the "Beil el Ual" at Omdurman. The place was well built, and surrounded by a zareba and palisade, and the interior remarkably clean for a Dervish dwelling. Near by was an immense graveyard, containing several hundred graves. It puzzled us to account for so many in this desolate country, and I can only suppose that the Hadendowas who were wounded in the fighting at Tamai and other places around Suakim crawled here to die, or were brought here for burial. We looked with interest at the various ranges of hills which we crossed over, because we were travelling over the route that would have been followed by the Berber Suakim Railway of 1884. When we saw the

network of khors which run down from the western slope of the ranges towards the desert, we could well understand that that wild enterprise was doomed to failure, even had there been no dense hoards of fanatical foes to oppose its progress.

It was evident that at certain seasons of the year the rainfall in this district must be very heavy, for the mountain sides are scored with deep gulleys choked up with heavy boulders and *débris* brought down by the floods. My colleagues and myself were impressed with the difficulties that would attend the construction of a railway, and we wrote to that effect in our respective journals. I have since learned that prior to our ride across the desert a powerful syndicate had been formed in London to acquire powers for the prosecution of this project, but that, as a result of our observations, the scheme has been abandoned. I entirely applaud that decision, for although a railway could undoubtedly be built across that country, it would be a very costly undertaking, and it could not possibly be made to pay for many years to come. It must not be forgotten that the population of the Soudan has been enormously reduced of late years. With the death of General Gordon at Khartoum, in 1884, a period of bloodshed was inaugurated in that unhappy country, and it only ended on the 2nd September in this year, when the Sirdar's army slew 12,000 men. The Soudan was never a thickly populated country, and what little wealth it had was derived from agriculture. With a large proportion of its male population wiped out of existence, and the remainder reduced to beggary by the tyrannical rule of the Baggaras, whole tracts of land have gone out of cultivation. Under the most favourable circumstances, no return for money invested in the Soudan can be looked for for many years to come. The trade that exists to-day between Khartoum and Suakim is practically nothing, and the transport for the merchandise which passes between the two places is abundantly supplied by camel caravans.

The hilly country of which I was speaking just now, extends roughly for 120 miles inland from the Red Sea, and it is all very beautiful. The valleys are filled with dense vegetation, and every kind of game abounds in them. We saw large quantities of ariel, gazelle, hares, partridges, and sand grouse. A sportsman camped up amongst these hills would have no difficulty in making heavy bags. Our road lead over three mountain passes, the highest of

which was 2,800 feet. On the morning of our tenth day out from Berber, we reached Tambuk, the most advanced Egyptian post on the Suakim side of the desert. Here we found a well-built fort—the garrison of which has now been withdrawn—and two wells of beautifully clear water. We indulged in a shave and a brush-up—both very badly needed—prior to our entry into Suakim, and shortly after resuming the road, we gained our first glimpse of the sea. It was an intense joy to us to see a limitless expanse of water, after so many months of wandering in the parched and dried-up wastes of the Soudan. With my arrival at Suakim, the Soudan campaign of 1897 ended for me, for I received a telegram from *The Graphic* telling me to go the North-West Frontier of India. Thither I made my way as rapidly as possible, and arrived at Peshawur just in time to join Sir William Lockhart's column, and go with it into the Bazaar Valley. At the conclusion of that expedition I went over to the Malakand Field Force, and joined the division which was led by Sir Bindon Blood, through the Bumer country. The frontier fighting then ended, and I returned to England, *via* Bombay, where I spent a few days among the plague hospitals and segregation camps. I was unfortunately unable to reach the Soudan in time for the battle of the Atbara, which took place on Good Friday, and I remained in England until the end of June, when I set out again for Egypt.

A story is told of a war correspondent who was sent off to a campaign from London at such short notice, that his only equipment was the frock coat and top hat which he happened to be wearing at the time. Such a slender outfit might serve in some countries where a man can pick up things as he goes along, but a campaign in the Soudan is a serious business, and needs a deal of forethought and preparation. Every article of food, and every drop of drink, has to be taken up from Cairo to the front, and in quantities sufficient to last for three months at the least. Transport for oneself, servant, horses, and stores, is also another great difficulty, for with only one line of communication to an army more than 1,200 miles from Cairo, blocks on the way are only to be expected, and when they occur, the correspondent's turn comes last. The only thing one can do is to rush on as far and as fast as possible when the conditions are favourable, and trust to luck for the rest. From the war correspondent's point of view, there is no such happy hunting ground as the Soudan.

Since the year 1895, a campaign in that country has been an annual affair. Although the Upper Nile cannot honestly be recommended as a summer resort, there are so many solid considerations to be set against the boiling heat, the choking dust, the tinned food, and the flies, that I have never yet heard of a man who refused the chance of going there. I think we correspondents have an infinitely better time of it than anyone else in the Soudan, because directly one campaign is over, we are hurried off to the North-West Frontier of India, Cuba, China, or elsewhere, and we return to the Nile just in time for the next. While we wander through fresh battlefields and countries new, the Egyptian army grills in the sun upon the ground it has won from the Dervishes, and waits patiently until the river rises and permits it to advance again and conquer fresh territory, but throughout each one of those weary months of waiting for the next fight, every officer and man in the force works hard, works patiently for the ends in view.

The result of each campaign has been that new provinces fall under the Sirdar's rule and have to be administered. There are also large populations to be governed—not after the manner of the Dervishes—and, above all, there is the great railroad to be extended southwards to the Cape. Vast possibilities hang upon the progress of this work, and to push it forward the rifle is laid aside and the pick and spade become the soldier's weapons. Never before has there been such a wonderful army, such perfect organisation, such mobility. In the summer it fights, ever victoriously, against a savage and a warlike foe, and the rest of the year it is busily employed in laying "permanent ways" across the sandy desert, fitting together locomotives and steam-boats, building hospitals, barracks, prisons, and resuscitating the trade of a once flourishing country. Already the strategic railway from Wady Halfa to Kermeh has developed into a going concern, commercially, and the day in not far distant when railway engines will be seen steaming in and out of Khartoum.

A few days after my arrival in Cairo a colleague and myself received permission from the Sirdar to proceed to the front, and the following morning we rose early to get our horses and sais sent off by the first freight train. Besides getting the stud entrained we had to see that the animals were all provided with seven days' rations. For four horses this amounted to a formidable pile of tibbin sacks, far too big

to be crammed into any English horse-box. But in Egypt the boxes are built differently, and gold letters on the outside of them inform you that they are called "animal trucks." The name is expressive and appropriate. They are not provided with swing-bars or partitions of any kind, and the consequence is that the horses get to fighting unless carefully looked after by the saïs. In the present instance it was so, and just before the train started a terrible kicking and squealing arose inside the truck, and my grey horse was up on his hind legs biting viciously at his neighbour, who returned the compliment with his heels. Both the saïs were hopelessly mixed up in the affair, and they had scarcely restored order when the train moved off, and we could only hope that none of them would be lame when they arrived at Berber.

We followed by the night mail which was filled with officers going to the front. What a striking scene that departure platform presents when the Sudan mail goes out. It is ill-lighted and crowded with people in tarboosh or turban, who apparently have no business there and perpetually get in one another's way. Uniform cases, portmanteaus, and camel-trunks are piled together in heaps, and dragged asunder again by gangs of swarthy porters, who yell and curse at one another, perspiring all the while. The individuals who own the luggage which causes all this commotion appear later on, dressed generally in grey flannel suits with tweed caps, looking very cool and very much like tourists. The tone of the proceedings is restored, however, by the presence of their friends, who come to see their comrades off in mess uniforms—both British and Egyptian. The final moment is marked by the ringing of bells, the blowing of penny trumpets, and the screech of the engine's whistle. Everyone is cheery as a schoolboy going home, and with many a jest and hearty hand-shake, the travellers clamber on board, and the train crawls out to the desert. How many splendid Englishmen have left Cairo by this night mail for the Soudan, never to return! The death-roll rises year by year, yet the old Nile still claims its victims, unappeased. Who can tell how many more will make their last bed beneath the palm-trees ere the autumn ends, and the river falls again, and the sand-banks reappear?

Such thoughts as these, no doubt, occur to many a man off to the front, but he leaves them behind with his dress-clothes in Cairo. The heat, the dust, and the other discomforts of the journey form a sufficient distraction to

most people, for they take a deal of circumventing. As yet there are no Spiers and Pond refreshment rooms along the track, so if a man will slack his thirst with a cool drink he must look carefully after his lump of ice and soda-water bottles. It is really painful to him to watch the ice melt, and form an ever-growing puddle on the carriage floor. How he will want it to-morrow morning when he wakes up literally covered with mud formed of dust and his own perspiration, and his tongue cleaving to the roof of his mouth! As a rule there is nothing new or interesting to be got out of the journey to Assouan, but I was fortunate in having for my travelling companion an officer who was formerly in the police, and is now in the Sirdar's army at the front. At Bahana, a village north of Luxor, he pointed out a building in which a band of captured brigands were burned to death with petroleum some years ago. It was one of the dove-cotes so common in this part of Egypt. They are square, and built of mud, and remind one of an Afridi tower. Clouds of pigeons inhabit them, and the yield of guano is very valuable. They are generally isolated buildings surrounded by a high wall, and desperate men could well defend themselves in one of them. Not long since brigandage was quite common in the provinces of Jirgeh and Kenneh, but a greatly improved police organisation has had its effect, and the bands have all been slaughtered, captured, or broken up, though isolated cases still occur from time to time. In due course we reached Shalal, where the railway terminates, and here we moved our baggage on board the Nile steam-boat leaving for Halfa. Shalal was a very important link in the long chain of communication with the front.

When we arrived there the first thing to arrest our attention was a deafening chorus of hammers ringing on the side of an iron barge propped up on piles by the river side. The barge was one of a fleet being built for the conveyance of "Mr. Atkins" to Omdurman or thereabouts. Each one was built in sections, fitted with a double deck, and carried 250 men. Speed of construction was the great thing necessary just then, and under Dragé Bey's able direction the little shipbuilding yard turned out one boat a week. We saw one launched, and a pretty sight it was. Steel rails well greased, had been laid from the shop to the water's edge, and one after another the barges came rushing down in pieces, and plunged into the river with a tremendous

splash; reminding one of the water chute at Olympia. Directly one section reached the water half-naked men seized it and dragged it to one side to make room for its fellows, and two hours saw the barge bolted together, ready for the voyage to Wady Halfa. The temperature was 124° Fahr. in the shade, but everyone worked as if his life depended upon it. I watched the performance in the shade, but even then the perspiration dropped like tears upon my sketch-book. From sunrise to sunset this is the condition of life upon the Nile in summer time, and no one but a stranger pays any attention to it.

The ship-building yard of Shalal, filled with every modern appliance and machine, its background formed by the ancient temple of Philæ, afforded one of the most striking pictures on the Nile. From Shalal we travelled to Halfa by the post-boat, and without delay proceeded to Atbara camp by the now completed military railway. General Gatacre and Captain Cox, his A.D.C., were on board the train, and I was fortunate to get a place in the saloon carriage. Many of the trains which leave the great railway depot at Halfa are not provided with first-class carriages, or indeed with carriages of any kind, and the traveller has to content himself with an ordinary open truck. This, for a journey of forty odd hours across the desert, is not exactly a vehicle to enjoy oneself in, especially when the sun is up. Matting and canvas covers were made for the trucks, so that when the British brigade came up, the men were well under cover from the sun.

The train which I travelled by from Halfa left at one o'clock in the morning, and it was typical of the Soudan military railway. Next to the engine were placed three water trucks for the supply of steam, and for some of the desert stations there was one of the new iron boats from Shalal travelling in sections, and here were several thousand rounds of ammunition and sacks of corn, biscuit-boxes, and field hospital stores. Recruits and details of "Gippy" battalions stored themselves away in odd corners of the trucks trying to find comfortable sleeping places. Just before leaving the station, Lieut. Blakeney, R.E., the traffic manager, an officer to whom I am indebted for many kindnesses, and who has recently received the D.S.O. for his splendid services in the Soudan, came to tell me that my Soudanese servant Ahdul had been caught trying to smuggle through a boy, a relation of his, who wanted to go to Berber. The boy was carried off howling by a policeman.

Every train has to be most carefully searched for stowaways, and no one is allowed to travel without a pass. There are eight railway stations between Halfa and Abu Hamed, and they are unique; they consist merely of a pass-by for trains and a signalman's hut built of sleepers, with a telephone wire passing through the roof. Nothing in the world could look more desolate, more forlorn, than these desert stations. By day they appear to be built in the middle of an island, and the rails to run north and south straight into a calm blue sea. The ever-changing mirage encircles them, the distant rocks and the telegraph poles dance and swing in the heat-waves. A remarkable feature about these desert stations is the little patch of fresh green "dhurra" (Indian corn) which the signalmen have raised in front of their cabins. The corn grows luxuriantly in the impossible-looking sand, and if only water could be procured in large quantities this ghastly desert could be transformed into a most rich corn country. Between Abu Hamed and Atbara the line follows the river banks for the most part, and passes several villages.

The natives look upon the engine as a sort of god, and stand in great awe of it. The sapper officers who built the lines have many amusing yarns to tell about their reception when first the locomotive came along. At Genannetti an Arab approached the officer in charge and asked him if his wife might creep under the engine. The reason for this extraordinary request was that the lady was anxious to have a child, so permission was at once given. Not content with crawling under the engine once, she asked if she might do it again, and her husband explained that this would ensure her having twins. A venerable sheikh, watching the railway battalion climb on to the long line of trucks, remonstrated with the officer in charge, saying that it was not fair to make the engine pull so many people at once.

Shortly after my arrival at Atbara camp I rode over one morning to Damali, 14 miles distant, where General Gatacre's British brigade was encamped. His force was divided, the Seaforth's and Cameron Highlanders being quartered at Damali and the Lincoln's and Warwick's at Es-sileur, a mile further north. The Sirdar, in his speech at the Mansion House, spoke in eulogistic terms of this magnificent brigade, and the invaluable services which they had rendered in the Soudan.

After the battle of Atbara this brigade was

brought here to await the final advance. Many people prophesied that this long period of inaction would be fatal to the health of British troops in the Soudan, and that these prophesies were not fulfilled was only due to the admirable arrangements made for their well-being by General Gatacre. With the exception of an epidemic of enteric fever, in which the Lincolns lost most heavily, there was practically no sickness. A certain number of men went down from time to time with ordinary fever, and it was found that the main cause of this was the chills caught by the men after bathing in the river. This practice was stopped, and covered baths were built away from the river, with the result that malaria disappeared. The greatest efforts were made to break the monotony of camp life, and supply the men with a certain amount of distraction. The most successful method and the most highly appreciated by the men was a river-trip down to Genannetti, a station at the head of the 5th Cataract. Two companies were embarked on barges and towed down by steamer to the head of the cataract, and after a visit of two days returned, the whole trip taking about a week. The squalid little village of Damali has become a great military station, possessing a theatre, a racecourse, a railway station, a street of shops and restaurants—at which none but teetotal drinks are obtainable—and an absolutely limitless parade-ground.

Damali has its graveyard, too, a small enclosure between the camp and the railway station. Within it lies exactly forty British soldiers who have died of wounds and sickness since the battle of Atbara. A high wall has been built round the graves to protect them from drifting sand, and when the troops leave for good the doorway will be closed up entirely. Everything within is plain and bare as the desert which surrounds it, but every grave is marked with a wooden cross, and several of them are adorned with some simple but pathetic tribute to the comrade who has gone. In some instances empty cartridge cases had been placed upon the grave in the form of a cross, with the initials of the deceased below it, while others were enclosed by a chain of rings formed out of telegraph wire.

The critical point in the campaign was reached when the Sirdar despatched the Soudanese and Egyptian troops from Fort Atbara to the advanced camp at Wad Habeshi, and filled up their places with the battalions which formed the new British Brigade. This

was the moment when the great strain came upon the vast chain of communications which stretched from Cairo to Atbara; this was the time when every link of it was tested to the utmost. It was for this that the Sirdar, his staff, and all his transport and commissariat officers had worked incessantly through the killing heat of the summer. If a breakdown had occurred at any one point a tremendous block and serious delay would have resulted, and the whole plan of campaign would have been altered. But the chain did not break; every link of it held good; it was a perfect piece of workmanship. I witnessed the departure of General MacDonald's brigade from Fort Atbara, and it was one of the great sights of the campaign. The men fell in along the river bank, dressed only in their white linen shirt and drawers. A gunboat, with a double decked iron barge lashed to either side of it, was in waiting, and at the word of command the men began to file on board two and two at a time. They swarmed over the gunboat and the barges, taking their places in long rows, and so closely packed were they that not an inch of deck was visible anywhere. The upper flooring of the barges bent visibly under the tremendous weight, and people on the bank wondered at the sight. An officer of high rank happened to be standing near me at the time, and I heard him remark that he thanked Providence the responsibility of the embarkation did not rest on his shoulders. A strong gale of wind was blowing at the time, the Nile flood was tearing down like a mill-race, and under the circumstances it was a daring thing to send off 1,200 men on a voyage of 100 miles in such a flimsy topheavy craft. I honestly believe that the Sirdar was the only man in the Egyptian Army who would have dared to do it. I know that great relief was felt when the news of their safe arrival reached Atbara.

Directly the Egyptian Army had gone south the British troops began to arrive. First came the Rifle Brigade, then the Guards, and they were followed by the 32nd Field Battery, the Howitzer Battery, two forty pounder guns, and the Royal Irish Rifles Maxim Battery. These were followed by the Northumberland Fusiliers, the 21st Lancers, and the Lancashire Fusiliers. The remarkable feature of the campaign was the way in which these battalions were brought to Atbara from Cairo. They arrived with a precision and regularity that would have been creditable to those responsible for their transport in England, but which in

that country was nothing less than wonderful. That the single line of railway which connects Halfa and Atbara should have been kept running without a hitch of any kind under the heavy strain of traffic speaks volumes for the watchfulness and forethought of the young sapper officers responsible for it.

The Sirdar gave the correspondents the option of going to Wad Habeshi either by land or water, so I decided to march with the 21st Lancers, who convoyed a large quantity of transport and an Egyptian horse battery along the left bank of the Nile. There is a great monotony and sameness about long marches in the Soudan; the present one was no exception to the rule, so I will only touch upon those points that possess the most interest.

The first two days were the most trying ones, for neither men nor horses were in condition, and it took some time for everyone to shake into their places. At Kitial, where we halted the second day, ten horses belonging to the 21st Lancers went lame with laminitis and had to be left behind. Their twelve days of continuous travelling up from Cairo had naturally prevented them from getting exercise, and the blood had accumulated in their feet. The result of this was that when they commenced to march across the desert the burning sand overheated the blood, and set up fever in the feet. The remedy for laminitis is a simple one. These horses were left in the charge of an Arab, who kept them standing in the wet mud of the river bank, and in three or four days they recovered and followed after the column. It was at Kitial also that Private Bishop of the 21st Lancers died of sunstroke. His death was indicative of the intense keenness exhibited by every officer and man in this fine regiment to get to the front. Bishop was sick when he arrived at Atbara camp, but he refused to report himself, and managed to elude the doctor's eye until the column started. On arrival at Zaidal Island, our first halting place, the poor fellow was just able to lead his horse to water and then fell down unconscious. Surgeon-Major Pinches, who had such a narrow escape during the charge at Omdurman, made every effort to restore him, but without avail. He was stripped naked and laid on a waterproof sheet under the shade of a tree, and two comrades fanned him on either side with blankets while others poured cold water upon him. This treatment had the effect of reducing his temperature from 109 to normal, but from the first it was a hopeless case,

and he died the following morning. Another touching incident of the march was the death of a British artilleryman at Magaweih. He fell from sunstroke fifteen miles from camp, and eight Egyptian gunners carried him that distance on a native bed. The party started at two in the morning, and reached Magaweih with their burden before the sun was hot. The loyal action of these Gippies is typical of the kindly feeling which existed between the coloured and the white men of the Sirdar's army. We marched over broad tracts of ground which at high tide is under water. Under the action of the sun this ground becomes fissured and cracked in all directions, and the progress of the column was considerably retarded, for the horses continually put their feet into the holes, and to avoid breaking their legs the men were ordered to dismount and lead them.

Wherever we camped we found these fissures infested with scorpions, and at one place I treated three of our servants who had been stung by them. The men were evidently suffering intense pain, and readily submitted to the rough and ready treatment. It consisted of making transverse incisions in the skin of the part affected, and thus produced bleeding, which was encouraged with vigorous squeezing. The wound was then washed and Scrubb's ammonia rubbed in. The remedy was not considered complete until the patient had swallowed a stiff mixture of brandy and water, and it is only fair to my treatment to say that the next morning these men were all alive, and declared themselves absolutely cured. Three days marching from Kitial brought us to the historic town of Metemmeh. Never shall I forget that place. It is a vast charnel house, and its 1,000 mud dwellings are filled with the bones of men and animals. They lie there to this day, the silent testimony of Dervish butchery. While yet many miles north of the city, we came across the carcasses of men, camels, oxen, goats, and donkeys scattered in all directions. In many instances the bodies were quite intact, and to look at them one might have thought that they had not been dead a week. The natural characteristic of Metemmeh is a dense clump of palm trees near the river, which, in this flat and barren country, forms a landmark for miles around. The town itself lies about a thousand yards away from the Nile, and further back in the desert is the "dame" or camp to which Mahmoud retired during the

bombardment of last year. Colonel Martin halted the column in the palm grove for three hours, and I took the opportunity of riding through the town and the camp beyond it. There were carcasses lying everywhere, and in every attitude. As I passed through the deserted streets not a sound broke the death-like silence of the place. My horse snorted fretfully as he breathed the tainted atmosphere, and started aside with fright when we came unexpectedly upon some dead body lying in the roadway. The only living thing that I saw in Metemmeh was a large tarantula which ran across the street, a meet inhabitant of this city of the dead.

While on the march, we were quite isolated from the post and telegraph service, and it became necessary to establish a system of our own. We sent our letters and telegrams down the river by native swimmers, of whom there was no difficulty in finding. Our amateur postman hunted about the river bank until he found a suitable log, launched it, wrapped his one and only garment in a huge coil round his head, with the letters inside, and departed. He had sixty miles to go, and we gave him six shillings at starting and the promise of an equal amount upon arrival, and with these terms he was thoroughly contented. Innumerable khors run inland towards the desert, and they were rapidly filling with water from the rising tide. Here was presented the anomalous sight of streams running out of a river, and not into it. The filling up of these khors proved a considerable drawback to our march up from Atbara, frequently necessitating detours from the road. The ground for several feet on either side of the khors became saturated with the water, which turned it practically into a quicksand. This rendered it extremely difficult to water horses and camels, for it is only possible to find firm spots here and there. Indeed, the horses were so frightened of sinking in the mud, that as a rule they would not approach the water, though they were dying of thirst. When one, a little bolder than the rest, could be induced to approach, he did so most gingerly, and often put himself into the most extraordinary attitude for drinking.

In advancing to the attack on Omdurman, the Sirdar had the advantage of most complete and accurate information with regard to its defences. He knew every inch of ground he was going to fight on, the exact position of the fortifications and guns, and the best points upon which to develop his attack. It is not

necessary to say that the greater part of this valuable information was supplied by Slatin Pasha. A soldier whose evil fortune compelled him to spend long years of captivity in his enemy's camp would naturally regard the defences of the place with an interested eye, and the splendid map—of which I was enabled to send home a sketch at that time—proved what advantage Slatin Pasha took of his position when the downfall of Omdurman took place; he must have at least had the satisfaction of knowing how largely he contributed to that great event.

The spies who constantly passed between the two camps kept the Intelligence Department informed of all that went on in the Khalifa's army, and their news was supplemented by deserters, who were numerous, especially since the battle of the Atbara. The Khalifa also employed spies, but they were perfectly well known at headquarters, and discreetly handled. They were supplied with false information, both with regard to the number of our troops and their movements. Through their medium the Khalifa learnt that the Egyptian army suffered terrific loss at the Atbara fight; that it was only advancing under compulsion, in great fear of the next battle, and so forth. He little knew that the only thing his enemy dreaded was the possibility of his running away, that such a calamity hung like a nightmare over our camp.

The confidence of the force in the probability of a fight was reassured by the events of the 31st August. On the afternoon of that day, the 21st Lancers made a reconnaissance up to Kererri, ten miles distant from Omdurman, where they came in touch with the Dervish cavalry. I happened to be present on the occasion, and saw Capt. Kenna and Lieut. the Hon. R. de Montmorency return from their scurry after the enemy in the bush, the former with a long Dervish spear in his hand. The news that the enemy in considerable numbers had been met with, spread like wildfire through the camp, and the next morning the whole force rose gaily from their slumbers, in spite of a drenching rain, confident that the weary months of waiting and the long marches would at last be rewarded by a battle. We left camp that morning in the formation that had been adhered to since the departure from Wad Hamed; that is to say, the 21st Lancers advanced along the river bank ahead of the infantry, and the Egyptian Cavalry and the Camel Corps on the right. I attached myself to the latter force, and gained from the top of

Kerreri Hill my first sight of Omdurman. It was a vast city; the first view of it staggered me. For miles and miles along the Nile bank stretched a dark mass of buildings, and from the centre of it rose a glittering dome—the Madhi's tomb. Little time, however, was devoted to looking at it through the binoculars.

Colonel Broadwood gave the word to advance, and the 2,000 men under his command moved off across the plain in a south-westerly direction. A mountain ridge, called Gebal Fareid, rises out of the desert, three miles due west of Omdurman. Towards these hills we made our way across swamp and wet sand into which the wheels of the field battery sank to their axles. It was terribly hard work on the horses, and the pace was slow in consequence, but Broadwood persevered, and about mid-day we halted at the foot of Gebal Fareid. There we dismounted, and scrambled up over the burning rocks to the top of it, eager for a nearer view of the city. For some moments there was absolute silence amongst the party—no one spoke. I confess that a feeling of awe took hold upon me. Omdurman lay at our feet; the mosques and the houses were plainly visible. Nothing that I had read or heard of it had ever conveyed an idea of its monstrous size. Then we began to look about for the enemy, and we soon saw them. A first glance at the city led one to believe that it was surrounded on the desert side by a wall or a zareba. But as we looked at it, this wall began to move, and gaps appeared in it, all at regular intervals. Then we saw that they were men, and that there were many of them. They were not bunched together in haphazard masses. They were formed up in regular brigades, and they were advancing. We could hear the deep-toned note of the ombeya, the Khalifa's war-horn, and we could hear our gunboats firing, and see the cloud of dust which their shells threw up when they burst. The distance between us and the enemy was rapidly diminishing. They were coming on very fast, and Colonel Broadwood, having thoroughly reconnoitered the position, gave the order to retire. The heat of the midday sun had considerably dried up the wet sand, and the guns and the camel corps made better progress over it; but even so the enemy were gaining upon us, and very shortly, after we had quitted Gebel Fareid, the Dervishes were upon it. It was a most interesting situation. We were six miles away from any support, and the whole of the Khalifa's army was within a mile of us. Once the

bugles rang out and the squadrons wheeled round, ready for a charge, because a trooper has been dismounted, and it was feared that he might be cut off. The rear guard however, brought him in all right, and we turned again and reached the Sirdar's camp at Agaiga as the sun was sinking in the west. On this occasion Colonel Broadwood displayed some of the finest qualities of a cavalry officer, and conducted the reconnaissance in the most masterly manner. He took every advantage of the ground he had to cover; he waited until the enemy's strength could be accurately gauged, and he withdrew exactly at the right moment and in perfect order.

The events which happened on September 2nd crowded one upon another in quick succession. I do not think it would be ever possible to pass another day so filled with stirring incidents, so pregnant with historical events. The Sirdar's army was fighting and marching incessantly for sixteen hours, and it is quite beyond my powers to condense the day's work into the present paper. The battle of Omdurman is of such recent date, and the details of the fight have been presented to the public so exhaustively by the Press, that I venture to conclude this paper by merely showing and explaining the sketches which I made upon the battlefield.

DISCUSSION.

The CHAIRMAN said it was usual for the paper to be followed by a discussion, but on this occasion he did not know that there was much room for comment or criticism. He would, however, ask Mr. Thomas, of the *Graphic*, to say a word or two.

Mr. THOMAS said every one must have admired the plain, straightforward account which Mr. Maud had given them of the Soudan campaign. He had resisted any attempt at sensation, and had given a narrative which all must feel to be true. The principal thing which struck him was the remarkable way in which the drawings had borne enlargement. They were made as quite small sketches, and yet, as they appeared on the screen they looked as if they had been intended for cartoons, they were so admirably drawn.

The CHAIRMAN said:—I am sure you will all agree with me that we owe Mr. Maud our cordial thanks for the interesting paper which he has just read, and for the reproduction of the sketches made by himself. About a year ago, when war artists and correspondents were for some unknown reason not very popular in the Soudan or elsewhere, I ventured

in this room, as one who had myself seen active service in the field, and who had known what difficulties war correspondents had to encounter on active service, to bear my personal testimony to the arduous, and at the same time useful, character of their duties; and I have therefore, on my part, listened with no little satisfaction to a paper which gives so good, perhaps I ought to say so graphic, an idea of an energetic war artist's experiences, although related with characteristic modesty so far as his own deeds are concerned; and I feel sure that Mr. Maud will always look back with pride to the recollections of his seventh campaign within three years, and to services performed with credit to himself, with advantage to the public, and with the cordial approval of the enterprising journal which he has represented. As the paper itself is one that hardly admits of criticism or discussion, I have but little to say in regard to it, except to corroborate the lecturer's account of the splendid railway work carried out in the valley of the Nile by the young officers of the Royal Engineers, under the guidance of Lieutenant—now Major—Girouard, and to bear my personal testimony to the appreciation of the Home authorities of that work. It forms, indeed, an honourable episode in the history of the recent operations, and carries us on, almost like a fairy tale, to the not distant prospect of a railway terminus at Khartoum, with branch lines, it may be, to the Cape and other parts of Southern Africa! Although no Englishman can look back without pride and satisfaction upon the recent campaign in the Soudan, which has been so well organised, so well led, and so well carried out by both officers and men, I think we may, by degrees, now calm down from our overflowing enthusiasm and settle down to business, as Lord Kitchener wishes us to do, in the shape of taking some steps towards the education and civilisation of those who have recently been our enemies, and towards the restoration to prosperity of a country which has suffered so terribly from the tyranny of the Dervishes since our disastrous abandonment of it some fifteen years ago. Gordon was indeed terribly avenged on the day of Omdurman, when justice was meted out with dire effect on the Mahdi's relentless horde; and if we can now honour his memory by making Khartoum the centre of civilisation and prosperity, England may well rejoice at having wiped out a blot in her history, and at having once more asserted her position as one of the great Powers of the world, whose aim is peace and goodwill, while not brooking insult or barbarism in her onward progress.

Mr. MAUD, in reply, after thanking the Chairman for his complimentary remarks, said he had that morning had an interview with the Sirdar just before his leaving for Egypt. He went to see him about the fund for the Gordon College at Khartoum, with regard to which the *Daily Graphic* had taken a prominent line. Lord Kitchener told him that he

regretted very much that his time was so much taken up that he had not been able to write to the proprietors of the *Graphic* to thank them for their services in this matter, but he hoped that he would convey to them his thanks, which he had done. This might be a favourable opportunity for any one who had not already subscribed to rectify the omission, and some one was in attendance who would be happy to receive names. Lord Kitchener said he felt perfectly confident that the sum for which he had asked would be forthcoming, and he thought it was the duty of every one to help him to realise his wish.

The CHAIRMAN then proposed a cordial vote of thanks to Mr. Maud, which was carried unanimously.

Miscellaneous.

TEXTILE INDUSTRIES IN SPANISH AMERICA.

A report has recently been prepared by the United States Bureau of Foreign Commerce on the textile industries of South America and Mexico, and on the import trade in textiles into the various countries. In Mexico there existed, in 1896, 98 factories of cotton goods and 23 woollen factories, representing a value in machinery and buildings of about £2,610,000. There were employed 21,963 workpeople and 370,570 spindles, and 12,454 looms were in operation. The annual production was 3,890,300 pieces of ordinary white cotton, 2,077,825 pieces of cambrics, muslins, &c., 188,500 coverlets, and 322,975 carpets, rugs, &c. There is a large factory of jute at Orizaba. Imports into Mexico of textiles from Great Britain in 1896 were valued at £814,000; from Germany £142,000; France, £241,000; Belgium, £2,000; and United States, £122,000. As regards the United States of Colombia, the statement is made that in Cauca common cotton and woollen cloths are manufactured. In Cundimarca, Boyaca, Antioquia, and Bolivar some manufacture of textile is carried on. In Santander handkerchiefs, cotton counterpanes, table cloths, towels, hammocks, hemp sacks, &c., are made in large quantities. The imports of textiles in 1896 from Great Britain were valued at £1,041,000; from France, £287,000; and from the United States, £34,000. The imports of textile into Venezuela, during the same year, were valued as follows:—From Great Britain £655,000, Germany £97,000, France £17,000, and the United States £140,000. There is no statement available as to local manufacture. In Brazil there are numerous cotton mills producing low grades of goods. Several are at Petropolis. The Cachoeira factory in Alagoas which has been in operation three years, paid in the first year a dividend of 48 per cent.; in the second

year, 50 per cent. ; and, in the third year, 40 per cent. It has 480 operatives, and produced in 1896, 122,783 pieces of cotton cloth. The machinery cost £14,000; the buildings for the factory, £8,000; the houses for operatives, £2,125; and various appurtenances, £700. The enterprise is protected by an export duty on raw cotton, and heavy import duty on cotton fabrics. In 1896 the imports of textile fabrics into Brazil from the United Kingdom were valued at £2,700,000. Into Uruguay the imports of textiles were valued as follows:—From Great Britain £814,000, Germany £176,000, France £86,000, Belgium £12,000, and the United States £36,000. There are no particulars as to local factories. In the Argentine Republic it is stated that the textile industries have scarcely a foothold. There is one large woollen factory in Buenos Ayres which turns out blankets, flannels, and cloth for soldiers' clothing; and there are several establishments for the production of knitted goods. The amount of woollen, cotton, and linen fabrics annually imported averages £6,000,000. In Paraguay the imports of textiles were as follows in 1896:—Great Britain, £3,481; Germany, £4,500; and none from the United States and France. The imports of textiles into Chile from Great Britain in 1896 were valued at nearly £1,200,000; from the United States, £136,000; Germany, £566,000; Belgium, £30,000; and from France, £243,000. There is no statement available as to local manufactures. As regards Bolivia, the imports of textiles *via* the custom-house of La Paz in 1895 were valued at £43,000; the imports of textiles *via* Mollenda, Peru, amounted to 377 tons, the value not being stated. The imports through Antofagasta, Chile, amounted to 2,820 tons. There are no details available respecting local textile industries. In Peru there are two cotton factories. The Peruvian Cotton Manufacturing Company at Vitarte has a capital of £130,000 and was founded in 1847. It manufactures *ecru* goods and has an output of 3,000,000 yards annually. The *Fabrica de Tejidos de Algodon* is at Ica. The capital is £10,000, and it is also employed in making *ecru* goods. There are three wool factories. The *Santa Catalina* at Lima; the *Lucre* at Cuzco, and the *Urecon* in the department of Ancachs. The imports of textiles in 1896 from Great Britain were valued at £687,354; from Germany, £200,000; Belgium, £2,800; France, £12,700; and from the United States, £28,000. In Ecuador cotton cloths are made in private houses and small workshops. There is a small woollen mill at Chillo. The imports of textiles in 1896 were as follows:—From Great Britain, £284,000; Germany, £47,000; France, £1,400; and from the United States, £11,000.

INDUSTRIAL CONDITION OF THE NEW HEBRIDES.

In a recent report by the United States Commercial Agent at Nouméa, it is said to be generally understood

there that the New Hebrides Islands are about to become a French possession. They were occupied by the French some ten years ago, but never officially. The entire trade of this fruitful group of islands (imports and exports), amounting to about £200,000 annually, has been hitherto in the hands of French and Australian syndicates. The trade is capable of considerable expansion, and the land is adapted to the cultivation of coffee, cacao, vanilla, tobacco, sugar, rubber, spices, and every kind of tropical and semi-tropical fruit. Land is given free to immigrants under certain conditions. The total area of the chain of islands known as the New Hebrides is 3,625,957 acres; the southernmost island of the group is about 1,565 miles from Sydney, Australia, and some 230 miles from Nouméa, New Caledonia. The soil, composed of the accumulation of the vegetable *débris* of many centuries, is of the greatest fertility, covered for the most part with a thick underbrush, which in places becomes a dense forest containing a great variety of trees adapted for cabinetwork, shipbuilding, &c., such as the kaori, rosewood, and banian. Wild ducks, black pigeons, doves, parrots, and a great variety of birds abound in the archipelago. The year may be divided into two seasons. During the five months from November to March inclusive it is very warm, and the islands are subject to typhoons; the months of April and October are cooler, and the intervening five months are of an agreeable temperature. The native population for the whole archipelago is estimated at about 60,000 Canaques, widely scattered. They are savage and treacherous in character, but they will not attack foreigners if they see that they are armed or capable of defending themselves. Upon these natives the European planters, mostly French and English, and numbering about 200, must depend for their workmen. There are few real European settlements except in the Island *Vaté*, where at Port Vila there is a French colony of about 100 inhabitants, including women and children. At *Undine Bay*, in the same island, there is a small English colony. Here is the most important station of a French society, comprising a large coffee plantation with 20,000 trees, a banana plantation, and fields of maize and tobacco. This society also possesses an important station at Port *Havannah*, in *Vaté*, and others at Port *Sandwich*, *Api*, and on the canal of *Segond*. To every immigrant possessing a capital of 4,000 francs (£160), the society gives 25 hectares (62 acres) of land. It is stated that the New Hebrides can undoubtedly be developed; spices, and all tropical fruits yield abundantly; as well as vegetables, beans, turnips, carrots, cabbage, pumpkins, asparagus, radishes, &c.: the only exceptions are cauliflowers, artichokes, and potatoes. Yams, which yield well, are substituted for the latter. The tobacco is of excellent quality. It is sown in rows like turnips, but before sowing, a good fire of brushwood is made to rid the soil of the parasitic enemies of the plant. At the end of three or four weeks the seedlings are transplanted. In

a good year two or three harvests can be obtained. The cultivation of coffee is remunerative, though not so profitable as that of tobacco, on account of the expense of manual labour. The coffee of the New Hebrides is similar to that of Caledonia; the kernels are smaller, but have a very fine aroma. A coffee plantation commences to yield in the third year, but it is not in full production until the end of five years. In 1895, 100 tons of coffee were exported; in 1896, more than 150 tons. Many planters manufacture copra with the cocoanuts, which they buy from the natives. It takes about 8,000 cocoanuts to make a ton of copra. About 160 cocoa trees can be planted to the acre. The cultivation of the banana is very easy, and it has assumed large proportions in the last few years; from 10,000 to 12,000 bunches a month are exported to Sydney, where they have a ready sale at from one shilling and sixpence to three shillings the bunch.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

DECEMBER 14.—“Commercial Education.” By SIR ALBERT ROLLIT, LL.D., M.P.

Papers for meetings after Christmas:—

“Tuberculosis in Animals.” By W. HUNTING.

“Canals and Inland Navigation in the United Kingdom.” By L. F. VERNON-HARCOURT, M.A.

“Preservation of Timber.” By S. B. BOULTON.

“Electric Traction and its Application to Railway Work.” By PHILIP DAWSON.

“Coal Supplies.” By T. FORSTER BROWN.

“Wireless Telegraphy.” By W. H. PREECE, C.B., F.R.S.

“Leadless Glazes.” By WILTON P. RIX.

“London Water Supply.” By WALTER HUNTER, M.Inst.C.E.

“Maïolica.” By W. BURTON.

“Wrought Iron Signs.” By J. STARKIE GARDNER.

“Vitreous Enamels.” By CYRIL DAVENPORT.

CANTOR LECTURES.

Monday Evenings, at 8 o'clock:—

PROF. VIVIAN B. LEWES, “Acetylene.” Four Lectures.

LECTURE IV.—DECEMBER 12.

The combustion of acetylene—Acetylene burners—Smoking and carbonising of burners—Burners for heating—Acetylene for gas engines—Diluted Acetylene and its applications.

DR. SAMUEL RIDEAL, “Bacterial Purification of Sewage.” Four Lectures.

January 16, 23, 30, February 6.

ARCHIBALD SHARP, A.M.Inst.C.E., “Cycle Construction and Design.” Four Lectures.

February 20, 27, March 6, 13.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 12.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Prof. Vivian Lewes, “Acetylene.” (Lecture IV.)

Imperial Institute, South Kensington, 8½ p.m. Major W. Beevor, “The Last Indian Frontier War.”

Surveyors, Savoy-street, W.C., 8 p.m. Mr. Wm Weaver, “The London Building Act and the Official Supervision of Buildings.”

Cleveland Institute of Engineers, Middlesbrough, 7½ p.m. Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. Charles Stewart, “Life Histories of Some Plants and Animals.”

TUESDAY, DEC. 13.—Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on paper by Mr. Francis Fox, “The Ventilation of Tunnels and Buildings.”

Statistical, in the Theatre of the United Service Institution, Whitehall, S.W., 5½ p.m. Annual Address by the President, the Rt. Hon. Leonard H. Courtney, “An Experiment on Commercial Expansion.”

Photographic, 12, Hanover-square, W., 8 p.m.

Zoological, 3, Hanover-square, W., 8½ p.m. 1. Mr.

F. E. Beddard, “The Cerebral Convolutions of the Gorilla.” 2. Mr. H. H. Brindley, “Certain

Characters of Reproduced Appendages in Anthro-poda, and particularly in the *Blattidae*.” 3. Mr

W. P. Pycraft, “Contributions to the Osteology of Birds.” (Part. II.—Impennes.)

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. Asiatic, 22, Albemarle-street, W., 4 p.m.

WEDNESDAY, DEC. 14.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Sir Albert Rollit, “Com-mercial Education.”

Sanitary Institute, 71A, Margaret-street, W., 8 p.m.

Dr. Edward F. Willoughby, “Some Prevalent Fallacies in Vital Statistics.”

Royal Literary Fund, 7, Adelphi-terrace, W.C. 3 p.m.

Royal Society of Literature, 20, Hanover-square, W., 1 p.m.

THURSDAY, DEC. 15.—Royal, Burlington-house, W., 4½ p.m. Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. H. J. Elwes, “Sketch of the Zoology and Botany of

the Altai Mountains.” 2. Mr. Thos. Scott, “Description of some Marine and Freshwater Crus-

tacea from Franz-Josef Land, collected by W. Bruce of the Jackson-Harmsworth Expedition.”

Chemical, Burlington-house, W., 8 p.m. 1. Pro A. W. Crossley, “The Interaction of Ethyl Sodio-malonate and Mesityl Oxide.” 2. Dr. F. S.

Kipping, “Derivatives of Camphoric Acid.” (Part III.) 3. Mr. W. H. Perkin, jun., and Dr. J. F. Thorp

“Synthesis of $\alpha\beta$ trimethylglutaric acid.” London Institution, Finsbury-circus, E.C., 6 p.m.

Rev. Prof. J. P. Mahaffy, “Pitfalls in Education” Electrical Engineers, 25, Great George-street, S.W. 8 p.m.

Historical, 28, Jermyn-street, S.W., 8½ p.m.

Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, DEC. 16.—Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. W. Daniell

“The Kentish Town Widening, Midland Railway Quickett Microscopical Club, 22, Hanover-square, W.C., 8 p.m.

Journal of the Society of Arts.

No. 2,404. VOL. XLVII.

FRIDAY, DECEMBER 16, 1898.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.**JUVENILE LECTURES.**

The usual short course of lectures adapted for a juvenile audience will be given on Wednesday evenings, January 4 and 11, 1899, at 7 o'clock, by Professor F. JEFFREY BELL, M.A. (of the Department of Zoology, British Museum). The first lecture will be on "Hands and Feet," and the second lecture on "Some Ways in which Animals Breathe." The lectures will be fully illustrated with lantern slides.

The lectures will commence at 7 o'clock. Special tickets are required for these lectures, which can be obtained on application to the Secretary. A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions each member is entitled to a ticket admitting two children and an adult. Members requiring these tickets should apply at once.

CANTOR LECTURES.

Professor VIVIAN B. LEWES delivered the fourth and last lecture of his course on "Acetylene," on Monday evening, 12th inst., On the motion of the CHAIRMAN a vote of thanks to the lecturer was passed.

The first lecture will be published in next week's number of the *Journal*.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

COVERS FOR JOURNAL.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied post free for 1s. 6d. each, on application to the Secretary.

Proceedings of the Society.**FOREIGN & COLONIAL SECTION.**

December 6, 1898; The Right Hon. Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., in the chair.

The CHAIRMAN said he had the very pleasant duty to perform of introducing his friend, Mr. Little, who would read a paper on what was one of the most important questions in the British Empire, viz., the circumstances attending the Yangtse Valley. This valley, from end to end, was the coming Empire—the British share of China and the sphere of influence. Mr. Little, who was the highest living authority upon the subject, had helped to navigate the river; he had dwelt on its banks and had traded in the districts along its basin. The paper, would be illustrated by a series of lantern slides taken from photographs by Mrs. Little, who would explain the different illustrations.

The paper read was—

THE YANGTSE BASIN AND THE BRITISH SPHERE.

BY ARCHIBALD LITTLE, F.R.G.S.

When approaching the coast of China from the sea at any point north of latitude 29° and up to the Gulf of Pechili in latitude 40° one is apt to run suddenly from out the deep blue waters of the ocean on to what has every appearance of being a hard yellow sandbank. At certain stages of the tides, the line of demarcation between the salt sea and the silt-charged brackish waters of the estuary of the great river, is as sharp cut as between sea and shore anywhere along our own coasts; and, but that one has full confidence in her commander, it is alarming to see the steamer running fifteen knots an hour full tilt upon the land, such as the thick yellow water appears to the eye when seen in contrast with the transparent azure of the surrounding sea. This mass of muddy water discharged by the Yangtse from its mouth near Shanghai has given the name of the Yellow Sea to the waters of the Pacific Ocean that wash the shores of China to the north of the Formosa Channel; while farther north again, and cut off from the

Yellow Sea proper by the projecting arm of the Shantung peninsula, lies the Gulf of Pechili, the depository of the similarly silt-laden waters of the Yellow River and of the Pei Ho in the north, whose combined deposits are fast filling up the basin, rendering, by the ever increasing sandbanks, the approach to Tientsin and the northern ports yearly more difficult to our steamers, and threatening, in the very distant future, entirely to close the "gulfports" of China to water communication.

That which the Yellow River is doing in the Gulf, the Yangtse is effecting along the coast of North China on a much greater scale. The sea that surrounds the Chusan Archipelago, a group of high rocky islands situated about one hundred miles south of Shanghai—the rendezvous of our fleets in the first Chinese war—is being rapidly filled up, the channels and harbours as delineated in the Admiralty charts drawn at that time being now scarcely recognisable. At the time of low water and at the season of spring tides, looking down upon the sea from a height on shore, the eye roams over an endless expanse of brown mud-flats, through which meander narrow river-like channels of muddy water; nearer Shanghai, and at the mouth of the river proper, the summer freshets of the Yangtse have built up wide flats, now embanked and cultivated, in reaches where the writer sailed freely thirty years ago. The great river is yearly extending its banks seawards and the time is not far distant, geologically speaking, when the islands of the Archipelago, now out of sight of the actual mouth, will be seen to stand forth abruptly out of a sea of paddy fields, as do to-day the isolated hills that here and there break the monotonous level of the great alluvial plain that surrounds Shanghai. And this is not astonishing if the estimate be correct that the Yangtse each year brings down no less than 267,000,000 cubic yards of soil, which is equal to the building up of an island one mile square and ninety feet in depth in the estuary each year. The great mountains of Tibet are being slowly worn away and cast into the sea, and the process is visible in the huge landslides and rock avalanches that suddenly fall across the valley paths on the Tibetan border in the monsoon season and often impede the progress of the traveller in that region for many days. I have myself had to halt a couple of days in the valley of the Tung, on the highway to Tibet, while a new rough path was being made, before it was possible to scramble over the pile of huge rocks that blocked the valley, the top of a mountain

having broken off and come down in the night the jagged cone whence the fall originated, having every appearance of an extinct volcano. These rock-masses, gradually broken up and triturated by the roaring torrents that here go to form the many sources of the Yangtse, are farther on gently borne on the comparatively tranquil bosom of the Lower River and imperceptibly deposited in the shape of fine particles of sand and loam throughout the wide area of the estuary.

The Yangtse is one of the four great rivers of the world; it is the longest and, in the number of its affluents, the most far-reaching of the many streams that drain the vast Eurasian continent. It is to Eastern Asia what the Amazons are to South America, the Mississippi to North America, and the Nile and the Congo to the continent of Africa. Of all these rivers the Yangtse is that which has the greatest fall in its bed and the swiftest current, as becomes a river taking its rise in the roof of the world, and in this respect standing in marked contrast with the great American rivers, the Mississippi and the Amazons. It is interesting to note here that the name Yangtse is practically unknown to the Chinese; it is an old book-name for a short stretch of the river flowing through the district of Yang and past the modern treaty port of Chinkiang situated 150 miles above the mouth, but no Chinaman to-day would understand your meaning if you were to speak to him of the river Yangtse. In Chinese maps it is called the Chang Kiang or Long River, and in ordinary conversation the Ta Kiang or Great River, or simply the Kiang, the river *par excellence*, as distinguished from the Ho the river of the North, an abbreviation for Hoang Ho, the Yellow River, that flows through that region. English geographers have, for convenience, given the name of Yangtse to the whole length of the river, and this old local name of a small portion only is fast becoming the world name for the whole extent of the stream, although it is unacknowledged by French geographers, who still call it the Fleuve Bleu, in contradistinction to the other great river of China, the Fleuve Jaune, or Yellow River. Both rivers have their sources in the Kwén-lun range in Northern Tibet, the ultimate source of each being within a few miles of the other. At starting, one river flows north and one flows south, though both ultimately pursue a western course in parallel lines to the Pacific.

The highest point on the Upper Yangtse,

where it traverses the Tibetan plateau before descending into the Red Basin of Szechuan, and thence onwards through the Hupeh gorges to its delta in Kiangsu, that has been scientifically determined, is in latitude $34^{\circ} 43'$ north and longitude $94^{\circ} 48'$ east: Shanghai, at the mouth, being situated in latitude 31° north and longitude 122° east. Colonel Prjevalsky, in 1873, found the altitude at this spot to be 13,150 feet above sea-level, and at this distance of 2,800 miles from its mouth, he found the river impassable, and speaks of it as a rapid torrent fordable in autumn after the floods have gone down, but only in a few places, with an average depth of 5 to 7 feet, and a width near the confluence of the Murui-usu with the Napchitai of 750 feet; but the whole river-bed from bank to bank was upwards of a mile wide, and, so his guide assured him, this was entirely covered during the rainy season in summer, when the river sometimes overflows its banks. Later, in 1879, the same indefatigable traveller followed up one of the affluents of the Murui-usu (the name given to the Upper Yangtse by the Mongols), almost to its source in the Tang-la mountains at a height of 16,400 feet, in latitude $33^{\circ} 50'$ and longitude $92^{\circ} 20'$.

This branch, the westernmost of all, and the farthest in distance of the many streams that go to form the navigable Yangtse, is commonly known as the Kin-sha Kiang, or Gold-sand River. Running parallel with the Kin-sha, and to the east of it, is the next largest stream—the Yalung. This branch takes its rise not far south of the Dring Nor, the lake in which the Yellow River has its source, the two basins being here separated by the Baian Kara range. The two streams flow in parallel ravines 60 to 100 miles apart, and run almost due south through seven degrees of latitude to their point of junction at the fork near the Yunnan border in 26° north latitude. The united streams here turn north-east and continue to flow in magnificent gorges past the foot of the Sun-ridge mountains, 15,000 feet high, the home of the independent Lolo, a distance of some 100 miles, to the city of Sui-fu. Sui-fu is an important distributing centre, and the first large city washed by the waters of the Yangtse after it issues from its fastnesses in Tibet. This city is built on high ground at the confluence of the Yangtse River proper, and its great affluent, the Min, which here joins it from the North. It is indicative of the fact that the Gold-sand River only becomes practically navigable after its confluence with the

Min, that the inhabitants of Sui-fu, with the disregard of accuracy, combined with practical knowledge characteristic of the Chinese, here designate the Min as the "Great River," and the Kin-sha as the "Small River." The Min appears from ancient times to have been regarded by the Chinese as the main stream, owing to the fact of its being navigable and flowing through a fertile, populous country, while the Kin-sha drains a wild, valueless mountain region still almost totally unexplored. Thus, in describing the Yangtse basin and the British sphere, so-called, we shall not err if we follow the Chinese in treating the Min River as the real head of the Yangtse region and this we propose to illustrate with our lantern slides to-night.

In the autumn of last year I had the good fortune to follow up the Min River to one of its sources on the edge of the Tibetan plateau, to a place called Djang-la, a day's journey north of the Chinese frontier fortress of Sung-p'an Ting; I say good fortune advisedly, because any European who can escape from the damp, hot-house heat of the windless Red Basin, and pass through the snowy range, up into the dry bracing air of the Tibetan plateau, is to be esteemed fortunate. For this lofty range arrests the monsoon clouds from the warm China Sea which bank up against the snowy mountains, not unlike the cloud curtain over the Terai in India, hung up against the Himalaya. On this grand plateau, I, like others, have found restored health and activity, and am confirmed in my estimate of its beneficent climate by the splendid contrast its inhabitants present in physique and good looks, to the pale, dyspeptic Chinese of the lower Szechuan basin. Although the true source of the Min, judged by length of flow, is nearly 100 miles to the North-West, yet, at the time of my visit in October, 1897, the Djang-la stream provided the larger body of water. This stream has its source in nine springs of warm water—so the natives call it, although the temperature was only about 50° Fahr.—which bubble forth out of a valley to the North, bordered by low hills of limestone, a temple marking the sacred spot. Away to the North-East dividing the plateau from the basin of Szechuan, rise the magnificent snowy peaks of the Shüch-pao-ting, apparently 22,000 to 24,000 feet in height, and the springs at Djang-la probably have here their source, and flow thence in underground channels until they spring to the surface at 11,000 feet above sea-level. Be this as it may, the water

is undoubtedly warmed by its passage through the ground, and never freezes in the coldest winters. These springs unite to form a good-sized stream, which flows in a rapid current of deep, pellucid water, through the centre of the main street of the little village of Djang-la, where its channel is lined with wooden walls and crossed by numerous wooden bridges. A short distance below it joins the Sung-p' an river, as it is locally called, in reality the Min, which flows hence in a deep ravine for a distance of 200 miles and more until at Kwan Hien, the "barrier city," it debouches into the famous Chêng-tu plateau and spreads out in many channels which ultimately reunite in the navigable Min, a short distance below the walls of the provincial capital Chêng-tu; these walls are defended by the wide swift-flowing streams of the upper Min, which form together a magnificent city moat surrounding this, the viceregal seat and busy metropolis of the vast province of Szechuan. Here navigation properly begins, at a distance, by the river's course, of 2,000 miles from the sea coast. Flat-bottomed boats, drawing under two feet of water, come up to the still-existing bridge of Marco Polo, outside the West Gate of the capital where, in the 13th century A.D., the Great Khan had his "Commercy" or Customs, which brought him in 1,000 gold pieces a day. These boats carry down the surplus produce of the rich Chêng-tu plateau, as well as the mountain products of the neighbouring Tibetan border: rhubarb, sheep, wool, musk, and skins. One hundred miles lower down a transshipment takes place into larger boats, which convey the goods 300 miles farther down stream—delayed at many *likin* stations on the way—to the treaty port of Chungking, the great distributing city of Western China, and future centre of its railway and navigation systems. Here the goods come under the tender mercies of the Imperial Maritime Customs, or the Foreign Customs, as they are generally called, and are sent on by junk again down river, the 500 miles of rapids and gorges which lead to the present head of steam navigation, Ichang. At Chungking, the Yangtse has already grown into a large, navigable river. In the summer flood season, the Yangtse at Chungking may be compared to the St. Lawrence, at Quebec, the Charles River there being precisely analogous in position to the Kialing River in Szechuan, that great affluent from the North, which unites with the Yangtse under the walls of Chungking; that city, like its Canadian analogue, being

built on a high rocky peninsula formed by the here nearly parallel courses of the two rivers. The city of Chungking presents a remarkable resemblance to Quebec in outline, although in detail the contrast is as great as that between the East and the West generally. Chungking is far the more populous; including the sister city of Kiang-peh (*i.e.*, North of the Kiang), and the suburbs on the east bank, the population is estimated at from 400,000 to 500,000, and, being crowded upon a narrow, inelastic tongue of land, its inhabitants are pinched for room, and the handsome streets of the business quarter are as crowded as those of Canton. It is a luxurious city, and contains an unusual number of beautiful buildings, stately guild-halls, belonging to the different groups of traders from all provinces of the empire; as well as the gorgeously-decorated residences of the wealthy merchants and bankers. The people generally are well, not to say handsomely dressed; an air of marked prosperity and wealth pervades the place, and although there is much poverty among the coolie class, whose scanty wages only allow them to live from hand to mouth, this poverty is mitigated by the free rice kitchens which are kept open to all throughout the winter, and whose expenses are liberally met by subscriptions from the well-to-do classes. The severest suffering to the poor is caused by the great rise in the river in the rainy season, usually 80 or 90 feet above the winter level, and often, as was the case this past summer, to over 100 feet. Land being so valuable the poor risk building their houses outside the walls below the level of safety; then comes a sudden and unexpected rise, due generally to the flooding of the affluents above Chungking or the right or Yünnan bank, when whole villages are occasionally swept away and large numbers of people drowned in the floods. I have known the river rise as much as 25 feet in a single night. During the persistence of such a freshet all navigation is stopped; the broad river is converted into a roaring torrent with high breaking waves, and communication between the towns on the opposite shores is often stopped for days at a time by the ferry-boat being unable to cross. The river is then widened to over 600 yards and with a depth of forty to fifty fathoms; at the lowest winter level and at the narrowest point opposite Chungking its width is about 300 yards, with an average depth of 30 feet. Hence, the main traffic on the river is carried on in winter when tracking is comparatively easy: in summer the land route

mostly a succession of stone staircases which lead up and down the steep ranges into which the province is broken up, form the easiest and only safe route for the conveyance of passengers and merchandise throughout this populous country. These roads are thronged by porters and the main roads are lined with tea and rest-houses which depend upon this traffic for their custom. The cost of moving merchandise, which amounts roughly to one shilling per ton per mile, would seem to be a deterrent to all commercial intercourse; but so strong are the trading instincts of the Chinese that this is not the case and we find limited quantities of Manchester goods on sale even in Ta-li Fu, in Western Yunnan, which is mainly supplied from Chungking, although the carriage thither amounts up to £38 per ton.

Leaving Chungking, where we have made, I hope, no longer stop than its importance deserves, we descend a distance of nearly 300 miles, as measured by the windings of the river, and by a course almost due north-east, through the rich district known as "Tung Chuan," *i.e.*, Eastern Szechuan, to the flourishing city of Wan, likewise situated, as are all the chief towns up river from and including Hankow, on the north, or left bank. In this section of the river the rapids, though numerous, are short and easily negotiated, while the river flows through a more open, though still exclusively hilly, country rich in every variety of sub-tropical produce, of which the noxious, yet beneficent drug, opium, is not the least. Wan Hien itself is, like all the cities of China, surrounded by picturesque mediæval fortifications, pierced by imposing gateways. It is a smaller Chungking, a great junk-building centre, and home of rich junk-owners, and does a large trade in sugar and paper. This paper is made from macerated bamboo and is extraordinarily durable when compared with the miscellaneous productions of Europe. Indeed, the Chinese libraries of to-day stand a chance of being still in a good state of preservation when much of the doubtful paper of our 19th century literature will have inevitably decayed. As is to be expected amongst a literary people like the Chinese, the paper trade is a most important branch of general commerce. Apart from its business activity, Wan Hien is remarkable for its beautiful natural scenery, due to its being situated in the heart of a region of new red sandstone, with stratification almost perfectly horizontal, which has led to the cutting of innumerable ravines with vertical walls, adorned with the abounding vegetation of a

moist, warm climate, where frost is unknown. One curious rock in Wan Hien, known as the "Celestial City," rises abruptly 1,200 feet above the walls. The ascent is by a toilsome staircase cut in the rock face, the summit of which leads through a handsome archway into a small walled city, its lofty stone crenelated battlements crowning the precipice which surrounds this unique city on all sides. By my aneroid I made the height 1,235 feet, but I was more surprised to find the, possibly 30, acres of the flat summit covered with houses. There is a fine spring of fresh water and a pond never dry at the top, and the inhabitants are mainly well-to-do families who continue to live there on account of the greater security of the place in times of riot and rebellion. The Szechuan Chinese think no more of steps than do the Maltese. The view from this elevation is superb, but if I dilate on it, as I should enjoy doing, we shall not reach the sea to-night.

Soon after leaving Wan we enter a poorer country, where the rainfall is no longer regular as in Tung Chuan, and where, in consequence, of late years the unfortunate inhabitants have been a prey to an alternation of torrential rains and prolonged droughts. The excessive rains of September, 1896, produced the phenomenal landslip of Yünyang 50 miles lower down, which in one night narrowed the river from 600 to 150 yards, suddenly creating a new and dangerous rapid. I must not linger here, but I may perhaps be allowed to point out that you will find a detailed description of this remarkable earthquake—the site of which I visited while the disturbance was still examinable in all its original wildness—in a new edition of the "Yangtse Gorges," recently brought out by Sampson Low and Co. Another 50 miles brings us to the noted Szechuan frontier city of Kwei-chow Fu, or "Barrier of Kwei," once the seat of a flourishing custom-house or "grand commercy," as Ser Marco calls it, the mainstay of the viceregal revenue, now ruthlessly undermined by the imperious barbarians through transit passes, and sadly fallen from the high estate it held when I first visited the place fifteen years ago. Then its great water thoroughfare was alive at night with sounds of music and revelry, and its lively and more or less rowdy populace was a terror to the foreign traveller. Now famine and rebellion have added to its misfortunes, fiscal and other; the place has a quiet, decaying air, and its population is miserable. The changes which we call improvements are, even when necessary, often a very doubtful benefit to the people

more immediately concerned, and measures which our diplomacy wisely enforces produce great hardship through natural hesitation to carry our interference still farther and provide that "compensation for disturbance," which the Chinese officials themselves are helpless to bring about. Let us hope that the new era of railways and mining which has at last been inaugurated will provide employment for the people and an increase of income to the disturbed officials; for, as things now are, the Customs revenue is required to pay the interest on the cruel money indemnity—in addition to the cession of the rich island of Formosa—extorted by the Japanese after their successful war, in imitation of the bad precedent set by Germany in her settlement with France—*Væ Victis!*

A transparency of Kwei-kwan will enable you to form a good idea of the extent of the city, and of its position; while, as another slide shows the entrance to the magnificent Bellows Gorge, or, as it is well-named in the old Chinese gazetteer, the Gorge of the Fear-some Pool. This is the uppermost of the grand gorges, of which we have taken photographs; these, however, in the absence of colour, and with the difficulty of portraying their huge proportions in the limits of a camera, can only give you a faint idea of their real magnificence and the awe-inspiring impression which they make on the ascending traveller in his fragile barque. These grand gorges of the Yangtse are formed by the clefts which the river has slowly scooped out while cutting its way through the rugged mountain barrier, 100 miles in breadth, and 4,000 to 5,000 feet in height, which separates the two provinces of Hupeh and Szechuan, and which made of the latter in ancient times a kingdom apart—a happy Rasselas valley unknown to and undisturbed by the restless outside world. The rapids occur with great regularity in the broken intervals between the gorges; in spots where the clean-cut walls of these latter have broken down and dammed the stream, assisted by affluents in the shape of great mountain torrents on either shore that have cut out lateral ravines of their own and helped to block the main stream with the resultant *débris*. The clean-cut cliffs consist almost entirely of hard pure limestone built up largely of spiral ammonites and the straight orthoceras; these latter are often found embedded in a hard slate and are cut into sections and polished and then sold as pagoda stones, and are

held in much esteem by the Chinese as a freak of nature imitating this sacred edifice of Buddhistic piety. On the other hand, where the river traverses granitic mountains, the rock is disintegrated by the water, and the river bank is composed of broken piles of gigantic boulders in lieu of the smooth cliff-walls of the gorges proper. In these latter the current is slow and the water astonishingly deep; with a lead line 150 feet in length I have often found no bottom, but I have never had the leisure to prosecute an accurate survey, and hence my figures are only approximate. Such a survey we trust our own Admiralty will shortly undertake, and its results must be of the greatest interest to geologists as well as to would-be navigators.

The last and lowest of the great gorges terminates five miles above the treaty port of Ichang, the present terminus of steam navigation. Here the alluvial plain begins, broken by mountain ranges athwart the stream, similar in character, but far less lofty and less continuous than those traversed by the gorges. From their flanks issue the great affluents from the South, two distinct and separate congeries of river net-works, each having an estuary of its own in the shape of a wide, shallow, inland lake, their combined waters more than doubling the volume of the Great River, below the point where the Szechuan waters, which we have hitherto been engaged in tracing, unite with those flowing forth from the Tungting and Poyang Lakes situated, the former 700 and the latter 450 miles from the Yangtse's mouth; between these two stands Hankow at the confluence of the Han and Yangtse. Hankow means Han-mouth and indicates its site. The Han is the great Northern affluent descending from the lofty Tsing-ling mountains which form the dividing range of the Yellow River valley from that of the Yangtse, and includes parts of the Northern provinces of Honan and Shensi in its watershed. From Ichang to the sea the river flows again through a fertile and populous country past towns innumerable, including three provincial capitals, of which two, Nganking and Nanking, are not yet open to foreign trade; and past five open treaty ports until the terminus of river navigation is at length reached in Shanghai, whence ocean lines radiate in all directions.

The Yangtse basin, of which the above is but a slight impressionist sketch—volume would be needed to describe such an immense region in detail—comprises a watershed of

600,000 to 700,000 square miles [compare Great Britain with its area of 80,000 square miles] over one-third the area of China proper. It is one of the richest, if not the richest, sub-tropical region on the world's surface, and is inhabited by a people as hard working in their way as that of the United States of America, with which country it has so many points of analogy. The whole region, except the high pastoral plateau of the Tibetan portion of the catchment area, is cultivated like a garden: the mountains of Szechuan are terraced to their summits, and a ceaseless rotation of crops is forced from a willing soil by the repeated application of manure carefully garnered from the cesspools of the countless towns and villages which abound throughout this thickly-populated country. The vast mineral resources have hitherto lain practically undeveloped, but foreign methods and foreign capital will ere long do for these what Chinese hand labour has done for the surface soil, *i.e.*, develop mining; and so, with the additional aid of steam communication, enable China in time to rival Europe and America, certainly in wealth, possibly in power. The share that Britain is to take in this awakening of China to a development of her resources is vaguely indicated by what is commonly known as the British sphere. This sphere has so far, officially, neither been geographically described nor have its privileges or obligations been in any way defined. A Cabinet Minister did once speak of it indefinitely as the British sphere of interest, meaning thereby, apparently, that China's attempted alienation of this sphere to any other foreign power than ourselves would be regarded as an unfriendly act, and (such is the inference) lead to our forcible interference. But this has never been positively stated: the only official act is the letter of the Chinese Foreign Office on the subject, addressed to the British Minister in Peking on the 11th February of this year. This quotes Sir Claude MacDonald as saying "that the Chinese Government were aware of the great importance that has always been attached by Great Britain to the retention in Chinese possession of the Yangtse region, *now entirely hers*, as providing security for the free course and development of trade," and goes on to say that never shall territory in it be ceded to another Power.

Unfortunately the Chinese have no means to prevent such cession should it be forced upon them by an alien European Power. The whole

crux of the position lies in the question—are we prepared to assist China to keep her promise? We can but give statesmen in this country the credit of understanding the situation, and being prepared, in the contingencies that spring out of the political weakness of the Chinese Empire, to act boldly as the best interests of this country demand. Meanwhile it is satisfactory to notice that the field is not being neglected by British capitalists, and that the lion's share of the work to be done, not alone in this special sphere, but throughout China generally, is falling into British hands, as befits those who have been mainly instrumental in opening up this wonderful and secluded country to the commerce of the world. In any case it is to be fervently hoped, as much in the interests of their own reputation as Christian Powers, as in the interest of the Chinese people, who, though with different ideas on the subject of patriotism, still love their country and their independence, that the nations of Europe will mutually agree to respect the integrity of this ancient empire. Harbours and fortified naval stations on the coast are now held by Britain, Russia, and Germany; it will be to the common advantage that the Hinterland of these posts of vantage should remain open as before, and it should, one would think, not be beyond the scope of an enlightened diplomacy to bring about common action to achieve a result so beneficial to all concerned.

At the conclusion of the paper, Mrs. Little described a number of lantern slides of the Upper Yangtse and beyond, which were shown on the screen.

DISCUSSION.

The CHAIRMAN, in proposing a vote of thanks to Mr. and Mrs. Little, said he had often presided at meetings of the Society, but he ventured to say that seldom, or never, had a more important paper been read, and a more valuable set of photographs exhibited within those classic walls. As might have been expected, the descriptions by the gentleman were the more scientific and more descriptive of important features, and those by the lady were the more graphic and beautiful. He should like to point out two great patriotic morals to be drawn from the paper and the photographs. As Mr. Little had spoken of the boundaries of the British sphere in the Yangtse Basin, he hoped that England would claim the whole of that sphere, the entire river, including that of Yangtse proper and the river of the Golden Sand, which was a continuation, with every affluent

and water-shed on the north and south. This, as they had been told, had not yet been delimited. There was a certain tone of complaint in Mr. Little's voice, as if he considered that England had not been quick enough, but it must not be forgotten that it was only since last March England took the matter in hand. Casting up results from that time, it would be seen that they had done pretty well. Further, Mr. Little said that one Cabinet Minister had been speaking of the sphere of British interests, but he had not gone beyond that. He (the Chairman) would point out that Cabinet Ministers were very apt to say what they thought Parliament demanded, and Parliament would demand that which the electors asked for. In the first place it was for experts like Mr. Little to explain the political and commercial aspect of the question to the electors, who in turn would make their voices heard in every great port and commercial centre of the British Isles, so that the magnitude of the interests concerned might become widely known, and it might be shown how vital these interests were to the livelihood of the working-classes in densely populated countries. If the electors of the country would do this they would accomplish a great deal, and in the long run it would be found that the House of Commons was the great centre of British patriotism. Further, he would recommend that the matter be brought before the Chambers of Commerce, who, when they found their interests were materially affected, would thunder at the gates of Cabinet Ministers. After that had been going on for a year or two, it would be found that Cabinet Ministers would speak quite as definitely as the country required. If they spoke indefinitely now it was because they were not quite sure as to the view of the nation, but, if the nation were prepared to make the sacrifice, the Cabinet would enter upon a truly patriotic and forward policy. No doubt the meeting was aware that, at present there was a railway which ran up from north to south; from Mandalay a railway had been sanctioned and was now in course of construction as far as the Ferry, where it stopped, because if it went further it would infringe on Chinese territory in the British sphere. It was for the electors of England to insist that the railway should be continued to the base of the Yangtse Plateau. When once they got to Talifoo, then the River of the Golden Sands was not very far off—and then they would get on to the navigable junction of the Min, and then to Mr. Little's sphere which he had won for the country by his commercial enterprise. When they got below the rapids they proceeded on to the Great Lake, and up that lake gunboats had been repeatedly taken from the Yangtse mouth in the rainy season. That was one way of asserting British supremacy in the Yangtse. What an imperial prospect would be opened out for British commerce! The day was not far distant when they would have a through line of communication from Rangoon in the Bay of Bengal to Shanghai, near the mouth of the Yangtse and the waters of the Pacific

—a through line of more than 3,000 miles of British communication, with Siam and Cambodia, the Malacca Straits and Tonkin, on the right, and the mountains of Upper China on the left. This was a thing to work and fight for, and he insisted that these grand imperial interests, which formed the future of the trade of this country, would be promoted by means of the paper to which they had just listened.

The vote of thanks was then put and carried unanimously.

FIFTH ORDINARY MEETING.

Wednesday, December 14, 1898; Sir Philip Magnus in the chair.

The following candidates were proposed for election as members of the Society:—

- Digby, William P., Valeyev, Wanstead-road, Bromley, Kent.
- Laing, John Alexander, Rosendale, Stanstead-road, Forest-hill, S.E.
- Hacking, Charles Leonard, The Gables, Nightingale-lane, Clapham-common, S.W.
- Harries, David, Portland College, High-road Chiswick, W.
- Moriarty, Hon. Arthur S., I.C.S., care of Messrs. Grindlay, Groom and Co., Bombay.
- Phillips, H. Fentum, Guildford Electrical Works, North-street, Guildford.

The following candidates were balloted for and duly elected members of the Society:—

- Agnew, Sir William, Bart., 11, Great Stanhope-street, W.
- Gardiner, Henry Nathaniel, 30, Finsbury-circus, E.C.
- Gibb, George S., North Eastern Railway, York.
- Hayles, George Edward, 12, Northampton-park, Canonbury, N.
- Jacob, Augustus Hamilton, M.A., 26, Maberley-road, Upper Norwood, S.E.
- Sears, Arthur Holroyd, Cae Glas, Llandrindod Wells, Radnorshire.
- Townsend, John Walter, Wendreda, Lancaster-road, Wimbledon, S.W.
- Walker, Arthur Tannett, Messrs. Tannett, Walker and Co., Leeds.

The paper read was—

COMMERCIAL EDUCATION.

By SIR ALBERT ROLLIT, M.P.

The subject of Commercial Education has become one of supreme and pressing importance, and having, as President of the London Chamber of Commerce and Chairman of its Commercial Education Committee, taken

an active interest in the question for some ten years, during which period it has attained its present prominence, I venture, in response to the request of your Council, and, I hope without undue presumption, to speak of it before your Society.

This reserve is due from me because, as a former Vice-President and member of the Council of the Society, I cannot forget that the Society of Arts, has for very many years promoted not only Technological, but also commercial, education by its examinations, formerly for its commercial certificate and since for proficiency in commercial subjects; while its Secretary, Sir Henry Trueman Wood, has also rendered great service at the Chamber of Commerce as a member of the Commercial Education Committee.

In this paper, I make no claim to originality, almost the most that can be said upon the subject having been already better said by others; what I seek to do is, rather, to summarise that which has already been accomplished,—and to make this a foundation from which to urge that further action which is so much needed in the interest of both the individual and the Nation, of commercialists and the community.

Moreover, I cannot claim to speak in any sense as an Educational Expert, like Sir Philip Magnus, but merely as a man of affairs.

From that practical standpoint let me first ask what is the modern conception of education in what Shakespeare calls "This work-a-day world," in which men cry "live and let live," and which

"Is a very good world to live in,
To lend, or to spend, or to give in;
But to beg, or to borrow, or get a man's own,
The very worst world that ever was known."

But, whatever it is, we must make the best of it; and education is the art whereby we seek to enable our youth, individually and as members of society, to make the best and most of themselves, intellectually and physically, by the development of the faculties and potentialities which they inherently possess, and also by furnishing them with suitable and adequate knowledge.

Most educationists are agreed that in the primary," or earliest stage of this process, the principal means should be, that the object, methods, and instruments should be not merely the loading of the memory, but formative, disciplinary, mind-making, with a view to the formation of character, and to that power and habit of good thinking which may

readily apply or adapt itself to any subject; just as, physically, the muscular system is best trained by general gymnastic exercises, before applying its developed powers to any special purpose of peace or war.

The etymology of the word "Education" itself,—derived from Educere, Educare, to draw out—attests the length and permanence of this view, and though the present signification of "information," indicates knowledge, even the word "informare" at first implied as fundamental an operation of the mind as educare forming and giving a defined form to a mere potentiality of thought in the human mind.

But even in the primary period, when any direct and special commercial instruction is, of course, out of the question, considerations of utility have never been entirely foregone, and, while the educational problem has been to form mind and character on general lines applicable to the vast majority of mankind, its solution has, nevertheless, properly proceeded in a resort to some subjects which, while disciplinary, are also of general practical service, such as are, indeed, the three R's.

Good grounding and thoroughness in primary work, (the term of which, both for whole and half-timers, in our public elementary schools ought to be extended in pursuance of the resolutions at the Berlin Conference), is the absolutely necessary basis of all secondary and higher training, whether professional, technical or commercial; and this was not only enforced at the recent Conference on Commercial Education at the Guildhall, over which I had the honour to preside, but has been impressed upon me by the reports of the staff of several Technical Schools which I have recently visited,—at Nottingham, Huddersfield, Blackburn, Keighley, Oldham, and elsewhere, in which the far too common complaint is that defects in elementary training in general knowledge and science are the great obstacle to the conveyance, and a full realisation of the value, of scientific and technical instruction.

Foreign experience is the same, e.g., Mr. Consul Powell, of Stettin, tells us that Germany has been able to cover the country with Commercial Schools chiefly within the last ten or twenty years, while we have been thinking and talking on the subject, just as she gave us the example of technical education, owing to the excellence of her general educational system, a system the primary part of which preceded ours by three-quarters of the century, and which must make memorable for ever the words of

the great minister, Stein, to his Prussian King, "Sire, we must make up intellectually what we have lost materially,"—words which sprang up from the field of Jena, like the mythical letters from the Dragon's teeth sown by Cadmus in Ancient Greece, and bore their fruit at Sedan, where the disciplined mind of Germany overbore the mind of their former conquerors. The Duke of Wellington said our battles were won in the playing fields of our public schools;—those of Germany were won in the schools themselves. So Moltke said the Prussian schoolmaster won the battle of Sadowa; it was a victory of the Prussian over the Austrian schoolmaster.

Equally, in the stage of secondary or intermediate education it is generally agreed,—and this agreement has just been almost unanimously re-enforced by our only Minister of Education, Sir John Gorst, and by both educationists and men of business at the Guildhall Conference,—that youths in this stage are to be regarded as still within the domain of the schoolmaster, and not of the man of business, and that specialisation in mercantile matters is premature, except, of course, to the extent of the conventional subjects I have mentioned; and except in the resolute insistence in "Modern Sides" of schools of more commercial arithmetic (including, of course, the metric system), and upon the inclusion of at least one foreign language taught conversationally, elementary drawing, and physical science (taught experimentally). The ordinary curriculum would naturally include English composition and geography and history, and the latter may well comprise the duties of citizenship.

Personally, as one who believes that the danger of over-pressure has been exaggerated, and has often been made an excuse for immobility in the beaten tracks, I would have attention given at this stage, in the case of youths known to be intended for business life, to commercial geography, a subject of great interest, and also to the elements of political economy, while others at the Guildhall Conference emphasised, I think rightly, the essential importance of good handwriting, and some the value of the early teaching of the principles of book-keeping. A few desired the addition of shorthand.

The principal subjects recommended at this stage may, by good teaching, all be made disciplinary; languages are best commenced young; experimental science appeals to curiosity and the imagination; and they will all

become, in business, absolutely necessary, too often when it is too late. Let them, then, be first taught, at any rate, how to be learned, by the schoolmaster; not, as in my own case, after four years at a great public school, by myself, and let us also take care, that in future the schoolmasters, as men of business have to do, quickly conform at all stages of education to demands and changes which may properly be made upon them and their curricula owing to the exigences of modern business life.

Subject to these observations, however, in which I think most men of business would concur, there is a general agreement that, at any rate in the earlier part of the secondary stage, not much, if any, more than the above is requisite, coupled, however, as it must be, with good and thorough teaching, with a view to the formation of character and to the cultivation of a love of knowledge, for if a man is once made to love learning he will have learning.

And, of course, variations must be made to meet special cases; indeed, the last thing to be desired in education is such a stereotyped uniformity as that of the older Lycées in France; it may be said even of Mr. Squeers that his methods were various and his instruments elastic.

On some points of principle and practice, however, we have come to a distinct parting of the ways between the older and the newer schools of education, between the ideas of the older dominie and the modern merchant and schoolmaster. When the generality of our grammar schools were first founded the classical portions of their curricula were in accord with the spirit and comparative leisure of the age, and, even now, if a youth's time for education is unlimited, much may be said for Greek, and much more for Latin, as most perfect instruments of mental discipline and culture, while even metaphysics may at least be heard in their own defence through their professor at Edinburgh:—"This road," chalked a student on the door of his class-room, "leads to nowhere." "Nevertheless," chalked the professor underneath, "a good road to take exercise upon."

But nowadays life-time is brief, and school-time is fleeting, and that time has been too often worse than wasted in Greek and Latin verse-making and word-mongering, without a hope of penetrating even the outermost chambers of the literature and language the pupil is supposed to be studying. Better, then, if such are the vestibules, to accept them at once as

the warning of Plato over The Academy: "He who is ignorant of Geometry may remain outside." As the schoolboy himself sighed: "It is a good thing the Romans never had to learn the Latin Grammar, or they would not have had time to conquer the world!"

And, let me here recall the historical fact that, even in these early grammar school days, which coincided with both the making of education and the making of our colonies and commerce—the times of the Tudors—the merchants of London realised that some special training for trade was a necessary supplementary part of the educational system of a great maritime and mercantile power. For they founded such a school for commerce as Gresham College, of which we know that its halls were so crowded out with students that they thronged the very courts, lanes, and alleys of the City, and, so great was the fame of its utility, that King Francis, of France, sent a Royal Commission to study its systems and success, whose Report led to the formation of the equally famous College de France. Thus England, in the time of the making of her trade, was the home of commercial education; may it never be quoted, as a symptom of her unmaking, that in these latter days we continued to import it wholesale,—like too many of our commodities,—in clerks "made in Germany," or in other human cases indelibly marked with some foreign country of origin?

Let us be warned by the story which has led up to such results. Our grammar schools became anything and everything but grammar schools, though it is quite true that many schools have been reformed by schemes of more or less merit, remitted by Parliament for discussion in the dead of night,—for they are taken only after midnight, when men who have business to attend to next day have mostly left the House. True, too, so-called "Modern Sides" of schools have been formed, but in many cases they are even yet shams, and in many are given no real chance, owing to the social atmosphere of our public schools. This I say on the authority of masters at some of the greatest of them. They are something very different from their nearest counterpart, the Realschule of Germany, whose teaching is practically the grounding for a business life.

Hence the growth of real reproaches—such as, that our pedagogues taught, instead of five languages,—

"The Languages—especially the dead;
The Sciences—especially the abstruse;
The Arts—at least all such as would be said
To be the most remote from common sense."

And satire, such as that put into the mouths of school men themselves, with methods so out of joint with the times: "We know nothing of science here—we don't even teach it." And students' sarcasms in their examination papers: "The Romans never produced a philosophy of any moment. Account for this." Answer: "I cannot unless it was that the Latin language was too clear for that sort of thing."

Remonstrance and reaction naturally followed, but, while, admittedly, improvement in our secondary teaching has even already resulted, that system and stage of public instruction itself is still in a somewhat chaotic condition, under no responsible Minister of Education, such as was authoritatively proposed by a Government so long ago as 1867; with no central or local authorities or areas; with no authorised tests of either teachers or their teaching, although we all know the truth of the Prussian maxim: "As is the master, such is the school," and "To make our education great we must make our educators great;" with no systematic grading or co-ordination, resulting in overlapping and waste of both educational and financial resources; and with little but voluntary, and often spasmodic and misapplied, and of any sort.

No, it is due to Parliament to record that it *has* granted some aid, in its usual fashion, leading partly to its most admirable use, partly to unwise economy of local rates, and to some extent to further waste.

A year or two ago, the Chancellor of the Exchequer proposed to tax their beer and spirits in order to reduce public-houses at the expense of the publicans; but the publicans, and even the teetotalers, were also sinners, and would have none of it; and so the "whiskey moneys" were thrown at the local authorities almost to drink or to do, or not to do, what they liked with them. Some did nothing; some something; most boroughs and some counties were wise enough to devote all to technical and also, in part, to secondary education, which, unlike the Science and Art Department, they were held to be at liberty to do; and some boroughs have even rated themselves for the same educational purposes.

Thus, just as some boroughs have recently had Peers for Mayors, whose arms and signs have thus been made to hang out not only from the public-houses, but also from the mansion houses of the country, so the unappropriated cash of the publicans was suddenly diverted from their casks into the coffers of

County and Borough councils, which, though absolutely inexperienced educationally, have justified the confidence of a Chancellor embarrassed by riches, and in this haphazard way Parliament has done something for technical and commercial education, while the schools have since been distilling learning out of liquor, and business out of beer.

And now, happily, whatever obstacles have existed to the production by the Government of a better Secondary Education Bill than those of 1896 and 1897, are, so far as concerns local areas, likely to be removed by a compromise effected between the county and non-County Boroughs, under which, while County-Boroughs and Counties will form, as of course, such local areas, non-County Boroughs may become so, if they satisfy the Central Authority that they have the necessary educational means and machinery—a compromise far better than the ministerial one, in 1896, of a population line drawn at 20,000 inhabitants; and, with the same object, some are prepared to vary the Bill of 1896, which was in this respect satisfactory to the Municipalities, by making the Local Authority to be a Committee appointed by the Town Council, with independent powers, and with members co-opted from School Boards and other educational bodies, and though, personally, I greatly prefer municipal autonomy, and reserve my own course of action, the principal consideration is, in the interest of Public Education, to secure, if not the best Bill, the best Bill we can get for the organisation and reform of secondary instruction, if, chiefly, with the object of promoting Commercial Education.

Meanwhile the popular demand for a greater adaptation of Education to the wants of the day has steadily grown, especially among the manufacturing and commercial classes.

And this feeling has been stimulated by the experience of the rapidly growing industrial competition of other nations, and an increasing knowledge of its contributory causes, one of which is firmly believed to have been greater knowledge based on better Education. *Fas est ab hoste doceri*, and the Reports of the Royal Committee on Technical Education, of the Iron and other Trade Delegations, of the Society of Chemical Industry, of our own Consuls, and of our Chambers of Commerce have opened men's eyes to our educational shortcomings and to the necessity of commercial self-preservation.

Happily, though late, but, let us hope, not too late, much has been accomplished for Technical

Education, partially by the State and partially by Local Authorities, much by City Companies and largely by local patriotism in founding scholarships, prizes, and otherwise, though, as ever, in the wrong order, for secondary general education is the proper basis of Technical Instruction, and we have put in half the third storey by shoring up, instead of building, half the second, and, though necessarily, before the first storey, and even the foundations, have had time to settle. However, let us be thankful for tardy mercies, and hope that what we have built, though much in skeleton, has had at least some benefit from that wisdom which, by avoiding mistakes, comes best from the experience of others. For instance, we have wisely blended in our splendid Municipal Technical Schools, theory and practice; we have made the school not the substitute for, but the complement of, the workshop, and have thus recognised the characteristic practicality of the English Artisan as compared with the somewhat too professional teaching of many foreign schools.

At the same time, we have unfortunately yet very much to learn from our foreign friends and rivals. Compare our best Municipal educational work, as at Nottingham, under the direction of such an able administrator and educational expert as the Town Clerk, (Sir Samuel Johnson), with such leaps and bounds as those at Strasburg, where, since France's Jena, only a quarter of a century ago, a University has risen, each of the eight departments of which is better than our best local work.

The University of the greatest modern seat of trade and commerce should be many-sided; it should be in closest touch with the commercial and business and trade life of the City of London and of all classes, including the masses, and it must, as I proposed at the Senate, unite commerce with culture, and training with trade by its highest teaching, and by degrees and diplomas in Technology and commerce, as many foreign and some British, Universities have already done. And, with these objects, it should be an outward and visible sign of culture, instead of being, as it long was, a tenant in a common lodging-house in Piccadilly, or as at least it is now, sole tenant of far too small a building in a back street, or an exiled outcast stowed away in a genteel suburb, far from most of those who want to use it.

Meantime, while Technical Education has most properly progressed, little or nothing has been done for its necessary complement, Commercial Education, by which we mean some

special training for trade, an education which aims directly at fitting the individual for the requirements of commerce, and the greater adaptation of general instruction to industrial purposes. The Science and Art Department has been restricted from making grants, or giving prizes, for commercial subjects, as for science and art; comparatively very little has been applied, though there is power to do so, from the Funds appropriated by Parliament to Technical Education purposes, though I have seen at some Technical Schools some slight provision for Commercial Classes; what has been done has been chiefly accomplished by voluntary action on the part of the London Chamber of Commerce since 1887, by the London School of Economics, by the Technical Education Board of The London County Council, with its wise liberality in scholarships and prizes, though, as I have said, the Examinations of the Society of Arts, and, very recently, by the establishment of a School of Commerce at Liverpool, and these seem to be the only present sources of Higher or Tertiary Commercial Instruction or Examination in our own country, though it is due to acknowledge the different, but still valuable, services to Commercial Education of The Birkbeck Institution, certain Polytechnics, and also of Clark's and Pitman's Commercial Colleges, both of which, while having constituencies of a different class, are doing, to my own knowledge, very good work, Pitman's School having a Bureau similar in principle to that which I shall mention in connection with the Commercial School at Genoa.

And yet to have improved production through Technical Education, and to have neglected provision for better distribution, through Commercial Education, is again doing only half our duty, and tends to make what we have done largely futile and even wasteful. Our commodities are made to sell; they are, owing to competition, very difficult to sell; trade is becoming more and more international, and, as we have found by our Exhibitions at the London Chamber of Commerce, many of our wares are being displaced by foreign competitors even in our own colonies. Yet, how can we properly commend, and sell them, if we neglect to arm our people, and their Business Managers, and Heads of Departments, our Travellers, Agents, and Representatives with the chief instruments of international trade—foreign languages; if we fail to make acquaintance with the best machinery and methods of business in other countries, and to

learn their terms of credit and systems of doing business; if we ignore their tastes and wants, and even their orders and directions; and if, instead of learning their weights, measures, and money systems, we still try to force them to swallow and digest the feet, hands, nails, palms, quarters, and even the hides, of our aboriginal ancestors?

As the mover in Parliament of the Select Committee which reported in favour of the adoption of the Metric System, I must, even again, urge the vital importance to our trade and traders of the universal teaching of this branch of arithmetic in, not only all Secondary, but also in Elementary Schools, a point which we attained, together with the complete legislation of metric weights and measures, by our deputation to Mr. Balfour, and through the Act of 1897.

At present, our ignorance of it isolates us commercially, and is a great impediment in our own international dealings.

Nevertheless, our own Consuls have told us, almost with one voice, that what I have spoken of are the banes of British business; they urge the dearth of educated British commercial travellers and agents, as compared with the representatives of other competing nations; and one of our Colonial Premiers himself told me of our want of trade knowledge and adaptation, in that we lost the supply of hosiery to his colony—a free trade one—and compelled it to manufacture for itself, simply because we either did not know, or would not believe that the average colonial thigh was proportionately longer than ours, but would insist on the colonists wearing our own common measures of "pants," whether they fitted their legs or not. The Consuls also tell us—what is simply commercial knowledge, *i.e.*, the product of commercial education—that other people will and do speak, write, commend, catalogue, quote, invoice, and the like, in tongues understood of other peoples, and that some of their travellers would almost have made their fortunes as universal interpreters at the Tower of Babel; and that if the natives prefer tea-pots with two spouts, or two handles, or goods of a different quality or design, they make them, while ours too often say they never heard of such things and won't trouble about them, when, of course, customers won't trouble to deal with them; and all this while the London Chamber of Commerce exhibitions, to which I have referred, have convinced those who saw and studied them, that if we could only learn to adapt ourselves more to the

requirements of other nations, which it is one great object of technical and commercial education to make us able to do, we could, in most cases, supply their wants better and cheaper than our more successful competitors.

I wish particularly to emphasise the case of commercial travellers, agents, and other representatives abroad, and the necessity of their greater acquaintance with the modern conditions of successful trading, and especially with foreign languages. The want of such skilled and qualified representatives of British traders is the bitter cry of our Consuls.

For instance, in Italy, the few travellers employed by us as compared with the German legion, with its samples, price lists, quotations, &c., in Italian, is one of the chief causes which militate against us. Again, in Denmark, the number of foreign commercial travellers may be ascertained from the licensing authority, and I find that while, in 1896, 84 visited that country from Great Britain, no less than 764 came from Germany, exclusive of 171 from Hamburg alone!

Even in the case of Africa, we are said to have been outnumbered by 20 to one. It is more satisfactory to read from Mr. Worthington's recent report on Argentine and Chili, that complaints on the score of languages are now not so much heard—some testimony to our past urgent encouragement of the study of Spanish and Italian—though the want of familiarising with general business conditions is still our great disadvantage.

My own experience has confirmed these Consular complaints, sometimes humorously. I have heard a Yorkshire merchant ask in a foreign shop for a kilometre of polony—upwards of half a mile of it; and an experience of an Alderman, manufacturer and merchant, who spoke nothing but English, was thus told me by himself: "I went to Paris, staying at the Hotel de Lille et d'Albion. Never having been before, I lost my way, and could not find my hotel again, because I neither spoke nor understood French. Thinking some of the people I met might understand written English, I went into a stationer's shop and bought a large card, on which I wrote 'Please tell me the way to the Hotel de Lille et d'Albion.' Again I sallied out, showing my card to several, but still to no purpose. At last a gentleman read it and silently beckoned me to follow him, which I did as silently, for a mile or more. Then he pointed, still silently, to the

sign of the hotel, and when I saw it, I broke the silence by exclaiming 'Thank you.' 'What,' he replied in amazement, 'are you an Englishman? So am I, but I took you to be deaf and dumb.'"

Now, we are lamenting some loss of British exports. I think little of the relative increase of the volume of trade of most other countries, much of it owing to our long monopoly of coal machinery and shipping, has sprung from comparatively very small beginnings, and, with the greater equalisation of instruments, there must be a large relative per-centage increase; but the comparative decrease of our exports demands some attention, in face of the fact that during the present decade those of Germany and Central Europe have increased 13 per cent.; those of France $1\frac{1}{2}$ per cent.; and those of the United States 18 per cent.; while British exports have decreased 5 per cent.

No doubt there is a plurality of causes for this, over some of which, such as that of the Suez Canal in restoring the old trade routes to and centres of distribution in Central Europe, we have not only no control, but compensation in benefit to our carrying trade. Neither do I stop to inquire whether freights in that trade—invisible imports—or interest on investments paid through imports, our living upon capital, &c., furnish adequate explanations of the balance of our trade in the excess of imports over exports. The fact remains that our exports are decreasing.

In a moment I shall ask what we know, but I first reinforce the argument by adding a reassuring instance of a lost trade retrieved entirely through technical and commercial education, as I might also add many instances of the saving of towns from the effects of dependence on one staple industry, which has become depressed by means of technical knowledge, which thus promotes the easier flow of capital from one industry to another by helping to overcome what I have elsewhere termed economic friction. This is one of the strongest arguments in support of technical and commercial education.

Luton was a chief seat of the straw-plait trade, which it very largely lost owing to foreign competition, so the Municipality and Chamber of Commerce jointly procured the best teachers and had taught the newest methods of manufacture and of business. Much local opposition had to be overcome, but gradually the expenditure and work produced its effect, and soon both the home and

port trades of the town were restored, the people being well armed for competition, and the wages of the working-classes were increased by 100 per cent.—a good objection in technical and commercial education.

Now, what do we know? That, languages being, as I have said, the chief instruments of international trade, have been sedulously cultivated abroad; that, for instance, at Hamburg, English has, for more than a quarter of a century, been a compulsory subject in its public elementary schools, and that one of our own Technical Commissioners tells us that he saw over a class-room door in a school in the interior of Germany: "Nothing but English to be spoken in this room to-day."

Again, the London Chamber of Commerce made, in 1888, a systematic canvass of our City offices, and found that no less than 35 per cent. of them employed foreign clerks for their knowledge of foreign languages, and ability to correspond in these commercially, though the principals generally preferred Englishmen, and three hundred leading firms have since signed an undertaking to give them the preference, other things being equal. One of these clerks said to have written to his friends at home, saying: "There are still some English in our office, but less than formerly."

This is now some few years ago, and let us hope that the tide of foreign invasion has been stemmed. It seems so, for the Chamber has never failed to get a good situation, at a salary higher than the average for students holding its Commercial Education certificate, if in other respects eligible.

The Chamber next inquired into the state of secondary and commercial education, and found much cause for the condition of affairs in the curricula of our schools not being sufficiently adapted to commercial training. This is the result of an independent examination conducted on behalf of a great mercantile London house, whose name I must not disclose, as an entrance examination for apprentices. The examiner wrote to the firm as follows:—"The experience I had last winter in the classes for your apprentices induced me, in setting the examination papers, to adopt a low standard with the object of finding out what the candidates *did know*, rather than what they *did not know*. The average marks were in mental arithmetic:—41·6 per cent., 7 candidates receiving less than 10 per cent.; in tots, 71 per cent.; in commercial arithmetic, 25 per cent., 11 candidates obtaining less than 10 per cent.;

in English composition and grammar, 29·6 per cent., four candidates obtaining less than 10 per cent.; in dictation and writing, 65 per cent., one candidate obtaining less than 10 per cent.; and in French, in which there were sixteen candidates, 32 per cent., five obtaining less than 10 per cent. The candidates were exceedingly weak in commercial arithmetic, letter writing, and in correcting ungrammatical sentences. They showed the best results in rapid addition of money columns, four obtaining full marks. I was amazed to find that most of them had not the slightest knowledge of geography. Pointing to the map of the world, I was informed by one that China was France; only one of the whole number knew Japan; South America could not be distinguished from Africa; only two could name any place in the world where sugar was produced, and the same thing applied to raw materials (cotton, silk, wool, &c.) and manufactured articles. I saw nothing to indicate that these boys were below the average of intelligence. Their condition of ignorance seems to me to reflect very seriously upon the teaching they have received. I naturally inquired what schools they had attended. Practically all had been to secondary schools, second grade grammar schools, private commercial schools, &c. If these candidates are representative of secondary education, I can only give it as my opinion that a revolution is required in the teaching staff and the methods of teaching, to put it on a satisfactory basis. Evidences of unsystematic teaching and slipshod methods occurred on every hand."

Again the head of one of our largest insurance offices, which also examines all applicants for its clerkships, has sent me a typical examination paper done by a boy from one of the greatest London public schools, of national reputation, of a boy who brought the head-master's leaving certificate that he had "been at the school for several years, and had made creditable progress in his studies." Yet this youth of nineteen managed to make two mistakes in spelling in four lines, and appeared to be like Mr. Weller, who said how to spell depended on the taste of the speller—*e.g.*, he spelt accommodate "accomodate," and Piccadilly "Piccadilee;" he was no good at compound addition or per-centages; he could not name the counties of two large county towns out of four; he wrote that Queen Victoria was of the House of Tudor (*sic*); and when asked where the National Gallery was,

he said in Leicester-square—a confusion of mind which indicated familiarity with amusement rather than art. The gentleman who sent me the examination paper—himself an experienced educationalist and an active member of the council of one of our university colleges and public schools, wrote me thus:—

“It has been my duty during some twenty years to examine young men candidates for commercial clerkships, and my observation has shown some serious defects in the practice of the so-called ‘public schools.’ The hand-writing, spelling, and knowledge of geography, have frequently shown sad deficiency. The badness of the first of these is probably to be attributed to the custom of exacting the writing of a thousand or more lines in play-hours as a punishment. This appears to be a cause of the loss of that elegant and legible handwriting so characteristic in former years, but that a pupil who carries off prizes for mathematics should fail in adding correctly simple columns of figures, or in a common Rule of Three calculation, or in correct spelling of English words, is to me very striking. The very rudiments of commercial education are thus neglected, as you will see exhibited in the examination paper (which I send you). This is not an exceptional case; I might furnish many such.”

These are the experiences of large business houses, and the testimony of independent examiners, which is confirmed by a letter I received from one of the higher masters at one of the greatest of our great public schools, who wrote that he agreed almost *in toto* with every word I am now expressing.

Then, the Chamber, through its Commercial Education Committee, which has had the very great assistance of such able and experienced advisers as our Chairman, the head-masters of King’s College School, the City of London School and others, set to work to try to change the aspect of affairs by rousing public attention upon the subject, and by giving to our equally capable and willing clerks and others more modern intellectual and mercantile equipments. And with what results? Latin, for literary reasons and for the sake of style and expression, many, including Sir John Lubbock, tried hard to retain as a compulsory subject, but we were told by the education experts themselves that if so we should not have ten candidates at our examinations! So we made it optional. Exactly the same advice was given us as to requiring, as we first proposed, two foreign languages. So, disappointed but practical, we contented ourselves for the time with one; and, after other similar deductions from a moderate standard of junior commercial education, we were again assured by many that it

was too high, but the mountain would no longer go down to Mahomet and so Mahomet has had to come—and has come—up to the mountain.

Moreover, we have done our best to teach through lectures and classes, with the aid of such men as the Rev. Dr. Cunningham, Cambridge, Professor Hewins, of the London School of Economics—of the co-operation of which the Chamber has had the advantage in joint work, and which has itself done such excellent work for higher education in London—Mr. Montague Barlow, and others.

It is also to be remembered that, at the Chamber, we have been no worshippers of what some people regard as the Divine right of examining other people.

On the contrary, we have regarded examinations as only rough and ready, though necessary, means to an end—as some test of learning and teaching; and, by our Table of Equivalents, prepared with great care and trouble, we have gladly dispensed with our own examinations, either wholly or in part, where equivalent knowledge has been certified by a competent educational authority. We have relied for the attainment of our objects more upon our senior and junior suggestive courses of commercial education (rather than on examinations), as indications of what youths ought to be taught and to know, and it is most satisfactory to be assured that the curricula of many secondary and other schools has been thus improved from the commercial point of view while we know that hundreds have been taught in school upon our prescribed lines of study, of whom only a very small percentage have entered themselves for examination.

The Lord Mayors and City Authorities have encouraged our work by giving prizes, and otherwise; the City livery and other Companies and firms and individuals have enabled us to offer travelling and other scholarships, prizes and rewards—the first for the better acquisition of foreign languages colloquially in the foreign countries themselves—and the results, numerically, have been very satisfactory, upwards of 1,200 candidates having presented themselves—those in 1898 being by far the largest number—of whom, the proportion having progressively increased, 681 have obtained the Chamber’s certificate for more general commercial education at the junior, or for one of more special branches of commercial knowledge at the senior, examinations.

The reports of the examiners, indicating, as they have done, a progressively improv-

tate of knowledge, have been satisfactory and reassuring, and continuity, and the practical and up-to-date character, and the standard of examinations, have been maintained by the appointment of mercantile members of the Chamber as moderators.

These commercial examinations have also been conducted by the Chamber in provincial centres, the list of which is still increasing, and in India. One incident of the last examination at Bombay is worth noticing. We hear much of Indian competition with Lancashire in the cotton trade, especially in the lower counts of yarn. Now, book-keeping is the basis of successful business, and the examiners in Book-keeping write thus of Indian candidates:—

“Special mention should be made of the fact, that whilst 13 out of 14 Bombay candidates passed, three with distinction, the average per-centage of marks gained by them was slightly over 11 per cent. higher than that obtained by those sitting at the London Centre, one candidate (No. 162) being entitled to special mention, he having been awarded more marks than any other candidate sitting in London.”

The Chamber is just raising, as it has done previously, among its own members and by an appeal to City companies and others, a fund to continue this work for some years yet, but its financial resources are limited, and ultimately the task must be undertaken either by the University of London or by the London School of Economics, and the City of London College and similar institutions in London and the provinces.

Already one significant, if experimental, new departure has been made. The Chairman of the School Board, the Rt. Hon. Lord Reay, himself an educationist of the highest standing, was a silent but apparently an appreciative member of the Guildhall Conference. Immediately afterwards, the School Board founded three evening commercial schools, at the opening of the first of which, in North London, I was present, and was greatly impressed by the large number of teachers and scholars assembled, and by the educational enthusiasm displayed. The curriculum is good, though of course more limited than that of a day school. Moreover, such a school may, of course, be said to want the broader basis of secondary instruction, but Higher Grade Board Schools really give this in many cases to School Board pupils, and so, though less completely, do the evening continuation schools; and there are qualifying examinations at the commercial schools themselves. And, at any rate, the step forms an experi-

mental advance in a right direction. Moreover, as in primary education, it behoves the secondary schoolmaster to be abroad, and the employer to be awake, or the craft of each may be endangered, while both may be outstripped by the output of our public elementary schools, for which they have themselves largely paid; and, if so, and if the State is thereby served, no question of class or vested interests will make it possible to retrieve such mistakes or to retrace such steps.

Of course, one conscientious objector immediately presented himself; in this case in the person of the Chancellor of the Exchequer of the School Board. This was, equally, of course, the one thing which made him anxious, in the preparation of his School Board Budget. He shuddered at the cost, as if the expenditure were not reproductive. An American statesman once said “Our School-rate is our highest one, yet we pay it the most cheerfully.” Properly administered, it is a source of saving to the State, in reducing other and more obnoxious taxes, and in making useful and creditable citizens. Some few may fail, and some few old women may immediately cry out, as one did at a case of forgery, “This is what comes of your reading and your writing.” But, regarding men and women in classes, the more educated they are the less they yield, as a whole, to temptation and lapse into vice and crime, and so become a burden instead of a benefit to the community. Or, putting it on a lower ground, let us remember what our Technical Commissioners were told at Chemnitz—“Our Technical and Commercial School has been worth ten times its cost, and you have paid for it in the higher quality and prices of our goods;” or, learning from our own industrial history, may we not remember that if, by enlarging the area of potential inventors, we should discover but one industrial genius like Watt, or Crompton, or Arkwright, or Stephenson, we should be repaid the cost of years, both capital and annual expenditure, a thousand fold.

It is to be remembered, too, that the policy of the Rev. Stuart Headlam, M.A., Chairman of the Evening Continuation Schools Committee of the Board, and his Committee, means, by prolonging education, the saving of much of the millions now spent on elementary instruction, at a cost of only some £40,000 a year, even when such continued education is free, as it now is; it also helps to redress the evil of the early age at which children

may leave our public elementary schools; it utilises school buildings and other educational machinery which would otherwise be idle; and it contributes to some increase of the emoluments of teachers, and thus helps to raise their influence and status, and to render their great profession more attractive.

Lastly, judging from experience at these foreign schools, and from the opinions (which are afterwards summarised by the Chamber Conference Committee) of experts and business men at the Guildhall Conference, what seem to be the most practical lines of procedure in order to effect our immediate purpose? First, to strengthen somewhat the staff of teachers in secondary schools, in order to secure more efficient teaching in their "Modern Sides." For this and other purposes, financial assistance should be given by both the State and Local Authorities, through grants in the nature of those of the Science and Art Department; but paid, preferably, for efficiency of the Modern Sides of schools, rather than by way of grants *per capita* for single subjects, which is not regarded as a satisfactory system. Municipal Corporations, County Councils, Urban Boards, and Chambers of Commerce, with or without the aid of the State, should co-operate in the establishment of Higher, or, as Mr. Macan has styled them, Tertiary Schools of Commerce, in the large commercial centres, and these should be affiliated, if possible, to University Colleges. The subjects should not only be special, but should be strictly adapted to the future career of the student. No rigid curriculum should prevail in any one institution, much less in the institutions generally, but there should be various definite courses of study, comprising the following subjects;—

1. *Economics and Allied Subjects*:—(a) History of Economics and Trade; (b) Political and Commercial Geography, including Trade Routes; (c) Study of Statistics.

2. *Modern Foreign Languages*.

3. *Business Methods*:—(a) Commercial Arithmetic; (b) Book-keeping and Accountancy; (c) Commercial Bureau; (d) The Machinery of Business, Banking, Insurance, the Stock Exchange, Lloyds, &c.; (e) Study of Commodities; (f) Transport and Means of Communication.

4. *Law*.—(a) Commercial Law; (b) Industrial Law: Factory and other Legislation; (c) Principles of International Law; (d) Fiscal Legislation—English and Foreign—Commercial Treaties.

5. *Commercial Subjects touching Local Industries*.

It is to be hoped that the Senior Examination of the London Chamber of Commerce, and of other Chambers, may be brought into close association with the work of institutions of this character, and that, on the results of these examinations, suitable scholarships and exhibitions may be awarded by City Companies and other bodies to enable the poorer scholars to avail themselves of the advantages provided.

As to employées in business, the attitude of the Guildhall Conference was not so definite, as it was felt that the members of this class, whose school education ended at the age of 12 or 14, might not, as a rule, or as yet, be educationally prepared to enter upon systematic courses of study. The discussion at the Conference also made it clear that, under this head, a large amount of important work is already being done in our admirable and most successful Polytechnics, Evening Continuation Schools and Classes, and Evening Technical Schools, in most county, and some non-county, boroughs and counties.

These should be encouraged in every way: continuation schools principally by the primary authorities, *i.e.*, school boards and voluntary school managers, and the polytechnics and technical schools by State and municipal authorities, and charity and other trustees. It must not be forgotten that, in the evening classes, the work done will be more limited in the range of subjects, and less complete in treatment, than in the day institutes. A system of Government grants for continuation commercial courses is very desirable.

In the Evening Continuation Schools the subjects to be encouraged, during a course of about two or three years, are chiefly:—Arithmetic, handwriting, book-keeping, shorthand, type-writing. The teaching of drawing, history, geography, and elementary science may well be given, especially to those who may not already have acquired in the day schools the elements of these subjects.

Exhibitions from the continuation schools are needed to enable deserving students who have shown capacity to proceed for further study into the classes of a polytechnic. In this (the polytechnic) stage, the subjects studied should be, to some extent, those of a tertiary day institute, and the premises, and possibly some of the teachers, may well be the same for both purposes. At this stage, again, a student of marked ability ought to have an opportunity of obtaining a maintenance

scholarship, which would enable him to leave his day employment for a few years in order to study at the tertiary day institute. This linking together of the two systems (day and evening), which is practically one of the bases of the scheme for the new Teaching University of London, has been followed, with marked success in several branches of their work, by the colleges of Victoria University, and justifies the expediency of appropriating public funds or the expenses of higher educational work.

Perhaps, public attention being at length directed upon the subject, it is less necessary than it was to appeal for active aid in carrying on the task of commercial education for the people. Even politicians and statesmen have at last spoken in its favour, and they seldom err until the quarry is in sight; they generally set out on the flowing tide. But, lest there be any doubt, let me, objectionable as it is to have to do so, once more stimulate my countrymen by the example of competing nations, as needed to be done, and was fortunately successful in the case of primary and technical education.

In Paris, Bordeaux, Genoa, Munich, Nuremberg, Cologne, Frankfurt-on-the-Maine, and other places in which I have personally visited schools, there are higher commercial institutes, colleges, and schools, and classes, which have scarcely any counterparts in this country. The same remark applies to business and commercial colleges of the United States.

The Paris Chamber of Commerce—and here let me say that Continental experience has shown that Chambers of Commerce, either alone or in conjunction with other bodies, are the best fitted for this work and for the administration of the necessary funds—has established two such schools, L'Ecole des Etudes Commerciales, in the Boulevard Malesherbes, and L'Ecole Supérieure de Commerce, in the Boulevard de la République; together with a third, L'Ecole Préparatoire. The first of these, which I visited some few months since, gives the highest instruction in commercial subjects, and has some 350 students from 17-25 years of age. It has a Musée des Marchandises attached to it for their use, and excellent physical and chemical laboratories and apparatus.

At the Superior School of Commerce, I was, a few days ago, most courteously received by the director, M. Cantagrel, who told me I had followed closely upon the heels of my friend and townsman, Sir Bernhard Samuelson. This school, founded in 1820, and acquired by the

Chamber of Commerce in 1869, has just been re-built, and is, architecturally, a fine edifice, thoroughly adapted to its purpose. It also is well equipped with physical and chemical laboratories, and has 200 residential students, of ages similar to those stated above, many of them university graduates. The hours of work are from 5.30, when the students rise, until 9 p.m. The commercial education given is of the very highest; indeed, these two Paris colleges really form a Commercial University, so far as that name can be considered a correct one. Perhaps, if any fault is to be found, it is that there are some indications of the characteristic defect of French education in the past—too much uniformity and routine, and too much of the professional, as against the practical, tone. Some of the domestic arrangements are almost ludicrous in their identity.

At Bordeaux I found a good High School of Commerce, and great interest in the work of commercial education; while at Genoa, again, located in an ancient palace, the Royal High School of Instruction in Commercial Studies, established in 1884, gives the highest instruction in commercial technology, economical and industrial science, and literary and philological culture, the results of which are attested by our Consul as excellent; moreover, successful graduates—the college confers a commercial degree—find immediate employment at high salaries.

A feature of the school is its "banco modello," or model office. Students in this department represent different firms in various parts of the world, and go through all the most minute operations of trading with each other, including transit of goods by sea and by land. Connected with these commercial houses are: a deposit and discount bank, a bank of issue, and a clearing-house, all being furnished with a complete supply of ledgers, forms, &c., such as are actually used in each department of trade. A good commercial library, machinery-room, museum of commercial samples, and a laboratory are attached to the school.

There is, I understand, a similar school at Venice, the trade of which, as of Genoa, is increasing rapidly; but this I have not yet had the opportunity of visiting. These great commercial cities of the middle ages, revived by the restoration of the old trade route from the East to Central Europe and the Hanse Towns, which Vasco de Gama—whose quincentenary we have celebrated this year—robbed them of for the benefit of Britain, are again rising, and seem fully alive to the modern con-

ditions of commercial success. It is interesting to note that the oldest commercial school on the Continent—the *Aula Commercio*—existed at Lisbon, the City of Vasco da Gama having been founded in 1759 by Pombal. So also, as the result of this change, are Hamburg and Antwerp greatly expanding,—the former the seat of the first commercial school in Germany and the latter of the best in Belgium. These cities are quickly becoming the great distributing centres for North and Central Europe, and are making their rivers and harbours attractive to commerce, at the expense of London, and one of them, Antwerp, we know from its own people, attributes much of its recent rise to commercial education at its Higher Institute of Commerce, of which many English youths have been compelled to avail themselves. Commercial education is also provided at the Universities of Liège and Ghent, which confer degrees in Commerce.

The Antwerp Institute itself is, except in name, a commercial university, giving the highest education, at a very moderate cost, encouraged by travelling and other scholarships; and its practical results are shown by the following figures, indicating the commercial careers of its former students: 249 are principals or managers of large mercantile houses in Belgium, 218 are bank managers or commission merchants, 6 are consuls-general, 32, consuls or vice-consuls, and one is Home Secretary to the Congo Free State, while others are professors at foreign institutes similar to that at Antwerp.

Two important things are to be said in reference to the commercial education of Germany: First, to repeat, that her primary and general education,—longer and still better in many ways than ours,—has given her a foundation on which she has been able to build a wide and deep superstructure within the last ten or twenty years, assisted by the previous possession of the oldest and best precedents and types of commercial schools—as at Hamburg from 1768; Leipzig from 1831; Gotha from 1817 (refounded in 1888); Lubeck from 1829; Dresden from 1854; Chemnitz from 1848; Munich from 1868; and at Nuremberg, Augsburg, Zwickau, Altenburg, and elsewhere.

And, secondly, that this building-up has been chiefly in her manufacturing districts—where, in some cases, attendance at commercial schools has now been made compulsory—enforcing by experience any argument that aid to productive and distributive industries should

be complementary, in the shape of both technical and commercial education.

But whether the increase of commercial schools in Germany is a cause or effect of improved trade and ability to compete, which matters little, since it is at least coincident with that improvement from the early seventies that country and its State, municipal, and commercial organisations of all kinds are alertly alive to the benefit which such schools have done, and can and must do for commerce and for competition; and commercial education has become widely distributed and is being quickly organised. Living languages are more than ever the study of commercial students and clerks, with English and English Correspondence—like French, taught conversationally—ever at the head of the list, and Italian, Spanish, and, already, Russian for colonists to German China. The mailed fist is being gloved.

There are now in the Empire one commercial university (Leipzig) and large numbers of commercial schools:—(1) Primary commercial schools for instruction in, and the continuation and extension of, mercantile knowledge; (2) schools for apprentices, giving exclusively commercial instruction in the early mornings and evenings; and (3) higher colleges and institutes or schools of commerce. Commercial education is also given in the higher public schools, as at Frankfort-on-Maine and other places, and Munich, where there is also a commercial school for girls, which I visited and found to be excellent, as is also its industrial university.

In somewhat more detail, the School for Commerce of Leipzig, managed by the Chamber of Commerce, gives the very highest mercantile education, and has its own mercantile museum, library, and laboratories, for research, &c. Since the foundation of this school it has been attended by 17,000 students, including 3,000 foreigners. In Leipzig, too, a new departure has recently been made in the foundation of a Commercial College University, which successfully aims at the provision of education and studies of university rank, which has for its object a broader field than both the highest and ordinary commercial school, and which seeks to eliminate, as far as possible, merely utilitarian considerations. Upon this subject the very able paper by Mr. Laurie Magnus, read, together with notes, by our Chairman at the Guildhall Conference, should be perused by all who desire to become

acquainted with the latest and best developments of commercial education.

Chemnitz, a great manufacturing centre, has its technical and commercial school, with a commercial curriculum of a high class, a library, a museum of mercantile productions, and laboratories. Arrangements also exist under which the students visit the local industrial works. This, it may be mentioned, is also done in the case of primary school scholars in Exeter, and is found to be a useful link between primary and technical education, as well as a good educational instrument in itself. The Practical Commercial Institute at Lubeck, a port of only some 60,000 inhabitants, gives the highest commercial instruction, with the peculiarity that there is no teaching in classes. Individualism is its principle, there being no school system and no fixed period of entry or exit, the students being separately taught practical office work and the conduct of business affairs, with sale, purchase, consignment, shipping, insurance, banking, and other departments. This, I may add, is also being done at Pitman's Metropolitan School in London.

There is also another High School of Commerce at Lubeck educating in many languages and in commercial subjects.

Munich provides, through its municipality, its Royal Commercial School, the means of acquiring what is required in practical business life, and has, in addition, its Royal School of Industry, and its Technical High School.

At Gotha, the Commercial School lays stress on the study of modern languages; the Commercial School at Stuttgart offers solid preparation for a mercantile career; as do Hankfort-on-Maine, through the Chamber of Commerce, in the shape of university extension lectures on high mercantile subjects by eminent university and business men; and Cologne, which has a Commercial School and a Higher School of Commerce.

The above are types. In Prussia alone—or the numbers in Germany are not known; (it they are very numerous)—there are now 16 primary commercial schools, with nearly 1,000 students, many of them females. The commercial expansion of Germany has thus been in part preceded, and in much greater part accompanied, by commercial education, the Consul at Stettin observing that the lightened German man of business is fully convinced of the necessity of a thorough and special commercial education, besides the usual general education given to all, and that this

feeling is advancing rapidly and fast permeating all commercial circles.

Much, indeed, the Consul adds, has recently been effected, City Corporations, Chambers of Commerce, Town Magistrates, and Mercantile Guilds, have, in both large and small communities, become alive to the fact that they not only serve their own, but also the interests of their country, by laying a greater importance upon secondary commercial teaching for their youths.

It is no secret that the whole of the Governments of the Federal States of Germany have recently given the most serious attention to the discussion of commercial education, in which discussion Prussia was, by no means, the least progressive. It is now stated that the Prussian Government is going to introduce, next Session, a Bill into the Landtag, to provide a considerable sum of money for the support of commercial education, not only with reference to the education of clerks, but also as a new department in University Extension, it being intended to attach to a number of Universities a special branch for the teaching of commercial knowledge in its more advanced and scientific regions, similar to the technical high schools at Karlsruhe and Darmstadt, which were the first to adopt the Leipsic method.

At Aix-la-Chapelle, Berlin, Hanover, and other places possessing technical high schools, special departments for commercial instruction are to be added, the efficiency and success of which can hardly be doubted. In short, the great interest in commercial education which has now been aroused in the various governments of Germany is sure to produce very considerable results before long.

A great and powerful union or society for the promotion of mercantile education (*Deutscher Verband für das Kaufmännische Unterrichtswesen*) has been formed, embracing all parts and States of the German Empire, which is working energetically and ardently for the establishment of new commercial schools. Courses are being given by this society for the instruction of teachers in commercial subjects in order to render them more efficient in the schools.

This union or society comprises in its membership 14 governments, 77 chambers of commerce and industry, 49 municipalities, 108 commercial societies, 101 commercial schools, 119 large firms in Germany together with wealthy individuals. This union or society has obtained the recognition and sympathy of 14

various governments to the extent of receiving pecuniary grants.

At the invitation of the Prussian Minister of Trade a large number of burgomasters, representatives of commerce and industry, headmasters of commercial schools met together on January 31 and February 1, 1898, in Berlin to deliberate on the different questions touching the development and extension of commercial education, the present state of the Kaufmännische Fortbildungsschulen," the "Handelschulen," and of the "Höhere Handelsschulen" was submitted to an exhaustive discussion, and the question as to whether or not it was advisable and necessary in Prussia to create besides the present commercial institutions already existing, new and independent "Handels Hochschulen," or to place them in conjunction with the Universities, resulted in the latter being decided on as the best means of forwarding the desired result."

These are incentives stated in the admirable report of our Consul at Stettin, in which the whole subject of commercial education in Germany is dealt with, even if one cannot concur in some of the conclusions of the writer.

We follow, we *must* now follow; but we follow with the advantage of the experience of other nations, and with, we may hope, the early assistance of a Commercial Intelligence Department, recommended by the Board of Trade Departmental Committee which sat recently under the chairmanship of Sir Courtney Boyle. This should greatly assist the commercial community, including commercial students, with information, and also by furnishing a library, and commercial museum, and exhibitions, and so aid the work of commercial education, in the foundation and spread of which the intelligence it is intended to collect and circulate must be of the greatest service.

We know already, however, that something must be done at once if we are going to arm our people with the weapons of intellectual precision which so many of our competitors hold and use against us. Let us then equip our equally capable citizens for the friendly fight, which still means for us national life or death, and enable each to realize the truth spoken nearly three centuries ago by a great townsman of mine, and the representative of that town in Parliament, an incorruptible patriot in an unpatriotic and corruptible age, one to whom our Metropolitan Council has very recently and rightly decreed a Memorial Tablet—Andrew Marvell:—

"How much one man can do
If he both act—and know?"

DISCUSSION.

The CHAIRMAN, in proposing a vote of thanks Sir Albert Rollit for his exceedingly interesting and able paper, said he was sure that all would agree that there was no man more competent than Sir Albert to place before a meeting the importance of the question of commercial education. He had approached the question not only from the educational side but also from the administrative side. He had sought the opportunity of visiting some of the principal commercial schools on the continent and had brought to bear upon his knowledge of those schools the experience which he had gained as Chairman of the Educational Committee of the Chamber of Commerce. But there were two or three observations which he (the Chairman) might be permitted to make. One arose out of the difficulty which everybody must feel in discussing the question of commercial education owing to its close connection with general education. In dealing with technical education, one felt that it rested on a solid foundation, say, of science and of drawing, but in the matter of commercial education one missed any distinctive basis on which it was founded. The defects which were at present found among commercial clerks, travellers, and others were due to a great extent to defects in general education; and if there was one fact which had been brought about by the discussion of this subject during the last ten or twelve years, it was that in commercial education it was certainly undesirable that specialisation should take place at too early an age. The recognition of this fact was most important, and had been emphasised by the remarks of the reader of the paper. Lord Reay, in distributing the prizes at the Mansion House the other day, very clearly pointed out that the classes of persons for whom commercial education was needed were commercial clerks, commercial travellers, the heads of mercantile houses and banks, and those in the consular service. As regarded commercial clerks the education which they required ought to be obtained in public elementary and high grade schools, supplemented by evening continuation schools managed by the School Board. He need scarcely point out that in evening continuation schools the work was a very great and important work in which the School Board might be occupied, and so long as the School Board did not venture to overlap the work that was done by other institutions and bodies, it was most desirable that they should endeavour to continue the education which was given in the public elementary schools in order to bridge over the interval that must elapse between the time when a child left the elementary school and was capable of proceeding to a technical school, properly so-called. As regarded commercial travellers, he thought that what they really wanted was a sound and thorough secondary education. In order that this secondary education might be available for all classes of the

immunity, and that secondary schools might be established where they were required, and that there might be no overlapping of effort or energy, it was most important that the Bill for the Organisation of Secondary Education, of which they had heard so much, should come into operation. In connection with this, he was sure the meeting would be glad to hear that a compromise had been established between county and non-county boroughs, which he hoped in future would lie down together like the lion and the lamb. The difficulty of reconciling their conflicting interests had been one of the causes which prevented the Bill for Secondary Education passing through Parliament. When they came to consider the difficulties to which Sir Albert had referred, and which had been spoken to by English Consuls over and over again, namely, that merchants and commercial travellers were unable to adapt their goods to the wants of customers, they must again feel that this probability was owing to some defect in education, and that no amount of special commercial teaching would enable them to remedy the defect complained of. It was surely due to some want of sufficient exercise of the faculties of observation and imagination which prevented their seeing those particular wants which it was their duty to supply. As regarded the higher class of education, or that which should be given to the heads of mercantile houses and large banking establishments, they came to a question which required very careful consideration. He had almost hoped that Sir Albert Collett would have suggested more fully than he had done the means by which this want might be supplied. He thought they all recognised that in that grade of education, called tertiary, there was room for special study and special instruction. At the present moment there were very few, if any, institutions in the country in which this kind of education was given. In connection with this phase of the subject he could not shut one's eyes to the activity which was being displayed by different continental countries, and they might be quite certain that Germany, France, Belgium, and Italy would not be spending money as they were now doing in establishing and maintaining large and important high schools of commerce unless they were convinced of the fact that the young men educated in those schools would be able to improve and advance the commercial interests of their country. That being so, they could not afford to be behind continental nations, and it behoved them to take some steps—he was not prepared at the present moment to say what steps—for instituting high schools for imparting commercial knowledge. Many hoped that in the newly-constituted University of London there might, at any rate, be formed a high school of economics and of commercial knowledge. All he would say was this, that if they desired that such a school should be established in London, they must not show apathy or be neglectful of their own interests, but must take such measures as were necessary to impress generally upon the public the

necessity of such a school being established. It was in the direction of a school of a university character that we in this country showed the greatest need of further development.

Mr. F. A. LUDWIG said he had been much interested in this paper because, though a naturalised Englishman, he was born in Germany, and was educated at Frankfort. When he came to England in 1883, he was much struck by the very low standard of education amongst city clerks; he often talked to them about subjects respecting which he found they knew nothing, and their reply would be that they only wanted to know figures, and how to write a letter, and that £ s. d. were the letters they were most interested in. He was much struck at the great success the English nation had achieved with such a very limited education, but they were beginning to see now that the continental countries were going ahead. In Germany, every one was bound to go to school, and all young men who wanted to get off with one year in the army, instead of three, had to pass a certain standard of education to which very few young men in the city of London would be equal. One thing, however, which the German had in his favour was the cost of education, a great portion being borne by the Government. For the highest schools they paid only £7 10s. a year, and had the very best teachers. In England, as he gathered from some of his friends, they had to pay much more, and, as far as he could understand, much more attention was paid to tennis and football, and more prizes were given for those sports than for education. He thought this was a mistake; there should be less attention paid to sport, and more to teaching.

Prof. W. H. H. HUDSON said the future of commercial education really depended on the weakness in the course of secular education. No doubt the primary object of education was to train the character, and this was done by training not only one or two, but all the faculties of the human mind. The great defect in our school education was the concentration of attention upon comparatively few of the mental faculties. By that he meant the general training given in the secondary schools, not the tertiary training. The faculties mainly insisted on in our schools were those of memory and imitation. These were valuable, but other faculties were neglected. He thought that memory could be better cultivated by learning selections from the great poets and foreign writers. To learn a proposition from Euclid was the wrong use of memory, and did not assist education at all. The imitative faculty should be properly educated by the arts, to begin with—handwriting, drawing, painting, and such things—and, to a comparatively slight extent, in scientific subjects. It was the predominance given to language teaching which was at the bottom of the mistaken notion that the only way to learn things was by imitating people or learning

by heart. He should like to see less of imitative work and more of observational work, and children taught to draw inferences from what was put before them. Nothing was better than elementary science for teaching, and there should be introduced into the curriculum of secondary schools, such subjects as botany, geology, and chemistry, but not all at once. Sir Albert had mentioned a large number of subjects which should be introduced, but it was to be hoped he did not mean they were all to be done at once. Certain subjects should be taken up at particular times, and then dropped to make way for other subjects when they had served their purpose. For the development of the reasoning faculty, there was nothing better than mathematics. A great mistake was made in many schools in not teaching mathematics as an exercise of reasoning, but only in obedience to authority. In the learning of languages, it was justifiable to use that method. To teach mathematics the pupil should see the chain of reasoning, and he was not necessarily to believe any statement merely because the teacher made it. To a large extent he attributed the failure of secondary education to the too great predominance given to languages. A great number of clever little boys at the present moment, from 9 to 12 years of age, were now struggling with three languages—French, Latin, and Greek, and many were learning German as well. Parents were ambitious that their children should obtain scholarships at the public schools, and it was this insistence that caused so much of the time of the boys to be spent in learning these subjects to the neglect of others.

Mr. H. MACAN said he was, in respect to one important point on the side of the Philistines. The Bishop of London, the other day, remarked that the successes of Englishmen in the past had been in a great measure due to the fact that while other people talked about a thing and made beautiful suggestions, Englishmen somehow had a knack of going and doing. As he was coming to the meeting, he bought an evening paper with an account of the football match between Oxford and Cambridge, and read it with great interest; and when he heard Sir Albert Rollit say, as he did both at the Mansion House and that evening, how very superior some mild Hindoos were to young Englishmen in the number of marks they obtained in the examination of the Chamber of Commerce, and when he heard him mention a certain commercial academy where the pupils continued their studies until nine p.m., he could not help wondering whether those youths ever distinguished themselves in the football field, and whether it would be better for England in opening up the great continent of Africa, and in winning such victories as Omdurman, that she should have boys who got 10 or 20 per cent. more marks in an examination or boys who could play in football matches such as had taken place that day. They heard a great deal about the

advantages of a general education and of secondary education as preparatory to commercial education, but they found that the boys who took prizes in public examinations and who did particularly well when they came into counting-houses, according to the verdict of practical men of business, were those who had been prematurely specialists in commercial education. He had not the slightest doubt that any practical man going over the apprentices in a business house and seeing which wrote the boldest hand, which did his tots and totals best, which was the sharpest at book-keeping, shorthand, typewriting, and the various other things which were appreciated, would find that they were those who had not had the chance of secondary education, but had been prematurely specialised. He quite agreed that that was all wrong, but he did not think business men had yet fully appreciated that point. A passage from the report of the consul at Stettin was quoted by Lord Reay, and had been quoted all over the country, that it was believed that the Germans beat us because of their superior commercial education, but that was not true; the reason was because of their superior general education, but there was a footnote to that passage, not generally quoted, which explains that by that the consul did not mean primary education, but the *realschule*; that kind of education which the late President of the National Union of Teachers spoke of in his presidential address in Wales two years ago, when he said that if secondary education remained unorganised very much longer, the county council with their *realschule* would solve the problem themselves. As one who had been solving this problem, who in the last few years had founded five or six schools of this type, giving a complete commercial education, at one of which he had been present that afternoon at the distribution of prizes, he might say to Sir Albert Rollit that if he sometimes had a little time to spare, when he was not visiting those valuable schools abroad, and would condescend to come to some of the smaller towns where such schools had been founded by the county councils, he would find that secondary education had set in and was already very far advanced. He regretted very much that whenever commercial education was discussed there was always this reference to the prospect of legislation in the coming Session. Sir Albert Rollit had made a remark which was echoed by the Chairman about a certain compromise which had been arrived at, but that compromise failed in one important point, because the senior partners, the persons who had the money at the present time, and were organising secondary education, had not been consulted, and he would venture to remark that unless they agreed to the compromise, the Secondary Education Act, which was so much desiderated would not take the direction they had been led to expect.

Mr. J. S. THORNTON said no one could be better fitted to deal with this subject than Sir Alber

ollit, who was every day meeting commercial men. doing so he must have formed the highest opinion of the value of initiative, and of the masterfulness and power of the individual in British commerce. He would, therefore, venture to expostulate with him and with the Chamber of Commerce for acting somewhat inconsistently, and blowing both hot and cold. That very masterfulness and individualism which they praised and exalted in commerce, they were determined to stamp out in the field of general education, and he ventured to say that if they did so the loss to England would be terrible; much more terrible than the Chamber of Commerce and leaders in politics were aware of. Sir Albert had spoken with pride of the polytechnics springing up all over London and elsewhere, and of day schools in connection with them, but both he and the Chairman skillfully avoided any mention of the higher grade schools, 56 of which in London were very soon to become secondary schools. What would be the result? The Polytechnic day schools charged £3 a year, one-fifth of the prime cost; and these commercial schools, which were really secondary schools in connection with Board schools, although under no statutory authority would give the education free. What would the cotton-spinners of Manchester, or the woollen manufacturers of Yorkshire say if the Government proposed to come in and pin wool at one-fifth the prime cost? It was said that when great improvements were introduced somebody must suffer, the good of the majority must be considered, and that some suffering to individuals was unavoidable. But it was not necessary that the good private schools of this country should go to the wall. If the present arrangements were to continue, however, not only the bad schools would go to the wall (of which they would all be glad), but the good schools would go too, because no private school could exist with such competition as that. But such an evil was quite unnecessary. Who started local examinations? The University of Oxford sometimes said they did, but Sir Henry Wood had said in that room that the Society of Arts was before the University of Oxford; and he would add that the private schoolmasters of England were before the Society of Arts, and they were the most successful in the work; they examined sometimes more than the two universities put together. The college they founded was examining 15,000 pupils annually, and he said they could not afford to do without the private initiative in education which showed such results. He would therefore expostulate with the Chamber of Commerce when they said that not a penny of public money should go to any private school however good the condition of that school might be. That was a false and fatal policy. He should like Sir Albert Rollit to visit Copenhagen and Christiania, and see the very excellent Trade schools and Trade gymnasia there, where from 150 to 250 young men and 72 young women were being trained in commerce and were acting as very capable clerks. In Denmark three-fourths of the secondary schools which were recognised by the State

were private schools, and in Norway three-sevenths, and the same thing was found in Sweden and Finland.

Mr. T. A. BAKER said he wished, if possible, to emphasize the importance of this question of commercial education from a practical point of view, by giving some instances showing how we were being beaten in commerce for want of knowledge in business men. Sir Albert had referred to the early commercial school in Lisbon, founded by the Marquis Pombal; only last month he happened to be in Lisbon, and there noticed the lack of commercial education in Englishmen. He went with a friend into a place of business to make some purchases, and found that the goods they were shown were not made in Manchester as they expected, but in Bohemia. His friend, however, noticed some other goods, which he said he was sure were English, because they were marked in yards, and priced in shillings. Whilst looking at them a gentleman stepped up and said they were not for sale; they were his samples. It appeared that he was a traveller for a Manchester house, but he was not an Englishman; he was a German. In Oporto, he came across another traveller for a Manchester firm, who was an Englishman, but he soon found on going about with him in the town that he was very imperfectly conversant with Portuguese. It was pretty plain that he would not be likely to gain, or even retain, much business; whereas the German, who knew Portuguese as well as English thoroughly, in a year or two would be starting in business for himself and selling German goods. This question of languages was very important, and it was quite easy for children to learn three or four languages when they were young. At the Antwerp school all the pupils had to correspond in three languages. In Scotland recently he met a gentleman who travelled for a jute house in the East, who spoke six or seven languages, and who was then learning Roumanian, but he feared there were not many English travellers who were similarly qualified. The great mass of our trade was being passed over to Germany. That afternoon he had been talking to Mr. Fraser, who had just returned from a cycling tour round the world, and he asked him if he had met a single English commercial traveller who could speak three or four languages, and he said he had not. It was very rarely you found an Englishman who did not get into a muddle with foreign money. The decimal system certainly ought to be taught in England. Some years ago he published a little book entitled "Our Foreign Competitors." It was written for English people, but they did not take very much notice of it. In the Antwerp University, however, it was seized hold of as a text-book, and read once a week. A very good feature of that University was the travelling scholarships, which he should like to see introduced into England, so that a young man might have his *wanderjahr*, and go abroad and study the commerce of other countries. Commercial geography

was of immense importance. The French had seized a great deal of the country on the West Coast of Africa which was thoroughly well known out there as the "Bristol coast," because the Bristol merchants worked up the trade there; and if that had been known throughout England he doubted if France would have been allowed to appropriate it. In Sweden and Finland education had made marvellous strides. He was travelling there recently with an engineer, who told him that in engineering the Swedes were ahead of us, they were working steam-engines with a pressure of 3,000 lbs. to the square inch. In Finland, he was told that the people in London had no idea what electricity and telephones could do, and although he was a little sceptical at first, in Helsingfors he found they were really far ahead of us. Not long ago he had a request from a small town in Austria, of about 5,000 inhabitants, for some articles for the English club; he was rather surprised, and on inquiry found that there was not an Englishman in the place, but they had a club in which nothing but English was spoken, and only English songs were sung. He should like to know if there was any small town in England in which there was a club in which only German and French was spoken. In conclusion, he thought the system of having commercial attachés would be of benefit, but they should not be young men fresh from a university, nor yet those who had failed in business, but thoroughly educated men, with practical and successful business experience.

Mr. F. OLDMAN, while he fully appreciated the merits of the paper, thought Sir Albert had covered rather too much ground, and would have done better to confine himself to a description of the methods by which commercial education could be systematised and made of greater value. He thought he had rather underestimated the facilities which already existed, and that it was a mistake to divorce commercial from technical education. The latter had taken a great hold on public imagination, and what was chiefly wanted was to direct the enthusiasm which already existed to some extent in favour of technical education towards commercial ends. Commercial education, of an elementary and intermediate type, was already largely supplied by the municipal authorities.

Sir ALBERT ROLLIT, in reply, said he had never suggested any divorce from technical education, nor had he failed to realise what technical schools were doing; on the contrary, he had been to several lately, and was fully conscious of the value of their work. But the commercial side had not been developed, and his object had been to stimulate that by every means in his power. With regard to what Mr. Macan had said as to the compromise, it was true that county councils would have to be consulted. The cleft between county and non-county boroughs had been made up, and on the following day he had to attend a meeting of county councils representatives,

when he hoped that all differences of opinion would be bridged over, and that the result would be the Bill to which he had already referred. Mr. Thornton was mistaken in supposing that the Chamber of Commerce had opposed the efforts of private schoolmasters, for so far from having refused aid to work, wherever it was done, the object had been to strengthen the modern sides of schools. This involved the recognition of private as well as public schools. He had not been to Sweden, but he had seen the school in Copenhagen, which he considered an excellent one. In the matter of special machines for special purposes they were being run very close indeed by Sweden and the United States, and this was a reason why they should improve technical education, and also the means of securing the best sale of the machines in question. He most thoroughly reciprocated what had been said by the Chairman as to the work of the University of London, and he thought he had referred to the necessity of a commercial college in many of the large commercial centres. With this object in view he had pressed on the Senate of the University of London the desirability of recognising engineering as a faculty, and he thought that economics and commerce might also be recognised.

Miscellaneous.

RICE CULTIVATION IN RUSSIA.

While rice has long been grown in Persia and the Transcaucasus, it was almost unknown in the interior of Russia up to 1886, the supply being imported from India and subjected to a high duty, which confined its use to the wealthier classes. The Russians commenced its cultivation in the early eighties, and in 1888 the first rice-cleaning steam factory was opened in Baku, producing 100,000 pounds (1,612 tons) the first year. According to Consul-General Holloway of St. Petersburg, there has been a steady increase in the production, and there are now five rice-cleaning steam factories in operation, with an annual production of 3,000,000 pounds (48,387 tons). An additional factory is now in course of construction which is to be supplied with the most improved machinery. The demand for rice is increasing, and it is now generally used by the peasants throughout the empire, the quality of the native product being equal to that of the imported article. The residue are utilised, the broken grain being made into starch while the flour is given to hogs. The finished product is packed and sold in jute bags, the four grade being marked as follows:—"Reshta," having a small round grain; "Alalau," large round grain; "Campa," a thin and short grain, and "Sedra," a long and thin grain, which is considered the best. In the Caucasus the Transbaikal, and Turkestan regions, rice is sown in the same way as wheat. The producers ship uncleaned rice to the ports of the Caspian Sea, where

is sold to middlemen and commission agents. The prices are controlled by the supply and demand. During latter years the annual export of rice from Yuku amounted to 3,000,000 pounds (48,387 tons), being valued at 4,500,000 roubles (£450,000). The principal consuming markets are Warsaw, Lodz, the Istula region, St. Petersburg, Riga, Moscow, Kief, Borkof, and on the Volga, Astrakhan, Nizhni Novgorod, Saratov, Tsaritsine, and Samara.

Correspondence.

TRANSMISSION OF ELECTRIC POWER.

Professor GEORGE FORBES writes:—Since my paper was read on the 23rd November I learn that the great advantage of raising a mortgage on the property used for long-distance transmission of electric power had been referred to in 1892 before the Manchester Association of Engineers by Mr. B. H. Hwaite. The African Concessions Syndicate, writing from 120, Bishopsgate-street, inform me that a concession was eventually granted to them for the water-power of the Victoria Falls and the Zambesi River on the 17th December, 1896. My paper had led people to think that the negotiations for such concession were permanently closed by the troubles in 1895-6 in Rhodesia.

Obituary.

SIR WILLIAM ANDERSON, K.C.B., F.R.S.—Sir William Anderson, whose death occurred at his official residence, Woolwich Arsenal, on Sunday, 14th inst., was a prominent member of the Society of Arts, and a member of the Council from 1885. His association with the Society was more than official, for he contributed several valuable communications to its records. His Howard Lectures on the "Conversion of Heat into Useful Work," delivered in 1884-85, have since been republished, and are now recognised text-book on the subject. Subsequently he read papers on the "Purification of Water by Ozon," on "Aluminium, and its Manipulation by the Deville Castner Process," &c. He was a frequent attendant at the evening meetings, and was chairman on several occasions. He was a member of Council from 1885 to 1888, Vice-President from 1889 to 1892, Treasurer in 1893, and Vice-President from 1894. He was also an active member of the committee which carried out the Society's motor trials in 1888.

Sir William Anderson was born in St. Petersburg, January 5, 1835, and was educated at the High Commercial School, where he was head of the school and silver medallist, and had conferred upon him the

freedom of the city of St. Petersburg. Subsequently he matriculated at King's College, London, and became a pupil of Sir William Fairbairn in Manchester. From 1855 to 1864 he was in partnership with Messrs. Courtney and Stephens in Dublin, and in 1863 he was President of the Institution of Civil Engineers of Ireland. On his return to London in 1864 he joined the firm of Easton and Amos, of which—under the style of Easton and Anderson—he later became head. In 1889 he was appointed Director-General of the Royal Ordinance Factories by Mr. Stanhope, then Secretary of State for War, and in 1897 he was created a Knight Commander of the Order of the Bath. He was a Vice-President of the Institution of Civil Engineers, and Past President of the Institution of Mechanical Engineers; in 1889 he acted as President of Section G of the British Association.

PROF. T. HAYTER LEWIS.—Mr. Hayter Lewis, who died at his residence in Kensington Gardens-square on Saturday, 10th inst., was elected a member of the Society of Arts in 1868. He was born in London on July 9, 1818. He was a student of the Royal Academy in 1837, and in 1839 he obtained a silver medal for architectural drawing. He was a pupil of Sir William Tite, and in 1854 he designed the Panopticon in Leicester-square (afterwards converted into the Alhambra Music-hall). In 1865 he was appointed Professor of Architecture at University College, and afterwards designed additions to the College buildings. He resigned his professorship in 1881, and was elected Emeritus Professor. He was chairman at the Society's evening meetings on several occasions when matters connected with architecture were discussed.

General Notes.

PAINTERS' COMPANY.—The Painters' Company offer a travelling studentship of fifty pounds for the encouragement of the study of decoration. This is open to competition by students between the ages of 20 and 35, in any recognised school of art or other institution devoted to the study of applied art in any form and situate within the limit of the larger metropolitan postal area. Particulars may be obtained from the clerks, Painters'-hall, 9, Little Trinity-lane, E.C.

FOREST PRESERVATION IN BOHEMIA.—Bohemia is one of the most populous countries in the world, its climate is relatively cool with rather severe winters, and therefore much fuel is used, which is largely taken from the forests covering the mountain sides. Yet after the many centuries during which these forests have furnished fuel and building material for a dense population, they retain nearly their original area. This, says Consul Mahin, is due to the forethought

of the Government in ordaining that as trees were cut down others should be planted to fill the vacancies. Vast stretches of dense forests cover the mountain slopes; the wood is mostly pine. Trees are constantly being cut, but wherever a clearing is made small trees are planted the next spring. What at a distance may appear to be a bare spot in the forest, on a nearer view is found to be covered with little trees set out in symmetrical rows, and varying in height according to the length of time since they were planted. The new trees are raised from the seed in small enclosures scattered in the mountains, and are thence transplanted.

MEETINGS OF THE SOCIETY.

JUVENILE LECTURES.

Wednesday evenings, at 7 p.m. Two Lectures by PROFESSOR F. JEFFREY BELL, M.A. (of the Department of Zoology, British Museum):—

January 4.—“Hands and Feet.”

January 11.—“Some Ways in which Animals Breathe.”

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

Papers for meetings after Christmas:—

“Tuberculosis in Animals.” By W. HUNTING.

“Canals and Inland Navigation in the United Kingdom.” By L. F. VERNON-HARCOURT, M.A.

“Preservation of Timber.” By S. B. BOULTON.

“Electric Traction and its Application to Railway Work.” By PHILIP DAWSON.

“Coal Supplies.” By T. FORSTER BROWN.

“Wireless Telegraphy.” By W. H. PREECE, C.B., F.R.S.

“Leadless Glazes.” By WILTON P. RIX.

“London Water Supply.” By WALTER HUNTER, M.Inst.C.E.

“Maiolica.” By W. BURTON.

“Wrought Iron Signs.” By J. STARKIE GARDNER.

“Vitricous Enamels.” By CYRIL DAVENPORT.

INDIAN SECTION.

The meetings of this Section will take place on the following Thursday afternoons, at 4.30 o'clock:—

January 19, February 9, March 9, April 13, May 11, 25.

FOREIGN AND COLONIAL SECTION.

The meetings of this Section will take place on the following Tuesday afternoons, at 4.30 o'clock:—

January 24, February 28, April 25.

APPLIED ART SECTION.

The meetings of this Section will take place on the following Tuesday evenings at 8 o'clock:—

January 31, February 21, March 14, April 18, May 2, 30.

CANTOR LECTURES.

DR. SAMUEL RIDEAL, “Bacterial Purification of Sewage.” Four Lectures.

January 16, 23, 30, February 6.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 19...British Architects, 9, Conduit-street, W., 8 p.m. 1. Mr. H. R. J. Burstall, “The Application of Electric Power to Practical Purposes in Buildings.” 2. Mr. Bernard M. Drake, “Some Practical Hints on the Production and Use of Electricity for Lighting Country Houses.”

Actuaries, Staples-inn-hall, Holborn, 7 p.m.

London Institution, Finsbury-circus, E.C., 8 p.m.

Dr. W. J. Russell, “How to Produce a Picture on a Photographic Plate in the Dark.”

TUESDAY, DEC. 20...Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. Francis Fox's paper, “The Ventilation of Tunnels and Buildings.” 2. Mr. John Handsley Dales, “High-Speed Engines.”

Pathological, 20, Hanover-square, W., 8½ p.m.

Photographic, 12, Hanover-square, W., 8 p.m. (Photo-mechanical Meeting.) Mr. E. Sanger Shepherd, “Some Colloid Printing Methods.”

WEDNESDAY, DEC. 21...Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Capt. A. Carpenter, “The West Indian Hurricane, September, 1898.” 2. Mr. W. H. Dines, “The Connection Between the Winter Temperature and the Height of the Barometer in North Western Europe.”

Geological, Burlington-house, W., 8 p.m. 1. Mr. E. T. Newton, “A Megalosauroid Jaw from Rhætic Beds near Bridgend, Glamorganshire.”

2. M. M. Ogilvie [Mrs. Gordon], “The Torsion-Structure of the Dolomites.” 3. Prof. J. B. Harrison and Mr. A. J. Jukes-Browne, “The Oceanic Deposits of Trinidad, W.I.”

Microscopical, 20, Hanover-square, W., 8 p.m. Exhibition of Binocular Microscopes.

Mining and Metallurgy, Geological Museum, Jermyn-street, S.W., 8 p.m. 1. Mr. Alfred James, “Notes on a Process for Treating Slimes without Filtration or Decantation.” 2. Dr. A. L. Simon, “Notes on Fouche's Aëro-Condenser.” 3. Mr. Walter McDermott, “The Tin Mines of Bolivia.” 4. Mr. Malcolm Roberts, “Minerals found in the Silver Lodes of Tatasi, and Portu-galete, Bolivia.”

THURSDAY, DEC. 22...Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. S. Evershed, “Telegraphy by Magnetic Induction.” 2. The discussion on Dr. Lodge's paper, “Improvements in Magnetic Space Telegraphy,” and on Mr. Evershed's paper, will be opened by Dr. Fleming and Mr. Preece, with experimental demonstrations.

Journal of the Society of Arts.

No. 2,405. VOL. XLVII.

FRIDAY, DECEMBER 23, 1898.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be given on Wednesday evenings, January 4 and 11, 1899, at 7 o'clock, by Professor F. JEFFREY BELL, M.A. (of the Department of Zoology, British Museum). The first lecture will be on "Hands and Feet," and the second lecture on "Some Ways in which Animals Breathe." The lectures will be fully illustrated with lantern slides.

The lectures will commence at 7 o'clock. Special tickets are required for these lectures, which can be obtained on application to the Secretary. A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions each member is entitled to a ticket admitting two children and an adult. Members requiring these tickets should apply at once.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

COVERS FOR JOURNAL.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied post free for 1s. 6d. each, on application to the Secretary.

Proceedings of the Society.

CANTOR LECTURES.

ACETYLENE.

By VIVIAN B. LEWES,

Professor of Chemistry, Royal Naval College, Greenwich.

Lecture I.—Delivered November 21, 1898.

At a meeting of the Royal Dublin Society in March, 1836, Edmund Davy, who was at that time Professor of Chemistry to the Society, first described acetylene gas and experimentally demonstrated some of its more remarkable properties. In the autumn of that year, at the Bristol meeting of the British Association, he read a paper upon it and the method of production, showing that when the metal potassium was made by heating a mixture of calcined tartar and charcoal in a large iron bottle, a black substance was frequently formed which was readily decomposed by water and yielded a gas which we now know as acetylene, but which he at that time christened bicarburet of hydrogen. It was in this paper that the author pointed out that from the brilliancy with which the new gas burnt in contact with the atmosphere, it was admirably adapted for the purpose of artificial light, if it could be produced at a sufficiently cheap rate.

Twenty years elapsed after Davy's discovery before any important addition was made to our knowledge of acetylene, and although Quet and Boettger made some observations on the formation of metallic acetylides in 1857, it was not until Berthelot's classical researches upon this compound, extending from 1859 to 1862, that anything was definitely known as to its true composition and method of formation.

It was Berthelot who showed that acetylene was formed during the decomposition of many organic substances by heat, and that ethylene, methane, alcohol, and ether, all yielded this compound when passed through heated tubes, and that it was therefore almost invariably found in the products of the destructive distillation of organic compounds, whilst he finally demonstrated the possibility of synthesising acetylene by passing the electric current between carbon points in an atmosphere of hydrogen.

Acetylene has shared with many other bodies the troubles incidental to the constant changes of nomenclature which have occurred during the past century. Christened bicarburet of hydrogen by its discoverer, it soon after became known as klumene, whilst at a much

later date the name acetylene was bestowed upon it, being derived from the hypothetical radical acetylene (C_2H_3), to which acetylene bears the same relationship as ethylene (C_2H_4) does to the radical ethylene (C_2H_3). It was also proposed at one time to give it the name of ethine, but the name which has survived the diseases common to incipient nomenclature is that of acetylene, by which it is now universally known.

On analysis this gas is found to contain :—

Carbon.....	92.3
Hydrogen	7.7
	100.0

It has a density of 0.92, and when prepared by the action of water upon calcic carbide, it has a very strong and penetrating odour, but when the gas is thoroughly purified from sulphuretted and phosphuretted hydrogen, which are invariably present with it in minute traces, this extremely pungent odour disappears, and the pure acetylene has a not unpleasant ethereal smell.

Acetylene is readily soluble in water, which at normal temperature and pressure takes up a little more than its own volume of the gas, and yields a solution giving a purple red precipitate with ammoniacal cuprous chloride and a white precipitate with silver nitrate, these precipitates consisting of acetylides of the metals. The solubility of the gas in various liquids, as given by different observers, is :—

100 volumes of		Volumes of acetylene.
Brine	absorb	5
Water	"	110
Alcohol.....	"	600
Paraffin.....	"	150
Carbon disulphide	"	100
Fusel oil.....	"	100
Benzene.....	"	400
Chloroform	"	400
Acetic acid.....	"	600
Acetone.....	"	3,100

It will be seen from this Table, that where it is desired to collect and keep acetylene over a liquid, brine, *i.e.*, water saturated with salt, is the best for this purpose, but in practice it is found that, unless water is agitated with acetylene, or the gas bubbled through water, the top layer soon gets saturated, and the gas then dissolves but slowly.

The great solubility of acetylene in acetone was pointed out by MM. Claude and Hess, who suggested charging acetone with the gas

under pressure, a litre of acetone dissolving 360 times its own volume of the gas under a pressure of 12 atmospheres. On relieving the pressure the gas again escapes, and it was thought that this would prove a better method of storing the gas than liquefying it, but experiment has shown that acetone saturated in this way under pressure shares many of the disadvantages of liquid acetylene itself.

When acetylene was first introduced on a commercial scale, grave fears were entertained as to its safety, it being represented that it had the power of combining with certain metals, more especially copper and silver, to form acetylides of a highly explosive character, and that even with coal gas, which contains less than 1 per cent. of acetylene, such copper compounds had been known to be formed in cases where the gas distributing mains were composed of copper, and that accidents had happened from this cause. It was therefore predicted that the introduction of acetylene on a large scale would be followed by numerous accidents, unless copper and its alloys were rigidly excluded from contact with the gas. These fears, however, have fortunately proved to be absolutely unfounded, and the original gas-fittings can be used with perfect safety with this gas.

In the summer of 1895, Mr. H. Gerdes, the chief engineer of Messrs. Pintsch, of Berlin, made an exhaustive series of experiments upon this point, not only with the gas under ordinary pressure, but with mixtures of acetylene with oil and coal gas at pressures of nearly 10 atmospheres.

This was done by placing the metals to be tested in steel cylinders, the slips being fitted in wooden frames so arranged as to prevent any contact either between the individual metals or the walls of the metal cylinder. Two of these cylinders were filled with pure acetylene, two with a mixture of 80 per cent. of acetylene, and 20 per cent. of oil gas, and one with a mixture of acetylene with 20 per cent. coal gas, a small quantity of water being placed into each cylinder in order that the gas should be moist, as it was expected that this would greatly facilitate the action upon the metals. These cylinders were filled with the gases at a pressure of nine to ten atmospheres, and they were exposed on the roof of a shed from July 18, 1895, to April 9, 1896, this range of time exposing them to the highest temperature of an exceptionally hot summer, and the lowering of temperature incidental to a very cold winter.

Of all the metals and alloys used, those which are known to resist ordinary oxidation in the air remained perfectly unaffected, whilst the easily oxidisable metals suffered on the surface, but in no instance was it possible to trace any acetylene compound, and no explosion could be produced by either heating or hammering, whilst further experiments with acetylene, ammonia, and water showed clearly that such corrosion as had taken place by the simultaneous action of ammonia gas and acetylene was due exclusively to the action of the former gas, and no explosive compounds were formed.

If acetylene be passed through an ammoniacal solution of cuprous chloride, copper acetylide is formed, and when dry this explodes with great violence when struck or when heated, and independent observations, made by M. Bullier at about the same period, showed that in order to obtain this explosive compound of acetylene and copper, it was necessary that the gas should come in contact with a sub-salt of the metal in the presence of excess of ammonia, and as in actual practice these conditions would never be realised, it is manifest that the alleged danger may be disregarded.

Acetylene shows some extremely interesting actions with regard to other metals. If acetylene be passed over red hot sodium or potassium, these metals burn in the gas with the formation of carbides, which on being brought into contact with water, decompose with explosive violence, again setting free acetylene, whilst Moissan and Mourreau have made the interesting observation, that with certain metals in the spongy condition, strong action takes place with acetylene, and that if this gas be passed over reduced iron which has been prepared at as low a temperature as possible, bright incandescence is produced, and carbon is copiously deposited and quickly chokes the tube, hydrogen at the same time appearing as a gaseous residue.

The second drawback that has always been urged against acetylene in its early days was that it was a highly poisonous gas, the researches of Bistrow and Liebreich having apparently shown that it acted upon the blood in the same way that carbon monoxide did to form a stable compound. Experiments upon the toxic action of gases, however, are open to considerable error, partly depending upon the method by which the gas has been prepared, and which will affect its purity, and partly upon the nature of the animals upon which the

experiments are tried, rabbits and other rodents resisting the action of gaseous poisons like carbon monoxide far better than carnivorous animals, such as dogs, and it is impossible to argue from the action of the gas upon the one what the action will be upon the other, whilst it has not yet been made clear that the action upon either is a very safe index as to the action of the gas upon man.

Very extensive experiments, however, made by Drs. Grehant, Brociner, Malooz, Crismer, and others, all conclusively show that acetylene is much less toxic than carbon monoxide and, indeed, than coal gas.

Acetylene gas can be condensed into the liquid state by cold or by pressure, and the experiments by Ansell show that if the gas be subjected to a pressure of 21.53 atmospheres at a temperature of 0° C. it is converted into the liquid state, the pressure needed increasing of course with the rise of temperature, and decreasing with the lowering of the temperature, until at 82° C. acetylene becomes liquid under ordinary atmospheric pressure.

The critical point of the gas is 37° C., at which temperature it requires a pressure of 68 atmospheres to liquefy it, whilst immediately that temperature is passed no pressure that could be brought to bear upon it will convert it into the liquid state. This phenomenon, which is common to all gases, of resisting all efforts to liquefy them above a certain temperature, was first investigated by Andrews, and the resolution of liquid acetylene into a gas on reaching its critical point can be very beautifully illustrated by taking a small tube half filled with the liquid and projecting an image of it upon the screen. On now gently warming the tube the meniscus of the liquid, which at first was perfectly clear, is seen to flatten itself, and in a few minutes to entirely disappear as the temperature passes the critical point. On now removing the source of heat and allowing the tube to cool, as soon as the critical point is again reached on the downward scale, a violent storm of acetylene rain is seen to be going on in the tube as the gas condenses to the liquid state once more.

Long before the discovery by Willson of the method of making calcic carbide on a commercial scale had placed acetylene at every experimentalist's disposal, acetylene had been liquefied by Cailletet, Andrews, and Ansell, but with the advent of calcic carbide, liquid acetylene assumed a position of commercial importance, and Messrs. Dickerson and Suckert, seeing the business possibilities,

made it on a fairly large scale, and kept it in steel cylinders, whilst some time afterwards Pictet also set up the manufacture of the liquid.

A great future was expected from its use in this condition, as a cylinder fitted with the necessary reducing valves would supply the gas to light a house for a considerable period, the liquid occupying between one-fourth to five-hundredths the volume of the gas, but in the States and on the Continent, where liquefied acetylene was made on a large scale, several fatal accidents occurred owing to its explosion under not easily explained conditions.

As a result of these accidents Berthelot and Violle made a very valuable research upon the explosion of acetylene under various conditions, and they found that if liquid acetylene in a steel bottle were heated at one point by a platinum wire raised to a red heat, the whole mass decomposes and gives rise to such tremendous pressures that no cylinder would be able to withstand them, these pressures varying from 71,000 to 100,000 lbs. per square inch. They, moreover, tried the effect of shock upon the liquid, and found that the repeated dropping of the cylinder from a height of nearly 20 feet upon a large steel anvil gave no explosion, but that when the cylinder was crushed under a heavy blow, the impact was followed, after a short interval of time, by an explosion; but this was manifestly due to the fracture of the cylinder and the ignition of the escaping gas, mixed with air, from sparks caused by the breaking of the metal, and a similar explosion will frequently follow the breaking in the same way of a cylinder charged with hydrogen at a high pressure.

Continuing these experiments, they found that in acetylene gas, under ordinary pressures, the decomposition brought about in one portion of the gas, either by heat or the firing in it of a small detonator, did not spread far beyond the point at which the decomposition started, but was local; whilst, if the acetylene was compressed to a pressure of more than 30 lbs. on the square inch, the decomposition travelled throughout the mass and became, in reality, detonation.

These results showed clearly that liquefied acetylene was far too dangerous for general introduction for domestic purposes, as, although the occasions would be rare in which the requisite temperature to bring about detonation would be reached, still, if this point were attained, the results would be of a most disastrous character; whilst the fact that several

accidents had already happened accentuated the risk, and in this country the storage and use of liquefied acetylene is prohibited.

When liquefied acetylene is allowed to escape from the cylinder in which it is contained into ordinary atmospheric pressure, some of the liquid assumes the gaseous condition with such rapidity as to cool the remainder below the temperature of $-90^{\circ}\text{C}.$, and converts it into a solid snow-like mass.

Acetylene has the property of inflaming spontaneously when brought in contact with chlorine gas, and if a few pieces of carbide be dropped into saturated chlorine water the bubbles of gas as they reach the surface spontaneously catch fire, whilst if a jet of acetylene be passed up into a bottle of chlorine it takes fire and burns with a heavy red flame, depositing its carbon in the form of soot. If chlorine be bubbled up into a jar of acetylene standing over water a violent explosion, attended with a flash of intense light, and the deposition of carbon at once takes place.

When acetylene is kept in a small glass holder exposed to direct sunlight, the surface of the glass soon becomes dimmed, and Mr. Bone has shown that when exposed for some time to the sun's rays it undergoes certain polymerisation changes which lead to the deposition of a film of heavy hydrocarbons on the surface of the tube. It has also been observed by Cailletet and later by Villard that when allowed to stand in the presence of water a solid hydrate is formed.

Acetylene as has been shown is readily decomposed by heat, polymerising under its influence to form an enormous number of organic compounds. Indeed acetylene which can itself be directly prepared from its constituents, carbon and hydrogen, under the influence of the electric arc, can thus really be made the starting point for the construction of an enormous number of different organic compounds of a complex character.

Acetylene in contact with nascent hydrogen builds up ethylene, ethylene acted upon by sulphuric acid yields sulphovinic acid, and this can again be decomposed in the presence of water to yield alcohol, whilst it has been proposed to manufacture sugar from this remarkable body. Picric acid also can be obtained from it by first treating acetylene with sulphuric acid, converting this into phenol by dissolving in potash and then treating the phenol with fuming nitric acid.

Acetylene is one of those bodies the formation of which is attended with the disappear-

ence of heat, and it is for this reason termed an endothermic compound, in contra-distinction to those bodies which evolve heat in their formation and which are called exothermic. Such endothermic bodies are nearly always found to show considerable violence in their decomposition as the heat of formation stored up within them is then liberated as sensible heat, and it is undoubtedly this property of acetylene gas which leads to its easy detonation by either heat or a shock from an explosion of fulminating mercury when in contact with it whilst under pressure.

The observation that acetylene would be resolved into its constituents by detonation is due to Berthelot, who, by starting an explosive wave in acetylene by firing in it a charge of 0.1 gram of mercury fulminate, succeeded in doing this. It has since been shown, however, that unless the gas is at a pressure of more than two atmospheres this wave soon dies out and the decomposition is only propagated a few inches from the detonator.

If acetylene be heated in contact with air to a temperature of 480° C. it ignites and burns with a flame, the appearance of which varies with the way in which the acetylene is brought in contact with the air. With the gas in excess a heavy lurid flame emitting dense volumes of smoke results, whilst if the gas be driven out in a sufficiently thin sheet, it burns with a flame of intense brilliancy and almost perfect whiteness, by the light of which colours can be judged as well as by daylight.

The ignition point of the gas being below that of ordinary gas, it can be ignited by any red hot carbonaceous matter, such as the brightly glowing end of a cigar.

For its complete combustion a volume of acetylene needs approximately 12 volumes of air, and forms as its products of combustion, carbon dioxide and water vapour. When, however, the air is present in much smaller ratio, incomplete combustion ensues, and carbon, carbon monoxide, carbon dioxide, hydrogen, and water vapour are produced. This is well shown by taking a cylinder one half full of acetylene and one half of air: on applying a light to this mixture a lurid flame runs down the cylinder and a cloud of soot is thrown up, the cylinder also being thickly coated with it and often containing a ball of carbon; on now waiting a few moments to allow some air to diffuse into the cylinder and again applying a taper, an explosion, due to a mixture of carbon monoxide and air, takes place.

It is probable that when a flame is smoking

badly, distinct traces of carbon monoxide are being produced, but when an acetylene flame burns properly, the products are as harmless as those of coal gas, and, light for light, less in amount.

When acetylene is mixed with air, like every other combustible gas, it forms an explosive mixture. Observers differ somewhat as to the range between which mixtures of acetylene and air are explosive, Dr. Clowes stating that any mixture containing from 3 to 82 per cent. of the gas is explosive, whilst Dr. Bunte gives a rather lower range.

These discrepancies are probably due to differences in the method of igniting the mixture, and also as to what is to be taken as explosion. A light applied to a mixture containing 3 or 80 per cent. of acetylene will propagate combustion throughout the mass, but so slowly under all ordinary conditions as not to attain to the dignity of an explosion, and for all practical purposes the explosive limit may be taken as 3.5 per cent. of acetylene, the upper limit being of no importance, as so large a volume of the gas is never likely to be present in the air. An explosive mixture of acetylene and air theoretically attains its maximum power with a mixture of about 12 volumes of air to 1 of acetylene, but in practice gives greater explosive pressures with mixtures far richer in acetylene, for reasons which will be fully discussed in a later lecture. Ordinary coal gas forms explosive mixtures between the limits of 6 and 29 per cent., and yields its maximum result with a mixture of 1 volume of coal gas to about 10 volumes of air.

The methods which could be, and have been, employed from time to time for the formation of acetylene in small quantities are excessively numerous, but, before the commercial production of calcic carbide made acetylene one of the most easily obtainable gases, the methods which were most largely adopted for its preparation in laboratories were: first, the decomposition of ethylene bromide by dropping it slowly into a boiling solution of alcoholic potash, and purifying the evolved gas from the volatile bromethylene by washing it through a second flask containing a boiling solution of alcoholic potash, or by passing it over moderately heated soda lime; and secondly, the more ordinarily adopted process of passing the products of incomplete combustion from a bunsen burner, the flame of which had struck back, through an ammoniacal solution of cuprous chloride, when the red acetylide of copper was produced, and this on washing and

decomposing with hydrochloric acid yielded a stream of acetylene gas.

This second method of its production, which was the one most usually adopted, has, however, the great drawback that unless proper precautions are taken to purify the gas obtained from the copper acetylide, it is always contaminated with certain chlorine derivatives of acetylene.

In the years 1890 and 1891 I devoted much time to trying to ascertain the various actions which take place in coal gas flames and which lead to their luminosity. The classical researches of Sir Humphry Davy first clearly showed that luminosity was due to particles of solid carbon heated to incandescence within the luminous zone, and my endeavour was to find the causes which led to the setting free of these solid particles. The gas which is supplied to us for illuminating purposes, whether it be coal gas, carburetted water gas, or oil gas, consists of a mixture of many gaseous bodies, of which hydrogen, carbon monoxide, and members of the methane and ethylene families form the largest proportion, whilst a small percentage is composed of gases such as carbon dioxide, oxygen and nitrogen, which are simply impurities.

When the homogeneous mixture of these varied constituents leaves the burner tip, and the gases find themselves in the presence of the atmosphere, they at once begin to diffuse into it with a rapidity inversely proportional to the square roots of their densities, with the result that the lightest and most abundant member of the gaseous mixture, hydrogen, finds its way quickly to the exterior, and methane soon follows. These two gases, constituting some 85 per cent. of the mixture, on meeting the air bear the brunt of the combustion, and in burning form the main portion of the sheath of complete combustion surrounding the lower part of the flame. The heavier constituents of the coal gas are naturally those least affected by diffusion, and the desertion of the hydrogen and methane concentrates them in the centre of the flame, and they flow upwards, forming the non-luminous inner zone of the flame, or as it is more often termed, the zone of non-combustion. These gases are chiefly the unsaturated and heavier members of the saturated hydrocarbons present in the coal gas, and in their upward travel the baking action of the heat from the completed combustion going on in the outer envelope of the flame causes a resolution of the more complex hydrocarbon molecules into the simpler com-

pounds, acetylene and methane. As these in turn diffuse outwards, they reach the outer wall of combustion, which is undoubtedly the hottest part of the flame, and just below the inner side of the outer zone the acetylene heated to above its temperature of decomposition instantaneously splits up into finely divided carbon and hydrogen, and the heat liberated by the decomposition and by the change of state of the carbon, being localised by the rapidity of the action to the solid particles, so augments the temperature given to them by the flame, that they glow with high incandescence, and form the luminous sheath which caps the inner zone of non-combustion.

Experiments made by withdrawing the gas from various parts of luminous flames showed that no matter what was the initial character of the hydrocarbon present, acetylene was always produced before luminosity made its appearance, and moreover that the illuminating power of the flame followed the ratio of acetylene so produced, and this fact, taken in conjunction with the observation that when acetylene, free from air, is allowed to flow through a Jena glass tube heated up to a temperature of 780° C., it is decomposed with luminosity whilst the carbon set free in flowing forward through the zone of heat is perfectly non-luminous, formed the basis of what is now known as the acetylene theory of luminosity.

Stated in its simplest form this theory is as follows:—In the same way that the decomposition of the acetylene in flowing through a heated tube endows the carbon particles with a luminosity which the heat of the tube alone is unable to impart, so does the decomposition of the acetylene generated in a hydrocarbon flame increase the light-yielding power of the carbon particles liberated by its decomposition over what might have been the light emitted had they only been heated to the temperature of the flame itself.

When it is considered what an enormous difference is produced by a few degrees of temperature in the light-emitting power of solids heated in a flame, it at once becomes manifest that it is at least injudicious for opponents of this theory to sneer at the effect likely to be produced by such increase in temperature as is given rise to by the decomposition of acetylene.

It is perfectly well known to everyone interested in the methods employed for burning coal gas that regeneration increases the light emitted by a flame over 100 per cent., and in some cases three times that amount, and yet

he increase in the temperature of the flame due to warming the gas and air before combustion is but a small one.

I freely admit that when I first brought this theory forward in 1895, I placed too much dependence upon the measurements of flame temperatures by the methods at our disposal or such investigations, and in so doing laid the theory open to attack, an opportunity that was taken full advantage of; but in spite of all the criticism which has been bestowed upon it, the main issue has never been shaken, and I am just as fully convinced now, as I was then, that in all luminous hydrocarbon flames acetylene may be truly looked upon as "the mother of the luminosity."

There are conditions under which acetylene can be burnt without the development of light. If acetylene be diluted with about 92 per cent. of hydrogen or carbon monoxide, the molecules are burnt up without decomposition, and there being no solid matter in the flame to react to incandescence, the flame remains non-luminous. This is due to the acetylene requiring a higher temperature to decompose it when it is diluted than when it is pure, and the greater the dilution the higher the temperature needed.

If burning alcohol, which in the open-air gives a faintly luminous flame, be placed under a bell-jar, the temperature of the flame is lowered by some of the products of combustion being checked in their escape, and the flame becomes absolutely non-luminous; if now oxygen be supplied to the flame its temperature becomes greatly increased, and not only does the flame become highly luminous, but freely deposits carbon on a cold surface held within. Whilst gas withdrawn from the interior of the flame under each condition is found to contain acetylene.

Another very striking example of the same kind is to be found in cyanogen, a gas which is always being noted for the beauty of the sea-pink flame with which it burns. Although cyanogen contains the same amount of carbon as acetylene, and is even more endothermic, no one until lately had ever thought of the possibility of its burning with a luminous flame, this being due to the fact that the temperature necessary to break up the molecule was so far above the heat of the flame that the cyanogen molecule burnt as a whole, and there being no deposition of carbon no luminosity would result.

If, however, the cyanogen flame be surrounded with pure oxygen instead of air, a

faint luminosity appears in the flame owing to the increase of temperature; whilst if the flame be surrounded by nitrogen dioxide, another endothermic compound, the temperature is so increased that the flame becomes more intense in its illuminating power than the acetylene flame itself, and yields a dense deposit of carbon and para-cyanogen to any cold surface held within it.

Miscellaneous.

METHODS OF PREPARING RUBBER.

BY R. H. BIFFEN.

So much has been written within the last few years on the subject of indiarubber, the sources of our supply, and the possibility of acclimatizing the best-yielding trees in our colonies, that at first sight it may appear that there is little more to be said. A study of the methods in use for preparing rubber from the latex, or milk, may however be of use to many interested in the formation of plantations, especially if some attention is paid at the same time to the inaccurate statements made in some recent publications, which apparently have disregarded the valuable series of papers on the subject contained in our one journal devoted to economic botany, the "Kew Bulletin."

The methods in use at present are either the outcome of the limited experience of uncivilised peoples, or the application of experiments made without paying due attention to what is known of the chemical constitution and physical properties of latex. As a good example of the latter we may take the experiments of Morisse,* who found that coagulation was brought about in the latex of *Hevea* by the addition of alcohol, phenol, hydrochloric acid, nitric acid, sulphuric acid, calcium chloride, ferric chloride, corrosive sublimate, &c. As the outcome of these experiments, a mixture of phenol in alcoholic solution, and dilute sulphuric acid, was recommended as a coagulating agent.

The latex is, as a general rule, a thick, white fluid, composed of small particles of rubber in suspension in a clear watery solution of various substances. Unfortunately, only the latex of a few trees has, as yet, been chemically examined when fresh.

The analysis of the latex of *Hevea brasiliensis* shows that it contains:—

Rubber	32 per cent.
Proteid matter	2.3 "
Calcium and sodium salts	9.7 "
Resin	traces
Water	55 to 56 "

It is slightly alkaline to litmus paper.†

* Seeligman, Lamy, et Falconnet; "Le Caoutchouc et la Guttapercha." Paris, 1896. p. 68.

† "Le Caoutchouc," &c., p. 94.

The presence of albumin, globulin, and other proteids, has been demonstrated by Green* in some other rubber-yielding latices.

As a general rule all these substances are to be found in rubber as it is at present prepared, often with others added to bring about coagulation of the latex, and accidentally or intentionally added impurities such as bark and clay. In all cases the percentage of impurities is large, how large we shall see later, and when it is remembered that some cause a rapid deterioration of the rubber it is obviously much to the interest of those connected with the industry that a method of preparation should be adopted which would minimize them or ensure their absence.

I propose now to consider a few of the better-known varieties of rubber.

Pará Rubber is the product of *Hevea brasiliensis*, a tree which thrives in many parts of the Amazon valley, British Guiana, &c. As pointed out by Churchill† in his consular report, there is no danger of this source of supply becoming exhausted, though this is the frequent cry of companies formed for rubber-planting, usually fated for an ephemeral existence. The tapping is done with considerable care by the natives, and even should a district become exhausted, in a few years a fresh supply of trees springs up. From the planters' point of view Brazil is hardly a suitable country, for the climate is bad, it is difficult to obtain labour, and the exchange is liable to endless variations. The trees have, however, been introduced into Ceylon, where small plantations exist, and into other colonies.‡

The method of preparing the rubber has been so frequently described that repetition is needless; but a "translation of a valuable article on rubber of the Orinoco"§ has received so much attention of late that it requires some examination. One of its most striking errors is the following:—"As the juice contains a considerable quantity of water, the preparation of rubber consists essentially in separating the former from the latter, which is performed by evaporating the water by means of a heating process or obtaining its coagulation by certain chemical processes. Although the last system is more rapid they prefer the former, as they pretend that the rubber thus obtained is of a superior quality—a supposition devoid of all reason."

As I have already had occasion to show,|| this statement is incorrect, for the heating continues for too short a time; ("the rubber" is not "dried in a few minutes") to evaporate off some 50 per cent. of water, and further there is no loss of weight until the clot begins to contract and squeeze out water. Neither is "the supposition devoid of all reason," for it is a well-known fact that the smoked rubber is far preferable to that obtained by chemical processes. A com-

parison of the prices of "Pará fine" and "sernamby" should be sufficient proof of this. Why it is so may be made clearer from the following experiment. At the end of a day's work I had several litres of latex left, to which an equal volume of water had been added, which would not keep over night without coagulating. To this a small quantity of acetic acid was added, and in a short time the whole of it had formed a stiff curd. On pressing and drying, a portion of the water exuded from this mass of sernamby but it still remained full of cavities, and the proteid matter in it quickly decomposed, so that ultimately stinking, inflated mass was obtained.

If this latex had been coagulated by smoking would have yielded a wet rubber, but the subsequent decomposition of proteids would not have set in, for the creosote contained in the smoke would have acted as an antiseptic and prevented decomposition, as does when meat is preserved by smoking.

Then again we find, "the rubber thus prepared (by smoking) acquires a darkish colour, due to the particles of coal which adhere to the outer skin. Some people believe that this tends to improve it, but such is not the case, for it is thus impregnated with impurity."* Now when these "bottles" of rubber are cut across, the fresh, laminated surfaces are a silvery grey colour, and as each layer is exposed to the same extent to the action of the smoke it is difficult to account for the outer layers only being so coloured. The freshly cut surfaces however soon darken and become black in turn, so that the explanation of oxidation seems far more probable, especially when taken in conjunction with the fact that the smoke is white and not black,‡ for the nuts are simply dry-distilled and not actually burnt. If the smoke of these heated urucuri nuts is condensed it forms two layers of liquid in the receiver, one a clear limpid solution consisting mainly of acetic acid, the other, darker in colour, creosote.

The hot vapour of acetic acid brings about the coagulation of the proteids of the latex, as may easily be proved by direct experiment.

A solution of alum is said to be in use for preparing rubber in some parts of the Amazon valley. Morris states that alum solution has no effect upon the latex of *Hevea* species however.

The loss in the factories on making up Pará rubber is as follows||:—(1) Pará fine, 10 to 15 per cent. (2) Entre-fine, the carelessly smoked pieces, 15 to 20 per cent.; (3) Sernamby, rubber pulled from the cuts on the tree and cups, coagulated by being allowed to stand, &c., 20 to 40 per cent. From the data we may safely conclude that the smoking method of preparation is by far the best in use at present.

which will be further strengthened when we compare the losses on making up other sorts of rubber. Ceara Rubber is the product of *Manihot Glaziovii*, a tree growing chiefly in the highlands of the State of Ceara, Brazil. Cross is responsible for most of the descriptions of the locality in which it grows, but his experience of it appears to have been limited to Pacatuba, in which place its habitat is far from typical, they are not very accurate. He records it as growing at an elevation of 200 feet above sea level, among granite boulders, in a country whose dryness is indicated by the fact that "ferns, weeds, grasses, and mosses" were absent. True, it does grow among granite boulders, in the scantiest of soil in such localities, but it is more at home in the mountains, up to a height of 3,500 feet, and even here, where there is an abundant rainfall. These facts will serve to show the wide range of conditions in which the tree will put up with, and were it not for the smallness of its yield (1 to 3 lbs. per annum) it would be invaluable for introducing into many of our colonies. Coagulation is brought about either by smoking, as on the Amazons, or by simply allowing the latex to dry on the tree-trunks or soil. The latter methods are objectionable, as the rubber invariably contains pieces of bark or grit. It may also be prepared by filtering the latex, and pressing the resulting clots. This method is not to be recommended though, for when the clots are cut into thin slices and exposed to the heavy pressure of a mandioca press, a considerable per-centage of water remains in its cavities, and decomposition sets in, but not to the same extent as in "Ceará scrap."

Although so impure it commands a price usually paid only to "Pará fine." The loss is from 20 to 30 per cent., which, in inferior qualities, may even amount to 55 per cent.

Mangabeira rubber also comes from Ceara. It is the product of *Hancornia speciosa*, a dwarf tree with somewhat the habit of a birch. The rubber is prepared by the addition of an excess of salt to the latex, by Strauss' method of adding alum. Even after forty days' drying in the sun it is spongy and full of cavities of liquid. As might be expected, the loss on purification is enormous, amounting to from 40 to 60 per cent.

By this method of coagulating with chemical agents it is impossible to get rid of the coagulated protein matter, to say nothing of the greater part of the water. Morellet's* remark that "le procédé de Strauss est ingénieux, mais les résultats de son application sont mauvais" may well be applied to all these chemical methods, and the sooner the search for purifying agents is abandoned the better.

The only other American rubber of importance, at present, is yielded by *Castilloa elastica*. It appears in the market in a number of different forms under various names of Mexican, Nicaraguan, &c. As far as we know *C. elastica* is the only species of the genus

yielding rubber, for the *C. Markhamia* of Collins turns out to be a *Perebea* species.*

The latex is obtained in a rough and ready fashion by hacking a spiral channel from the crown of the tree to the ground, or by making great gashes with a machete.

Collins† has recommended a timber-scoring knife for tapping, and since then most writers have followed his lead. On experimenting with one, I found it was practically useless, as little latex exuded, possibly owing to the closure of the vessels by the drag of its edge. Stabbing with a broad-bladed knife, or with a chisel, as practised in Ceylon,‡ gives good results without much damage to the tree. In the previously-mentioned article in the "Trinidad Bulletin" (1898), there is some slight confusion as to the localities suitable for the growth of *Castilloa*. In one place (p. 122), "it will scarcely thrive in regions that are not equally suited to *Hevea spp.*," which (p. 130) grow "on land which is periodically inundated, even to a depth of five feet." Then (p. 121), "the tree (*Castilloa*) avoids marshy or boggy land, and manifests a preference for warm, deep loam, or sandy soil." The latter statement is the correct one.

The most general method of preparation in Mexico is to add an extract of the leaves and stem of the moon-flower (*Ipomoea bona-nox*), and allow the mixture to stand over-night. The floating clot which forms is then pressed to remove some of the water.§ As in all these cases of preparation by "wet" methods the rubber contains large quantities of water, it loses from twelve to thirty per cent. on drying. Another method is in use in Nicaragua.|| The latex is mixed with about three parts of water, and allowed to stand over-night, when the rubber comes to the surface in particles, which do not unite to form a solid mass. The water is then drained off from below, and the rubber particles are mixed with a fresh supply of water, and the process is again repeated. The particles are then brought into a solid mass by pressure. The latest account of this method is apparently given by Hart, in an article on the "Coagulation of Rubber,"¶ who appears to have rediscovered it. I quote it in full as I may be mistaken. "After the addition of water, the mixture is well shaken; the globules of rubber (having a lighter specific gravity than the albumenoids and proteids [*sic*] contained in the latex) will float quickly to the surface. It is found moreover that on the addition of further volumes of water and the removal of albumenoid liquors from below the floating rubber, the globules rise much more quickly to the surface."

* "Le Caoutchouc," &c., p. 64.

The following criticism of this "creaming" process is given in "Le Caoutchouc et la Gutta Percha":—"Ce mode de préparation est bien rudimentaire et ne peut fournir qu'un produit de qualité inférieure, qui perd souvent plus de 50 %, surtout lorsqu'il fraîchement préparé."*

Recently there has been some talk of extracting rubber from leaves and twigs by means of solvents, as has been done in the case of gutta-percha. A description of this latter process may therefore be of interest. It originated in the smallness of the yield of the *Isonandra gutta* trees, a tree from 25 to 30 years old, only giving 1·3 lbs. of gutta-percha when felled. The explanation of this fact is to be found in the work of De Bary,† who showed that the laticiferous system of the tree consisted of short, closed sacs. This being the case, a great many would remain unopened, and thus a considerable per-centage of the gutta-percha would remain in the bark. As the demand for gutta-percha has been large, and the supply has been obtained by felling the trees, they have become almost extinct.‡

Serullas proposes to utilise the leaves and twigs of the shoots from the old butts to extract the gum from. They are dried, treated with caustic potash to destroy colouring matters, and treated with a solvent for gutta-percha. The solvent is then distilled off and may be used again and again.

Rather more than 1 lb. of gutta-percha is said to be yielded by 30 lbs. of chopped up fresh leaves and twigs,§

For several reasons I do not think this process could profitably be applied to the preparation of rubber. The most important of these are (1) on gathering the leaves and twigs there would be an immense loss of latex, and (2) stripping trees of their foliage (the part which builds up their food supply) invariably kills them.

The direction in which research work should tend, I venture to think, is to prepare rubber free from the other constituents of latex, so that among other things, freight and customs charges on these impurities may be avoided.

Now it has been shown conclusively that the chemical constitution of latex varies with its source, so that it is improbable that any one reagent can be found capable of coagulating any given latex. Thus from the fact that acetic acid coagulates the latex of certain *Hevea* species, it cannot be argued that it will coagulate the latex of a *Kicksia* species.

Then expert opinions, as we have seen, show that the preparation of rubber by these chemical means is not satisfactory, for the product is far from pure.

I have recently succeeded, however, in preparing pure rubber by a physical process, and so demonstrated that chemical methods are not necessary.

This is effected by centrifugalizing the latex in a special form of separating machine, when the rubber particles, which have a smaller specific gravity than the medium in which they are suspended, are thrown out of the bowl in an almost dry state. They may then be converted into a solid mass by slight pressure, or by draining off the small quantity of water which remains with a porous tile. So prepared, the rubber forms a translucent mass, free from its usual smell and from all danger of decomposition.

The merits and demerits of this mode of preparation must rest entirely with me, but I cannot be responsible for any statements made in Trinidad, where a copy of my experimental machine was recently exhibited without my consent or knowledge.

COMMERCIAL EDUCATION IN BELGIUM.

The necessity of a more complete system of technical and commercial education has been much experienced in England of late years, and it is well known that this question has also greatly occupied the attention of foreign countries and of our own colonies for some time past. Opinion in England for some time hesitated in this matter, and the slowness in adopting a fundamental change in the system of public instruction probably resulted from the once generally accepted idea that a liberal education consisted mainly of classical and mathematical studies. A "general education" has been held to form the true foundation for whatever a pupil's destiny in life may ultimately be, and it was difficult to abandon the traditional opinions at once and to substitute a radical change of system for it. A glance at the Belgian mode of instruction, especially as regards commercial training, may supply some useful information on the subject. The education in the public schools of the country, the "Athénées," was originally, in the main, classical, and it was only of comparatively recent years that these establishments were separated into two divisions, or sections, as they are called, that of the *Humanités* (classical school) and the *section professionnelle* (commercial and scientific school), or, the latter has been termed, *Les Humanités modernes*.

The *Section professionnelle* of the "Athénées" took its place as an integral portion of the public school system of Belgium. It was felt, however, that more was needed to develop the intellectual capacity of young men intending to enter mercantile life, and that the means should be provided for prosecuting a higher range of study in that direction to correspond with the instruction furnished in universities in respect of the classical and mathematical curriculum. A college was founded at Antwerp by Royal Decree dated October 29th, 1852, under the designation "Institut Supérieur de Commerce" for the purpose of supplying this deficiency and the establishment has been in full and successful operation ever since. The Antwerp Institute of Commerce is practically speaking, a commercial university, although not so in name.

§ "Kew Bulletin," ccxiv., p. 231.

Consul General de Courcy Perry states that it underwent reorganisation in 1897. The diplomas awarded by the Institute are two in number, viz., that for the degree of "Licencié en Sciences Commerciales" and that for the degree of "Licencié du degré supérieur en Sciences commerciales et consulaires." To obtain the superior degree a course of five years in length must be followed, but the lower diploma may be obtained at the end of the second year's study. The superior degree is granted on the student passing an examination in the following subjects. General commercial affairs, commercial and general geography, political economy and statistics, the general history of commerce and industry, the general principles of commercial and maritime law, international law as far as it relates to commercial affairs, customs regulations in Belgium and other countries, commercial products, shipping and maritime construction, languages, French, Dutch, German, English, Spanish, or Italian. The syllabus of subjects for the third year's examination (for the diploma of "Licencié du degré supérieur en sciences commerciales consulaires" is the same as the above with the addition of three subjects, viz.:—Constitutional law, transport, and Consular regulations. The third year's curriculum was introduced in 1897, mainly with the object of providing a complete course of study for candidates for the Consular service, the two years' course being deemed sufficient for students destined for ordinary commercial pursuits. The course of technical commercial instruction given at the Antwerp Institute is one of the most important features of the establishment. A knowledge of business is inculcated by means of what is known as the "Commercial course." The students attending this course are supplied with commercial data from the Antwerp Exchange, and from all parts of the world, and under supervision of their professors, carry on imaginary transactions of all kinds. In this manner a knowledge of business principles and methods is gained, and at completion of the course an attentive student would have attained a fair, all-round acquaintance with the ordinary transactions carried on in a mercantile house. Such objects as importation, exportation, shipping, commission, insurance, bank- &c., occupy a foremost place, and endeavours are made to lead the students to bring to bear on practical cases the principles and theories they have learned in the various special courses of the Institute. The instruction in science is limited to those branches thereof as may prove of use in chemical and mercantile pursuits, and the technical and scientific studies at the Institute are greatly facilitated by an excellent museum where raw and manufactured products, minerals, &c., are carefully classified according to their commercial or industrial importance. With the object of giving the students a practical insight into the working of modern industrial establishments, periodical visits are made to large manufacturing works, engineering works, &c. When making these visits the students are accompanied by a

professor who explains the nature of the machinery and appliances in use, and gives, both in the factory or workshop, and subsequently in the lecture hall, a general review of the particular industry under consideration. The minimum age at which it is considered desirable that a student should enter the establishment is seventeen.

Mr. W. Layton, one of the professors of the Institute, gave some details of the entrance examinations, &c., in a paper read before the Society of Arts, in which he said:—"The students are divided into two classes, viz., 'regular' and 'free.' The former attend all the lectures with a view to obtain the diploma or degree at the end of the second or third year's course. The 'free' student is one who follows only the course of lectures which he considers of paramount importance to him in his commercial career. A 'regular' student must pass an entrance examination in which he must show a competent knowledge of at least two foreign languages, of book-keeping by single and double entry, of geography, arithmetic and algebra, commercial law, and the elements of political economy."

The cost of education at the Antwerp Institut de Commerce is very moderate, as the establishment is maintained partly by the Belgian Government and partly by the Antwerp municipality. The fees paid by the students only amount to £8 for the first year and £10 for the second and third years. These fees are applied to the purpose of supplementing the fixed salaries of the professors. In connection with the Antwerp Institut de Commerce, several travelling scholarships are awarded every year to Belgian students who pass their examination with distinction. These scholarships carry with them a grant of £200 a year for three years, and the holder is expected to go abroad and send home at intervals reports on commercial and economic subjects connected with the country he may have elected to visit. The Antwerp Institut de Commerce is not the only educational establishment in Belgium where advanced commercial studies are made the object of a special curriculum. By a Royal decree, issued in 1896, the faculty was given to the State Universities of Liege and Ghent to confer the degree of 'Licencié du degré supérieur en sciences commerciales et consulaires.' The superior commercial degree is conferred at the Universities, and at the Antwerp Institute under somewhat different conditions. In the first place, the certificate of middle class education required as a preliminary qualification on entering the University courses, involves the students having passed through a six years' curriculum at a middle-class school, and thus having received a fairly comprehensive general education, whilst the licentiates of the Institute may obtain their degrees after having gone through a programme embracing only special subjects. The same remark holds good with regard to the other certificates which are accepted as preliminary qualifications for the University commercial courses. They

are evidence of a more complete general education than is demanded by the Antwerp Institute. The University commercial courses are said, by practical authorities in Belgium, to be less suitable for the education of young men destined for ordinary commercial life than for those who intend to enter the Consular service, to practise as commercial lawyers, or to enter on any of those careers in which the principles of commercial law and mercantile customs are a necessary part of a man's intellectual equipment.

THE SALMON FISHERIES OF BRITISH COLUMBIA.

The British Columbia coast of the Pacific Ocean, extending from the 49th parallel to Alaska, is extensive and deeply indented. Vancouver Island and Queen Charlotte Islands, standing out seaward, are separated from the mainland by numerous channels and thousands of islands grouped in minor archipelagos. Stretching inland are many long inlets, the whole configuration being irregular, but exceedingly picturesque and rich in food fishes. To take the fishes first in the order of their importance, there is the salmon, of which there are several varieties, enumerated as follows:—Quinnat, chinook or tye salmon, silver salmon or coho, sockeyes or blue-black salmon, dog salmon, humpback, cutthroat trout, steelhead, and Dolly Varden trout, all of which, according to a recent report of the British Columbia Bureau of Statistics, are abundant. The quinnat, the first salmon to appear, is the largest, varying from ten to seventy-five pounds in weight. It is the most important of the salmonidæ family, and for table purposes is the most highly prized. For canning purposes the sockeye is preferred, being more uniform in size and colour, running in immense shoals, which the spring salmon does not, and being higher in colour. On the Columbia River, the former is the most generally used for canning. In British Columbia, the bulk of the fish used for canning is the sockeye, and it is during its run, usually in prodigious numbers at the height, that the pack is made up. As many as 2,000 boats are seen at the mouth of the Fraser at one time, and in big runs they will average from 100 to 500 fish each in a night. It is scarcely possible to estimate the number of these fish that go up the river. The cohoes are a less prized variety, but running later are utilised very often to make a pack, if the run of sockeyes should not be sufficient. When caught in salt water the coho is infinitely superior to the sockeye as a table fish, though not so rich in flavour as the tye salmon. The spring salmon is plentiful on the coast from November to April, the sockeyes make their appearance in July, and run in July and August, and the cohoes in September. The dog salmon and humpback are not commercial varieties, and are never used except by the Indians. The run of salmon first begins in the northern waters, the fish entering the

various inlets and rivers a little later in the seas until the Fraser is reached. Canneries are situated on the Naas and Skeena Rivers, Gardner's Can Rivers' and Knight's Inlet, Alert Bay, and other points on the coast, but the principal business is carried on in the Fraser, where some 42 canneries are in operation, there being 62 in all, with others in course of construction. The industry began in 1876 with a pack of about 10,000 cases (48 lbs. to a case). This has steadily increased, until, in 1897, it is estimated that it reached over 1,000,000 cases, valued at £800,000. The principal market for the output is in England, though it finds its way to many other markets of the world. The commercial varieties of the salmon as a rule do not rise to the fly, and therefore are not fished for sport except that at certain times of the year they are trolled for in the bay, near the cities of the coast. The trout, which abound in nearly all the rivers and inland lakes of British Columbia, and the salt water trout, as well, though differing locally as to size, colour, and flavour, are said to be identical in species. They make up to the sportsman for the obstinacy of the salmon, and attain in places to a size of thirty or forty pounds. They are not to be mistaken, however, for the "speckled trout," the charr, of which there are two varieties, but much less frequent and more limited in their habitat.

General Notes.

—**SOFIA COMMERCIAL MUSEUM.**—A Commercial and Industrial Museum has lately been opened at Sofia by the Ministry of Commerce and Agriculture, and a catalogue of the exhibits has been published.

—**FOOD EXHIBITION AT BORDEAUX.**—Information has been received from the Foreign Office, through the Science and Art Department, that an Exhibition of Food and Sanitation will be held at Bordeaux for three months, commencing on the 20th inst. The classification consists of nine groups. Foreign exhibits will be received up to the 28th inst. The address of the director is M. A. Balasse, 8, Rue de Palais Gallien, Bordeaux.

—**SISAL IN MEXICO.**—The production of sisal grass or ixtle has largely increased in Mexico, and with the exports in 1894-95 were 4,342,621 kilograms, valued at £72,820, these in 1896-97 were estimated at 9,635,000 kilograms, valued at £179,200 sterling. The traffic is monopolised by a few commercial houses chiefly settled in San Luis Potosi and Cerritos. These houses send their products to the markets at New York, Hamburg, Havre, and small quantities are sent to Antwerp.

Journal of the Society of Arts.

No. 2,406. VOL. XLVII.

FRIDAY, DECEMBER 30, 1898.

*All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.***Notices.****JUVENILE LECTURES.**

The usual short course of lectures adapted for a juvenile audience will be given on Wednesday evenings, January 4 and 11, 1899, at 7 o'clock, by Professor F. JEFFREY BELL, F.A. (of the Department of Zoology, British Museum). The first lecture will be on "Hands and Feet," and the second lecture on "Some Ways in which Animals Breathe."

A sufficient number of tickets to fill the room have been issued to members, but a few tickets are still being supplied to such members as have not received any, if application is made at once.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

COVERS FOR JOURNAL.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied post free for 1s. 6d. each, on application to the Secretary.

Proceedings of the Society.**CANTOR LECTURES.****ACETYLENE.**

By VIVIAN B. LEWES,

Professor of Chemistry, Royal Naval College, Greenwich.

Lecture II.—Delivered November 28, 1898.

In my last lecture I pointed out that Edmund Davy first made acetylene from a compound produced during the manufacture of potassium cyanide from potassic tartrate and charcoal, which under certain circumstances yielded a black

compound decomposed by water with considerable violence and the evolution of acetylene.

This compound was afterwards fully investigated by Berzelius, who showed it to be carbide of potassium. He also made the corresponding sodium compound and showed that it evolved the same gas, whilst in 1862 Woebler first made carbide of calcium, and found that water decomposed it into lime and acetylene.

During the past few years a wordy war has raged as to whether the discovery of the processes by which calcic carbide is now produced is due to the French chemist Moissan, or to the Canadian experimentalist Willson, and many still seem to imagine that it is the discovery of calcic carbide and acetylene that is in question. In point of fact our knowledge has advanced but little, save in details, since the labours of Davy, Woebler, and Berthelot clearly defined the preparation and properties of this beautiful illuminant, and the only question in dispute is as to who translated the manufacture of carbide and the preparation of acetylene from the ranks of a laboratory experiment of mere scientific interest to a commercial success.

Carron, in 1860, obtained an alloy of calcium and zinc by heating lime and zinc to a high temperature, and Woebler made his calcic carbide by heating to a very high temperature a mixture of lime, zinc and carbon, which first formed the calcium zinc alloy and then the carbide, the zinc being volatilised, and the compound which he obtained was impure and very unlike the beautiful crystalline substance obtained at the present time.

It was Sir Humphry Davy who first demonstrated the heat and light of the electric arc, and it was late in the seventies that Sir William Siemens inaugurated an entirely new era in experimental and metallurgical work by patenting his electrical furnace, in which the electrical energy could be converted into heat, thus yielding a temperature which had never been before available, and which has been estimated by Violle as approximating to 3,500° C. As gradually the utility of the electrical furnace came to be recognised, other patents began to be taken out, Bradley patenting a furnace in 1883, whilst Cowles took out his patents in 1885, and in 1886 patented a lining of lime and carbon for the furnace, as being more refractory. Although these furnaces were used for making aluminium, large quantities of carbide of calcium were accidentally made by the action of the heat on the furnace lining, and during 1886 and 1887 the lads employed

in the works used often to amuse themselves in the dinner hour by putting water on the old crucible linings and igniting the gas which was set free. Even before this date it was recognised and published that in the Cowles electric furnace the oxides, not only of the alkaline metals, but of calcium, magnesium, aluminium, silicon, and boron could be reduced in the presence of carbon and could be made to form alloys with other metals present, whilst with aluminium and other metals the crystalline compound made with carbon could be obtained, and further that silicon and the compound of silicon with carbon could be produced.

It is clear, therefore, that as early as 1886 calcic carbide was made in the electric furnace, but its formation was merely accidental, and no commercial importance was attached to it.

Soon after this date Willson conceived the idea of reducing aluminium in the presence of copper to make aluminium bronze, and employed practically the same method as that used by Cowles, but as his attempts to make the bronze were not successful, and as he was unable to make aluminium owing to the Cowles patents, he attempted to reduce magnesium and calcium to the metallic state. It was in the spring of 1892 that he attempted to reduce lime by carbon, and he found that he obtained by this means a fused bath, the boiling of which caused the short circuiting of the electric arc, and in order to prevent this spitting of the liquid and the unequal loading of the dynamo which interfered seriously with the working of the machinery and water turbines, he added to it carbon which prevented the splashing of the liquid against the sides of the electrode, the only portion of the surface exposed being in the immediate path of the arc.

It was in the May of 1892 that carbide was obtained by Willson in quantity, and samples were sent by him to various scientific friends in America, and it was on September 16, 1892, that he privately sent specimens of his carbide to Lord Kelvin with a letter. A copy of this letter I have seen in Willson's letter book, and it amply proves that he was perfectly aware of the importance of this product. It was acknowledged by Lord Kelvin in a letter, dated October 3, 1892.

About this time M. Moissan was conducting his classical researches on chemical actions at high temperatures, using for his experimental work an electrical furnace identical with the one patented by Siemens in 1879. Whilst experimenting with calcium he found that the

vapours of the metal acted upon the carbon electrodes, forming calcic carbide in small quantities, a fact which he incidentally mentioned in a paper read before the Academic des Sciences on December 12, 1892. This discovery contained no more of the germs of a commercially possible manufacture than had the discovery of calcic carbide by Wöhler, or the attempts of Borchers to make calcic carbide in his experimental furnace, which had extended from 1885 to 1891. Borchers had succeeded in making this body although he had no idea of the importance of his investigations, which certainly were not of a practical kind.

The history of the manufacture of the carbides was also added to in this year by M. L. Maquenne, who showed on October 17, 1892, that barium carbide could be made by heating barium carbonate with magnesium in the state of powder and charcoal; whilst Mr. Travers, on February 6, 1893, published his method of making carbide of calcium by heating a mixture of chloride of calcium with metallic sodium and carbon.

It is quite clear that up to the end of 1892 it was Willson, and Willson only, who had made calcic carbide on anything like a large scale, and nothing would ever have been heard of this material on a commercial scale, had it not been that he, in attempting to get capital invested in his process, came across several men of sound practical knowledge, whose business instincts led them to grasp the possibilities of carbide and acetylene, and who sooner had these commercial possibilities been noticed abroad than others began to try and make capital from them. In France, in 1892, Bullier took out a patent for the preparation of the carbides of the alkaline earths, based on Moissan's researches. M. Moissan himself had never claimed priority in the manufacture of commercial carbide, and, indeed, whilst lecturing before the New York section of the Society of Chemical Industry, on October 26, 1896, he distinctly stated that the credit of the first production of calcic carbide on a commercial scale, and the industrial utilisation of acetylene belonged to the Americans, and it seems to me that when this is shown on Moissan's own evidence, further comment is needless.

Willson continued his experiments on the manufacture of carbide on a commercial scale through 1892 and 1893, and, having formed a company, of which Major Morehead was the president, the manufacture was continued at the works at Spray, in North Carolina, in which a dynamo, worked by water-power, at

generating a current of 2,000 amperes and 100 volts, was employed.

By this time the manufacture of carbide was well launched, and the first English plant for its production was erected at Leeds, whilst later on a large installation driven by water-power was erected at Foyers and has been working ever since. This is the source from which nearly all the self-titled manufacturers of calcic carbide in this country obtain their supplies.

On the Continent at the present moment large numbers of works have been erected, whilst others are in progress; the rapid demand for carbide which has arisen owing to the introduction of acetylene for railway carriage lighting and the illumination of small towns has outstripped the supply, and from time to time carbide famines are threatened, whilst the price of the material fluctuates considerably. Practically the same condition exists in America, although the output amounts to between 10,000 and 12,000 tons per annum, so that although the manufacturers and generators in this country are fond of jumbling at their orders not being filled as rapidly as they wish, they may console themselves with the fact that they are far better off than their rivals in most parts of the world. Even in Germany, which claims pre-eminence in the various branches of chemical manufacture, they obtain up to the present by far the largest portion of the supply of carbide from Switzerland, where the works at Neuhausen turn the carbide out at a lower price than can be charged by the Bitterfeld works in Prussian Saxony, which had used steam instead of water-power. The latter company, however, has now removed its plant to Neuhausen, where it will re-open with water-power for the generators, and is erecting works capable of turning out a very large yield.

The reports of Mr. Frank H. Mason, the American Consul-General at Frankfort, which constitute perhaps the most valuable contribution to our knowledge of Continental industries, owing to the writer's great practical experience and the accuracy of his information, point out that the whole of the carbide industry, so far as Central Europe is concerned, is now in a transitional stage. The conditions of supply and price are likely to be greatly modified by the enormous increase of production which is now being arranged for, as not only have the factories in Germany, Austria, and Switzerland, at work and in course of construction, arranged for the

utilisation of 35,000 horse-power to be devoted to this purpose, but another important accession will come through the operations of a big combination, headed by the Schukert Electrical Manufacturing Company of Nuremberg. This company expects to have in operation during the course of next year works in various parts of Europe where water-power can be obtained cheaply, to the amount of about 18,000 horse-power, capable of producing some 20,000 tons of carbide per annum. There are also ten factories at work in France, whilst four others are in course of construction.

In the manufacture of calcic carbide in the electric furnace, lime and hard metallurgical coke, of the highest possible degree of purity, are employed. A good working mixture of these materials may be taken as being 100 parts by weight of lime with 68 parts by weight of carbonaceous material, and about 1.8 lbs. of this is used up for each pound of carbide produced. It must not be forgotten, in computing the cost of carbide, that lime of sufficient purity for the purpose is not only costly, but difficult to obtain in large quantities.

It is found that as the ingot of calcic carbide is formed in the furnace, although the ingot itself consists of pure crystalline calcic carbide, it is nearly always surrounded by a crust in which the carbide contains a certain proportion of imperfectly converted constituents, which, therefore, give a lower yield of acetylene than the carbide itself, and in breaking up and sending out the carbide for commercial work, packed in air-tight drums, the worst of the crust is, as far as possible, picked out and rejected. It is, perhaps, misleading to state the amount made per E.H.P., as a certain amount of loss is of necessity entailed during the breaking down and packing, for instance, in practical working I have found that whilst the furnace return was 0.504 lbs. per kilowatt hour, this amount has been brought down to 0.406 lbs. per kilowatt hour when the material has been broken up, sorted, and packed in air-tight drums.

It will be sufficient for practical purposes to state that the cost of material, labour, and wear and tear of plant, independent of the power used in the electric furnace but inclusive of packing, for making a ton of packed carbide will amount to from £3 to £4, according to locality, and this, of course, entirely governs the cost of the materials used, whilst the cost of the electrical horse-power necessary for the conversion of the material will entirely depend on whether it is obtained from steam, gas-

engines, or water-power, the latter where obtainable being the cheapest, and in this country costing nearly £4 per E.H.P. per year.

The two principal processes utilised in making calcic carbide by electrical power are the ingot process and the tapping process.

In the ingot process, the coke and lime are finely ground, and carefully mixed in the right proportions to suit the chemical actions involved. The arc is struck in a crucible, and the powdered mixture allowed to flow in, and partially fill the crucible. An ingot gradually builds up from the bottom of the crucible, the carbon electrode being raised from time to time automatically or by hand to suit the diminution of resistance due to the shortening of the arc by the rising ingot. The crucible is of metal, and considerably larger than the ingot, the latter being surrounded by a mass of unreduced material which protects the crucible from the intense heat. When the ingot has been made and the crucible is full, the latter is withdrawn, and another substituted. The process is not continuous, but a change of crucibles only takes two or three minutes under the best conditions, and only occurs once in every ten or fifteen hours. The essence of this process is that the coke and lime are only heated to the point of combination, and are not "boiled" after being formed.

In the tapping process a fixed crucible is used lined with carbon. The electrode is nearly as big as the crucible, and a much higher current density is used. Fine grinding is unnecessary, as combination probably only takes place after fusion of the raw materials which mix more or less as liquids. The carbide is heated to complete liquefaction, and tapped at short intervals. There is no unreduced material, and the process is considerably simplified, whilst less expensive plant is required; but on the other hand, the output in carbide per E.H.P. per day is considerably less than in the ingot process, and it is only more economical where power is comparatively cheap.

Many attempts have been made to economise the amount of current necessary in making the carbide by heating a mixture of lime and carbonaceous material before exposing it to the action of the arc, but it has never been clearly demonstrated that any economy has been gained by doing this.

When the manufacture of calcic carbide was in its infancy, the idea of pre-heating the constituents to save the current was a

favourite one with inventors, and a large number of patents were taken out for electric furnaces working on this principle, but with extended practice the fallacy of this economy has become apparent.

The best carbide is made when a finely powdered and intimate mixture of pure lime and coke of very low ash is presented to the action of the arc for just sufficient time to fuse it and convert it into carbide; if, however, attempts are made to pre-heat this mixture by exterior heating, some of the carbon is burnt away and the proportion of carbon to lime altered, whilst if interior heating be attempted, the rush of hot gases carries away the lighter particles and destroy the homogeneous nature of the mixture in that way as well as by burning off carbon. If attempts be then made to overcome these evils by using a coarsely ground mixture of the ingredients a bad carbide is produced owing to the interaction between the carbon and the lime never being properly completed. In attempting to overcome this last trouble the material is often kept too long in the arc, thereby lowering the quality of the carbide still further by overheating.

M. Nicolai has shown that overheating leads to dissociation of some of the carbide, and the result of this is well shown by re-melting a sample of carbide of known composition, after which it develops about 12 per cent. less gas than before, whilst a second re-melting more than doubles the loss. A second grave disadvantage of overheating also is that metallic calcium is produced, which, during the decomposition of the carbide by water, gives rise to hydrogen.

In one class of furnace the raw coke and lime are heated before entering the furnace crucible by being placed in a metal bin subjected to the action of the hot furnace gases, and sometimes heated by a fire underneath.

Pictet places a mixture of comparatively large pieces of lime and coke, with a considerable excess of the latter, in a refractory crucible which has a hole at the bottom, below which a horizontal arc furnace is situated. A row of tuyeres round the upper part of the crucible supplies a hot-air blast which consumes some of the coke that has been previously ignited, and thereby heats the descending charge. A second row of tuyeres lower down in the crucible supplies water gas and hot air simultaneously, and heats the mixture to a still higher temperature. The mixture then passes out between the carbon poles, and

the carbide is said to be made. Here, again, it is very doubtful whether the economy claimed for this process is borne out in practice, as the gain from the prior heating of the material, if any, is more than counterbalanced by the difficulty of reducing the large lumps, whilst the expense of the water gas and air blast would be no small item, and the quality of the carbide in all probability would not be of the best.

There is a rotating furnace which is used in one large works in the United States, and modifications of this are, I believe, being tested by Mr. Willson, and have been fitted up at Niagara.

A rotating drum of cast-iron is fitted round its periphery with a number of removable iron plates, thus forming an annular space on the outside. The carbon electrodes are placed in a hopper made of refractory material at one side of the drum, the electrodes being parallel to two opposite sides of the hopper, and meeting with the formation of an arc just over the annular space in the drum. Only one-half or two-thirds of this annular space is closed at one time, the closed part extending from just below the hopper to the other side downwards. A mixture of powdered coke and lime is fed into the hopper, some falling between the electrodes, which are then drawn apart as carbide is formed until a block of carbide four or five inches thick is built up between the electrodes, whilst an arc plays on both sides of the block between them. The electrodes are not clamped down, and as the ingot tends to short-circuit the arcs, the drum is rotated a little by means of worm-gearing, thereby drawing a little of the ingot and mixture into the annular space and introducing more raw material to the arc.

This process goes on continuously until the carbon poles are exhausted; the carbide forms round the drum and is broken off in pieces on the other side by removing the periphery plates as they come round.

I have had the good fortune to be able to secure photographs of some of the most interesting machinery connected with the carbide manufacture, and you will see that the plant used at nearly all the large factories may be looked upon as developments of Willson's original plant as used at Spray—the figure of which on the wall I think is of exceptional interest.

During the past year the air has been full of reports as to various processes for making carbide without the aid of electricity, and it is said that this has been successfully accom-

plished; but I confess that until I have the evidence of my own senses to go upon, I shall remain sceptical as to the carbide being produced more economically by such means than by electricity, even if produced at all on a large scale.

In 1894 and 1895 I made many experiments in this direction, built up small experimental plant, and used every method for generating high temperatures that was available, and succeeded in fusing practically everything save the mixture of lime and carbon. It was an easy matter to run down the lining of the furnace, indeed, to melt up the whole furnace itself, but the direct combination of the carbon with the lime was not to be obtained in that way. It then seemed probable that the result might be obtained by highly heating lime in the presence of decomposing hydrocarbons, so that the nascent carbon might combine with the lime at the moment of its liberation; but this was tried in many different ways without any very encouraging results, although it is possible by decomposing such organic compounds as calcic tartrate by heat, and raising the temperature of the mass to get traces produced; the price, however, under these conditions of the organic compounds, would be prohibitive.

Another point which always seemed to me to be against the direct formation of calcic carbide by heat is that the temperature needed for its formation is $2,700^{\circ}$ C., and if you take calcic carbide and attempt to fuse it at any obtainable temperature short of the electric arc, you fail to do so, whilst if the oxy-hydrogen blow-pipe be used for this purpose, not only do you fail to fuse the carbide, but you decompose that which you already have, and the lump which you have left behind consists mainly of carbon, carbonate of lime, and lime. It is possible, however, that by using carbon burning in oxygen a sufficient temperature could be reached to fuse the mixture of lime and carbon with the formation of carbide, but the temperature which would do this would prove fatal to the furnace itself. There is not the slightest doubt that the next year will see very many experiments made with gaseous mixtures, rich in oxygen, made at a remarkably cheap rate by methods such as the Linde process for liquefying air and allowing the nitrogen to boil off, and some of these may be successful in overcoming the existing difficulty.

It is reported that Dr. Borchers has succeeded in making carbide by some method akin to this, but there are many considerations

which lead to the belief that even if this feat has been accomplished, its practical value will be but little. Given water gas, regenerative settings, and cheap oxygen, an enormously high temperature can be attained, but the material of which to build a crucible or furnace that will stand it has yet to be discovered.

In using the electric furnace the intense heat of the electric arc is generated in the centre of the mass to be fused by it and so the wear and tear to the furnace is avoided, but this would be impossible even if the requisite temperature could be reached by a combustion process, and the result would be that the electrical heating would probably be less expensive than the other.

It is perfectly well known that if a temperature commercially practicable is to be used, some metal with a strong affinity for oxygen must be employed to reduce the lime to calcium before combination with the carbon will take place. Such metals as will do this, potassium, sodium, and magnesium, or even zinc, are, however, costly, and if a process were devised in which the vapours of such metals were liberated by reduction from their salts, and were made to interact with carbon and lime at a high temperature, it could only be made commercially possible either by a large demand being created for the bye products, or by its being capable of being cheaply worked up and used over again. In either case the probabilities are that the cost would exceed that of making carbide by electricity generated by water-power.

Another point of a purely unscientific character is that during the past few months very large amounts of capital have been subscribed for the erection of factories for making carbide by water-power on the Continent, and practically little or none can be traced for processes for making carbide without electricity, which shows no great amount of confidence in the many schemes suggested.

There is a company at Leipsig, having works at Cassel, who are supposed to make calcic carbide without electricity, by smelting the constituents by acetylene blow-pipes, working under considerable pressure, but it does not appear possible that this could be made to compete economically with the ordinary electrical method.

One of the schemes for the manufacture of carbide is for producing it from blast furnace slag, which contains a certain amount of lime, together with all the impurities derived from the fuel, ore, and limestone used in the furnace.

According to the inventor, this mixture is to be run into Bessemer converters, impregnated with coke powder blown into it through the converter trunnion, and then poured out between a series of carbon electrodes, between which a powerful current is flowing, and in twenty minutes this converts the slag into a material named by the inventor "carbolite," and which is supposed, on contact with water, to yield 5 cubic feet of gas per pound. Such a substance might contain 40 per cent. of calcic carbide, but the impurities would be so pronounced that it would be practically useless for the generation of acetylene for indoor lighting.

Carbide of calcium, as formed in the electric furnace, is a beautiful crystalline semi-metallic-looking solid, having a density of 2.22, and showing a fracture which is often shot with iridescent colours. It can be kept unaltered in dry air, but the smallest trace of moisture in the atmosphere leads to the evolution of minute quantities of acetylene, and gives it a distinctive odour. It is infusible at temperatures up to 2,000° C., but can be fused in the electric arc. When heated to a temperature of 245° C. in a stream of chlorine gas it becomes incandescent forming calcic chloride and liberating carbon and can also be made to burn in oxygen at a dull red heat, leaving behind a residue of calcic carbonate. Under the same condition it becomes incandescent in the vapour of sulphur, yielding calcic sulphide and carbon disulphide, whilst the vapour of phosphorus will also unite with it at a red heat. It is a compound of—

	Per cent.
Calcium	62.5
Carbon	37.5
	100.0

Acted upon by water calcic carbide is at once decomposed, yielding acetylene and calcic hydrate. Pure crystalline calcic carbide yields from 5.5 to 5.8 cubic feet of acetylene per pound at ordinary temperatures, but the carbide as sold commercially is a mixture of the pure crystalline material with the crucible which in the electric furnace surrounds the ingot, and which of course yields less gas. The two being blended together yield an average of 5 cubic feet of gas per pound of carbide under proper conditions of generation; but as we shall see later on, the volume of gas to be obtained from the carbide depends very largely upon the form of apparatus used, and whilst some will give the full 5 cubic feet

er apparatus will only yield with the same
bide $3\frac{3}{4}$ feet.

The purity of the carbide entirely depends
on the purity of the materials used in its
manufacture, and before this fact had been
fully grasped by the manufacturers of carbide,
and only the purest material obtainable em-
ployed, the carbide contained notable quantities
of compounds which, during its decomposition
in water, yielded a somewhat high proportion
of impurities in the acetylene generated from

Although at the present time a mar-
vellous improvement has taken place all round
the quality of the carbide produced, the
acetylene nearly always contains minute
traces of hydrogen, ammonia, sulphuretted
hydrogen, phosphuretted hydrogen, siliciur-
retted hydrogen, nitrogen, and oxygen, and
sometimes minute traces of carbon monoxide
and dioxide.

The formation of hydrogen is caused by
all traces of metallic calcium occasionally
and free in the carbide, and cases have been
known where this was present in such
quantities that the evolved gas contained
nearly 20 per cent. of hydrogen. This takes
place when, in the manufacture of the carbide,
the material is kept too long in contact with
the arc, as this over heating causes the dis-
sociation of some of the calcic carbide, and the
evolution of metallic calcium in the remainder.

The presence of free hydrogen is nearly
always accompanied by siliciuretted hydrogen,
which is formed by the combination of the
nascent hydrogen with silicon in the carbide.
It has usually been stated that this siliciuretted
hydrogen has been formed by the decomposi-
tion of silicides present in the carbide, but in
the course of a long series of experiments which I
have made, I have never yet been able to
form a metallic silicide which will decompose
in water with the evolution of this gas, and
the silicides which analyses prove to be present
in the carbide are certainly not decomposed in
this way.

The ammonia found in the acetylene is due
to the presence of magnesium nitride in the
carbide, and this is formed by the metallic
magnesium in the molten condition in the
arc, not taking up nitrogen from the air, and
when this comes to be decomposed by water
ammonia is produced by the action of steam
on the nascent hydrogen on the nitride, the
quantity formed, however, depending very
largely upon the temperature at which the
carbide is decomposed.

The formation of nitrides by actions of

this kind and their easy conversion into
ammonia will probably, at some no very
distant date, prove to be a useful method of
fixing the nitrogen of the atmosphere and
rendering it available for manurial purposes,
although it could never compete in price
with the ammonia formed in the destructive
distillation of coal for coal gas.

Sulphuretted hydrogen, which is invariably
present in commercial acetylene, is formed
by the decomposition of aluminium sulphide,
and it has been shown by Murlot that
aluminium sulphide, zinc sulphide, and cad-
mium sulphide are the only sulphur com-
pounds which can resist the heat of the elec-
tric furnace without decomposition or volatil-
isation, and of these aluminium sulphide is
the only one which is decomposed by water
with the evolution of sulphuretted hydrogen.

In the early samples of carbide this com-
pound used to be present in considerable
quantity, but now it has been reduced to
so small a limit that one rarely finds more
than one-tenth per cent. of sulphuretted
hydrogen in the acetylene generated from
commercial carbide.

Phosphuretted hydrogen, one of the
most important impurities, which has been
blamed for the haze formed by the combus-
tion of acetylene under certain conditions, is
produced by the action of water upon traces
of calcic phosphide found in carbide. Al-
though at first it was no uncommon thing to
find half a per cent. of phosphuretted hydrogen
present in the acetylene, this has now been so
reduced by the use of pure materials that the
average quantity is rarely above one fifteen
hundredth of a per cent., and it is often not one-
fifth of that.

I have made many experiments on the effect
of the impurities in calcic carbide upon the
safety of the material, and have come to the
conclusion that such impurities as are now
found in the commercial carbide may be looked
upon as practically innocuous. With proper
care and supervision in the selection of the
materials for making the carbide, all trouble
on that score may be disregarded, as spon-
taneous ignition due to the liberation of phos-
phuretted hydrogen would be the chief risk
dependent upon the use of the impure material.

In the earlier days of carbide manufacture
several cases of spontaneous ignition of the
gas occurred, and although the analyses of
many different brands of carbide from all
countries of the world show that in the carbide
itself there is not sufficient impurity to bring

about this result, it seemed possible that the concentration of the phosphorus compounds might take place in the outer crust formed around the ingot during manufacture, and experiments were made to see if this were so.

By the courtesy of the Acetylene Illuminating Company a portion of an ingot with its crust intact was obtained, the crystalline material of the ingot containing 96.7 per cent. of true carbide, whilst the crust, although varying very much in composition according to its distance from the ingot, contained an average of 51.9 per cent. of carbide. A second couple of ingot and crust gave even better results, the ingot containing 90 per cent. of carbide, and the crust 77 per cent.

Analyses were made of the acetylene from these samples, but the results showed no indication of the poorer material being richer in phosphorus compounds than the ingot itself.

On breaking up some ingots of calcic carbide, metallic nodules manifestly differing from the pure carbide are observed, and are far more abundant in specimens of foreign manufacture than in English made carbide. These nodules are generally found in a spherical or oval shape, and have evidently separated from the molten mass on the crystallising of the true carbide.

From this it seemed highly probable that a concentration of the impurities might take place, and that the presence of these nodules might be an active source of danger.

In order to verify this point calcic carbide was obtained in bulk, and both English and foreign makes were represented. This carbide was then carefully broken up, and the nodules and anything which appeared to differ from the true carbide were collected. The nodules differed somewhat in appearance, two distinct varieties being clearly noticeable:—

(a.) Grey nodules, not attracted by the magnet, not oxidised when exposed to air or heated as a solid lump in the blowpipe flame. Specific gravity, 3.5 to 5.8. In a fine powder some had a very faint garlic-like odour, gained 5 per cent. when heated for half-an-hour, and attacked platinum when heated on it for some time. These nodules gave no gas when acted upon by water.

(b.) Steel-like nodules, which were strongly magnetic, and became coated with iron rust when exposed to moisture and air for some time, and which gave no gas when acted on by water. Specific gravity, 6.3 to 6.8.

Analysis showed that the foreign matter present in the carbide consisted of carbo-

rundum or silicide of carbon, metallic silicide iron, occasionally metallic calcium, manganese, aluminium, and traces of nitric phosphorus, and sulphur compounds. On the nodules on analysis yielded:—

	Per cent.
Silicon	30.76
Iron	58.06
Calcium	2.65
Aluminium	3.01
Magnesium	0.64
Carbon, &c.	4.89
	100.00

None of these substances gave spontaneously inflammable gases when acted upon by water, but in a few instances a nodule was found which evidently contained magnesium silicide, and which when powdered and acted upon by hydrochloric acid, gave a few bubbles of spontaneously inflammable gas.

M. C. Gerard, chief of the Municipal Laboratory at the Prefecture of Police, Paris, has also analysed some of these nodules, and the following results, and found that the alloys, pulverised and treated with concentrated acid, gave off siliciuretted hydrogen:—

	I.	II.
	Per cent.	Per cent.
Iron	55.027	53.250
Silicon	33.172	31.800
Aluminium	5.579	8.910
Calcium	2.764	4.120
Not determined and lost	3.458	1.920
	100.000	100.000

In some cases it was found that the carbon deposited by holding a cold surface in the acetylene flame contained traces of silica. This seems to support the idea that siliciuretted hydrogen may occur in the acetylene, but, does, the amount is so small as certainly give no danger of spontaneous ignition.

A sample of gas which appeared to give a considerable quantity of silica was bubbled under such conditions as to allow of the silica being collected, and on estimating the quantity formed it was found to correspond to 0.01 per cent. of siliciuretted hydrogen in the original gas.

M. Gerard also carried out a number of extremely interesting experiments upon the products found in the residues left after treating the calcic carbide with water, and succeeded in extracting from them minute diameters. The residues were, as far as possible, dissolved in hydrochloric acid, and the insoluble portion separated by filtration and washing with water.

d the metallic portions separated by sieving. The finer portions were collected in a filter paper, washed and dried, and were then heated with potash in a silver capsule, and the insoluble portion treated with aqua regia. After repeating this drastic treatment two or three times, the residue was put into a separating funnel containing a saturated solution of the soluble iodide of mercury and potassium, which has a density of 2.9, in which silicide of carbon will float, whilst graphite sinks. This silicide of carbon is then purified by being treated several times with concentrated hydrofluoric acid, and after washing is dried, whilst the graphitic bodies are treated and separated with iodide of methylene, which has a density of 3.29. The separation of diamondiferous bodies from the silicides of carbon is effected by a saturated solution of cadmium bromo-oxystate or iodide of barium and mercury.

FIG. 1.

SILICIDES OF CARBON FROM ENGLISH CARBIDE.

Microscopic slides of these various bye-products were sent by M. Gerard to Mr. Worth, of the Acetylene Illuminating Company, who from the first has kept in touch with all the leading chemists in Europe, and has supplied them with any samples of English carbide that they needed, and it is through the courtesy of Mr. Worth that I am able to show you these microscopic slides prepared from the bodies extracted by M. Gerard.

FIG. 2.

DIAMONDS FROM ENGLISH CARBIDE.

The labour entailed in the separation of this diamond-containing powder may be esti-

mated, when it is stated that it was necessary to treat no less than between 700 and 900 lbs. of carbide in order to obtain 15.4 grains of this material.

FIG. 3.

VARIOUS SILICIDES OF CARBON.

The evidence upon which M. Gerard bases his assumption, that these minute crystals are in reality diamonds formed at the intense temperature of the arc, is that when they are burnt in oxygen they yield nearly the theoretical volume of carbon dioxide. M. Moissan has failed to find diamonds in the specimens of carbide he has examined, but this is probably due to the quantities worked with, being far smaller than those treated by M. Gerard.

There is no more risk in the storage of calcic carbide than there is in storing any other inert material, provided it is packed dry and warm in hermetically sealed drums so as to render it impossible for it to come in contact with water or moist air.

The real risk is in the removal or redistribution of the material, as after opening a drum it may not be again properly closed, and if the drum be left in this condition in the moist air of an ill-ventilated cellar, it is quite possible for a slow generation of gas to take place, and an explosive mixture to be formed by its accumulation.

All carbide stores should be thoroughly ventilated and above ground, and when this is the case all danger is practically done away with.

For the carriage of carbide it is important that not only should the drums be air-tight, but that they should be of sufficient strength to resist the rough usage incidental to the handling of a heavy product, and where tins are used they should always be protected by an exterior wood case.

Miscellaneous.

PINEAPPLE FIBRE.

The Calcutta periodical, "Capital," as reported in the *Board of Trade Journal*, states that it appears somewhat curious that pineapple fibre was years ago experimented with and condemned by English spinners. In India also, although no difficulty apparently attends the separation of the fibre, it is

turned to very little account. The far-famed weavers of Dacca, when long since an attempt was made to induce them to bring the staple into use, would have none of it. In Burma again, where the plant is so abundant, the fibre seems to be utterly neglected.

On the other hand, there is a considerable amount of information extant which seems to furnish corroborative evidence as to pineapple fibre actually possessing the essential properties required to make it a good substitute for flax. It has even been claimed that in both its wild and cultivated forms the pineapple yields fibres which, when spun, surpass those obtained from the ideal flax in strength, fineness, and lustre.

It has been stated that a certain quantity of the fibre prepared at Singapore tested against an equal quantity of flax sustained 350 lbs., while the latter could not bear more than 260 lbs. Another advantage held to be peculiar to pineapple fibre is imperviousness to moisture. Ropes made of it are thus said to withstand constant immersion in water; and for the same reason and its non-liability to rot it is used in India for threading necklaces.

As to the characteristics that render it readily adaptable for textile purposes, it has been observed by one writer on the subject that the mere process of bleaching suffices to destroy the adhesion between the bundles or fibres, and so renders it fit for spinning in the same way as flax. The isolated filaments are described as very fine, of a tolerably regular diameter from end to end, but of different size, of remarkable flexibility, curling and crisping readily under mechanism. It has been confidently asserted that the fibre can be employed as a substitute for silk, and as a material for mixing with wool and cotton, as silk is now so extensively employed. For sewing thread, twist, trimmings, laces, curtains, and the like, its particular qualities seem to render it specially applicable.

From the pineapple of the Philippines a famous cloth is manufactured, much esteemed for its fine hair-like fibres, but this is considered as perhaps belonging to a different species. Reference has also been made to a plantation established years ago at Singapore by a Chinaman, who there prepared pineapple fibre for export to his native country to be used "in the manufacture of linen."

GRAPHITE IN BOHEMIA.

Since the Cumberland and also the Siberian deposits of graphite, or plumbago, have been practically exhausted, the chief supply of this mineral has been derived from Bohemia, in the south of which country, near Schwartzbach and Murgan, deposits of pure graphite are found in the gneiss, accompanied by crystalline limestone. The mines and works at the former place are owned by Count Schwartzenburg, and those at the latter by the peasants; and these two centres yield the purest graphite now available,

that of Krummau being far inferior. When the mineral is not sufficiently pure to be sent away as natural graphite, it is ground in mills constantly traversed by a stream of water that takes up the powdered graphite, which is afterwards thrown down in the form of mud; and when the mud layer has attained a sufficient thickness, it is subjected to a pressure of six atmospheres (88 lbs. per square inch) in a filter-press. The resulting cake, containing more than 20 per cent. of water, being then dried in a stove heated to 90 or 100 degrees (mean 203 Fahr) for 24 hours. Out of the 9,000 quintals (885 tons) of graphite which are turned out yearly on an average in Bohemia, two-thirds are exported; but it is only during the last few years that the production has been considerable. Out of the twelve graphite mines in Bohemia only the three named above are actively worked, occupying 728 hands. Although the prices of graphite, and especially natural graphite, have slightly fallen since, the best quality now obtain only 15.2 florins (28s. 7d.) instead of 20 florins (38s. 4d.) per metric quintal (2 cwt) as formerly, the mean annual cost of production has increased from 3.22 florins (6s. 0½d.) to 5.12 florins (9s. 7¾d.), owing to the better qualities being more in demand than the inferior.

THE MANUFACTURE OF PERFUMES IN FRANCE.

Enormous quantities of flowers are used in the Alpes Maritimes in the manufacture of perfumes. It has been estimated that of roses alone 2,000 tons are annually treated; orange flowers, 2,500 tons; jessamine, 200 tons; cassie (*Acacia Farnesiana*), 15 tons; tuberose, 150 tons; and violets, 200 tons. The average selling price per pound of flowers is, in the case of violets and cassie, 1s. 8d.; tuberose, 1s. 3d.; jessamine, 1s.; roses, 3½d.; and orange flowers, 3½d. Of the flowers producing essence the orange flower produces 1 lb. of essence—which is called "neroli"—for each 500 lbs. of flowers. As regards the proportionate yield of the other flowers, it is as follows:—Rose, 12,500 lbs. flowers, 1 lb. of essence; geranium, 500 lbs. flowers, 1 lb. of essence; mint, 500 lbs. and 1 lb. of essence; lavender, 500 lbs. of flowers to 1½ lb. of essence, and the same proportion for eucalyptus. There are two processes used for the purpose of extracting perfume from flowers which do not contain the volatile essence. The first may be described as the cold process, and the second as the hot process. The former is generally used for cassie (*Acacia Farnesiana*), jessamine, jonquils, tuberose, violets, and some other flowers. Freshly gathered flowers are spread upon a layer of pure lard a quarter of an inch in thickness, spread over a sheet of glass about two feet square, which is framed with wood and forms a kind of tray. These trays—sometimes about 40 or 50 together—are then piled upon or

ther, the flowers are then changed every 12, 18, or 24 hours, according to circumstances, and the process is continued until the lard is sufficiently charged with perfume. Jessamine and tuberose are frequently changed as often as 50 times before the lard is considered to be sufficiently impregnated, cassia 10 times, and violets from 30 to 40 times, and jonquils about 100 times only. The fat thus obtained can be packed in air-tight tins and conveyed anywhere. When the process is resorted to for the purpose of obtaining impregnated fat, about 40 lbs. of grease are placed in a copper vessel together with about 10 lbs. of flowers; the vessel is then placed over a slow fire and the contents are well stirred. After allowing the compound to boil for 10 minutes the vessel is removed to cool for some hours; an additional 10 lbs. of flowers are then added, and the process is repeated until the fat has absorbed the requisite amount of perfume. The hot liquid is then poured through a sieve, and the greasy flower paste that remains is rejected by hydraulic pressure. It is in these two processes that the "pommades" of trade are produced. From these "pommades" perfumed and alcoholised essences are extracted by means of grain spirit and rectified by spirits of wine. These are the "extraits" of perfumery, and it is by the judicious blending of the different essences and concentrated perfumes, obtained by the processes above described, that the numerous varieties are produced.

THE USES OF POPYRISTITE.

According to the United States Consul at Zurich, a new artificial stone or moss has recently made its appearance on the builders' technical market called popyristite, on account of the ingredients entering into its composition, principal among which is refined paper pulp, obtained from waste paper. Popyristite is an improvement on popyrolith, both having been invented by M. F. Gehre, a civil engineer, of Zurich. It can be used in various ways, but is specially intended to serve as a solid, impermeable, and jointless roof or floor, which when once laid will present a smooth surface as if made of one continuous layer. This new material is stated to be a non-conductor of heat, cold, or sound, and although as hard as stone, has a soft linoleum-like feeling to the foot, and is noiseless. Accumulations of dust, vermin, or fungi are impossible, there being no grooves or joints. The weight is much less than that of stone or cement. One hundred kilogrammes (220 lbs.) of this preparation in a powdered form, when mixed for use and spread to a thickness of 10 millimetres (.3940 inch), will cover a surface of 10 square metres (91½ square feet). No machinery is necessary to prepare the compound, although, to save labour, when great quantities are to be made, an ordinary press can be utilised to advantage. It can be moulded or spread in any form or shape, as

is the case with cement, the mixing is done on the spot where it is wanted, and it is transported like cement in barrels or sacks. The drying or hardening process is effected in twenty-four hours after spreading and then if desired it can be polished to a high gloss. The inventor's numerous experiments have given good results, and his persistent efforts seem at last, it is said, to have been crowned with success. Taking the opinion of prominent architects who have experimented with the new material there seems to be no doubt that a valuable building material has been discovered which can be utilised in many ways. It is as hard as marble and is practically indestructible, yet it is elastic and possesses all of the qualities mentioned above. It can be cut, sawn, and bored, given any desirable tint, and made to look like marble or mosaic. For roofing purposes it is also valuable. A light iron framework has been invented by Mr. Gehre, and the material is put on in the form partly of plates and partly of mortar, which when united produce a smooth continuous surface. It is adapted to cold as well as to tropical regions, and its stone-like qualities protect it against mice or other vermin. Trials of this material have been made in Russia and Brazil, and the reports received are said to be very encouraging. The material once laid will never contract or warp, and it is elastic, light, and inexpensive in production. For school-rooms, public halls, corridors, bath-rooms (both floor and walls), terraces, barns, poultry yards, &c., this material can be used, and as a non-absorbent of moisture, filth, or other unhealthy substances, it is said to be without equal as a building material.

Notes on Books.

THE PRANG STANDARD OF COLOUR. Louis Prang, Boston, Mass., U.S.A.

This is an attempt to provide a complete scale or chart of colours by reference to which any given colour may be matched or identified. The inventor takes the spectrum colours (with the addition of the purples formed by mixing the colours at the ends of the spectrum), and classifies them after the manner of the points of the mariners' compass, thus:—red, red red orange, red orange, orange red orange, orange. For convenience sake, the colours are designated by their initials, R., R.R.O., &c.

To form the colour chart, the twenty-four pure colours thus selected are arranged in a horizontal row, while in vertical rows under each colour, appear patches of that colour diluted with successively increasing additions of white. There are six such patches under each patch of pure colour, so that this first chart or plate consists of 7 × 24, or 168 patches. Each horizontal row is designated by a number, so that each individual patch is designated by a number

combined with initials, as R.O.3, R.R.O.5, &c. The second chart is a repetition of the first, with a certain addition of black — to represent colours which are less luminous, and this is followed by other plates, with successive additions of black, or diminutions of luminosity until in the last, or sixth plate, nearly all the colour has disappeared, and we have almost a monochromatic scale of dark and light.

The idea is carefully worked out, and is not without a theoretical value. Its practical value would depend entirely on the permanence of the printed colours—assuming their correctness in the first instance—and it is obvious that permanence could not be trusted after a very brief period.

CATALOGUE OF THE LIBRARY OF THE PATENT OFFICE. Vol. I. Authors. London: 1898. 4to.

This volume contains 1,007 pages in double columns, with about 38 entries in each page, some of these being cross references. There is no preface, but as this first volume is described as an alphabet of authors it may be presumed that the second volume will be devoted to an index of subjects. Although this volume is described as an authors' catalogue, it contains entries of anonymous books and periodical publications. Unfortunately, by the adoption of a fanciful (although a constantly-followed) rule of placing the titles of anonymous works under the first word not an article or preposition, many of the books will not be easy to find before the index is ready—as for instance, A B C of Photography under A, and several treatises under *Account, Description, &c.*

LECTURES ON THE NATIONAL GALLERY. By J. P. Richter. London: Longmans. 1898.

This volume, which is fully illustrated, contains the result of the author's researches concerning certain pictures in the National Gallery, which were the subject of his lectures at the Royal Institution in February of the present year. The topics of the lectures are:—1. The Paintings of the Fourteenth Century. 2. The Origin of the Venetian School of Painting—Giovanni Bellini. 3. Sandro Botticelli and his School.

Prof. Wickhoff, of Vienna, in his essay on Guido da Siena, expresses a doubt whether any pictures can now be determined as the works of Cimabue, and Dr. Richter is of opinion that the doubt is fully warranted. The latter believes the altarpiece of the Rucellai Chapel of the Church of Santa Maria Novella, Florence, which is said to be the masterpiece of Cimabue, to be really the work of Duccio, of Siena. The great mosaic of St. John the Baptist, the authenticity of which is attested by contemporary documentary evidence, still exists in the Cathedral of Pisa. Cimabue only provided the cartoon, and did not execute the mosaic. This has been so frequently repaired, that as Dr. Richter affirms, it would never in its present condition be ascribed to any great master.

Further, Dr. Richter believes that not a single

picture in the National Gallery comes from the hand of Giotto himself, but he adds that in this the National Gallery is not at a disadvantage when compared with the picture galleries of the Continent, "for it seems to me that only one of them can claim to possess a genuine picture by that great artist, namely the Gallery of the Accademia in Florence, with its large Madonna picture." Of Bellini, Dr. Richter says that in his capacity of State painter to the Republic of Venice it was his duty to execute the official portraits of the Doges. During his long life he saw eleven Doges, and was State painter during the reigns of four. In spite of this, only one likeness of a Doge by Bellini has been preserved, and that is the magnificent portrait of Leonardo Loredano in the National Gallery, which Dr. Richter describes as "one of the most perfect portraits of the Quattrocento, remarkable alike for the great simplicity of the conception, and for the brilliancy of the colouring."

General Notes.

DÜSSELDORF EXHIBITION, 1902.—Since 1880, the population of the Rhine and Westphalia provinces of Prussia has increased from 5,710,078 to 7,807,422, and is expected to attain 9,000,000 in 1902, in which year an industrial exhibition is to be held at Düsseldorf similar to that visited with so much interest by the Iron and Steel Institute in 1880. The North-West Group of Iron and Steel Makers, the Association of German Metallurgists and the Düsseldorf Association for Trade Interests have combined to give importance to the exhibition, for which the Municipality will furnish the land, and also contribute a guarantee fund.

INTERNAL NAVIGATION IN RUSSIA.—The total length of rivers and canals in European Russia—according to the *Revue de Statistique*, quoted in the *Board of Trade Journal*—is 67,596 miles, of which 46,202 miles are available for use, *i.e.*, 30,338 miles navigable and the remainder for floating purposes only. The canals aggregate 499 miles in length and canalised rivers 648 miles. The Volga alone accounts for nearly 50 per cent. of the navigable waterways. The average length of time for navigation varies naturally according to geographical distribution; it may be reckoned at about 158 to 220 days for the Neva and the Ladoga and Onega lakes; at from 221 to 240 days for the Niemen; at from 213 to 244 days for the Western Dwina, and at from 156 to 190 days only for the Northern Dwina. During the last five years the Russian Government has devoted nearly 150,000,000 francs (£6,000,000) to the improvement of navigable waterways. The goods carried are principally wood for building purposes, grain, petroleum, &c., salt, iron, coal, sugar, hemp, cotton, fish, and spirits.

Notices.

JUVENILE LECTURES.

On Wednesday evening, 4th inst., Professor F. JEFFREY BELL, M.A., delivered the first lecture of his course, addressed to a juvenile audience, the subject being "Hands and Feet."

The lecturer, after pointing out the differences in the functions and the resemblances in the structure of the hand and foot of Man, explained that this was an interesting example of the law known as the "Division of Physiological Labour." The resemblances and differences between a Man and a Gorilla were shown to be to the advantage of the former, and it was pointed out how, under the stress of circumstances, Man could put his foot to some of the uses to which the hand was generally devoted.

The marked differences between the foot of a man and of a horse were dilated on, and evidence was afforded that a continuous chain existed between early Eocene five-fingered *Phenacodus* and the one-fingered existing horse. The lecturer showed how this chain might be regarded as demonstrating gradual "evolution."

The fact that different animals attained the same result in different ways, was shown by the different structure of the wing in a bat or a bird, and, in conclusion, some of the more marked modifications of hands, such as that of the seal and of the mole, were briefly described.

The second lecture, on "Some of the Ways in which Animals Breathe," will be delivered on Wednesday evening next, 11th inst., at 7 o'clock.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

CANIOR LECTURES.

ACETYLENE.

BY VIVIAN B. LEWES,

Professor of Chemistry, Royal Naval College, Greenwich.

Lecture III.—Delivered December 5, 1898.

Familiar as I have been with chemical actions of all kinds, more especially in the development and use of gases, I shall never forget the impression made on my mind when, in the autumn of 1894, I first generated acetylene by the action of water upon calcic carbide obtained from Mr. Willson, in America. There was something almost "uncanny" in the development of this wonderful gas from the simple contact of the carbide with water. I was the more impressed by it as I had spent several years in researches necessitating the making of considerable volumes of acetylene, and I realised to the full the laborious and unsatisfactory nature of all the earlier methods for its production. It was with this carbide that I then made the experiments detailed by me in this room in January, 1895, when I showed you for the first time in this country the reactions which had caused me such keen delight, and also showed for the first time in any country how the gas could be consumed so as to develop to the full its marvellous illuminating power.

In the generation of acetylene from calcic carbide and water, all that has to be done is to bring these two compounds into contact, when they mutually react upon each other with the formation of lime and acetylene, whilst if there be sufficient water present, the lime combines with it to form calcic hydrate.

The wonderful simplicity of the reaction is its great beauty, and one would imagine that but little scope was afforded to the ingenuity of inventors in devising methods by which the contact between the interacting bodies should be brought about, but a glance through the patent literature of the last few years shows that where there is a will there's a way, and many of the weird devices protected under the

name of acetylene generators would lead one to suppose that the formation of this beautiful illuminant was one of the most complex problems ever submitted to the ingenuity of man.

There are manifestly two methods by which the carbide and the water can be brought together—by adding either water to carbide, or carbide to water, whilst a slight amount of novelty can be introduced by allowing the water to rise in contact with the carbide from below, *i.e.*, by adding the water to the bottom of the carbide instead of the top.

I showed these three methods of procedure when I first described acetylene, and at the time thought that the question of generators was practically done with, but within a few months the idea arose of making automatic generators in which the space necessary for a small holder should be saved by making the apparatus only generate the gas as it was needed, and a multitude of devices for stopping the generation of the gas when the consumption ceased were designed and placed upon the market.

Unfortunately, the designers of these machines, although gifted with much ingenuity and mechanical skill, had but little idea of the properties of the body with which they were dealing, and as a result many of the generators, if not actually dangerous, are so arranged as to generate the gas in anything but its pure form, whilst some give a far smaller yield of gas per unit weight of carbide decomposed than others constructed on more rational principles.

The different forms of apparatus shown in the Exhibition at the Imperial Institute, held in the summer under the auspices of this Society, may be taken as representing the best types on the market, and when in a few weeks hence the report of the Committee is published, much interesting matter will be found in it. As a uniform quality of carbide was used throughout the Exhibition for over a month's continuous working, direct comparison between the performances of the various generators becomes possible.

In considering the various forms of apparatus it will be well to divide them, in the first place into two classes—(1) the *automatic*, in which the storage capacity for acetylene is less than the total volume of gas the charge of carbide is capable of generating, and which depend upon some special arrangement for stopping the action of water on the carbide when the consumption ceases; (2) the *non-automatic*, with which there is a holder of sufficient size

to contain the whole of the gas generated from the charge of carbide which is used.

Each of these classes may be subdivided under three heads:—

1. Those in which water is by various devices allowed to drip or flow in a thin stream on to a mass of carbide, the evolution of the gas being regulated by the stopping of the water feed.
- 2A. Those in which water in volume is allowed to rise in contact with the carbide, the evolution of the gas being regulated by the water being driven back from the carbide by the increase of pressure in the generating chamber, or—
- 2B. by the rising bell of the gas-holder drawing the carbide up out of water.
3. Those in which the carbide is dropped or plunged into an excess of water.

The points to be attained in a good generator are:—

1. Low temperature of generation.
2. Complete decomposition of the carbide.
3. Maximum evolution of the gas.
4. Low pressure in every part of the apparatus.
5. Ease in charging and removal of residues.
6. Removal of all air from the apparatus before generation of the gas.

When carbide is acted upon by water considerable heat is evolved, and to determine what this amounted to, a good sample of commercial carbide containing 92 per cent. true carbide was experimented with as follows:—

A rough calorimeter was made by jacketing a beaker about 5 inches in diameter with cotton wool. This arrangement, though crude, answered its purpose well, as experiment showed that some hot water placed in it only lost 2°C . after standing for ten minutes in a room at 18.6°C ., a loss which could be neglected.

One piece of carbide, the weight of which was known, was dropped into a litre of water at a known temperature in the beaker, and the moment that the evolution of gas ceased, the temperature of the water was taken, the results being as follows:—

Grms. of water taken.	Grms. of calcic carbide	Rise in temperature °C.	Corresponding calories liberated.	Number of calories liberated per gram of carbide.	Time of reaction in seconds.
1,000	42.7	17.4	17,400	407	62
1,000	28.9	11.4	11,400	394	91
1,000	19.7	8.2	8,200	416	73

which give, as an average, 406 calories liberated for each gram of carbide.

Broken up carbide, the pieces of which weighed from 1 to 5 grams, was thrown into a litre of water in the beaker in quantities of 30, 40, and 50 grams respectively—

Grms. of water taken.	Grms. of calcic carbide	Rise in temperature °C.	Corresponding calories liberated.	Number of calories liberated per gm. of carbide.	Time of reaction in seconds.
1,000	50	17.6	17,600	352	248
1,000	50	18.4	18,400	368	86
1,000	50	18.3	18,300	366	123
1,000	50	18.4	18,400	368	106
1,000	40	15.6	15,600	390	109
1,000	40	15.8	15,800	395	101
1,000	40	15.0	15,000	375	196
1,000	40	15.5	15,500	387	110
1,000	30	11.7	11,700	390	76
1,000	30	10.8	10,800	360	89
1,000	30	11.8	11,800	393	114
1,000	30	11.4	11,400	380	85

or 377 calories liberated for 1 gram of carbide.

The last experiment was repeated with carbide still more finely divided, and the results gave 384 calories for each gram of carbide.

From these figures it will be seen that contrary to expectation, the smaller the carbide the less was the yield of heat, but the reason for this can soon be made evident. More time is spent in weighing out the finer carbide than in taking the weight of one large piece, and the larger surface presented by the small pieces, causes greater decomposition by the moisture in the air than with the single lump, hence the carbide is of poorer quality, and moreover the rapid evolution of gas in the case of the small carbide prevents the water abstracting all the heat from it.

Taking this into consideration, the 406 calories will most nearly represent the heat evolved by the decomposition of 1 gram of good commercial carbide, and this would be equivalent to 414.6 calories for pure carbide.

With this figure as a basis, it is evident

that the action develops about one-twentieth of the heat evolved by the combustion of carbon. As, however, the intensity of the temperature developed is a function of the time needed to complete the action, and as the decomposition of the carbide by water is extremely rapid, and the degree of heat attained varies with every form of generator, whilst the water in one form may never reach the boiling point, the carbide in another may become red hot and give a temperature of over 800° C.

When water drips upon carbide as in generators of subdivision 1, the temperature rapidly rises until it reaches a maximum after about 18 to 25 minutes, the actual heat developed depending upon the rate of flow of the water and the way in which it is distributed over the mass, but it is quite possible with generators of this class to reach from 400 to 700° C., and it is probable that in some parts of the mass the higher limit is nearly always attained, traces of tar being generally found in the residual lime. In some cases it is in sufficient quantity to make the lime yellow and pasty, whilst vapours of benzene and other polymerisation products pass freely off with the gas.

Leaving the question of the temperature developed in this class of generator, another important point is the length of time over which generation of gas continues after the addition of water to the carbide has ceased. Makers of automatic apparatus of this type seem to think that in order to stop the evolution of acetylene, all they have to do is to cut off the water supply. This would act very well if the generation of gas really ceased then, but this is not the case, as the gas continues to be evolved, although with increasing slowness, for a considerable period after the cutting off of the water. The length of time over which this after-generation extends will of course, to a certain extent, depend upon the amount of water added, the amount of carbide undecomposed, and the temperature of the carbide at the time when the water supply is stopped; whilst the generation will itself depend upon—

(a). The dehydration of the calcic hydrate first formed.

(b). The decomposition of water condensed from the gas present as the temperature of the generator falls.

As we have before seen, the first result of the action of water upon the carbide is the formation of quicklime and the evolution of acetylene, whilst if sufficient water be present, the lime takes up another molecule of water to

form calcic hydrate. This molecule of water, however, at temperatures of 420-430° C., is driven off from the calcic hydrate, and the affinity of the carbide for any water present causes the reaction

A series of experiments was made by placing a known weight of carbide in a generating cylinder, running in a known weight of water in a given time, and carefully measuring the volume of gas for the first ten minutes, and again when the action had practically ceased, and not more than 1 cc. of gas was evolved in ten minutes.

The results so obtained showed clearly that in any apparatus on this principle the cut off should be so arranged that at least one-fourth of the total holder capacity is still available to store the slowly generated gas.

An important point was noticed in these experiments, viz., the large excess of water required to ensure complete decomposition of the carbide over and above the theoretical quantity. The excess of water needed was largely dependent upon the form of generator employed.

According to theory 64 parts by weight of carbide require only 36 parts by weight of water to completely decompose them and convert the lime into calcic hydrate.

This would mean that each pound of carbide needs a little under half a pint of water to complete the action, whilst in practice, owing to the evaporation due to the heat of the action, half the added water is driven off as steam with the acetylene, or left mechanically adhering to the lime, and the smallest quantity likely to complete the action would be a pint to a pound of carbide, whilst in reality the only safe way is to add sufficient water to drown the residue.

If this is not done the lime forms so protective a coating to the carbide that small quantities often remain undecomposed, and if the residues are thrown into a drain or cesspool, the evolution of acetylene would give an explosive mixture which, on account of its low point of ignition, would be a serious danger.

The second subdivision of generators (2A), in which water rises to the carbide, is very popular, and over-heating can be avoided in these, provided they are so arranged that the water is never driven back from the carbide, and if the charge of carbide used is not too great. Under these conditions the slowly rising water is always in excess at the point where it decomposes the carbide, so that the

evaporation by rendering heat latent keeps down the temperature, and although the steam so formed partly decomposes the carbide in the upper portion of the charge, the action is never sufficiently rapid to give any very great rise of temperature. In order to fulfil these conditions it is necessary that there should be a holder of considerable capacity, and that the leading tube conducting the gas from the generator to the holder should be of sufficient diameter to freely conduct away the gas, the water being allowed at the same time to rise in the generator so slowly as to do away with any risk of over-generation.

In the best generators of this class these conditions are more or less approached, and it is unusual to find that the melting point of tin, 228° C., has been reached in the charge of carbide during decomposition.

Where apparatus of this class are automatic and have no rising holder to take the gas, it is found that they work satisfactorily when supplying the number of lights for which they were designed; but if they are over-driven and the action becomes too violent, excessive heating takes place, whilst the turning off of the gas and consequent driving back of the water from the carbide also has a tendency to cause it. If, however, the water has risen sufficiently slowly, the carbide below the surface has been practically all decomposed, so that the heating only takes place over a limited zone.

The generators of subdivision 2B are the worst offenders as regards excessive heating, the charge of carbide in some of them frequently becoming red hot, whilst the lime taken from them is highly coloured and often black from the formation of tar and carbon.

The moment that acetylene is subjected to the action of high temperatures changes of great complexity begin. These at first are purely synthetical; at temperatures which are comparatively low the acetylene begins to condense to benzene; as the temperature rises the condensation of four molecules of acetylene yields styrolene; a further increase in the temperature may cause the styrolene and benzene to interact, yielding anthracene and hydrogen, and it is probably at this point that the brown tar vapours appear, while naphthalene also is formed. At this temperature, moreover, a fresh set of interactions start, the nascent hydrogen combines with acetylene to form ethylene, and this body under the action of heat breaks down into methane and acetylene once more.

When the outer layer of carbide decomposes, the gas is evolved so rapidly that there is no time for the heat to act upon it, but as the decomposition spreads into the centre of the mass, the acetylene generated has to pass through the external layers, which as shown may be at a temperature above the point of its decomposition, and it is under these conditions that a considerable volume of gas is lost, and the tar, often found in the residue, or distilled out into the generator and tubes, is formed.

In generators in which excessive heating takes place, the tar is likely to cause considerable trouble, as it is of a very viscid nature, and if it condenses in the delivery tubes causes the lime dust and carbon particles to collect and bring about stoppage.

A still more important evil, however, is to be found in the alteration which takes place in the composition of the gas, and which reduces its illuminating value to a serious extent.

Two samples of gas taken whilst the charge in one of these generators was over-heating gave the following results on analysis:—

	Per cent.	Per cent.
Acetylene	70.0	69.7
Saturated hydrocarbons ..	11.3	11.4
Hydrogen	18.7	18.9
	100.0	100.0

and such a mixture would only have about one-half the illuminating value of pure acetylene.

The large amount of hydrogen present in these samples also shows that decomposition of some of the acetylene has taken place, and a considerable deposit of carbon is often found in the generator.

At first sight these results seem an absolute condemnation of the second subdivision of apparatus, and the rising bell which draws a mass of wet carbide above the surface of the water is bad from every point of view. But generators in which water rises from below and so attacks the carbide can be made safe if the arrangements are such that the water is never driven back from the carbide, and the bulk of carbide is sufficiently subdivided.

The generators of the third class are those in which carbide is allowed to fall into an excess of water, and these have many advantages.

In such generators, as long as there is water present, it is impossible to get above a temperature of 100° C., unless lime sludge is allowed to collect at the bottom, when the carbide will sometimes get hot enough to melt zinc, but with a properly arranged tank the

temperature never exceeds the air temperature by more than a few degrees. Under these conditions, the absence of polymerisation and the washing of the nascent and finely-divided bubbles of gas by the lime water in the generator yields acetylene of a degree of purity unapproached in any other form of apparatus.

The one thing that has militated against it is that it is not easy to design such a generator which shall be automatic, and as this seems to be the craze from which the generator makers are at present suffering, its advantages have been apparently overlooked by them, although fully recognised by all scientific men.

This form of generator, however, although exhibiting the great advantages enumerated above, has the drawback of being one of the least economical in the output of acetylene per pound of carbide used, as the gas having to bubble through the water is rapidly dissolved by it, whilst in an apparatus in which only the surface of the water touches the gas, the amount dissolved is comparatively small. The result of this is that with generators of this class the generation rarely exceeds 4.2 cubic feet of acetylene per lb. of carbide instead of 5 cubic feet per lb.

As regards the complete decomposition of the carbide, it has been already pointed out that in generators of the first subdivision there may be a small quantity of the carbide left undecomposed if water enough to flood the residuum be not admitted, whilst in non-automatic generators of the second subdivision this is practically impossible. In generators of the third subdivision, in which carbide drops into a large excess of water, it might be imagined that any carbide in the residue was an impossibility, but in point of fact this class is often the worst offender in this respect, as, if the generation has been in action for some time, a thick sludge of lime collects at the bottom of the generator into which the carbide sinks, and a large lump of carbide will often make for itself so tough a layer of oil and lime, that it resists the action of the water, and is found unacted upon when the generator is cleaned out, the usual explanation given by the generator-maker being that it is crust present in the "bad carbide."

In a good generator the maximum yield of gas should be evolved from the carbide. But a fact which the generator-makers have entirely overlooked up to the present time is, that if you take a number of different machines, and supply them all with exactly the same carbide, no two will give the same yield of gas; the

best generators giving volumes approximating to 5 cubic feet per lb. of carbide, whilst the worst will give barely four, a result, as usual, placed at the door of the carbide.

The causes which tend to diminish the volume of acetylene given off are:—

1. Undue pressure in the generator.
2. The acetylene after generation having to pass through a column of water.
3. Undue heating causing polymerisation.

The first of these is very noticeable, and is due to the increased volume of gas dissolved by water under pressure, as although ten volumes of water at ordinary atmospheric pressure only dissolve eleven volumes of acetylene at two atmospheres pressure it dissolves double the quantity.

When acetylene is generated at or above the surface of water, but little dissolves at once, the top layer of water rapidly becomes saturated, but when the gas has to bubble up through a mass of water, as in generators of the third class, a heavy loss from solution takes place.

The last cause has already been discussed, and is not so noticeable in its result.

The pressure in all parts of a generator should be as nearly as possible equal and as low as possible, and this is best obtained by working freely into a gas-holder of sufficient size.

The Home Office fixed 100 inches of water as the limit of pressure permissible in generators, but I think myself it was a mistake to allow more than 20, and I certainly should not advise the use of a generator which gave more than that amount.

Every part of the generator should be easily accessible, and complicated taps and valves should be avoided, whilst ease of charging and clearing should be attended to, ample room being provided in the generator for the increase in bulk which takes place when carbide is converted into lime.

One pound of pure calcic carbide yields 1.15 lbs. of slacked lime—one kilo of carbide yields 1,156 grams of slacked lime—and the volume this will occupy depends entirely upon the way in which the water is brought into contact with it.

In an automatic generator of the first subdivision where water drips slowly upon the carbide in sufficient quantity to decompose it but not to flood it, the lime swells up and occupies from 2 to 2.5 times the bulk of the original carbide; when, however, the water flows in more rapidly, the impact of the water

beats down the lime and the space occupied is large.

In generators of the second type, in which water rises from below, the weight of the undecomposed carbide above it presses down the lime below and keeps it in a compact mass occupying about one-half more space than the carbide from which it was formed.

In designing a generator of the third subdivision, the tank containing the water into which the carbide falls should be provided with a false bottom so as to leave at least 8 inches to 1 foot of water below the point at which the carbide is decomposed for the lime sludge to settle in, and experiments were made to see the rate at which the settling of the excess of lime took place.

In these experiments known weights of calcic carbide were dropped into a beaker containing a litre of water, and the results obtained were as follows:—

Water taken.	Calcic carbide.	Volume of Lime Paste deposited.		Volume of Lime Paste deposited, calc. for 1 gm. CaC ₂ .	
		30 mins.	90 mins.	30 mins.	90 mins.

			Mean	9.8	8.6

After 30 minutes the volume of lime was 10

c. per gram of carbide. After 90 minutes the volume of lime was 8.1 c.c. per gram of carbide. So that approximately after an hour's standing, each kilo. of calcic carbide will give 10 litres of lime sludge, or 1 lb. of calcic carbide will yield eight pints, which can be got rid of by a cock at the bottom of the apparatus. The rapidity with which settling takes place, of course, slightly affected by the form of the apparatus.

Another requisite of a good generator, overlooked up to the present time, is that there should be an arrangement by which the air present in the generator can be rinsed out with some of the acetylene already made in the boiler, or by some inert gas like carbon dioxide. I think this is a most important precaution, as recent researches by Mr. H. Gerdes show that, instead of acetylene requiring to be diluted with about twelve times its bulk of air in order to obtain the maximum pressure on explosion, mixtures of equal volumes of acetylene and air give the most powerful result. It must be remembered that the temperature at which acetylene decomposes into carbon and hydrogen with evolution of heat is 780° C., and the temperature of ignition is 480° C., and in such a mixture the degree of heat needed to cause explosion will more nearly approach the latter than the former temperature. It is quite conceivable that in working on a big scale, the carbide might easily reach the necessary temperature whilst such a mixture of acetylene and air still remained in contact with it; indeed I have come across several cases of explosion which could only be explained by this.

Working with 90 litres of the various mixtures in an explosion cylinder, and measuring the pressures by means of a manometer and indicator, the following results were obtained:—

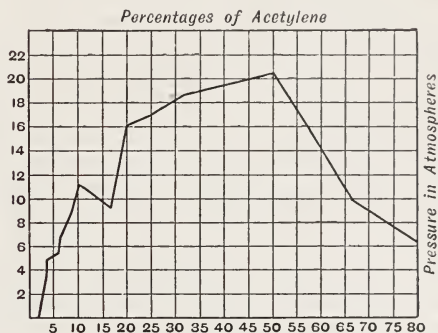

Pressures given by exploding mixtures of Acetylene and Air.

Per-centage Acetylene.	Atmospheres Pressure.	Per-centage Acetylene.	Atmospheres Pressure.
2.5	0.05	11.1	11.1
3.7	3.7	12.5	10.6
4.7	4.9	16.6	7.2
5.5	5.2	20.0	16.0
6.6	6.8	25.0	16.9
7.7	8.2	33.0	18.4
8.3	8.6	50.0	20.3
9.1	9.7	66.0	10.0
10.0	11.1	80.0	6.3

If these results be plotted out in a curve, it will be seen that there are two maxima of explosive force.

The first maximum of pressure occurs when completed combustion yields the greatest heat effect, and the acetylene is burned to carbon dioxide and water vapour, and this mixture explodes with the greatest noise.

Mr. Gerdes explains the second maximum of pressure by the assumption that the carbon is gaseous at the moment of liberation, but I do not think this theory is tenable. If a mixture of equal volumes of acetylene and air be ignited in an open cylinder 18 inches high a lurid disc of flame runs down the cylinder and a vast cloud of carbon is given off, but no sign of anything approaching explosion occurs. If, however, this be done in a closed vessel the very slowness of the combustion brings about the explosion, as the combustion of the portion of the mixture first ignited creates a pressure under which the remainder detonates at the temperature of combustion and gives the high pressure noticed in these experiments.

In experiments which I have made I have found it extremely difficult to ignite such a mixture of air and acetylene in a tube by means of an electric spark, but if a flask be employed so that a considerable volume of the mixture be present, the spark at once causes a violent explosion, the finely divided particles into which the glass is blown being an ample proof of the explosive force having been of an extremely sharp character.

The fact that a mixture of one volume of air and one volume of acetylene burns extremely slowly in an open cylinder, and also the fact that it is difficult to ignite by a spark the mixture in small portions, is no argument against the explosibility of the mixture, as if you take a mixture of carbon disulphide and nitric oxide in a short cylinder it burns with simply a bright flash of light which is noted for its richness in actinic rays, whereas if a very long narrow cylinder be employed, it burns down to a certain point and then detonates,

blowing the cylinder to pieces, such phenomena being entirely due to the increase in rapidity of combustion which finally terminates in an explosive wave.

A good deal of the trouble arising in generators is due to the irregular development of the acetylene, which at first comes off with tremendous rapidity, and then as the exterior carbide becomes coated with lime gets slower and slower, whilst the after cracking-off of this coating then gives irregular rushes of gas. Many attempts have been made to get over this trouble, perhaps the most successful being the decomposition of the carbide by means of a solution of sugar, which has the power of dissolving the lime as it is formed, and so gives a uniform and less rapid evolution of gas, but of course this increases the expense, and would only be available in the generators of table and bicycle lamps where cost is a secondary consideration; alcohol also when mixed with the water tends to regulate the generation. The effect of various oils in regulating the evolution of the gas has also been tried with a certain amount of success; as, if the carbide be coated with oil, it is protected from the action of water all the time the oil is clinging to the material; and in one form of automatic generator a layer of light oil is placed on the surface of the water. As the water rises past the carbide the oil rises with it, and the action of the water on the carbide commences a few minutes after the water has come into contact with it and has had time to displace the oil, whilst on cutting off the gas the water is again driven down. As the oil on its surface comes in contact with the partially decomposed carbide it is supposed to coat it and stop the after generation. With very small generators working well within their capacities this may be successful, but with any large charge of carbide the heat remaining in the lumps of solid material would probably be sufficient to distil out some of the light oil employed.

In concluding this part of the subject I can only say that I believe that as time goes on the tendency on the part of acetylene consumers will be to use the simplest form of generator available with a holder proportionate to the needed consumption.

Abroad, a good deal of work has been done on the purification of acetylene, and although this is desirable with the smallest installation, it becomes imperative when small towns or villages are to be supplied with acetylene instead of coal gas.

As was pointed out in the last lecture the purity of the acetylene gas primarily depends upon the purity of the carbide from which it is formed, and as long as it is commercially possible to use absolutely pure calcic oxide and carbon, so long will there be always present in this material calcic phosphide, calcic cyanide, aluminium sulphide, and magnesium nitride, which, on the decomposition of the mass with water, will yield a gaseous and unwelcome addition to the acetylene of phosphuretted hydrogen, sulphuretted hydrogen, and ammonia.

Phosphuretted hydrogen, when it burns in the acetylene flame, gives rise to phosphorus pentoxide, which escapes into the atmosphere in the form of white fumes, and although the quantity is so minute that it is invisible as it leaves the acetylene flame, still, when mingled in quantity with the air of an ill-ventilated room, it is the primary cause of the production of a light haze which ever since the introduction of acetylene for illuminating purposes, has been recognised as a serious inconvenience connected with it.

The atmosphere of a warm room always contains large quantities of water vapour derived both from the respiration of the occupants and from the products of the combustion of the illuminating flame, and under ordinary conditions this moisture remains suspended in the atmosphere in an invisible state, but as soon as traces of phosphorus pentoxide escape into it, this substance having a marvellous affinity for water, causes a condensation of a portion of the water vapour and converts it into phosphoric acid, so that a very small trace of phosphuretted hydrogen in the gas itself gives rise to an amount of haze totally out of proportion to the actual phosphorus present. Where there is a considerable quantity of acetylene consumed and no proper method of changing the air of the room, this haze will often be found, and it is undoubtedly injurious to health. I do not myself think that the whole of the onus of the haze can be laid at the door of the phosphuretted hydrogen in the acetylene, but it undoubtedly plays an important part in this action upon which I am at present experimenting.

The sulphuretted hydrogen formed by the action of water on the aluminium sulphide in the gas is objectionable, not so much because it renders the smell of the acetylene offensive, but because in its combustion in the acetylene flame it forms sulphur dioxide, which in ill-ventilated apartments will absorb moisture and

oxygen from the air, and will in this way become converted into minute traces of sulphuric acid which, concentrating themselves upon any cold surface in the room in the form of impalpable moisture, give rise to corrosion of metals and in time to destruction of the binding books, although the effect is but small upon rich fabrics as have not the power of absorbing moisture or condensing it from the atmosphere. The chief objection to the third impurity present in the acetylene gas ammonia is that it leads to rapid action upon the brass gas fittings, and is also an important factor in producing explosive compounds of acetylene with metals, although the experiments of Mr. Gerdes have shown that this is not a very real danger. The ammonia, on burning in the flame, also forms nitrous acid, and when acetylene is burnt for some time in an enclosed space ammoniac nitrite can be detected, and salts of this character may add to the formation of the haze."

It is quite clear, however, that acetylene, if it is to be used on a large scale as a domestic luminant, must undergo such processes of purification as will render it harmless and innocuous to health and property, and the purifier it is recognised as absolutely essential to purify acetylene before consuming it, the purifier will the gas acquire its deserved meed of popularity, whilst I think I shall be able to show in the next lecture that many other troubles will at the same time be overcome.

The only one of the impurities which offers any difficulty in removal is the phosphuretted hydrogen. There are three substances which can be relied on to more or less remove this compound. The three methods are to pass the gas to be purified either through acid copper salts, through bleaching powder, or through chromic acid, and in experiments with these various bodies, it is found that they are all of them effective in also ridding the acetylene of the ammonia and sulphuretted hydrogen, provided only that the surface area presented to the gas is sufficiently large.

The method of washing the gas with acid solutions of copper has been patented by Herr Frank, of Charlottenberg, who finds that a concentrated solution of cuprous chloride in an acid, the liquid being made into a paste with Meselgühr, is the most effective to be employed, and where the production of acetylene is going on on a small scale this method of purifying is undoubtedly the most convenient one, as the acid present absorbs the ammonia, and the copper salt converts the phosphuretted and

sulphuretted hydrogen into phosphates and sulphides. The vessel, however, which contains this mixture has to be of earthenware, porcelain, or enamelled iron, on account of the free acid present; the gas must be washed after purification to remove traces of hydrochloric acid, and care would have to be taken to prevent the complete neutralisation of this acid by means of ammonia.

The second process is one patented by Dr. Ullmann, of Geneva, who utilises chromic acid which oxidises the phosphuretted and sulphuretted hydrogen and absorbs the ammonia; whilst the third process owes its inception to Lunge, who recommends the use of bleaching powder for the purification of acetylene: but Dr. Wolff has found that when this is used on a large scale there was a risk of the ammonia present in the acetylene forming traces of chloride of nitrogen in the purifying boxes, and as this is a liquid which detonates with considerable local force, it occasionally gives rise to explosions in the purifying apparatus. If, however, the gas be first passed through a scrubber so as to wash out the ammonia, this danger is got rid of, and Dr. Wolff employs purifiers in which the gas is washed with water containing calcic chloride and is then passed through bleaching powder solution or other oxidising material.

The form of apparatus employed in the generation of acetylene has a remarkable influence upon the proportion of sulphuretted hydrogen and ammonia present in the gas, although it affects but little the quantity of phosphuretted hydrogen. A long series of experiments which I have made shows that when the acetylene is generated in machines of the third subdivision the ammonia is entirely eliminated, whilst the passage through the lime water reduces the amount of sulphuretted hydrogen present to a mere trace, which may be neglected, but has little or no effect upon the phosphuretted hydrogen.

Analyses given by Dr. Wolff of acetylene generated from American, German, and Swiss carbide as at present made give the following results:—

	American.	German.	Swiss.
Phosphuretted hydrogen	0.05	0.03	0.03
Sulphuretted hydrogen	0.08	0.07	0.10
Ammonia	0.08	0.07	0.11
Hydrogen	0.09	0.07	0.16
Nitrogen	0.42	0.20	0.34
Oxygen	0.87	0.55	0.63
Acetylene	98.41	99.01	98.63
	100.00	100.00	100.00

whilst analyses which I have lately made from the ordinary commercial English carbide, and from the pure carbide made in France in the Herolt furnace by tapping process, are as follows:—

	English carbide.	French carbide.
Phosphuretted hydrogen....	0·138	0·045
Sulphuretted hydrogen	0·064	0·048

On taking a sample of English carbide and decomposing it by the dripping process there is found 0·138 per cent. of phosphuretted hydrogen, and 0·064 per cent. of sulphuretted hydrogen; whilst if this carbide is allowed to fall into water, the acetylene so generated contains 0·126 per cent. of phosphuretted hydrogen, and the sulphuretted hydrogen is practically eliminated.

When the carbide is dropped into a solution of sugar the same result is obtained, and practically no sulphuretted hydrogen can be detected in the gas so generated.

Miscellaneous.

WORKMEN'S DWELLINGS IN GERMANY.

The United States Consul at Chemnitz writes that there is a movement on foot to furnish working men with better dwelling places in Germany. At present they are crowded into buildings which often look like barracks. The proposed houses will be built upon plots of ground about 16½ feet wide by 102 feet deep, thereby allowing for a front yard for flowers and a back yard for a vegetable garden and shed, the latter for the keeping of poultry or some domestic animal. The houses will contain five rooms. A parlour and kitchen will be on the first floor, the parlour containing a porcelain stove and heating pipes; and the kitchen, a wash boiler and stove. The three bedrooms on the second floor will easily hold five or six persons and can be made to accommodate ten. In the largest, an iron stove will be placed. A pump will provide water where the city waterworks do not extend to the house. The cost of such a house and plot of ground when a number are built at a time will be between £170 and £190. It will let for about £9 a year—that is for the same price the working man has to pay for two rooms in the barrack-like tenements of the large cities.

PRODUCTION OF BEER IN HAMBURG.

There are at present fifteen large breweries in and near Hamburg, the aggregate capital of which amounts to about £1,000,000. It is stated that all

these breweries together produce annually a little over 22,000,000 gallons of beer, but that this quantity could, if required, be easily increased by 8,000,000 9,000,000 gallons per annum. Consul-General Wa says that by far the greater portion of these 22,000,000 gallons is consumed in the district itself, only a comparatively small proportion of the Hamburg-made beer being exported to foreign countries by sea, or land to the interior of Germany. The beer made for exportation is of a stronger quality than that consumed on the spot, and it is mostly subjected to "Pasteurisation," especially when destined for shipment to hot climates. Most of the beer brewed in Hamburg is of a light colour and medium strength and is brewed on the same principles as other good German beer; a small quantity of porter and ale is brewed in Hamburg, but the latter is chiefly for exportation. All the Hamburg breweries are stated to be fitted with the newest and best brewing machinery. It appears, according to an article recently published in the leading Hamburg commercial paper, that the quantity of beer annually exported by land and sea from all parts of Germany has been gradually diminishing during recent years. The total value of these exportations, in 1897, was about 950,000, while in 1885 their total value is stated to have largely exceeded that figure. The value of the exportations by sea from Hamburg alone fell from £748,061, in the year 1889, to £498,310 in 1897. This decline in the annual exportation of beer from Germany has been due, on the one hand, to the gradual falling off of the demand in France, which country, it may be observed, has always been, and still is, the best consumer for German beer, but which, during the last ten years, has largely increased its own beer production by the introduction of improved brewing methods. The exportation of German beer to France, and also to a minor extent, to Belgium and Holland (for shipment from Antwerp and Rotterdam, respectively, to oversea countries) is still of considerable importance; but these exports being, like those to most other parts of continental Europe, effected by land they of course do not affect Hamburg. The greater proportion, however, of the entire German seaborne beer exportations pass through, or are made from the port, whilst only a comparatively small share of the export trade is in the hands of Bremen-Bremerhaven and the quantity of beer annually shipped from German Baltic ports is quite inconsiderable. Hamburg is indeed, at present, the most important continental port for the shipment of German and also of some quantities of Austrian beer, as well as of some small amounts of British, Norwegian, and Danish beers. Of the German beer exported hence, a certain proportion is brewed at Hamburg, the remainder being chiefly of Bavarian origin. The Austrian beer comes nearly all from Pilsen in Bohemia. The export trade of beer from Hamburg, both of that brewed in the district, and that produced elsewhere in Germany, which had experienced a remarkable development between 1880 and 1890, has of late years lost

uch of its importance in consequence of the growing competition in various oversea countries, where breweries have been erected, and where, owing to the improved refrigerating machinery now employed, good beer can be produced, even in tropical countries. The excessive production, moreover, at Hamburg, as well as in most other parts of Germany, has depressed prices to such an extent that the profits formerly enjoyed by the export trade have dwindled to almost nothing. Australia and the Cape Colony have conquered during the last two years to be the best markets for German beer, next to the United States and British India; but the recent extensive exportations from Hamburg to Australia of various sorts of machinery used for making beer, would seem to point to the probability of some parts of the Australian continent soon being able to provide for their own wants in this respect.

Correspondence.

TRANSMISSION OF ELECTRIC POWER.

Professor GEORGE FORBES writes:—"Referring to the suggestion made in my recent lecture to the Society of Arts that the copper used in electric works should be mortgaged, I find that the mention made of Mr. Thwaite's name in a subsequent notice in the *Journal* (see *ante*, p. 103), led some people to believe that he was the originator of the scheme. This is not the case; my attention has been drawn to the facts that his paper was read on the 12th November, 1892, and that in my Cantor Lecture to the Society of Arts on the 25th January, 1892, I had said "That far more copper would be put down in mains if people realised the low rates at which money could be raised in debentures on them."

Obituary.

EUGEN OBACH, PH.D.—Dr. Obach, whose important series of Cantor Lectures on "Gutta Serena" was delivered before the Society of Arts in November and December, 1897, died at Graz, Styria, on 27th December, 1898, after a long illness. Eugen Obach was born at Stuttgart, in Wurtemberg, in April, 1852, of Swiss parentage, his father being an artist. He was educated at the Real and Polytechnic Schools of his native town, and from 1873 he continued his studies in natural science at the University of Leipzig, where he obtained his doctor's degree. In 1875 he began his practical career in the house of Messrs. Siemens and Halske, at Charlottenberg, near Berlin, and

in the following year he came to England to occupy a position in the English firm of Messrs. Siemens Bros., at their Telegraph Cable Works at Woolwich. In 1879 he accompanied the expedition for laying the Trans-Atlantic Cable in Messrs. Siemens's s.s. *Faraday*. Afterwards he devoted himself mainly to the study of the chemistry of gutta-percha and india-rubber, his extensive knowledge of the former substance being embodied in his Cantor Lectures. He was also the author of many papers on electrical and other subjects in foreign and English journals. Dr. Obach was elected a member of the Society of Arts in 1880.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 18.—"Canals and Inland Navigation in the United Kingdom." By L. F. VERNON-HARCOURT, M.A. Sir E. LEADER WILLIAMS will preside.

JANUARY 25.—"Tuberculosis in Animals." By W. HUNTING.

FEBRUARY 1.—"The Cost of Municipal Enterprise." By DIXON H. DAVIES. The ATTORNEY-GENERAL will preside.

FEBRUARY 8.—"Leadless Glazes." By WILTON P. RIX.

FEBRUARY 15.—

FEBRUARY 22.—"Electric Traction and its Application to Railway Work." By PHILIP DAWSON.

Dates to be hereafter announced:—

"Liquid Fuel." By Sir MARCUS SAMUEL.

"Preservation of Timber." By S. B. BOULTON.

"Coal Supplies." By T. FORSTER BROWN.

"Wireless Telegraphy." By W. H. PREECE, C.B., F.R.S.

"London Water Supply." By WALTER HUNTER, M.Inst.C.E.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 19.—"Railways in Burma and their Proposed Extension across Yunnan." By J. NISBET, D.Sec. Conservator of Forests, Burma. Sir ALEXANDER MACKENZIE, K.C.S.I., late Lieutenant-Governor of Bengal, will preside.

FEBRUARY 9.—"The Penal System at the Andamans." By Colonel RICHARD CARNAC TEMPLE, C.I.E., Chief Commissioner of the Andaman Islands.

MARCH 9.—"Leprosy in India." By H. A. ACWORTH, C.I.E., late Government Municipal Commissioner for the City of Bombay.

APRIL 13.—“Judicial Reforms in Egypt in Relation to the Indian Legal System.” By Sir JOHN SCOTT, K.C.M.G., D.C.L., Deputy Judge Advocate-General, and late Judicial Adviser to H.H. The Khedive.

MAY 11.—“The Port of Calcutta.” By SIR CHARLES CECIL STEVENS, K.C.S.I., late Acting Lieutenant-Governor of Bengal.

MAY 25.—“The Revenue System and Administration of Rajputana.” By MICHAEL FRANCIS O'DWYER, I.C.S., Settlement Commissioner, Alwar and Bhurtpore.

The meetings of January 19, February 9, and March 9, will be held at the Imperial Institute; those of April 13, May 11 and 25, at the Society of Arts.

FOREIGN AND COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 24.—“Rhodesia and its Mines in 1898.” By WILLIAM FISCHER WILKINSON, F.G.S., Assoc. M.Inst.C.E. The Hon. Sir DAVID TENNANT, K.C.M.G., Agent-General for Cape Colony, will preside.

FEBRUARY 28.—“Persian Trade Routes.” By A. HOTZ.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

JANUARY 31.—“The Centenary Exhibition of Lithographs, with remarks on further Developments of the Art.” By EDWARD F. STRANGE.

FEBRUARY 21.—“Vitreous Enamels.” By CYRIL DAVENPORT.

MARCH 14.—“Craftsmanship and its Place in a National Scheme of Art Culture.” By Sir WILLIAM BLAKE RICHMOND, K.C.B., R.A.

APRIL 18.—“Modern Changes in Taste relating to Domestic Furniture.” By GEORGE LOCK.

MAY 2.—“Maiolica.” By WILLIAM BURTON.

MAY 30.—“Wrought Iron Signs.” By J. STARKIE GARDNER, F.G.S.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

DR. SAMUEL RIDEAL, “Bacterial Purification of Sewage.” Four Lectures.

LECTURE I.—JANUARY 16.

Primitive methods—Earth disposal—Cesspools—Infiltration through soil—Water-carriage—Pollution of rivers and effects of dilution—Irrigation—Early results.

LECTURE II.—JANUARY 23.

Recognition of the function of bacteria, and researches on them—Massachusetts, Barking, and Sutton experiments—Schemes for aeration: Lowcock,

Waring, Ducat—Materials—Garfield's coal filter—Manchester and Leeds experiments.

LECTURE III.—JANUARY 30.

Anærobic preparation—Mouras' automatic scavenging—Moncrieff's earlier experiments—Exeter septic tank.

LECTURE IV.—FEBRUARY 6.

Differentiation of the organisms—Scott Moncrieff's later process—Nitrification and nitrification—Adeny's “oxygen system”—Conditions for aerobic and anaerobic change, and criteria for judging the purity of effluents—Resumé and suggestions.

ARCHIBALD SHARP, A.M.Inst.C.E., “Cyclo-staircase Construction and Design.” Four Lectures—February 20, 27, March 6, 13.

PROF. HENRY R. PROCTER, “Leather Manufacture.” Four Lectures.

April 10, 17, 24, May 1.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 9.—Imperial Inst., South Kensington, 8½ p.m. Mr. Arthur Diosy, “The New Far East in Relations to the British Empire.”

Surveyors, Savoy-street, W.C., 8 p.m. Discussion on the paper by Mr. Wm. Weaver, “The London Building Act and the Official Supervision of Buildings.”

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. J. W. Rudler, “The Records of the Rocks.”

TUESDAY, JAN. 10.—Medical and Chirurgical, 20, Hanover-square, 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. J. H. Dales, “High Speed Engines.”

Photographic, 12, Hanover-square W., 8 p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m.

Biblical Archaeology, 37, Great Russell-street, W.

Annual Meeting.

Asiatic, 22, Albemarle-street, W., 4 p.m.

United Service Institution, Whitehall, S.W., 3 p.m. (Juvenile Lecture.) “The Navy during the Reign of Queen Victoria.”

WEDNESDAY, JAN. 11.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 7 p.m. (Juvenile Lecture.) P. Jeffrey Bell, “Some Ways in which Animals Breathe.”

Royal Literary Fund, 7, Adelphi-terrace, W., 3 p.m.

Royal Society of Literature, 20, Hanover-square, W., 1 p.m.

THURSDAY, JAN. 12.—Antiquaries, Burlington-house, 8½ p.m.

Electrical Engineers, 25, Great George-street, S.W., p.m.

Mathematical, 22, Albemarle-street, W., 8 p.m.

FRIDAY, JAN. 13.—Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Dr. A. B. C. “The Application of the Science of Mechanical Engineering Practice.”

Astronomical, Burlington-house, W., 8 p.m.

Philosophical, University College, W.C., 8 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

SATURDAY, JAN. 14.—Botanic, Inner Circle, Regent's-park, N.W., 3¼ p.m.

Journal of the Society of Arts.

No. 2,408. VOL. XLVII.

FRIDAY, JANUARY 13, 1899.

*All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.***Notices.****SWINEY PRIZE.**

The adjudicators under the will of the late Dr. Swiney are summoned to meet at the house of the Society of Arts, John-street, Adelphi, London, on Friday, the 20th January, 1899, at 4 p.m., to make the award in conformity with the terms of the bequest contained in the will of the testator.

(By order),

HENRY TRUEMAN WOOD,
Secretary.

JUVENILE LECTURES.

On Wednesday evening, 11th inst., Prof. JEFFREY BELL delivered the second and last lecture of his course addressed to a juvenile audience, the subject being "Some Ways in which Animals Breathe." The lecturer, after reminding his audience of the results of being in a "stuffy" room, and of the advantages of fresh air, pointed out that what was called fresh air was wanted by every part of the body, by the toes no less than by the brain.

The essential part of the air in breathing is oxygen, and the problem is how is this gas conveyed all over the body?

The mechanism is two-fold: first there is a pumping and circulating apparatus which, in man, unceasingly drives blood through the body; this blood contains among other things corpuscles impregnated with a special compound called hæmoglobin. This has an avidity for oxygen, but is equally prone to give it up. The corpuscles start then on their journey conveying "oxy-hæmoglobin;" they return with "reduced hæmoglobin." Colouring matters equally capable of existing in two conditions of oxidation are found in various

invertebrate animals, and it is probable that they also serve in the processes of respiration.

The process of physiological division of labour is to be seen in the organs of respiration; some animals, like the starfish, have the whole surface covered with little sacs, which merely separate the sea-water from the fluid of the body-cavity. Others, like oysters, have several plates of considerable size, while the lobster has a definite series of gills placed in a definite cavity.

In insects and their allies air-tubes penetrate between the organs of the body and carry the air to them; in these the blood takes no part in oxidising the tissues.

The CHAIRMAN proposed a vote of thanks to Professor Bell for his course of lectures, which was carried unanimously.

Proceedings of the Society.**CANTOR LECTURES.****ACETYLENE.**

BY VIVIAN B. LEWES,

Professor of Chemistry, Royal Naval College, Greenwich.

Lecture IV.—Delivered December 19, 1898,

As I have before stated it was in the autumn of 1894 that I first received a supply of American carbide, and in reporting on this material on November 26th of that year I wrote:—

"This gas when mixed with an equal quantity of air can be burnt at a No. 4 Bray burner, and the illuminating power of the mixture would be equal to 65.7 candles per five cubic feet of gas consumed, which would give the acetylene an illuminating value of 131.4 candles per five cubic feet. The presence of an inert gas such as the nitrogen in the air is well known to exercise such a cooling power on the flame as to seriously reduce its illuminating value, and I find that if the acetylene be burnt by itself at a suitable burner, it develops no less than 230 candle-power per five cubic feet of gas consumed."

Further experiments made during December, 1894, with carefully purified gas, yielded a slightly higher result, and in the paper read before this Society in January, 1895, I gave the illuminating power of the gas when burnt under the best conditions as being 240 candles.

A considerable amount of vagueness exists as to what is meant by the illuminating value of a gas, and the only assumption which can

be arrived at is that it is the highest illuminating effect which can be produced from the gas without the aid of regeneration or artificial air supply other than that created by the flame itself.

The proper combustion of any hydrocarbon gas, however rich, can be effected by supplying the flame with exactly the amount of air necessary to prevent smoking, and it is under these conditions that the highest illuminating effect possible with the particular burner is obtained.

With flat flames the ratio between the air supplied and the gas consumed is governed by two factors:—(a) The thickness of the flame; (b) The pressure under which the gas issues from the burner.

When a gas issues from a burner under pressure, the uprush of the escaping gas mechanically draws in air, so that when consuming a poor coal-gas in a flat flame the pressure has to be kept down, or too much air would be dragged in, which would consume the hydrocarbons too rapidly, and so seriously affect the amount of light emitted. As the gas increases in illuminating value, more and more air is required for proper combustion, and this can be obtained by increasing the pressure at the burner.

Experience has shown that with ordinary sized flat flame burners, seven-tenths of an inch in pressure gives practically the best results with coal-gas of the quality supplied in London, and up to a certain limit the same flat-flame burner can be used for richer gases by increasing the pressure. When this limit is reached, a thinner sheet of flame has to be employed, *i.e.*, a smaller burner used, low initial pressure resorted to, and then by increasing pressure this can be made to consume gases of increasing value, until the pressure reaches a point at which the flame becomes distorted, when a still smaller burner has to be taken. By such means as these even acetylene, with its enormously high illuminating value, can be satisfactorily consumed, whilst by thickening the flame and reducing the pressure to the point at which the uprush almost ceases to cause a mingling of air with the flame and leaves the supplying of the oxygen to diffusion, even a poor gas can be made to develop its illuminating power.

On consuming acetylene from a 000 union jet burner, at all ordinary pressures a smoky flame is obtained, but on increasing the pressure to four inches a magnificent flame results, free from smoke and developing an

illuminating value of 240 candles per five cubic feet of gas consumed. Slightly higher values have been obtained, but 240 may be taken as the average value under these conditions.

This figure is the one quoted by most manufacturers of acetylene apparatus, who argue from it that acetylene is fifteen times as valuable in illuminating power volume for volume as London coal gas.

Such a comparison is, however, absolutely misleading, as in contrasting the value of acetylene with coal gas one must always bear in mind that the illuminating power of the London gas is determined by consuming it at the rate of 5 cubic feet per hour in the London argand, whilst in practice any power from 8 to 90 candles can be obtained from this volume, according to the form of burner in which it is consumed. Although small flat flame burners only emit from 1 to 2 candles per cubic feet of gas consumed, good incandescent mantles will yield about 18 candles per cubic foot, and certainly 17 on the average; and as incandescent gas lighting is rapidly displacing other methods of burning gas—and as this tendency will be enormously increased when the lapsing of the Welsbach monopoly reduces the price of the mantles to the figure now charged in Germany—it is evident that no calculation is fair that does not include this as a factor.

Moreover, a very short experience soon shows that burners consuming 1 cubic foot of acetylene per hour are the largest that can be practically used for domestic purposes, and that taking such burners all round 32 candles per cubic foot is a fair average of the light developed by them, although out of a big batch of burners you occasionally find a few which will go as high as 36 or even 40 candles per foot. The influence which the size of the burner and the rate of consumption has upon the illuminating power of coal gas is well known, and is shown in the following Table:—

Flat flame Burner.	Candles per cubic foot.
No. 7	2.44
„ 6	2.15
„ 5	1.87
„ 4	1.74
„ 3	1.63
„ 2	1.22
„ 1	0.85
„ 0	0.59

And as the consumption of acetylene is regu-

lated by exactly the same factors as act in the case of coal gas, it is evident that the smaller the burner and consumption, the lower will be the candle-power per foot of acetylene, and in practice with a one-half cubic foot burner 24 candles per cubic foot is a good result.

Taking a series of burners of the Naphey type, obtained from Falk Stadlmann and Co., the following results were obtained :—

No. of burner.	Pressure. inches.	Gas consumed. cubic feet	Light. candles.	Candles per foot.
6	2·0	·155	0·7938	5·3
8	2·0	·27	3·2	11·6
15	2·0	·40	8·0	20·0
25	2·0	·65	17·0	26·6
30	2·0	·70	23·0	32·85
40	2·0	1·00	34·0	34·0

From these considerations it is evident that the only fair way to contrast the light obtainable from coal gas and from acetylene is to take the incandescent burner on the one hand and the 1 cubic foot flat flame on the other, when it is seen that instead of being fifteen times the value of the coal gas as an illuminant, it is only about twice its power. The acetylene burner, however, has one advantage over the mantle, and that is that you can more or less regulate the light to the amount you require.

When acetylene is burnt in air under such conditions as to complete its combustion, it is converted into carbon dioxide and water vapour, the same compounds as are produced by all combustible hydrocarbons.

and 1 cubic foot of acetylene requires 2½ cubic feet of oxygen.

The researches of Dr. Grehant have shown us that when burning with a smokeless flame no carbon monoxide can be detected in the products emitted by its combustion, and its sanitary position will therefore be defined by the amount of oxygen abstracted from the air and carbon dioxide produced as compared with other illuminants.

Taking the average-sized room, which would be well lighted by an illumination equal to 64 standard candles, we find that this amount of light from various illuminants would have the following effect on the atmosphere :—

Illuminant.	Oxygen removed from air. cub. ft.	Products of combustion.	
		Water vapour. cub. ft.	Carbon dioxide cub. ft.
Sperm candles	38·5	26·2	43·6
Paraffin oil	24·9	14·0	39·8
London gas—Batswing ...	26·1	29·4	19·2
Argand....	23·0	25·6	17·0
Regenerative	10·6	8·3	5·2
Incandescent	3·1	4·6	1·8
Acetylene.....	5·0	2·0	4·0

So that light for light it fouls the air less than any of our ordinary illuminants with the exception of the incandescent gas burner.

In comparing the heating effect of various illuminants on the air of a room, it is necessary to determine the calorific value of the combustion of a cubic foot of the illuminating gas employed, and it is manifest from theoretical considerations that a highly endothermic compound like acetylene must have a far higher heating power than ordinary coal gas. The mean of a number of experiments made in Junker's calorimeter gave as the thermal value of the ordinary London gas supply 158 calories, whilst under the same conditions acetylene yielded 320.

The theoretical amount of heat emitted by the combustion of a cubic foot of acetylene is 349·08 calories, but this would only be given by the absolutely pure and dried gas, and the experimental number determined in the calorimeter represents more truly the heating power of the moist gas under ordinary existing conditions.

Taking now the case in which a room is lit up with a power equal to 64 candles, we find that if we call the heating effect produced by an incandescent mantle giving this amount of illumination 100, then—

Ratio of heat emitted to yield a light of 64 candles.

Incandescent mantle	100
Acetylene	115
London Argands	571
Flat-flame burners	914

so that for all practical purposes the heating effect on the air by acetylene illumination is the same as with mantles.

When one comes to compare the cost of acetylene and coal gas, one is again struck with admiration at the statements made by the advocates of the former as a rival to the well established coal gas industry. At the present time the wholesale price of carbide is £20 a

ton, but I believe that to fill large cash orders it can be obtained at £16 at Foyers, which would mean at least £20 a ton at the works where it is to be decomposed and the gas distributed. The decomposition of carbide is not a costly operation, but at least 10 per cent. would have to be added to the price of the carbide for handling, water, repairs, interest on plant, purification, &c., and this would bring the price of the acetylene to £2 per 1,000 in the holder. Coal gas in the holder when made on the scale common in our big cities costs, however, about 1s. 2d. per 1000 in the holder, and about 100 per cent. has to be added to this to cover charges of distribution and profit. The power of doing this is dependent on the amount of gas sold, and whilst the South Metropolitan can make a fair profit on gas at 2s. 3d. a 1,000, there are many small country works that cannot pay a dividend with gas at three times the price. With acetylene the smallness of the output would necessitate a heavy charge over cost price, and I should be surprised to find an installation of acetylene even in a fair sized town paying its way with a less charge than £3 per 1,000.

Looked at from this point of view it is at once manifest how absurd it is to talk of acetylene as a possible rival of coal gas, and the sooner this is realised the better will it be for the future of this brilliant illuminant.

Abroad, where coal gas is dear, it is possible, by taking the price of acetylene in the holder and comparing it with distributed coal gas, to make acetylene out to be, light for light, as cheap as the latter when consumed in a flat-flame burner; but even this method of calculation breaks down before the high light emissivity of the incandescent mantle.

It is in those districts where no coal gas exists that the true field for acetylene is to be found, and here its ease of generation and the beauty of its light makes it a pleasant companion after the greasy dimness of the candle or the smell of the oil lamp.

When I first attempted to burn acetylene I used the Bray nipples, which could be had on the market, and found that I obtained very high illuminating effects, and could, for a time, continue the combustion in a satisfactory way by using three or four inches pressure at the burner. This high pressure was, however, undesirable, and I then devised a cubic foot burner in which, by drilling the union jet holes of very small size and at a more obtuse angle, I was able to burn the gas at an inch pressure. About this period, also, Bray made specially small tips

for use with acetylene, and both these nipples answered extremely well for a time and developed from 30 to 36 candles per cubic foot of gas, but they both had the same weakness, and after a few hundred hours began to smoke, and as a smoking acetylene flame covers everything in a room with a thick deposit of soot in a very short space of time, such burners were manifestly not fitted for the work they had to perform.

The trouble generally commenced with a filiform growth of carbon appearing at the nipple, which quickly distorted the flame and caused a cloud of soot flakes to descend. If the burner was cleaned and relighted the trouble commenced again in an hour or two, and the only thing to be done was to replace the nipple by a new one.

If the nipple had been burning some time and was then removed and broken, it was found to be carbonised for some depth into the material, showing that a liquid hydrocarbon had soaked into the material and had been split up there by the heat with deposition of carbon.

The generally accepted idea was that the heat of the nipple polymerised some acetylene to benzene, and this, forming a drop, did the mischief, and efforts to keep the burner cool were looked upon as a likely direction in which to search for success.

Whilst these troubles were going on in England, attempts had been made in America to use acetylene diluted with a certain proportion of air, which permitted it to be burnt in ordinary flat-flame nipples, but the danger of such admixture being recognised, nipples of the same class as those used in England were employed, and the same troubles ensued.

In France single jets made of glass were first employed, and then Risener Luchoire, Ragot, and others, made burners in which two jets of acetylene coming from two tubes, spaced some little distance apart, should impinge and splay each other out into a butterfly flame. Soon after Bullier introduced the idea of sucking air into the flame at or just below the burner tip, and at this juncture the Naphey or Dolan burner was introduced in America, the principle employed being to use two small and widely separated jets instead of the two openings of the union jet burner, and to make each jet a minute bunsen in which each jet of acetylene dragged in from the base of the nipple enough air to surround and protect it whilst burning from contact with the steatite.

These burners were hailed with delight, and their success led to their being pirated right and left, but although these burners mark a very great improvement and will burn several hundred hours without smoking (unless in a fit of false economy the user insists on turning them down, and leaving them for an hour or so as two small separate flames, in which case they generally start smoking on being again turned on), the trouble is by no means got over, and a Naphey burner will often be found smoking as heartily as one of its more humble brethren.

The fact is that the cause of smoking is to be found quite as much in the generator as in the nipple, and over-heating during generation is undoubtedly a prime factor in this worrying phenomenon.

If smoke or tar vapour be examined under a high microscopic power it is seen that it consists of minute vesicles or bubbles in a most marvellously active condition of movement, and fulfilling in a most perfect manner the conception one forms of molecular motion. Ever bombarding each other but never colliding, these small vesicles filled with gaseous matter continue their career until some mechanical action bursts them, and deposits the minute trace of liquid which formed the skin of the microscopic balloon.

It is for this reason that the most successful form of washer for extracting tar during the manufacture of gas consists of fine jets or orifices through which the gas passes at considerable velocity, afterwards coming in contact with a baffle which breaks up the vesicles; and anyone with experience in carburetted water-gas making knows the trouble that arises from filiform growths of carbon, when, owing to an insufficient temperature in the cracking and superheating chambers, the carburetted gas contains vapours instead of permanent gaseous products.

When acetylene has been made in a generator at an undue temperature, it carries with it benzene vapour, which as it commences to condense assumes this vesicular form, and on coming to the extremely minute holes which form the apertures of the burner, the mechanical scrubbing which it encounters causes the breaking up of the vesicles and the deposition of the benzene and other hydrocarbons held in suspension by benzene, which soak into the steatite and carbonise. The presence of finely-divided carbon has a great effect in determining the decomposition of the acetylene itself, so that a rapid growth of carbon takes

place at the burner, and no ordinary clearing of the deposited carbon from the exterior will ever make the nipple fit for constant use again, as the catalytic action of the carbon deposited in the pores of the steatite, and which cannot be got rid of, causes the deposition of a fresh supply of carbon; whilst, when the benzene vapour gets past the nipple and burns, as it requires three times as much air as acetylene, it often starts the flame smoking from this cause.

The impurities, however, in acetylene other than vapours also play a certain part in the choking of the burner, as if there be much phosphuretted hydrogen in the gas a small quantity of phosphoric acid is apt to be deposited in the burner nipple and helps to distort the aperture, whilst silica from siliciuretted hydrogen has the same effect.

It will be found with experience that the prevention of smoking in a burner will be overcome quite as much by attention to the temperature in the generator as to the burner itself, and where a generator which gives over-heating is in use, a well-arranged scrubbing apparatus that would get rid of the benzene from the gas would be found a distinct advantage in stopping burner troubles, while, when proper purification is introduced, the burner troubles will be found to have been practically solved.

At the Acetylene Exhibition, held in Berlin early this year, all the newest forms of burner were shown; the best burners of each class were tested at the Imperial Physical Institute for consumption and light-giving power, and it was found after eighteen hours' burning that several had to be eliminated on account of their commencing to smoke. Thirty hours proved fatal to another batch, while a few only continued giving satisfactory results after that period, a result which shows that the same troubles which have been rife in England have been equally marked on the continent.

The results also obtained as to the candle-power of these burners fully bear out the figures which I have obtained. It may be of interest at this point to record the candle-power of some of the many burners which I have personally tested—(see Table, p. 146)—and these really represent the best results obtainable by the combustion of acetylene under domestic conditions.

The Dolan or Naphey tip was a great advance at the time when it was introduced, but the arms which carried the tips were made

Date.	Name of Burner.	Pres- sure.	Gas con- sumed	Light.	Candles.	
					per ft.	per 5cft

	Bilwiller....	3.0	1.0	40	40	200.0

of metal, and this was perpetuated in the first batch of piracies made. The effect of heat after a time is to slightly distort these arms, thus throwing the two jets of gas a little out of line. This trouble has now been got over by making the arms of the burner entirely in steatite, which, although adding to the cost, is a distinct advantage.

The incandescent mantle has made such a revolution in coal-gas lighting that it is not surprising that attempts should have been made to adapt acetylene for this purpose, and the first thing which had to be done when taking steps in this direction was to construct an atmospheric burner which would satisfactorily consume the gas.

One would expect that acetylene when consumed in an atmospheric burner would give an excessively hot flame not only on account of its composition, but also on account of its endothermic character. Le Chatelier calculates that the temperature of a non-luminous acetylene flame will range from 2,100 to 2,420°C, the temperature varying with the ratio of acetylene to air as shown in the following calculations:—

Per-centage of		Air,	Temperature, °C.
Acetylene.			
7.4	92.6 2,420
12.9	87.1 2,260
17.37	82.63 2,100

In order to make a bunsen burner for acetylene, the tube has to be extremely narrow, and it is even then found to be very liable to flash back, whilst it needs a high pressure in order to bring about satisfactory combustion of the gas with an absolutely non-luminous flame. One of the chief difficulties which has to be

overcome is due to the range over which mixtures of air and acetylene are explosive. This we have seen lies between the limits of 3 per cent. and 82 per cent. of acetylene and it must also be remembered that the velocity of the explosion of acetylene when mixed with air is greater than with a mixture of air and coal gas, and the propagation of the explosive wave down the burner tube can not be satisfactorily stopped by the ordinary device of using wire gauze on account of the low igniting point of acetylene and air mixtures. If high pressures are used so that the rate of flow shall be greater than the velocity of propagation downwards, more air is sucked in by the uprush of the gas and the velocity of the explosion is again increased.

The best results have been obtained by taking a bunsen burner in which a constriction in the air-tube creates a high velocity at that point which on the principle of the Smithell's flame separator prevents the propagation downwards just at that point.

Le Chatelier has shown that the rate of propagation of an explosive mixture of air and acetylene depends upon the diameter of the tube through which the wave is being propagated, and he has worked out the limits between which the explosive wave would pass through tubes of certain diameters.

Diameter of Tube. Inches.	Explosion.	
	Lower Limit.	Upper Limit.
	Per cent. Acetylene.	Per cent. Acetylene.
1.57 2.9 64
1.18 3.1 62
0.79 3.5 55
0.24 4.0 40
0.16 4.5 25
0.08 5.0 15
0.03 7.7 10
0.02 0.0 0

It will be seen that in a tube 0.02 inches, or 5 mm. in diameter you have the propagation of the explosive wave ceasing.

These investigations have been used as a basis upon which to construct acetylene burners for heating purposes, and burners have been made by the Allgemeine Carbid and Acetylen-gas Company of Berlin, in which, by means of constricted tubes satisfactory consumption is ensured. It is found that the diameter of the tube at the constriction must be in a definite proportion to the particular mixture of air and acetylene consumed, as the more air employed the greater must be the constriction in the strangulated portion of the tube. Such

burners have a flame which is very valuable for heating purposes, and gives a very intense temperature.

The same company has also used these burners with incandescent mantles of somewhat different shape and composition to those ordinarily employed, and states that the photometric result is 30 to 40 per cent. higher than that obtained by the combustion of pure acetylene alone. I have lately been experimenting with an acetylene bunsen and get much higher results than these. With a Welsch No. 2 mantle I have obtained as much as 90 candles per cubic foot of acetylene consumed, and as far as I have gone the mantle appears to be hardened and strengthened by the intense heat to which it is subjected, but it yet remains to be seen how the life of the mantle is affected by the temperature of the flame.

Acetylene atmospheric burners are now also employed for heating, cooking, and metallurgical operations on a small scale, and with a reduction in the price of the gas these uses for which will undoubtedly open up a wide field of utility.

The value of acetylene in photographic work is now universally recognised, and Mr. W. H. Holmesley has determined its relative value as compared with the ordinary sources of light, determining the time needed to fully expose equally prepared plates, with the following results:—

	Seconds.
Direct sunlight	1
Acetylene 1 cubic foot burner	3
Diffused daylight reflected from mirror	12
Incandescent mantle	24
Coal gas	} 240
Oil gas	
Oil lamp	

It is also to a certain extent used for projection work, but it is not so well suited for this, as in common with multiple wick lamps and incandescent mantles, the flame is too large a surface of illumination.

F. Molteni has attempted to determine the relative value of various illuminants by a photometric process in the following way:—

The measurements were made with an ordinary lantern, the stage of which carried an opaque card in which was cut an aperture 1 cm. square, and the distance of the lantern from the screen was such that each side of the aperture on the screen measured 1 metre.

The screen was replaced by a disc of paper,

the opposite side being illuminated by a standard lamp burning 42 grams of oil per hour. The distance of this lamp was varied in order that equality of illumination might be obtained on the screen, and the photometric values of the light were determined from the distance of this lamp.

Carbide will probably some day become an important factor in the transmission of power, as a cubic foot of solid carbide would weigh 62.26 kilos or 137 lbs., and if of commercial purity would yield 685 cubic feet of acetylene having a thermal value of nearly 232,215 calories.

In practice, however, the weight of carbide which can be got into a cubic foot space is dependent on the size to which the material is broken, and with the ordinary commercial carbide a fair average would be 80 lbs. per cubic foot, yielding 400 cubic feet of acetylene gas, with a thermal value of 139,600 calories. It is at once manifest that solid carbide is as economical a method of transporting acetylene as if liquid acetylene itself were employed, as the liquid will only yield about 400 times its own volume of gas, and the carbide has the advantage of being practically safe in transit.

There are several people at present working on the utilisation of acetylene for gas motors, but there are many difficulties to be overcome before this is successfully accomplished, as the deposition of carbon when the air supply is insufficient, and the violence of the explosion are troublesome factors to deal with.

The trouble of completely consuming acetylene without smoking in the early days of its inception caused Dickerson and Suckert to

attempt the combustion of acetylene diluted with air. In 1894 it was in this way that the gas was consumed, but not only did the cooling action of the nitrogen lead to a considerable decrease in the illuminating power of the acetylene so diluted, but as will have been seen from the experiments of Gerdes and others a very serious risk was incurred, it becoming merely a question of the breadth of the delivery tubes and the rate of flow of the gas whether an explosive wave was propagated back to the mixing machine or not. It was on account of the danger of this that this process of burning it in America was abandoned.

The idea has, however, cropped up from time to time since, and both in France and Holland has been, to a certain extent, used on a practical scale. Even at the present time an attempt is being made in Manchester to introduce a process by which acetylene can be so diluted with air as to burn in an ordinary Bray burner.

The danger of diluting acetylene with air being so manifest, attempts have, from time to time, been made to dilute it with other gaseous material. In 1895 Bullier took out a patent for improvements in carburetting air and gas, in which he claims the use of acetylene for enriching water gas, whilst having then apparently found that acetylene was useless for this purpose, he, later on in the same year, took out a second patent for diluting it with nitrogen. It was about this time, also, that Mr. Gerdes commenced his experiments upon the enrichment of oil gas with acetylene, which have borne such ample fruit on the Continent. He showed that when oil gas is enriched with 25 per cent. of acetylene a valuable increase in its illuminating power is obtained without any danger of explosion of the mixture owing to heat or shock. This mixture is now employed to a very large extent on the Prussian railways; the quantity of carbide already used this year for this purpose has reached a total of 3,000 tons, and it is computed that before the end of next year 10,000 tons per annum will be needed for this purpose.

In consequence of the great Continental success of this admixture application was lodged at the Home Office to sanction such a mixture in England under the ordinary railway carriage cylinder pressure of 10 atmospheres. The safety of the mixture and of mixtures considerably richer in acetylene was completely established by a series of tests carried out in the presence of the Home Office officials, and in consequence, by an order of the Secretary of

State, dated March 28, 1898, a mixture of oil gas with 20 per cent. of acetylene is allowed to be used at a pressure not exceeding 150 lbs per square inch.

In order to determine the increase in illuminating power given by various per-centages of acetylene in oil gas, and whether the mixture could be employed with economy, the following experiments were instituted. Oil gas containing 20 per cent. of acetylene was compressed into a cylinder under a pressure of ten atmospheres, some of the original oil gas being also compressed in a second cylinder to the same pressure. Both cylinders were then blown off to 5·8 atmospheres, and the illuminating power of each was taken under identical conditions. The burner used was a "40 litre" one, and the results were as follows:—

Pressure.	Gas Consumption.	Illuminating Value.	
		Oil Gas.	Oil Gas and Acetylene
5·8	.. 1 cubic foot ..	7·4	15·6

An analysis of the gas showed that the mixture contained 22 per cent. of acetylene, although but 20 per cent. was originally added, the increase being due to the loss of some of the oil gas in which under pressure some of the vapours of benzene and toluene condensed to the liquid state. Working from these figures it will be seen that the addition of 22 per cent. of acetylene caused an increase of illuminating power of 110 per cent., or 100 per cent. when compared with 20 per cent. of acetylene.

The original oil gas and the mixture of oil gas with acetylene were next determined photometrically in an ordinary railway carriage lamp at angles below the horizontal on a Diodin radial photometer.

ving that the addition of 20 per cent. of acetylene increases the illuminating power of oil gas by over 110 per cent. at all angles. These figures show therefore that the addition of the 20 per cent. of acetylene doubles the illuminating value of the oil gas.

With regard to cost, as we have before seen, acetylene at the present price of carbide will cost about £1 18s. to £2 per 1,000 in the burner, and 200 cubic feet will accordingly cost 7s. 8d. The compressed oil gas costs 6s. to 12s. per 1,000. With oil gas at 8s. per 1,000, 800 cubic feet will cost 6s. 5d., so that the total cost of 1,000 cubic feet of the enriched mixture will be 14s. 1d., but as the illuminating value of the mixture is double that of the plain gas, there is an economy of 1s. 11d. per 1,000. As the oil gas is dearer the saving will be greater, and *vice versa*, so that with cheap oil gas the addition of acetylene would not pay. With oil gas at 6s. 6d. per 1,000 there is practically no difference, but the advantages accruing from the use of acetylene would make the mixture more desirable than the plain gas. Amongst the advantages are these—that the burners would last for double the length of time they would with the oil gas having the one burner, and there would be not so much evaporation of liquid hydrocarbons due to condensation with consequent reevaporising when the pressure is reduced, thus causing inequality in the illuminating power.

The whole question of diluting acetylene with other gases has had a very great interest in me, and I have made many experiments in order to determine how it is that when 10 per cent of acetylene is added to a diluent such as blue water gas, carbon monoxide, or even hydrogen, the resulting mixture is practically luminous, and I have worked out the

enrichment value for acetylene for all those gases which might be employed for its dilution.

I soon discovered from these experiments that methane is the only diluent which sustains the illuminating power of the acetylene when mixed with it in small proportions, and the fact that the same phenomenon is observable in comparing the illuminating power of mixtures of gases containing only some 30 per cent. of methane gives at once a clue to the methods which must be adopted in making a diluting gas for acetylene.

It is perfectly obvious that in many places it would be a great advantage to have an illuminating gas of about 20 candle-power for general distribution in the same way as a good coal gas could be used, if such a mixture could be produced at a price comparing favourably with coal gas under the same conditions. In order to do this, although it would be impossible to use pure methane as the diluent for acetylene on account of the cost of its production, it is quite easy to make diluting gas which shall contain 30 per cent. of methane at a comparatively low rate.

In order to make this, a slightly modified form of water gas generator is employed, and the fuel having been blown up to incandescence by an air blast, tar, creosote oil, heavy oil residues, or practically any waste liquid hydrocarbon is injected into the body of incandescent fuel by a steam injector or atomiser. If these hydrocarbons were allowed to run into the fuel by themselves, they would simply be burnt up to carbon and hydrogen, but steam being injected with them, the steam is decomposed by the fuel with the formation of water gas which to a certain extent envelops the hydrocarbon, and instead of its undergoing complete decomposition it is broken down to methane and hydrogen and mingles with the water gas, whilst any residual carbon is left behind in the fuel. It is quite possible by such means to make a diluting gas containing—

Hydrogen.....	45
Carbon monoxide	15
Methane	30
Unsaturated hydrocarbons....	5
Carbon dioxide and nitrogen..	5
	100

This gas costs from 8d. to 10d. per 1,000 cubic feet, and has an initial illuminating value of about 10 to 12 candles, and on mixing with it 5 per cent. of acetylene, a gas having an illuminative value of 18 to 20 candles is obtained, which being a mixture of perfect

gases gives no trouble as regards layering, and which having the same specific gravity and illuminating value as coal gas, can be distributed and burnt in precisely the same way.

It is also found that mixtures of this gas with 50 per cent. of acetylene are not detonated when compressed for railway carriage lighting by any temperature which it would be possible to attain in the cylinder, and it seems that this method of utilising acetylene is pre-eminently the one which promises for it the largest and most remunerative future.

In concluding this course of lectures, I am oppressed by the feeling that the limited time at my disposal has prevented me from doing full justice to my subject; and I should have far preferred a course of forty rather than four lectures in order to deal with the many important points and side issues which of necessity have been omitted. I leave my subject with the sincere hope that as time wears on those points which appear to us now to be difficulties will be made clear, and that in the future cheapened carbide will enable this beautiful hydrocarbon to take its proper place in the foremost ranks of our illuminants.

Miscellaneous.

CULTIVATION OF FILBERTS IN ITALY.

Filbert plantations exist on a large scale near Piazza, Armerina, and Aidone, in the province of Caltanissetta, and Palagonia, province of Syracuse, at an elevation of from 1,968 to 2,625 feet above the sea. They are also cultivated in large quantities in the regions of Etna, in the valleys between Linguaglossa and Cartiglione, Randazzo and Bronte. In these localities the filberts are the rivals of the grapes in commercial importance. The plants, which are made to grow as bushes, forming groups, consisting of about ten shrubs, well cultivated, thrive in deep fresh ground tending to clay, possibly irrigated when not endowed with natural freshness. A position not exposed to cold winds is preferred. According to the United States Consul at Catania, the land selected for the culture of filberts may be broken up partially or entirely, according to the means at disposal. After having laid out the ground and marked off the places where the bushes are to stand, the groups 16 to 25 feet apart (when too close together they are deprived of air and light, and the production is restricted), a circle of about four feet is marked around the stake and dug out to the depth of 16 inches around the circumference, gradually inclining towards the centre where the hard ground is reached.

About eight inches apart, within this periphery, to ten slips of some 32 inches in length are planted so as to leave about two or three buds above the earth. The hole is now refilled with fine earth stratified with fermented stable manure. A number of suckers will sprout from some slips, others yield none. The proper season for planting is the first rainfall, from November to December. Sprigs for reproduction are derived from the new bushes. Filberts can be produced from the seed but this is never done, because the plant produced from seed not only would require much more time to bear fruit, but would naturally grow wild, and afterwards would have to be grafted, and therefore suckers (shoots or sprouts) are preferred. Cereals, barley, rye, or wheat are sown in the filbert plantations during the first years; afterwards vegetables are cultivated therein. The first manuring is done as already stated, when the sprigs are planted; afterwards every three years. The annual cultivation consists of a thorough digging in January, followed by a shallow digging around the roots, and a second superficial one in July. The purpose of the superficial digging is essentially to clean the soil of the weeds, which are chopped down, work into the soil, and help to retain the moisture. During this operation care should be taken not to destroy the cavities. During the next two or three years the plant does not bear fruit; it commences the third year. Any blossoms appearing before this time should be removed, otherwise the young brush would suffer. According to the same authority the roots should be bared and recovered. The pruning is done when the leaves are falling, and consists of cutting the offshoots, sprigs which are too long, the old and dried branches; the latter are replaced by young sprouts, and in this manner the plantations can be revived indefinitely; in fact, there are plantations 50 to 100 years old. Irrigation takes place from June to August, once a week. Gathering is from the end of August to the middle of September, according to the season. The filberts are subject to serious diseases, but hail storms and winds cause the greatest damage.

DESTRUCTION OF LOCUSTS IN ARGENTINA.

The central commission for the extinction of *langosta* or locusts in Argentina has made an interesting report to the Minister of Agriculture of that country. The commission was appointed for the purpose of obtaining all the information possible regarding the locust, its habitat, procreation, migration, &c., and to inaugurate concerted efforts for its extinction. To this end the commission organized many local commissioners, and these again formed a sub-commission, and all investigated and adopted such means of destruction as seemed most effective. The results are that the habits of the locust have

studied, enormous quantities of eggs and *saltonas* (ants before they have wings) were destroyed, and destruction of crops greatly lessened. The means of extinction employed were, a preparation of various liquid extirpators, the plough and fire. Quantities thus destroyed in 1893 are estimated thousands of tons weight, and the area of crops killed at hundreds of thousands of acres; and it is proved that if, with what has been learned, those untried efforts be assiduously continued, the locusts will be controlled, or its ravages greatly restricted. The arrest of the ravages of the locust, whether through the efforts mentioned or other causes, has not only encouraged the agriculturists of Argentina, but improved the general condition of the country.

FLAX RETTING IN FRANCE.

Many attempts have been made in France in past years to substitute for the antiquated process of retting flax in the river a more practical process. The United States Commercial Agent at Roubaix reported that a few years ago Messieurs Doumer and R. de Sarte invented a process of steeping in closed vessels, which has been thoroughly tested by a commission appointed at Lille by the Minister of Agriculture. A report of the president of this commission states that the value of the process has been tested by direct experiments. It consists in immersing flax in closed vessels, with the addition of certain microbes. The temperature, gauged so as to prolong the vitality of the microbe to the greatest possible extent, is carefully maintained. Under these favourable conditions the retting is reduced to the shortest possible time for each species of flax. As soon as the flax is retted, the vessels are drained. The drying process is accomplished without disturbing the flax, by means of hot air introduced by a ventilator. This operation requires but little time, and the drying is uniform. After having ascertained that the new process accomplishes retting in the most thorough manner, the sub-commission proceeded to study the retting and bleaching of flax retted and dried by this process, and published as its opinion that this process, adopted in the different flax-producing countries, would give a far superior retting to that practised on the farms. Flax retted as at present has less value if it had been subjected to a proper process, and frequently occasions loss to the farmer. The first experiments were made with a vessel containing only 40 kilogrammes (88 lbs.) of raw flax. Since then Messieurs Doumer and de Swarte have opened a factory at Valenciennes, department of the Nord. In a recent preliminary report the president of the commission states that the retting and drying is as well accomplished in a vessel containing 2,000 kilogrammes (4,400 lbs.) as in the small one; also that the system was arranged that any quantity desired can be retted with the same satisfactory results. The

importance of this process is commented upon in various French papers. Its adoption, in their opinion, will save the farmer the cost of transport of his flax to the Lys, as he can have the retting done as well, if not better, in a factory in his own vicinity, with the additional advantage that the cost will be less.

General Notes.

MAP OF LONDON.—The New Year's number of the *Builder* (Jan. 7) contains a large map of the County of London, showing the boundaries of the surveyors' districts under the Building Act, taken from the official map of the London County Council. The names and addresses of the district surveyors are added.

MEEINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 18.—“Canals and Inland Navigation in the United Kingdom.” By L. F. VERNON-HARCOURT, M.A. Sir E. LEADER WILLIAMS will preside.

JANUARY 25.—“Tuberculosis in Animals.” By W. HUNTING. R. BRUDENELL CARTER, F.R.C.S., will preside.

FEBRUARY 1.—“The Cost of Municipal Enterprises.” By DIXON H. DAVIES. The ATTORNEY-GENERAL will preside.

FEBRUARY 8.—“Leadless Glazes.” By WILTON P. RIX.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 19.—“Railways in Burma and their Proposed Extension across Yunnan.” By J. NISBET, D.Oec., Conservator of Forests, Burma. Sir ALEXANDER MACKENZIE, K.C.S.I., late Lieutenant-Governor of Bengal, will preside.

The meetings of January 19, February 9, and March 9, will be held at the Imperial Institute; those of April 13, May 11 and 25, at the Society of Arts.

FOREIGN AND COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 24.—“Rhodesia and its Mines in 1898.” By WILLIAM FISCHER WILKINSON, F.G.S., Assoc. M.Inst.C.E. The Hon. Sir DAVID TENNANT, K.C.M.G., Agent-General for Cape Colony, will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

JANUARY 31.—“The Centenary Exhibition of Lithographs, with remarks on further Developments of the Art.” By EDWARD F. STRANGE.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

DR. SAMUEL RIDEAL, “Bacterial Purification of Sewage.” Four Lectures.

LECTURE I.—JANUARY 16.

Primitive methods—Earth disposal—Cesspools—Infiltration through soil—Water-carriage—Pollution of rivers and effects of dilution—Irrigation—Early results.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 16.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Dr. Samuel Rideal, “Bacterial Purification of Sewage.” (Lecture I.)

United Service Institution, Whitehall, S.W., 3½ p.m. (Juvenile Lecture.) Colonel E. T. Browell, “General Gordon, the Mahdi, and the Reconquest of the Soudan.”

Imperial Institute, South Kensington, 8½ p.m. Rev. Gilbert Reid, “Personal Experience in China.”

Cleveland Institute of Engineers, Middlesborough, 7½ p.m.

British Architects, 9, Conduit-street, W., 8 p.m. Award of Prizes and Studentships.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Paper on “Glacial Action in the Southern Hemisphere.”

London Institution, Finsbury-circus, E.C., 5 p.m. Professor A. K. Douglas, “The Future of British Trade in China.”

TUESDAY, JAN. 17.—Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lankester, “The Morphology of the Mollusca.” (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. William G. Kirkaldy, “The Effects of Wear upon Steel Rails.” 2. Sir William C. Roberts-Austen, “The Microphotography of Steel Rails.”

Statistical, in the Theatre of the United Service Institution, Whitehall, S.W., 5 p.m. Sir Robert Giffen, “The Excess of Imports.”

Pathological, 20, Hanover-square, W., 8½ p.m.

Photographic, 12, Hanover-square, W., 8 p.m. (Photo mechanical Meeting.) Mr. J. E. Johnson, “Some New Half-tone Screens of English Manufacture.”

Zoological, 3, Hanover-square, W., 8½ p.m. 1. Dr. Arthur Willey, “General Account of his Zoological Expedition to the South Sea.” 2. Prof. D'Arcy W. Thompson, “The Characteristic Points in the Cranial Osteology of the Parrots.” 3. Miss Isa L. Hiles, “Report on the Gorgonacean Corals collected by Mr. J. Stanley Gardiner at Funafuti.”

Colonial Inst., Whitehall-rooms, Whitehall-place, S.W., 8 p.m. Hon. Sir Horace Tozer, “Queensland's Progress.”

WEDNESDAY, JAN. 18.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. L. F. Vernon-Harcourt, “Canals and Inland Navigation in the United Kingdom.”

Meteorological, 25, Great George-street, 7½ p.m. Annual General Meeting. Address by Mr. F. Campbell Bayard, “The Government Meteorological Organisations in various parts of the World.”

Geological, Burlington-house, W., 8 p.m. Microscopical, 20, Hanover-square, W., 8 p.m. Annual General Meeting. Address by the President.

Entomological, 11, Chandos-street, W., 8 p.m. Annual General Meeting.

Archaeological Association, 32, Sackville-street, 8 p.m.

THURSDAY, JAN. 19.—SOCIETY OF ARTS (Indian Section) Conference Hall, Imperial Institute, 5 p.m. 4½ p.m. Mr. J. Nisbet, “Railways in Burma and their Proposed Extension Across Yunnan.”

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. R. Murray and Miss F. G. Whitting, “New Dinaceae from the Atlantic.” 2. Mr. Arthur Maslen, “The Structure of Lepidostrobilus.”

Dr. W. G. Ridewood, “Some Observations on the Caudal Diplospondyly of Sharks.”

Chemical, Burlington-house, W., 8 p.m. 1. W. Ackroyd, “Researches on Moorland Water (I. Acidity).” 2. Dr. F. S. Kipping and Mr. A. Hill, “ α -ketotetrahydronaphalene.” 3. Mr. A. Bone, “A New Method for Preparing Dimethyl- and Trimethyl-succinic Acids.”

Messrs. Thomas Purdie and William Pitheche, “Reduction of Optically Active Mono- and alkyloxysuccinic Acids from Malic and Tartaric Acids.” 5. Dr. Siegfried Ruhemann, “Action of Ammonia on Ethereal Salts of Organic Bases.”

6. Dr. J. J. Sudborough and Mr. Lorenzo L. B. Smith, “(a) Esterification Constants of Substituted Aromatic Acids; (b) ‘Di-ortho Substituted Benzoic Acids.’ Part IV.—Formation of Salts from Di-ortho substituted Benzoic Acids and different Organic Bases.” 7. Mr. J. Holmes Pollock, “The Effect of Dilution.” 8. Mr. D. B. H. V. Rees, “The Changes of Volume due to Dilution of Aqueous Solutions.”

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. A. F. Sievking, “Gardens: their History and Literature.”

Society for the Encouragement of Fine Arts, 9, Great George-street, W., 8 p.m. Mr. J. S. Sheppard, “Chopin—his Masurkas, Polonaises, and Mazurkas.” (With Musical Illustrations.)

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. H. Savage Landor, “Tibet and the Tibetans.” (Lecture I.)

Historical, 28, Jermyn-street, S.W., 8½ p.m.

Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, JAN. 20.—Royal Institution, Albemarle-street, 8 p.m., Weekly Meeting. 9 p.m., Prof. D. B. H. V. Rees, “Liquid Hydrogen.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Physical, Chemical Society's Rooms, Burlington-house, W., 5 p.m. 1. Mr. Edwin H. Barton, “The Equivalent Resistance and Inductance of a Wire to an Oscillatory Discharge.” 2. Mr. A. Appleyard, Exhibition of (a) a Deprehendible (b) a Temperature Tell-tale. 3. Mr. T. Littlewood, “The Volume Changes accompanying the Solution of Gases.”

SATURDAY, JAN. 20.—Royal Institution, Albemarle-street, 3 p.m. Sir Alexander C. Mackenzie, “Lithography with musical illustrations.”

Journal of the Society of Arts.

No. 2,409. VOL. XLVII.

FRIDAY, JANUARY 20, 1899.

*All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.***Notices.****CANTOR LECTURES.**

On Monday evening, 16th inst., Dr. SAMUEL RIDEAL delivered the first lecture of his course on "Bacterial Purification of Sewage."

The lectures will be printed in the *Journal* during the summer recess.

ALTERATION OF MEETING.

The attention of Members is called to the fact that an alteration will be made in the arrangements for the Wednesday evening meetings. The reading of the paper by Mr. WILTON P. RIX on "Leadless Glazes," announced for the 8th of February, will be postponed until the 1st of March, and on the 8th of February, a paper will be read by Mr. JAMES SWINBURNE on "Nernst's Electric Light."

Proceedings of the Society.**SIXTH ORDINARY MEETING.**

Wednesday, January 18, 1899; Sir E. LEADER WILLIAMS in the chair.

The following candidates were proposed for election as members of the Society:—

Affalo, Frederick G., Newark, Bournemouth.
 Anning, Edward Herbert, 51, Bethune-road, Stamford-hill, N.
 Birt, Sir William, Great Eastern Railway, Liverpool-street Station, E.C.
 Campbell-Johnston, Ronald C., Nelson, British Columbia, and 86, York-street, Westminster, S.W.
 Cotton, Ross, Cape Town and Suburban Electric Lighting Company, Rondebosch, Cape Colony.
 Darby, John Henry, Pen-y-Garth, Brymbo, Wrexham-

Davis, William, Engineer's Department, Stock Exchange, E.C.

Grugene, Charles, 49, Wickham-road, S.E.

Hartmann, George H. J. Newlands, Thames Ditton, Surrey.

Herman, Benjamin Richard, McLeod-road, Karachi, India.

Immisch, Otto Claude, 102, Tollington-park, N.

Kenward, James, 43, Streatham High-road, S.W.

Marsden, Miss Kate, 11, Redcliffe-gardens, S.W.

Mumford, Arthur George, Culver-street Ironworks, Colchester.

Nicholson, H. Godfrey, Bellevue, Montenotte, Cork.

Preston, Edward Stuart, M.A., 63, Drayton-gardens, South Kensington, S.W.

Regan, William Frederick, 41, Threadneedle-street, E.C.

Ridley, Henry N., M.A., Botanic-gardens, Singapore, Strait Settlements.

Steel, Charles, Great Northern Railway, King's-cross Station, N.

Stewart, George Lawrence, M.A., Queen Anne's-mansions, St. James's-park, S.W.

Stobie, Harry E., Grand Junction Railways, Cook-house, South Africa.

Waterhouse, Colonel James, Oak-lodge, Eltham, Kent.

Webster, Arthur Harold, Brooklands, Riverhead, Kent.

The following candidates were balloted for and duly elected members of the Society:—

Granger, Arthur Otis, Girard-buildings, Philadelphia, U.S.A.

Johnson, Alexander Banks, Bringewood, Mulgrave-road, Sutton, Surrey.

Kitching, Henry, J.P., The Grange, Great Ayton, Yorkshire.

Lutwyche, Stanley, 3, Chichester-terrace, Brighton.

Stevens, Charles, 10, Wemyss-road, Blackheath, S.E.

Winch, Richard, Morden-grange, Kidbrook, Blackheath, S.E.

The paper read was—

INLAND NAVIGATION IN EUROPE AND NORTH AMERICA, WITH SPECIAL REFERENCE TO INLAND NAVIGATION IN ENGLAND.

BY LEVESON FRANCIS VERNON-HARCOURT, M.A., M.Inst.C.E.

Two extreme, and absolutely opposite opinions have been occasionally expressed with regard to inland navigation in England, namely, that since the introduction of railways the waterways of the country have become useless; and, on the other hand, that the canals should be purchased and improved by the Government for the public benefit.

The first view appears to derive a partial justification from the fact that as soon as the railways entered into competition with the canals, which had rendered such services to trade in England in the latter part of the last century and the early portion of the present century, the traffic on most of the canals greatly declined, some of the canals were eventually abandoned, and in a few instances canals were converted into railways. These results, however, and the present condition of inland navigation in England, must to some extent be attributed to the diversion of public interest and capital from canals to railways, leading to the neglect of improvements of the waterways to cope with the new competitor; the want of uniformity in dimensions of adjacent canals, and the divided ownership of through routes, in some of which important limbs fell into the hands of the competing railway, obstacles which fettered some of the main lines of railways in early days, but were overcome by the adoption of a uniform gauge and by amalgamation. The incorrectness of the general assumption that canals have become useless in Great Britain is readily proved by a reference to the Birmingham Canal Navigations, which, though under the control of the London and North-Western Railway, possess a yearly traffic of about 7,750,000 tons; whilst the Aire and Calder, and Weaver navigations, and the Grand Junction, Leeds and Liverpool, and Bridgewater canals as independent concerns, and the Trent and Mersey and Forth and Clyde navigations, and the Shropshire Union Canals, belonging to railway companies, have a yearly traffic of between 1,000,000 and 3,000,000 tons.

In support of the second opinion, the general practice in other countries might naturally be cited; for not only on the Continent of Europe, but also in Canada and the United States, the Government takes charge of the maintenance, improvement, and extension of most of the waterways. The State, moreover, reaps the indirect benefits which result from the expansion of trade and the increased prosperity of the community, by the improvement and cheapening of internal communications; whereas a company can only obtain the direct profits which may be derived from the undertaking. In a waterway, also, traversing a very long stretch of country, in which a variety of interests are concerned, the State possesses a greater unity of purpose, authority, control of large funds, and regard for the general good, than is likely to belong to any company.

State purchase and control of the waterways is however, opposed to the system hitherto followed in Great Britain, where private enterprise has been relied upon for the prosecution of commercial undertakings, with remarkably satisfactory results. Moreover, Great Britain possesses a very complete network of railways as well as roads; and as the extreme southern and northern counties of England, the western portion of Wales, and a great part of Scotland are almost devoid of inland navigable waterways, the improvement of the existing canals and navigations could not be regarded as benefiting the whole community, except to the extent that it might facilitate and cheapen the general distribution of goods and produce in the country. As the canals also have, for the most part, been constructed in the most favourable localities, the only economical method of extending better means of communication than roads to localities where the traffic would necessarily be small, would be by almost surface lines of light railways and tramways, laid, where practicable, alongside the existing roads.

The true solution of the problem of the best way of dealing with inland navigation in Great Britain, appears to lie somewhere between the extreme opinions quoted at the outset. Certain inland waterways in the country attract a large traffic in bulky goods, in spite of the severe competition of railways, and are fulfilling, with profit to their owners, the very important function of providing the trader with an alternative route, and thereby keeping down the railway rates with advantage to the public; whilst some waterways are actually used by the railways themselves to relieve portions of the over-burdened lines of some of the bulky goods traffic, and thus enable them to defer the expense of widening their system. Whether the insignificant traffic on many of the waterways of Great Britain is to be mainly attributed to the variety in dimensions, the neglect of improvements, and the divided ownership, or to unfavourable conditions and lack of suitable traffic, can be best determined after examination of the inland navigation in other countries, where greater interest has been manifested in the development of the waterways, and the State has provided funds for the improvements. The intervention of the British Government for the general improvement of the waterways of the country, involving the competition for traffic, by the use of public funds, with the vested interests of the railway companies, could only be justified

if it was proved that an adequate development of the waterways could not be effected by other means, and that such a step would be of great public benefit to the country at large.

Recent Interest Evinced in Inland Navigation.—Signs of an increasing public interest in inland navigation, as a means of further promoting and cheapening the transport of minerals and bulky merchandise in England, have been manifested from time to time of late years. Thus in 1872, a Joint Committee of the two Houses of Parliament on Railway Amalgamation pointed out the injury that had been done to the free competition of inland navigation with railways, by the purchase of important links by the railway companies on the main lines of water communication, and urged that not only should no inland navigation in the future be permitted to pass under the control of a railway company, but that the compulsory purchase of canals from railway companies should be favourably entertained by Parliament, and that the utmost facilities should be afforded for the amalgamation of adjacent lines of inland navigation.* In 1883, a Select Committee of the House of Commons was “appointed to inquire into the condition and the position of the canals and internal navigation of the country, to report thereon, and to make such commendations as may appear necessary.” A considerable amount of evidence was given before this committee on the existing condition of inland navigation in the United Kingdom, which was published the same year in a Blue-book †; but as the recommendation of the committee, that it should be re-appointed the following Session, was not acted upon, no report was ever made by the committee. In 1888, a Canal Conference was held at the Society of Arts, extending over two days, at which several papers relating to inland navigation were read and discussed; and a full report of the proceedings of the Conference was subsequently published in the *Journal* of the Society, ‡ and also in the form of a pamphlet, accompanied by a small map showing the canals and navigable rivers of England and Wales. The Railway and Canal Traffic Act of 1888 was passed in the same year; and

under the provisions of this Act a Blue-book was issued by the Board of Trade in 1890, giving the returns in respect of the canals and navigations in the United Kingdom for 1888, in which the capital, dividends, traffic, revenue, expenditure, method of traction, length of the navigation, number and dimensions of the locks, length of the tunnels, with the width of the waterway and minimum headway above the water-level in them, the supply of water, and the dimensions of the largest barges that can pass, are furnished in tabular form for each canal and navigation, the independent canals being kept separate from the canals owned by railway companies. In 1895 the Federated Institution of Mining Engineers arranged a Conference on Inland Navigation, which took place during their Birmingham meeting, when several papers on canals and navigations in England were read and discussed; and the proceedings of the Conference were published,* to which a map of the canals and navigable rivers of England and Wales was appended, prepared and published by Mr. L. B. Wells in 1892.

Neglect of inland navigation on the introduction of railways, and a subsequent revival of interest in the subject have not been confined to Great Britain; for in France, for instance, public attention was for a time concentrated on railways, and some of the canals were allowed to pass out of the control of the State; but about 1860 a reaction commenced in favour of the maintenance and improvement of the waterways of the country, which has continued with increasing force ever since. In the United States, also, little effort was made for a long time to enlarge the existing canals to meet the growing requirements of the grain traffic, and some of the canals have passed into the control of the railways; but recently the deepening of the Erie Canal has been commenced, and proposals are under consideration for a considerable enlargement of the canal to accommodate the vessels navigating the Lakes. Germany also, since 1880, has spent large sums on the improvement of its inland waterways, with the object of increasing and cheapening the means of transport, and thereby promoting the prosperity of the country.

Interest also in the development of waterways, and the various matters relating thereto, has been strikingly manifested by the eight

* Report from the Joint Select Committee of the House of Lords and the House of Commons on Railway Companies Amalgamation, 1872.”

† Report from the Select Committee on Canals, Minutes of Evidence, 1883.”

‡ *Journal of the Society of Arts*, May 25, June 1 and 8,

* The Federated Institution of Mining Engineers, “Report of the Proceedings of the Conference on Inland Navigation, Birmingham, Feb. 12, 1895, with Map of English Canals.” Newcastle-on-Tyne, 1895.

international congresses, dealing mainly with inland navigation, held in the last 14 years, at Brussels in 1885, Vienna 1886, Frankfort 1888, Paris 1889, Manchester 1890, Paris 1892, the Hague 1894, and Brussels 1898, largely supported by the Governments of the respective countries of the Continent in which they were held, and attended by delegates from various parts of the world. These numerously attended meetings have led to the collection of a large quantity of information on inland navigation in different countries, the discussion from different points of view and elucidation of undecided matters of importance, and have afforded an insight into the conditions, practice, and progress in the improvement of the waterways of the countries visited.

INLAND NAVIGATION IN NORTH AMERICA.

Waterways from the Great Lakes to New York and Montreal.—The United States and Canada possess the finest chain of lake inland navigation in the world; and it has only been necessary to improve the connection between Lake Superior and Lake Huron, by the St. Mary Falls Canal, and between Lake Huron and Lake Erie by the St. Clair Flats Canal, to obtain an inland waterway from Chicago at the head of Lake Michigan, and from Duluth and Port Arthur, on Lake Superior, to Buffalo and the Erie and Welland Canals at the north-eastern end of Lake Erie. From thence, New York is reached by water along the Erie Canal and the Hudson River, and Montreal by the Welland Canal, Lake Ontario, and the St. Lawrence and its canals, avoiding the rapids of the river. The distance from the head of Lake Superior and from Chicago to Montreal by water, is about 1,280 miles, of which only about one-eighteenth is canal, the remainder being open river and lake navigation; whilst to the ocean, at the outlet of the Straits of Belle Isle, the distance is about 2,380 miles, 150 miles longer than from the Straits of Belle Isle to Liverpool. The distance from the heads of the lakes to New York is about 1,420 miles, out of which 352 miles are comprised by the Erie Canal; but with the exception of the St. Mary Falls Canal, only $1\frac{1}{4}$ miles long, and the cut along the St. Clair River into Lake St. Clair, known as the St. Clair Flats Canal, the rest of the distance is open lake and river. Lake Superior, however, is 602 feet above sea-level, the most abrupt change of level being encountered between Lake Erie and Lake Ontario, amounting to 326 feet, resulting in the Niagara Rapids and Falls. The difference

in level between Lake Superior and the St. Lawrence at Montreal, of 551 feet, is surmounted by a large lock of 18 feet lift on the Canadian side of the St. Mary River, by 25 locks on the Welland Canal, $26\frac{3}{4}$ miles long, connecting Lake Erie with Lake Ontario, all comprised within the 10 miles nearest Lake Ontario, and having a total lift of $326\frac{1}{4}$ feet, and the locks of the six lateral canals of the St. Lawrence, $46\frac{1}{2}$ miles long altogether, where the difference of level amounts to $206\frac{1}{2}$ feet. Along the route to New York from Lake Superior there is a large lock on the American side of the St. Mary River with a lift of 18 feet as on the Montreal route; but there are 10 locks to be passed on the Erie Canal between Buffalo on Lake Erie and the Hudson River at Albany. Moreover, the available depth of the Erie Canal is only 7 feet, which is being gradually increased to 9 feet, and the locks are 18 feet wide, and the available length of the shorter ones is only 98 feet, admitting barges of 240 tons; whereas the available depth of the improved Welland and St. Lawrence canals is 14 feet, in place of 9 feet formerly, and the locks are 270 feet long and 45 feet wide. The American St. Mary's Falls Canal and the Canadian Sault-Sainte-Marie Canal, having to accommodate the large lake traffic, have been recently provided with lock 800 feet long, 100 feet wide, and 21 feet deep of water on the sill, and 900 feet long, 60 feet wide, and $20\frac{1}{2}$ feet depth respectively.

Various Waterways in North America.

The other Canadian canals of importance are the Ottawa canals, avoiding the rapids of the Ottawa River, with locks 200 feet by 45 feet and an available depth of 9 feet, and there is providing a navigable waterway between Ottawa and the St. Lawrence, and the Chambly Canal, 12 miles long, 7 feet deep and having nine locks of 118 feet by $23\frac{1}{2}$ feet forming part of the Richelieu Navigation connecting the St. Lawrence with Lake Champlain, and thence by the Champlain Canal with the Hudson River.

Several canals were constructed in the United States in the earlier half of the present century in addition to the Erie Canal, with depths of four to seven feet, and locks ranging from 176 feet by 17 feet, to 78 feet by 15 feet, having an aggregate length of 1,700 miles, about 2,100 including the Erie Canal and its branch to Oswego,* but they have for the most

* "Respective Uses of the Waterways and Railways for General Transportation in the United States," Thos. Roberts, Fifth International Congress on Inland Navigation, Paris, 1892, p. 17.

part been superseded by railways. Canals, however, are by no means regarded as obsolete means of communication in the United States, for the Government engineers and others have been urging the construction of an improved waterway between the Lakes and the Hudson River, the need of which has been generally acknowledged; and the only question upon which a difference of opinion exists, is whether the Erie Canal should be enlarged and merely deepened to 12 feet, to accommodate barges of 1,500 tons, or a canal, 18 ft deep, should be constructed along a more suitable route, to admit larger vessels navigating the lakes, or a ship-canal, 24 feet deep, accessible for ocean-going steamers.* The Chicago Drainage Canal also has been made sufficiently deep to form the first section of an ample waterway between Lake Michigan and the Mississippi; whilst the Government is providing a similar connection on a more modest scale by the Illinois and Mississippi Canal, to join the Illinois River to the Rock River, at present in progress, 75 miles long and 7 feet deep, rising 196 feet by twenty-one locks, and then descending 93 feet by ten locks, and designed for the passage of 600-ton barges, 140 feet long, 34 feet beam, and 6 feet draught.†

Since the Government took the waterways under its control in 1860, its efforts have been mainly directed to the improvement of the chief rivers by dredging, removal of obstructions, the construction of lateral canals at places to avoid rapids, and the canalisation of several of the tributaries of the Mississippi and the Ohio. The rivers are free; and the tolls were abolished on the Erie Canal in 1882.

Traffic on United States Waterways.—

The traffic of the principal waterways of North America, is indicated by the thickness of the red bands following the lines of these waterways on Diagram 1, shown on the wall. The traffic on the open lakes is naturally very large, being greatly assisted by the improvements in the communications between them, the amount passing out of Lake Superior by the St. Mary's Fall Canal, having reached 8,288,000 tons in 1890; and this traffic being increased by the accession of traffic from Lakes Michigan and Huron, attains a maximum, where it can be measured in passing through the St. Clair Flats Canal at

the Detroit River, which was about 20,000,000 tons in 1890 reaching Lake Erie. On leaving Lake Erie, it is dispersed, the greater portion going on to the railways at Buffalo, and, to some extent, at other parts on the lake, only between 3,000,000 and 4,000,000 tons going on by water along the Erie Canal, and about 1,000,000 tons by the Welland Canal. The Hudson River, between Albany and New York, has a traffic which amounted to 18,600,000 tons in 1890, second only to the traffic passing between Lake Huron and Lake Erie, owing to its being a large open waterway in direct communication with New York and the sea to the south, and with the Erie and Champlain Canals and Albany, Troy, and other important towns to the north. The Ohio flowing through the most flourishing and populous portion of the United States, is, next to the lakes and the Hudson, the most important waterway, having a traffic of about 6,000,000 tons between Pittsburg and its confluence with the Mississippi at Cairo, a distance of 967 miles—a much longer length of navigation than on the Hudson. The Mississippi has a good traffic between St. Paul and its mouth, a distance of 1,950 miles, ranging from a maximum of 4,131,000 tons between St. Louis and Cairo, with a minimum of 2,862,000 tons between New Orleans and its mouth. Several comparatively short waterways, tributaries of the Ohio and rivers connecting important towns with the sea, have a considerable traffic of between 1,000,000 and 5,000,000 tons; but the only other long waterways of any consequence are the Arkansas River, with a traffic of 1,700,000 tons, and the Missouri, remarkable rather for the great distance its navigation extends up the river than for its traffic, which drops from 849,000 tons to quite a small amount above the mouth of the Big Sioux River. The waterways whose traffic is under 100,000 tons have been omitted from the diagram; and considerations of space have necessitated leaving out the few waterways on the Pacific Coast, of which the Columbia River, up to Portland, with a traffic of 1,633,000 tons, and the Sacramento and San Joaquin rivers, near San Francisco, with 1,006,000 tons and 350,000 tons respectively, are the only ones of importance.

Traffic on Canadian Waterways.—The Welland Canal, affording a navigable waterway between Lakes Erie and Ontario, and therefore forming a link between Lake Superior and the St. Lawrence, has the largest traffic, somewhat exceeding 1,000,000 tons;

* "Report of the Chief Engineers, U.S. Army, 1897," Part 4, pp. 3328-3265; and Transactions of the American Society of Civil Engineers, vol. xxxix., pp. 273-322.

† "Report of the Chief of Engineers, U.S.A., 1897," Part 4, p. 2825-2879, with map and Longitudinal Section of Canal.

the St. Lawrence and its canals, between Lake Ontario and Montreal, have a traffic of between 800,000 and 900,000 tons; the Ottawa River and its canals between Ottawa and the St. Lawrence, have a traffic of between 500,000 and 600,000 tons; and the Chambly Canal, on the route between the Hudson and the St. Lawrence, has a traffic of between 200,000 and 300,000 tons.*

Remarks on North American Waterways.—In spite of very keen railway competition, the waterways possess a large traffic where the rivers pass through a populous district, and there is a large supply of bulky goods, provided even a very moderate depth can be secured. The great improvements also in the connections between the lakes has enabled a large trade to be attracted to the through route between Lake Superior and Lake Erie, notwithstanding its being closed by ice during four or five months in the year. The great diversion of the lake traffic to railways at Buffalo, though largely caused by the antiquated condition of the Erie Canal, in view of the increased requirements of shipping, is also due to the railways having established lines of vessels of their own on the lakes as feeders of their traffic. The small traffic on the Welland Canal, as compared with the Erie Canal, in spite of its larger dimensions, may be traced to 89 per cent. of the vessels navigating the lakes belonging to the United States, and also to the Soulages Canal, the final link in the enlargement of the St. Lawrence Canals, not having yet been opened for traffic. If Canadian lines of steamers, built for passing through the improved waterway between Lake Erie and Montreal, are put on the lakes, the traffic is quite certain to increase with the development of Western Canada.

The traffic on all the inland waterways of the United States has been estimated at 25,000,000,000 ton-miles, or nearly one-third the number of tons carried one mile on the railways.† The average length of journey of the lake traffic has been reckoned at 566 miles.

INLAND NAVIGATION IN GERMANY.

Navigable Rivers in Germany.—Germany possesses the advantage of being traversed by some large rivers which, rising in countries to

the south, have their lower and more navigable portions situated in Germany, thereby providing important natural waterways, notably the Rhine and the Elbe, and in a smaller measure the Oder, the Vistula, and the Niemen. These rivers, with their principal tributaries, and the comparatively short canals connecting them, constitute the main inland waterways of the country. The Weser, situated wholly in Germany, and the Danube rising in it, are relatively of little importance as German inland waterways; whilst navigation along the valley of the Ems, a wholly German river, has had to be provided for the most part by a lateral canal.

The main rivers, with the exception of the Ems, are open navigations, and also some of their chief tributaries, having been improved by regulation works and dredging; but the available depth naturally decreases on ascending the river. A few of the principal tributaries of the large rivers have been partially canalised, namely, the Lippe, the Ruhr, the Lahn, the Main, and the Saar in the Rhine basin, the Elde, the Spree, the Havel, and the Saale in the Elbe basin, and the Netze in the Oder basin. The sizes of the locks on these canalised portions have been determined by the depth of the waterway and the importance of the traffic, varying from 90 feet in length, 15 $\frac{3}{4}$ feet in width, and 3 $\frac{1}{2}$ feet depth on the sill, up to the Spree lock, 361 feet by 31 $\frac{1}{2}$ feet and 6 $\frac{1}{4}$ feet depth at the low stage, and the five lengthened locks on the Main, between its mouth and Frankfort, 1,148 feet by 34 $\frac{1}{2}$ feet and 8 $\frac{1}{2}$ feet depth.

Canals in Germany.—Most of the canals in Germany have been constructed to connect two river navigations across the waterparting of their valleys. Thus, the Rhine-Marne and the Rhine-Rhone canals, starting from the Rhine near Strassburg, connect the Rhine with two main French river basins; the Ludwig Canal, 83 $\frac{1}{2}$ miles long, and having a summit-level 1,372 above sea-level, connects the Main and the Danube through the canalised Altmühl; the Finow Canal joins the Oder to the Havel, and consequently to the Elbe, and the Oder-Spree Canal also furnishes another connection between the same rivers; whilst the Vistula-Netze Canal connects the Vistula with the Oder. Thus the Elbe, the Oder, and the Vistula are connected; but there is no regular inland connection between the Rhine, the Ems, the Weser, and the Elbe. A mid-land canal, however, has been proposed, which, starting from the Elbe below Magdeburg, and passing

* "Annual Report of the Minister for Railways and Canals, 1895-96," Ottawa, Appendix A, p. 154.

† "Relations Between Railroads and Waterways in the United States," E. P. North, Fifth International Congress on Inland Navigation, Paris, 1892, p. 2.

by Hanover, would cross the Weser near Minden, and after joining the Ems lateral Canal at Rheine, would make use of this canal as far as Henrichsburg, and thence by a prolongation along the valley of the Emscher, would join the Rhine near Ruhrort, and thereby complete the connection between all the main German rivers.

The Ems-Jade Canal has a depth of nearly 7 feet, and the Oder-Spree Canal a depth of $5\frac{1}{2}$ feet, whilst the Ems Canal has been made $3\frac{1}{2}$ feet deep; but most of the other canals have depths of between five and six feet. The locks on the canals vary considerably in dimensions, according to the importance of the navigation or the date of construction, ranging for the most part between 105 feet by $15\frac{1}{2}$ feet, with a depth of $4\frac{1}{2}$ feet, the size of the 100 locks on the Main-Danube Canal, and 180 feet by $28\frac{1}{2}$ feet, with a depth of $3\frac{1}{2}$ feet for the seven locks on the Oder-Spree Canal; but there are a few smaller locks than those on the Main-Danube Canal, and the largest canal locks are the nine locks on the Ems Canal, 541 feet long, 33 feet wide, and $3\frac{1}{2}$ feet in depth.

Length of German Waterways.—The total length of rivers used for inland navigation is 5,100 miles, of which only between one-sixth and one-seventh consists of canalised rivers; while the inland canals have a length of about 1,300 miles, making altogether about 6,400 miles of inland waterways in Germany.

Traffic on German Waterways.—The Rhine with its large open waterway has attracted the largest amount of traffic, especially between the Dutch frontier and Ruhrort; and the traffic continues large up to Mannheim, for the minimum depth at the lowest stage, which is 8 feet up to Cologne and $7\frac{1}{2}$ feet to above Coblenz, does not fall below $6\frac{1}{2}$ feet as far up as Mannheim, except for a short distance near St. Goar. The Elbe also possesses a large traffic all the way between Hamburg and the Austrian frontier, for it connects Hamburg, the largest seaport of continental Europe, with Magdeburg, Dresden, and Bohemia, and also these places with Berlin by the Plaue Canal, the Havel, and the Spree. There is a fair traffic on the Oder between Stettin and Breslau, and on its connections with Berlin; and there is a moderate traffic on the Vistula between Dantzic and the Russian frontier, and the waterway connecting it with the Oder, and on the short portion of the Niemen in German territory and its connection with Königsburg. There is also a good traffic on the canalised

Saar, the Saar Canal, and the Rhine-Marne Canal, which is increasing, in spite of the summit-level of this latter canal, reached by 51 locks from the Rhine, being 878 feet above sea-level; but the traffic on the Rhine-Rhone Canal, whose summit-level is 1,143 feet above sea-level, and is reached by 85 locks, is small, owing mainly to the small importance of the Rhone basin in regard to inland navigation, as well as the great difference in level that has to be surmounted. The traffic on the Main between the Rhine and Frankfort, which, before it was canalised, was smaller than higher up, has greatly increased since the works were completed in 1886, in spite of the railways on either bank, as along the Rhine; and this result has been experienced in other improvements of large waterways in Germany, and has no doubt led to the provision of the large waterway to Dortmund along the Ems valley, where formerly the traffic was very small. The traffic on the other German waterways is comparatively insignificant, and has not been indicated on the diagram where less than 100,000 tons.

On the average, the goods traffic on the German navigable waterways is rather greater in proportion to their length than on the German railways; and the average journey by water of 217 miles, is about double the average journey of goods by railway; but owing to the much greater length of the railways, the traffic on the waterways is only about one-third of the goods traffic on the railways.

Remarks on German Waterways.—The Government not only maintains the existing waterways in Germany, but also spends large sums of money every year in their improvement and extension, though all the main lines of railway and numerous branch lines are owned by the State. In consequence, the inland navigation traffic has greatly increased in recent years, in spite of the waterways being closed for about three months in the year. Tolls are levied on the canals and canalised rivers, but hardly amount to one-third of the costs of maintenance. The view entertained, however, is that certain classes of goods are carried more economically by water, that the railways do not suffer from the improvement, and consequent increased traffic of the waterways, and that the extension of the means of communication of a country is a public benefit, and promotes trade and agriculture.

INLAND NAVIGATION IN FRANCE.

France is the country in Europe in which

inland navigation has been most carefully attended to. Like England, it possesses no rivers which were naturally navigable for long distances inland; and it also possesses an extensive seaboard, for the sea constitutes more than half of its entire boundary; while the connection of its river basins by waterways involved surmounting considerable elevations.

Navigable Rivers in France.—There are four main river basins in France—namely, the Seine, the Loire, the Garonne and Dordogne, which join to form the Gironde, and the Rhone. The Seine, which has been made accessible for sea-going vessels up to Rouen, has been canalised from Rouen up to Montereau, a distance of 214 miles, giving a minimum depth of $10\frac{1}{2}$ feet between Rouen and Paris, and $6\frac{1}{2}$ feet between Paris and Montereau. Its tributaries also, the Oise with the Aisne, the Marne, and the Yonne, have been made first-class waterways, with a minimum depth of $6\frac{1}{2}$ feet, by canalisation for considerable distances; and the main river and its tributaries are more or less navigable a good way further up.* The navigation of the Loire above Nantes is greatly impeded by the rapid current and the variable and defective depth; and no portions of the Loire above Nantes, or of its tributaries are first-class waterways, with an available depth of $6\frac{1}{2}$ feet, though considered navigable as second-class waterways for long distances inland. The tidal Garonne and Dordogne are first-class waterways from their confluence in the Gironde up to Castets and Libourne respectively; but above these places they and their tributaries are second-class waterways. The canalised Saône from Corre to its junction with the Rhone at Lyons, a distance of 231 miles, is a first-class waterway, with a minimum depth of $6\frac{1}{2}$ feet; but there is no other river in the Rhone basin which occupies this position; for the Rhone itself between Lyons and the sea, in spite of the extensive regulation works carried out and its fairly uniform flow, has a rapid current, and a depth in places of less than $6\frac{1}{2}$ feet at a low stage. Accordingly, in contrast to Germany, the rivers of France have only been made thoroughly satisfactory waterways for inland navigation by means of canalisation.

Canals in France.—Canals have been chiefly constructed in France as lateral canals to supersede defective river navigations, and to connect the navigations of

different river basins across the waterparting of their valleys. Thus there are lateral canals to the Upper Seine, the Oise, the Aisne, the Marne, and the Yonne in the Seine basin, the Loire, and the Garonne; whilst the Upper Scheldt in France is connected with the Oise by the St. Quentin Canal. The Sambre, and therefore the Meuse, is also connected with the Oise by a canal; the canalised Meuse is connected with the Marne-Rhine Canal, and with the canalised Saône by the Canal de l'Est; and the Loire lateral Canal is connected with the Seine by the Briare and Loing canals, with the Yonne by the Nivernais Canal, and with the Saône by the Canal du Centre. The Yonne also is connected with the Saône by the Bourgogne Canal the Marne is being joined to the Saône by a canal approaching completion, and the Garonne lateral Canal is in communication with the Mediterranean by the old Canal du Midi. The summit-level of the southern branch of the Canal de l'Est is 1,184 feet above the sea, of the Bourgogne Canal 1,241 feet, of the Nivernais Canal 858 feet., of the Canal du Centre 989 feet, and of the Canal du Midi 610 feet. With the exception of the Upper Seine lateral Canal, the Sambre-Oise Canal, part of the Loire lateral Canal, the Nivernais Canal, and the Garonne lateral and Midi canals, the canals named above are in the first-class, namely, canals which have a minimum depth of water of $6\frac{1}{2}$ feet, and locks of not less than $126\frac{1}{2}$ feet available length, and 17 ft. width, and affording a minimum headway under bridges of $12\frac{1}{2}$ feet. Canals, and also rivers, of the second-class are those whose depth or locks do not come up to these dimensions; whilst there is a third class of rivers only suited for having good floated down them. The canals are almost entirely confined to the north-eastern and eastern central districts of France, with the exception of the Brest-Nantes Canal, the canal between Rennes and St. Malo, some short canals in the neighbourhood of La Rochelle and Rochefort, the Garonne lateral and Midi canals, and canals branching off from the Lower Rhone.

Lengths of French Inland Waterways.—

The chief objects aimed at with regard to French waterways in the last forty years, have been the improvement of some of the principal rivers, the formation of important connections by canals, the repurchase by the State of conceded waterways, and especially, since 1879, the carrying out of the necessary work to make all the main lines of waterways compl

* "Guide Officiel de la Navigation Intérieure." Paris.

with the standard dimensions given above for first-class waterways determined in that year, so that barges of 300 tons may be able to traverse all the main lines of navigation throughout the country. Since 1860, the Seine has been greatly improved by canalisation between Rouen and Montereau, as well as some of its tributaries; the Rhone has been regulated between Lyons and Arles; and 528 miles of canals have been constructed.

The lengths of the French inland waterways actually used for the transport of goods in 1897, were 483 miles of rivers on which the goods had to be floated down, 4,120 miles of navigable rivers, and 3,014 miles of canals, making a total of 7,617 miles.* Of this length of waterways, 7,459 miles are owned by the State; and only 152 miles of the conceded canals, and six miles of the canalised Lez are under other control at the present time, as the Aronne lateral and Midi canals with their branches, 306 miles in length, reverted to the State by purchase last July.

The progress made towards securing uniformity in dimensions along the main waterways, as decreed in 1879, is manifested by comparison of the lengths of first-class rivers and canals in 1878 and 1897. These lengths were 619 miles of rivers and 146 miles of canals, or a total of 765 miles of first-class waterways in 1878, and 1,267 miles of rivers and 1,528 miles of canals (of which 401 miles were constructed since 1878), or a total of 2,795 miles of first-class waterways in 1897, so that the length of first-class waterways conforming completely with the standard dimensions is now over three and a-half times their length in 1878. The lengths of inland waterways used for traffic in 1878 were 4,095 miles of rivers and 2,616 miles of canals, or a total of 6,711 miles, as compared with 7,617 miles in 1897, so that the first-class waterways were 114 per cent. of the whole length in 1878, and 117 per cent. in 1897.

Traffic on French Inland Waterways.—The large traffic on the waterways is almost wholly confined to the waterways converging on Paris from the northern ports, from Belgium, from Germany by the Marne-Rhine Canal, and from Montereau and Rouen along the Seine, and only other waterways in France having a traffic exceeding 500,000 tons being the route connecting the Saône with the Seine through the Loire valley, and therefore the Rhone and

Loire basins with Paris, by the Canal du Centre, the Loire lateral Canal, and the Briare and Loing Canals, and also the Berry Canal joining the Loire lateral Canal below Nevers. The largest traffic, as shown by the thickness of the red bands on Diagram 3, clusters round the neighbourhood of Paris, where the various streams of traffic concentrate, converging mainly to the environs of Paris, and also diverging by three principal lines, namely, by the St. Quentin Canal and the Oise, with a maximum of 4,604,000 tons in 1897 on the canal near Cambrai, by the Lower Seine with a maximum of 4,152,000 tons between Conflans and La Briche, and by the Upper Seine with a maximum of 2,632,000 tons between Corbeil and Paris; whilst the traffic by water within the Paris section was 3,594,000 tons in 1897. The traffic of all the French waterways, down to 100,000 tons, is indicated by red bands on Diagram 3 on the wall; whilst the course of some of the long canals with an insignificant traffic, such as the Garonne lateral and Midi canals, the Rhone-Rhine Canal, and some canals in the extreme west, is indicated by red lines. Traffic exceeding 100,000 tons was carried in 1897 along a length of 3,205 miles of river navigations and canals, which is less than half the length of the navigable waterways.

The total tonnage of goods carried on the French waterways in 1897 amounted to 30,125,000 tons, one-third of which consisted of building materials, over 28 per cent. of coal, 13·7 per cent. of agricultural products and provisions, 7·7 per cent. of timber, and the same of metals, and 5·4 per cent. of manures. The traffic in 1897, reckoned by the number of tons carried one mile, was 2,669,870,000 ton-miles; and consequently the average tonnage throughout, assuming it was evenly distributed over the whole length of waterways traversed, was 350,500 tons; whilst the average journey, obtained by dividing the ton-miles by the total actual tonnage, was 88 miles.

The waterways were separated by the decree of 1879 into main and secondary lines; and the large traffic is confined to the principal lines, and for the most part to those which conform to the dimensions of first-class waterways, the only exceptions being the Sambre-Oise Canal, the Ourcq and Berry Canals, and a portion of the Loire lateral Canal. There are at present 3,732 miles of main waterways, which, however, do not all as yet conform to the standard dimensions, and 3,885 miles of secondary waterways; and the large increase

* "Statistique de la Navigation Intérieure, Ministère des Travaux Publics, 1897." Paris, 1898.

in the average traffic, and in the number of ton-miles in the last 25 years, has been almost wholly restricted to the main lines, the increase having mainly occurred since 1880, when tolls were entirely abolished, and the improvements decreed in 1879 were beginning to be brought into operation. Thus, in 1880, when there were 3,461 miles of main waterways, and 3,337 miles of secondary waterways, the number of tons carried one mile and the average traffic were 1,142,000,000 ton-miles and 330,000 tons on the main lines, and 85,500,000 ton-miles and 25,500 tons on the secondary lines; whilst in 1897, the corresponding quantities were 2,552,000,000 ton-miles and 684,000 tons on the main lines, and 118,000,000 ton-miles and 30,500 tons on the secondary lines. Accordingly, the traffic on the main lines has more than doubled in 17 years; whereas the traffic on the secondary lines has only increased 20 per cent. in the same period, though owing to the augmentation of 16 per cent. in their total length, the increase in their ton-miles has been 38 per cent., as against an increase of over 123 per cent. on the main lines. The proportions of the traffic carried by the main and secondary waterways respectively, which were 93 per cent. and 7 per cent. in 1880, amounted to 95.6 per cent. and 4.4 per cent. in 1897, which proves that in spite of the present greater length, and greater increase in the length since 1880 of the secondary waterways than of the main lines, there is a very great preponderance of traffic on the main waterways, which is actually on the increase.

The length of the average journey is gradually increasing, having been 68½ miles in 1881, the first year in which complete returns were made, 82¾ miles in 1886, averaging 87 miles from 1891 to 1896, and reaching 88¾ miles in 1897. The increased average tonnage on the various sections of the waterways in 1897, as compared with 1882, is shown on Diagram 3 by the amount by which the red bands overlap the purple bands which represent the traffic in 1882. The increase is most marked in the lines converging to Paris, especially the waterways from the northern ports, the Oise, the Seine, the Aisne and Marne canals to the Rhine, and the northern part of the Canal de l'Est; whilst the small traffic on the Rhine Canal and the Garonne lateral and Midi Canals has decreased since 1882.

Remarks on French Waterways.—In spite of the care expended in improving, completing,

and giving uniformity of dimensions to the waterways during the last twenty years, the traffic is very unevenly distributed, being concentrated on the portion of France north of Montereau; whilst except along the waterway joining the Seine, the Loire, and the Saône, with its branch the Berry Canal, the traffic is very small elsewhere. Two diagrams have been published by Mr. Nördling showing the traffic on the railways and waterways of France in 1882 side by side,* from which it is evident that the railway traffic, though more concentrated in the northern and north-eastern portions of the country than elsewhere, is far more evenly distributed than the inland navigation traffic, having a large traffic between Paris and Marseilles, following the Rhone valley between Lyons and Arles, and also between Avignon and Toulouse and on to Bordeaux and between Bordeaux and Paris along routes where the inland navigation traffic is insignificant.

INLAND NAVIGATION IN BELGIUM.

Belgium is very well supplied with waterways in proportion to its area, being traversed for a portion of their course, by the Scheldt and its tributaries, and by the Meuse and its tributary the Sambre, which have been canalised and numerous canals have been constructed especially in the flat western half of the country.

Lengths of Waterways, and Standard Dimensions.—The length of navigable waterways in Belgium is reckoned at 1,365 miles consisting of 765 miles of rivers and 600 miles of canals, in which there are 123 miles of river on which goods can be only floated down, 30 miles of open navigable rivers, 341 miles of canalised rivers, 143 miles of small canals, and 457 miles of canals accommodating barges over 200 tons.† In 1830 the State had control of only 97 miles of waterways out of a total length of 1,006 miles, or 9.6 per cent.; but now the State controls 1,118 miles, or 82 per cent. having regained possession of some waterways, repurchased others, and constructed new canals.

The standard dimensions, in accordance with which Belgian canals have been constructed in late years, are, bottom width 345 feet, depth 8 feet, and headway under bridges 13 feet, and

* "Die Selbstkosten des Eisenbahn-Transportes und der Wassen-strassen-Frage in Frankreich, Preussen, und Oesterreich," W. von Nördling, Vienna, 1885.

† "Guide Programme, VII^{me} Congrès International Navigation," Brussels, 1898, p. 6.

the locks, 134 feet available length and 17 feet width, and sills lower than the bed of the canal.

Traffic on Belgian Inland Waterways.—Statistics of inland navigation in Belgium have been collected regularly since 1879; but it is only since 1888 that the returns of inland navigation traffic have been completely separated from sea-going traffic. The length of the waterways for which the returns are made is only 1,012 miles, composed of 535 miles of rivers and 477 miles of canals.* The Belgian waterways are so intimately connected with the French waterways that their traffic has been conveniently exhibited on Diagram 3. The traffic consists of coal and coke, building materials, metals, minerals, pottery, glass, agricultural and industrial products, and timber. The traffic is largest on the portion of the tidal Scheldt between Antwerp and the mouth of the Rupel, where it nearly reaches 2,750,000 tons; it is about 1,500,000 tons on the Scheldt below Antwerp, on the Rupel, and on the Brussels-Rupel Canal; it exceeds 1,000,000 tons on the Maestricht-Bois-le-Duc Canal, and nearly reaches this amount on the Lower Scheldt and the Liège-Maestricht Canal; it exceeds 500,000 tons on the Meuse-Scheldt Canal and the canalised Meuse, and nearly attains this quantity on the canalised Sambre; whilst the Charleroi-Brussels Canal and the Upper Scheldt have an average traffic of over 500,000 tons, and most of the other central waterways have a traffic of between 100,000 and 500,000 tons. On the other hand, the branch canal to Hasselt has an insignificant traffic; and all the canals between the Ostend-Brabant Canal, the Lys, and the French frontier appear to be devoid of traffic.

There was a considerable increase in traffic on most of the waterways between 1888 and 1896, exceeding 50 per cent. in some important instances; whilst the actual tonnage carried on all the waterways included in the returns, increased from 24,444,000 tons in 1888 up to 38,816,000 tons in 1896, and the traffic from 59,500,000 ton-miles in 1888 up to 489,000,000 ton-miles in 1896, being an increase of 36 per cent. in eight years. The average density of the traffic also, assumed to be distributed over the whole length of the waterways, rose from 59,000 tons in 1888 to 483,000 tons in 1896. The average journey must necessarily be short in a country of such small extent as Belgium;

and as no material extensions of the waterways have been made within the period over which the exact returns extend, the length of journey has remained fairly uniform, ranging between 13.8 and 14.7 miles, with an average of 14.35 miles.

Remarks on Belgian Waterways.—Considering the limited area of Belgium, the length of its navigable waterways is large and the traffic on them is considerable; whilst, like in Germany and France, the traffic is concentrated on the lines converging to Brussels and the chief industrial and mining centres, and the main waterways connecting important towns, or leading from them to convenient ports on the seacoast. This traffic, moreover, has been obtained in spite of a very complete network of State railways; for in Belgium, as in Germany and Russia, the Government considers that the simultaneous improvement and extension of waterways and railways conduce to the development of trade, and the general prosperity and advancement of the country.

INLAND NAVIGATION IN ENGLAND.

The conditions of the United Kingdom in respect of inland navigation differ somewhat from those of the other countries dealt with, in having a considerably larger extent of seacoast in proportion to the area of the country, in having a greater number of navigable tidal firths and inlets, and owing to London, Edinburgh, Dublin, Liverpool, Glasgow, Belfast, and several of the other most important towns being situated within easy access of the sea, to which Manchester has been recently added by the construction of its ship-canal.

Scotland, though lavishly supplied by nature with firths and lochs, penetrating in some cases a considerable distance into the interior, is not well suited for inland navigation, owing to its hilly character, the small size of its rivers, and the absence of inland mining and industrial centres. It possesses only five canals, with a total length of 122 miles, only two of which, connecting Edinburgh and Glasgow by a waterway across the country, have a traffic exceeding 100,000 tons, namely, the Forth and Clyde Navigation, with about 1,250,000 tons, and the Edinburgh and Glasgow Union Canal with about 130,000 tons, both belonging to railway companies.

Ireland, with the Shannon, the Barrow, the Bann, and the Boyne, the Grand Canal connecting Dublin with the Shannon, 79½ miles long, the Royal Canal, 96 miles long, going

* Guide Programme, VIIe Congrès, p. 201.

from Dublin into County Longford, and some other waterways, possesses 610 miles of inland navigation. Owing, however, to the absence of mineral resources and manufacturing centres in the interior, the traffic on the waterways, as given in the returns of 1888, amounts altogether to little more than half a million tons, only two waterways having a traffic exceeding 100,000 tons, namely, the Grand Canal with about 230,000 tons, and the Lagan Canal with 140,000 tons.

Wales, with its hills and absence of fair-sized rivers, is badly adapted for inland navigation, which comprises only four waterways in the south, two of which communicating with Cardiff and Swansea have a good traffic, and two branches of the Shropshire Union Canals in the north. Accordingly, the main interest in inland navigation, as regards the United Kingdom, is centered in England.

Traffic on Inland Waterways in England.

—The canals and navigations of England have been to a great extent described in the evidence given before the Select Committee on Canals in 1883, and in the papers read at the canal conferences held here in 1888, and in Birmingham in 1895; and their positions are shown on Mr. Wells' diagram map. It will therefore suffice to draw attention to the distribution of traffic upon them, as indicated on the wall diagram, prepared from the traffic returns of 1888, for those waterways whose traffic is given as exceeding 100,000 tons.* The returns only give the actual tonnage carried on each separate waterway, and not the ton-miles or the distance along which a given tonnage is conveyed, as furnished for the other countries of which diagrams of traffic are exhibited. Accordingly, in default of proper statistics, the thickness of the band indicating the amount of traffic has had, in most cases, to be made uniform throughout the whole length of each waterway, as if the tonnage given traversed the whole distance, which is generally not the case; but, in a few instances, where the existence of branches converging on to a main line, or other circumstances, give evidence of a variation in the amount of traffic along different portions of a waterway, the thickness of the band has been modified to be more nearly in accord with the actual conditions. Though, however, it is impossible to

make a correct diagram of the traffic on the English waterways, comparable to the other diagrams, in the absence of any returns as to the actual tonnage traversing the different sections of each waterway, or to form a proper idea of the amount of the traffic and of its intensity in different places without any indication of the ton-mileage and the average journey, the diagram shows clearly enough the situation of the waterways whose traffic is large. The inland navigation traffic in England, as compared with the other countries referred to, is evidently very unevenly distributed; but whereas in the other countries, the traffic is chiefly concentrated round the inland capitals, in England since London has direct access to the sea, the main traffic is concentrated around the midland and northern inland towns which are mining or manufacturing centres, such as Birmingham, Wolverhampton, Leeds, Sheffield, Rochdale, Wigan, Stoke, and Northwich. The Grand Junction Canal, with apparently increasing traffic as it approaches London, is the only important waterway having a traffic of over 1,000,000 tons which extends into the southern portion of England, which, however, is exceeded by the short Regent's Canal near London. The only other waterways south of Birmingham whose traffic exceeds 500,000 tons are the Staffordshire and Worcestershire Canals connecting Stafford and the Potteries with the Lower Severn at Stourport, only about a quarter of which is south of Birmingham, the River Lee Navigation connecting Hertford with London, and the Thames Navigation between Oxford and London, for the traffic on the Oxford Canal does not quite reach this amount whilst the traffic on the rest of the southern waterways in England is very small. The large traffic in fact on the English waterways with the exceptions mentioned above, is comprised within the district bounded by the Birmingham and Shropshire Union Canals, the Leeds and Liverpool Canal, the Aire and Calder Navigation, the Don Navigation, a line from Sheffield to Stoke, and the Trent and Mersey Navigation. None of the systems of waterways within this area have a traffic of less than 100,000 tons, only three less than 500,000 tons, seven of between 500,000 and a 1,000,000 tons, three of between 1,000,000 and 2,000,000 tons, three of between 2,000,000 and 3,000,000 tons, and the Birmingham Canals having a traffic of 7,750,000 tons. Moreover, out of a total traffic for England and Wales of 34,750,000 tons, 23,500,000 tons, or rather over two-thirds of the whole, belong to the waterways of the

* "Returns made to the Board of Trade in respect of the canals and navigations in the United Kingdom for the year 1888," London, 1890.

January 20, 1890.]

ited district, having a length of only 624 miles out of a total of 3,374 miles used for traffic in England and Wales, or less than one-fifth of the whole; whilst only 1,975 miles of waterways have a traffic exceeding 100,000 tons in any part of their system, or rather less than three-fifths of the whole length.

The large traffic in the districts lying between Birmingham, Liverpool, Leeds, Goole, and Sheffield, cannot be attributed to the commodiousness of the waterways; for though undoubtedly these waterways are the most spacious, and probably possess the greatest capacity of traffic, which in the case of the Weaver Navigation and the Aire and Calder Navigation have been improved and enlarged to meet the requirements of the traffic, and the locks 220 feet long, 42 feet wide, and 15 feet of water over the sill, and 202 feet by 18 feet 8½ feet respectively, the rest of these waterways have locks only 61 to 80 feet long 7½ feet wide, or 17 feet wide, and depths ranging for the most part between 3½ and 5 feet. In fact, with the exception of the Weaver and Aire and Calder Navigations, and the widening of the locks and a few improvements on some of the other waterways, little has been done to meet the increasing requirements of traffic, and to compete on favourable terms with the railways for the bulky traffic; and it is remarkable that, in spite of the great development of railways and the facilities they offer, the antiquated waterways should have remained so much traffic.

Remarks on English Inland Waterways.
The inland navigation traffic in England, in France, is very unevenly distributed; for, except along two or three waterways leading to London, the waterway connecting Birmingham and the Potteries to the Severn, and two short waterways communicating with Cardiff and Swansea, the bulk of the traffic clusters round Birmingham and Wolverhampton, Staffordshire, Cheshire, and the southern portions of Yorkshire and Lancashire, where the chief mineral and manufacturing inland centres are situated, and the routes by which access is obtained by them to seaports. Whereas, however, in France every effort has been made within recent years to give uniformity in dimensions to the main waterways, and to promote inland navigation, and almost the whole of the waterways have been brought under a single control, little has been done in England to procure uniformity or to enlarge the routes, except the Weaver and Aire and Calder Navigations, or till quite lately to

take waterways out of the hands of railway companies, and to secure undivided control of main lines of navigation belonging to different companies.

In 1895 a Sheffield syndicate, constituted under the name of the Sheffield and South Yorkshire Navigation Company, purchased the Don Navigation, connecting Sheffield, Rotherham, Barnsley, and Doncaster with the Trent at Keadby and the Ouse at Goole, from the Manchester and Sheffield Railway Company. The Grand Junction Canal Company also has recently acquired control of the tolls between Birmingham and London, by arrangement with the Oxford, Warwick and Napton, and Warwick and Birmingham Canal Companies, and has obtained powers to quote through rates for the conveyance of coal from the Derbyshire coalfields to London, by making agreements with the Leicester and Loughborough Navigations and Erewash Canal Companies. Moreover, in order to expedite the traffic on this latter route, a lift is being erected at Foxton, in place of a flight of ten locks with a total rise of 75 feet. These are steps in the right direction, placing navigations in the hands of bodies who will be interested in developing them; but these are only two out of several main routes greatly needing similar arrangements. Much, moreover, requires to be done to make these routes thoroughly satisfactory waterways, capable of accommodating a large traffic. The Don Navigation has, indeed, the good available depth of 6½ feet, and width of locks of 17 feet, corresponding to the standard dimensions on the main French waterways; but the length of the locks is only from 61 to 69 feet. The Grand Junction Canal also, which accommodates vessels 72 feet long, 14 feet beam, and 4 feet draught, has a link, known as the Grand Union Canal between Long Buckley and Foxton, connecting it with the Leicester Navigation, where the width of lock is only 7¼ feet; whilst the new waterways, over which the company has acquired control, have locks similar in dimensions to the main route, but an available depth of only 3½ feet. The canals also forming its route to Birmingham, have locks giving an available width of only seven feet and depth of 3¾ feet. These waterways leading to Birmingham have a moderate traffic, though some of it must follow the Oxford route; but the Grand Union Canal and the Leicester and Loughborough Navigations have a traffic of under 100,000 tons, and the Erewash Canal only slightly over this.

These routes furnish an illustration of the want of uniformity on the main routes of English waterways.

COMPARISON OF RAILWAYS AND WATERWAYS.

A Table has been drawn up giving a few statistics furnishing a comparison, as regards length, traffic, and average journey, between the railways and waterways in England, France, Belgium, and Germany. The absence of proper returns has rendered it impossible to complete the statistics for England. The Table shows that England, including Wales, has a much larger railway mileage in proportion to its area than the other countries, and that Belgium comes nearest to it; but that Belgium possesses the largest proportion of waterways to area, and that England comes second, considerably in advance of France, and with nearly double the proportion of Germany. The actual railway mileage in England is only about two-thirds that of France and of Germany; but the mileage of the United Kingdom is only slightly less, having reached 21,433 miles in 1897. Holland, indeed, the land of canals, having 20 miles of waterways per 100 square miles, is far in advance in this respect of any other country;* but this very flat, low-lying country stands apart from other countries as regards its water communications, and does not afford a proper basis of comparison.

The absolute goods traffic is far larger on the railways in England than in France or Germany, and about nine times the traffic on the English waterways; but the actual weight of goods conveyed on the waterways in England was somewhat larger in 1888 than it is at present in France or Belgium, and much greater than in Germany, in spite of the great improvements effected in the waterways, and constant encouragement afforded to inland navigation on the continent. The large tonnage, indeed, carried on English waterways, in the face of culpable lethargy, great obstacles, and the unusual facilities offered by the railways, furnishes some indication of the very flourishing condition inland navigation would have attained in the mining and manufacturing districts of England, if anything like the energy displayed in railway extension had been devoted to making the old waterways suitable for modern requirements.

* "Rivers and Canals." L. F. Vernon-Harcourt, 2nd edition, 1896, vol. ii., p. 488.

Unfortunately there is no possibility of ascertaining the ton-mileage, the density of the traffic, or the average journey of goods on English railways and waterways, for comparison with similar statistics in other countries. It will be noticed that the average density of the traffic, represented by the average ton per mile of way, is very similar for the railways and waterways in France and in Germany, though owing to the more central position of Germany and the favourable conditions of its large rivers, the traffic is larger there than in France. The average traffic on the Belgian waterways is considerably larger than on the railways; but this difference would be considerably reduced if the statistics had related to the whole length of waterways. The ton-mileage is the real measure of the traffic of the railways and waterways of a country, as it depends upon the distances along which the goods are carried, as well as their amount; and it is the return from which the average traffic and average journey are deduced. The ton-mileage is in all three countries larger on the railways than on the waterways, a result naturally due to the greater length of the railways. The density of the traffic is greater on the waterways of Belgium and Germany than on the railways; whilst the average journey on the waterways of France, and notably on those of Germany, is greater than on their railways. The waterways in regular use in France, Belgium, and Germany evidently carry a full proportion of the goods traffic; for the railways, which comprise 76.6 per cent. of the combined length of the railways and waterways of these countries, convey a traffic whose ton-mileage amounts merely to 75.7 per cent. of the whole, so that the waterways carry about 1 per cent. more of the traffic than their proportionate amount according to their length.

CONCLUSIONS RESPECTING INLAND NAVIGATION IN ENGLAND.

In all the countries which have been considered, a considerable inland navigation traffic exists; but the large traffic is confined to certain waterways suitably situated for securing a large traffic in bulky goods. And in all these countries, with the exception of England, after a period of indifference on the advent of railways, strenuous efforts have been made in recent years to improve, render more efficient, and complete the main waterways of the country, thereby securing a benefit to the country, providing a useful automatic check on the railway rates, and serving

B. Wells, Manchester, 1892. 3 "Statistique des Chemins de Fer français au 31 Décembre, 1896," Paris, 1898, p. 179. 4 "Statistique de la Navigation intérieure, Relevé général du Tonnage des Marchandises, 1897," Paris, 1898, vol. i., pp. 14 and 66. 5 "Chemins de Fer, Royaume de Belgique, Compte Rendu des Opérations pendant l'Année 1897," Brussels, 1898, pp. A 9 and A 10. 6 "Le Congrès International de Navigation, Guide Programme, Bruxelles, 1898," pp. 204 and 206. 7 "Fourth International Inland Naviga-

tion Congress, Manchester, 1890," "Traffic on German Waterways for the years 1875 and 1885," Sympher, p. 4. 8 The French Railways consist of 20,768 miles conceded to private companies, and 1,895 miles of State railways. 9 In Belgium, 2048 miles of railways are in the hands of the State, and only 27 miles belong to private companies. 10 The actual length of navigable waterways in Belgium is 4,365 miles; but returns are only rendered of 1,012 miles. 11 The length of railways open in Germany in 1896, was 28,071 miles, which gives 13.29 miles per 100 square miles. 12 The present length of inland waterways in Germany is about 6,400 miles, or 103 miles per 100 square miles. 13 As the number of ton-miles is not given in the returns of the Belgian railways, the average goods train journey has been taken as the nearest approximation available.

relieve the railways of somewhat burdensome traffic.

In the early days of canal enterprise, the waterways of a country formed the chief routes of economical carriage; but on the introduction of railways, the scope of waterways became necessarily restricted. Where the population is scattered and there is an absence of minerals or manufactures of bulky goods, and especially where the country is also somewhat rugged, a railway which can follow more nearly the irregularities of the surface, by gradients in place of level reaches, and can adopt a more direct course, serves more suitably the requirements of the district, and has better prospects of a return on the expenditure. Old waterways in such situations might advantageously be maintained, at a moderate cost, to serve the immediate district they traverse; but a large improvement of such waterways would not be economically justifiable.

In the present day, in face of the competition of railways, the primary requirement for a waterway is the existence of bulky goods which it may convey to large towns, or from inland mining or manufacturing centres to a seaport. Without such traffic, a very commodious waterway will languish; whereas with minerals or bulky manufactures, even a waterway of very inadequate width and depth may maintain a good traffic, as evidenced by the Birmingham, the Leeds and Liverpool, and other English canals. The second requisite, to enable a waterway to compete successfully with railways and enlarge its traffic, is uniformity of dimensions along the whole course of its main line, with a good depth and width, and ample size of locks, so as to afford a passage for large barges, and expedite their transit. Great differences of level on a waterway are prejudicial to its prospects of traffic; for not only do such conditions greatly increase the cost of first construction and subsequent enlargement, but unless inclines are adopted, or costly hydraulic lifts, there is a great delay in the passage through flights of locks and a large expenditure of water. Canals, under these circumstances, which might be expected to form useful links between important navigations, fail to attract trade, such, for instance, as the Ludwig Canal, connecting the Rhine and the Danube; whilst a second-class waterway, with a more moderate summit-level, may be preferred to a first-class waterway, as in the case of the Loire lateral Canal, which secures the greater part of the traffic between the Saône and the Seine,

though there is a shorter and larger waterway by the Bourgogne Canal. Every improvement in the main waterways of Germany has been accompanied by a large increase in traffic, and the enlargement, extension, and promotion towards uniformity of the main lines in France and Belgium have been attended by a remarkable growth of traffic, as illustrated in the case of France by Diagram 3.

The experience gained from a review of traffic returns of all the countries for which such statistics are available, shows that improvement and unification of dimensions of English waterways should be confined to those waterways included within the zone of the mining and manufacturing centres, leading from them to the Mersey, the Humber, the Thames, and the Severn. These waterways should form the subject of a careful thorough inquiry, in order that the improvements needed, their extent, and their cost, may be accurately ascertained, as portions in the case of a complete scheme. England does not possess the magnificent natural waterways of North America, the large rivers of Germany, or even opportunities for such long artificial waterways as France; but it possesses in a limited region, in bulky goods, what even the neglect of about three-quarters of a century has not sufficed to drive away from its antiquated waterways; and it is evident that the enlargement of these waterways, if feasible within reasonable limits of expenditure, would even at this late period, judging from the experience of the Weaver, the Aire and Calder, and the principal waterways of Europe, be attended by most satisfactory results to the waterways themselves, the trade of the country, and the population in general. If the future water-supply of London is considered of sufficient importance to engross the attention of two Royal Commissions, it cannot be much to ask that a Commission may be appointed to hold an inquiry on the means of promoting inland navigation to the industrial centres of England, a subject which has been considered worthy of the cordial support of the Governments in other foremost countries of the world, and which has an important bearing on the trade of the country and the general prosperity of the community. In the meantime, considering that the statistics of the canals and navigation of the United Kingdom are already ten years old, are acknowledged to be incomplete, and do not afford any indication of the distribu-

the traffic on the several waterways, the Board of Trade might be urged to collect a fresh set of complete statistics to assist the labours of the proposed Commission, to indicate the growth or decrease of traffic on the waterways since 1888, and to afford suitable statistics as to the distribution of traffic on the waterways, as furnished by the Governments of the United States, Germany, France, and Belgium. Ways of communication are to a country like the arteries to the body; and the waterways which affect the central and most flourishing and industrial portion of England cannot, any more than the arteries near the heart, be suffered with impunity to be paralysed or neglected.

DISCUSSION.

The CHAIRMAN said that having spent a large portion of his life in the improvement of canals and rivers, it was a great pleasure to him to take the chair on that occasion, and he had listened to the paper with great interest, for it summed up the matter very completely, and he perfectly agreed with the conclusions arrived at. Mr. G. R. Jebb, engineer to a large series of canals mentioned in the paper, carrying a traffic of $7\frac{3}{4}$ million tons—the Birmingham Canal and Shropshire Union connecting the Birmingham Canal with the Manchester Ship Canal, had written the following letter:—

“18th January, 1899.

MY DEAR LEADER WILLIAMS,

“I am leaving this to express my regret that (at the last moment) I am prevented from being here to-night to listen to Mr. Vernon-Harcourt's paper on canals, and to support you in the Chair. I shall look forward with interest to seeing his paper in the *Journal* on Saturday. I trust he may have been inspired to make some practical suggestion for the betterment of our poor, narrow canals. I confess the more I study the problem the more of a pessimist I become—*i.e.*, so far as the enlargement of our narrow canals is concerned. I think some amelioration of their condition may be effected by (1) the construction of lifts or inclined planes in lieu of locks, as is being done on the Grand Junction, and as was contemplated by the Birmingham Canal Company a few years ago: Parliamentary plans were deposited for two inclined planes in the Black Country, but the Bill was not gone on with in consequence of the action of the Board of Trade with reference to canal tolls; and (2) by improvement in method of haulage: as, as you know, is a most difficult subject on the narrow shallow canals with locks about 7 feet 6 inches deep, and from 4 feet 6 inches to 5 feet of water on the sills. Mr. Parker, the eminent electrician of Southampton, went very thoroughly with me into

the question of electrical haulage a few years ago, but failed to suggest a practical scheme. The problem is still being worked out by others. In the autumn of last year I made some experiments on the Birmingham Canal with “compartment” boats, similar in principle to that adopted so successfully many years on the Aire and Calder by Bartholomew. I shall go on with the experiments in the spring. One meets with a good deal of opposition from the boatmen, who look with much suspicion on any innovation.

“G. R. JEBB.”

The Weaver Navigation, to which he (the Chairman) was engineer for seventeen years, had been prominently referred to; for that he designed and partly carried out certain improvements, which were continued by Mr. Wells, his successor, when he joined the Manchester Ship Canal, and the result showed what an advantage it was to increase the width and depth of a Navigation. When he joined in 1857, having previously assisted his father in improving the Severn Navigation, he found the traffic conducted in barges of from 60 to 70 or 80 tons, drawn by two horses, from Winsford to Weston Point, on the Mersey, from whence they went by the tide to Liverpool, the traffic, which was salt, being about $1\frac{1}{2}$ million tons a year. Much of the trade was carried by rail, and the owners of the navigation had to consider what should be done. He advised certain improvements, and the result was that to-day steamers carrying 200 to 300 tons, drawing 10 feet, passed down that canal, and each steamer towed two other craft behind, with an equal burthen, so that the gross amount was nearly 1,000 tons. The cost of taking it all the way from Winsford through the Mersey to Liverpool was something like 6d. per ton, and none of the railways carried salt to the docks at Liverpool; it all went by water. The railways could not compete at such a rate, and there was the additional advantage that warehouse room was saved, as the barges lay outside the ships, and discharged direct on board, whilst the other cargo was being loaded from the wharf. It was then his good fortune to be appointed to the Birmingham canals, and the question arose whether the traffic there could be improved. It would have been a very costly matter to introduce steam navigation, because there was only a barge canal; but it was not a narrow canal, and it had to be remembered that the cost of working a barge did not increase in the same ratio as the size of the vessel. The same crew would work 50 tons with the same ease as a smaller boat, and if there was sufficient depth, and a good sectional area, the same horses would do it. On the Bridgewater Canal they had something like 350 horses, and when they got the glands amongst them, and about 150 had to be shot, he made up his mind to use steam, although the depth was only $3\frac{1}{2}$ or 4 feet. He put on 25 small steam tugs, and three 50-ton barges, which worked at a speed of $2\frac{1}{2}$ or 3 miles an

hour, with great regularity. The class of men who worked the horses on a towpath were fit for nothing else, and great delay and difficulty was constantly arising, but on the steamboats they had a good class of men, who got a bonus for good behaviour, and they took great care that the three barges behind followed all right. The result was that the working expenses were reduced 40 per cent., and the company paid 8 per cent. dividend. The value of a canal to a country like England must not be judged merely by the amount of traffic carried; it lay in the competition. When Sir James Allport was asked in the Parliamentary Committee, when the Midland Railway was trying to buy the Worcester and Birmingham Canal, so as to control the traffic from the South Welsh ports to Birmingham, how it was that the traffic from the East Coast was not cheaper than from the South-West, he said there was the River Severn Navigation, and though it did not do a large traffic, if the Midland did not keep their rates down to the same point they would lose the trade. The canal they wished to purchase was the branch from the Severn to Birmingham, and on that evidence, of course, the case was gone. Sir Richard Moon, the late Chairman of the London and North-Western Railway, made a similar statement at a shareholders' meeting, when he was asked why, between certain points, the rates were different; he said presumably, in that case, there was water competition. The paper showed that every improvement in the main waterways of Germany had been followed by a large increase of traffic. That was what all our foreign competitors were doing, and Germany especially was our great competitor. He went into a shop the other day to buy some tools, and was offered some of German make, better finished than the English, and 30 per cent. cheaper. That was in a country town in Cheshire, and it showed how Germany was beating us. That class of goods, and many others, were of considerable weight, and the cost of carriage was important. France, Belgium, and other nations were giving every facility for cheap carriage. He saw in the *Times* that the German Emperor, in his speech at the opening of the Diet, referred to the subject of inland waterways, and said that a Bill would be submitted for the construction of canals connecting the Rhine and Elbe canals, and facilitating communication between the navigable rivers. The great value of this paper lay in the general considerations it put forward. They must build railways where speed was required, but canals could carry much more cheaply, there were no rails or sleepers required, they were more economical in working, and for slow traffic were preferable. It was difficult to say how the work should be done. It might be that it should be a national undertaking, as it was in America, France, Belgium, and Germany, where the Government assisted the canals the same as the railways. He agreed with Mr. Harcourt that it would not pay to improve small canals in agricultural districts, but only where there was heavy traffic,

mineral or otherwise. Mr. Lloyd, of Birmingham, who took a great interest in this question, suggested a main canal joining the Severn, Birmingham, and Wolverhampton with the Mersey at Liverpool, and another from Birmingham to London utilising the Grand Junction Canal. This would unite the main parts of the kingdom, and would to a very large extent meet the case.

Sir DOUGLAS GALTON, K.C.B., F.R.S., said he had been connected for many years with the Birmingham Canal, which had special difficulties in connection with its construction and maintenance. There were many parts which when he joined it first were cuttings which were now on embankments of a considerable height, and there were in some places bridges which used to go over the canal which were now standing 40 or 50 feet in the air above the surface of the ground. That canal rested very largely on the coal measures, which had been gradually taken away and the ground had sunk, so the engineer had had to keep the canal watertight whilst the rest of the country had been sinking away from it. Mr. Jebb therefore, deserved the greatest commendation for the manner in which he had maintained that canal. In the same way, as the locks were being perpetually pulled to pieces, Mr. Jebb devised a system of inclined planes to supersede them in certain places, but Parliamentary proceedings connected with the tolls, made the directors consider it inexpedient to go on with the scheme at the time. He agreed with the Chairman that it was very desirable to have a canal from the sea or from the Manchester Ship Canal, perhaps to Birmingham on one side and to London on the other, and he should also like to see it go to Bristol, where Birmingham would be in a very satisfactory position with regard to its inland trade. He had never seen a paper on canals which treated so fully and admirably the whole subject of waterways, and the Society and all England in fact, ought to be very grateful to Mr. Harcourt for the trouble he had taken in preparing it.

Mr. L. B. WELLS said he had been interested in canals for twenty years or more, having followed the Chairman on the Weaver Navigation; and the work he initiated there had now been completed in the main, the old style of lock having been recently cleared away by his successor, so that ships of 200 feet length and 30 or 40 feet beam could now go to the head of the salt district. He found only one of those large locks completed, and he himself completed four others; and in the meantime the river was being deepened. He found that whenever an additional 6-inch draught was given, traders took advantage of it, and when facilities for an additional 5 feet length were afforded, many of the most enterprising lengthened their vessels. The great point to be looked to was the cheapening of transport, for the charges were higher in England than in any other country in the world. If we were to compete with other countries for the trade of the world, we must be able to transport

goods as cheaply as they did; and as railways not compete in rates, all real competition could be obtained by an independent route, such as a waterway. On a waterway any trader who thought could do better for himself than by employing a steamer could have his own boat, and this was a great check on the charges. It did not pay anyone to carry for themselves; but on the other hand, where large tonnage was despatched by individuals or firms, they built their own boats, and loaded their own salt from their works to the ships at Liverpool. The Bridgewater, which was a very narrow canal, as a barge canal, was vastly improved by the Chairman, when he adopted steam traction. It served a coalfield in Lancashire much as the Weaver served the saltfield in Cheshire. The Weaver had a depth of 10 feet, and the tonnage carried to Liverpool and the Mersey was two-thirds the whole output of the salt district, while the railways only taking one-third. The Bridgewater also took one-third the output of the coalfield, and the railways two-thirds. That was a conclusive proof of the advantage of large canals. The condition of the country was well shown by the Table in which there were six squares at the bottom not filled up because there was no information available. It was extraordinary that a great commercial country should be content to remain in such a state of ignorance. The idea was that as canals existed before the Board of Trade, the Board was afraid to press for information and returns, as it did in the case of all new public enterprises, such as tramways, electric light companies, and so on. There had been only one return called for with respect to canals, and that was ten years ago. He received a circular was issued at the beginning of this year, asking for further information, and he hoped it would produce further returns than had been obtained heretofore. Seeing the attention paid to intercommunication in France and elsewhere, although the traffic carried was much less than in England, it was surely time that something should be done at home at least to obtain full information.

Mr. MARTIN WOOD said it was ten years since the Society of Arts had a Conference on Inland Navigation, and he was about to suggest that some steps should be taken to ascertain and publish in the *Journal* the progress which had been made since then, but the present paper had done that to a certain extent; though, as had been pointed out, there were no official statistics since that time. It was a most valuable suggestion that the Board of Trade should be urged to fill up the gap; but a Royal Commission was almost a word of dread, and he hoped some more efficient means might be devised for bringing the subject before the minds of the public and of responsible statesmen. The extraordinary negligence which had been displayed was well described in the paper. Of course there was a constant powerful, passive obstruction in the way, the great railway interest, and the great popular

feeling in favour of railways. It was therefore very important that such a paper as this should be published, and he hoped it would open the eyes of public men to the necessity of developing inland navigation, especially in view of the competition to which we were exposed by other countries.

Mr. HUBERT THOMAS, general manager to the Grand Junction Canal, said he had acted on one of the recommendations of the Board of Trade, viz., for amalgamation. After the inquiry of 1888 his company said they would adopt the suggestion then made, and amalgamate as far as possible the inland navigations with which they were concerned, viz., between London, Birmingham, Leicester, and the coalfields of Derbyshire. It had only been going on for a short time, but they had purchased two canals and entered into working arrangements with eight others, and were now in a position to quote a through toll for a distance of over 300 miles. That principle ought to be adopted in the north as well as the south; and if there were one or two great combinations, they could free themselves from railway control. A large trader came to him to know if he could arrange for his traffic from Manchester to London, and he said he could. He was paying a fabulous sum by rail, and he had no doubt that if the arrangement was carried out, as he hoped it would be, that traffic would be carried for one-fourth what was now paid. The person referred to said if he once put his goods on the canal he should keep them there; but unfortunately the experience of canal managers was that the canal was simply used as a lever to keep down the railway rates. If it were not for the canals, the rate for the carriage of coal to London would be 8s., 9s., or 10s. a ton. He did not agree with one part of the paper, where, as he understood, the author said there would be little advantage in widening long sections of inland navigation, because that was exactly what his company were doing for some 150 to 200 miles, where there was no great centre of traffic; this, however, would enable them to connect London and the coalfields, so that barges of 60 or 80 tons could come straight through.

The CHAIRMAN said he thought Mr. Harcourt was only referring to agricultural traffic in the passage to which Mr. Thomas had alluded. It was quite true that the canals did not get their fair share of the traffic. They did an enormous good to the public in keeping down heavy rates, and the least the public could do was to put more traffic on them. He begged to move a cordial vote of thanks to Mr. Vernon-Harcourt for his paper.

The vote of thanks having been carried unanimously,

Mr. VERNON-HARCOURT, after expressing his gratitude to the meeting for the vote of thanks, said he thought that if Mr. Thomas would examine the paper

he would find that they were entirely in accord. The Grand Junction was one of the canals which he had drawn attention to as a proper one to be improved. Those which he thought it would not pay to improve, were some of those in the south where there was no bulky traffic to be carried, such as coal or other minerals, and large merchandise.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 25.—“Tuberculosis in Animals.” By W. HUNTING. R. BRUDENELL CARTER, F.R.C.S., will preside.

FEBRUARY 1.—“The Cost of Municipal Enterprise.” By DIXON H. DAVIES. The ATTORNEY-GENERAL will preside.

FEBRUARY 8.—“Nernst's Electric Lamp.” By JAMES SWINBURNE.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 9.—“The Penal System at the Andamans.” By Colonel RICHARD CARNAC TEMPLE, C.I.E., Chief Commissioner of the Andaman Islands. The EARL OF NORTHBROOK, G.S.I., D.C.L., F.R.S., will preside.

FOREIGN AND COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

JANUARY 24.—“Rhodesia and its Mines in 1898.” By WILLIAM FISCHER WILKINSON, F.G.S., Assoc. M.Inst.C.E. The Hon. Sir DAVID TENNANT, K.C.M.G., Agent-General for Cape Colony, will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

JANUARY 31.—“The Centenary Exhibition of Lithographs, with remarks on further Developments of the Art.” By EDWARD F. STRANGE. Major-Gen. Sir JOHN DONNELLY, K.C.B., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

DR. SAMUEL RIDEAL, “Bacterial Purification of Sewage.” Four Lectures.

LECTURE II.—JANUARY 23.

Recognition of the function of bacteria, and researches on them—Massachusetts, Barking, and Sutton experiments—Schemes for aeration: Lowcock, Waring, Ducat—Materials—Garfield's coal filter—Manchester and Leeds experiments.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Dr. Samuel Rideal, “Bacterial Purification of Sewage.” (Lecture II.)

Imperial Institute, South Kensington, 8½ p.m. Mr. E. T. Scammell, “The Work and Wear of Western Australia.”
Surveyors, Savoy-street, W.C., 8 p.m. Mr. E. T. Scammell, “Rating of Collieries.”
Geographical, University of London, Burlington-gardens, W., 8½ p.m.
British Architects, 9, Conduit-street, W., 8 p.m. Presidential address to students, and presentation of prizes.
Medical, 11, Chandos-street, W., 8½ p.m.
London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Shelford Bidwell, “Optical Illusions.”

TUESDAY, JAN. 24...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Foreign and Colonial Section.) Mr. William Fischer Wilkinson, “Rhodesia and its Mines in 1898.”
Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lankester, “The Morphology of Mollusca.” (Lecture II.)
Medical and Chirurgical, 23, Hanover-square, W., 8½ p.m.
Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers by Mr. William Kirkaldy, “The Effects of Wear upon Steel Rails,” and Sir William Roberts-Austen, “The Metallurgy of Steel Rails.”
Photographic, 12, Hanover-square, W., 8 p.m. Technical Meeting. Mr. John Sterry, “The Development of Gelatino-Chloride Papers.”
Anthropological, 3, Hanover-square, W., 8½ p.m. Annual Meeting.

WEDNESDAY, JAN. 25...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. Hunting, “Tuberculosis in Animals.”
Japan Society, 20, Hanover-square, W., 8½ p.m. Conversazione.
British Astronomical, Sion College, Victoria-embankment, W.C., 5 p.m.

THURSDAY, JAN. 26...Royal, Burlington-house, W., 4½ p.m. Antiquaries, Burlington-house, W., 8½ p.m. London Institution, Finsbury-circus, E.C., 6 p.m. Mr. F. W. Sawyer, “Our National Songs.”
Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. H. Savage Landor, “Tibet and the Tibetans.” (Lecture II.)
Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. J. Pegg, “Rules for the Regulation of the Wiring of Premises for Connecting Public Supply Mains.” 2. Mr. C. H. Worham, “The Regulation of Wiring Rules.” 3. Mr. R. E. Crompton, “The Institution Wiring Rules.”

FRIDAY, JAN. 27...Royal Institution, Albemarle-street, W., 8 p.m., Weekly Meeting. 9 p.m., Sir M. Stuart E. Grant Duff, “Epitaphs.”
Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. F. C. Grieg, “King's Lynn Water Works.”
Junior Engineering, Westminster Palace Hotel, S.W., 8 p.m. Prof. J. A. Ewing, “Measurements of Elasticity.”
Clinical, 20, Hanover-square, W., 8½ p.m.
Physical, Chemical Society's Rooms, Burlington-house, W., 5 p.m.

SATURDAY, JAN. 28...Botanic, Inner Circle, Regent's-park, N.W., 3½ p.m.
Royal Institution, Albemarle-street, W., 5 p.m. Sir Alexander Mackenzie, “Tschaiakowski.” (Musical illustrations.)

Journal of the Society of Arts.

No. 2,410. VOL. XLVII.

FRIDAY, JANUARY 27, 1899.

*All communications for the Society should be addressed
to the Secretary, John-street, Adelphi, London, W.C.***Notices.****SWINEY PRIZE.**

A meeting of the adjudicators of this prize, appointed by the will of the late Dr. Swiney, was held on Friday, January 20, 1899, at the Society of Arts, at 4 p.m., Sir JOHN WOLFE BARRY, K.C.B., Chairman of the Council, in the chair.

The Secretary read the advertisement concerning the meeting.

The Secretary read a report from the joint Committee of the Society of Arts and the College of Physicians, recommending that the prize should be awarded to Dr. J. Dixon Mann, for his work entitled "Forensic Medicine and Toxicology."

It was thereupon moved by Sir John Wolfe Barry, seconded by Dr. Cheadle, Senior Censor of the College of Physicians, and resolved, That the prize, a silver goblet value £100, containing gold coin to the same amount, be adjudged to Dr. J. Dixon Mann, F.R.C.P., Professor of Forensic Medicine and Toxicology Owens College, Manchester, the author of a published work on 'Forensic Medicine and Toxicology.'"

The cup has been executed by Messrs. Garrard, from a design made for the Society by the late Daniel Maclise, R.A.

CANTOR LECTURES.

Dr. SAMUEL RIDEAL delivered the second lecture of his course on "Bacterial Purification of Sewage," on Monday evening, 23rd inst.

The lectures will be printed in the *Journal* during the summer recess.

FOREIGN & COLONIAL SECTION.

Tuesday afternoon, January 24th, 1899; the HON. SIR DAVID TENNANT, Agent-General for Cape Colony, in the chair.

The paper read was "Rhodesia and its Mines in 1898," by William Fischer Wilkinson, F.R.G.S., Assoc. M.Inst. C.E.

The paper and report of the discussion will be printed in the next number of the *Journal*.

COVERS FOR JOURNAL.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied post free for 1s. 6d. each, on application to the Secretary.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

Proceedings of the Society.**INDIAN SECTION.**

Thursday afternoon, January 19, 1899; Sir ALEXANDER MACKENZIE, K.C.S.I., in the chair.

The paper read was—

RAILWAYS IN BURMA, AND THEIR PROPOSED EXTENSION ACROSS YUNNAN.

BY JOHN NISBET, D.Oec.,
Conservator of Forests, Burma.

When considered as to ultimate effects, there is probably no question of foreign policy which at present more closely touches the commercial interests of Great Britain than the series of problems gradually solving themselves in China. Whether the Chinese Empire continue to remain more or less consolidated, even though honeycombed by "spheres of influence," or whether it be ultimately partitioned into territories actually under the dominion of Russia, Germany, France, Japan, and Great Britain, there can be no doubt that British interests in China at the present moment bulk largest in every way.

The study, unbiassed by any political prejudice, of the numerous articles which have recently appeared with regard to China and Chinese trade in all of the leading reviews—articles of praise, of censure, and of exhor-

tation — will show that, within reasonable limits, the Government of the day have been fully alive to the political and commercial interests of Britain in the Far East, and that they have amply paved the way for the further development of these interests. This being the case, it is gratifying to find that commercial bodies and industrial syndicates are now energetically bestirring themselves, and taking the necessary steps to push their own individual or collective interests. The onus of further action rests mainly with them, and not merely with our diplomatists.

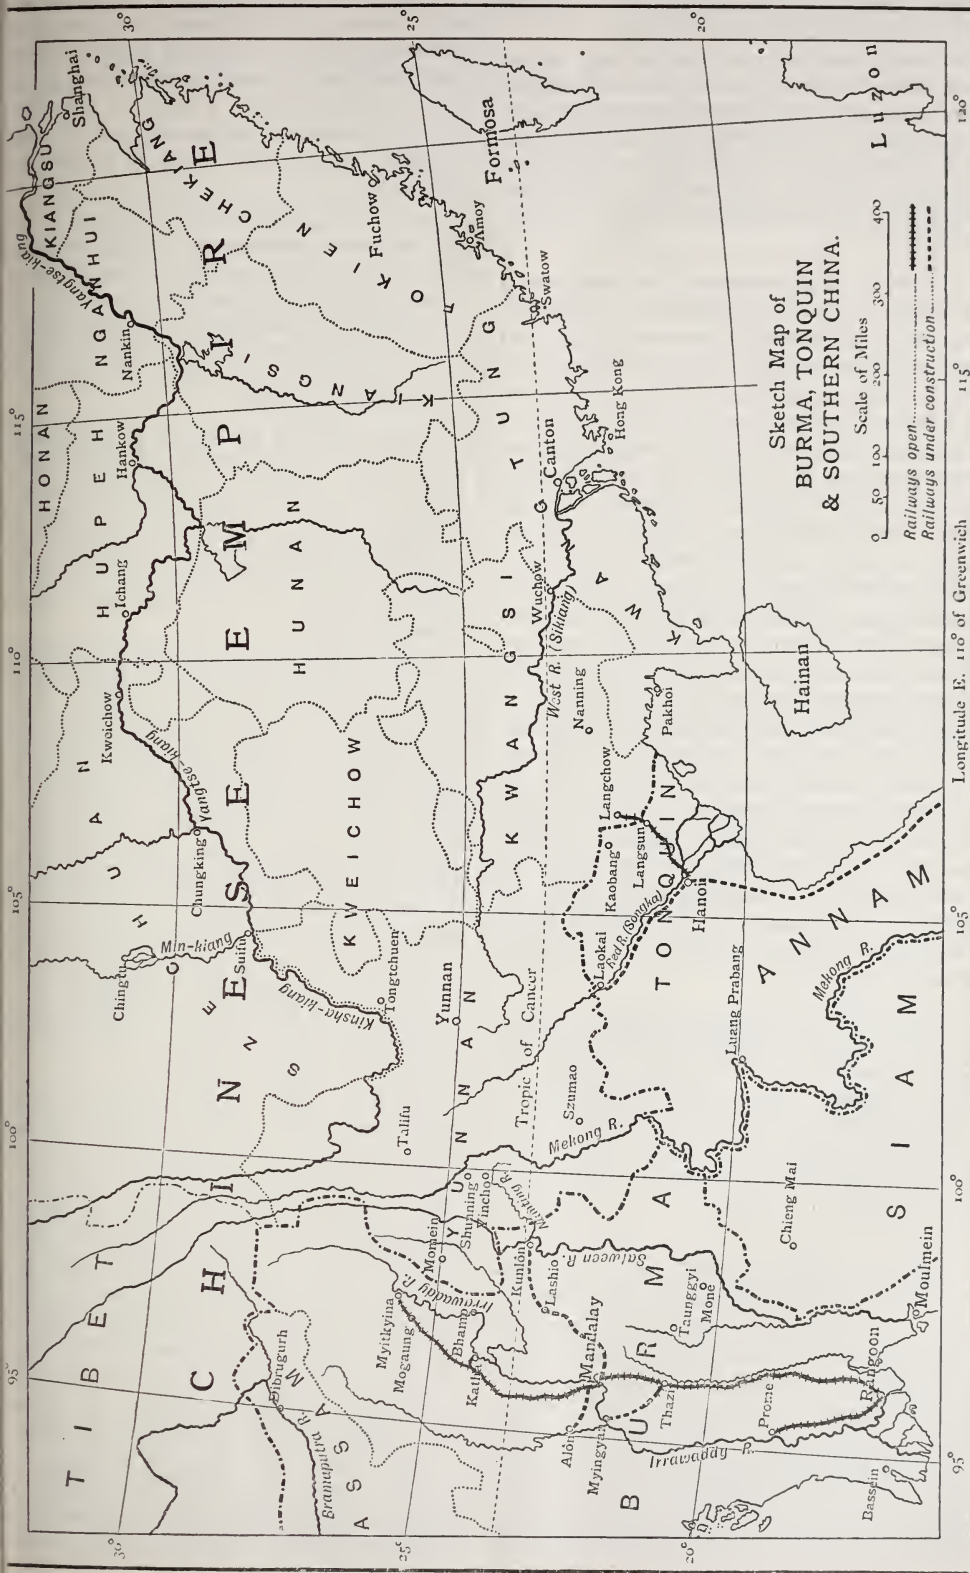

As the object of the present paper is to deal more particularly with the proposal to extend the railway now under construction from Mandalay to the Salween River so as to push it on further eastwards to tap the trade of Yunnan—presuming that there is any trade really worth tapping—and perhaps even to reach an objective point on the Yangtse-kiang whence steam communication to and from Shanghai may ultimately be possible, it is hardly necessary to consider the present political position in the Far East of any other rival European power except France in connection with this special phase of the China question.

The Yangtse drainage comprises the rich provinces of Kiangsu, Nganhui, Kiangsi, Hupeh, Hunan, Szechuan, and the northern portions of Kweichow and Yunnan, the trade to and from all of which must naturally proceed by way of the Yangtse-kiang. If the supremacy of British interests in this sphere, the most important part of China, were to be threatened, as some have predicted, by France endeavouring from the south to join hands with Russia from the north with a view to excluding the British from the Yangtse Valley, this might, and in all probability would, necessitate the valley being formally assigned to us as a recognised "sphere of influence," or it might even lead to a British protectorate being formed there. We hear much of the "open door" policy. It must, however, be clearly understood that we require not only such an open door but also a through passage from Shanghai and Hongkong to Assam and Burma. So far as British commerce in the main portion of the Yangtse Valley is concerned, the natural lines of transport all converge towards Shanghai, and the trade capable of development in that sphere could never profitably find its way out through Burma; while the promise extended to France with regard to the three southern provinces

(Kwantung, Kwangsi, and Yunnan) marching with French Indo-China, is very far from being equivalent to granting that empire the sole right of trading there. At the same time we shall indeed be blind to the lessons learned during the past decade and a half if we do not carefully watch the action of our French neighbours, our political and commercial rivals in south-western China.

The recent railway reconnaissance survey by French officials from Kwangtung through Hunan to Hankow, referred to in the *Nineteenth Century* for September, 1898 (page 389) shows how essential vigilance and a definite attitude are. And if there is any real political danger from such causes, then the simplest and cheapest method of frustrating unfriendly intentions is obviously to be beforehand in enterprise. The attainment of this end would probably be assisted by the commercial occupation of all essential points by means of increasing the number of British consuls. Between the present consular posts of Chungking, in Szechuan, and those of Momein and Szumao, in Yunnan, the distance is about 600 miles. The diplomacy which early in the present year obtained from China the indirect and informal guarantee against cession of any portion of the Yangtse Valley to any foreign power and the right to construct a railway from the Burmese frontier to that valley, should, if necessary, be able to obtain the privilege of posting consuls and allowing British subjects to establish themselves and to trade at important points further west, such as Suifu, Chingtufu, Tongtchuenfu, and Talifu. In addition to the consuls at Momein and Szumao, the only other resident British officials now on that Chinese frontier are the subalterns in charge of detachments of the Burma military police force stationed at Sima and Sadon, between Momein and Myitkyina, and at Satisu, about forty miles to the north-east of the Kunlón ferry on the Salween river.

The natural outlet for trade throughout practically the whole of the Yangtse Valley is, as already stated, eastwards towards the coast. Even under the most favourable circumstances it would be only a small and comparatively insignificant portion of its commerce which could be profitably diverted towards Burma. With the Yangtse navigable for 2,000 miles as to its main branch, and for another 1,000 miles as regards its chief affluents, there seems little chance of any important deflection of trade from this natural outlet towards Shanghai. Mr. Little's evidence is very clear on this

Walter & Bacon's sc.

point, as given in the *Contemporary Review* for September, 1898 (page 366)—

“Szechuan is a land apart; and, although tedious land roads, literally footpaths, climb by wearying staircases over the wall in other directions, giving it communication with Peking, to the north-east, and with Talifu, the great city of the Yunnan province in the south-west, yet the only really serviceable communication with the outside world is by way of the Great River.”

Moreover, this description can equally well be applied, so far as the mule and cattle tracks are concerned, to the trade routes leading westwards from the province. What trade there is on the Yunnan plateau, which varies from 5,000 to 8,000 feet in elevation, and whose capital is Yunnanfu, though by far its most important trading centre is Talifu, may very possibly find its way into Burma. It probably already does so, even without any expensive railway. So far as concerns the bulk of the traffic that will interest Europeans, however, this must naturally proceed eastwards down the Yangtse-kiang. Mr. Bourne, of the Blackburn Commercial Mission, has shown that the first step towards tapping this trade is not a railway, but the extension of steam navigation on the Great River from Ichang to Chungking and thence to Suifu, 1,700 miles from Shanghai. Towards this end the recent promise of China to open the rivers to trade and to establish a treaty port in Hunan is a distinct step, while the following Reuter's telegram, despatched from Peking on 14th January, and appearing in all the London papers three days ago, seems full of hope and promise:—

“Mr. Liverkaye, representing a British Syndicate, has proposed to survey the Yangtse Gorges with a view to removing obstructions to navigation. At present navigation between Ichang and Chungking is slow. Several attempts have already been made by the Chinese to effect an improvement. The proposal, if realised, will confer an enormous advantage on British commerce. Repayment will be effected by tonnage tolls.”

These are obviously sound commercial proposals which are already receiving consideration, and which are certain to be seriously entertained as soon as ever merchants obtain something in the shape of guarantees respecting the capital involved in extensive investments of this nature. Obviously to give or to obtain such guarantees is equally the duty of the British Government in the interests of British commerce. The recent loan to China of £12,000,000 at 3 per cent. is, strengthened

by the conditions attached to it, in itself almost of the nature of an informal guarantee that British commercial interests in the Yangtse Valley will be adequately safeguarded by the British Government. Viewed in this light Mr. Little's further information is here again of great interest and worthy of serious consideration:—

“It is no exaggeration to say that, given a stable and progressive Government, affording encouragement to capitalists with security for their investments—resulting in improved means of communication—a corresponding development of its natural resources—the Yangtse Valley will increase its trade by leaps and bounds, and the £30,000,000 of to-day will be £300,000,000 to-morrow.”

If this statement be correct, or if mercantile men can see any probability of their position being sound, British capitalists can surely be trusted to step in and make their profitable investments without much fear of French competition in districts far distant from the French base situated to the south of the Nanlin mountain range.

There seems to be no doubt that Chungking—“the great commercial metropolis of the West. Estimated population 400,000” (Little, “Through the Yangtse Gorges,” 1898, page 134), distant about 500 miles in a straight line north-east from Talifu—is the proper point from which Anglo-Chinese railways should be constructed so as to radiate throughout Szechuan and Kweichow, and perhaps ultimately to become connected with the Burma railway system at the Kunlön ferry at least 300 miles distant by road or rail. The census of 1882 showed the population of Rangoon to be 180,324, and of Mandalay to be 188,815; hence Chungking vastly exceeds either of the important towns in population.

The first definite proposals for a railway from Burma into Western China were those formulated by Mr. Colquhoun after his journey “Across Chryse,” from Canton to Bhamo, in 1882, and by Mr. Hallett in 1884, on his completing a personal reconnaissance. Mr. Hall advocated the construction of a railway starting from Moulmein, the seaport at the mouth of the Salween River in the Tenasserim province of Lower Burma, and proceeding by way of Zimmè (Chieng Mai), in Siam, northwards to the Mekong Valley to Szumao, in Yunnan and possibly capable of extension to Talifu.

Apart from any financial questions, the political circumstances in Burma, Siam, and Tonquin, have altered so vastly in the meantime that such a project can never again be serious

mentioned. A much less ambitious proposal is one for a line from Moulmein, down the Meinam Valley to Bangkok, the capital of Siam, which would bring important advantages to both countries.

So far as the trade of the south-eastern portion of the province of Yunnan is concerned, consideration of the geographical and physical features of the country seems to indicate that the natural lines of export are either down the West River (Sikiang) to Canton and Hongkong, or else following the Red River (Songka) to Hanoi, the capital of the French possessions in Tonquin. The French maintain that in the latter route they have solid advantages. They are certainly nearer to the tracts to be tapped; but the commercial advantages gained by China's agreement of June, 1896, to throw open the West River to foreign trade as far as Wuchowfu, may tend to equalise the possibilities between Hongkong and Hanoi. In any case, however, the commerce throughout by far the greater portions of the provinces of Kwangsi and Kwangtung, must proceed down the valley of the Sikiang to Canton and Hongkong. If the trade of South-Eastern Yunnan and its natural outlet through Tonquin, and even if, in addition thereto, a considerable share of the Western Kwangsi trade be attracted towards the French railway now being pushed on from Hanoi, in the direction of Nanningfu about 200 miles to the north-east—the great trade centre on the Yu River, the main southern tributary of the Sikiang—there still remains a ample and promising field for commercial energy radiating from Hongkong and Canton. Just as has already happened in the case of Chungking and the Upper Yangtse Valley, so also will trading developments or other considerations in due time lead to the extension of the agreement of June, 1897, and gradually include the upper portions of the West River. Now, what have our French neighbours done in the way of railway construction in Tonquin, and what projects appeal most directly to them in the immediate future? The Tonquin railway running north-east from Hanoi to Langsun, begun in 1890, has been extended northwards to Langchow, within the borders of Kwangsi. Endeavours will perhaps be made to push it on towards Yunnan, by way of Kaobang, though it seems more probable that it will first be extended north-east to Taiping and Nanningfu (about 100 miles), and thence to Sienkiang (about 150 miles), or else to Sinchow, or to the treaty port of Wuchow on the West River. From Nanningfu a

branch will extend to the seaport of Pakhoi. It was strongly urged by M. de Lanessan, ex-Governor-General of Tonquin, in his book "La Colonisation Française en Indo-Chine," 1895 (pp. 327-329), that priority in railway construction should be given to extending the Langchow-Hanoi line to the south of the Red River delta, and thence, following the hill-slopes of Annam and the coast line, to Saigon. On the completion of this main line he then recommended that the railway next in importance was a branch running north-westwards from Laokai, on the borders of Yunnan, to receive the trade of the southern part of that province.

On 8th December, 1898, the Colonial Committee of the French Chamber finally agreed, on M. de Lanessan's report, to guarantee 70,000,000 francs (£2,800,000) for the line from Hanoi *via* Laokai to the frontier of Yunnan, and thence into Yunnan. And on the 13th December the Chamber "almost unanimously" adopted the Bill for a loan of 200,000,000 francs (£8,000,000) for the construction of other railways guaranteed by the Government of Indo-China. The chief projects covered by this latter grant are a coast line in the direction of Annam, and a line terminating in Cochin China. The reasons and arguments used by M. de Lanessan in advocating the extension of the Hanoi-Laokai line into Yunnan will be found in detail in the *Rappel* of 22nd December, 1898. Taking a comprehensive and liberal view of affairs, Britain can well give her best wishes to a French line from South-Eastern Yunnan down the Red River to Tonquin, provided Britain secures possession of all trade routes trending S.W., W., or N.W. through Talifu or other northern tracts into Burma and Assam.

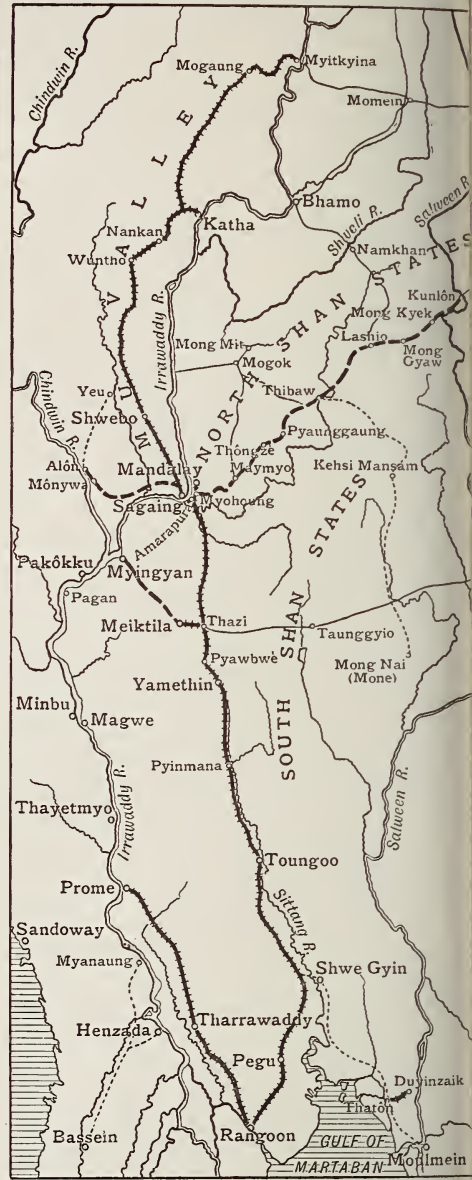

Previous to the Panthay or Mohammedan insurrection of 1854, in Yunnan, when the population is supposed to have been reduced from something between 10,000,000 and 15,000,000 to about 5,000,000, the commerce of this highland region is reported to have been extensive and valuable. The present population is variously estimated at from 5,000,000 to upwards of 11,000,000, and some assert that it is quite as large now as ever it was. The main lines of export are northwards into the Yangtse Valley, eastwards down the West River, southwards into Siam and the Shan States, and westwards into Burma. French activity must naturally attract towards Hanoi a certain proportion of the trade that now exists or that may be capable of being developed.

Even if such attraction amounted actually to deflection it would not be of much consequence were it not that British commerce is handicapped against French trade by heavy import duties in Tonquin. But it is by no means certain that the possibilities of South-Eastern Yunnan have not been much exaggerated; while the opening up of the West River will help that route to recover at any rate some share of the prosperity it is alleged to have formerly enjoyed. In any case, the commerce of South-Eastern Yunnan is little likely to be affected by the proposed railway line from Burma into China.

The railways in Burma are all of metre gauge. They consist of two main trunk lines of very unequal length, both of which were originally State railways. That constructed first and opened to traffic in 1877, the Irrawaddy Valley State Railway, runs from Rangoon, the capital and the chief seaport of Burma, situated near the mouth of the Irrawaddy River, north-west; for 163 miles to Prome, an important town on the left bank of the Irrawaddy. Throughout most of its length the railway follows the military road constructed at the close of the second Burmese war (1852-53) to connect Rangoon with the old frontier station of Thayetmyo, 45 miles north of Prome. This line passes through rich ricefields, and has all along been a remunerative investment. Apart from the strategical objects which were of considerable influence in determining the Government of India on its construction, it has contributed in a very marked degree to the spread of rice cultivation and the increase of revenue throughout the Hanthawaddy, Tharrawaddy, and Prome districts. Where 25 years ago in Tharrawaddy there were vast compact areas of tree forest only broken into here and there by patches of permanent cultivation, there are now enormous stretches of rice lands; while the area still under forest on the plains has been reduced to far lower proportions than are desirable in the interests of agriculture. Fortunately the summer rains brought by the south-west monsoon never fail throughout the central and southern portion of the districts traversed by the railway, so that anything like a famine consequent on excessive clearance of the primeval forest need not be feared. The only tracts that still remain uncleared for rice cultivation within easy reach of the line of railway are areas reserved as State forests for fuel and fodder or as grazing grounds set apart for the plough cattle.

After the completion of this first short line,

the survey was put in hand of a similar line of about equal length (166 miles) running north east through the Pegu and Shwegyin district to Toungoo, the other old frontier military

station on the Sittang River. The prospect of this Sittang Valley State Railway paying, as well as the line on the Prome side were no so promising at first; but strategical reason

ere far stronger in this than in the previous se. From Rangoon to Prome and Thayetmyo ere had always been good river communication by means of the Irrawaddy Flotilla Company's steamers, whereas the troops in Toungoo ere much more out of touch with the central litary authorities. Toungoo could, it is true, e reached either by land or water. But the ad route involved marching for more than 160 les over a very bad road crossed by several ge streams, some of the largest of which re neither bridged nor served by ferries. oreover, only the first 50 miles or so of the ad were metalled, and very badly metalled o, so that this route was only practicable tween the months of November to April. e river communication was equally bad. e passage from the Pegu River to the Sittang, and consequently the ascent of the latter, ould only be made during the fortnightly ring tides, at which periods the strong bore shing up the winefiller-shaped mouth of the ttang river was sometimes dangerous. The cent by river from Rangoon usually took m 10 to 20 days, in great discomfort, and it is all but impracticable during the flood ason lasting from June to October. For at at time, prior to 1884, there were few steam unches in Rangoon, and the conveyance of ops and of other travellers took place in ats roofed in with a thin low awning of atch. It was uncomfortable to have to lie wn all day long, and day after day, on the rd boards of a so-called Chittagong boat, d a relief to be able to get out and walk up d down a sandbank while the evening meal is being cooked. All movements of trade tween Rangoon and the Sittang River were wise limited to the high tides recurring ightly, as at other times the Kyasu creek, iding from the Pegu River across into the ttang, was blocked for want of water. Such s the rather unpleasant state of affairs until e opening of the Sittang Valley State Rail- y in 1884.

Permanent cultivation near this new line of lway soon began to extend, though nothing e so rapidly as had been the case in the less ly populated tracts traversed by the Prome e. The Sittang Railway had, however, this at advantage, that it was capable of exten- n northwards to Mandalay whenever circum- nces might render such a scheme feasible. at this opportunity was actually forced upon e mainly through the action of the French, now a matter of history. The annexation of pper Burma on 1st January, 1886, and the

military operations entailed thereafter in the occupation and the pacification of the new territories, necessitated the extension of the Sittang line to Mandalay. The work of survey and of construction was carried on in tracts that were most seriously disturbed by predatory bands of "dacoits" or gang robbers; and it is perhaps the finest achievement of our civilisation in Burma that this extension, measuring 220 miles from Toungoo to Mandalay, was opened to traffic early in 1889, within 3½ years of the annexation of Upper Burma. This will ever remain an honourable monument of Sir Charles Bernard's administration of Burma during the troublous years immediately following upon the announcement of annexation: for it was mainly through his personal insistence that the extension scheme was somewhat reluctantly approved by the Government of India.

One of the results of this through railway communication between the moist tracts of Lower Burma and the central dry zone of Upper Burma—in which, owing mainly to excessive clearance of the original forest covering, the humidity of the atmosphere is very low and the storage capacity of the soil for retaining moisture has been ruined, while the surface-soil is easily eroded and washed away during heavy rainfall—has been that in years of scarcity, such as have been of frequent recurrence recently, large supplies of rice and other foodstuffs can be poured into the afflicted districts. At the same time the people can easily, if they like, be transferred by rail to the vicinity of tracts not far distant in Lower Burma, where danger from drought does not exist, and where good land can still readily be obtained from Government for clearance and permanent occupation on uncommonly easy terms.

On the completion of the line to Mandalay, a survey was almost immediately put in hand for opening up the new province by extending the railway system northwards towards Shwebo, and then beyond that to Katha, to Mogaung, and to the upper portion of the Irrawaddy River, about 100 miles north of Bhamo. The Myohaung, or "old metropolis" station, a few miles south of Mandalay, was chosen as the most convenient point of junction, and from this a short branch was thrown out westwards to Amarapura. Here the Irrawaddy has to be crossed in large and powerful ferry steamers to the town of Sagaing, whence the Mu Valley State Railway was constructed running northwards through the Sagaing, Shwebo, Katha and Bhamo districts.

to Mogaung and Myitkyina. In its course through Shwebo and Katha it passes within 12 miles of the Wuntho goldfields, from which so much was expected and so little has up to date been obtained, mainly owing to the want of liberality in the existing mining regulations. This railway was opened to traffic in sections, first of all to Shwebo in 1893, then to Katha on the Irrawaddy, which is connected with the main-line by a short branch, in 1895, then to Mogaung in 1897, and now to Myitkyina during the autumn of 1898.

This line gives a great deal of trouble at one particular point in the Katha district where it passes through the Nankan gorge of the The stream. In 1897 there was a bad landslip which dislocated even light traffic so much that passengers had to walk across the breach to a train on the other side. On 24th and 25th September, 1898, there was very heavy rainfall which flooded the stream and destroyed the railway line in the gorge, making far worse breaches than had ever previously occurred. Even in December, 1898, the breaches were not yet completely repaired, and only one train a day was then being run.

Myitkyina, the head-quarters of a new district of the same name, is the terminus of the railway line up the Irrawaddy Valley, at a point 724 miles distant from Rangoon by railway and about 1,000 miles by river. It is situated on the right bank of the river, about 25 miles below where the two branches, the Malika and the Meika unite to form the Irrawaddy. At Myitkyina, and for about 12 miles further north, the river is navigable for steam launches; but beyond that steam navigation is and must remain impracticable. From December till May steam launches can run between Bhamo and Myitkyina, but not during the rainy season from June till the end of November; for in the gorge known as "the first defile" the floods, rising over 80 feet high and pent up till they pour over a narrow opening called "the Pashaw's gate," render navigation either up or down stream equally impossible. Even in the dry season there are stringent regulations as to the departure of launches upwards from Bhamo and downwards from Sinbo, in order to obviate casualties in the defile. Under no circumstances could large steamers make the journey at any time of the year; and whatever traffic there is, or there ever will be, the requirements of commerce are far better served by the railway than they

possibly could be by river steamers running between Bhamo and Myitkyina.

From Wuntho northwards the line passes through thinly-populated districts which are certain to be more extensively cultivated later on. To the north and east, Myitkyina is situated in by lofty hills, thickly wooded and sparsely inhabited by wild jungle tribes. Any remunerative extension of this main line beyond Myitkyina is, therefore, hardly to be thought of in the meantime, though a branch from Mogaung northwards, by way of Kamain up the Hukong Valley to connect with the Assam railway system has been considered so far as to have been the object of a reconnaissance survey during 1895-96. The results were, however, not sufficiently encouraging to hold out any hope that the project can at the present be considered remunerative. This is, however, a scheme much more worthy of consideration by British capitalists than a railway into Yunnan.

After the opening of the Mu Valley Railway the various lines were amalgamated and called the Burma State Railways; but this name was altered when the Burma Railway Company, Limited, took over all the existing lines and projects on the 1st September, 1896. This company, formed in July, 1896, contracted to take over from the Secretary of State for India the open system of railways in Burma, then aggregating 834 miles in length, and to complete and eventually work other lines in progress, amounting to 360 miles more—about 1,200 miles in all—and to construct and work such other lines as the Secretary of State may think fit to entrust to it, Government arranging to contribute further capital or enabling the company to raise the same. The capital is £2,000,000, of which half has been called up and on which the Indian Government guarantee a dividend of 2½ per cent. per annum together with one-fifth of the surplus earnings beyond that interest. It was also guaranteed that this one-fifth should not be less than ¼ per cent. for the first five years ending with June, 1901. Provisions were likewise made in the contract as to the utilization of the net earnings for discharge of interest on any debentures raised, and for paying to Government interest at 2½ per cent. per annum on the capital expended in constructing the railways. Further, Government reserved the right of determining the contract at six months' notice in 1921, or in any tenth year thereafter, or in the event of the undertaking not paying its expenses for three successive

lf-years. In the event of such determination, the share capital is to be repaid at par. That is to say, the onus of finding money for the constructions within British territory really falls on the Government of India, whose financial position does not justify their rushing to rash expenditure. Beyond that, for surveys and other charges in Yunnan the Government of India can have no responsibility. The present status of the Burma railways is thus clear and definite. The company not only took over the active management of the existing open lines of railway, the lines in course of construction, and the projects under consideration, but they also voluntarily incurred the liability to construct further extensions ordered by the Government of India on the guarantee from the latter of an uncommonly low rate of interest for investments of the nature in question in a country like Burma.

The principal line in course of construction is the branch extending from Myohaung, near Mandalay, which is also the junction for the Mu Valley section to Mogaung and Yitkyina, eastwards through the Northern Shan States by way of Maymyo (the new "hill-station" of Burma), Thibaw and Lashio (about 170 miles distant) to some point within reasonable touch of the Kunlön ferry on the Irawaddy river. These facts being fully understood and appreciated, the question of extending the line thence by some as yet unsurveyed route into South-Western Yunnan and onwards, so as ultimately to reach some objective point on the Yangtse river, can now be viewed in its political and commercial aspects.

The Anglo-Chinese agreement of June, 1897, (Article XII.) provided for the construction of railways in Yunnan being considered, in the event of trade conditions justifying this, and such railways being connected with the Chinese lines. This concession, coupled with the right of posting consuls at Momein and Namao, had long been desired by commercial men in Britain, whose knowledge of Burma, the Shan States, and of Yunnan was and is personal but mostly hearsay. These important concessions have of course aroused commercial feeling, both in China and in England, and are very naturally being used for the purpose of bringing political pressure to bear on the British Cabinet so as to compel the latter to take steps of some sort in the name of commerce. The London daily press simply teems with examples of pressure thus being brought to bear on the Foreign Office. And what is the position of the British Cabinet in an affair of

this sort? No matter whether a Conservative, a Liberal, or a Radical Government be in power, the British Cabinet is subject to Newton's first law of motion: it remains in a state of rest or of uniform motion in the straight line of its own party policy, except in so far as acted on by extraneous forces. These impelling forces are twofold in their nature. They may be either the political and commercial acts of foreign Powers, or they may be the resultant of manifestations of public opinion throughout Britain and the British Empire. Unfortunately, when the action of either or both of these extraneous forces becomes manifest in the foreign policy of the British Cabinet, it must usually happen that the energy then displayed exerts itself too late to reap the full political and commercial advantages that might otherwise have been obtainable. Public opinion should be, and is being, educated to join forces with the efforts of commercial men in order to break down through British influence the barriers that exist to the progress of free trade and of civilisation throughout nearly the whole of the Chinese empire. Several commercial syndicates are already taking active steps by sending out small survey parties to make special investigations and to collect information of all sorts required before the Chinese and the British Governments can reasonably be approached with definite requests for concessions or guarantees. Public opinion will be unanimous in approving such enterprise and in wishing it success. At least three different parties are now already engaged in, or are about to commence, commercial and engineering investigations in Yunnan and the Yangtse valley. Two of these, working in the same interests, will concern themselves with the exploration of Yunnan, one party ascending from the Burma side and the other from the Yangtse river. When both parties join hands at Talifu or elsewhere, as is hoped will be the case in March or April next, the results of the expeditions will be worked out by Captain Davies, of the Oxfordshire Regiment and of the Army Intelligence branch, who is in charge of the party from Burma, and whose work in his own special department is so favourably known. No selection could have been better, and the results of the investigations of Captain Davies's expedition, which is accompanied by a young engineer officer, will be awaited with full assurance that they will be well conducted. Public opinion will here again be unanimous in approving the loan by Government of their officers for commercial enterprises of this adventurous and

energetic nature. But it is to be regretted that these various syndicates do not co-operate instead of remaining as separate mercantile interests. Union is strength: and no nation appreciates the advantages of co-operation more intelligently than the Chinese, or knows better how to trifle with divided interests of this sort.

If matters advance beyond these preliminary steps undertaken by merchant adventurers of the City of London, then all further negotiations regarding concessions and guarantees must in equity be guaranteed by the British Government; otherwise, to involve the Government of India in such a matter will be adding yet another to the many financial wrongs already done to India in the name of Imperial requirements. The Secretary of State may indeed bring pressure to bear on the Government of India to have the railway constructed up to the very limits of Burma; but, beyond that, arrangements for the extension into Yunnan, if ultimately decided on, must rest entirely with the British Government on its own financial responsibility. This is more essentially the case if political and strategical reasons with regard to British interests and influence in China are to be allowed greater weight than purely commercial interests connected with the trade of Burma. If Imperial political considerations are to rule the British policy, then no doubt the City of London can very easily furnish millions of capital for railway construction at the low guarantee of $2\frac{1}{2}$ to 3 per cent. with prospect of a share of further surplus earnings when (or if) realised.

The commercial prospects of enterprise in Yunnan, however, unfortunately appear anything but promising. British Chambers of Commerce, which have been told to look upon Yunnan as an Eldorado, must prepare themselves for the probability of disenchantment and disappointment. Such at any rate are the opinions held by the most reliable of those who are personally acquainted with the country through which the line of railway must pass in its proposed ascent into the mountainous tracts beyond the Salween. Consequently there are solid reasons for believing that British commercial interests in the immediate future would be better served by devoting the money which railway extension beyond the Salween would cost to linking together the Burma and Assam railways, to the construction of branch lines as feeders of the existing trunk lines, and to the formation of short new lines falling entirely within our own territories. There exist very favourable

openings in Burma for profitable investment of capital, and it seems much more desirable that money available in Britain should be well invested in our own fertile but only partly developed province than that it should lie sunk in as yet questionable enterprises in the mountain tracts of Yunnan. I put these views forward merely as my own individual opinions, which are based on a knowledge of Burma acquired by a service there extending over nearly a quarter of a century, on personal acquaintance with almost every district in the province, and on recent travels in the Northern and the Southern Shan States. But they coincide with other opinions in official and commercial circles, with the opinions reflected by the Press, with those recently placed before the Rangoon Chamber of Commerce by Mr. Hebbert (late Agent of the Burma Railways Company) when on the point of leaving Burma in August last, and with those of the Viceroy expressed in Durbar at Rangoon on 8th December, 1898.* Any abnormally expensive endeavour to tap the trade of Southern Western Yunnan by means of a railway would not be remunerative, for the very simple reason that this lofty plateau produces nothing in the nature of a trade capable of great expansion. It is not asserted that it is in any way impossible, as beyond our engineering skill we could construct such a line to Talifu or further east to the banks of the Yangtse; but it is maintained that it will be enormously expensive to build and to work, that it will not yield adequate returns, and that in any case extensions and ramifications of the railway throughout Burma are preferable—unless ca

* What Lord Elgin said concerning the railway system of Burma was as follows:—"It is already a great system and is capable of great development, and I say so after travelling over pretty nearly the whole of the 900 miles of which it consists and proceeding as far as it could for the present time in the direction of what I conceive must be at least the ultimate objects of its ambition—namely, connecting Burma with Assam on the one side and China on the other. It is not to be understood to mean that the realization of these objects is near at hand. On the contrary, though I have no doubt in my own mind that the railways of Burma are doing some day to join hands with those of India and to tap the adjacent provinces of the Chinese Empire—and perhaps should add, form a connection with the friendly kingdom of Siam—still, a good deal of this work lies outside the sphere of the Government of India, and, so far as we are concerned for the present, there are, in my judgment, more urgent calls upon us from within the province itself. I venture to say that the course which the Government of India has taken is eminently calculated to ensure that our endeavours are turned in the right direction. I am more than ever satisfied that we did right when we handed over the management of the Burma railways to a strong company, which can do better than any Government department the necessities of commerce and command the support of European capital. If, as I believe is the case, this port of Rangoon, which

ercial principles are to be subordinated to political and strategic considerations. To be profitable, or even possible, trade must be reciprocal; and there seem to be no products of Yunnan which can be utilised in exchange for goods of British manufacture to a sufficient extent to make the railway in question remunerative.

The present population of Yunnan, numbering probably between 5,000,000 and 6,000,000 dependent mainly on agriculture, while one of the presumptive objects of the proposed railway is to exploit the reputed mineral wealth of the province. But no coal has yet been found in Yunnan, and even firewood for fuel is comparatively scanty; and this will much increase the cost of working a railway. As for gold, why not to Yunnan when the Wuntho gold-fields are within 12 to 20 miles of the Mu Valley railway, and while the Paunglaung range of hills, east of the Sittang river but within easy reach of the Rangoon-Mandalay line, is known to be rich in precious metals? Coal is being worked at Kabwet, between the Irrawaddy and the railway in the Katha district, and more important fields are believed to exist throughout the Northern Shan States within reach of the Mandalay-Kunlön line. And, *fortiori*, if development of agriculture is another object in view, why not concentrate efforts on the vast stretches of rich lands lying uncleared and uncultivated throughout the plains and valleys of Burma itself? Again, if the agricultural produce Yunnan can yield (peas, hillies, onions, ginger, &c.) can be equally well raised in Burma and in the Shan States, while the cotton, betel-nuts, cutch, piece-

benefited by the first fruits of railway enterprise, has doubled trade and population within the last 20 years, surely there is no reason why we should not look forward to a continued growth of prosperity and wealth as the varied products of your country are given access to the markets of the world. There is no failure in the demand for grain, sugar, oil, coal, and other minerals, all of which you possess and all of which, I hope, you will be increasingly able to use and export owing to the gradual extension of your railways to the sources of supply as well as by the completion of the main lines of road, which are already bringing their way outwards from the centres of population to the undeveloped parts of the country.'

The policy of the Government of India, above referred to, at the annual Railway Conference of experts which meets annually considers all railway projects suggested by the various provincial governments through India. The recommendations made to the Government of India by the conference are submitted after due deliberation and consideration of all the various factors concerned, having regard both to the means of command and to the probable results obtainable from an administrative, commercial, political, and strategic points of view. This seems to be at once the most practical and the most advantageous system that can possibly be devised for the interests of the Indian Empire.

goods, &c., required for Yunnan, necessary in fact, *must* be taken inland, either from the Irrawaddy at Bhamo, or else from emporia situated on our Burma railways. Hence, under any circumstances, we command the bulk of the trade that is possible, without embarking on questionable railway extensions of considerable financial magnitude in Yunnan.

The open railway lines in Burma convey a large and a steadily increasing traffic. The extension of the main line to Mogaung and Myitkyina will not be immediately remunerative, but it will become so in course of time. Between these two small towns the railway passes through dense malarious jungle, which will have to await the arrival of settlers before the forests can be cleared for permanent cultivation. The tapping of Yunnan by a railway would not bring down cultivators from Yunnan, for mountaineers soon sicken and die on the plains. Mogaung receives the produce of the jade mines at Nanyaseik, above Kamaing, and the amber coming from Maing-khwan; while india-rubber from the wild forest tracts to the north, formerly taken by boat to Bhamo before it could be sent south, is now brought to Mogaung and Myitkyina for direct transport to Rangoon.

Since railway construction was commenced at Myitkyina a considerable portion of the Yunnan trade formerly borne on pack-mules and bullocks westwards through Momein to Bhamo has now been deflected from the Taiping Valley towards Myitkyina. It is quite likely that this deflection of the petty inland trade may continue, and that Myitkyina, a brand-new town, will, to a certain extent, grow at the expense of Bhamo. But, *cæteris paribus*, the valley route by the Taiping River is the easier track, and there seems no fear of the trade at Bhamo becoming extinguished. It is most probable that trade may increase considerably, both at Myitkyina and Bhamo, though the limits of its possible expansion seem somewhat narrow. Bhamo, in addition to trade via the Taiping Valley, must continue to be the emporium for the Chinese muleteers coming down through Namkhan, our frontier town on the Shweli River, which was last year connected with Bhamo by means of a well-cleared track 56 miles in length.

In connection with the intimation that the preliminary surveys, arranged for by the enterprise of syndicates in London, has wisely been assisted by Government with regard to the loan of officers, statements have recently been

made in the Press that work on the Mandalay-Kunlön line is proceeding rapidly, and that 200 miles are already all but complete. This is incorrect and misleading. From Myohaung junction to the foot of the Shan hills, a distance of about 13 miles, is all that was open, even for construction trains, last autumn. The ascent of the Shan hills, from a level of about 500 feet on the plain to 3,000 feet on the edge of the plateau within a distance of less than 10¹/₂ miles, involves, with two reversing stations, a gradient of the unusual steepness of 1 in 25, which may ultimately, for public safety, have to be reduced at great expense to 1 in 40. The line should be opened as far as Maymyo (over 35 miles) next spring. The alignment follows a zig-zag course across the face of a precipitous hill, rounding sharp curves, passing under heavy cuttings and going through rocky galleries. When once this short section is opened and rails can reach the plateau, the laying of the permanent track can follow very rapidly up to about the 80th mile. Here the Gokteik Gorge offers a natural obstruction that will probably take the best part of two years to overcome. Earthwork and bridging are completed thus far, ballast has been collected, and only the rails are wanted to enable the permanent way to be laid.

The Gokteik Gorge is, however, a very formidable obstruction to further progress. A fissure in the hills, incomplete in one short portion resembling rather a geological fault, apparently resulted in once damming up the bed of the Gokteik stream, now lying hundreds of feet below. A lake must have been formed until in course of time the waters forced an outlet for themselves, by percolation and pressure, in the form of a subterranean passage extending for about half a mile through the dam of limestone rock. The stream now disappears for this considerable distance into a huge cavern, while the fault above it forms a *ngók*, or natural bridge, across which the old trade route from China to Mandalay passes.* Such *ngók* are common throughout the Shan

* On the *ngók*, just below where the bridge will cross, stands a quaint little monument, about 7 or 8 feet high. It is Chinese in form and appearance, and bears inscriptions in Chinese and Burmese. The latter runs as follows:—"On the second day of the waxing moon of Tabauing, 1233 (*i.e.*, about March, 1871), during the reign of the Thibaw Sawbwa, Mahawun-tha-thiha-dama Raja, this Yattaung pass, which was in bad condition, was repaired by the two Heins (headmen) of Yattein and Taungdeik, so as to make it passable for men and laden oxen. Hence they have earned the good wishes of the Nats (guardian spirits) and of men." It is to be hoped that this quaint record will not be destroyed when the bridge work begins.

States, where the prevailing rock is limestone. This gorge will be crossed by a lofty iron bridge between 400 and 500 feet above the stream, and 2,000 feet or more in length. The construction of this bridge will be costly and tedious. But when once this obstacle has been surmounted, there will be nothing of unusual difficulty to hinder the rails being rapidly laid through Thibaw up to and beyond Lashio, the capital of the Northern Shan States, distant about 170 miles from Mandalay. An extensive bridge, crossing the Namsin stream about eight miles before reaching Thibaw, will cause some delay: for, though the foundations are now being laid, further construction must be delayed till the girders, &c., are brought up by railway. The earthwork of the line is practically completed, and the station buildings, platform, &c., are already constructed as far as Lashio, though the rails are not likely to be laid for about a couple of years.

Some who have had exceptionally good opportunities of forming a sound judgment on the matter, are very strongly of opinion that one or other of the small towns of Mong Gyaw or Mong Kyek, respectively about 25 and 30 miles east of Lashio—and preferably the former—should definitely form the terminus of the railway line. Beyond that, the country descending to the Salween again becomes difficult, and the expense of construction and working will be considerable. The extension from Mong Kyek to the Salween River, will be about 50 miles in length. But it seems now practically certain that construction up to the Kunlön will be pushed on as rapidly as possible.

Beyond the Kunlön ferry it will be about 30 miles further to Talifu. Consul Jamieson, Szumao, in his report issued by the Foreign office in December, 1898, quotes Baber's remarks with approval:—"By piercing half a dozen Mont Cenis tunnels, and erecting a dozen Menai bridges, the road from Burma to Yunnanfu could doubtless be much improved. To begin with, Baber's remarks do not apply to the route now accepted as probably the most feasible; and, in the second place, this tone of flippant exaggeration is not the proper manner in which a question of such importance should be approached from an official point of view. Great engineering difficulties undoubtedly exist, but they must be examined in the true critical and practical spirit, neither deliberately underestimating nor unduly magnifying them.

It may be anticipated that the railway will reach Kunlön on the Salween in 1901 or 1902. From the Kunlön ferry, about 1,700 feet ab-

a-level, a line can be formed on the farther side of the Salween, extending north-east up the Namting Valley and across a *col* about 500 feet in elevation to Yincho (Yunchu)*, and thence northwards for about 25 miles to Shunningfu, both of which places are about the same elevation. This extension would be about 160 to 170 miles long. Over 30 miles of this would have to be of a gradient of 1 in 40. It is only after reaching Yincho or Shunningfu that the really great obstruction becomes unavoidable. The Mekong, flowing from 20 to 30 miles to the east of these towns, presents a formidable obstacle as a gorge 2,000 feet deep, 100 feet between two and three miles in breadth. Beyond that, the ascent to Talifu (7,000 feet) will again entail a gradient of not less than 1 in 40 for at least 20 to 30 miles. Beyond Talifu the possible route and its obstacles are as yet mere conjecture. But I think sufficient has been said to show that railway construction into the heart of Yunnan will be abnormally high, and that the cost of working over high gradients will be unusually heavy without natural supplies of good steam-producing fuel near the eastern end of the line.

If for political purposes it be desired to extend the Mandalay-Kunlón line into Yunnan, it could not in the meantime proceed beyond Yincho or Shunningfu, either of which would serve as an additional focus and distributing centre for any commerce capable of development. Later on, further knowledge would be required which should make additional extensions, amounting to vast investments, less of a leap in the dark than must be the case if large works are hurried on prematurely. It may perhaps be permissible to remark here that (or when) the Burma line is extended across Yunnan to the Kinsha-kiang or River of Golden Sand, the main branch of the Yangtse, a further extension is much more likely to be northwards through Western Szechuan towards Thibet than eastwards through the wilder country towards Suifu.

There seems to be an idea in England that the Shan States are rich, and that the tracts

beyond them, *omne ignotum pro magnifico*, must be still richer—capable of developing an enormous amount of trade, in fact. This is hardly the case in the former instance, and it is not likely to be a correct estimate in the latter. When travelling along the roads leading up from the plains of Burma into the Northern and the Southern Shan States, one continually meets caravans of bullocks carrying small loads of about a hundredweight per head, packed in bamboo baskets slung over the withers of each animal, while the Chinese caravans consist both of bullocks and of mules carrying loads of about 120 lbs. But it must be recollected that, even with the limited number of trucks necessitated by the high gradients on parts of this line, one train could convey about 3,000 bullock loads; and when several hundreds of thousands of possible bullock or mule loads are converted into tons of traffic, the amount of commerce thereby represented is comparatively so unimportant that it fails to promise anything like adequate returns to a high-grade railway abnormally expensive to construct and to maintain and work.

Long caravan routes can never compete successfully with direct transport by river or rail when once this is provided. Hence, with regard to the railway line under construction towards the Kunlón ferry, this will absorb all the caravan traffic now proceeding by way of Lashio and Thibaw to Mandalay. With the Kunlón ferry as terminus in the meantime, caravan trade will be attracted towards the line both from our own Shan States and from the territories beyond. The bulk of whatever trade exists or is capable of development in the south-western portion of Yunnan must naturally, following the lines of least resistance, find its way into the Irrawaddy Valley, either through Sadón to Myitkyina, or down the Taiping Valley (Manwaing) or the Shweli Valley (Namkhan) to Bhamo, or by the Kunlón ferry to the railway line from Mandalay. The caravan traffic from the south of that which now crosses the Salween by the Takaw or other ferries and passes through Taunggyi, the head-quarters of the Southern Shan States, and thence proceeds down a fairly good road for 106 miles to the railway line at Thazi (or to the Pyawbwè station south of that, which offers better natural advantages as an emporium), may perhaps not be affected to any appreciable extent until the proposed branch line is, in course of time, made from Thibaw southwards through Kehsi Mansam to Mong Nai (Mone),

Lieut. Roux, of the French Navy, who accompanied Prince Henri d'Orléans (vide "From Tonquin to India," 1898, pp. 372, 373), puts Meinningfu (Namting drainage) at 5,207 feet, the pass between the Salween and the Mekong at 7,767 feet, Yunchow at 7,531 feet, Shunningfu at 5,584 feet, the Mekong River at 3,604 feet, the pass on the north of the Mekong at 8,688, and Talifu at 7,007 feet. Unless Captain Davies's new survey shows these observations of a highly-trained naval officer to be vastly over-estimated, then the construction of a line will require far longer stretches at 1 in 40 than are here being suggested as probable.

the capital of the Shan State bearing the same name.

Much can, of course, be done to facilitate the attraction of trade to the existing railway and steamer lines. It seems to me that it would be of enormous advantage if British commercial syndicates could, in the first instance, in anticipation of subsequent railway concessions, secure the control and management of inland trade routes between the Yangtse and the Irrawaddy and Brahmaputra on guaranteeing to the Chinese Customs Department a sum in excess of the *likin* dues annually derived on the average during the last five years. This ought not to be impossible: nor should it be impossible to organise a semi-military transport system along improved trade routes in these western provinces marching with our Indian Empire. Apart from purely political and strategical considerations, the improvement of existing communications converging on important points on river or railway and the formation of branch lines of railway within Burma seem to afford much more promising commercial opportunities than the immediate construction of a railway into and across Yunnan. The Government of Burma can be confidently trusted to do its duty in this respect, so far as lies within its power; but it has for many years been the main grievance of this rich province that an undue share of its surplus revenue is usurped by the Government of India for Imperial purposes instead of being more liberally allotted for the improvement of communications in Burma. Last year the road from Bhamo to Namkhan, 56 miles, was made, and also another leading east from Bhamo for about 30 miles to Sinlungaba, while this year one is to be constructed from Myitkyina to the frontier on the route to Momein. A good mule track has been opened out from Momeik, on the Shweli River, through Mogók, the head-quarters of the Ruby Mines district, to Mainglón in the Thibaw State, whence it can easily be extended south-west and south-east to meet the new railway line at Maymjo and at Pyaunggaung. With regard to fresh railway projects and the ramification of the existing railway lines throughout Burma, a field of commercial enterprise presents itself with far better prospect of immediately remunerative results than the scheme for traversing Yunnan. Thus, for example, Moulmein can easily be connected with the Rangoon-Mandalay line; while the sea-port of Bassein is not yet served by any railway, although good opportunities are offered by the

rich rice tracts extending northwards and eastwards from it, back from the main river communication. Again, numerous small branches could be very profitably thrown out from the Prome and the Mandalay lines to act as feeders in facilitating the transport of rice and of timber, the two main staple products of Burma to Rangoon.

In Upper Burma two important branch lines are now in course of construction. One of these about sixty miles in length, begun in 1896 as famine work, runs from Meiktila, the head-quarters of the Meiktila division and an important military station, to Myingyan on the Irrawaddy, near where this receives from the north-west its chief tributary, the Chindwin River. This line traverses the principal cotton-producing district in Burma, whose short-stapled crop is largely exported into Yunnan *via* Bhamo. From Sagaing another important branch, about seventy miles long, is being run through Myinmu and Mònywa to Alón, on the Chindwin, which will pass through fertile rice lands and tracts producing cotton, cattle and salt. And in the near future a branch about 200 miles in length will most likely be extended southwards from Thibaw through Kehsi-Mansam and Laikha to Mong Pan (Mone) in the heart of the Southern Shan States. Here a certain amount of trade already exists, which is capable of being greatly increased. The country is fairly fertile and possesses a good climate suitable for growing tea, coffee, fruits, vegetables, and grain, as well as for breeding cattle. Hence, given the railway, there would probably soon be a large development of trade eastwards from Kengtung and the country beyond: for the Shan States are endowed with very keen trading instincts. Moreover, it will bring our military station at Kengtung, now 350 miles distant from the railway line at Thazi, in considerably better touch with its main bases at Mandalay and Rangoon.

The Shan States are not everywhere capable of being opened out to an unlimited extent. Thibaw, the most important of the Northern Shan States, which is being traversed from west to east by the railway from Mandalay to Lashio, irrigation is extensively adopted and cultivation. The soil, a very clayey loam resulting from the decomposition of limestone rock, is fertile so long as it has a sufficient supply of moisture. Already the original forest covering on the hillsides has in many places been so much denuded that extensive further clearings for cultivation may interfere prej

cially with the water-storage capacity of the soil, and consequently with its productivity and with the well-being of the cultivators and of their cattle. This is, however, a danger that will no doubt be guarded against in due time by those responsible for the administration of the State. The Forest Department has already been put to work in the matter.

Remunerative extensions of the railway will so ultimately be feasible beyond Mogaung; in the country in the north of the Myitkyina district, though poorly populated and as yet only partially administered, is rich in future possibilities. The project of linking up the Burma line with the Assam Railway, for which the preliminary surveys were completed in 1906, will probably again in due course be brought forward for more favourable consideration.

And now to summarise briefly in conclusion. It has been above remarked, the despatch of Captain Davies's reconnaissance party into Yunnan is a spirited and enterprising commercial movement. But unless it can be shown that railway construction extending far beyond the Salween will be less unduly expensive than as hitherto been surmised, and can offer the prospect of better returns than are anticipated by those most competent to form an opinion on the subject, then the reasons for advocating the immediate further development of the railway net throughout Burma, and for connecting it with Assam seem much stronger than those for extending the line eastwards into China. No pressure has been brought to bear on Government by the Rangoon Chamber of Commerce, the Press of Burma, or the Burma Railways Company. If the project were really so promising as some would have us believe, these could probably have been the first to urge the necessity for action on the part of Government; or they have most to gain by whatever will increase the bulk of the trade passing through Rangoon. They, however, would prefer that the inland communications of Burma by road and rail should be improved, and that private capital should be encouraged to flow into Burma for the rapid development of the province, rather than that the British or the Indian Government should commit themselves in the immediate future to guarantee extensive railway works extending across the mountainous tracts of Yunnan. By all means let our position there be strengthened both politically and commercially; but this

need not involve the construction of railways prematurely.

The paper was illustrated by a series of 28 views in Upper Burma and the Northern Shan States prepared from photographs kindly lent by Mr. Bagley, late engineer-in-chief, Burma Railways Company.

DISCUSSION.

The CHAIRMAN said this was a most interesting paper, and embodied the views which he, as Chief Commissioner of Burma, had formed and frequently expressed. With regard to the extension of the railway to Western Yunnan he never could convince himself that the trade that now existed was enough to justify the investment of British capital in railway extension, and he was perfectly clear that it would be monstrous to expend the revenues of India in extending the railway beyond British territory into China. He had had occasion from time to time to make inquiries into the existing trade between Burma and China, and it consisted largely of contraband—arms and opium—and instead of encouraging it every effort was made to stop it. The bulk of the rest of the trade coming from the parts of Yunnan they had heard of that evening consisted of opium and straw hats. He did not know how many caravans of straw hats it would take to make a load for one railway train, but he entirely endorsed the opinion that it would be very rash to form sanguine estimates of the prospects of a railway without careful inquiry as to the real value and bulk of the existing caravan trade. When he was Chief Commissioner in the Central Provinces in India, there was a plan proposed for the construction of a railway across the Satpura Hills, and he was told the traffic was very important, but on examination he came to the conclusion that one railway train a week would carry all the caravan trade of a month, which was not encouraging as a prospect for British investors. He entirely endorsed Dr. Nisbet's warning as to the difficulty of gauging caravan trade. He could not quite agree with Dr. Nisbet's opinion that it was as essential to have a through route from Shanghai and Hongkong to the Brahmaputra and the Irrawaddy, as it was to have a through route from Alexandria to the Cape. He believed trade ought to be left to follow its natural lines, and the natural line of trade from that portion of China was eastward by the Yangtse River. You might make railways at an expenditure of millions, but they would not draw the trade from that river down to Burma, nor did he believe the trade and produce of the country was such as could bear the charges of railway conveyance from Yunnan to Rangoon. In any case, if that railway were made at all, it must be done at the cost of those enthusiasts who advocated it, and of those who believed in them, and not at the expense of the Government of India. With

regard to the railways in Burma, he endorsed every word of what had been said about the desirability of their extension, having had a good deal to do with suggesting and carrying out some of the lines mentioned in the paper read. With regard to the line to Myitkyina, he did not suppose the amount of Chinese trade which would be attracted there, or the produce of the country itself would for many years provide a paying traffic for the railway, but they were compelled to make it, and it paid indirectly. As had been explained and shown in the views, the defiles were practically an immense difficulty to keeping up communication by the river; but there were frequent outbreaks amongst the tribes in that neighbourhood, and expeditions had constantly to be sent there, and all the year's supplies for the military police had to be sent by river through these defiles while they were open, within a very limited period of time. This was a costly process, and entailed the maintenance of a large flotilla of river steamers, which were constantly getting wrecked in the defile. The making of the railway would enable this flotilla to be dispensed with, and he believed there were great capabilities in that part of the country. At one time certainly it was populous, and if they ever got that direct communication between Assam and Burma which was advocated—wisely he believed—it would be through the Hukong Valley. He had no doubt that the Lower Burma lines would pay, and that there was a practically unlimited field for extension there. Turning once more to the Mandalay and Kunlôn line, the view he had always taken of it was this: He advocated the construction of the line as far as Thibaw, and up to there he believed it would pay, but he deprecated its continuation to Kunlôn because he did not believe it would get any traffic worth considering, at any rate not until British capital was able to penetrate into Yunnan, and develop the mineral wealth, if such existed. He advocated strongly the extension southwards from Thibaw through the Shan States, of which he thought Dr. Nisbet had taken rather an unfavourable view. These were small principalities which prior to the annexation had been torn by internecine war, and when we took possession of them they were depopulated by constant warfare, but had since been recovering in the most marvellous way. Population was returning, trade was developing, and on the hills there the climate was as good as that of England at its best—far better than we were enjoying at present. The Superintendent of the Southern Shan States told him that he could wear all the year round the same clothes he wore in London; that he grew every description of English fruit and vegetables, and was prepared to grow potatoes for the whole British army if he had sufficient encouragement. He added that he kept his box of matches open on the table, and they never failed to strike, and anyone who knew the difficulty there was in getting a match to strike at all in Burma would understand what that meant. Sanitaria for the troops in Burma were sadly wanted, and up in

the Shan hills there were magnificent and healthy sites—almost, in fact, suited for European colonisation. It had been suggested that France would be disposed to make decent arrangements in Madagascar and elsewhere if she could get Siam, but he hoped this would never be allowed, for if she did we should certainly have trouble in Burma; and he looked upon the extension of the railway down through the Shan States as one of the most important strategic movements which could be made, because it would protect the flank of Burma against any advance from Siam or Annam. He agreed with Dr. Nisbet that there was a good deal to be done for the development of the industries as well as the railways of Burma; and he did not think the Government of India had done all that it might, and that our regulations had been far too grandmotherly. They were always trying to protect the British investor; but his experience was that the investor was able to protect himself. All that was necessary was to take care that the truth was laid before him, and to punish anyone who did not state the truth in prospectuses, and so on; and he thought our Judges, both in England and India, might be trusted to do that, but the rules for developing the gold mining, coal mining, and other such industries ought to be very materially relaxed, and a fair chance ought to be given to British capital to develop the country. He was not surprised to hear it said in Rangoon that it would be a good thing for Burma if it were cut loose from India altogether, and there was undoubtedly a strong feeling amongst the European commercial population there that Burma did not always get fair treatment. He was perfectly satisfied that if Burma stood by herself, under the Colonial Office, it would pay its way, taking the two provinces together; but being attached to India it was saddled with much expenditure which more properly belonged to the country. However, if more prosperous days were coming in India, no doubt Burma would share in them. The first requirement was the free investment of British capital, both in India and Burma, which would never come about until they had got a stable par of exchange; and that he hoped the committee now sitting at the India Office would see its way to long to provide for—though how it was to be done he would not attempt to say. Dr. Nisbet said the tracts of country on the Myitkyina line would be uncultivated for some time, because the mountaineers who came to cultivate them could not live in the plains; but on the Bhamo side there had been tribes coming over the Chinese border who in past years cultivated nearly the whole of the Bhamo Valley, and were ready to do so now if only the Chinese would let them emigrate. If we could only establish free trade in the fullest sense, across the border, we should soon see the whole of that valley recultivated, and a large revenue arising therefrom.

Mr. ARCHIBALD LITTLE said he was afraid, after hearing such a detailed account of the border country

between Burma and Yunnan, they would say that the immediate connection of Chungking—the part of China in which he was personally interested—with Burma was not likely to be accomplished in the near future. Even the line to the Kunlön ferry on the Salween river would not be completed for several years, and the possibility of extending it on to Yunnan seemed rather remote. He feared that until Yunnan was properly governed and re-populated—or it had been devastated by the cruel massacres which accompanied the outbreak of the Mohammedan rebellion and its suppression by the Chinese, and the officials appointed by the Government to revive the province and restore confidence were totally incapable,—there was very little hope. Even if the French took possession of it, it would be better than leaving it as it was. Seeing the natural difficulties of the country, Hong Kong was practically nearer to Yunnan than Rangoon. The natural route to the Yunnan plateau was by the eastern ascent, because it was very gradual and was not interrupted by the high mountains and—in a railway sense—terrible country which separated Burma from China. There was already an open part at Woochow on the West River of Canton, and the river was navigable from its mouth, 510 miles to Posai, where there was said to be about 3 feet of water; there was then every possibility of light draught steamers being able to get there. From Posai the ascent was gradual, and though the country had not been surveyed travellers said there was no difficulty in pushing a railway from there to the high Yunnan plateau, at least as far as Yunnanfu. It appeared to him, therefore, that practical men who wished to invest their money, would do better to open the route from the east, in which no serious difficulties occurred, than to push for a scheme which was quite impracticable in the near future. Dr. Nisbet referred with pleasure to the telegram from Sir Lister Kaye, who had obtained a concession from the Chinese Government for the conservancy of the Yangtse river, and was to reimburse himself by means of a toll, but he must say that he hoped no private company would be allowed to impose tolls on that river. If any expenditure were required, it should be carried out by our own Admiralty, for, in a country like China, it would be bad policy to tax the junk traffic with a toll, especially as the cost would be comparatively trifling. For six months of the year the rocks were so far below—for the Yangtse rises 100 feet—that there was no need to interfere with them at all; and if a few rocks were removed from some of the rapids, the navigation would be safe all the year round. He agreed with Dr. Nisbet that it would be well if some of the many Chinese syndicates would join their forces and co-operate. Our Government should try and arrange for something like an international commission or permanent railway and mining board in China, to whom all proposed schemes should be submitted. Nothing was more needed at present than liberty to mine;

there was no liberty for Europeans nor even for the Chinese themselves. One had to go in a round-about way and get the consent of the local authorities, and then to go to Peking and spend large sums in bribery, and even if one got a concession it was on such onerous terms that he doubted if many of the railways now being promoted would ever be built. One concession he saw stipulated that the whole line, including the rolling stock, should be handed over to the Chinese Government at the end of 30 years! He could not believe that such concessions were intended to be honestly carried out. With regard to mines, the Chinese Government ought to give leave to any *bonâ fide* resident in the country, in partnership with the natives, to open a mine and so enrich the people and enable them to buy more of our goods; for at present the masses were in abject poverty. The country would never be developed until anybody who had capital and agreed with the local proprietors was allowed to work a mine.

Mr. HORACE BELL being called upon, said the only points he could have raised had already been covered by the Chairman. However easy or difficult it might be to get across from Burma into Yunnan with a railway, he feared the traffic obtainable would not be sufficient to pay interest on the cost; and he agreed with Mr. Little, that the traffic was much more likely to be with Hong Kong than with Rangoon.

Sir STEUART BAYLEY, K.C.S.I., C.I.E., congratulated the Society and the Indian Section on the high character of the paper with which the session had been inaugurated, and tendered the cordial thanks of the meeting, both to the author and to the Chairman, for his kindness in presiding.

Mr. C. McCL. MCHARDY said if it was not too late, he should like to ask for a little further information from the Chairman on one point. They had been told that much advantage was not to be expected from an extension of the railway from Burma into Yunnan, but that it would be of great advantage to continue it northward into Upper Burma, and to make certain branch lines, also to make a line from the east into Yunnan. He should like to know something more of the population and products of Upper Burma, and as to whether there was a large population in Yunnan to buy goods sent from the east, and what produce there was to export from Yunnan. He rather gathered, from what had been said to-day, that beyond some straw hats very little was to be had from Yunnan, and that there was but a small population, most of whom had been killed in the Mohammedan rebellion, in which case we could not expect them to buy much or produce much. If such be the position of affairs, what was the use of constructing a railway? His own impression was that Yunnan was one of the very poorest and most thinly-inhabited part of the Chinese empire, and that there were other parts in which British capital could be more profitably invested.

The CHAIRMAN said Lower Burma was one of the richest rice-producing countries in the world. Upper Burma had in the centre a dry zone, consisting of half-a-dozen districts, which frequently suffered from a low rainfall, but when they did get rain were very fertile. When the rain did not come they had what were called famines, but a famine in Burma was a very mild affair compared to a famine in Madras. These dry districts, he had very little doubt, could be made perfectly free from drought by a system of irrigation works, not of the expensive nature usual in India, but by the cheap and easy methods formerly adopted by the Burmese kings. North of this dry zone there were districts with as fertile a soil as could be wished, growing wheat and rice. The population was sparse compared with Lower Burma and parts of India, and in some places there were large tracts of forest, where a good deal of money was made by cutting timber. The mining capacities of the country were as yet hardly explored; coal mining had not been very successful, and the gold was barely touched, and he should be glad to see the conditions made easier for those who liked to take the risk. When you got to Mogaung in the north, you were close to the jade mines, and for this mineral very large prices were paid by the Chinese, and that would be one of the principal things sent down by the railway. Farther north again there was another tract at present very sparsely populated, where you got rubber and amber, especially the former. That tract had hitherto been in the hands of tribes who had done a good deal of damage to the trees, but he thought the capacities of the country were fairly good. He did not advise people to rush and invest money in enterprises in Upper Burma; but there was certainly a field for exploration and development, and financially the fact remained that up to the present we had supplied the country with the whole paraphernalia of decent administration, and yet had almost succeeded in making it pay. When he first went to Burma he had 18,000 men in the military police, a great number of them Pathans, the finest fighting material in India, though when they were in cantonments with nothing to do they were apt to get unruly and dangerous. Many of them had now been drafted into the regular regiments of the Madras Army, thereby reducing the cost of occupation; the country was rapidly settling down, and taking Lower Burma and Upper Burma together the Government might congratulate itself that it practically paid its way. With regard to China, he would rather that Mr. Little should answer the question. His own impression was that Yunnan was a very poor country; but he thought that the English Government had succeeded in getting valuable concessions for British syndicates in China, more valuable than the public had any idea of, but as to whether those concessions would prove workable or not he expressed no opinion. It was said that in the north Russia was of opinion that she could not work her railways without making military stations in connection with them. If it were

necessary for the employment of British capital in Central China to support it by a military force, he doubted greatly whether the British Government would undertake that responsibility.

Mr. LITTLE said the eastern part of Yunnan was fairly good country, producing—apart from its copper and tin mines—the best opium in China, which cost in carriage very often 10d. to 1s. per ton mile, and against $\frac{1}{2}$ d. or 1d. per railway. The route from the West River would be for 500 miles by water, and was not more than 300 miles from Posai to Yunnanfu. It would also tap Kwaichow, with rich valleys, producing rice and other subtropical crops. He did not deprecate a railway from Burma to Chungking, if it could be made to pay; but it would be an expensive line, whereas the route from the West River by water would be inexpensive, and he was confident there would be a good traffic in Manchester goods going inland, and opium and minor products coming back. As a Britisher, he should much like to see the railway made, because it would relieve us from the iniquitous transit of 10 per cent., which the French imposed for passing through a little corner of the territory, whilst French goods went through free. It was little matters like that which made them jealous of any French expansion; otherwise, the country would be better under French rule than under Chinese. The easiest way to oppose them peacefully was to make a line through from Hong Kong to Yunnan fu.

SEVENTH ORDINARY MEETING.

Wednesday, Jan. 25, 1899; R. BRUDENEL CARTER, F.R.C.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

- Bunyard, George, Kenmore, Maidstone.
- Capel, G. W., Montana, Park-lane, Croydon.
- Collis, John William, 55, Glenwood-road, Catford S.E.
- Colman, Russell J., Carrow Works, Norwich.
- Evans, Peter MacIntyre, M.A., Clothworkers' Hall, Mincing-lane, E.C.
- Flint, Stanley, 12, Museum-chambers, Bury-street W.C.
- Gray, Frank James, 9, Upper King-street, Norwich.
- Hunter, Walter, 17, Victoria-street, S.W.
- Ramsay, James, Listoke, St. Stephen's-road, Ealing W.
- Ranger, Charles Peter, Easthoathly, Sussex.
- Wilson, John, Leadenhall-house, 101, Leadenhall street, E.C.

The following candidates were balloted for and duly elected members of the Society:—

- Digby, William P., Valyevo, Wanstead-road, Bromley Kent.

cking, Charles Leonard, The Gables, Nightingale-
ane, Clapham-common, S.W.
ries, David, Portland College, High-road,
hiswick, W.
ng, John Alexander, Rosendale, Stanstead-road,
Forest-hill, S.E.
riarty, Hon. Arthur S., I.C.S., care of Messrs.
irindlay, Groom and Co., Bombay.
illips, H. Fentum, Guildford Electrical Works,
North-street, Guildford.

The paper read was—

TUBERCULOSIS IN ANIMALS.

BY W. HUNTING.

Once every month the daily papers publish extracts from the returns of the Registrar-general showing the causes of mortality among the population of these islands. When typhoid, small-pox, or scarlet fever destroy an extra hundred of human lives, popular attention comes arrested, and, should the mortality continue, public agitation soon arises. A dozen deaths from hydrophobia in one year is a signal for issuing most stringent regulations—enforced by fine or imprisonment. One case of suspected cholera in any of our ports is sufficient to cause something approaching panic. A report that a ship has reached our coast, and that a death has occurred on it from plague, is an event noticed by every newspaper in the country.

All this is well known, and the general public approve of the stringent measures taken by our authorities—central and local—to prevent further loss of human life. The diseases mentioned are dangerous plagues, and it is in accordance with reason and common sense that every precaution should be taken to prevent their spread. The public appreciate the danger, and the Legislature has provided measures of protection.

There is a disease that destroys more human beings than all the plagues I have named put together. There is a disease the returns of which the Press and the public are apparently ignorant, and which the Legislature ignores.

We constantly hear of typhoid, small-pox, and cholera, but we seldom hear of tuberculosis outside of medical books. The absolute want of knowledge of the disease is what protects it from any public movement, and from all legislative interference. At Marlborough House on the 12th December Sir William Broadbent stated that 70,000 persons die every year in Great Britain and Ireland from tubercular disease. The chief cause is the death of 100 persons from typhoid,

or of a dozen from hydrophobia a cause of popular indignation, whilst the death of thousands every month from tuberculosis goes on unnoticed and unchecked? The explanation is that the public recognise the preventability of those diseases but not of this. The loss from one is slow, obscure, and constant. The loss from the others is sudden, evident, and occasional. We all know the dangers of small-pox, typhoid, and hydrophobia; we take what precautions we can, and look to legislation for assistance in limiting their spread. The greatest of all plagues is lost sight of—its very name is unused, and it is disguised in the published returns of mortality by inclusion in “disease of the respiratory organs,” or “disease of the digestive organs.” To class a specific disease like tuberculosis in this way is as logical as to include small-pox in the list of “diseases of the skin.” Such returns defeat the object of publicity—they disguise a grave public danger instead of exposing it. Seventy thousand deaths per annum from one disease—one preventable disease—is a terrible event; more terrible from the fact that no public alarm is raised and no legislative attempt made to stay its progress.

But what has this to do with the subject of my paper? What has human mortality to do with bovine tuberculosis? A very great deal. Tuberculosis in cattle is one of the causes which leads to the annual hecatomb of human beings, a cause which might be most easily removed. Sir Richard Thorne, in a lecture delivered last November, drew attention to the fact that during the last half-century a great reduction in the death-rate from many forms of tuberculosis in man had taken place. This he attributed to the improved sanitary arrangements now adopted—to improved ventilation, to better hygienic surroundings, and to less over-crowding in houses and workshops. When, however, the statistics were examined of those forms of tuberculosis which were not from infection through the lungs but through the stomach, it was found that no decrease was apparent. On the contrary, the mortality of children under one year old from abdominal tuberculosis had increased, and this increase had gone hand-in-hand with the steady increase in the consumption of cows' milk. No other explanation can be found for this constant annual slaughter of the innocents—except infected milk, and the medical profession accept the cause pointed out by the chief medical officer of the Government.

What is tuberculosis? It is a disease

affecting man and animals. It is due to the existence of a living organism—a microbe—in the system of the victim. It spreads solely by the transmission of the microbe from diseased to healthy bodies. The usual method of human infection is by a person suffering from consumption, *i.e.*, from tuberculosis affecting the lungs. Another method is the ingestion of infected flesh and milk derived from tuberculous cattle. A Royal Commission sat for four years enquiring into this question, and reported in 1895 that the danger of infection from tuberculous milk is a serious one, while the danger from tuberculous meat, though slighter, must not be disregarded.

Here then is authoritative evidence showing the connection between tuberculosis in man and in animals. The degree of danger depends upon the extent to which disease prevails among cattle, and there is reason to believe that at least 20 per cent. of the cattle over two years old are more or less affected with tuberculosis. In some districts the disease is almost unknown, in others it is common. Cows kept for milking purposes show the greatest amount of infection, and some sheds have been found in which 60 per cent. of the stock was infected.

The two channels through which tuberculosis may be transmitted from cattle to human beings are: meat and milk. Each is worth a little separate consideration.

MEAT.

Under various Public Health Acts some attempt has been made to protect the public from the danger of consuming tuberculous meat. Sanitary inspectors, acting under the direction of medical officers of health, may seize diseased meat in shops or slaughter-houses, or wherever it is exposed or prepared for sale. Where animals are killed in public abattoirs inspection is easy, and when the inspector understands his duties—which is seldom—no dangerously diseased meat is likely to escape seizure. In this country by far the larger proportion of meat is prepared in private slaughter-houses, where inspection practically does not exist, and where its proper performance would entail the appointment of a small army of inspectors. All infected carcasses are not equally dangerous. Tuberculosis may be indicated in one animal by a few nodules in one organ, in another by a general disease implicating the whole body. The latter state requires seizure of the whole carcass; the former may be treated as a local

infection and the carcass passed after removal of the diseased organs. Between these two extremes of infection every imaginable degree of disease-distribution is to be met with, and the decision as to whether a carcass should be seized in whole or part becomes a question for an expert. When inspection has been lax, the inspector incapable, much dangerous meat has been passed for human consumption. On the other hand, when inspection has been based upon the theory that any visible infection of a carcass contaminates the entire body, great hardship has been inflicted upon butchers by confiscation of the whole animal.

There are few cattle in which the detection of tuberculosis is difficult after death. There are many in which during life no sign of disease is discoverable, but which prove on examination after slaughter so extensively diseased as to render the carcass unfit for human consumption. Hence arises a serious hardship to the butcher, who after having purchased an apparently healthy animal, has the carcass seized by the authorities. It is argued that this loss to the butcher must be looked upon as an ordinary trade risk, and that whilst he is deserving of sympathy he must not be allowed to sell meat which is a grave danger to human life. Not unnaturally the butcher replies: "I am not to blame. I bought an apparently perfectly healthy animal, and only discovered the dangerous condition after slaughter. The public health should certainly be protected—but at the public cost. My property may be justly seized, but in equity and justice I should be compensated for it." I shall refer to this question again, but here I would point out that the effect of seizure without compensation is to drive away from slaughter-houses where inspection takes place all the suspected or diseased animals which the owner thinks—be he butcher or not—might fail to pass inspection. The worst tuberculous carcasses do not go to public abattoirs, but they find their way through private slaughter-houses to the kitchens of the meat consumers. Fortunately, thorough cooking renders tuberculous meat harmless, but not everyone is satisfied with an over-cooked joint.

The controversial question of having no public slaughter-houses I have no time now to discuss. It is a very large one and includes much more than the detection of tuberculous meat. Public abattoirs in towns are of little use if private slaughter-houses are permitted to remain, or even if meat killed outside the

is allowed to enter by road or rail without inspection. To protect the public completely from tuberculous meat by inspection, would require the total prohibition of private slaughter-houses and prohibition of movement of carcasses until officially stamped. For other reasons this may be found advisable and practical, but as a protection against tuberculosis, it would be more cumbersome and costly than the stamping-out of the disease.

MILK.

The transmission of tuberculosis from animals to man by means of infected milk is a much more serious danger than the possibility of infection by meat. Large quantities of milk consumed uncooked, and constitute a grave danger. Especially is the danger from this source imminent for infants and young children, or invalids weakened and debilitated from recent attack of typhoid or scarlet-fever.

Not every tuberculous cow produces impure milk. It seems in fact that only those animals do have tubercular disease of the udder, and infective milk. If the specific condition of the udder were always prominent and easily detected, the danger might be guarded against by removal of the cow, but it is not so. The disease commences insidiously, progresses gradually, and infects the milk in the gland in very early stages. Milk from a tuberculous udder is virulently infective, and one case is recorded where half a wine-glassfull mixed with food of two rabbits caused their death from cerebral tuberculosis in a few weeks.

In a remarkably able paper by Dr. Niven, Medical Officer of Health for Manchester, read before the meeting of the Sanitary Institute at Birmingham last year, some definite information concerning the infection of milk is given. From this paper I take the following:

In Liverpool, 144 samples of milk from city cow-sheds were examined, and 29 per cent. were found to contain tubercular infective matter. Of 24 samples of milk taken at the railway stations, 2 per cent. were infected.

In Manchester, the milk from 19 tubercular cows was examined; that from five contained tuberculous infection, and all five cows had tuberculous udders.

In Manchester, 93 samples were taken at the railway stations, and 18 per cent. were found by Professor Delapine to contain tubercular infective matter. By permission of the farmers from whom these infected milks were received, Mr. King, the City Veterinary Officer,

examined the cows on 16 farms. On 14 of them, at least one cow was found with disease of the udder.

"It thus appears," says Dr. Niven, "that at the present time an enormous stream of infectious milk is pouring into our cities, and that the matter is truly one of urgency."

That this grave condition is urgent and serious will be better understood when I say that at present there are no powers afforded by law for the seizure of cows in the last stages of tuberculosis, although their udders are loaded with disease, and their milk is mixed daily with the produce of large cowsheds.

Probably enough has been said to show that tuberculosis in animals is a danger to public health, and at the same time a cause of great loss to butchers and cowkeepers. Neither butchers nor cowkeepers have any interest in owning diseased animals. They sustain nothing but loss through them, and are unable to avoid purchasing them. The disease prevails widely in the stock owned by breeders and feeders, from whom the cow-keeper and butcher must obtain the necessary animals to carry on their business. It is essential that human life should be protected against the transmission of disease by meat and milk, but the most stringent inspection of cow-sheds and slaughter-houses will not affect the prevalence of disease outside those places. By thorough inspection and ruthless seizure of diseased products in the possession of butchers and cow-keepers, partial protection may be given to public health, but so long as disease in the stocks of breeders and feeders of cattle is left untouched, so long will fresh supplies of infected animals enter the places from which the direct supply of food for man is obtained.

The usages of trade do not provide for warranties of soundness on the sale of cattle. The diagnosis of disease is impossible in fairs and markets. The butcher who buys an animal for the production of meat, and the cowkeeper who buys stock for the production of milk have no ready means of self-protection against the seller of tuberculous cattle. If the public is to be protected against disease, it is unfair to place the whole cost of such protection on the shoulders of the butcher and cowkeeper, whilst the breeder and feeder, who have full opportunity for recognising the state of their stock, are allowed to keep diseased cattle and sell them without restriction and without loss.

The agriculturist is, however, himself a sufferer, and deserves all the assistance that

can be given him. Tuberculosis causes continuous loss to him through abortion and sterility, through wasting disease and death, through the interference with fattening and the excess of food required to feed diseased animals. Although probably 20 per cent. of the adult cattle of the country are more or less infected, only about 1 per cent. show visible signs of the disease, and prove a total loss in any year. If we take the cattle stock of the kingdom at 6,500,000, and put aside those under two years old as being very slightly affected, we have 4,000,000 animals concerning which the estimate may be made that 1 per cent. are distinctly diseased—unfit either for meat or milk production. This would put the annual loss from bovine tuberculosis at 40,000 animals, and is sufficient to warrant legislative assistance and control.

Firm control of the disease would be an advantage to all classes. Public health and national wealth would both benefit by the suppression of a plague that injures all and does good to none. Regulations for its control are loudly called for by every interest, but most loudly by the requirements of public polity. Everyone who has given the subject a little thought is satisfied that something ought to be done. Some would trust in voluntary effort, others insist on the necessity of legislative action. Let us examine both methods.

VOLUNTARY EFFORT.

Without some voluntary effort on the part of stockowners legislation can achieve little. Voluntary effort alone has never yet stayed the spread of contagious disease among animals. Carelessness, ignorance and greed are not peculiar to any classes of the community, and until human nature is exempt from these vices only the best of men will endure trouble and loss for the protection of others' interests. The easiest and most profitable method of getting rid of contagious disease in animals is to pass it on to your neighbour by selling the stock in the open market, and thus increasing the spread of infection. There is no law to prevent it, and the approval of thick-and-thin advisers of voluntary effort will doubtless be given. The public by voluntary effort may protect themselves against the dangers of tubercular infection from meat and milk. This can be done by well boiling all milk before consuming it, and by thoroughly cooking all meat before eating it. This is so simple that logically the public have not very strong

grounds for insisting that meat should be from the tubercle bacillus. It is harmful when cooked, and so everyone can protect himself. And yet no one has objected to provisions of the Public Health Acts which provide for the seizure of tuberculous meat.

Again with milk, safety can be obtained by boiling, and yet Sir William Broadbent claims in his speech at Marlborough House that "the public had a right to insist that their milk should be absolutely free from the tubercle bacillus."

The supporters of purely voluntary action should apply to the consumers of meat and milk the same arguments they enforce to the owners of diseased cattle are referred to. If we are to do nothing by law save when self-protection is impossible, let us do nothing all round. I expect this argument will gain few supporters. It will be said that we want meat and milk without the addition of a virulent poison, that over-cooked meat and boiled milk is not palatable, and some will agree with that the digestion of meat and milk is assisted by excessive cooking.

The butcher, the cow-keeper and the agriculturist may do a great deal by voluntary effort to guard themselves against disease in their animals and at the same time protect the public.

Before I discuss what they may do, it will be necessary to say something about the meat we have at our disposal for the detection of disease.

A few years ago it was quite impossible to detect the majority of cases of tuberculosis in any animal. The majority of cases are always those which have not yet caused any marked disturbance and which present no indication of their existence to the ordinary observer. Tuberculosis is usually of slow development. After infection, months may pass during which no indication of the disease is given, but a post-mortem examination would reveal distinct lesions in perhaps many parts of the body. Every infected animal has a chance of spontaneous recovery, and a still greater chance of existence for a time without apparent injury. During the stage of late disease, whilst lesions are developing in the body and centres of infection gradually increasing, many exciting causes come into play, give rise to systemic disturbance and distinct appearances of disease. Probably during the latent period of tuberculosis not much danger of infection to other animals exists, but in those cases where the lungs or bowels are implicated

is impossible to say at what time infective virus may be expelled by coughing or may escape with the excreta. The detection of the advanced cases, which afford visible symptoms of disease, is not difficult, and they may be removed from the possibility of infecting other animals. It is clear, however, that the spread of the disease can only be controlled by detecting the latent cases before they reach the stage at which they constantly transmit infection. Having detected them, they must be submitted to such isolation as will prevent their contaminating healthy stock when they reach that stage of disease which is surely contagious.

A few years ago this was quite impossible, but now, thanks to Dr. Koch's discovery of tuberculin, every infected animal can be rapidly detected and provision made for suppressing the transmission of disease. The tuberculin test for tuberculosis in cattle has, by innumerable experiments, been established on a firm foundation as harmless, yet trustworthy. In a few hours it is possible to determine, on a farm or in a shed, which animals are infected and which are not. Then they may be separated and the diseased kept strictly by themselves.

By voluntary effort the agriculturist is able to detect the existence of tuberculosis in his stock, to separate the healthy from the infected, to keep only healthy animals, and to dispose of all the diseased. Professor Bang, of Copenhagen, has demonstrated the practical success of this method on a large scale, and has even shown how a breeding stud of infected animals may be continued for years without implicating the offspring, if care be taken to avoid contagion. Sir Gibson Carmichael, in Scotland, adopted this voluntary method on his pedigree stud at Castlecraig and has now a herd free from tuberculosis. The late Lord Vernon, at Woburn, quite recently put into practice the tuberculin test, followed by weeding out the infected, with great success. The Duke of Westminster and the Earl of Crewe have also given practical approval to this method. A number of other private owners have partially adopted it and a few have gone so far as to detect all their infected stock by means of tuberculin, and then have disposed of them so that sportsmen may enjoy the loss they have incurred. Supporters of the "voluntary system" do not often describe the tuberculin test and its proper sequelæ as simple, easy, and efficacious. It is indeed efficacious, but it is far from simple and easy. The use of tuberculin requires, first of all, a trained veterinary surgeon for its

application. This means expense. Next, the separation of infected stock must be carried out, and this means space for the purpose and extra buildings for isolation. To sell all the infected animals is a "dirty trick," if it is not reckless waste, as many would not be in condition for the butcher. Valuable breeding cows could be kept for their special services, but only under conditions which are available to rich men, or on places where sheds and pastures are unlimited. The voluntary suppression of tuberculosis on a farm by the tuberculin test and rigid separation is at present only practical for rich men and philanthropists. It is quite possible if capital and space are obtainable. It is even profitable under those conditions and where the stock is one of valuable pedigree animals.

In town cow-sheds, the provisions for isolation do not exist, besides which it is next to impossible to prevent the re-introduction of disease by newly purchased cows. Furthermore there is no inducement to keep only non-infected cows. The customers will not pay an extra price for pure milk, and even public institutions such as schools, hospitals, &c., offer no encouragement to a cowkeeper, either by extra payment or by compulsory regulations, to guarantee purity. There is, too, less commercial inducement for the cowkeeper than for the breeder, to employ tuberculin and thorough voluntary effort. The breeder keeps his stock for years and need seldom introduce animals from without. The cowkeeper retains his only so long as they yield a full supply of milk, and then he replaces them by new purchases from farmers and breeders. Tuberculosis runs a slow course, and, therefore, may occasion little loss by spreading among animals when a year is the average time of their existence.

When the public awaken to the danger of tuberculous milk, the Legislature will be obliged to insist upon the absence of tuberculous cows from milk-sheds. Then the cowkeeper will be forced to adopt measures of self-protection. He will have to clear his herd, and he will have to guard against the constant risk of purchasing infected cows. He may do this by a trade combination insisting upon all purchases being warranted free from tuberculosis. The individual who attempted to enforce such a warranty at the present time, would fail to obtain the stock he required to carry on his business, or he would have to pay from three to four pounds per head more for them. A strong trade combination might enforce a

warranty, but the effect of such action would at first be to give the careless and dishonest man the pick of the best milkers on the market. This would right itself in time because the negligent buyer would soon have evidence of disease in his shed, and suffer accordingly. The cowkeeper who bought on a warranty could only ensure the value of it by testing his new purchases with tuberculin. The warranty would have a time limit, so that the vendor might not be unfairly treated. But even with this care, and supposing a trade combination could be effected, the voluntary effort would not be safe. Any one can obtain and use tuberculin; after a few injections the reaction ceases or becomes very dubiously indicative. Dishonest dealers might by repeated injections render cows immune against reaction, and then a cowkeeper would have no means of defence against tuberculosis even if he had a warranty. Voluntary effort is insufficient, and unless the law steps in to assist honest traders the public must continue to face the risk of tuberculous milk.

The butcher is at present in the worst position, because the law provides penalties for the sale of diseased meat. The law puts no restraint on tuberculous disease affecting animals in farms or in cow-sheds, but it seizes the infected carcass when it comes into the possession of the butcher. The butcher buys what he believes to be a healthy beast; he is unable to detect disease during life, which may be laid bare by post-mortem examination, but he has to suffer for whatever the meat inspector detects. How is the butcher to apply voluntary effort? There are only two methods open to him. He may form trade combinations to purchase only on a warranty of freedom from disease—not, of course, an absolute freedom, but such a practically sound condition as will enable an inspector to pass the carcass in whole or part. This is being tried in some districts, but is very difficult to enforce, as the salesmen throw in their lot with the farmers to oppose the butchers.

Another plan which is being tried, but which has not made much advance, is for the butchers of a district to form a mutual insurance fund, as is done by shipowners. So much a head on all purchases is paid to the fund, and all loss sustained by seizure at the slaughter-house is made good from the fund. This would be a fair system if the vendors of animals also subscribed, but it is only paying out of one pocket into the other when butchers alone found the fund. It pleases some people

to talk of the loss from contagious diseases in animals as "a trade risk," and of insuring by butchers against it as a thing quite analogous to insurance by shipowners. This argument takes no notice of an extremely important difference. No regulations, either voluntary or legislative, will ever put a stop to storms and accidents at sea. They are an inevitable trade risk which cannot be suppressed, and can only be insured against. With contagious diseases of animals there is no such inevitable and unpreventable condition. The same argument prevailed for a time when the cattle plague invaded this country in 1865—the disease spread, herds were exterminated, and stock-owners ruined. Then stamping out with liberal compensation was tried, and in a few months the plague was exterminated. Similar measures have been attended with success in the case of two other serious diseases—pleuropneumonia and foot and mouth disease. Contagious diseases of animals are more than a trade risk, they are a national disaster, and should be faced as such. They are preventable and, in time, extinguishable. By man's ignorance disease has been allowed to spread—but by man's knowledge it can be controlled. All classes may well be called on to share the expense of suppressing a widespread disease, if it can be shown that it is a public danger, and can be controlled at a reasonable cost, and within a reasonable time. The butcher, the cowkeeper, and the agriculturist must all be called upon to use due care, and to put up with some unavoidable loss, but the public may also be logically included among those who pay the cost of legislative measures beneficial to all.

VOLUNTARY EFFORT *plus* INSPECTION OF MEAT AND MILK.

Those who would rely upon voluntary effort for the control of tuberculosis in animals, overlook the danger to human beings, and treat with too little gravity the constant infection of man which results from disease in cattle. This danger received recognition when, in 1896, a Royal Commission was appointed "to enquire what legislative procedures are advisable, and would be desirable, for controlling the danger to man through the use as food of the meat and milk of tuberculous animals. This Commission issued a report in 1898 which recommended:—

- (1) That local authorities should have powers given them to erect public slaughter-houses, and provide for the inspection of meat.

- (2) That the Local Government Board be empowered to issue instructions prescribing the degrees of infection which cause a carcass to be seized in whole or in part.
- (3) That notification by the owner of every disease of the udder of cows should be made compulsory.
- (4) That milk should be analysed and tested.
- (5) That cowsheds should be kept in proper sanitary condition.
- (6) That the Board of Agriculture should assist stock-owners to detect disease in their animals by the offer of a gratuitous tuberculin test, under conditions that compel separation and isolation of all diseased animals.

These authoritative recommendations are a very great advance upon mere voluntary efforts. The regulations applying to butchers and cowkeepers are stringent, especially the one requiring notification of all udder diseases. Even the gratuitous tuberculin test is made subject to conditions of separation and isolation equal to any similar regulations now applied to other diseases under the Animals Diseases Act.

It will be noticed that the Commission was invited by its instructions to the question of protecting human beings from the danger of tuberculosis in animals. It, therefore, made suggestions for the control of the disease in cattle except such as would indirectly allow voluntary efforts on the part of stock-owners, and the conditional use of tuberculin by the Board of Agriculture. The fact is the Commission could do no more, and their report is to be looked upon as the irreducible minimum of necessary legislation for saving human life. I shall try to show that their instructions so limited their view of the subject as to render it insufficient for any useful legislation, and that what they desire to attain can be more easily and certainly arrived at by a different course—by a course that will not only protect man, but will also assist the agriculturist, and do justice to the cowkeeper and butcher. The report of the Commission certainly did good by directing public attention to the subject, but its suggestion for compulsory interference without payment of compensation has alienated many of the interests concerned. By a majority of one the Commission decided against payment of compensation to the butchers for seizure of tuberculous carcasses. Thus, by one man's vote, the meat

trade has been made to take a position of opposition to proposed legislation, and the agriculturist has accepted the no-compensation verdict as an authoritative hint of what he may expect should he assent to any administrative action.

LEGISLATIVE CONTROL.

To know what authoritative opinion on tuberculosis in animals is, we must read with the report of the 1898 Commission, the recommendations of a Departmental Committee, which took evidence in 1888, on the question of measures required to control the disease in animals. It reported:—"That in order to ensure the gradual extirpation of tuberculosis, we are of opinion that it should be included in the Contagious Diseases (Animals) Act for the purposes of:—

- (1) Slaughter of diseased animals.
- (2) Payment of compensation for slaughter.
- (3) Seizure of diseased animals in fairs and markets, or during transit.

Reading these recommendations in conjunction with those of the recent Royal Commission we obtain guidance as to the necessary measures for the protection of man and animals. The two objects are not separable. The control of tuberculosis in animals and in man is one subject, and unless the double object be kept in view administrative measures will be partially applied, insufficient, and unsuccessful.

I am supported in this contention by the report of the Royal Commission, which clearly recognised the insufficiency of its recommendations, and says: "All precautions against the communication of tubercular disease to human beings (from the consumption of meat or milk of diseased animals) must be regarded as temporary and uncertain palliatives, so long as no attempt is made to reduce the disease among the animals themselves." This sentence is the keynote to useful legislation. To protect man against a contagious disease of animals the logical plan is to control infection at its source—"to reduce the disease among the animals themselves." A good illustration of how this can be done is afforded by the success which has attended Mr. Walter Long's well-sustained effort against rabies in dogs—with the consequent disappearance of hydrophobia in man.

To protect human life against tuberculous meat and milk it is not sufficient to wait until disease has so nearly reached its goal, as when it is in the hands of butchers and cow-

keepers. Safety requires that the first effort should be to prevent it ever arriving so near the human stomach.

Looking at the control of tuberculosis in animals from the wider standpoint, we may find guidance in the combined recommendations of the two bodies who have taken evidence on the whole subject—on its danger to man and its danger to animals. If we place alongside of each other the reports of the Departmental Committee of 1888 and the Royal Commission of 1898, it will be seen how they are complementary to each other, and how the two must be jointly adopted to give the greatest amount of success with the least friction and cost.

The recommendations are :—

<i>Departmental Committee.</i>	<i>Royal Commission.</i>
Scheduling the disease in the Animals Diseases Act.	Compulsory notification by owners of all udder disease in cows.
Inspection of diseased animals.	Inspection of meat, milk, and cow-sheds.
Seizure of diseased animals in markets or during transit.	Seizure of diseased cows in slaughter-houses and cow-sheds.
Slaughter of diseased animals on owners' premises, and payment of compensation.	Voluntary use of tuberculin, but followed by isolation of all infected animals.

The Committee offer no suggestions for the protection of man from tuberculous meat and milk. The Commission leave untouched the mass of disease existing among all the stock not in the hands of butchers and cowkeepers. The defects of either recommendation would be eliminated by the adoption of both. I will very briefly consider each of these authoritative recommendations, and I may possibly show how some may be modified or extended.

Scheduling Tuberculosis in the Animals Diseases Act.—The first step in providing for legislative control of a disease in animals is to schedule it. When scheduled it becomes "a disease" under the Act, and further provisions may be added. That tuberculosis should be scheduled is the opinion of the whole veterinary profession. It was recommended by the Departmental Committee 11 years ago. This step need not be accompanied by any further regulations to do inestimable good. At present the regulation of cow-sheds depends chiefly upon the Cow-sheds' and Dairies' Order, one clause of which refers to the "Existence of disease among cattle," and provides that "if at any time disease exists among the cattle in a dairy

or cow-shed the milk of a diseased cow therein shall not be used for human food. This would seem to afford all the protection necessary against tuberculosis. But the clause is a useless one, because the Act does not define tuberculosis as "a disease." Two or three other affections of cows which are not transmissible or dangerous to man are defined "diseases," and the milk from such animals must not be sold. The greatest danger to man from animal disease is tuberculosis, but this is untouched by the Cow-sheds' and Milk-sheds' Order. If the Board of Agriculture were to schedule tuberculosis under the Animals Diseases Act, no diseased cow could remain in a shed supplying milk for human consumption. Here is the means for the protection of man ready at hand—a stroke of the pen could bring it into action—but the Board of Agriculture make no move, while 70,000 deaths from tuberculosis are registered annually. Such fatuous indifference is inapplicable. If tuberculosis were scheduled under the Animals Diseases Act nothing more would be required to enable the medical officer of health to guard human beings against tubercle-polluted milk supply.

This first step could be made without imposing on agriculturists the slightest restraint without interfering in the smallest degree with healthy stock, or with any diseased animals outside of a cow-shed. Great as would be the good attained by merely making tuberculosis "a disease" under the Animals Diseases Act, I should not propose to limit the action of the Board of Agriculture to this one essential step. There are regulations which must be enforced for the protection of animals as well as for man.

Notification of Udder Disease in Cows. One of the recommendations of the Royal Commission is that compulsory notification of the owner of all udder disease in milk cows should be enforced. This is very necessary because official inspectors cannot attend every day, and udder infection must be detected at the initial stage. The disease develops rapidly and requires attention at the earliest possible moment if contamination of milk is to be prevented. The owner and his servants have daily opportunity to detect anything amiss, and they therefore may well be required to notify the danger immediately it is discovered. As I have said before, the Royal Commission cut down their recommendations to the irreducible minimum. Had they not done so they would never have insisted upon the notification

January 27, 1899.]

udder disease, whilst leaving unnoticed generalised tuberculosis, which may not affect the udder, but which implicates every other part of the body. Cows suffering from generalised tuberculosis are quite as common in cow-sheds as those affected with tuberculous udders. From them there is a constant escape of tubercle bacilli in the excreta and in the sputum. The front of the stall in which such cows stand is plastered with half-masticated food, mucus and sputum, whilst the tail and udder of the animal are fouled by the mucus-laden excreta. Even for human safety, generalised cases of tuberculosis in cow-sheds should be included with udder disease for notification. When we take a wider view and admit that some control of disease among animals themselves should be enforced, the question arises why disease should be notified in cows and not in oxen? If compulsory notification of disease in one gland and one animal is advisable, why not extend the requirement to include all clearly distinguishable tubercular disease in cattle? No disease has ever been scheduled in the Animals Diseases Act without compulsory notification being the very first regulation enforced. Curiously enough the Departmental Committee of 1888 declined to recommend compulsory notification. The reason they gave for this omission was, "That the disease might exist and yet show no signs of its presence." The difficulty of diagnosis existed in 1888, but tuberculin has now rendered it possible to diagnose every case. The reason which ruled the committee no longer exists, and we may infer there is no other objection to compulsory notification. It even in 1888 the recommendation of the committee was inconsistent with the course adopted with other contagious diseases. Hundreds of cases of pleuro-pneumonia in cattle and of glanders in horses then existed with no sign of their presence. Those two diseases required compulsory notification by the owner, under pain of fine or imprisonment or neglect; but of course no man was ever punished for not notifying a case he could not detect. No one now proposes to ask owners to stock to do impossibilities and no one proposes to seize or slaughter those cases which can only be detected by the aid of tuberculin. What is necessary is the notification of clearly diseased animals in cow-sheds or wherever they exist.

Inspection of Meat, Milk, and Cow-sheds.
The danger from meat is not so urgent as

that from milk. If local authorities put in force all the powers they possess, very little harm from tuberculosis in animals would result from meat. The worst meat is now smuggled into shops, evasion of inspection is deliberately carried out, and no respectable butcher has anything to do with it. The most effective method of protecting the public against such meat is not by expensive abattoirs and an army of inspectors, but by making it worth the while of the owner of stock not to sell diseased animals, but to report their existence to the authorities, who would then seize and compensate. Another method of protecting the public is to enable the butcher to protect himself from loss by giving him a claim on the man who sold him a diseased animal. So far as tuberculosis goes, the whole danger of infected meat would be better controlled by scheduling the disease in the Animals Disease Act than by any other course.

As to milk, the Royal Commission propose inspecting and testing. Every precaution and every check would be placed on tuberculous milk by the action of the Cow-sheds' and Dairies' Order provided its regulations were made potential by the inclusion of Tuberculosis in the Animals Diseases Act.

The inspection of cow-sheds is now undertaken by sanitary officers and medical officers of health. All that the Royal Commission require further is the inspection of the cows by veterinary surgeons. This also would be effected if tuberculosis were scheduled. The inspection suggested by the Royal Commission is of course useless unless provision be made for seizing and removing diseased cows.

Slaughter of Diseased Animals.—The Royal Commission said nothing of the seizure and slaughter of diseased animals, but those measures are implied by their recommendations for inspection of milk, and for notification of udder diseases. It is evident that the discovery of diseased animals would be useless unless they were removed. To compel a dairyman to kill diseased cattle at his own cost by stopping his business until he did so, would be an indirect meanness without precedent. I conclude the Royal Commission would wish local authorities to have power to remove and slaughter all dangerous animals in cow-sheds. The Departmental Committee unanimously advised slaughter of diseased animals and payment of compensation. Here again we see that if the Board of Agriculture would schedule tuberculosis, and deal with it

as they have dealt with other contagious diseases, they would only be adopting what the Royal Commission and the Departmental Committee both recommend.

Compensation for Slaughter.—It is hardly necessary to offer any argument in favour of paying compensation to an owner for the seizure of his property for the public good. For more than thirty years the precedent has obtained of paying compensation for the slaughter of animals under the Animals Diseases Act. That a new departure should be made in the case of tuberculosis requires some reasons stronger than have yet been formulated. The owners of animals have been taught by previous experience to look to Government for assistance as well as for measures of confiscation. Authorities have found it easier, more effective, and less expensive, to pay the owner for his co-operation in notifying disease and isolating infectious animals than to refuse compensation whilst trusting to constant inspection and compulsion for the detection and control of disease. Liberal compensation has been found by the Privy Council and by the Board of Agriculture a necessary and expedient corollary of the compulsory slaughter of animals. Compensation is of course only partial, and the owner of stock is always a heavy loser, even when he receives the most liberal compensation.

Seizure of Diseased Animals.—This was advised by the Departmental Committee whenever animals were in such a position as to be likely to spread disease to other animals, as at fairs and markets, or on roads or during transit. The Royal Commission would only advise seizure where danger to man existed. If we are to avoid limiting preventive efforts to what the Commission called "temporary and uncertain palliatives," seizure of all diseased animals likely to injure man or spread disease, should be adopted. Power to seize animals away from home pre-supposes some regulations against movement of diseased cattle, and such regulations have always formed part of any scheme for the suppression of scheduled diseases.

Use of Tuberculin.—I accept as most valuable the recommendation of the Royal Commission that the Board of Agriculture should supply to any stock-owner who desired it a gratuitous testing of his stock. As the acceptance of the test is purely a voluntary act, the stock-owner cannot object to conditions that he shall separate all the diseased from the healthy and not sell those which are infected

except for slaughter. These conditions though fair are likely to be so troublesome to many stock-owners, that I fear little request for the tuberculin test would follow its establishment by the Board of Agriculture. Cow-keepers would be well-advised to accept it if the opportunity occurs, still more willingly should breeders hold out their hand for it. The voluntary use of tuberculin, whether the test be applied by authorities, or by private veterinary surgeons, puts the owner in a position of command over the disease. He learns which animals are diseased and is able to separate them from the healthy stock and so prevent further spread of the plague.

The compulsory use of tuberculin should be provided for in some cases if the recommendations of the Royal Commission or of the Departmental Committee are given practical effect to. The cases I refer to are those where the inspector is doubtful as to his diagnosis. These doubtful cases have always been a source of trouble, and half the quarrels of stock-owners and the officials carrying out the provisions of the Animals Diseases Act, are traceable to disputed diagnosis with consequent delay in action and increase of trouble and cost. Tuberculin would assist to a correct diagnosis in a few hours. Udder diseases are many, and to differentiate every case of tubercular disease from induration due to non-specific causes is impossible. Tuberculin produces a local reaction in all affected organs, and so renders diagnosis of tubercular udder disease certain.

The various measures I have now discussed have all been recommended either by the Royal Commission as necessary to protect man from danger, or by the Departmental Committee to control disease among stock. The Government has ordered two select bodies to take the best evidence they could obtain and then to report what they considered necessary for the control of tuberculosis in animals. These authoritative bodies have reported, and from their published recommendations we may safely compile a complete scheme. It would be as follows:—

Tuberculosis to be scheduled in the Animals Diseases Act.

Compulsory notification to be enforced.

Inspection of meat, milk, and cow sheds to be carried out.

Movement of diseased animals to be regulated.

Slaughter of visibly diseased animals to be enforced.

Compensation to be paid to owner for slaughter.

Seizure of diseased animals in markets or during transit.

Power to use tuberculin in doubtful cases to be given to authorities.

Offer of gratuitous tuberculin test to all stock owners, subject to isolation of all infected animals.

Our administrators know perfectly well what their trusted advisers have said, and what ought to be done. The loss from tuberculosis is 70,000 persons and 40,000 cattle every year. Is this not sufficiently serious to demand action? It would be absurd to suppose there was any doubt. Legislation is inevitable, and it must follow the lines sketched by the authorities I have quoted. The hesitation of Government to adopt legislative interference is due simply to fear of movement until the public, or a majority, are convinced of the necessity. The public are being rapidly educated. The trade interests most directly concerned will do well not to assume indifference, but to take an active part in promoting the public weal, at the same time that they defend themselves against any injustice.

There is one question that all sensible men endeavour to answer before commencing any scheme, viz.,—what will it cost? The control of tuberculosis among animals is not a small matter and no scheme of legislation with this object has the slightest chance of adoption by a Government department until the heads are satisfied of a probability of success, commensurate with the cost.

The State of Massachusetts and the Kingdom of Belgium have shown by failure the impossibility of stamping out the disease by such radical measures as have been successful with some other animal plagues. If we accept the estimate that 20 per cent. of 4,500,000 of cattle are infected, and then assert that all these animals must be slaughtered and partially paid for, we enter on an undertaking that neither the owner of stock nor the taxpayer would approve. There is no necessity for such wholesale slaughter. The majority of infected cattle are not infective to others—they are neither dangerous to man or other animals, and their slaughter would be a wicked waste. Only the visibly affected are dangerous, and their number does not exceed 40,000. This estimate would include every animal whose carcase is wholly unfit for human food and every cow whose milk is unfit for consumption. The slaughter of these would be a loss to the

owners, but it would be a public benefit, and it is expedient and just that the public should share the loss.

I suggest that local authorities should pay as compensation £2 per head for all compulsorily slaughtered of a value not exceeding £8; and a sum equal to one-fourth the market value of all others seized—but no animal should be valued at over £24. Any salvage on carcases, minus the cost of removal and slaughter, should be repaid to the owner.

The payment of £2 as compensation for miserable animals that are a danger to man or to other stock may seem an illogical proceeding, but unless some such inducement is offered, many of them would be sold to the lowest class of butcher and find their way into human food. A payment of £2 per head would make it worth the while of the owner not to evade reporting to the authorities, and so the existence of disease would become known with greater expedition. Infected premises once recognised could be supervised in such a way as to assist the owner and protect the public.

The difficulty of doing justice to the butcher might be met in another way. In any Act of Parliament dealing with the subject a clause might be inserted enforcing a warranty by the vendor of freedom from tuberculosis, whenever a butcher bought cattle and distinctly stated he was buying for the purpose of slaughter for human consumption. Such a clause would take from the butcher any claim for compensation, would protect the public by eliminating any reason for hiding disease, and would lay the burden upon his seller who is able to protect himself by testing the stock before going to market. This compulsory warranty would be limited to a period of eight or ten days.

The Royal Commission used as an argument against the payment of compensation, the evidence given it that butchers very seldom had much loss, and that the few cases occurring might easily be met by mutual insurance. If the argument has any basis, the fact may be used to show how slight the burden of my proposed warranty would be on stock vendors. The breeders and feeders are certainly more to blame for disease and its non-detection than butchers; they should, therefore, be held more responsible. By eliminating the butcher's claim for compensation measures of control are simplified because we then may deal with all stock and all claims under the Animals Diseases Act, which would provide assistance to the owners of stock, and compensation for all notified disease.

Compensation at the rate of £2 for all animals below the value of £8, and compensation at a higher rate on all over that value would probably reach a cost of £100,000 in the first year and a constantly decreasing sum every year afterwards until no disease existed. This is less than is now paid every year for the attempts to stamp-out swine fever.

For this payment, what should we receive? A guarantee against human infection from animals, and a gradual but rapid suppression of disease among stock.

I have now laid before you arguments in favour of legislative action. I have shown what danger and loss the disease causes. I have offered an estimate of the probable cost of proper control.

I hope I have been able to prove that voluntary effort is insufficient, and that the protection of human life will be most effectively undertaken by measures which apply to all animals, and not to those only which are in the hands of butchers and cowkeepers. The cheapest and best method is the one which is effective; the most costly is that which the Royal Commission well described as "temporary and uncertain palliatives."

DISCUSSION.

The CHAIRMAN said they were very much indebted to Mr. Hunting for throwing the light of his special knowledge and experience on a question which it was quite evident was one of national importance. Figures were apt to slip from one's mind without producing much impression, unless they were connected with something tangible, and when reference was made to the fact that 70,000 deaths occurred annually from tuberculosis, it occurred to him that there were scattered over the country a considerable number of flourishing market towns, having a population of from six to ten thousand; if, then, they considered that the whole population of something like ten of such towns was annually swept away by this plague, it would give a more realistic idea of the magnitude of the evil. Everything which brought home the facts to the public mind was a great benefit. Not long since, England might be said to be in the van of sanitary science, but of late years she had somewhat lost that position, and had been outstripped by other countries, the reason being that the rulers of those countries, acting under the best scientific advice, had become prone to take the initiative and to introduce legislation, which was not only effective, but also educational. Our rulers would do nothing in such matters until they were forced on by public opinion, and therefore the sooner that public opinion was formed on the best possible data, the better it would be for all. He

would ask if it were not a slight exaggeration to say that milk must be well boiled to render it safe, because he was under the impression that Dr. Klein had stated that raising it to 150° Fahr. and then cooling it, was sufficient, and that temperature did not spoil the flavour of the milk or render it less digestible, as boiling did. That it ought to be protected in some such way in the household, pending the time when it would be protected by statute, was clearly shown by an interesting report published in the *Lancet* a fortnight ago, of some researches made by Dr. Sladen, of Cambridge, under the supervision of the late Professor Kanthack. Search was made for the presence of the tubercular bacillus in the milk supplied to the colleges at Cambridge, and, out of sixteen samples, nine were found so actively infective that they caused the death in a few weeks of guinea pigs, under whose skin a few drops were injected; and the creamy layer at the top and the sediment at the bottom of the vessel were found equally fatal. All those samples were, no doubt, supplied by tradesmen of good position. Similar researches in Berlin and elsewhere had shown an abundance of these same bacilli in butter, and it must be remembered that milk was an admirable cultivating medium for the bacillus, so that when the milk from one cow with a diseased udder was mixed with that from healthy animals, the bacilli would multiply at an almost incredible rate, and the whole milk would be quickly contaminated. He had listened with great interest to the remarks on the question of compensation, which was clearly one which would have to be faced, and on which it was quite possible to entertain different views. He had heard of a district in India where a premium was paid for every poisonous snake which was destroyed; there was a man in the neighbourhood who called himself a hunter of snakes, and he brought in a great number every year, for which he was duly paid, until at length it was discovered that he had a small snake farm and bred them, killing and bringing in to the public officer as many every year as he thought would pass muster. Was there not a possibility that under a system of compensation it might become a business to deal in tuberculous cattle.

Professor PENBERTHY said he cordially agreed with the greater part of Mr. Hunting's remarks. He had shown how great was the danger, and also that it was preventable. Sixteen years ago a paper on the same subject was read in that room at the first meeting of the National Veterinary Society, when the same recommendations were resolved upon, and made public as far as possible; but they were then impracticable of application, because they had at that time no certain means of discovering the disease. That power had now been obtained, and they could at any time discover how many animals were affected, and it was also now thoroughly recognised that the disease in human subjects was to a large extent derived from animals. Only that morning he had

received a letter from Jersey pointing out that the disease was almost non-existent amongst cattle in the Channel Islands, and at the same time the Registrar-General's returns showed that the diseases of children due to tuberculous milk were almost unknown. There ought to be a grand effort made to stamp out this great enemy which had destroyed during the present reign more lives than all the wars of Great Britain during the last 1,000 years. Even if it cost £200,000, it was not the price of one battleship, and it ought not to be taken into consideration. It was an advantage to the farmer to discover, if he could voluntarily, what animals were affected, and at once deal with them to the best advantage, and this, to some extent, would be a protection to human health. But the elimination of tuberculosis in the lower animals could scarcely be compared with the eradication of pleuro-pneumonia or cattle plague. The latter diseases were only communicable from one animal to another, while tuberculosis affected not only cattle and human beings, but a large number of other animals: rabbits, pigs, fowls, and horses, to a certain extent. Moreover, though the plan proposed would have a good effect, he doubted whether it could secure the extirpation of the disease. The case of other animals must also be dealt with. The education of public opinion, whether legislation followed or not, would act with very great force in reducing the danger to the public. The knowledge that this disease existed in more than 20 per cent. of our cattle had already produced a considerable effect on stock owners, though the matter had only been before the public for a short time. Already 20 corporations were applying their powers to the question; and he could say from his own knowledge that between 4,000 and 5,000 animals had been tested with tuberculin, and that was probably only a small proportion of those which had been so treated. It was absolutely necessary, however, that the Legislature should take the matter up seriously, and whatever money was required, he could not see why it should be refused. No doubt the reports of the Royal Commission had gone a little further than their instructions warranted, and indirectly they had considered the difficulties of eradicating tuberculosis. A very large number of animals would have to be dealt with immediately, and the dairies could not be readily restocked, but that should not be urged as a reason for neglecting the matter. He hoped that the publication of this paper would have a very material effect in the education of public opinion.

Mr. LOVEJOY asked if some suggestions could not be made to the Board of Agriculture to offer facilities for applying the tuberculin test gratuitously. Every breeder would rather produce a healthy animal than an unsound one, and he should think they would all be glad to avail themselves of this method of diagnosis.

Dr. A. GASTER remarked that if all the tuberculous

animals in England were destroyed, it would not prevent infection by milk coming from abroad. Meat was much more easy to deal with, and in most cases the bacilli were not found in the muscle but in the lymphatic glands and in the lungs, which were not used as human food; neither did people eat meat raw, and if the bacilli were killed at a temperature of 150° Fahr. they would hardly survive ordinary cooking. In the case of milk, there was no possible test, except by experiment on rabbits or guinea-pigs, and therefore people ought to boil their milk. While they were trying to stamp out tuberculosis in cattle, they must not forget that the disease existed in thousands of human beings, by whom it was spread, and also in other animals, rabbits, and particularly in fowls. All meat should be inspected, and, of course, compensation should be paid to those whose cattle were destroyed for the good of the public.

Mr. PRAED asked how the tuberculin test acted.

Colonel BURKE asked how much of the mortality of 70,000 annually was due to infection from animals; also, how it was proposed to deal with animals which were only slightly affected.

Mr. EDWARD C. DE SEGUNDO said people often made the remark that their fathers and mothers drank milk and got no harm by it, and why could not we do the same; but, as a matter of fact, the statistics given by Sir Richard Thorne Thorne in his last Harveian lecture showed how worthless that argument was. The mortality amongst adults from tubercular disease had greatly diminished, owing to improved sanitation and so on, but infant mortality from *tabes mesenterica* had increased very largely, and he attributed that to a great extent to the importation of milk and butter from foreign countries. In this country inspection was carried out to a certain extent, but on the Continent there was no such control over the dairies, and the frozen milk and butter sent here might be infected to any extent with the tubercle bacillus. The Chairman had drawn attention to the rapidity with which this bacillus multiplied in milk, and he should like to emphasise that by quoting some figures from an article entitled "microbes in milk," which appeared in *Chambers' Journal* of August last. It appeared from some experiments made by Professor Freudenrich at Berne, that a quarter of a cubic inch of milk, which contained 9,000 microbes, seven hours later contained 80,000, and 25 hours later 5,000,000; while, if the temperature were raised to 95° Fahr., about blood heat, the population of the same milk in the same time would reach 812,000,000—to follow the Chairman's illustration, equivalent to a thriving market town of 10,000 inhabitants becoming in 25 hours nearly 200 Londons. Nothing could be more clear and convincing than the arguments brought forward in this paper, and it was perfectly incomprehensible how the subject had been allowed to remain dormant so long. However, if the wheels of legislation ground slowly, they must hope they would grind exceeding small. He would now refer to

a process which might be called only a palliative, but from a practical point of view had a good deal to recommend it, viz., the sterilization of milk, which, as an engineer, he had to investigate some four years ago. One important question, of course, was that of the cost, and he quite agreed with Mr. Hunting that people would not pay a higher price for pure milk. But they need not do so. By placing the matter under control of the Municipality it would be possible to sterilize all the milk sent up from the country and to distribute it, in sealed glass bottles, absolutely free from any germs at 4d. per quart without causing any burden on the rates. He was speaking with an intimate knowledge of what was at present being done in this direction in London on a commercial scale. In this way something could be done to diminish the number of victims of infected milk (particularly among children), until the recommendations contained in Mr. Hunting's admirable paper could be carried into effect and the disease stamped out, at least as far as cows are concerned.

Professor LONG said this paper was one of the best he had heard on this subject, and he wished the author would come to one of the monthly meetings of the Central Chamber of Agriculture which were held in that room, and address the farmers upon it. The last speaker had referred to the number of bacilli present in a given quantity of milk, but they must not go away under the impression that those were all disease germs, because they were not; the majority of them were friendly germs, which were useful not only in the milk, but also in the body of a human being. With regard to the importation of milk from abroad, he might say that large quantities were being imported at Southampton from parts of France where disease was known to be rife amongst the cattle. With regard to butter he did not think there was so much danger as might be supposed. Cream was nowadays mostly obtained by means of a separator, in which the cream was gathered in the centre, and experiment showed that the bacteria were to a large extent thrown to the periphery of the drum. This had been clearly established in Massachusetts. At any rate, with regard to butter, it might be obtained from the West of England, where the cream was scalded, or from Ireland, where it was produced on the Danish or Swedish system, under which the whole of the cream or milk was Pasteurised, and the disease germs destroyed; and not only the disease germs, but all others. Now it was essential to good butter that there should be some germs present, and, therefore in these factories the superintendent added a small portion of "starter," which was a pure culture of the butter germ, and this set up the acid process necessary to the production of good butter. The only germs present, therefore, were those thus introduced, which were innocuous. Personally, he had suffered severely from the presence of tuberculosis in cattle, and had made various investigations, but

nothing seemed to stop it. He had sold and killed great many animals, and yet the disease would break out again in an apparently healthy beast. The Corporation of Glasgow had got a Bill passed giving the power to follow any milk delivered in the city to its source, and if they found a diseased cow in the district he believed they could order it to be destroyed. Those powers had not been put in force, but Mr. Hunting said there were twenty different corporations seeking for similar powers. He should object to this strongly, though he should quite agree that powers rather more limited might be conferred. They should have power to trace the milk, and if a cow were found with a diseased udder, or with generalised tuberculosis, it should be destroyed, but not any other cow.

Mr. HUNTING, in reply, said that whatever measures were applied to producers of milk in this country should equally apply to milk imported from abroad. It was not very easy to say exactly what should be done. All meat affected by tuberculosis should be seized, but it was not so easy to deal with milk. There was no immediate method of testing it; if you inoculated a guinea-pig you had to wait some time for the development, and in the meantime the risk was gone, and the next lot of milk might be innocent. If one source of milk were clearly shown to be tainted, you must forbid further importation from that same source, but he feared the commercial instinct would get round such prohibition by sending it from another port. Measures for protecting the health of human beings were not at all antagonistic to measures dealing with animals, and, in the latter case, compulsory regulations were much more easily applied, as no conscience clause was allowed to interfere. He understood the Board of Agriculture was still waiting for an application to be made to it with regard to the tuberculin test. Mr. Walter L. recently said that no public body had yet asked for it, but if it did, he saw no reason why he should not apply to the Treasury. The Royal Commission had suggested the expenditure of £5,000, which Mr. L. said was a small matter. He quite agreed with Mr. Penberthy that you could not compare this disease with cattle plague, or pleuro-pneumonia, and some of the officials of the Board of Agriculture said the same thing, meaning that they could not do anything under the Animal Diseases Act. But it could be compared with some of the other diseases dealt with in that Act, notably with one, to which it was in many ways analogous, viz., glanders in horses. That disease might lie latent for months, and the regulations now applied to glanders might very well be applied to tuberculosis. If the authorities seized a horse worth 80 guineas, and gave the owner £2, a farmer would not have much to complain of if they seized a cow worth £10, and gave him £2 for that. The effect of tuberculin was this: when injected into an unhealthy animal it raised the temperature 3 or 4 degrees, the effect being most marked at the thirteenth hour. It also affected any local disease which might exist.

were tuberculosis of the lungs, it would set animal coughing; if the intestines were ed, it would produce diarrhoea for a little; if the udder were affected, it would some pain and heat in the indurated portion. Unfortunately, however, it did not tell you amount of tuberculous disease in the animal. It d produce as great a reaction if the animal had or three portions of tubercular matter the size of as if the whole of the lungs or abdomen were ted. That must be borne in mind in considering to do with the animal. All lean stock that ed should be isolated until fit for the butcher; ling stock should be kept separate, as long as id did not "waste," and were likely to throw a good

Milking cows must still be milked, because the may be perfectly innocent; but the udder should arefully examined from day to day, and on the ttest sign of enlargement or disease, the milk should topped. If Dr. Klein said 150° Fahr. was suffi- t to make the milk safe, he should be sorry to it was not; but the ordinary housekeeper knew ing about a thermometer, and the simplest ce was to boil the milk. He did not know how y of the 70,000 deaths were attributable to als, but if they were only 7,000, or 700, or even and you could certainly prevent them, would it be well worth doing? With regard to the irman's suggestion about the snake farm, he ht say that Dr. Legge, the late Secretary of the al Commission, made a similar remark, that pensation would open the door to fraud, but any who had anything to do with compensation er the Animals Diseases Act knew there was ing in it. Feeding snakes was probably not y expensive, and the capital required was not e, but the feeding of cows costs money, and ing tuberculous cows and keeping them even a k in the hope of getting £2 for them would not be ery tempting speculation. As an official who ht have something to say to that question, he uld say the very best thing which could happen ld be for some one to speculate in tuberculous ck. When that man had reported about four cases, uiries would be made where they came from, l the end would be that instead of making a profit would get locked up whilst he would be inval- ue as a voluntary detector of diseased herds.

The CHAIRMAN then proposed a cordial vote of nks to Mr. Hunting, which was carried unani- usly; and the meeting adjourned.

Miscellaneous.

INTERNAL TRAFFIC OF FOREIGN CITIES.

At the end of his Address at the Opening Meeting of the Society (November 16), the Chairman of the

Council, Sir John Wolfe Barry, referred to the valuable information which he had received through the Foreign-office, and from the Mayors of Washington, New York, and Boston, in answer to inquiries which he had made as to certain particulars relating to the means of communication in foreign cities. Viscount Gough, First Secretary to H.M.'s Embassy at Berlin, sent information relating to that city; the Burgomaster of Brussels, through H.M.'s Minister, supplied statistics respecting Brussels; Mr. Austin Lee, C.B., gave the particulars of Paris traffic; and Sir Horace Rumbold, Bart., G.C.M.G., Ambassador at Vienna, supplied information respecting that city.

The information received may be classified under the following headings:—(1) Daily number of persons entering or leaving the cities; (2) Particulars of traffic; (3) Number of vehicles at fixed points; (4) Width of streets.

I.—DAILY NUMBER OF PERSONS ENTERING OR LEAVING BERLIN, VIENNA, AND NEW YORK.

The average daily number of persons entering Berlin is stated to be about 150,000; but the daily ebb and flow of the population of the cities of Europe and of the United States do not appear to be available.

In 1896, 5,291,317 persons entered the city of Vienna by rail, or an average of about 14,500 daily.

In New York the average number of passengers daily crossing New York and Brooklyn-bridge, during 1897, is given as 138,473. The average number of vehicles daily crossing is 4,500.

	Passengers.	Vehicles.
November 10, 1897 (24 hours).	144,509	4,617
The highest number in one hour is from 3 to 6 p.m., viz.	19,262	472
The lowest number, from 3 to 4 a.m., viz.	422	27

2.—MEANS OF TRAFFIC.

Berlin.—The annual working expenses for the passenger traffic in Berlin are given as follows:—

	£	£
Railways.....	150,000 to 200,000	
Tramways (including electric lines).....	650,000 to 750,000	
Omnibuses.....	200,000 to 250,000	

Brussels.—In Brussels the number of different lines of tramways and railways, with the annual number of passengers, are as follows:—Tramways—Les Tramways Bruxellois, 16 lines (horse and 5 electric), number of travellers in 1896, 39,760,989; 1897, 39,304,795. Société Generale Chemins de fer économiques, 5 lines (horse), number of travellers in 1896, 3,146,300; 1897, 4,098,451 Société des Chemins de fer vicinaux, 1 line (horse), number of travellers in 1896, 910,360; 1897, 905,020. Société du Central Car, 1 line (horse), number of travellers in 1895, 796,149; 1896, 1,018,801; 1897, 1,445,195. Société du Tram Car, 1 line (horse), number of

travellers in 1896, 2,658,493; 1897, 2,806,330. Railways—Société de Chemins de fer à voie étroite, 5 lines (electric); Société Nationale des Chemins de fer vicinaux, 8 lines (7 steam, 1 electric), number of travellers in 1895, 1,687,737; 1896, 2,110,830; 1897, 2,303,881.

Paris.—In Paris the daily average of travellers from Paris to Auteuil and from Paris to Versailles is:—Railways—Paris—Auteuil, travellers going and returning, 63,000; fares, 1st class, 60c., second class, 30c. Versailles, by circular railway, passengers, 311,936; fare, 1 f. 16 c.

The annual movements by tramcars and steamboats are:—Tramways—(fares, 1st class, 40c., 2nd class, 20c.) St. Cloud and Sèvres, 3,141,244 passengers; Vincennes, 7,739,350 passengers; North, 29,887,943 passengers; South, 27,160,032 passengers. Boats—Paris to Suresnes, 2,545,745 passengers, fare, 30 c.

Vienna.—In Vienna there are no electric railways. A metropolitan railway is in course of construction, and 21 miles 223 yards are open to the public. Fares per kilometre—1st class, 3½ kreutzers (¾d.); 2nd class, 2½ kreutzers (½d.); 3rd class, 1½ kreutzers (¼d.).

There are 35½ miles of tramway lines and 738 tramcars, of which 70 are driven by electricity. The zone tariff is in force as follows:—5 kreutzers (1d.) from the 1st to the 2nd zone, 7 kreutzers (1½d.) from the 1st to the 3rd zone, 10 kreutzers (2d.) from the 1st to the 4th zone, 15 kreutzers (3d.) from the 1st to the 5th zone, 20 kreutzers (4d.) from the 1st to the 6th zone; 2 kreutzers charged from 2nd to 3rd, 3 kreutzers from 3rd to 4th, &c.

The omnibuses number 520. Fares:—7, 9, 12, 15, kreutzers, according to distance. The zone tariff applies to omnibuses and to the metropolitan railway.

Of Hackney carriages there are (numbered) 972 with two horses, 1,514 with one horse, and (un-numbered) 1,298 with one and two horses. Fares, from one district to another, two-horse cab, 90 kreutzers (1s. 6d.), one-horse cab, 60 kreutzers (1s.); from one point to any other in the same district, two-horse, 60 kreutzers (1s.), one-horse 40 kreutzers (8d.); for every quarter of an hour beyond the ride, two-horse, 40 kreutzers (8d.), one-horse, 30 kreutzers (6d.); the same extra charges are made for coming from or going to railway stations, or for setting down at theatres.

New York.—The chief means of communication in New York consists of elevated railways, surface railroads, and steam ferries. Passengers carried on railroads for the year ending June 30, 1897, for the territory now comprising New York City, 862,552,517. Fare 5 cents for any distance. A passenger may make one continuous trip of 17 miles around the city on the Manhattan Elevated Railway for one fare of 5 cents.

Washington.—There are 180 miles of asphalt-paved streets in Washington, and the number of bicycles on these roads is given as 40,000. The average daily number of passengers carried by street railways (electric and cable) is 143,302. The fare for one adult

passenger in the cars, with privilege of transfer about 4½ cents (2¼d.).

The number of licensed public hack cabs and carriages in Washington is 441. The fares are divided into day rates (5 a.m. to 12.30 a.m.) and midnight rates (12.30 a.m. to 5 a.m.) and are charged by trip and by the hour. The fares for two-horse vehicles are about double those for one-horse vehicles.

3.—NUMBER OF VEHICLES AT FIXED POINTS

Berlin.—The points of greatest traffic (daily, 6 a.m. to 10 p.m.) are as follows;—

	Foot pas.	Vehicle
Potsdamer Platz (west district)	85,580	16,51
Brandenburger Thor (west district)	70,600	9,25
Unter den Linden (corner of Friederich Strasse, west district)	120,800	13,24
König Strasse (corner of Spandauer Strasse, central district)	92,300	12,97
Alexander Platz (central district)	151,220	11,91
Belle Alliance Brücke (south-west district)	112,751	10,24
Oranien Brücke (south district)	98,680	7,84

Paris.—The average number of vehicles passing the Avenue de l'Opera during the 24 hours is 29,400, the vehicles being drawn by 36,185 horses.

Washington.—The number of vehicles passing the corner of Pennsylvania Avenue and Seventh street (one of the most frequented points in the city) during the 24 hours from 12 o'clock noon, Nov. 5, to 12 o'clock noon, Nov. 6, 1898, was 9,726. The number of passengers in the vehicles was 16,848.

4.—WIDTH OF STREETS.

Berlin.—Unter den Linden (includes a broad way with two rows of trees for nearly half of the whole length), 196 ft.; Leipziger Strasse, 72 ft.; Friederich Strasse, 72 ft.; Friedrich Strasse, from the corner of Behren Strasse to Unter den Linden, 41 ft.; Köpenicker Strasse, 57 ft. The width of the pavements on both sides of the street is included.

Bruxelles.—Le Boulevard Circulaire, between the Places de Namur and Louise, 220 ft.; L'Avenue Louise, 183 ft.; L'Avenue du Midi, 118 ft.; Le Boulevard Anspach, 91 ft.; Le Boulevard du Nord, 78 ft.; Le Rue de la Nord, 65 ft.; Le Rue Royale, 65 ft.

Paris.—Rue de Rivoli, 88 ft.; Rue Montmartre, 72 ft.; Avenue de l'Opera (Boulevard St. Germain), 98 ft.; Grands Boulevards, 114 ft.; Avenue des Champs Elysées, 229 ft.; Avenue de Grande Armée, 295 ft.; Avenue Bois de Boulogne, 393 ft.

Vienna.—Ringstrasse, 187 ft.; Kärntnerstrasse (Upper), 62 ft.; Kärntnerstrasse (Lower), 121 ft.; Praterstrasse, 118 ft.; Rennwegg, 65 ft.; Hauptstrasse, 3rd and 4th district, 65 ft. each; Hauptstrasse, 5th district, 72 ft.

any 27, 1899.]

York.—The streets vary in width from about 60 to 150 feet. The ordinary residence streets begin at First-street and extending across the city of Manhattan from east to west, up as far as Broadway street are 60 feet wide, excepting at intervals of about half a mile, when they are 100 feet. The streets which run north and west at right angles to the cross streets are 80 to 150 feet wide.

Houston-street or First-street, on Manhattan Island, the streets and thoroughfares are of various widths, following for the most parts lines of streets, lanes, or roadways originally followed for the convenience of the early colonists or settlers.

Washington.—Most of the Avenues named after the different States are 160 feet wide from building to building line, with 50 to 107 feet roadway respectively.

Correspondence.

TRANSMISSION OF ELECTRIC POWER.

Attention has been drawn to Professor Forbes's works under the above heading. (See ante, p. 139.)

Professor Forbes will refer to pages 240 to 243 of the Proceedings of the Manchester Association of Engineers, 1892, he will find my article "On the financial risk involved in laying down long lines of Electric Conductors;" he will see that my conclusion, [e.g. "that the capital required to cover the cost of trunk transmission lines should be obtained from the special issue of mortgage debentures at the rate of interest specified"] was the result of a somewhat elaborate investigation into the range of fluctuations of the value of copper—extending over the period of 30 years—or from 1877 to 1891.

The average ratio of risk was compared with that of the bank rate of interest and also with that of the Government stock. The investigation led to a conclusion on the figure of 3.15 per cent. as a fair mortgage rate of interest for a long distance transmission trunk line, pure copper conductors, laid down in this country. A graphic diagram also accompanies my article and defines the average value of copper (Chilian bar) during a period of 13 years.

Although I cordially wish Professor Forbes every possible success in his African project, I doubt if the financial world would encourage the investment of money at even double that of the rate of interest suggested.

January 11th, 1899.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 1.—"The Cost of Municipal Enterprise." By DIXON H. DAVIES. The ATTORNEY-GENERAL, G.C.M.G., M.P., will preside.

FEBRUARY 8.—"Nernst's Electric Lamp." By JAMES SWINBURNE.

FEBRUARY 15.—"The Balloon as an Instrument of Scientific Research." By the Rev. JOHN M. BACON, F.R.A.S.

FEBRUARY 22.—"Electric Traction and its Application to Railway Work." By PHILIP DAWSON.

MARCH 1.—"Leadless Glazes." By WILTON P. RIX.

MARCH 8.—

MARCH 15.—"Liquid Fuel." By Sir MARCUS SAMUEL. Sir EDWYN S. DAWES, K.C.M.G., will preside.

Dates to be hereafter announced:—

"Preservation of Timber." By S. B. BOULTON.

"Coal Supplies." By T. FORSTER BROWN.

"Wireless Telegraphy." By W. H. PREECE, C.B., F.R.S.

"London's Water Supply." By WALTER HUNTER, M.Inst.C.E.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 9.—"The Penal System at the Andamans." By Colonel RICHARD CARNAC TEMPLE, C.I.E., Chief Commissioner of the Andaman and Nicobar Islands. The EARL OF NORTHBROOK, G.C.S.I., D.C.L., F.R.S., will preside.

MARCH 9.—"Leprosy in India." By H. A. ACWORTH, C.I.E., late Government Municipal Commissioner for the City of Bombay.

APRIL 13.—"Judicial Reforms in Egypt in Relation to the Indian Legal System." By Sir JOHN SCOTT, K.C.M.G., D.C.L., Deputy Judge Advocate-General, and late Judicial Adviser to H.H. The Khedive.

MAY 11.—"The Port of Calcutta." By SIR CHARLES CECIL STEVENS, K.C.S.I., late Acting Lieutenant-Governor of Bengal.

MAY 25.—"The Revenue System and Administration of Rajputana." By MICHAEL FRANCIS O'DWYER, I.C.S., Settlement Commissioner, Alwar and Bhurtpore.

The meetings of February 9, and March 9 will be held at the Imperial Institute; those of April 13, May 11 and 25 at the Society of Arts.

FOREIGN AND COLONIAL SECTION.

FEBRUARY 28.—"Persian Trade Routes." By A. HOTZ.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

JANUARY 31.—“The Centenary Exhibition of Lithographs, with Remarks on further Developments of the Art.” By EDWARD F. STRANGE. Major-Gen. Sir JOHN DONNELLY, K.C.B., will preside.

FEBRUARY 21.—“Vitreous Enamels.” By CYRIL DAVENPORT. Sir OWEN ROBERTS, M.A., D.C.L., will preside.

MARCH 14.—“Craftsmanship and its Place in a National Scheme of Art Culture. By Sir WILLIAM BLAKE RICHMOND, K.C.B., R.A.

APRIL 18.—“Modern Changes in Taste relating to Domestic Furniture.” By GEORGE LOCK.

MAY 2.—“Maiolica.” By WILLIAM BURTON.

MAY 30.—“Wrought Iron Signs.” By J. STARKIE GARDNER, F.G.S.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

DR. SAMUEL RIDEAL, “Bacterial Purification of Sewage.” Four Lectures.

LECTURE III.—JANUARY 30.

Anaerobic preparation—Mouras' automatic scavenger—Moncrieff's earlier experiments—Exeter septic tank.

LECTURE IV.—FEBRUARY 6.

Differentiation of the organisms—Scott Moncrieff's later process—Nitrification and nitrosification—Adeney's “oxygen system”—Conditions for aerobic and anaerobic change, and criteria for judging the purity of effluents—Resumé and suggestions.

ARCHIBALD SHARP, A.M.Inst.C.E., “Cycle Construction and Design.” Four Lectures. February 20, 27, March 6, 13.

PROF. HENRY R. PROCTER, “Leather Manufacture.” Four Lectures.

April 10, 17, 24, May 1.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Dr. Samuel Rideal, “Bacterial Purification of Sewage.” (Lecture III.)

Imperial Institute, South Kensington, 8½ p.m. Miss M. H. Kingsley, “West Africa.”

Actuaries, Staples-inn-hall, Holborn, 7 p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. Walter Raleigh, “Lord Chesterfield.”

TUESDAY, JAN. 31...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. Edward F. Strange, “The Centenary Exhibition of Lithographs, with Remarks on Further Developments of the Art.”

Royal Institution, Albemarle-street, W., 3 p.m. Professor E. Ray Lankester, “The Morphology of the Mollusca.” (Lecture III.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Adjourned Discussion on papers by William G. Kirkaldy, “The Effects of Wear Steel Rails,” and Sir William Roberts-Austen, “The Microphotography of Steel Rails.” 2. J. A. Jones, “The Waterworks of the Metropolitan Presidency.”

Colonial Inst., Whitehall-rooms, Whitehall-1 S.W., 8 p.m. Miss Flora Shaw, “Canada.”

WEDNESDAY, FEB. 1...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Dixon H. D. Jones, “The Cost of Municipal Enterprise.”

Geological, Burlington-house, W., 8 p.m.

Obstetrical, 20, Hanover-square, W., 8 p.m. A. Alcock, Meeting.

THURSDAY, FEB. 2...Royal, Burlington-house, W., 4½ p.m. Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. E. Stanley Salmon, “Notes on the Genus *Naristium*, Lindberg.” 2. Dr. F. W. Stansfield, “The Production of Aposporangia by Environment in *Filix foemina* var. *unco-glomeratun* an apparently barren fern.” 3. Mr. Gilbert C. Boyle, “The Genus *Lemnalia* (Gray) with an Account of the Branching System of the Order *Alycanaceae*.”

Chemical, Burlington-house, W., 8 p.m. 1. Dr. H. T. Brown and Mr. J. H. Millar, (a) “Molecular Dextrin, its Oxidation, Products, and Constitution;” (b) “Attempts to prepare Pure Sugar Derivatives through their Nitrates.” 2. Professor H. Lloyd Snape and Arthur Brooke, “An Isomer of Amarine.” 3. Dr. G. T. Moody, “Propionylsulphonic Acids.” 4. Messrs. W. H. Jones and T. H. Basterfield, “Derivatives of Dibenzosilylene.” 5. Dr. Sydney Young, “The Action of Chlorosulphonic Acid on the Paraffins and Hydrocarbons.” 6. Messrs. F. D. Chattaway and Kennedy J. P. Orton, “The Preparation and Properties of Nitrogen Iodide.” 7. Messrs. J. D. Chattaway and H. P. Stevens, “The Action of Reducing Agents on Nitrogen Iodide.” 8. Mr. F. D. Chattaway, “The Composition of Nitrogen Iodide.” 9. Messrs. F. D. Chattaway and Kennedy J. P. Orton, (a) “The action of Light upon Nitrogen Iodide;” (b) “The action of Alkaline Hydrates of Water, and of Hydrogen Peroxide upon Nitrogen Iodide.” 10. Messrs. F. D. Chattaway and H. P. Stevens, “The action of Acids upon Nitrogen Iodide.” 11. Messrs. F. D. Chattaway and Kennedy J. P. Orton, “Theory of the Formation and Reactions of Nitrogen Iodide.”

London Institution, Finsbury-circus, E.C., 6 p.m. Prof. W. F. R. Weldon, “Worms.”

Society for the Encouragement of Fine Arts, 9, Abchurch-lane, W., 8 p.m. Mr. John Wilson, “The Sacred Lake of the Incas.”

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. H. Savage Landor, “Tibet and the Tibetans.” (Lecture III.)

FRIDAY, FEB. 3...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Mr. Viscount Horsley, “The Roman Defences of South-Eastern Britain.”

Geologists' Association, University College, W., 7½ p.m. Annual Meeting.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

SATURDAY, FEB. 4...Education Department, Lecture Theatre, South Kensington Museum, S.W., 3½ p.m. (Lecture.) Dr. Lockyer, “Astronomical Instruments.”

Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander C. Mackenzie, “Brahms.” (Musical illustrations.)

Journal of the Society of Arts.

No. 2,411. VOL. XLVII.

FRIDAY, FEBRUARY 3, 1899.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.**ORDINARY MEETING.**

The discussion on Mr. DIXON H. DAVIES'S paper on "The Cost of Municipal Enterprise," read at the meeting on Wednesday evening, 1st inst., was adjourned to Thursday evening, 2nd inst., at 8 p.m. The EARL OF WEMYSS will open the discussion.

CANTOR LECTURES.

On Monday evening, January 30, Dr. SAMUEL RIDEAL delivered the third lecture of his course on "Bacterial Purification of Sewage."

The lectures will be printed in the *Journal* during the summer recess.

APPLIED ART SECTION.

Tuesday evening, January 31st, 1899; Major-General Sir JOHN F. D. DONNELLY, K.C.B., Vice-President of the Society, in the chair.

The paper read was "The Senefelder Centenary Exhibition of Lithographs, 1898-99," by Edward F. Strange.

The paper and report of the discussion will be printed in the next number of the *Journal*.

Proceedings of the Society.**FOREIGN & COLONIAL SECTION.**

Tuesday, January 24, 1899; The Hon. Sir DAVID TENNANT, K.C.M.G., Agent-General for Cape Colony, in the chair.

The paper read was—

RHODESIA AND ITS MINES IN 1898.

By WILLIAM FISCHER WILKINSON, F.G.S.,
Asscc. M.Inst.C.E.

Nearly three years have passed since I had the honour of contributing to the Society's *Journal* a paper on the gold mines of Rhodesia.* At that time, in 1895, the country was but little known, and the most extreme opinions were offered as to its resources; while some thought that it would become as large a producer of gold as the Transvaal, others again were equally confident that the country was nothing but a fever-stricken swamp, destitute of mines, and unfit for a white man to live in. Events march rapidly in Africa, and the question of interest is no longer whether or not payable gold reefs exist, but to what importance the mining industry is likely to attain. Having spent the greater part of last year (1898) in travelling about among the different mining districts, and having examined the most advanced mines, I shall endeavour to answer that question. In considering the progress that has been made in the last three years, it must be remembered that Rhodesia has had little time to devote to the peaceful development of her resources. What with the native rebellion and the rinderpest all work was practically stopped during 1896 and 1897, and it was not till 1898 that any real progress could be made. It is not my intention to trouble you much with statistics, but I want in the first place to draw your attention to the great size of the country, and to remind you that a large portion of it is still practically unexplored. At the present time the river Zambesi is the dividing line between the occupied and administered part of Rhodesia and the unoccupied portion, over which only a small show of authority has so far been made. Southern Rhodesia, which embraces the provinces of Matabeleland and Mashonaland, is about one-and-a-half times, and Northern Rhodesia is about twice, the area of Great Britain and Ireland, an enormous extent of country, about the economic importance of which it is obvious that for some time no final conclusion can be come to.†

* Vol. xliv., No. 2276, 1896.

† The British South Africa Company, by their original Charter, acquired rights over all the territory between the Molopo River (the northern boundary of British Bechuanaland), on the south, to the Zambesi River on the north. Subsequently the rights were extended up to the Congo State. The country, however, beyond the Molopo River and Zambesi, lying to the west of the Shashi and Ramaquaban rivers and the Pandamatenka road, is now under the direct contrb

In the matter of communications with the rest of the world great progress has been made in the last three years. To reach Matabeleland in 1895 a costly and fatiguing journey of several days' duration from Mafeking or Pretoria had to be undergone. To-day through trains from Cape Town convey passengers and goods at a reasonable cost into the heart of Matabeleland. Buluwayo is brought within $3\frac{1}{2}$ days of Cape Town and 20 days of England.

The railway, besides being an enormous benefit to the commercial development of the country, adds very much to the safety of the inhabitants, as assistance can now be brought in rapidly, should any further disturbances with the natives take place, and, moreover, it is a valuable security against famine. This is a point in favour of the extension of railways in undeveloped countries which must always carry considerable weight. In India we know that railway communication and cheap transport have now made the occurrence of a famine on the scale of former years impossible. In discussing the advantages to China of railways, Mr. Colquhoun says: "It is mainly the difficulty encountered by the Government in transporting the food supply that leads to the terrible loss of life." In South Africa the importance of it received a practical illustration in 1896 when owing to the rinderpest the ordinary means of transport failed, and food which was plentiful in some districts, rose to famine prices in others.

The present terminus of the Cape line is Buluwayo, but it is not likely to be so long. The survey to Gwelo (110 miles) has already been made and the line may be expected to be built in 1899. From Gwelo to the shores of Lake Tanganyika, a distance of 800 miles, the route is still uncertain, but an expedition was sent north last autumn to make a preliminary survey. The line will probably pass through the Mavain and Sinanombi or Sebakwe gold belts, and tap the extensive coalfield that lies

away north towards Mafunga-busi, crossing the Zambesi River where it narrows at the Kariba Gorge or at a point lower down the river and nearer to the Portuguese boundary.

When the railway reaches the southern shore of Lake Tanganyika, it will have arrived at the northern boundary of Rhodesia. From this point there are 400 miles of waterway to the northern end of the Lake which will be within comparatively easy reach of Uganda and its railway communications with Mombasa. The distance from the northern shore of Tanganyika to Khartoum is approximately 1,500 miles, of which a considerable portion will be water-way.

Another line that has been proposed is from Buluwayo to the Victoria Falls, a distance of about 250 miles, which besides bringing into easy reach one of the wonders of the world, which electricians are already anxious to make use of, will assist the development of the northern coalfield of Wankie and of the teak forests of the Gwelo Valley.

A branch line from Buluwayo to the Gwelo district, about 100 miles south-east of Buluwayo, is also being surveyed. In Mashonaland a railway line connects Umtali with the coast and connection will soon be made with Salisbury.

Although the railway has brought places like Buluwayo and Salisbury, places which no every globe-trotter visits, into touch with civilisation, the interior of the country for the most part is still primitive Africa, where the traveller can enjoy undisturbed the freedom of the veldt, off which big game has not yet been entirely destroyed. Many travellers have written of the peculiar charm of waggon travelling in South Africa, and in the dry season few countries can rival Rhodesia. The gipsy life, the variety of the sport, the pleasure of coming to rivers and mountains which has as yet no place in the map, and above all the certainty of fine weather, all combine to make life spent in this way pass only too quickly.

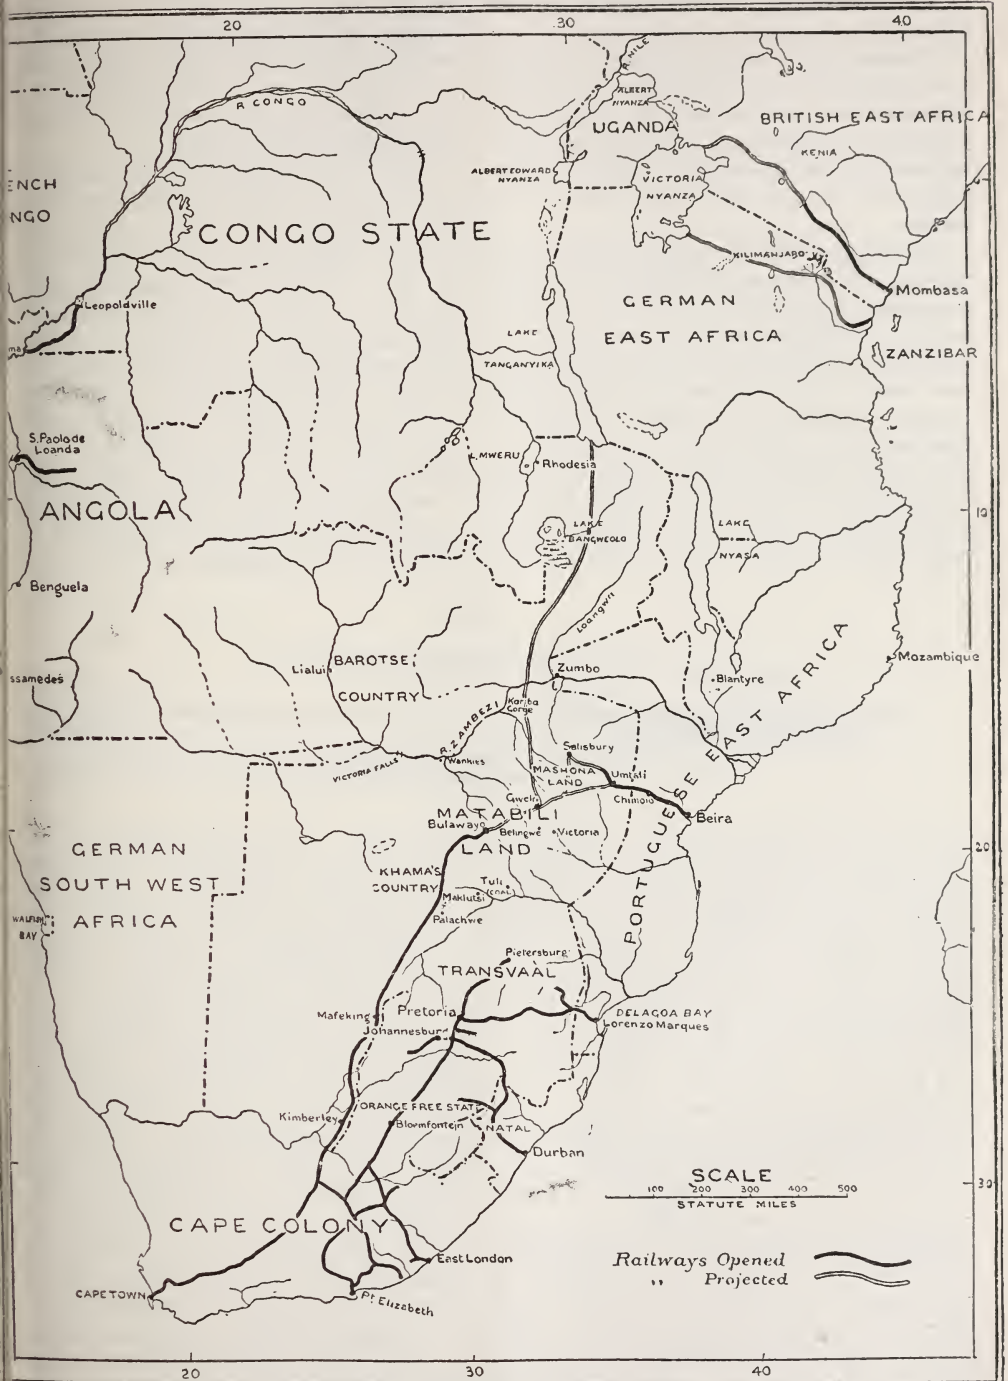

The different mining camps are connected by very fair natural roads, made by the waggons passing to and fro, the principal of which are the main coach road between Buluwayo, Gwelo and Salisbury, which serves the mining districts of the Gwelo district, and the Tuli road, formerly the coach route to the Transvaal, but now only used as far as Gwanda. There is also a fair road to Belingwe. The road from the Transvaal to Mashonaland via Tuli and Victoria, is now very little used.

of the High Commissioner of South Africa, and called the Bechuanaland Protectorate. The boundaries of Southern Rhodesia are defined in Section 4 of the Southern Rhodesia Order in Council, 1898. Using Bartholomew's latest map (1898), and putting the Bechuanaland Protectorate back to the Pandamatenga road, the areas work out as follows:—

	sq. miles.
Northern Rhodesia, or British Central Africa, administered by the British South Africa Company.....	244,000
British Central Africa Protectorate, administered by the Foreign Office.....	38,000
Southern Rhodesia, administered by the British South Africa Company.....	156,000
Bechuanaland Protectorate, administered by the High Commissioner of South Africa	232,000

ce the advent of the railway, and the same
y be said of the Mafeking Tati Buluwayo
d.

attention was between Selukwe and Belingwe,
and Belingwe and Gwanda, so as to enable a
traveller to make a circular tour and visit all

MAP OF SOUTHERN AFRICA.

In Matabeleland the part of the country
where the roads seemed to me most requiring

the most important mining districts. The road
between Selukwe and Belingwe is difficult, I

believe, at all times, and especially in the rainy season. A road between Belingwe and M'patene would also be a great convenience for travellers visiting the Gwanda district from the east.

In an appendix to this paper will be found some Tables showing the approximate distances between trading stores and water, which may be useful to travellers. I have also tabulated my observations for latitude altitudes by boiling point thermometer and the variation of the needle.

The minerals that have been discovered in workable quantities are coal and gold, of which the latter has naturally so far attracted most attention. There is good reason, however, to believe that, as a source of wealth in the future, coal may rival in importance the precious metal. The principal coalfield is along the Zambesi Valley, and coal has been found at a place called Wankie and at Sengwe. In the Gwaai Valley I was credibly informed that the most southern outcrop of coal formation occurs at the junction of the Gwaai and Bubi rivers,

the same sequence of rocks occurs at the outcrop in the Mafunga-busi district north of Gwelo.

The future of the Tuli coal area depends largely on the success that awaits the gold mines of the Gwanda district, which are distant about 75 miles, and would naturally draw the fuel supplies from here when the timber round the mines becomes scarce.

Before describing the work that is being carried on in the different gold mining districts, it is advisable to make some general remarks on the geology and physical features of the country. Matabeleland is bounded north and south by two great rivers, the Zambesi and Limpopo, and the backbone, or watershed, runs, approximately, half way between the two rivers. The high ground is composed of granite and constitutes the healthy portion of the country, attaining an altitude of 5,000 feet above sea level. The land slopes gradually towards the rivers, the altitude on the Limpopo at Tuli being about 2,000 feet, and on the Zambesi, on the meridian of Buluwayo, about

FIG. 1.

and a line drawn from that point to the known outcrop on the Sengwe River, and parallel to the Zambesi River, would roughly define the southern limit of Rhodesia's great coalfield. There is another coal area, which I have myself visited, near the Transvaal border and about 50 miles east of Tuli, but I think it is of minor importance to the Zambesi coal. At Tuli the coal can be seen outcropping in the bed of the Umzingwani River, and some prospecting shafts put down to the east of the river have picked up the seam, which I was informed is 9 ft. 6 in. thick, of which 4 ft. 6 in. is fair steam coal. The unfavourable feature is the large occurrence of trappean or igneous rocks in this district, and it seems probable that the seam or seams will be found to be much broken and disturbed. The coal formation consists of shales and sandstones, which are very flat and lie probably unconformably on a much older formation composed of garnetiferous micaceous schists, which are well exposed in the bed of the river. (Fig. 1.)

I was informed of the interesting fact that

3,000 feet. The granite itself, as far as I am aware, does not contain any mineral deposits of economic importance. The auriferous quartz veins or "reefs" are found in rocks of a different character, namely, metamorphic schists and slates, which occur over a wide area in certain well-defined belts.

There is considerable uncertainty as to the origin of the metamorphic rocks, it being doubtful whether they were originally sedimentary rocks or igneous rocks made schistose by dynamic metamorphism. It seemed to me that both classes of rocks were represented at all events, I have seen slates that had every appearance of being of sedimentary origin and in close relation to them schists that are evidently altered igneous rocks, a change which can be noticed even in small hand specimens.

In order to further investigate this subject I have had sections cut from several of the specimens of the rocks that enclose the mineral veins, so that they might be examined under the microscope. The sections show that the dominant country rock is

abase, and bring out clearly how a hard impact igneous rock may be altered into a ft schist by dynamic action. There are also any places in the country where unmistakable dykes are seen traversing the schists. Good examples are to be seen in the Criterion and Bonsor mines.*

A further point of interest in connection with the origin of the metamorphic rocks is that at their contact with the granite, the latter becomes schistose in character and altered into gneiss, indicating some dynamic change. A section (Fig. 2), taken in the Insiza district, will illustrate this point.

Although their origin is doubtful, the belts of metamorphic rocks, which locally go by the simple name of "formation," are the home of the gold reefs. The average prospector will not think of looking for reefs in the granite, and I know one man, who on finding some auriferous quartz associated with granite, indignantly said it was an insult to geology.

Prospecting in Matabeleland has been made easy for the present inhabitants owing to the

probable that the difficulties of mining below a certain depth alone accounts for the shallowness of the old mines. Thanks to the work of the ancient miners the country has been very rapidly prospected, no skilled miner being required to find the reefs. It is true there is an unfavourable side to the old workings, and that is that a portion of the reef has already been removed; still on the whole I think that the ancient miners have done more good than harm to the present inhabitants.

The new comers were not slow to discover that the old workings were the key to the gold reefs, and any place that showed a trace of the ancients was immediately pegged off, as well as a considerable length of ground called an "extension" on each end of the old working in the direction of the reef.

This wholesale pegging of old workings or of "extensions," accounts for the large number of claims and "miles" of reef that appear in the statistics of the Chartered Company.

With regard to the reefs themselves, the greater number are fissures in the schist

FIG. 2.

fact that the country has been carefully explored by an earlier race, whose old workings are to be found in every direction on the schist formation. Indeed, so thoroughly does the work seem to have been done, that the chance of a new discovery of importance being made is small. I described the old workings at some length in my first paper, and I need only say now that they take the form of shallow trenches or pits, filled up almost to the present level and overgrown with bushes and trees, but still easily traceable. These old workings which mark the outcrop of a reef, are seldom found to extend to a greater depth than 70 feet from surface, so that the modern miner can soon recommence operations. It was at one time thought that the shallowness of the old workings signified a want of permanency in the reef, but modern developments have shown this view to be quite erroneous, and it is

formation parallel to the strike, and, therefore, interbedded. These fissures have been filled with quartz, and other minerals deposited from solutions. In width they vary very considerably, both in vertical or horizontal direction, being what are known as lenticular deposits. Fig. 3 will illustrate the shape they

FIG. 3.

taken in plan and section. The thicker portions of the reef, where payable, are traceable by the presence of old workings, and the longer their line is, the greater the strength and permanency of the reef below. The truth of this statement is confirmed by the fact that the most promising mines to-day have all a

* Those interested in this subject should not fail to read a valuable paper by Messrs. Chambers and Hatch, published in the "Geological Magazine," May, 1895.

long line of old workings marking their outcrop. If the converse of this is true, namely, that small old workings only exist on small reefs, which I believe to be the case, then with the knowledge we have of the value of the largest reefs (and practical results are happily forthcoming) we can draw conclusions as to what importance the mining industry is likely to attain. I may remark here that in mining a reef that has a well-defined outcrop, a contraction in strike or dip need not cause any alarm, as the probabilities are that the reef will again widen within a short distance; on the other hand, where only one or two small old workings occur at surface, it is probable that, outside the limits of the old workings, no reef of any size will be met with. While I have confidence that the stronger reefs will continue in depth to a sufficient distance to allow of profitable mining to be carried on, I think that the smaller reefs will prove disappointing owing to the small quantity of quartz available for mining. So far I have endeavoured to show that the old workings are extremely valuable as a guide to the position and importance of the gold reefs, and that, as they are so easily found, much of the uncertainty as to the mineral wealth that exists in a new country is thereby removed.

After these general remarks, I shall now pass on to describe the mining work that was being carried on in Matabeleland in 1898. Of Mashonaland I have had no experience, but I may say that the geological and economic conditions there are similar to those existing in Matabeleland. More progress, however, seems to have been made in the western than the eastern province, where the mining districts, except as regards Umtali, are less accessible.*

I do not pretend, of course, to have compiled an exhaustive list of the mines working, but I have endeavoured to include all the best known properties and those that I know to be, whether ultimately successful or not, at all events genuine mining ventures, so that a fair idea may be formed of the scale upon which mining is being carried on. I have purposely omitted any figures to show the value of the reefs,

* I must draw attention to an interesting paper recently published "on the Future of Goldmining in Mashonaland," by Mr. C. T. Roberts, President of the Salisbury Chamber of Mines. Although I am in sympathy with a great deal that Mr. Roberts says, I disapprove of his method of estimating the length of reef available for mining. Very false conclusions must, I think, be come to when the length of ground pegged is mixed up with the length of payable reef; further I do not think any comparison between the blanket beds of the Transvaal and the quartz reefs of Rhodesia is permissible.

except in the case of the producing mines, since assay results without a good deal of explanation as regards quantities of ore, are sure to be misleading. When I tell you that even in the hands of an experienced engineer the correct valuation of a well-developed quartz mine, in which a large number of samples to be taken is a lengthy and laborious process, you will understand how dangerous are predictions as to the future of a mine when based on data derived from an insignificant amount of development work.

I mentioned above that the geological information forms a reliable guide as to the situation of the reefs, the metamorphic rocks being favourable and the granite unfavourable. In different mining districts are the belts of metamorphic rocks which are fairly evenly distributed along a line joining Tati and Salisbury. Although distinctive names are given to the belts, it does not follow that they are distinctive in themselves, and when a geological survey is made, it seems to me probable that some of the belts now marked separate will be found to be connected. In Mashonaland the most prominent mining districts are those of Umtali, Salisbury, Mazoe, Hartley, and Lo Magonda. In Matabeleland the most advanced districts are Selukwe, which lies about 25 miles south of Gwelo, and the Gwanda which is about 100 miles south-east of Buluwayo. In the Buluwayo district, several reefs are being worked, some in the immediate neighbourhood of the town. The mine on which most work has been done is the Criterion, which lies about eight miles south of Buluwayo, and which, on account of its accessibility, is one of the silver mines of the country. The management most courteously give every facility to visitors to make a thorough inspection, an example which I may say in passing is followed by almost every other mine in Matabeleland.

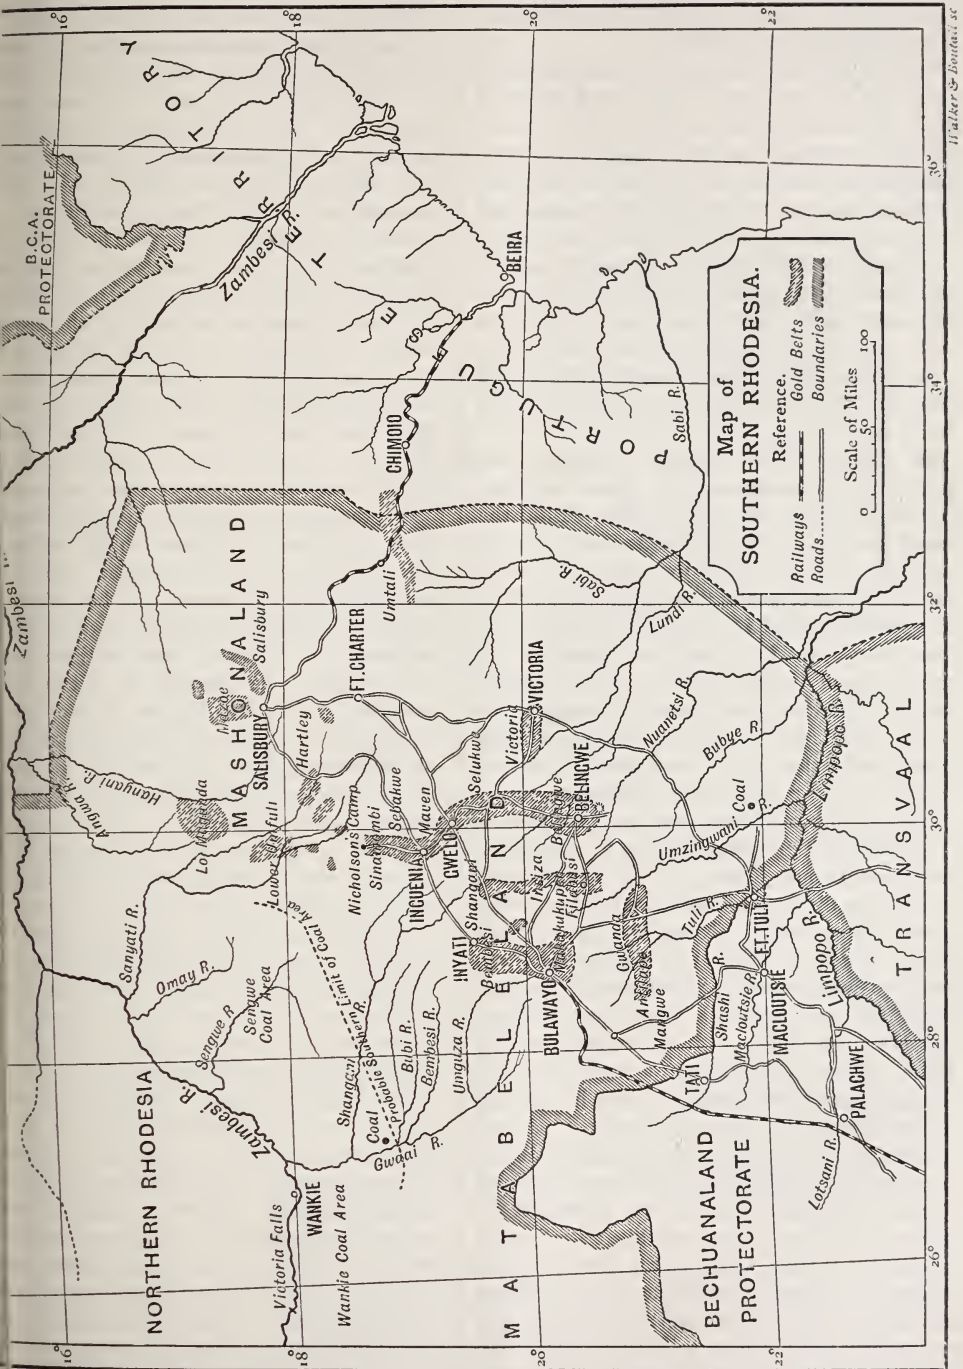

The system adopted of proving the property is that of sinking in the old workings and driving a level along the strike of the reef below the lowest point reached by the ancient reef, a depth which is usually 70 feet. In this way reliable data is obtained as to the length and value of the pay chutes, from which the scale upon which the mine should eventually be worked can be calculated. Eight shafts have been put down, the deepest being 250 feet, and several hundred feet (about 1,600 feet) of driving have been done on the first level of 150 feet.

A fine reservoir to hold 30,000,000 gallons has been made at a cost of £6,000, so as to

vent any stoppage during the dry season. No-stamp battery is in course of erection to roughly test the value of the mine. At the

economical work, and has the great advantage of being in a very healthy district.

Leaving Buluwayo by the northern road, a

Walker & Howland sc

of my visit the mine was employing 16 es and 200 natives. The mine is perhaps best situated in all Matabeleland for

drive of about 25 miles brings one to the Bembesi district, which has been extensively pegged upon; but when I visited it in the early

part of 1898 the Queen Mine was the only property being worked. It is only fair to say that I went at the most unhealthy time of the year, and later on I heard of work being done on other properties, especially on the Umguza river, with promising results.

The Queen Mine has some good old workings, and has been worked on and off since 1895. The mine makes a good deal of water, and the development work has been slow probably on that account. There were about six white men on the mine, and preparations were being made to erect a rock-drilling plant, so that it is evidently the intention of the management to push ahead with the work. The main shaft, which can boast of an iron headgear and a winding engine and pump worked by steam, is down about 100 feet, and there was about 150 feet of driving done at that depth.

On leaving the Bembesi district, and travelling in a north-easterly direction along the old Hunter's Road to Hartley Hills, the traveller will reach the goldfields that lie to the north of Gwelo, called the Mavain, Lower Gwelo, Sebakwe, and Sinanombi districts. The old Hunter's Road is now but little used on account of the bad drifts or fords at the Shangani and Umvungu rivers, and the traffic between Buluwayo, Gwelo, and Salisbury takes a road some miles to the south that follows more closely the line of watershed. The old Hunter's Road passes through the picturesque granite kopjes of Taba-y-momba, used as a stronghold by the natives during the rebellion, and the Somabula Forest, a thick belt of trees which from their size deserve rather the name of wood than forest. Except during the rainy season anyone visiting the mining districts north of Gwelo should certainly take this route. There are no wayside stores between Inyati and Fort Ingwenia, a distance of about 76 miles. There used to be a store between these two places, but the owner lost his life during the rebellion, and it was not reopened. As an illustration of the way in which an Englishman can adapt himself to circumstances in an out of the way place, I may be permitted to mention that the owner of this store had a passion for cricket, which of all games is least suitable for anyone condemned to a solitary life, and I was told that he never lost heart, but always did his best to play a match with any traveller who happened to pass along that lonely road. The love of outdoor games has always had a healthy influence on English character, and there is no doubt that we owe

much of our success in colonizing to the qualities which games inspire. It is characteristic of our country that when Ca Lawley, the Administrator of Matabeleland, went only a few months back on a diplomatic mission to the Zambesi to meet King Lewan of Northern Rhodesia, the conference should be wound up by a display of athletic sports, which of all the ceremonies that took place during the visit was probably the most impressive, and the one that will be the longest remembered. In the Mavain, Ingwenia, and Sinanombi districts a good deal of prospecting and development work has been done, but it seems to have been undertaken more for the purpose of fulfilling the requirements of the Mines Ordinance, which insist on an annual footage being done, than seriously testing the value of the properties. My experience is that the reefs though often of good value are small, and the problem will be to work small quantities of high grade ore, rather than a large tonnage. These reefs do not appear to be sufficiently encouraging to warrant further expenditure under present circumstances, but when the railway is extended to Gwelo, and possibly to Sinanombi or Sebakwe, some of them may be made to pay. At present the difficulties of supervision, the unhealthiness of the climate, the scarcity of water, and the cost of transport all militate against exploratory work except on the most promising properties. Doubtful properties are in most cases being left alone until the results of the best properties are known. These remarks apply not alone to these districts but generally to the whole of Matabeleland. Of the Sebakwe district I am not able to speak from personal knowledge and I am glad to say that I have very favorable reports of its prospects. Among the best known properties are the Globe and Phoenix, and the Gaikwa and Chicago mines.

The Selukwe district, which lies south of Gwelo, a small township to which the success of the mines is of vital importance, is perhaps the most advanced of all the mining districts of Matabeleland. The most important mines are the Camperdown, the Dunraven, the Bonanza, and the Selukwe (formerly Tebekwe) mines. The three latter have already reached the producing stage. From a geological point of view, the Tebekwe reef is the most regular of all the reefs that I have seen in Matabeleland, being a nicely-banded six foot quartz reef with well-defined walls. The old workings are traceable about 3,200 feet in length. Sh

ve been sunk at intervals along the outcrop and the 100 foot level has located the pay reefs. The main shaft was down 200 feet, and a second level was being driven. The connecting winzes from the first level have proved the continuation of the reef to the second level, where it maintains its strong character.

The Bonsor Mine also possesses a strong reef, and the lowest workings, some 300 feet below the outcrop on the hillside, looked very richly. I have pleasure in mentioning this, as the mine was one of the first to offer an ample proof that the reef continues below the workings of the ancients, in short, that the reefs are, at all events in some cases, of a permanent nature. The development of the Selukwe mines has been facilitated on account of the hilly character of the country, which has enabled the reefs to be opened out by adits or galleries driven into the hillside.

The Camperdown reef is of an exceptional character, being apparently not interbedded with the majority of the reefs in Matabeleland, but cutting across the formation which is largely composed of iron shades. The reef is small on the first level, averaging perhaps twelve inches, and contains a remarkable amount of visible gold which makes the correct sampling of the mine a matter of difficulty owing to the great variation in the assay results. A mine of this description requires to be developed on a large scale to enable reliable estimates to be made of its capabilities.

The Selukwe district has a fair timber and water supply, and offers every facility for economical mining. The higher parts, where the reefs above-mentioned are situated, has an altitude of between 4,000 and 5,000 feet, and consequently ought to be healthy. During the last wet season, however, there was a large amount of malarial fever, but bad living and the turning over of new ground may have done a good deal to with this.

In the same chain of mountains as Selukwe, about 75 miles south, is the mining district of Belingwe. The mountains terminate somewhat abruptly in a prominent landmark called Belingwe Peak, which lies seventeen miles almost due south of the Central Camp, where the police camp, the native Commissioner's quarters, and the general store that serves the district are situated. It is here that the advantages of centralisation as regards management are well illustrated. A large number of the mining claims belong to one

Company, which, unlike other companies with interests, scattered about the country, can afford to keep a capable staff at a central establishment, provided with a laboratory, smith's shop and a trial crushing plant, within easy reach of the mines, thus enabling the development work to be carried on in the most economical manner. By amalgamation of interests this system of management might advantageously be followed in other districts. The road to the Peak, which passes an interesting outcrop of serpentine, containing small veins of asbestos, is alive with claim beacons, but the Wanderer's Rest Mine was the only one on which work was being done. The reef is about 2 ft. 6 in. wide, interbedded in hard slate, and dips south at an angle of 35°. The main shaft is down 130 feet on the incline.

The Dobie Mine is situated close to the Central Camp. The Ancients have attacked the reef, which outcrops on a hillside, by an adit, and have worked out a good slice of the hill. Where they left off the quartz was poor, but recent development work has struck some remarkably rich ore, composed of honey-combed quartz, below the old workings. It is a good example of the erratic character of quartz-mining, one day rich and another poor, and shows how necessary it is, in order to prevent disaster, to have the development of the mine well ahead of the mill.

At the Confidence Mine, which is situated about two miles north of Belingwe camp, there is a nice run of old workings, extending about 400 yards. The mine is well equipped with portable machinery, and is a model of what a prospector's camp, far removed from supplies and workshops, should be. Among other properties that were being developed in this district, but which I did not visit, may be mentioned the Zalandia, Fondoque, Sabi, and Mount Wedza claims.

So far the indications go to show that Belingwe has several reefs containing chutes of high grade quartz which with small batteries ought to make in the future no unimportant contribution to the gold output of Rhodesia.

About halfway between Belingwe and Buluwayo is the Insiza gold belt which runs approximately north and south, and upon which several reefs are being developed. Judging from what I saw the reefs are small and good examples of the lenticular character of the quartz reefs in this country. At the southern end of the belt, the Ancients Mine was the only one being worked. Other belts within no great distance of the Insiza district,

with which some may be geologically connected, are the Shangani, with the Eagle mine, the Umzingwani, Balla Balla, Makukukupen and Filibusu districts.

Further south again, and some 75 miles south of Buluwayo, is the important district called Gwanda. It contains some very promising properties, including the Geelong Mine, which was the first mine in Matabeleland to declare an output. The belt, which is comparatively narrow being only about 12 miles across, runs for about 50 miles east and west, commencing on the east at the Umzingwani river, where are situated the Geelong and the West Nicholson reefs.

The Geelong reef outcrops on a kopje upon which are the mine workings. The reef is a wide body of quartz, being as much as 20 feet wide in some places. The strike is east and west and the dip north at about 30°. The underlying rock looks like a granite which has been altered into gneiss for about 18 inches from the reef. The specimens, which I brought home, when examined under the microscope, showed that the rock on the footwall was a fine white mica schist, resting on gneiss. On the hanging wall of the reef comes the ordinary schist with a thickness of about 50 feet, and then there is another quartz reef, but not so wide as the first. Beyond this I do not know what the formation is, but the granite cannot be very far off, and the mine seems to be situated very near the eastern end of the Gwanda gold belt. Some of the old workings, which are extensive, have been cleared out and the mine restored to its condition as left by the Ancients. The blackened walls, proving that mining was carried on by fire, and the round diorite stone hammers which are found in many places about the mine, are evidence of the primitive methods employed. The main shaft, which is a three-compartment shaft, timbered with mopani, the local ant-resisting wood, is down to about 300 feet, opening up the reef for two levels. A 20-stamp mill (1,050 lbs.) has been erected, and crushing was commenced in the month of October, 1898, but no cyanide plant is yet in operation. It is intended to double the stamping power as soon as possible. At the time of my visit 53 white men, many temporarily engaged on construction work, and 300 natives were being employed. The Geelong camp has been laid out with great care, and the *employés* made as comfortable as possible. A plentiful water supply has been brought in from the Umzingwani river,

distant three miles. Good wood and iron buildings have been erected and lighted by electric light. One of the most noticeable things at Geelong was the kitchen garden, for fresh vegetables in Matabeleland are, as a rule, outside towns, unprocurable. A clearance had been made in the bush and the land irrigated by water pumped up from the river. The gardener was in charge of a coolie gardener, and I was informed that all the ordinary vegetables grew well. There is a great need for fresh vegetables here as the place is very unhealthy. It was told that last season not a man escaped malarial fever, and that there were two deaths. The natives, too, also suffered severely. About seven miles from the Geelong is the West Nicholson Mine, which is being actively developed, employing six white men. It is supposed to have the same characteristics as the Geelong, but is a wider body of quartz. The district is well supplied with timber, but mostly small. There are, however, some large mahogany trees, and I saw a log going through the saw-mill that measured 27 by 19 inches.

Another promising reef in the Gwanda district, upon which development work has been carried on, is the Eaglehawk or Vulture, which is situated about halfway between Geelong and Manzimnyama. A 5-stamp battery has been erected for testing purposes. The reef is in schist formation, and the old workings extend for at least 1,500 feet, auguring well of the strength of the pay chutes. The mine is fitted with iron headgear, engine and boiler, and was down about 150 feet. I was informed that development work was also being carried on in a greater or less degree on the Ismain, Australian, Camel, and Jackal reefs. The Antelope Mine was being vigorously prospected, employing 15 white men. The reef, which is composed of blue quartz, was 2 feet wide, at a depth of 400 feet. The old workings extend for 400 feet. A 10-stamp battery is to be erected. Most of the Gwanda properties lie to the east of the main Buluwayo Tuli road, but there are some claims to the west, amongst others the Umchabesi, Tuli River, and Lady reefs, of which a little work was being done.

The Gwanda district promises to be one of the most important in Matabeleland. It is unfortunately unhealthy and badly off for water. It is proposed to connect it with Buluwayo by a railway that will follow the Umzingwani valley, and when that is built, many of the difficulties that now retard progress will be removed.

From the above description of the workings which was being done in Matabeleland during

bruary 3, 1899.]

ill be seen that the list of mines producing clearing the production stage is not a long ; still it is sufficient to show that the min- industry is one that will flourish on a lerate scale. The number of stamps shing at the end of 1898 was 100, exclusive small trial batteries, and I understand that ut 200 more are on order, exclusive of any t may be wanted for Mashonaland. As ards the number of persons engaged in ing, it was stated at the last general meet- of the Chamber of Mines at Buluwayo, t 2,000 whites and 10,000 natives were ployed in mining pursuits in Rhodesia. ese figures do not agree with the census t I took, but the difference may be partly ounted for in that the figures mentioned ve include officials in the towns while mine ot. For an individual to take a census may ear difficult, but, as a matter of fact, it is y, since in each mining district it is sure to known at the trading stores what work is ng on. I made the number of whites on mines of Matabeleland to be under 400, l of natives under 4,000. The Mashona- d total must be less than this, so that the nd total for Rhodesia would be considerably s than that quoted above. The gold pro- tion so far from the four mines crushing Matabeleland has been on the whole satis- tory, and proves the payable nature of the fs.

Below I give the figures, which are for the ld won by amalgamation from the mill, and lusive of the gold in the tailings, which uire a cyanide plant for treatment.

cluded in these figures, which nevertheless compare favourably with those of the Rand, where the costs for 22 outcrop mines in 1897 were 27s. 7d. White labour is about the same in both places, but explosives and native labour are less in Rhodesia. Anxiety has been felt that a sufficient supply of native labour would not be obtainable, but no serious trouble has yet been caused in Rhodesia on this account.

The figures given above show that the costs of working will not be an obstacle to the successful development of the mines. Judg- ing from the results so far obtained, it seems likely that in each district there will be one or more successful mines. A gradual expansion is, of course, to be expected, but it must not be forgotten that it is the pick of the mines that are now been opened, and that the same promising results must not be awaited from those properties that follow after.

Although it is about the mines that I par- ticularly wished to speak, I would not have you believe that it is on their success that the future of Rhodesia entirely depends. I think it is a mistake to hold this view. In my opinion the future of the country is bound up with its pastoral and agricultural possibilities.

Farming is certainly not yet carried on to any great extent, but poverty of the soil is not the reason. The mealie fields of the natives, which are to be met with all over the country, and the market gardens round Buluwayo and other townships demonstrate that the soil is capable of successful cultivation, and it is well known that before the rinderpest came, the

The official working costs at the mines vary from 27s. to 18s. 3d. per ton, exclusive pre- mably of expenses at headquarters and of ppreciation, the average probably being out 24s. per ton milled, which is very asonable considering the situation of the ines and the small size of the batteries. yanide costs, as above stated, are not in-

country supported a large number of cattle. The high veldt in particular, with an elevation of 4,000 feet, is suitable for farming.*

It is to other causes, preventible, I think, in

* The area available for farming above 4,000 feet is estimated by Mr. Selous at 26,500 square miles, and above 3,000 feet at 99,000 square miles.—British Association, Toronto Meeting, 1897.

most cases, such as malaria, drought, cattle disease, locusts, and absence of markets that the backwardness of farming is due.

The greatest curse of the country, as it is of all tropical Africa, is malaria. "Malarial fever," says a distinguished writer, "is the one sad certainty which every African traveller must face." In travelling about the country at the close of the wet season of 1898, admitted on all sides to have been the worst on record, I saw what a paralysing effect this disease had on the progress of the country. Buluwayo is practically free from malaria, and it is encouraging to note that places which are occupied have a tendency to become more healthy, but in the outside districts, among the prospectors, the traders, and the police, malaria was only too common, and had many victims.

Whether malaria is preventible is a question that has received much attention, and last month a striking paper, by Dr. L. Westenra Sambon, was read before the Royal Geographical Society, and was followed by an interesting discussion in which many prominent African travellers took part. Although the meeting was unanimous that malaria was the most important obstacle to the colonisation of tropical Africa, those present were not all so sanguine as the author that medical science would before long find a means of destroying the power of this crushing disease. Still, it is encouraging that some, at all events, should believe that it can and will be done. May I be allowed to quote from Dr. Patrick Manson's remarks, words which cannot fail to be welcomed by many in Africa:—

"There are, however, signs that the day of deliverance from this worst curse of mankind is at hand. Fact after fact is coming to light about the malarial germ, and step by step we are approaching that complete knowledge of its life history which alone will enable us to crush out this terrible parasite, or at all events to protect ourselves from its attacks."

So much has already been done in preventing the spread of disease in the animal kingdom, that I feel confident that some practical means of overcoming malaria will be found. The discovery will be of far-reaching importance and will accelerate the opening up of Africa.

Turning now to some of the other disadvantages that the farmer has to contend against in Rhodesia, I may refer to drought. Nearly all the rainfall comes within two months, the rest of the year being practically dry, and the consequence is that during the wet season the rivers are flooded and during the dry they are little else than rivers of sand.

During the winter months water is found pools in the river beds, but is on the whole very scarce. It is obvious that in a country like this the storage of water for irrigation purposes is required, necessitating a considerable capital outlay.

Besides malaria and a scarcity of water the farmer has other troubles to contend with. Rinderpest and lung sickness decimate his cattle, locusts more than decimate his crops, his young trees and plants are eaten by white ants, even his poultry have a special complaint. Fortunately science is coming to his rescue and many of the plagues that formerly might have driven the farmer to despair are now mitigated, if not entirely conquered, by the inoculation system.

The British South Africa Company has taken the greatest pains to stamp out rinderpest. Inoculation stations have been placed on the main roads, and no cattle are allowed to pass that have not the Government brand. I spent some time at one of these stations, and learnt a good deal about inoculation. The system at first adopted was to inoculate with serum or the blood of a "salted" ox (*i.e.*, an ox that has recovered from rinderpest) on one side simultaneously with the blood of a rinderpest sheep on the other; the animals were then put in quarantine for ten days. I am sorry that I have no statistics to show what percentage of animals survived this treatment, but I was informed that very few animals were lost. The inoculation with rinderpest blood has now been done away with and only the serum is injected, and no quarantine imposed. It may be of interest to state that rinderpest can only be transmitted through three species, as in the third remove it becomes too virulent. The cattle belonging to the natives are now compulsorily inoculated, as this might lead to trouble, for if there is one thing that a native objects to it is any interference with his cattle.

Among the reasons why farming does not flourish, I have put down absence of markets. This is a difficulty that, I think, the improvement in the means of communication will gradually overcome. Distance from markets nowadays does not seem to be of much account. It is curious that at the present time Buluwayo should be eating New Zealand mutton, and that it should pay to bring up fresh fruit and vegetables from the Cape Colony. In a large country like Rhodesia, with an altitude ranging from 2,000 to 5,000 feet, and with a soil which is admitted to be in many parts most productive, there ought to be a wide range of products grown.

In bringing this imperfect sketch of the sources of Rhodesia to a close, I should like say one word as to the administration of the Chartered Company, and in doing so I ought to add that I travelled about the country armed with no letters of introduction to officials, and that I have no pecuniary interest in the country whatever. The impression I obtained was that the settlers in Rhodesia have every reason to be satisfied with the way in which the administration of the country is being carried on. It is only natural where there are so many difficulties to contend against, where progress is slow and success only attained after many disappointments, that some of the settlers would complain that it is the administration that is to blame. The accusation seemed to me entirely unfair. For what are the facts? In a country which only six years ago was in the hands of a savage people, you now find installed the machinery of a civilised Government; you find law and order administered by judicial and civil service of high standing, a native department that is just and which commands respect; railway, postal, and telegraphic communication with the outside world. You find the Government making experiments as to what products are suitable for the country, taking every precaution to stamp out cattle disease, subsidising the hospitals, and making preparations for a trigonometrical survey. I do not think the Chartered Company can be accused of shirking its responsibilities to the settlers; on the contrary, it seemed to me that they were offering them all the assistance in their power to bring the development of the country's resources to a successful issue.

DISCUSSION.

The CHAIRMAN said Mr. Wilkinson had given very fair and impartial account of the prospects in Rhodesia, neither exalting nor depressing its future unduly, and it might be gathered that the future would be a very bright one. They were indebted to the energy and foresight of one man for this large and valuable addition to the Empire, and the country was very properly named after him. They could only hope that he would achieve such success on his present visit to England as would secure the construction of the railway tapping the coal-field and so ensure a supply of fuel for the mines. They would then be able to follow in the wake of the ancient workers to revive the memory of Solomon and obtain abundance of wealth from that territory.

Sir SIDNEY SHIPPARD, K.C.M.G., said he had visited Matabeleland in 1888, when Lobengula was at the zenith of his power, just before

concession had been granted on which the Chartered Company was ultimately founded, and the difference between the present state of the country and what it was then was something marvellous. The contrast and the growth of the country in 10 years was enough to give a reasonable ground for hoping that even apart from mineral wealth, Matabeleland would in time become a highly prosperous and valuable addition to the Empire. He did not know that he could add anything to the paper, but he could not but endorse what the Chairman had said as to the importance and the work done by Mr. Rhodes.

Sir RICHARD TEMPLE, Bart., G.C.S.I., said he could hardly claim to say anything on this question, never having been in South Africa, but he was glad of the opportunity of expressing to Mr. Wilkinson and their African friends sentiments entertained by that imperial party in England to which he was sure every one present would be proud to belong. The author had made many things clear which were important and interesting to the future of the Empire. The paper was not only valuable from an engineering and engineering point of view, but was full of sound political economy, and showed what the future of Rhodesia was to be. There was a discriminating amount of the different mining districts, and he was glad to learn that in some parts the supply of gold would be permanent. One could not help catching a kind of weird and romantic interest to the antiquarian part of the subject, which showed that from the earliest times gold had been worked in that district; but the chief point of interest was that Matabeleland and Matabeleland could be colonised under peculiarly favourable conditions. In most of our colonies the difficulty was with regard to labour: where there were only white men labour was scarce and expensive; and on the other hand, where in Northern Australia there were coloured races, the climate was generally too hot for Europeans; but, if he understood rightly, the climate was fairly good for Europeans, and yet there was good native labour supply. There seemed to be a short rainfall, but it was abundant, and there could be no doubt that in future it would be stored for irrigation purposes; there would be great reservoirs formed on the river like the anicats in Southern India, and the water would thence be pumped up, even on the uplands, and there would be gardens everywhere. As to the malaria, he doubted if the doctors would cure it, but the engineers would, because those who had been in India knew very well that malaria arose from putrefying vegetation, which again arose from stagnant water, and when the land was drained malaria would disappear. He had no doubt that in the future they would cure the rinderpest, and so by degrees there would be a great improvement in sanitation, and the extension of European habitation supported by a large native population, which, no doubt, would in-

crease and multiply under the human and wise administration of the Chartered Company. With regard to the strictly financial and economic aspect of the question, he could assure the Europeans in South Africa that the commercial world was watching their enterprise with the deepest interest. If they were successful the supply of gold would increase, which would rectify the relative value of gold and silver, the disturbance of which had caused so much trouble in many parts of the world. The constant increase of the precious metals would, at all events, lower prices for the consuming portion of mankind. Lastly, there was the grand political question to which no Englishman could listen without emotion. Extensions of the railways were shown on maps, exhibited this afternoon, from the Cape right up to within almost measurable distance of the Zambesi, and no doubt they would be extended ere long to the river. Perhaps there might be some trouble to get across it, but when once the railway had been carried to the right bank, it would be carried on from the left bank to the Tanganyika lake. Such a wonderful thing was almost enough to make the bones of Livingstone turn in his grave for joy! He could never have imagined when he lay sick unto death in that region, that within one generation a railway would come up from the Cape to that very spot. When once the lake was reached, there would be an extension some way or other to the watershed of the Nile, and from there the route was now easy enough to the Mediterranean, so that they were not far from realising the dream of Mr. Rhodes, and of having a through communication from the Cape to Cairo, and on that route lay the region which had been so lucidly described that evening. He was sure they would all join heartily in the eulogium passed on Mr. Rhodes by the Chairman, and he could assure all gentlemen interested in the Cape, that at the present moment, despite all that might have been said, there was no name more respected and regarded by patriotic Englishmen than that of Mr. Rhodes. The imperial party regarded him as one of the men who had enlarged the British Empire and left their mark on the 19th century.

Mr. FRANKLIN WHITE said his knowledge of Rhodesia, though not so good as that of Mr. Wilkinson, enabled him to endorse his statement that there was a very fair field for mining open there. It was quite true that the gigantic operations in the Transvaal dwarfed the possibilities of Rhodesia, but the gold-bearing areas in that country were numerous and widely distributed, and he thought possibly in the future would prove more conducive to the general prosperity of the country than one central field, as in the Transvaal. Allusion had already been made to the great fairness of the statements put forth. Mr. Wilkinson had laid great stress on the necessity for developing the coal-fields, the railways, and the roads, but he thought the energy already shown in acquiring and developing

Rhodesia would not be found wanting in future, even to the extent of providing storage reservoirs for water. The author had been very modest in describing his travels as a pleasant picnic in fine weather, for no doubt in wet weather his experiences had not been at all pleasant, and his little remark about the vegetable garden at Geelong showed how often he must have been short of vegetables. The pictures he had shown gave a very fair idea as to the life led by those who were developing this country.

Mr. P. B. WAUGH said that he had just covered some of the ground which had been so fully and impartially described by Mr. Wilkinson, and heartily agreed in his conclusions. The old workings, of which they had seen some views on the screen, ought to reassure the minds of the British investing public, because although they served as valuable indications, they were the main cause which had prevented any great influx of miners to Rhodesia, such as had been witnessed in California and Australia. Another interesting feature was the transition from igneous to schistose rocks, which the author had proved by microscopic sections, and which he (Mr. Waugh) had himself noticed in specimens he had picked up in the country. Many people considered that the gold-fields of Rhodesia were sedimentary, but there was a good deal of evidence that such was not the case, but that they were derived from igneous rocks, which pointed to the permanence of the gold veins in depth.

The CHAIRMAN then proposed a cordial vote of thanks to Mr. Wilkinson, which was carried unanimously, and briefly acknowledged.

EIGHTH ORDINARY MEETING.

Wednesday, Feb. 1, 1899; The ATTORNEY-GENERAL, G.C.M.G., Q.C., M.P., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Beveridge, Edmund Walter, Kelly's Hotel, Bombay.
Gjers, Lawrence F., Woodlands-road, Middlesbrough.
Hill, Gray, Mere Hall, Birkenhead.

The following candidates were balloted for and duly elected members of the Society:—

Aflalo, Frederick G., Newark, Bournemouth.
Anning, Edward Herbert, 51, Bethune-road, Stamford-hill, N.
Birt, Sir William, Great Eastern Railway, Liverpool-street Station, E.C.
Campbell-Johnston, Ronald C., Nelson, British Columbia, and 86, York-street, Westminster, S.W.

Cotton, Ross, Cape Town and Suburban Electric Lighting Company, Rondebosch, Cape Colony.
Darby, John Henry, Pen-y-Garth, Brymbo, Wrexham.
Davis, William, Engineer's Department, Stock Exchange, E.C.
Gruceon, Charles, 49, Wickham-road, S.E.
Hartmann, George H. J., Newlands, Thames Ditton, Surrey.
Herman, Benjamin Richard, McLeod-road, Karachi, India.
Immisch, Otto Claude, 102, Tollington-park, N.
Kenward, James, 43, Streatham High-road, S.W.
Marsden, Miss Kate, 11, Redcliffe-gardens, S.W.
Mumford, Arthur George, Culver-street Ironworks, Colchester.
Nicholson, H. Godfrey, Bellevue, Montenotte, Colchester.
Preston, Edward Stuart, M.A., 63, Drayton-garde, South Kensington, S.W.
Regan, William Frederick, 41, Threadneedle-street, E.C.
Ridley, Henry N., M.A., Botanic-gardens, Singapore, Straits Settlements.
Steel, Charles, Great Northern Railway, King's Cross Station, N.
Stewart, George Lawrence, M.A., Queen Anne mansions, St. James's-park, S.W.
Stobie, Harry E., Grand Junction Railways, Cotham, South Africa.
Waterhouse, Colonel James, Oak-lodge, Eltham, Kent.
Webster, Arthur Harold, Brooklands, Riverhead, Kent.

The paper read was—

THE COST OF MUNICIPAL ENTERPRISE.

BY DIXON H. DAVIES.

SYNOPSIS.

General economical principles of limitation of State functions applicable to Municipal Government as well as Imperial.—Relative fiscal importance of Local and Imperial Governments—Representative check upon local expenditure inoperative and insufficient—Growth of proper Municipal functions requiring all the attention and resources of Authorities—Repressive effect of Bureaucracy, lacking both the stimulus and restraint of private enterprise. *Four arguments in favour of Municipalism.*—(1) Cheap money—Community entitled to profit of communal service—(2) Social motives of private enterprise—(3) Private Monopolies objectionable. Governments will not take a risk and can invent, therefore Municipal enterprise tends to stagnation—Speculations on the results of such stagnation—Co-operative Societies v. Trade Unions—Municipal interferes with electricity—Its oppressive proceedings analogous to the abuses of the old Corporations, therefore dangerous to our modern Municipalities themselves, for such a policy alienates public confidence—The warning of Milton.

The laws defining the limits of state action to the elucidation of which so much of the best thought, both public and private, of the present and the two previous generations has been devoted, have by this time received a fair

neral acceptance by our imperial authorities. It is now recognised that Parliament cannot itself initiate the energies of the nation, nor apply the spirit of adventure. These develop-

aims at in this regard is the preservation of the open door, the maintenance, that is, of a favourable medium of security and liberty within which the free activities of an indus-

FIG. 2.—LOCAL DEBT, 1878-97 (INCLUDING SCOTLAND AND IRELAND, FOR THE YEARS 1895 AND 1896).

ments and qualities must be the product of the brains, and the enterprise of the people themselves. All that the Imperial Government

trious and adventurous people can (whether at home or abroad) operate without let or hindrance. It is true that it is the fashion of

certain speakers and writers, who aim at cheap popularity by appealing to the shallower instincts of the uninformed, to disparage these doctrines of free trade, of fair field and no favour, but notwithstanding proposals seductive to class interests, the preachings of Adam Smith, Stuart Mill, Cobden, Bright, and Herbert Spencer, have taken such a deep hold of the intelligence of the nation that they may be said to have been adopted as fundamental maxims by Parliamentary economists of whatever political colour.

There is a portion of the State, however, into which these important truths do not seem to have yet permeated. The local administrative authorities are as much a part of the State as the imperial. They have similar rights to regulate the conduct, and tax the pockets of the subjects as has Parliament itself. Indeed, it is probably not generally recognised how large a part of the State these authorities constitute if measured by their relative fiscal importance.

The Charts given in figures 1 and 2 show the relative amounts of the debt imposed upon the country by Parliament and the local authorities respectively, and the contrasted rates of decrease of the imperial, and the increase of the local burdens, respectively, during the twenty years from 1878 to 1897, and while the imperial debt has fallen from £775,000,000 to £641,000,000 (a deduction of £134,000,000) the local debt has more than doubled itself by an increase of £138,000,000, and it now amounts to the enormous sum of £252,000,000, or, allowing for the accumulated sinking fund, £245,000,000 sterling?

The rapid growth of these local liabilities is still further illustrated by another set of figures which are exhibited on Chart No. 3, and which show that during the past 20 years the local debt has increased 120 per cent., and the annual amount of local taxation has increased 77 per cent., against an increase in the population (the Paymaster who has to meet these increasing burdens) of only 23·6 per cent., and in the rateable value of his property of only 26·7 per cent.

These figures relate to the whole of England and Wales, including the country districts whose authorities have hitherto been content, mercifully, with a much more modest conception of their functions than the municipalities. If we take the great towns by themselves (which should give us, on the principle that what Manchester and Birmingham think to-day England will think to-morrow, a more trust-

worthy indication of the future) the figures of the local debt appear to be more serious still. Well might a citizen in Manchester cry to his local governors, "The State has chastised me

FIG. 3.—INCREASE OF RATES, DEBT, POPULATION AND VALUATION, 1878 AND 1897.

with rods, but ye have chastised me with scorpions," for while his debt to the nation is only £16 6s. 9d., his debt to the municipal

£29 1s. 4d. (see chart No. 4). The comparison of the local with the national debt is so startling when the relative ages of the cities are recalled, for whereas the vital need of the nation's defence and other imperial

4.—NATIONAL DEBT PER HEAD FOR 1896-7.

necessities throughout centuries are covered day-by-day by a debt of £641,000,000, these local burdens, the creation of the last 30 years' ready amount to £252,000,000. It must be remembered that the national debt is not really a debt at all. There is no liability on

the State to repay the principal. The reverse is the case with regard to local debts. If we except some few stocks which are only

FIG. 5.—AMOUNT OF LOCAL DEBT PER £100 OF RATEABLE VALUE.

redeemable with the consent of the holder, these moneys are real loans repayable at fixed periods, whether the assets on which they have

been expended continue to exist or not, and independently of the success or failure of the works for which they have been raised, and they constitute therefore a most serious and continuing hamper upon the taxable margin of the nation's resources, the margin which it is of high importance to conserve as far as possible intact as the nation's war-chest. Further, whereas the wisdom of the imperial legislators has been devoted throughout the late years of prosperity to the reduction of the country's liabilities on national account by the systematic redemption of the annuities, the local legislators have been steadily augmenting the liabilities of their citizens. To such an extent is this the case that if the same rates of decrease and increase are maintained for another 20 years the local liabilities will exceed the national debt.

It is sometimes said that, as these liabilities are imposed by representative authorities, the matter is in the citizens' own hands. But this does not seem to be a sufficient answer. To a large extent the representative system, though existent in form is in practice inoperative in regard to these local bodies. They are so numerous. In addition to Municipal Corporations there are County Councils, Parish Councils, District Councils, Boards of Guardians, School Boards, Highway Boards, Burial Boards, Harbour Boards, Vestries, Commissioners and probably others. The consequence is that not one householder in a thousand understands the machinery by which he is governed, or can afford the time to find out how to exercise his franchise. All he knows for certain is that the rates grow heavier year by year, and that they must be paid, and he pays and grumbles. He does not vote. To such a state of wearied apathy have the voters been reduced that ratepayers' associations are common for the purpose of checking the proceedings of the elected representatives, and a "Citizens' Sunday" has been instituted in London in order to arouse the enfranchised townsman to a better sense of his growing responsibilities.

But, apart from this, the representative check would not be sufficient even if it were in operation. The House of Commons is also representative, and yet the power of Parliament to levy taxation is much more restricted than that of the local authorities. In the first place, the imperial finance is really under the control of the members of the House of Commons for the time being, because the liabilities of the year are (apart from war responsibilities of the

past) provided for out of the taxation of the year as proposed by the annual budget, where the local liabilities are mainly met by loans spreading over a period of twelve to six years, over which, once undertaken, the councillors have no control. Besides, by the standing orders of the House of Commons, it is well known, no grant of public money can be made except upon the initiative of the responsible Ministers of the Crown, and after discussion in Committee of the whole House. The value of these restrictions is probably appreciated by no one so much as by the members of Parliament themselves, for were it possible for a member of the House to rise in his place, as a member of the London County Council frequently does, and advocate some grand new scheme involving the immediate expenditure of millions of public funds, our legislators would be the perpetual prey of a hungry pack of place seekers. Even as things are, it is rumoured that the life of a member, for, say, a dockyard constituency, is not an unburdensome existence. The member of a corporation on the contrary, has no such safeguards on which he can rely. Probably he runs his business himself, and surrounded with business friends on whose good will he is to a great or less extent dependent, he has constantly to run the risk of offending some of them if he affects a rigid adherence to economy, and the mixing up of his relations towards the working class, on the one hand as master (for the corporation is often the largest employer of labour in the town), and on the other hand as a representative, must make his position as guardian of the public purse a difficult one. Surely to leave the corporation surrounded with these direct incentives to extravagance without any adequate check on their power to expand their functions and increase their borrowing is, to say the least of it, unwise.

Let us for a moment consider the United Kingdom in the light of a banking company with its head office at Westminster and branches in every town. We find that at the head office the rule, founded on the experience of centuries, is that no loans are granted out of the funds of the shareholders except upon the unanimous recommendation of the managing directors approved at a full Board meeting while at the branches (which the managing directors never visit, and the affairs of which the Board give no attention to) are engaged on a policy of extension, to meet which loans are being undertaken equivalent to those at the head office, and threatening to involve the

re resources of the proprietors, without of the restrictions which long practice had posed upon the more responsible chiefs. Only the shareholders should say to the board "you must give these local managers one rule, a rule to limit their enterprising tendencies," and one rule would certainly be "avoid the risks, lend money upon sufficient security as you like where you are sure of getting it back sooner or later in meal or in malt, and in the meantime sure of getting a revenue upon it out on no account embark the funds of the bank upon the chance of an adventure which may or may not succeed. Leave all such risks to your customers; let them have the profits as well as the losses of them."

If this would be sound policy for a bank or a company, why is it not so for national finance? There are many reasons in favour of its adoption. The portion of the local debt at present invested in trade enterprises is, according to a recent writer,* about one-half of the total. The rest of the expenditure has been upon matters of public health, improvement of public streets, provision of public parks, and the like, which are admittedly better suited to private enterprise. It is evident, however, that the debt cannot be pulled down on this side. The increasing standard of public comfort, the increasing demand for sanitation, and so forth, will continue to impose upon our local authorities duties of an onerous and costly nature which are well within their proper arena. Indeed, is it not the constant cry that these duties are inefficiently attended to? Witness the clamour, men, alas! in vain, for the municipal dust-cart. In a recent and most able address delivered before this Society by Sir John Wolfe Barry, Chairman of Council, a strong case was made out for the immediate expenditure of millions upon a new system of thoroughfares for the road traffic of London. The urban and suburban railways had been neglected, and new lines constructed since 1858 (Sir John said), at a total cost of some £60,000,000 sterling, while the public authorities had not spent a tenth-part of that sum upon the not less important public highways. These necessities must continue to grow, and if for no other reason than that these very important and increasingly onerous duties should not be neglected, it is desirable that whatever can be should be left to private traders. Where a tub can stand on its own

bottom, do let it do so, if only because you have so many tubs whose inherent equilibrium is unstable, and which are bound to exhaust all your collective stability to keep them right end up.

The worst part of trading adventures for a corporation is that there is no closing their capital account. Take the case of electricity. Corporations have hitherto only dealt with this great subject in a small spirit. The total indebtedness under this head in the last published figures is only some £3,000,000, so that there is yet time to pull up. But electricity is fast advancing into almost universal use for trade as well as private purposes. If the authorities retain possession of this industry and keep pace with the needs of the future, they will have to spend £100,000,000 where they have at present spent one. Surely such a vista of capital commitment should give pause to the counsels of those adventurous spirits who, with a vicarious enterprise, are so ready to land the ratepayers in further trading risks.

It is submitted, however, that the financial aspect of this question, how fully so ever we may comprehend it, in its prospective as well as its present condition, and serious as it undoubtedly is, does not itself constitute an adequate measure of the cost of municipal trading enterprise by any means.

In addressing a deputation in 1893, the late Prince Bismarck used the following words:—

"My fear and anxiety for the future is that the national consciousness may be stifled in the coils of the boa-constrictor bureaucracy which has made rapid progress during the last few years."

The encroachment of municipal governors into the domain of commercial enterprise must be restricted, and undoubtedly it does restrict, and repress individual enterprise.

It has this effect, not only by restricting the progress in the particular undertakings upon which it embarks, but also by hindering and obstructing individual speculation in other directions which the corporation have not yet undertaken themselves, but which it or some of its members apprehend they may possibly in the future desire to undertake. It is not creditable to municipal enterprise that in no less than 104 cases local authorities should have obtained, and are holding, provisional orders for electric lighting without doing anything to carry the powers into effect. It is difficult to resist the conclusion that these powers have been taken for the dog-in-the-

* "Local Taxation and Finance." Blunden, p. 19.

manger purpose of keeping companies out, and so have had a directly retarding effect restricting the growth of the towns in an important direction.

No doubt many well-meaning people have come to look on municipal enterprise as the only means apparently available by which many useful public purposes can be accomplished, and doubtless the formation of building societies, electric companies, railway companies, and other private organisations is a very difficult matter, but the very difficulty contributes both a restraint and a stimulus which are highly advantageous, and the absence of which is one of the disadvantages municipalities labour under in embarking upon trade. It is not a good thing that capital should be had for the asking. "Borrowing dulls the edge of husbandry." When money in plenty is to be had at 3 per cent., a rigid economy seems supererogatory. Again, if any portion of the community is so lethargic as to be incapable of making the effort necessary to set any such concerns which it may require on foot in a legitimate manner by private exertions, they had better be left without them, and learn the consequences of laziness. It is a wrong principle to train people to suppose that they can sit still, and that luxury and comfort will wait upon them.

There, however, are four arguments commonly advanced by the supporters of municipal trading with which it may be convenient to deal here. First, it is said that a public authority can raise money more easily and cheaply than a private company can, and that therefore to leave large undertakings in private hands is to sacrifice an economical advantage. Is there not a fallacy lurking here? Nothing for nothing is a sound rule. Depend upon it the astute persons who finance public loans take care to exact the full market value of the risk they take. If the public authority pays less for money than the company would it is because the authority undertakes a higher obligation. The obligations of a company are devoid of personal responsibility, while the ratepayer has to repay his loans as already pointed out, independently of the success or failure of the undertaking, and is in fact a shareholder in an unlimited concern. Further, the present credit of the local bodies is to a large extent the product of adventitious circumstances. It is not due to any improvement in the financial conditions of the bodies themselves, because no such improvement has

taken place. Taxation is higher and capital burdens heavier. It rests, on the contrary, the thrift of the Imperial Government, which by reducing the interest on its stock, has forced large amounts of money to seek a high return, and by annually purchasing and cancelling consols, has raised the price of the to its present level. If the National Debt Commissioners were to suspend the operation of the sinking fund, there is not a corporation in the country that could borrow at 3 per cent. Besides, the cost of borrowed money is a very small element in the success of a trading concern compared with personal talent. If we were otherwise we should have no new firm starting to compete with established traders. Indeed, the command of large capital is frequently the ruin of a business. It leads to overtrading. So that even if this advantage were a real one, and one to be permanently reckoned on (which for the reasons given is least doubtful), it is not of the importance commonly attributed to it.

The second argument is that if a profit can be made out of the general supply of some commodity for the community, why should not the community realise that profit for itself? We seem to have heard of this system before in the Shetland Islands, where, as the pupil teacher told her examiner, the inhabitants earned a precarious livelihood by taking in each others washing. But the great difficulty of a corporation engaging in a trade is to hold the balance evenly between the ratepayer as proprietor of the corporation works and the ratepayer as consumer. The two are not by any means identical. In Nottingham the corporation makes a large profit out of its gas, and in one of the Committees of Parliament last year a prominent manufacturer spoke very bitterly of the feeling of the large gas consumers that they were charged unduly for their gas in order that the rates might be relieved. He stated that the profit on the gas was sufficient to defray the entire cost of the admirable Technical University of Nottingham, so that the large manufacturers were compelled to provide lavish educational facilities for the town out of their own pocket for no reason except that they were for the purposes of their business the largest gas consumers. In fact, such a process is the same as complain stealing from the rich to give to the poor. Again, in Sheffield the corporation have just realised a handsome profit out of the working of the tramways, and they propose to appropriate £12,000 of this profit to reduce

amount which otherwise would have to be paid by increasing the general district rate levied in the £. But the working-class who live along the tramway route are up in arms against his proposal. They say that they are practically the sole users of the tramway, that increasing of the district rate means hardly anything to them, that the people who will benefit by that will be the rich property owners. In fact, that such an appropriation of the profits means a stealing from the poor to give to the rich.

Suppose, in his bewilderment, the Town Council, thus attacked on both sides, says it will not make any profits at all, "we will reduce the price or the fares, so that the profit shall be extinguished altogether," this would still be unjust to the ratepayer, who does not burn gas or does not use the tramway, for he will have been burdened with an additional capital debt for the purpose of subsidizing his neighbour who has commercial interests that do not affect him. Such a ratepayer will say "Why should I be dragged unnecessarily into a huge trading venture with a large capital in which I take no interest, and be called upon to elect directors for it, and otherwise spend my attention upon a thing which I do not understand." The reasonableness of this will be understood from the case of the Liverpool electricity works, where (the figures are quoted from a recent speech of the Town Clerk) the customers of the works only number 3,000, whereas the entire population of the city—some 700,000 people—is laid under contribution or liability to provide the capital to keep the works going, a disproportion which is surely a strong argument for the immediate disestablishment of electricity from municipal control.

The third contention of the advocates of municipalism is that the motives of private enterprise are self-seeking and sordid, and contrast unfavourably with the disinterestedness of the Town Council.

There is a great deal of cant—or at best arrogance—in this cry: Where is the inherent selfishness or nobility in those who merely venture other people's money? On the other hand, no one who has seen the carrying out of a great public undertaking by private enterprise can have failed to be impressed by the high degree of courage, steadiness in adversity, tenacity of purpose, faith and loyalty, which is required to steer it through the troubled waters of its early career. It is a mistake to attribute the motives of such

individual adventure merely to pecuniary interest. The pleasure of accomplishing a great work of public utility and of deserving public fame, of vindicating the soundness of private opinion and higher considerations also enter largely into such motives. In fact, the adventure becomes, as Leroy Beaulieu has put it, a refined species of sport. That this is so will be evident to anyone who has studied the account of Stephenson's great battle with Chat Moss, and the dogged and devoted manner in which the great engineer was backed up by the capitalists and others who were associated with him. Such mercantile adventure affords a legitimate outlet for the sporting proclivities so firmly implanted in the Anglo-Saxon race, and one of the consequences of discouraging it or limiting the opportunity for such adventure, will be to stimulate gambling of one kind or another. No doubt the reason why gambling is so prevalent in the working-class is that, as wage earners, they have no share in the risks of their business, and so have to seek other fields for the exercise of their sporting instincts. To fence off by the staves of officialdom field after field of enterprise from the adventure of the individual capitalists is to deaden commercial activity, and to atrophy those energetic faculties of our nation, which hitherto have been the main-spring of its progress. In a recent letter to the *Times*, Sir Edward Fry says:—"What is it that has made Englishmen what they are but their passion for individual freedom, their habit of acting on their own judgment and their own initiative, and their dislike, I may say their scorn, for the leading strings of official authority? Without that freedom of individual action, England can never continue to be in the future what it has been in the past." Bureaucracy cannot create advancement any more than grammar can create literature, and for our municipal governors to affect to sneer at the commercial motives of their citizens is, having regard to the mercantile authorship of our corporations, in as good taste as for a *nouveau riche* to turn up his nose at the commercial origin of his own father.

Fourthly, it is sometimes urged that certain fields of commerce are necessarily monopolies, and that it is better that the Government should be a monopolist than a private person. There is some reason for this in such a case as the public supply of water, which, as a matter of common necessity, and one connected with vital questions of public health, may

well be entrusted to the management of the civic officers, more especially as it does not involve any manufacturing risks, and cannot possibly be replaced by another article. But in other matters this cry of monopoly is only a pretence by which people are induced to concur in the municipalisation of various trading undertakings. That such concerns are bound to become monopolies in the hands of the corporation may be admitted, for the whole power and authority of that body is used to defend them as such, and to prevent any one else conducting a competing trade which, but for the corporation, they would be entitled to do; but to say that they are monopolies when they are in private hands is an abuse of the term. They are only monopolies so long as by reason of their efficient service, or of the apathy of the community, the public do not choose to make the effort necessary to establish a rival undertaking.

What ground is there for alleging that in private hands such trades are monopolies? Because of their magnitude or their territorial stability? This merely means that those who allege it have not imagination sufficient to conceive how such undertakings can be duplicated. In the thirties everyone believed that the trunk lines of railways were virtual monopolies. Had the present doctrine of the State traders then prevailed, we should no doubt have had the railways in the hands of the Government. Does any one believe that if that action had been taken we should have had by this time four main lines of railway running from London to the North, and a fifth about to be opened, each independent of the other, and engaged in the keenest competition to improve and accelerate its service so as to obtain a larger share of the public patronage? Railway travelling between London and the North has reached a pitch of convenience and luxury, even to the third-class passenger, which would never have been dreamed of even twenty years ago. A pitch of convenience incomparably superior to that of France, where the railways have been installed under Government auspices, and where the public are saddled with nearly £4,000,000 sterling of guaranteed dividends to the railway companies every year. This state of efficiency never could have been reached by a Government railway department, for the simple reason that Government never takes a risk if it can help it. Why should it do so? and yet risk taking is the parent of progress. Can any one imagine a Civil Service Department recommending the construction of a new line of railway from

Bedford to London at a cost of many millions when the whole of the traffic authorities of existing line of railway between the two points asseverated over and over again that they were ready and able to deal with the whole of traffic on that route, both existing and prospective? Of course, the risk would never have been taken, and the Midland Railway would not have been in London to-day, and who can say with effect that deprivation would have had in retardation the general trade of the country. It may be guessed at from the single fact that the coal sent to London from collieries on the Midland system was in the year 1867 157,246 tons, and in 1869 after the opening of the extension to London the Midland carried 760,000 tons of coal to London, a tonnage which has gone on increasing ever since till it now reaches about 3,000,000. Surely this instance shows that a serious must be the effect of restricting private enterprise, for the results of such enterprise are indirect, obscure, and not to be foreseen, and of much greater importance than the direct and calculable results.

Another deficiency in Government or municipal enterprise is that it is non-inventive. A Government never invents anything, nor does it itself start anything new, and is very slow to adopt inventions of other people. The Post Office did not invent railways, or telegraphs, or telephones, or boy messengers. These things, with more or less reluctance, adopted the inventions from outsiders. Steam was not introduced into our warships till years after it had been used in the mercantile marine. Hydraulic lifts are conspicuous by their absence in the public buildings of London, and the metropolitan police have not yet learnt the use of the telephone. It is natural that this should be so for a Government department (whether civil or municipal is immaterial) in effect a huge machine, in which the members are subordinated one to the other in an arranged succession like the parts of a machine. This gives stability and precision to the whole; it does not give individual freedom. Each member of the department must of necessity confine his activities to the particular channel assigned to him in the general design of the machine. He must not on account strike out a line of his own, neither can the machine itself operate except in the pre-ordained groove. It is obvious that invention, the initiation of new methods, whether mechanical or social, is not a crop that will grow in a soil of this kind. Such things are the product of free and independent thought.

clear, therefore, that a system of bureaucracy tends not to progress, but to stagnation: to the fixing, that is, of ideas at their existing level of development. It may be able to carry on a simple trade such as the supply of water, a commodity of universal necessity, which, therefore, needs pushing cannot ever be replaced by the advancement of science, and can be managed on a system of strict routine, in any branch of industry which is of a stable character, and which depends on the satisfaction of the public, and the tempting of customers, the private capitalist who understands his own business and is free to conduct it in his own way without having to reckon with the opinion of a host of other people who know nothing about it must have an incalculable advantage. To attempt to presurmise how a stagnating tendency inherent in municipal enterprise will operate must necessarily be to some extent speculative, and, for sheer lack of imagination, must fall short of the realisation. The probable effect may be noticed: our municipalities, naturally on account of their democratic basis, and very properly on all occasions, take a great interest in the welfare of the working-classes. They consider they can best conduce to this welfare by supporting the regulations of the trade unions. There can be no doubt that these bodies have been of great service in raising the condition of the workmen, but it is equally certain that some of their methods are infected by gross economic error, and have tended not merely to the raising of wages, but to the restriction of the production per head. The prevalence of these errors, and the serious results of the recent industrial wars in which the trade unions are ranged on one side, and employers on the other, have set thoughtmen in all classes searching after some new form of industrial organism which will set the men out of the position of mere wage earners (to the conservation and promotion of which position the efforts of the trade unions are directed) and make them partners in the whole produce of their industry. The germs of such developments have already shown themselves in the co-operative manufactories, and in the labour partnerships which have, in some instances, made promising progress with every indication of success in the removal of the fatal rivalries referred to.

The evolution of such new collective fabrics, and the progress of them, is devoutly to be wished by all friends of the working-classes, and by all patriotic citizens, and must one of those improvements which ex-

perience and theory show to be impossible of development in the sterile medium of government routine. Further, the action of the trading municipality, always insisting on trades union regulations being observed, not only in its own works but even by the manufacturers or contractors who deal with it, does much to hamper the free spirit of experiment in these directions, and to retard the operation of those spontaneous tendencies which in an open market would work towards the accomplishment in due time of such new industrial plans.

There is no need, however, to draw upon the imagination to illustrate the deplorable effects of the enslavement of free energies which results from handing over an industry to municipal enterprise. We have one existent example of it in the state of the electrical industry.

How is it that this country, which taught the world the use of steam, should be so backward in electricity? How is it that whilst great systems of electrical power transmission are common in America, in Italy, in Germany, in Austria (constituting as such systems do, an important new development in the division of labour, by enabling the small workman in a remote village to obtain his power on tap as it were, and so to produce almost as cheaply as can be done in the great steam workshops in the town), Englishmen are content with insignificant installations in monopolised areas? How is it that while English machinery in the mechanical departments still holds its supremacy at home, as well as abroad, in electrical matters, we have to give place to other nations, and the whole of the plant for the electric traction of the underground railways of London is being ordered from America, and also that for the tramways of Leeds, Liverpool, Sheffield, of Gasgow, and of many more towns that can be named? Surely this state of things can only be accounted for by the unwise action of the Legislature in discouraging and restricting the enterprise of the capitalist and in committing this promising industry to the sterile and monopolist hands of municipal enterprise. What is the history of this subject?

Parliament yielded to the fears of gas-owning corporations (municipal adventurers are always protectionists of the most timid order) and the Electric Lighting Act of 1882 was passed. Under this Act the municipal authorities were enabled to obtain power to supply electricity under license or provisional order

from the Board of Trade, but private capitalists who might apply for such power were subjected to two disadvantages, first they had to obtain the consent of the local authorities, and, secondly, the municipalities could, at the end of the 21 years, step in and acquire the undertaking at the then value of its material effects without paying anything for compulsory purchase, or for prospective profits, or for the cost of pioneer and educational work. In effect, therefore, municipal enterprise was encouraged to embark in this promising field, and every obstacle was thrown in the way of private enterprise doing so. The result was of course that the discouragements were too great for private adventurers to encounter, and they soon left the business alone. The municipal trader, in spite of the legislative encouragement, remained true to his tradition of taking no risks, and of avoiding new inventions. He sat down, and did nothing, and the industry stagnated until 1888, only one provisional order having been granted in the previous four years. Parliament then thought it time to interfere, and passed an amending Act by which, while the encouragements to the municipalities were not one bit abated, the obstacles to a private enterprise were partly removed by the extension to 42 years of the period during which the concern was exempt from expropriation by the authority.

Still municipal enterprise stagnated, but commercial adventure made a fresh start, and almost all the existing electric stations were established in London, in Liverpool, in Sheffield, in Nottingham, in Birmingham, and all over the country by electric companies. In many cases the undertakings of these companies have since been acquired by the town before the right of compulsory purchase matured, at of course a handsome price, for a municipality can never drive a good bargain in an open market, and with the tardy advent of the municipal trader his monopolist tendencies begin to assert their mischievous influence. There is not of right any monopoly in electric supply in this country. The first section of the Electric Lighting Act of 1888 reads as follows:—"The grant of authority to any undertakers to supply electricity within any area whether by license or provisional order shall not in any way hinder or restrict the granting of a license or order to the local authority or to any company or person in the same area."

Whenever electric stations belonged to companies the local authorities were most anxious to take advantage of this section, and to pro-

mote competition. They readily gave the consent to two or more rival companies working together in the same area. In London, for instance, there are two electric companies competing against each other in every parish except the City, and in Westminster there are three. But what was sauce for the company good was by no means to be sauce for the municipality. When the means of insulating high tension currents became improved, it was discovered that the parochial limits (which were fixed as are told in the time of Alfred the Great) did not form a scientific division for confining peculiarly elastic and transmissible forces. Some parties therefore proposed, in full reliance on the section of the Act of Parliament above quoted, to establish electric transmission systems on a much larger and more moderate scale than has hitherto been known in this country, and, in consideration of the economy that would thereby be effected, to subject themselves to a maximum charge less than one-half the rate which the corporations were authorised to charge, and were, as a general rule, charging for the electrical unit.

This interesting and novel proposition was submitted to Parliament last year. No monopoly was sought for the Company, who merely wished to trade in competition with any existing stations, just as a new railway seeks power to compete in the carrying trade. The right to disturb the streets was confined to cases where the authorities refused, unreasonable facilities for the deliverance of the Company's wares through the Corporation's wires. The proposal was welcomed by the trading community as one would have expected. The Chambers of Commerce petitioned in its favour and no one opposed it except the municipalities. The nature of their objections is sufficiently indicated in the following recent resolution of the Municipal Corporations Association, passed in reference to this very Bill:—"That the Association affirms the principle that where local authorities have, with the sanction of Parliament, established or are in course of establishing undertakings for public benefit and have not failed in their duties, it is not right or expedient that powers should be granted to companies to compete with them."

Surely here we see the municipal trader in his true colours. He does not wish to trade the same way that any commercial man trades, facing difficulties as they come, contending with his rivals whoever they may be, adapting himself to new conditions, scrapping his existing plant as soon as it is superseded, a

February 3, 1899.]

stituting more efficient plant often at great
 rifice. Your municipal trader won't hear
 scrapping superseded plant. He wants
 protection for the ratepayers' trade. If science
 is shown that he is on the wrong lines, and
 is made an improvident investment, so much
 worse for science, which must go to the wall
 before the necessities of municipal trading.
 Science must wait until his machinery wears
 out, that will be quite time to introduce
 anything new.

The Bill, however, having in principle re-
 ceived the approval of a Joint Committee of
 the two Houses, was passed by the Select
 Committee of the House of Lords. At both
 these inquiries the corporations were strongly
 represented, and clauses were inserted for
 the protection of their interest. Not content
 with this, however, these bodies continued their
 hostility, and took the course, unusual in the case
 of a private Bill, of organising a strong opposi-
 tion to its second reading when it reached the
 second House. There was thus presented the
 strange spectacle of the corporations opposing
 the granting of facilities to traders whose ad-
 vantage to their town their own Chambers of Com-
 merce were actively supporting, and whom the
 same corporations would, as they candidly ad-
 mitted, have themselves cordially welcomed had
 they appeared a year or two earlier, before they
 the corporations had embarked in the electrical
 business. The opposition was conducted not
 in the usual way, each town upon its own
 account, but by a kind of centralised union of
 corporations, called the Municipal Corporations
 Association. This body raises its funds for
 such proceedings by a rateable levy over the
 whole of the affected towns, so that although
 ostensibly preserving its local character, the
 opposition is centralised, and rendered un-
 amenable to local influence. Further, such an
 organisation wields a power which, for the
 purpose of a second reading opposition in the
 Commons is most formidable. For the Associa-
 tion calls upon the corporations all over the
 kingdom to bring pressure upon their respec-
 tive borough members, so that in this case,
 which could not affect the interests of a single
 person north of Barnsley or south of Derby, the
 member for a borough in the north of Scotland,
 and the member for one in the extreme south
 of Ireland, would be whipped each by his own
 town clerk, to vote against this private Bill.
 When it is borne in mind how great (and,
 speaking generally, justly great) is the Parli-
 amentary influence of the corporations, whose
 councillors are elected very often through the

same organisations as are employed for the
 political elections, it can readily be conceived
 how great a bar to the initiation of an enter-
 prise which requires Parliamentary sanction is
 the mere risk of having to face such an
 opposition. It is hardly too much to say that
 such a one-sided use of the united power of
 these local bodies (power granted, be it
 remembered, for the common good, not for
 the protection of selfish interests) for the
 purpose of stifling a new enterprise at its birth,
 and so securing for themselves a monopoly
 which they would not otherwise be entitled to,
 savours more of oppression than of fair dealing.
 Now oppression is not to be tolerated on the
 part of our local bodies. If we were capable
 of tolerating injustice we should cease to be a
 people worthy of free institutions, and if the
 effect of the acquisition by the corpora-
 tions of these trading undertakings is to put
 partiality in the seat of authority, then the
 cost of municipal enterprise will be much
 more serious than any that has yet been con-
 templated.

Surely the corporations have forgotten the
 sins whereof they have been purged. It was
 because of the monopolies and restrictions
 which the old self-elected corporations im-
 posed on the trade of the towns that, strong
 as they were in Parliamentary influence,
 (for the old corporations actually elected
 the borough members themselves), they for-
 feited the public confidence, and they were
 abolished by the Act of 5 & 6 William IV.,
 cap. 76, section XIV. of which read as
 follows:—"Be it enacted that, notwithstand-
 ing any custom or bye-law, every person in
 any borough may keep any shop for the sale of
 all lawful wares and merchandize by wholesale
 or retail, and use every lawful trade, occupa-
 tion, mystery and handicraft for hire, gain,
 sale or otherwise within any borough." The
 consequence of this new policy of freedom for
 industry is the extraordinary growth of popu-
 lation and resources which has succeeded the
 reform. But the oppressive treatment of the
 electrical traders would seem to indicate a
 reactive tendency towards the old mischief
 again.

All this points to yet another danger of
 municipal trading, a danger that is to the
 stability of the municipal institutions them-
 selves. These institutions, which are the
 most ancient, and, as they exist to-day since
 their constitution was broadened by the
 Act referred to, among the most efficient
 examples of the self-governing faculties of our

race, are deserving of our uncompromising support. The towns are, besides, dependent upon them to an incalculable extent for some of the first necessities of modern life. It is therefore a duty imposed on all by self-interest, as well as by gratitude and patriotism, to point out fearlessly the insidious error which is creeping into the practice of these bodies, and to use every effort to arrest it before the decadence becomes irretrievable. It would be wrong to overlook the serious state of the municipal institutions of America, arising, as competent advisers tell us, from the unlimited enlargement of the functions of the Government. The consequence is that public employment is excessively multiplied, and the municipal debts have risen to colossal dimensions. The affairs of the cities are left to professional politicians, and are conducted in such a nauseous atmosphere of class corruption and party trickery, that the better class decline to have anything to do with them. A distrust of the servants and representatives of the people is everywhere manifest.* We are a long way from such a state of things in this country, but can it be doubted that this ambition to embark in trade will be injurious to the corporations, for their efficiency must depend, not upon the profits which they may be able to make out of their various trading advantages, but upon the degree to which they can absorb into themselves the energies of the most capable citizens? Is a course of action which puts them in competition with their own traders, which results in the imposition of something like an octroi duty upon a commodity that is fast becoming the necessity of every manufacturer calculated to secure the respect of the trading community? Further, is it calculated in the long run to secure the respect of the working class? The expenditure of public money in a district; the establishment of municipal works; the employment of large numbers of the ratepayers at municipal wages; these are very popular things while they last, but they are also very difficult things to stop, for they necessarily create in the minds of the more ignorant of the ratepayers false ideas of the function of the local government. How can you blame the wage-earner if he comes to think that it is the duty of the municipality to find employment for him, and how can you blame him if, when the inevitable disillusionment comes, he is disappointed and disgusted on finding that he is mistaken? Municipal

trading is thus infected with the communal poison. It begins by alienating the confidence of the manufacturers, and ends by alienating the confidence of the workmen from institutions which, so long as they confine themselves to their proper functions, are productive of so great good to the country. Surely, therefore, the corporations would be well advised to confine their functions to those important public matters in which all their constituents are equally interested, and which must of their nature be performed by the ratepayers in common, and which involve no taint of partiality, or suspicion of class bribery, such as the administration of justice and police, the care of the public health, the provision of parks and open spaces, and so forth. Let them leave to private enterprise whatever private enterprise will undertake, keeping themselves in an impartial position, so that they may secure the unsuspecting loyalty, and the obedience of all the traders to the regulations which they impose upon them for the protection of the common interest. Let them adhere to the spirit of the constitution of Alabama which declares "That the sole and only legitimate end of Government is to protect the citizen in the enjoyment of life, liberty, and property and when the Government assumes other functions it is usurpation and oppression."

A policy of antagonism to the trading corporations on the part of our Corporations would be an undoing of their own work. The immediate cause of the active commercial energies, which so much jealousy has been expressed to the liberty which has been secured to the individuals in the towns by municipal institutions, "that liberty which is the nurse of a great wits," and for these institutions to interfere with and repress trading liberties is both unnatural and self-destructive.

The following words, addressed by one of the great apostles of liberty to the Lords and Commons of England, so long ago as the first half of the 17th century, are still pregnant with wisdom worthy of the attention of our reformed municipalities on the eve of the 20th:—

"Ye cannot now make us less capable, less knowing, less eagerly pursuing of the truth, unless ye first make yourselves, that made us so, less the lovers of our true liberty. We can grow ignorant again, brutish, formal, slavish, as ye found us, but then ye must first become that which ye cannot be oppressive, arbitrary, and tyrannous, as they were from whom ye have freed us."*

* See Lecky on "Liberty and Democracy," vol. i., pp. 80-86. American authorities there cited.

DISCUSSION.

THE CHAIRMAN said Mr. Davies had brought forward in a most attractive manner a subject which, at first sight, appeared very dry, and had not only relieved it by pointed and humorous observations, but had presented some very serious points for consideration. As he was unable to remain until the close of the discussion, he would make a few remarks which occurred to him at once. The Tables on the whole would, he hoped, be reproduced in the *Journal*, as they were very valuable, but he thought their value could be enhanced by a further subdivision showing the amount of local debt which had been incurred for what might be broadly termed trading purposes. Whatever might be said as to the profit made out of undertakings such as gas or tramways, worked by corporations, his belief was that if the matter were brushed out, it would be found that the burden on the ordinary ratepayer was less where no such risks were undertaken. Of course, he did not pretend to lay that down as a fact, from personal knowledge, and therefore he thought it would be very useful if such an addition could be made to the Tables. It was the more important, because it was stated that, according to the most recent statistics, one-half of the total local debt was due to trading risks. Valuable as the paper was, he should have been glad if Mr. Davies could have drawn some more precise conclusions as to where the line should be drawn. He had indicated one limit, viz., that corporations should confine themselves to such works as sanitation, parks, open spaces, police, and possibly water; but those limitations might be further developed. He had the strongest feeling in favour of the main argument of the paper; indeed, he thought it might have been put even more strongly. Not only was the power of a corporation to earn money as traders quite a modern development, but in the beginning of the reign it was contrary to

law. He remembered arguing a case many years ago with regard to the duties and powers of a corporation which was contemplating supplying gas to outlying authorities, and Lord Chief Justice Cockburn laid it down as an axiom that, except for statutory authority, a corporation had no power to make profits. That was not a mere accident owing to the want of development of modern enterprise, but was due to a sound system of political economy, that it was almost impossible to put the burden of a trading undertaking on the right shoulders, and so to regulate the charge that you did not put a burden on those who derived no benefit. Some people still thought it would be well to have toll-gates, because then those only who used the roads would pay for them. But without going so far as that, every one could see that it was extremely difficult to make the cost of an undertaking and the charge for it exactly balance; and he did not believe any corporation could so adjust its affairs that the burden should be borne only by those who used the undertaking, especially when, as in most cases, a sinking fund had to be provided for. It was a burden on the ratepayers of to-day for the benefit of those of the future. Again, the absolute necessity of inventive competition in this kind of undertaking was of great importance to the argument. He knew of nothing in which this was more marked than in connection with telephones, electric lighting, the supply of gas, and so on. History showed what difficulty there had been in introducing economic changes, and in inducing people to discard old machinery in favour of new even where there was the inducement of greater profit. There was practically no inducement to a corporation to discard old plant and buy up new until it was worn out, and all history showed that to private enterprise and energy all the great inventions of the world were due. A great deal of cant had been talked about monopolies, and after all there was no greater monopoly than to give a corporation the sole right of supplying electricity. No local authority would be likely to give its consent to a private undertaking supplying electricity in competition with itself, but he was satisfied that competition was essential in connection with electric lighting as with any other question of supply and demand. Possibly a distinction might be drawn in favour of water, and certainly drainage was a matter out of which no profit ought to be made. Everybody benefited when the health of a town was improved. He admitted that water was very near the line, and within certain limits every one ought to require about the same quantity. He would not go into questions which were extremely important and very far-reaching, and of which they did not know what the outcome might be, such as the evils which might be created by a fictitious rate of wages being established by municipal authorities as compared with the price at which honest contractors could get the work done. Those persons who had not had to do with practical business might say

no harm was done by the present rate of wages being raised, but an end must come, and the general result on trade, and ultimately on the prosperity of the working-classes would be harmful. One point which perhaps Mr. Davies had a little exaggerated was the ease in getting money on the part of the local authorities. Though they might raise it on lower terms than a private company, they had to provide for repayment within a certain time, which a company had not, and one thing must be put against the other, but that was a point which would bear a great deal of discussion. He concluded by formally moving a vote of thanks to Mr. Davies.

Sir WALTER PRIDEAUX here took the chair.

Mr. BRYDGES said he should like to say a few words on behalf of corporations. In the first place with regard to the comparison made between the local and the national debt it must be remembered that in the case of the local debt there was something to show for it, whereas there was nothing to show for the national debt; it represented hardly anything but the expense of a number of wars which, however necessary, were only necessary evils. In the time of George IV., after the Napoleonic wars, the national debt was something like £900,000,000, though it had been considerably reduced since; and it was not like a debt which had been incurred in the purchase of assets, tangible and to a certain extent realisable. With regard to the probable increase of local debt, Mr. Davies said if it went on at the present rate, in another 20 years it would equal the National Debt; but it did not follow that because an increase had taken place in the past it would continue at the same rate in future. On the same principle, the national debt having been about £30,000,000 in the time of Queen Anne, an economist in the days of George IV. might have said that in another 100 years it would amount to £127,000,000. Half the debt incurred by corporations had been for purposes of sanitation, and the towns having been put in decent order, it might be hoped that similar expenditure would not have to be incurred again. He did not understand how half the total amount had been incurred for trading purposes if half had been spent on sanitation. Four arguments in favour of municipal enterprise had been mentioned, and objections raised to each. As to the low rate at which money could be raised, it was said that was because corporations were found to pay their debts; if so, he thought it was a very good reason why their credit was good, and there was no blame to them for that. Then it was objected that the cost of borrowing money was of less importance than the employment of talent and energy. That seemed to be giving away the whole question, if it was meant that private companies could secure superior talent, but he should think a corporation might engage persons equally talented with those who served a private concern.

Then it was objected that corporations could earn a profit because they paid higher wages, and could make a certain dividend and yet increase the wages to some extent. There was a general feeling in favour of raising the minimum rate of wage, and he thought it was to the credit of corporations that they had done something to reach that ideal. Then it was said there was no motive in the case of private enterprise, and there was a sneer at corporations being disinterested. No one supposed a town council was disinterested on its account, it acted as trustee for the ratepayers. With regard to monopolies, he always understood the principal objection raised to them was that the public suffered, and, in fact, the charges of gas and other companies had to be regulated by Parliament. In many cases corporations had done good work in taking over the undertakings of gas and water companies, and he did not believe any complaint had arisen in consequence. With regard to the rise in rates, Mr. Davies seemed to think there was an unlimited power of borrowing, but that was not so. In the first place there was the power of the electors, and many candidates put in the forefront of their addresses that they were advocates of strict economy. Gentlemen might laugh at that, but very many had been elected who acted up to the principle. No doubt there was a strong tendency in human nature to spend other peoples' money freely, but there was also a tendency in many men to be guided by their principles. And if that were not enough for security, it must be remembered that every loan had to receive the sanction of the Local Government Board. If there was any question about the expediency of the expenditure, a local inquiry was held. There was no danger, therefore, of money being borrowed recklessly without the sanction of the ratepayers.

Mr. GRAHAM HARRIS said the paper was a very good one—too good, in fact, for there was too much in it to be appreciated on merely hearing it. It was a big subject, which tempted one into all sorts of bye-paths, but he admired the way in which the author had kept to the main road. With regard to Sir Richard Webster's suggestion that a note should be added to the paper giving the proportion of debt incurred by different municipalities for purposes other than draining public parks, &c., &c., he thought it would be very useful. He noticed that Manchester had the biggest municipal debt, and he should like to imagine a large part of that was due to the Manchester Ship Canal. Whether that was a trading concern or not, he would leave to the shareholders to decide. His firm were engineers to the particular electric undertakings which had been referred to in three Bills were coming before Parliament this year, one of which he might specially refer to. That was the Leicestershire and Warwickshire Bill. The proposal contained in this Bill was to supply

tricity from a central station on the coal-fields an area of nearly 1,300 square miles, for lighting, and any purpose for which it could be used; having regard to what was being done in many, America, Austria, and Italy, it was quite plain that it could be supplied at something like one-fourth the rate at which it was sold at present. The total area in that district, at present supplied by the municipalities who were opposing the same, and stirring up opposition all over the kingdom, was four square miles, and the whole work might be done by one small engine working continually. They had 1,020 customers, but the whole population was counted by millions. The suggestion of the municipalities was that the company could be prevented from supplying that area, and that the millions of people in the area, including their 1,020 customers, should be prevented having electricity at the price the company were prepared to supply it at. This was a serious matter, especially having regard to the difficulties with which English manufacturers were at present contending as against foreign competitors.

Mr. W. M. ACWORTH thought it was hardly fair to blame corporations for claiming a monopoly. They were highly organised bodies, and they showed that even the lowest organisms had an instinct of self-preservation. Now anybody who knew the working of a corporation, as distinguished from a private trading body, knew that if a corporation had not an absolute monopoly it was bound to go to the wall. He had received a document which seemed very germane to the question before them, viz., a summary of which appeared in the *Times* that day. It was issued by the School Board for London, and had reference to a conference on assessment matters. He received as chairman of the Finance Committee of the Metropolitan Asylums Board, a body of which not a ratepayer in a hundred had ever heard, though it was responsible for an annual expenditure of a quarter of a million. The document pointed out that public bodies had to pay 10 per cent. more than a private individual whenever they sought to acquire land, and that they were at a similar disadvantage when making contracts for building. For the latter statement various reasons were given, and he might mention one which was put to him by a gentleman who had done work in bricks and mortar for the ratepayers of London certainly to the extent of a £1,000,000, if not more. He said when he made his estimates for any public body he always assumed that the workmen would do less work for a contractor working for a municipality than for a private owner; he did not know why they should, but experience proved that it was so. The London School Board had spent about £6,000,000 in buildings, the body represented about £3,000,000, and he believed 10 per cent. was a modest estimate of the difference in cost, and that more than wiped out the advantage of

which they heard so much, of raising money cheaply. He had lately read the proceedings of the Committee on the Bills to which Mr. Harris referred, and he found there were two points made by the municipalities. One was that they were entitled to a monopoly, because it was in the interest of the ratepayers that they should have it. They always made that assumption but never attempted to prove it. The other point was that they owned the roads, and that nobody else ought to be allowed to interfere with them. It had just been decided by the Court of Appeal that this claim by the municipalities was a mistake, that they did not own their roads, but only had a certain qualified control over the surface, and when an electric company without any right whatever pulled up the road and put in a main two feet deep, the municipality had no right to follow them. They were told that if the municipality only dealt with the roads, they would not be so constantly pulled up as they were by private bodies. It might be so if all municipal matters were managed by one committee; but, as a fact, he was informed that the main street of an important town was pulled up three times in one year—by the sanitary committee, the gas committee, and the water committee of the same corporation. He thought if the result of this discussion was to lead people to go behind some of these claims and examine the grounds for them, it would be greatly in the public interest. Mr. Brydges said municipal debt was not likely to increase as fast in the future as it had done in the past, but if so, he did not know what would become of the development of electricity. Here they were told that municipalities had invested three millions in electric undertakings; in America in electric traction alone not less than fifty millions was invested. If the municipalities were going to keep this business in their own hands, and were not going to increase their debt, he did not know what would become of the industry.

Mr. EWING MATHESON said it was a pure fallacy to say that corporations could borrow more cheaply than other people because they were obliged to pay their debts. They ran risks which often doubled and sometimes trebled in effect the interest they paid. The Manchester Ship Canal was largely contributed to out of the rates, and as it cost vastly more than was anticipated the money raised by the rates had to be doubled. He knew of a considerable town in the north, which built a large reservoir for a water supply, costing a quarter-of-a-million. They thought it cheaper to do it themselves because they could borrow cheaply, but when it was finished and the water was let in it all ran out at the bottom, because it was made cheaply. After ten years delay it was put right at a cost of another £250,000. If a private company had done the work, they would have had to bear the loss instead of the town. The risk was not always directly in money, but sometimes in the use of obsolete machinery. Some towns had constructed or acquired

electric installations incapable of performing the service required of them, but if a private company attempted to compete, the whole power of the corporation was used to prevent them. If it were the other way and a private company had an obsolete or insufficient plant, the corporation would go to Parliament with a very strong case for setting up a private undertaking. The question in towns was often in the hands of officials, who liked to magnify their position and keep out other people.

Mr. SYDNEY MORSE agreed with the Attorney-General that it would be well if the author could have given one or two suggestions as to how the question could be dealt with practically, as it would be a burning one in the next Session of Parliament. No less than seventy municipalities were applying either to Parliament or the Board of Trade for powers to trade in electric fittings, thus coming actually into competition with private manufacturers; and in addition to that a large number of Bills were coming forward in which municipalities were seeking to become trading corporations. Manchester was proposing to inaugurate a system of tramways within sixteen adjoining districts, in which it claimed that no company whatever should have a right to put down or work tramways. The Manchester Corporation did not say they would make all necessary tramways, but only those should be made which they approved. The practical point was how was this question to be met? One way was to oppose these Bills in Parliament, and he was glad to hear that the Postmaster-General was opposed to this kind of thing. As Parliament had already permitted local authorities to undertake certain work it was no use proposing an absolute negative, and the more difficult question remained, to what extent should they be authorised; and they could only go on the lines, how far it should be allowed. That raised a very difficult question, and he would ask all those present, and those who attended the adjourned meeting, to endeavour to give some assistance on that point. It must be admitted that no municipality ought to be authorised to do work for the benefit of other people at the cost of the ratepayers. They ought not to encourage expenditure on behalf of one section only of the ratepayers, and they should be confined strictly within their own area. If there were a scheme proposed in London which would greatly benefit Islington, it was not right that those who lived in Kensington should be heavily rated for the purpose. Health was a matter in which all were deeply interested, and therefore, there could be no question with regard to sentiment, but when it came to carrying on a big undertaking all over the country it was a different thing. If Manchester got a line of trams to the big towns surrounding them they would want next to come to London, and logically there was no reason why they should not. In the City of London they were going to fight this matter out to the bitter end, and he hoped

that everyone would do their best to get Members of Parliament to take the right course in this matter and prevent the further extension of a very dangerous principle.

Sir JOHN ROLLESTON desired to thank Mr. Davies for his valuable paper. He was in association with a community in which a very important and important section were pressing forward doctrines of a contrary nature. It had a population of over 200,000; a large section—in addition to the nationalisation of the land, railroads, and so on—were bringing forward a programme of the municipalisation of all industry. This, of course, encouraged the corporation to enlarge its system of municipal trading. In that town none of the public works—water, gas, or tramways—were done on a municipal initiative, but to private enterprise. It must except electricity, which the corporation took over after several companies had applied to the Board of Trade for licenses. The first Act was obtained in 1879, but until 1894 no electricity was supplied, and then it was at 6d. per unit. Since the passing of the Bill to which Mr. Harris had referred, there was a prospect, however, of the price being reduced. The borough was the head-quarters of the boot and shoe trade, in which thousands of people were employed, and most of them supported these schemes, though a little reflection might teach them to think that, if that industry had been left to the municipality, not one pair of boots would have been made, and a shilling invested in the manufacture.

The meeting was then adjourned to Thursday, February 9th, when the EARL OF WEMYSS will introduce the adjourned discussion.

Miscellaneous.

NEW SURVEYING INSTRUMENT.

To devise an instrument able to record automatically not only the distance travelled by a bicycle or other vehicle but also the various directions followed during the journey and the hills ascended or descended, would be by many people pronounced an impossibility. Nevertheless a little piece of apparatus has recently been designed which appears to do all these things. The record of distance travelled, of course, presents no difficulties. The record of directions is not so simple, but, as might be expected, it is obtained by means of a compass. The needle is suspended at the top of the pathometer, as the instrument has been named, directly above the tape on which the records are taken, and is so arranged that all its movements are exactly reproduced by the stamping portion of

marking apparatus, though the act of stamping performed independently of the needle and without arbing it in the least. The indications appear on tape in the form of fine arrows, all, of course, ding magnetic north and south. Now the run of tape represents the direction in which the bicycle els, hence the series of arrows constitutes a record ne course steered. As to the third point, that of ents and declines, the problem is solved by a adulum. The pathometer is fixed to the frame of vehicle in such a way that this pendulum is free ve to and fro in the line of travel, its oscillations ng damped by the well-known method of immer- in glycerine or other viscid fluid. Against the rding tape, which is carried on a drum that is ated as the bicycle moves by the action of a icker" as in an ordinary cyclometer, there presses heel with sharp teeth, able to cut into the paper. s wheel is controlled from the pendulum in such a y that when the latter is hanging in its middle ition—as it does when the road is quite level—the e cut in the tape is straight and parallel to the ges of the strip, but when the pendulum is swung wards or backwards the line is diagonal, its iquity being proportional to the steepness of the pe traversed. Hence with a knowledge of the istants of the instrument the gradients over which vehicle has passed can be easily calculated. The entor does not expect an error of more than 1 per t. in the cheaper and smaller forms, while he eaves that in larger ones carefully constructed for entific purposes it can be reduced to 1 in 1,000. e instrument is not yet on sale.—*The Times*.

ARTIFICIAL SILK IN GERMANY.

Artificial silk consists of prepared cotton or wool re and has been known to the trade under this nomination for some years. It possesses an extremely silky lustre and can therefore be employed an imitation of silk. Count Chardonnet, a French- an, the inventor of this material, converted the llulose (cotton or purified wool fibre) by a process scribed in German letters patent of the year 1884, rough nitro-sulphuric acid into nitro cellulose. He en freed the same from the acid and dissolved it in mixture of alcohol and ether. The solution thus tained, collodion is pumped through glass pipes hich are provided with extremely fine holes, and ese collodion threads are passed through warm ater (acidulated), which causes the alcohol and ether evaporate, and only the fine nitro cellulose threads main. A number of these fine threads are brought egether, slightly twisted and spooled. The United ates Consul at Barmen says that this extremely strous, but easily inflammatory—even explosive— issue was put on the market at the time of the Paris xhibition in 1889. Owing to its great liability to tch fire, it did not come into practical use, but

after this difficulty was overcome by removing the nitro groups (a process called denitrating), the harm- less fibre was employed in the textile industry. By a similar method artificial silk was produced by a chemist of Augsburg, Dr. Lehner. Lastly, however, a method has been invented in which the use of the injurious nitro cellulose is omitted. Cotton waste is dissolved in copper oxide of ammonia and the solution is pumped through fine tubes. The delicate threads are passed through diluted acid, which separates the copper and ammonia, the result being an extremely fine lustrous fibre which is employed as an imitation silk. This process, which is patented in Germany and other countries, is said to have the following great advantages over those of Chardonnet and Lehner:— (1) That the manufacture as well as the product is in no way dangerous; (2) that the production is much simpler; and (3) as a consequence imitation silk can be manufactured by this process at con- siderably less cost.

TOBACCO IN KOREA.

The Koreans are great smokers, and both sexes and all classes begin smoking early in life and keep it up most diligently. Tobacco is not used by them in any other form than smoking. The pipe is the constant companion of every Korean man and woman. How- ever poor an individual may be there always seems to be some method of obtaining tobacco for the pipe which he or she is sure to possess whatever else may be lacking. The tobacco used by Koreans is almost entirely home grown. Every farmer or gardener has his little patch of tobacco, much of which is very good in quality, but is injured in curing, being simply hung up under the wide eaves of the houses to dry. It is quite strong. The supply seems to be ample and the price is very low. No leaf tobacco is imported. According to the United States Consul-General at Seoul the Korean pipe is a brass bowl of fair size with a brass mouthpiece. These are connected by a hollow reed stem of from one to four feet in length, some of these stems being beautifully ornamented and all neat and light. The common people use shorter pipes for convenience in working, but all who can, affect the long pipe both for coolness and for the appearance. The mouthpieces are often made of jade, amber, or other costly material, and of late mouthpieces of clouded glass have been offered for sale at such cheap rates as to make them more or less popular. The long pipe can be smoked with comfort only when the smoker is sitting down. Accidents often occur from persons falling with a long pipe in the mouth, the stem of which is driven down the throat, through the cheeks, or into the soft palate. During the reform period that followed the Japan-China war, an order was issued forbidding the use of the long pipe by the common people. Many short foreign pipes were sold thereafter, and the use of the cigarette became less

common. This order is now practically a dead letter, and the long pipe is reinstated, but cigarettes have become so popular because of their convenience, that it is said they will probably never be given up, but will increase steadily in favour. Native cigarettes of the poorest quality are made and sold at a very cheap rate. American cigarettes are used exclusively at the palace, where large quantities are consumed. Some English cigarettes are now to be found in the shops, and Russian and Egyptian brands are kept for the consumption of the European population.

THE YUCCA PLANT IN VENEZUELA.

The great staple of Venezuela is coffee, but as prices are low, farmers have been turning their attention to other plants which give a more lucrative return. Yucca, according to Consul Plumacher, of Maracaibo, appears to have a great future before it. It is a very productive plant, and although well known in Venezuela, no one as yet has taken any special care to develop it. One hectare (2.47 acres) of land upon which yucca is grown will produce 150 quintals (15,000 lbs.) of starch, or 200 quintals (20,000 lbs.) of tapioca. The plant is easily and cheaply cultivated. It will stand bad weather, and the dry season does not affect it, and it can be raised on any soil. The yucca will thrive on the same soil as peas, beans, and corn, and ground so utilised becomes far more remunerative than land planted with coffee. One hectare (2.47 acres) of tilled soil will produce 1,600 coffee plants. Allowing the maximum yield of coffee per plant, a hectare will produce 8 quintals (800 lbs.) of coffee, and on the same ground the yucca will yield 150 quintals (1,500 lbs.) of starch, exclusive of other crops from the same soil. The means of cultivation are primitive. Ploughs and other modern farming implements are almost unknown in Venezuela. All the work is done with old-fashioned hoes, as neither man nor beasts have been trained to use modern ploughs.

Notes on Books.

NEW METHODS IN EDUCATION. By J. Liberty Tadd. London: Sampson Low, Marston and Co., 1899.

The value of drawing, as a means of education, appears to be attracting more and more attention. For some years the Royal Drawing Society and its founder, Mr. Ablett, have been urging the importance of teaching children to draw, as a means of general education and with the object of developing their faculties rather than of training artists. And now from the other side of the Atlantic there comes

this elaborate and handsome volume by Mr. Philadelphia. According to the account given in his book, Mr. Tadd has been extremely successful in applying in the schools of Philadelphia something of the same principles as those which have been advocated by Mr. Ablett before the Society of Art elsewhere.

The book itself is very handsomely got up and very fully illustrated, indeed it justifies the statement on the title page that it contains "a wealth of illustration." Most of the pictures are from photographs, showing children and adults at work, and the work they do on the blackboard; there are a very large number of diagrams.

Mr. Tadd describes his whole system with considerable minuteness. He first teaches children to draw circles and curves on the blackboard until they can draw any required curve or circle can be struck instinctively and accurately, the hand being trained to carry out almost automatically the idea conceived in the mind. The curves are then elaborated into simple patterns, leaves, shells, &c., and then into more complicated designs. In this he differed from Mr. Ablett in that he regards such mechanical training as injurious to a child's own spontaneous attempt, and blackboard drawing as unsuited for children. Next the child is taught to draw from natural objects, and the importance of memory drawing is especially insisted upon. There is little evidence of systematic training, either in observing or distinguishing between real and apparent form, shade, &c. Further data are required in order to form any precise idea as to the character and value of production of much of the work. To judge from the results shown, Mr. Tadd seems to have been very successful in training children; though it is not natural to assume that the illustrations here selected are the work of children who have a special aptitude for drawing, not the mere average work produced in the school. As to the merits of his system there is room for much divergence of opinion, and probably experts would find much to criticise, as well as something to approve.

The same method of teaching is adopted in modelling and wood-carving, while the final chapter gives the application of drawing to elementary science teaching, the forms of objects being improved on the students by their being made to draw them direct from the model, and also from memory.

SELECTED EXAMPLES OF DECORATIVE ART FROM THE SOUTH KENSINGTON MUSEUM. Edited by J. E. Witthaus. Part I., Jan. 1899. Longmans, Green and Co. Folio.

This is the first number of a publication which is intended to be continued monthly. Each number will contain 12 plates of photographic reproductions of objects in the Museum, and the object of the publishers is to supply teachers and students in art and technical schools, designers and producers of artistic and useful articles, with the best type of

mental objects for their study. It is intended to include in the series examples of sculpture in wood and stone, carved woodwork and furniture, bronzes, hammered and cast-iron, brass, silver, and lead work, silversmiths' work, glass work, leather work, textile fabrics and embroidery, &c.

THE PRESENT DAY METALLURGICAL ENGINEERING ON THE WITSWATERSRAND. By John Yates; with an Appendix on the Economics of the Transvaal Gold-mining Industry. By Hennen Jennings. London: *Mineralogical Journal*. 4to.

This work was originally intended only to contain a description of the engineering connected with the industry of the Witswatersrand, but its scope has been enlarged in accordance with the terms of the contract, and the details of the various companies are fully illustrated by a series of plates of machinery. The author, who dates his preface from Johannesburg, refers to the tardiness of the Transvaal Government in encouraging the industry which is vital to the prosperity of the State. The appendix contains the statement read before the Mining Commission at Johannesburg, May 12, 1897.

General Notes.

COAL FIELDS IN WESTPHALIA.—An account of these is given in a report to the Foreign Office from S. H. Gastrell, Commercial *Attaché* to H.M. Legation in Berlin. The discovery of a seam of coal of a depth of 464 metres has recently been made by the Dortmund Coal-boring Company in the neighbourhood of Natelyn, in the district of Soest. It appears, therefore, that the beds of coal extend much further to the east from Dortmund than was formerly supposed. The seam discovered is reported to be of good quality, and it would appear that the coal of the Dortmund district are considerably more productive than those hitherto worked.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 8.—“Nernst's Electric Lamp.” By JAMES SWINBURNE. ALEXANDER SIEMENS, President, C.E., will preside.

FEBRUARY 15.—“The Balloon as an Instrument of Scientific Research.” By the Rev. JOHN M. GIBSON, F.R.A.S.

FEBRUARY 22.—“Electric Traction and its Application to Railway Work.” By PHILIP DAWSON.

MARCH 1.—“Leadless Glazes.” By WILTON P. RIX.

MARCH 8.—“Cornish Mines and Miners.” By J. H. COLLINS, F.G.S.

MARCH 15.—“Liquid Fuel.” By Sir MARCUS SAMUEL. Sir EDWYN S. DAWES, K.C.M.G., will preside.

MARCH 22.—“London's Water Supply.” By WALTER HUNTER, M.Inst.C.E.

Dates to be hereafter announced:—

“Preservation of Timber.” By S. B. BOULTON.

“Coal Supplies.” By T. FORSTER BROWN.

“Wireless Telegraphy.” By W. H. PREECE, C.B., F.R.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 9.—“The Penal System at the Andamans.” By Colonel RICHARD CARNAC TEMPLE, C.I.E., Chief Commissioner of the Andaman and Nicobar Islands. The EARL OF NORTHBROOK, G.C.S.I., D.C.L., F.R.S., will preside.

MARCH 9.—“Leprosy in India.” By H. A. ACWORTH, C.I.E., late Government Municipal Commissioner for the City of Bombay.

APRIL 13.—“Judicial Reforms in Egypt in Relation to the Indian Legal System.” By Sir JOHN SCOTT, K.C.M.G., D.C.L., Deputy Judge Advocate-General, and late Judicial Adviser to H.H. The Khedive.

MAY 11.—“The Port of Calcutta.” By SIR CHARLES CECIL STEVENS, K.C.S.I., late Acting Lieutenant-Governor of Bengal.

MAY 25.—“The Revenue System and Administration of Rajputana.” By MICHAEL FRANCIS O'DWYER, I.C.S., Settlement Commissioner, Alwar and Bhurtপুর.

The meetings of February 9, and March 9 will be held at the Imperial Institute; those of April 13, May 11 and 25 at the Society of Arts.

FOREIGN AND COLONIAL SECTION.

FEBRUARY 28.—“Persian Trade Routes.” By A. HOTZ.

MARCH 21.—“The Commercial Development of Germany.” By C. ROZENRAAD, F.S.S., and Fellow Institute of Bankers.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

FEBRUARY 21.—“Vitreous Enamels.” By CYRIL DAVENPORT. Sir OWEN ROBERTS, M.A., D.C.L., will preside.

MARCH 14.—“Craftsmanship and its Place in a National Scheme of Art Culture. By Sir WILLIAM BLAKE RICHMOND, K.C.B., R.A.

APRIL 18.—“Modern Changes in Taste relating to Domestic Furniture.” By GEORGE LOCK.

MAY 2.—“Maiolica.” By WILLIAM BURTON.

MAY 30.—“Wrought Iron Signs.” By J. STARKIE GARDNER, F.G.S.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

DR. SAMUEL RIDEAL, “Bacterial Purification of Sewage.” Four Lectures.

LECTURE IV.—FEBRUARY 6.

Differentiation of the organisms—Scott Moncrieff’s later process—Nitrification and nitrosification—Adeny’s “oxygen system”—Conditions for aerobic and anaerobic change, and criteria for judging the purity of effluents—Resumé and suggestions.

ARCHIBALD SHARP, A.M.Inst.C.E., “Cycle Construction and Design.” Four Lectures.
February 20, 27, March 6, 13.

PROF. HENRY R. PROCTER, “Leather Manufacture.” Four Lectures.

April 10, 17, 24, May 1.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 6...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Dr. Samuel Rideal, “Bacterial Purification of Sewage.” (Lecture IV.)

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Inaugural address by the President, Mr. John Corry Fell.

Imperial Institute, South Kensington, 8½ p.m. The Hon. Thomas Mackenzie, “Explorations in Fiordland, New Zealand.”

Surveyors, Savoy-street, W.C., 8 p.m. Adjourned discussion on the paper by Mr. William Weaver, “The London Building Act, 1894, and the Official Supervision of Buildings.”

British Architects, 9, Conduit-street, W., 8 p.m. Mr. A. H. Tiltman, “Public Baths and Wash-houses.”

Medical, 9, Conduit-street, W., 8 p.m. Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Dr. Kidd, “Protection among Animals.”

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. H. W. Handcock, “Everyday Applications of Electricity.”

TUESDAY, FEB. 7...Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lancaster, “The Morphology of the Molluxa.” (Lecture IV.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. J. A. Jones, “The Waterworks of the Madras Presidency.”

Pathological, 20, Hanover-square, W., 8½ p.m. Biblical Archaeology, 37, Great Russell-street, W.C. 8 p.m.

Zoological, 3, Hanover-square, W., 8½ p.m. F. E. Beddard, “The Cerebral Convolut the Gorilla.” 2. Dr. R. O. Cuninghame, “on the Presence of Supernumerary Bones on the place of Prefrontals in the Skull of Mammals.” 3. Mr. G. E. H. Barrett-Hamilton, “The Mice of St. Kilda.” 4. Prof. W. B. Benham, “Notes on *Nolornis*.”

WEDNESDAY, FEB. 8...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. James Swinburn, “Nernst’s Electric Lamp.”

Sanitary Institute, 74A, Margaret-street, W., 8 p.m. Mr. R. E. Middleton, “Supply of Water to London by the Welsh Scheme.”

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

Royal Society of Literature, 20, Hanover-square, W., 1 p.m.

THURSDAY, FEB. 9...SOCIETY OF ARTS, 4½ p.m. (Various Sections). Colonel Richard Carnac Temple, “The Penal System at the Andamans.”

Antiquaries, Burlington-house, W., 8½ p.m. London Institution, Finsbury-circus, E.C., 5 p.m. Prof. E. Arber, “Stories from the *Sphenacodon* 1711-1712.”

Royal Institution, Albemarle-street, W., 8 p.m. Dr. A. Macfadyen, “Toxins and Anti-Toxins.” (Lecture I.)

Electrical Engineers, 25, Great George-street, W., 8½ p.m. 1. Mr. J. Pigg, “Rules for the Regulation of the Wiring of Premises for Connection to the Public Supply Mains.” 2. Mr. C. H. Worden, “The Regulation of Wiring Rules.” 3. Mr. E. Compton, “The Institution Wiring Rules.” 4. Mr. Miles Walker, “Electric Traction by Secondary Contacts.”

Mechanical Engineers, Storey’s-gate, Westminster, S.W., 7½ p.m. Annual General Meeting. Sir William C. Roberts-Austen, “Fifth Report of the Alloys Research Committee: Steel.” 2. Mr. William Powrie, “Machinery for Book and General Printing.” 3. Mr. Harry G. V. Oliver, “Evaporative Condensers.”

Mathematical, 22, Albemarle-street, W., 8 p.m.

FRIDAY, FEB. 10...Mechanical Engineers, Storey’s-gate, Westminster, S.W., 7½ p.m. Reading of Papers and Discussion.

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Prof. H. S. Gantt, “The Motion of a Perfect Liquid.”

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. William Middleton, “The Electrical Driving of Engineering Workshops.”

Astronomical, Burlington-house, W., 3 p.m. Meeting.

Junior Engineering, Westminster Palace, S.W., 7½ p.m. Joint Meeting with the Discussion Section of the Architectural Association. Mr. J. H. Pearson, “Factory Design.”

Philological, University College, W.C., 8 p.m. Physical, 20, Hanover-square, W., 8½ p.m.

Physical, Chemical Society’s Rooms, Burlington-house, W., 5 p.m. Annual General Meeting. Address by the President. 2. Mr. Benjamin Davies, “An Ampere-Meter and a Voltmeter with a long scale.” (This will probably be read by Dr. Lodge.)

SATURDAY, FEB. 11...Education Department, South Kensington Museum, S.W., 3½ p.m. Mr. J. H. Prynne, “Furniture.”

Botanic, Inner Circle, Regent’s-park, N.W., 10 p.m. Royal Institution, Albemarle-street, W., 8 p.m. Lord Rayleigh, “The Mechanical Properties of Bodies.” (Lecture I.)

Journal of the Society of Arts.

No. 2,412. VOL. XLVII.

FRIDAY, FEBRUARY 10, 1899.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.**ADJOURNED ORDINARY MEETING.**

The discussion on Mr. DIXON H. DAVIES' paper on "The Cost of Municipal Enterprise," read on Wednesday, February 1st, was resumed on Thursday, the 9th, Sir WESTBY B. PERCEVAL, K.C.M.G., in the chair.

The report of the discussion will be printed in the next number of the *Journal*.

CANTOR LECTURES.

Dr. SAMUEL RIDEAL delivered the fourth and last lecture of his course on "Bacterial Purification of Sewage," on Monday evening, 6th inst.

On the motion of the CHAIRMAN, a vote of thanks to the lecturer was passed.

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, February 9, 1899 (at the Imperial Institute); the Right Hon. the EARL OF NORTHBROOK, G.C.S.I., D.C.L., F.R.S., in the chair.

The paper read was "The Penal System at the Andamans," by Colonel RICHARD CARNAC TEMPLE, C.I.E., Chief Commissioner of the Andaman and Nicobar Islands.

The paper and report of the discussion will be printed in a future number of the *Journal*.

COVERS FOR JOURNAL.

For the convenience of Members wishing to bind their volumes of the *Journal*, cloth covers will be supplied post free for 1s. 6d. each, on application to the Secretary.

Proceedings of the Society.**APPLIED ART SECTION.**

Tuesday evening, January 31st, 1899; Major-General Sir JOHN F. D. DONNELLY, K.C.B., Vice-President of the Society, in the chair.

The paper read was—

THE SENEFELDER CENTENARY EXHIBITION OF LITHOGRAPHS, 1898-99.

BY EDWARD F. STRANGE.

The circumstances which led to the organization of this exhibition are pretty well known; but for the sake of the record it may be advisable to shortly recapitulate them.

It had been clearly shown that the year 1798 was that to which the invention should properly be ascribed, inasmuch as it saw the discovery of what Senefelder himself called "chemical printing," the essential principle of lithography. An early representation to this effect was made by Mr. Joseph Pennell, who pointed out to the Society of Arts the importance of the opportunity and the advantages that might accrue to the art by a formal celebration and exhibition of work. The Society, from the years 1818 and 1819, when medals were awarded to Senefelder and Hullmandel, one for his invention, the other for skill in the use of it, has taken a keen and practical interest in the subject. Its *Journals* contain many important communications, and from time to time papers have been read before it and awards made for various improvements. The proposal was therefore welcomed, and a committee formed to carry it out; but after several meetings and the most careful consideration, it was decided to seek for some means of making the exhibition more comprehensive than was possible with the immediate facilities at the Society's disposal. Ultimately it was suggested that the Department of Science and Art should carry out the scheme and hold a loan exhibition in the South Kensington Museum. This proposal was accepted by the Department in July last, a committee including the whole of that formed by the Society, with some few additions, was called together, and the exhibition opened to the public on the 21st November, 1898. It will remain open till the 28th February next.

The total number of exhibits exceeds 2,200, and on the whole the collection is very representative of the artistic and historical sides of the art; but it was not possible at so short a

notice to provide space for the important technical and industrial interests involved. These might well prove a subject for a future exhibition, if it should be found possible to hold one.

On the present occasion I do not propose to enter into any systematic examination of the history of lithography. But the exhibition has afforded a means of making comparisons between the varying fortunes of the art; and perhaps of arriving at an estimate of the characteristics of successive phases, with more accuracy than has hitherto been possible. To this end I shall direct my endeavours in the hope that the suggestions I have to place before you may be found worth consideration, discussion, and, if necessary, refutation.

There still exists, if the published criticisms on the exhibition may be trusted, a considerable amount of ignorance as to the so-called "Polyautography," a collection of which prints occupies the earliest place at the beginning of the British Section. Within the last few days the prints have been said to "appear to have been produced from drawings made on paper, whilst Senefelder drew directly on the stone." (As we know, one of the first things Senefelder invented was a transfer paper.) The writer goes on to remark, sagely enough, "But it is worth noting they were all by the pen, and consequently we may suppose chalk or coloured drawings were beyond the power of polyautography, which apparently resembled some of the processes still employed in offices for manifold copies." Now a conclusion of this sort really seems to call for a precise statement of the circumstances, as far as they are known, under which this special and easily recognisable class of lithographs came to be produced.

Senefelder came to London in 1800. He stayed with his agent, Philip André, who, says he, "kept me in a perfect seclusion from society, for fear of losing the secret, for seven months, before even the first step towards obtaining our object, was taken." He did succeed in getting his patent, No. 2518, dated the 20th June, 1801, and returned to Germany, having "sufficiently instructed" André. "I also," says he, "made some progress in the aqua-tinta manner, in which Mr. Gessner . . . an artist of talent, drew some pleasing landscapes." (These, by the way, I have not been able to trace.) "I am convinced," he proceeds, "that the public would have a greater number of masterly productions of the new art before them, if it had been my fortune to

fall in with an enterprising printseller, who employed proper artists, and undertook interesting works."

It seems very much as if, for purposes of his own, André had misled Senefelder, for one can with difficulty otherwise explain this complaint in the face of the fact that on the 30th April 1803, André published "Specimens of Polyautography, consisting of Impressions taken from original Drawings made purposely for this work." André heads his title, "By His Majesty's Royal Letters Patent," and styles himself "Patentee." But as a fact he never took out a patent for any process whatever and his "specimens" are ordinary lithographs in the "pen manner." Senefelder was clearly under the impression when he wrote his book in 1817-18 that he had not had a fair chance at the hands of British artists. But André's prints are by Stothard, West, Barry, Fuseli, Sir R. K. Porter, R. Corbould, T. Hearne, W. Delamotte, T. Barker, and R. Cooper, and surely no more representative set of artists could have been got together at the time. The earliest of these is by West, and is dated 1801. He evidently gave the process a fair trial, for in 1802 he produced another in the chalk manner. From this date until 1811 a constant succession of dated prints has been found of similar character. Afterwards, only a few, until 1816, the period of the last in the style. Most of these are in the so-called "pen-manner," or, in imitation of engravings, etchings, or woodcuts, but in the exhibition will be found, in addition to the print by West, already mentioned, Nos. 13 and 14, by H. B. Chalon (1804), No. 35, by Fuseli, and No. 46, by Varley (1811), all in the chalk manner; while several are entitled "printed from stone," and No. 28, "printed from a pen and ink drawing on stone"—evidence as to their nature which is too explicit to leave room for any doubt. There are also numerous references to the "Polyautographic Office," and Voluieler printed the illustrations to the Frescoes of the Chapel of the Holy Trinity, Stratford-on-Avon, before April, 1807, in precisely the same manner—"from stone, at the Polyautographic Press."

The preface to Francis Moser's specimen book (1819) sufficiently explains the failure of polyautography, and, at the same time, identifies it beyond a doubt with lithography. It also confirms our impression as to André's treatment of Senefelder, whose very name Moser does not mention. He says: "The unfavourable opinion of lithography, which

now prevails, may be traced to the circumstances under which it was introduced into their country. When Mr. André came to England in 1803, many of the first artists in the kingdom practised lithography, but as the art of printing from stone was not then brought to perfection, the impressions obtained were few in number, and not good." Also, lower down: "Drawings may be made with ink or chalk. The latter is the best for use, but the more difficult to print." The specimens in the book are by Hullmandel, Blore, H. Corbould, and G. Scharf, sen.

After Senefelder, it is most certainly to Charles Joseph Hullmandel that we must give credit for the propagation of lithography in this country. It was he who in 1819 gained the Silver Medal of the Society of Arts for the "Best specimens of lithography executed on German stone," the work submitted including specimens of the various styles, and especially of the "imitations of acqua tinta." This latter method he afterwards developed into what he called lithotint—a process used with such fine effect by Prout, Hulme, Cattermole and Taylor. The patent (No. 8683), for this is dated 5th November, 1840, and the title describes it as a "new effect of light and shadow, imitating a brush or stump drawing, or both combined, being an impression on paper from a prepared paper or stone, preparing the said plate or stone."

It is, I think, one of the sad conclusions forced on a visitor to the exhibition, that this beautiful process should have been allowed to die. With the exception of a single print, by Mr. Frank Short, which is more nearly akin to mezzotint, I am not aware of any modern attempt at anything of the kind. It would be claiming too much to set it on a level with mezzotint at its best; but surely the examples shown display effects and capabilities worthy of any artist's attention. The technique does not seem to have been too laborious—it certainly cannot be compared in this respect with that of mezzotint—and it seems not unreasonable to expect that for certain classes of subjects it should prove to be absolutely the right tool to use. A well-known lithographer told me recently that he did not know of a single man who was now practising lithotint. Perhaps the advantages of distinguished isolation may induce someone to take it up.

In looking at the exhibition as a whole, one is bound to remark the curious manner in which the exhibits classify themselves. With the polyautographic prints we have already

dealt, and I shall only supplement my earlier remarks by now pointing out that the device of enlisting the services of prominent artists in order to popularise lithography has been tried in this country on no less than three occasions, and that each time the results of their experiments are very nearly all that we could find to represent the nation during each specific period. The polyautographic prints form the first of these series. The second is due to the exertions of Mr. T. Way, who in 1871 induced E. J. Gregory, R.A., R. Thornwaite, F. R. Stocks, J. Parker, A. Morgan, Sir J. D. Linton, Joseph Knight, J. W. Buxton Knight, E. Hayes, Charles Green, and J. W. Chapman to try the merits of drawing on stone. The results form the set published as "Hogarth Sketches;" but I think I am right in saying that the movement was not followed up. It is to a demonstration by Mr. T. R. Way, at the Art Workers' Guild in 1893, that is due the next effort to awaken interest in lithography. On this occasion transfer paper and chalk were served out to several of the members, and a practical proof given of the ease with which a print could be produced by this means. Consequently, on the approach of the Paris Exhibition of 1896, when it was found that unless something heroic was done, this country would be represented by only two or three names in the catalogue, Messrs. T. R. Way and Goulding again approached a number of prominent artists, and so secured a reasonable set of studies under circumstances of great difficulty. The work produced on this occasion was in many instances of such merit, and had the added advantage of being so easy for the artist, that many were induced to continue its practice both on the stone and on paper with results that are perhaps too recent for criticism. At all events the revival in the eyes of the public became an accomplished fact: though it must not be forgotten that lithography has never been dead to the same extent as engraving on wood, and even more, on steel. It has been, and is, continually practised by hundreds of draughtsmen, thoroughly skilled in its technique, but whose business in life is to do work for various industries rather than for art galleries or illustrated books. It is hardly likely that so large a body of craftsmen should not contain some artistic talent; and it is a matter for regret, that although the exhibition was widely announced both in the trade periodicals and all the other journals of importance, very few works were contributed to us from this source.

But to go back to the question of grouping. The first case is the set of lithographs executed for Baron Taylor's "Voyages Pittoresques." The early volumes are illustrated by Baron Atthalin, Fragonard, Isabey, Horace Vernet, Villeneuve, and others; but very early in the series will be found examples of the work of Bonington, Prout, Louis Haghe, Boys, and G. Barnard. We may claim that these stand out clearly from the work of their French collaborators; but this may, none the less, have been due to the influence of the latter. And by way of Harding, Lane, Nash, and their school, it reacted on British lithography. However this may be, we have for our next group the productions of the famous circle of artists gathered together by Baron Taylor for his monumental work. Time is too short to do more than specify some of the other groups. In England, we had the drawing-master type, perfect in technique from the mechanical point of view, but with little originality; and, later on, the group of portrait lithographers, Bagniet, Lynch, Maguire, Fairland, and Messrs. J. A. Vinter and J. R. Dicksee, who are still with us. Taylor, Cattermole, and Hulme I have already dealt with. Louis Haghe and Nash are each at the head of small schools of disciples, and again their merits lie rather in the excellent reproduction of a drawing, or true representation of an object, than in any exercise of imagination or design. In fact, this must be looked on as the prevailing characteristic of British lithography—and I am inclined to think that the influence of Baron Taylor's work was not too remotely responsible for it.

But in France the sharp changes of political fortune and general unrest of the nation have produced very different results. There is nothing in the history of the art to compare with the battle pieces and military episodes of Raffet and Horace Vernet, with the satires of Daumier and Vernier, the early artists of *Charivari*, with the often grotesque force of Delacroix, and the keen and pathetic characterization of Gavarni. Géricault, whose album was published in London in 1821, has occasionally received the credit of having inspired the outburst of lithographic work in this country which undoubtedly marked the years succeeding that date. But it will be difficult to trace his influence in contemporary British work. Isabey stands alone as a master of original landscape work, both in his surpassing technique and the beauty of the subjects selected by him.

Then comes another great group of workers: those associated with the publication, *L'Artiste*. Much of their work is limited to the reproduction of pictures; and they developed a close, highly-finished method which is not without a charm of its own, but cannot for a moment stand by the side of the great original painter-lithographers just mentioned.

In Holland we have the series of lithographs produced since 1840, for the *Kunst Kroniek*, on much the same lines, though I fancy it is hardly so well known. The work is not so good on the whole as that of the French series; though some of the plates issued in the Sixties have a distinct value.

Germany, the home of the art, has proved singularly barren, so far as its earlier lithographs are concerned. The reproductions of pictures in the great galleries, which engaged so many French and Spanish artists, were, perhaps, by none so well executed as by Piloty and Strixner, who were closely associated with Senefelder himself. It is perhaps a pity that the only work of the inventor in the exhibition should have been the specimen-plates of his book, but a loan exhibition cannot command the public, and no examples were offered.

It will, I hope, have been seen then, that while on the Continent lithography had the support or stimulus of a series of great undertakings or movements of national feeling, it never received any such in England. Lane was indeed an Associate of the Royal Academy, and Her Majesty the Queen, who is deeply interested in the art, has always supported it by the institution at court of the post of Lithographer in Ordinary, so long and honourably held by Mr. J. A. Vinter. The men, who in the Sixties might have made a brave show with their own work instead of relying on the transcription of the wood engraver, seem not to have tried it even in the least degree; and whatever reputation may be gained by British Lithography—I speak for the present, of the original work of artists only, and not of the excellence of British workmanship on the industrial side—lies in the hands of the artists of my own generation. Happily there are those who already give notable promise and have even already achieved much.

But the questions still remain to be answered. Is artistic lithography alive again, what has it got to show, and what is it going to do? Well, more or less in this country there are perhaps half-a-dozen British and two American artists, Messrs. Shannon,

R. Way, Rothenstein, C. J. Watson, Lang, McCulloch, Oliver Hall, Whistler and Tennell, who practise the art in the proper use of the word. And there are perhaps 40 or 50 other artists who have tried their hands at it to the extent of from one to five six prints. And that is all. But when we get across the Channel in France, Holland, Germany, we can number the new lithographers by the score. Fantin-Latour, whose splendid series is one of the remarkable features of the exhibition, and Menzel, who is by no means equally represented, I do not include. But Delille, Carrière, Cheret, Blanche, Charpentier, Rivière, Dillon, Ten Cate, Havermann, Van Nooyema, Greiner, Burger, Orlik, Daur, Schnopf, Hans Thoma, Kampmann, Langhein to name only a few—are all hard at work. And they are not content with the mere chalk sketch, or even the more highly-finished drawing. Most of them are using colour, not, as was so finely done here in the early history of chromo-lithography in the reproduction of oil water-colour pictures, but as an integral part of the design from the beginning. It is early yet with doubtful results. With the exception of Whistler's well-known experiments, I believe the device has never been tried before. And the specimens so far seen are calculated to provoke the most varied criticism. But in some instances, I think it must be conceded that the result is a technical success; and that even the maddest or weakest productions may serve to show that there is a future for lithography in colour. But it must stand on its own merits, with all its limitations and advantages. The most fatal quality in lithography is the facility it affords for imitating any other process of illustration on the face of the earth. And yet it is capable of individuality. The works of Daumier and Gavarni, of Raffet, Menzel, and Isabey have proved that in the matter of black and white. It will have to be the same in colour. If the limits imposed by the use of a few tints only are frankly accepted, and the convention of the picture adjusted to them, whether the result be a decorative panel like those of Rivière or an almost realistic landscape like the "Winter" of Baum, its success will depend on the artist. The process is competent enough. I see no reason why the colour-print produced in this manner should not achieve the fine results of the wood-cuts of Japan; and be as widely popular here as those beautiful prints were in their own country. It does not follow that the subjects need be restricted to the acute symbolism of one school, or the slavish adherence

of another to alleged decoration. If British—and American—artists would give us just their own ideas with the added charm of colour, I think they would find us appreciative. I am not skilled enough in the technique of colour lithography to know how far it is possible for transfer-paper to be used in the production of such prints as we are getting from Karlsruhe and Munich. I do know that several of the artists at the former place are working lithographers in every sense of the word, and that part of their employment is on what is rather invidiously known as commercial work. But even if the paper be impossible, it seems as if salvation might be found in the aluminium plate. The colour-work of Thoma certainly indicates great possibilities.

Within my limited space I have had necessarily to confine myself to a few phases only of the art. Its application to industrial purposes is an enormous and most interesting question, including as it does not only that of the competition of the photo processes, but also the assistance afforded by them to the further development and extended use of the lithographic stone. I have been compelled, as I say, to speak of lithography as if the artistic side of it was the only one; but institutions whose scope and interests are as wide as those of both the Society of Arts and the Department to which I belong could not confine themselves to so rigid if attractive a boundary, and I hope that the technical and industrial portions of the subject may shortly engage the attention of both bodies. As to artistic lithography, the artists have its future in their own hands. Perhaps I may be forgiven if I suggest that more of them should invest a little enterprise in a process which should by no means be always identified with inferior or commonplace productions.

The paper was illustrated by a series of lantern slides of historical lithographs chosen from the Exhibition and from the Print Room of the British Museum. There were also shown on the walls some framed foreign lithographs from the Exhibition, lent by the Science and Art Department, and some modern German lithographs lent by Mr. Charles Holme.

DISCUSSION.

Mr. F. GOULDING said the exhibition at South Kensington had been very instructive to many, and if the authorities would follow it up by an exhibition

of black and white art generally or of engraving, it would be still more beneficial.

Mr. CRANE said he remembered some fifty years ago his father having a set of Cruickshank's Bottle Series, which were certainly lithographs, but he did not think a set could be got now.

Mr. JOHN LEIGHTON said he had a set of Cruickshank's "Bottle," but they were done by Palmer's process, a method for producing a relief printing surface from an engraved or etched plate, though an ordinary observer would take the result for a lithograph. It was very remarkable what good effects of light and shade could be produced in lithography, even by an unpractised artist who knew nothing of the technique. There were two methods of working—ink and "chalk," though the latter was not chalk at all, but a mixture of grease and some powder, whilst the ink was rubbed up on a palette with water; and also two sorts of surface employed—the smooth stone and the grained. Lithography was the only mode of printing in which a scraper was employed, the surface being perfectly flat, not raised as in letterpress, or sunk as in etching and engraving. Fifty years ago in that room he made a drawing on stone to illustrate a lecture given by Mr. Blair Leighton. One great point about it was the weight of the stone, which had led to the use of zinc plates, and much which was called lithography was really zincography. Another difficulty from a commercial point of view was that copies could not be produced at a high rate of speed, as they required careful printing. One very fine series of prints which had not been mentioned was the Dresden Gallery, which were all lithographs. He did not think that a drawing on transfer paper—though it had the advantage of being as a print would appear—ever equal to one direct on the stone, though some very bold effects could be obtained. On the stone, one could get a finer touch, and by working with ink and chalk together, could obtain a double power.

Mr. J. PENNELL said Mr. Strange had not yet been thanked for the great work he had done at South Kensington in hanging and cataloguing, for though a committee was appointed, of which he had the honour to be a member, Mr. Strange practically took all the work out of their hands and the whole success of the exhibition was due to him. Having seen all the large exhibitions, including Paris and Düsseldorf, he could say that this one at South Kensington was much more complete. Like Mr. Strange he had never seen an actual lithograph of Cruickshank's, but it was well known that many of his engraved plates, as those of Leech and Seymour, were put upon stone and printed and sold as etchings. Mr. Strange had shown up to some extent the intelligence of the professed art critic, but had not referred to the most remarkable instance. It

had been stated again and again in the Press that lithograph was of no artistic value, nor worth the attention of a collector, because it could be produced by the million in absolute *facsimile*. One would think that if you could get an absolute *facsimile* of an artist's work it would be a good thing but in lithography you got the artist's handiwork multiplied. With regard to the unlimited number which could be printed, those who knew anything about the subject were well aware that the finer the drawing the fewer proofs could you get which were at all like the original. There was an enormous loss in effect if the drawing on the stone was elaborate, and a large number could not be printed. The most wonderful art magazine ever published, *L'Artiste*, had ceased to publish lithographs because they could not print enough copies from stone to supply the subscribers. On the other hand, it was said that you could not get as many proofs from a stone as from a copper-plate; but Seymour Haden had said over and over again that with steel facing, as now practised, one should never take a proof from a copper-plate at all. If you steel faced a copper-plate you could pull an enormous number of prints, because you could re-steel it as soon as it began to show signs of wear. In wood-engraving it was pointed out by Papillon that 250,000 impressions could be taken, and he had been informed by the printers of *Punch* that so long as they used wood engravings they printed from the original blocks and never thought of taking electro or stereos. But in lithography no more proofs could be printed than from etchings, and the original stone could not be protected. It, therefore, appeared that lithography would give a fewer number of impressions from the original than anything else. He did not say what might be done in future—he was simply referring to the past. Mr. Strange said no one had been using lithotint, and, unfortunately, there were but few, but Mr. Whistler had done a great number. He had tried it himself, but found it extremely difficult, and made an awful mess of it. As to printing from paper in colour, he believed all Lunois' work, and he had made many lithotints, was done from paper and he considered that as elaborate work could be done from paper as from stone, owing to the perfection to which paper and presses had been brought. He thought, in justice to Mr. Goulding, more credit should be given him, and to Mr. Alfred Gilbert, the sculptor for the English Section in the Paris Exhibition. He rather objected to calling lithography a process. Senefelder invented everything except photo-lithography, and he did not speak of different processes but of different manners. Process, to his mind implied photo-engraving or something of that kind.

Mr. J. S. MORRIS said they were all indebted to Mr. Strange for getting together such a magnificent collection. He was interested, not so much from an artistic as from a trade point of view. Lithography was not a process; it was one of two things: it was either an art, the work of an artist who put his design

the stone; or, from his point of view, it as a craft, the skilful reproduction of the design upon the stone by the artist. With regard to the number of copies obtainable from the graphic plate, he could say that they had reproduced 193,500 copies, and the plate was in good a condition as when they started. One reason why lithography was not more practised in this country was that artists, as a rule, worked at home, and it was not an easy thing to carry stones weighing half a ton, such as would be required for a decent-sized picture, backwards and forwards, and it had to be printed in seven or eight colours, the weight would be two or three tons; there would be risk also of a stone being broken after a design had been put upon it. This difficulty had been overcome recently by the use of algraphic plates, which weighed very little more than a sheet of millboard of the same size, and could be carried about or sent by post, and the artist could turn it about when working it, to suit his convenience. This also met the other objection about the artist's work being lost when transferred to the stone. If the artist drew directly on the plate, every point and every line of such drawing was reproduced, and that he considered the acme of artistic perfection. For over eighteen years he had been connected with lithography, and he had never known a transfer go on to a stone or plate or any other material exactly as it had been put on the paper. The loss might be infinitesimal, but there was a loss. If one were printing a very fine work from the stone, by the time six or seven thousand copies had been taken, the lines began to thicken; if one used a zinc plate, the lines would be gone. Consequently, lithography did not give a true reproduction of the artist's original except for the first few copies.

Mr. MORGAN said they knew that for many years lithotint fell into disuetude, after the death of Hullmandel, but it was revived by Mr. Way during the early seventies, and Mr. Whistler made several of his finest drawings in that medium; one called "A Nocturne," another "Limehouse," and "A View from the Savoy Hotel," were shown there some months ago when Mr. Pennell read a paper on "Lithography." Mr. T. R. Way also made an excellent drawing in lithotint, entitled "Seagulls;" and anyone looking at those specimens would say they were equal to any produced by Hullmandel. It was said by some that drawings done on transfer paper were not equal to those done on stone, but if anyone would compare Mr. Whistler's drawings of St. Giles' Church and The Manager's Room, he would defy him to say which was done on paper and which on stone. Mr. Morriss had ridiculed the idea of taking a large number of copies from a stone, but three months ago he had printed 80,000, and the last copies were quite equal to the first. At the same time, when you were speaking of fine-art production, it was quite true that only a small number could be

obtained; he should not think of undertaking to print 80,000 copies of a fine art work. He thought some of the work done by Shannon, Rothenstein, Pennell, Whistler, and others, was quite equal to anything produced in the palmy days of lithography.

Mr. P. B. WATT was rather surprised at the diversity of opinion as to the number of copies which could be produced, and asked if the 80,000 were all printed from one stone.

Mr. MORGAN said they were.

Mr. WATT said he had had many years practical experience of lithography, and never knew of such a thing being done. He desired to thank Mr. Strange and Sir John Donnelly for the honour they had done lithography in holding this exhibition at South Kensington. If the art had been lost, as some said, they were certainly recovering it again, but it was just as well not to take an exaggerated view, and when they spoke of fine art productions, it would be better to speak of two or three hundred, or two or three thousand copies, instead of the large numbers they had heard of. Although England was the first to take up Senefelder's invention, she was now far behind other countries, especially France. It was not a question of technique, it really turned on the artists who were engaged. If we were to recover our position we must train artists and show that this art was thoroughly suitable for book illustration. He was sorry Mr. Strange had not said more about the invention of grained paper, which though suggested by Senefelder himself had been much improved and brought to perfection by Nelson, of Edinburgh. Few English artists practised lithography, mostly preferring to scratch on a piece of copper, which they called etching, but there was not a finer art than lithography if they would only take it up. At South Kensington the whole history of the art from the beginning was shown; and one could not but regret the decadence that had taken place, for he could not agree that the modern men were equal to Bonington, Lane, Cattermole, and others. He hoped that any artists who were inclined to practice this art would try what could be done with grained paper.

The CHAIRMAN said it was his duty as chairman to propose a vote of thanks to Mr. Strange, but the words had been taken out of his mouth by previous speakers. He could not pretend to any practical knowledge of lithography, though he did once something which he was told was chalk—though he now heard that it was not—on a piece of stone, and the printer afterwards brought him proofs of it, but he was glad to say that no copies had been preserved. They owed a great deal to Mr. Strange for the trouble he had taken in getting up this exhibition; and he was very glad that the work of the Department in organising it at the suggestion of the Society of Arts had been so highly appreciated, and hoped it might assist to some

extent in the revival of lithography. It had never died, but latterly had not been very much appreciated, and that, probably, was one of the reasons so few artists had practised it. The effect of the exhibition could be seen already, by the number of old coloured lithographs now exhibited in shop windows, which two months ago had nothing of the kind. A great deal had been said about the reproduction of lithographs, but he thought that some confusion was caused by the use of the word reproduction in this connection, it was rather multiplication. Reproduction was where one was making a lithograph from a picture or a drawing, but it was a question of multiplication when one spoke of the number of copies which could safely be taken from a stone. The advantage or disadvantage of such multiplication might be looked at in different ways. One gentleman seemed to think it was a disadvantage, whilst others thought it a great recommendation. From the consumer's point of view, the power of taking large numbers was a benefit, but for the producer it was probably better that there should be only a few choice prints of higher value, as in the case of etchings when there was no "steeling" of plates. His own feeling was in favour of stone lasting as long as possible. No one had gone very fully into the question of why lithography had fallen in the public estimation within the last 20 or 30 years, but to some extent he thought it was due to the fact that lithography, especially of the commercial kind, had been applied to a kind of work for which it was not properly adapted, until at last the word "chromo" became a term of reproach. It was always said that when you became mechanical you destroyed all art, and that was no doubt true to a large extent, but it must strike everyone that there were some exceptions. For instance, when printing superseded manuscript, nothing could be more mechanical than printing, yet they knew that the printed page, as it had been printed by some of the great men who produced the first fonts of type, was really as fine a work of art (and was valued as such), almost, as many of the MSS. That arose from the fact that the early printers did not slavishly copy the handwriting of the missals and fine books, but formed a letter which was adapted to its purpose—that of being used mechanically. In the same way he would suggest that chromo-lithography fell into disrepute, because instead of using lithography for purposes for which it was intended, it was employed to imitate water-colours, which were not adapted for reproduction in that way.

The vote of thanks having been carried unanimously,

Mr. STRANGE, in reply, said the reference to the lithographs attributed to Cruickshank reminded him of one of the most interesting experiences he had, and that was the weeding out of a number of soft ground etchings and wood-cuts, which were sent in to be exhibited as lithographs. It had been re-

marked that the quality of a lithograph was partly dependent on its being printed from a perfectly flat surface; that was so, as generally practised; but the old system survived for a long while in the Low Countries and in France, and in Senefelder's own book there were specimens which he variously described as etched stone and engraved stone. In some cases the relief of these was so high, that you could hardly tell from an engraving by passing your finger over it. He was glad to hear that there were some few specimens of modern litho tint which he had overlooked, though it still did not appear that the art was being practised. His mission was rather to bring the matter before the public, and let them deal with it, and he would not attempt any apology for the many omissions in the paper. He was simply the agent to collect material from one branch of the public, and pass it on to those other interested, who were sufficiently educated to appreciate it. He was sorry if he had given the impression that the work of Mr. Goulding in connection with the 1896 Exhibition was not sufficiently noticed; but he feared Mr. Goulding had himself to thank if it were so he was so completely identified with black and white work that his enthusiasm was taken for granted. An objection was taken to the word "process" because it had become identified with the very modern art of photo-reproduction. The public had a right to use their own language, and if they preferred to let the modern meaning of the word supersede its old meaning, that was their affair. He must say that he had been very fortunate in this matter. It was very rare, according to his experience, that a servant of the Crown coming into personal contact with an outside body of interested workers should receive such strong and cordial support. He had been simply the agent, and it would have been utterly impossible for the work to have been carried out to the public satisfaction if he had not had the co-operation, which probably he only could fully appreciate, of his colleagues in the Science and Art Department. In so large an institution it was absolutely necessary that the work should be subdivided, and it was very seldom that any portion of the work of a Government office could be identified with any individual. In accepting the vote of thanks therefore, he wished to make it quite clear that he did so on behalf of his colleagues; he should take care that it was conveyed to them, for it would be a valuable encouragement to them in their work which, although interesting in itself, was sometimes more thankless than generally supposed.

NINTH ORDINARY MEETING.

Wednesday, Feb. 8, 1899; ALEXANDER SIEMENS, Member of the Council, in the chair

The following candidates were proposed for election as members of the Society:—

February 10, 1899.]

yans, Herbert William, 38, Chester-terrace, Regent's-park, N.W.
 tlin, William Henry, B.A., Irthlingborough Iron Works, Wellingborough.
 mpion, Alfred, Blochairn Steel Works, Glasgow.
 ucar, Alexander Louis, Hauteville, St. Germans-place, Blackheath, S.E.
 effcken, Arthur W., Wyandotte, Shirley, Southampton.
 uedalla, Florance Montefiore, 33, Addison-road, W.
 ingham, R. T., 6, Finsbury-square, E.C.
 orris, Major Stephen L., R.E., 6, Wemyss-place, Edinburgh.

The following candidates were balloted for and duly elected members of the Society:—

nyard, George, Kenmore, Maidstone.
 apel, G. W., Montana, Park-lane, Croydon.
 ollis, John William, 55, Glenwood-road, Catford, S.E.
 olman, Russell J., Carrow Works, Norwich.
 vans, Peter MacIntyre, M.A., Clothworkers' Hall, Mincing-lane, E.C.
 hint, Stanley, 12, Museum-chambers, Bury-street, W.C.
 ray, Frank James, 9, Upper King-street, Norwich.
 Hunter, Walter, 17, Victoria-street, S.W.
 Ramsay, James, Listoke, St. Stephen's-road, Ealing, W.
 Ranger, Charles Peter, Easthoathly, Sussex.
 Wilson, John, Leadenhall-house, 101, Leadenhall-street, E.C.

The paper read was—

NERNST'S ELECTRIC LIGHT.

BY JAMES SWINBURNE.

Before describing Nernst's invention, it may be profitable to spend a few minutes reviewing the position of electric lighting. The whole industry is at present controlled by the incandescent lamp. We are so accustomed to this, and it is taken for granted in such an unconscious way, that we do not realise how much everything depends on the maker of the carbon incandescent lamp.

In very early days, that is to say, in the early eighties, there were a few Edison lamps at 100 volts, with an efficiency too horrible to mention, but the Swan lamp came along made for 50 volts. I say made for 50 volts advisedly; I mean that the makers tried to make 50 volt lamps, and produced lamps taking from 40 to 60 volts. If the lamps were not bright enough you ran the engine faster, or put a smaller pulley on the dynamo. (The belt then generally slipped, but that is not to the point.) For about four years, which is a long period in the development of such a

rapidly growing industry as electrical engineering, the makers of incandescent lamps, or in fact the makers of the Swan lamp, decreed that the electro-motive force used should be from 40 to 60 volts. There was no appeal. There was no development of central station supply at that time, but still, even then in large buildings there was the longing for higher pressures on account of the cost of the mains.

About 1885, the Swan 100 volt lamp came into use. It was a clumsy affair, with little loops of platinum at the sides. At first the lamps were pretty bad, but they gradually improved; and 100 volts, or in some cases 110 volts, became the recognised pressure for electrical supply.

As town lighting from central stations came into being, the limit of 100 volts became a serious trouble, and the evil was partly mitigated by the use of three or even five wire systems. I must point out that the incandescent lamp exercises its tyranny in two ways. It not only insists on a low pressure, such as say 100: and thus demands large leads to feed it, but it is so sensitive to variations of pressure that the system of distribution has to be arranged to give a practically uniform pressure at the terminal of the lamp. The necessity for uniform pressure probably gives more trouble, and costs more than the mere low pressure; and it would be cheaper to supply at 100 volts with a good margin of permissible variation of pressure than supply at 200, with a very small per-centage of variation.

Quite lately the incandescent lamp makers have produced things called 200-volt lamps, and some make them for 250 volts. So there is a general tendency on the part of supply companies to jump to a 200 volt supply. The innocent consumer is therefore pressed by the company to change over to 200 volts. The company likes the change very much, and the lamp maker also enjoys it, as he makes more lamps and charges more for them.

Considering the enormous importance of the incandescent lamp, its improvement has received extraordinarily little attention. It limits us as regards pressure, it used to hamper us by its cost, it limits us as to variation of pressure, and it limits us very seriously by its inefficiency. Yet, in spite of these, the carbon incandescent lamp has made practically no advance in 15 years. Of course mere detail improvement in manufacture has taken place, and this has led to better quality and greater uniformity, hence cheapness; but

there has been no radical improvement. The jump to 200 volts from 100, or from 50 to 100, did not depend on any sort of radical improvement in the incandescent lamp; it was merely the result of detail improvements, making it possible to produce long thin filaments. Other things being equal, it is easy to see that the long thin filaments must be weaker. If the carbon has the same specific resistance, the relation between pressure and length is $E = L^{\frac{3}{2}}$, and $E = D^{-\frac{3}{2}}$. If the filaments are flashed, the proportions will be still more extreme. The question of high pressure incandescent lamps is thus — How far can we make the filaments longer and thinner and flimsier without exasperating our consumers? Unfortunately the consumer is rapidly getting saddened as it is. The 100-volt 8 c.p. lamp does not please him much, and the 200-volt 8 c.p. lamp has in no way delighted him; if the lamp is made with two 100-volt filaments in series, it combines the disadvantages of both, without the advantages of the small candle-power of either. But it adds some further disadvantages peculiar to the higher pressure which I have not so far touched upon, and that is that the higher the pressure the more troubles there are through the silent discharge, or whatever it is called. I need only refer to the well-known experiment, in which a third terminal is sealed into the lamp. A galvanometer then shows a current going across country inside the lamp. This is no doubt intimately connected with the life, or rather with the death of the lamp.

I have dealt with the question of high pressure incandescent lamps at some length because the subject is really of vital importance, and is too much neglected. Our technical colleges, and our technical press, and our technical societies pay the greatest attention to questions of a per cent. or two in the efficiencies of dynamos and transformers, and give a good deal of attention to engines and boilers. That is because there is plenty of room for calculations in connection with these subjects; but the incandescent lamp, which at present holds the whole career of the lighting industry in the little curl of flimsy red-hot carbon that can hardly support its own weight, receives no attention at all. How much does the average electrical engineer know about incandescent lamps? The only subject that is treated in the same way is the cable. About half the money in town lighting goes in the cable, a mere fraction in the dynamos and transformers themselves; so

the average electrical engineer knows nothing about cables.

So far I have only discussed the incandescent lamp; the arc lamp has also to be considered. I will not say much about the arc lamp just now, but will add a little more when the Nernst lamp is compared with it. The ordinary arc is limited in pressure to about 50 volts, including the series resistance necessary for regulating. The enclosed is a new development which is more satisfactory as regards pressure and as regards consumption of carbon.

The lamp I describe to-night is the invention of Professor Walther Nernst, of the University of Göttingen. Though he is a young man, Professor Nernst's name is already known to all modern chemists as a leading authority and original thinker in the field of physical chemistry. It is unusual for a man who has climbed to the top of one tree to jump to the top of another.

Nernst's, like most great inventions, is exceedingly simple as soon as it is understood. The efficiency of an incandescent body, as far as radiation goes, depends simply on the temperature. The efficiency of an incandescent lamp, for instance, depends on the temperature of the filament only, providing there is no loss by convection. The carbon will not stand at sufficiently high temperature, especially as, in addition to its low specific resistance, the filament has to be long and slender, and thus weak. Nernst, therefore, chose a material that would stand higher temperatures than carbon, and his material has the incidental advantage that its specific resistance is so high that strong rods can be used for high pressures instead of thin filaments. The most refractory materials so far used in lighting are zirconia, which has been used to replace lime in the limelight, and the oxides or so-called rare earths, in the Welsbach mantles. I am aware of course, that many people suppose that the Welsbach mantle is not very hot, treating it as if it were at a temperature, for instance, below the melting-point of platinum. The light emitted is supposed to be due to some special power of selective emission due to the oxides employed. I have had a good deal to do with incandescent gas mantles, and I find no reason to suppose there is any magic effect of this sort going on. The part of the flame where the mantles hang fuses platinum wire easily, and very few materials can stand the temperature without fusing or volatilising. Lime and many other oxides

limes slowly from the mantles. I do not think that the mantles are above the boiling-point of lime; I have some idea of its melting-point, as I have made a few pounds of melted lime and run it out on the floor to look at it. (Welsbach mantles, which are now chiefly used, are at a temperature near their softening-point, and in the making are raised to a temperature at which they begin to soften.

The Nernst takes highly refractory oxides as his material. It does not seem promising, because refractory oxides are notoriously good insulators. Such insulators are electrolytes when hot; the Nernst, therefore, heats the rods to make them conduct, and then heats them electrically, preventing a temperature which is within the limits the material can bear without softening. This means that he can take the most refractory bodies supplied by the whole range of chemical research, and can heat them to a temperature short of their softening point, and thus get an efficiency unknown to workers in the incandescent lamp. Such efficiency means whiteness of light, so long as the efficiency is not too high. Thus the crater of an arc being at a temperature of boiling water, gives a light that is unpleasantly blue. The material is worked up into little white rods.

Each rod is mounted on two platinum wires, a little paste made of refractory oxides being applied to the joints. The little rod with two wires is then mounted in a holder which is ordinary electric-light fittings. As the rods have a resistance as the temperature increases, in the manner of electrolytes, an increase of current produces a decrease of resistance. This tends to give some instability in running in parallel on supply circuits. This instability is corrected, as in an arc lamp which has inductive properties, due to a different cause, by a series resistance. The Nernst rod has a resistance in series. This is made of exceedingly fine wire, and for ordinary lamps amounts to 10 or 12 per cent. of the resistance of the lamp. The consumption, including the resistance, is 1.5 watts per candle for large lamps, and 1.6 for small lights at low pressures. In small or low-pressure lamps the loss of heat at the ends is larger in proportion.

Such a lamp as I have described will not light up of itself, for the rod is an insulator when cold. The simplest way to start it is to heat it up with a match, or better with a small gas-lamp. Such a lamp as this is not only cheap as regards first cost, but very economical in running. The life of rods,

running at an efficiency of $\frac{2}{3}$ of a candle per watt, including the resistance, is already more than 500 hours in good specimens. If the Nernst lamp advances as much in the first few years of its existence as the carbon lamp did between 1880 and 1882, it will soon be made so well that the rods last a life-time. When the rod is worn out a new rod with its wire mounts is all that is replaced. The whole lamp is not thrown away at all.

The method of lighting I have described, though it may be used in many cases, such as large public rooms, is really a savage mode of ignition, fit only for dealing with uncivilised commodities, such as gas and tobacco.

The small lamps and the lamps of medium size are in practice started by a heating resistance. This is arranged close to the rod, and in shunt to it. As soon as the rod is hot enough to conduct, its current works a tiny cut-out in the resistance circuit. In large lamps the heating system is a little more elaborate, as the resistance arrangement is arranged as a sort of hood which covers the rod. As soon as the rod conducts, not only is the resistance circuit broken, but the electromagnet lifts the little hood clear off the rod. In all these forms, the rod and its mounting are replaceable without interfering with the rest of the lamp.

We now have to consider the part the Nernst lamp is probably going to play in the near future.

Compared with the small incandescent lamps, as you deal with a material of much higher specific resistance, it is easy to give both small lights and high pressures. The question of lighting is exceedingly important though it appears trifling at first sight. People are so accustomed to lamps being turned on from the door without any further trouble, that they will generally object to having to light them with matches or spirit lamps, but there are many cases in which it will be quite satisfactory to have one lamp with an automatic lighter to show you the way into the room, the rest being lighted with matches or a spirit lamp as needed. There will be, however, a considerable opening for the cheap, small power, high efficiency lamp; and the disadvantage as to lighting is small in such cases as cafés, restaurants, churches, hotels, railway stations, and in short in most public rooms, is small.

Coming now to the next size, that is to say lamps of 20 to 200 candle-power, and even small lamps in which it is worth while to

have automatic ignition, the first cost of such lamps will be higher than the first cost of incandescents, but as the rod itself has alone to be replaced, that is a matter of very slight importance. This size of Nernst lamp has further every chance of completely ousting the carbon incandescent on the score of cheapness, as to renewals, higher efficiency, better coloured light, and perhaps more especially high pressures. Once the Nernst lamp becomes so general that systems of distribution are laid out to suit it, instead of to suit the carbon lamp, the carbon lamp is practically "out of the running." It must be remembered that the Nernst can compete with the carbon filament at any pressure that suits the filament, but the Nernst lamp can easily go right out of the depth of the filament and have the higher pressures to itself. It must be remembered that at present the cost of cables in a system of distribution is an exceedingly large item.

Turning now to the large lamps, they compete with the arc lamp in efficiency. Of course the efficiency of the arc lamp is not a very definite quantity. The candle-power is generally determined by multiplying the current by two and adding zeros at discretion. All I can say is, that however many zeros the good-nature of the maker may supply, a Nernst lamp taking the same power gives a better light. When carefully arranged on the photometer, the arc may be better in given directions, but a lot of light given in directions that you do not want is not the same as the same light distributed with a uniform spherical emission. The arc lamps shown here will give the audience a good idea of the relative values. The Nernst gives a pleasanter, and of course a perfectly steady light. Coming to costs, the Nernst will be very much cheaper in first cost, but enormously cheaper in maintenance. It also goes quite away from the arc as to pressures. There is no trouble for instance in making large lamps to work in parallel at 500 volts and by using double rods at 1,000 volts. This puts an entirely new development of electric lighting in the hands of the engineer.

There is one point I have said little about yet. The incandescent lamp which is still with us, gives trouble not only because of the low pressure it needs, but also because it demands that the pressure shall be kept uniform. It seems quite possible that the Nernst lamp may be made to stand a much greater variation of pressure than the filament.

If this proves true it means an enormous difference in the designing of distribution mains. I do not like to say much about it yet as the invention is too young, and too little time has been available to make much progress in that direction. Results are promising, but it is best not to be sanguine.

It is difficult to discuss an invention like this without being carried away by enthusiasm. I feel, however, that I have but feebly sketched forth the probable future of what seems to me the greatest invention in electric lighting we have seen for many years. Still I am sure I have not been too sanguine.

DISCUSSION.

The CHAIRMAN, in inviting discussion, said that Mr. Swinburne had fascinated them all by the many suggestions which he had put forward all the good points of the Nernst lamp, including the possibility of going back to old habits and lighting electric lamps with a normal

Prof. AYRTON, F.R.S., congratulated Prof. Nernst on having achieved such a wonderful result by such simple means, viz., rendering an insulator conductive by heating it; and Mr. Swinburne on the way in which he had put the matter before the meeting. The knowledge that an insulator could be made to conduct electricity by heating it was much older than the recent experiments of Sir W. Roberts-Austen. Some twenty-three years ago a paper appeared in the "Transactions of the Royal Society" on the subject of the extraordinary diminution of resistance in a solid electrolyte by heating. In Japan, at that time, plates of zinc and copper were put on each side of a glass plate, which was heated, and the electromotive force passing, as indicated by a high resistance voltmeter, after short circuiting the electrodes, appeared almost as rapidly as if the electrodes had been immersed in dilute sulphuric acid. It had also been known ever since carbon filament lamps had been on the market that there were many difficulties connected with them, and many experiments had been made, and patents taken out, with the object of using refractory earths, but, apparently, no one before Professor Nernst had thought of the simple expedient of heating a very good insulator with a match or spirit lamp, applying a current of suitable potential, and thus obtaining a brilliant light such as they had now seen for the first time. The result was clearly of enormous commercial importance and would be an entirely new departure in globe electric lighting. It was also extremely interesting from the purely scientific side, touching on a question which Mr. Swinburne had passed over rather lightly as if it was only a few foolish people who were ignorant of there was something in the Welsbach mantle which they did not entirely understand. This invention shows that at any rate, that illuminating gas was not necessary.

ning light by incandescence from the rare
 Some five or six years ago he asked an
 of his to look up the literature on the
 of the Welsbach burner, and see if any report
 a made throwing any light on the question
 the effect of the burner depended solely on
 a temperature. He gave him a reference
 erman paper in which experiments were
 which seemed to show that the high tem-
 was not the sole factor. Later on he
 d the matter with a very distinguished English
 who agreed in the view that it was not
 question of temperature, and a year or two
 ds he again discussed it with Professor Elihu
 n in America, who took exactly the same
 Many people thought that the material of which
 the mantle was made had the power of absorbing oxy-
 in the air or the gas, and compressed it, such as
 black absorbed hydrogen and oxygen, and so
 these gases to burn under considerable molecu-
 sure. It was not merely that the Bunsen flame
 the material to a high temperature, but that the
 air were compressed together in the pores of
 erial, so that the gas was burnt under pressure,
 you got a much higher temperature than you
 ise would. In the glow lamp, as they were
 aling with gas, it did not seem that the mate-
 ould play any such part. There seemed to be
 ing in that idea because it was necessary for the
 to be a certain exact composition; you could
 ce thorium or zirconia at random and use it; you
 ave a certain definite combination to produce
 cient mantle. In fact it was the addition of
 r cent. of ceria which converted the Wels-
 urcher from a ghastly failure commercially into
 derful success. He should like to know whether
 the mantle was not at a much higher temperature
 he flame which surrounded it, and whether a
 ular combination of materials did not reach a
 higher temperature than another combination
 sed in the same flame. If so, it was not merely the
 nature of the flame which produced the result.
 was one great advantage about the Nernst lamp,
 not seem to require a thin glass bell and a
 m, and thus got rid of a very serious difficulty,
 se these bulbs were very fragile, and were easily
 oyed by a touch of a broom or carelessness in
 ge; many lamps also were defective, not from
 fault in filament, but because the vacuum was
 lect. He should like to know the reason of
 difference in the colour of the light of the
 back and the Nernst lamps—was it a difference
 erial or in temperature? He understood from
 olleague, Dr. Armstrong, who visited Professor
 st some time ago, that it was essential to use an
 ating current, as with a direct current the in-
 escent rod soon ceased to make good contact
 one of the platinum terminals.

depend entirely on the temperature. There were
 many things in nature which gave light without any
 heat at all; such were glow-worms and fireflies.
 His opinion was that any substance, if there were
 any, which did not volatilise at all, would give a light
 proportionate to the temperature; that platinum or
 iridium, or iron, if the iron was not burnt, would all
 give the same light at the same temperature, pro-
 vided none of the material was wasted. Of course if
 the least particle passed into the air the flame would
 be coloured. In all probability the light emitted did
 not increase as the temperature directly, but as the
 square, some said as the cube, and some said as the
 fifteenth power of the temperature, and he was in-
 clined to think that a slight increase in temperature
 increased the lighting power a great deal. In the
 Welsbach burner the light was not white, and that,
 he thought, indicated that some change was going on
 which made the apparent light higher than that due
 merely to the temperature. If carbon were heated to
 the same temperature it would not give the same light.

Mr. R. S. ERSKINE said it would be an enormous ad-
 vantage to central supply stations when these lamps
 came on the market. There was a great difficulty in
 getting satisfactory 200-volt lamps, though he did not
 know that they were much worse than the 100 volts.
 The fact was the public were now educated up to a
 much higher standard of light, and wanted much
 more than satisfied them some years ago, when they
 were only used to candles and ordinary gas burners.
 Those who were formerly well satisfied with two wax
 candles in their dressing-room would now put up two
 32 candle-power lamps over their dressing table, and
 the lighting all through the house was on the same
 scale. They were not content with an 8 candle-
 power lamp that gave eight candles, but wanted it
 overrun so as to give ten or twelve candles, and the
 200-volt lamps would not stand this; the old 100
 volts stood it to a certain extent, but soon got in-
 efficient. The great trouble with all central stations
 was that the lamps took more current than they used
 to. It looked as if these lamps would give the public
 what they wanted at a reasonable price.

Mr. W. M. MORDEY thanked Mr. Swinburne for
 speaking the truth about the 200-volt lamps. The
 supply of lamps was a matter which really required
 attention, because it led to a great deal of dissatisfac-
 tion. He thought the correct plan would be for the com-
 panies to supply not electricity, but light; and instead
 of persuading customers to buy lamps of any par-
 ticular kind, they should make an inclusive charge,
 and supply them with lamps themselves, this would
 prevent dissatisfaction. He congratulated the Society
 on this paper, which he thought would mark a new
 epoch in electric lighting; it was the first page in a
 new volume, recording an invention which would
 rank with that of the Swan lamp, since which there
 had been nothing brought forward so pregnant with
 results. They must also congratulate Professor

r. HIRAM MAXIM said he had always under-
 stood that the light in the Welsbach burner did not

Nernst on his invention, and take care that he had the credit of it, and was not robbed by a number of people, who would be immediately writing to the *Times* to say that they did the same thing in their back kitchen 20 years ago. That was what always took place in the case of a new invention. Mr. Maxim had anticipated what he was about to say about the glow-worm. Professor Langley, in America, dealt with the radiation from fireflies and glow-worms in a paper a few years ago, and gave a diagram showing the total radiation, and what proportion was luminous; the result proving that the glow-worm had solved the problem which Tesla, Hertz, and many others had been working at, of making nearly the whole of the rays luminous. If they could only get a glow-worm to come and read a paper explaining how it was done, Dr. Nernst's lamp would have no future before it. One advantage these lamps possessed was that they would be able to light their cigars and pipes at them. He agreed with Mr. Swinburne that the possibilities of the carbon filament were about exhausted; there had been very little improvement for a long time, and it was a remarkable thing that just when the carbon filament was failing to meet their requirements, this new invention should be made, which seemed to meet the case. It was like the discovery of gutta-percha at the critical period, which got electric cable-makers out of their difficulties. But, though the new lamp was evidently a very robust child, it was still a child, and it would at any rate take a little time to displace existing lamps. If lamp companies' shares went down at all on account of the Nernst lamp, he would like to buy some, as they would have time to rise again before the incandescent carbon disappeared.

Dr. FLEMING asked if there was any deterioration in the quality of these lamps after a time, such as occurred with carbon filaments and Welsbach mantles; because this would be very important in considering the commercial value of the invention. If the lamp only required 1 watt or $1\frac{1}{2}$ at starting, and, after a few hours' work, 4 or 5, it would be a serious disqualification. It was well known that most of these radiants did deteriorate after a time; with the lime-light, for instance, after a few minutes, the radiant quality of the lime diminished, although it was played upon by an oxy-hydrogen flame at a constant temperature; and turning the lime round would markedly increase the amount of light on the screen.

Major FLOOD PAGE, having congratulated Mr. Swinburne on his paper, said he was much interested in this subject, though he was not a scientific man. When he saw Professor Nernst some months ago, in Germany, he was very much astonished to find that so young a man had been able to attain such a high scientific position. Mr. Swinburne had spoken of the carbon lamp having reached finality, but he might say those connected with carbon lamps, as he was, were as much interested as anyone in this new departure.

They had a higher interest than that of any patent lamp, and that was in the advance of electricity. He quite agreed that nobody but Professor Nernst could claim the credit of this invention. It was everybody had been expecting, and it could be used in conjunction with existing systems, so that those who were connected with electric work would find themselves indebted to Professor Nernst. In the old days there had had Maxim, Edison, and Swan; and some thought one was going to kill the other, but it was of that they all helped the general advance. The time was to a certain extent going back, for Swan had worked at a rod, but, he believed, it was an advance which might benefit all connected with electricity.

Mr. H. COLEFAX said several applications for patents had already been put in, which appeared to claim the benefit of this discovery, but he did not think they would prove successful. With regard to the question of deterioration, he was told by Professor Nernst, some eight months ago, that as far as he could discover, these lamps did not deteriorate; but, of course, this could only be proved by experiment; but if it were so it would be very remarkable, especially that in every other form of incandescent lighting tried there was this deterioration. He showed glad if Mr. Swinburne could tell them what it was which limited the life of the filament, because, when he saw Professor Nernst, he did not think he had then arrived at any explanation. He was astonished at the progress which had been made in the eight months since he first saw the invention; the limit then was 200 hours, though his experiments only having attained 40 hours.

Mr. CAMPBELL SWINTON said Professor Nernst was not strictly accurate in saying that this was his first attempt to use a heated electrolyte. Some ten years ago, Jablochhoff showed a lamp in London consisting of a strip of kaolin, along the top of which he put what he called a match, which consisted, he believed, of carbon mixed with treacle; this conducted the electricity—100 volts—until it heated the kaolin, and that then formed the conductor. He would not go into the question of how far this was an anticipation of the present invention, but he wished to correct the impression that nothing of the kind had been tried. They must all admire the advance which had now been made, and they thought that the Jablochhoff lamp never came to anything. With regard to the lighting power of incandescent gas mantles, he had made many experiments on this subject with cathode rays, by which you could heat the mantle to a very high temperature without the use of gas. In ordinary sense, and he found there was no appreciable difference in the amount of light given by a mantle of pure thoria, and one with the addition of a small per-centage of ceria.

Mr. SYDNEY MORSE said he was interested in this question on the commercial side, and especially as connected with the competition of mu-

ities, who were now commencing to manufacture and sell electric fittings, which he feared seriously interfere with the progress of invention. They had heard that invention in connection with carbon filaments was exhausted, but opened up a new industry, which he hoped would be set on foot and improved by English engineers and inventors, for they could not suppose that everything had been done.

J. G. LORRAINE asked what amount of heat was emitted by this lamp compared with an ordinary incandescent one.

A. H. DYKES asked what was the power required for these lamps. He had been working out the same for street lighting, and he found the difficulty was that, while arc lamps were too large, ordinary incandescent lamps were not a great success. A lamp appeared to have many advantages for domestic purposes, and particularly the volume of light-giving material being so much larger than a carbon filament, it would have much greater penetrative power in foggy weather. With regard to lighting up, it could go round and apply heat underneath lamps as well as he could turn on the ordinary lamps.

SWINBURNE, in reply, said the question of the temperature of a Welsbach burner was a very large one, with which he could not attempt to deal.

If you examined a burner with the mantle off, there was a zone of very high temperature, which could not easily fuse platinum; but most measurements were erroneous, because they were taken with a thermopile, which never got the real temperature of the burner; the great difficulty was to get what was the temperature of the burner. In connection with the light given by incandescent bodies it should be remembered that the light depended on the emissivity. If the only temperature at which you got light was very high—very close to the temperature of the gas—you must use something of very low emissivity; if it were large, the heat given by the burner would rapidly given off, and if infinite the temperature of the mantle would remain at the average temperature of the room, and you would not get any light. On the other hand, if the emissivity were very low, though the mantle would get to a high temperature, it would give little light for want of emissivity. A pure white oxide such as pure zirconia, gave very little light, because the emissivity was too low, though the temperature was high. To get the highest efficiency a mantle must have emissivity enough to give plenty of light without robbing the flame of its heat too soon. A white oxide like thoria you did not get much light, but if you added a small percentage of ceria or other coloured oxide—it did not matter much what you got light. A great deal of unnecessary mystery has been introduced into the subject because it was known that erbia gave some curiously characteristic spectrum, but erbia was only present as an impurity.

Another point was that cerium had two sets of compounds, and it was supposed that it was continually hopping backwards and forwards from one state of oxidation to another. In dealing with a subject like this, he thought the proper way was to take a simple explanation if it fitted the case, and only if it did not go to a more complicated one. He saw no reason to suppose that temperature did not account for the results, if it would fuse platinum, and if it would soften the mantle, as it would. In making Welsbach mantles—though having advised the company he must not say everything he knew—they were sometimes raised to such a high temperature that they softened, and then they gave more light. Professor Ayrton had quoted several anonymous authorities, but had not given the reasons for their opinions, and so it was impossible to deal with them. They involved questions of thermo-dynamics into which there was not time to go. The case of spongy platinum was altogether different, there was a chemical combination started by the heat, which would not otherwise take place. Here there was no reason to suppose there was such a combination, spongy black would give no light, and a solution of platinum put upon a mantle would destroy its light-giving power. He believed that colour was largely a question of temperature; but you could produce different colours by using different materials. The emission was the complement of the absorption. A blue body when heated gave an orange light. With regard to a vacuum, its effect was to get rid of convection. If you tried to heat a long thin filament of carbon, it would be inefficient on account of convection; but with a short, thick rod the convection was not serious. Practically, he believed these Nernst lamps would not work in a vacuum. He had not tried many experiments himself, but so he was informed. The reason generally given was that electrolysis was going on, and that oxygen was being absorbed from the air at one terminal, and being given off at the other. That was Professor Nernst's explanation, but he thought there was another factor to be taken into account. It was perfectly simple on paper to electrolyse salt, and get out chlorine and sodium; but when you tried it you did not get either. The reason appeared to be that the chlorine and the metal were dissolved to some extent in the fused bodies, and got across very quickly. He did not think true electrolysis took place to any extent, but there was a continual diffusion of the substances across which was undoing the work of electrolysis all the time; but that was not sufficient to make it work properly in a vacuum. All the lamps shown were on the alternate current, but he had tested them with the direct current and found their efficiency continued right through. That was some six months ago, when they lasted 200 hours; now they had got to 500 hours, and he had no doubt they would go much higher. He did not know anything

about glow-worms, and doubted whether any one else did; but he did not think such questions had much to do with the matter; it was more a question of the red-hot poker order, quite simple. With regard to the emission of light at a given temperature, it was not the least likely that there was any such simple law as Mr. Maxim had suggested. The simple law would be as to the emission of power or energy. Light was only a certain small octave of vibrations that affected the human retina, it was not distinct from heat, or the radiations of still higher frequency. It was not likely there was any definite law as regarded light; probably it depended, for one thing, on the eye looking at it. With regard to deterioration and its cause, after running some time the material appeared to get crystallised; what else happened he did not know. Probably there was a gradual tendency for the rod to get uneven; then it would get more heated in one part, and softer, until at last it melted. Professor Ayrton seemed to think that the compound in the Welsbach mantle was chosen entirely for giving light; but anyone who used those lights knew that the strength of the mantle was of great importance. You could get a very good light from yttria, but you could not get a strong mantle that would not warp. The manufacturer had to consider strength, portability, and durability; and one point about that was that both the Welsbach and Nernst were at a very high temperature, just short of the fusing point, at which the material very slowly evaporated. If you took a thoria mantle, and put lime on it, it would give a very nice light at first, but the lime would soon volatilise; so would many other substances; ceria went off quicker than thoria, and the result was that after running a thoria mantle with a small amount of ceria for some time you had a pure thoria mantle. It was not that the power of the ceria was exhausted, but that it was not there. He did not know what caused the deterioration of the lime light; probably the lime really began to sinter together, and therefore you did not get the same temperature as before. He congratulated Major Flood Page on the exceedingly broad-minded view he had taken of the subject. With regard to the early Jablochhoff lamp, he had no information; his own impression was that the Jablochhoff candle was the only thing which was at all successful; that was in use in 1878. There was another lamp which depended on a hot material between the poles called the *Lampe Soleil*, in which an arc was struck across a surface of marble which got very hot, and finally conducted and gave an illuminant surface. The cathode rays experiments referred to by Mr. Swinton bore out what he had said about the earths, that it was simply a question of temperature. There was another inventor, he believed, working on a lamp with cathode rays, and no doubt they could be made to give an efficiency equal to the Nernst, if the earths were raised to a sufficiently high temperature. With regard to the amount of heat given off, it depended

on the amount of power used; if you took 100 w. probably nearly 100 would go off in heat, as only a small per-centage of the energy was converted into light, and until Mr. Maxim and Mr. Mordey came to tame their glow-worms he was afraid it would always be so.

The CHAIRMAN, in proposing a vote of thanks to Mr. Swinburne, reminded the audience that, with their enthusiasm, the commercial success of this lamp depended on the price at which it was offered as to this they had, as yet, no information. When electric accumulators were first discovered, it was supposed they would revolutionise the industry and do all sorts of wonders; but though they have been certainly useful, they had not done what was expected of them. In the case of these lamps, if they were sold at 1s. 1d., all charges included, an ordinary carbon lamp was sold at 1s., he feared the latter would be generally purchased.

The vote of thanks was carried unanimously and the meeting adjourned.

Miscellaneous.

HISTORY, DEVELOPMENT, AND VARIATIONS OF THE PIN AND NEEDLE.*

There is no record of the period when pins and needles were first employed in their primitive form. The earliest needles were not pierced at the end opposite the point; but the pre-historic needle was rather an awl, which served to make holes in furs or in skins that were worn ages before textile fabrics were invented. The long underground roots of plants, bindweed, and leathern thongs, were passed by hand through the holes thus made; and it was not until more recent times that the idea was conceived of attaching the thong to the primitive needle, for fear it to follow the path thus made, whence arose the first idea of the needle proper. In remains of the Stone Age splinters of stone, pierced with a hole at the end opposite the point, are met with; and it is evident that these tools, sometimes a little curved, served as needles in those remote periods.

Flat needles with a split in the end opposite the point, are found among the remains of the Bronze Age, the two branches being slightly separated, and brought together again, and crossed at their ends, whereby a kind of eye was formed, while the two parts were sometimes united by a rivet. It is not known when the eye was first formed by piercing the end, which must have been a difficult operation on a cylindrical rod of iron or steel, so that, subsequently

* "Die Nadel und ihre Entstehung, eine technologische Skizze," von Franz Büngenbach. Aachen. Ignaz Schwabe, 1898.

flattened where the eye occurs; but no can be formed as to the shape of these cause they could not withstand atmospheres, while, on the contrary, specimens of pin, for which bronze or the precious often employed, have been very well The true type of a sewing needle was, so Greek and Roman times, pointed at one end at the other; and it is only when machine was invented that needles were the eye near the point.

period when the first true needle made since be unknown, as also its exact form, be no doubt that this essentially domestic had attained a very high degree of perfection times. So ancient a poem as Homer's " gives a detailed account of the mantle embroidered by Penelope for Ulysses on his or the Trojan expedition. It was not, however only who used the needle, because needles among the fine arts, and it is probable that derers of the period made their own needles, late as a century or two ago, painters made es and prepared their own colours.

only about 1785 that the first mechanical producing the double steel rod, for making is joined together, was introduced. At first, before they were completely finished, underwent many manual and mechanical operations, several times between the factory and the dwelling; and it was only about 1870 needle was made for the most part by methods, while during the last fifteen years been entirely finished in this manner.

Leffeld, Aachen, or Aix-la-Chapelle, has been for the needle industry during the last two and it is in this city that were established mechanical appliances connected with it. The invention and perfection of the pointing a skilful workman could point 25,000 in a day of ten hours; but a machine now this operation with greater precision on needles in the same time and with one work-

needle manufacture is now concentrated in the United States of America, and Germany, Aix-la-Chapelle, which is by far the most important, and also at Iserlohn, Altona, Schwabach, and Ichtshausen. While no needles in France, that country produces a large of pins—it is stated ten thousand millions—assuming more than ten millions daily, so that exports of this domestic article are considerable. There are at least 250 varieties of the needle for alone, to say nothing of those for embroidery, cartridge-making, book-binding, sail-making, larding (in cookery), and many other purposes or less connected with the original object. The pin, called *Steck-Nadel* in German, has even varieties than the needle, while being still more and generally used. The pin must also have

been employed before the needle, for connecting the skins which served as garments before the idea of sewing them together was conceived. Examples of artistically wrought pins are found among Egyptian as well as Greek remains; but it was especially the Romans who made very elaborate fibulæ, which have developed into the modern brooch. Simple pins with mere head, shank and point, were, however, largely used in antiquity; and the estimation in which they were held is proved by many proverb and popular sayings connected with the pin in various languages.

Different kinds of wire are required for making the pin and the needle; for while that of the latter must be stiff and yet yielding, to a certain extent, as well as polished to the highest degree, that of the pin must also possess a certain amount of stiffness, while it must also permit of bending without being broken, though a too highly-polished pin becomes easily detached. Scarcely a hundred years ago the steel pin was rarely used; but this variety has now been so much improved that the steel pin may be said to have now come into general use. The lengths of steel wire are prepared in the same manner as those for the needle, so as to constitute two pins, separated into equal parts before the operation of heading; and one end must be softened before receiving the head. For this delicate operation alone an automatic machine has been devised, that brings each head in turn within the influence of small gas flames, and which can soften 150,000 shanks in a day, five or six machines being tended by one person. Very small brass or iron pins are headed by simple "upsetting" or crushing down the end, as in riveting; but for those of larger size, the heads must be prepared previously, in a particular and very ingenious manner, from a piece of wire twisted spirally, two and a-half turns being required to make the head, of which 500,000 may be produced daily by one worker. Whereas before 1835 each pin was headed separately by hand, between five and six thousand pins may now be headed mechanically in ten hours.

Enamel-headed pins constitute a branch of industry special to Aix-la-Chapelle, where was first conceived the idea of adapting the "enamel" or glass head to the steel shank. A manufacturer of that city, seeking means for utilising the needles spoilt in manufacture, conceived the idea, after visiting some Venice glass bead factories, of fixing the bead on the end of one of the "waster" needles, so as to form a pin; but it was only after long and tedious trials that he succeeded in attaching the enamel strongly enough to the shank, and also in finding a composition of glass sufficiently tough to stand the usage to which a pin may be subjected.

The general introduction of the steel pin was not easy, because it was found that the early examples readily became detached, owing to their high polish, while they often broke through want of sufficient pliability. During the last thirty years, however, the consumption of steel pins has greatly increased; and at a single Aix-la-Chapelle factory it has been found

necessary to put up separate works to make the glass for heading pins, that now turn out half a ton of "enamel" daily for this purpose, while the same establishment consume two-thirds of it. The consideration that only 0.2 gramme (3 grains) of this glass is, on an average, required for heading a pin, will afford some idea of the enormous quantity of pins that can be headed with half a ton.

Owing to the greatly increased consumption of steel pins, the "waster" needles now form only a very slight proportion of the shanks required. For preparing the latter, pointed lengths of iron wire are introduced, a million together, into a cast-iron drum containing a special carbon dust for cementing them—*i.e.*, turning them into steel, by subjecting them to the necessary heat during a certain length of time. This process imparts the necessary degree of hardness; and the almost imperceptible flange formed in cutting the wire to length is favourable to the holding fast of the head, while it is seldom that an enamel-headed pin loses its head.

The enamel, or glass, has to be made specially for the purpose, because it must be easily fusible, and must also remain viscous sufficiently long for the forming of the head, while it must also be bright without the necessity for polishing, and yet not brittle. Two workmen with iron rods, like that of the glassblower, except that they are not hollow, take up on the end of them sufficient glass, which is rounded by turning so as to assume the form of a pear. With their rods they proceed quickly to a drawing-out walk, like a rope-walk, straight, horizontal, and about 50 metres (56 yards) long. Standing in the middle, the men unite the balls of viscous glass, and then proceed in opposite directions to the ends of the walk, thus drawing out the glass to the whole length, its thickness varying with the rapidity of the movement between three and seven millimetres (mean 3-16th in.), after which the glass rod is cut into lengths and made into bundles.

The head is formed and fixed at the same operation with great skill by a work-woman seated before a table, on which are mounted a frame, about 15 cm. (6 in.) high, carrying the glass rod placed horizontally (its end being brought to a convenient distance) a gas-burner at about the height of the rod and a air-jet for giving a blow-pipe flame, all adjustable. The work-woman, who has before her a quantity of steel shanks, takes several in each hand and passes each one in succession, alternately with the right and left, into the heated and viscous portion of the glass rod, withdrawing the shank by a special turning movement so as to take up a little of the glass; and a turn of the thumb and first finger gives the shank a rotary movement, so that the glass taken up becomes formed into a head which remains attached to the end of the shank, the head cooling while the complete pin falls into a channel. This somewhat complex operation is executed with remarkable address and rapidity; and a skilful worker can head from 25,000 to 30,000 pins daily.

There are fifteen sizes of these pins, of which vary in diameter from 1.5 to 3.5 mm. — from 1-16th to 1-8th of an inch—length of the shank varies from 1.5 to 5 cm. (19-32 in. to 2 in.)

According to the report of the Aix-la-Chapelle Chamber of Commerce, there are now in the forty pin and needle factories, employing 14,000 workpeople, or two-thirds of the total engaged in that industry in Germany. From needles alone from 800 to 900 tons of steel are worked up yearly; and the following are the principal finished products that are turned out per annum:—Hand-sewing needles, 3,100,000; sewing machine needles, 65,000,000; various needles, 35,000,000, and pins 1,300,000,000; total of 4,500,000,000, representing a value of 6,000,000 Marks (£300,000), and giving a price of 1s. 4d. per thousand, although the actual prices actually vary from 7½d. to 8s. per thousand.

Of the lightest needles there are forty in an ounce and therefore 1,200 in an ounce, while no more than 7,000 of the highest enamel-headed steel pins are a pound avoirdupoise.

Manufacturers who produce none but the highest quality complain bitterly that the harm is done to the Aix-la-Chapelle market for inferior products, which can scarcely be distinguished by their appearance from those of good quality. While a good needle may be bought at three or four pence, those of inferior quality are sold for a penny; but the difference in price is far more than set off by frequent breakage, bad work, difficult threading, wearing of thread, and loss of temper. It is only the miller who gains by the bad needle, the producer and consumer both suffering.

HUMAN HAIR INDUSTRY IN FRANCE

According to recent reports of the representatives of the United States Government in France, the central departments of Corrèze, Creuse, Cher, Haute Vienne, and Dordogne are frequented by hair merchants having orders for human hair from the United States. The dealers in this article are poor, and the inhabitants must be very poor to put their girls to sell their hair; then there must be a great variety in quality and shade to meet the requirements of the market, and thirdly there must be a regular place where those requiring to sell their hair can find buyers. All these conditions are met in the mentioned departments. The soil is poor, and is hard to cultivate; these low mountains might be called the foothills of the Alps. They are almost part bare, or covered with heather and pasture for goats and sheep. Almost all the inhabitants are masons, stonemasons, and builders. They leave their homes in the spring for different parts of the country to work at their trades, returning when empty-handed.

ger obtainable. The women and girls look after the farm and tend the cattle, goats and sheep. Their income is very small, and in order to buy a dress or provide some luxury, the girls consent to cut off but the front part of their hair. Ashamed and humiliated by this act, however, they always wear a *coiffe* or handkerchief to cover their shorn hair. During the fair of St. Loup, and the fair that takes place on the last Thursday of August each year, there are regular meeting places where the seller and the buyer make their bargains. The average price for a full, long head of hair is about 8s., but an especially fine growth will bring 25s. These are counted upon in the annual income of the family. The hair shipped to New York goes through the hands of commission houses in France. Their agents make the purchases in the provinces, the payments being often made part in cash and part in dry goods. There is a difference of 10 per cent between the buying and selling price of hair. To make up lots of hair, the darker shades of which are mixed with blonde and light hair from Italy and Switzerland. A few ounces of white is added to a bunch of cheap stuff to make it sell. In some instances the French and German buyers pay 20 per cent, so as to supply the markets of the two countries. This industry is increasing annually, and the facilities are that it will be more extensive in the future than at present.

General Notes.

GENERAL AGENTS.—On the initiative of the Union des Charbonnages, Mines et Usines Argiques, the Federation of Commercial and Industrial Associations has decided to found at Liège a school or college of advanced commercial and consular studies, with a programme specially arranged for training out consuls and commercial agents.

PHILADELPHIA EXHIBITION, 1899.—The following is the gist of an Act of Congress (so far as it relates to foreign exhibitors) providing for a national exhibition of American products and manufactures at Philadelphia this year (1899) for the encouragement of the export trade has been commented upon by the Lords of the Committee of the House of Commons on Education:—"There may be admitted to the exhibition such articles not of American manufacture, and such other objects as may conduce to the interest of the exposition and may be useful for comparison with American products and manufactures. All articles imported from foreign countries for the sole purpose of the exhibition will be admitted free of duty or customs fees." The Act stipulates that the United States will not be liable for any of the expenses, proceedings, or representations of the Trustees of the Philadelphia Museums or

the Philadelphia Exposition Association, under whose auspices the exhibition is to be held, except under the conditions as set forth in the Act.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 15.—"The Balloon as an Instrument of Scientific Research." By the Rev. JOHN M. BACON, F.R.A.S. Captain BADEN-POWELL will preside.

FEBRUARY 22.—"Electric Traction and its Application to Railway Work." By PHILIP DAWSON.

MARCH 1.—"Leadless Glazes." By WILTON P. RIX.

MARCH 8.—"Cornish Mines and Miners." By J. H. COLLINS, F.G.S.

MARCH 15.—"Liquid Fuel." By Sir MARCUS SAMUEL. Sir EDWYN S. DAWES, K.C.M.G., will preside.

MARCH 22.—"London's Water Supply." By WALTER HUNTER, M.Inst.C.E.

Dates to be hereafter announced:—

"Preservation of Timber." By S. B. BOULTON.

"Coal Supplies." By T. FORSTER BROWN.

"Wireless Telegraphy." By W. H. PREECE, C.B., F.R.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 9.—"Leprosy in India." By H. A. ACWORTH, C.I.E., late Government Municipal Commissioner for the City of Bombay.

APRIL 13.—"Judicial Reforms in Egypt in Relation to the Indian Legal System." By Sir JOHN SCOTT, K.C.M.G., D.C.L., Deputy Judge Advocate-General, and late Judicial Adviser to H.H. The Khedive.

MAY 11.—"The Revenue System and Administration of Rajputana." By MICHAEL FRANCIS O'DWYER, I.C.S., Settlement Commissioner, Alwar and Bhurtpore.

MAY 25.—"The Port of Calcutta." By Sir CHARLES CECIL STEVENS, K.C.S.I., late Acting Lieutenant-Governor of Bengal.

The meeting of March 9 will be held at the Imperial Institute; those of April 13, May 11 and 25 at the Society of Arts.

FOREIGN AND COLONIAL SECTION.

FEBRUARY 28.—"Persian Trade Routes." By A. HOTZ.

MARCH 21.—"The Commercial Development of Germany." By C. ROZENRAAD, F.S.S., and Fellow of the Institute of Bankers.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—
FEBRUARY 21.—"Vitreous Enamels." By **CYRIL DAVENPORT.** Sir **OWEN ROBERTS, M.A., D.C.L.,** will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—
ARCHIBALD SHARP, A.M.Inst.C.E., "Cycle Construction and Design." Four Lectures.

LECTURE I.—FEBRUARY 20.

Introduction—The modern bicycle—The frame—Strength and stiffness—Pedal pressure—Chain-struts—Round, **D**, and rectangular tubes—Frame of lady's bicycle—Tandem frames—Front-fork—Spring-frames.

LECTURE II.—FEBRUARY 27.

Ball-bearings—Hubs—Pedals—Crank-brackets—Steering-head—Adjustment—Wheels—Direct-spokes—Tangent-spokes—Rims—Materials used in cycle construction—Steel—Malleable-iron castings—Wood.

LECTURE III.—MARCH 6.

Driving gears—Length of crank—Block chain—Roller chain—Chain-wheels—Bevel gear—Lloyds' cross-roller gear—Compound gears—Two-speed gears—Free-pedals—Tricycle-axle.

LECTURE IV.—MARCH 13.

Steel, rubber, and pneumatic tyres—Detachable tyres—single-tube tyres—Tubeless tyres—Valves—Inflators—Side-slip—Brakes—Saddles.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 13.—United Service Institution, Whitehall, S.W., 3 p.m. Major E. S. May, "Artillery in Conjunction with a Force Awaiting Attack."
 Imperial Institute, South Kensington, 8½ p.m. Richard Davey, "Cuba."
 Geographical, University of London, Burlington-gardens, W., 8½ p.m.
 Medical, 11, Chandos-street, W., 8½ p.m.
 London Institution, Finsbury-circus, E.C., 5 p.m. Professor W. B. Bottomley, "Darwinism."
TUESDAY, FEB. 14.—Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lancaster, "The Morphology of the Mollusca." (Lecture V.)
 Asiatic, 22, Albemarle-street, W., 4 p.m.
 Medical and Chirurgical, 20, Hanover-square, 8½ p.m.
 Civil Engineers, 25, Great George-street, S.W., 8 p.m. Messrs. Jeremiah and P. Head, "The Lake Superior Iron Ore Mines, and their Influence upon the Production of Iron and Steel."
 Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.
 Photographic, 12, Hanover-square, W., 8 p.m.
 Annual General Meeting.
 Colonial Inst., Whitehall-rooms, Whitehall-place, S.W., 8 p.m. Sir Robert Giffen, "The Relative Growth of the Component Parts of the Empire."

WEDNESDAY, FEB. 15.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Rev. John M. Bacon, "The Balloon as an Instrument of Scientific Research."

Meteorological, 25, Great George-street, S.W. 7 p.m. 1. Mr. Edward Mawley, "Report on the Phenological Observations for 1898." 2. Profess

W. M. Davis, "The Circulation of the sphere."

Microscopical, 20, Hanover-square, W., Mr. Julius Reinberg, "Exhibition of Objects by Multiple-colour Illumination."

United Service Institution, Whitehall, S.W., p.m. Major-General R. L. Dashwood, "French in Newfoundland."

Archæological Association, 32, Sackville-street, 8 p.m.

Patent Agents, 19, Southampton-building, 7½ p.m. 1. Mr. A. Du Bois-Reymond, "Actions before the German Law." 2. Dr. on Mr. A. V. Newton's paper, "Procedural Patent Litigation—A Reminiscence and look."

Mining and Metallurgy, Geological Society, Jermyn-street, S.W., 8 p.m. 1. Discu

Mr. Franklin White's paper, "Notes on Crushing on the Witwatersrand." 2. M

Thomas, "Notes on Economical Mining at the United Gold Mine, New South Wales."

Mervyn Smith, "Mica Mining in Bengal."

THURSDAY, FEB. 16.—Royal, Burlington-house, W., 8½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Gilbert C. Bourne, "The Genus *Lennea*. G

with an Account of the Branching System of Order Alcyonacea." 2. Messrs. J. H. B

C. H. Wright, "Some African *Labia*, Alternate Leaves." 3. Messrs. Jame

Melville and Robert Standen, "Report on Marine Mollusca obtained during the First

expedition of Prof. A. C. Haddon to the Torres Straits." 4. Prof. A. C. Haddon, "The Torres Straits Chemical, Burlington-house, W., 8 p.m.

W. N. Hartley, "The Absorption Spectrum of Cyanuric Acid." 5. Prof. A. C. Haddon, "The Torres Straits London Institution, Finsbury-circus, E.C. 6

Dr. C. W. Pearce, "Samuel Wesley's Times, and Compositions."

Society for the Encouragement of Fine Arts, 11,duit-street, W., 8 p.m. Mr. T. R. Spence, "Elements of Design in Painting."

Royal Institution, Albemarle-street, W., Dr. A. Macfadyen, "Toxins and Antitoxins (Lecture II)."

Historical, 28, Jermyn-street, S.W., 5 p.m. Meeting.

Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, FEB. 17.—Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Dr. R. Holmes, "George the Third as a Collector."

Quekett Microscopical Club, 20, Hanover-square, W.C. Annual Meeting, 8 p.m.

Geological, Burlington-house, W., 3 p.m. Annual General Meeting.

SATURDAY, FEB. 18.—Irish Literary Society (at the THE SOCIETY OF ARTS), 8 p.m. Mr. F. "The Jacobite Songs of Ireland."

Royal Institution, Albemarle-street, W., Lord Rayleigh, "The Mechanical Properties of Bodies." (Lecture II.)

Education Department, South Kensington, S.W., 3½ p.m. Mr. J. H. Pollen, "Furtive

ERRATUM.—In the report of Mr. Sydney remarks on "The Cost of Municipal Enterprises" in the *Journal* for February 3rd, page 240, in the paragraph from the commencement of the paragraph, "Postmaster-General" read "Attorney-General" and line 8 from the bottom of the column read "sentiment" read "sanitation."

Journal of the Society of Arts.

No. 2,413. VOL. XLVII.

FRIDAY, FEBRUARY 17, 1899.

communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

NEXT ORDINARY MEETING.

In consequence of the indisposition of Mr. ALIP DAWSON, his paper on "Electric traction," announced for the 22nd inst., has to be suddenly postponed. In its place a paper on "The Gold Mines of West Africa" will be read by Mr. JAMES IRVINE.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained from the Secretary on application to the Secretary.

Proceedings of the Society.

DISCOURSED ORDINARY MEETING.

The discussion on Mr. DIXON H. DAVIES'S paper on "The Cost of Municipal Enterprise," opened on Wednesday, February 1st, was renewed on Thursday, the 9th, Sir WESTBY B. RICEVAL, K.C.M.G., in the chair.

The CHAIRMAN said this was a special meeting, intended to give a further opportunity of discussing the paper on "The Cost of Municipal Enterprise," by Mr. Davies. The Attorney-General was unable to be present that evening, and the duty devolved on him, therefore, of presiding. Those who had heard the paper read would admit that it opened in a very able manner a most important subject; and he trusted they would have that night champions both of the progressive policy of the municipalities, and those upon the other side. He would first call upon Lord Wemyss.

The Earl of WEMYSS said he thought it would be well if some practical turn could be given to the discussion by passing a resolution emphasising what

was in the paper, as coming from such a body it would have a material bearing on the question in which they were all interested. He, therefore, drew up the following resolution:—"Having regard to the numerous Local Bills now before Parliament, containing provisions for trading by municipal authorities, it is desirable in the interests of the ratepayers and of national progress that such powers should be suspended until a joint committee of both Houses of Parliament, or until a royal or other commission has inquired into this matter, and defined the extent to which municipal trading shall be sanctioned by the Legislature, and that a petition to this effect be presented to both Houses of Parliament." However, he was informed that resolutions were not possible at these meetings, but that it was competent for the Society itself to meet and petition in the sense of the motion. He hoped the Society might be induced to do so, and that the result of the discussion would be a petition on behalf of the Society practically embodying what was in the resolution. He had always been an individualist. He believed in individual enterprise, and that neither State nor municipalities should interfere or meddle with enterprise. It was individual enterprise that made the country what it was, and the danger they ran at the present time was that State or municipal interference would unmake what had so satisfactorily been done up to the present time. What did they owe to the State and municipalities in the way of successful enterprise? Take some of the most important—steam, lighting, and water. When he was quite a boy he recollected hearing that a grandfather of his used always to go by water to London from Leith, and was once becalmed for 14 days opposite his own house on the Firth of Forth. Now they went against wind and tide and accomplished the voyage in 35 or 36 hours. Was that due to the municipality of Leith or even to that of London? No, but to private enterprise. Then again, take travelling by land. As late as his Oxford days he used to go from Edinburgh to London shut up in a state box on wheels, where he was kept for 48 hours, only getting an occasional outing of a quarter of an hour for meals. Now he got into the train at London at 2.30, and landed at his own home at 10.30, and could dine on board on the road. Did they owe that to the State or to the municipality, or absolutely to the unfettered liberty of private enterprise? You could go on in that way, and refer to all that steam had done in setting millions of hands at work in the cotton or other trades, but they did not owe it to the State or to the municipalities. Taking lighting again: going back to his youth they had tallow dips and snuffers. Now every little cottage had its paraffin lamp, and you had electricity in the streets and houses, and if the municipalities did not interfere the probability was that within a generation the electric light in many districts would be burnt even in cottages. So far from owing that to the State, all that the State had done with regard to

electricity was to stop it for a time. It stopped it completely in 1882, and a committee had to be called together to amend the Bill which had stopped electricity. Coming now to water: they heard a great deal about the water in London. He found no better water than he got in London, and always had an abundant supply. There was a great outcry on the part of the London County Council, who proposed if they were allowed by Parliament to spend £50,000,000 of money, and to rival the Manchester debt by bringing water from Wales. Why? Because through the waste by people in the eastern district, and because of this exceptional year there was a scarcity of water. He had an estate in Perthshire, and during the last summer every drop of water had to be carted. But he looked upon that as exceptional. He was not going to spend a lot of money in bringing water from the Grampians. By the Report of the Commission over which Lord Balfour presided, it appeared that the present water companies, with the little additions such as they could make, would find water enough for 12,000,000 of people for 40 years. Those who managed these things in London denounced the water companies as a monopoly, but it was not the State that brought the water to London, it was the companies which were denounced for making such profit as they were allowed to do under their Acts of Parliament. If it had not been for them they would now have been drinking Thames and Lea water flavoured with cats and dogs plus the sewage of 4,000,000 or 5,000,000 people. The other night he went to the Palace Theatre and saw a wonderful photographic exhibition, which included Lord Kitchener at Dover as he walked off the quay alongside the Mayor of that Borough. He thought to himself was it to the Mayor of Dover that they owed this and those wonderful photographs which showed all that passed, and other scientific developments, by means of which they could now really physically see through the human body? Was it to municipalities that they owed such strides and wonders as those? No. And if the State and municipalities did not step in and put a stop to all this sort of thing, invention was as yet in its infancy, its possibilities were endless, and the only thing which could stop it was municipal trading, by which as soon as a thing succeeded the municipality put out their hands and took possession of it. Science discovered and invented a thing, and then a few men formed a company and exploited it to make money for themselves in the first place, but no doubt what they were doing tended for the good of humanity. That was the way the world progressed, and must progress. Everything else was an absolute mistake. What was at the bottom of all this, more or less, was the wish to make the State and the municipality omnipotent, and to put the individual under the heel of the State. Last summer, some members of the St. James's Vestry, of which he was a member, thought it would be desirable, in the interests of the ratepayers, to establish an Association, and he got them to call it

the St. James's Anti-Socialist Association: and there must be no mistake as to what socialism meant. He drew up a manifesto, but being only just beginning they thought that what he had written was too strong meat for babes; however he hoped it would not be too strong for the digestion of such a body as he was now addressing. In that he pointed out that the whole tendency of socialism, as the German writer Lieberand in a book called "This Age of Our Times" had remarked, was to make the State omnipotent; of course, the State embraced municipalities. He said—and this was the key to all the socialistic questions—Socialism means "State omnipotence." Whenever a Bill was brought into Parliament by which a municipality tried to take possession of any enterprise, they had merely to put the test of it, was it a step in the direction of State omnipotence. One point he put in the paper he referred to was this: "All this means State omnipotence, or a step towards it." That, he believed, would be the ultimate end of this interference with private trade and enterprise. It would be the most backward step which could be taken. Major Flood-Page had written an admirable letter to the *Times*, in which he showed that at the present moment there were 70 Bills before Parliament by municipalities, all of them trying to grow and make themselves manufacturers of everything connected with electricity—and if with electricity why not with everything else? There was a movement now, and there had been a petition headed by a member of Parliament, on the subject of bakeries. It was proposed that all baking should be done by the State. There was to be a complete system of municipal bakeries for the whole of London for which it was said £10,000,000 would be required, exclusive of the ground value and compensation which would have to be paid for the disturbance of existing property. Supposing the gentlemen succeeded, there would be no private bread-making, it would all be done by the municipalities then the men would strike for higher wages, and the public would be starved out, because there would be no means of getting bread. The only way to prevent starvation would be for each person to keep a supply of sea biscuits, or peas and beans. Such a scheme that would be open to any amount of abuse in the hands of those who were now pressing it forward. He would ask whether in the past the success of municipal trading had been so great as to encourage with regard to the future. He held that there ought to be a series of Parliamentary returns up to date which would give the debtor and creditor account of all the trading by municipalities in the United Kingdom. They knew that in the case of gas the Parliamentary returns showed that the great majority of cases private enterprise got more than a corporation did, and his belief was that if they went through water undertakings or anything else they would probably find the same result. As to the ratepayer it cost him what was shown on the diagram.

for. It was that which had made the nation and State, and municipal inroads on liberty would unmake it. He hoped when he passed away his epitaph would be—"He loved liberty."

Mr. JOHN BURNS, M.P., said the noble lord, with characteristic rashness and demagogic irrelevance, had departed from the subject of the paper read at the last meeting, and had embarked upon a series of observations about the growth of socialism and the danger which would accrue both to the people and the nation if municipal socialism was not retarded. He would venture not to follow the noble lord into the narrow paths and bye-ways through which he had diverged, and which otherwise might have been an interesting subject of discussion. He intended to deal with the paper which had been read, and incidentally to take one or two of the noble lord's arguments. Much which he had said was inappropriate and generally speaking was archaic, where it was not absolutely worthless. For instance, Lord Wemyss said—what did we owe to the State? He would like him to put that question to the House of Lords to-morrow morning in secret session, and he would be told by his fellow Peers that the State had given them that power which they undoubtedly exercised; it had given to the class he belonged a great deal and it was because the State had been used by a class unjustly for the expropriation of the people as a whole in the interests of a section of the classes, that the community as a whole wanted to resume possession of that instrument of State, in order to do for the nation what it had hitherto done for a privileged few. The noble lord said what had the State done for steam? That had as much bearing on the present debate as if he were to ask how much wages the carpenters got for building Noah's Ark, and, with regard to electricity, the same argument applied. Then he came to water and said he was satisfied with the London water supply. The firemen in the Minories that day were not, and the people in the East-end of London had been considerably disappointed with the London water supply. The noble lord said they wasted it. That was an *ex parte* statement, probably coming from a director or shareholder, and it came with peculiar bad grace from the representative of a class who taunted them with being the great unwashed, and would not give them water to make them clean. He did not see that the defence of the London water supply as it existed helped Lord Wemyss much, and if that was the only argument he could bring against the municipalisation of water supply he was in poor straits. He would suggest to him that if what he said as to the results of municipalisation were true it was an indictment against the common sense of the most practical people on the whole face of this earth. He said we were rapidly going to dissolution because municipalities were assuming duties which should be left to the individual. He ought to know that the answer to that was that those eminently

practical British people had in the course of the last two centuries taken from private enterprise 800 waterworks in England, Scotland, Ireland, and Wales beginning with the Plymouth Municipal Waterwork in the time of Sir Francis Drake, and not in one instance had they abandoned municipal water supply and reverted to private enterprise. The fact that they had held on to a municipal supply was evidence that the British people believed that if it was right to help monopolies for the benefit of a few individuals it was doubly welcome and beneficial when its advantages accrued to the whole community to use that power. He asked what had the State done? He ought to know they were indebted to the State for life, liberty, and property. They were indebted to it for national defence, and if the exigencies of national defence compelled men to submit to co-operative effort, and by cohesion to do what would be futile if attempted by an individual—if it was right for destruction it was right for production and any industry which that community cared to undertake. The noble lord said the time had arrived when the people should band themselves against the exaction by municipalities. What were the facts? Whether a man were a Conservative, a Liberal, a Radical, or a socialist in political life, he found that the necessities of modern life, modern industrialism, municipal institutions, and national interest compelled either the municipality or the State to resist monopolies in abusing their powers and in carrying the power of capital too far. Socialism was called into existence less by an instinctive desire for socialism as a theory than to use it as a matter of defence forced upon the community as a last resource against the exaction of private enterprise, and the tyranny of monopoly pushed too far. If Lord Wemyss feared the growth of socialism, as he did, it synchronised with, and was proportionate to the way in which the gains of industry and monopolies had called socialism into existence, by the way in which they had pushed the tyranny of private property too far. There were 800 waterworks, 250 gasworks, 5 tramways, 100 electric lighting systems, 12 docks, and so forth under municipal control, with the result that the capital value of the property owned by the different municipalities in Great Britain was equal to £500,000,000. He was not frightened by diagrams. It was said that figures never lied: that was true but liars sometimes figured. The people through the local authorities had £500,000,000 worth of capital property for which they had contracted loans of £250,000,000, as the diagram indicated, but not a word was said about the assets and remunerative property in hand. When he came to an analysis of the objections to municipal enterprise, he found it was not against the loans as a means of securing better assets, but it was simply the dividend hunter deploring the profit going to all instead of to a few. He said the other evening that Sir Richard Webster talked about municipal enterprise creating a fictitious rate of wages. It had done no such thing, and

was only the uninformed who made that allegation. He might take the London County Council as an instance, as he happened to be the author of that very much debated trade union clause. What did it consist of? The London County Council (and 300 local authorities had followed its example)—bad news for Lord Wemyss, but excellent for the community and the workmen, though bad for the contractors who made the Embankment—adopted this regulation: "The rates of wages and hours of labour recognised by and in practice obtained by associations of employers and trade unions of workmen." What a revolutionary document! What a most mischievous doctrine that the rate of wages in practice obtained and agreed on by associations of employers and workmen should be subject to so much impotent and frenzied discussion on behalf of the noble lord and his supporters! He saw alleged in the paper that a great deal of maladministration was due to the spirit of municipal enterprise which prevailed. As one who had been to America—and the noble lord would probably approve of much that he said in the teeth of the American people about the way in which greed, jobbery, and maladministration were rampant, he might tell him that neither he nor the reader of the paper could get down to socialism or municipal enterprise anything like the jobbery and maladministration that here prevailed. Maladministration existed in America simply because of private enterprise, and because millionaires bribed judges, squeezed senators, and purchased legislators? What for? In the interests of the community? No, but to extend the tyrannical influence of private property still further—to get contracts, to make money—and in so doing they were debauching the community and demoralising the State. Wherever you saw municipal enterprise undertaken in America, either in water, electric light, or tramways, there you had the beginning of good government, and it was from municipal enterprise and to its success in England and the absence of jobbery and generally of pure administration, that the Americans were following our example, and were beginning to set the crooked paths straight. When the reader of the paper attributed to the State and municipalities the defects which were patent to any observer in America, he was very far from the mark, and was certainly not speaking from actual experience as everyone could affirm.

Mr. DAVIES said he quoted his authorities; he did not speak from his own observations, but from American observers, who reported from their experience in America.

Mr. JOHN BURNS said his advice to Mr. Davies was to abandon those authorities henceforth, to throw those political Jonahs overboard, and make a trip to America himself, when he would come to the conclusion that every competent observer in America

had come to. Then, the noble lord asked if municipal trading would pay. Was it likely that Scotch Conservative aldermen in the City of Glasgow, retired captains of industry, would be in favour of municipal enterprise unless it did pay? The answer to that was that there municipal enterprise gave 50 or 60 gallons of better water per head to citizens for 6d., but London people had a worse quality and less of it for 1s. 2d. With regard to gas, Lord Wemyss ought to know, as every engineer did, the number of 1,000 cubic feet produced by a ton of coal; although it varied, it was all over the country practically about the same, and where the municipalities produced a rather less quantity they did it because they preferred a better quality and higher candle-power than the average private companies did. Where that did not prevail it was on account of better wages, shorter hours, and fewer accidents than the private gas-holding shareholders could show in London that the difference between the company and municipal systems was accounted for. The noble lord said the time had arrived when the ratepayers should be aroused, and with the next breath he doubted if it could be aroused, because he knew, as well as anyone, that they could not arouse the ratepayer in London, or anywhere else where any public policy was beneficial to his interest, and they would only regret municipal enterprises when they ceased to be profitable. He was one of those socialists who believed in making municipal enterprise pay wherever it could, and he was not afraid of comparison. To hear the noble earl speak, one would think that the 800 waterworks had been taken from their private owners by force of arms, but he saw that every one of them had been compensated, not only up to the market value, but over the market value. He knew full well that whenever, in any instance, where the State or municipality had superseded private owners in this country, no harm had been done to the people who had been dispossessed. Take the case of the tramways. The London County Council paid them £800,000 for plant which really was not worth more than £500,000. The company got what the House of Lords itself declared to be not only a full price, but a generous price, and, in every case where compensation had been awarded, no one had been despoiled. It was said the House of Commons had a great duty passed upon it to throw out these 70 Bills. The House of Commons would do no such thing; the House of Lords might attempt it. He presumed the noble earl wanted an inquiry to put an end to municipal enterprise, but he could assure himself of this fact, that the House of Commons had ceased to be a chapel-of-ease to the London Stock Exchange, and the House of Lords would cease to be some day an appanage of the big landlords of this country. Slowly, but surely, the people were coming by their own. They were using the local authority as an instrument of spreading over the many what monopoly had hitherto given to the few, and they would carry that some day to the extinction

of the House of Lords, of which the noble earl was so distinguished a member, and would sweep it away, because it represented nothing but property—nothing but mere money. Hitherto the function of the State had been used for robbing the people, and it was because the people wanted the State to be the protector and defender of the people that municipal socialism was gaining ground. The noble earl was a mere Dame Partington with a broom trying to rush back an ocean which was now at his feet, and if he did not mind it would soon be up to his neck, but in the interests of liberty he trusted it would not drown him.

Lord WEMYSS said he should like to ask Mr. Burns whether it was his view that all private property, what he called the instruments of production, should be in the hands of the State or the municipality?

Mr. BURNS—Yes.

Mr. DUNDAS PILLANS said he felt sure that very seldom within that hall had a speech, similar to that which they had just listened to, been delivered; an admirable speech of its kind, and most valuable to those who took the opposite view, because it disclosed, in all its naked hideousness, the policy the speaker had persuaded the people of this country to adopt. It was a speech, however, inappropriate to the occasion; it should have been delivered either in Trafalgar-square or under the Reformer's Tree in Hyde-park. They were there for the purpose of following up the debate so ably opened last week, and to discuss a matter which, however much their opinions might differ, they would all agree was of the greatest public importance. It was a matter which did not only affect one class of the community, but everyone, and the poorer classes to a greater extent than the richer, because any municipal expenditure must ultimately press heaviest on those who had least money to spend. He would attempt to bring back the debate to commonsense, and to avoid flights of rhetoric. It seemed to him the subject presented itself from two different points of view. In the first place it might be considered from the purely business standpoint. Could enterprises involving profit-earning be conducted as profitably and economically under Government administration as under private control. He had had considerable knowledge of various forms of business administration, which might be divided into three classes; first, business under exclusively private control; second, those conducted by joint stock companies; and third, those conducted by municipalities or the Government, and he submitted that those three forms represented three degrees of efficiency and economy. Where personal supervision directed a business you had the greatest efficiency and success. It was notorious that the master's eye had a great effect in obtaining the utmost possible work with the least degree of expenditure, and, therefore, you frequently found businesses

which prospered under private control when converted into joint stock companies showed a fall-off in profit and not unfrequently reached a state when a liquidator took them in hand. Why was this? Because, after all, success in business depended on self-interest, that was the only sound principle on which business could be conducted. It was manifest that when a company organisation the motive of self-interest was distinctly weakened; the officials had not the same personal interest in the concern as if they were the owners. They had some interest, because if the company were not a success they would not receive their salaries. But when they went further and placed the business under municipal or State control the motive of self-interest became eliminated to such a degree that it might be put out of the question; whether the business succeeded or not the salaries would be paid because they had the purse. Fortunatus to fall back upon; the wretched ratepayer would be called upon to pay whether the business were successful or not. In the case of a company it would be wound up, but in the case of a municipality or State the salaries would continue to be paid. Therefore, on the face of it, it was fairly arguable that an organisation under State or municipal control was the most wasteful, extravagant, and least successful of any, and they knew from experience that that was so. It had been discovered in the building of ships that the Government got much better value for their money if they put those enormous contracts into the hands of private traders instead of building them in State dockyards. As a member of the municipality of Richmond in the neighbourhood of London, first as a Councillor and afterwards as an Alderman, he found the greatest extravagance was to be feared where a business was organised under the control of a small locality, because there you had certain circumstances which tended to increase the danger of corrupt administration. There was always the tendency of town councils to indulge in experiments at the expense of the ratepayers. The town councillors all knew each other; they were companions and friends, and there was always a tendency to play into each other's hands. One great point which came under his notice was that there was a principle adopted in giving contracts for work under the town council to keep the business in the locality; a sort of spirit of local patriotism existed and there was a tendency on the part of members without any intention of corruption or jobbery, to give contracts to their friends, and to keep the business in the locality. This tended to extravagance, because it was manifest the wider the area of contracts and tenders the greater must be the efficiency and economy. They were often told that places like Glasgow were very successful in administering waterworks, tramways, and so on, but there was no guarantee that in drawing up their balance-sheets any allowance was made for depreciation of plant, and he was not aware whether, in Glasgow, they had debited against their income an equivalent for the rates which would be

January 17, 1899.]

ed in the event of the tramways being under private enterprise. There was no audit corresponding to audit which company's affairs were subjected to for purpose of laying them before shareholders' meeting.

When they were told about the wonderful results which the Glasgow tramways claimed to have achieved, it was almost incredible that it could be true. It was alleged that they had not only reduced the cost of labour and increased the wages, but they had increased the profits. Before these statements were made, they ought, as business men, to be satisfied that they had debited against their income all those expenses which would have been debited if it had been private concern. Then, coming to the other branch of the subject, and considering it from the ethical point of view, the evils that municipal trading had wrought were very much more serious. Mr. John Burns had asserted that eight hundred waterworks had been taken over by municipalities, and that they had all been managed without the slightest corruption, and with due regard to the welfare of the district.

Mr. JOHN BURNS said he did not say so, but it was a curious fact that no corruption had yet been proved.

Mr. DUNDAS PILLANS said they must not only take into consideration the actual facts, but also the probabilities, and they knew that within short periods there had been disclosures with regard to the Works Department of the London County Council which had thrown considerable suspicion on that illustrious body. When a public idea was first put into action the greatest amount of public interest centred in the experiment, and was only in the nature of things probable that those managing the concern would be exceedingly careful that they were about. But as time went on, he feared that public interest would be considerably diminished, and by degrees it would be found, as it was always found, that abuses crept into public departments. One great danger was that the employees of a municipality were also voters, and there was a tendency on the part of a representative to make things pleasant for those who elected them. If they could tell the people that they had been able to raise their wages, and to shorten their hours, there was a great temptation on the part of representatives to do these things, forgetting that they were not there for the purpose of paying fancy prices to labourers, but as trustees of the public to administer public funds, and to conduct the business entrusted to them precisely in the same way as they would if they were private persons employing these same people. He recollected during a recent election for the London County Council, in going through the borough of Southwark, seeing on the hoardings posters appealing to the electors to vote for so and so, who would pay the scavengers a minimum wage of 25s. a week. That was a serious element of corruption and a source of danger

which thinking men would do all they could to guard against. There was a theory now abroad that by the direct employment of labour they could save the profits of the contractors and obtain them for the community. He believed that to be a great delusion. The contractor was a man who knew what he was about; he understood his business and knew how to obtain the maximum of labour from the men under him. It is all very well to flatter the working-classes and tell them the State was going to restore to them what they had been deprived of. That would do for the Reformers' Tree, but was not suitable to an intelligent audience. It would be much better to tell the working man that he had no more claim to consideration by the municipality with regard to wages or hours of labour than any other class of the community. The contractor had no such sentimental influences at work. He appointed a foreman who would get the utmost possible work out of the men, as it was only right he should. The British working man was a very good fellow, but he needed a lot of looking after. They found the greatest difficulty at Richmond to persuade the British workman to do a fair day's work for more than a fair day's wage. It was a very difficult thing, in view of the omnipotence of the ballot-box, to get any foreman to properly superintend work, and make the men do an honest day's work. As soon as their foreman tried to do what a contractor's foreman would have done, the men immediately came before the Surveyor's Committee, and held him up to execration as an oppressor of the poor. He himself had been taken in like that several times. He used to boil over with indignation at the treatment received by the labourer at the hands of the tyrannical foreman, until he learnt better by experience. The consequence was that jobs lasted twice as long as under a contractor, were worse done, and cost a great deal more. It was very undesirable to increase the power of a bureaucracy as he knew through having lived for some years on the Continent, especially in Italy. There was no greater danger to the community than that it should be over-ridden by bureaucrats. There was no more objectionable person than a man who got into a uniform, and swaggered about lording it over his fellow creatures, and he wanted to prevent the progress of that sort of thing in this country. They owed their greatness mainly to the spirit of independence and individualism which was characteristic of the English character, and he trusted they would adhere to that faith. That had made the country great, and that only could keep it great in the future.

Mr. C. FAIRFIELD said interesting as was Lord Wemyss's address, his most important recommendation was the practical one that they should try to get the Government to hold an inquiry into this matter. Most contradictory statements were made as to the profits of municipal experiments, and Mr. Burns's speech showed the absolute necessity of getting the facts and figures. There was a formidable table on

the wall which showed £250,000,000 of municipal debt for the most part piled up within the last few years, half of it admittedly spent for "sanitation" which could return no direct profit to ratepayers. They wanted to know about the other half. It was expenditure which had grown so much of late years since a wave of socialism had come over the House of Commons. Mr. Burns said there was £500,000,000 of assets to put against that, and they wanted to know if there was any truth in his assertion, or whether a great portion, consisting of waste material, enterprises which had since become obsolete, with which the ratepayers were now saddled, did not represent a net loss. They also wanted to know the facts about the Glasgow tramways and other schemes there; was it really true that the private company which had been superseded paid £30,000 a-year rent—all thrown away when the tramways were municipalised? Lord Wemyss, who was an Individualist, was not in the habit of running to Parliament for protection, but in this case Parliament was responsible for the evil of which they complained. Mr. Balfour's answer was that ratepayers had the remedy in their own hands. That was true in small areas, and to a certain extent, but the growth of modern cities had altered the whole phenomena of local self-government. The ratepayer to-day was powerless, he was a helpless unit, it was so in London and in New York, and Mr. Burns must know from his journey to America that it was only in the large cities that municipal corruption was rife, and that malpractices prevailed. In the small municipalities administration was pure. He had lived five years in the West in cities of 2,000 or 3,000 inhabitants, where the ratepayers could take an active interest in local matters, and the administration there was pure and businesslike. The success of local government was in inverse ratio to the size of populations. What did the people of Manchester know about the agenda paper which came before the City Council every day? The men who had to deal with it ought to have a salary of £1,000 a year each, but these gentlemen were busy professional or business men, and the result was that proposals to municipalise everything fell into the hands of committees, and were carried without the knowledge of the ratepayers. That was why they asked for a Parliamentary inquiry. Assertions that municipal socialism paid came from Mr. Burns and a small section who thought with him, but the great majority who had been active in advocating municipal socialism did not take the trouble to declare that the thing paid on its merits. They said it ought to be based on higher considerations than £ s. d.; that the promotion of great ethical, moral, reforms was a justification for schemes which ignored ordinary business principles. Mr. Burns asserted that they paid, but he should prefer to see a balance-sheet. Many "municipalisers" boldly asserted that the scheme they advocated did not pay, and ought not to pay. They were benevolent, philanthropic people,

who said it was their duty to give good wages to working man, to make his life better, and his home brighter, more purple-tinted than it was before. All that sort of thing could not pay. Apart from the question of debt, there was the question of the growth of municipal bureaucracy, which was a terrible danger in this country. The Government had already called into existence an enormous State bureaucracy in the shape of school-teachers, virtually salaried State officials, banded together in a trade union whose main principle was self-interest—raising salaries and increasing the privileges of its members. Added to that, there was the approaching threat of a bureaucracy to administer an enormous mass of the ratepayers' money, which would be a formidable political danger. That municipal bureaucracy already had a trade union, and they claimed for themselves not the right to compete with private traders, because they did not want to compete—Lord Farrer once, in a moment of economic remorse, challenged the London County Council to compete with the contractors by doing work outside bodies—they did not want to compete, they wanted a monopoly. Most of these corporate officials were able and energetic men, very probably some of the most respectable men in the kingdom, but still there was a terrible temptation to jobs of various kinds, and, as this was increasing every day, he thought it was high time that Parliament should inquire into the matter.

MR. PERCY SELLON said as he read the paper he did not consider it was an indictment of municipalisation as such. The average man took the view quite rightly that it was too late to attack the whole principle of municipalisation. He certainly held that it had thoroughly justified itself with regard to certain classes of commodities, and that it was good for society at large that these commodities should be provided by the municipality and not by private enterprise. On the other hand he believed the average man held, and probably even Mr. Burns would agree so far, that there were certain classes of commodities which carried with them big trade risks which the municipalities ought not to take in hand, because they were not so well qualified to do so as private enterprise. Between those two extremes there were certain number of cases with regard to which men of both schools held sincere and diverging views. As he understood the paper it amounted to this: that with regard to the particular matter of the electric industry, which was the one in respect of which the municipalising question had chiefly arisen in the last 20 years, municipalities had not given so good an account of their stewardship as private enterprise would have done. Now was it possible to make out a *bonâ fide* case before competent judges whether the municipalities had in fact conducted electrical enterprises worse than private bodies. In such a case could be made, the question was what was the proper remedy. There was one point which

d not yet been alluded to, namely, the light which the experience of foreign countries threw on the matter. He had had exceptional opportunities of seeing and hearing what was going on in America, Germany, and in Switzerland, and he believed it was beyond dispute that in those countries electrical science was far more highly developed in the interests of the public than in this country, and, secondly, that in those countries it had not been handled chiefly by municipalities. In America, out of 2,589 electrical enterprises, 2,250 were private, and only 330 municipal; but in this country there was a majority of local authorities. If these figures had any significance, the deduction was that electrical enterprise had moved relatively slowly here because it was in the hands of municipalities. Those who held the view put forward in the paper were of opinion that the suggestion made by Lord Wemyss was a practical one—that Parliament should be asked to appoint a commission of inquiry. It was not a matter in which there need be any antagonism of interest. The municipality represented the ratepayers, and the ratepayers were the public. They wanted to know whether their money should be taken from them in rates or whether they should be allowed to invest their money freely in industrial affairs. Therefore the interest of the local authorities, and the interests of those who held the private enterprise view were identical, and they might well join hands in presenting a joint petition to the two Houses of Parliament asking for his important commission.

Mr. SPENCER HAWES said he hoped to have been able to deal with several points raised in the paper and the discussion, and to have had the opportunity of showing how municipal enterprise in relation to electric lighting had given vastly superior results to those attained by company operations, but time did not allow him to do so fully. He would, therefore, only take the point Mr. Sellon had referred to, that local authorities had not given so good an account of their stewardship as companies had. That view he held was entirely opposed to the facts. Local authorities indeed were giving consumers a cheaper supply, and were carrying on their undertakings at a lower cost than companies. Taking first the average price charged to the private consumers of 39 companies whose accounts had been filed, it would be found that no less than 15 per cent. showed an average price of between 7d. and 8d. per unit. On the other hand there was not a single local authority in the kingdom which charged so high a price; 28 per cent. of the companies charged between 5d. and 6d., as against 4d. per unit in the cases of 60 local authorities. Only 21 per cent. of the companies charged under 5d. per unit, the lowest charge by a company undertaking was 4.06d. per unit; but you had 52 per cent. of local authority undertakings charging lower than 5d., the lowest price being 3½d., charged by the Edinburgh Corporation. There were seven local authorities charging less than 4d. From

the arguments that had been adduced that evening, it would appear that a board of directors alone possessed the necessary qualifications for the proper administration of electric supply undertakings. The practical control of all these works was in the hands of the administrative officers and officials, and under the local authorities there were as capable and clever engineers as in any of the private undertakings. Let them take the working expenses, exclusive of interest, sinking fund, or depreciation charges, and they would find that of the 39 companies referred to, 26 per cent. had produced their outputs at a cost of over 4d. per unit, whilst amongst local authorities, only 8 per cent. of the 60 had to record similar costs. There were only 5 per cent. of the companies, whose total costs were lower than 2d., and of the local authorities there were over 25 per cent., and in one case they were down nearly to one penny. Replying to a question, he said that the profits being determined by the rate of charge to the consumers, the gross amount of profits was not a clear indication of the success or otherwise of any undertaking. The Brighton Corporation, for instance, in 1897, made a surplus profit of £2,800 only because its charges for electricity to private consumers were as low as 3¾d. per unit. A company undertaking of similar size—Chelsea—had to its credit a net surplus of £9,800; but it had charged its consumers 5¾d. per unit. Had its charges been as low as those at Brighton it would have had only £1,000 for distribution to its shareholders.

Mr. E. GARCKE said this subject was very large, and he would endeavour to refer to one or two new points; but first he must say a word on the statements made by the last speaker, which, he ventured to say, were entirely erroneous. He had referred to a lower price for electricity being charged by corporations, and to a lower cost of working; but taking the cost first, he had ignored altogether that the corporations omitted from their accounts items which had to be incurred by companies, and ought to be charged. The corporations managed to charge the services of the town clerk, the borough surveyor, and many other items to other accounts. Then with regard to the price charged, the local authorities had the question of public lighting in their own hand, and they adjusted that according to the needs of the accounts. With regard to profits, he had made a most egregious blunder, and it was the statement which Mr. Burns made that was at the bottom of the whole question. He stated that it was not the object of local authorities to make a profit, but Mr. Burns simply said the object and policy of the corporation was to make a profit; therefore it was an important question for Parliament to determine not only what was to be the scope of municipal enterprise, but the principle on which it was to be conducted: were the local authorities to make a profit or not. He had lately had occasion to analyse the net result of the working of electrical supply undertakings by corpora-

tions, and he found that although a profit of about half a million was made by all the municipal corporations carrying out electrical lighting, they had taken more from the rates during that period than they had returned to the ratepayers. Then where did the benefit to the ratepayers come in? He endorsed the practical suggestion that every effort should be made to obtain reliable facts upon this important question. They were all ratepayers, and were anxious to learn, and he was quite sure that Mr. Burns, notwithstanding the recklessness of some of his statements, would be very glad to be corrected if he was wrong. A practical social revolution of the industrial conditions of this country should not be allowed to take effect without careful consideration by Parliament, and it should not come about by various private Bills promoted by this or that municipality, but should be determined after careful consideration. He therefore endorsed the suggestion that the Society should petition Parliament, as it had done on former occasions, for the appointment of a Commission; and, further, that the excellent paper of Mr. Davies should be reprinted for general circulation. One thing which had come out was the enormous complexity of the question, and the apparent want of knowledge of its complexity. He had always found the majority of people took very little interest in it, and therefore the more they could disseminate sound literature upon the subject the better. One point which had occurred to him was the danger of extension of municipal enterprise arising from the want of efficient management. He did not question that efficiency at present, though it might be open to doubt, but he would ask, if this tendency were to go on, who was going to do the work of the municipality? At present a few gentlemen who were enthusiastic for the welfare of the community devoted themselves to this work; but if the London County Council undertook not only electric lighting, but tramways, electric traction, and all other industrial enterprises, who was going to do the work? Was it fair to say that a human being, whenever he is acting as a private individual is greedy and self-seeking, but the moment he joins a Town Council he becomes no longer self-seeking, but is entirely devoted to the welfare of the public. It was not fair to put upon any individual the huge amount of work it was proposed to put upon Town Councillors and not remunerate them; but if you did, it would introduce an entirely new factor to the question. Then you had to consider whether it was better to carry on these enterprises by means of self-interested public companies, or whether they should have the State or the municipality-employed officers. Again, if the municipal corporations were going to be authorised to do this large amount of work, they ought to be put under the same restriction and responsibility with regard to the rendering of accounts. There was no other spending body in the State which was not called upon to render accounts. Why were not the

municipal accounts published in the same uniform manner as the Board of Trade required tramway companies, gas companies, and electric light companies to publish their accounts? It would be said no doubt, that the accounts were published, but they were published in such a manner that they never knew whether it was the electric department which paid or some other. Another important question was the difficulty of securing continuity of policy. During many years he had had to carry on negotiations with local authorities, and the difficulty he always experienced was this—he would attend a Council meeting, when the question would be discussed, and a gentleman of great eloquence would get up and make a speech, which carried the whole Council with him, and for the time the matter was disposed of, but the next meeting, when that policy was to be continued, that gentleman was not there and somebody else got up of equal eloquence on the other side, and the whole policy was reversed. This was not a business-like way of carrying on business undertakings. He did not think there was any great danger threatening the development of industry through the careless indefinite way in which this question was dealt with. It ought to be defined one way or the other. If these things were to be carried on by municipal corporations, let the public know that they would have to put their savings into corporation stock, and become corporation officers, or else to leave the country with their capital and energies and go elsewhere.

Major FLOOD-PAGE said he wished to enforce the suggestion that the Society of Arts should petition Parliament, in favour of the Joint Committee, and he spoke as a member of the Council of the London Chamber of Commerce, where the question originated from the fact that seventy municipalities were making an attack this session on the electrical industry, asking for powers to manufacture lamps and other things. This was a matter vital to the trade and commercial interests of the country, and they were in communication with every Chamber of Commerce in the kingdom, and he believed there was none which would not support the petition they had originated. Electricity was as yet in its infancy, but, according to Mr. Garek, who was a great authority on all statistical matters in connection with it, about £100,000,000 of money had been spent in electricity. Going back to the time when Lord Wemyss, as he has told us, gave up his seat in Parliament in 1846, railways were then in their infancy, but they have spent £1,000,000,000. Who had spent it, private enterprise or the municipalities? Why were they behind every other country in the world in electricity? Simply because Parliament had put them under the local authorities. There were not less than 104 municipalities which had the power to introduce electricity, but had not done so and kept everybody else from doing it. There were now a number of companies asking Parliament for power

take cheap electricity all over the North of England, but the municipalities were up in arms, and wished to prevent their interfering with their monopoly. In Liverpool there were 700,000 people, 300 only of whom took the electric light, but we want at every man should have the electric light as he had water, and this could only be accomplished if the destruction of municipal trading was put an end to.

The CHAIRMAN said he must now bring the meeting to a close in the usual way of proposing a hearty vote of thanks to the reader of the paper. Whether they agreed with his opinions or not they could all join in thanking him for it, and it was not only valuable in itself, but it had, he hoped, evoked a very valuable discussion though it was true the range only of the subject had been touched. With regard to the request which had been made, that the Society of Arts should petition Her Majesty's Government to institute an inquiry into the whole question of municipal enterprise, he should have pleasure in submitting the wishes of the meeting to the Council of the Society of Arts, but if he might venture to make a suggestion, he thought a very happy sequel to the proceedings would be if Mr. John Burns would add to their indebtedness to him for taking part in the discussion by moving from his seat in Parliament for the inquiry which was so eagerly sought for. He was quite sure that he was anxious to get at the facts as anybody else, and would support any petition the Society might make in the direction suggested.

The vote of thanks having been carried,

Mr. DAVIES, in reply, said his thanks were due to the audience, and especially to the Council of the Society for giving him the opportunity of discussing this exceedingly interesting though somewhat complex scientific question; they were also due to the Attorney-General who was so gracious as to take the chair when the paper was read, and also to those who had joined in the discussion. He might say he was specially indebted to Mr. Burns for having been so courageous as to come forward in an almost entirely hostile audience to put, with perfect candour and frankness, his view of the matter. The subject was not a new one to him, as he had been engaged in a professional capacity in fighting a kindred question, namely, the right of private traders to come and push their electric wires into the boroughs in the North of England. In that effort he had been met with a unanimity of malignant opposition on the part of the officials of municipalism, which had been startling. The subject had been a subtle and difficult one, which could not be dealt with in a few paragraphs in a newspaper, nor could it be dealt with at a scrappy meeting of one or two ratepayers who might get together and sanction opposition to a private Bill. It could only be dealt with in any sort of rational manner when a scientific society like that gave both sides a full opportunity of expressing their views. The Council

had been so good as to accede to his request and especially invite the town clerks of those corporations who were opposing this important commercial innovation, and as he was anxious they should know exactly what his views were, his paper was distributed amongst them beforehand; but he must confess that his gratification at the proceedings which had taken place was tinged by a drop of bitterness inasmuch as he had not had one of those honourable opponents there to say one word in answer to his reasoned justification of the attitude he had ventured to take up. Might they not assume from this silence that these experienced and learned upholders of municipal institutions were in their hearts as convinced as he was that municipal trading was prejudicial to the best interests of the corporations. There had been some admirable contributions to the discussion, most of which struck the note of liberty, and he was glad that that was followed by Lord Wemyss in his peroration, when he told them that he should like to have written as his epitaph that he loved liberty. That epitaph might be written—he hoped it would be a long time first—equally well on the grave of Mr. John Burns. The question was not whether they loved liberty, because they all loved liberty, but by what method would liberty be best assured to our citizens. Would it be assured by absorbing into the embrace of municipal government every activity and industry, or would it be better accomplished by leaving activity and energy free to trade in the old way. He honoured those who held the socialistic view and frankly stated it, but he hated the man who called himself a municipalising radical, or democratic conservative, or some such misleading name. He wanted all those disguises thrown off and the principles at stake freely stated. No doubt Mr. Burns reflected the feelings of a great many of the working-class, that the method of wealth production had hitherto been absorbed by the propertied class. It might be that certain methods of wealth production had in the past been so absorbed, and that the power of the State had been used to protect that absorption. But the methods of wealth production, of which he had been advocating the freedom, namely, the brains and activity of the people, were not capable of being enslaved or owned by means of any property title whatever. The real activities he wished to see freed the most, existed not in the ownership of so many miles of copper wire, or of railway track, but in the brains and energies of the people themselves. It was impossible those brains and energies could operate to their full capacity for the advancement and advantage of society except in a medium of entire liberty and independence. Mr. Burns said that if the discipline of militarism was good for the organisation of methods of defence and attack, was it not equally good for industry? It was not. The same systems of discipline and methods of organisation which might be all very well for military purposes were not adaptable to industrial developments. With regard to the limit which should be drawn to define the boundaries of the

functions of the local governments, it seemed to him that if you went back to the principle of democracy, you got the true line. That principle rested on no assumption that the many were wiser than the few, or the poor wiser than the rich, but on the single law—the result of experience—that a man could be trusted to attend to his own interests, and not to anybody else's. Therefore each man, as he had an equal interest, whether poor or rich, in the defence of the country, was entitled to an equal voice in the appointment of the Government, but it followed from that that the Government should confine itself to matters which were of common interest to everybody, and the Government or municipality should not engage in matters which were of interest only to a small proportion of the community over which they were appointed to rule.

Mr. DAVIES writes:—Owing to the late hour of the evening to which the discussion was prolonged, the writer did not feel himself permitted to enter upon statistical points in his reply. He would not, however, like those who honoured him by examining his Tables to think him neglectful of their criticisms. The supplementary Table (No. 6) has been compiled to meet the suggestion of Sir Richard Webster. The figures in this are taken from the last edition of the "Official Intelligence" and show the proportion of outstanding indebtedness of the typical towns which is attributable to remunerative, that is, presumably, trading expenditure. This proportion varies it will be seen from 75 per cent. of the whole debt in the case of Manchester to nearly 50 per cent. in the case of Nottingham. How far, if at all, the outlay of these large sums has relieved the burden of the ratepayers it is very difficult to ascertain. Owing to the complexity and lack of uniformity in the accounts of the different corporations, and in the system of valuation, to say nothing of the disturbing element of large corporate property, the revenues of which are applied in the relief of the rates in some towns—the Corporation of Liverpool, for instance, is a large owner of landed property in the very heart of the city—it is impossible to compare the rates levied in one town with those in another. All that can be said is that the rates in the six towns mentioned are high. The amount collected in Manchester last year was, according to the last edition of the Municipal Year Book, 7s. 1½d. in the £, in Liverpool it is 6s. 0½d., in Sheffield it is 7s. 11½d., in Leeds 7s. 2d., and in Nottingham 6s. 11½d. In regard to Mr. John Burns' statement that the assets are neglected in the Tables, this is hardly correct. The assets (as stated in the paper) are duly reflected in the statistics of rateable value, for of course the justification for the outlay of ratepayers' money in the making of roads or the laying of pipes and wires up to his property, and the supply through those pipes and wires of various commodities which he has need of is the amenities which those works have added to his property. These amenities

are duly taken note of when the valuation list is revised, and the point remains that the indebtedness and also the rates in the large towns have increased during the last 20 years out of all proportion to the growth in value of the ratepayers' property.

PROPORTION OF LOCAL DEBT ATTRIBUTED TO REMUNERATIVE EXPENDITURE

until at a certain elevation, varying on different days, the decrease is arrested, and, for a space of from 2,000 to 3,000 feet, the temperature remains nearly constant or even increases, the regular diminution being afterwards resumed, and generally maintained at a rate slightly less rapid than in the lower part of the atmosphere, and commencing from a higher temperature than would have existed but for the interruption noticed."

Let us look at this on a diagram drawn alongside Mr. Glaisher's general curve (Fig. 1). I

FIG. 1.

have taken a clear day in August, but the curve drawn would almost serve to illustrate each and all of Mr. Welsh's experiences. The remarkable halt he speaks of occurs in the clear air, commencing at 7,200 feet. Nine days previously, when the sun was constantly obscured, the bend in the curve commenced at 4,000 feet. On October 21, when he ascended in cloud and showers, the same bend occurs, but at 2,500 feet. Once more, on November 10, when he surmounted all cloud at 4,900 feet, the curve remains fairly regular until a height of 5,100 feet was reached, when, now well in the clear, the same remarkable check and recovery is recorded. This, I think, calls for further consideration, but returning for the present to Mr. Glaisher's account, we find him calling attention to a most instructive case which again can be illustrated by a simple figure.

It is now early spring, with wind from the S.E., the ascent commencing some two hours before sundown. The diagram explains itself, but the most important comment was supplied by Mr. Glaisher himself, who says:—"Our

course was most remarkable. After passing over the Thames into Essex, we must have crossed the river, and moved in an entirely opposite direction until we approached the earth again, when our direction was the same as at first." (Fig. 2.) And now, at this par-

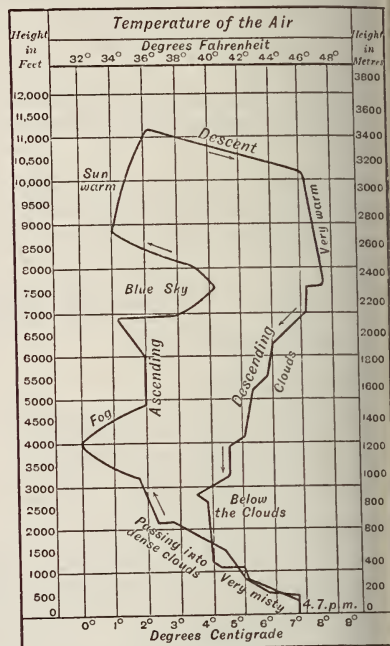

FIG. 2.

lar stage, let us compare these early results obtained by the balloon with typical diagrams prepared from recent records systematically taken by high-flying kites.

Here, under a clear sky, the decrease of temperature is practically regular up to a mile or more, but on an occasion where cloud was present the decline has been abruptly arrested. (Fig. 3.)

FIG. 3.

se curves accord well with those just con-
 ed, and point to an agreement in the two
 ems of observing, each method, however,
 orming its special function. The types of
 uments used with kites should be noticed,
 they may be considered scarcely of such
 aracter as could respond very readily to
 l changes of temperature. Indeed, it has
 customary to assume that five minutes
 required to overcome the sluggishness of
 nstruments used, while, on the other hand,
 bserver in a free balloon can apply con-
 and needed corrections, as, for instance,
 e use of a simple "sling" thermometer.
 s, when the balloon is balanced, by a mer-
 ul barometer; and he can read from
 ent to moment the fluctuations in a deli-
 air or other thermometer as he penetrates
 e shallow layer. Further, the kite-flyer
 rly cannot, equally with the aeronaut,
 e sure of what is to be seen above the
 st cloud floor.

owever, we can already duly interpret, in
 light of thirty years ago, as well as of
 ay, a typical picture of our skies. Take a
 in rainy July, as given by Mr. Glaisher,
 h, briefly described, reads thus:—Leaving
 mperature of 61° on the ground, mist and
 rain are quickly reached, and the first
 ds left behind at 1,200 feet, where the
 perature was 59° ; further cloud is sur-
 nted at 2,800 feet, the thermometer reading
 then 55° , and again 53° ; then with a
 rt descent dry fog is reached, growing
 er lower down, at a temperature of 57° ;
 nding again to 3,300 feet, the thermometer
 stered 53° , and finally getting down
 ugh squalls of wind and rain, the tempera-
 of earth was found unchanged. Clearly
 is not been established that visible cloud,
 that alone, affects temperature in upper
 ons according to any fixed law. Humidity
 ever has proved a very variable quantity,
 most obvious law involved perhaps being
 so commonly made patent to the eye, by
 ilar cumulus clouds forming in daytime at
 ight, say of from 3,000 to 6,000 feet, and
 ppearing again at night.

n all-important matter, however, which had
 o this point been generally agreed upon by
 al observers, is that various currents are
 commonly to be found flowing within
 uite but shifting beds, at all and varying
 hts until the dominant drift is reached.
 prevalent trend of these greater streams
 indeed seriously considered as long ago
 he days of Green in England and Wise

in America, both of these experienced aeronauts
 having been prepared to essay a voyage across
 the Atlantic by a main upper current thought
 to prevail in the direction of the earth's
 rotation.

We can now with proper appreciation pass
 on to consider the work embraced in the
 scheme rapidly developing under the auspices
 of the international organisation now in active
 progress in other countries. Supplementing
 the work done by simultaneous ascents of
 captive and free balloons, we find that far
 beyond the limits of human endurance the un-
 manned or sounding balloons, despatched from
 large centres lying in the heart of extended
 country, have ascended and brought down
 self-registered readings showing altitudes and
 temperatures never dreamed of. The experi-
 ments with this class of balloon, which have
 been conducted at Berlin under the direction
 of Assmann, Berson, and others, have been as
 successful as they have been ambitious, and
 with a free balloon of 8,800 cubic feet, and
 possessing a net lifting force of nearly 300 lbs.,
 an altitude has been reached of upwards of
 60,000 feet, as indicated by a barometric
 pressure of about 2 inches of mercury, while a
 temperature of -88° Fahr. was recorded. A
 temperature lower yet by 6° has also been
 recorded by a very similar balloon despatched
 from Paris.

Let us look first at some of the equipment of
 these balloons. The German instruments have
 been rendered extremely perfect by the use of
 photographic registration, and by mechanical
 ventilation of the aspiration apparatus. It
 will be supposed that a certain unavoidable
 lag attaches to any such instrument, tempera-
 ture measurements reading too high in ascents
 and too low in descents, and it must also be
 observed that while the mean temperature of
 the whole mass of air is unknown, the altitudes,
 which are calculated on the well-known formula
 of Laplace, cannot be regarded as exact.
 Moreover, in spite of every possible pre-
 caution, it is open to question whether at
 extreme heights the registration can be relied
 on, and whether on that account the readings
 be not somewhat in error.

Balloons of the above description designed
 for high flights, being without controlling
 hand, are subject to certain disadvantages,
 among which must be mentioned the rapidity
 of vertical motion and the liability of the top
 of the balloon to become hollowed inwards by
 the pressure of the air as shown in the lantern
 slide. To obviate this an ingenious plan was

devised by Capt. Kowanki, for automatically emptying ballast and dropping the bag. Other considerations affect this class of miniature aerial craft. M. de Fonvielle has recently pointed out that the ascending power of the free balloon is found to depend greatly on the character of the envelope by which the enclosed gas may be caused to maintain a considerably higher temperature than the surrounding air, and thus it is found that the altitude attained may vary as much as 6,000 feet between winter and summer, and 8,000 feet between day and night.

The result of these modern researches may be to modify somewhat that sectional drawing of the atmosphere which we have hitherto regarded. I submit a diagram for which I am indebted to M. de Fonvielle of the temperature readings given by a balloon sounding the depths of the aerial ocean up to some 42,000 feet. (Fig. 4) It goes without saying that within

FIG. 4.

the circumscribed area of our own country, it is hardly possible to compete on equal terms in the celestial competition now being organised on the Continent, but outside meteorology there is still a field as wide as the heavens open to the balloonist for scientific inquiry.

Many years ago, we find Professor Tyndall

expressing a desire to make use of a captive balloon to determine whether sound travelling to windward may not be tilted the heads of observers; and it is with general disappointment that we read on and find on communicating with Mr. Coxwell here that the experiment was deemed too dangerous to be carried out.

Having the solution of this question a chief end in view, I made arrangements for a series of right-away balloon ascents to place during the past summer and autumn and seven in all were carried out, under conditions differing as widely as a long-continued dry season would admit of, and including a night ascent at the end of September. From observations were secured that at least directly, throw light on the above question. The first other facts came more readily to hand. Professor Tyndall, in a series of laboratory experiments of great refinement, showed that in a tunnel or cupboard, which remained optically clear, the passage of sound was perceptibly influenced by differences of temperature, whilst the densest fumes within these chambers offered no appreciable obstacle to sound, so long as a uniform temperature was secured. I proceed to submit and illustrate as the outcome of my own aerial research, if not a slight aspect of this matter, at least further considerations of the travel of sound in our own atmosphere. Broadly speaking, there have been days during the past summer, equally clear and brilliant (as judged of by the eye, by photographs taken on the ground), in which sounds travelling upwards have differed very much in penetration. This has been tested in various ways. The heights have been carefully recorded when certain sounds have ceased to be audible, and these have very generally occurred in their own due order. We find M. Marion stating that the whistle of a locomotive rises to near 10,000 feet, the noise of a railway train to 8,200 feet, the bark of a dog to 5,900 feet, the crow of a cock and the sound of a bell to 5,000 feet, and so on, but these records must be taken as mere averages, they may, on occasions, have to be added or diminished by as much as one-half, even on such days as (so far as can be determined) on earth, optically or by meteorological readings have been practically identical. Similarly the test of echoes from earth, verified by continuous repetition, have told the same tale. Another test tried with the same result has been an adjustable resonator applied to the ear, tuned to catch most readily the continuous

rumor from earth, sometimes to be detected in this way, over a vastly extended vertical range.

The two series of pictures I proceed to show represent two days when acoustic conditions were normal, the photographs at all heights were equally and very unusually brilliant, but the noteworthy fact is that on one occasion the air up to 3,000 feet was unusually dry, and on the other was nearly as the point of saturation. The next two series of pictures were again taken in brilliant sunshine, as shown, and each were characterised equally by a blinding glare when seen from above, while acoustic conditions were then entirely at variance. As one proof of this, it may be stated that ground echoes throughout one voyage could not be heard anywhere at 1,000 feet, while on the other they were heard up to 2,500 feet. I would draw special attention to the glare to which I have alluded. It is presumably due to reflection of matter in suspension. Certain particles in the ether air present their sunlit surfaces to the observer or camera aloft, causing a dazzling reflection of light which admits of no mitigation, but which to the observer below has no effect. That these particles are other than those of water vapour would seem probable from the photographs I have shown. Are they?

I have made a great number of experiments to determine the presence of dust in the air during my balloon ascents by the use of an Aiken's dust-counter, and also by passing a known volume of air into samples of liquid, which have been subsequently compared. I have been driven to the conclusion that dust exists at different heights, and, as it would seem, not only in mere strata, but in discrete masses possibly comparable with visible clouds. I would have a similar remark to make with regard to the presence of carbonic acid. There appear to be more traces in certain tracts, and, tending to bear out this view, I would add that I have made several series of uniform exposures with sensitive films with the object of testing the actinic qualities of light from the sun at different heights, and, so far as my experiments have gone, it would appear as if altitude were not the only factor in the case. In the clearest sky, and in the same quarter of the globe, it would seem as if clouds of some kind were intervene perfectly transparent to the observer below, but offering resistance to certain waves of light and sound. Tracts of relatively warmer air are very commonly present above. During a night ascent, having

armed myself with a delicate air-thermometer, to which I gave the closest attention, I found over different localities, and at many different heights, sheets or pools of air, often shallow, 12° or 15° warmer than the temperature of the earth; and, from Mr. Welsh's records already referred to, it is conceivable that something akin to an aerial gulf stream may for a whole season flow but a few thousand feet aloft.

Were an eye so constituted as to be able to see, say, cumulus masses of warmer air, strata mottled with traces of other gases, and beds of invisible matter in suspension, one might suppose that what we deem the clearest sky would then appear flecked with forms as many and various as the clouds that adorn our summer heavens.

With regard to motion in the atmosphere, it may be stated that if the loftier and broader streams of air are found confined within definite courses, it is common in lower levels to find the wind blowing in gusts that, as it were, break up aimlessly into wandering rills. This has been particularly noticeable in kite-flying experiments, before upper currents have been reached. I submit that we have an analogy here in the way in which a drop of ink, when falling through water breaks up into numerous curling streamlets. If we can picture gusts traversing by some such mode the lower strata of air, it becomes conceivable that these may be the vehicles that convey for a fleeting interval those fugitive sounds that appear for a moment to leap across great distances. These are well-known phenomena in balloon voyages, which I have studied with the conviction that, when borne upward, they are carried by ascending shafts of air leaning or wandering with the wind. A chance sound that has reached the silence above by a "long shot," has been noticed to come not so often overhead as to windward of its source. Other evidences, too, are not wanting of the erratic or sportive course of lesser currents. At upwards of 3,000 feet we have seen thistle down pass us from below, straying aloft on some unseen "up-draught." Again, we watch the cloudlet fray out in writhing wisps and twisting streamers betraying the wanton fluctuations of the stream that bears it. Professor Tyndall's observations in Hyde-park on the fitful hearing of the Westminster clock, though not made under very advantageous conditions, would support the view that the fickleness of distant sound may be in great measure due to the play of various currents. The ear was confessedly assailed by a tumult of other noise,

but clearly also the air traversed was influenced by a multitude of intervening thoroughfares, blocks of buildings, and stacks of chimneys, which must have been the certain cause of conflicting currents.

Following up the experience gained in ballooning travel, I have lately made investigations of these fugitive sounds during continuous observations carried out through day and night hours on the Maplin lighthouse, standing far out at sea, and built on framework, against which there is no appreciable lap of water. Here sometimes the higher, and again sometimes the lower, galleries catch sounds more readily, and on one noteworthy occasion the first sounds heralding the approach of a distant steamer rose momentarily over an interval estimated at five miles. In this instance there could be no argument in favour of sound waves being tilted either upwards or downwards, and I conceive that the important question of the inaudibility of sounds at certain points within due range may need very searching investigation, in which the balloon must surely be an all-important instrument of research.

I would mention, in this connection, that in one recent voyage where the balloon lazily floated at low elevation, following the line of the Bath-road westward from Newbury, the voices of countrymen, and more particularly of children, were heard easily in our wake, over distances well exceeding a mile, the wind being very light, but a party of Tyrolese singers were unheard, though performing at no greater distance in a direction across the wind.

A very special advantage of researches made by an observer in a free balloon will always lie in the complete isolation of his observatory. He has command of a region of perfect silence and tranquility, and he has the power of altering his scope and station rapidly and without disturbance. Even the direction and rate of travel of the balloon is often under control to a very considerable extent, not so much by any method of guiding, which is very limited, and attended with obvious disadvantages, but by due observance and use of the variety of those currents already spoken of, which are often within reach. As far back as the historic voyage of the "Nassau" balloon, in 1836, Green's keen observation and admirable judgment enabled him by a masterly stroke of navigation to avoid being carried, at night-fall, out over the North Sea, and to hold his desired course across the straits of the Channel.

The track of one instructive balloon journey occurring in my own experience, and extending over the mere width of Sussex, will serve to further illustrate this point. In the Pala grounds the wind was so light that, at suggestion, the heavy grapnel was left behind so as to give us more lifting power, and with a lazy drift to the eastward we ascended on an easy gradient to a height of 2,400 feet, which time we were over Penge, and maintaining the same direction. So also until we had reached 3,300 feet, and dropped again to 2,400 feet, at which point we were over Bromley and there entered a considerable current from the north-west. Steering then a fair direct course with sundry fluctuations of height and direction, an altitude of 8,500 feet was reached near Hawkhurst, when, our course being rapid and nearly due south, we were quickly carried over Hastings old town. At this moment, though the management of the balloon was wholly entrusted to the unrivalled skill of Mr. Percival Spencer, I confess I was unable to see any way to avoid our dropping into the sea, save by trying conclusions among the forest of chimney-pots that already lay before us. But the discrimination of our aeronaut was prompt and unerring, and with a display of perfect judgment, a descent was made where the lower westerly current was once again encountered, now blowing stiffly along shore, and we were thus brought to near the verge of the cliffs, in the outskirts of Fairlight Glen.

But there are possibilities in the balloon much other physical investigation, and this virtue of the fact already insisted on, that an aerostatic observatory, we may remove ourselves from all disturbing influence of earth. Mountain observatories may show an elevation of 4,000 feet and upwards, and even claim certain freedom from radiation off the valley by reason of lower circumjacent fogs, but the very nature of a mountain is such that gross air is attracted and hangs about its height, and, as a consequence of the neighbourhood of rock surfaces more or less heated, currents of local origin, even under most favourable conditions, must be constantly finding upward and downward passage on slopes of unequal and varying temperatures.

The force of the wind is another difficult matter to be reckoned with. It was said at one time that Mount Hamilton that the wind often blew at the rate of 60 miles an hour, and that a greater velocity was never recorded only because at that point the anemometers carried away.

the additional instrumental aid of properly designed spectroscopic and telescopic instruments, it is reasonable to hope that at high altitudes we may penetrate with greater success than heretofore into the ultra-violet spectrum, and even under conditions of filtered air-glare to photograph the sun's disk without eclipse. It is easy to conceive valuable experiments can be made when this is "British" of the atmosphere is left undecided with questions of refraction and problems; and, I think, we may go on and even venture to hope to put to a test some of the markings on sister planets and other celestial wonders that have elsewhere claimed as visible with very powerful instruments, or else, by yet happier means, to banish them for good beyond the limits of all controversy.

DISCUSSION.

THE CHAIRMAN said they had had the most interesting details of Mr. Bacon's numerous ascents, and that as many of his experiments were of a quite unlike any previously made. The aerological experiments were of special interest, and would doubtless prove to be of considerable importance. He could quite appreciate what had been done, but the variability of gusts of wind, from his own experience with kites, though he was inclined to think there had been some exaggeration with regard to the currents in different directions in the upper air. He said to him that if there were any great variety of winds, they would be shown by the clouds, and that he occasionally they did see clouds moving in different directions, yet on ordinary occasions they all seemed to be going more or less the same way. He had watched the stream of highest cirrus in the neighbourhood of the trade winds, and it was wonderful how the current seemed to flow in the opposite direction to the trades, though the motion appeared very slow and would probably escape the notice of the casual observer, unless it were watched against a celestial body, such as the moon. He knew that there was in ballooning from not being able to depend on one current of air. On one occasion he had made an ascent from Aldershot, with the intention of going to Ascot; the day was cloudy, but they got through the clouds, and, after a time, thinking they were about over Ascot, descended, and found themselves on the other side of Guildford, having gone in almost exactly the opposite direction to what they intended. This led to the question of balloon steering, and he could not help referring to the latest reports with regard to the bold adventurers who some two years ago to explore the Arctic region. These reports seemed to have more value of truth than some previous rumours,

and though it would be very sad if the death of those brave explorers were confirmed, it would be some satisfaction to have a record of their journey. Several attempts had recently been made to test the principles adopted by Andree—of steering by a sail and a guide-rope—but, unfortunately, they had been rather meagre, and he hoped to take part soon in some more thorough tests of longer duration. But, after all, this method was somewhat rough and primitive; and what the public wanted to know was when there would be a really navigable balloon. There was, in his opinion, only one simple reason why that had not been attained, and that was that they could not get the needful money. Hitherto, all attempts had been on a very small scale, and the balloon of to-day must be compared to the coracle of the ancients. It was a small vessel, capable of lifting two or three men, and simply drifted with the current. Occasionally attempts had been made to propel a balloon against the wind, and on several occasions one had been propelled at the rate of some 14 miles an hour, but they were only small experiments in what we may call aerial canoeing. They had recently read about the greatest attainment in modern shipbuilding, the *Oceanic*. He had made calculations, from which it appeared that if, instead of being an ocean liner, she had been an aerial vessel with a length of 700 ft. and a diameter of 70 ft., she would contain 2,500,000 cubic feet of hydrogen, and would lift a weight of 180,000 lbs. With due allowance for the weight of such a structure with engines of some 2,000 horse power, there would still be available lifting power to carry 200 passengers, or soldiers with their arms, and he could not see any insuperable difficulty in constructing a balloon of that size, with engines which would give a speed of 30 miles an hour. Even if such a vessel were dependent upon fine weather, would it not be most useful? He looked on these things from a military point of view, and he thought such an instrument would be of incalculable value not only in a European war, but for such purposes as fighting amongst the pathless mountains on the Indian frontier, or the swamps of Africa. They had heard a good deal lately about universal peace, but he thought this would be a solution of the difficulty, for if one nation possessed such powerful machines, she could dominate all others. England, by possessing a strong navy, was able to dictate to other nations, and she would be in a still stronger position if she possessed powerful machines capable of traversing the air. Perhaps this was rather diverging from the subject of the paper, but with regard to scientific research also, most extraordinary results would be attained by means of navigable balloons. If they had frequent reports of the state of the atmosphere at all heights, round the country and out at sea, practical meteorology would be very much assisted. All difficulties, too, of geographical research would disappear.

Admiral Sir ERASMUS OMMANNEY, K.C.B.,

asked whether the magnetic compass retained its directive force at high elevations.

Mr. PERCIVAL SPENCER said he had listened to the paper with the greatest pleasure, for though he had had the honour of accompanying Mr. Bacon on most of his ascents this was the first time he had seen the photographs. The meetings of the Aeronautical Society generally dealt with abstruse subjects more visionary than real, but here they had seen the actual results. The last time he was in that room it was to listen to an account of a flying machine by Mr. Davidson; it seemed to be a cross between a navy's pick-axe and a blacksmith's anvil, and though the author demonstrated theoretically how well it would work, he was not aware that he had ever got an inch off the ground with it. In former days the Balloon Society dealt occasionally with this subject, but it had now ceased to exist, and given place to the Aeronautical Society, and he should like to see its discussions take a more practical turn. Mr. Bacon had shown how a balloon could be used as a floating observatory, and it was evident that a great deal could be done with balloons even as they existed at present. It was all very nice to talk about steering balloons, but there was one unfortunate point to be borne in mind. When in an ordinary balloon, going with the wind, you were in an absolute calm; but if an immense aerial machine such as the Chairman had described, were constructed, propelled with enormous force, all that would be changed, and the pleasures of ballooning would give way to the ordinary discomfort of a sea voyage. He well remembered how tranquilly he floated across to Havre recently in a balloon, and how in coming back by steamer, he was interrupted many times in writing his article for the *Times*, by occurrences which were anything but pleasant.

Mr. ERIC S. BRUCE thought one of the first things to be aimed at in balloon manipulation was an improvement in the power of vertical motion, so as to be able to rise without a sacrifice of ballast, and to descend without a sacrifice of gas. It had been said that ballast was the life-blood of a balloon, and it was quickly exhausted. It was, of course, a difficult problem, but he could not help thinking that Professor Dewar's achievements in liquefying hydrogen might be turned to advantage. At any rate, this was the most important thing; the direction of horizontal motion was quite secondary. Mr. Bacon was to be congratulated on his efforts to explore the higher regions of the atmosphere, for meteorological science was being kept back from the want of men of sufficient heroism to trust themselves to a bag of gas; and it was a great pity that more systematic experiments could not be carried on in this direction. Mountain stations were always affected by terrestrial disturbances, and the value of isolated observations had been

shown even in the case of the Eiffel Tower. He believed that the varying currents depended very much on the electrical condition of the atmosphere, for they were very frequent during thunderstorms. He had made a number of experiments in Switzerland with pilot balloons when thunderstorms were in progress, and found that numerous currents were flowing in different directions, though he had no means of measuring them on the balloons by which the currents could be measured. The thanks of all interested in aerology were due to the Chairman for having practically suscitated the Aeronautical Society. He had increased not only the number but the quality of the members, having persuaded some eminent men of science to join, and to take an interest in the subject, which must tend to stimulate invention and discovery.

Mr. G. FENTUM PHILLIPS thought Government ought to find the money necessary for constructing aerial machines. The nation which first possessed a navigable balloon would certainly be in a position to dictate to other powers; and such an achievement would be far more practical than any amount of money spent about universal peace. When they saw governments like that of the United States or Great Britain spending a million and a-half on a battle-ship, which would be utterly useless in the presence of an aerial machine, he thought the Government might reasonably be asked to vote a certain sum of money to a committee of scientific men and engineers, to be practically with this question. You could not entrust a private individual, even if he were a millionaire, to devote half his life and the whole of his fortune to a project from which he would derive no benefit.

Mr. LEON GASTER said an ordinary sized balloon was quite sufficient for scientific research, and he did not think an immense structure, such as the Chairman had alluded to, rendered buoyant by gas, would be a practical machine. For the purposes he had in view, a flying machine would have a much greater prospect of success.

The Rev. J. M. BACON, in reply, said he would regard to the magnet, Mr. Glaisher had reached a great altitude as anyone, and it was one of his favourite experiments to test the oscillations of a magnet under all circumstances. He had never recorded any failure of the directive power. His instrumental equipment was so inadequate that he could not give any personal opinion on the question raised.

The CHAIRMAN then proposed a cordial vote of thanks to Mr. Bacon, which was carried unanimously, and the meeting adjourned.

Miscellaneous.

FOREST WEALTH OF BRITISH COLUMBIA.

In consideration of the economic products of Columbia, the timber wealth naturally takes a prominent part, as apart from minerals it represents the most important and readily available results. British Columbia may be said to possess the greatest concentration of merchantable timber on the North American Continent, and if it had not been for the great forest fires that have raged in the interior since the war of 1862, during which a very large portion of the surface has been denuded of its forests, the timber supply would have been much greater than in any other part of the continent. As far north as Alaska, according to a recent report by the secretary of the British Columbia Department of Statistics, the coast is heavily timbered, the western coast line following the indentations and river valleys and ascending the mountain sides. Logging operations have been extended to Knight's Inlet, a point on the coast of the mainland opposite the north end of Vancouver Island. Here the Douglas fir, the most abundant and widely dispersed of the valuable trees, stands side by side with the cedar, hemlock, spruce, and yellow pine, and the cypress or yellow pine takes its place. North of this, cedar, hemlock, spruce, and yellow pine are the principal timber trees. It will be interesting to know that the Douglas fir was named after James Douglas, a noted botanist who explored New Caledonia in the early part of the century. It is a widely distributed tree, being found from the base of the summit of the Rocky Mountains, and as far east as Calgary, and as far north as Fort McMurray. On the coast it attains immense proportions, sometimes towering 300 feet in the air, and with a base circumference of from 30 to 50 feet. It is the staple timber of commerce often classed with the Oregon pine. It has about the same specific gravity as oak, with great strength and has a wide range of usefulness, being especially adapted for building purposes. It is scientifically described as being midway between the spruce and the cedar, and in the opinion of the Dominion Forestry Commission is a valuable pulp-making tree. Probably the next most important representatives of the timber wealth are the red cedar and the yellow cedar. The yellow cedar is found all over the province, but reaches its greatest development on the coast where it outstrips all others. In addition to its commercial value for building and finishing purposes, it is the friend of the settler, inasmuch as out of its straight-grained wood he can build his house, make his furniture, and run his farm, and that with the use of the most primitive tools only. It is especially valuable, however, for interior finishing, being rich in colouring, and taking a beautiful polish. For this purpose it has an extended market in the east of Canada. The most important as the red cedar is, the yellow cedar,

though much more limited in area and quantity, is still more important and useful. It is very strong, comparing with the Douglas fir in this respect, is wonderfully durable, finishes to perfection, and grows to great dimensions. The cypress, which is found in great quantities in the interior of Vancouver Island, and on Mount Benson, near Nanaimo, comes within 1,200 feet of the sea. Towards the end of the island, on Queen Charlotte Islands, and on the north coast of the mainland, it is found lower down and is very plentiful. It is out of the cedar that the Hydah Indians build their celebrated war canoes, some of which have an eight foot beam, are 60 feet long, and can stem the heaviest seas of the coast waters. Next comes the white spruce. Its habitat is principally low, swampy, and delta lands, usually interspersing the forest of fir and other trees, but in no place is it found on very large or compact bodies. From its comparative scarcity and the many uses to which it may be put, it is commercially more valuable than the Douglas fir. It attains a circumference almost equal to the latter, but does not grow so tall or so clear of branches. It is utilised largely in making doors, salmon boxes, barrels, fruit boxes, and many other similar purposes, being as it is, the best adapted for these uses of all the native timbers. It is *par excellence*, the wood for pulp manufacture, which is expected to become one of the most important industries of the province. Hemlock is a common timber, and up the coast is found in considerable quantities. It is a useful tree and answers about the same purpose as the Douglas fir, and for that reason it will not be in general demand until the latter has become to some extent exhausted. White pine for cabinet purposes and general utility is very valuable, but is limited in quantity. Balsam poplar is widely distributed, being found principally in river valleys, but is commercially of little value except for pulp. With the exception of the yew, and tamarack, of which there are several varieties, the foregoing are the representatives of the family of coniferous trees. Of deciduous trees, the large leaf maple, vine maple, alder, crab apple, oak, two varieties of poplar or cottonwood, and aspen poplar, arbutus, birch, willow, and juniper, are the principal. The maple, alder, and arbutus make first-class cabinet woods, though they are not abundant enough to be extensively used for this purpose. They also make popular finishing woods. Poplar, or as it is most commonly called, cottonwood, will, it is expected in the future, be greatly used in paper making. The aspen poplar is common in Vancouver Island and the northern interior of the province. It is also a good paper maker. The oak is mainly confined to the southern end of Vancouver Island. It is a stunted, gnarled species, of little use, but very picturesque. Crab apple is plentiful in swampy places, around ponds, beaver meadows, and along river banks. The hard woods are usually found in bottom lands and indicate fruitfulness of the soil. There is no part of British Columbia where the timber supply is not

sufficient for local demands. There are over eighty sawmills in the province, large and small, with a daily capacity of about 2,000,000 feet, mainly on the coast, but the limit has never been reached, the annual cut running between 50 and 100 million feet. Various estimates have been made of the amount of timber in sight. These range between 40 and 100 billion feet. The average of timber under lease is about 1,175 square miles, and the total area of forest and woodland put down by the Dominion statistician as 285,554 square miles, but this must not be taken as all of commercial value, as much of this is covered with small trees suitable only for a local supply of fuel and lumber. The future of the lumber industry in British Columbia is very promising, and when foreign demand fully revives, and the Nicaraguan Canal has been completed, it cannot fail to receive an immense impetus.

Correspondence.

THE JABLOCHKOFF KAOLIN-CANDLE LAMP OF 1877-8, COMPARED WITH PROF. NERNST'S NEW ELECTRIC LAMP OF 1898-9.

Mr. G. HURLSTONE HARDY writes as follows:—As the instructive discussion lasted so long after Mr. Swinburne's most excellent paper describing Nernst's new invention, I thought it as well, the hour being late, to refrain from intruding my observations upon the audience. However, after reading this week's *Journal* I do think that something should be said for a more adequate appreciation of the career of Mons. Paul Jablochhoff. I had the opportunity of taking the greatest possible interest in Jablochhoff's inventions, by reason of my then superintending (on behalf of the late B. Woodcroft, F.R.S.) the Patent-office abridgements relating to electricity and magnetism, a revision of which unwieldy work I was then engaged upon preparing in the six distinct groups which have been adopted with but little change (and no improvement) by the new Patent-office technical staff. The late W. H. Walenn, and the late Dugald Campbell, then engaged by the Commissioners of Patents, were both concerned, the latter especially, as professional experts in the British exploitation of Jablochhoff's inventions which were said to have suffered from not falling into good hands, financially. However, I, as the very intimate colleague of Mr. Walenn and Mr. Campbell, am here only concerned in upholding the high merit of Jablochhoff's inventions. One speaker, at least, predicted shocking attempts to rob Professor Nernst of his glory and due reward. The real merits of the eminent professor hardly require to be enhanced by such observations, which seemed to me to savour of the slightly too obtrusive championship of the company promotor type. Professor Nernst's fame

will survive paltry attacks as well as overwrought flattery; it must in the end be gauged by real and critical study, without shutting one's eyes to any source of knowledge new or old.

Jablochhoff's "kaolin-candle" lamp can be read about in his specification of Letters Patent 1877, but the whole series of the specifications patented inventions should be perused to ascertain the exact degree to which Jablochhoff advanced common knowledge in the direction of Professor Nernst's brilliant invention. My own recollection and persistent inquiries of Messrs. Campbell and Walenn, respecting the kaolin-candle, enable me to be very confident that Jablochhoff was a conscientious worker, and no mere presumptuous patent applicant anticipated but untried possibilities.

At the great electrical exhibition, held in the Albert-hall, Jablochhoff's kaolin-candle lamp was shown and lighted up, but the inventor and his exploiters chose rather to expend their energy on electric lighting, with the aid of their "carbon-candle," which consisted of two parallel carbon rods cemented together by a white material (clay or whiting, &c. I was much surprised by Jablochhoff's persistence in maintaining that his "carbon-candles" owed much of their light-giving power to the glow of the incandescent cement. To this day I have inclined to believe him against the allegations of electricians who assured me to the contrary, giving as their inconclusive proof that Jablochhoff's arc lamp consumed more current than the more ordinary forms of arc lamp. Apart from financial troubles, the disuse of Jablochhoff's carbon-candles was attributable to the imperfection of carbon rods as then made; this fact rendered the automatic re-lighting of the Jablochhoff arc lamp, when accidentally extinguished, not as facile as other arc lamps.

Now, as to the comparatively unknown "kaolin-candle" lamp. Jablochhoff has placed on record the patent specification, No. 1996 of 1877, with necessary detail with admirably lucid explanation, considering the state of electrical knowledge at that time. The illustrated description of the kaolin-candle lamp, together with the public exhibit thereof, establish facts that cannot be impeached. I was myself told at the Albert-hall that the kaolin-candle was ignited by the use of a piece of lead attached to the porcelain "slab" as an initial conducting "match." Remembering to be content with this explanation my eager inquiries were satisfied by Mr. D. Campbell, who informed me that the igniting match was composed of graphite or carbon powder and treacle dried upon porcelain, in fact what a housemaid would call lead paste. This confusion of lead and black reminds me of the misunderstanding of a puisne judge who (in a trial for the infringement of a patent for soldering lead pipes) astonished the Court by his observation:—"Do you know," said the judge, hearing of all the bystanders, "I read a singular case the other day; there is only one single lead mine in the world; it is in Cumberland, and in order to

the supply it is opened only for three days in the

Lochhoff certainly thought that his two kinds of candles greatly resembled each other in principle, although he clearly observed that his carbon-candles were consumed rapidly, whilst the kaolin-candle was consumed so slowly as not to require daily renewals. Lochhoff said that his kaolin-candle (or as a substitute a slab of some other refractory body) yielded a constant light, whilst the substance was slowly consumed. From my own casual observation I should have called the light bright, but by no means dazzling, and should have said that the so-called "candle" was not consumed in the slightest degree, the "carbon" only being consumed.

Lochhoff gave one single explanation of the difference of the led electric arc or glowing air-gap. Respecting the convection of current through "non-conductors," he said that where one electric spark travels, there is a space prepared whereby a succession of sparks can travel their way; that a non-conducting refractory (placed between two terminals) will, under the influence of the electric current, become an active conductor along all points touched by the sparks; that it will become heated to incandescence. A "tension current," he explained, is his object best, and that a "quantity" current will consume the kaoline. He worked his lamps, not only by the alternating current, but they could be stalled on a continuous current circuit by the introduction of interrupters and condensers.

As far as the progress of the world at large is concerned, the only gauge of merit is success. Hence the re-discovery of a forgotten invention, or the reduction and improvement of a neglected invention may be as great a benefit as any other moral invention. As ranking in a purely theoretical order of merit, an extra meed of praise seems due to a man who achieves a great discovery at the early stage when scientific knowledge did not so clearly lead the way, and who may have utterly failed to achieve success, perhaps, because countenance and support were lacking to his best efforts.

Obituary.

GEORGE A. SPOTTISWOODE.—By the death of Mr. George A. Spottiswoode the Society of Arts loses a member of 46 years' standing. Mr. Spottiswoode had joined the Society in 1853. He was born in London and at an early age became associated with the printing establishment whose fortunes he had successfully directed for many years before his death. He took great interest in Church matters, having been connected with many Church institutions, and being at the time of his death Vice-Chairman of the House of Bishops of Convocation. Mr. Spottiswoode served as a Member of Council for a short time in the year

General Notes.

IRON FELT.—This is the name given to a new insulating substance made at the Adlershof Works, near Berlin, and for which numerous applications have been found. The felt consists essentially of long and strong woollen fibres, impregnated with a by-product of petroleum, and then coated (with a certain amount of penetration) by gelatine rendered insoluble, and also (alternatively or in addition) with india-rubber, afterwards vulcanised. After being subjected to considerable pressure, the iron felt assumes the form of plates, measuring 20 sq. dm. (2 sq. ft. 22 sq. in.) and upwards, with a thickness varying from 1 to 5 centimetres (13-32 in. to 2 in.). These plates are very elastic, being practically imperishable, while they will stand a pressure of 1,458 kg. per sq. cm. (20,736 lbs. per sq. in.); and their surface is so hard as not to be cut by the sharp edges of bolt heads or of iron girders. Placed as a cushion between rails and their chairs, or sleepers, underneath plumper-blocks or between engines and their foundations, this substance is also stated, by *La Nature*, to prevent vibration.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 22.—"The Gold Mines of West Africa." By JAMES IRVINE.

In consequence of the indisposition of Mr. Philip Dawson, his paper on "Electric Traction," announced for the 22nd, has had to be suddenly postponed. Due notice will be given of the date on which it will be read.

MARCH 1.—"Leadless Glazes." By WILTON P. RIX.

MARCH 8.—"Cornish Mines and Miners." By J. H. COLLINS, F.G.S.

MARCH 15.—"Liquid Fuel." By Sir MARCUS SAMUEL. Sir EDWYN S. DAWES, K.C.M.G., will preside.

MARCH 22.—"London's Water Supply." By WALTER HUNTER, M.Inst.C.E.

Dates to be hereafter announced:—

"Preservation of Timber." By S. B. BOULTON.

"Coal Supplies." By T. FORSTER BROWN.

"Wireless Telegraphy." By W. H. PREECE, C.B., F.R.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 9.—"Leprosy in India." By H. A. ACWORTH, C.I.E., late Government Municipal Commissioner for the City of Bombay.

This meeting will be held at the Imperial Institute.

FOREIGN AND COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

FEBRUARY 28.—“Persian Trade Routes.” By A. HOTZ. Major-General Sir OWEN TUDOR BURNE, G.C.I.E., K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

FEBRUARY 21.—“Vitreous Enamels.” By CYRIL DAVENPORT. Sir OWEN ROBERTS, M.A., D.C.L., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

ARCHIBALD SHARP, A.M.Inst.C.E., “Cycle Construction and Design.” Four Lectures.

LECTURE I.—FEBRUARY 20.

Introduction—The modern bicycle—The frame—Strength and stiffness—Pedal pressure—Chain-struts—Round, D, and rectangular tubes—Frame of lady's bicycle—Tandem frames—Front-fork—Spring-frames.

LECTURE II.—FEBRUARY 27.

Ball-bearings—Hubs—Pedals—Crank-brackets—Steering-head—Adjustment—Wheels—Direct-spokes—Tangent-spokes—Rims—Materials used in cycle construction—Steel—Malleable-iron castings—Wood.

LECTURE III.—MARCH 6.

Driving gears—Length of crank—Block chain—Roller chain—Chain-wheels—Bevel gear—Lloyds' cross-roller gear—Compound gears—Two-speed gears—Free-pedals—Tricycle-axle.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 20...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Archibald Sharp, “Cycle Construction and Design.”

Imperial Institute, South Kensington, 8½ p.m. Sir Horace Tozer, “Thirty-eight Years in Queensland.”

Surveyors, Savoy-street, W.C., 8 p.m. Mr. J. L. Crouch, “The Management and Valuation of Brickfields.”

Cleveland Institute of Engineers, Middlesbrough, 7½ p.m.

British Architects, 9, Conduit-street, W., 8 p.m. Messrs. J. M. Brydon and F. J. Burgoyne, “Municipal and Public Libraries.”

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Professor Beale, “Life.”

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Sidney Lee, “Shakespeare in Folio.”

TUESDAY, FEB. 21...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. Cyril Davenport, “Vitreous Enamels.”

Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lancaster, “The Morphology of the Mollusca.” (Lecture VI.)

Civil Engineers, 25, Great George-street, S. p.m. Discussion on paper by Messrs. Jeron and Archibald P. Head, “The Lake Superior Ore Mines and their Influence upon the Production of Iron and Steel.”

Statistical, 9, Adelphi-terrace, W.C., 5 p.m. Price Howell, “Comparative Statistics of Australian Railways.”

Pathological, 20, Hanover-square, W., 8½ p.m. Photographic, 12, Hanover-square, W., 8 p.m.

F. H. Glew, “Demonstration with Violet E. Waves for actuating Photographic Apparatus for Photographing Lightning in Daylight.”

Anthropological, 3, Hanover-square, W., 8½ p.m. Zoological, 3, Hanover-square, W., 8½ p.m.

F. P. Moreno, “A Portion of Skin, *Neomylodon listai*, from a Cavern near Co Cave, Last Hope Inlet, Patagonia; with a description of the Specimen by Mr. A. Smith Woody.”

2. Surgeon P. W. Bassett-Smith, “The Formation of the Coral Reefs of the N.W. Coast of Australia.”

3. Mr. G. A. Boulenger, “A Collection of Reptiles and Batrachians, made by D. La Touche in N.W. Fokien, China.”

WEDNESDAY, FEB. 22...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. James Irvine, “Gold Mines of West Africa.”

Geological, Burlington-house, W., 8 p.m. 1. T. G. Bonney and Miss C. A. Raisin, “Vegetation of Serpentine and Associated Rocks in Anglesea.”

2. Miss J. Donald, “Remarks on the *Clectomania*, Kohlen, and *Hormotoma*, Salter, Japan Society, 20, Hanover-square, W., 8 p.m.

Mr. Chokuro Kadono, “Japanese Railways.” British Astronomical, Sion College, Victoria-embankment, W.C., 5 p.m.

THURSDAY, FEB. 23...Royal, Burlington-house, W., 4 p.m. Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 8 p.m. Rev. Canon Benham, “Winchester Cathedral.”

Sanitary Inst., 74A, Margaret-street, W., 8 p.m. Dr. Herbert Manley, “Sanitary Law.”

Royal Institution, Albemarle-street, W., 8 p.m. Dr. A. Macfadyen, “Toxins and Anti-Toxins.” (Lecture III.)

Electrical Engineers, 23, Great George-street, W., 8½ p.m.

FRIDAY, FEB. 24...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Prof. Lodge, “Cohereers.”

Civil Engineers, 25, Great George-street, W., 8 p.m. (Students' Meeting.) Mr. R. C. Mackay, “The Loss of Heat from Buildings.”

East India Association, Westminster Tower, 3½ p.m. Lieut.-Col. R. C. Temple, “The Development of Currency in the Far East.”

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Chemical Society's Rooms, Burlington-house, W., 5 p.m. 1. Mr. E. F. J. Lovell, “Joule-Thomson Thermal Effect.”

2. Mr. Griffiths, (a) “A Study of an Apparatus for the Determination of the Rate of Diffusion of Gases.”

(b) “Note on the Rate of Diffusion of Gases in Liquids;” (c) “Note on the Rate of Diffusion of Gases in Solids.”

(d) “Note on the Rate of Diffusion of Gases in Liquids.”

SATURDAY, FEB. 25...Education Department, South Kensington Museum, S.W., 3½ p.m. Mr. William L. Bragg, “Pottery.”

Botanic, Inner Circle, Regent's-park, N.W., 8 p.m. Royal Institution, Albemarle-street, W., 8 p.m.

Mr. J. H. Leigh, “The Mechanical Properties of Bone.” (Lecture III.)

Journal of the Society of Arts.

No. 2,414. VOL. XLVII.

FRIDAY, FEBRUARY 24, 1899.

Communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

Monday evening, 20th instant, Mr. HIBALD SHARP, A.M. Inst. C.E., delivered first lecture of his course on "Cycle Construction and Design." The lectures will be published in the *Journal* during the summer recess.

APPLIED ART SECTION.

Wednesday evening, February 22, 1899; Sir W. C. ROBERTS, D.C.L., F.S.A., in the chair. Paper read was on "Vitreous Enamels," by ERIC DAVENPORT. The paper and report of the discussion will be printed in the next number of the *Journal*.

The paper announced for March 14, on "The Art of Craftsmanship and its place in a National Scheme of Art Culture," by Sir WILLIAM BRIDGES RICHMOND, K.C.B., R.A., is unfortunately postponed.

COVERS FOR JOURNAL.

For the convenience of Members wishing to purchase their volumes of the *Journal*, cloth covers will be supplied post free for 1s. 6d. on application to the Secretary.

Proceedings of the Society.

REPORT OF COMMITTEE ON ACETYLENE GENERATORS.

Committee.—Major-General Sir Owen Tudor, G.C.I.E., K.C.S.I. (Chairman); Sir Frederick Bramwell, Bart., D.C.L., F.R.S.; and Professor James Dewar, M.A., LL.D., F.R.S.;

Harry Jones, M.Inst.C.E.; Professor Vivian B. Lewes; Boverton Redwood; Professor Sir W. C. Roberts-Austen, K.C.B., F.R.S.; Professor J. M. Thomson, LL.D., F.R.S.; Sir Henry Trueman Wood, M.A. (Secretary).

The following is the Report of the Committee on the Exhibition of Acetylene Generators at the Imperial Institute (opened June 15th, 1898):—

To the Council of the Society of Arts.

GENTLEMEN,—We, the undersigned, having been constituted a Committee by the Council of the Society of Arts, to enquire into and report to them on the requisite conditions of safety in Acetylene Gas Generators, and also to lay down rules as to the admission of apparatus to the Exhibition of Acetylene Gas Generators held at the Imperial Institute in 1898, have the honour to submit to you the following report:—

It being common knowledge that amongst the large number of generators constructed and sold to the public, there were some which did not conform to the ordinary conditions of safety, it was felt that in undertaking an Exhibition of Generators for Acetylene to be held at the Imperial Institute, a preliminary test should be made of all the generators submitted for exhibition, and that the generators which did not satisfy the necessary conditions should be rejected.

The London County Council generously placed at the disposal of the Committee, premises in the Harrow-road, where the preliminary tests of all the generators submitted were carried out, and the various forms of apparatus as they were passed having been forwarded to the Imperial Institute, the Exhibition there was opened on June 15th, 1898.

Although beyond the scope of their instructions, your Committee felt that in the interests of the public, it was advisable to carefully test the various forms of generator working for the period of a month, as it was possible that defects which might not be apparent in the test extending over a few hours might be detected on working over a longer period.

Professor Vivian B. Lewes and Mr. Boverton Redwood were appointed as a Sub-Committee to examine into the working of the acetylene generators exhibited at the Imperial Institute, and to report to the Committee as to the results obtained and as to the generators to which

certificates should be granted. The method adopted for testing is shown in Appendix C.*

As the result of these tests, the Committee advised the granting of certificates for those forms of acetylene generators, a list of which is appended, the certificate, however, merely setting forth that the generator had complied with the requirements of the various tests to which it had been submitted, and had worked safely and satisfactorily during a month's every day use.

The Exhibition at the Imperial Institute has clearly demonstrated that many types of acetylene gas apparatus can be so constructed as with ordinary precaution to be absolutely safe, and that lighting by acetylene need be no more fraught with danger than are any of the other forms of artificial lighting in general use.

In granting certificates to the various makers of apparatus herein-before mentioned, we wish it, however, to be clearly understood that such certificate can only apply to the type of machine examined and tested by us, and must not be taken as applying to all and every class of machine which may be offered for sale by the same makers. By type of machine is meant apparatus of the designs shown in Appendix E.

We consider that the various makers of apparatus who, at so early a period in the development of acetylene lighting, submitted their machines to the rigid tests as to safety laid down by your Committee, and have obtained certificates, are entitled to the first consideration from the public.

There may be other forms of generators not exhibited at the Imperial Institute, which are perfectly reliable, but we strongly recommend that no machine should be purchased from any maker or dealer unless a certificate can be shown from some competent authority to the effect that it complies in substance with the rules laid down in Appendix B, and that it has been submitted to and has satisfactorily passed the tests indicated in that Appendix. In this respect, fire insurance companies could render great assistance to the public in refusing to insure without such certificate being forthcoming.

General conclusions as to the working of each generator during the testing period are given with the diagrams. All the machines to which certificates were granted worked satisfactorily, some better than the others. It is only fair to state that in the few instances where shortcomings are indicated the defects were in many cases remediable, and that

possibly, owing to the experience gained by the exhibitors during the testing period, may have since been remedied. Apparatus, therefore, should not be condemned because during the trials the working in any particular case was not all that could be desired.

A point of considerable interest is the volume of acetylene gas produced per lb. of carbide used in each generator. Amongst the *automatic* generators there were three which gave during the whole of the testing period an average slightly more than 4.5 cubic feet per lb. the remainder varying from slightly under 4 to as low as 3.55. Amongst the *non-automatic* generators one gave an average of 4.5 cubic feet, the others showing much less.

The carbide of calcium used both at Harrow-road and at the Imperial Institute was supplied in bulk by the Acetylene Illuminating Co., Ltd., from Foyers, and was found throughout of excellent quality. It was weighed out and supplied to the exhibitors by Mr. Duffield, the assistant appointed by the Committee.

Although it does not follow that the generator which yields the largest amount of gas is necessarily the best, yet this factor is a most important one in the choice of any apparatus. The generators which combine the largest yield of gas with strength of material, simplicity in charging the carbide, and in emptying the residue are those which will recommend themselves to the public.

Where the public is most likely to be misled is by the exaggerated claims made by makers as to the number of lights which a generator machine will supply, and herein may possibly be an element of danger due to excessive heating caused by too rapid generation. Even if there be no danger, the overheating will considerably lessen the quantity and lower the quality of acetylene gas evolved from the carbide, as explained as tending to cause smoking of the burners as pointed out in Appendix F.

We recommend that every apparatus should be accompanied by a written guarantee that it will light a specified number of burners, consuming a given quantity of gas per hour, over a consecutive number of hours without increasing the temperature in any part of the carbide receptacle, above 228°C , it is to say, the fusing point of tin.

In regard to precautions to be taken we endorse the suggestions of the Public Corporation of the London County Council of the Corporation of the City of London.

As to licenses for storing carbide of calcium

* The Appendixes are printed separately, and are not given in the *Journal*. See note at end of Report.

n, we consider that Local Authorities need e no hesitation in granting such licenses storage provided it be shown to their satisfaction that the material is properly packed, l that it is intended to store it in some dry l well ventilated place.

We consider that no carbide should be purchased without a guarantee that it is free from impurities in quantities sufficient to cause danger, and the name and address of the manufacturer should be given on each package. It should also be guaranteed to give off an average of 5 cubic feet per pound of carbide when used in a good generator.

As will be seen from Appendix G, the Home Office regulations allow 5 lbs. of carbide to be kept without a license in packages of 1 lb. each. We recommend that however small the quantity, it should always be kept in closed cans or bottles, under lock and key, and in a safe place. When its properties are more fully known, these precautions may not be necessary as it is no more dangerous than many other substances in daily use.

It was not within the scope of the work of the Committee to report upon portable apparatus and lamps to be used within the house. Your Committee, however, feel it their duty to state that it is as safe as they consider acetylene gas to be, when generated in a properly constructed apparatus outside the building to be lighted, and in accordance with the rules and suggestions contained in this report, they are of opinion that the generation of gas within the house is not unattended with danger, except in the hands of skilled hands.

As to cycle lamps, carriage lamps, &c., though requiring only small charges of carbide, we consider that great care is required in their manipulation.

We consider that non-automatic generators which a holder capable of taking the gas generated from the largest charge of carbide the generator will hold, are free from objections and that all automatic generators examined by us, and we are of opinion that every generator could be fitted with an arrangement by which the gas can be rinsed out of the generating chamber by acetylene or some inert gas before the operation is allowed to commence between the generator and carbide.

We are also strongly of opinion that every generator should be fitted with a purifying chamber or chambers, in which the acetylene is purified from ammonia and sulphuretted and phosphuretted hydrogen and from other impurities.

The thanks of the Committee are due to Mr. F. G. Worth, of the Acetylene Illuminating Company, for the help he has given them throughout the investigation.

We have the honour to be

Your obedient servants,

OWEN TUDOR BURNE.
FREDERICK BRAMWELL.

The Report is also issued in pamphlet form, with appendixes giving particulars of the tests, diagrams of the apparatus, &c. The price is one shilling; it can be obtained from the Secretary, Society of Arts, John-street, Adelphi, London, W.C.

Any member desiring a copy of the pamphlet can obtain one gratis on application to the Secretary.

INDIAN SECTION.

Thursday afternoon, February 9, 1899 (at the Imperial Institute); the Right Hon. the EARL OF NORTHBROOK, G.C.S.I., D.C.L., F.R.S., in the chair.

The paper read was—

THE PENAL SYSTEM AT THE ANDAMANS.

BY COL. RICHARD CARNAC TEMPLE, C.I.E.,
Chief Commissioner of the Andaman and Nicobar Islands.

Let me commence my remarks this evening by inflicting on you a little geography. The Andamans form, no doubt, a portion of the earth not very well known: they may be said to be practically unknown, except for one startling and very tragic event, the murder of the Viceroy of India, Lord Mayo, in 1872. So, if any of you have no previous knowledge of the islands, you may fairly consider your ignorance excusable. But that is all the more reason why I should say something to enlighten you this evening.

The territory in my charge, under the Government of India, is known as the Andamans and Nicobars, and consists of a long and narrow string of very numerous islands, running north and south down the middle of the Bay of Bengal. The extreme south of the Nicobar groups is within 100 miles of Sumatra, and the extreme north of the Andaman groups is somewhat further from the coast of Burma. The territory is thus about 600 miles long, and nowhere more than 40 miles wide. The great Penal Settlement of Port Blair, the head-

quarters of the Administration, is situated the South Andaman Island and somewhat about the centre of the whole territory.

It is about this place that I address you this evening, and for my present purpose I may also tell you that the convicts are located round the shores of a large, land-locked and very beautiful harbour. The choice of this situation is due to the fact that Port Blair is 300 miles from the coast of Burma, 400 miles from any part of the Malay Archipelago, and 700 miles from the coast of India, and all this across a stormy and often dangerous sea. Escape is therefore very difficult. But convicts are often desperate people, and escapes are in rare instances effected. In every such instance, of course, it is the result of splendid courage exhibited in a wrong direction.

The population of Port Blair and neighbourhood consists of the convicts, their guards, their descendants, officials, and a small trading community, and, of the rest of the Andamans, of a perfectly harmless, naked race of savages of the Negrito type. The population of the Nicobars consists of a peaceable, jovial trading community of Malays, who, however, until quite recent times, were dangerous wreckers and pirates. There is nothing of that kind there now, the nuisance having been effectually abated by the settlement of troops and convicts in Nancowry Harbour for the 17 years ending with 1889.

I may as well add here that the great harbours of Port Blair and Port Cornwallis in the Andamans, were first used as sites for Penal Settlements between 1789 and 1796, and that it was in order to check persistent murder and ill-treatment of shipwrecked crews by the Andamanese that the Government of India made up its mind in 1856 to try the experiment again, the actual commencement thereof being hastened by the difficulty of dealing with the great number of mutineers, deserters, and rebels that the Government had on its hands as the result of the Mutiny of 1857.

Having thus put you in possession of certain information of the necessary sort, I will go direct into my subject, with just the further preliminary information that the convicts received at the Penal Settlement are the men and women sentenced annually to lifelong imprisonment in India and Burma, and certain others sentenced to very long terms. The average number present at any given time is about 11,000 men and 800 women; say, 12,000 altogether.

Now, the first things that strike one o

ing at Port Blair are the great beauty also the depression of the place, the noble tranquillity and good order there, the obviously peaceable demeanour of the convict population, and their equally obvious desire to please the powers that be. But let not the visitor be deceived by all this, just as every man and woman of them have been the cause of some striking tragedy of some kind, so do these people cause tragedies of the life sentence. Every village and hamlet, every barrack and workshop, every locality, almost every nook and corner of Port Blair has its ghastly story. It is, indeed, a fearful fact that the evil nature will out.

Let us consider a moment how a convict reacts to Port Blair. First, there is the tremendous excitement of the murder, or the madness of the riot or affray, or the sudden heat of the gang robbery, or the haunting fear of execution after the great forgery or breach of trust, or the horrible misery of the deserted convict: the very height of tragic excitement, anywhere. This is followed, in many cases, by the extremity of excitement that human beings do not know—the trial for life with all its wildness, the hope that perhaps the case will not be proved, the hope that perhaps the death penalty will not be inflicted. This is followed further, sometimes, by the despair of the convict when the death sentence, when, however, hope is given by any means dead, for are there not left the appeal, the pardon, at least the commutation of sentence? But in the end, whether it happen in the dock itself or in the condemned cell, there comes that last solemn moment when the convict steps out of the world he has known, out of the life he has lived, out of all the past excitement—into a blank future—into the silence of that land where so few return.

It is when the excitement is over and the great reaction has commenced that, forgotten in the world and cast out of society, the convict passes into our charge, a prisoner for the life of his generation in any case, with just an even chance that it is for ever.

Let us consider now what it is that has happened to him. Hitherto he has been a free man, secured in his freedom by all the arrangements that his fellow men have created around him for his and their own protection. Now he has no rights and knows no law but the orders of those in charge of him—he has become a mere machine for the obeying of others.

You will perceive the relative positions of the convict and his master, and what a very serious responsibility is thus laid on the master, and

what I wish to explain this evening is how that responsibility is borne in the Penal Settlement of Port Blair.

Let us begin by some remarks on the convict nature, for so much of his treatment depends on his master's conception thereof; and as a preliminary to these remarks, I wish to say that the Port Blair system has slowly grown up into what it is out of the practical experience of the various superintendents, and the careful orders of the Government of India, based on the consideration of their recommendations. It is no paper constitution, drawn up to suit any particular theories. There have always been the convicts in their thousands, and there have been the climate and the necessity of treating the convicts in the way best calculated to benefit them, and for so employing them as to bring down their cost to the tax-payer to the lowest limits compatible with climatic conditions and beneficial treatment. Trusted agents of the Government have pondered these things on the spot in the light of an ever-increasing experience, and their ideas and suggestions have passed under the criticisms of highly experienced administrators, and have in the end produced the system, which I will now attempt to make clear to you. It would be easy to prove that the Andaman system is the result of the constant attention of the Government which created it, and is the outcome of the measures of practical men, devised to meet the difficulties with which they have found themselves face to face, and reduced to order and rule by some of the keenest intellects that have worked in India for many years past. The very names of some of these who have taken a leading part in building up the system are a guarantee of the administrative ability brought to bear on it: Lord Mayo, Lord Napier of Magdala, Sir Henry Norman, Sir Donald Stewart, Sir Clive Bayley, Sir Charles Lyall, Sir Alfred Lethbridge, Mr. Scarlett Campbell, Dr. Mouat, General Henry Man, General Montague Protheroe, Colonel Cadell.

Now, it is a fair question to ask of any one situated as I am, What is your conception of the convict nature? Wherein do you think that the average convict differs from the average free man? My personal answer to this question from experience is this:—The convict is very like other men, except in one particular—self-control. Want of self-control is the fundamental characteristic of the convict temperament. It comes out in everything that convicts do—it is the root and origin of the

vast majority of their offences against morality and society; it is always present; it must always be looked for and guarded against. There is also, I should add, a certain number of human beings born who are entirely vicious, but such are not very many—not even amongst life convicts. Out of the 12,000 lifers at Port Blair, I regard about 250 as desperately wicked, positively dangerous, and about 250 more as sufficiently bad to make it a common-sense precaution to keep them permanently in a jail. Of the rest the majority are not like this, and can be brought to a considerable height of respectability. Many are not vicious at all, but merely liable to fits of unrestraint.

But I would not be misunderstood here. I do not wish to speak in this place as a theoretical enthusiast, but as a practical administrator, burdened with serious, common-place responsibilities, and bound to take a plain, common-sense view of the subject. I wish to say that, in however kindly a light one may be disposed to look at his case, the clear fact is that the ordinary convict for life is not safe—his liability to lose self-control on quite inadequate provocation should never be lost sight of.

Now, though I have never seen these ideas as to the convict nature officially stated, they are nevertheless those on which our system has instinctively been based, as you will presently see. Port Blair is, roughly speaking, a huge practical reformatory—it contains an organisation labouring steadily for the reform of the criminal. One great factor working for this noble end is that good behaviour of the right kind can of itself commute the life sentence at Port Blair to one of 20 or 25 years, as the case may be.

I will now proceed to explain how we educate the lifer to be fitted to use aright this very great boon—the result, I may say here, chiefly of the combined personal efforts of Sir Donald Stewart, once Chief Commissioner of the Andamans, and of the great Viceroy, who met his reward in the senseless, but typical, murder that has made the Andamans famous.

We commence by placing our newly-arrived convict in the Cellular Jail, by way of breaking him to harness. Here all is discipline. There is no hard work. It is discipline, the sternest of discipline, from morning till night—hard, rigid, uncompromising. We oblige him to bend his rebellious nature to the yoke for six months at least. He remains in his cell all day and all night, excepting the time

he spends in exercise in company with others in the yard outside. In his cell he performs some light, but useful and suitable work. The irksomeness of the discipline is shown in action at exercise. It is not exciting exercise exactly, as he has to walk round and round a ring; yet so irksome is that perpetual round that he walks round and round the ring hard as he can and impatiently during the whole of the allotted time.

Having thus compelled him to submit to a severe discipline, we next transfer the convict to an Associated Jail, where the system is the usual one of hard labour in gangs under a strict discipline, and where he sleeps in a separate cubicle. Here he stays for a year and a half.

He has now gone through two years, and for the next three he is employed as a slave. That is, he sleeps in barracks, locked up with other slaves, and works hard all day under supervision—an unpaid, unrewarded labourer but well-fed, housed, and cared for, and always under watch and guard.

Five years have now passed and the severities of the life is eased down a little. The tasks are not so irksome, the employment is varied, personal capacities are more studied, the capable are eligible for petty posts of supervision, and so on. The convict at last now gets a very small allowance, with which he may buy little luxuries for himself, or if he chooses, he may place it in the Savings Bank. An educating institution I will later on explain.

This condition lasts until 10 years are completed. Many a lifer has now served half his time, and if he shows that he has the capacity to support himself, and if we have sufficient grounds for trusting him, we grant him a long ticket-of-leave. He cannot, however, leave the Settlement, and is still a convict. At Port Blair he is called a self-supporter.

The convict is thus at last in a sense free. He earns his living in his own chosen way; lives in a village in his own house; he farms a little land; he keeps cattle; he can manage about unwatched; he can send for wife and children, or, the far more frequent course, can marry a convict woman, who under our own regulations is eligible for marriage; he can thus become *pater familias*, with a little hoard of his own earning, and differing only in the way in which he is supported, from a properly conducted member of human society. In reality, however, he differs so greatly from the free man that he misses all those things that “free” men prize so highly. He has no civil rights un-

ordinary law, and all the affairs of his life dealt with by the executive authority; he lives where he is told; and generally conducts his life as he is told; he may move out beyond his village and his fields by permission only; he cannot leave the Settlement; he may not be idle under pain of a return to ordinary labour. In this state he remains 10 or 15 years, according to the orders that have sent him to prison, until the day arrives when the order for absolute release is placed in his hands and he goes free like other men.

As in the other portions of his life in transportation, even in the condition of self-support, the convict passes through two distinct stages. In the first stage he is assisted at the beginning with a house, food and tools, and then by exemption from rent, taxes, fees, and other expenses, payable by the free towards the common benefit. In the second stage he receives no assistance whatever, but finds the means of his means of livelihood, and is charged with every public payment, which would be exacted from him in his own country. The women are dealt with on the same lines, but more gently, as becomes the gentler sex. In the first three years the convict woman works in the female jail as a mere slave, fed, clothed, and cared for. Then for the next two years she is treated to the same sort of severity as is granted to the men, and after a total of five years she becomes eligible for marriage and domestic service. Assuming that she marries, she joins her husband in his village, where she leads the ordinary life of an Indian woman, but subject to the same disabilities as her husband, until she has completed 15 years in transportation, when she may go free with him, whithersoever she may go.

Now, through all this long education to full citizenship there run continuous threads of practice in self-help and self-restraint, and inducement to profit by the practice. The length of the convict's stay in the Cellular Jail depends entirely on his conduct in it, and so it remains throughout his career to the point of self-support. Effort to behave well and submission to control mean promotion upwards from grade to grade in due course. Every serious relapse means the retarding of promotion, or actual retrogression. And when he has obtained his ticket-of-leave it is to his own merit, his own thrift, his own steadiness, that he has solely to look for that little hoard, which will be so much to him when he goes back to

his native land—no pauper, no mere jail-bird, no unwelcome burden on his relatives—but a self-respecting citizen, with a little capital of his own earning, for years habituated to provide for himself in an orderly way, and thoroughly broken to harness, as it were.

It does not require much imagination to contrast the difference in the personality of the same human being as he reaches and leaves Port Blair. He that arrived an outcast, void of restraint, and unfit for association with his kind on equal terms, goes forth a useful citizen, broken to restraint, and not only fitted for human society, but well used to submit to the conventions by which alone that society can be maintained. And men so reformed are not sent back to India by ones and twos, but by scores every year. The incorrigible are kept till death, and the slow to learn are kept till they mend their ways, while those only that have good in them and are capable of reform are returned to the society they once disgraced.

You will have perceived from what I have just said, that the Port Blair system is one of continuous education in self-restraint. It instinctively assumes, as I said at the outset, that the distinctive feature of the convict temperament is want of self-restraint. The Penal Settlement is a reformatory in practical result.

Now, the special difference between the result of the Settlement system and that of the ordinary jails appears to lie in this: while the Port Blair returned convict is a man fitted and habituated to support himself, the prisoner released from a jail is not only a pauper, but has become pauperised. That is, he has become unaccustomed to find for himself, and this disability has grown upon him with the length of his imprisonment. At Port Blair we do not part with a life convict until we believe that there is a reasonable hope of his living the rest of his life at home in an ordinary, orderly way.

So far we have been considering the direct personal education that the convict receives at Port Blair, but besides this he is taught various lessons of general importance in indirect ways. There is the value of justice, for instance. For though his life is absolutely controlled by executive officers, everything that happens to him is the result of a quasi-judicial procedure. No punishment can be inflicted without a proceeding, without registration, or without record of the evidence on which it is awarded. There is a regular course of appeal, and a further untrammelled appeal to the head

of the Administration himself. Thus, though the punishments in such a place as Port Blair must on occasion assume a form of deterrent severity, there is as much security of justice in award as elsewhere. You will see the importance of this, and that it regulates the relation between the convict and those over him.

Then there is the system of local marriages, about which I wish to speak a few words, as it is so frequently and persistently misunderstood; the same old misrepresentations being regularly reproduced for the public about every ten years or so, partly by the facetiously mischievous, and partly by the ill-informed, though well-intentioned. I wish to explain clearly that a local convict marriage is no concubinage, no temporary or irregular alliance. Every enquiry is made and every step is taken that is necessary to render convict marriages legal, according to the customary personal law of the contracting parties. Long is the waiting in many cases between proposal and completion, and many are the disappointments, when the conditions are found to bar completion. Once married, the husband and wife are clearly made to realise their legal condition, and must depart together or not at all. The practice in regard to these marriages in my own time is, I believe, that of every one of my predecessors; namely, the Chief Commissioner personally enquires into each case, and then sanctions each marriage himself, for without such sanction no convict marriage can take place. Finally, when a marriage has taken place after sanction, the Chief Commissioner registers it himself, and thus completes the precautions necessary for its legality.

The children are, of course, a very serious question, but the best is done by them. Their health is so well cared for that in Port Blair, probably alone in all the East, it is the rule to successfully rear the whole of a young family; primary education is there compulsory, again probably alone in all the East; and technical training is free to all. Their inheritance of temperament and their early associations are the points of anxiety regarding them, and these matters may be fairly said to be beyond control.

I have already mentioned the Port Blair Savings Bank as a factor in the education of the convict. How great has been the effect of this truly beneficent institution will be seen from the fact that for years past more than a fourth of the resident convicts have kept their savings in it; first, out of their little allowances, and then out of the earnings of their holdings.

They have thus shown how well they have taken to heart the two great lessons of the and of faith in the honesty in the Governm-

I must also mention the hospitals and the great good they do. Every convict, whether in the labouring or in the self-support classes, has care in sickness, as it were, thrust upon him. He is taught to look to the doctor as his friend, and it is a great pleasure to be able to testify here, as I have often done before, to the humanity and good sense with which the medical officers of the Settlement perform their duties. The proof of the pudding is in the eating. The death and sick rate at Port Blair are, for the East, exceptionally low. The sanitation is the best I have seen in the East, after an unusually wide experience, and the result is what?—We have no cholera, no small-pox, no malignant epidemics.

The picture I have thus drawn for you is undoubtedly open to criticism as being optimistic. But I would remind you that your attention has been more than once drawn already to the fact that there is a seamy side to life in Port Blair. It could not be otherwise. Life convicts are not an honourable nor a scrupulous class; they are not ladies and gentlemen; their manners are not mild nor are their impulses repressed. Life and limb, in fact, are by no means secure in Port Blair, and if I were to lay myself out to describe to you the life in a convict village, or in convict barracks as I only too well know it to be, and the condition of perpetual irritation in which convicts live arising out of their own mutual ill-will and distrust, I could easily send you home as miserable as the veriest pessimist could desire. However, instead of doing this, I have hoped rather to have impressed on you, that we, who have to deal with the convicts, look on them as physicians do on their patients. We cannot deny the existence of the disease, but we try to diagnose it correctly, alleviating where we can and curing where we can, but not laying a claim to the working of miracles.

It would, indeed, be easy enough for me to paint a lurid picture of the inhabitants of the Penal Settlement, easy enough to preach scathing condemnation of the envy, hatred and malice, the uncharitableness, the evasiveness, lying and slandering, the murder and the cruel death, of the amazing immorality, the callous depravity, the downright, unabashed wickedness, that are so constantly forced upon my view. But such is not my purpose. Human faults are easily seen and easily denounced, but such things lie on the surface. The diffic-

ing always is to perceive aright the good that there is in bad men, and bring that out; that is what we officials are sent to Port Blair for; that is our duty and the object that the Government is aiming at in the system just outlined.

Now, a question that has been asked of me, and which is a natural one, is: What do you do with all those men and women? It is not easily answered, because Port Blair comprises itself a separate community of human beings, with practically only one source of labour, the convict. The convicts, therefore, do anything that the labourers of a whole community do. And in this way, though there are in the daily our books between 8,000 and 9,000 hands a day, every one of whom has a definite task allotted him, there are—though this may seem to be a paradox—not enough for the work to be done. The work has, indeed, to be carefully allotted throughout the year, so that it may be all accomplished.

But here are some of the things that the convicts do in various directions:—They clear swamps, drain swamps, reclaim coral banks, and make out of them grazing and arable lands. They do all the cultivation and grow the food and fodder—cereals, fruit, vegetables, tea, coffee, cocoa, tapioca, arrowroot, pepper, oil, and so on. Jerusalem artichokes are grown by the acre. They also catch the fish required. They prepare and cook all the food, and make all the kitchen utensils, pots and pans. They breed and tend the cattle, sheep, pigs, and poultry; the success in sheep-breeding has formed a new departure in such matters in the damper portions of the tropics; they take out the fuel of the forests and cut it up; they make the salt from seawater. They do the portage and all the carriage, whether in boats, barges, tramways, carts. They build all these things—anything from a steam-launch to a wheelbarrow, or any kind of machine. Carvel-built boats are a speciality. They provide the materials for what they make of wood out of the forests and ironwork out of pig-iron. They build and construct every public and private work in stone, brick, wood, iron—the fine barracks, and the huge jails, the beautiful church, the factories, mills, houses, chimnies, the long sea-walls and piers, the harbour breakwaters, the roads and drains, the earthworks and embankments, the reservoirs and wells. They provide all the materials and lime and mortar from the coral banks, stone from the quarries, bricks and tiles from local sources. They cut timber in the forests and prepare

it in the mills. They manufacture and make up all the iron, brass, copper, and other metal work. They do the plumbing, glazing, and painting required, both for vessels and buildings. They make rope, yarn, string, and fishing-nets from the hemp and cocoanuts they themselves grow. They make cane and wicker and basket-work from the canes and bamboos of the forests, which they fetch. They, *i.e.*, chiefly the women, make all the clothing and bedding, cotton, woollen, cloth, and leather; tanning the skins of their own cattle, spinning the cotton from the rough hank, cleaning and spinning the wool as it comes from the sheep's back; their sheeting, towelling and cotton carpeting is stout and unusually good.

They drive and run a great mass of machinery—steamers, engines, saw-mills, brick-mills, rice and flour mills, water-works, huge steam workshops. And were it not for the machinery, the work we have to do would never be got through. They do other work of a superior sort, such as port-signalling, tide-gauging, meteorological reporting and designing of many kinds. Some of the wood-carving, hammered brass and iron work, fine wicker and basket work is excellent.

They do nearly all the domestic and messenger service, all the washing, scavenging, and cleansing, and all the petty supervision of the work. They do much of the clerical, account, and statistical work, too, and all the printing, lithographing, and stereotyping.

This is something of what the convicts do, and you will begin to perceive why it is that the Superintendent is often put to it to find labour for what has to be done. The object of employing the convicts thus is to save the taxpayers' pockets, to make the cost of keeping the useless of their kind out of their way as small as is reasonably possible. We interfere with no trade and we compete with no honest labour. What we aim at is to find for ourselves with as little expenditure in cash as we can manage.

The question just answered raises another: How do you manage all this? Who are your experts? Well, we have hardly any experts. The officers and their subordinates have first had to learn what is wanted as best they could, and then to teach that very bad and unpromising pupil, the convict.

What a mighty and endless task this is you may gather from the facts, that only about three per cent. of the convicts at Port Blair can be employed at the occupations they are supposed to have pursued before transportation,

and that casualties among convict artificers are constantly occurring, owing to release, promotion to self-support, or punishment for serious misbehaviour. There is no end to this. I remember once losing the services of the leading men in the printing, lithographing, and stereotyping establishments in one moment, because these worthies were found employing the metal supplied them in stereotyping rupees instead of printed formes. The present chief designer of carpentry work is a born artist, but spends half his time beating cocoanuts in jail, because of his inability to behave decently for more than six months at a time. The finest accountant we had passed his last years in a very ignoble way, owing to his habit of ingeniously cooking his accounts. Another man I remember, a house painter, with as neat and certain a hand as one could wish even at the finest work, had suddenly to change his occupation, being unable to resist the temptation of trying to sell the materials supplied him. And so it goes on always.

The Superintendent's duty is to watch, direct, and order, and the duty of those under him is to carry out the orders intelligently. It is to the intelligence, loyalty and honesty of the executive and subordinate officers that what may be fairly called, in spite of all drawbacks, the satisfactory condition of Port Blair is so largely due. Their work indeed proves once more what is to me a favourite theme—Put the average Englishman on his metal and he will do anything.

Now, I need hardly say that my official position precludes me from making any remark on the merits of the system I have described. I can only describe it, and in doing so I expressly wish to draw no comparisons; remembering that what is suited to India and the Indian peoples is not necessarily suited to, say, England and the English.

The only general opinion I will venture is this. Were I asked to give advice to a novice in the treatment of convicts, I would say to him: Remember that the convict is a born rebel, without self-control or right impulses; therefore, if you would succeed with him and lead him on to orderly ways, be firm without favour; never forgive him a fault, but never punish him vindictively.

Having thus described to you the system at Port Blair, I now propose to give you some small idea of the place itself by the aid of a series of slides, some of which are prepared from photographs supplied by Mr. E. H. Man, C.I.E., Deputy-Superintendent of the Andamans.

I commence with a general view of the inner harbour of Port Blair, taken from the low western slopes of Mount Harriet, which was so named after the wife of General Tytler, one Superintendent of Port Blair. The view gives some idea of the great natural beauty of the Andamans. The whole of the islands are indeed, surprisingly beautiful, and, fortunate for the residents, are so studded with room and safe harbours, that one can get about in all kinds of weather. I have, of course, been everywhere and all over them repeatedly, and anything but a beautiful scene is hardly anywhere to be met with. In the distance of the view are the Viper and Chatham Islands, situated inside the harbour. On the former is Viper Jail, where the very worst criminals in all India are more or less permanently confined; and on the latter are the great saw-mills, in which is cut up and prepared the export timber, the chief source of actual revenue to the local government, and the existence of which greatly reduces the cost of the convict to the public.

I now give a view of South Corbyn's Cove which shows many little points relating to the Penal Settlement. Mr. Corbyn was once chaplain there. In the foreground is a specimen of the beautiful and often exquisite Andaman jungle; and also of a creek, *i.e.*, salt-water estuary of one of the small rivers of the Settlement. These are almost always of great beauty. The view also shows a road and embankment, and behind them rice-fields, reclaimed from the creek by convicts. And in the background, on a small hill, is Corbyn Cove Village, inhabited by self-supporters and ex-convicts. I have not mentioned the latter so far. The ex-convict is the man who, on his release, desires to remain in the Settlement and to earn his living there as a free man, who returns to the Settlement of his own accord after he has obtained his release and lived for a while in India. This class is much encouraged, though many do not avail themselves of the privilege, so great is the love of home in the native breast—perhaps stronger there than among any other peoples on the earth.

Next comes a view of Aberdeen Harbour. Here is shown a coconut grove, planted on a reclamation from the sea. Coconuts are now indigenous to the Andamans, and though they are already producing an appreciable income, every tree has had to be planted and specially cared for. The seed nuts have all come from the Nicobars, where the tree was, even in the days of I-Tsing, the Chinese traveller of the

century A.D., the staple source of livelihood, as it still is. Here again are roads and ankments and a tank or reservoir. Here is a small harbour of safety for open boats barges, with two long solid stone piers posing it. The whole of the works above described were brought into existence by vict labour. The name Aberdeen is interesting. For some reason, perhaps, because of the great Indian marine surveyor of the century and eponym of the place, came to Aberdeen, there are several places about Port Blair named after that neighbourhood—the lunatic and leper asylums, and one of the great hospitals of the Settlement are situated at Haddo.

There is a view of Chatham Island from Haddo, exhibiting the saw-mills and invalids' working-shed. All the invalids and infirm convicts, able to do some work, are settled on this island, where they make baskets and string, and do such like sedentary and light work. The view also shows a signal station, which is interesting. Out of the necessities of the case has arisen a very complete system of semaphoring at Port Blair—*i.e.*, of signalling at any time and in any weather by means of flags, heliograph, or night-lamps, worked by a military police force of the Settlement from Haddo to island and from point to point. The forms are ordinary telegraph forms, and there is a charge per word, as in ordinary telegraphy, for private messages. The system is so complete that the Superintendent can have in his hands an answer to a circular message from every semagraph station in the Settlement within half an hour of its despatch. He can thus know in a very short time, in any necessary detail, what is going on generally at any hour of the day or night.

I now show three views of Viper Island, so named after a Royal Naval gun-boat of the 18th century. This island contains chiefly the abode for the very bad characters already mentioned, and its accessories. On it is also situated the picturesque building where once were kept the European convicts, but there have been none confined there for 30 years. The Settlement is not really suited to them. The building is now used as a signal station and a military police guard-house, and is in reality on a separate island, called Buknipur; but long ago the two islands of Viper and Buknipur were united by the reclamation scheme, which gave me only a piece of flat land thereabouts. I may notice here that at Port Blair reclamation from the sea is not only of

economic but also of sanitary value, as it is usually carried out over a coral bank or mangrove swamp. Neither, especially the former, can be made healthy, except by being covered over with fresh wholesome soil from the neighbouring hills to a point well above tide-level. The views also show another point of interest—the boat harbour of Viper Island, made by means of a breakwater with a very narrow entrance close to a sentry-box, from which it is brightly lighted. As all up-harbour boats have to be counted into this harbour every evening, this makes it difficult for boat-escapes on the part of the most desperate convicts in the Settlement. Every boat has also loose brass rowlocks, which have to be delivered up to the police sentry on duty at the entrance all the while a boat is lying in the harbour. This gives some notion of the constant state of precaution in which the officials of the Settlement live. Opposite Viper to the west is Navy Bay, so called because of its depth and size. It is five miles from the open sea, and round the corner from the entrance of the main harbour, but is still capable of holding deep draught vessels in some numbers.

I now pass on to Ross Island, the head-quarters, which shuts in the outer harbour from the sea: chosen for the head-quarters because it is nearest the open sea of all the islands in the general harbour, and so every boat must pass it to get out, and because on it can be safely kept the spare food supply, the records, and the small amount of money necessary to finance the place, out of the way of any rising or attack. Supposing the convicts to rise, they would be easily starved into submission in a very short time. On it are Government-house, the British infantry barracks, the church, the Settlement mess-house, the local volunteer head-quarters, and other large buildings; all fine examples of what convicts can be made to do. The church has a fine stone spire, all convict work, designed by General Man, while Superintendent, and subsequently constructed under Col. Horsford, Chief Commissioner, and myself, as a memorial to the only too-numerous Europeans who lost their lives in the great cyclone of 1891. The barracks, as you perceive, are a handsome castellated building in dark grey sandstone, entirely constructed by convicts. The views also show the ice-house, where solid ice—a matter of life itself often in the moist tropics—is artificially made daily by the ton.

Some of the views on Ross Island will show

you convict life and work. Here they are feeding in the appointed place, all in the open, be it observed, without a single free guard of any kind present. All the men with belts are warders, but every man of them is himself a convict. This shows something of local methods and system. Here is Ross Harbour, with its steam launches and boats; another example of convict activity, for every boat and barge there has been built by the convicts. In the foreground are some bad characters in light chains hauling in a log for boat-building, with only a convict guard and no free man over them. Here is Ross Bazaar, where only free people live. The people in the lively street shown are all free—traders, native soldiers in plain clothes, police—with only a convict warder here and there off duty, to show that we are in a Penal Settlement.

I also give three slides of Government-house, because it so well exhibits convict labour and work of the superior mechanical sort. The building, as it now stands, was re-planned and re-constructed by myself from my own plans. It is a many gabled design of the old English type, adapted to tropical needs, and was constructed roughly thus: I drew a ground plan and elevation in single line to the scale of an inch to a foot, and with these and nothing else—no working plans whatever, excepting a few rough detailed drawings as required from time to time—one of the locally-trained foremen-builders in wood, a carpenter by trade, and an ex-captain of banditti by occupation, constructed the large elaborate building you see, with the help of personal explanations from time to time. The building is the joint work of myself as architect, a trained Government Public Works Supervisor to draw up specifications and superintend, and a convict as builder and technical constructor.

The ground floor also shows something of our methods. The old floor was too low and the old building, every stick of which has been preserved (for reasons of economy) that could be used, was too much injured by time and the cyclone to stand underpinning and lifting; so, in order to get height, the ground on which it stood, the apex of a hill, was cut away from under it and round it, bit by bit, until the required height was secured. The new hill slopes thus made necessary were constructed by myself with the aid of a local genius, whose occupation at home had been that of scavenger, but who under us became an experienced and most expert foreman for earthwork of all sorts. There were no plans used; there were only the

laying down of lengths of string and verbal instructions.

The interior view of the building shows a great staircase and the painted frieze of the hall, and also the carved doors and ornate carved wooden screen of the ball-room. Elaborate as all these are, they are all convict work from local designs, the carvings being from the design of the Burmese convicts themselves. The painted frieze is by a locally trained painter, who in his free days had kept an oilman's shop, but who can now paint, as you see, from paper stencils cut to full size by myself.

The ornamental stone balustrade in front of the house is convict work made from the local grey sandstone, which is first roughly fashioned into the form required and then turned on a steam lathe used in turning metal. The difference in working is this: The lathe for metal work is sent round at a great speed, but for stone work it must turn very slowly, either the stone or the chisels will chip. About two-and-a-half stones were turned per diem.

I now show a copy of the scene of Lord Mayo's murder made by Major Jervois at the time and on the spot.

Lastly, there are three views exhibiting Andamanese life and ways. The first is a fine *mahwa* jungle in the North Sentinel Island, about 60 miles from Port Blair, where are to be found some of the Jarawa tribe of the Andamanese, who are still and always have been, entirely irreclaimable, neither kindness nor force having had as yet any appreciable effect on their repugnance to strangers of any kind, even of their own Andamanese neighbours of other tribes. With every other tribe we are on the most friendly terms. The other two views show the Andamanese spearing and shooting fish before our advent their chief and often our source of food, and making canoes out of logs.

DISCUSSION.

The CHAIRMAN said, on hearing this paper read and seeing the views, his mind was irresistibly brought back to the tragical event to which the lecturer had alluded at the beginning of his paper, and he felt sure that there must be several present whose memories had also been recalled to that sad event. Lord Mayo seemed to have been, from his commanding presence, his genial manners, and his generous nature, marked out to be a ruler of men. When he came

January 24, 1899.]

he said in one of his first utterances there, he was confident, with God's help, he would be to devote himself to the interests and welfare of millions put under his charge. There never was a sentiment more thoroughly realised than that by his career while Governor-General. A very few years before his death he had to deal with a very difficult subject, in which the generosity of his nature was displayed in the most prominent way. He would not refer to it further than by saying that he wrote a letter to the Duke of Argyll, who was then Secretary of State, giving his views upon it. That letter was communicated to the Cabinet, and was afterwards communicated to him (the Chairman) for his information, upon that letter Mr. Gladstone had written, in his own hand, "a noble relic." The devotion with which Lord Mayo was served by those under him was well known, and the affection which he inspired, amongst the native princes of India, was very remarkable. He is remembered having had a conversation with the Maharaja of Jeypore, one of the most intelligent of them about Lord Mayo, and he could not say that it was with great difficulty that he could restrain his tears. Those who followed him knew better than anybody else how well he performed the duties of his high office, and no one could better appreciate this than he did, for he felt, with his much superior qualifications, how difficult a task he had in endeavouring to follow Lord Mayo's footsteps. He would not refrain from this short notice of the event which took place at the beginning of Colonel Temple's career, and he would add that the most careful investigations were made after the catastrophe, and it was ascertained beyond doubt that no fault could be attributed to anyone who was responsible for the safety of the Viceroy on that occasion. Moreover, although there were at the time suspicions that there might have been some political conspiracy at the bottom of the crime, it was found on inquiry that that was not the case, the circumstances absolutely impossible. At the same time, that tragic event led to an observation which was connected with this penal colony, namely, the extraordinary contrast shown between Western civilisation and the customs of many of those with whom we had to deal in the East, and who had hardly emerged from a primitive condition of society. The assassin, Shere Ali, was a very brave man belonging to one of the Afridi tribes who had done excellent service to several Commissioners at Peshawar, and distinguished himself as a soldier. He was entirely trusted by Colonel Reynolds Taylor, one of the best of our Indian officers, when at Peshawar, and he used to go about with his children, and, in fact, was the confidential servant of the house. This man, however, belonged to a society in which tribal feuds were a hereditary custom. There was such a feud in his family, and he was led upon to take his part in avenging his side in the quarrel. If this man had committed the murder on the other side of the frontier no notice could have been taken of it, and it would have been considered

by everyone connected with him as only a proper thing for him to have done under the circumstances in accordance with the religious feelings and customs of the tribe; but as he committed the crime near the cantonments of Peshawar it was necessary that he should be tried by English laws. He was tried and sentenced, and it was supposed at the time that it was a privilege to send him to the Andaman Islands instead of inflicting the sentence of death. The man himself, however, desired to be put to death rather than be sent there; he thought himself unjustly treated, and took the first opportunity he had of revenge. He knew of another case of the same kind equally striking in connection with one of the tribes in the centre of Bengal. A man came home to his house after being away for a time and found his house burnt, his cattle were all driven away and his wife with them. He followed the robber, caught him up, and with a bow and arrow shot him dead on the spot. Here again, according to English law, was a murder, but it was not a murder according to the views of the tribe to which he belonged. That man was afterwards pardoned. That showed the difficulties with which they had to contend in India, and how different the cases of crime were in that country from those which occurred in England. He would not attempt to express any opinion with regard to the management of the penal settlement; they had heard Colonel Temple's account of it, and there were others present who could speak of it with much more knowledge than he possessed, but he might say, with regard to the paper, that he heard it with very great pleasure, and congratulated the author on having inherited those qualities of graphic description which his father so eminently possessed.

General Sir HENRY W. NORMAN, G.C.B., G.C.M.G., C.I.E., said he had heard, with great regret, that Sir Donald Stewart was not able to be present that afternoon, as he could have told them a great deal about the Andamans, where he was for several years, and many great improvements were carried out during his residence. He himself could tell them but little, as he was there but a short time, some twenty-five years ago, when he was sent there by Lord Northbrook. After the lamentable occurrence of Lord Mayo's assassination, Lord Napier and Ettrick, the acting Viceroy, sent down Mr. John Starlett Campbell to inquire into all the circumstances, and to make any suggestions he thought desirable with respect to the organisation of the settlement. Mr. Campbell sent in a very full and valuable report which came under the consideration of the Government of India after Lord Northbrook's arrival. Some references had to be made to the settlement, and eventually he was desired to go down and report on certain doubtful matters, and to make any suggestion that he thought proper. He need not enter into any of the points with which he dealt, which would not interest the audience, but after conference

with Sir Donald Stewart, he came to the conclusion that certainly one important measure should be adopted, and it was that every convict should have the prospect of returning to India, after, however, a long period of penal servitude, if he continued to behave well. That view was not taken by everyone; some thought that those who went there should remain for life, the great majority at any rate being life sentences, but it seemed to him that if they extinguished the hope which all persons sent from India had of returning to their own country, they would simply be made desperate. They had heard from Colonel Temple that even now there were a certain number of that character, and, he believed, that number would have been much increased if all hopes of returning to their own country were removed. He, therefore, urged that a regulation should be drawn up, under which, after many years' good conduct, it should be possible for a convict to return home. Lord Northbrook took the same view, and that was carried out, and he believed with good results. Even in those days he was much struck with the excellent arrangements made in all departments. With regard to the medical department, the hospitals were admirably conducted, and great efforts were made by the principal medical officers, though they had not been attended with complete success, to cure leprosy, because amongst so many convicts from India there were certain to be some lepers. At one time it was thought that the administration of gurjun oil would eradicate the disease, but although it had greatly improved the condition of the patient, and had been introduced into Jamaica and other places, and was used with great effect, he was afraid in no instance had it effected a complete cure. Some years afterwards he found himself pretty near the great French penal settlement of New Caledonia, where there were not quite so many convicts as at Port Blair—only about 10,000. At Port Blair the convicts were kept quite securely with a small military force, one company of European soldiers and four of natives, but in New Caledonia there were two complete battalions of French infantry, a company of artillery, and a number of European warders. He was not inclined to think that the management at Port Blair could be much improved by any hints derived from New Caledonia, but it would be interesting if someone well acquainted with the Andamans could visit New Caledonia, and make a comparison between the two systems. In one respect the convicts very much resembled each other, namely, in their desire to escape. New Caledonia was about 700 miles from Queensland at the nearest point, much farther than Port Blair was from Burma or the coast of India, and the sea between New Caledonia and Australia was as dangerous as that in the Bay of Bengal, but still incessant efforts were made to escape. In one year, he believed, 48 French convicts reached the shores of Queensland and considering the frail boats and canoes in which they got

away, he should think at least as many must have been drowned on the way. These convicts almost invariably fell into the hands of the Queensland police immediately on landing, and under the extradition treaty they were soon sent back, and, according to the French system, they got an extra number of years imprisonment. Under that system they added to a man's term quite irrespective of the length of his life, and he found that one or two convicts, who had been in Queensland, had already earned more than 100 years' imprisonment. He was sure they were much indebted to Colonel Temple for the information he had given them in regard to what was, he believed, the greatest penal settlement in the world.

Sir CHARLES JAMES LYALL, K.C.S.I., C.I.E., said he could do very little more than enforce the lessons which Colonel Temple had put before them. He visited Port Blair some nine years ago at the request of the Government of India to report on the system in force at the time, when Sir Alfred Lebridge, a most experienced gaol officer, was his companion, and their visit was made because some had suggested that transportation had lost its terrors to the Indian criminal, and that the system of discipline required bracing up and strengthening. Their conclusions were that a great misconception had prevailed, and that any loss of terror which there might be was chiefly to the custom of sending term convicts there, who returned after four or five years' transportation and told their friends at home that the place was very comfortable, that people lived there in villages and grew crops, and did not appear to suffer from any great severity. At their suggestion the practice of sending short term convicts there was stopped, and now, with the exception of Burma, all convicts sent there were life convicts. Port Blair was not only one of the most important penal settlements in the British Empire, but perhaps the only place where a reforming discipline was brought to bear upon the criminal. He was much struck by the passage in the paper in which the author spoke of a convict discharged from an ordinary gaol as being "pauperised," by which he meant that he was deprived of those methods of fighting the battle of life which the natural man possessed. He had been looted after for so many years by the State that he was deprived of all self-reliance, and the result was that our gaols were crowded with recidivists—men who had been convicted time after time. Port Blair was a great contrast to that. The system there began with severe discipline, the bonds of which were gradually relaxed on good conduct; when the twenty-year period was half through the convict was more in some respects a free man; he was started to work on his own livelihood, and assisted by the State in growing his crops and building his house, and living with his friends or his wife, and became again a respectable member of society. One of the recommendations he and his colleague made was that a greater resort should be had to the penalty

transportation by courts in India, so that in place of those melancholy failures which habitual criminals underwent in Indian gaols as they did in England—men convicted time after time, who never moved or made any effort to retrieve their situation—they should be sent to Port Blair. There is a section in the Penal code which enabled it to be done, and the report of those who looked up that code recommended that it should be done. Unfortunately, their recommendation did not find favour with the judicial authorities. The phrase "transportation for life" seemed so terrible that they were unable to advise the sessional courts, which had to deal with these crimes, to impose so terrible a penalty, when what seemed a milder penalty of seven or ten years imprisonment might be imposed instead, and so this opportunity of reclamation was lost. He hoped Colonel Temple might be persuaded at some future time to give some further information about this extremely interesting colony. The Andaman Islands were not only interesting as a convict settlement, but they were one of the most remarkable parts of the globe from a scientific point of view, and it would be very useful to learn something about their geology and their flora and fauna.

Mr. WILLIAM TALLACK (Secretary, Howard Association) said many present must have been pleasantly reminded by this paper of the interesting remarks which Colonel Temple's honoured father had written on India and Palestine. Colonel Temple had taken an assured position amongst those able Indian administrators whose services the noble Chairman had already alluded to; but there was one name mentioned in the paper which was particularly interesting to himself, as being an old friend of the Howard Association, and one with whom he had had the pleasure of conversing on many occasions. He referred to Dr. Mouat, who was the principal order of the work in the Andamans. He well remembered him as one of the most genial, as well as one of the ablest, of men. He was at the London International Prison Congress in 1872 and again at the Stockholm Congress in 1878, and on each occasion his geniality and encyclopaedic information rendered him one of the most important persons present at those gatherings. When he took over the superintendence of the prisons of Bengal in 1855, about two years before Dr. Mutiny, he was told by the then Inspector that he would find them in such a state of irregularity and confusion that he had given up all attempts to set them right, and simply handed over the task to Dr. Mouat. He set to work vigorously, and it was his aim especially that they were indebted for the trying into practice the operation of the great principle of reformation, and especially reformation by remunerative industrial labour. He made that the most prominent matter in the Indian prisons, not only in the Andamans but in the prisons on the

mainland, and he had had many excellent successors and imitators in that matter. He (Mr. Tallack) believed the system of varied and useful industry was carried farther in the Andamans than in any other penal establishment in India, and possibly than in any other place in the world. The practical point which impressed itself most on his mind was that the example set by the administration of the Andaman penal settlement pointed to a matter in which England particularly needed to make progress, and that was not only to aim at reformation but to take the necessary time for the formation of good habits and the eradication of bad ones. That required time, a thing which was overlooked by the public, and by many public writers. A great deal of fault had been found lately with English prison systems, because a majority of the prisoners were recidivists, who came back again and again, showing they were not reformed. It must be borne in mind that only one in fifty of English prisoners were detained more than six months, and about three-fourths of them were only in from a fortnight to a month. What reformation could you make in a few days, or a few weeks? How could inveterate habits of drunkenness or vice be eradicated in so short a time? The very idea was absurd. In the Andamans they had years to do it in, and not only so, but before the actual period of penal servitude was over, there was an intermediate stage, which was also a part of Dr. Mouat's plan. The convicts were then allowed to marry, which was a very important thing in connection with their reformation. They were encouraged to save, and in various ways were assisted to form habits which were necessary for their getting on in ordinary life. In this country, some reforms had been made of recent years, and any one who knew the present condition of the prison service knew there were excellent men both in the higher and lower departments, but we had not adopted the plan of testing the reform before releasing the prisoners. If a man were found unsuitable for liberty, if there was every probability that when he was let out he would commit murder, or again become a burglar, he ought not to be set at liberty. It was not absolutely necessary to have long sentences, but it was necessary that the detention should be long enough to form good habits. In the best American prisons they were increasingly aiming at reformation, especially in New York, Massachusetts, Illinois, and Ohio. There, generally speaking, the terms were too short, but, considering the short terms, they had had some remarkable successes. He should add that in the United States there were also some of the worst gaols in the world, and no words could sufficiently describe the evils of the convict leasing-out system which prevailed in some of the Southern States. They were much indebted to Colonel Temple for this paper, and also to the illustrious Administrator who had occupied the chair.

The Rev. Dr. W. DOUGLAS MORRISON (late

Assistant-Chaplain at Wandsworth Prison) said he wished to join in congratulating Colonel Temple on this admirable paper. He had read a great deal of prison literature, but he did not think he ever came across so much information in so small a compass as they had had that afternoon. He was much struck with the remark on the conditions which produced the criminal population. In a great number of cases the criminal was the product of what might be called his individual conditions and characteristics, but he felt sure also that the criminal population, especially in this country, was to a great extent the product of evil social conditions. If an individual had no chances in the world, if he were born and bred in the midst of the deepest misery of every kind, how could you possibly expect him to be anything else in the end but a criminal. He had seen hundreds and thousands of cases of that kind. No doubt many criminals were the result of depraved conditions and characteristics which they might have inherited, but in the majority of cases, he believed, criminals were not the products of those conditions, but of the adverse social conditions in the midst of which so many were born and had to live. If they wished to diminish crime, the proper way of doing so was not by gaols and reformatories, but by doing all they could to ameliorate the social conditions of the most degraded of our population. Even that would not abolish crime, but it would go a long way to mitigate it. Mr. Tallack had pointed out time as an essential element in reformation. Lord Kimberley, in his Report on Prisons in 1879, went over all this ground most carefully, and at the end of the inquiry then conducted by him he came to the conclusion that in those prisons where most time had been given to reform the criminals the result was that the regimen to which they had been subjected not only failed to reform the offenders, but produced a deteriorating effect upon them. If you kept people too long in prison you not only did not reform them, but depraved them. He had seen that occur in hundreds and thousands of cases during his work in English prisons. He was delighted to see that the system in operation in the Andaman Islands was to a large extent different from that at home. There, there, was a really progressive system, not a sham as it was here. The convict was gradually accustomed to liberty and to depend upon himself; he was allowed privileges which would never be dreamed of in this country, and he felt sure as the result of what was going on that there was infinitely less recidivism. In this country habitual offenders were perpetually on the increase, but he understood that in the Andaman Islands there was hardly such a thing known. The reason was as plain as possible, because there was a proper system of progressive stages by which the prisoner was accustomed to liberty, and the result was when he was ultimately freed he felt so little the restraint of the prison that he remained in future a respectable member of society. He hoped this paper

would be widely read, and would produce some impression upon the home administration, so as to reduce the great number of habitual offenders which crowd our prisons.

Sir OWEN TUDOR BURNE, G.C.I.E., K.C.S. said that it gave him sincere pleasure to propose a formal vote of thanks to Colonel Temple for a paper which was not only well put together but well giving an example of terseness and good delivery. The noble Chairman had alluded in feeling terms to the tragic event which happened at Port Blair on February 8, twenty-seven years ago. As one who had been closely associated with Lord Mayo, who was Viceroy, it might be of interest to those present if he mentioned that on assuming office in India the nobleman frequently spoke of his great interest in the Andamans and his wish to visit that settlement with a view to see what improvements, if any, could be effected in the administration, and the special object of civilizing the convicts, shortening the term of their transportation, instructing them in trades, and, in short, putting the settlement on a basis so well carried out during past years or so, as was so admirably and impartially described by Colonel Temple. Lord Mayo also had a special wish to visit Mount Harriet, which he thought might be made into a sanatorium for Calcutta. But, alas, all the beneficent views held by the Viceroy were cut short, at the moment, by the mournful event so accurately described by Lord Northbrook, an event which deprived India of one of her noblest and best viceroys, notwithstanding the precautions against danger taken, not only by the personal staff, but by the Chief Commissioner of the settlement. In proposing a vote of thanks to Colonel Temple, he hoped he might also be allowed to express the obligations of all those present to the noble Chairman for so kindly and so ably presiding over their proceedings.

A vote of thanks having been carried unanimously.

Colonel TEMPLE said he would only refer to a few points which had been raised in the discussion, and, first, in reply to a query from the audience, he would say that the climate of Port Blair was that of an ordinary tropical island situate in about 10 to 12 degrees north latitude; it was very hot and very wet, there being about 200 inches of rain, otherwise it was not unhealthy. The temperature was hardly ever below 75 and hardly ever above 100, but a shower of rain would wet you through in less than two minutes. Firstly, then, about escape, they were exceedingly difficult, and he should say that perhaps not more than three or four per cent of the men who tried to get away ever lived to accomplish it. There were a certain number of men missing every year, but most of them were either drowned or got lost in the jungle. Those who did get to foreign country were almost immediately picked up by the police and sent back, and they had

wonderful stories to tell of what had happened to them on the way. He had known six or eight escape in an open boat in the middle of a moon, when the weather was so bad that the steamer was detained one day on a journey of six hours! But these men, without food or clothing, managed to get across to Burma, where, at the moment they landed, they were taken by the police and sent back. The native Andamanese always help to catch escaped convicts, because these having no food or means of support had to steal from the natives, which, of course, excited their hostility. Secondly, there was hardly any recidivism of the 400 or 500 who were released every year; perhaps one or two per annum came back: but for all there were two reasons, one was the system which he had described, and the other that the released convicts were not young. Every man was kept for 20 years, and the majority of them about 20 years, so that they were somewhat advanced in age when they were discharged, and in India a man of 50 years of age was quite old. Although they were extremely anxious to get back home, he did not think they lived very long afterwards, as the change of climate probably killed them off.

SEVENTH ORDINARY MEETING.

Wednesday, February 22, 1899; Sir WESTBY PERCEVAL, K.C.M.G., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

- Mr. A., 2, Albion-street, W.
- Mr. Arthur Frederick, 140, New Bond-street, W.
- Mr. Mason, Sir Samuel G., Nottingham.
- Mr. John Arnold, 6, De Grey-road, Leeds.
- Mr. Raw, W. J., Woodfield, Streatham-hill, S.W.
- Mr. Bread, S. Howard, M.A., J.P., Southill, Biggleswade.
- Mr. White, Franklin, Hazlewood, Keynsham, and Johannesburg.

The following candidates were balloted for and duly elected members of the Society:—

- Mr. Mans, Herbert William, 38, Chester-terrace, Regent's-park, N.W.
- Mr. Hill, William Henry, B.A., Irthlingborough Iron Works, Wellingborough.
- Mr. Simpson, Alfred, Blochairn Steel Works, Glasgow.
- Mr. Pearson, Alexander Louis, Hauteville, St. Germans-place, Blackheath, S.E.
- Mr. Jackson, Arthur W., Wyandotte, Shirley, Southampton.
- Mr. Meddalla, Florance Montefiore, 33, Addison-road, W.
- Mr.ingham, R. T., 6, Finsbury-square, E.C.
- Mr. Harris, Major Stephen L., R.E., 6, Wemyss-place, Edinburgh.

The paper read was—

THE GOLD MINES OF WEST AFRICA.

BY JAMES IRVINE, F.R.G.S.

Unlike the Transvaal and Westralia of today, or of California and Australia of fifty years ago, the Gold Coast of Africa has a history, which it is necessary should be understood and remembered in order to appreciate fully its importance now; and, with your permission, I propose to give a brief sketch of that history, although I am aware that to many of you I shall not be able to unfold anything new.

The first records we have of gold in that part of the world take us back to the days of Herodotus, the "father of history," some 450 B.C., who tells us that the Carthaginians obtained their supplies of gold from black people who brought it across the great desert from the western shores of the continent; and he thus, in an unintentionally amusing manner, describes the trade by sea which was then carried on:—

"There is a nation beyond the Pillars of Hercules which they are wont to visit, where they no sooner arrive but forthwith they break cargo, and having disposed their wares in an orderly way along the beach, leave them, and returning aboard their ships raise a great smoke. The natives when they see the smoke come down to the shore, and laying out to view as much gold as they think the worth of the wares, withdraw themselves afar. The Carthaginians upon this come ashore and look. If they think the gold sufficient, they take it and go their way, but if it does not seem enough, they go on board once more and wait patiently. Then the others draw near and add to their gold till the Carthaginians are content. Neither party deals unfairly with the other, for they themselves never touch the gold till it comes up to the worth of the goods, nor do the natives even carry off the goods till the gold is taken away."

And evidence of this early trade is also said to be supported by other writers upon this part of the world, though whether they describe it in the same glowing terms of simplicity and goodwill I cannot say. It is very clear that those days are far removed from ours, with their "grabbing" of hinterlands and keen jealousies between race and race.

I shall not, however, detain you over those far-away histories and these modern moralities, but bring you down to a comparatively recent period, though even here we are forced to go back to the early 14th century, when the French were said to have recommenced the trade in gold with the natives then resident at

Elmina; just 100 years before the arrival of the Portuguese.

Whether the claims of the French are good or not, it is certain that the Portuguese under Baldeza brought gold in 1442, and that in 1470 other navigators brought supplies of it from the mouth of the Prah; also about this period another Portuguese merchant, Fernando Gomez, bought the monopoly of trading in gold dust for five years for the sum of £50 a year, and on giving an undertaking to explore annually a line of 350 miles of coast.

This exploration led to the opening of large and important mines, to defend which it is assumed that the Castle of Elmina was built, and a flourishing trade was carried on till early in the 17th century, when the mines were shut down and the digging of gold made fetish by the King, since which time no gold has been worked in that neighbourhood. This trade was continued in gold and slaves from other districts of the Gold Coast until Guinea became the great gold-producing area of the old world. This name of Guinea, which gave the designation to our 21s. piece on account of the mineral from which it was made coming from this district, is supposed to have arisen ages before from the natives of Jenna on the Niger, who traded in large numbers with the Gold Coast, and when asked by the Europeans from which place they came, replied Jenna, or Genna.

The first Englishman who brought away the precious metal was Captain Thomas Wyndham who, in 1551, brought to England 150 lbs. weight of gold dust, worth about £10,000. This result so encouraged the merchants of those days that they fitted up three vessels, the *Trinity* and the *John Evangelist*, each of 140 tons, and the *Bartholomew*, of 90 tons, and these three vessels returned with gold, ivory, and grains of Paradise, valued at £34,100, and some slaves.

Stories of sensational riches come down to us from those ages, and the barbaric splendour of some of its past rulers freely justify such traditions. Ghana was famous among the ancients for its golden throne, Bontuko for its golden stool, while Bowditch tells us that the King of Gaman, of which Bontuko was the capital, had steps of solid gold by which he ascended to his bed. The Ashantis were most proficient in the manufacture of ornaments made from gold, but were surpassed by the people of Dagwumba, who inhabited a large territory to the north-east of Ashanti, ornaments being made in weight to the extent of more than 1,000 ounces.

To conclude this part of my subject, particulars of which I have freely used from the pages of Bowditch, of Ellis, and of MacDonald, I will quote from the late Sir Richard Burton in his book, "Wanderings in West Africa." Sir Richard says that about this period, cupidity having mastered terror of the Papal Bull which had assigned to Portugal the exclusive right to this trade, English, French, and Dutch adventurers hastened early in the 16th century, to share the spoil, when a flood of gold poured into the lap of Europe, and as much as £3,000,000 was shipped from Elmina alone early in the 17th century. Sir Richard also says, and upon this I shall have some remarks to make later, that as we advance northwards from the Gold Coast the yield becomes richer, and that in Ashanti the red and loamy soil, scattered with gravel and grey granite, is everywhere impregnated with gold.

I now come to the present day, and it is to Sir Richard Burton we are indebted, more than to any other man, for drawing public attention once again to this ancient gold-field. In 1857 was published the book I have already named, "Wanderings in West Africa," to be succeeded by his joint work with Commander Cameron, C.B., entitled, "To the Gold Coast for Gold," and published in 1882. In both of these books he expressed his amazement at the intelligence and enterprise of the present day had not sent men and machinery, for he remembered all the wealth described had been obtained in the most primitive manner by surface washings, or by pounding the quartz in hand, which had been obtained from shafts rarely exceeding 50 feet in depth—at what depth the natives, having not the smallest idea of pumps or modern machinery of any sort, were invariably drowned out.

In parenthesis I may say that all the merchants trading to the entire West Coast of Africa, notably Messrs. Swanzy and Co., were testified in a Blue-book fifteen years ago that their firm had received in exchange for English manufactures not less than £1,000,000 in gold dust—were aware of this vast wealth, but had no steps, as I have said, had ever been taken scientifically to develop the mines until about the years 1880 to 1882. At that period several companies were started, most of them with totally insufficient capital, and the few who had enough had neither experienced men to guide them nor scientific knowledge of any kind on their Boards, and the result was natural and inevitable.

ere is this to be said, however, in defence of the management at that period, that really worthy experts and managers were few and far between. Gold mining had not become a science it is to-day, for all will admit that knowledge in this respect has been obtained by leaps and bounds during the last ten to fifteen years, and an enterprise which can now be carried out with the Bankè formation of the Wassau with as much precision and with as great certainty as with a well-defined coal formation in Cumberland, had not then been thought of. It is also to be remembered that East Indian mining, and the early days of the Transvaal were calling for all the experienced managers, and that West Africa with its evil example came in as a bad third, only getting men as a rule, could not find employment elsewhere; nevertheless those pioneer days, full of misfortune to many shareholders, and distress, often very undeserved to others, had to be borne, and the workers of the present are being led into their labours and reaping the fruits. In this manner. Not one single company which afterwards came to grief did so because they found no gold—absolutely everywhere—found gold, ranging from so many dwts. on the surface to 9 ozs. at greater depth, and 10 dwts. cover all working expenses, it is not beyond question that with capital to develop, every mine would pay dividends in abundance. Unfortunately, however, in each instance the capital, often, as I have already said, was too small, had become exhausted at a time when the entire commercial world was in a backwater of depression, caused partly by the losses (less in Africa, however, than in America), but still more by the political unrest which has weighed so very heavily on all enterprise during the last 10 or 15 years.

That all African gold companies did not then have some held their ground through good management, and the use of money advanced by those who had the power and who believed in a great future. The result is that we have a company which gave an average yield last year of 28 dwts., with crushings of about 6,000 tons of conglomerate, and which has an estimated amount of gold of £5,000,000 sterling, and all intents and purposes proved.

At a meeting of the Geological Society of London, held on the 20th April last, a paper was read on the origin of the Wassau conglomerates, and in the discussion which followed, an experienced authority on the subject said he did not agree with the reader of the

paper in thinking that the West African conglomerates were derived from the disintegration of the existing range of mountains which were found a little further inland, but he thought they undoubtedly belonged to a far earlier period, and were similar in age to those in South Africa. They were evidently part of the series of sedimentary deposits which so largely predominates over the surface of the African continent. He thought that in these conglomerate beds of West Africa there would be found to be deposits as extensive and as rich in gold as those of South Africa.

Regarding this property just referred to, one of the directors, whose experience and whose character gives weight to his opinion, said, publicly, in July last:—"I am looking to the time when, like the Crown Reef, we shall be paying 200 per cent.; their stuff is very much poorer than ours."

Another company which, under continuous crushings since June of last year, has given an average of over 1½ ounces to the ton, but, so far as I know, the directors of which have not ventured on an estimate of their gold in sight; another which has held up its head since 1880 has obtained an average of fully 1 ounce to the ton, with many thousands of tons crushed; another, the gold of which was so pure that 84s. per ounce was offered, or if the quartz could be shipped home uncrushed, the smelters at Swansea agreed to buy it at £20 6s. per ton on the standards of samples assayed.

It may not be out of place to recall Sir John Glover's statement, made in the Town-hall of Liverpool on his return from the Ashanti War of 1874, that on that splendid march of his from the Volta to Kumassi he passed through districts where you could dig up gold as you would dig up potatoes. Some of us heard that statement, and Sir John was not given to exaggeration, though, of course, in this there was allowably some hyperbole. I can make many other similar statements regarding the value of the West African reefs, for which I hold documentary proof, but these will suffice.

I am not here to advertise any single mine, but I am pleased to have the opportunity of drawing attention to the phenomenal richness of the mining districts on the Gold Coast of Africa, and to state as my well-founded conviction, that we are on the eve of a success which has probably no parallel in the history of any era or of any colony.

I said in a previous part of my address that I would refer to Ashanti. This kingdom, as you all know, has only recently come under the

Government of Great Britain, and sufficient time has not been afforded for the same amount of development, but what development has taken place has been absolutely surprising. About two years ago a concession was obtained which left no doubt about the richness, and as the capital—in this case not too small—was easily obtained, steps were at once taken to send out and erect machinery, with the result that a reef 25 feet wide was attacked, not by expensive shafts, but as a quarry, and crushings of many hundreds of tons have yielded an average of three ounces to the ton; indeed a well-authenticated rumour has it that at this very moment they are crushing quartz which is giving eight ounces to the ton.

Another property which adjoins it was inspected and reported upon by an expert of high standing, but his story was considered so improbable that a second mining engineer, of experience and probity, was sent out at great expense, and he not only confirmed the previous report, but placed an actual estimate upon the property, valuing the amount of gold easily recoverable at £6,000,000 sterling.

Mr. MacDonald, from whom I have already quoted, estimates, at page 112 in his book, that gold to the value of not less than £600,000,000 to £700,000,000 had from time to time come out of the Gold Coast.

I feel sure I must in this hasty review have said enough to prove the enormous richness in gold, and that the name of the Gold Coast is a correct description of the territory.

I shall now proceed to speak of the titles under which these concessions are held. The properties are, in the first instance, obtained from the chiefs who have, by native consent and approval, owned them for generations—by purchase, or by the payment of an annual rental, or by royalty on the gold won. A regular deed, with all the formality and tautology of a similar document in England is drawn up and signed in the presence of the English District Commissioner, who explains, through an interpreter, the meaning of it, and who then affixes his seal to a statement that the vendor clearly understands its import; the deed is then taken to the duly appointed English official and registered. In the main this has answered very well in the past, though difficulties not infrequently arise afterwards, when other natives come forward to say that the first vendors did not own this property—but I have never known a case where the English purchaser had to give it up, as with

tact and reasonableness every native case dealt with.

These cases and other points, such as the possible overlapping of properties, have, however, led the Government to see the necessity of guiding and controlling such native grants, and a Lands Ordinance Act has therefore been introduced under arrangement for some time; and one will be passed after due consideration, not until due consideration has been given to it, not by Government officials only, in the desire of everyone.

In this connection I may state that considerable anxiety was caused by the proposed Lands Bill of the late Governor, which, however, fortunately was rejected by Mr. Chamberlain, who assured a deputation of native traders sent over to this country to represent native interests, that the future Bill would be framed on just and equitable lines, and acknowledging the laws dating from time immemorial of the native kings, chiefs, and families; a full report of this interview is to be found in a large pamphlet published on the 5th August last, by Messrs. Ashurst, Morriss, Crisp and Co., the solicitors representing the deputation, and I am pleased to be enabled to quote from a letter which I received a few days ago from Cape Coast Castle, as follows:—

“To-day there was a mass meeting in the Chamberlain square to receive the message from the representatives of the aborigines who went to England on the Lands Bill. By what I can understand, everything is settled amicably for them, and the king retains their right to sell or dispose of their lands as they think fit; the Government recognising the native customary laws.”

Let me now speak of that all-important question of climate, which has so far been the greatest, perhaps the only real difficulty, and that it is a difficulty of grave and sad importance no one will deny.

The experience of everyone during the last 10 or 15 years has unfortunately been that the engineer-in-chief after six or twelve months of his mine, if he has not died, has sickened and fled, and another, after perhaps weeks of months of anxiety on the part of boards in England, has been found, sent out, and many instances with the same result, and despair has well nigh broken the heart of every director; but that all this has come from the climate itself is far from the truth—much perhaps one half, of the illness has been caused by the men themselves. I had the misfortune to know one case in point where the director of a company waited for six months to get

particularly experienced man whom they brought home from Venezuela, but whose character had undergone sad deterioration since the chairman had last seen him. This man drank 34 bottles of brandy, champagne, and beer on his journey of 24 days, landed drunk, lived drunk, and in 21 days died drunk, the climate got the blame. This is an extreme case, but cases half as bad, or even one-fourth as bad are common and bad enough, and it is this more than the climate itself which gives the character to West Africa.

I do not hesitate to say, and there are gentlemen in this room who by practical experience can bear me out, that given sobriety, common sense, and plenty of work to do, with the best food and the best quarters which they can procure, the climate of West Africa is not one whit worse than many other of our tropical possessions. The experience of our important company is worth giving here in support of my last remark. This company has been working successfully, and during the last ten years has only had four deaths directly due to the climate and two others indirectly due to the same cause.

When I ought also to point out that the mortality and sickness, especially of late years, I think, been largely among Government officials; it is, therefore, much more in evidence. This is to be traced to two extremes of life: one which calls for our respect, admiration, and sympathy in the case of those grand fellows, most of them young, who are the makers of our empire, and who are forced to bear hardships of exposure, irregular and of insufficient food, and who, without a murmur, endure, do their life-work—die. The other extreme is thus referred to by Mr. MacDonald, in that capital book of his, from which I have already quoted:—“So the Gold Coast has gone on from year to year with its death-rate much about the same . . . work in the same department, limited recreation, scanty amusements, poor and insanitary quarters, have all contributed to keep up the bad state of the colony, and to embarrass commercial progress in one of the richest of our tropical possessions.”

But these conditions are not going to continue. They are not a necessity of West Africa, and they are already disappearing; already we are finding a very different class of officers and miners, partly because we have begun to increase of the mining industries of the world, which afford schools of education, and much larger and a more respectable field

from which to choose our managers and men, and partly because of the attention drawn to the question of health.

In this connection it is fitting that I should refer here to the magnificent offer of the President of the African Section of the Liverpool Chamber of Commerce, Mr. A. L. Jones, who has undertaken to give an annual grant of £400 to cover, in Liverpool, the cost of research into the origin of malarial fevers, and it is perfectly reasonable that we should look for such an improvement in the sanitary condition of West Africa as we have had, say, in Calcutta, under which our young men of the next generation will prefer Africa to India.

What do we find was the condition of Calcutta when that city of palaces and of wealth was founded. Sir William Hunter says in his delightful book, “The Thackerays in India:” “Our ancestors found Calcutta a swamp, and they created on it a capital;” and this is the description of it. After stating that one or two families of Sets and Baisaks, just as one would say one or two families of Bonny men, Calabarese or Fantees, settled at the Cotton Mart overlooking the river, he adds:—“That bank sloped down into a swampy jungle which at places came right down to the river’s edge, at others there was a strip of fairly raised ground between the river and the swamp, and behind it spread the vast agglomeration of brackish lagoons, a pestilential region, long given up to the tiger and the crocodile.” “By creeks through the narrow strip of high ground along the river bank the fetid ooze from these fens swayed backwards and forwards with the rise and fall of the tide.” This description, which those of you who know West Africa would consider an exaggerated one for even the worst part of it, is what Calcutta was at its foundation, and which, as late as 1757, gave the result mentioned in a letter from the Admiral’s surgeon, when he reported “that of the 250 soldiers who came with Kilpatrick in August of the previous year only five survived their commander.”

Another authority—Rennell—speaks of it as a climate which proved so prejudicial to European constitutions that scarcely one out of seventy men returned to his native country.

This is what Calcutta was only a few generations ago, infinitely worse than anything we have ever had in West Africa, except, perhaps, in the epidemic which visited “the rivers” in 1860, or thereabouts, and we are entitled, therefore, to hold the conviction that, with the superior knowledge and appliances of

the present day, we shall have a state of things and at no distant date, which will raise the health of West Africa to a level of that rejoiced in by the thousands of our countrymen in India.

I must now bring this paper to a close, but I cannot do so without acknowledging our indebtedness to Mr. Chamberlain for the extreme interest he has taken in the development of this part of our colonial empire. It is true that he is only carrying out the resolution come to by Lord Ripon, his predecessor in the last Liberal Government, who pledged himself to the extension of railways and other developments; but none the less, or perhaps all the more, do we feel our indebtedness to him, and it is fitting we should state that he has not only met every deputation and every request with the accustomed courtesy of the Colonial-office, but what is not so usual, he has fulfilled his promises, and has given a fostering hand to every scheme which has had for its end the welfare and the advancement of this part of Her Majesty's dominions.

It is with pleasure I quote from his speech at Manchester on the 16th of November last, on which occasion he is reported to have said:—

“We had secured a sufficient hinterland for our colonies on the Gold Coast and at Lagos, and he ventured, standing here, to predict that before five years were over those colonies would be amongst the most valuable possessions of the Empire.”

I now very briefly refer to the railway so happily begun from Secondee to proceed to the Wassau Reef, and thereafter to Kumassi along a gold belt unequalled in its richness in the whole world. That this line will pay from its opening day there cannot be an atom of doubt, for there are a dozen mines—I might well say dozens of mines—waiting to begin operations until they can get up their machinery and material at profitable rates. At present the cost of transport ranges from £18 to £50 per ton according to weight of packages, but that is the least part of it; the impossibility of getting up heavy enough machinery forms the most serious obstacle to the success of the mines, and this will disappear with the opening of the line; it will then also be possible to carry up a large traffic in coal for driving the machinery (a necessity becoming rapidly very urgent owing to the growing scarcity and expense of wood), or perhaps, and still better, crude petroleum for the same purpose, of which there is every reason to believe an unlimited

supply exists only fifty miles to the westward and on the sea coast.

I shall not detain you longer. We have seen during the 15 years an extraordinary race on the part of English, French, and Germans for possessions on the continent of Africa—though we might have had a larger share, indeed, but for the folly of our Government. Liberal and Conservative alike, 20 years ago we might have had the whole of it—I think we might have had a larger share, but we have by no means come off badly, as, with the exception of the richest portion has fallen to the French, though much of that obtained by the French, though much larger in area, is, as Lord Salisbury humorously said some years ago, what our farmers would call “light soil,” and as for the German portion, it is probably valuable, and will be fairly well developed, nevertheless, I make the statement that neither French nor Germans knew what they were after when this race began, and I venture further to prophesy that in another 20 years they will be heartily sick of it, and anxious to hand all over to us. It has already been made apparent that they had not counted the cost, and that they cannot successfully deal with the native races as England can. She has proved her powers, her fairness, kindness, commonsense, all over the world, and not least, in recent years, in Africa, and to-day we have on her coast, and in her far interior men of refinement, as well as others who are blocks of rough-hewn British manhood, some of them, perhaps, not beautiful personages, but the founders of England's greatness have not usually been those who wear soft raiment and dwell in king's houses, but men who had a work to do, and do it with no thought of self and with a resolute courage which no dangers can daunt and no difficulties turn aside.

DISCUSSION.

The CHAIRMAN, in inviting discussion, said he hoped they would hear something from those who had had experience on the Gold Coast, with regard to the three important questions of the supply of labour, water, and fuel, because unless those questions were satisfied, there would be great difficulty in getting the gold, however abundant it might be.

Mr. F. SWANZY said he had no personal experience of the Coast, though his name had been connected with it for a century, and he himself had had a great deal to do with gold-mining there. With regard to labour, the Governor of the Gold Coast told him a few nights ago that the supply was very large, and

had been proved by experience in the construction of the railways. Something like 10,000 men employed in the construction of the three railways, and though at the time of the first survey it was estimated that Coolies or Chinamen might have to be introduced, nothing of the sort was found necessary, two of the railways had been constructed entirely by native labour. A large mahogany industry had been started, and there had been no lack of labour for squaring and shipping the logs. They had been working at mines there for some years, and that they would have the *pax Britannica* over a portion of the hinterland, the tribes, instead of fighting one another, when they found there was work to be had, would be glad to get it. Miss Kingsley had written to him to say that she could get him a large supply in a short space of time, if needey. In evidence of the traffic in gold in past times, he would refer to the presence in the country of aggrey beads, which were referred to by Ellis. They were a curious sort of mosaic, which were now imitated by Venetian manufacturers, and they were found chiefly in the western part of the Gold Coast; and were precisely similar to beads found in the mummy cases in Egypt. The theory was that the Venetians in past times came to the Gold Coast, and exchanged their beads for gold. The natives dug them up in the ground, and the current saying was that they were worth their weight in gold, which was as suggestive as to their origin. One writer referred to an ancient lamp having been found in mining operations, and to other traces of mining having taken place centuries ago. Coming to later times, there was an interesting book called "The Golden Coast," published in 1616, which bore the pertinent Latin motto, "Quis nisi mentis inopis tum reput aurum?" which he should translate, "Who but a fool will refuse gold when it is offered?" In the preface the author referred to the wonderful amount of gold to be obtained there, and said that when he remembered what was related of the past and of the present, he was reminded of a passage in Sallust, in which he referred to men being incited to worthy deeds by the sight of images or portraiture of their ancestors, his idea evidently being to urge the men of his own day to go to the Gold Coast and make their fortunes. Another author, writing in 1799, said the natives believed that rain descended from God, rendering the earth fruitful, and the trees productive, and washing down the gold from the mountains. Also that in the beginning God gave the black men the choice of having either gold or a knowledge of the arts and sciences, and the blacks, having chosen gold, He condemned them, for their cupidity, to be slaves of the whites. It was related in Beauchamp's "Ashanti and the Gold Coast," that his (Mr. Swanzy's) grandfather gave evidence, in 1816, before a Commission, when the Government thought of taking over the Gold Coast from the African Company, and stated that at that time it was supposed that

the Gold Coast produced 10,000 ounces annually; that the soil of Ashanti yielded a large amount, and that on one stream alone 8,000 or 10,000 slaves were employed in washing for two months in the year. There were also mines, the gold from which was called "rock gold," but many of the richest mines were dedicated to the national deities and were protected by popular superstition. The reference to the emulation amongst European nations in Africa reminded him of the similar competition in past times which was referred to by Mr. Bosman; he enumerated the Dutch West Indian Company, the English African Company, the Zealand and English interlopers, the Portuguese, and the French.

Mr. T. J. ALLDRIDGE said he knew nothing about the Gold Coast, and could only speak of the climate on that part of the West Coast with which he had been connected for twenty-eight years, viz., Sierra Leone, and which was as bad now as when he first went there. But if you left the mangrove swamps and went into the interior, the climate was entirely different, and you could live there almost as well as in England. The great thing was temperance, and there was no doubt many men took more liquor than was good for them; at the same time every excuse should be made for men who were compelled to reside in isolated places, seeing nobody, and one or two hundred miles from any kind of civilisation. He had only just returned from West Africa, having had to pass through the massacre at Sherbro and other parts of the protectorate of Sierra Leone, and he must say he was very glad to get home with a whole skin, for at one time things looked very black. He never experienced so much pleasure as when a British ship came into the harbour and landed a force of bluejackets and marines, which in all probability saved their lives.

Miss MARY KINGSLEY said she had nothing to add to what Mr. Irvine had said about the gold mines, except to say that the accounts given of the enormous quantity of gold in that region was fully supported by all the literature regarding it, with which she was acquainted. The great Company of Royal Merchant Adventurers of England, of the time of Charles II., used to coin from 30,000 to 50,000 guineas a year from gold obtained there, and though those coins were originally intended to be worth 20s., their intrinsic value never fell below 21s.; they were, she understood, always stamped with the elephant, which was the seal of the company. With regard to the labour question, she agreed with Mr. Swanzy that there need be no difficulty if they treated the people properly, and did not spoil the market by commencing paying too high a price for absolutely untrained labour.

Mr. W. H. SWIFT said he had been on the Gold Coast from 1883 to 1896, and had worked on the reefs and alluvial deposits in the neighbourhood of Tarkwa and the Ancobra river. The bankè reef was one of the finest reefs in the world. One quartz reef had

been traced for 20 miles, and to his own knowledge averaged 7 or 8 feet in width; it was a true fissure vein. He did not think Mr. Irvine had made quite enough of the transport difficulty which, in his experience, had been the chief cause of the failure of West African mining. Secondly came inefficiency of capital, and thirdly the companies in London made a great mistake in rushing for returns before the mines had been developed; they sent out stamps and expected returns before any real mining work had been done on the property. The transport difficulty, however, was the chief obstacle. He knew one company which had lost from £10,000 to £15,000 on the bar in the Ancobra river in specie and machinery. The railway would be the saving of the country. When the railway got to Taquah that would be the centre of a large and rich gold-mining camp, and eventually it would reach Ashanti, where there were enormously rich reefs. There were parallel reefs right across the country from the sea, and his firm belief was that it was the richest country in the world. There was plenty of water for all mining purposes, and, up to now, plenty of fuel. He found no difficulty with regard to labour. He had had experience of Chinamen, Dyaks, and others, and he found the men of the West Coast quite equal to them. They were superior to those in South Africa, as they made good artisans, engine-drivers, carpenters, and fitters.

Mr. B. A. COLLINS said he could endorse what Mr. Swift had said; but one of the principal questions had not been touched—that of roads. There were lots of roads marked on the good charts which did not exist at all; you had to cut your way as you went along. The chiefs of each village, however, were perfectly willing to cut the roads provided they had a little encouragement from the Governor, and that was the only complaint he had against the present administration. He was taken ill at Dunkwa and was told that he could meet Captain Donald Stewart and Dr. Henderson who were going with him to Kumassie if he could push ahead. He sent word ahead that there was a white man ill who wanted to get on, and the natives came out and cleared the road for him for forty-five miles; but he found afterwards that this was done because they thought he was a Government official.

Mr. F. P. T. STRUBEN, who said he claimed to be the discoverer of the Johannesburg gold-fields, having had a battery running there before anyone else came, said the conglomerates of the West Coast were absolutely identical geologically with the Johannesburg bankèt; and not only so, but they had been proved to extend over a very large extent of country. The reefs, as they were called, were nothing more than beds of a sedimentary deposit, and those on the West Coast were equal in size to anything in Johannesburg. They had been proved to 300 ft. in depth and 18 in. to 7 ft. in thickness. Their richness had

also been proved to be equal to those in Johannesburg. Mines had been running over two years from which an oz. and upwards had been obtained running over the plates or in the first process, whereas a greater yield than was obtained in the T. vaal. He did not mean to say that the conglomerates on the West Coast on the whole were richer than those in Johannesburg; but if they were not good, they were good enough. In Johannesburg they produced something like £16,000,000 worth annually, and very likely this year the yield would reach £20,000,000, and at least an equal quantity might be obtained from the West Coast. There was also the advantage that the mines were within about forty miles of a port, and the distance from Europe was not much more than so that great economy would be effected in that respect. With regard to fuel, it was the general rule that the conglomerates went with the carboniferous series, and, from a geological point of view, coal must be found in the neighbourhood. His own opinion was that coal measures would be found in a north-westerly direction from the gold mines. But even if they were not, coal could be sent from Europe at a reasonable rate, and the gold in that region being purchased for £4 an ounce against £3 15s. at Johannesburg, the difference would meet any extra expenditure for fuel, if it were necessary. It had been demonstrated in Johannesburg that conglomerate beds, if once found of a payable nature, could be worked as a regular industry, not as a speculation. The depth was, practically, unlimited, because the formation which extended for 25 or 30 miles on the surface must be of great depth; it could not be a mere streak.

Mr. LOUIS GOWANS said he could corroborate what Mr. Struben had said as to the conglomerates on the West Coast being identical with those in Johannesburg, but he would say that there were no present gold mines on the Gold Coast, in the sense in which the word was used in the Transvaal, and would not be until they were made. Conglomerate mining on bankèt could be made a regular industry, but it required patience. It took time to make a mine, sometimes from two to five years before any substantial returns could be expected. Therefore, it required faith. You might always have faith in bankèt, but not always in quartz. Money invested in bankèt was as safe as in a bank. As to climatic and other difficulties, they could all be overcome by engineers with plenty of money at their back; but you must put money into the country before you could expect dividends.

Dr. D. MARTINI asked what was the weight of stamps and other machinery necessary to properly work these conglomerates. He had heard of some machinery being sent to a mine 85 miles inland which had to be abandoned half-way, and left to rot.

STRUBEN said he should not advocate any machinery being sent out; it would be simply a waste of time and money. To work conglomerated stamps weighing from 9 cwt. to 12 cwt., and the want of such stamps which had been available for a good many failures. For such heavy machinery, of course, good means of transport were essential. If it was made to take apart in small pieces for convenience of transport it never worked satisfactorily when put together. The boilers, of course, had to be of large size to work the stamps, as was required from 1 to 1½ horse-power.

THE CHAIRMAN, in proposing a vote of thanks to the speaker, said no reasonable man could doubt after what had been said, that there was gold in large quantities on the West Coast of Africa. Hitherto, the great difficulty had been that of transport; but now it seemed that the railway was just approaching completion. He had often discussed it with Sir George Ommamney, and no doubt it was a work which had cost the country both money and lives, but the difficulty would soon be at an end, and it looked as if there would then be a good field for the investment of capital there.

A vote of thanks having been carried unanimously,

MR. IRVINE, in reply, said there was not the least doubt there was coal there. Some 20 years ago he had all the details given him of the discovery of coal in the direction Mr. Struben had indicated to, north-west of the gold district, but yet nothing had been done to work it. The question as to the cost of transport had been discussed by several speakers, and no doubt it was of great importance, second only to that of health; but the difficulty was rapidly disappearing, and by the end of the year he hoped they would be able to transport machinery up to the mines on the Wassau range of hills; and from there he believed the line would go on to Kumassi as fast as it could be completed. There it would open up a very large and important district, and would also be of great importance locally in securing order in the whole country.

Notes on Books.

THE FRENCH COURSE. By Alphonse Mariette. London and Paris: Hachette. The first part of this manual consists of a number of exercises and remarks bearing on the difference of construction between the English and French languages, arranged under the various parts of speech. Though intended for beginners, it will perhaps be more useful

to those who have made considerable progress in the language, and are capable of appreciating such shades of meaning as the difference between *j'en doutais* (I doubted it) and *je m'en doutais* (I suspected as much) who would not consider that "a volatile Frenchman" would be idiomatically rendered by *un français volatile*, who do not consider that *un coin* is equivalent to *une pièce de monnaie*, or that *faire une tour* would be the proper translation of "to take a stroll."

The second part contains graduated exercises for translation from English into French, which afford ample opportunity to the pupil for the use of the information provided in the first part.

TELEGRAPHY. By W. H. Preece, C.B., F.R.S., and Sir J. Sivewright, K.C.M.G. Fifteenth Edition. London: Longmans. 1899.

This well-known work—first issued in 1879—has now reached a fifteenth edition. For the ninth edition the shape of the book was recast, and it is now said to have been freshly revised and to have received considerable additions.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MARCH 1.—"Leadless Glazes." By WILTON P. RIX. Professor J. M. THOMSON, LL.D., F.R.S., will preside.

MARCH 8.—"Cornish Mines and Miners." By J. H. COLLINS, F.G.S.

MARCH 15.—"Liquid Fuel." By Sir MARCUS SAMUEL. Sir EDWYN S. DAWES, K.C.M.G., will preside.

MARCH 22.—"London's Water Supply." By WALTER HUNTER, M.Inst.C.E.

Dates to be hereafter announced:—

"Preservation of Timber." By S. B. BOULTON.

"Coal Supplies." By T. FORSTER BROWN.

"Wireless Telegraphy." By W. H. PREECE, C.B., F.R.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 9.—"Leprosy in India." By H. A. ACWORTH, C.I.E., late Government Municipal Commissioner for the City of Bombay.

This meeting will be held at the Imperial Institute.

MAY 11.—"The Revenue System and Administration of Rajputana." By MICHAEL FRANCIS O'DWYER, I.C.S., Settlement Commissioner, Alwar and Bhurtpore.

MAY 25.—"The Port of Calcutta." By Sir CHARLES CECIL STEVENS, K.C.S.I., late Acting Lieutenant-Governor of Bengal.

FOREIGN AND COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

FEBRUARY 28.—“Persian Trade Routes.” By A. HOTZ. Major-General Sir OWEN TUDOR BURNE, G.C.I.E., K.C.S.I., will preside.

MARCH 21.—“The Commercial Development of Germany.” By C. ROZENRAAD, F.S.S., and Fellow of the Institute of Bankers.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

MARCH 14.—The paper announced to be read by Sir WILLIAM BLAKE RICHMOND is unavoidably postponed.

APRIL 18.—“Modern Changes in Taste relating to Domestic Furniture.” By GEORGE LOCK.

MAY 2.—“Maiolica.” By WILLIAM BURTON.

MAY 30.—“Wrought Iron Signs.” By J. STARKIE GARDNER, F.G.S.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

ARCHIBALD SHARP, A.M.Inst.C.E., “Cycle Construction and Design.” Four Lectures.

LECTURE II.—FEBRUARY 27.

Ball-bearings—Hubs—Pedals—Crank-brackets—Steering-head—Adjustment—Wheels—Direct-spokes—Tangent-spokes—Rims—Materials used in cycle construction—Steel—Malleable-iron castings—Wood.

LECTURE III.—MARCH 6.

Driving gears—Length of crank—Block chain—Roller chain—Chain-wheels—Bevel gear—Lloyds' cross-roller gear—Compound gears—Two-speed gears—Free-pedals—Tricycle-axle.

LECTURE IV.—MARCH 13.

Steel, rubber, and pneumatic tyres—Detachable tyres—single-tube tyres—Tubeless tyres—Valves—Inflators—Side-slip—Brakes—Saddles.

PROF. HENRY R. PROCTER, “Leather Manufacture.” Four Lectures.

April 10, 17, 24, May 1.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 27...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Archibald Sharp, “Cycle Construction and Design.”

Sanitary Institute, Margaret-street, W., 8 p.m. Lecture on “Laws relating to Food Supply.”

Institute of Public Health, 20, Hanover-square, W., 8½ p.m. Professor J. McFadyean, “Tuberculosis in Cattle.”

Imperial Institute, South Kensington, 8½ p.m. Mr. E. P. Rathbone, “The Right and Wrong Routes to the Klondyke Gold-fields.”

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Actuaries, Staples-inn Hall, Holborn, 7 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 8 p.m.

Professor W. Ramsay, “Recently Discovered Gases of the Atmosphere.”

TUESDAY, FEB. 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Foreign and Colonial Section.) Mr. A. Hotz, “Persian Trade Routes.”

Royal Institution, Albemarle-street, W., 3 p.m.

Prof. E. Ray Lancaster, “The Morphology of Mollusca.” (Lecture VII.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Messrs. W. T. Douglas and J. A. I. “Improvements in Dioptric Apparatus for Lighthouses.”

Photographic, 12, Hanover-square, W., 8 p.m. Birt Acres' “Apparatus for Animated Photography.”

WEDNESDAY, FEB. 29...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Wilton P. “Leadless Glazes.”

Sanitary Institute, 74A, Margaret-street, W., 8 p.m. Prof. A. Bostock Hill, “Trade Nuisances.”

Archæological Association, 32, Sackville-street, W., 8 p.m.

Obstetrical, 20, Hanover-square, W., 8 p.m.

THURSDAY, MARCH 2...Royal, Burlington-house, W., 4 p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m.

Chemical, Burlington-house, W., 8 p.m. 1. Mr. H. J. H. Fenton and Mildred Gostling, “Methylfurfuraldehyde.” 2. Dr. Augustus E. Dixon, “The Action of Metallic Thiocyanate on certain substituted Carbamic and Oxamic Acids: and a new method for the production of Thioburets.” 3. Mr. W. Trevor Law, “Ethylic ββ dimethylpropanetetracarboxylic Acid.” 4. Professors Wyndham R. Dunstan and G. Goulding, (a) “The Reaction of Alkyl Iodide with Hydroxylamine.” (b) “Formation of Alkyl Hydroxylamines and Oxamines.”

London Institution, Finsbury-circus, E.C., 8 p.m. Rev. Canon Benham, “St. Alban's Abbey.”

Society for the Encouragement of Fine Arts, Conversazione at the Galleries of the Institute of Water Colours, Piccadilly, W., 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. Macfadyen, “Toxins and Anti-Toxins.” (Lecture IV.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. B. Marconi, “Wireless Telegraphy.”

FRIDAY, MARCH 3...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Sir Frederick Pollock, “King Alfred.”

Geologists' Association, University College, Gower-street, W., 8 p.m. Mr. George Abbott, “Honeycombed Rocks: other Forms of Surface Weathering of Sandstone and Limestone.”

Junior Engineering, Westminster Palace, S.W., 8 p.m. Mr. W. R. Cooper, “Consuming Batteries, and their Possibilities.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

SATURDAY, MARCH 4...Education Department, South Kensington Museum, S.W., 3½ p.m. Mr. W. Burton, “Pottery.”

Royal Institution, Albemarle-street, W., 8 p.m. Mr. W. R. Cooper, “Consuming Batteries, and their Possibilities.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. B. Marconi, “Wireless Telegraphy.”

Junior Engineering, Westminster Palace, S.W., 8 p.m. Mr. W. R. Cooper, “Consuming Batteries, and their Possibilities.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. B. Marconi, “Wireless Telegraphy.”

Junior Engineering, Westminster Palace, S.W., 8 p.m. Mr. W. R. Cooper, “Consuming Batteries, and their Possibilities.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. B. Marconi, “Wireless Telegraphy.”

Junior Engineering, Westminster Palace, S.W., 8 p.m. Mr. W. R. Cooper, “Consuming Batteries, and their Possibilities.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. B. Marconi, “Wireless Telegraphy.”

Junior Engineering, Westminster Palace, S.W., 8 p.m. Mr. W. R. Cooper, “Consuming Batteries, and their Possibilities.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. B. Marconi, “Wireless Telegraphy.”

Junior Engineering, Westminster Palace, S.W., 8 p.m. Mr. W. R. Cooper, “Consuming Batteries, and their Possibilities.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. B. Marconi, “Wireless Telegraphy.”

Junior Engineering, Westminster Palace, S.W., 8 p.m. Mr. W. R. Cooper, “Consuming Batteries, and their Possibilities.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. B. Marconi, “Wireless Telegraphy.”

Junior Engineering, Westminster Palace, S.W., 8 p.m. Mr. W. R. Cooper, “Consuming Batteries, and their Possibilities.”

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. B. Marconi, “Wireless Telegraphy.”

Journal of the Society of Arts.

No. 2,415. VOL. XLVII.

FRIDAY, MARCH 3, 1899.

Communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

MUNICIPAL TRADING.

The following Memorial has been addressed to the Council of the Society of Arts to the Secretary:—

Society for the Encouragement of Arts, Manufactures, and Commerce, John-street, Adelphi, London, W.C., February 23rd, 1899.

The Right Honourable SIR MATTHEW WHITE RIDLEY, BART., M.P., One of Her Majesty's Principal Secretaries of State.

SIR,—The Society for the Encouragement of Arts, Manufactures, and Commerce have been giving very full consideration to the increasing tendency of municipal and local authorities to embark in trading enterprises which may be in competition with, or to the exclusion of, private enterprise, and they have had deeply impressed upon them the fact that as yet no regulations have been defined as to what enterprises should in the general interests of the nation be undertaken by municipalities and local authorities, and what ought to be left to private effort.

They therefore venture to approach you in the hope that you may see fit to advise Her Majesty to appoint a Royal Commission to consider the whole subject, and to lay down the principles and limitations on which Parliamentary powers should be granted to municipal and local authorities. They further venture to submit that until such Royal Commission has investigated the subject and reported thereon, no other powers for trading purposes ought to be delegated to such bodies.

We have the honour to be, Sir, Your obedient servants, (Signed) J. WOLFE BARRY, Chairman of the Council. (Signed) HENRY TRUEMAN WOOD, Secretary to the Society.

CANIOR LECTURES.

Mr. ARCHIBALD SHARP, A.M.Inst.C.E., delivered the second lecture of his course on "Cycle Construction and Design," on Monday evening, 27th February.

The lectures will be published in the Journal during the summer recess.

FOREIGN & COLONIAL SECTION.

Tuesday afternoon, February 28th, 1899; Major-General Sir OWEN TUDOR BURNE, G.C.I.E., K.C.S.I., in the chair. The paper read was "Persian Trade Routes," by A. HOTZ.

The paper and report of the discussion will be printed in the next number of the Journal.

ACETYLENE REPORT.

The Report of the Committee on the Exhibition of Acetylene Generators at the Imperial Institute has been published as a pamphlet, with appendixes, giving particulars of the tests, diagrams of the apparatus, &c. The price is one shilling; it can be obtained from the Secretary, Society of Arts, John-street, Adelphi, London, W.C.

Any member desiring a copy of the pamphlet can obtain one gratis on application to the Secretary.

Proceedings of the Society.

APPLIED ART SECTION.

Tuesday evening, February 21, 1899; Sir OWEN ROBERTS, D.C.L., F.S.A., in the chair.

The paper read was—

VITREOUS ENAMELS.

By CYRIL DAVENPORT.

I.—EARLY ENAMELS.

I do not intend this evening to trouble you much about the technical part of the art of vitreous enamelling on metal, but rather to mention a few elementary points only in order that you may more clearly understand the one or two simple terms I shall use in describing the finished examples, slides of which I have to show you on the screen.

Enamelling is, of course, the outcome of the very ancient art of glass-making, and it is likely enough that the discovery that certain kinds of glass will, under particular conditions, adhere to metal, was accidental.

I define an enamel, for my present purpose, as a glass film fused upon, and adherent to, a metal groundwork.

Glass, as we know it, is not one substance alone. (Silica 5, crystal borax $3\frac{1}{2}$, and nitre $3\frac{1}{2}$ makes glass easily with a blowpipe.) The main ingredient in all glass is silica, or, as we popularly know it, flint, and with this are mixed various other substances, which render it easier to fuse, and softer when fused.

A Japanese receipt for an enamel glass is given by Mr. Bowes as follows:—

	Per cent.
Oxide of lead.....	37·15
Lime....	4·92
Magnesia.....	0·90
Soda	5·19
Silica	51·84
	100·00

This is colourless, but for the purposes of enamel workers such glass would rarely be needed; colour becomes a necessity, and it is easily produced by melting the proper kind of glass with the oxides of various metals. There are now many shades of enamel colours procurable, but in olden days they were few and simple—such as

Red, probably due to oxide of lead with mercury (Watson), or might be oxide of iron (Bowes).

Blue, oxide of cobalt.

Green, oxide of copper.

Different proportions of iron will give grey, yellow, and pink, and black may be iron or copper or manganese. The oxide of tin makes an opaque white, and the oxide of gold, on gold, a rich ruby red. When used with the oxide of tin any of these colours will make opaque enamels—without the tin they are generally translucent in different degrees. On impure metal translucent enamels are always likely to become opaque after the firing.

The most usual metals on which enamels are fused are gold, silver, and copper. Translucent colours will sometimes fuse satisfactorily on all these, but they are only to be relied on when they are on a fine gold ground. The process, roughly speaking, is to grind the enamel to a fine powder in a mortar, and apply it wet to the metal where required—then fuse all together at a red heat, either by blowpipe or furnace.

The earliest enamels existing are now to be found on some of the pieces of exquisite jewellery made by the Greeks and by the Etruscans about the 6th century B.C. The enamels are small and accessory to the finest work in gold ever made. Little shallow spaces were outlined by means of a fine twisted wire soldered on to the metallic groundwork, and into these “cloisonné” spaces the enamels were fused, most likely by means of a blowpipe.

The colours used are dull blue, dull green, and white. Besides these little cloisonné pieces there are also found among the Etruscan jewellery several instances of earrings, small pendant figures of animals and birds, and white enamel fused on a gold wire fashioned in a proper form, after these there are no enamels to be found for a considerable time. Whether the art was lost or whether simply the examples of it have been lost I cannot say, but there seems to be no trace left of it until we come to the 3rd century A.D., when a Greek writer, Philostratus, in a work called the “Icones,” mentions variegated household trappings, and writes: “They say that the Barbarians who live in, or by, the bay (Ἐν ὠκεανῶ) pour colours on to heated brass, and they adhere, become as hard as stone, and preserve the designs which are made in the metal.” This undoubtedly refers to vitreous enamels, and moreover it seems very likely that it refers to Britain, as the dwellers in an island might well be described as “living in the sea,” but some authorities think the Gauls were intended. Although we now have no instances of enamelled work done in Britain so early as the 3rd century, there are many specimens of household furniture belonging to the late Celtic period which show clearly enough that such objects were in all probability commonly made. On these the colours are simple, dull red, blue, and dull yellow being almost always found. Specimens have been found in Yorkshire, Somerset, and Norfolk particularly.

In Ireland were made beautiful cups, shields, and bell-covers, ornamented with enamels. In niello work at a very early date, the Argyll cup being perhaps one of the finest pieces, it is supposed to date from the 9th or 10th century.

The Romans brought the art of enamelling on bronze with them, and practised it largely here up to the 5th century—(Romans in Britain 436)—and after them, what may be called the Anglo-Roman work, nearly resembling the actual Roman, continued for some

Arch 3, 1899.]

the colours being dull red, dull blue, green, and white rarely. These enamels are usually on small objects—læ or brooches, pins of various kinds, is, and numerous small articles of little artistic merit. Some of them appear to have been made of brass (copper and zinc) and some of bronze (copper and tin, with sometimes phosphorus, manganese, lead, or zinc), but they appear in many cases to have been first cast from a mould, and subsequently finished with a graver, in the *champlevé* manner, in preparation for the enamel. The larger pieces often have a beautiful green patina upon them.

From the 5th century, until the coming of the Normans, during the Anglo-Saxon period, much beautiful jewellery with *cloisonné* work was done here, probably by Celtic workmen. At present sight much of this appears to be enamelled, but actually it resembles the Egyptian work of the same character, the *cloisonné* spaces being filled with accurately-cut pieces of stone, glass, or other material, in position, kept in place either by some soft cement underneath, or else by the slight projection of the upper edge of the *cloison* itself. Generally, if the *cloisons* are close *deep* hollows, this inlaid work may be expected; but if the hollows are *shallow*, they are more likely to have been enamelled.

During the reign of King Alfred, in the 9th century (879-896), it is possible that a much earlier kind of enamelled work than any that had preceded it in these islands was produced. There are now, I believe, only four specimens of this work left, and they are fine instances. One is at the Ashmolean Museum, Oxford, and is known as the "King Alfred's Jewel;" round the setting is a legend, saying, "Alfred caused me to be made;" the other three are in the British Museum, one known as the Dowgate-hill brooch, because it was found there. It bears the crowned portrait of a king, supposed to represent Alfred himself. Another, known as the Hamilton brooch, because it belonged to Sir Wm. Hamilton's collection, has a charming conventional design in the centre; and the last bears a female bust, the enamel of which is discoloured by time. All these are most skillfully and beautifully worked in the finest *cloisonné* manner, and many of the colours are translucent; the three brooches in the British Museum are, moreover, set in gold, and some of them with pearls. They are pieces of jewellery of which any nation may be proud, and, moreover, they are amongst the very

earliest existing enamels in which any attempt at portraiture has been attempted. Even if the Alfred Jewel and the female bust brooch are not meant for any particular person, there seems to me little doubt that the Dowgate-hill brooch is intended to represent an actual king, as it is crowned with a similar crown to those which are shown on coins of about the same time.

All the fine arts received a stimulus under King Alfred. There is a tradition that he sent Bishop Sigelin to India. This expedition brought back stores of treasure, precious stones, and jewellery of various kinds, the study of which is supposed to have encouraged Alfred's goldsmiths, who are said to have worked under his personal supervision, a supposition to some extent supported by the words on the edge of the setting of the Alfred Jewel, "Aelfred me heht gewurkan."

I will first show you slides of two pieces of metal work that have no enamel or inlays left in them, but which will make more clear than any words the meaning of the terms, "cloisonne," "champlevé," and "basse-taille."

II.—BYZANTINE.

The school of enamelling to which I shall now draw your attention, is that known as the Byzantine, remembering always that this term must be considered to represent a style, rather than only such work as was actually done at Byzantium, a style moreover which spread widely, and had great influence for a long time in the entire world of art.

Byzantium was an ancient city of Thrace, founded by a Greek colony under the leadership of "Bύζας," whence its name, in the seventh century B.C., but it did not arrive at any importance until about 330 A.D., when Constantine the Great made it his capital, and called it after his name, when Constantinople became the centre of the Byzantine or Eastern Empire.

The Byzantine school of art developed from the classical during the fourth and fifth centuries A.D., and flourished until the conquest of the Empire by the Turks in 1453, and the more nearly it approximates to its Greek original, the finer it is.

The style spread largely, and its influence strongly survives, even to the present time, in Russia. It is always rich in colour, often to an exaggerated extent, and the Byzantine workmen are said to have jealously guarded the secrets of vitreous enamelling in metal

until the latter half of the eleventh century, after which the knowledge became widely spread, owing partly to the migration of their own workmen, and partly to the incoming of foreign workmen, who took the knowledge back with them to their own countries.

The very early Byzantine enamels which still exist are largely figure subjects, and in all probability those which preceded them, if there were any such, were of the same character. It is very likely owing to this that nothing now remains to which an earlier date than the tenth century can with any probability be assigned. This is supposed to be about the date of the small pectoral cross or reliquary which formerly belonged to the Beresford Hope collection, and is now in the British Museum. It is very delicately cloisonné, and bears representations of Christ, His Mother, and Saints.

An explanation of the disappearance of the very early Byzantine enamels may be found in the existence of a curious sect or party founded in the Eastern Empire by the Emperor Leo the Isaurian, and continued by his immediate successors, Constantine Copronymus, Leo the Armenian, and Theophilus. This sect was called the "Iconoclasts," and their mission was to destroy all images of any kind wherever they could find them. They lasted until the ninth century. It is very likely that in the churches were many enamels of saints and holy personages, and it is quite possible that the Iconoclasts made practically a clean sweep of them.

There is fortunately one magnificent piece of enamel work still existing, which makes it easy to realise that the Iconoclasts may have had full provocation for the destruction of such treasures. This is known as the "Pala d'oro," and is the back of the altar at St. Mark's Cathedral at Venice. It is about 11 feet long by 5 feet in height, and consists of a silver-gilt framework, richly worked, and studded with jewels, set, moreover, with enamels of different dates and sizes, portraits, saints, and scenes from Biblical history.

The two largest enamels represent our Saviour and the Archangel Michael, and parts of both of these are in relief and jewelled, the relief pieces being added after the enamels were finished. In the lower part are two most interesting figures, one a portrait of the Doge Ordelafo Faliero, and the other the Empress Irene. There are also two panels of silver with engraved inscriptions which seem to have been added about the 14th century. These inscriptions tell us that—(1) Under the Doge

Ordelafo Faliero in 1105 the Pala "Nata facta fuit," and that under the Doge Pietro Ziani in 1209 it was "Renovata;" (2) That under the Doge Andrea Dandolo in 1343 it was restored, "Novatur."

So from its own evidence we gather that it certainly was older than the date of the Doge Ordelafo Faliero, and it further appears from the ancient chronicles of Venice that in the 10th century the Doge Pietro Orseolo (976-977) ordered a "tabula" to be made for St. Mark's, which is supposed to be the Pala, but Francesco Sansovino in his book on Venice says that it was not actually brought there until the 12th century.

No doubt the Doge Ordelafo Faliero altered the Pala considerably, and one of the ancient enamels of a Byzantine emperor has been newly lettered with his name in Latin, and in other ways changed especially as to the cross.

There has been considerable difference of opinion among experts on the question which of the Byzantine emperors this figure originally represented. Ludwig Pasini thinks it may have been John Comnenus, as the companion figure is that of an Empress Irene, the name of his wife, who was a daughter of King Ladislas, King of Hungary. It is, however, equally likely that it represented the Emperor Alexis Comnenus I., whose second wife was also named Irene. The enamel of the Empress still has its original inscription in Greek, and has not been so much altered as the other. It is a figure full of dignity, and, I think, may be considered one of the finest Byzantine enamels existing.

The peculiarities of the royal dress of the Byzantine emperors are admirably shown in these two figures, and it is interesting to see how they are almost in exact correspondence with the figures of an ancient crown which was discovered in 1860, in a field at Nyitra-Tran, in Hungary. The plates of this crown are seven in number, and are of different sizes, rounded at the top; the largest is enamelled with a portrait of the Emperor Constantine, called Monomachos, the two next largest are his wife, the Empress Zoë, and her sister Theodora, the remaining enamels being of various designs, dancers, and allegorical figures of Humility and Truth. The date of it is about the middle of the 11th century; the Emperor died in 1042. These plates doubtless formed part of a crown designed after the Byzantine fashion, the best existing example of which is the crown of Charlemagne, now in the Royal Treasury at Vienna.

sequent researches resulted in the discovery of fragments of jewelled edges and miscellaneous pieces, by the aid of which the quarry, Franz Bock, has made a restoration of the complete crown.

Besides these, I have to show you a few antique enamels on bookbindings, and, as was the crown of Charlemagne, already mentioned, there are fine plaques of a similar nature on the very curious crown of Hungary, at Buda-Pesth.

III.—LIMOGES AND FRANCE.

Limoges, a town of central France, there was in the 12th century an output of enamelled work, which lasted until the 18th century. There is documentary evidence of work having been made at the earlier date, and, what is more to the purpose, a few old pieces have survived, and during the 13th century particularly there was a very large production of ornaments of the altar, shrines, reliquaries, pyxes, crucifixes, candlesticks, harness, horse trappings, sword pommels, belts, and a host of other miscellaneous objects of art as well as ornament. This work was known as "Opus Lemoviticum," or "Opus Lemovigina."

The enamels used were, as far as I have observed, always opaque, and they were applied to thick copper in the *champlevé* manner. Signs are frequently repeated, a sign that commercial value of these enamels was at no time lost sight of.

It is possible to make a rough classification of the earlier Limoges enamels, chiefly by means of the different manners of treating the backgrounds, and also by the manner of treating the figure-subjects.

In the twelfth century the backgrounds were in gilt metal, with delicate engraved designs, the figure-subjects in enamel.

In the thirteenth and fourteenth centuries the backgrounds were enamelled, generally in blue, and the figure-subjects were in gilt metal, either engraved or in partial or whole relief.

During the whole of this time some of the enamel colours were allowed to gradate into one another without the interposition of a distinct boundary line. The colours which are treated in this way are usually in small bosses, medallions, or monumental scrolls; they are arranged in two sets—deep red, dark blue, and blue and white, and dark blue, green and white. This merging is not, however, to be considered as an absolute sign of Limoges

work, as it also occurs on German enamels of an early date, the blue gradating to white, and the greens to yellow.

Towards the end of the 14th century a lull came over the large production of enamels from Limoges, possibly to some extent due to over-production, but also to the growing appreciation of works of art in ivory, the precious metals, and other media; but during the latter half of the 15th century a remarkable reaction set in, not that the old *champlevé* manner of working recovered its lost ground, but a new, freer, and more artistic method came into existence. This is known as the "painted" style, and in it the copper is left plain, the enamels being applied direct upon it. The painted enamels are in two distinct manners, one known as "grisaille," and the other in rich colours. In the case of the *grisaille* enamels the surface of the copper is all covered with a very dark enamel, and on this the design is "painted" in white, layer after layer, thick in the high light and thin in the shadows. On these enamels there is here and there a little red or flesh colour, and a liberal use of fine gold painted lines and scrolls. One great value of the painted gold lines in enamel work is that as it alone looks the same before firing as it does after, the artist can accurately judge the effect he is producing. The painted enamels in colour are, so to speak, inlaid side by side, or, in some cases, where special parts are required to be particularly brilliant, shaped pieces of gold or silver foil are applied with translucent enamels over them, the rest of the enamel being finished first. On these coloured enamels there is also a free use of painted gold lines and scrolls, often used to mask the lines of junction of the different colours, which are likely to show accidental defects, and to some extent run into each other.

A convenient classification of the painted enamels into three styles was suggested by Sir Wollaston Franks, *i.e.* :—

1. The "Early Style," from 1475 to 1530.
2. The "Fine Style," from 1530 to 1580.
3. The "Minute Style," or the decadence, from 1580 to the close of the manufacture in the 18th century.

The peculiarities of these three styles may be briefly described as follows :—

1. The "Early Style" (1475-1530) was on thick copper, nearly flat, the whole surface being smoothly covered with a very dark, nearly black, enamel; in this the design, as I have already mentioned, is painted in white enamel, with traces of colour and gold lines. Some-

times large pieces of foil under translucent enamels were used in such enamels as were also painted in colour, but these *paillettes* are never used with *grisaille* work alone.

2. In the "Fine Style" (1530-1580) the copper is much thinner, and there is a marked Italian influence seen in many of the designs. Large pieces of foil under translucent colours were discontinued, but the use of very small pieces of jewel-like form and arrangement called "*paillons*" came into use. Artists of the family of Penicaud used these "*paillons*" freely, they also frequently stamped the letters "P.L." on the copper of their enamels—probably standing for "Penicaud Limousin." The *paillons* are not much more satisfactory than their predecessors the *paillettes*, as in both cases the translucent enamels have a special tendency to chip off, and otherwise fine enamels are often spoilt by bare patches caused by the disappearance of these accessory pieces, colour and foil as well.

To the "Fine" period belongs the greatest enameller whose name is known, "Leonard dit Limousin, Esmalieur peintre, valet de chambre du Roy." His earliest signed work is dated 1532, and his last 1574. His work took many forms, vases, cups, chessboards, dishes, &c., but the most important are the wonderful series of portraits, generally the best only, of the most notable personages of his time in France, ranging from King Francis I. and his Queen downwards. The frames of many of these portraits are also often ornamented with small enamelled plaques.

There are several other names of note among the Limoges enamellers of this time, among them may be mentioned Pierre Raymond, who usually painted in *grisaille* with slight colour and gold; Jean Courtois, who used "*paillons*," and produced an especially fine black for his background; and Pierre Courtois, whose figures are beaten out in relief before the enamelling is done. Jean Court, dit Le Vigier, worked largely in *grisaille* with slight flesh colour, and is known to have made caskets his especial study.

3. The "Minute Style," or as it may well be called, the *decadence*, began about the end of the 16th century. It is marked by finical execution, probably due to the discovery of a new medium which would carry the metallic colours—resembling what we now call "oil colours." Susanne Court worked faces in profile, finished freely with fine gold painted lines, and the Limousins (Jean, Léonard, Joseph, and François) all made small works, the

designs on which are freely taken from contemporary prints.

After 1620, the Limoges enamels lost ground rapidly, the best work of the period being produced by artists of the family of Landi; these enamels usually have brilliant black background, and in the 18th century, the manufacture, as an important industry, came to an end.

Limoges was not the only place in France where enamelled work was made. From so-called workshop in Southern France comes a splendid gold cup, now in the British Museum known as "St. Agnes Cup," as it bears the history of that saint upon its sides and lid, *basse-taille* with translucent enamels. It is the finest existing specimen of this kind of work, and is supposed to have been made during the 14th century.

During the 17th and 18th centuries a minute style of painted enamels, used probably with an oil medium, developed largely in the direction of watch cases, and exquisite work of this kind was done by several artists, or note, in latter times much of it being made at Blois. I regret I have no slides of the to show you; the finest work of this kind I have yet found are by Toutin, Dura Muisard, Camille André, Bouvier, Molière Vauquer, Petitot, Bordier, and Zinc, who for quite modern French work that of Fernand Thesmar is perhaps most to be noted, the skill shown in his work in *Plique à jour* being quite wonderful.

IV.—MISCELLANEOUS.

Besides the three large divisions into which I have divided my slides there are many other schools of enamelling to which I can only draw your attention by means of a few simple examples.

In Italy and Germany the art is old, but in the rest of my miscellaneous slides you will only see comparatively modern work.

The best Japanese work was done during the last century, and is, I think, unequalled in the minute working of *cloisonné* enamels; the delicacy of workmanship and intricate designs they have never been equalled. The modern Japanese work is in all technical ways mastered to the last degree, but the design is usually weak.

English work in enamels has found a worthy champion in our member, Mr. Starkie Gardner, and, as he says, no doubt whatever a careful examination would reveal many treasures of home production which are now credited

eign workmen. What we know is fine, but there is still to be known. The Garter plates at Windsor range from the 14th century onwards, and in the same century and during the 15th there was a large production of enamelled vessels, usually silver gilt, cups, ornaments of knobs and sword pommels, some of them with translucent enamels. At Oxford and Cambridge, and at many other places are preserved several splendid cups, exquisitely wrought in silver as a rule, and with enamel ornaments.

During the last century there were the manufactories at Battersea and Liverpool, from both of which there was a large output of small articles. These are on copper, covered all over with a groundwork, usually white, on which designs are painted in "oil colours," and sometimes gilded. The best of these are probably the candlesticks, some of which are graceful enough. The enamels vary considerably in artistic value, but generally they are not particularly good.

There is to-day a revival in England of interest in the beautiful art of enamelling. We have been fortunate of late years in having had the opportunity at the Royal Academy, the South Kensington Museum, and elsewhere of examining and appreciating the fine work done in this medium by artists such as Messrs. Geo. Frampton, Hubert Herkomer, Alex. Asher, and Nelson Dawson, and also a helping hand of great value has been given by the excellent technical school of arts and crafts under the auspices of the London County Council.

It is only of comparatively late years that fine enamels have been made in India, among other places, at Lucknow and at Jeypore, the last being remarkable for the fine ruby red (oxide of gold) in a gold ground work.

At Partabgarh, a peculiar kind of enamel made, designs cut out of thin gold are inlaid in a dark green ground work.

At Damascus and other places in the East a easy and very effective way of producing enamels apparently laboriously made by means of champlevé work, has been hit upon. The outline of the design is simply repoussé on the back of the copper, and the hollows thus made on the other side are roughly filled with opaque enamels.

In Russia, a considerable quantity of enamel work is done on silver and copper. It is usually cloisonné, but sometimes painted on a silver enamel groundwork, always in opaque colours; most of it is not earlier than the last

century. The cloisons are variously produced by soldering, casting, or repoussé work.

Charming work in Plique-a-jour is done at the present time by I. Tostrup, of Christiania, and by M. Hammer, of Bergen, often in bowls and spoon-handles.

During the last century many small enamels, snuff-boxes, candlesticks, &c., were made at Dresden.

The paper was illustrated by a series of lantern slides of the different classes of enamels, coloured by Mr. Davenport, as follows:—

EARLY ENAMELS.

1. Gold armlet from the Oxus, with cloisons and champlevé work. 2nd or 3rd century B.C.
2. Silver Italian medallion showing basse-taille work. 15th century.
3. Greek necklace with enamels. 5th or 6th century B.C.
4. Etruscan enamelled earring. 5th or 6th century B.C.
5. Late Celtic horse's bit, from Hull.
6. Late Celtic helmet, found in the Thames.
7. The Ardagh cup. Celtic work. 9th or 10th century A.D.
8. Anglo-Roman enamelled plate.
9. Anglo-Roman enamelled brooches.
Celtic, under the Anglo-Saxons.
10. The "King Alfred Jewel," enamelled portion. 10th century.
11. The "Dowgate Brooch." 10th century.
12. Brooch with portrait of a lady. 10th century.
13. The Hamilton Brooch. 10th century.

BYZANTINE ENAMELS.

14. Reliquary. 9th century.
15. Bookbinding. 9th century.
16. Plaque. 10th century.
17. Bookbinding. 9th or 10th century.
18. Plan of the Pala d'Oro. 10th century.
- 19, 20, 21, and 22. Enamels on the Pala d'Oro.
23. Crown of Constantine Monomachos. 11th century.
24. Crown of Hungary. 11th century.
25. Crown of Charlemagne. 11th century.
26. Bookbinding. 11th century.
27. Earring. 11th or 12th century.

LIMOGES ENAMELS.

28. Plaques of the Virgin and St. John. 12th century.
29. Bowl, by G. Alpais. 13th century.
30. Bookbinding. 13th century.
31. Casket. 13th century.
32. Candlestick. 13th century.
33. Plaque, by Nardon Penicaud. c. 1503. (Early style of painted enamels.)

34. "Charles Tiercelin," by Leonard Limousin. c. 1540.
35. "Sibylla Europa," by Leonard Limousin. c. 1550.
36. Plaque, by Jean Penicaud. c. 1540.
37. Ewer, by Pierre Raymond. c. 1540.
38. Plaque, by Pierre Courtois. c. 1560. (Figs. 34, 35, 36, 37, and 38 are examples of fine style of painted enamels.)
39. Purse, by J. Laudin. c. 1690. (Decadence of painted enamels.)

MISCELLANEOUS ENAMELS.

40. German medallion. 12th century.
41. St. Agnes' Cup. 14th century.
42. German cup with with "Plique-a-jour." 15th century.
43. German spoon. 15th century.
44. Italian plaque. 15th century.
45. Italian pendant. 16th century.
46. Persian dagger. 17th century.
47. Chinese vase. 18th century.
48. Japanese sword-guard. 18th century.
49. Jeypore dagger. 18th century.
50. Jeypore dagger. 18th century.

SUPPLEMENTARY SLIDES OF ENAMELS.

Shown on a table screen.

1. Greek necklace. About 600 B.C.
2. Celtic bronze shield with enamelled bosses.
3. Anglo-Roman vase, found near Ambleteuse.
4. Late Celtic armllet with enamels.
5. Byzantine bookbinding. 9th century.
6. Byzantine bookbinding. 10th century.
7. Byzantine cup with enamelled rim and foot.
8. Byzantine cup with enamelled inscription.
9. Byzantine bookbinding. 11th century.
10. Limoges crozier head. 13th century.
11. English bookbinding with enamels. 1570.
12. Italian jewel. 16th century.
13. Italian jewel. 16th century.
14. Spanish jewel. 16th century.
15. English bookbinding (in gold) with enamels. 1590.
16. English candlestick. 17th century.
17. English candlestick. 17th century.
18. Russian candlestick. 17th century.
19. Jeypore dagger. 18th century.
20. The iron crown of Lombardy.

DISCUSSION.

The CHAIRMAN, in proposing a vote of thanks to Mr. Davenport, said he had not listened to a more interesting paper for some years. Not knowing much about the subject previously, he took the precaution of reading the article on "Enamels," in the "Encyclopædia Britannica," and this paper had whetted his appetite still more.

Mrs. NEWMAN said the ground had been so well covered by Mr. Davenport that there was very little more to say. She had been particularly interested in the remarks about the Greek and Etruscan jewels in which little bits of enamel were let into the gold work by means of a blow-pipe. That was one of the most interesting ways of enamelling even now, and produced very beautiful effects. She could produce however, that it was quite possible for English workmen to do as fine work as any of the Etruscan for much is done. She would not say the designs were original, because they were generally copies, as there were English workmen doing gold work as fine and delicate, and in as good relief, as anything shown in any museum in Europe.

SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., said he could not leave the meeting without first giving hearty expression to his gratitude toward Mr. Cyril Davenport for the valuable and most interesting paper with which he had favoured them. Mr. Cyril Davenport was doubly a master of his subject by his comprehensive and intimate knowledge of and his wonderful artistic skill in illustrating. Nothing like his accurate and vivid photo-chromal reproductions of the objects illustrating his paper had ever been seen before; and he only hoped that Mr. Cyril Davenport would soon either edit a revised reprint of some such standard illustrations of enamels as those given in Du Sommerard's *Album* or bring out a book of his own on the enamels of all ages and all countries, not omitting the enamels of India (Jeypore, &c.), illustrated from the truly magic "lantern slides" with which he had charmed them that evening. He must say that he sympathised with Mrs. Newman in her protest against Mr. Cyril Davenport's unqualified condemnation of the English people as art workmen. Rather he would condemn our indiscriminating insistence on cheapness; and that much abused "British workman" was to be commended for graduating the skill he put into his work by the wage he received for it. There was, in truth, nothing in the way of technical dexterity the British workman could not achieve if he was paid for properly. What had very forcibly struck him in Mr. Cyril Davenport's exquisite and brilliant illustrations was the proof they afforded, at a glance, of the absolute unity of the decorative arts of the Old World, and of their unbroken antiquity from the date of the ancient Egyptian, Assyrian, and Babylonian Empires, to that of the introduction of the use of machinery in their production (*i.e.* machinery) in Europe, and down to the present day wherever the handicraft arts still survive in Asia. This unity and continuity are especially conspicuous in the altars, the eucharistic vessels, the sacerdotal vestments, and the ecclesiastical furniture generally, of the Eastern and Western Churches, and in the traditional regalia of the older kingdoms of Christendom. The eight-sided "crown of Charlemagne," enriched with opaque cloisonné enamels, and studded with glowing

ious stones, which Mr. Cyril Davenport had produced with such startling reality, was the crown of the German Emperor, the crown of the Czars of Russia, and the parcel gilt crown of the Negus Theodore of Abyssinia in the South Kensington Museum, and the golden crown, *i.e.*, *taga* of the Abuna [labelled Abima] of Abyssinia, in the museum; and these all go back to the imperial crown of the Byzantine Cæsars; and this to the tiaradomed crown of the Assyrian kings of the "Seven Marbles;" which is almost identical with the diadem tiara of the greater gods of the Hindu Pantheon. And all these evidently originated in the cap which the terra-cottas of Cyprus show as worn by the priests of Venus, and which was identical with the cap of the Roman augurs, with the *cidaris* (Cicero) of the ancient Persians, with the so-called Egyptian cap, and with the *taj* of the modern India, and the *fez* of Turkey. In another form, that of a closely-folded turban, it was the "ephod" of the Hebrews, and one of Mr. Cyril Davenport's illustrations, showing a patriarch in "amice" (superficial) and pectoral, threw a strange light on the puzzling connection between the "ephod" and the Hebrew "breastplate of judgment." The amice, Latin *amictus*, "head-wrap," "kerchief," is the primary Bedouin yellow and green *kaffia*, which in its simplest form is a fine cloth (*imneh*), as worn by the women of Egypt, *farudiyeh*) thrown lightly over the head and shoulders; as in Milton's lines:—

"Morning fair

Came forth with pilgrim steps, in amice grey."

When twisted round the head, as the "ephod" is, it is called in Hindustani *shamlah* [c.f. *shamiana*, a canopied sun-screen under which *darbars* are held in India]; and in some unexplained spiritual significance it is also called in Arabic *tilsam*, *i.e.*, "talisman" [Greek, *telesma*], which associates it with "the helmet of salvation" of Isaiah l., 17, and I. Thessalonians v., 8. Here is an undoubted suggestion of a solution of the riddle of the confusion of the ephod with Aaron's breastplate, and the Urim and Thummim, in Exodus xxviii., and vitæ viii., &c. It appears also in sacred legend as "St. Veronica's handkerchief," and in heraldry as "mantling" about helmets—the "*pugri*-cloth" and round "*s(h)olar topis*." Only by a reference to the East can we ever hope to clear up the many difficulties that obstruct our research into the origin of the ecclesiastical vestments and religious symbolism of the West, and directly we turn to the East light begins to flow in on our darkness. "Ex Oriente Lux" that is the moral of all thoroughly detailed and exhaustive expositions of Western art, such as that in which Mr. Cyril Davenport has instructed and enlightened them that evening. He heartily seconded the vote of thanks to him moved by the Chairman.

Mr. LEWIS F. DAY said he must say something in praise of the beautiful illustrations accompanying the paper, which enabled one to appreciate

the objects much better than mere black and white reproductions. It was wonderful how closely they approached the colours of the originals; he would not say they were actually facsimiles, for he did not think that was possible; but those who knew the things themselves could say how nearly they approached to them; and those who had tried to colour slides would wonder most at Mr. Davenport's success. He should like to ask two or three questions. In the first place, with regard to the "Alfred Jewel," if the inscription said "Alfred made me," why should not Alfred be the name of the maker? Was there any documentary evidence on the point? He would also like to know where the book-cover with the border was, which Mr. Davenport said would have been more interesting if it had been enamelled; to him it was more interesting because it was not enamelled, but inlaid with bits of glass. The connection between those two things was very interesting; he thought enamelling was probably an imitation of glass inlaying, and glass inlay an imitation of jewellery. With regard to the early Limoges enamels on copper gilt, would Mr. Davenport tell him if the enamel was put on over the gilt. He must demur to the statement that enamel in *baisse-taille* was the most artistic. It gave more scope for finicking detail, but not necessarily for higher art. In his judgment a bolder style, which did not depend upon modelling under the enamel, was more artistic. The simpler such kind of work was the better. He could not see where the extraordinary artistic value of the St. Agnes Cup lay, though he had tried again and again. It was a most wonderful piece of enamelling, but difficulty did not make art. One other question. Could Mr. Davenport account for the difference between the colouring of Japanese and Chinese enamels? They were done in the same way; but the Chinese were more brilliant, and generally bright in tone. It might be said that it was due to a difference in the national characteristics; but he thought it was more probably due to a difference in the materials used. In looking at the work shown a while ago at the Burlington Fine Arts Club, he noticed that the colour of some quite early mediæval enamels, which he understood were English, was very much like the Chinese, so much so as to deceive even an artist at a short distance, though close inspection would reveal the difference of detail, and he thought that resemblance must arise from using the same material and working in the same way. Early British enamels, which were again not bright, were perhaps somewhat lowered in tone by age.

Mr. STARKIE GARDNER said Mr. Davenport had given them a wonderful series of illustrations, which he did not think anyone else could have produced, and the labour of preparing such a series of slides must have been immense. To see them was as good as seeing the enamels themselves in some respects, as they were magnified very considerably, and in many

cases the originals could only be seen in museum-cases, where the details could not be examined. He was delighted to find that Mr. Davenport recognised that the series of Anglo-Saxon enamels were really Anglo-Saxon and not Byzantine. One of the brooches shown was found in Italy, and it was a great argument against the other two being Anglo-Saxon that they were so much alike, and Sir Wollaston Franks himself used that argument, but he could not see the force of it; and most people now agreed that there was an Anglo-Saxon school, which differed considerably from the Byzantine. The fact that the Alfred Jewel bore the name of Alfred was a strong proof that it was of English origin. Many rings and other articles bore a name, but in all cases he believed it was the name of the person for whom it was made, not of the actual workman. There were many more beautiful enamels than those shown, many bowls and cups were far more beautiful. There was no doubt they were of British origin, and, in fact, this was probably the only nation then working in enamel. As a rule, similar works of the same date made abroad were inlets of glass. The low tone of colour to which Mr. Day had referred was due, he believed, to the fact that they were enamelled on cast bronze, and the zinc or tin in the bronze got into the enamel and stained it. That did not apply to the translucent Japanese work. He hoped some day Mr. Davenport would take the trouble to make a slide or two of some of the rarer German enamels, and also that he would collect some of the many beautiful Elizabethan enamels which were scattered about the country, and had never been seen together; some of them were beautiful little arabesques, which were quite peculiar in this country.

Mr. CYRIL DAVENPORT, in reply, said he should agree with Mrs. Newman with regard to enamel work, but what he referred to was the Etruscan gold work. He had good authority for saying that both Tiffany, of New York, and Guiliano had tried their best to get similar work, but in vain. He had been much interested in what Sir George Birdwood said about the Abyssinian and Babylonian crowns, and should endeavour to study that point more. He showed the bracelet from the Oxus as a specimen of cloisonné and champlevé work; the one he had shown was the one at South Kensington; he knew there was a duplicate in the British Museum. South Kensington gave £1,500 for it. He should say the gilding on the Limoges enamels did not extend under the enamel. The "Alfred Jewel" was of course doubtful, but it was a beautiful thing, and was carefully preserved. It was probably the top of a sceptre, because there was a socket with a pin in it, and no doubt originally had a handle; the figure in the enamel held two sceptres. Mr. Starkie Gardner was right in saying that the workman rarely put his name; any name that appeared was generally that of the owner. Workmen's marks came later. The St. Agnes Cup he did not like to abuse, as he was officially connected

with it. It would take too long to go into the differences between Chinese and Japanese enamels. He had been obliged to omit a great deal, not only with regard to German enamels, but also English, for a matter of fact, any single division of the subject would afford material for over an hour's lecture.

TWELFTH ORDINARY MEETING

Wednesday, March 1, 1899; Professor JOHN MILLAR THOMSON, LL.D., F.R.S., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

- Brooks, Christopher P., New Bedford, Mass., U.S.A.
- Butler, Joseph Margerison, 33, Dorset-street, Portman-square, W.
- Clare, Harcourt E., Liverpool.
- Davies, Dixon Henry, Chesterfield.
- Drummond, C. J., St. Bride Foundation, Bridewell-lane, Fleet-street, E.C.
- Fullerton, Major John Davidson, R.E., Bath Hotel, Nantwich, Cheshire.
- Lloyd, Edward Honoratus, 5, Crown-office-row, Temple, E.C.
- Norton, Robert, Coombe Croft, Norbiton, Surrey.
- Radcliffe, F. M., Liverpool.
- Ward, Septimus H., Shire-hill, Sheffield.
- Writer, N. N., 7, Beverley-road, Anerley, S.E.

The following candidates were balloted for and duly elected members of the Society:—

- Hawkins, Bernard, 123, Victoria-street, S.W., London, and Bangalore, S. India.
- Lazenby, Walter, Castlebar, Sydenham-hill, S.E.
- Lewis, Valentin Townshend, Dene Hollow, Burgess Hill, Sussex.

The paper read was—

LEADLESS GLAZES.

BY WILTON P. RIX.

The use of lead in pottery is most probably coeval with the use of glaze. If the adoption of bitumen and of cerates, to obviate porosity, is considered the first advance, their abandonment in favour of a material requiring arduous heat for its fusion certainly marks the second and the more important change. Though at an early time the potter discovered the use of alkaline glazes, there is little doubt that lead was first sprinkled on the ware gave the first suggestion, and the first desire for the permanence of the wares. Through the ages lead has ever held the foremost place amid all the changes of form, and colour, material, or decoration, facing

s results, brilliant in its effects, yet everous in its influence on human life. Egypt Assyria have both left examples of supreme mic skill, in which the admixture of lead played a leading part, this gives evidence to mean intelligence in the craftsmen of e days.

here have always been those who in their dicraft are thus intelligent and observant, , moreover, have nursed the incentive to pass their fellows. Nor have there been ating many also who, for the considerations self, were willing to remain ignorant and ambitious, satisfied merely to follow their ers' track, and justify their path on this ount. But new days bring new problems. e potter of the present is faced with fresh iculties and impelled to new efforts, and the least of these is the subject which comnds our attention this evening. Its solution st finally rest with those men of enterprise ong us to whom the mention of a need is the incentive to attainment.

hough it is a fact that lead has held its e so long, the use of glazes free from lead no new practice in ceramics. The hard celain of the Orientals, so long the unained ideal of the Western potter, dates far k into the early centuries as an example uch productions, while the Rhodian and ersian" wares afford the altogether different e of soft alkaline glazes, yet still free from d contamination.

Coming to more modern times, we have the man ware of the Roman era, probably the mplest type of glaze known, and certainly surpassed in many points by any modern al. Scarcely differing in construction are e salt-glazed wares of Staffordshire, also oduced without lead. Nor must the beautiful mples of early Sèvres porcelain be omitted m the series of leadless glazes, which sufficiently comprehensive in its range, d of which I am glad to be able to show ecimens.

The importance of the elimination of lead m all glazes needs no demonstration. The ention lately called to its deleterious effects, d the statistics which have been published specting them, make it necessary for the elfare of the industry that every means should e taken to reduce, if not finally to eradicate, e cause of such serious results.

The total number of persons employed in ttery works throughout the country is over 0,000, of which about 20,000 are under 18 years age, about equally divided between both

sexes. Two-thirds, however, of the total em- ployed in England and Wales are located in the Staffordshire Potteries, and engaged in the production of ware in which lead glazes are constantly used.

In a considerable number of potteries lead is absent, and after deducting the operatives in these we may fairly conclude that not less than 60,000 persons of both sexes are occupied in works where precautions against lead poisoning become necessary.

It is quite true that a comparatively small proportion of this total are actually exposed to contact with lead; and it is equally true that a very large number of those so exposed, work in lead processes for years, and even for life, with complete immunity. Nevertheless we have to face the fact, that to a certain per-centage of these, say about 1 in 300, the employment is eventually fatal, while not less than 1 in 8 of the workers so exposed are more or less affected by plumbism.

Such a condition of things, arising as it does entirely from the use of lead glazes, and alto- gether distinguishable from the loss of life occurring through the deleterious effects of dust and heat, naturally demands the best efforts of the manufacturer to rid his establish- ment of so insidious an enemy.

The noxious influence of lead upon the human system has been so fully dealt with lately, and the statistics of lead poisoning have been so constantly analysed and discussed to the disparagement of the pottery manufacturers at large, that it is needless to occupy time in repeating the facts. The disastrous effect of lead in certain cases cannot be too strongly stated. When developed in its most virulent form, lead poisoning is the undoubted precursor of paralysis, blindness, and death.

It is true that the number of cases in which such terrible results ensue form a very small per-centage of the whole number of workers tainted with lead; and these again form a still smaller proportion of the total number em- ployed.

The operation of the Act of 1895 may be considered to have produced fairly reliable statistics; and though the absence of earlier data makes it impossible to compare the present with former conditions of pottery workers, there are certain facts that deserve notice.

The returns of last year giving the cases of lead poisoning reported in 1896 from the potteries are as follows:—

Dippers	78
Ware cleaners, after dippers	} 78
Dippers' assistants	
Glost placers	70
Majolica painters	42
Ground layers	48
Printers' transferrers	10
Various	56
Total	382
Out of a working total of, say	45,000

There is reason to believe that the returns for the year just ended will show a marked improvement in some branches, though at present the figures have not been made known.

As might be expected the dipping, cleaning, and placing of the ware in the ovens contribute most to lead diseases, while the decorating is only responsible for one-third of this number. The increasing use of spraying processes as well as the large proportion of free lead in majolica glazes is no doubt the cause of the heavy percentage of cases in this branch. My own experience, however, leads me to say that this is partly due to want of reasonable precaution on the part of the workers themselves. It is not too much to say that the utmost recklessness often exists among those employed. On the other hand, it is possible to point to instances such as that of the Mersey Lead Works, Warrington, in which the absolute immunity for years from lead poisoning is almost entirely attributed to the loyal co-operation of the workers in observing the regulations.

Statistics also go to prove that the employment of girls in dipping and placing is most undesirable, owing to their greater susceptibility. Of the two, placing is the most dangerous, as the glaze is dry. The peculiar susceptibility of some constitutions is also a well established fact, corroborated by many of the leading employers. Though many have worked a life time without contracting any taint, others are found who inevitably become affected in two or three weeks. For this reason, one cannot too strongly approve the adoption of the new regulations which make compulsory the monthly examination of all women and young persons employed in lead processes by the certifying surgeon, who may order suspension from employment of those affected. Such a law is most beneficial, by inducing care on the part of the worker, and promptly eliminating those of susceptible constitutions.

The necessity for such a regulation becomes

sufficiently obvious from the Chief Inspector's last report, in which it is stated, in regard to the effect of lead upon maternity, that of 77 married women reported as affected by lead, only 36 had borne living children, and of these 40 per cent. had died in infancy.

Space will not allow notice of the various conditions which tend to induce plumbism. It may be sufficient to point out that they resolve themselves into two main groups:—

Want of cleanliness, both of worker and workshop; and

Want of ventilation.

Both of these are dealt with under the new regulations, but success can only be secured by the co-operation of the workers, and it is admitted that apathy in this matter is to present the greatest obstacle.

But while the regulation of existing conditions may be important, far greater benefit must obviously accrue from the elimination of lead in pottery operations. In short, it becomes necessary to consider—

1. Whether at present, or by gradual stages, it is possible to exclude the use of lead entirely.

2. If this cannot be done, how far the regulation of its use will mitigate its noxious effects.

3. To what extent the characteristics of wares now manufactured can be modified, and public taste so educated and directed that the demands for lead glazed wares may eventually cease.

These problems are by no means new in this country, and also on the Continent, for the last half-century at least, constant efforts have been made by manufacturers, and also on the part of the respective Governments, by means of regulation and research, to mitigate the evils referred to.

So long ago as the year 1794, the Society of Arts offered the premium of a gold medal of £30 "to the person who should discover to the Society the cheapest, safest, and most durable composition fit for use for the purpose of glazing the ordinary kinds of earthenware without any preparation of lead, and preferable to any hitherto in use."

This offer was repeated annually for no less than 25 years before anyone accepted the challenge, and it was not till 1820 that a smaller or Isis Gold Medal was awarded to Mr. J. Rose, of Coalport, Shropshire, for an improved glaze for porcelain. It will be noticed, however, that this glaze was prepared for porcelain and not for earthenware.

indeed, it has never proved itself in any satisfactory for the latter.

will be interesting to those present to that by the kind permission of Sir A. Ie, I am enabled to place before you this ing an early specimen of ware, glazed this glaze, from the collection in Jermyn-t Museum, which is known to have been ible before 1826. I am also pleased to be to place in comparison with it speci-s of modern manufacture from the same ery. In connection with these latter ples, the Coalport China Company make mportant statement that a leadless glaze been in constant use up to the present and that all services sent out are dipped

the manufacture of earthenware greatly eds that of porcelain and china, the offer he Society of Arts can hardly be said to e accomplished its purpose. It is true that view of the fact the original offer was inued in a modified form as "Glazing umon Red Earthenware without Lead," two years later the Gold Medal was rded to Mr. Meigh, of Shelton, for the overy of such a glaze, but this again could be made available for general use upon white earthenware body which forms the le manufacture.

otwithstanding the unsuccessful result of e early efforts, manufacturers have not e been indifferent to the matter. During ensuing 30 years, several patents were n out, and in the year 1865, the subject brought before the British Association at ingham, when Mr. H. Coghill, of New-le-under-Lyne, propounded a formula which med to have solved the problem of an ocuous glaze. A copy of this recipe is ed:—

Crystallised boracic acid (84 per cent.)..	75 lbs.
Washed soda crystals	75 "
Devonshire stone or felspar	75 "
White, ground, or silex.....	30 "
Devonshire clay	13 "
Carbonate of lime	50 "
The above to be fritted in a furnace in the usual way.	
Weight of the above fret	450 lbs.
Devonshire stone.....	150 "
Devonshire clay	50 "
Carbonate of lime	29 "
White or silex	20 "
The above ground in water in the usual way, stained as required.	

Though persistent efforts were made to employ this glaze by some makers, they were only partially successful; and though it has been repeatedly tried, it fails to meet the demands of present manufacture. I am informed by Mr. T. Speck Walker that it was in use at Thornaby-on-Tees Pottery for some 10 or 15 years, but after making many efforts to improve it, the attempt was finally abandoned in favour of lead glazing. Uncertainty of result in firing, and consequent heavy loss, as well as the loss of brilliancy in colours, were the chief causes of failure.

At the South Wales Pottery, Llanelly, more than 30 years ago, and for long subsequently, a leadless glaze was used by Mr. Guest, but this also was finally abandoned for similar reasons. Owing to its opalinity, the colours were less bright, and the ware lower in quality, than when glazed with lead. It has, unfortunately, been impossible to obtain verified examples of this glaze.

It appears probable that some, at least, of the early wares made at Bow, Chelsea, Nantygaw, Worcester, and Derby were actually produced with lead-free glazes; but there are clear indications that for china these various potteries were unable to avoid the gradual introduction of lead for glazing purposes.

The formula for the Nantygaw china glaze has been stated in a book by Taylor, of Shelton, date 1847, to be as follows:—

Lynn sand	8
Chalk	6
Stone	2½
Borax	10
China clay	40
Felspar.....	3½
Flint.....	0½
Soda.....	6
Nitre.....	3

These are fritted together.

Although the quality of the Nantygaw ware was certainly high, attempts to produce the above glaze have not proved successful, nor is it certain that it have ever been in general use.

Of the potteries already mentioned Derby and Worcester are the only survivals. It may, therefore, be well to note in passing that both at present find it necessary to adopt the use of some proportion of lead in glazing china.

At the Worcester China Works a leadless glaze of fine quality has been used from time to time and is still adopted both for china and semi-porcelain. By the courtesy of Mr. E. P. Evans I am able to show specimens of these wares. I am told, however, that though colours

stand fairly well under it the difficulties of working this glaze are considerable, the oven losses being much too heavy.

Attention has already been called to the hard felspathic glazes for porcelain, such as Chinese, Japanese, and hardware. These have usually required the exclusion of lead, owing to the high temperature at which the glaze takes fire.

An altogether different type of leadless glaze is to be found in the soft alkaline glazes of old Persian and Rhodian wares. Neither of these classes of lead-free glazes are of much practical value to the average commercial potter.

Most of the porcelain glazes are too hard for bodies in general use in this country. The alkaline glazes, though fusible enough, limit, by their powerful chemical action, the range of colours available. Besides this, many of them have the serious objection of instability.

In view of the facts, it is not surprising that potters have gradually succumbed before the tempting inducements offered by the use of lead glazes. Indeed, when we realise the exigencies of a market ever demanding finer finish, more perfect texture, greater brilliancy of surface, as well as increasing variety of colour: and these improvements accompanied withal, by a persistent tendency to reduction in price, it is difficult to see what other course was open.

Without the use of lead, none but the most enterprising could be expected to undertake the task of supplying such demands, in face of the difficulties experienced with all other compositions, and it is much to the credit of our leading houses that they have patiently and unremittingly set themselves to solve the problem. With what success, so far, it will be one of the objects of the present paper to demonstrate, and also to show the chief obstacles surrounding it. Before doing so, it is necessary to glance at the commercial considerations which have hitherto made the use of lead almost indispensable to the manufacture as now carried on.

Foremost among these is that of economy.

It is necessary that the firing temperature should be kept as low as possible to save fuel. Losses must be reduced by extending the margin of risk in every stage that will allow of it. Many bodies and glazes, admirable in all other respects, have now to be abandoned solely on this account. Unfortunately in both these directions leadless glazes stand at a disadvantage in comparison with those now used.

There are also many other points of importance to be demonstrated before so important a change can be universally brought about.

The potter's art is essentially complex. Each process, though simple in itself, is one of many, all affecting the final result, and the possible combinations of which are infinite. Even when a successful result is obtained it must be proved capable of withstanding great diversity of treatment before it can be put on to the market.

The potter is compelled to move with caution when leaving the beaten track, otherwise he would soon be lost in a confusion of results, the causes of which he would be unable to trace.

Any changes made call for exhaustive tests, as to loss in production, or failure in actual use, and these experiments may often occupy months and even years.

The manufacturer builds up the reputation of his product by a process of selection, based on the survival of the fittest methods, patiently noting those best adapted to his object. He is essentially and rightly conservative, but is well aware that all the various details of each stage are so inter-related and interdependent that a readjustment of one may destroy the balance of the whole.

Evolution, and not *revolution*, is the watchword of a potter, and economy dictates among the many combinations he should limit his selection to some definite treatment.

Given a certain material, the heat at which this can safely be biscuited is limited by its composition. This, again, must define the range of possible glazes. These in their turn govern the character of colour available as well as the method of production and decoration. Such radical departures from well-known lines as are involved in the abandonment of lead can therefore only be arrived at through the lapse of time. Meanwhile it is possible that the more complete introduction of proof-fritted lead may prove a means of mitigating the evils in question, while experience is being gained for the final change.

Leadless glazes inevitably affect colour when used at present in a different manner, so that the elimination of lead would probably involve a readjustment of the underglaze colour compositions, and the disappearance of some from the potter's palette, and this in itself is a serious consideration.

In short, potting with leadless glazes applied to earthenware—by far the largest

n of the trade—becomes practically a manufacture. And it is doubtful whether tempt to suit present bodies and match at colours is in all instances likely to ed. It is true that there are times when the best interest of a manufacturer to ret his methods to new conditions. Such al changes, however, always involve large ice of plant and serious outlay. But the potter with limited capital has no margin ch sacrifice. To him such a change if ulsory would mean ruin.

twithstanding these obstacles it is clearly uty of every manufacturer to do all that is ble, having due regard to commercial ss, towards erasing lead from the potter's f materials, and the present is an attempt ow what advance has already been made s direction.

en under the most favourable conditions hange to lead-free wares is likely to lead reased cost of production, and unless it be shown that foreign manufacturers are ed under similar conditions any attempt at compulsory exclusion of lead could only the trade away from the country. In words nothing short of international lation is likely to bring about the entire onment of lead in favour of other rials.

periments have doubtless been made *ad nitum*, but from the experimental to comal stage is a long step. A glaze must e itself worthy over a large series of ovens, erage state of repair, and also be proved ble of standing equally in all parts of the . It must give sound texture on all kinds are. Very few leadless glazes have surd the preliminary ordeal, while still fewer yet entered the commercial stage. Exles of all these have been obtained as far ossible, and by the courtesy of the various ers are shown here this evening. In tion to these, a number of specimens of es which are promising, but not yet fully ed, are placed for comparison. I have ner thought it well to illustrate the chief cts of such glazes by a few typical failures. may perhaps be allowed to add one or two s, giving the salient characteristics of the t important of these examples.

ext to those of Coalport, the works from factory of Messrs. Thomsberger and Herin, of Colditz, command notice. This firm persistently given its special attention to less wares, wisely accepting, however, the tations of material. The specimens show

that good effects can be obtained with under-glaze colour even in those delicate tones usually liable to be destroyed by such glazes.

In this country, the revival of attempts to abandon lead has been carried on with great energy at Minton's works, where Mr. George Leason has been successful in making a glaze suitable for earthenware. This has now passed beyond the experimental stage, and is being used on ware over all colours under ordinary conditions. It is fired without special treatment at the same temperature as lead glaze, and in all parts of the same ovens. This ware has for the last six months been thoroughly tested, both on land and sea, with very good results. It must, however, need the lapse of a somewhat longer time to make it possible to give a final verdict as to the soundness under all circumstances. Examples of this ware are on the table, from which it will be seen that the glaze is equally successful on china and earthenware. The workpeople using it, however, state that the difficulties of manipulation are greater, and in dipping especially much care is necessary.

Messrs. Doulton, with their usual enterprise, have faced the problem of non-poisonous glazes, and made an exhaustive series of experiments. The examples shown prove the glaze, when carefully fired, to be of good texture, free from injury to most colours, and equal to the requirements of the market.

Among the remaining pieces, those emanating from Messrs. Copeland's, of Stoke-on-Trent, appear to have many good qualities, and hold their own, in comparison with lead glazes, on the score of texture, freedom from injury of colours, and opalinity when very thinly dipped. As, however, the quantity of ware hitherto produced is limited, it is not yet possible to speak definitely on its merits.

The examples of ware produced by Mr. Reeves, of Fenton, are interesting, as showing the behaviour of leadless glazes upon coarser earthenwares when fired at a lower biscuit heat. The chief difficulty of working such glazes, lies undoubtedly in the comparatively low temperature of the biscuit fire at present adopted.

It appears certain that more satisfactory results could be obtained if bodies were so composed that biscuit could be fired some 100° C. (say to cone 6 or 7) than at present, thus enabling the heat of the glost fires to be increased in the same ratio. By this means a higher per-centage of alumina could be introduced into the glaze, and compounds of the felspar lime type would become available. But

the heavier cost of fuel would often preclude the use of harder biscuit. It is therefore satisfactory to find that this is not absolutely necessary to success.

Of the remaining examples which are without colour, those of the well-known factory of Villeroy and Boch, of Mettlach, claim attention. Regarding these, the makers state that, providing due care is used, they do not experience greater loss with leadless glazes, and that the treatment in firing is the same as for lead glazes. The results obtained with underglaze colours depend upon the adjustment of these as well as on the firing.

Among those producing for the general market, Messrs. Harrison and Son, of Hanley, have already shown themselves successful in furnishing leadless glazes of high quality, capable of use without injury to colours. The examples include printed and handpainted decoration underglaze, besides others demonstrating the suitability of the glaze for use with lithographic overglaze transfer. These last show the effect of second fire on the glaze, also that the texture is sufficiently smooth to receive the transfer without loss of detail.

Among those who have devoted attention to the matter, Mr. Furnival, of Stone, has experimented with some success, and examples of his most promising glazes are here shown. They have been tested with approval by some manufacturers, and they appear to have the merit of working well with most underglaze colours.

Notwithstanding the apparent success of the elimination of lead in the foregoing specimens, it must by no means be assumed that they afford decisive proof that the general adoption of lead-free glazes is yet possible. A very large range of body mixtures, fired at various biscuit heats, are now in use, and for many of these glazes without lead may prove unsuitable. It is necessary to prove whether greater expenditure in fuel is needed, and also how far the more accurate control of the glaze-dipping and firing can be met. Such a change cannot be made till the new product is shown to be free from greater expense in manufacture.

It is, therefore, still necessary as a precaution, while further experience is being gained, to find the best means of reducing the necessary lead in the present glazes, and to secure the permanent fritting of the whole.

It has long been known that the combination of the various elements in question takes place in the ratio of their equivalent weights, and unless the frit mixtures are adjusted with

due regard to the combining weight, the excess of base or acid must remain in a free state.

Hence the fritting of lead with silica, borax or stone, can only produce innocuous results when the proportions of each are such that the whole is chemically combined in a stable form. Some indications of the effect of incorrect proportions are given in the Table appended:—

Analyses, showing amount of free lead in various frits, dissolved from 1 part by 50 parts of a solution containing 0.33 per cent. hydrochloric acid and at a temperature of 100° Fahr.

I.				
White lead	80	66	60	50
Flint	20	34	40	46
Per-centage of free lead ..	24.01	19.47	12.95	14.75
II.				
White lead	80	66	60	
Stone	20	34	40	
Per-centage of free lead ..	23.55	15.02	12.95	

This problem of proportions would appear simple enough were it not that some of the more complex mixtures produce frits, which are either soluble or are liable to disintegrate on exposure.

The addition of borax in any large proportion is especially to be avoided when fritting lead; and it is definitely ascertained that if the per-centage of boracic acid and lead amounts to 40 per cent. the frit is noxious.

The combination of such frits can be better controlled by the preparation of alkaline lead frits separately, thus checking the tendency to form unstable compounds. The addition of alumina also assists in overcoming these difficulties, though it increased the difficulty of fusion. It is, however, clear from what has been stated, that unless combined in definite proportions, the fritting of lead is no safeguard. Experience has already shown that many lead frits are noxious. Professor Lallemand has shown, as a result of his investigations, that silicate of lead was soluble under the usual test to the extent of 12 per cent.; and the inquiry recently completed by Professor Thorpe, when issued, will no doubt afford the potter full information on this important point.

Another important point to be decided is the minimum of lead possible to retain with success. In this connection I am pleased to be able to produce specimens of Messrs. Copeland's china, the glaze for which contains only 9 per cent. of lead, the quality of the ware being entirely satisfactory.

well to note that in comparison with other material, equal increments of heat far greater effect on lead as regards *γ*, and this property insures that smooth texture and extreme brilliancy of glaze, is, so far, conspicuously absent in most ss glazes.

It has been shown that those glazes which possess the highest degree of lustre and greatest power of refraction, are those which possess the highest specific gravity. But it is an important point that the exclusion of lead from glazes removes from the list the only material capable of imparting the needful *γ*. We can, therefore, hardly expect to obtain equal brilliancy in glazes, so essentially dependent on refractive power.

Undoubtedly, we possess in baryta one notable exception, and in glass-making fair success is attained with it, as will be seen in the example here shown. It is, however, a question whether this material is sufficiently fusible to be admitted as an available substance.

It has also the important quality of resisting devitrification, thus ensuring stable results. The tendency of many alkaline glazes to become reconstituted on exposure to damp air is well known, and the elimination of lead gives one of the most efficient antidotes.

We have in most leadless glazes three objectionable properties, viz., opalinity, sluggishness, and inequality of texture.

The defects of *opacity* and *opalinity* cause the rejection of many otherwise suitable materials. Such examples of leadless frits are not rare here, as well as a comparison of lead and leadless glaze on red body fired together. We have endeavoured to deduce from the structure of some of these the actual causes of their opacity. From examination under the microscope by polarised light this defect seems in many cases due to semi-opacity, or suspension of fine particles in a transparent matrix. It is apparently caused rather by a want of commensurate uniformity in the construction of the mass, than in reality made up of two or more separate elements of differing refractive indices, distinctly non-crystalline, and in no way opaque. On the other hand, the opaque, glassy frit here shown exhibits altogether a different construction, being merely translucent and not of uniform texture.

The fault of *sluggish fusibility* is also a serious objection. It leaves the slightest inequality of thickness still apparent after firing. A small scratch on the unfired piece also

remaining unchanged—instead of “healing” in the oven, as with lead glaze. The mending of such fault on the raw glaze by pencilling, is impossible for the same reason.

The production of combination least liable to this defect, is one of the most important problems connected with it. The absence of lead appears to have two effects. It causes the glaze to be more viscid, but it also makes it slower in its response to the fusing temperature, as well as to the accession of heat.

To demonstrate this, I have had prepared by the very kind assistance of Mr. William Burton, a series of examples showing the behaviour of both types of glaze under precisely the same conditions. A comparison is given of the effect of firing rapidly up to Cone 01-1 (*i.e.*, hard-glost heat) in six hours, demonstrating very clearly the greater tractability of lead glaze under quick firing.

For this reason, as well as many others, glazes without lead must be dipped as thinly as possible, besides being used at a lower “slop” weight than lead, and much more uniformity of dipping is necessary.

The defect of surface inequality gives rise in some glazes to an egg-shell or pitted texture, which deprives the ware of the smoothness so essential to cleanliness, at the same time causing it to lack that brilliancy now demanded by the public. It is of course too early to say that these difficulties cannot be overcome, but much attention and experience are still needed to accomplish this.

We have next to consider the possible substitutes for lead, and in doing so we are compelled to exclude those which are too expensive or scarce, those which are too low in colour, and, lastly, those which are noxious.

Of the rest the list at present is limited to the alkalis and borax, the alkaline earths, and boracic acid. Taking these in order, we find in *soda and potash* danger of disintegration, destructive influence on colours, and tendency to crazing, to be the chief defects which limit their use in any large proportion.

Of the *alkaline earths* we have lime, magnesia, and baryta. The former can only be used in small proportions. If the maximum exceeds one-eighth opalinity ensues.

Magnesia is insufficiently fusible, and hitherto no very satisfactory glazes have been produced with it.

Barytes has received the careful attention of that able chemist Dr. H. Seger, who has undoubtedly produced many successful glazes from it. They are, however, subject to the

some drawbacks as to texture and do not yield a sufficiently glossy surface.

Boracic acid, though imparting hardness and brilliancy to glaze, has injurious influence on some colours. Its use is therefore limited; but, in conjunction with silica, in carefully adjusted proportions, it has produced some of the best glazes at present discovered.

In considering the possible treatments in composition it is necessary to decide the glost temperature. Naturally the practical potter prefers to keep this as before. But the want of fluidity already noticed suggests an increase of heat in the glost oven as desirable. Dr. Seger pointed out that for lead-free glazes heat should exceed 1,050° C. But, as a rule, the earthenware biscuit is only slightly above this, and serious loss would result unless the body were changed.

Another expedient for assisting fluidity is the increase of the number of basic oxides, and this is certainly practicable. That it is, however, not absolutely necessary is shown by the formula of a successful glaze, in which it will be noted that there are only two bases:—

The examples shown are certainly good.

The appropriateness of including baryta as a substitute for lead is rather doubtful. It is difficult to trace any directly harmful effects to its use, and it has been distinctly stated by those constantly working with baryta that no evil result has ensued. Such glazes have been largely used, to my personal knowledge, for many years without the slightest ill effect on the workers. On the other hand, the distinct opinion is expressed by medical experts that it has several of the properties of lead, and, being a poisonous metal, it cannot be considered very safe. Notwithstanding this, Dr. Seger has proposed the substitution of barium glazes containing boracic acid for those of lead, of which the following are examples:—

		No. I.	
<i>Frit.</i>		<i>Mill.</i>	
Heavy spar	125.3	Frit	... 292.5
Calcined } soda... }	13.25	Zettlitz } clay.. }	25.9
Crystal } borax.. }	143.2	Sand....	18.0
Sand.....	126.0	$\text{BaO}, \text{NaO } 4.5 \text{SiO}_2 \cdot 1.5 \text{BO}_3 (3:1)$	
Charcoal..	15.0		

This fuses about midway between silver and gold heat.

		No. II.	
<i>Frit.</i>		<i>Mill.</i>	
Heavy spar	125.3	Frit	... 297.5
Crystal } borax }	191.1	Zettlitz } clay.. }	25.9
Sand	... 111.2	Sand....	3.0
Charcoal ..	15.0		

This type of glaze is said to have been successfully worked in some German pottery though there is no instance of its adoption in this country.

In America, Mr. Karl Langenbeck of Zanesville, Ohio, who has given some attention to the matter, states that he has used glazes from Dr. Seger's formulae, and practically applied them with complete success on a manufacturing scale, comparing favourably with lead glaze in regard to cost. On the other hand, however, to their egg-shell texture and absence of the brilliant glaze required on porcelain their introduction did not satisfy public opinion. As regards their effect upon colours the barium glazes suitable for earthenware showed to be of great advantage. But in the case of soft glazes requiring quick muffle-firing of the type of the Seger formula here quoted the brilliancy of colour was even greater than those made with lead.

As an additional example of these glazes we quote the following which has been prepared by Mr. Charles Binns, of Trenton:—

Besides the barium glazes above-named it is also possible to produce leadless glazes having lime and alkalis for the bases, and in this direction also Dr. Seger made considerable research.

His experiments go to prove that the following formula—

gives a glaze fusing at silver heat, and slightly above gold heat. Also that the following formed a glaze of general utility

the possible limits being

gives a clear glaze, but the boracic acid, v

ed, causes opalinity, and this quantity on again doubled, produces a milk-white

th regard to the proportion of bases, the is—

0.2 } as more lime causes opalescence in all cases.
0.8 }

question of permanence and stability of glazes without lead is one of no small importance. Owing to the large place occupied by the alkalis as fusible basic substitutes for lead it is easily possible to obtain combinations which would prove disastrous in this respect, for whereas lead has proved a reliable agent for stability, the alkalis are notoriously deleterious. I am able, however, to show you a glaze which has been exposed for nearly 12 months which shows no change. I understand that Messrs. Mintons also have for consideration tested their new ware under trying conditions of temperature and climate, so far with complete success.

A doubtless little opportunity has occurred to me to roughly prove the latest mixtures. All that can be said is that they have at present stood up to the most severe exposure and the roughest use without injury. It may, however, be pointed out that with the exercise of due diligence in compounding a formula no serious risk need be incurred. The scientific methods available are amply sufficient to protect the potter if he will. But if he still persists in mixing ingredients in haphazard proportion without regard to the unalterable laws of chemical combination, he can only expect haphazard results.

In the face of the important problems at issue, we need to recognise that pottery manufacture is a *science* as well as an *art*, and that it is subject to laws as definite as those which govern the use of electricity, light, or heat. More than a century has elapsed since the first attempt was seriously made to eliminate lead from pottery. The use of leadless glazes has been fitful and exceptional. Up to the present it cannot be said that for the bulk of the trade they have proved practicable. Within the last five years every Staffordshire potter has pronounced their adoption impossible. Since that time such advance has been made that we are, at least, of the most strenuous opposers have confessed that their views are modified, and that for many classes of ware lead is no longer a necessity. Some go so far as to think that, with increased experience, leadless glazes may become available for nearly all kinds of goods.

I am inclined to believe that such a result is only a matter of time. Having become fully cognisant of the limitations and difficulties attending their use, the potter will, no doubt, bestow renewed energy upon the task of bringing their treatment under his complete control. Herein, most emphatically, lies the opportunity for the craftsman of the future. Conquest of the technique rather than the initiation of new processes, must occupy his skill. Scientific economies rather than empirical discoveries will, undoubtedly, mark the progress of the coming century; and that progress must be along the line of a more accurate knowledge of the operations of great principles already laid down, rather than in the search after new ones.

I have myself entered with diffidence upon this unexplored region of ceramics, hoping to call the attention of those better qualified to the opportunity for further research, believing that no better employment can be found for scientific investigation than the beneficent task of mitigating the suffering of mankind.

It only remains for me to acknowledge my great indebtedness to those who have so kindly afforded me the benefit of their personal experience in regard to the glazes in question, and to those manufacturers who have been good enough to contribute specimens to illustrate the paper. Among these, in addition to those already mentioned, I wish to include Mr. Frank Litchfield, Messrs. Julius Hulsen, of Newcastle-on-Tyne, Mr. Karl Langenbeck, of Zanesville (O.), and Mr. Charles Binns, of Trenton (N.J.), who have afforded important help in various ways.

DISCUSSION.

The CHAIRMAN said the question dealt with in this important paper divided itself practically into two heads; the specific question relating to the manufacture of these articles, and the general question of its relation to the health of the public and the work-people. He was not able to discuss it from the mercantile point of view, but from the scientific point of view, he thought the first object of the chemist should be to obtain a silicate glaze, formed from alkaline silicates and lime, which would be a perfectly hard substance. There seemed, however, to be certain technical difficulties about this, and no doubt lead had advantages from its introducing a low fusing point, and from certain optical properties which it possessed. The paper, however, showed that in very early times the ancients were able to do without lead, and also that at the present day, work-

ing with much better apparatus, we could also produce a glaze without this noxious substance. He hoped that with improved furnaces, it would be possible to introduce such glazes. There were certain points in connection with silicate glazes which were very difficult to deal with, the higher point of fusion necessary having an effect on certain colours; but the question arose whether the public had not been too greedy of late in requiring so many shades of colour. The Easterns were content with fewer and more stable colours, and the shades obtained by mixing them, and did not seek for the innumerable shades which were now used. There was also the very serious question of the expense to the manufacturer; but when it was considered that they were dealing with a poisonous substance, the question arose whether manufacturers would not have to be told, sooner or later, that some restriction on the use of a non-poisonous material must be imposed. He regretted that Dr. Thorpe was not present, as he had been making a very exhaustive inquiry into the matter, both in England and on the Continent. There seemed reason to expect, however, that with the more modern methods now available, they might hope to obtain a glaze which, if not absolutely free from lead, would have it reduced to the minimum quantity, in which case it might be retained in a fixed state as a lead silicate, and avoid the presence of free lead which was the cause of the evils complained of.

Mr. F. W. RUDLER said he must express his gratification at the very able and judicious manner in which Mr. Rix had treated the subject. Having charge of the collection of pottery in Jermyn-street, he was specially interested in this subject, and looking at the fine series of specimens which Mr. Rix had collected, it seemed to him that there were a good many which were in every way satisfactory. There were many underglaze colours which did not seem to be seriously affected by the coating of leadless glaze. Possibly the eye of an expert might not be altogether satisfied with some of the shades, but he thought with the Chairman that we could afford to dispense with some variations of tint if they could only be obtained by the use of poisonous glaze. If manufacturers would mark their wares "leadless," he thought there would be sufficient philanthropy abroad to make them popular. The same argument would apply to the point of brilliancy, as to which some little sacrifice might be made if necessary, out of regard for the health of the workpeople. He feared the substitution of barium for lead might be rather dangerous. If leadless glazes required to be fired at a higher temperature, more fuel would be required, and it must be more expensive; but surely the public would be willing to meet the manufacturers on this point. He hoped, however, that it would be possible to find glazes which did not require such high temperatures; and, considering what had

been done during the last few years, they might hopefully to the future.

Mr. J. EYRE thought the paper was rather in favour of lead glazes than otherwise; and it seemed to him that these glazes developed colours much better than the white glazes did. They had a very creamy and fusing at a low temperature, they developed colours and preserved them, which would be destroyed hopelessly at a higher temperature. Yellows and pinks under the white glaze got very crude in tone, and he feared a yellow green would be destroyed. From the artistic point of view, therefore, it would be a great loss to abandon the lead glaze. Some of the things he saw before him looked nice and very clean, but there was no tone whatever in them. If you compared any of these hard white pieces with a sample of Wedgwood Queen's Ware, the latter was infinitely superior. He should like to know if the people employed in glazing were more subject to disease than painters and plumbers, who worked with lead. He had not the slightest doubt that the workers brought a great deal of this trouble upon themselves from their own carelessness. He had known dippers who had been working in glaze all day, with their hands covered with it, and their clothes saturated with it also, begin eating their food without washing their hands. A great deal of the evil might be prevented if better conditions were insisted upon. Fritting would reduce the poisonous action to a very great extent, but to abandon lead altogether would be to sacrifice a great deal of artistic effect. None of the specimens he saw around him seemed to recommend themselves from the artistic point of view.

Mr. G. G. MACWILLIAM said Mr. Rix was to be thanked for ventilating this subject. He seemed rather to favour leadless glazes, and he might say he had seen some plates made by one of the firms he had named which were very beautiful. Though they had an earthenware body, their appearance was like that of porcelain; but they had only been made three months, and had not been out of England. It was a well-known fact that the severest test to which earthenware could be put was to send it to the South Sea Islands or the West Indies, where it was greatly exposed to the sea air, and under such conditions it was unfrequently crazed. Until this system had been tried, year or two's experience in various parts of the world, no manufacturer would be justified in making it largely and sending it out as a commercial article. It would be quite useless to mark the wares "leadless," the public would not care a pin about that; but the question of not using such delicate colours had been in use of late years was well worth consideration. If stronger and less volatile colours were used, and leadless glaze was found to stand, they

have some other shades which would stand a temperature. It had been said that there must be many more cases of disease and death than were reported, and, no doubt, many cases had occurred which were not reported in the papers; but, on the other hand, he could say, from personal knowledge, that many cases had been attributed to lead which had nothing at all to do with it. Persons had been known to suffer from lead poisoning, and had even been treated for it by doctors, when it had been ultimately shown that they had never been near the lead at all. The greater part of the disease had resulted from the fault of the people themselves. A new place where hot and cold water, soap, and towels were provided, and a certain amount of supervision exercised, and yet the people would not make use of them. In that particular case it was not so much matter, because the lead was not so highly fritted, and a certain amount of care exercised; and he believed if the lead were always highly fritted, and a certain amount of care exercised, very few cases indeed of lead poisoning would occur, and those would be comparatively mild. Very few interests were concerned, and if public pressure were brought to bear too strongly, without sufficient knowledge as to cause a revolution in the manufacture of sufficient knowledge had been obtained, it would be a very serious matter. He hoped, therefore, that there would be no drastic legislation until the proposed alterations had had a fair trial.

MR. GRAHAM HARRIS said he did not know much about the manufacture of earthenware and porcelain, but he did know about the making of glass of all kinds, and therefore knew something about glaze. He had wanted to know, and should be glad if Mr. Rix would tell him, what was the glaze used by the Chinese and Chinese on those beautiful pots in which the colours were as delicate as they could be, and yet as intense as they could be. Was it a lead glaze or a silica glaze, or was it a glaze which he knew nothing about? If they could make it, he might be able to make it. It seemed to him that the essence of the whole paper was contained in two particulars where Mr. Rix said that if the Government regulations were properly carried out, and sufficient supervision exercised, the results were all very slight. The use of lead glaze gave the ware, at a low cost, and with all sorts of latitude as regards temperature, dipping, and the place in the kiln, a very much better result than he could obtain otherwise. If that were so, could they blame the potter for picking to that which he knew, which he could make with easily, and out of which he could make a profit. All they could do, was to put upon such restrictions and regulations as would ensure that he was doing his best for his employés, and then if they would not look after themselves, it was they who should be blamed, and not the potter himself.

MR. RIX, in reply, said there was no doubt that a softness was given to the colours by the use of

lead; and most of the wares prepared with leadless glaze showed a hardness of result, irrespective of colour, which came from want of fluidity; there was an absolute definition of the design under the glaze which was much stronger, and artistically more unpleasant than was the case with lead glazes. The same thing held good with regard to the old Persian ware. As a rule, the lead glazes as used, were softer, but that was not absolutely necessary; lead glazes could be made as light and clear as the leadless glaze. As to the indifference and carelessness of workpeople, he had purposely avoided going into that question. These people were many of them uneducated and undisciplined, and no one could exaggerate the extreme want of common-sense, amounting to absolute recklessness, of those concerned about this matter. At the same time they had long since come to the conclusion that these people should be protected against themselves, and he did not think that aspect of it had much bearing on the question. The question was were the workers injured by the lead glaze, and how far could that result be prevented? There was no doubt that further experience was needed, but the question of crazing was one of chemical expert pottery. It was not necessary that ware should craze at all, if it were correctly compounded in the first instance. Unfortunately, the manufacturer did not and could not entirely control his manufacture scientifically, and, consequently, they had to go through these proofs, and it was no use to cut the matter short. Manufacturers had been absolutely ruined by their ware crazing after it had left their hands, because it was a standing witness against them, and they could not stop the discredit which attached to it. It was necessary, therefore, to act with the greatest caution, and he fully agreed that no one should recklessly introduce leadless wares. With regard to Mr. Harris's question, there was no doubt the glazes he referred to were leadless, and were made of felspathic materials, very often of materials which needed no compounding. There were one or two favoured places in the world where the glazes were to hand ready made. One was near Limoges, where you go and dig out of the ground a beautiful glaze, grind it up, dip the ware in it, and produce a better effect than by any mixture you could make; hard, clear, and in all respects suitable. A good deal of the old Chinese and Japanese porcelain seemed to be of that character; but there were two things which distinguished that class of ware from that with which he had been dealing; they were vitreous in body, but not earthenware, which was fired at a much lower heat, so that the glazes referred to would not fuse at the heat at which the earthenware glazes were used. They would undoubtedly do so on the American hard, semi-porcelain wares, but not on English earthenware. The pottery industry had been built up through many ages, and its present position was the result of adding continually to the experiences of many years. Obviously, therefore, they

could not expect to arrive at finality in six or twelve months.

The CHAIRMAN then moved a vote of thanks to Mr. Rix, which was carried unanimously, and the meeting adjourned.

Miscellaneous.

AMERICAN FIBRE PLANTS.

Mr. G. E. Walsh, writing in the *Scientific American*, says:—Commercially there are 30 or 40 species of fibre plants found throughout the world, but botanically there are over 1,000 species the fibre of which can be made more or less useful in the arts and industries.

In view of the territorial changes produced by the war, the fibre industry is of peculiar interest to the farming and manufacturing world. The islands affected by the war are all noted for the fibre plants raised on them; and taken together—that is, Porto Rico, Cuba, and the Philippines—they produce a large bulk of the best plants, except cotton, used in a commercial and manufacturing way for their fibre. Manilla hemp has long been familiar wherever civilisation exists; sisal hemp comes from Cuba, in times of peace, as largely as from Yucatan or the Bahamas; Cuba bast is essential to the millinery trade of the world; and Sunn hemp and cebu hemp are but trade varieties that come from the same islands.

The Philippines, in particular, are rich in fibre plants, with possibilities for development and expansion scarcely conceivable. Throughout the archipelago, it is estimated, all the fibre used in the manufacturing world could be produced at a cost that would annihilate similar industries anywhere else in the East. This is not entirely true, however, for neither cotton nor flax could ever find a foothold in the Philippines to compete with the United States. Our cotton is already seeking Eastern markets in ever increasing proportions, and great prospects are anticipated for this trade. But in turn we must secure our hemp and jute, and other fibre-material, from the lands where they best grow.

There are over thirty species of fibre plants that can be raised in this country, but most of them are unimportant in the commercial world, and most of the others thrive only very indifferently in the United States. Should we, however, extend our colonial possessions, so that in time they included Cuba and the Philippine Islands, as well as Porto Rico, we would be the greatest fibre producing country on the globe.

At present the leading vegetable fibre that is imported into the United States, according to statistics of 1897, is sisal grass. Most of this sisal

grass comes to us from Cuba, Yucatan, and the Bahamas. Attempts have been made to introduce its culture in Florida, and with some success; superior growth in its native islands, and their proximity to the United States, will for ever prevent it from becoming an important industry here.

Next to sisal grass comes Manila hemp of commercial importance. The imports of this amount to nearly \$4,000,000 annually. This hemp has also been experimented with in this country, and in other countries, but the world's trade will always look for its supply to the islands of the East, where it flourishes as naturally as cotton does in our Southern States. It can be produced and shipped to this country cheaper than our farmers can raise it at home. Manila hemp comes from the Philippine Islands also, and is merely a trade variety that has its useful purposes in the manufactures.

Jute and "jute butts" stand third on the list of imported fibre plants. Jute comes from a variety of countries. Originally India controlled the trade in jute, but the West Indies and Cuba have entered the market in competition with her, and they are rivals that cannot be ignored. The possibilities for Cuba in this line are only partly appreciated. The rebellions and wars have so long agitated the country that little experiment has been made in any other line outside of sugar and tobacco-growing.

Since 1890 the Department of Agriculture has been engaged in making experiments with fibre plants in various parts of the country, and farmers have been encouraged to grow certain fibre plants for manufacturing purposes. Nearly all the commercial fibre plants have been tested by the Department, and some of them have been recommended for general culture. This movement, started seven or eight years ago, has not exactly proved all that the inauguration of it anticipated. Ramie has been raised to some extent in Florida; sisal hemp from Yucatan has been established in a limited way in parts of the State, and a little impetus has been given to the rejuvenation of flax culture—one of the oldest and most natural products in this country. Great efforts have also been made to utilise some of the plants that grow naturally here for fibre manufacturing. The palmetto fibre and vegetable hair of the Southern States, the moss growing on the trees of the Southern States, have found some use that makes the product of some value. Several of the leading varieties of flax in Florida have been cultivated for the fibre in the stalks and leaves, and the palmettoes have been utilised for making brushes and brooms. Jute culture has been extended, so that we produce an annual fair crop. Yet this weed is natural to this country, and some varieties are the finest and best grown in the world.

It is possible to double the annual production of fibre plants in the United States, and thus increase the manufactures; but the history of many of our agricultural products hardly warrants one in predicting that we can raise successfully most

ents needed in this land. The flax industry one time an important industry in New d; but it has steadily declined for half a now, because farmers could put their land to profitable use in raising other crops. No of push and energy has ever been able to his industry, although spasmodic efforts have tly been attempted. There was plenty of the world where flax throve better than in ited States, and it could be cultivated cheaper han in this country.

wise the hemp industry in the South has been ng ever since 1870. It flourished and expanded early sixties, and just prior to the rebellion it important industry, promising in time to rank only to cotton. But sisal and Manila hemp ed in the market, and the Southern hemp could mpete with them. Our hemp lost its position manufacturing world, and sisal and manila oon used in its place. No amount of study and nent could rejuvenate the decadent industry.

ile there are undoubtedly many native fibre growing in this country that will be found use-many industries, it will be impossible to make compete with the low-priced fibres that come many of the tropical and semi-tropical islands. hall we ever be able to introduce these foreign into this country, so that their culture will successful enough to supply us with the raw al for all of our manufactures. The world will ok to the Philippines, the West Indies, Cuba, l America, and China and India for the fibre that supply material for cheap clothing, bagging, and similar products.

the islands that have been acquired from Spain, er, we have the soil and climate to produce all bre plants that are lacking in this country. resources in this respect are so great that could soon supply the world with all the raw ial used for cheap textile goods, cordage, nets, indred necessities. In Porto Rico alone we raise successfully a dozen of the leading fibre s, while in Cuba and the Philippines there are peculiar only to those islands.

PERUVIAN FUEL.

e of the fuels competing with coal in mining tions in Peru is called "yareta" by the natives. otanical name is *Bolax glebaria*, according to ent report of the Bureau of the American blic. This is a highly resinous plant, firm and act, growing on the tops and sides of the moun- cropping out from beneath the boulders, and ding out into large mounds, some of which are ch as 20 feet across. These mounds are broken y means of chisel-headed bars, and the pieces are o dry for three or four months. The labour is great, and the cost of preparing it is merely nal. It must be delivered during the dry season, a continues from May to November. Being of

slow growth, yareta is becoming scarcer every year, and now costs, delivered at the Amalgamation Works, about 35s. per ton. At the same time a good quality of coal costs about £7 per ton, as it has to be transported from the railways to the mines on the backs of mules or llamas. Other fuels used in Peru are turf, costing about 20s. per ton at the mines; petroleum shale costing about £4 10s., and "taquia" (llama chips) costing 6s. 6d. per ton. The petroleum shale is obtained at an altitude of 18,000 feet above sea level, near Calloma. This shale is in three beds, two feet apart, varying in thickness from $\frac{1}{2}$ inch to 2 inches. The Peruvian turf is cut from a marshy ground, and is more or less decomposed root-matter of a species of stiff moss. Taquia is collected from the corals and pastures of the Indians, and its use as a fuel is increasing.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

MARCH 8.—"Cornish Mines and Miners." By J. H. COLLINS, F.G.S. H. BAUERMANN, Assoc. M.Inst.C.E., F.G.S., will preside.

MARCH 15.—"Liquid Fuel." By Sir MARCUS SAMUEL. Sir EDWYN S. DAWES, K.C.M.G., will preside.

MARCH 22.—"London's Water Supply." By WALTER HUNTER, M.Inst.C.E.

Papers for meetings after Easter :—

"Coal Supplies." By T. FORSTER BROWN.

"Electric Traction." By PHILIP DAWSON.

"Telephones." By JOHN GAVEY.

"Wireless Telegraphy." By W. H. PREECE, C.B., F.R.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

MARCH 9.—"Leprosy in India." By H. A. ACWORTH, C.I.E., late Government Municipal Commissioner for the City of Bombay. The EARL OF ONSLOW, G.C.M.G., Under-Secretary of State for India, will preside.

This meeting will be held at the Imperial Institute.

APRIL 27.—"Judicial Reform in Egypt." By Sir JOHN SCOTT, K.C.M.G., D.C.L., Deputy Judge Advocate-General, and late Judicial Adviser to H.H. The Khedive. The LORD CHIEF JUSTICE OF ENGLAND, G.C.M.G., will preside.

It has been found necessary to change the date of this meeting from April 13 (as formerly announced) to April 27.

MAY 11.—"The Revenue System and Administration of Rajputana." By MICHAEL FRANCIS O'DWYER, I.C.S., Settlement Commissioner, Alwar and Bhurtpore.

MAY 25.—"The Port of Calcutta." By Sir CHARLES CECIL STEVENS, K.C.S.I., late Acting Lieutenant-Governor of Bengal.

FOREIGN AND COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

MARCH 21.—“The Commercial Development of Germany.” By C. ROZENRAAD, F.S.S., and Fellow of the Institute of Bankers.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

MARCH 14.—The paper announced to be read by Sir WILLIAM BLAKE RICHMOND is unavoidably postponed.

APRIL 18.—“Modern Changes in Taste relating to Domestic Furniture.” By GEORGE LOCK.

MAY 2.—“Maiolica.” By WILLIAM BURTON.

MAY 30.—“Wrought Iron Signs.” By J. STARKIE GARDNER, F.G.S.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

ARCHIBALD SHARP, A.M.Inst.C.E., “Cycle Construction and Design.” Four Lectures.

LECTURE III.—MARCH 6.

Driving gears—Length of crank—Block chain—Roller chain—Chain-wheels—Bevel gear—Lloyds' cross-roller gear—Compound gears—Two-speed gears—Free-pedals—Tricycle-axle.

LECTURE IV.—MARCH 13.

Steel, rubber, and pneumatic tyres—Detachable tyres—single-tube tyres—Tubeless tyres—Valves—Inflators—Side-slip—Brakes—Saddles.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 6...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Archibald Sharp, “Cycle Construction and Design.” (Lecture III.)

Sanitary Institute, Margaret-street, W., 8 p.m. Dr. Alfred Hill, “Diseases of Animals in Relation to Meat Supply.”

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. E. Wynter Wagstaff, “The Shan Hill Country and the Mandalay Railway.”

Imperial Institute, South Kensington, 8½ p.m. Captain H. Vere Barclay, “Northern Australia.” Surveyors, Savoy-street, W.C., 8 p.m. Mr. F. J. Smith, “The Working of the Light Railways Act, 1896.”

British Architects, 9, Conduit-street, W., 8 p.m. Mr. A. Hessel Tiltman, “Public Baths and Wash-houses.”

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Prof. Beale, “The Nature of Life.”

TUESDAY, MARCH 7...Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lankester, “The Morphology of the Mollusca.” (Lecture VIII.)

Medical and Chirurgical, 20, Hanover-square, 5 p.m. Annual Meeting.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. J. T. Milton, “Water-tube Boilers

for Marine Engines.” 2. Sir A. J. Durston, Mr. H. J. Oram, “Recent Trials of the Machinery of Warships.”

Pathological, 20, Hanover-square, W., 8½ p.m. Anthropological, 3, Hanover-square, W., 8½ p.m. Biblical Archæology, 37, Great Russell-street, 8 p.m.

Zoological, 3, Hanover-square, W., 8½ p.m. 1. J. E. S. Moore, “Exhibition of and Remarks

Specimens of the *Medusa* of Lake Tanganyika.” 2. Dr. A. Keith, “The Chimpanzees and their Relationship to the Gorilla.” 3. Dr. C. A. Windle and Prof. F. G. Parsons, “The Myology of the *Edentata*.”

WEDNESDAY, MARCH 8...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. H. C. Coles, “Cornish Mines and Miners.”

Geological, Burlington-house, W., 8 p.m.

Sanitary Institute, 74A, Margaret-street, W., 8 p.m. Mr. William Arthur Bond, “The Establishment of Public Abattoirs in the Metropolis in relation to the prevention of Tuberculosis.”

Royal Literary Fund, 7, Adelphi-terrace, W., 3 p.m. Annual Meeting.

Royal Society of Literature, 20, Hanover-square, W., 1 p.m.

National Association for the Promotion of Technical and Secondary Education, in the Hall of the Mechanical Engineers, Storey's-gate, S.W., 3 p.m. Annual Meeting. Address by the Duke of Devonshire.

THURSDAY, MARCH 9...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) (Abercrombie Imperial Institute.) Mr. H. A. Acworth, “Leprosy in India.”

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Sanitary Institute, 74A, Margaret-street, W., 8 p.m. Dr. Sykes, “Objects and Methods of Inspection, Nuisances, &c.”

Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. Poel, “English Playhouses in the Sixteenth, Seventeenth, and Eighteenth Centuries.” (Lecture I.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m.

Mathematical, 22, Albemarle-street, W., 8 p.m.

FRIDAY, MARCH 10...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Prof. E. Callendar, “Measuring Extreme Temperature.”

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. H. Lapworth, “The Construction of the Elan Aqueduct, Birmingham Waterworks.”

Astronomical, Burlington-house, W., 8 p.m.

Philosophical, University College, W.C., 8 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Chemical Society's Rooms, Burlington-house, W., 5 p.m. 1. Mr. Albert Griffiths, “(a) Study of an Apparatus for the Determination of the rate of Diffusion of Solids dissolved in Liquids.”

(b) Note on the Source of Energy in Diffusion Convection.” 2. Mr. A. A. Campbell Swinton, “An Exhibition of Dr. A. Wehnelt's Electric Current Interrupter for Ruhmkorff Coils.”

SATURDAY, MARCH 11...Junior Engineers, Westminster Palace Hotel, 7 p.m. Reception by the President.

Sir W. H. White, and Lady White, the Chairmen.

Mr. B. H. Joy, and Mrs. David Joy.

Botanic, Inner Circle, Regent's-park, N.W., 3 p.m.

Royal Institution, Albemarle-street, W., 8 p.m. Lord Leigh, “The Mechanical Properties of Bodies.” (Lecture V.)

Journal of the Society of Arts.

No. 2,416. VOL. XLVII.

FRIDAY, MARCH 10, 1899.

Communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

On Monday evening, 6th inst., Mr. ARCHILD SHARP, A.M.Inst.C.E., delivered the 4th lecture of his course on "Cycle Construction and Design."

The lectures will be published in the *Journal* during the summer recess.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1899 early in May next, and they, therefore, invite members of the Society to forward to the Secretary, on or before the 8th of April, the names of such persons of high distinction as they may think worthy of this honour. The medal was struck in reward "distinguished merit in promoting Arts, Manufactures, or Commerce," and has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., for distinguished merit in promoting, in many ways, his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by his abolition of passports in favour of British subjects."

In 1866, to Michael Faraday, D.C.L., F.R.S., "for discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measurement and uniform standards by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I., "for services rendered to Arts, Manufactures, and Commerce, by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the Department of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvement in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential services in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., late Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy and in magnetism, and by his improve-

ments in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong (now Lord Armstrong), C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious labour."

In 1879, to Sir William Thomson (now Lord Kelvin), LL.D., D.C.L., F.R.S., "on account of the signal service rendered to Arts, Manufactures, and Commerce, by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science to industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin, "for eminent services rendered to the Industrial Arts by his investigations in organic chemistry, and for his successful labour in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and as Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce by promoting an accurate knowledge of the floras and economic vegetable products of the several colonies and dependencies of the Empire."

In 1884, to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world."

In 1885, to Mr. (afterwards Sir) Henry Doulton, "in recognition of the impulse given by him to the production of artistic pottery in this country."

In 1886, to Samuel Cunliffe Lister (now Lord Masham), "for the services he has rendered to textile industries, especially by the substitution of mechanical wool combing for hand combing, and the introduction and development of a new industry—the utilisation of waste silk."

In 1887, to HER MAJESTY THE QUEEN, "in commemoration of the progress of Arts, Manufactures, and Commerce throughout the Empire during fifty years of her reign."

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S., "in recognition of the value of his researches in various branches of science and their practical results upon music, painting, and useful arts."

In 1889, to John Percy, LL.D., F.R.S., "for his achievements in promoting the Arts, Manufactures, and Commerce, through the world-wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy."

In 1890, to William Henry Perkin, F.R.S., "for his discovery of the method of obtaining colouring matter from coal tar, a discovery which led to the establishment of a new and important industry, and to the utilisation of large quantities of a previously worthless material."

In 1891, to Sir Frederick Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S., "in recognition of the manner in which he has promoted several important classes of the Arts and Manufactures, by the application of Chemical Science, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great services he has rendered to the State in the provision of improved war materiel, and as Chemist to the War Department."

In 1892, to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy, in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S., "for their joint services to scientific agriculture, and notably for the researches which, throughout a period of twenty years, have been carried on by them at the Experimental Farm, Rothamsted."

In 1894, to Sir Joseph (now Lord) Lister, F.R.S., "for the discovery and establishment of the antiseptic method of treating wounds and injuries by which not only has the art of surgery being generally promoted, and human life saved in all parts of the world, but extensive industries have been created for the supply of materials required for carrying the treatment to effect."

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his inventions."

ica researches and the resulting development of iron and steel industries."
 a 1896, to Prof. David Edward Hughes, F.R.S., recognition of the services he has rendered to s, Manufactures, and Commerce, by his numerous entions in electricity and magnetism, especially printing telegraph and the microphone."
 n 1897, to George James Symons, F.R.S., "for services he has rendered to the United Kingdom affording to engineers engaged in the water ply and the sewage of towns a trustworthy basis their work, by establishing and carrying on ing nearly forty years systematic observations w at over 3,000 stations) of the rainfall of the fish Isles, and by recording, tabulating, and phically indicating the results of these observa- as in the annual volumes published by himself."
 n 1898, to Professor Robert Wilhelm Bunsen, D., For. Memb. R.S., "in recognition of his nerous and most valuable applications of Chemistry Physics to the Arts and to Manufactures."

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday afternoon, February 28th, 1899;
 Major-General Sir OWEN TUDOR BURNE,
 C.I.E., K.C.S.I., in the chair.

The paper read was—

PERSIAN TRADE ROUTES.

By A. HOTZ.

At last a start has been made to provide Persia with roads. Before describing what is now being done by Russia from the North and England from the South, it may be useful to give a short summary of this question, which has become a vital one for Persia ever since the depreciation of silver has necessitated an increased export to restore the balance of trade.¹

The drain on Persia in consequence of the great difference between her imports and exports has of recent years become very serious, and has been the indirect cause of some disturbance in her finances. People cannot now pay the taxes they are liable to, and the prosperity of the country is diminishing. Its resources, however, are capable of expansion. The reorganisation of the Customs, for instance, has lately been taken in hand by the Shah's Government, with the result that Persia has secured the services of one of the chief inspectors of Customs in Belgium, M. Naus, who has been lent by his Government for that purpose. He is assisted by several of his countrymen, all trained in the Belgian service, and he has already, by his energy and tact, obtained most satisfactory results. The Custom-houses, as is well known, are farmed in Persia, and in some cases they now pay nearly double the amount they used to send to Teheran. But, of course, an increase in the revenues obtained by stricter collection does not increase prosperity.

Those who are best acquainted with the country have been the most persistent in pointing out the want of roads. Among the more recent papers on this subject, three of which were read in this room, may be mentioned those by General Sir Frederic Goldsmid,² General A. Houtum Schindler,³ Colonel J. Bateman Champain (two),⁴ Captain H. L. Wells, R.E.;⁵ Drs. F. Stolze and F. C. Andreas;⁶ General Sir R. Murdoch Smith (two);⁷ Colonel M. S. Bell, V.C.;⁸ the Hon. G. N. Curzon, M.P.,⁹ and Mr. H. F. B. Lynch.⁹ Besides these special papers, constant mention is made in consular reports of the absolute necessity of improved communication between the Persian Gulf and the interior; those by H.M.'s Consul at Isfahan, Mr. J. R. Preece, are particularly instructive in that respect.

If we consider the present means of conveyance, it is indeed astounding that a country of about 636,000 square miles without navigable rivers;¹⁰ but inhabited by 9,000,000 people, of whom it is estimated that one-fourth are settled in towns and half are agriculturists, and who are remarkable for their intelligence and industry, should have to carry on its foreign trade and local traffic along mule tracks, the like of which are hardly to be met with in any other part of the world, however backward. The passes between the Gulf ports and the Persian plateau are in the same condition as Herodotus described them, and as they were found by Marco Polo and his innumerable successors. But it will not be necessary to enlarge on this subject, which has been repeatedly put before the public by those most qualified to deal with it, neither would it serve any purpose to discover the reasons why the Persian Government have not themselves provided their country with roads, or do not apparently intend to do so in the near future. We have to face the question as we find it:

⁹ "Proceedings of the Royal Geographical Society," September, 1890.

¹⁰ The Karun in the south-west is only navigable for little over 200 miles (with an obstruction about midway). The rivers whose waters join the Caspian Sea become quite shallow a few miles from their mouths.

an immense country on the high road between the East and Europe totally unprovided with efficient means of carriage either by land or water.¹¹

The total trade of Persia with foreign countries is estimated¹² at £3,975,984 imports, and £2,100,901 exports, and it is carried on along the following trade routes :—¹³

I.—FROM THE SOUTH.

1. *Bushire to Shiraz, Isfahan, Teheran.*—Imports, 1897, £1,145,329. (1895, £1,016,917; 1887, £655,315.) Exports, 1897, £392,532. (1895, £528,827; 1887, £469,891.)

2. *Bender Abbas to Kerman, and via Yezd to Meshed and Central Asia.*—Imports, 1897, £381,562. (1895, £478,254; 1887, £349,142.) Exports, 1897, £230,781. (1895, £324,920; 1887, £292,624.)

3. *Lingah.*—The imports are mostly distributed in the neighbourhood or re-exported. Imports (omitting specie), 1897, £442,472. (1895, £429,991; 1887, £550,501.) Exports (omitting specie), 1897, £384,714. (1895, £368,739; 1887, £474,573.)

4. *Mohammerah—for Shushter, Dizful, &c.*—Imports, 1897, £121,407. (1895, £180,631; 1890,¹⁴ £146,141.) Exports, 1897, £87,473. (1895, £91,457; 1890, £53,096.)

5. *Bagdad to Khanikin Kermanshah, Hamadan, Teheran.*—Between one-third and one-fourth of the imports are in transit for Persia; of the exports a somewhat smaller proportion comes from there. Imports from India and Europe, 1897, £1,182,645. (1891,¹⁵ £914,886; 1887, £761,499.) Exports to Europe and America, 1897, £522,960. (1891, £564,900; 1887, £514,840.)

II.—FROM THE NORTH.

1. *Resht and other ports on the Caspian*

¹¹ In "Persia and the Persian Question," vol. i, pp. 485-92, and vol. ii, p. 574, the Hon. Geo. N. Curzon, M.P. (now Lord Curzon of Kedleston) gives a clear *résumé* of the condition of things then existing (1890) and which has not since altered.

¹² "Almanach de Gotha," 1899.

¹³ The following figures have been taken from the English Consular reports of Bushire, Resht, Bagdad, Trebizond, and Meshed. The amounts are not reliable, but approximate, as it is impossible under the present system of farming Custom taxes to collect exact statistics. Only the chief ports and Custom-houses are here mentioned, so that the total of their imports and exports does not correspond with the estimated total trade of the country. A large proportion of the imports (notably those of the Gulf ports) are re-exported to other Persian ports or to the Arab coast. The same thing will take place to a less extent at the Caspian Sea ports.

¹⁴ First report since establishment of vice-consulate.

¹⁵ The consular reports for 1892-5 do not give the usual statement of imports and exports.

Sea.—Imports from Baku, 1896,¹⁶ £842,655 (1895, £1,152,479; 1891,¹⁷ £806,327.) Exports to Baku, 1896, £365,342. (1895, £301,762; 1891, £294,053.)

2. *Tabriz, for Azerbaijan,* and distribution east and south as far as Teheran, Meshed and Kurdistan.—Imports, 1896-7, £648,920 (1894-5, £350,339; 1886-7, £795,370.) Exports, 1896-7, £256,720. (1894-5, £162,808; 1886-7, £253,023.)

3. *Meshed, for Khorassan,* trades by way of Astrabad, near the Caspian, and *via* Kushan, to Ashkabad on the Trans-Caspian Railway.—Imports from Russia and the Khanates,¹⁸ 1897-8, £121,307. (1895-6, £86,929; 1889-90,¹⁹ £110,408.) Imports from Afghanistan, 1897-8, £12,178. (1895-6, £11,859; 1889-90, £17,272.) Imports *via* Trebizond, Tabriz, Teheran, 1897-8, £26,673. (1895-6, £24,166; 1889-90, £39,103.) Imports from India, *via* Bender-Abbas, 1897-8, £130,282. (1895-6, £199,167; 1889-90, £184,583.) Exports to Russia and the Khanates, 1897-8, £79,454. (1895-6, £67,889; 1889-90, £111,442.) Exports to Afghanistan, 1897-8, £1,149. (1895-6, £908; 1889-90, £1,143.) Exports to Afghanistan (Foreign goods in transit), 1897-8, £15,857. (1895-6, £11,760; 1889-90, £17,156.) Exports to India, *via* Bender-Abbas, 1897-8, £40,083. (1895-6, £22,269; 1889-90, £38,958.)

Besides these chief trade channels, there exist some of minor importance by which goods enter Persia from Turkey on the West, and from Afghanistan on the East, by Hera Meshed. A new route from which great results are anticipated for the trade between India and Persia (and in transit to Central Asia) has been opened two years ago from Quetta, on the Indian Railway system, by Nushki, Chah Amir, Kuh Malek Siah, Nasratabad, Birjan Kain, and Turbat-i-Haideri to Meshed (1,000 miles, 53 stages).²⁰ The Indian Government has caused wells to be dug on the line of march as far as the Persian frontier. The boundary between Afghanistan and Khazan has been rectified, so that the road does not touch Afghan territory, and a line of telegraph has been projected, following the road as far as Chah - Amir, there branching off to Lad Regan, Kerman, and Kashan, where it will join the existing Indo-European telegraph line, thus making the latter independent of the

e between Bus'hire and Kurrachee.²¹ This e will be chiefly used for the carriage of but since the Central Asian Frontier has a virtually closed against non-Persian proe entering from Persia, its importance as a commercial highway will be confined to con- pation in Seistan and Khorassan.

ll these roads are what have been called "atural" ones; in other words, mere mule ks.

he cart roads (more or less metalled) at sent existing in Persia are the following:— eiran-Kasvin (1880), 96 miles; Teheran- n (1883), 97 miles; Meshed-Kushan-Ash- ad (1890), 150 miles, of which 30 are on ssian territory; and some short roads in imediate neighbourhood of Teheran, efly to Royal palaces.

oncessions have been granted, or have been red from time to time, for the following ds:— Teheran (Kum)-Burujird-Shushter- was, with branch road from Burujird to han; Teheran-Tabriz-Julfa (on the Aras); eiran-Kermanshah-Khanikin-Bagdad); Ta- z-Ardebil-Astara; Tabriz-Khoi-Bayazid; jan-Hamadan-Burujird; Kasvin-Resht- i-Bazaar (with the right of purchasing existing road, Kazvin-Teheran); Kazvin- madan.

Of these roads only the last but one men- ed is in course of construction. Different umstances have prevented the carrying out the other projects. The principal one of se was undoubtedly that from Teheran to waz, known as the "Karun Road." It is a matter of great regret for the development of rsia that this important scheme has not en carried out, as it would have secured the ate which alone answers all requirements, ng the shortest and least difficult one from e capital to the sea, besides opening up the y well-watered provinces of Persia.

oon after the Lower Karun had been de- ed free to all flags, and the Imperial Bank e Persia had been established (1889), when a short while the country attracted the eention of the English promoting world, the e Shah Nasr-ed-Din, amongst other schemes hich were doomed to failure (tobacco regie, e monopoly, lottery, &c.) gave a con-

A land route from India to Eastern Persia was ocated by Sir Frederic Goldsmid as long ago as 1877, in a er read before the Society of Arts on the 20th of April of e year (*Journal*, No. 1275), viz., along the Mekran coast wadar or Kej, and thence by Bampur to Kerman. The longation of the Indian railways beyond Quetta, and the ification of the Southern frontier of Afghanistan have icated the route that has now been selected.

cession to his Minister of Commerce—Yaya Khan, Mouchir ud Dowleh—for the construc- tion of a road from Kum to Ahwaz, by way of Sultanabad, Burujird, Khorremabad, Dizful, Shushter, with a branch road from Chelunchuan to Isfahan. Later on, the option was granted to continue the road to Mohammerah at the confluence of the Karun and the Shat-'l Arab. This concession, which gave the right of levy- ing tolls, was bought of the Mouchir ud Dowleh by the Imperial Bank of Persia, with the in- tention of forming a separate company to con- struct and work the road. This plan could, however, not be carried out, as the short spell of speculative prosperity had passed away. Meanwhile, capable engineers had been sent out, and much money was spent in making a survey of the whole road, and on repairing the existing section, Teheran-Kum, which had been sold to the Bank by the Emin es Sultan, who is now Sadrazem.²² Unfortunately this work was done in such a thorough manner that it soon exhausted the amount which the Bank felt justified in advancing, whereas the prospect of ceding the concession to a separate com- pany became more and more remote. With this latter object, however, a regular service of diligences and fourgons between Teheran and Kum was established, and carriages were let for the same journey. It was hoped that these conveniences would create a want. The attempt did not prove a success financially, and the Bank has since tried the experiment of farming the road to a Persian, but after some time it has again taken the service under its direct management, conducting it in a somewhat rougher fashion than it was started originally, and therefore more in proportion to the real requirements. (Recently authority was obtained to prolong the road by way of Kashan to Isfahan, there to meet the road from Ahwaz, through the Bakhtiari country, which will be described later on. This authority does not, however, interfere with the existing rights for the construction of a direct road from Kum to Ahwaz.)

The construction south of Kum was stopped. This result was all the more deplorable, because the concession remained with the Imperial Bank of Persia, and if the Shah's Government or some European combination should sooner or later feel inclined to under-

²² The road had been built in 1883 by this minister's father, who was also styled Emin es Sultan. The bridges were in bad repair and the road itself had not been looked after for years. The five Mehman Khanehs were extensive and well-planned.

take the work, they would have to come to terms with the Bank, which would, in the first place, endeavour to be refunded the amount (£85,000) which had been written off as spent on the easy first section, on surveys, and on the purchase of the concession; an outlay which would be altogether out of proportion to the strict cost of the whole work. There is no doubt that the project of making a self-supporting road, fit for wheeled traffic, all the way from Teheran to Ahwaz (about 530 miles), and a branch road from near Burujird to Isfahan (210 miles), was too ambitious a one. The money spent on the first section and surveys would probably have been sufficient for the complete work if the promoters had been satisfied with good mule tracks in the mountainous parts, leaving further improvements to the future.²³

Meanwhile, Russia had been roused from her apathy with regard to public works in Persia, first by the action of those "who blew so loud and foolish a trumpet over the opening of the Karun to foreign trade in 1888,"²⁴ as Lord Curzon of Kedleston, says in his well-known work on Persia, and afterwards by the establishment of the Imperial Bank of Persia, and the concession of the Karun road. As a result she claimed and obtained the right to construct roads for wheeled traffic from Kazvin to Resht, with the option of buying the existing road from Kazvin to Teheran.

Of late years Russian trade has made undoubted progress in Persia. This is in no way surprising if we consider her geographical position, and the truly wonderful development that has taken place in her industry. In this,

²³ Unless assisted by a Government guarantee of a minimum interest, a well-built road fit for wheeled traffic all the year round can hardly be expected to earn a reasonable return on the capital laid out. At a low computation, about £200,000 would be required for such a road, so that with cost of animals, rolling stock, concession and working capital, about £250,000 would have to be invested. It has been estimated that for a roughly-metalled, fair-weather cart-road (*i.e.*, fourgons when the nature of the soil and the weather permit, baggage animals when this would not be practicable), 15 feet wide, which could in many places be reduced to 10 or 12 feet, with a maximum gradient of 1 in 9, could be made for about £85,000. This would include:—The present road, Teheran-Kum, with 7 guest-houses, at purchase price plus cost of improvement, and a roughly-metalled road from Kum to Ahwaz, and branch road to Isfahan, with the necessary number of caravanserai, but with ferries, no bridges, at Dizful and Shushter. Adding to this £30,000 for concession and working capital, the total investment would amount to £115,000, that is supposing that the pack animals would be contracted for, to work for a certain sum per diem, their keep at the charge of the owners; the company undertaking the transport of goods at a tariff, and charging tolls to outsiders.

²⁴ "Persia," by the Hon. Geo. N. Curzon, vol. ii., p. 387.

as in other respects, she is slowly but steadily fulfilling her destiny.

Russian sugar reigns now supreme in north of Persia, having beaten all competitors. Prints from Moscow are paramount in North-West; they divide about equally the Teheran market, with those from Manchester and they are beginning to appear in the bazaars of Central Persia. At Tabriz, Manchester only been able to keep a firm hold of the market because the freight from Moscow is higher than that from Lancashire.²⁵ At any time, a change in the railway freight between Moscow and Odessa may alter the situation in favour of Russian prints. In glass and earthenware, candles, petroleum, and a few other articles of less importance, Russia is, in most cases, without opposition in North Persia. So far the chief articles are, however, sugar and cotton. It is well known that their success in Persia has been secured by an elaborate system of bounties. This system has been often decryed in England, but Russia is a new country in an economic sense, and her commercial policy should be judged in that light. Her tariff is in any case created a flourishing industry, and the sugar, candles, and certain classes of cotton goods which she exports to Persia, generally represent the over-production of her works. Their output helps to cheapen, rather than enhance the profit on what is sold in the home market, and the whole system has the same effect in Persia that the Continental sugar bounties have on consumers here. The trade that Russia does in Persia may be called artificial, but it is nevertheless a rapidly growing one. It is, however, confined to the north. We find clear proof of this in the consular reports. For instance, at Bushire the total imports in 1897 amounted to £1,145,329; in this the United Kingdom and India contributed £974,386, Russia £750. The exports amounted to £392,532, of which £172,653 went to the United Kingdom and India, and only £119,825 to Russia. If we compare these figures with those of the Tabriz and the Meshed reports (which indicate a large proportion of English trade notwithstanding the fact that Russia is

²⁵ The freight from Moscow to Odessa, I was told, is high as that from Odessa to Bagdad. There exists a special railway tariff in Russia for goods exported to the Far East but this tariff does not apply to the Levant or Persia.

²⁶ In 1895-6, Tabriz imported 9,784 bales; in 1896-7, 9,774 bales of cloth and grey shirtings from Manchester, and none from Russia. Of prints, Manchester sent, in 1895-6, 9,000 bales (in 1896-7, 9,080 bales), and Moscow 678 (in 1896-7, 572 bales). For details of imports of Khorassan, see p. 342.

er) there seems no reason to grudge her an extension of trade which has been obtained at such great sacrifices.

The new road from Resht to Teheran is the latest move that Russia has made to widen the scope of her Persian trade.

During a recent visit to Teheran and Russia I had an opportunity of obtaining the following details with regard to this undertaking.

The concession to construct this road was granted in 1893, and includes the right of widening the entrance to the Murdab at Enzeli. It was granted to "The Compagnie d'Assurance de transports en Perse," founded by Mr. S. Poliakow, of Moscow, who is also the manager of the International Commercial Bank of Moscow, which has a branch office at Teheran. It is said that the Russian Government have shown a keen interest in this scheme, and that it was at their request that Mr. Poliakow undertook the enterprise. At these events, it was no doubt through official assurance that the chief merchants and manufacturers at Moscow who have, or are in the future likely to have, business relations with Persia, became shareholders of the company in which the concession was sold, and which was formed with a capital of 1,000,000 roubles, 1,000 shares of 1,000 roubles. Some of the Moscow firms took as many as 100 and 150 shares.

At first the work was taken up with much ardour, but possibly discouraged by the formidable difficulties met with as soon as the higher ranges of the Elburz were reached, and which necessitated a larger expenditure than may have been foreseen, this energy became gradually less until it looked as if the plan had been abandoned. In 1897, however, Colonel Mszichovski, who had been given charge by the company of the whole work, came to Persia on a visit of inspection, and soon after his return the Russian Government decided to refer to the assistance of the company by issuing debentures to the amount of 1,000,000 roubles, on condition that the work should be finished without delay. According to the terms of the concession, the road should have been ready for traffic at the end of last year, but a prolongation of one year was obtained. Finding that the 2,000,000 roubles were not sufficient to complete the road, the Government again came to the aid of the company by issuing another 500 debentures of 1,000 roubles, on condition this time that the capital should be increased by 700,000 roubles. This was done (most of the shares were taken by the

original shareholders), so that the company is now working with a capital of 3,200,000 roubles (1,700,000 rouble shares, and 1,500,000 rouble stock), or, say, £340,000.

This no doubt seems a large amount, but it should be borne in mind that it includes the cost of the concession, Enzeli-Kazvin, with extension to Hamadan, at £40,000 and the purchase of the Kazvin-Teheran road at the same price. The cost of the actual road-making has been 30,000 francs per kilometre, and that certainly does not seem excessive, as the difficulties have been great. Between Pir-i-Bazaar, Resht, and Kuhdum, for say twenty miles, where the soil is exceedingly marshy, large quantities of stone, brought from distant mountains, had to be used in many layers before a sound foundation could be obtained. This work went on for two years, and was much hampered by the fact that rice is cultivated in many places on both sides of the road: the complicated system of dams and dykes for irrigation purposes making the work very tedious. At first, Russian workmen were employed, but the mortality among them in the lowlands near the Caspian was very great; during the first year 30 out of 300 died of malarial fever. They have been replaced by Italians, who resist the climate better. After reaching the mountains difficulties of another, but hardly less costly nature arose. Near Rudbar, Menjil, and Mullah Ali not less than 50 miles had to be cut through solid rock by means of "roburite" imported from England.

The local management is in the hands of Captain Glinofski, who has had much experience of road building.²⁷

Starting from Pir-i-Bazaar on the Murdab, the road (6 miles) turns to the left quite near Resht, crossing the Rudbar by a wooden bridge, thus avoiding the town with its narrow streets. It then follows the old track to Kuhdum, and was practicable last spring for carriages as far as Ziah-rud, 8 farsakhs, or about 30 miles from Resht. The road now begins to climb in earnest, and it frequently leaves the old mule track. In April I found it levelled and ready for use as far as Rudbar (14 farsakhs, or about 47 miles from Resht), and I have just heard from Colonel Mszichovski

²⁷ Both Col. Mszichovski and Capt. Glinofski were educated at Government colleges, and have the rank of Colonel and Captain of Engineers respectively. But they are not in Government employ, although they may be called to do service at any time. I am indebted to the first-named gentleman for much of the following information regarding the Resht road.

that it has been opened for traffic as far as Menjil, that is half the distance between Enzeli and Kazvin.

From Rudbar to Menjil and Paichenar several gangs of seemingly over a hundred men each were at work, blasting and pickaxing the solid rocks of limestone which line the Sefid Rud so impressively.²⁹ All travellers to Teheran will remember the approach to the Menjil bridge coming from Resht, and will realise the enormous expenditure of work that was required to cut a road with a practicable gradient through these forbidding masses. Here the old road, a veritable rock ladder, on which the unfortunate mules or chapar horses have to clatter as best they can, has been of no use whatever to the new one. Under these circumstances, it was necessary to limit the width to the narrowest possible dimensions. At such places the road is 5 metres (16½ feet) broad, but at distances of 200 metres it has a wider stretch, so as to allow for the passage of two carriages. The normal width between Resht and Teheran will be 3 saschens (21 feet), the usual gradient is 1 in 24 to 1 in 20, in a few exceptional cases 1 in 15.

Nothing has been done, so far, to the bridge at Menjil, of which, as usual of late years, a couple of arches have fallen in. Caravans have at present to pass with great precaution by a very ricketty construction of wooden rafters, supported by and attached to the pillars of the bridge. Carriages could not possibly use this quaint structure, which is very narrow, and about 142 yards long. As it is cheaper in Persia to build a new bridge than to repair an old one, it has been decided to replace the present structure by one of iron. The material has arrived from Russia, but as the Sefid Rud is a stream with a considerable current, the work of spanning it will take time, and it will be no doubt necessary, for some months after the

completion of the road, to change carriage at the bridge, crossing it on foot with the horse.

At Paichenar a young engineer, M. Wolseider, has his headquarters. So far, the new road has followed on the tracks of the old one, except for a few short deviations. But it is now approaching the Kharzan Pass (about 7,500 feet), a conclusive barrier to anything on wheels. The two roads here part company, and the new one, following the telegraph line as far as Kuhin, makes a detour of about 12 miles by following the left bank of the Yabashi river, and, passing by Mullah-Ali, where another iron bridge will be built, rejoins the old road at Agha-Baba.³⁰ I have not visited this part of the road. Last spring, work there had not been commenced. It is now well on its way. General Schindler is, as far as I know, the only traveller who has described this s-

²⁹ The same plan is followed on the road from Tiflis to Vladikavkaz whenever snowdrifts block the passage. This was the case last winter between Goudaur and Kobur about a verst. Arrays of vehicles of all descriptions, from the humble tarantass to the lumbering diligence, were found ready on both sides of the obstruction waiting for arrivals.

³⁰ It may seem strange that a busy traffic, such as exists between Teheran (and Kazvin) and Resht, has been sufficient for many years to pass by mountain defiles which, in winter, are often blocked by snow for weeks, and which levy an annual toll on men and animals perishing from cold. It may be asked why the detour by Mullah Ali was not discovered and made available for caravans long ago. The same thing, however, occurs in Persia in many places.

The stages of the post road between Resht and Teheran are at present as follows:—

	Farsakhs.
Resht-Kuhdum	6
Kuhdum-Kustumabad ..	5
Rustumabad-Menjil ...	5
Menjil-Paichenar	4
Paichenar-Kharzan	4
Kharzan-Agha-Baba	4
Agha-Baba-Kazvin	4

32 Farsakhs

or say 112 miles.

Formerly the section Paichenar-Kazvin was divided into 10 stations: Paichenar-Mezreh and Mezreh-Kazvin, both of about the same distance (5 farsakhs). With the exception of the last 4½ farsakhs, nearest Kazvin, the road passes over such difficult ground that it was decided a few years ago to establish two post-houses: Kharzan and Agha-Baba, not far from Mezreh. Although the road still passes by the latter place and follows in every detail the old track, the former distance of 10 farsakhs has apparently grown into 12; the explanation is that fractions of farsakhs are calculated as entire ones for the hire of horses, which are charged by distance: at present 1½ kran per farsakh. It used to be 1 kran in 1892, and ¾ kran some 15 years ago. The fall in silver has reduced the power of the kran. At Kharzan and Agha-Baba no post-houses have been built; travellers are accommodated in caravanserais, the one on the Kharzan being ruined, the other the most primitive description. The advent of the "Russian road" round the Kharzan has put a stop to any progress that may have been contemplated.

²⁹ The following details about the staff and workmen employed may be of interest. Besides the chief engineer, M. Glinofski, there are, in Persia, 2 engineers, and 12 assistant engineers, or chiefs of sections (this number has been gradually reduced as the work advanced.) Further, a chief book-keeper with 2 clerks, and 5 or 6 juniors. Also a doctor and several assistants. The number of workmen was, at first, about 4,000 (1,000 horses and donkeys for the transport of gravel), but at present there remain only a few hundred in the few sections that have not been completed. They are chiefly Persians and Kurds, and a small number of Greeks, Turks, and Italians. There are few Russians employed now, for reasons already explained. On the whole, nearly a million cubic metres have been dealt with, of which about one-third, in rocky parts, was where the European workmen were chiefly engaged, because the Persians of the Caspian provinces are deficient in energy and strength, on account of the climate.

Sketch Map of the road PIR-I-BAZAAR-KAZVIN.

Scale of Miles

Scale of Farsakhs

Longitude E. 50° of Greenwich

tion,³¹ and his itinerary is the same as that adopted by the Russian company. The following is a brief summary:—

“Leaving Teheran (in July, 1879, just before the construction of the present Kazvin road) Agha Baba is reached by a good road of 14 miles. Continuing almost due west, the Bascher is crossed (2 miles) and passing Bumehin a descent to the Do-deh plain, followed by an easy ridge, leads to the large village of Kuhin (5,106 feet) situated in a fertile valley (5 miles from Agha Baba). Nearing the Azalek, a small stream, by a somewhat sharp climb, the Aspabin plain is reached, dominated by the Piruz. The direction has now become north-west, and at Beg Baghi (3,056 feet) changes to north, when the road traverses the broader watershed of the Yuz-bashi,³² where, as a sign of a milder climate, figs and oleanders are observed. Following the windings of this valley the winter settlements of the Ghaswend nomads are passed. The road now enters the valley of Mullah Ali (also called Hassan Khani) with the finely-situated village of that name, which is deserted in summer. Here a bridge is required during the spring floods. A couple of miles further, passing the village of Kogir, the post-house of Paichenar is reached (1½ miles beyond Paichenar the Yuz Bashi joins the Shah rud, which at Menjil unites with the Kizil uzun, forming together the Sefid Rud). In a footnote the general character of the road is described as offering much less difficulty than the one crossing the Kharzan pass. The undulations are more practicable, the winters are milder and more free from snow. Many villages are met with. Incidentally the road is mentioned as being the one chosen for the then (1879) projected railway from Resht to Teheran.”

Between Paichenar and Kazvin two new post-houses will be built, on the other sections the existing stations will be put in thorough repair.

At Agha-Baba the gradually rising plain is entered that stretches to Kazvin and Teheran, and there are now no more engineering difficulties to contend with; in fact, a rough cart road has been in use for some time as far as Kazvin, and all that has to be done is to metal it and provide for drainage. From Kazvin to Teheran a regular carriage service has been in existence for about 18 years. It is at present farmed by a Persian, who keeps the service in a fairly efficient state. The distance

of 96 miles, divided into six stages of equal length, is covered in 16 hours under average circumstances. After a heavy snowfall the is delay. The road has an excessive width and is not metalled. The bridges are in bad repair and unsafe. The Russian company will have to spend a considerable amount of money to bring this road up to the level of what is being done beyond Kazvin; but this in good time, will be accomplished.

The company does not intend for the present to undertake the carriage of passengers, mail and merchandise, although it has acquired the right to do so. The revenues of the road will therefore, have to be derived entirely from the tolls. These have been fixed at 4 krans (say 1s. 6d.) per pack animal (horse, mule, donkey or camel), from Resht to Kazvin, and the same from Kazvin to Teheran. Carriages pay 42 krans (17s.) for four horses, 30 krans (12s.) for three, 20 krans (8s.) for two, and 10 krans (4s.) for one. Loaded carts pay 50 krans (20s.) each. A proportionate deduction is made for a shorter distance.

People at Teheran are waiting impatiently for the completion of the road, and no doubt much polite pressure is being exercised, not the least by the different legations. In fact, the chiefs of the two principal ones have had personal experience of the hardships of the old order of things. Both Sir Mortimer Durand and M. Argiropulo have been detained for days in very uncomfortable huts near the Kharzan waiting till a path had been made through the snow. The sufferings of the great often bear good results for the multitude. Foreign ministers travel too seldom on other roads in Persia.³³

M. Mszichovski is very sanguine that the entire road will be finished by the end of May, and it will be opened with some ceremony in the presence of the Sadrazem and the Russian Minister at Teheran, who have been invited by the company to visit Resht for that purpose. Should there be unforeseen delay, the inauguration will probably be postponed until the autumn, because the weather in Persia between May and September is too hot for such a prolonged picnic.

Supposing the road to be ready, which will certainly be the case, in August or September this year, the question remains how to improve

³¹ “Zeitsch. der Ges. für Erkunde,” Berlin, vol. xiv. p. 119. The paper is accompanied by a map, Resht-Teheran scale 1 : 600,000, published and annotated by H. Kiepert.

³² Near here, at the site of a ruined Shah Abbas caravanserai, the extension to Hamadan has been planned to start. This, however, will not be taken in hand before the Resht-Teheran road has commenced to pay good dividends.

³³ Last November M. Mszichovski came all the way from Teheran to Resht by carriage, with the exception of about 10 miles between Paichenar and Mullah Ali, for which he had to use the saddle. No doubt he was able to arrange special facilities.

existing primitive state of things between Pir-i-Bazaar and the Caspian. Ultimately, no doubt, the road will be prolonged to Enzeli, but this, it is estimated, will cost from £80,000 to £100,000, the ground being very marshy, and a long detour round the Murd-ab will have to be made. For the present it is intended to content with a service of lighters and tugs across the ten miles' broad lagoon. For an interrupted communication between Enzeli and the sea, it will be necessary to deepen and widen the channel that unites the waters of the Murd-ab and the Caspian so that steamers can enter the lake which itself is of sufficient depth.³⁴ The concession to Mr. Poliakov provides for this option. I was told the best place for a port seems to be to the south-east of the present town of Enzeli.

Resht has grown rather prosperous of late years. The silk industry, which had suffered greatly through a disease of the silkworm, has been revived by the introduction of seed from France and Italy. The fisheries on the Caspian are flourishing, and altogether the place gives an impression of welfare compared to other towns in Persia. The Governor, H. E. Saltaneh, is spoken of as an enlightened, energetic man.

The journey from Western Europe to Teheran will be greatly facilitated and shortened by the new road. From London to Resht 12 to 13 days are at present required—that is if no delays are encountered, viz. :

	Days.
London to Batum, <i>via</i> Berlin.	
Warsaw and Odessa	7
Delay at Batum $\frac{1}{2}$ day, Batoum to Baku $1\frac{1}{2}$ days	2
Baku to Enzeli	$2\frac{1}{2}$
Customs at Enzeli, steam launch to Pir-i-Bazaar, carriage to Resht, and arranging for journey..	1
	12 $\frac{1}{2}$

This represents the shortest time with no delays on the way, and immediate embarkation at Odessa in the weekly steamer that

touches at only three intermediate ports. At Baku also there must be no time lost, and as there is no "connection" between the services of the two companies (the Russian Navigation Company on the Black Sea and the Kavkaz-Merkur on the Caspian) this can only be the case by a happy coincidence. If going by Constantinople, instead of Odessa, the time is the same, but the connection at Baku is equally uncertain. A route that is much adopted is the one by Petrovsk (London-Berlin-Moscow, 4 days; Moscow-Petrovsk, 4; Petrovsk-Enzeli, 5; Enzeli-Resht, 1; together, 14 days). The steamer from Petrovsk to Enzeli remains 48 hours, and sometimes longer, at Baku. Notwithstanding that delay, this route will be found the shortest in most cases, and certainly the more reliable one. The two or three days lost at Baku can be avoided by going from Moscow to Vladikavkaz; thence by carriage along the beautiful military Georgian road to Tiflis (24 hours, including a rest at Mlete) and to Baku by train (18 hours). But this route is uncomfortable in winter and in spring.

There is a weekly service between Petrovsk, Baku, and Enzeli in summer, and a fortnightly one in winter, besides numerous cargo boats. The mail steamers touch at Lenkoran and Astará. The larger ones of the steamers that are employed on this line, for instance, the *Imperator Nicholas II.*, which runs 13 knots, and is a most comfortable boat, could perform the trip (from Baku) easily in 20 hours if going direct.

With post horses the ride from Resht to Kazvin (carriage as far as Ziah rud) takes from 30 to 36 hours, according to the state of the road, and from Kazvin to Teheran by carriage requires 16 hours under ordinary circumstances. In fair weather 48 hours is a reasonable allowance for the whole distance Resht-Teheran, but this demands some perseverance.³⁵ When the road is fully organised it will be quite possible to reach Teheran from Resht without exertion in a day and a half. At present, in case of need, and if all goes well, Teheran can be reached from London within two weeks. When the railway Petrovsk-Baku is opened (which will be the case in about a year) and if direct steamers are put on the line to Enzeli, the journey will be further reduced by about four days. This will no doubt for many years to come be the quickest time.

³⁴ The Caspian at Enzeli is very shallow for more than 300 yards from the shore. Steamers have, therefore, to anchor at some distance, and if a strong wind is blowing it is impossible to load or unload. It often happens that passengers for Resht have to return by the steamer to Baku. Last winter some English travellers had the rather unprecedented experience of making the voyage twice in vain. It was only after the completion of a third journey from Baku that they succeeded in landing. In such cases it is often advisable to land at Astará, which has a better protected roadstead. Mr. de Windt, in his "Ride to India . . ." describes the road from this (the frontier) town to Resht, which takes three days by caravan.

³⁵ One of the couriers of the British Legation at Teheran is in the habit of performing this distance in 30 hours.

It has been suggested that the *tracé* of the new road to Resht could be used for a Decauville railway, but this is not the case. The turnings are so abrupt, and there are so many of these, that a railway along this road is out of the question.³⁶

If the plan of a railway to Teheran does exist, it will be rather carried out by gradual extension of the line Petrovsk-Baku to Astara, along the Caspian Sea to Resht, and then by Kasvin to Teheran. In the fulness of time the Caspian coast line will have to be prolonged to Astrabad and some point on the Trans-Caspian Railway, say Kizil Ararat, to be followed later on by the equally political line, Teheran-Yezd-Kerman, to some point on the Arabian Sea, say Chahbar, which is more accessible and less unhealthy than ports further north.

From the north-west Russian railways are approaching Persia at a rapid pace. The Tiflis-Alexandropol-Kars line is very nearly completed, and it has been decided to construct a branch line from Alexandropol to Erivan. From the latter place to Tabriz the distance is only 209 miles, and there are no engineering difficulties to overcome except the bridging of the Aras at Julla.

The shortening of the time occupied by goods to travel from the Caspian to Teheran will have far-reaching consequences for the current of trade in Persia.³⁷ The object aimed at by the measure of closing the Caucasus against transit for Persia (whilst remaining open for the transit of Persian goods for Western Europe) will be attained, and Russian goods will be enabled to penetrate farther into Persia, whereas imports by way of the Gulf ports and Bagdad or Trebizond will not be benefited. Teheran, already the most populous centre in Persia, will become of greater importance as a distributing market. The exports to Russia of dried fruit from the neighbourhood of Kazwin,

³⁶ The concession for the road provides that the company will have the preference for a railway from the Caspian to Teheran. Should others offer better conditions, and obtain the concession, they will have to compensate the company by the payment of a sum of money, the interest of which, at the rate of 5 per cent., will be equal to the average earnings of the road.

³⁷ A calculation made some time ago resulted in the curious fact that the freight (in summer, *i.e.*, using the Volga) for cotton goods from Moscow to Isfahan was almost exactly equal to that paid from Manchester by way of Bushire. Isfahan is about equidistant from the Caspian Sea and the Persian Gulf. It is thought that the new road will reduce by one-half the present freight between Resht and Teheran. This result is arrived at as follows:—A horse carries, on an average, 8 pound, but it can draw 24—in fact, two draught-horses can transport 50 pound. This difference allows amply for cost and wear and tear of the cart.

and of cotton, will be further stimulated,³⁸ and altogether the commerce between the two neighbouring countries will gain about as much as the importation from the south all the west will lose.

Considering the indifference shown by England in assisting Persia in providing good communications from the South, there is nothing in this course of events that ought to surprise us. "For many years (in Lord Curzon's words) "Persia has alternately advanced and receded in the estimation of British statesmen occupying now a position of extravagant prominence, anon one of unmerited obscurity. At one time she has been the occasion or the recipient of a lavish and almost wanton prodigality; at another she has been treated with penurious meanness. Public opinion in this country and in India with regard to Persian politics has been either at a white heat, or has subsided into an inert stupor."³⁹ English aspirations in Persia seem to have entered for some time into the latter state. Last spring, however, through the able exertions of the Hon. C. Hardinge, who was in charge of the Legation during the absence on leave of the Minister, Sir Mortimer Durand, a step in the right direction was made by securing the opening of the much-discussed trade route from Shushter to Isfahan through the Bakhtiari country. The situation was favourable, and was taken advantage of. The present chiefs of the still mighty Bakhtiari tribes,⁴⁰ following the intentions of the late Husein Kuli Khan had begun to show increasing willingness to facilitate the creation of a high road through their dominions. Their former power had been undermined. Incessant quarrels between the tribes after the execution of Husein Kuli Khan in 1882, aided by the traditional policy of the Central Government: *divide et impera* had gradually resulted in impoverishing them and breaking their pride.⁴¹ Recently there has

³⁸ The importation of these and other Persian produce assisted by Russia by means of low import duties, as compared with what is charged for the same articles imported from other countries.

³⁹ "Persia," by the Hon. G. N. Curzon, M.P., vol. i. p. 605.

⁴⁰ The principal chiefs at present are: the *Ilkhani*, Imam Kuli Khan, brother of the late Husein Kuli Khan; the *Ilbegi*, Isfendiar Khan; Sardar Asad, eldest son of Husein Kuli Khan; Hajee Ali Kuli Khan, brother of Isfendiar; and *Sertip* of the Bakhtiari horse at Teheran; Reza Kuli Khan, a brother of Husein Kuli Khan, and Governor of Cheha Mahal; his son the Kargham es Saltaneh. The latter two chiefs are on bad terms with the others.

⁴¹ For a full and fascinating account of the Bakhtiaris and their ancient and modern history see "Persia," by the Hon. G. N. Curzon, M.P., vol. ii, pp. 233-303.

in famine in places as far south as Ramermuz and Behbahan, and great numbers of horses and sheep had died. Apart from political motives (*i.e.*, a wish to come into closer relations with England as a bulwark against oppression), they had begun to realise that continued isolation would in the end lead to extinction. Even in those inaccessible regions a wish for greater prosperity by legitimate means had taken root: at least among the leaders. On the other hand, the Government at Teheran was not likely to raise any objection to a scheme which would slowly but surely implant their authority over a people which hitherto had successfully resisted all roads on their rugged independence.

As a result, and after protracted negotiations, was arranged, with the sanction of the Shah's Government, and of the British Legation, that the tribes would enter into a contract with an English firm on the following conditions:—The firm would advance the necessary funds (about 5,500) to build certain bridges, the revenues of the road would consist in tolls to be levied on all animals passing with loads, *viz.*, camels and mules 5 krans (2s.), donkeys 3 krans (s. 2½d.), per load; the tribes would guarantee the safety of the road and 6 per cent. interest on the money spent, which guarantee the Teheran Government undertook to enforce in case of need; they would further contribute labour for the improvement of the passes, and would maintain them in good working order. They also promised to provide the necessary rules for the traffic: a valuable condition, as it will take time to instil sufficient confidence in the minds of the much-suffering muleteers to make them abandon their present avocations for the dreaded Bakhtiari country.⁴² No provision was made for the building of caravanserais, but it is thought that in summer there is no great need for these, and during the bad season the road will, unfortunately, not be available, as the snow in the high passes will stop all transport.⁴³ It is hoped, however, that gradually the large traffic on the Bushire-Teheran-Ispahan route (estimated at 30,000 mule loads annually) will be diverted to this new

road, in which case caravanserais will be built as a matter of course, and a continual stream of caravans would no doubt prevent the snow from settling. Some travellers have formed a less optimistic opinion.

The firm of Messrs. Lynch Brothers, of London, with branches at Bagdad and on the Karun (the Tigris and Euphrates Steam Navigation Company, Limited) were found willing to enter into the enterprise on those conditions, and on behalf of the tribes the contract was signed (March, 1898) by Hajee Mohamed Khan (the Sefardar), Isfendiari Khan (Sardar Assad), and Hajee Ali Kuli Khan (the Sertip of the Bakhtiari Horse at Teheran).

It may be useful to precede the itinerary of the intended road by a brief summary of recent journeys from Shushter to Isfahan, and *vice versa*. In recent times, the road has been described by several travellers. Mr. George S. Mackenzie was the first who tried to extend to practical purposes the fact that Isfahan is some 220 miles nearer Shushter on the Karun, than to Bushire on the Persian Gulf. He travels from Isfahan to Shushter, by way of Ardel and Dopulun in 1875, and three years later he goes in the opposite direction by Bazuft.⁴⁴ At that time, the Lower Karun had not been opened to navigation, and it was not found possible to utilise the practical experience gained by these journeys. In 1877, General Schindler travels from Shushter to Isfahan, and describes his journey in a detailed manner.⁴⁵ His account is accompanied by an excellent map. The itinerary gives 291 miles, as compared to 267 by Mackenzie (first journey), 277 by Wells, and 249 by Lynch; but the difference is accounted for by the more southern route adopted between Shushter and Malamir by Joru (121 miles) instead of by Gurgir (78 miles). From Dopulun he selects the Naghan and Chigakhor route, instead of the more northern one by Ardel.

In 1881, the late Colonel (then Captain) H. L. Wells, R.E., goes from Isfahan to Shushter by way of Kahu-i-Rukh, Shelamzar, the Gerdan-i-Zerreh, Ardel, Dopulun, Malamir, Gurgir, and gives a critical description of the difficulties of improving the mountainous parts into a trade route.⁴⁶ The Lower Karun was declared free to all flags in October, 1888, and in the latter half of the next year, Mr. H. F.

⁴² The Bakhtiari breed of mules are the best in Persia, and perhaps in the world. They are not big, but compact and very strong. Until a few years ago they have been bought by the Indian Government in such numbers that the supply for caravans ran short, and mule carriage in central and southern Persia rose considerably.

⁴³ Well mounted travellers can get through sometimes; as did Major Bruce and Lieut. Macinnney in 1890. Last winter the snow was very high, but a Ghulam succeeded in making his way from end to end.

⁴⁴ See "Proceedings of the Royal Geographical Society," March, 1883, p. 132.

⁴⁵ "Zeitschr. der G. für Erdk." 1879, Map.

⁴⁶ "Proceedings of the Royal Geographical Society," March, 1883, Map.

B. Lynch, whose firm had been the first, almost immediately after the publication of the decree, to take advantage of this concession to Western pressure (thus repeating the introduction of the English flag on the Tigris by Commodore Blossé Lynch in 1862), makes his way from Shushter to Isfahan by Dara Kul, Gurgir, Malamir, Dopulun. He then adopts Schindler's route by Naghan and Chiga-Khor, but keeps more to the south than Schindler, and passes by Paradomba, the residence of the Ilkhani.⁴⁷ Others have travelled between Shushter and Isfahan, but their accounts may be considered to be superseded by those mentioned above. Their names and works have been fully noticed in the publications referred to.⁴⁸

The complete itineraries of four of the journeys, of which the main features have been mentioned, will be found on p. 355.⁴⁹

The four routes all vary as far as Malamir, where they converge.

If starting from Shushter, Lynch's is undoubtedly the shortest, but the river from Ahwaz to Shushter (Shelalieh, on the Gurgir)

is tortuous (by water 90 miles, by land miles), and as transshipment is required Ahwaz, on account of the rapids, it has been decided to begin the land transport at the latter place. Following the river as far as Weiss (14 miles), the road then strikes across to Kaleh-i Tul, probably by Rud Zerd, Kalg and Bagh-i Malek (see Schindler's and Wells' routes), and thence to Malamir. There is only one road from there to Dēhdiz, by Guda Balutak, where a bridge will be built to cross the Karun. From Dēhdiz to Dopulun the Shelil route will have to be taken, as Wells, who went by Rudbar, admits that the former route, taken by Mackenzie and Schindler, the easier of the two, and Lynch, who chose the one by Sarkun, explains that he had to do so on account of the ruined state of the bridge at Pul-i Amarat, where the Ab-i Bazuft has been crossed to reach Shelil. This bridge is now being repaired.

At Dopulun, where the brick bridge, built by the Ilkhani, is in good repair, the different roads once more meet. Of the three or four paths that lead from here to Kahu-i Rukh, a large village belonging to Isfendiar Khan, the one by the Ardel Pass will, no doubt, be chosen, but in order to avoid the 9,300 feet high Gerdane-i Zerreh pass, "a rough and very steep track, only passable for mules, and blocked even for them in winter" (Wells), the road cannot go from Ardel to Tishniz, but will make a detour to the north, and pass by the Teng-i Darkash Warkash, and probably Chulcheh (Mackenzie's second journey), Sireh and Shehrek.

From Kahu-i Rukh the road reaches Isfahan without further difficulties by Lajebid, Bagh Wahsh and Pul-i Wargan.

However grateful we may be for the energy displayed by H.M. Legation at Teheran, in securing this new trade route, giving access to the interior of Persia from the south-west, and whatever may be ultimately the political advantages, it cannot be denied that, for commercial purposes, the undertaking compares unfavourably with what Russia is doing in the north. The £5,500 which will be invested in the Bakhtiaris road cannot hope to compete in results with the £340,000 that is to be spent between Resht and Teheran (with Hamadan in the background). The question may be asked whether the relative importance of these figures is to express the value in which the two countries hold the Persian trade which they divide between them?

At all events, the road that is now in course

⁴⁷ "Proceedings of the Royal Geographical Society," September, 1890, Map.

⁴⁸ It is not necessary to refer here in detail to the extensive journeys in the land of the Bakhtiaris by Prof. Haussknecht in 1868. He published his map in 1882; Col. Bell, 1884; Mrs. Bishop, 1890; and Captain Burn, 1894. Of these travellers, the last-mentioned alone traversed the whole route (*vide* J. As. Soc. of B., 1897, No. 3), the others branching off to the north or south before reaching Shushter. Mr. J. R. Preece, H.M. Consul at Isfahan, travelled, some years ago, from that town to Shushter by way of Pul i Wargan, Kahu i Rukh, Shelamzar, Naghan, Dopulun, Hilisat, Pul i Amarat, Deh Diz, Malamir, Malseyidi, Gurgir, Beitavand, but the report of his journey has not been published.

⁴⁹ For comparison they have all been given as from Shushter to Isfahan, although Wells travelled in the reverse direction. The spelling has been made uniform following that adopted by Curzon. Mackenzie's second journey (1878) by Bazuft has not been included, because this northern route was only employed (and is still frequented by the tribes in their annual migrations with their numerous herds), in order to avoid the passage of the Karun on rafts at Gudar-i-Balutak, whereas, in the present road scheme, a bridge at that place is the leading feature. The Bazuft road is "far more difficult in winter, owing to the high elevation it crosses. In fact, it is said to be impassable at that season." (Wells.) The stages of Mr. Mackenzie's second journey are:—

	Farsakhs.		Farsakhs.
Shushter	—	Ab-i Enari	2
Gotwend	4	Guelle i Kedjuz	3½
Bam-i Ferra	2½	Bazuft	2½
Lálee	3	Mowarz	2
Teng-i Baba Ahmed ...	4	Hul-i Zamanek	3½
Chulbar	3½	Maze-i Khaki	3
Pa-i Monar	2	Kurun	2½
Shimbar	3	Al-i Kuh	2
Chillaw	2	Chulcheh	5
Mori	4	Kahu-i Rukh	5

This itinerary is delineated in Schindler's map.

construction will be a very poor substitute the Karun one. Travellers' accounts abound with references to the physical difficulties met with. General Schindler, who visited both the Bakhtiari and the Karun roads at the Shah's order, with the object of erecting a telegraph line between Shushter and the capital, unhesitatingly selected the latter. The late Colonel Wells, who, by his extensive travels in Persia, was well qualified to form an opinion, has pronounced against it both on account of the uncompromising formation of the ground, and of the absence of towns or villages of any importance on the line of march. The road will for ever remain a mule track. Wheeled traffic is out of the question, and a railway by this *tracé* still more so, considering that about 80 miles to the north the country is all but level, between Isfahan and Sultanabad, by way of Khonsar, and is excellently adapted for railway building.⁵⁰ The population, sparse as it is, has no elements of character that are reassuring in relation to political economy. The various objections to the road may be found summarised in the account of the address delivered by Lord Curzon of Kedleston at the Royal Geographical Society meeting of 12th May, 1900.⁵¹ It is, however, as well to remember that there is no immediate prospect of the construction of the Karun road, and not to forget that "the half is more than the whole." If the Bakhtiari chiefs keep their word, if they contribute labour and mules, and if they keep the road safe, and will indemnify merchants and travellers for any pilfering or robbery

Sultanabad is about 75 miles from Hamadan which is on one of the important trade routes from Bagdad to Teheran via the Khanikin and Kermanshah, and it is believed that it is possible to lay this line that the only possible self-supporting railway to be built that is to give access to Persia from the south. The length would be roughly 500 miles; it would serve the needs of pilgrim traffic to the Shiaah shrines of Kerbela and Mecca, and it would be connected with the Persian Gulf by means of the existing steamship lines on the Tigris. It has been proposed to continue the intended prolongation to Sultanabad of the Anatolian line, on to Bassorah and even to Bagdad, but it would be much less costly and answer the requirements sufficiently well, as far as Persian trade is concerned, to put a larger number of steamers on the Tigris, than is at present the case, and to have the Turkish Government would give the necessary subsidies, or increase and improve their own fleet of river steamers. (Strange to say, like the Turkish Empire, they have been in a precarious position from time immemorial, but they remain afloat.) The banks of the Tigris ought also to be cleared and improved. At present its water is much wasted, and during the summer there is too little for even the very lightest steamers that are in use.

⁵⁰ 'Proceedings of the Royal Geographical Society,' November, 1890, p. 523-4, also discussion.

occurring in their districts, then the enterprise will, at all events, be an improvement during the fair weather months on the existing Bushire-Shiraz-Isfahan road, the first section of which is of the most deplorable description.⁵²

Besides, however insufficient it may be as the main trade route from the south, the new road offers possibilities of a more local nature, that need not be overlooked, and which make it well worth the small investment that is being made on its behalf; this money, in fact, will not have been spent in vain if it assists in settling the Bakhtiari and in opening up trade with them.

Yet, the chief advantage of the opening of the Bakhtiari route will be the impetus it is sure to give to the traffic on the Karun, which

⁵² In the matter of distance also this road compares unfavourably with the new road. The approximate figures are:—

From	To	Miles.	Caravan Stages.	Days.	Highest Pass.	Feet.
Bushire	Shiraz	170	12	—	Kotel-i Pirazen	7,410
"	Isfahan	482	27	—	Dehbid	7,500
"	Teheran	757	39	—	Kuhrud Pass	7,250
"	Mohammerah	117	—	3	steamer	—
Mohammerah	Ahwaz	117	—	1-2	river steamer	—
Ahwaz	Isfahan, via Ardel	260	15	—	about	8,500
"	Teheran, via Ardel and Isfahan	572	27	—	about	8,000
"	Isfahan, via Burujird	502	28	—	Dehliz Pass (many short stages)	5,750
"	Teheran, via Burujird	533	35	—	ditto	5,750
Mohammerah	Bassorah	22	—	1	steamer	—
Bassorah	Bagdad	510	—	5	river steamer	—
Bagdad	Isfahan, via Kermanshah and Burujird	550	33	—	Feng-i Girra	4,630
"	Teheran, via Kermanshah & Hamadan	510	31	—	ditto	4,630

For comparing the time occupied on the three routes from the coast to Isfahan and Teheran, two days should be added to the routes starting from Ahwaz to cover the time required for the steamer to discharge cargo at Bushire and for the voyage from that port to Mohammerah. On the Bushire-Teheran road the number of stages does not correspond with that of the days required. Caravans take on an average sixty days for the whole road.

will result in an improved state of things at Ahwaz and Shushter. With increased trade at those places, which in former times used to be important centres,⁵³ the want will be felt of further developments, and it may be that in this way the Ahwaz-Isfahan road will in the end be the means of obtaining the much-desired road from Ahwaz to Teheran. This latter one will always remain the ultimate aim. Its advantages are numerous, and may be recapitulated as follows:—

1. The road will be easier to construct, the passes are less formidable, and will be kept open more freely during the winter. Wheel traffic can be arranged for at a comparatively small additional outlay, and it should always be borne in mind that of whatever value may be, even in Persia, the gain in time of a few days, yet it is of still more importance to prevent the daily unloading of mules, &c., during the long marches (causing breakage), and to enable the transport of heavy pieces of machinery for industrial purposes.⁵⁴

2. It will traverse well-watered provinces, of which the chief centre is Dizful, that now trades by way of Amarah on the Tigris, and pass by Burujird, the centre of a very fertile district; Sultanabad, the chief town of a prosperous province with a flourishing carpet-weaving industry; Kum, a noted shrine. The trade of the important towns of Hamadan and Kermanshah (surrounded by districts that produce wheat in abundance) will be tapped, and by a branch road starting from near Burujird it will be connected with Isfahan (210 miles). Finally, it will have for its terminus the capital, with an increasing population of over 200,000, and destined to become more important as a trade centre as soon as the Resht road is completed.

3. The Karun road will not be so much at the mercy of semi-independent chieftains. It is only on part of the road between Dizful and Khorremabad that the Feili Lurs may be said to require attention, and a few military

⁵³ Under the Abassides, Ahwaz was a most prosperous town, and the province produced sugar and grain in very large quantities. (See "Ainsworth's Personal Narrative," vol. ii., p. 229-7.) Now the stagnation here and at Mohammerah forms a sad contrast with the prosperity of the neighbouring port of Bassorah.

⁵⁴ The freight on bulky or heavy pieces is enormous. These have at present to be sent *via* Bagdad-Khanikin (the hotels between Bushire and Shiraz are quite impracticable). A cottage piano, sent some time ago to Teheran, cost to send from Bagdad to Kermanshah (220 miles) £12 11s.; two safes of ordinary size, £31 for the same distance.

posts or some small subsidies to the chief would no doubt be sufficient to keep the under control. In this part of Luristan the tribes are far from being so powerful, united and unassailable as their Bakhtiari kindred and they are, therefore, more likely to submit to the inevitable.

Colonel Bell, who has visited both the Karun and the Bakhtiari roads, is an enthusiastic believer in the former. He sums up his careful investigation by declaring that "the line Mohamrah, Dizful, Khorremabad, Burujird, Sultanabad, Kum, Teheran, may be considered the main commercial artery of Persia," and he gives a comparative statement of distances to prove the accuracy of his verdict.⁵⁵

The Indian Government has for some years paid a subsidy for the maintenance of a fortnightly steamer service between Mohammerah and Ahwaz. If the new road should realize the expectations that are formed of it, the subsidy could probably be dispensed with, and the money could certainly be employed to better purpose as a means to enable the Government to guarantee the interest of the required capital to build a road from Ahwaz to Teheran, utilising the concession that is now in the hands of the Imperial Bank of Persia. It has also been proposed to use the money to subsidise the Lur chieftains on condition that they keep the road safe. It is thought that £1,000 to £1,200 a year judiciously distributed would attain the object. But there would be then no funds available for guaranteeing interest on capital, and the road would remain a mule track. On the other hand, the existing concession to the Imperial Bank of Persia would be left undisturbed, and if the measure of subsidising the tribes succeeded, it would enhance the value of this concession, and would perhaps make it possible after a time to raise the necessary capital (without Government guarantee) to build a well metalled road for wheeled traffic all the year round.

There is no reason to fear Russian opposition to this road. In fact, the commercial position of Russia will become so strong by the construction of the Resht road, that the stimulating question will arise, which trade will be most assisted by the Karun road; that from the North or that from the South.

DISCUSSION.

The CHAIRMAN, in opening the discussion, observed the subject of the paper was an important one, and would, he hoped, bring out an interesting discussion. It seemed to him that the question was beset with exceptional difficulties on account of the moribund condition of Persia, the want of money for enterprise in that country, the peculiar formation of the country, which made it a sort of table-land surmounted with difficult mountain ranges and hills, the absence of navigable rivers, and, last but not least, the paucity of the population, seeing that London and its suburbs contained almost as many inhabitants as the whole kingdom of Persia, although in area it was about five times larger than the British Isles. He shared Mr. Hotz's regret that the so-called Karun canal had not been carried out in its entirety, as it was the least difficult route from the sea to the interior, and would open up to trade the most flourishing and best watered provinces of the kingdom. It was only too true, as observed by Mr. Hotz, that, as put it in Lord Curzon's polite language, Persia had "advanced and receded in the estimation of

British statesmen;" and this arose greatly from the late Shah's fears of his powerful neighbour on the North, who put the screw on him the moment he favoured any scheme or any influence from the South. As now in China, in fact, so had it been in past times in Persia, although our efforts to open up trade routes in the latter country in times gone by were weighted, not only by the veiled opposition of the Shah, under Russian pressure, but by the indifference and, indeed, veiled opposition of our own Treasury, which, until quite lately, had acted on the principle that no one should pay for anything eastwards except the taxpayers of India. Thus, what little had already been effected in the Karun was more due to private enterprise than to the Government; such as the efforts of Mr. George Mackenzie, Messrs. Lynch, Messrs. Gray, Dawes, and others, with such little assistance as the Indian Government could give them. In considering this matter, however, it was only right to remember that for some years past both the Imperial and Indian Governments had been compelled to concentrate their attention on objects of greater importance, and nearer

home, than Persia. He, himself, remembered with interest, that when Sir Henry Rawlinson and himself were appointed to be with the late Shah during his visit to England in 1873, they had many important conversations with His Majesty on trade routes and other questions. Owing, however, to the Government then in power feeling unable to accord him the direct military protection he desired, he ceased to have any confidence in England, or any desire to see her in control of his southern trade routes and commerce, and, in fact, preserved a veiled opposition to both, for reasons already stated, till his death.

Mr. GEORGE SUTHERLAND MACKENZIE, C.B., said it was 25 years since he had travelled in Persia, since when there had evidently been many changes in the roads and other matters; in his time there were no wheeled vehicles in the north. He was the pioneer on the route from Ispahan to Shushter; there was a difficulty in those days in any European travelling in the Bakhtiari country, those tribes being supposed to be hostile and fanatical. He, however, did not find them so; the chief met him with a hearty welcome as an Englishman, and he travelled through the country in different directions, and always met with the greatest civility. He brought the subject under the attention of the Government, and pointed out the feasibility of navigating the Karun far enough to open up a direct route, and the Bakhtiari chief himself was anxious that this should be done, going so far as to give a letter of guarantee that if any caravan passing through his country were looted, any loss should be made good; he also offered to put down half the money for the steamer to navigate the river. Unfortunately, they could not get the Government support necessary to attract the capital required. A great deal of obstruction he believed arose from the commercial rivalry between Russia and England, one being played off against the other. It was a great pity that some common understanding could not be arrived at, because there was a natural dividing line between the sphere of influence of the two countries. He was pleased to hear what Russia was doing in the north, and if we would not do anything in the south, there was no reason why Russia should remain passive. The water base of the Black Sea was naturally Russian, and the Persian Gulf was English, and it was extraordinary that an intelligent people, like the Persians, did not see how much it would be to their own advantage to open the road in the south by the Karun valley; at present a great deal of the trade went by way of Bagdad, paying duty to Turkey. By opening up the direct route, she would at the same time open up an enormous tract of agricultural land in Kermanshah and Hamadan. Cereals could not pay the expense of carriage on mules for great distances. Through the energy of Messrs. Lynch, a great deal was being done to remove or minimise the difficulties which existed on the road from Ispahan to Shushter, which ought to

supersede the circuitous route by way of Shiraz. So thought it would be better to make the road by way of Dizful and Khorremabad to Teheran; but it would not meet the requirements of the Ispahan district and he should say that both roads were necessary. The great need in Persia was capital, and the great difficulty was the want of security, for which the Persian Government was mainly responsible, because there was no possibility of obtaining justice in the Persian Court in any claim against a Persian subject. It was this which had compelled his firm to close their establishment in Ispahan, though with great regret. They did not get the support of the British Minister in the same way as he understood Russian subjects did. Capital would not be attracted to Persia until both the British and Persian Governments took steps to see that when contracts were entered into they should be carried out. The whole of the traffic had been carried on for many years by the muleteers, of whom a photograph had been shown, and he should like to bear his testimony to the excellent character of those men. Every one who travelled in Persia was much indebted to them for their kindness and civility, and their honesty was proverbial. When he was there, treasure was sent in bags to Ispahan for the purchase of cotton and opium, and in no single instance did he hear of it not being safely delivered. Of the people, generally he could speak in high terms. There was no fanaticism; nor did he know a pleasanter country to travel in. All the evils it suffered came from the Government.

Mrs. ISABELLA L. BISHOP said she had great pleasure in corroborating what Mr. Mackenzie had said as to the muleteers of Persia. They were a splendid set of men, and their fidelity and honesty were wonderful. During a year's travel she only once had occasion to find fault with them, and that was not on the ground of honesty. She had travelled considerably in Persia, from Bagdad and Kermanshah and Kum to Teheran, and thence to Ispahan, and for four months was in the country of the Bakhtiari, travelling from Dopulun up to the actual source of the Karun, where seven springs break out at a full-grown river under a limestone rock. Thence she went by Khorremabad to Burujird, which seemed to her about one of the best centres of trade in Persia, being placed in a most productive region, within 310 miles of Ahwaz, 92 of Hamadan, 130 from Kermanshah, and 60 from Sultanabad, the centre of the carpet trade. It is also within 140 miles from Kum, on the direct road to Ispahan, or 230 from Tihiran, and there was no place in Persia which seemed to present such openings for English trade, provided only the road were made from Ahwaz. From thence she went by Hamadan, and through what is called Persian Khurdistan, to Oroomiyeh. Whilst living amongst the Bakhtiaris, and other nomadic tribes, numbering about 2,500,000 altogether, she was interested in noticing what sort of

[vol. 10, 1899.]

ings they purchased, and where they came from. Far south as Ardel and Dopulun one would expect to find that the majority of imported articles were Russian, but such was not the case. There were Russian printed cottons in large numbers, mirrors, and light and heavy woollen cloths. What might be called knickknacks from Russia were scattered throughout the Bakhtiari Lur tribes, and the same thing among the nomads of Western Persia. Again, north of Burujird, and in that town itself, she visited many of the houses, and entered into conversation with the women about the prints she saw, which she learned were Russian, and inquiring why they were preferred, because the cost of carriage must be greater from Russia than from the Persian Gulf, she was told that the Russian merchants understood their taste better as to colours and patterns; the Manchester prints are large fiery patterns, with a great deal of scarlet in them, which were probably intended to suit the proposed barbaric taste of Persians, whilst the Russian prints were in smaller and quieter patterns, and more subdued colours, which the Persian women wore with ease, because they gratified their refined taste. To send staring patterns to Persia, where good taste is proverbial, is the most absurd thing possible. Everything in Persia depended on the roads. Coming from Bagdad to Teheran in the depth of winter, there are 6 feet of snow on the road a good part of the way, and in some parts there was only one narrow track, and if caravans met one had to turn out into the snow, where very often the mules fell and were loaded. Yet there was a perpetual stream of caravans along that road; in one day she counted 73 caravans labouring along, containing from 27 to 100 mules, all loaded. Between Kum and Teheran there are caravans of coffins floundering through mud two or three feet deep, and almost impassable, so that a mile was a good day's work. Everywhere in Persia, during late autumn, winter, and spring, there is this horrible mud, through which everything had to flounder—far worse than in China. Roads were evidently the great requisite; and perhaps it would be well for English trade if some of the money which seemed to find some difficulty in investing itself, were sent to Persia for road-making, under the guarantees which Mr. Hotz had spoken. Her remembrances to Persia were delightful, and she thought the Persians deserved a happier lot.

Sir THOMAS EDWARD GORDON, K.C.I.E., C.B., F.R.S.I., said this was a very old subject, for the present trade routes of Persia were the same as in the days of Darius, and the trading centres were the same, though the names had changed, as new towns had sprung up on the ruins of the old, or near to them. This very road which was now being made from Shushter to Ispahan, was a line of commerce in antiquity, leading from Susa towards Persepolis. There had existed in all ages a great thoroughfare of communication between Media and Babylonia,

Hamadan and Bagdad, and he believed it would continue to be so. The first railway into Central and Southern Persia would enter by that route. An effort was made to open up a trade route from the Karun waterway at Ahwaz to Burujird, and beyond, as Mr. Hotz mentioned. The late Shah had entertained the idea, and hoped capital and trade would be attracted to it; under his orders General Schindler, in 1887, commenced work on the direct mountain route between Khorremabad and Dizful, improved the worst parts of the old track, erected a telegraph line, built a few caravan-erais, and arranged with the marauding Lur tribes, through whose territory the road passed, a paid system of "watch and ward" for the protection of trade and traffic. This was supposed to prepare the way for a cart road, and to establish firmly the Shah's authority over the predatory tribes. When he (Sir Thomas Gordon) went along the route in 1890, accompanied by the engineer of the proposed new road, they found that a cart road would be impossible the whole length of the line, and that a considerable deviation would be necessary. Owing to weak Provincial administration, and the complaints of the tribesmen that the promised payments for the preservation of order had not reached them, the telegraph line was broken, the road became unsafe, and the Lurs reverted to their old state of chronic rebellion. The same state of things seemed to exist there still. The telegraphic communication with Shushter and Ahwaz is now carried on from Teheran *via* Shiraz and Behbanan. In the old days of Susanian prosperity, this direct route was not used for general trade and traffic. For communication with the fertile plains beyond the mountains, a circuitous, commodious, and easy route along the foot of the Zagros range was followed. This joined the route from Babylon, which avoided traversing the several parallel ridges of that range, and gave access to the great plateau of Persia by one single pass. There were evidently quite as good practical students of physical geography in those days as in our own. Examination of the Bagdad-Teheran road shows how easy this ancient route is, and that it is the natural outlet for Kermanshah and Hamadan. The Messrs. Lynch deserved great credit for improving the old trade route from Shushter to Ispahan; it was a well frequented route in the days of Darius, and the Bakhtiari, through whose country it passed, had come to follow a certain system of trade and traffic, and so became humanised. While their Lur brethren in the north-west had remained semi-savage, the Bakhtiari had advanced into civilization, and become in some ways a romantic and attractive people. He was very glad to hear they were partners in this road enterprise. We had been told of Russian trade beating back English trade, and of Russian road enterprise. He passed over the Russian road in November last; it was a fine piece of work, and looked like one of the great Caucasian military roads; but that road was only for Russian traders, whilst the wide "open door" in the south was for

the commerce of the world. Some of the goods which entered in the south, however, were erroneously supposed to be from Manchester. A consular report about two years ago mentioned the fact (with which he was acquainted) that Manchester goods of certain descriptions, long well known in Persia, were being imitated by goods coming from Holland, and bearing the same well-known trade marks of the Manchester goods. It could hardly be expected of the British Government to build and subsidise roads in Persia if the result was to assist in this way the commerce of the Continent. He thought road-making in Southern Persia would have to be done by private enterprise, with the partnership of Persian subjects, as in the Shushter-Ispahan road, and the British merchants should try and put a stop to the piracy of their trade marks.

SIR LEPHEL GRIFFIN, K.C.S.I., said no one who, like himself, had had a great deal to do with Persia, and who had some experience of road making there, could fail to realise the importance of the subject which Mr. Hotz had so ably brought forward; and no one could see his photographs without understanding what was the initial and final difficulty in carrying out any work in that country. You saw irrigation dams a thousand years old, and bridges many hundred years old, every ancient building, and every public work of importance falling into decay and ruin, for want of a central government which would spend money on their repair. That had been, and would continue to be, the difficulty. The Imperial Bank of Persia, with which he was connected, had a concession for the road about which so much had been said, from Teheran through Kum, Sultanabad, and Burujird, to Ahwaz and Mohammerah, the great road of the south to which they all looked for the development of English commerce. Although what Mrs. Bishop and Sir Thomas Gordon had said with regard to the road by Bagdad and Hamadan was no doubt correct, there were many things to be considered besides difficulty of construction. The question of guarantee had been alluded to by the Chairman, who truly said you could not expect the British Government to guarantee undertakings in all parts of the world. Still there were some who thought that the Foreign Office might make an exception to its general rule in favour of certain roads, which were essential to British commerce, and without which our trade from the south would be entirely overborne by the trade from the Caspian and Russia coming down the new road from Resht. The line which divided Russian trade influence in Persia from English was differently placed by different people; but, as a rule, the latitude of Ispahan was about the limit of English trading superiority. At Teheran and to the north, and still more in Tabriz, Russian goods had the advantage from their propinquity to the frontier, and it would be useless to attempt to compete with Russia in the extreme north. The last time he had the pleasure of hearing Mrs.

Bishop speak was at a meeting over which he presided at the United Service Institution, the subject being Manchuria; and the question of Russia at Manchuria then was the same as that of Russia at Northern Persia to-day. We could no more oppose the influence of Russia in Northern Persia than we could in Manchuria, and it was unwise to attempt it. He quite agreed with Mr. Mackenzie that it would be well to come to some frank arrangement with Russia whereby our several spheres of influence in both parts of Asia might be determined. With that he was sure there would be great if not insuperable difficulty.

THE CHAIRMAN having proposed a cordial vote of thanks to Mr. Hotz, which was carried unanimously.

MR. HOTZ, in responding, said he had been much interested in the discussion, which was very valuable but there were only two points on which he should like to say a word. He agreed with Sir Thomas Gordon that the route which he had alluded to from Bagdad to Teheran was the natural route for a railway, whenever it was built; but the 1 per cent. which had to be paid to the Turkish Government was a drawback from a commercial point of view. Besides, the route is often closed by the Turkish Government on the mere pretext of contagious disease in Persia. The question of roads might be looked at either politically or commercially, and as a merchant he looked at it from the latter standpoint. He should think the road from Ahwaz to Kum (the Karu road) was the best route, because it went through the most fertile districts, and it could, later on, be easily connected, by way of Burujird, Nihavend, and Kangawar, with the railway which may hereafter be built from Bagdad. With regard to Dutch goods in Persia, he was afraid the consular report was somewhat exaggerated. His firm naturally bought in the cheapest market, but they could only buy white goods in Holland at any advantage, not prints, and even those white goods were in many cases made in England, and only sent to Holland to be bleached.

MR. HOTZ writes further:—I find that I have omitted in my reply to refer to Sir Thomas Gordon's remark that, with regard to the importation of Dutch goods in Persia, merchants should "try to put a stop to the piracy of trade-marks." I may be well to explain that there is no occasion for any display of energy in that direction. The marks which these Dutch goods bear are those of the importers or consignees. They are their own marks which they put on all the goods that they send to Persia, whether they are made in England or elsewhere, and they have of course a perfect right to do so. The Consular Report which Sir Thomas Gordon has referred to mentions, in connection with the importa-

of Dutch goods, that : "The trade-marks are the same as on those hitherto imported from Manchester," meaning the marks of importers, not of manufacturers. This makes all the difference, and has evidently caused the misunderstanding. The following table, taken from the latest Consular Report (Annual Report No. 2186), will confirm my assurance that there is no cause whatever to fear that Manchester is being superseded by the Continent :—

TABLE OF THE TOTAL VALUES OF IMPORTS FROM PRINCIPAL COUNTRIES, IN THE YEAR 1897, AT BUSHIRE, LINGAH, BENDER-ABBAS, AND ALL PORTS IN THE PERSIAN GULF, AND AT MOHAMMERAH.

Country.	VALUE.				
	Bushire.	Lingah.	Bender- Abbas.	All ports in the Per- sian Gulf.	Moham- merah.

The reports from Basjorah (and Bagdad) do not give a table of "Principal Countries."

In no case is Holland, among other countries, mentioned in this Table: the reason being that her exports to Persia are sent *via* England in transit. (They are therefore subject to the Merchandise Marks Act, and bear the inscription, "Made in Holland.") I could say not more than about £8,000 worth of white and grey goods are imported annually from Holland, and of prints none whatever, because Dutch printers are only organised for the Java and adjacent markets; they do not produce any of the designs required for Persia. There is no reason to think that an increased trade by means of new roads from the South will alter the state of affairs shown by the above Table. Wherever new roads are made and doors opened, English merchants as a rule manage to secure by their energy a very fair share of the new business. Why then should it be supposed that they will not be able to do the same, and to hold their own on the Carun road, when it is built, as well as on that through the Bakhtiari country?

THIRTEENTH ORDINARY MEETING.

Wednesday, March 8, 1899; HILARY BAUERMAN, Assoc. Mem. Inst. C.E., F.G.S., in the chair.

The following candidates were proposed for election as members of the Society :—

- Greg, Ernest William, Higher Dunsard, near Bolton.
- Lorrimer, Maurice, The Spinney, Coundon, near Coventry.
- Samuel, Alderman Sir Marcus, 20, Portland-place, W.

The following candidates were balloted for and duly elected members of the Society :—

- Grove, A., 2, Albion-street, W.
- Hill, Arthur Frederick, 140, New Bond-street, W.
- Johnson, Sir Samuel G., Nottingham.
- Lupton, Arnold, 6, De Grey-road, Leeds.
- McCaw, W. J., Woodfield, Streatham-hill, S.W.
- Whitbread, S. Howard, M.A., J.P., Southill, Biggleswade.
- White, Franklin, Hazlewood, Keynsham and Johannesburg.

The paper read was—

CORNISH MINES AND CORNISH MINERS.

By J. H. COLLINS., F.G.S.

Preliminary.—The West of England mining district comprises the whole of Cornwall, and the western part of Devon, which is, geologically, mineralogically, and to a large extent racially, one. For the purposes of this paper, it will all be spoken of as Cornwall, and its men as Cornishmen.

Geological Outline.—The geological structure of Cornwall is well known; a series of stratified rocks, mainly of Palaeozoic age, has been pierced and penetrated by granitic rocks of various periods and at many points, and afterwards extensively fissured. In these fissures, which may be numbered by thousands, various kinds of ores have been deposited, and especially the ores of tin and copper. Subsequent denudation of the area, to the extent of thousands of feet, has laid bare, so to speak, the roots of the mountains, and so brought these mineral lodes within the reach of the miner, and furnished the materials of the stanniferous valley gravels. In the formation of these lodes the granitic intrusions have played a predominant part, for although it cannot be said that all the metallic minerals have been brought into the vein-fissures by

their agency, or that all the granite junctions are metalliferous, yet it is certain that more than half the valuable ore deposits have been found within a few hundred yards of such junctions, and within what St. Claire Deville called "the granitic penumbra" of altered rocks.

Antiquity of Tin Mining.—There are few who realise that mining in Cornwall has been carried on for more than 3,000, if not more than 4,000 years, and that the tin required for fixing the colours of the scarlet curtains of the Hebrew tabernacle, and in making the "brass" for Solomon's temple, as well as that used for the bronze weapons of Homer's heroes, was pretty certainly derived from the gravels of our West country valleys. We have abundant evidence that tin was not only mined but smelted in Cornwall, and, while there is every probability that some of it was shipped from St. Michael's Mount more than 3,000 years ago, it is certain that another portion was shipped from Falmouth, for one of the peculiarly-shaped blocks, exactly of the "knuckle-bone" form described by ("αστραγαλον") Diodorus Siculus (lib. v., c. 9), was long ago dredged up in Falmouth harbour, and is now in the Truro Museum. Having given the subject much consideration I do not see how anyone can reasonably doubt that the conclusions set forth many years ago by Dr. Barham, and afterwards by Sir Henry James, also by Dr. George Smith in his most interesting book called the "Cassiterides," and by the late Mr. R. N. Worth in his "Antiquity of Mining in the West of England," are substantially correct, and that the Phœnicians traded for tin in the West of England with the inhabitants of a group of supposed islands, long before Solomon's temple was built.

The Valley Gravels.—No doubt these were the first to be worked for tin. Most of the granite moors and many of the valleys coming down from the moors have afforded abundant indications of these early works, some of which continued to be wrought down to our own times; indeed, I am not sure but there are still some veritable "streamers" at work each winter on the flanks of Helmen Tor, and on the Bodmin moors, as well as on the moors to the west of Penzance. The West country museums contain many most interesting relics of those early stream works, as also of the early smelting works, especially from Tremethick moor, Marazion, and the Carnon and Pentewan valleys; the transactions of the Western scien-

tific societies are replete with valuable paper on the same subject, among which I may particularly mention those by my old friend, the late Wm. Jory Henwood.

Submarine Tin-gravels.—The lower portions of several most important tin-bearing valleys have been submerged to considerable depths since the gravels were first formed, that the tin is still lying far below low-water mark. There may be some here who will remember the visit of the Institution of Mechanical Engineers to Cornwall, in 1873, when they examined the interesting tin-gravels then being worked by Messrs. John Taylor and Sons, under the waters of Restronguet creek.

The "Old Men."—We owe much to the early streamers, known as the "ancients" or "the old men," for they were the discoverers of nearly all the lodes which have been extensively worked in Cornwall during the last seven or eight centuries. The best of all ways of discovering a lode, from a miner's point of view, is to remove all the surface soil and loose material, so as to lay bare the solid rock, the "shelf" as it is called by the tinner. And this is what "streaming" is sure to do. Thus also, the tin deposits known as stock-works were discovered. These were quarried out and the "backs" of lodes were worked away until the water flowing into the excavation even in dry seasons, became too great to be dealt with by the rude appliances of ancient times; adits were then driven into the hillsides for the sake of the "backs" of tin ground thus drained, and bit by bit the idea of the shaft formed in the mind of the worker and was practically carried into effect.

Copper and Other Minerals.—These were no doubt discovered while working for tin. At first supposed to be worthless or even found to be very injurious to the smelted tin, such ores were carefully avoided—left behind in the workings, or thrown away. But uses were gradually found for the rejected copper, at first by the prehistoric hunters and warriors who discovered the merits of bronze and the methods of producing and working it; afterwards uses for the other minerals were found by chemists and manufacturers. They were diligently sought for, and so it has come about that almost every metallic mineral of importance in the arts except platinum and quicksilver, has been obtained from the West of England mines during the past two centuries.*

* I may here recall the interesting fact that, in 1750 the Society of Arts awarded a premium of £30 for the best cobalt found in England to Mr. Beauchamp, who found some

ill, it may be said that the only metallic minerals that have been produced on a large scale and for lengthened periods are tin and copper. For comparatively brief periods mines of lead, antimony, zinc, iron, or manganese, have been worked at a profit; while ores of nickel, cobalt, uranium, bismuth, tungsten, and other more or less rare metals, have usually been saleable when met with, though very rarely in themselves remunerative. Lately arsenic has been in demand, and that grand group of mines, the Devon Great Consols at Tavistock, has given many substantial dividends as the result of working great bodies of arsenical pyrites, formerly left behind in the *Precious Metals*.—It has been suggested that the West of England only needs to be properly prospected to discover payable deposits of gold and silver. It is, of course, well known that gold has been found in minute quantities in all the stream works; that considerable bodies of rich silver ores have been discovered in several of the mines; and that gold and silver in small proportions exist almost universally in the copper ores. I am sure the miners have often suffered from their ignorance of this latter fact, and from their refusal to have the ores fully analysed. I well remember Mr. Charles Fox, of Falmouth, telling me that he knew of a mine in the east of Cornwall from whose ores the smelters had extracted £60,000 worth of silver for which they had never paid the miner one penny, and, as I am greatly mistaken, I could give you the name of the mine, and also of the smelter. However, with a knowledge of these facts, I am still bound to say that I see no reason to expect that either a paying gold mine or a paying silver mine will be found in the West of England. It is, at any rate certain that the whole precious metal yield of the West of England, past and present, has not equalled the yields respectively of a single gold or silver mine of the first rank for a single year. On the whole, I think it will be admitted that, with a few exceptions, the only ores that have been profitably and extensively worked in the district during any lengthened period are those of tin and copper, although for a short time lead ores have been of considerable importance.

Progress of Mining.—A mere sketch of the progress of mining in the West of England would occupy more time than we have at our

disposal this evening. But I may perhaps venture to set up a few land-marks, referring you to the transactions of the local scientific societies for many others.

Deep Mining.—I have already referred to the evidence existing elsewhere, which shows that tin-streaming is at least 3,000, and probably 4,000 years old, while tin-mining in a strictly accurate sense of the term, *i.e.*, underground mining, dates at least from the 15th century, and is probably much older.* When Carew wrote, at the end of the 16th century, there were already several mines more than 50 fathoms deep. Copper mines “more than 60 fathoms in depth” are also referred to so far back as 1678, and Tonkin, writing in 1733, speaks of “Puldyce in Wennap” (*i.e.*, in Gwennap) as being over 100 fathoms deep, and supplied with regular ladder-ways; a remarkable depth to be reached without wire ropes, and before Watt had improved the steam-engine. The Cornish mines were then the deepest in the world. We have now attained a depth more than four times as great, but we no longer have the pre-eminence in this respect, for there are many mines in many different countries which very largely exceed the present depth of Dolcoath, now our deepest mine. It must, of course, be admitted that, in shaft-sinking, Cornwall does not at present stand in the first rank. There are, indeed, special reasons why the very finest shafts should not be found in connection with vein-mining, which I will not further refer to at present. Yet there are many good shafts in the county, and I can say that many of the best shafts ever sunk in the United States, in the Transvaal, and elsewhere, have been sunk by Cornishmen, while the Cornish systems of stoping and timbering are almost universally adopted in vein-mining. It is right to say, however, that these methods, as well as the use of gunpowder, appear to have been introduced from Germany in the reign of Queen Anne.

Pumping Machinery.—As already intimated, tin ores have often been worked downwards, right from surface, but, with a few exceptions, among which may be mentioned Wheal Virgin in Gwennap (first discovered in 1757), and Wheal Maria near Tavistock, which was discovered in 1844, valuable and extensive deposits of copper ore have not been found far above the natural “drainage-level” of the country, *i.e.*, the depth at which some system of artificial drainage becomes necessary.

Wennap parish associated with bismuth, which latter was thrown away until Dr. Herbert Schlosser discovered a method of separating and utilising both in the year

* See “Seven Centuries of Tin-Production.” “Trans. Min. Assoc. and Inst.,” 1892.

The development of copper-mining into one of our great industries may, therefore, be considered to have begun with the employment of powerful pumping engines.

Some of the early pumping engines were worked by water power, but this is by no means so generally available in the West of England* as many people imagine, so that until steam power was employed, many of the best mines remained unworked. Mr. Carne† states that the first steam-engine employed in Cornwall for pumping was erected at Wheal Vor, a famous tin mine in Breage, which was extensively worked between the years 1710 and 1714, as well as long before and long after. He considers it doubtful whether the engine was on the plan of Savory or that of Newcomen. It might well have been the latter, as Newcomen's patent was granted in 1705. Dr. Borlase mentions the existence of "fire-engines" in his time at no fewer than eleven mines, of which six were copper mines. Some of these—probably all—were on Newcomen's system, and some were very large; thus the engine at Herland mine had a cylinder of 70 inches diameter.

The employment of these great engines alone rendered it possible to work the mines, which were often very wet; and, at the same time, the fact that they were so employed is strong evidence of the importance to which copper mining had then attained.

Duty of Cornish Engines.—The subsequent improvements in the Cornish pumping-engines, which were effected by Watt; and those of the boilers, which were carried out by Trevithick—followed up by the minor inventions of Woolf and Husband, and combined with the admirable Cornish system of pit work, enabled our engineers, in spite of crooked shafts and bad water for the boilers, to reach a degree of perfection 50 years ago which, all things considered, has never been exceeded. When I tell you that they were able to raise a ton of water 450 feet high by means of the steam produced by burning only one pound of coal, and at a cost of about half a farthing, you will appreciate that fact. At present the duty is not much more than half of what was at one time "reported" for the best engines, such as those employed at the United Mines in Gwennap, and at Fowey Consols, near Par, and the reason for such falling off is often asked. It is not so much that the engines,

though generally old, are absolutely worn out; in fact, it is one of the merits of a Cornish pumping-engine that even when 100 years old it will often do better work than a new engine of another and less perfect type. But they often have to work through old and crooked shafts, fitted with leaky or choked pump columns, and balancing arrangements which are so worn that they are scarcely capable of being kept in proper order, and the boilers are too often old and worn out. The result is that the "duty" is often far behind that realised at the great waterworks, though Cornwall still raises its water more cheaply than many mining regions which are thought to be a-head of her in all respects.

Winding Apparatus.—If Cornwall has taken the lead in pumping large quantities of water from great depths at small cost, it cannot claim equal merit for the greater part of the winding apparatus employed even in the larger mines, for the West-country methods have been improved upon greatly in almost every Cornish mine as well as in all the larger foreign metal mines. Yet Hayle foundry has turned out, and still turns out, some of the finest engines ever made, while Mr. Stephens, of Ashfield, near Falmouth, was among the first to make ropes of wire. The Cornish miners too were quick to use them, indeed without these ropes it would have remained quite impossible to raise ore from deep mines except by a costly system of separate stages. Incidentally, however, this invention has led to the supercession of the Fahrkunst or "man-engine," the introduction of which the Royal Cornwall Polytechnic Society did so much to encourage 15 years ago, when the first Cornish man-engine was erected at Tresavean Mine.

Ore-dressing, &c.—In the West of England, as in other countries, only the richer ores were worked in the earlier days of mining, but it was in time found that many of the mines were capable of yielding large quantities of low grade "dredgy" ores in which small particles of the tin and copper ores sought were associated with much larger quantities of iron pyrites, arsenical pyrites, and other metallic substances, together with quartz, felspar, mica, schorl, chlorite, and other earthy compounds. As regards tin, stamping was a very early method adopted for freeing such ore particles from the waste, so as to obtain a marketable product; and supplemented by calcining and fine grinding, this has continued to be the method almost exclusively employed up to the present. But in the case of copper ore it

* It has, however, been extensively employed at Devon Great Consols for more than fifty years.

† "Trans. R.G.S.C.," iii, p. 60.

soon found that stamping entailed a very loss, so that a system of breaking with rammers, called "bucking" and "cobbing," was introduced by jigging in a hand-sieve, was used, as it had been a long time before in the lead mines in the north of England. And after, when a difficulty was experienced in getting a sufficient number of "bal-maidens" to "buck" the large quantities of dredge ore obtained at Wheal Friendship, Mr. John Taylor introduced the method of crushing by means of rollers. I have heard the late Mr. Richard Taylor say that the first rolls were made by dressing up a large "pump" and filling the spaces with wooden blocks, in which were fixed rollers on which they revolved. The jigging was replaced by the well-known brake-jig, this by Collom's and a great many other forms of continuous jigger, which made it possible to deal with very large quantities of ore of a grade hitherto valueless. Much of the ore could not be dressed up to any very high grade, yet the cheapness of the process was such that it is likely the profits were, on the whole, very larger on the low grade than on the higher ores. The gradual fall in the price of the Cornish copper ores is very noticeable. Thus:—

Year	the produce was	per cent.
1771,	12.0	
1800,	9.6	
1801-10,	9.0	
1811-20,	8.5	
1821-30,	8.0	
1831-37,	8.125	
1848-50,	7.5	
1851-60,	7.0	
1861-90,	6.5	

The highest price (of ore) of which we have any record (Jan. 1765) is £60 per ton, the lowest price, at the same date, was £1 10s. per ton, while the average of four centuries has been about £6 per ton.

In tin dressing generally, I do not hesitate to say that, considering the peculiar conditions of climate and wages, and of the work to be done, the simple, cheap, and easily repaired common gravitation stamp, the plain wheel buddle, the Stephen-Toy grinder, the revolving table, the self-acting dead frame, and the wheel elevator, leave very little room for improvement. I doubt whether they will ever be generally superseded by the more expensive Cornish stamps and the Frue-vanners which have been so largely and successfully employed for quite other conditions in gold-mining; but, I believe that in this department of

tin-dressing Cornwall has very little to learn from any part of the world.

Boring-machines.—The Cornish were among the first to employ boring-machines in mining, and my friend Prof. Le Neve Foster, the son of your former able secretary, was one of the persons concerned in their introduction in the year 1866, when experimental trials were conducted at Falmouth under the auspices of the Royal Cornwall Polytechnic Society and the Miners' Association, he being at that time secretary of both societies. Soon after this, Mr. Döring made his first contract for machine boring in Tincroft Mine, where I saw his machines at work early in 1863. At that time steam was used as the motive force, now compressed air is almost invariably used, to the great advantage of the ventilation. The first machines were all, I believe, made abroad, in France, Germany, Sweden, and the United States, but Cornwall now builds machines for mining purposes, which are at least equal to any that the world can produce.

Safety Fuse and High Explosives—Cornwall was also very early in this field. The safety-fuse of Bickford, Smith and Co. has long been known wherever mining is carried on, and has undoubtedly been the means of saving hundreds and even thousands of valuable lives. The use of high explosives, with their superior economy and safety, for many kinds of work followed immediately on the introduction of the boring-machine. Many of the early experiments and trials were promoted by the local societies already mentioned, as their reports for over a quarter of a century abundantly show.

Cheap and Effective Working.—It is not generally known how very cheaply work is done in Cornwall when the conditions are favourable. Let me give you an instance which has come under my own notice. At Great Wheal Fortune, in Breage, is an ancient tin-stockwork, which is now worked by open quarrying. In the five years 1893-8 some 35,000 tons of stuff were treated from this quarry, of which one-half was broken down from the solid, while the other half was already broken. The stuff was selected into one-third waste and two-thirds ore. The whole was loaded into waggons, trammed to an average distance of 300 yards, the one-third waste tipped over the dump, the two-thirds ore tipped into stamps or jiggers, crushed, and dressed for sale. I will not now trouble you with the details of the expenditure, but the total cost, including local supervision, but ex-

cluding management expenses, which were trifling, was only very slightly over one shilling per ton.

It is right to say that the rock broken was soft and slaty, and very full of joints, so that very little blasting was required; also that the stamps and jiggers are worked by water-power. I doubt whether this record has been broken anywhere, but I could mention many places where it has been nearly equalled.

Were the quantities dealt with, the supply of water for power and ore-dressing purposes and the tipping-ground all largely increased; and were there large funds available for the erection of a more modern plant, which is not the case, even then I am persuaded the cost of the work could not be lessened materially.

So much for open-quarrying and water-power. I will now give an illustration from the deepest and one of the wettest mines in Cornwall, where only steam-power is available, and where the ground is excessively hard. I refer to Dolcoath Mine.

In the last six months of 1898 there were broken, raised from an average depth of nearly 2,000 ft., crushed and dressed, over 40,000 tons of stuff at a cost of £41,000, just over £1 per ton, or, excluding royalties, 19s. per ton. It is not easy to find a case elsewhere which runs quite on all fours with Dolcoath; but, taking all the conditions favourable and unfavourable into account, I doubt whether much cheaper work is done anywhere.

Peculiarities of Lode Mining.—This is not meant for a technical lecture, and I do not propose to say much about the peculiarities of the lodes, which yield the greater part of the metallic wealth of the West of England, nor yet with the methods of working usually adopted. Yet it may be well to touch briefly upon both these subjects. And, first, let me try to give you an idea of one of our great tin-lodes—that which has for so long been worked in Dolcoath, Cook's Kitchen, Tincroft, and Carn Brea Mines.

I shall speak by-and-by of the enormous riches of this lode—yet if we look at the facts in another way (as suggested by M. Moissenet), we shall see how insignificant a feature it forms in the earth's crust. Let us suppose a model of the lode made to a scale of one-thousandth the real size—it could be easily made from a sheet of lead 12 feet long and 3 feet wide. In many places the thickness would have to be reduced to a mere film, but in some it would require to be thickened up to a quarter of an inch or a little more. The sheet

might be placed on edge, its length in a direction nearly N.E., S.W., and with a considerable dip to the southward. If now it were lengthwise, in such a way that the thin portions stand more nearly vertical than the thicker, and the lower portions more nearly horizontal than the upper, it would very well represent the relative proportions of the lode and also its position in the ground. "Viewed in this manner, the vast and richly-filled tertiary channels, which by the implementation of the miner are transformed into cavernous imposing extent, appear what they are—as veins in the ground."

The ordinary method of working such a lode may be easily understood by reference to the plan and section of the old Tolcarne Mine, which has been lent to me by Mr. William Thomas, of Camborne, and still better by the fine section of Levant Mine, for which I am indebted to Messrs. Henderson and Sons of Truro, and in particular to their assistant and former pupil, Mr. E. Maxwell-Lefroy, who has surveyed most of the ground and made the plans shown. This is a very ancient mine, and it has been worked both for tin and copper for three-quarters of a mile beneath the Atlantic Ocean. You will see that a main shaft has been sunk near the shore in the lode itself, and following its inclination. From this shaft levels have been driven along the lode, usually 10 fathoms or 60 feet apart, and finally the richer parts of the lode have been stripped away between the levels. The waste and the ore-stuff are both raised to the surface by powerful steam machinery working through the main shaft, and on reaching the surface the ore is crushed and dressed until it is fit for the market.

Levant is not the only mine which has been worked under the sea. The ores at Botallack, Wheal Cock, and many other mines in Cornwall, have been followed beyond the surface line for considerable distances, though not so far as in the case of Levant.

Besides the metallic minerals wrought in the West of England, there are other important mineral substances, such as china clay,* granite, stone, potter's clay, and granite, of which 897,793 tons were raised in the year 1896, the value at the pits being £415,677. With reference further to this part of the Cornish

* A lecture on the china-clay industry was given by the present author in this room in the year 1875. Since that time the industry has been very greatly extended, but very few discoveries have been made, or methods adopted since that time.

Vol. 10, 1899.]

eral industry, I will now briefly review the
 se of our great tin and copper industries.
Production.—It has already been stated
 tin mining has been carried on in Cornwall
 three, and perhaps for four, thousand years,
 I have elsewhere given* some reasons for
 owing that the “black tin” produced in
 West of England, from pre-historic times
 to the end of the 12th century, could
 have been less than 350,000 to 400,000
 tons, or, say 250,000 tons of “white” or
 allitic tin.

The first historical notices of tin production
 are from the reign of King John (1199 to
 1216), when the tin revenues of Cornwall and
 Devon were farmed for £266 13s. 4d. per
 annum, from which amount we may infer with
 fair degree of probability† that the annual
 production of white tin in the two counties was
 very much over 100 tons. A century later
 the quantity had risen to about 400 tons for
 Cornwall, and perhaps half as much for Devon.
 Towards the close of the 14th century the
 quantity had somewhat fallen off, and it seems
 to have remained at between 400 and 600 tons
 per annum for the two counties, up to the end
 of the 16th century, and at least a dozen years
 of the 17th. Delabeche says:—“In the
 reigns of James I. and Charles I., the two
 counties are said to have raised together from
 1,000 to 1,600 tons per annum, but this could
 only have been in years of maximum produce
 and was only about 500 tons in 1611.” On the
 whole, and for reasons given,‡ it would not be
 safe to reckon more than an average of 1,050
 tons for the first 40 years of the 17th century.

In Charles II.’s reign the revenue is stated
 to have been “small,” but under Queen Anne
 and George I. the annual output is stated to
 have exceeded 1,600 tons, so that for the
 period 1650-1725 we may probably reckon
 with safety an annual average of 1,400 tons.

In 1742 the average produce of Cornwall
 alone for several years is stated at 2,100 tons,
 and adding, say, 50 tons for Devon yearly (for
 at this time the productions of Devon had
 ceased to be important), we may reckon an
 average of 2,150 tons for the second quarter of
 the century. From 1750-1779, the average for
 Cornwall was 3,000 tons, or, again adding 50
 for Devon, 3,050 tons for the two counties.
 From 1780-1799, Cornwall produced each year

3,377 tons, and, again adding for Devon 50,
 we get a total of 3,427 tons.

All the above figures are for “white” tin,
i.e., metallic tin. From the beginning of the
 present century we have the figures for black
 tin, *i.e.*, dressed tin ore fit for the smelter.

The following are the figures for the two
 counties (Devon being only a contributor to
 the extent of about 50 tons per annum) for
 decennial periods; partly calculated from the
 figures given by Delabeche, and partly from
 the mineral statistics of Mr. Robert Hunt and
 his successors:—

<i>Black Tin.</i>		Tons.
1800-1809	4,294
1810-1819	4,650
1820-1829	6,344
1830-1839	5,840
1840-1849	8,912
Mean of 50 years, 6,008 tons; total, 300,400-		

1850-1859	9,535
1860-1869	12,585
1870-1879	13,513
1880-1889	13,480
Mean of 40 years, 12,278 tons; total, 491,130-		

1890	14,911
1891	14,488
1892	14,357
1893	13,689
1894	12,910
1895	13,612
1896	7,663
1897	7,120

Mean for 8 years, 11,969 tons; total, 95,750.

The remarkable increase during the second
 half of the 19th century took place in the face
 of very large competing supplies from Aus-
 tralia, Tasmania, the Dutch East Indies, and
 the Straits Settlements. The supplies from the
 last-mentioned source, however, have been so
 much greater during the last few decades, and,
 following the depression of silver, have been
 profitably sold at such low prices, that the
 West of England production has lately shown
 a serious decline, owing to the closing of
 nearly all the mines except those in the neigh-
 bourhood of Camborne, while even the rich
 Camborne mines have been worked for the
 most part for several years at a loss.

From the best sources at my disposal I am
 inclined to think that the following generalised
 Table gives figures of the production which are
 not very far from the truth:—

* “Origin and Development of Ore Deposits.” “Journ.
 Soc. Inst.,” Cornwall, xi., 1895.
 † “Seven Centuries,” &c., 1892.
 ‡ “Seven Centuries,” *passim*.

	Per annum.	
	White tin. tons.	Black tin. tons.
13th century.....	300	461
14th "	538	828
15th "	476	732
16th "	526	809
17th "	1,170	1,800
18th "	2,560	3,938
19th "	5,737	8,857

A number of interesting enquiries are suggested by these figures, as for instance, the reasons of the remarkable "leaps and bounds" in the production; the proportions of tin yielded respectively by "stream works," "stock works," "backs of lodes," or "coffin lodes," used by true underground mining; as well as the relative proportions yielded by West Cornwall, East Cornwall, and Devon.

A remarkable increase of production is noticeable towards the end of the 14th and the beginning of the 15th century, and this may have been occasioned by the great demand for bell-metal from which to cast the innumerable church bells required for the many churches built after the Wars of the Roses were ended. Good bell-metal contains about 20 per cent. of tin, and the quantity required at that period must have been very great.

A second period of especially rapid advance—the latter part of the 18th century—is that of the common use of bronze for artillery. The third period arose within our own recollection, and may be known as the "tinned meats" period. As to the ratio between the quantities of "stream-tin" and "mine-tin," there are very few and no exact statistics available until near the middle of the 19th century, by which time the proportion of stream-tin had fallen to about 2 per cent. of the whole. We know, of course, that in the two or three thousand years of working before the time of King John, the production must have been almost, if not exclusively, from the gravels; and so it must have been for some centuries after that reign. But there were some mines as much as 50 fathoms deep in Carew's time (towards the end of the 16th century), among which we may doubtless reckon Wheal Vor and perhaps Polgooth and Botallack, although these were not likely to be large producers at that time. No doubt, too, the backs of many other lodes were being worked in the 16th, and even in the 15th centuries, as well as such stock works as Carclaze, Minear Downs, Gover, and Great Wheal Fortune. But, on the whole, we are not likely to be far wrong if we look to the

valley gravels as the source of the bulk of tin raised up to the end of the 18th century.

It is most unlikely that all the mines mentioned were worked simultaneously. On the whole, I do not think we shall underestimate the mine product of black tin if we put 1,394,500 out of the total of 1,742,500 raised during the past seven centuries.†

As to the previous 20 or 30 centuries, generally, so far as we have any evidence of the relative production of the two counties, it would appear that Devon has only produced about 6 per cent., as compared with Cornwall's 94 per cent.‡

I call special attention to this fact, because several writers have commented on the enormous extent of the ancient workings in Devon, and have speculated upon large populations supposed to have been formerly engaged in tin mining in and around Dartmoor.

As regards Cornwall itself, it is certain that the western part, from the Carnon Valley to the Land's End, has produced greatly more tin than all the rest of the county taken altogether, and that the flanks of Carn Breath Hill have, so far, been the most productive part even of West Cornwall, although very great riches have been obtained from the Ives, Land's End, and Breage districts, the first of which is in any sense worked out.

Of individual tin mines many are known to have been large producers, and to have yielded large profits before there were any offic-

* Many of these were no doubt worked out when Henwood wrote of them in the first half of the 19th century. See, however, the long list referred to by him in 1873 in his Presidential Address to the Royal Institution of Cornwall. At the close of the 16th century there could not have been more than from 12 to 25 mines proper producing tin, as at Balnoon, Botallack, Ballewidden, Wheal Reeth, Great Wheal Vor, Polgooth, Bucklers, Beam Bunny, Carclaze, Polberro, and Wheal Kind are pretty nearly all of which we have distinct evidence in West and Central Cornwall up to the middle of the 18th century, with Drakewalls in East Cornwall, but it is probable that we might add to this list of open works than those already mentioned, as Wheal Grey Breage, Mulberry and Wheal Prosper in Lanivet, and Wheal Whisper in Warleggan, Great Trevadoc, in St Neot, and some others on the borders of Dartmoor.

	Mines.	Streams.	Total.
† 13th century ...	5,000	41,100	46,100
14th "	10,000	72,800	82,800
15th "	27,000	53,200	73,200
16th "	30,000	50,900	80,900
17th "	135,000	45,000	180,000
18th "	338,800	55,000	393,800
19th "	845,700	30,000	885,700
	1,394,500	318,000	1,742,500

See also "Seven Centuries, &c." pp. 18c-18d.

† *Ibid.* p. 183.

istics published. The following may be particularly mentioned:—Balleswidden, Botal-Levant, St. Ives Consols, Great Work, Llanannance, Wheal Kind, Providence, Dingy, Wherry, Wheal Vor, Great Beam, Gwennep, &c. In more recent times, besides several of those just mentioned, the following have been, and some still are, very profitable:—Metal, Dolcoath, Carn Brea, Tincroft, Pool, Wheal Eliza, &c.

Copper Production.—Up to the year 1700 it is likely that a great deal of the copper mined had been got while working for tin, and about that time more systematic operations appear to have been commenced. It is probable, too, that up to that time most of the mines were either open works or comparatively shallow mines, drained by means of adits only, although "the pits sometimes exceeded 100 fathoms in depth," so far back as 1678.

In 1729 we are told that North Molton Mine, Devon, was at work, and raising ores which sold for £6 10s. per ton, and Tonkin, writing in 1733*, mentions Wheal Rose in St. Agnes, Cornish Downs, and Trevascus in Gwinnear, as the most profitable mines then working. Pryce mentions that in 1737 there were raised in Cornwall no less than 9,000 tons of ore; a greater production than the present, by far, if we take into account the greater richness of the ores in these days.

In the period from 1718 to 1758, Borlase mentions the following as the most profitable copper mines:—Chacewater in Kenwyn (afterwards known as Wheal Busy), North Downs, Redruth, Huel Rös in St. Agnes, Roskear, Huel Kitty, Dolcoath, Bullen Garden, Entral, and Longclose in Camborne, Huel Fortune in Gwinnear, Huel Virgin, Metal Works and Trevascus in Gwinnear, Binner Downs, Herland and Clowance Downs in Gwinnear, Huel Cock and Rosmorran in St. Agnes. He remarks that very few copper mines gave much profit until near the end of the 18th century. Towards the end of the century, and especially in and around Gwinnear parish, the mines already at work were in many cases greatly extended, so that the six ore-purchasing companies of 1751 had increased to thirteen by the year 1778.

Wheal Virgin, in Gwinnear, was discovered in the year 1757. The ore "made" quite near the surface, and according to Borlase, the first ore produced in the first fortnight ore which

sold for £5,700 at a cost of £100. In the next three weeks and two days ore was obtained which sold for £9,600 at a slightly increased proportional cost. No other such great and sudden discovery as this was made for near 100 years; but, besides most of the mines already mentioned, there were many others of importance, among which may be mentioned the Carharrack mine, Wheal Lovelace, East Wheal Virgin, West Virgin, and Wheal Fortune (afterward worked extensively as the Consolidated Mines), Ting Tang, Wheal Squire, Poldroy, Ale and Cakes, East Ale and Cakes, and Wheal Friendship (afterwards worked together as the United Mines), Wheal Chance, and many others.

The first great collapse of copper mining.—Before the end of the 18th century, besides the mines just named, Dolcoath, Cook's Kitchen, the Pool Mine, and many others in Camborne and Illogan, as well as some in Redruth and St. Agnes, had become important copper producers. Dolcoath itself, now including Bullen Garden, and sunk to a depth of 160 fathoms, had already yielded ores worth £2,000,000 before the end of 1778. Several mines in Devonshire were also producing important quantities of ore, Wheal Friendship in particular being both extensive and profitable. But the West Country mines received a very heavy blow by means of the great discovery of copper at Pary's Mountain in 1772, and the consequent heavy fall in the price. Watt, writing to his partner, Boulton, in 1785, gives a very dismal picture of the principal mines, and in particular of the Chacewater Mine (Wheal Busy), Poldice, Wheal Chance, the Pool Mine, Roskear, the United Mines, Wheal Union, and Cook's Kitchen. Owing to the increasing depth of these mines, and to the inadequacy of their pumping machinery, they were unable to compete with the Anglesey mines. Several of the largest were abandoned, but others struggled on in hope of better times, and at length the better times came. The introduction of Watt's improvements in engines, and the improved price of copper following on the stoppage of the Pary's Mountain in 1792, gave some of the mines, and especially Dolcoath, a new lease of life, and the last year of the century saw copper selling at £128 per ton.

The Great Revival.—Counting small and great, there were at the beginning of the present century 45 mines working for copper alone in Cornwall, besides 18 working for copper and tin, one for copper and silver, and one

* See "Four Centuries of Copper Mining." "Trans. A. and I. of Corn.," 1894-5.

for copper and cobalt. In Devon there were 10 copper mines at work, but these were all of small importance at this time. The following were the leading mines at the various periods mentioned :—

1800. Wheal Alfred and Dolcoath were the largest producers. The former employed 1,500 people. It continued working until 1831, and, as Wheal Alfred Consols, until 1856. Dolcoath at this time was just beginning its second period of prosperity. Other important mines about this time were Wheal Unity, Wheal Damsel, Wheal Virgin, the United Mines, Treskerby, Cook's Kitchen, Tincroft, Oatfield (Crenver), and Godolphin. These were all large producers, but not all very profitable.

1815. Dolcoath had now the leading position, its ores selling this year for £66,839. It continued to produce copper largely until 1846, the mine being then 210 fathoms deep, but only drained to the 160. Other productive mines at this time were Crinnis, Wheal Alfred, Wheal Unity, the United Mines, Wheal Damsel, Treskerby, Wheal Abraham, Wheal Towan, and Gunnislake, but only the first two mentioned were at this time profitable.

In 1814 the costs at Wheal Alfred were £1,000 per month, and at Crinnis £2,000 per month. Tresavean now began to be an important producer.

1817. The United Mines had now reached the first place, its ores selling for £63,116.

1822. The Consolidated Mines, only recently reopened, sold ores to the amount of £80,311. Fowey Consols now began to yield largely, and Great Wheal Busy (the old Chacewater Mine), Wheal Baller, Wheal Beauchamp, Binner Downs, and other large producers were beginning to affect the market.

1827. In this year the Consolidated Mines gave 13,487 tons of ore, Penstruthal 12,078 tons, and 18 other mines, all in Gwennap, raised the produce of that parish alone to a total of 46,809 tons.

1838. By this time there were, according to Sir Henry Delabeche, over 76 mines producing copper in Cornwall, besides several in Devon. The three largest producers were now the Consolidated Mines, which sold 19,489 tons of ore for £126,211; Fowey Consols came next with 15,254 tons for £85,435; and Tresavean followed with 12,303 realising £76,272. This latter mine—one of the oldest copper mines in Cornwall—had been a very large producer ever since 1829. At this time there were, besides those mentioned, above 30 other mines in Cornwall, each producing over 1,000 tons of

ore per annum. The prices ranged £18 11s. 6d. per ton at Botallack, £12 12s. at Levant, down to £2 4s. 6d. at Wheal Burrow; the average price being £5 17s. 6d. per ton.

1842. This year Tresavean was the leading mine. From a return made at this time appeared that from June, 1834, to June, 1842, it had yielded over 99,000 tons of ore, realising £610,893. The same return showed that the average annual profit from 1838 to 1843 was £30,693, and the average number of people employed about the mines was 1,300.

1845. In this year the great discovery at Wheal Maria, near Tavistock, which had been made in the previous year, began to tell on the market. Devon Great Consols, which besides Wheal Maria, included Wheal Fanny, Wheal Josiah, and other mines, at once took the leading position among the West Country copper mines, and, with a few short periodical exceptions, has held it ever since.

1850. In the 50 years from 1801 to 1850, 500 mines in Cornwall, and 3 mines in Devon sold ores realising over £13,000,000 sterling, the Consolidated Mines in Gwennap leading with near £2,000,000; the United Mines coming next with about £1,500,000; Devon Consols, Dolcoath, Fowey Consols, and Tresavean, each contributing over £1,000,000; and the remainder falling in with amounts varying from about £700,000, in the case of Wheal Friendship, in Devon, down to about £100,000 in several others. Besides these, there were, of course, many smaller mines.

The Culmination (1851-1860).—This period of ten years witnessed the culmination of Cornish copper mining, as well as the commencement of its decline. In 1853 there were 98, and in 1859 no fewer than 170 mines producing copper ore in Cornwall and Devon, the chief producers being Devon Consols, Fowey Consols, and the new and rich mines then recently discovered in the Caradon district. In the year 1856, Messrs. Phillips and Darlington published a list of 76 mines which had each up to that time sold over £100,000 worth of ore since the beginning of the century, and of 107 more which had sold between £10,000 and £100,000 worth. In Cornwall copper mining reached its actual high-water mark in 1855, when 161,576 tons of ore were sold for £1,064,474. Next year Devon reached its highest output with 42,024 tons, which sold for £215,644; but the highest value was attained in 1857, when 37,800 tons sold for £222,416.

The Decline.—This, at first, was not ve

but its progress was soon accelerated, and will appear from what follows :—

19. There were at this time 102 mines producing copper, 84 in Cornwall, and 18 in Devon. Of these, Devon Consols came first with 15,988 tons, Clifford Amalgamated followed with 7,579 tons, West Seton, Marke Valley, and South Caradon, each produced 6,000 tons, and there were six others whose output exceeded 1,000 tons each.

24. The number had now fallen to 92 (78 in Cornwall, and 14 in Devon), Devon Consols being first with 5,694 tons, Marke Valley following with 4,325, and twelve others with upwards of 1,000 tons each.

29. The copper-producing mines were reduced to 47 (40 in Cornwall, and 7 in Devon), Devon Consols led with 10,261 tons, then came Mellanear with 6,528, and South Caradon with 6,000. Seven others produced each over 1,000 tons.

34. Devon Consols still led with 10,420 tons, followed by Mellanear with 6,928, South Caradon 4,096, Wheal Crebor 2,924, and Bedwin United 2,311. Four other mines produced upwards of 1,000 tons.

36. There were now only three mines producing over 1,000 tons, Devon Consols coming first with 6,077, Mellanear next with 4,019, and Wheal Crebor, 2,562. The whole copper production of the two western counties was now below the production of several individual mines in the middle of the century.

37. The diminution still continued, only three mines rising above the 1,000 tons output, Devon Consols 4,209, Mellanear 1,939.

38. The production rose a little, as Devon Consols yielded 4,784 tons, Mellanear 2,857, Wheal Crebor 1,286, and Levant 1,209.

39. This year again showed a serious depression, less than 8,000 tons of ore having been produced, and this of very low grade for the most part, yielding in all less than 700 tons of fine ore. To meet with such a small quantity in former years we must go back to the end of the 17th century. Levant took the first place in the year with 1,505 tons of ore, and was followed by Wheal Crebor and three other mines, each with over 1,000 tons. Devon Consols sold very little ore during the year, so losing the leading position which it had held for so many years.

40. This year saw a little improvement, Devon Consols taking first place with 1,979 tons, sold for £6,798. Devon Consols followed with 1,333 tons of very low grade ore, sold for £1,100, and was followed by Callington

United, which sold 1,417 tons for £4,055. The total production of the West of England this year was 11,309 tons, worth £24,498, or only about two guineas per ton. Since 1890 the production has been as follows :—

Date.	Tons.	Value.
1891	8,329	£17,924
1892	5,631	10,601
1893	5,144	12,540
1894	5,676	13,691
1895	7,512	21,840
1896	7,204	21,159
1897	5,557	15,343

Average of 7 years.. 6,436 16,157

The West of England production of copper, once so important in the world's market, is now quite insignificant, as it forms less than one four-hundredth part of the world's production.

Relative Production of the Two Counties.

—We have seen that Devon has only produced 6 per cent. of the tin of the West of England. In copper she shows up somewhat better. Before the year 1845 the great bulk of the copper ores raised had come from Cornwall, and probably the whole product of Devonshire up to that time had not exceeded 300,000 tons. But in that year Devon Great Consols began to yield largely, and was soon followed by Devon United and other mines, so that the Devonshire production of the last 50 years has been over 1,100,000 tons out of nearly 5,000,000, or approximately one-fourth of the whole, and of this large quantity Devon Consols has yielded nearly 750,000 tons. But taking the whole period into account from 1501 to 1890, of the 11,500,000 tons of ore yielded by the two counties, Devonshire can hardly be credited with more than 1,500,000 tons at most, or little over 12 per cent.

In the following Table, the total production of the two counties is given; from official returns, wherever possible, at other times from the estimates of the best authorities available, with some carefully considered interpolations for intermediate periods. The figures, therefore, can only be regarded as approximations up to the year 1726, from that time to the year 1856 they are still partly estimated, though probably very near the truth; since that time they are either altogether accurate, or very nearly so.

Thus, the production of ore, which averaged about 100,000 tons per annum, from 1801 to 1840, increased to an average of 160,000 tons during the next 30 years (1841-1870), and

declined to an average of 34,000 tons during the next 20 years (1871-1890), since then the produce has been insignificant, as already stated.

ESTIMATED PRODUCTION OF COPPER ORE IN THE WEST OF ENGLAND FROM 1501 TO 1895.

Date.	Average production per annum.	Totals.	Totals. (Centuries.)
	Tons.		
1501-1550 ..	100	5,000	16th century 30,000 tons.
1552-1600 ..	500	25,000	
1661-1650 ..	750	37,500	17th century 100,000 tons.
1651-1700 ..	1,250	62,500	
1701-1725 ..	4,520	113,000	18th century 1,700,500 tons.
1726-1750 ..	7,600	193,000	
1757-1775 ..	19,500	487,500	
1776-1800 ..	36,400	910,000

1891-1897 ..	6,426	45,953	
Grand Total . . .		11,487,223	

The number of people employed in and about the copper mines is believed at one time to have reached the important total of 25,000. At present it is less than 1,000, a number which has been frequently and largely exceeded at a single mine.

The Great Extent of our Mining Operations.—I will now try to convey to you some faint idea of the enormous amount of work that has been done by the miners of the West of England. As regards what may be called the pre-historic periods of tin-mining, our guesses must be of the roughest kind. Yet in 30 or more centuries of work the total production of black tin must have been very large.

I have shown that the stream-tin production of the past seven centuries has probably been about 348,000 tons of black tin; and we may reasonably suppose that the 20 or 30 previous centuries produced at least as much, or say, 700,000 tons in all.*

* I believe the stream-tin production has been much more than this, judging from the former extent of the valley gravels.

Now, to get this quantity of black tin would be necessary to remove at least four times as much tin ground, and probably ten times as much overburden, or, in all, not less than 3,080,000,000 tons, or say 1,500,000 cubic yards. Much of this has, of course, been removed with comparative ease by the running water, which would readily carry away the finer sands and slimes. But, on the other hand, much of the stonier portion has been turned over several times. Certainly, the whole represents an enormous amount of work done, it as we may. Let me try to illustrate this. The coast line of England and Wales, exclusive of the minor promontories, is said to be 2,000 miles in extent, so that a wall of 14 inches length would fairly enclose it. I have calculated that the ground removed by the streamers would make a mound all round the country 42 yards wide and 10 yards high. The stone broken underground and brought to the surface from an average depth of perhaps 1,000 feet, and which yielded 1,394,500 tons of black tin, must have been at least 70,000,000 tons. The stone broken and brought up from an average depth of perhaps 600 feet, and which yielded 11,500 tons of copper ore, must have been not less than 60,000,000 of tons. If now we add to this amount of "dead" ground brought out by cross-cut adits and vertical shafts, as all the ground excavated in mining for lead, iron, and other minerals, the total cannot be less than 180,000,000 or perhaps 200,000,000 of tons, and this would be sufficient to build a wall on the top of the mound 5 yards thick and 4 yards high. The metallic tin and copper extracted from the whole of the ores produced from the mines and streams in the West of England would make a solid railing of 14 inches all around the wall 14 inches thick.

I have estimated in some detail in another paper* that the amount of sinking and dressing necessary to obtain the copper alone would amount to not less than 1,485 miles of work, at most moderate computation. For the tin excavations must have been considerably more, and if we add in the work necessary for getting the other metals, a total estimate of 2,000 miles will not be at all excessive.

I will not weary you with further details of such calculations, but I know I am worth the mark in saying that the West of England mining region, from a small part only of a mere strip of country, has yielded more than 100 minerals to the value of upwards of £200,000,000.

* "Four Centuries of Copper Mining."

ng. In getting this, forests of timber have
used to support the ground, while rivers
ater have been brought to surface by the
f fleets laden with coal.

Financial Results.—And what has been the
cial result of all this work? I will first
a few instances from mines that are still
ous and flourishing.

Wheal Great Consols.—This great copper
arsenic mine is situated on the banks of
Tamar, about four miles from Tavistock.
first discovery was made in a pheasant
rve, belonging to a former Duke of
ord, who for years would not permit any
g operations to be undertaken. At last,
e year 1845, work was begun by a small
company, under the name of Wheal
a. I have the pleasure of the personal
aintance of several of the discoverers and
workers, among whom I may mention
ain Clemo, the present, and Captain Isaac
ards, a former manager. The lode in
al Maria rapidly yielded enormous quanti-
of yellow copper ore. Other discoveries
made in the immediate neighbourhood,
the whole group—under the name of Devon
t Consols—has been working continuously
to-day, and is likely to do so for very
years to come. At present there are 12
shafts and over 2,000 fathoms of pit-work
ll working order, 45 miles of galleries,
y 3 miles of underground, and 2½ miles of
ce tramways, 11 powerful steam-engines,
any large water-wheels (worked by the
s of the Tamar), 7 calciners and 3
ic refineries, 6 miles of railway, 2
otive engines, 50 ore and timber
gons, a quay, &c., all paid for out of
ngs, and certainly worth more at
e-up value than the whole of the sub-
ed capital, which is only £20,000. By
s of this insignificant working capital,
er ores worth over £3,500,000 sterling,
arsenic to the value of £500,000, have been
16: dividends amounting to £1,250,000
to the shareholders, while the Dukes have
ved no less than £280,000 in dues.*
Dolcoath Mine celebrates its centenary of
errupted working this year. On a total
scribed capital amounting to £120,252,
s paid dividends amounting to nearly
00,000 sterling, and Lord's dues amount-
o £309,478. In 100 years of working it
produced and sold ores to the value of

£6,218,086.* I am mainly indebted to the able
managing director, Captain Josiah Thomas,
for the following additional particulars:—There
are five working shafts sunk under adit 455,
440, 425, 375, 338 fathoms respectively.
Adit 28 fathoms from surface. The levels
have a total length of about 75 miles.
There are three pumping engines, the cylinders
85, 60, and 60 inches diameter respectively;
also five winding engines, three being new and
working at high pressure. The ore is crushed
by means of 60 heads of Californian, two of
pneumatic, and 236 of the old Cornish pattern;
it is dressed by means of 27 Frue Vanners,
capable of dealing with 120 tons of ore per day,
and a great many buddles revolving frames,
Bilharz tables, &c. For working the rock-
drills underground there are three air-com-
pressors. The pit-work consists of about 1,500
fathoms of various sizes. About 1,200 people
are employed below and at the surface.

East Pool Mine.—This was once a rich
copper mine but now, like its near neighbour
Dolcoath, it produces mainly tin. It was
started in the year 1834 and has worked ever
since. It is now 300 fathoms deep. On a total
called-up capital of a little over £3,000 it has
given dividends amounting to about £500,000.
In the year 1896 it took over its neighbour
Wheal Agar, calling up then and since a
further £12,000 or so of new capital for the
purpose. The "lords" have received over
£100,000 in dues. The amalgamated mines
have already begun to pay dividends on the
enlarged capital and seem to have entered on
a new career of prosperity.

Coru Brea and Tincroft United.—These
mines, together with Cook's Kitchen, have
been lately amalgamated. They have all been
highly profitable in the past, and although a
little under a cloud just now are looked upon
by all who know their history as very likely to
be again rich in the near future.

West Kitty.—This is one of the famous St.
Agnes tin mines—it has been working con-
tinuously since 1879, has called-up £66,000,
and has paid £120,000 in dividends.

Wheal Kitty, its older adjoining neighbour,
on a called-up capital of £25,000, has given
dividends amounting to about £60,000.

Levant Mine has been worked continuously
since 1820, and has given dividends amounting
to many times the called-up capital. Brilliant

* For some of these particulars I am indebted to Mr. Fefer
n, the able managing director.

* Dolcoath had been long and profitably worked before
1799, when the present working began, but the records are
lost.

as the career of these mines has been, it has been equalled by scores of others in the past. Among copper mines I need only mention South Caradon, West Caradon and Marke Valley, Wheal Friendship, Fowey Consols (with Lanescot), Crinnis, the Consolidated and the United Mines, Tresavean, North Roskear, South Wheal Basset, Wheal Buller and Beauchamp, Condurrow, Crenver and Wheal Abraham, the Godolphin Mine, &c.; and among tin mines, Wheal Kind, Trevaunance, &c., Providence mines, St. Ives Consols, Ballewidden, Great Work, Great Wheal Vor, Wheal Metal, &c.

The Characteristics of the Cornish Miner.

—What then are the qualities which characterise the men who have done all this work, and who, while doing it, have in many instances converted desolate moors into productive fields and gardens? I have known the miners of Cornwall for thirty years; I have had them working under me in Canada, the United States, and Mexico, as well as at home, and I am intimately acquainted with their work in Spain, India, Chili, Peru, Australia, and Burma. The Cornish miner's never-failing skill and inventiveness is appealed to whenever there is a difficult piece of work to be done. He is supposed to be rather unprogressive at home, but abroad I have ever found him enterprising. It must be admitted that he is more fond of scheming than of hard work; doubtless, his patron saint, St. Piran, taught him, "Ef e'e caant schamy 'ee must louster," but, after all, his scheming is often more valuable to his employer than his loustering could ever be. He has inherited from many preceding generations the handiness, resource, and intrepidity of both sailor and miner. He is a born prospector, and an ideal tributor. Almost every lode discovered in depth by cross-cutting in Cornwall is found to have been worked by "the ancients" at surface, and, if worth anything, as far down as the natural water level. He has a keen eye for the phenomena of mineral deposits everywhere, and one attendant disadvantage of the modern methods of mining—driving a-head by the aid of rock-drills and high explosives—has been the fact that the cool observation and consideration of the tributor has been rendered difficult or impossible, and, owing to this fact, I do not doubt that many payable branches and sidelodes have failed to be discovered. Among other personal characteristics, he is religious and a little superstitious, temperate, enthusiastic, and even heroic on occasion, but

generally quite level-headed; a general satirical comrade and a true friend.

Education.—Until lately, the Cornish miner has laboured under the disadvantage of a great lack of education—elementary as well as technical. The Elementary Education Board have done much for the present generation, but there are still many most able and experienced miners of middle age who can neither read nor write, and who could not "pass" in the elementary stage of the Science and Art Department's examination in the "Principles of Mining" to save their lives. They do not know well how to do all kinds of difficult work, but they cannot explain themselves even to a *viva voce* examiner; and this lack of education often prevents them from filling responsible positions for which they are otherwise well fitted.

Technical Education.—The first attempt to provide what is now known as technical education for the Cornish miner, was made by Sir Charles Lemon, of Carclew, more than sixty years ago.*

In October, 1838, he issued a circular to the "mine-agents and others" throughout the country and, after alluding to the need of scientific instruction, he made the following very liberal offer:—

"With a view to ascertain how far there is a demand for such instruction, I will take on myself the expense and responsibility of an experiment for two years. If I should find, on considering the details, that my plan affords a reasonable prospect of success, and if at the end of two years the experiment should take up the subject, and carry it forward to my death, I will endow the Institution in such a manner as shall afford a reasonable hope of its permanent establishment."

This liberal proposal was warmly responded to by the Royal Institution of Cornwall, and appears from their "Report" of that year, published in 1839, wherein the following judicious remarks occur:—

"What is required for the greater part of the population of this kind . . . is a practical education in those sciences which are connected with every man's daily occupation, the sciences of experiment, the sciences of observation, the expedients of art. This desideratum is now, we trust, in a fair way of accomplishment, through the noble offer of Sir Charles Lemon. . . . The advantages which result from this Institution from the establishment of a school, will, we feel confident, induce the members of this society to place their museum and premises at the full disposal of the council in order that the

* See "Mining Schools of Cornwall," Rep. M. S. Soc. Cornwall and Devon, 1872.

every assistance in their power to Sir Charles in his arduous undertaking. The completion of his lecture-room and laboratory will afford facilities for giving instruction to a mining class, and for chemical and metallurgical research."

The school was started almost immediately, and primary instruction in algebra, geometry, and mine surveying, and mechanical drawing, being given by Mr. Joseph Dickinson, the Rev. T. G. Hall was appointed professor of mathematics, the Rev. H. Moseley, of physics, and Mr. John Prideaux, of chemistry and mineralogy. The course of instruction was the same as at King's College, London, and was continued during the years 1839-40, when Sir Charles Lemon proposed the establishment of a permanent college at Truro, offering to provide a site, to subscribe £500 towards the building, and to endow the institution at a rate with the sum of £20,000. There were, however, two conditions which led to the abandonment of the scheme. The first was a stipulation that the mines should contribute half a penny in the pound on the value of the ores for twelve years, which it was found they were not willing to do. The second obstacle was the condition that the college should be a Church of England institution, although objections were suggested to prevent its being taken to the Dissenters who might attend its classes.

It is quite evident that the scientific education of the working miner was not a part of Sir Charles Lemon's plan at this time, since no provision was proposed for his support while he was at the mine, but it would undoubtedly have aided greatly in giving better education to the sons of mine agents, pursers, and other mining officials.

However, the plan failed, and nothing more was done for 12 years, when, in 1853, the Royal Institution took the lead in another effort, and was supported to some extent by the Geological Society of Cornwall and by the Royal Cornwall Polytechnic Society. The school was again located at Truro, under the care of Messrs. Hobson and Rickard, as teachers of mathematics and mechanics, and Mr. Hodge, as teacher of chemistry and mineralogy. The attendance was small, though some good work was done, and several of the pupils were afterwards distinguished in connection with mining pursuits.

This second effort failed, like the first, for want of general support, and the school was abandoned towards the end of 1858. Still, the Royal Institution was not disposed to give the

matter up without a further effort, and a peripatetic school was started. This scheme embraced a somewhat advanced course on chemistry and mineralogy at Truro, for about three months in the year, with classes open to working-miners in the various mining districts; some being of the nature of mutual improvement classes, where the members recounted and discussed their experiences, while others were under the direct instruction of the teacher. Mr. Richard Pearce, who had been the laboratory assistant in the second Truro school, and is now the able managing partner of the great Argo Smelting Works in Denver (Colo.), was appointed as teacher and director of this third school, and at once established a class at Pool near Camborne. About this time, too, Mr. Robert Hunt interested himself in this peripatetic plan for carrying the instruction to the immediate neighbourhood of the mines and of the miners' cottages. A considerable subscription-list was secured, from landowners and other sympathisers, and from a few of the leading mines, to defray the necessary travelling and other expenses, and the Miners' Association of Cornwall and Devon—the fourth of Cornwall's mining schools—was established at Camborne on the 26th of October, 1859.

Mr. Pearce was engaged as lecturer to the new institution—another lecturer, Mr. Charles Twite, was soon after engaged, classes were opened in a great many mining centres, and the work hitherto carried on by the Royal Institution of Cornwall was soon absorbed into the general scheme of the new association.

The Miners' Association continued its work under Messrs. Pearce and Twite, then under Dr. Clement Le Neve Foster and his successors, and, occasionally, aided by liberal grants for special subjects from the City and Guilds of London Institute, and the Society of Arts, until the year 1885, when it was amalgamated with a younger society, hitherto known as the Mining Institute. The work of instruction by means of local classes still went on, under the control of the Mining Association and Institute of Cornwall, Camborne being now the headquarters, a change due mainly to the fact that, owing to the liberality of various members of the Basset family, excellent class-rooms and modern laboratories had been built there, and a number of scholarships for needy students had been established. In 1895 a further change took place, for the Mining Association and Institute was then practically absorbed into the Camborne School of Mines, the local classes in other districts being now left to

themselves. The Camborne Mining School, under the direction of Mr. J. J. Beringer, Mr. W. Thomas, and their able assistants, is now a most successful and prosperous institution where every branch of mining engineering is taught, and well taught. Besides laboratories, class-rooms, &c., and a museum, it owns and runs the South Condurrow tin mine, not for profit but for experience. There are 80 students working in this mine, each for two or three days a week. The shaft, tram-roads, head-gear, &c., are all in thorough order. The air-compressing plant and rock-drills are always at work, and there is now to be added a new compound engine, Californian stamps, and up-to-date dressing plant. There are also from 50 to 60 students of mine surveying.

Another off-shoot of the Miners' Association is the Redruth School of Mines, which was first established in the year 1860, and is now under the direction of Mr. J. P. de Castro, B.A., and his assistants. It has a good laboratory and museum, and is doing very good work.

There are also minor offshoots at Penzance and Helston, while at Truro the private school under the direction of Messrs. Henderson and Son, is of particular advantage to those who desire to have first-class instruction in mine-surveying and other branches of mine engineering.

For the last few years most of the local efforts have been aided by grants of money from the Cornwall County Council. The result of all this is that Cornwall is continually producing and sending out into the world miners who are second to none in the profession, and who are capable of doing the best possible work—of making as good "bricks" as can be made where they are supplied with the necessary "straw," in the shape of capital. Cornwall has now become in a very real way a mining school for all lands, and has provided mining inspectors for Kimberley, British Guiana, and several of the Australian Colonies, as well as managers of such mines as the De Beers, Ferreira, Sheba, and Rio Tinto, and for such metallurgical establishments as the Argo Works in Denver. And I may add that the transactions of her local scientific societies will ever be classics to students of mining and chemical geology.

The Decline of Cornish Mining.—The present generation has indeed witnessed a most serious decline in mining, and the closing of a great majority of the mines. Thus, if we compare the statistics of the year 1897, the last yet issued, with those for 1867, we find that the value of the products of the tin and copper mines has fallen from £1,106,807 to

£269,511. My object will now be to point out the causes of this decline as far as possible, and to consider the prospect of a revival.

But before going on, I may remark that Cornish mining has been supposed to have been ruined several times, "scat up," as the saying is, and has several times recovered, and reached heights before unknown. The first such period of ruin in the reign of Elizabeth, before Sir Walter Raleigh became Warden of the Stannaries. There was another in the reign of William III., and still another at the close of the last century, when Valentin wrote his dismal account which I have already quoted. But a Cornish miner is never discouraged till his "neck's broke," and that is not yet.

The chief cause of the decline of Cornish mining has no doubt been the partial exhaustion of what has been called the copper lodes. This is in general limited to those portions of the lodes which are included between 100 and 250 fathom levels; but in some rare instances it has started almost from the surface and extended downwards, far below 300, as in several of the great mines of the Gwennap district. That this partial exhaustion was really the prime cause of the decline is evident from the fact that the culminating price was reached in the years 1855-6-7, while yet there was no very serious fall in price, such as has not have been generally met by improved methods of ore treatment, for 20 years. Another cause was no doubt the increasing cost of working mines, which were becoming continually deeper and wetter. The decline having set in, it was then accelerated by serious falls in price, consequent on the supplies from foreign sources, and especially from Chili, Spain, and the United States.

The average prices of fine copper nearest pound sterling, before 1856, had well over £100 per ton for very many years. The prices since then, taking periods of 10 years, are as follows:—

	Per Ton.	
	Fine copper.	Chili & G.M.
1856-60	£115	—
1861-65	100	—
1866-70	78	—
1871-75	87	—
1876-80	72	—
1881-85	61	—
1886-90	62	£58
1891-95	—	44
1896-98	—	50

The present price of Chili bars or G.M. is about £71.

pects of a revival of Copper Mining.—
 be true that the copper zone is practically
 isted, it is evident that no considerable
 il is to be looked for. I doubt whether it
 much exhausted as many suppose; rather
 a question of price, and partly a question
 thods of working and of sale.

th the prices ruling from 1881 to 1897,
 with the old methods of working, few of
 great West Country mines of the past would
 been able to pay large and regular
 ends, and many of them could not have
 their way. But I do not believe in any such
 anent low-level of price. In the mean-
 methods of working have been greatly
 ened, and, before concluding this paper,
 ll endeavour to set forth some reasons for
 in the future. I do not, of course,
 ose that Cornwall will ever again supply
 really important part of the world's con-
 ction of copper, large as this has now
 me. But if the recent considerable
 nce of prices is maintained, or nearly so,
 eed a price of £50 for crude copper can
 ounted on, many of the too-hastily aban-
 d mines of the Marazion, Gwennap, St.
 ell, Caradon, and Tavistock districts, can
 ade to pay if they are worked on a suffi-
 y large scale, and with the best modern
 ances. There is an additional reason for
 pening and deepening such mines in the
 roved tin prospects, for, with the expe-
 ce of the Carn Brea district before us, the
 ability of meeting with valuable deposits
 n by sinking below the copper zone must
 e regarded as an important consideration.

ead, Zinc, Iron, Arsenic, &c.—As already
 ed, these have only been important com-
 ents of Cornwall's mineral riches under ex-
 onal circumstances. At present, only the
 is of importance, but it may happen that
 others will again attract attention, and
 d notable profits, though they can never,
 arately or combined, play the part which
 per and tin have played.

in Mining.—This has never sunk so low
 copper mining, and I believe it has a good
 ure—perhaps a future as brilliant as its past.
 late depression was due to a run of excep-
 ally low prices, and not, as some assert, to
 austion of the mines, or the lack of proper
 hods and appliances. I do not say that
 can be proud of all that is done in Corn-
 l. But even with the best appliances, and
 best methods, the price of tin has been for
 rs unremunerative. I believe the depres-
 a was in the main due to purely temporary

causes, which have to a considerable extent
 passed away, and which may perhaps never
 return.

Complex Ores.—A great many of the low-
 grade and complex ores of the West could, no
 doubt, be more advantageously dealt with by
 raw smelting methods, or by wet processes, to
 be carried on at or near the mines. In this
 way, the almost universal presence of "values"
 in gold and silver could be made a source of
 profit to the miner.

In some respects we are not so well situated
 in Cornwall for the sale of mineral products as
 our competitors are in the Rocky mountains;
 a great many of our lodes, and even many of
 our burrows, are capable of yielding large
 quantities of low-grade and complex ore sub-
 stance which would, by a rough calculation,
 yield a product of composition somewhat as
 follows:—

Iron	20·0 to 30·0	per cent.
Copper	2·0 ,, 3·0	,,
Zinc	3·0 ,, 8·0	,,
Tin	— ,, 0·5	,,
Arsenic	4·0 ,, 8·0	,,
Sulphur	2·0 ,, 30·0	,,
Silica and silicates ..	15·0 ,, 25·0	,,
Silver 1 to 3 oz.,	Gold 1 to 3 dwts.	per ton.

Were there a steady demand for such stuff here
 as there is in Denver and other parts of the
 United States, thousands, perhaps millions of
 tons could be produced by a rough concentra-
 tion from the waste heaps, "stowage," and
 selvages of our mines at such a cost as would
 yield a fair profit to the miner. At present,
 unfortunately, there is no market for such a
 product, either in Cornwall or Swansea. In
 Colorado it would often sell for 20s. and even
 30s. per ton, being used as a flux in smelting
 siliceous silver and gold ores.

Royalties.—Since the mines have for the
 most part reached considerable depths, so
 involving heavier hoisting and pumping
 charges, these have in general been much
 reduced, particularly in the case of tin. But
 there are still many cases where the dues are
 far too high, and especially as regards
 copper. Under modern conditions of the
 copper trade, and until the principle of paying
 dues only on profits has been adopted, the dues
 on copper ought rarely to be more than one-
 fortieth of the sale value, and even then they
 will absorb as much as 30 or even 50 per cent.
 of the profits.

But more vital even than a reduction of dues
 is a removal of the restrictions in modes of
 treatment and of sale. In many cases of low

grade and complex ores the sale by private contract is far more advantageous than by the sham semi-public competition, which is called ticketing, and yet this latter mode is usually insisted on. It is even insisted on in some instances when the ores could be advantageously "refined" up to a certain stage on the mine itself. For example, many ores need to be "burnt" at an early stage of their treatment, and this has been absolutely forbidden in a great many leases even when the lessees are prepared to give substantial guarantee to do it in such a way as to avoid

chance of damage to the surrounding property. In this connection, however, I am bound to say that the larger landowners are usually considerate, and it is the small men who are most disposed to churlishness and greediness.

Working Capital.—From all this it will appear that, in my opinion, our principal need is working capital. Modern conditions of mining call for much larger capital expenditure than did those of former times. The mines are deeper and wetter, and they require more and better plant, as well as to carry their explorations farther ahead. I have shown how very successful the Cornish mines have been in the past. Why is it, then, that the necessary capital is not forthcoming?

1. In these days of Imperial expansion—with which I do not doubt all in this room are in sympathy—there is yet a danger that some of our home industries may be overlooked or neglected, even when they are well worthy of attention. And this applies particularly to mining. It cannot be denied that this West of England mining-field has been thus neglected for many years past. The extension of the empire is a fine thing, and it makes careers for our boys. But could not a little be spared to keep the home pot boiling?

2. One cannot but remark that to the ordinary speculator the word *gold* acts like a charm, and this "open sesame" we cannot use in Cornwall. And yet in general, and in spite of the great fluctuations in price, which, in the case of gold have been prevented by legislation, mines of the common metals are far more profitable, on the average, than gold mines. Let me give you a notable example from present-day experience.

The dividends paid by the Rand Gold Mines during 1898 amounted to very nearly £5,000,000 sterling. But this was the result of the investment, directly or indirectly, of over £100,000,000 sterling, in more than 400 com-

panies, which are still in existence, besides a considerable amount lost in companies that have lost all their capital and disappeared. In the course, those lucky investors who got into successful mines at par before their stock was assured, who have held on till now and who have also been fortunate enough not to get into the failures, have made large profits. But the general investing public cannot do this. They have made an average of 2½ per cent., and very many have lost everything. What would we not do in Cornwall if we had £100,000,000—but £1,000,000 of mere working capital? This amount spent honestly and intelligently, under your eyes so to speak, would re-open and equip twenty groups, each of three or four mines, that ought never to have been closed; and would, I believe, give us a dozen dividend mines for a long series of years.

And now to sum up. I believe the Cornish mines and the Cornish miners are second to none in the world. No country has had more mining triumphs than the West of England can show, and the few I have mentioned to-night might easily be extended into a list twenty times as long. The known mines are by no means exhausted, and it is certain that very many valuable ore deposits still remain unworked, and probable in the extreme that many others will yet be discovered. The reason to believe that prices, both of tin and copper, will in the future, as in the past, average far higher than they have done during the past few years; our men are skilful, and our landlords in general are disposed to be considerate. "We've got the stuff, we've got the men, we want the money too." But this necessary working capital we must have. It must be done on a larger scale than hitherto, and the mines must be grouped under a central control, so as to secure the advantages of the best class machinery and plant, and thorough management. Let us have just a small percentage, nay; even a penny in the pocket of the capital which has been so lavishly expended in India, South Africa, West Australia, and Klondyke, and I am sure that our home mines will be as profitable in the future as they have been in the past.

DISCUSSION.

Mr. WILLIAM SEMMONS said he could bear witness to the good work done by Mr. Collier in connection with the School of Mining in Cornwall.

he had modestly omitted his own name from of men who had been engaged there. As one former secretaries of the old Mining Association, years ago, he had a distinct recollection of Collins coming into the county, making himself at home there, and doing a good deal of work. In connection with the improvements of mining, he said that a mine with which he was connected was the second one to introduce wire rope, and he remembered the difficulty they had in getting the judgment of Captain J. Thomas, then manager of Dolcoath, so that he was pleased to find that mine was now prominent in bringing in machinery. Seeing the immense dividends paid out of the old mines with their primitive appliances they could imagine what might have been done had they had the mechanical contrivances they now used. Those who had travelled about the world have noticed that many of the most prominent operations in connection with mining were held by old graduates of the Mining School, and also that there were very good miners who could not read or write, during the last fortnight he had come across two of whom they wanted to send down a mine as timber men, neither of whom could do a common sum in arithmetic.

He should like to emphasise the closing part of the paper as to the probability of future profits made out of Cornish mining. His experience bore out the view that smelting than mining, but he could say that the several extensive districts of Cornwall, such as Scorrier, had never yet been developed to any considerable depth; about 100 fathoms was being like the limit to which the old mines were worked, because at the time of their prosperity there was not the same facility for pumping, and there were no compressors or boring machines. If a million pounds were laid out in Cornwall there would be a greater return for it than the same expenditure would secure in any other part of the world, and he thought something would be done. There were large works in Wales for the manufacture of spelter, and then, during the recent excitement about Fashoda, he thought that possibly their supplies of ore from the Continent might be interfered with, spelter mines were opened in Wales, and he hoped great results would follow: at any rate, it was a step in the right direction, and he hoped there would be a still further development of English mines, with English capital.

MR. MAURES HORNER said he was only acquainted with the east of Cornwall, and there was a great deal in the county that anybody who had to do with it did not know. His connection with the county was quite accidental, being asked to join a company which he found on his return from abroad after a year's absence was anything but flourishing, and he was not boasting much knowledge of mining, his object was to regenerate it were not successful. He had, however, what were the difficulties which met him there, the greatest of which was that all the best men had left the county. If there were two or

three years of good prices, no doubt many of these men would come back, and then there would be some chance for the county. He also thought improved methods of treating the tin ores were required; there ought to be better modes of concentration and of smelting.

MR. J. I. TRACY said it appeared as if the Cornish miner had been starved out, and was now found in every other part of the world, but not in his own county. The same thing had happened elsewhere. Mexico produced silver for the world, but the Mexicans were still poor.

MR. E. ASHMEAD said he had listened with much interest to the paper, and though he could not speak as a geologist or an engineer, he had been more or less connected with mining for the last 50 years. Mr. Collins had given statistics of some mines which paid remarkably well, but the real question was, would Cornish mines, as a whole, produce profitable results. He was recently looking at a book, published in 1856, called "British Mines as a Means of Investment," by the late J. H. Murchison, a gentleman largely connected with Cornwall, and he there gave a list of 92 mines which had paid dividends for the nine years ending in 1854, to the aggregate amount of nearly two millions. The question was, Could Cornish mining be revived, and could capital be found for it? His impression was that Cornwall could not do it by herself, and that the capital must come from outside to a large extent. The rich men in Cornwall had not assisted outside adventurers as they ought. Whenever a mine had been started from outside, with an office in London, Cornish men stood aloof. He could instance three mines, of which he was secretary, formed upon the reports of eminent Cornishmen, which were looked upon as being certain of success, and they appealed to the merchants and smelters of Cornwall to assist; but on looking over the list of shareholders in one of those mines, he found only three Cornishmen out of 150. If Cornwall wanted her mines worked, she must join with the outside adventurer as a brother, and there would then be more prospect of success. The working also must be on a more vigorous scale, and carried to greater depths. In Africa, where mining was quite recent, they already had deep mines, and they must have the same in Cornwall, and better machinery. The whole system had been too antiquated; people nowadays wanted to see a return for their money within a year or two. Again, the lords in Cornwall did not treat shareholders in a proper manner; all the leases were drawn by Cornish lawyers, and they were all in favour of the lord and against the adventurer. He had known companies to pay large sums for damaging land which could not possibly be damaged, because it was worthless.

MR. A. O. GRANGER said his experience was confined to the United States, but if Cornish miners

were as well distributed over the rest of the world as they were over that country, he should be surprised to hear that there were any left in Cornwall. In the States they found Cornish miners to be resourceful and good emergency men. In mining you were constantly running against snags of some kind, which required prompt action, and it was usually found that a Cornish man would get over the difficulty successfully before he reported it to the manager.

Mr. B. KITTO said he remembered meeting a clergyman in Cornwall, twenty years ago, who told him that he had travelled a great deal, and he found the Cornish miner the most intelligent working man he had met anywhere. If he went down a mine and spoke to one of these men, he could tell him the depth at which he was working, the size of the lode, the way it ran, the dip, and would give an intelligent answer to any question he asked; whereas in the colliery districts he could never get such information at all. Mr. Frank Oats, a St. Just man, who was largely interested in the Levant Mine, said, at a public meeting very recently, that the Cornish miner was the best in the world, but the best miners were driven away from the county by the small wages they were paid. Whether there were enough men left to do the work, he could not say, but when he was there he found a robust and intelligent class of men still there; and the mining schools, now established, were doing very good work in the way of technical instruction, which had been much needed. On the Continent, where the minerals belonged to the Government, mining schools had been in existence 150 years, and there had been a long succession of excellent professors there. Years ago Cornishmen used to go there to study mining, but he did not think they did so now. About 1716, a mining school was established at Chemnitz, which was also very successful. Some time ago he met a man who had considerable experience of mining on the Continent, and asked him what school he liked best to draw his men from; whether the Royal School of Mines or the Cornish school were equal to those on the Continent? His reply was that he should invariably choose a man from the English School of Mines if he could; the other men had a higher scientific instruction, but their knowledge seemed to be in their way—they were not able to apply it. He would remark that there were other minerals of value in Cornwall besides tin and copper. A large quantity of arsenic had been produced, and of late years wolfram had been turned to account for the manufacture of tungstic acid. Formerly it was left on the rubbish heaps, and anybody might take it away; but it was now worth £70 a ton, and East Pool, Carn Brea, Tincroft, and other mines had sold considerable quantities of it. Cobalt and uranium were also valuable, and within ten years a regular lode of the latter ore had been opened up in the St. Stephen's parish, and 150 tons had been exported to Germany.

Probably one reason why there had been a deficiency of capital of late years was that many people did not like what was called the cost-book system. The price of tin had fluctuated very considerably; sometimes it was only half the price it was at others, and when the price fell very low the mining captain thought it would be sure to go up again shortly, and in some cases he kept back in the accounts large sums of money which had been expended for fear of discouraging the adventurous, with the idea of wiping them off when the price improved. Two or three cases of the kind had had a very bad effect, and though the cost-book system, when properly worked, was undoubtedly the best, he believed that any great extension of it in Cornwall would have to be on the limited liability company system.

Mr. B. H. BROUGH said he was not quite clear from the paper at what date the Dolcoath Mine was originally worked. He understood Mr. Collins to say in the place that it was at work in 1768, and in another place that it was this year celebrating its centenary. He presumed, however, that it had been worked for a much earlier date. One could wish that Mr. Collins had extended his study of the history and statistics of metal mines to other parts of the kingdom, as he might have removed a great deal of the ignorance which seemed to exist on the subject. The other day there was a sensational account in a mining newspaper of the discovery of some Phœnician mines in the Mendip hills, the writer being evidently ignorant of the fact that Mr. Robert Hunt had published in his book on "British Mining," plans of the "Maidnips," as they were then called only a few years ago. With regard to the story of the fortunate amateur who obtained his first-class at the examination with so little practical knowledge, he thought it was probably due to the fact that Mr. Collins had written an admirable little manual on the subject, that any man who learned it by heart could easily obtain a first-class distinction.

Mr. COLLINS, in reply, said several of the names mentioned by Mr. Kitto would be found referred to in the paper when it appeared in print. He thought it very probably future mining companies would be carried on, on the limited liability principle, but he did not see that keeping back accounts was anything to do with the cost-book system. It might be kept back under any system, if the auditor did not do their duty, but not otherwise. Mr. Ashmead, for instance, had to audit the accounts, and did not think they could be kept back under any system. They did not know when Dolcoath began to work—probably several hundred years ago—but he knew that before 1785 it had produced £2,000,000 worth of copper. It was then stopped for 15 years and began again in 1799, and it was the centenary of that event which was being celebrated this year.

The CHAIRMAN, in proposing a hearty vote

Mr. Collins, said there was certainly one in the paper, and that was any reference to the work done by himself in connection with the Cornish Mining Institute, though the names of other gentlemen had been mentioned. Last year he had occasion to examine the Camborne School, which was a very remarkable institution, supported mainly by private enterprise, with but a small amount of assistance from public funds. To imitate the foreign schools of mining, in addition to scientific training, it provided for practical work, which was very valuable. Apart from the aid for Cornwall, it was a great assistance to other and others in the Central School in which it formed a sort of branch, and Mr. and Mr. Thomas did all they could to assist students in their work. With regard to the Cornish mining, his recollections went back to the culminating point of copper mining about 1850, possibly, what he saw then left too vivid an impression on his mind, but he was in considerable sympathy with Mr. Collins in his anticipations. It seemed remarkable that all work should be done in the great copper region of Scorrier. There were wonderful mines at one time, and one could hardly believe that they were exhausted completely. But if they were taken up again, it would be on a larger scale, and with better machinery. The great curse of Cornwall had been the old boilers, and especially the old boilers, for however good an engine you might have, you could not get good work out of it without a good boiler. He quite agreed that the Cornish miner was the best in the world, but, he says, he must have good machinery and plant with.

Vote of thanks was carried unanimously.

October. The average price paid was about £17 per 1,200 litres (317 gallons) of must. On the middle Haardt hills prices averaged £18 15s., and on the lower Haardt, £16 13s. per 317 gallons of must. On the Nahe, the must of early burgundies gauged 75° to 85° with an acidity of 7 to 8 per cent. Early burgundies realised £26 13s., and Portuguese £17 14s. per 317 gallons of must. The gathering of the red wine grapes of the Middle Rhine dragged along to the end of October. The result was extremely meagre. The must gauged 68° to 90°. The general gathering of the grapes began at the end of October, and was accomplished by the middle of November. In Rhenish Hessen the crop averaged one-tenth to one-third of a normal year, according to the location of the vineyards. In the Rheingau, the grapes were not juicy, and it took 39 to 40 cwts. to produce 1,200 litres (317 gallons) of must. Vineyards of 12 to 14 acres produced only from 150 to 230 gallons of must. In the valley of the Middle Rhine, the result was no better. The must gauged 60° to 75°, with an acidity of 12 to 15 per cent. The vintage on the Upper Moselle, resulted in a fourth of that of a normal year. Prices of must averaged £24 per 317 gallons. On the Middle Moselle prices averaged about £46 per 317 gallons. Must gauged 70° to 80°. On the Lower Moselle prices ranged higher than in 1897, notwithstanding the poorer quality. In the valley of the Nahe, the quantity was very small, and, judging by the must, the quality promises to be similar to that of 1896. The vintage of the white wine grapes of the Haardt hills was rather unsatisfactory. In the other wine-growing provinces of the German Empire—Baden, Franconia, Wurtemberg, and Alsace-Lorraine—the year's vintage was equally disappointing.

THE FRENCH SILK INDUSTRY.

Miscellaneous.

THE 1898 VINTAGE IN GERMANY.

1898 vintage in Germany will go on record as the poorest, both as to quantity and quality, of recent years. The main cause, in the opinion of the United States Consul at Mainz, is to be sought in the unfavourable state of the weather during the ripening period of the vines. At the same time, the diseases of the vine spread to an alarming extent. On an average, hardly one-fifth to one-fourth of a normal crop has been gathered, and prices have consequently fallen; but it is very doubtful whether they can be picked up, owing to the rather poor quality of the vintage. In Rhenish Hessen, early burgundies were sold from £35 to £42 per 1,200 litres (317 gallons) of must. According to the Oechsle system, the must gauged 70° to 80°. The Portuguese grapes of the Haardt hills were gathered at the beginning of

The production of the Lyons silk factories in 1897 was, according to the Commercial Attaché to H.M. Embassy in Paris, estimated at £16,200,000 as compared with £16,000,000 in 1895. This is the largest figure that has ever been reached. The steam weaving mills were kept busy, especially during the last six months of the year, and the hand weaving machines were particularly brisk. On the other hand, the manufacturers of plain pure silks complained seriously of the dearth of orders. Black silk tissues were little in demand, having given place to the more modern coloured silks. From 1896 to 1897 the production of plain pure silk tissues, not including silk handkerchiefs, fell from £5,200,000 to £4,440,000, while the production in 1896 had already fallen off by £600,000. With regard to the other manufacturing districts for pure and mixed silks, such as St. Etienne, Roubaix, Tourcoing, and in Picardy, and the various hosiery, trimming, and lace factories, their output is valued at £24,600,000. In 1897 the manufactories of St. Etienne turned out goods to the value of

£3,500,000, as compared with £3,466,800 in 1896. The total production of the district is valued at £3,680,000. On account of the change in fashions, the manufacture of plain pure silk ribbons shows a decrease of £320,000, but about one-half of this loss is compensated for by the increased production of plain mixed ribbons. The manufacture, also, of finished ribbons and velvets continues to increase, and the French houses still hold the first rank, notwithstanding the keen competition of the Swiss and German manufacturers. The United States now manufacture more pure silk ribbons than the French, and the production in that country appears to increase. The importations of silk tissue into France in 1897 amounted to £2,080,000 against £2,012,000 in the preceding years, and the exportations to £10,836,000 as compared with £9,880,000 in 1896.

EMIGRATION FROM BRITISH INDIA.

The *Board of Trade Journal* contains some statistics relating to emigration from India in the year 1897-98, obtained from the India Office.

The figures relate solely to emigration as carried on under the laws regulating emigration, and they take no account of the numbers who leave India as passengers, not having been recruited by emigration agencies for service in the colonies. They are also exclusive of the persons who leave India in pilgrimages to the holy places in Arabia, of whom small but uncertain numbers settle out of India.

The number of emigrants from India during the eleven years, 1887-88 to 1897-98, amounted to 156,388, making an annual average of 14,217 persons. Few, if any, quit the country with the intention of permanently establishing their domicile elsewhere, but leave in hope of returning with their savings to their homes in a few years. The number of persons who returned during the last eleven years amounted to 69,686, an average of 6,335 yearly; or less than one-half of the number who left India; this is also very nearly the proportion for the twenty years for which the facts are stated in the Tables.

The mortality among emigrants is high in some of the colonies to which they go, and of those who survive, a substantial proportion elect to continue to work in the colony after their term of indenture expires, and many of these never return to India. In Mauritius, for instance, about 69 per cent. of the population (256,000 out of a population of 372,000) are Indian settlers and their descendants, and in Trinidad and elsewhere the settled Indians are increasing in numbers.

There are five places in India from which emigration may legally be carried on—Calcutta, Bombay, Madras, and the two French settlements of Pondichery and Karikal. From Bombay emigration ceased many years ago, and general recruiting has never been resumed, labour in the Western Presidency being, on the

whole, so well paid that there is but little inducement to emigrate to the coolie-employing colonies. That port and the port of Karáchi, however, have recently been used for the shipment of male labourers destined for work on the Uganda Railway, who were recruited under agreements made with or on behalf of her Majesty's Government under the powers conferred by section 106 of the Indian Emigration Act, XXI. of 1883, as amended by Act I. of 1896. From the French settlements there has been no emigration since 1884, except in one year, 1888-89.

The Port of Calcutta is the most convenient for the shipment of emigrants drawn from the impoverished masses of the thickly-populated districts of Oudh, Bihár, and the eastern section of the North-Western Provinces, and the main stream of emigration flows from that region down the Hooghly. Of the persons who emigrated from India in 1897-98, as many as 7,347 (being 54 per cent.) were shipped from Calcutta, almost all of them from the North-Western Provinces, Oudh, and Bihá. From Madras 3,345 were shipped during the year, recruited exclusively from the Madras Presidency, and mostly from the southern (Tamil) districts. From Bombay and Karáchi 2,793 male labourers left during the year under agreement to work on the Uganda Railway, and these were mostly recruited from the Panjab.

The number of emigrants in the last three years has been relatively small, notwithstanding the distress in the tracts whence the emigrants are principally drawn, probably because the cane-sugar industry has been suffering from depression.

The destinations of the emigrants in the last seven years were as follows:—

To	1891-2	1892-3	1893-4	1894-5	1895-6	1896-7	1897-8
Mauritius ...	989	...	485	1,029	1,746	802	426
Natal.....	3,349	3,119	2,612	3,592	3,337	4,038	6,036
Demerara....	5,231	4,723	5,883	7,200	1,908	2,417	1,194
Trinidad	3,285	2,620	1,926	3,185	2,177	3,043	1,851
Dutch Guiana	698	1,075	1,104	1,279	1,696	500	618
Fiji	1,985	781	1,082	1,432	565	1,953	567
Jamaica	1,000	...	486	711	470
St. Lucia	157
Mombassa	2,819	2,793
Total ...	16,597	12,318	13,735	18,428	11,899	15,572	13,485

The emigrants who sailed from Calcutta during the year went to British and Dutch Guiana, Trinidad, Natal, Fiji, and Mauritius. The emigrants from Madras went to Natal and Mauritius. There is a considerable flow of native labourers from Madras to Ceylon and the Straits, but this traffic is not conducted under the provisions of the Emigration Act.

TOBACCO CULTIVATION IN SZECHUAN.

The tobacco plant is grown all over the province of Szechuan, but more abundantly in the districts of

Pe-shan Hsien, which is about 150 li (60 miles) north-east of Chung-King, and Kin-t'ang Hsien, about 100 li (40 miles) east of Chengtu, the provincial capital. The plant grows to the height of about 2½ to 3 feet from the ground, and the usual time for planting the seed is during the tenth or eleventh moon (November or December). The method before putting the seed into the ground is to sift out a quantity of soil and manure it. When dry, the seed is wrapped with this soil, and put into the ground at intervals of a foot-and-a-half. The soil must not be rich, and ground where cereals have not been already planted is generally chosen. According to Consul Smithers, of Chung-King, there are three crops a year—the first is cut six months after it has been planted, the second twenty days afterwards, and the third crop twenty days after the second crop. As soon as it is cut it is hung up to dry for about a fortnight in a sheltered place, with a good draught of air, so that it may dry quickly. When ready for sale it is done up in bundles weighing 70 to 80 catties (93 to 106 lbs.) a piece. The Kin-t'ang tobacco leaf receives a little more care; after it is dried it is put into a press to enable some of the juice to be pressed out, and the leaf made much milder than the other leaves that are sold in the market. It is done up in bundles of 40 to 50 catties (53 to 66 lbs.) each. The seed is sown under shelter. When the leaves are ready they are picked and exposed to the dew for several nights; they are then dipped in a dye and hung up to dry again before being taken to the markets for sale.

Obituary.

J. M. COOK.—Mr. John Mason Cook, head of the firm of Messrs. Thomas Cook and Son, the travelling agents, who died on Saturday, the 4th inst., was a member of the Society of Arts since 1883. In 1893, when the Council, acting as the Royal Commission for the Chicago Exhibition, arranged for a special private excursion of the members of the Society to the Exhibition, Mr. J. M. Cook carried out the arrangements with great success. Mr. Cook had previously assisted the Executive Committee of the British Section at the Paris Exhibition of 1889, by acting as their passenger agent.

Mr. Cook joined his father, Mr. Thomas Cook, in 1864, and greatly developed the business founded by him. He had previously served in the offices of the Midland Railway Company. In the obituary notice of Mr. Cook in *The Times*, it is said, "By the time of the opening of the Paris Exhibition, of 1867, the business had become very large. The next important stage was the invention of the hotel coupon system; the next, the development of the Harwich route to the continent, in which all the difficult negotiations with the Belgian and German railway officials were

brought to a successful issue by Mr. J. M. Cook after a long struggle; and next, the opening up of the East to the British tourist."

General Notes.

MUNICIPAL ENTERPRISE.—The Government have decided to appoint a joint Committee of the Houses of Lords and Commons to consider the trading enterprises of municipalities, and the following statement was made in the House of Commons on Thursday, 2nd inst.:—Mr. Bartley asked the First Lord of the Treasury whether he would consent to the appointment of a Select Committee of the House to consider the clauses which appeared in so many private Bills this Session authorising municipalities to enter into trading enterprises, and the resolutions of the various Chambers of Commerce on the subject. Mr. Balfour: "In answer to the hon. member I have to say, the important question he refers to is one deserving further investigation, and we think a proper method of investigation would be by a joint committee of the two Houses." Sir J. Lubbock asked whether the Government would take steps to appoint the committee at an early date, and whether the reference would be wide enough to include the whole subject. Mr. Balfour: "We shall proceed at once to appoint the committee; and no doubt the reference will be sufficiently wide to include all the subjects referred to in my hon. friend's question."

ELECTRIC RAILWAYS IN GERMANY.—According to the United States Consul at Hanover, up to the end of the year 1891, the number of cities in the German Empire enjoying the advantages of electric street railways, was three; up to the end of 1892, five; 1893, eleven; 1894, nineteen; 1895, thirty-two; 1896, forty-four; 1897, sixty-one; and on the 1st of September, 1898, no less than sixty-eight. In thirty-five other cities or districts, railways are in course of construction, or finally determined upon. The entire length of electric lines in operation in Germany on September 1st, 1898, was 885 miles, the number of motor cars was 3,190. The length of the new lines in course of construction, or about to be begun, at that date was 677 miles. Most of the large industrial cities in Westphalia and the Rhine Province are connected by a network of electric roads, which serve not only for passengers, but for goods traffic.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MARCH 15.—"Liquid Fuel." By Sir MARCUS SAMUEL. Sir EDWYN S. DAWES, K.C.M.G., will preside.

MARCH 22.—"Electric Traction." By PHILIP DAWSON. Sir FREDERICK BRAMWELL, Bart., D.C.L., F.R.S., will preside.

Mr. WALTER HUNTER's paper on "London's Water Supply," which was announced for this evening will be read after Easter, and Mr. Dawson's paper, which was postponed from February 22nd, will be taken in its place on March 22nd.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

APRIL 27.—"Judicial Reform in Egypt." By Sir JOHN SCOTT, K.C.M.G., D.C.L., Deputy Judge Advocate-General, and late Judicial Adviser to H.H. The Khedive. The LORD CHIEF JUSTICE OF ENGLAND, G.C.M.G., will preside.

It has been found necessary to change the date of this meeting from April 13 (as formerly announced) to April 27.

MAY 11.—"The Revenue System and Administration of Rajputana." By MICHAEL FRANCIS O'DWYER, I.C.S., Settlement Commissioner, Alwar and Bhurtpore.

MAY 25.—"The Port of Calcutta." By Sir CHARLES CECIL STEVENS, K.C.S.I., late Acting Lieutenant-Governor of Bengal.

FOREIGN AND COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

MARCH 21.—"The Commercial Development of Germany." By C. ROZENRAAD, F.S.S., and Fellow of the Institute of Bankers.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

MARCH 14.—The paper announced to be read by Sir WILLIAM BLAKE RICHMOND is unavoidably postponed.

APRIL 18.—"Modern Changes in Taste relating to Domestic Furniture." By GEORGE LOCK.

MAY 2.—"Maiolica." By WILLIAM BURTON.

MAY 30.—"Wrought Iron Signs." By J. STARKIE GARDNER, F.G.S.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

ARCHIBALD SHARP, A.M.Inst.C.E., "Cycle Construction and Design." Four Lectures.

LECTURE IV.—MARCH 13.

Steel, rubber, and pneumatic tyres—Detachable tyres—single-tube tyres—Tubeless tyres—Valves—Inflators—Side-slip—Brakes—Saddles.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 13...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Archibald Sharp, "Cycle Construction and Design." (Lecture IV.)

Imperial Institute, South Kensington, 8½ p.m. Dr. F. S. Zaytoun, "Cape Juby and the Western Sahara."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

Sanitary Institute, 74A, Margaret-street, V Dr. J. Priestley, "Ventilation, Warm Lighting."

TUESDAY, MARCH 14...Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lankester, "Phylogeny of the Mollusca." (Lecture IX) Medical and Chirurgical, 29, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, W., p.m. Discussion on papers by—1. Mr. Milton, "Water-tube Boilers for Engines." 2. and by Sir A. J. Durston, Mr. H. J. Oram, "Recent Trials of the Engines of Warships."

Photographic, 12, Hanover-square, W., p.m. Capt. W. de W. Abney, "Theoretical Considerations in Choosing Colours for Three-colour Printing."

Colonial Inst., Whitehall-rooms, Whitehall, S.W., 8 p.m. Hon. John A. Cockburn, "Australia as a Federal Unit."

Asiatic, 22, Albemarle-street, W., 4 p.m.

WEDNESDAY, MARCH 15...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Sir Marcus Samuel, "Liquid Fuel."

Meteorological, 25, Great George-street, W., 7½ p.m. 1. Mr. F. J. Erodie, "The Probable Deficiency of Rain in 1897 and 1898." 2. H. W. Yorke, "The Climate of Jersey."

Microscopical, 20, Hanover-square, W., p.m. Mr. Lewis Wright, "The Projection Microscope." Archaeological Association, 32, Sackville-street, W., 8 p.m.

Mining and Metallurgy, Geological Institute, Jermyn-street, S.W., 8 p.m. 1. Mr. R. Thomas, "Crushing and Concentration of Lead Ore, Cornwall." 2. John I. Williams, "Charcoal Precipitation from Auriferous Solutions." 3. Mr. Sherard Cowper-Coles, "Notes on the Electro-Deposition of Vanadium."

THURSDAY, MARCH 16...Royal, Burlington-house, W., p.m. Antiquaries, Burlington-house, W., 8½ p.m. Linnean, Burlington-house, W., 8 p.m.

Chemical, Burlington-house, W., 8 p.m. P. H. O. Forster, "Influence of Substitution on Specific Rotation in the Bornylamine Series." Messrs. Thomas Purdie and James C. Watson, "Rotatory Power of Optically Active Ethoxy-propionic Acids Prepared from Lactic Acid."

Society for the Encouragement of Fine Arts, Conduit-street, W., 8 p.m. Mr. E. Doran, "The Diary of a Sarum Worthy of the Twentieth Century."

Sanitary Institute, 74A, Margaret-street, W., p.m. Dr. H. R. Kenwood, "Infectious Diseases and Methods of Disinfection."

Royal Institution, Albemarle-street, W., p.m. Mr. W. Poel, "English Playhouses in the Seventeenth, and Eighteenth Centuries." (Lecture II.)

Historical, 28, Jermyn-street, S.W., 8½ p.m. Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, MARCH 17...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Prof. Gotch, "The Electric Fish of the Nile."

East India Association, Westminster Tavern, S.W., 3¼ p.m. Sir Charles Roe, "Tribes of the Punjab."

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

SATURDAY, MARCH 18...Royal Institution, Albemarle-street, W., 3 p.m. Lord Rayleigh, "Mechanical Properties of Bodies." (Lecture

Journal of the Society of Arts.

No. 2,417. Vol. XLVII.

FRIDAY, MARCH 17, 1899.

Communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

On Monday evening, 13th inst., Mr. ARCHIBALD SHARP, A.M.Inst.C.E., delivered the 7th and last lecture of his course on "Cycle Construction and Design."

On the motion of the CHAIRMAN, a vote of thanks was passed to the lecturer.

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

On Thursday afternoon, March 9, 1899; The Hon. G. OF ONSLOW, G.C.M.G., Under-Secretary of State for India, in the chair.

The paper read was "Leprosy in India," by Mr. A. ACWORTH, C.I.E.

The paper and report of the discussion will be printed in the number of the *Journal* for March 31.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1899 early in the next, and they, therefore, invite members of the Society to forward to the Secretary, on or before the 8th of April, the names of such persons of high distinction as they may think worthy of this honour. The medal was struck in honour of the late Duke of Wellington, and is awarded "distinguished merit in promoting Manufactures, or Commerce," and has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c.

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S.

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S., late Astronomer Royal.

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong (now Lord Armstrong), C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson (now Lord Kelvin), LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin.

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

In 1884, to Captain James Buchanan Eads.

In 1885, to Mr. (afterwards Sir) Henry Doulton.

In 1886, to Samuel Cunliffe Lister (now Lord Masham).

In 1887, to HER MAJESTY THE QUEEN.

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S.

In 1889, to John Percy, LL.D., F.R.S.

In 1890, to William Henry Perkin, F.R.S.

In 1891, to Sir Frederick Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S.

In 1892, to Thomas Alva Edison.

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

In 1894, to Sir Joseph (now Lord) Lister, P.R.S.

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S.

In 1896, to Prof. David Edward Hughes, F.R.S.

In 1897, to George James Symons, F.R.S.

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

Proceedings of the Society.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 15, 1899; SIR EDWYN S. DAWES, K.C.M.G., in the chair.

The following candidates were proposed for election as members of the Society:—

Oppenheimer, Hermann L., 55, Redcross-street, Barbican, E.C.

Sanders, Henry Archibald, Somersall-hall, Chesterfield.

Wernher, Julius Charles, 82, Piccadilly, W.

The following candidates were balloted for and duly elected members of the Society:—

Brooks, Christopher P., New Bedford, Mass., U.S.A.

Butler, Joseph Margerison, 33, Dorset-street, Portman-square, W.

Clare, Harcourt E., Liverpool.

Davies, Dixon Henry, Chesterfield.

Drummond, C. J., St. Bride Foundation, Bride-lane, Fleet-street, E.C.

Fullerton, Major John Davidson, R.E., Brine Baths Hotel, Nantwich, Cheshire.

Lloyd, Edward Honoratus, 5, Crown-office-row, Temple, E.C.

Norton, Robert, Coombe Croft, Norbiton, Surrey.

Radcliffe, F. M., Liverpool.

Ward, Septimus H., Shire-hill, Sheffield.

Writer, N. N., 7, Beverley-road, Anerley, S.E.

The paper read was—

LIQUID FUEL.

BY SIR MARCUS SAMUEL.

The subject of Liquid Fuel, although now coming into great prominence in England, is by no means a novel one. Russian petroleum has been in use for this purpose, both in Russia and America, for very many years. Its advantages, compared with coal, are well known and appreciated, and the sole obstacle to its universal adoption, has been that the supply has been insufficient hitherto to warrant arrangements being made, except in Russia itself, for its use.

In a paper of this kind, it can hardly be inappropriate to touch for a moment upon the nature of petroleum. No experts have yet been able to define how petroleum is, or has been produced, whether it is recuperated by nature as it is drawn off, or whether, as would appear from experience obtained in the Penn-

sylvanian fields, and in a region very far from this, namely, the Langkat territory, the yield decreases, and ceases entirely after a certain time. Where experts disagree, it will be admitted that it is most difficult for an ordinary layman to express an opinion that carries any weight, and, until much greater experience has been obtained, those who handle petroleum must resign themselves to the fact that territories which differ almost as much as individuals do, may yield that whilst on some it is undoubted that the yield ceases after a time, on others it will almost appear that nature recuperates, and that wells which have apparently been exhausted have yielded their treasures of oil again. At least, this has been the experience in many of the Russian territories.

Again, oil would appear to be found in layers, much below one another, the pressure of gas increasing with the depth attained by boring, and it is not an uncommon thing in putting down an oil well to go through strata which might have yielded a fair flow of oil, to cease them off, and then some hundreds of feet deeper, to hit upon a well which has spouted 50 to 60 feet above the derricks, and in spite of all attempts to catch the fountain, a vast escape of oil has taken place.

The surface indications of the existence of oil in a given territory are by no means uniform. In the fields of Baku, nothing so arid and sand is to be seen. In Pennsylvania the oil fields are among the richest pasture lands, whilst in Borneo thick jungle has had to be cleared before boring could be commenced. The two pictures shown illustrate a well in Baku and one in Borneo. The former is a spouting well, and is an apt illustration of an instance I have cited.

The subject is such a large one, that I must not dwell at too great length upon the preliminary stage of formation and production. Yet, had these facts not been very recently brought to my notice, I should not have been either justified, or able, to prepare the paper which it is now my privilege to read.

The incidents that I have just narrated actually occurred in the oil fields which the "Shell" Transport and Trading Company Limited, are developing in Borneo. It was intended, when the exploration of these fields (situated in the Sultanate of Kotei, and under the jurisdiction of the Dutch Government) was undertaken, to explore for oil which, as I have proved of a similar description to that which is found in Sumatra, would have been specially adapted for illuminating purposes, and I must,

frankly state that the discovery of liquid in the enormous quantities in which it has found in these fields was the result of chance than of skill. The very first bored yielded a supply of oil of a character which showed that, with very little treating, it was an ideal fuel. But the mere production of oil is almost its least value and least interesting state. Markets have to be found, in this case almost had to be created, and it is a well-known axiom in business "Nothing sells itself," and the instance is well authenticated of a man who won a fortune, undertaking to stand at the corner of a London-bridge and offer sovereigns for pennies to the first oil finding takers for them. So it is not every commodity which is first brought to market. Prejudices have to be overcome, and means of using treasure have to be shown. It is proved, and in such an article as liquid petroleum not only has transport got to be provided, but special arrangements for storage have to be made, and it was also obvious that, in actual success was to be obtained, liquid petroleum would have to be sold at a price which would enable it to compete with coal. *As to this* should be easy, when the cost of oil in mining for coal is taken into account, together with its transport from the fields to the place it is found to a place of shipment, and the great cost incurred in placing it on board and discharging it, and the space occupied by it in the hold of a ship (this being about 45 feet to a ton of 20 cwt.), and, as this is known and realised, the danger of transport arising from the highly inflammable gases contained in Eastern coals, renders the holds and bunkers far more numerous than the public are at all aware of. It is, of course, impossible to transport oil in bulk in steamers built for ordinary cargo-handise. Special arrangements have to be made by which the cargo is broken up into sections fixed by the regulations of the Suez Canal as not exceeding 400 tons in any one compartment. It may not be out of place here to recount as the pioneer, and even, up to the present, the only exporter of oil in bulk through the Suez Canal, the great difficulties which had to be overcome in starting the transport of oil in bulk. Owing to interested and bitter opposition, almost years elapsed before regulations were framed under which steamers carrying oil in bulk were allowed to pass through the Suez Canal at all, and there was not a single port to which we wished to introduce it, but obstacles, more or less formidable,

had to be surmounted. In almost every case special regulations were devised to control what was looked upon as a very dangerous trade, yet I am happy to say that though the business has been conducted for now over seven years, not a single accident of any kind has happened, either to a ship whilst engaged in carrying oil, or to an installation. The picture now shown gives the internal arrangements of an oil steamer specially constructed to the Canal regulations. The section shows the arrangements made by the construction of coffer-dams fore and aft for isolating the oil against danger from the boilers or furnaces, which, it will be observed, in these ships are placed quite in the after part of the vessel—a practice which it is a pity is not adopted in more steamers, because the risk of accident from the breakage of the shaft is almost non-existent in this form of structure, the lead being a small one, and the shaft being under the constant observation of the engineers, since there is no tunnel. Under the regulations of the Canal Company, pumps are provided which are capable of a minimum discharge of 500 tons of oil per hour, the pumps in the ship shown being capable, in actual practice, of delivering an even larger quantity than this. To show the progress of the business, I may state that the first steamer employed in the business of transporting oil in bulk through the Suez Canal was a vessel of 4,000 tons burden of oil, whilst the largest of those employed now carry 6,500 tons, and we have three steamers in course of construction to carry 9,000 tons of oil each, or 3,000,000 gallons.

We must realise that the conditions in the production and transport of oil are different to those of coal. When once a well is drilled oil flows without any further labour. It is pumped through pipes from the well to the place of shipment, and thence into the ship, and it is discharged in exactly the same manner, not a single human being but the pump-man being visible; and in this connection a very curious incident arose. When the first tank steamer arrived in China, the curiosity of the native labourers was very much aroused when they were told that a steamer bringing something like 1,500,000 gallons of oil would be discharged from the ship without a single labourer being employed, and this is in the space of 48 hours! Some thousands of Chinese gathered along the wharf where the steamer was lying, and to the astonishment of the most intense description was depicted upon their usually phlegmatic

faces. The ship rapidly rose out of the water as the oil was pumped on shore through the pipes, and the manager of the wharf, accosting a Chinaman, asked him what he thought of it. "Well," said the Chinaman, "I can't make it out at all. Nobody pushes; nobody pulls; but the cargo is discharged like mad all the same," and this is, in fact, what would strike an ordinary observer in the handling of liquid fuel in bulk.

The facilities for landing and handling oil necessarily differ very much at various ports. The surroundings, too, of the tanks are essentially different, many being placed amidst scenes of natural beauty, with deep water right up to the walls of the embankment, such as Nagasaki, Japan, a picture of which I now show, where it will be seen Nature admits of the steamer lying next to the wharf, whilst in the next picture I show the installation at Kobe, Japan, where a pier had to be constructed, it being impossible for a steamer to get alongside. The next illustration shows the Port of Madras, where a breakwater of almost a mile in length has been constructed before water sufficiently deep to allow a steamer to get near of the size employed in this trade could be found, and even then, as the picture shows, a contrivance had to be constructed to connect the discharging pipe of the steamer with the breakwater. In spite, however, of these drawbacks, it is found that a steamer can easily discharge into the tanks, placed at one mile distant from the ships, at the rate of fully 200 tons an hour. I should also like to show a picture of the island of Freshwater, where the business for Singapore is conducted. The Government, not understanding how free the business was from danger, would not allow the tanks to be erected on the island of Singapore itself, and compelled us to go to the picturesque spot shown, and, as a final example of the progress of liberal ideas, I show the installation at Bombay, where permission to land the oil was only given some two years ago, and after experience had shown the immunity from danger attending the transport of oil in bulk, and it will be seen that these tanks are placed almost in the middle of the shipping, railway sidings have been taken right up to them, whence oil is pumped into the tank waggons for conveyance all over India. I will show a train of tank waggons, specially constructed for the India service, and these are very interesting, inasmuch as they are the only tank waggons which are entirely welded by electricity, and not a single rivet is employed in

them. This picture shows the bodies of oil waggons ready for shipment. The next shows a wagon completed, as used actually in India, covered by a corrugated iron sheet allowing air to freely circulate round the tank and so protect it from the effects of the sun. To complete the history, I show an up-country station at Ranaghat in India, and show the bullock carts, showing how oil is distributed to the shops at Colombo.

It is necessary to go into these details in order that it may be understood what an enormous future lies before this fuel, even if it is only depended upon its relative cost compared with coal, but when we come to the collateral advantages it enjoys, the benefits of using it as compared with coal, are simply overwhelming.

It is unfortunate that it should be so early that one cannot fail to recognise the fact that the demands for purposes of war must take priority of those of peace, and the first great advantage to vessels of war, especially to torpedo boats, in using liquid fuel, as compared with even the best coal, is the entire absence of smoke arising from its employment. When combustion is complete, not a trace of smoke issues from the funnel of a vessel using it. How important this is to torpedo boats the least initiated can understand, but it is no less so to cruisers, or even to battleships, which, when using liquid fuel, could shadow an enemy's fleet without being detected.

I show, in this connection, a picture of the steamship *Trigonia*. In September 1900 the *Haliotis*, a sister to this steamer, was brought round from her port of construction (Newcastle-on-Tyne, where she was built by Messrs. Armstrong and Company) to the Thames for exhibition purposes, her funnels being fitted with an arrangement for burning liquid fuel. They are, however, available for coal in the ordinary way, if required, it being possible to make the necessary alterations for a change of fuel in a very few hours. From the bunkers, which are so constructed that they can be used for either oil or coal, oil is pumped to a service tank above the boilers, whence it flows by gravity to a distributor at the furnace doors, where, by means of a steam jet, it is pulverised or broken into small particles. The diagrams now shown will illustrate the arrangements made for the utilisation of this system, and I might say that a vast field is open for the ingenuity of engineers in devising other methods for the utilisation of oil—in fact, almost daily discoveries are

de of means by which liquid fuel may be used to greater advantage than any yet discovered, and it would surprise me very much if, with practice, the methods employed do not continually improve. Under the system adopted in this ship, steam is used to spray oil, but this is certainly not the most economical method, and already a system has been found, invented by a Dutchman, called the Kloos System, which entirely dispenses with the use of steam. The diagrams now shown will illustrate this system.

The main point of difference between the burning of coal and liquid fuel is that, while coal remains quietly in its place until it is burnt, liquid fuel would offer too small a surface to the air when lying in a tank to burn with so much heat as is required. It therefore, to be sprayed out in small particles to augment its surface. If, however, the oil is sprayed mechanically, the rush of cold air chills the spray, and many of the small drops reach the funnel before combustion has taken place, thus producing smoke and soot. By heating the air well above the burning temperature of the oil, before it reaches the spray, this is remedied, and combustion takes place freely.

In the heated air system, the oil is forced under about 50 lbs. pressure through a Körting's sprayer into the furnace. In this sprayer the current of oil has to pass a screw thread, which gives a rapid turning motion to it, so that the centrifugal force causes the liquid to fly out in dust. The air is brought by a sliding plate at the back of the furnace, turns along cast-iron ribbed plates which are heated by the flames above it, and meets tangentially the current of fine sprayed-out oil, the air being heated to about 500° Fahr. The hole in the sprayer through which the oil is injected is under 1-16th of an inch in diameter, the liquid must be well filtered, and to assist the centrifugal force in spraying it into fine particles, the oil is heated to about 500° Fahr.

I am well aware that it is alleged, as a drawback to its use in the British Navy, that liquid fuel has, so far, only been produced in Russia and America, but the territories in Borneo under the flag of a nation that has ever been friendly to Great Britain, and is scarcely likely to be hostile, and, at all events, provided ample storage arrangements are made, such a stock of liquid fuel could be provided in our eastern ports as to render the naval authorities practically independent of renewed sup-

plies if, unhappily, hostilities broke out. Neither must the fact be lost sight of that, if oil has been found in the Dutch Indies, there is no reason why it should not be found, too, in territory under British rule. The production in Burma is already of an important character, and, as in most things, we shall see the demand create the supply.

Experiments have demonstrated that the calorific power of oil is almost as two to one compared with Eastern coals. This is in ordinary marine boilers, but in launches the economy in its use is very much greater, and in one craft, used in Hongkong, repeated and carefully checked tests have shown that, whilst the consumption of coal was 7 lbs. per minute, the consumption of oil was only 2 lbs. per minute. The pressure of steam realised by 7 lbs. of coal was from 96 to 105 lbs., whilst that raised by 2 lbs. of oil was sustained at 116 to 120 lbs. The speed realised in the launch under coal had never exceeded 9 knots, whilst under oil a speed of 10½ knots was readily maintained.

It is well known that for locomotives great advantages are experienced in using liquid fuel as compared with coal, and the economy is equivalent to the ratio of 1 ton of oil to 2½ tons of coal, and, in addition, it has been found that, whilst a locomotive burning oil will maintain the same head of speed up the steepest gradients, the same feat cannot be accomplished upon coal, where the mere firing of the boiler with every renewal of fuel serves to damp the furnace, whereas every injection of oil, going into immediate combustion, tends to raise and maintain the speed.

One of the first men in England to recognise the great advantage of using liquid fuel on locomotives was Mr. Holden, the engineer of the Great Eastern Railway Company, on which line, in spite of the cost of liquid fuel compared with coal, most of the express trains are run by that fuel to-day. The diagrams shown illustrate this system, which is the best for this purpose yet invented, and by its means steam is readily obtained upon every description of boiler. The next diagram shows its application to a Lancashire boiler, which form is still a favourite among mill and factory owners, and the adaptation of the Holden system to this type of boiler has been very successful. I believe a great future exists for this fuel in smelting works for metallurgical purposes—the intense heat which it is capable of generating, reducing the most stubborn of ores.

Great economy is effected also in the

stowage of oil compared with coal. We have found, from careful experiment, that the Borneo oil stows in a space of only 38 feet to the ton, and, deductions from the figures which I have furnished, as compared with coal, will show the much longer duration of supply in a given space of liquid fuel than of coal, and the consequent less frequent stoppages for filling tenders, or of transporting to them the respective fuels, since it is manifest that if oil is used, only one ton is to be carried up-country, as against at least two tons and a half of coal. I cannot help thinking what enormous possibilities develop in countries where coal is at famine price, as on the projected line from Cairo to the Cape, through the introduction of liquid fuel.

In this connection, and as showing the great progress that has already been made in the use of liquid fuel, and its widespread application, I show a slide which represents a later express engine of the Great Eastern Railway, designed by Mr. Holden last year. It has drivers 7 feet diameter and cylinders 18½ in. by 26 in., and a boiler with 1,292 square feet of heating surface and a working pressure of 160 lbs. per square inch. The tender, it will be noticed, is of a particularly neat design, and is capable of carrying 2,790 gallons of water, 715 gallons of liquid fuel, and 30 cwt. of coal. It is provided with a water-scoop for replenishing the tank whilst running. The total weights in running order are—engine 49½ tons, and tender 36 tons: total, 85½ tons. The oil firing arrangements embody a number of ingenious details; among them the supply of hot air for combustion from a series of cast-iron heaters placed around the inside of the smoke-box, the air being drawn from the front through the heaters to the burners by the exhausting action of the steam jets used for injecting the oil fuel. The latter is warmed before leaving the tender in a cylindrical heating chamber, through which the exhaust steam from the air-break pump circulates.

The next slide shows the footplate and interior of the cab of one of these engines. The regulation of the oil supply is effected by a neatly designed gear attached to the cover or hood of the ordinary fire-door. These engines have been specially constructed for running the fast Cromer service, on which they have rendered a good account of themselves during last summer.

The slide now shown represents a small four-coupled shunting engine, of the London and North-Western Railway, fired with oil-fuel on

Mr. Holden's system. It carries the oil by the footplate in a long reservoir, from where the burner lifts it by suction. Engines of this type are used in the Liverpool Docks.

Next is an engine of the Metropolitan Railway for service on the Underground in London.

One of the suburban engines of the West of France is shown in the next slide. It is working between Paris (St. Lazare) and Germain.

The succeeding picture shows the Vienna Paris express, with a heavy Golsdorf compound engine in front, burning oil fuel on Holden's patent system. The train is shown standing at St. Anton, just prior to entering the Arlberg tunnel, six miles long. All trains, goods and passenger, passing through the tunnel are fired with oil fuel on Holden's system.

I have now a view of the Coronado express of the Southern California Railway standing at San Diego, with an oil-burning locomotive in front. Oil fuel is now the common fuel in South California, immense deposits being worked at Los Angeles.

The next slide shows a winding plant or mining machinery with portable locomotive type boiler fired with oil. This fuel is adopted here on account of the cost of transport, only one ton of oil being carried instead of two tons of coal.

The last slide shows a traction engine, 40 indicated horse power, for South Africa, running between Umtalla and Salisbury, burning oil fuel. Coal being expensive, and wood scarce, oil fuel has been used here.

Nothing can give a better indication than these slides of the widespread use that liquid fuel has already attained, and it is quite certain that in countries where it can be put down as it can unquestionably now from Borneo to the ports east of the Suez Canal, at prices which will enable it to successfully compete with coal, its use is quite certain, and that in the immediate future.

The advantages of the use of liquid fuel on steamers, however, are even more manifest than in its employment on land. None of those concerned in the actual management of steamers know what trouble and anxiety attend the employment of what is known as the "black element," namely, the stokers. By the use of liquid fuel the services of these men are almost entirely dispensed with, because the fuel flows by gravitation from service tanks placed well above the boilers, direct to the furnaces. The expansion and contraction caused by the frequent opening of the furnace door is

avoided, and the life of a boiler, constantly, greatly prolonged. No ashes are and the strain and distress to firemen of these overboard before commencing watch is entirely saved, and no grit (so in its working to delicate parts of the) is created. I fear it is only a practical who will realise how much this means. anyone who has seen the almost in manner in which the large crew needed torpedo-boat or destroyer are berthed, in consequence of having to stoke the enormous used upon these craft, the fact that the use of liquid fuel the crews of these can be reduced to less than half of now necessary is, in itself, an argument overwhelming that, were this its only stage, it would suffice to compel its introduction into this class of vessel by those in, but, when it is borne in mind that men torpedo craft literally carry their lives in hands, depending solely on the speed of vessel, and not upon her armament, it is that a great step is attained when the carried upon these vessels is reduced. can be carried in spaces which it is impossible to utilise in any other way, and especially in such craft as torpedo-boats, where the of the vessel under water renders the thing of stability a difficult problem. Oil d in the bottom of the steamer, below the -line, would be impervious to shot, and, the system of service tanks patented by Sir scue Flannery, as oil is pumped out of the st-tanks of a steamer, water can readily ken in to replace it, because if the mix- s put into a service tank, and allowed to, water is quickly precipitated to the n, and can be drawn off, the oil remain- ing pumped pure into the second service a whence it flows to the bunkers, and it eadily be conceived how many spaces lost in vessels can be utilised for the ge of oil, allowing a much greater weight mament or quantity of cargo to be carried ace now used for bunker purposes only, or ntirely through being too small or in- sible for the storage of coal. The import- of the new departure has been promptly nised by Lloyds, who have issued regula- allowing liquid fuel, having a flash point er 200° Fahr. to be carried in steamers' st tanks, and this will greatly facilitate eral use. e much longer time that a vessel ped with liquid fuel can keep at sea is a factor which must not be overlooked,

and, provided relays of supplies are furnished at ports not too far apart, the carrying capacity of an ordinary merchantman is increased by some hundreds of tons, dependent necessarily on the size of the vessel, whilst the saving in time in taking in oil instead of coal as bunkers can be best estimated when I state that oil can easily be put on board at the rate of 300 tons per hour, and this without the slightest dirt—a great characteristic of the Borneo oil being too that it is almost odourless.

The experimental stage in the burning of liquid fuel, as stated at the commencement of this paper, has long since been passed. The uses for it in Russia itself are innumerable, and the latest statistics show that no less than 7,000,000 tons per annum are consumed in Russia for liquid fuel alone. Lately it has been largely adapted for naval purposes as well, whilst for many years the steamers navigating the Caspian Sea have used it exclusively. There are no less than eight steamers at present engaged in the Eastern trade which are fitted for it, and the results attained have answered the expectations of their owners beyond their most sanguine anticipations, whilst large numbers of vessels are under construction expressly for the use of liquid fuel, and a great number of steamers hitherto burning coal are also being altered. In the Far East tanks have been erected at ports ranging from Yokohama to Suez, including all the Indian ports, whilst cargoes of the Borneo oil have also been landed at the principal ports, and 4,000 tons is on passage to London. Under the advantages which I have enumerated it will be understood that it is rapidly going into general consumption. In Europe the Russian, the Italian, and the German navies have partially adopted it, and it will be a curious circumstance if, with the great engineering skill available in the British navy, our naval authorities should not also see their way to use it to advantage in the immediate future.

DISCUSSION.

Admiral SELWYN said he had been trying experiments for many years with regard to the use of fuel for naval purposes, and was now prepared to prove that fluid—not liquid—fuel was the real solution of the question; he said fluid, because he considered liquid fuel alone was quite obsolete; they must use gaseous fuel very largely, and while all gases were fluid, many which would be used in future were not naturally liquid. Principal amongst these was the nitrogen of

the atmosphere as well as its oxygen, and the hydrogen of steam as well as its oxygen. All these were capable of exothermal action in a very high degree, under certain circumstances as had been proved by Mendeleeff and Professor Dewar. The result of their experiments was to show that when these gases were raised to the temperature of the electric arc, an enormous amount of heat was given out by their combination. By his own experiments in 1886-87, he had shown how the efficiency of the British Navy could be trebled, and the important point was that in our own country we had a more reliable source of heavy oil—not petroleum—than existed either in the United States or Asiatic Russia, and it could be produced at a much lower price, considering its evaporative value, than coal. He congratulated Sir M. Samuel on his paper, and hoped it would prove useful; but he would remind them that whenever a ship got run aground, some of the fuel had to be thrown overboard, and then they wanted it to sink to the bottom, not float round the ship. There were also dangers of fire on board ship, any increase in which would lead to higher rates of insurance. He had come to the conclusion, from his experience, that light oils, which only evaporated 17 lbs. of water per lb. of fuel, ought not to be used for naval purposes, whilst with the heavier oils more than three times that amount of duty could be obtained. This had been done since 1865, and with this heavy oil there was no danger of enhancing the rates of insurance. By burning the hydrogen in the steam you added 7 units of heat to that obtained from the oil itself, and if you could get the nitrogen to burn you added another 22 units, and, going on in that way, you would reach a point where you would be able to drive a large cruiser round the earth in 40 days, and she would still have enough fuel on board to take her across to America and back. He hoped, therefore, that the chemical idea would not be dropped; and also that the question of utilising our own shales would be borne in mind. There was an enormous bed running from Portland right across to France, and enough fuel could be obtained from that by convict labour at Portland as would keep the whole navy going. There was another seam, 600 feet thick, right across from the Humber to the Wash, where it split, and one portion went into Northumberland, where he was told it had been found 40 feet thick, and another portion went to Hanover. Some of these shales, when properly treated, would yield from 60 to 120 gallons to the ton of heavy oil.

Dr. DVORKOVITZ said when he was in Baku, in 1878, he found the same prejudice against the use of petroleum as still existed in many parts of Europe. At that time a small portion of the crude oil was used for burning, and a still smaller portion for lubricating, and the remainder had to be let run to waste. No one, at that time, would dream of taking it in pipes for the purposes of fuel. Russia, however, had set

the example, and last year she used 7,000,000 tons for fuel; in 1878, only half a million tons were produced. Now all the passenger steamers on the Black and the Caspian used oil. He introduced it in the neighbourhood of Moscow in 1884, on his return from Baku, but with difficulty. He asked a friend of his, who had a large manufactory, to try it, but his engineers were consulted, they were afraid the whole works would explode. The same factory used 5,000,000 poods a year. It was a mistake to consider the question of liquid fuel simply from the point of view of its calorific power, because it possessed enormous advantages in other respects over coal, particularly in the matter of storage, saving of labour in handling, cleanliness, and storage on board ship. Sir Marcus Samuel had referred to the importance of the matter to the British Navy, and, no doubt, the British Government would have to pay attention to seeing what was being done by the French and other navies. But, after all, he was a man of peace, and he looked more to the use of liquid fuel for passenger steamers. By its means, a saving of time to the extent of one-fourth might be effected, and it could go to New York in four days instead of five, which was worth doing. With regard to shale oil, he believed the Scotch shale producers worked very hard and did not produce any dividend by producing a burning oil for which they charged a high price, which as would never be paid for fuel. There was no doubt the Shell Company had got one of the largest quantities in the world, and, seeing the energy with which it was worked, there was no doubt that liquid fuel would soon be in general use, and he thought Sir M. Samuel had done a public benefit by bringing the matter forward.

Mr. W. F. LANE said he had been connected with the petroleum trade for many years, and was naturally much interested in this paper. Practical men in business could not be expected to keep abreast of the progress of science for one reason, because they had to go their way as they went on. The production, manufacture, and merchandising of petroleum presented many varied questions that he could not admit to his skill and energy with which Sir M. Samuel had to deal with a problem which was by no means so simple as it looked. The first requisite to the introduction of liquid fuel was that the consumer should be assured a constant supply, as required, at a reasonable price, but the vast organisation which the Shell Company had created, which embraced storage at every port in the East from Aden to Japan, formed a sufficient guarantee that the supply would be equal to the demand. They had been very fortunate in discovering a supply in Borneo, which was unique in character, and seemed to be ample for the wants of the East beyond that there was a vast activity going on in many other directions, and the comprehensive organisation of the company would provide a supply being forthcoming wherever it was required.

F. W. FLETCHER said as he had had some experience in the use of petroleum furnaces for melting cast-iron and as muffle furnaces, he should like to know what were the advantages and disadvantages of the one he used. He considered petroleum furnaces useful for melting alloys of the precious metals, especially those containing silver and copper, as there was considerably less oxide formed during the process, and these oxides were the chief cause of defects in castings and unworkable metal. One great advantage in this class of furnace was that you could regulate the heat of your furnace to something near the melting-point of the metals you wished to melt, before putting in the pot containing those metals, so that the process of melting commenced almost immediately, thereby saving a considerable amount of time, and at the same time preventing, to a large extent, the oxidation of the metals, which occurred when a muffle furnace was used and one had to put cold fuel into the pot; though he considered the absence of noxious gases in the petroleum furnace one of its great advantages. A furnace that was brought to his notice about 1878 was one in which crude petroleum was used in conjunction with a steam blast. It worked splendidly at times, but occasionally the steam injector-pipes got stopped up and caused considerable trouble, and the noise was so great that the men who worked it seemed afraid of it. A different kind of petroleum ejector was brought to his notice about four or five years ago, in which the force of the steam from the mains (which averages 45 lbs. per square inch) was used to cause a pressure behind the petroleum, and so forced it through the small ejector-pipes of the burner. The reservoir consisted of a cylindrical tank, in the top of which was a pipe connected to the water-supply, and passed very nearly to the bottom of the tank. Another tube passed from the top of the tank to the burner. The tank was then filled with ordinary paraffin oil, and when required the steam was turned on, and the supply of oil was continuous; but still the great difficulty was the clogging of the small holes of the burner, which had to be continually cleared with a piece of wire. This would be a very useful arrangement for a muffle furnace, especially if the defects mentioned were rectified. Another furnace that he had used for small experimental work, was one in which kerosene was used with an air blast. This might appear at first sight a very dangerous affair; but if a steam vapouriser was used it was perfectly safe. For melting and certain porcelain work it was invaluable, as the open flame without a muffle could be used without gassing the work, as it is called; and without altering the colour, as was frequently the case when coke or gas was used, and there was a slight draught in the muffle. The temperature attainable by these furnaces was far above the melting point of gold, and therefore could be used for all kinds of melting and muffle work. While speaking of furnaces for small work, he might mention a material which he had used for making or lining small

furnaces with very good results. It was a certain kind of asbestos, termed "asbestic;" it was far preferable to fire-clay or the baked clay of which muffles and small furnaces were generally made. He added about 10 per cent. of good plaster to it to make it bind well, and a larger proportion for the outside, or when a smooth surface was required. It could be easily packed into an iron case, or even a wooden one, being a good non-conductor of heat, and could be built up to any shape required, either for a muffle or an open furnace, and stood a high temperature remarkably well. The asbestos it contained gave a rough surface to the interior of the furnace, which helped to break up the flame as it passed round the pot or muffle.

Mr. LOWICK said some years ago some experiments were made with the burner that was used to take the *Baku Standard* across to America, while on the other side of the ship there was an ordinary marine boiler; the boiler using oil had the two wing furnaces bricked up, and only the centre one was used. After both boilers had been running some time, the steam was turned off from the one using coal, and the whole of the work was thrown on the one using oil. For the first minute or two the pressure fell, but only a few pounds, and after that it kept the same machinery running as well as the other had done, and that was continued for about a quarter of an hour. The other boiler had three furnaces and a forced draught.

Mr. R. TRAILL said the firm in which he was engaged had been experimenting for many years to find out the best form of burner and furnace for liquid fuel. In the long run, they found a burner which did very well, and had since fitted up a number of steamers for the Caspian and Black Sea, and other parts of the world. He thought Admiral Selwyn, in speaking of the chemical action of gaseous fuels, had hardly put the matter fairly. No one had yet told them the actual value of liquid fuel; the calorific value of the Borneo oil was 24,000 units, which, as compared with 15,000 for the best Welsh coal, gave an advantage of about 30 per cent., but beyond that, in the burning of liquid fuel the combustion was so perfect that the practical effect on the evaporation of water, compared to coal, was as two to one. Under ordinary conditions, with a marine boiler, 1 lb. of oil would evaporate 15 lbs. to 16 lbs. of water, whilst with the best Welsh coal the result was about 8 lbs. He had recently had to make a list of the advantage of liquid fuel, the oil chiefly experimented with being one obtained from Borneo, which could be used in the crude state as it came from the wells, and which was far superior to shale oil for the evaporation of water. Amongst the advantages were the absence of acids or residues, which saved a great deal of time and work in cleaning and scouring the tubes, and a great saving of labour in handling on

board ship; no coal trimmers were required. Then there was a saving of room, thus adding to the carrying capacity of the ship, and the oil could be carried in places where coal could not, for instance, where water ballast was carried. The wear and tear of the boilers was reduced to a minimum, owing to the absolute uniformity of temperature in the furnace. Steam could be slightly raised by a small number of burners, and in going through the Suez Canal, or when steaming slowly, the blowing off of steam might be avoided in the same manner. The consumption of fuel could be regulated to a nicety. The only thing requisite to enable shipowners to use it in preference to coal, was the certainty of a sufficient supply at a moderate price. The necessary alteration would involve but a very small expenditure.

Mr. ROBERT BRUCE said he had not the slightest doubt there was a great deal to be gained by the use of liquid fuel; but he regretted that no proper comparison had been drawn between the results obtained by it and those got from a modern marine boiler. They had been told that an ordinary boiler evaporated 8 lbs. of water per lb. of coal, but a great deal more than that could be done. There were steamers running now which were developing an indicated horsepower with $1\frac{1}{2}$ lb. of coal. He knew Mr. Kloss, of Amsterdam, and that he had obtained very good results; but he was improving all the arrangements continually, and no doubt in future he would effect a still greater economy. In working the oil jets a considerable amount of steam was used, which meant coal or other fuel to generate it. What was required was an increased supply of air, so that the combustion of the fuel would be more complete than it was with the steam-jet. There were many points in the paper which could be much further elucidated if time allowed; and he hoped the comparisons made between liquid fuel and coal would be received with some amount of caution.

Admiral SELWYN said, in reply to a remark by a previous speaker, that so long as the Scotch shale companies tried to compete with Nature in the formation of light oils, it was not very likely they would be successful, but when they gave that up and made heavy oil, they paid dividends. During his 33 years experiments, he had only used old marine boilers or Cornish boilers, but every pound of oil he used was carefully measured, and so was the water actually evaporated. He evaporated 22 lbs. of water with an old marine boiler, and with a Cornish boiler, 48 lbs. The common theory was that you could not get more heat out of the hydrogen in the steam than you gave to make it into steam, but this was absurd. When you burned hydrogen, you did it at 3,000°, for at a lower temperature it would not burn. Messrs. Johnson and Matthey, whom he had taught how to use liquid fuel, now melted platinum like lead, in large crucibles containing 100 lbs.

The CHAIRMAN said, on the whole the discussion

went to support what they had heard in the about the great value of liquid fuel. He was sufficiently scientific to appreciate all A. Selwyn's remarks, but they were very valuable and particularly his reference to the possibility of utilising our own stores of shale. They were indebted to Dr. Dvorcovitz for his information to what was been done in Russia, where they knew liquid fuel had been used for a long time. Some thirty-three years ago, when travelling in Persia, he heard a great deal of what was done on the Caspian, and came home, as a friend told him, with oil on the brain. Mr. Bethell, who had extensive works at the Docks for creosoting timber, took down there and showed him a tank with the oil from the creosote works, where a man simply put a tap and the oil ran through a nozzle, and a steam distributed it over a mass of incandescence and so kept a continuous heat. He thought the difficulty was solved, and expected to see in a short time half the steamers running with liquid fuel instead of coal. Next time he saw Mr. Bethell, however, he told him that coal had got much cheaper, and he had discontinued the use of oil. He noticed a good number of shipowners present, but they had maintained a judicious silence, which was perhaps partly explained by Mr. Lane. He said it was simply a question of £ s. d., and if shipowners could see their way to make an extra 1 or 2 per cent., and could feel certain that liquid fuel would be found at the various ports which they called, and that they could run 300 miles on board in an hour without dirtying their ships, and carry more cargo, and so on, it would not be long before liquid fuel was adopted. At present there was a good deal of hesitation; they were not quite certain that the supply would be sufficient and permanent. They were indebted to Mr. Traill, who represented the Wallsend Slipway and Engineering Company, for the information he had given as the result of very careful experiments. He would ask Sir Marcus Samuel to inform the meeting as to the supply of oil available.

Sir MARCUS SAMUEL, in reply, said he was a little alarmed when Admiral Selwyn said the fuel advocated was better than the underwriters' position than liquid fuel. Probably he did not know that the London underwriting world was largely represented that evening, and he might have caused grave injury to the company which he represented. However, he felt that those gentlemen had such a sense that they would never think of putting up with premiums on ships burning liquid fuel. Although they could not say they were charged such low prices as they ought, still the Shell Line steamers were placed almost on a level with mail steamers, and he present he did not know that they had much to complain of, though in the beginning prohibitive rates were asked. The Chairman was a man of practical common sense, and he would ask him whether the body of gentlemen as the directors of the Shell

would invest something like two and a-half sterling in a "will-o'-the-wisp" undertaking? Production in their field was already very large, would stake his reputation that, to the extent of millions of tons, a year at any rate, the field alone could furnish liquid fuel for the world. He was anxious that this should be generally well known. The field in numerous places an area of 60 miles had been tried, and the same production of oil had been found, and, therefore, it would be forthcoming to meet any probable demand. Still, oil production was, in a sense, a will-o'-the-wisp. Whilst some few men had made millions out of it, it had been the cause of ruin to innumerable explorers. From the days when Sir Walter Raleigh wrote "The Golden Butterfly" to the present, it had been men who found oil only to lose it.

But the finding of the oil was the least part of the work; it was the enormous expense and difficulty of organising the means of distribution which was generally the stumbling block. The company he had mentioned opened their arms to everybody; they did not have a monopoly. All supplies would be available, and the company were ready and willing to provide all means of transport and distribution. It was recently undertaken the distribution of the oil from the vast fields of the Moera Emin in Turkey, who had a property quite as rich as that owned by the Shell Company. It was practically controlled by the Standard Oil Company of America, and the Dutch Government interfered, and it was now being sold and would be managed by the Shell Company, to whom the prejudices of the Dutch Government did not extend. There was, therefore, no assurance for the commercial world that all the oil required would certainly be produced. Roumania is now producing immense quantities, and during the last month proposals had been made for laying a pipeline from the fields to Castenji, so that immense quantities at a reasonable price were assured. It was of the greatest interest to the world in general, and the Shell Company in particular, that supplies of oil should be found, and there were evidences appearing of new oil fields hitherto unknown. Galicia and Roumania were almost unexplored; they were rich in heavy oils. He was very pleased to say that the late Mr. Armstrong were taking an interest in the question; they had requested the company to supply them with a large supply of oils, with which they intended making exhaustive experiments, contented on the success they had already attained. No one who knew that firm, it was almost a foregone conclusion of success when they took up anything. The Borneo oil was absolutely limpid and contained nothing whatever, so that it was impossible it could be used in the tubes. The difficulty was, it was so light that it when spread by the steam jet it dispersed too quickly, but that would be obviated by the use of Mr. Kloos's plan appeared to offer a solution; anyhow, all these questions of detail could only be solved by men of science.

The CHAIRMAN then proposed a vote of thanks to Sir M. Samuel, which was carried unanimously; and the meeting adjourned.

Miscellaneous.

COMMERCIAL EDUCATION.

The Special Sub-Committee of the Technical Education Board of the London County Council have reported to the Board, and the Report has been published. Among other points dealt with in the Report the following may be specially mentioned:—Interest of London in the question—different views of commercial education—its function—the kind of education that is needed—principal points in which our present systems of education can be improved so as to give a better training for commercial life. The following are some of the recommendations of the Committee which have been adopted, as summing up what appear to them to be the results of their inquiry:—

That further and better provision for commercial education is urgently required in London; and that it should be the object of the Technical Education Board, so far as its resources permit, and so far as is consistent with due regard to other claims, to assist in supplying this need.

That the commercial education required is of several distinct grades, and must be adapted to the different needs of many distinct groups.

That, to meet the needs of those who enter business offices about the age of 14, day continuation schools are required, which should give a two years' course of training specially adapted for commercial life; and that some of the Board's junior county scholarships should be tenable at such schools.

That it is desirable that there should be in many of the public secondary day schools in London of the second grade departments devoting themselves, primarily and avowedly, to the preparation for commercial life of boys who will leave school at 16; that in such departments, while a good general education should be given, special attention should be devoted to modern languages, in such a way as to turn out pupils able to speak and correspond fluently in at least two modern languages; to the teaching of arithmetic, so as to secure perfect facility in the use of the metric system; and to ensuring a good general acquaintance with the commercial geography of foreign countries.

That negotiations be entered into with a view to the development of such a department in one or more of the existing public secondary schools of the second grade.

That it is desirable that there should be provided in London in at least one public secondary day school of the first grade a department devoting itself primarily and avowedly to the preparation for business life of boys leaving school at 18 or 19; that the curriculum of such department should not lead up to a classical of mathematical career at the Universities, but should qualify its pupils either to enter the higher ranks of commercial life or to pursue an advanced course of study in the economic and commercial faculty of the new London University, or in other institutions of higher commercial education.

That negotiations be entered into with a view to the development of such a department in one or more of the existing public secondary schools of the first grade.

That it is desirable that a certain number of intermediate county scholars should hold their scholarships in the commercial departments of second grade and first grade schools, when such departments have been established.

That it is desirable that full and express recognition should be given to higher commercial education in the re-organisation of London University; and that it be referred to the special Sub-Committee of the Board, dealing with the University, to consider whether it would not be wise to urge upon the Commissioners the establishment, from the first, of a separate faculty of economic and commercial science; the provision of endowed professorships in the various subjects of higher commercial education; and such arrangements as will facilitate and encourage those designed for or engaged in the higher ranks of business to take advantage of university teaching.

That it is desirable that a certain number of senior county scholars should go through a university course in subjects of higher commercial education; and that, in addition, travelling scholarships be offered to enable teachers of some experience to study in higher commercial institutions abroad, in order to qualify themselves as teachers of commercial subjects.

The other recommendations deal with the best mode of carrying out the recommendations.

The Appendixes to the Report are:—1. Evidence; 2. Report of Mr. Fishbourne's Interviews with Employers, containing an expression of their views on the subject of Commercial Education; 3. Information respecting Foreign Commercial Schools; 4. Select Bibliography of works relating to Commercial Education; 5. Information supplied by Head-masters and Principals of Public Educational Institutions on the subject of the existing provision for Commercial Education in London.

JUTE AND HEMP MILLS IN INDIA.

According to information received through the India Office, the *Board of Trade Journal* says that there were in India, excluding one jute mill

closed early in the year owing to damage by quake, 33 mills working jute and one mill ing hemp at the end of 1897-98, and employing daily average number of 95,930 persons, 162,247 men, 17,000 women, 5,740 young persons, 10,853 children. The mills contained 13,615 and 274,907 spindles. The nominal capital of the mills as are worked by joint stock companies stated in the returns at a little over Rx. 4,600,000 but the figures are not complete, some of them (privately owned) having furnished no returns of capital. Probably about Rx. 250,000 or Rx. 3,000,000 may be added to the total on account of these.

All but two of the mills are in Bengal, most of them in the vicinity of Calcutta, and one in the settlement of Chandernagore. All of them are owned and worked by joint stock companies, the Alipore Jail Jute Mill, which belongs to Government, and the Hastings Jute Mill at Rishra, which is privately owned. Of the two not in Bengal, the small one is at Vizagapatam (this being the mill which works hemp), and the other at Cawnpore. Both of these are privately owned.

The progress of the industry during the last few years is illustrated by the increase shown in the figures below in the number of mills, looms, spindles and persons employed. It will be observed that while the number of mills has largely increased during this period, their working capacity has been more largely augmented. In the last two years there has been a marked addition to the number of mills and to their working capacity.

Year.	Mills.	Looms.	Spindles.	Persons employed.
1888-89.....	26	7,819	152,667	22,000
1889-90.....	27	8,104	158,326	23,000
1890-91.....	27	8,204	164,245	23,000
1891-92.....	27	8,605	174,156	23,000
1892-93.....	27	8,976	181,172	23,000
1893-94.....	28	9,590	192,688	23,000
1894-95.....	29	10,048	201,217	23,000
1895-96.....	29	10,579	216,139	23,000
1896-97.....	32	12,784	258,154	23,000
1897-98.....	35	13,615	274,907	23,000

JEWES IN PALESTINE.

The United States Consul at Beirut, in an interesting report which he has recently addressed to the Government, says that in view of the impetus given to the Zionist movement by the Second Zionist Congress held at Basle in September last, and also in view of the Palestine journey of the German Emperor, the status of Jews in Palestine becomes a matter of general interest. Out of a total population in Palestine of some 200,000 souls, about 40,000 are Jews, against 14,000 twenty years ago. In Jerusalem there are 22,000 Jews, half of whom have immigrated from Europe and America, and are called Aschkenazi.

ish them from the Oriental Israelites, the lists. Nine hundred and sixty families, ing about 5,000 souls, inhabit the 22 Jewish in Palestine, which have been founded and ed by Europeans, ten by Baron Edmond de hild, representing the Alliance Israelite Uni- d, the rest by the Jewish Colonisation Associa- d by the Odessa Company. The idea of ng in Palestine homeless Jews scattered all e globe, was championed in the forties, but d different success. In the eighties, however, migration of Jews into Palestine assumed ant proportions. Of the 22 present colonies the Memorial" is the largest, supporting more 00 souls. It boasts a school with five teachers, gogue, &c., and 4,000 acres of land under tion, on which are grown fruit (chiefly grapes) ulberry trees, the rearing of silk worms being a ; industry. The "First to Zion" is another ant colony owning 2,000 acres of land. Some wo-storied stone dwelling-houses greet the eye approaching stranger; also a schoolhouse with ew library, a synagogue, and a hospital. One e five hundred thousand vines, and 25,000 l, orange, and mulberry trees, belong to this e, which also possesses famous wine cellars. e Hope of Israel," a mile below Yafa, in the i of Sharon, is, perhaps, best known for its tural school, in which one hundred or more are taught gardening. Recently, a high school ish girls was established in Yafa. The "Head e Stone" amid the hills beyond Tiberias, with capped Hermon in the background, is another rous Jewish colony in Palestine. Being near ource of the Jordan, water is plentiful, and its on high up above the level of Lake Gennesareth s fair climatic conditions. In the "Door of e" dairy farming is profitably followed, and ments made in tea planting. This colony is o have 1,000,000 vines. The Consul adds e entirely irrespective of whether or not the ts will succeed in awakening in the Jewish e a national spirit, and forming a Judean rchry or republic, with its Parliament in ulem and its representation in foreign capitals, resent agitation makes for the development of a ty which is but a shadow of its former self, and h will generously respond to modern influences. Sultan seems quite disposed to grant railway, ur, and other franchises, and it is possible that ew Jewish Colonial Bank, the organisation of h was decided upon in Basle, will be permitted e certain guarantees to play an important part industrial advancement and growth of Palestine. b movement is furthermore bringing out new ies in the Jews residing in Palestine. The ul is of opinion that the prospects are brighter o than ever for the Jews in Palestine and for ne itself. European influence has obtained a old in the country, and the tide of modern ideas ot be long resisted.

CALABRIAN BERGAMOT.

It will be interesting to English perfumers to note that great efforts are being made to secure the purity of the essence of bergamot, which is largely exported from Calabria, and forms the basis of many principal perfumes. According to Consul Neville-Rolfe, the crucial test is the proportion of a substance called *Acetato di limiale*, which is the ingredient which gives the odour to the essence. The essence has been frequently adulterated with lemon juice, thereby, of course, diminishing the proportion of the essential ingredient in the fluid put upon the market. The Chamber of Commerce of Reggio delegated the examination of samples to the Agricultural School of Palermo, and asked for information on the two points—first, whether they could suggest a method for discovering adulteration; and secondly, whether the perfume of the essence of bergamot arose exclusively from the limiale contained in it. The replies obtained were unsatisfactory, as the tests proposed, such as the polarisation of light, are not sufficiently practical for the use of ordinary people, and are only suitable for a scientific man in a specially-fitted laboratory. In August, 1897, a law was passed by the Italian Parliament against the adulteration of essences, but as it includes shumac and other substances, it will be inoperative as to bergamot, on account of the present insufficiency of chemical methods to detect adulteration, and thus to set the law in motion. The export of bergamot from the province in 1896 was 180,835 kilogrammes (398,000 pounds avoirdupois) at about 6s. 1d. per pound. Now, this is a low price, the price in 1891 having been 11s. 7d.; and, taking the average price of the last 10 years, it appears to have reached 8s. Essence of lemon brings 4s. 9d. and essence of orange about the same. It will be seen from this that until the adulteration of bergamot with lemon juice can be detected, there is great temptation to increase the quantity of the more expensive essence by the addition of the cheaper one. It is strange, says the Consul, that the attention of the perfumery trade should never have been directed to South Italy. The flowers of the orange and lemon trees, so carefully collected in the South of France, are allowed in South Italy to rot upon the ground, and might be had in any quantity for the asking. Roses and many other scented flowers grow there in wonderful profusion. Bergamot, which is the active ingredient of many scents, is to be had in plenty, and it looks as if there were a good opening for perfumery works. The soapmakers alone would be large customers.

Obituary.

SIR DOUGLAS GALTON, K.C.B., D.C.L., F.R.S.
—Members of the Society of Arts will have received with deep regret the news of the death of Sir Douglas Galton, which took place on Friday, the 10th inst.,

at his house, No. 12, Chester-street. The fatal illness commenced on the evening of February 13, when Sir Douglas was seized with a sharp pain in the right ear, which afterwards affected the arm and hand, and caused the most acute suffering. It was evident to his medical advisers that Sir Douglas' illness was due to a serious attack of blood-poisoning. For many days, however, genuine hope of his recovery was entertained, as he was enabled to take sufficient nourishment to arrest the effects of the poison. But, despite the devoted nursing which was given to him and the sustenance received, other symptoms set in, and Sir Douglas endured acute agony from phlebitis of the legs. For the last ten days of his illness, the greatest anxiety was felt by Lady Galton and all the members of her family, as they feared he would scarcely be able to survive so much suffering. Yet they did not abandon all hope until Wednesday, March 8, when it was apparent to all that the beginning of the end had set in; and on Friday, March 10, Sir Douglas Galton passed peacefully away. In him the Society of Arts loses one of its oldest, most valued, and most energetic members. He joined the Society in 1856, very soon began to take an active interest in its work, and continued in intimate association with it until a few weeks before his death. In 1870 he became a member of the Council, and from that year up to the present he has been almost continuously upon it, indeed he acted either as a member of Council or a Vice-President in every year from 1870 to the present, except in 1877 and 1882. He held office as Chairman of Council in 1886 and 1887.

Born in 1822, he went from Rugby to the Royal Military Academy at the age of 15; and when he obtained his commission in the Royal Engineers he passed the highest examination on record, taking the first prize in every subject. Although a soldier, his career was almost entirely a civil one, indeed he never attained a higher rank in the army than that of captain. In 1847, he acted as Secretary to the Commission that investigated the application of iron to railway structures, and soon afterwards became an Inspector of Railways and Secretary of the Railway Department of the Board of Trade. This position he resigned in 1860, but his knowledge of railway matters led to his still carrying out a good deal of important work in connection with railways. Perhaps the most important of these was the series of experiments for testing automatic brakes, carried out in 1878 and 1879. In 1860 he was appointed Assistant-Inspector-General of Fortifications, and two years later he became Under-Secretary of State for War. After his retirement from this post he became Director of Works and Public Buildings in Her Majesty's Office of Works, an appointment which he held until 1875.

To the general public he was best known as an eminent sanitarian. For the greater part of his life he devoted himself to the investigation of sanitary questions, and of late years these attracted his atten-

tion almost to the exclusion of other matters. He was one of the referees when the Metropolitan Drainage Scheme was under consideration in 1855, and after the Crimean War he took part in the preparation of a report on military sanitation. It can certainly be said with truth that in recent years no movement of any importance for the improvement of public hygiene occurred in which Sir Douglas did not take an active share. He was a leading member of the various sanitary institutions: he took a prominent part in the Health Exhibition of 1884, which was a prime mover in the International Congress of Hygiene held in London in 1891; and was always ready to devote his time and trouble to any project which seemed to hold out a prospect of benefit to public health. Sir Douglas Galton took the deepest interest in methods to promote the care and substitution of education of defective brain power, and it is due to this that he assisted in founding the Child Welfare Society, of which he was elected Chairman, in 1887. Egerton of Tatton, being President. Dr. F. Warner and Dr. G. E. Shuttleworth were among the members of the Council. He was long and closely associated with the British Association, acting as one of its general secretaries for twenty-five years, and it was only in 1895 that he gave up that office to become President of the Association. He was elected a Fellow of the Royal Society in 1863, and an honorary member of the Institution of Civil Engineers in 1850. He is D.C.L. of Oxford, and an LL.D. of several universities. He was made a C.B. in 1865, and a K.C.B. in 1887.

As above-stated, and as, indeed, is well known by most of the members, his association with the Society of Arts was of the closest and most intimate character. Besides taking a very large share in the general management of the institution, as a regular attendant at the meetings of Council, he contributed largely to its proceedings. His first paper, read in 1868, was "Ventilating Stoves for Military Buildings;" his next, in 1890, on the "Sliding Railway." Between these two dates he read papers on "Economy of Fuel," "Sanitary Progress in India," "Tramways," "Sanitary Heating," "Economy in Sanitation," "Metropolitan Sewage," "Mechanical Motors," and "The Sanitary Functions of County Councils." He also, as Chairman of the Council, delivered the opening address at the Sessions of 1886-7 and 1887-8. He took part in the proceedings of the Conferences on Public Health, Domestic Economy, Water Supply, and Canals, and on very many occasions presided over the Society's meetings.

LORD HERSCHELL, G.C.B.—The Society of Arts has lost a distinguished member by the sudden death of Lord Herschell at Washington on March 1st. Lord Herschell took part in the discussions of the Society and presided at the meeting of the Indian Section on January 28th, 1897, when Sir William Lee-Williams read his paper on the "Moral Advance of the Empire."

during the Reign of Queen Victoria." At the same time he specially referred in his remarks in connection with the administration of justice in India. Herschell was born 2nd November, 1837. He was Licitor-General (as Sir Farrer Herschell) from 1885, and he twice held the office of Lord Mayor. He was Chairman of the Governors of the Royal Institute, Chancellor of the University of London, and Captain of Deal Castle. The particulars of Herschell's distinguished career have been frequently related in the newspapers, that it is not necessary to repeat them here.

REW D. CHADWICK, F.C.A.—Mr. Andrew Chadwick, auditor of the Society, died suddenly at Deal on 28th February last. Mr. Chadwick was several years associated with his father, the late Mr. Oldfield Chadwick, in the auditing of the Society's accounts, and on his father's death, in November, 1897, he succeeded him in the office of Auditor. He had been a life member of the Society since 1890.

General Notes.

PHILADELPHIA COMMERCIAL EXHIBITION.—The Department of Science and Art has received from the Foreign Office, a communication from the Director of the Commercial Museum, Philadelphia, calling attention to a Universal Commercial Exposition to be held there, under its auspices, during the autumn of the present year. The building is being erected for the purpose of the exhibition a series of buildings, in which will be displayed such American manufactures as are most representative, and best adapted to foreign requirements, but it is intended also to accept as exhibits articles from European manufacturers, in order to afford an opportunity for a thorough comparative study of the world's industries. The Congress will be presided over by the President of the United States at the opening Session on September 10th, and all nations will have an opportunity of being represented, and having a voice and influence in its deliberations, through duly accredited delegates sent by the various Governments and commercial organisations.

DÜSSELDORF INDUSTRIAL EXHIBITION, 1902.—Information has been received at the Foreign Office that there will be held at Düsseldorf, in 1902, a large exhibition which is now being organised by the North-West Group of German Iron and Steel Industrialists," and by the "Society of German Iron-works." It will represent all the vast industrial resources of Rhenish-Westphalia. A provisional committee has been appointed, and it is now making the necessary arrangements for constructing suitable buildings. The town of Düsseldorf has granted

a sum of £200,000 for a site. It is said that, as this Exhibition is now secured, the principal industries of Rhenish-Westphalia will probably not take part in the Paris Exhibition of 1900, as they consider that their interests will be better served by such a large local exhibition than by a small section at Paris.

ST. PETERSBURG HORTICULTURAL EXHIBITION.—Notice of this proposed Exhibition to be held in May next was given in the *Journal* for September 23 last (xvi. 856). The following regulations respecting the Exhibition have been received from the Foreign-office through the Science and Art Department:—1. The carriage of plants and other objects from the Russian frontier to St. Petersburg will be effected without any reduction in the usual tariff, but these goods will be exempted from Customs dues if returned from Russia, *via* the same frontier station as that by which they entered. 2. The carriage of the aforesaid objects from St. Petersburg to the frontier station of entry will be free of charge. 3. In order to avoid any misunderstanding at the Russian frontier, all goods intended for exhibition must be marked "transit exposition," and also bear labels, which will be supplied to any exhibitor, upon application, in numbers corresponding to the number of packages. 4. Packages will be examined by the Customs in the Exhibition buildings. 5. All plants will be provided with a phylloxera certificate. The Russian Railways Administration likewise propose to adapt several of the carriages specially for the transport of plants, by fitting them with water-pipes for watering and heating.

EXHIBITION OF ELECTRICAL APPLIANCES IN BRUSSELS.—At a meeting of the Belgian Society of Electricians, recently held in Brussels, it was decided to open an Exhibition of all sorts of electrical appliances applicable to domestic uses. The Exhibition is to be held in May next, in the new Post and Telegraph Office, Place de la Monnaie, Brussels. It is the intention of the society, according to Consul Roosevelt, to make a complete exhibition of the various uses to which electricity may be applied in the household. Besides appliances for illuminating purposes, there will also be exhibited small motors for operating dumb waiters, cleaning and polishing shoes, heating kitchens, cooking-stoves, bath-rooms, and bath-tubs, electric teapots, sad-irons, domestic telephones—in fact, all appliances operated by electricity—with a view to the total suppression of the use of coal for domestic purposes.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MARCH 22.—"Electric Traction." By PHILIP DAWSON. Sir FREDERICK BRAMWELL, Bart., D.C.L., F.R.S., will preside.

Papers for meetings after Easter :—

"Coal Supplies." By T. FORSTER BROWN.

"Electric Traction." By PHILIP DAWSON.

"Telephones." By JOHN GAVEY.

"Wireless Telegraphy." By W. H. PREECE, C.B., F.R.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

APRIL 27.—"Judicial Reform in Egypt." By Sir JOHN SCOTT, K.C.M.G., D.C.L., Deputy Judge Advocate-General, and late Judicial Adviser to H.H. The Khedive. The LORD CHIEF JUSTICE OF ENGLAND, G.C.M.G., will preside.

It has been found necessary to change the date of this meeting from April 13 (as formerly announced) to April 27.

MAY 11.—"The Revenue System and Administration of Rajputana." By MICHAEL FRANCIS O'DWYER, I.C.S., Settlement Commissioner, Alwar and Bhurtpore.

JUNE 1.—"The Port of Calcutta." By Sir CHARLES CECIL STEVENS, K.C.S.I., late Acting Lieutenant-Governor of Bengal.

FOREIGN AND COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

MARCH 21.—"The Commercial Development of Germany." By C. ROZENRAAD, F.S.S., and Fellow of the Institute of Bankers. J. M. MACLEAN, M.P., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

PROF. HENRY R. PROCTER, "Leather Manufacture." Four Lectures.

April 10, 17, 24, May 1.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 20...Sanitary Institute, 74A, Margaret-street, W., 8 p.m. Dr. Louis Parkes, "Water Supply and Pollution."

Imperial Institute, South Kensington, 8½ p.m. Mr. G. Wilson Hall, "Life in Australia."

Surveyors, Savoy-street, W.C., 8 p.m. Col. G. W. Raikes, "The Report (No. 2) of the Royal Commission on Local Taxation, especially dealing with Valuation and Rating in respect of Tithe Rent-Charge."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. John Bilson, "Norman Vaulting in England."

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Prof. J. Duns, "Marks of Mind in Nature."

TUESDAY, MARCH 21...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Foreign and Colonial Section.) Mr. C. Rozenraad, "The Commercial Development of Germany."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lankester, "The Morphology of the Mollusca." (Lecture X.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on following papers: 1. Mr. J. T. Milton, "Water-tube Boilers for Marine En-

gines." 2. Sir John Durston and Mr. H. J. "Recent Trial of the Machinery of Warships." 3. Robert Abbott Hadfield, "Alloys of Iron and Nickel."

Statistical, in the Theatre of the United Kingdom, Institution, Whitehall, S.W., 5 p.m. Mr. Udney Yule, "Causes of Changes in Pauperism in England, chiefly during the last two Interglacial Decades."

Pathological, 20, Hanover-square, W., 8½ p.m.

Photographic, 12, Hanover-square, W., 8 p.m.

(Photo-mechanical Meeting.) Mr. W. G. Adams, "Automatic Adjustment of the Half-Tone Scale."

Zoological, 3, Hanover-square, W., 8½ p.m.

W. P. Pycraft, "Contributions to the Osteology of Birds" (Part III.—Tubinares). 2. Mr. G. B. Arden Brady, "The Marine Copepoda of New Zealand." 3. Mr. F. E. Blaauw, "The Breeding Habits of the Weka Rail and the Snow-Goose in Australia."

WEDNESDAY, MARCH 22...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Philip Duns, "Electric Traction."

Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS), 12 noon. Annual Meeting. 1. Address by the Chairman, the Earl of Hopetoun. 2. Sir John Durston, "Trials and Experiments made on the H.M.S. Argonaut." 3. Captain A. Rasmussen, "Some Steam Trials of Danish Ships."

Geological, Burlington-house, W., 8 p.m.

Japan Society, 20, Hanover-square, W., 8 p.m.

Mr. W. Harding Smith, "Cha-No-Yiu."

THURSDAY, MARCH 23...Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS). Annual Meeting. 12 noon.

—1. Commodore G. Melville, "The local Arrangement of Motive Power of Warships." 2. J. Bruhn, "The Stresses at the Discontinuities in the Ship's Structure." 3. Mr. C. F. Munday, "The Advantages of using Tchebyscheff's Rule in Association with the Integrator to obtain Oscillating Curves of Stability." 7 p.m.—1. Mr. Charles Haswell, "Reminiscences of early Marine Engineering Construction and Steam Navigation in the United States of America from 1807 to 1850" (continued).

2. Mr. J. T. Milton, "Steam Pipes."

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 3 p.m.

Mr. W. Poel, "English Playhouses in the Sixteenth, Seventeenth, and Eighteenth Centuries." (Lecture III.)

Electrical Engineers, 25, Great George-street, W., 8 p.m. Mrs. Ayrton, "The Hissing of the Electric Arc."

FRIDAY, MARCH 24...Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS). Annual Meeting. 12 noon.

1. Mr. W. I. Babcock, "Portable Pneumatic Riveters for Shipbuilding." 2. Mr. C. E. Prosser, "Practical Experience on the Strenuous Boilers." 7 p.m.—Prof. W. E. Dalby, "The Balancing of Engines, with Special Reference to Marine Work."

Royal Institution, Albemarle-street, W., 8 p.m.

Weekly Meeting. 9 p.m. Lord Rayleigh, "Transparency and Opacity."

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Chemical Society's Rooms, Burlington-house, 5 p.m. 1. Dr. Barton and Prof. M. G. B. "The Criterion for the Oscillatory Discharge of a Condenser." 2. Mr. A. P. Trotter, "The Variations of the Clark Cell."

SATURDAY, MARCH 25...Royal Institution, Albemarle-street, W., 3 p.m. Lord Rayleigh, "The Mechanical Properties of Bodies." (Lecture I.)

Botanic, Inner Circle, Regent's-park, N.W., 3 p.m.

Journal of the Society of Arts.

No. 2,418. VOL. XLVII.

FRIDAY, MARCH 24, 1899.

communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

REIGN & COLONIAL SECTION.

Tuesday afternoon, March 21, 1897; J. M. CLEAN, M.P., in the chair. The paper read was "The Commercial Development of many," by C. Rozenraad.

The paper and report of discussion will be printed in the number of the *Journal* for the 7th.

Proceedings of the Society.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 22, 1899; Professor CHARLES A. CARUS-WILSON, M.A., in the chair.

The following candidates were proposed for election as members of the Society:—

W. Mann, Charles Theodore, Moorside, Ealing, W.
 W. Ke, Cyril L. C., St. Neots, Eversley, Winchfield.
 W. Phillips, Lionel, 33, Grosvenor-square, W.
 W. Per, John Edwin, LL.B., 16, Middleton-road, New Vandsworth, S.W.
 W. Bak, Joseph Henry, 28, Grosvenor-road, Highbury New-park, N.
 W. Ed, Arthur H., P.O. Box 120, Cape Town, South Africa.

W. Pittow, Thomas, 35, Oxford-gardens, W.

The following candidates were balloted for and duly elected members of the Society:—

W. G, Ernest William, Higher Dunscair, near Bolton.
 W. Rimer, Maurice, The Spinney, Coundon, near Coventry.
 W. Duvel, Alderman Sir Marcus, 20, Portland-place, W.

The paper read was—

ELECTRIC TRACTION AND ITS APPLICATION TO SUBURBAN AND METROPOLITAN RAILWAYS.

BY PHILIP DAWSON.

There is no longer room for doubt that electricity is the one pre-eminently successful motive power for tramways. This is proved by the rapid growth of electric traction. The words "experimental line" have fallen out of use, yet it is only a few years ago that those who ventured to foretell that the trolley system would be generally introduced into this country were ridiculed. There is no country in which electric traction is advancing more rapidly, and in which finer plants are being installed than in Great Britain. The day is not far off when horses and steam will have disappeared from the streets as far as tramways are concerned, and when the horse 'bus as a competitor will be no longer known.

The problem of greatest importance, however, in which electric traction will be a principal factor, is the rapid transportation of large crowds from and to their business in our cities. The object of this paper is to investigate in a general way the special requirements of this service, and to demonstrate the special adaptability of electric traction to it.

It is evident that the only solution of rapid transit lies in railways which must be either overhead or underground, and of both London possesses a greater mileage than any other town in the world. The factor of initial expenditure must restrict the number of tracks available for the up and down traffic.

The stopping places on such lines must of necessity not be far apart, and to diminish the crowds on the platforms and to increase the number of passengers the trains must follow each other with the greatest possible frequency. Consequently the average speed of the trains must be increased as much as possible without unduly diminishing the distance between two consecutive trains, which would be dangerous.

Steam locomotives have probably reached their approximate maximum development, and the results so far obtained with them for the class of traffic in question are far from satisfactory. They do not get up speed rapidly owing chiefly to the torque on the driving axles constantly varying in consequence of the reciprocating motion of the pistons. They are not economical as their fuel consumption is practically the same whether they are exerting

their fullest power, coasting or standing still, and their maintenance is very costly.

There is a commercial limit as far as distance is concerned beyond which transmitting power electrically will not pay. But that limit varies with each case, and cannot be ascertained except by the most careful calculation after all the conditions that obtain have been minutely examined. England was the first country to introduce electric traction on railways, both underground and overhead, as instanced by the City and South London, and Liverpool overhead electric railways. But, to prove commercially that very much heavier traffic could be handled, that much greater distances could be traversed, and to develop on a large scale the necessary machinery was again left to America, and hence the necessity of being practically confined to American experience and examples in this paper.

There are practically three methods of handling electrically the traffic on a railway, namely :—

- 1. By locomotives or motor cars hauling a train of trailer cars.
- 2. By independent motor cars.
- 3. By a set of independent motor cars formed into a train and handled from the front car or from a so-called controller car. Each car, however, can be separated from the train, and it then becomes an independent motor car.

As regards the supply of the necessary current for the motors, there are three distinct methods :—

Firstly. By accumulators or storage batteries which may be carried either on the motor car or locomotive, or on a tender.

Secondly. By having a car containing a stationary engine, dynamo, and boiler, which supplies the necessary current to the motors on the cars comprising the train of which it is part, and as proposed by W. Heilmann.

Thirdly. By continuous or multiphase current supplied directly from a generating station or from a sub-station which, in its turn, gets its supply of energy from the main station, the current being distributed either in the form of direct or polyphase to conductors running along the lines, and from which the power is supplied, through sliding contacts on the cars to the motors.

The two former methods, as far as this paper is concerned, will not be discussed, as sufficient data are not available to justify their being considered.

The system of transmission of energy to the

motors by means of conductors laid along track, will therefore alone be considered.

This method allows of several variations as far as the generation and distribution of power is concerned, amongst which the chief method set down as follows :—

(a) One continuous current generating station supplying current direct to contact rail. Voltage drop in pressure owing to distance becomes excessive, a negative "booster" may be used, it serves, so to speak, to pump back the current to the station, and is self-regulating, not taking at any period more power than is actually required to pump the current back. Should there be one or two lines too long to enable them to be worked this way, polyphase generators should supply the power at one or more sub-stations along the line, as may be found necessary, in which rotary converters are located, which transform the current into continuous. The polyphase generator may be driven by continuous current motors at the generating station. As an example of this system, the new Dublin tramway power house may be taken.

(b) One central station generating continuous current with sub-stations in which accumulators are located along the road, and which are recharged by means of a booster and special cables. As an example of this system, the London tramways may be taken as designed by Mr. Hopkinson, carried out by, the late lamented Dr. Hopkinson.

(c) A series of stations, as described in (a) and (b), situated at various distances connected together one with the other. As an example of this, the tramways and light railways in and round Boston, Mass., may be taken, owned by the Boston Elevated Railway Company, which has absorbed the well-known West End Company.

Data of Boston Elevated Railway.

Track miles operated	0
Number of cars	4
Car miles run during 1898	29,780
Passengers carried during 1898	172,760
Number of power stations	
Total capacity of power stations in kilowatts	10
Total rated indicated horse-power of engines	210

(d) A power station generating polyphase currents, which, by means of static step-down transformers, are transmitted at tensions run from 2,500 to 40,000 volts to sub-stations where static step-down transformers run them to pressures of 300 to 350 volts.

ent at this pressure enters rotary trans-
formers, which deliver direct current at 500 to
volts to the line. As an example of this
system, the Central London Railway,
which is now under construction, may be
mentioned.

) A three-wire system with continuous
current, the rails or return forming the neutral
wire. This has been tried and found wanting,
and the engineers of the Central London Rail-
way most carefully investigated its possi-
bility and decided in favour of polyphase
transmission and rotary converters, and
notably so.

From careful calculations and the investiga-
tion of what has been done both in Europe and
America, there is no getting behind the fact that
any power station which will exceed 4,000
kilowatts in capacity, the polyphase system is
very certain to prove commercially the only
viable one. This statement is upheld by
an authority as Mr. H. F. Parshall,
A.C.E. It is evident that in the particular
cases at present under consideration (suburban
and metropolitan communication), more than
10,000 kilowatts will be under consideration, and
before nothing, as far as the power station
transmission is concerned, but polyphase
systems will be considered.

There are two distinct varieties of service to
be catered for. One that on a system like the
metropolitan and District, where the stops are
frequent and the runs short. The other the
case of long distance lines with few stops. In
the present paper it is only proposed to con-
sider the first variety. In this case the use of
polyphase motors need not be considered, as
the work entailing frequent stopping and start-
ing they have not up to date proved satis-
factory.

A short examination of the importance of
rapid acceleration on lines having stopping
trains at short intervals is interesting. Prac-
tical experience with electrically-driven motor
trains, or locomotives on the experimental track
of the General Electric Company, at Schene-
ctady, has proved that it is perfectly feasible to
run at a speed of 30 miles an hour 10 seconds
after starting from a standstill. Assuming a
straight track, and that during 65 seconds the
current is cut off, and the train allowed to
run, that the brakes are then put on, the
train will be brought to a standstill 15 seconds
after, and the total time from start to stop will
be 80 seconds. Under these conditions it will
be found that the average speed will have been
about 25 miles an hour, and that the total dis-

tance run will be about 1.55 of a mile. Assum-
ing that instead of attaining the 30 miles an
hour in 10 seconds, it took 30 seconds, and
that this full speed of 30 miles an hour was
kept up for 40 seconds longer, and the brakes
then put on, the train would be brought to a
standstill in 90 seconds, and the average speed
would work out as 21.66 miles an hour, or an
average speed of about 10 per cent. less than
in the previous case, the consumption of power,
however, being much greater.

It is evident that the most important point is
to attain a high average speed, and to keep
the maximum speed attained as low as
possible, as by so doing less power is required
in braking the train, and also less power is
required to run the train. The time between
the moment when the maximum speed is
attained, and when the brakes are put on,
should be at least from 4 to 6 times that re-
quired for stopping the train, so as to allow for
errors in judgment on the part of the driver,
and also to enable him to make up lost time.
On the Manhattan Elevated Railway, in New
York, the trains which are drawn by steam
locomotives take 20 seconds to attain a speed
of 14 miles an hour, or less than half the speed
in double the time as compared with electric
traction just mentioned.

A much larger current will be required to
attain a rapid acceleration than to attain a
slow one, but the current will be required
during a much shorter time, and the total
energy supplied will be less in the case of rapid
than of slow acceleration. This fact must not
be lost sight of when calculating the feeders
for such a system, and the train service should
be arranged in such a way that as few trains as
possible start together. Furthermore, the more
rapid the acceleration required the larger will
the motors have to be, and therefore there will
be a limit, above which it will not be advan-
tageous to push the rapidity of acceleration.
In new tunnel lines, such as are now being
constructed all over London, it will be evident
that it is an advantage to have the stations
built with a down-grade for the trains to start,
so as to help the motors and reduce the current
required at starting, and that similarly it will
be an advantage to have an up-grade when
nearing a station, so as to reduce the amount
of power required in braking. By properly
choosing these gradients it is found that a
total economy of from 40 to 50 per cent. in the
total power required by a train may be made.
According to Mr. Potter's tests it was found
that during acceleration an average power of

32 amperes per ton of weight of train was required.

With a complete train composed of one motor car and two passenger cars, weighing complete 148,000 lbs., a maximum horizontal effort of 9,750 lbs. was required in acceleration, the maximum current was 780 amperes at 500 volts, the maximum speed attained was 32 miles an hour, and the time taken to attain the speed was 34 seconds, the motor car being equipped with two 200 horse-power motors.

METROPOLITAN ELEVATED, CHICAGO.

In another case, with a train composed of one motor car, equipped with two 125 horse-power motors and one trailer car, the total weight of train being 103,000 lbs., a maximum speed of 31 miles an hour was attained in 37 seconds, the maximum current being 500 amperes, and the maximum horizontal effort required to attain acceleration 5,640 lbs. In a series of tests made on the Nantasket Beach line it was found that with a heavy motor car, 51 feet in length overall, carrying 100 passengers, weighing 31 tons, on an average distance of 2,980 feet between stations, a maximum speed of 40 miles an hour was attained, the average

In an experiment with a train composed of one motor car and one trailer car, weighing 57 tons, with an average distance between stations of 4,280 feet, a maximum speed of 31 miles was attained, the average speed being 17 miles an hour, the power required being 0.098 Board of Trade units per ton mile.

From a comparison of the actual results obtained on the elevated electric railways of Chicago and on the Metropolitan and District line in London, we see that whereas the maximum speed of 25 miles an hour is obtained in 10 seconds with electric traction, it takes 30 seconds to do it with steam locomotives, and that whilst the electrically propelled train could do the distance of 1,880 feet in 10 seconds, with steam it would take 93 seconds or nearly half as much time again. In the case of electric traction the power is cut

arch 24, 1899.]

ment the maximum speed of 25 miles an hour is obtained, and the train allowed to start before the brakes are put on, the distance considered would be done in 76 seconds. The same driven train even then would take more than 25 per cent. more time to do the same distance.

Having tried to show the advantages which electric traction possesses as regards the possibility of increasing the frequency of the trains without decreasing the factor of safety, namely, the distance between two trains, it may be advantageous to see how, from an economical stand-point of generating power, electricity is a cheaper method of operation than steam locomotion. An electrically driven train only requires one man instead of two to drive it, and when the train is not running no power is consumed and no coal or water wasted. Steam locomotives, it is well known, use but very little less coal and water when they are standing still than when they are running, and are much less economical, consuming, as they do in America, from five to six pounds of coal per indicated horse-power. On the main line English roads it is stated that three to four pounds are consumed, and taking an average power of 400 horse power per locomotive, a train plus engine weighing 250 tons, at a speed of 40 miles an hour, we get at the most economical rate about 0.65 lbs. of coal per mile, or compared to the electric power required by electric traction 13 lbs. of coal per Board of Trade unit required, which is enormous—under favourable conditions it would take much over 3 lbs. of coal to give one Board of Trade unit at the switchboard. A properly designed electric station with these units would probably never consume more than 2 lbs. of coal per indicated horse-power hour, or 2.65 lbs. per kilowatt hour at the switchboard, and engines of the size of 4,000 horse-power would be guaranteed to consume not more than 12 lbs. of steam per indicated horse-power hour. A large station would not justify a comparatively large initial expense in coal handling and stoking machinery, and the location of the station could be chosen so as to be most advantageously situated as regards both coal and water, the coal without being handled being taken from either the colliery or the railway truck, conveyed automatically to the coal stores, and from there automatically to the fires, the ashes being conveyed away automatically as well. At such a station but very few men would be required, and the cost of power could be re-

duced below one halfpenny per Board of Trade unit, including expenses of every kind.

Comparing again the coal consumption per train mile on large English main line railways, which varies from 35 to 58 lbs. of coal per train mile, we get a coal consumption of from 0.146 to 2.32 lbs. per ton mile, corresponding to 28.12 to 46.4 lbs. per Board of Trade unit, required to be generated at the power-house. The following results actually obtained with slow-speed Corliss type engines and standard American railway generators, may be of interest:—

Total coal consumed, Brooklyn City Railway Company, per Board of Trade unit, 3 lbs.

Total cost, everything included, of Board of Trade unit at switchboard, 00.5,195 cents (about one farthing).

Cost of coal per unit, 0.2307 cents, about 0.166 of a penny; Union Traction Company, Philadelphia.

Poorest coal, 3½ lbs. consumed, per Board of Trade unit at switchboard.

In another case cost of coal, 0.272 cents per Board of Trade unit at switchboard, about 0.186 pence.

Total cost of unit, all included, 0.591 cents, about 0.296 pence.

Coal consumption in another case with Corliss engine, average for one year, per indicated horse-power hour, 1.65 to 1.76 lbs.

What good slow-speed Corliss engines, properly designed for railway work, compared to other engines' mean are shown by the fact that by such a change in a large American station the coal consumption was reduced from an average of 8.3 to 4.9 lbs. of coal per car mile.

From a series of figures obtained from the various Chicago electric over-head lines, from 0.16 to 0.135 Board of Trade units are required at the switchboard to drive the trains, the average speed of the trains being 13½ miles an hour, and the maximum speed obtained varying from 28 to 35 miles an hour.

The coal and water consumption, per Board of Trade unit, must necessarily be very low, the losses in the step-up and step-down transformers and in the transmission and rotary converters would not be very great, and it would be perfectly feasible to attain an efficiency of 60 per cent. at the motor terminals and of 50 per cent. on the power applied to the car axles. Large engines and large generators and converters are designed so as to take an overload of 25 per cent. for any period of time, and be capable of overloading 50 per cent. for a short time without injury, and by a selection

Metropolitan Elevated, Chicago.

Length of street 3¼ miles.
 Average distance between stations .. 1,600 feet.
 Time interval between consecutive trains 2½ minutes.
 Average speed in miles per hour .. 13 miles.
 Maximum speed 28 miles.
 Total rated power of generating station 5,000 kilowatts.

South Side Elevated, Chicago.

Length of street 18½ miles.
 Average distance between stations .. 1,720 feet.
 Time interval between consecutive trains 1½ minutes.
 Average speed in miles per hour .. 14 miles.
 Maximum speed in miles per hour .. 26 miles.
 Total rated power (4 units 800 kilowatts each) of generating station 3,200 kilowatts.

Lake-street Elevated, Chicago.

Length of line 15 miles.
 Power of station 3,000 kilowatts.

North-Western Elevated, Chicago.

Length of Line 15 miles.
 Rated power { 3-1,500 kilowatts. }
 of station.. { 1-800 kilowatts. } 5,300 kilowatts.

Loop, Chicago.

Length 4 miles.
 Rated capacity { 4 units }
 of station .. { 1,500 kilowatts. } 6,000 kilowatts.
 Number of trains passing over line in 24 hours 3,000 trains.
 Total rated power of Chicago elevated lines, approximately 22,500 kilowatts.

Nantasket Beach.

Length of line 20 miles.
 Rated power of station 1,800 kilowatts.
 Average distance between stations .. 4,280 feet.
 Maximum speed per hour 43 miles.
 Average speed 25 miles.
 Board of Trade units per ton mile, at switchboard
 Weight of two-car train 55 tons.

The elevated railroads of New York and Brooklyn have been losing business during the last few years so rapidly that the financial condition of the Brooklyn system is serious and the return on investment of the New York system much reduced, and is still declining. The elevated railroads of Chicago have, however, been able to earn a satisfactory dividend. The general introduction of electricity in the Chicago system has greatly improved the

ago situation, in spite of the competition of the surface trolley lines, which parallel the elevated lines in most cases. The elevated road problem is resolved into a discussion of speeds, station frequencies, and relative cost of service. Any railroad of this class which aims to maintain a high schedule must use a motive power in which the possibilities of rapid acceleration are a maximum, and—all conditions being equal—should choose that particular motive power which will bring about the quickest acceleration, consistent with due economy.

The Manhattan system is a comparatively simple one, with four main through lines, without branches of importance, while the Brooklyn and Chicago systems are composed of many lines with branches, involving more or less complicated switching arrangements. Until about a year ago, the three Chicago companies, the Lake Street, the South Side, and the Metropolitan, had independent termini in the business heart of the city. Now, however, they have constructed "Loop," encircling the business district, is used as a terminus for all three, and for a fourth, the North Western, now under construction, and all the elevated trains of the city pass round this loop on each trip. The

Brooklyn elevated system has lately secured a new terminus on the Manhattan Island side of the Brooklyn Bridge, and experiments are being made with a view to converting the entire Brooklyn system to electricity in the near future. The entire New York system, however, is at present operated by steam locomotives.

The little locomotives in use on the New York system weigh 47,000 lbs., of which 31,500 are on the four 42-inch driving wheels, and 15,500 are on the four 30-inch truck wheels. The total wheel base is 193 inches, of which 60 inches is rigid. The cylinders are 12 inches in diameter, and have a 16-in. stroke. The grate area is 16.5 square feet, and the total heating surface is 4,034 square feet. There are 154 flues 1½ inches in diameter and 75 inches long.

The Standard Manhattan Car weighs 29,088 lbs., has seats for 48, and frequently carries 100 passengers. It is mounted on eight 30-inch wheels.

The total weight of a 5-car loaded Manhattan train is about 130 tons. The weight on the drivers is 12 per cent. of the total train weight, and with 25 per cent. adhesion, the maximum drawbar pull possible for the locomotive to exert is 7,875 lbs.

Ch 24, 1899.]

The exciting E.M.F. is 125 volts. The rotating rings are of copper, and carbon brushes are used. The armature winding is connected to 12,000 volts alternating. The temperature rise of the machine after ten hours' run at full load is well under 40° C. The efficiencies are as follows:—

	Per Cent.		Per Cent.
Full load	90	½ load	92.5
¾ load	95.5	¼ load	88
Efficiency	95	Inherent Regulation.	9

The steam engines which drive these dynamos are cross compound Allis vertical engines, 46 inches high and 86 inches low pressure cylinders, and 60 inches stroke. They will develop 4,500 indicated horse power at the full economical load, and will be able to work continuously at 6,000 horse power if required, and for a short space of time they are to be able to work at 7,000 horse-power. The crank is of solid steel, bored and forged, with a 16 inches diameter the entire length, and 37 inches in diameter where the wheel and crank pin are located. The diameter of the crank pin in the bearings is 34 inches, and the diameter of the bearings 60 inches. The flywheel will have cast steel centres, and the rim will be built up of steel plates riveted together. The rim will weigh 225,000 lbs., and the engine complete, about 600 tons, and it is expected that as good results as 12½ lbs. of steam per indicated horse-power will be easily obtained. There will be several sub-stations which will be located step-down transformers of 1,000 kilowatts each, which will lower the voltage from 6,600 volts to 350 volts. At this pressure the current will enter rotary converters of 900 kilowatts each, and will be converted in the shape of a continuous current of 600 volts to the tramway system.

This company operates some 250 miles of tracks and carries approximately 250 million passengers every year. The Third Avenue Road is now engaged in replacing all existing horse and cable lines with electric traction, and for this purpose has just given out a contract for a power station which will eventually contain 16 3,000 kilowatt generators. The generators will be very similar to those described above, and are being supplied by the Westinghouse Company, who are the sole contractors for the whole work. The lines will be Marine type, vertical, and are being built by the Westinghouse Machine Company. Sub-stations with rotary transferers

will be used, as in the case of the Metropolitan system.

To give an idea of what may be done as regards power transmission the following few figures may be useful. The first attempts at this class of work were made during the Frankfort Exhibition of 1891, 300 horse-power being satisfactorily transmitted a distance of 106 miles with a pressure of 30,000 volts. Since that time electrical power transmission has largely increased, and the results obtained have been very satisfactory, 4,000 horse-power at the present moment are regularly transmitted a distance of 85 miles to the City of Sacramento, California, at a pressure of 30,000 volts, where they are transformed into low pressure three-phase and continuous current for lighting, power, and traction purposes. At Telluride, Utah, 1,000 horse-power are transmitted 55 miles at a pressure of 40,000 volts; 4,500 horse-power are transmitted a distance of 40 miles to Salt Lake City at a pressure of 15,000 volts; 1,400 horse-power are being transmitted 35 miles to Fresno, California, at a pressure of 11,000 volts; 2,000 horse-power are being transmitted 30 miles to West Kootenay, British Columbia, at a pressure of 20,000 volts; 10,000 horse-power are being transmitted from Niagara to Buffalo, a distance of 22 miles, at a pressure of 10,000 volts. All the plants are working and giving satisfaction, and have nothing experimental about them, and there are hundreds more such.

In the designing and carrying out of a large system, there are three points which are frequently overlooked and which may cause a disastrous failure. These are good and adequate bonding; thoroughly good insulation, both mechanically and electrically; and trucks suited for the work for which they are intended.

As regards the bonding, the bonds used should be flexible, but, at the same time, should contain no solder or brazed joint, and they should be expanded against the side of holes drilled in the web or foot of the rail, and held in place by pins. Bonds of this description, when properly applied, can be absolutely relied upon, the contact resistance of the bond with the rail not being greater than the resistance of the solid bond.

With regard to the third rail insulators, very good results are obtained by using insulating bolts screwed into base plates which are fixed to the sleepers, cast iron chairs being fixed to the head of the bolts to hold the rails.

DISCUSSION.

The CHAIRMAN said they were all much indebted to Mr. Dawson, who was well known as one of the leaders in the introduction of electric railways into this country, for giving them so much interesting information on a subject which was now of universal interest, and he hoped for a good discussion. The author's remarks on the subject of the drop in the feeders, and the different methods of overcoming this difficulty, were of great interest, and he might say that this question was of more importance to us than to American engineers, since in this country, fortunately or otherwise, we had a Board of Trade, and had not such a free hand as they had in America. One of the methods suggested was the use of the negative booster, which was practically a series generator with the fields in series with the feeder, so that the generator added just as many volts as was necessary to compensate for the drop in the feeder. Mr. Dawson had dismissed rather peremptorily the three-wire system, about which there was a good deal of difference of opinion. He understood that this system was going to be tried on the extension of the City and South London Railway, and he trusted that it would not prove a failure in this case. He hoped there were some present who would take up the cudgels on behalf of polyphase motors, as he did not himself feel disposed to acknowledge that they were out of the question for railways running over short distances, where rapid acceleration was required. In considering the question of the amount of energy required for operating trains under the circumstances dealt with in the paper, the question of the efficiency curves of the motors was really not of much importance, because the speed of the motor was continually changing, and the value of its efficiency at a certain speed did not go for very much. The real question was, what was the least amount of energy in watt-hours per ton-mile required to cover the given distance. On the Central London Railway inclines were being used outside the stations, so that the engines might have the benefit of the incline during the process of starting. Calculation showed that the value of these grades was greatest when they acted during the first few seconds, but this was practically impossible, and he was inclined to think that rather too much was made of the advantage of these inclines. He understood that a difficulty had occurred in connection with the grades on the Waterloo and City line, which was virtually a switch-back railway. It seemed that the equipment was not sufficiently powerful to haul the train up the steepest grades backwards, being designed simply with a view to the trains running in one direction only. In any railway where grades were used, the equipment should be able to haul the trains in either direction in case of emergency, such as might occur when a single line

had to do duty for two. Mr. Dawson thought steam locomotives were unable to compete with tric motors in rapid acceleration; he hoped there were some steam engineers present who would up that question. Steam engineers did not see realise the importance of designing locomotive short runs with rapid acceleration. It might be correct that such a curve as had been shown was fair average sample of what a steam locomotive could do at present; but he thought that if steam engines set to work to improve the design, they might curve more nearly approximating to that of the electric locomotive. The process going on during the that a steam locomotive was getting up speed was one about which very little was known, and very few experiments had been made with a view to ascertaining what it was which prevented the rapid acceleration which was obtained in an electric locomotive. The figures given with regard to the South London Elevated Railway, Chicago, were of importance. It was assumed that under the head of transportation included the cost of the motor-men and conductors, and it was interesting to hear that on the railway, when steam was employed, the cost was 2·8 cents per car-mile, and that when electricity was substituted it fell to 1·9 cents. In that connection, Mr. Sprague's method of multiple unit control had been referred to, and he should be glad to hear more particulars about it, as it appeared to effect a great reduction in the cost of operation of a train. He understood that the method consisted in having a single motor man located at the front part of the train, who, by a system of switches, operated a number of motors, which might be placed on every axle; so that one man could do the work of many. There was also the advantage of having a motor on each axle, which greatly increased the adhesion effect. He was not behind in one in his appreciation of what the Americans had done in connection with electric railways, but he was sorry to see so many large contracts go across the water—especially that for the Central London Railway. The advantage to be looked for from such a system, such as this, was that Englishmen might be so posted in what Americans were doing, that they would be able to beat them on their own ground.

Mr. LEON GASTER said trains had been worked for some time in Switzerland on the three-phase system. The circuit was conveyed to the train by a phase motor direct without rotatory converters. The London Central Railway has made use of the three-phase current, but uses rotary converters, which, according to Mr. Parshall's design, ought to work with very high efficiency; but there were several facilities there, the electricity being generated by water-power, and conveyed a good distance. The question of bonding was very important, as it prevented a great drop of voltage, and it was a question which was the best method

many respects he thought that of electric traction should be substituted for steam, the alteration should be made. It might be said that the Chicago line was a small one, and, therefore, the abandonment of the plant did not so much matter, but then they might refer to the New York Elevated Railway, which had been running a great many years, and that also had found it worth while to abandon the old plant and substitute new. Such examples ought to make Englishmen ashamed of themselves. He wished Mr. Dawson had included in his illustrations one or two of the common American electric tramways which ran from the half-finished towns of the west or south into the backwoods. Before any roads were made, a line was laid down running into the country, and rapidly drew around it a number of outlying suburban houses. A year or two ago, when he was in Tampa, which at that time was being developed as a watering place, he found that there was not a road into the surrounding country on which a human being could walk, or a horse or vehicle travel; but there were several excellently equipped electric tram lines on which you could go a mile or two into the country, and walk back through the woods.

MR. E. KILBURN SCOTT thought they ought to have a better understanding of what was meant by a great distance; was it such a distance as that between the stations on the Metropolitan or District Railways? The railways which had been referred to in Switzerland were working very well indeed, and he considered the traffic was going to be increased entirely by the three-phase current. The photographs, of which photographs had been shown, did not in many cases show lines in which the stations were so close together; those in California, for instance, were a fair distance apart. There they worked with a three-phase current, and they might just as well go through with it, and put three-phase lines on the cars, and do away with rotary converters. He suggested that we should not be in too much of a hurry to copy the American overhead system, or we might find that by the time we had introduced it they had discarded it in favour of the conduit system, which was already being introduced in the Washington and Third Avenue lines. It would also be a pity not to give the three-phase system a trial. He believed it would accelerate quite as much as a continuous current; and that, for such purposes as were required in London, it would be just as economical as a combination of the three-phase and continuous.

MR. S. H. TRUEMAN WOOD said one important conclusion which might be drawn from this paper by the general public was that the time had come for insisting on electric traction on the metropolitan railways. As in Chicago when the South Side Elevated Railway was constructed—not six years ago. It was built from Chicago to Jackson Park, and it was not until the World's Fair had been open for some time. It was then worked by steam; it was a new system furnished with new plant. Yet the owners had insisted on it to their advantage to give up all the steam engines they had and work it by electricity. It was an excellent lead line, and he did not suppose that it mattered much to the passengers whether they were drawn by steam or electricity; but that was not the case in London. Here we were taken through tunnels in an atmosphere which nearly asphyxiated one, and the public had a right to demand that if other means of

traction could be substituted for steam, the alteration should be made. It might be said that the Chicago line was a small one, and, therefore, the abandonment of the plant did not so much matter, but then they might refer to the New York Elevated Railway, which had been running a great many years, and that also had found it worth while to abandon the old plant and substitute new. Such examples ought to make Englishmen ashamed of themselves. He wished Mr. Dawson had included in his illustrations one or two of the common American electric tramways which ran from the half-finished towns of the west or south into the backwoods. Before any roads were made, a line was laid down running into the country, and rapidly drew around it a number of outlying suburban houses. A year or two ago, when he was in Tampa, which at that time was being developed as a watering place, he found that there was not a road into the surrounding country on which a human being could walk, or a horse or vehicle travel; but there were several excellently equipped electric tram lines on which you could go a mile or two into the country, and walk back through the woods.

MR. T. TREMLETT CARTER said he should not like it to be supposed that in America the trolley system was being given up for the conduit system to any appreciable extent, or that the former system was not perfectly successful. The conduit system was only adopted for special reasons, as in Washington, where it was obligatory; but directly the lines got outside the district of Columbia the trolley system was used, notwithstanding the delay which was incurred in transferring the cars from one system to the other. Some of the local authorities insisted on the conduit system, but there was no failure of the trolley system.

MR. JAMES SWINBURNE said the growth of electric traction was so rapid that it would be a kindness to engineers if Mr. Dawson would give a lecture every few months, showing how far it had gone. In England they were apt to take a sort of parochial view, and neglect what was being done in other countries, so much so that those who did know what was going on abroad were sometimes rather ashamed of their own country. We were kept back in England by a kind of conservatism, which objected to anything new, and also by too much officialism. But, after all, that kind of pigheadedness which kept us back at the beginning had one good result, that when we did make a start we generally did our work very well, better often than it was done in other countries; and an industry which had got past the youthful age was often carried on better in England even than in America. He did not wish to say anything against the Americans, for whom all who knew them had an immense respect, but they had rather a way of putting down a station

and making it go somehow, and then pulling it all up and putting down a better one. We could not do that in England; if we made a mistake once, it practically gagged the industry at the start, and in some respects it was better to go slowly. One of the most important questions with regard to large power distribution for electric railways, was the use of the polyphase system. The polyphase motor on a car had two drawbacks—first, that it wanted three contacts instead of two, and the second was said to be that you could not get enough torque at starting. He could not see why this should be, and had never got a satisfactory answer to the question. With a direct current, if you wanted to get a large torque, you gave it as large an armature current as you could, and as large field excitation as possible; you increased both elements. But a polyphase motor would do that equally well. He did not care which was the armature, and which was the field, you had the two elements in the polyphase. One was connected to the line, and got the alternating current, and you could increase the field, or the induction, by reducing the number of turns, and in that way you got one element. The other element had an induced current in it, and that depended simply on what resistance you put in the circuit to start with. There was no inherent reason why you should not multiply the two effects in the polyphase as much as in the direct current motor. He could never find out what the real difficulty was from that point of view. Another subject of some importance was that of electrolysis. When electric traction was first proposed in England everybody was against it, and the first objection made was to overhead wires, which obscured the blue light of heaven and obstructed the traffic, and so on. That was now got over, because when people found that this mode of traction was adopted in all the most beautiful towns of the Continent, there was no æsthetic reason why it should not be employed on the Underground Railway or along the Old Kent-road. Then a new danger was discovered in electrolysis, and that was more serious because even engineers did not know much about it. The bald assumption that it could not take place unless you had more than $1\frac{1}{2}$ volts was nonsense, the least difference of pressure was enough to start electrolysis when you had metals which were greedy of oxygen, such as iron. The negative booster seemed to be a solution, but on a large scale it might be difficult to work. This was a matter on which they had gone ahead immensely in America, and when Mr. Dawson gave his next periodical lecture he hoped he would tell them how the gas and water pipes were getting on, if there were any left at all. Surface-contact systems did not get over this difficulty at all; they only got over the imaginary difficulty of the trolley. There were three small points mentioned which seemed to be looked upon as American, one, the feeder booster, which was proposed first by Major Cardew; another, the compounding up of dynamos, which was proposed

by Dr. Hopkinson in his three-wire patent of 1883 and was used in this country by all dynamo motors since 1883 or 1884. He was not sure that Edison did not invent the same thing in 1882, many of the patents of Edison about that time were almost the same as some of Hopkinson, Marcel Deprez, and other European inventors. Putting a motor on a wheel was also an old English idea, but it did not come into use because we did not have any more. With regard to steam locomotives, the difficulty of acceleration might be put very easily. In an electric motor you could always, by increasing the number of elements, get a great torque, but you could not get a large initial torque in a locomotive without having the whole engine large, because you could not start to work the engine. You could only fill the cylinder with steam, and if you had a large cylinder which was full of steam to start with, the result was, when you were running rapidly, you were expanding the steam much. The question of starting torque was better understood by locomotive engineers. The Dickson engines, for instance, were specially designed for their work; they were not designed for starting, and would not draw an express train. Mr. Dawson said that in the United States they were giving up high speed engines, and using Corliss engines which were always comparatively slow, even the American ones, which were the fastest. But he should like to know what the high-speed engines were which were replaced—were they up to the standard of the English high-speed engines? He could not see any advantage in using a Corliss engine for an electric railway. It had been said that the American high-speed engines were really tests of how much steam would go through a 3-inch pipe, and others, again, said that definition was incorrect, as they were really a small obstruction to a 3-inch pipe.

Mr. W. M. MORDEY said the discussion seemed to turn more on the future than the present, perhaps because that was more interesting. With regard to polyphase working, they might take comfort from the fact that, if there was any future for it, they were starting in one important case in London with the phase generators, so that if found possible, later on to carry the alternate current direct to the motor of the cars, it could be done with a comparatively small alteration. The generating plant and mains would not require to be altered. This question of alternate current traction was being worked out in Switzerland, where so many good things in alternate current work had been done, and they were all watched with great interest the experiments being made by Mr. Brown on the Jungfrau Railway and elsewhere. As far as he could gather, the future of polyphase traction work was going to be very great. At the present rate, there did not seem to be anything like a difficulty about starting that was supposed; even if there were some difficulties, it must be remembered that there was an inherent economic

ernating current machinery in one im-
 respect, which might compensate for some
 acks. For starting, whichever system was used,
 wanted a large current but a small E.M.F.
 ect current working, the starting was done
 conditions of great wastefulness, because large
 nces had to be inserted in the motor circuit.
 an alternating current they could put in a
 E.M.F., which was not wasteful. They
 not forget that they owed to America practi-
 the present electric tramway system. He
 ten many of the tramway systems in America,
 Europe as far as Buda-Pest, and he must
 he was astounded at the way in which the
 cans had developed the system, often in the
 f great difficulties, and when there was not
 sufficient knowledge to enable them to deal
 tely with the problems. They did the best
 ould at the moment, and were not afraid to
 plant when they had developed anything
 America had been described as the labora-
 f the world, and it was certainly the electrical
 tory. While we are glad to benefit by all
 perience, we must not be misled into sup-
 that finality had been reached, or that the
 American practice is necessarily best for
 gh conditions. England, as Mr. Swinburne
 aid, was slow to begin, and that was why
 as the banker of the world. They must all
 Mr. Dawson for having given them so much
 ation on what is now being done.

DAWSON, in reply, said the first time the
 ve booster was tried in England was at Bristol.
 e found there that when they had a fall of
 ial of 7 volts, by introducing the booster they
 reduce that fall by four, and bring it down to
 well within the Board of Trade limits. It was
 re there might be a difficulty in using boosters
 arge system, and that was why he said that in
 as of above 4,000 kilowatts the polyphase system
 e financially the only possible thing; otherwise
 ould practically have to make the street into a
 r mine. The question of the three-wire system
 ne they had been fighting over for a long time,
 e did not suppose they would agree now. It
 e interesting to see what were the results on
 e south London extension; at present it had not
 d so satisfactory on lighter train lines as was
 ed, and for that reason, as well as on
 etical grounds, he did not think it would be satis-
 y. If he proved to be wrong, he should be glad
 nnowledge it. With regard to what was to be
 lered a short distance, he meant such distances
 etween the stations on the District Railway.
 e experiments hitherto made with three-phase
 s, for which they were much indebted to the
 and especially to Mr. Brown, had been on
 nning longer distances, and there the power
 ally cost nothing. With regard to the multiple-

control system, there was very little information yet
 given as regards the financial results, but it seemed to
 be working very satisfactorily, and had been taken up
 by several large American companies. It would be
 very useful in cases like the Metropolitan District,
 where there were branches or junctions, because the
 train could be divided, and one part go in one direc-
 tion and the other in another. He should like to
 see the polyphase motor system tried in England,
 but the question was, who would run the risk. They
 knew that the continuous current was economical for
 a certain class of work, and it could be guaranteed,
 but they were not so sure whether a polyphase motor
 would do it. The question of electric welding had
 been raised, but it had been abandoned in favour of
 cast welding, chiefly on account of the great expense
 attending it. It required a power of about 200 kilo-
 watts to make a weld. With reference to the conduit
 system, he might say that he did not intend to raise
 the question of tramway at all; he was dealing rather
 with suburban and metropolitan railways. The
 conduit system had been carefully examined by hard-
 headed men of business and skilful engineers, and
 they came to the conclusion that practically there
 were a very few streets, in a very few towns, where
 conduits would be justified, the chief reason being
 the enormous cost, which would be much greater in
 England probably than in America. Here, engineers
 were not allowed to put a town in a state of siege; in
 Brussels, when the conduits were being constructed,
 four or five miles of the finest streets were absolutely
 closed to carriage traffic, and almost to that of foot
 passengers. He welcomed Sir Henry Wood's remarks
 with reference to the District Railway, which he had
 to use daily, and knew what the atmosphere was like.
 If electricity were used, it would be much more com-
 fortable, and it would not only cost less to work the
 line, but many more people would travel on it. The
 object of the paper was to bring before the public
 what was being done in other countries. He had been
 sometimes accused of trying to introduce American
 goods and machinery in place of English, but his
 desire was just the opposite. If we did not know
 what other people were doing, and why other
 people's machinery was better or was supposed to
 be better than our own, we should never
 be able to compete with them. The result of our
 conservatism had simply been that we had waited
 until Americans had come over here and found that
 we were practically not in a position to do the work
 which was wanted at a reasonable price, and they
 stepped in and got the business. Had we realised
 seven years ago what a success electric traction
 was going to become, we should have heard
 very little of American competition. The ques-
 tion of electrolysis was a difficult one, but
 so far there had not been much complaint in
 England. One reason why our lines were safer than
 the American was that ours were laid on concrete,
 which had a very appreciable resistance; moreover
 our tracks were very well bonded, and he did not

think there would be much trouble. There was only one safeguard—good bonding and heavy returns. That was why, when you got to long-distance transmissions, you must use polyphase machinery. Otherwise the amount of copper would be too great.

The CHAIRMAN then proposed a hearty vote of thanks to Mr. Dawson, which was carried unanimously.
