## Encyclopædia Britannica.

VOL. XXIII.-(T-UPS).
Total number of Articles, 625.
PRINCIPAL CONTENTS.

TABARI. M. J. de Goeje, Professor of Arabic, University of Leyden.
TABLES, MATHEMATICAL. J. W.L.Glaisher, F.R.S., President, Royal Astronomical Society.
TAHiti. Baron Axatole von Hügel.
TALES. Andrew Lang, M.A.
TALMUD. S. M. Scimler-Szinessy, M.A., Ph.D. TAMILS. Reinhold Ross, Ph.D., LL.D., C.I.E. tape-Worms. W. E. Hoyle, M.A.
TASSO. J. A. SYmonds, M.A.
TASTE. Prof. M'Kendrick, M.D., LL.D., F.R.S.
TAXATION. J. Shield Nicholson, M.A., D.Sc., Professor of Political Economy, University of Edinburgh.
TAXIDERMY. Montague Browne, Author of "Practical Taxidermy."
TEA. James Paton. [F.R.S. TEAK. Sir Dietrich Brandis, K.C.I.E., Ph.D., technical education. Sir Philip Magies.
TELEGRAPH. Thomas crar, B.Sc., F.R.S.E.
TELEMETER. Major Artitur W. White, R.A. TELEPHONE. Thomas GRay.
TELESCOPE. DAvid Gili, LL.D., Astronomer Royal, Cape of Good Hope.
TELL. Rev. IW. A. B. Coulidge, M.A.
TEMPLARS. T. A. Archer.
TEMPLE. W. Rohertson Smitif, LL.D.
TENIERS. Henri Hyanss, Conservateur, Biblinthèque Royale, Brussels.
TEVNIS. Julian Marshall, Author of "Annals of Tennis."
TENTILES. J. H. Midnleton, M.A., Slade Professor of Fine Art, University of Cambridge.
THACKERAY. Walter H. Pollock.
THALES. Prof. G.J. Aliman, LL.D., F.R.S., and Henry Jackson, Litt. D.
THEatre. Prof. J. H. Midnletor and James Williams, B.C.L.
THEBES. A. W. Verrall, M.A., Lecturer in Classics, Trinity College, Cambridge.
theisil. Rev. Rubert Flint, I.D., LL.D., Professar of Divinity, University of Edinburgh.
THEODORA. James Bryce, D.C.L., IJ.P.
THEODORIC. THomas Hodgetr, D.C.L., LL.D. THEOLOGY. Prof. R. Flint.
Theosophy. Animet Setil, M.A., Professor of Logic, University of St. Andrews.
THERMODYNAMIUS, P. G. Tait, M.A., Professor of Natural Philosophy, University of Edinburgh.
THERMOMETER. H. R. Mill, D.se.
THESSALONIANS, EPISTLES TO THE. E. Schürfre, Professor of New Testament Theology, Giessen.
THibaUt. Jonn Machonell, M.A., Author of "The Land Question."
THIERS. George saintsbery, M.A.
THOREATT. Whliam Sharp, Author of "Life of Shelles."
THiOAT DISEASES. J. O. Affleck, M.D.
THUCYDIDES. Prof. R. C. Jebrs, LLID.
THUGS. Reinhord Rost, LL.D., C.I.E.
THULE. Sir Enwarn H. Bunbury, Bart.
TIBET. General J.T. Whaker, R.E., C.B., F.R.S., and Prof. A. Terrien de Lacouperie.
tides. G. H. Darwin, M.A., F.R.S., Plumian Professor of Astronomy and Experimental Philosophy, University of Cambridge.
TIME. J. L. E. Dreyer, Ph.D., Astronomer, Armagh Observatory.

TIMUR. Major-Gen. Sir Frederick J. GoldSmid, K.C.S.I., C.B.
TIN. Prof. W. Ditmiar.
TITHES. W. Robertson Smith, LL.D., and James Williams, B.C.L.
TITIAN. W. M. Rossetti.
TITLES OF HONOR. Frederick Drummond. tobacco. James Paton and Prof. W. Dittmar. TONNAGE. W. Moore, Principal Surveyor of Tonage, Board of Trade, London.
TORPEDO. Commander Edinin J. P. Gallwey, H.M.S. "PoIyphemus."

TORT. Frederick Pollock, LLL.D., Corpus Professor of Jurisprudence, University of Oxford.
Tortoise. Albert Günther, M.D., Ph.D., F.R.S.

TORTURE. James Williams.
TOTEMism. J. G. Frazer.
TOUCH. Piof. J. G. M'Kendrice.
ToURNEUR. A. C. Swinberne.
TRACTION. J.A. Ewing, B.Sc., F.R.S., Professor of Engineering, University College, Dundee.
TRADE UNIONS. Fred. Drummond.
TRAMWAY. Tromas Codrington, C.E.
TRANSIT CIRCLE. J. L. E. Dreyer, Ph.D.
TREASON. James Williams.
TREATIES. Thomas E. Hollana, D.C.L., Chichele Professor of International Law and Diplomacy, University of Oxford.
TREMATODA. W. E. Hoyle.
TRENT, COUNCil OF. Rev: Dr. Littledale. TRICYCLE. C. V. Boys.
TRIGONOMETRY. E. W. Hobson, M.A., Lecturer in Mathematics, Christ's College, Cambridge.
TRIPOLI. A. M. Broadley, Author of "Tunis, Past and Present."
TROAD. Prof. R. C. Jebb.
TRUMPET. Victor Mahillon, Conservatoire Royal de Musique, Brussels.
TRUST. James Willifams.
TUNiCATA. II. A. Herdman, D.Sc., Professor of Natural History, University College, Liverpool.
'TUNNELLING. Benjamin Baker, C.E.
TURKEY-
History and Literature. E. J. W. Gibb, Author of "Ottoman Poems," and C. A. Fyffe, M.A., Author of "History of Modern Europe." [Keane.
Geography and Statistics. Prof. A. H.
TURKS. Prof. M. Th. Houtsma, University of Leyden.
TURNER. George Reid, R.S.A.
TYPIIUS, TYIFIOID, AND RELAPSING FEVERS. J. O. Affleck, M.D.
TYPOGRAPHY-History. J. H. Hessele, M.A. -Practical. John Socthward.
tyrol. A. J. Butler, M.A.
ULFILAS. Rev. C. Anderson Scott, B.A.
UMBria. William Ridgeway, M.A., Professor of Greek, Queen's College, Cork.
UNITARIANISMI. Rev. J. F. Smiti.
UNITED STATES-

II. Phyrical Gengrapily and Statistics. III. Political, Geograpmy and Statistics. Rt. Rev. Sameel Fallows, D.D., late Professor of Physics, Lawrence Universits.
UNJVERSITIES. J. Bass Mulilinger, M.A., Librarian, St. John's College, Cambridge.

# ENCYCLOP 灰DIA BRITANNICA. 

Ti.the twentieth symbol in our alphabet. It has varied out little in form since the earliest days when it appearc in Greece and Italy, though some of the Italic alphoets exhibit variants: e.g., in Umbrian and Etruscan inserytions we find the horizontal stroke sometimes on one side nly, and slanting; sometimes the form is nearly that of or ordinary small $t$ without the ornamental turn at the bttom. In value it has been in all languages a surd or viceless dental, corresponding to $d$, which is voiced. But.he term "dental" includes some varieties of position, of wich the most definite are-(1) where the point of the tonge touches the teeth (true "dental"), as in French ; (2) whee the tongue touches the gum behind the teeth, and nothe teeth at all, as in English; (3) where the point of the:ongus is slightly bent back against the palate, producingthe sound much heard in south India (often called "ceebral"). T when followed by $i$ or $y$ is liable to pass in the $s$-sound ; this happened in the local dialects of Itys before the Christian era; at Rome the transition was lar. This changed sound passed on into the Romance languges, e.g., in French "nation," pronounced "nasion," wence in England it was sounded first as "nasiun" and nci as "nashun." Similarly in English $t$ followed by $u$ udergocs a change of sound ; this is due, however, to the wil sound of $u \bar{u}$, viz., long French $u$, or Old English $y$. This $\log y y$ developed into the iu sound beard in "use," "ure," \&c.; then the new $i$ affected the preceding $t$, and th result is tsh, as in "nature" (natshure); similarly $d$ in "ferdure" is sounded as dzh (verdzhure).
English employs the digraph $t h$ to denote two sounds, $d f i$ ring as voiceless and voiced sounds-the initial sounds c "thin" and "then" respectively. It would be a great onvenience if $d h$ could be used for the voiced sound, so bat "then" should be written "dhen." But it would be wen better if the single symbols could be employed to tenote these single sounds, as was to soine extent the case I the earlier days of our language : in Anglo-Saxon we have the two symbols $\delta$ and $p$. The first is only a $d$ crossed ; the econd was a rune and wascalled "thorn." These, however, were not consistently employed one for the voiceless and no for the voiced sound; also the is actually found in the oldest texts and later on it occurs together with 8 and $p$. it is prebable that the voiceless sound was originally the
only one in Teutonic. It was eventually differentiated into two sounds; but, as is usually the case, writing remained more archaic than speech. In modern English and Icelandic, and probably in the parent Teutonic also, initiad th is voiceless, except in English in a small number of pronouns and particles in common use, as "thou," "this," "that," "then," "than," "though," "thus"; and it is regularly voiceless when final. The nature of the two sounds is this: the tongue is pressed against the back of the teeth (sometimes, especially when used by foreigners, against the bottom of the upper teeth) and either the breath for th or the voice for $d h$ is forced through the interstices of the teeth. This pair of sounds is found in modern Greek, where thappears as $\theta$ and $d h$ as $\delta$. In Spanish and in Danish under certain circumstances the sound denoted by $d$ is $d h$.
tabarí and Early Arab Historians. Arahian historians differ from all others in the unique form of their compositions. Each event is related in the words of eje-witnesses or contemporaries transinitted to the final narrator through a chain of intermediate reporters (rawis), each of whom passed on the original report to his successor. Often the same account is given in two or more slightly divergent forms, which have come down through different chains of reporters. Often, too, one event or one important detail is told in several ways on the basis of several contemporary statements transmitted to the final narrator through distinct lines of tradition. The writer therefore exercises no independent criticism except as regards the choice of authorities; for he rejects accounts of which the first author or one of the intermediate links seems to him unworthy of credit,' and sonetines lie states which of several accounts seems to him the best. Modern jndgment does not always confirm this choice; some authorities much esteemed by Moslems are by Luropean scholars deemed untrustworthy, and vice versa. Fortunately the various historians did not always give preference to the same account of a transaction, and so one supplies what another omits.

A second type of Arabian historiography is that in which an author combines the different traditions about one occurrence into one continuous narrative, but prefixes a statement as to the lines of authoritios used and states which of theh he mainly follows. In this case the writer
recurs to the first method, already described, only when the different traditions are greatly at variance with one another. In yet a third type of history the old method is entirely forsaken and we have a continuous narrative only occasionally interrupted by citation of the authority for some particular point. But the principle still is that what has been well said once need not be told again in other words. The writer therefore keeps as close as lie can to the letter of his sources, so that quite a late writer often reproduces the very words of the first narrator.
From very early times the Arabs had great delight in verses and tales, and the development of their language was certainly much influenced by this fact. In ancient times story-tellers and singers found their subjects in the doughty deeds of the tribe on its forays, in the merits of horse or camel, in hinting adventures and love complaints, and sometimes in contests with foreign powers and in the impression produced by the wealth and might of the sovereigns of Persia and Constantinople. The appearance of the Prophet with the great changes that ensued, the conquests that made the Arabs-till then a despised race-lords of half the civilized world, supplied a vast store of new matter for relations which men were never weary of hearing and recounting. They wished to know everything about the apostle of God, whose influence on his own time was so enormous, who had accomplished all that seemed impossible and lad inspired the Arabs with a courage and confidence that made them stronger than the legions of Byzantium and Ctesiphon. Every one who had known or seen him was questioned and was eager to answer. Moreover, the word of God in the Koran left many practical points undecided, and therefore it was of the highest importance to know exactly how the Prophet had spoken and acted in various circumstances. Where could this be better learned than at Medina, where he had lived so long and where the majority of his companions continued to live? So at Medina a school was gradually formed, where the chief part of the traditions about Mohammed and his first successors took a form more or less fixed. Soon divers fathers of Islam began to assist memory by making notes, and their disciples sought to take written jottings of what they had heard from them, which they could carry with them when they returned to their homes. Thus by the close of the 1st century many dictata were already in circulation. For example, Ḥasan of Baṣra (d. 110 A.f.; 728 A.d.) had a great mass of such notes, and he was accused of sometimes passing off as oral tradition things he had really drawn from books; for oral tradition was still the one recognized authority, and it is related of more than one old scholar, and even of Hasan of Basra limself, that he directed his books to be burned at his death. The books were mere helps, and what they knew these scholars had handed on by word of month. Long after this date, when all scholars drew mainly from books, the old forms were still kept up. Tabari, for example, when he cites a book expresses himself as if he had heard what he quotes from the master with whom he read the passage or from whose copy he transcribed it. He eren expresses himself in this wise ; "Omar b. Shabba has related to me in his book on the history of Basra."

## Historians before Tabarí.

Naturally, then, no independent book of the 1st century from the Flight. has come down to us. But in the 2d century real books began to be composed. The materials were supplied in the first place by oral tradition, in the second by the dictata of older scholars, and finally by various kinds of documents, such as treaties, letters, collections of poetry, and genealogical hists. Genealogical studies had become necessary through 'Omar's system of assiguing state pensions to certain classes of persons according to
their kinship with the Prophet, or their deserts dering his lifetime. This subject received much attention evel in the Ist century, but books about it were first writte in the 2d, the most famous being those of Ibn al-Kalid ( d . 146 A.f.), of his son Hisham² (d. 20t), and of Al-Sharki ibn al-Kotéami. Genealogy, which often called for eluciduions, led on to listory. Beladhori's excellent Ausáb al-Ah hrá́ (Genealogies of the Nobles) is a history of the Arabson a genealogical plan.
The oldest extant history is the liography of the Ppyhet by Ibn Ishak (d. 150). This work is generally trustwrthy. Mohammed's life before he appearel as a prophet and the story of his ancestors are indecd mixed with manyfables illustrated by spurious verses. But in Ibn Ishakk's daf these fables were generally accepted as history-for many dithem had been first related by contemporaries of Mohanmedand no one certainly thought it blameworthy to put pious yerses in the mouth of the Prophet's forefathers, tough, according to the Filurist (p. 92), Ibn Ishak was dwoed by others with regard to the poems he quotes.

The Life of the Prophet by Ibn 'Okba (d. 111, based on the statements of two very trustworthy men, 'Orva ibn az-Zobair (d. 94) and Az-Zohri (d.124), seems to bi c, rite lost, Sprenger having vainly made every effort to find a copy. It was still much read in Syria in the 14 th century. But we fortunately possess the Book of the Campaiyns of the Prophet by AI-Wakidi (d. 207) and the important Book of Classes of his disciple Ibn Sa'd. ${ }^{\text {. }}$ Wákill hadmuch more copious materials than Ibn Isḥak, but gives way much more to a popular and sometimes romancing style of treatment. Nevertheless he sometimes helps us to recognize in Ibn Ishakk's narrative modifications of the genuine tradition made for a purpose, and the additional details he supplies set various events before us in a clearer light. Apart from this his chief merits lie in his studies on the subject of the traditional authorities, the results of thich are given by Ibn Sadd, and in his chronology, which is often excellent. A special study of the traditions about the conquest of Syria made by De Gocje in 1864 led to the conclusion that Wakidi's chronology is sound as regards the main events, and that later historians have gone astray by forsaking his guidance. This result has been confirmed by certain contemporary notices found by Nöldeke in 1874 in a Syriac MS. of the British Museum. And that Ibn Ishak agrees with Wakidi in certain main dates is important evidence for the trustworthiness of the former also. For the chronology before the year 10 of the Flight Wakidi did his best, buth here, the material being defective, many of his conclusions are precarious. Yet, though we have good ground for doubts, we are seldom able to construct a better chronology. Wákidi had already a great library at his disposal. He is said to have had 600 chests of books, cliefly dictata written by or for himself, but in part real books by Abú Nikhnaf (d. 130), Ibn Ishâk (whom he uses but does not name), 'Awina (d. 147), and other authors. Abú Nikhnaf left a great number of monographs on the chief events from the death of the Prophet to the caliphate of Walid II. These were much used by later writers, and We have many extracts from them, but none of the works themselves, except a sort of romance based on his account of the death of Hosain, of which Wüstenfeld has given a
${ }^{1}$ Of Hisbím b. al-Kalbi's boot there are copies in the British Museum and in the Escorial.
${ }^{2}$ Ibn Ishák's original work seems to be still extant in the Këprilii library at Constantinople; the edition of it by Ibn Hishám bas been edited by Wustenfeld (Göttingen, 1858-60) and transláted into German by Weil (Stuttgart, 1864).
3 Wákidí bas been edited from an imperfect MS. by Kremer (Calcutta, 1856). A condensed translation by Wellhausen appeared in 1882. The great book of Ibn Sa'd is unpublished, but there are some useful papers on it by Loth.
translation. With regard to the history of 'Irák in particular he was deemed to have the best lights, and for this subject he is TTabarl's chief source, just as Madáini, a yonnger contemporary of Wakidi, is followed by preference in all that relates to Khorásán. Madáini's History of the G'aliphs is the best if not the oldest published before TTabari; but this book has quite disappeared and is known only by the excerpts given by later writers, particularly Beladhor1 and Tabari.' From these we judge that ho had great narrative power with much clear and exact learning, and must be plaçed high as a critical historian. His plan was to record the various traditions about an event, choosing them with critical skill; sometimes, however, he fused the several traditions into a continuous narrative. A just estimate of the relative ralue of the historians can only be reached by careful comparison in detail. This has been essayed by Brünnow in his study on the Khárijites (Leyden, 1884), in which the narrative of Mobarrad in the Kámil is compared with the excerpts of Madaini given by Beládhori and those of Abú Mikhnaf given by Tabarí The conclusion reached is that Abú Mikhnaf and Madaini are both well informed and impartial.

Among the contemporaries of Wakidf and Madáinf were non Khidash (d. 223), the historian of the family Mohallab, whose work was one of Mobarrad's sources for the History of the K'harijuiles ; Haitbam ibn 'Adr (d. 207), whose works, though now lost, are often cited; and Saif ibn "Omar atTamimí, whose book on the revolt of the tribes under Abubekr and on the Mohammedan conquests was much used by Tabarf." Saif, however, seems to have been little esteemed ; Beládhorí very seldom cites hin, and nothing can be found in Arabic literature about his life and those of his authorities. He is barely mentioned in the Fihrist, the writer plainly ${ }^{\text {'having nothing to tell of him, and }}$ blundering in the one thing he does say by representing his disciple Sho aib as his master. Hájji Khalifa knows nothing bat his name. His narratives are detailed and of ten tinged with romance, and he is certainly much inferior to Wakid in accuracy. Besides these are to be mentioned Abú 'Obaida (d. 209), who was celebrated as a philologist and wrote several historical monographs that are often cited, and Azraki, whose excellent History of Mecea was published after his death by his grandson (d_244). With these writers we pass into the 3 d century of Islam. . But we have still an imporiant point to notice in: the 2 d century; for in it learned Persians began to take part in the creation of Arabic historical literature. Ily Molaffa translated the great Book of Persian Kings, and others followed his example. TTabarf and his contempuraries, senior and junior, such as Ibn Kotaiba, Yałkubib, Dinawari, preserve to us a good part of the information aliout Persian bistory made known through such translations. ${ }^{1}$. But even more important than the knowledge conveyed by these works was their influence on literary strple and composition. Half a century later began versions from the Greek either direct or through the Syriac. The pisces translated were mostly philosophical; but the Arabs diln learned something, however superficially, of ancient histöry. ${ }^{1}$
The 3d century was far more productive than the 2 d . A.bu' 'Obaida was presently succeeded by Ibn al-A'rábi (d. 231), who in like manner was clietly famous as a plilologist, and who wrote about ancient poems and battles. Muck that he wrote is quoted in Tabrizi's commentary on the H!amása, which is still richer in extracts from the historical elucidations of early poems given by Ar-Riyáshi (d. 257). Of special fame as a genealogist was Ibn Ḥabib

[^0](d. 245), of whom we have a booklet on Arabian tribal names published by Wüstenfeld (1850). Azralí again was followed by Fakihi, who wrote a History of Mecca in 272, ${ }^{2}$ and 'Omar b. Shabba (d. 262), who composed an excellent history of Baṣa, known to ns only by excerpts. Of the works of Zobair b. Bakkár (d. 256), one cf TTabari's teachers, a learned historian and genealogist much consulted by later writers, there is a fragment in the Köprïlii library at Constantinople, and another in Göttingen, part of which has been made known by Wüstenfeld (Die Familie 1l-Zobair, Göttingen, 1878). Yalkủbi or Ibn Wadih wrote a short general history of much ralue, published by Houtsma (Leyden, 1883). About India he knows more than his predecessors and more than bis successors down to Bèrúní. Ibn KZordádbeh's historical works are lost. Ibn 'Abdalhakan (d. 257) wrote of the conquest of Egypt and the West. Extracts from this book are given by De Slane in his Histoire des.Berbères, and others by Karle and Jones, from which we gather that it was a medley of true tradition and romance, and must be reckoned, with the book of his slightly senior contemporary, the Spaniard Ibn Habib, to the class of historical romances (see below, p. 5). A high place must be assigned to the historian Ibn Kolaiba (d. 276), who, as Rosen has well shown, wrote a series of books with a view to raising the scholarship of the large class of kátibs or official scribes. To this serics belong his veryuseful Handbook of Hislory (cd. Wuistenfeld, Göttingen, 1850) and his 'Oyún al-Akihtar, though the latter book according to the arrangement falls rather under the class of littera humaniores. Much more eminent is Beladhori (d. 279), whose book on the Arab conquest (ed. De Goeje, Leyden, 1865-66) merits the special praise given to it by Mas údŕ. Of his great Anscib al-Ashraf a large part exists at l'aris in the valuable collection of M. Schefer and another part was published by Ahlwardt in 1884. A contemporary, Ibn abi Ṭáhir Taifúr (d. 280), 'wrote on the 'Abbásid caliphs and was drawn on by Trabari. The sixth part of his work is in the British Museum. Of the universal history of Dinawarl (d. 2S2), entitled The Long Narratives, an edition by Girgas is now (1887) in the press.

## TTabarí.

All these histories are more or less thrown into the shade by the great work of TTabari, whose fame has never faded from his own day to curs, and who well deserves to have this article on early Arabic histories placed under his name. Abú Ja'far Mohammed b. Jarir at-Tabari (so his full name runs) is described as a tall lean figure, with large eyes, brown complexion, and hair which remained black till his death. His learning was astounding and few could speak so well. Born 224 A.H. (838-9 A.d.) at Amol in Trabaristán, he came to Baghdad as a young man and heard there the nost famous teachers of the age. He travelled through Syria and Egypt (where he was in 263), and finally settlcd down in Baghdad, where he remained till his death iu 310 ( 922 A.D.), always active and surrounded by pupils. He is said to have written forty pages daily for forty years. This no doubt is an exaggeration, but certainly he must bave been a man of most persistent industry. His two chief works are a great Commentary on the Koran and his Annals. There is an aneciote to the effect that each originally filled 30,000 leares, but that his pupils found them too extensive to be written to his dictation, and that be then resolved to condense them to a tenth of their original size, exclaiming, "God help us! Ambition is extinct." One cannot say how far this story is true, bat it is probable enough that his materials, at least for the Annals, were many times greater than the book itself.

[^1]Whêre tne same topic comes' up in the Annats and in the Commentary we often find different traditions quoted, or the same tradition derived through different channels, and this shows the copious variety of his sources. Various parts of the 4 nnals give the impression of being condensed. The Commentary was published before the Annals, and is better ${ }^{-}$composed It is the head corner-stone of Koran exēgésis, as the Annals are of historiography. It came into general uso mainly through the abridgnent of Baghawi in the beginning of the 6th century of the Flight, being itself too large to be nuch read. The great book exists complete in the viceregal library at Cairo, and ought to be published at once. ${ }^{1}$
The Annals are a general history from the creation to 302 A.H.; and are in the course of publication at Leyden. They will fill some 7000 to 7500 pages, one and a half printed pages corresponding roughly to one leai of TTabarl's original MS. Tabari added a supplement about his authorities, an abridgment of which is to follow the Leyden edition. It contains biographical notices of traditionalists, contemporaries of Mohammed, and their successors to the second half of tho 2 d century. ${ }^{2}$ Other works by Tabari will be spoken of in detail in the preface to the Leyden edition.
The success of the Annals and Commentary was due above all to the author's personality. The respect paid to him by his contemporaries appears in various anecdotes preserved in his biograply. His pupils had an unbounded admiration for his extraordinary knowledge, and what he said seemed to them the best that could be said. In truth, both his great works were the best of their kind, especially the Commentary, which, in the judgment of all impartial critics, has not been equalled, before or since, in completeness, learning, and independent judgment. A contemporary says that "it would be worth a journey to China to procure the book." So general was this view that the opinion of TTabarf was quoted as a legal authority.

The inferiority of the Annals as a literary composition may be due partly to the author's years, partly to the inequality of his sources, sometimes superabundant, sometimes defective, partly perhaps to the somewhat hasty condensation of his original draft. Nevertheless the value of the book is very great: the author's selection of traditions is usually happy, and the episodes of most importance are treated with most fulness of detail, so that it deserves the high reputation it has enjoyed from the first. This reputation rose steadily; there were twenty copies (one of them written by Tabarl's own hand) in the library of the Fátimite caliph 'Aziz (latter half of the 4th century), whereas, when Saladin became lord of Egypt, the princely library contained 1200 copies (Makrizir i. 408 sq.). Only princes and rich men could own a book which in the time of 'Aziz cost one lundred dinars. We know that it bad a place in most great libraries in other countries, for we find that it was used in all lands. Thus the fact that no complete copy can now bo found anywhere, and that the Leyden edition rests on odd volumes lying in various places, gives a striking image of what the East has suffered from barbarism.

The Annals soon came to be dealt with in rarious ways. They were pablished in shorter form with the omission of the names of authorities and of most of the poems cited; some passages quoted by later writers are not found even in the Leyden edition. On the other hand, some interpolations took place, one in the author's lifetime and perhaps by his own hand. Then many supplements were written, e.g., by Ferghání (not extant) and by Hamadhání (partly preserved in Paris). 'Arib of Cordova made an abridg-
${ }_{2}^{1}$ See the excellent article by Loth in Z.D.M.Q., xxxv. 588 sq.
${ }^{2}$ The MS. contaning this abridguent is described by Loth in $\%$ D.M.G.. इxxil. 581 sq. It is uow iu the British Museum.
ment, adding the history of the West and continuing the story to about $365 .{ }^{3}$ Ibn Jashkawaih wrote a history from the creation to 369 A.H., with the purpose of drawing the lessons of the story, following Tabari closely, as far as his book is known, and seldom recurring to other sources before the reign of Moktadir; what follows is his own composition, and shows him to be a writer of talent. ${ }^{4}$ In 352 an abridgment of the Annals was translated into Persian by Bal'amí, who, however, interwove many fables. ${ }^{5}$ Ibn al-Athr (d. 630) abridged the whole work, usually with judgment, but sometimes too hastily. Though he sometimes glided lightly over difficultics, his work is of service in fixing the text of Tabari. He also furnished a continuation to the year 620. Later writers took Tabari as their main authority, but fortunately sometimes consulted other sources, and so add to our knowledge,especially Ibn al-Jauzf (d. 597 ), who adds many important details. These Jater historians had valuable help from the biographies of famous men and special histories of countries and cities, dynastics and princes, on which much labour was spent from the 4th century onwards.

## Historians after ȚTabart.

Tho chief historians after Tabari may bo briefly mentioned in chronological order. Rázi (d. 325) wrote a History of Spain; Eutychins (d. 328) wroto Annals (published by Pocock, Oxford, 1656), which are very important because he gives tho Christian tradition; Ibn 'Abd Rabbihi (d. 328) has very valuable historical passages in his famons miscellany called Al.'Tl:d al-F'artd (3 vols, Cairo, 1293 A.H.) ; Șili (d. 335) wrote on the 'Abbásid caliphs, their viziers and conrt poets; Mas'údí (see Mas'ÚDY) composed various historical and geographical works (d. 345). Of Tabari's contemporary Hamza Ispahàni we have the Annals (published by Gottwaldt, St. Petersburg, 1844); Abu 'l-Faraj al-Ispaliání (d. 356) in his Book of Songs (Kilidib al-Aghdni, 20 vols., Cairo, 1285) gave tbe lives of fioets vhose songs were sung; Ibn al-1 Kitíya (d. 367) wrote a History of Spain; lbu Ziták (d. 387) a History of Egypt; "Otbi wrote tho Hzstory of Mahmuid of Ghazna (1. 421), at whose court ho lived (printed on the margin of the Egyritian cdition of Ibn al-Athír); Tha'labi (d. 427) wrote a well-known History of the Old Prophets; Abui No'aim al. 1spaháni (d. 430) wrote a History of Ispahan, chiefly of tho scholars of that city; Tha'alibi (d. 429 or 430 ) wrote, inter alia, a wellknova History of the Poets of his Time, now (1887) in course of pablication at Damascris. Berini (d. 440) takes a high placo ameng historians by his Chronolugy of Ancient Nations (ed. Sachau. Leipsic, 1878 ; Eng. trans., Londou, 1879) and his contributions to the history of India and Khwárizm; Koda'l (d. 454) mroto a Dcscription of Egypt and also various historical pieces, of which somo are extant; Ibn Sadid of Cordova (d. 462) wroto a View of the History of the T'arious Nations. Baghdad and its learned men found an cxcellent historian in Al-Khatib al-Baghdádi (d. 463), and Spain in Ibn Hayán (d. 469), and half a century later in Ibn Khakán (d. 529) and lhu Bassám (d. 542). Snm'áni (d. 562) wroto an cxcellent book on gencalogies; lbn "Asákir (d. 571) a History of Damascus and her Scholars, which is of great value, and cxists in whole or in part in several libraries. The Biographical Dictionary of tho Splaniard Ilin Pascual (d.578) and that of Dabbi, a somewhat junior contemporary, aro edited in Colcra's Bibliotheca Arab. IIisp. (1883-1885); Saladin found his historiau in tho famous 'Imad addin (d. 597). Ibn al-Jauzi, who dicd in the same ycar, lias been already mentioned. Abdalwahid's History of the Alnzohadcs, written in 621, was published by Dozy (2d ed., 1881). The geographer Yákit (d. 626) wrote also some historical vorks, now lost. Abdallatif ( d .629 ) is known by his writings about Egypt (trans. De Sacy, 1810); 1bn al-Athír (d. 630) wrote, in addition to the Chronicle already mentioned, a Biographical Dictionary of Contemporaries of the Prophet. Kifti (d. 646) is especially known by his History of Arabic Philologists. Sibt ibu al-Jauzi (d. 654), grandson of the Ibn al-Janzi already meationed, wrote a great Chronicle, of wbich much the larger part still exists. Codera has odited (Madrid, 1886) Ibn al-'Abbár's (d. 658) Biographical Lexicon, al. ready known by Dozy's excerpts from it. Ibn al-'Adiun (d. 660) is
${ }^{3}$ Of this work the Gotha library has a portion contsining 290-320 A.H., of which the part about the West has been printed bv Dozy in the Layan, and the rest is to be published at Leyden.

4 A fragment.(198-251 A.E.) is printed in Do Goeje, Fragn. Hist. Ar., vol. ii., Leyden, 1871. Schefer possesses an excellent MS. of the years 249-315; Oxford bas another fragment, $345 \cdot 360$ A. H. ; the second part is in the Escorial.

- The first part was rendered into French by Dubeux in 1836. We. have now an excellent French translation by Zotenberg, 1874.
famed for his History of Aleppe, and Abú Sháma (d. 665) wrote a well-knewn History of Saladin and Nurcddin, tsking a great deal from 'Imád addia. A. Miller has recently published (1885) Iba abl Ossihia'a (d. 688) History of Physicians. The History of 1bn
 Erpenius in 1625 . Ibu Sa'id al-Mlaghribi (d. 673 or 685 ) is fameus for his histories, but still more for lis geograpbicsl writings. The noted theologian NAWAwt ( $q . v$; d. 676 ) wrete a Biographical Dictionary of the Worthics of the Fivst Ages of Islam. Pre-emluent zs a biographer is 1bn Klhsllikía (d. 681), whose much-used work was partly edited by De Slane and completely by Wuistenfeld (1S3540), and translated inte English by the former eckiolar (4 vols., 1843.71).

Abu '1-Faraj, better knowu as Bar-Hebreus (d. 685), wrote besides his Syriac Chronicle an Arabic History of Dynastics (ed. Pocock, Oxferd, 1663). Ibn'Adhári's History of Africa and Spain has been published liy Dozy ( 2 vols., Leyden, 1848-51), and the Ķartds of Ibn sbi Zar' by Toruberg (1843). Orre of the hest known of Arab writers is Abulfeda (d. 732 ), whoso Annales Nruslenicxa were publishled with a Latiu versien by Reiska (Copenhagen, 5 vols, 4to, 1780.94). Tho Histor'y of the Time before Mohanuncd bas been published by Fleischer (1831). Not less famous is the groat Eheyclopartic of his contemporary Nowairi (d. 732), but only aome extracts are as yet la print. Ibn Sayyid an-Nís (1, "34) Yrote a full biography of the Prophet ; Mizzi (d. 742) an extensive work on the men firem whom traditions have been derived. We still possess, nearly conullete, the great Chronicle of Dhahabl (d. 748 ), a very learucd biograuher and listerian. A complete edition of the geographicel and historical Masilitic al-Absar of 1bn Fadlallia ( $L .749$ ) is much to be desired. It is known at 1 tesent ly citracts given by Quatremère and Amari Ibn al-Wardí (d. 749 or 750 ), best known by his Cosmography, wrote a Chronicle which has been printed it Egypt. Safadí (d. 764) got a great name as a biographer. Yaini' (d. 768 ) mrote a Chronicle of Islam and Lives of Saints. Sobki (d. TT1) published Lites of the Theologians of the Shafitite School. Of lba IKathir's Ifistory the greatest part is extant. For the history of Spsin and the Maghrib the writings of Ibn al-Khatib (d. 776 ) are of acknowledgcd value. Another history, of vhich we possess tho greater part, is the large work of Ibn alFerit (d. 807). Far superior to all these, however, is the famous Ibn Khaldin (d. 80S), who proves himself a great thinker in the Prelcgonena to lis Universal History. Of the Prolcgomena there are an edition ly Quatremere (1858) and a French version by Do Slana (1863). The latter scholar also published text and version of the History of the Berbers, and there is a poor Egyptian edition of the whole work. Of the historical works of the famous lexicographer Firizazaill (d. 817) only a Lifc of the Prophet romains. MarrızI (d. 845) is apoken of in a separate articla; Ibn Hajar (d. 852) is best known ly his Biographical Dictionary of Contcmporaries of the Prophet, now in courso of publication in the Biblio. threcu Indica. Ibn 'Arabshál (d. 854) is koown by bis. History of Timuir (Lícuward3n, 1767). 'Aini (d. 855) wrote a Gencral History, still extant. Abu'1-Ma hásin (d. 874) wrote at length on tho histery of Egypt ; the first twe parts have been publishcd by Juynboll. Fligel has publishal Ibn Kotlubogla's Biographice of the بḷtanafte Jurists. Ibn Shibna (d. 890) wrota a History of Alcppo. Of Sakhámi we posiess a bibliographical work on the historians. Tho polymath Soyuti (d. 911) contributed a History of the Caliphis and many biegraphical pieces. Samhídi's History of Mcd ina is known through the excerpts of Wustenfeld (1861). Tbu Iyás (d. 930) wrote a Ilistory of Egyph, and Díyirbekri (d. 966) a Lifc of Mo. hammed. To these names must be added Markaril (q.ev.) and IIajji Khalifa, the famons Turkish bibliographer (d. 1068), who, besides his Bibliographical Lexicon and bis well-known grography, the Jihuin-numa, wrote bistories, mostly in Turkish. He made use of Europeaa sources, and with him Aralic historiography may be said to cease, tbought ha had aome unimportant successors.
A word must beasaid of the bistorical romances, the beginnings of which go back to the first centuries of 1slam. The interest in all that concerned Mohammed and in the allusions of the Koran to old prephets and races led many professional narraters to cheoso inese subjects in place of tho doughty deeds of the Belouins. The incressing veneration poid to the Prephct and lowes for the marvelleus soon gave risa to fables about lis chrildheod, bis visit to heaven, \&ce, which havo found their' way oven into soler hisforics, just as many Jewish legends told by the converted Jew Kab al-Al:oár and by Wahb ibn Monabbih, and many fables ai.wut the old princes of Yemen told by'Abid, are taken as genuine bistory (see, hewever, Mas údi, iv. 88 sq.). A fresh. field for ronantic legead mas found in the history of the victeries of Islam, the exploits of the first heroes of the faith, the fortuacs of 'Ali and his houso. Even under the first Omsyyads there were in the mosques of most great cities prezchers wlio edified the people by atories about Islam and its victories, and there is ample ovidence that these men did not stick to actual fact. Sbo'bs said of them "they get from us a handbreadth of tradition and mako it an ell." Thore too, linitory was often expressly forged for party ends.

The poople swallewed all this, and so a romantic tradition sprang up side by side with the historical, and had a literature of its own, the begianings of which must be placed as early as the secoud ceutury of the Flight. The oldest amples still extant are tho fables about the conquest of Spain ascribed to lbn 1Iabib (d. 238), and those about the conquest of Egypt aod tha West by Ibn 'Abdalhakam (d. 257). Iu these truth and falsehood are mingled, as Dozy has shown in his Recherches. But most of the extant literature of this kind is, in its present form, much more recent; c.g., the Story of the Dcath of Hosain by the Pseude Abu MFikhnaf (translated by Wiustenfeld); tho Conquest of Syria by Abú Ismáil al-Baçri (edited by Nassau Lees, Calcutta, 1854, and cliscussed by De Goeje, 1864) ; the Psende-Wákidi (see Mamaker, De Expugnatione Memphidis et Alcxandris, Leyden, 1835) ; the Pseudo-1bo Kotaiba (өee Dozy, Recherches) ; the book ascribed to A'sam Kuffi, \&e. Further inquiry into the origin of these works is called for, but some of them were plainly directed to stir up fresh zeal against the Christians. In the 6th century some of these books had gained so mneh authority that they were used as sources, and thus mauy untruths crept into accepted history.
(M.J. DE G.)

TABERNACLE, the portable sanctuary of Israel in the wilderness wanderings. Critical analysis of the Pensatevcir ( $q . v$. ) teaches us to draw a sharp line between the sld aotices of the tabernacle contained in the pre-Denteronomic history sowik (JE) and the account given by the post-exilic priestly narrator. The latter throws back inte the time of Moses the whole schene of worship and ritual of which the second temple was the centre, and, as this scheme necessarily implies the existence of an elaborate sanctuary on the pattern of the temple, he describes a tabernacle of extraordinary splendour pitched in the middle of the camp, with an outer aud inncr chamber and a courtyard, and all the apparatus of sacrificial and atoning ritual, just as in the temple, only constructed of boards, posts, and curtains so that it could be taken down and moved from place to place. The whole description is ideal, as appears not only from the details but from the fact that the old history knows nothing of such a structure. The Chronicler indeed, who had before him the Pentateuch in its present shape, assumes that.after the Israelites entered Canaan the tabernacle continucd to be the one legitimate place of sacrifice until it was superseded by Solomon's temple, and represents it as standing at Gibeon in the days of David and his son (1 Chron. xxi. 29 sq.; 2 Chron. i. 3). But the book of Kings knows Gibeon only as "the greatest high place" (1 Kings iii. 4). ${ }^{1}$

Again, the tabernacle of the Priestly Code is pre-eminently the sanctuary of the ark, bearing the name mishkan ha educh." "the tabernacle of the testimony," i.e., the habitation in which lay "tho ark of the testimony" or chest containing the stones on which the decalogue was inscribed. But between Joshua's days and the building of the temple the ark migrated from one tent or habitation to another ( 2 Sam. vii. 6 ; I Chron. xvii. 5), and at Shiloh it was housed not in a tent but in a temple ( $1 \mathrm{Sam} . \mathrm{iii} .3,15$ ). And, while in the Priestly Code the tabernacle is the only legitimate sanctuary and its priests are tho ouly legitimate priests, the whole history shows that no such restriction was even thought of till after the time of the prophet Isaiah.

With all this it agrees that the oldest parts of the Pentateuch speak indeed of a tabernacle, but one of a quite different kind. The tabernacle of the Elohist (for of the two narratives-Elohistic and Jahvistic-which are combined in the so-called Jehovistic history only the former seems to mention it) is a tent which Moses pitched outside the camp (Exod. xxxiii. $7,8 q$.), and where Jehovah was wont to reveal Himself to him in the pillar of cloud, which descended for the purpose and stood at the door (Num. xi. 25 ; xii. 5 ; xiv. 10); it is therefore called ohel möed, " the

[^2]tent of tryst." No description of it is given, nor is its origin spoken of but something of the old narrative has obviously been lost before Fixod. xxxiii. 7, and here what is lacking was probably explained. It appears, however, that it was very different fsom the tabernacle described by the priestly narrator. Tt was not in the centre of the camp but stood some distence outside it, ${ }^{1}$ and it was not the seat of an elaborate organization of priests and guarded by a host of Levites, bat had a single minister and custodian, viz. Joshua, who was not a Levite at all but Moses' attendant (Exod. Exxiii. 11).

The existence of such a simple tent sanctuary presents none of the difficulties that beset the priestly narrative. Portable shrines we:e familiar to Semitic antiquity, and tents as sanctuaries were known to the Israelites in much later times at the high places and in connexion with irregular worships (Fzek. xvi. 16, "thou didst take of thy garments and madest for thyself sewn high places," i.e., shrines of curtains sewn together; 2 Kings exiii. 7, where for "bangings for the grove" read "tents for the Ashera": comp. Hos. ix. 6 and Syriac prakk, Assyrian parakku, a small chapel or shrine, from the same root as Hebrew pārōketh, the vail of the Holy of Holies). Such idolatrous tabernacles were probably relics of the usages of the nomadic Semites, and it is only natural that Israel in its wanderings should have had the like. And it is noteworthy that the portable chapels of the heathen Semites were mainly used for divination (comp. Journ. of Philol., xiii. 283 sq .), just as the Mosaic tabernacle is described by the Elohist not as a place of sacrifice (such as the tabernacle of the Priestly Code is) but as a place of oracle.

The heathen shrines of this sort contained portable idols or baetylia (see Selden, De Diis Syriis, i. 6); but what the Mosaic tabernacle contained is not expressly told. The ordinary and seemingly the easiest assumption is that the ark stood in it, and Dent. x. 1.sq., which must be drawn from the lost part of the older narrative already alluded to, certainly places the construction of the ark, to contain the tables of stone, just before the time when the tabernacle is first mentioned by the Elohist. But neither in Deuteronomy nor before it are the ark and the tabernacle ever mentioned together, and of the two old. narrators it is not clear that the Jahvist ever mentions the tabernaclo or the Elohist the ark. The relation between the two calls for further investigation, especially as the ark retains its importance after the occupation of Canaan, while the "tent of tryst" is not mentioned after the time of Moses, who, according to the Elohist (Exod. xii.), enjoyed at it a privilege of direct access to the Deity not accorded to later prophets.

TABERNACLES, Feast of. The original character of this Hebrew feast, celebrated at the close of the agricultural year as a thanksgiving for the produce of the seasons, but especially for the vintage and olive harvest, has been explained in Pentateveh, vol. sviii. p. 511. As such it is described in the old law of Exod. xxiii. 16, under the name of "the feast of ingathering, at the end of the year" (which, in the old Hebrew calendar, ran from nutamn to autumn), "wheu thou hast gathered in thy labours out of the field " (comp. Exod. xxxiv. 22). The same feast is spoken of in Deut. xvi. 13 as "the feast of booths" (E.V. "taidernacles," whence the current name of the feast), when "thou hast gathered in thy corn and wine" fror the corn-floor and the wine-press. No explanation is here giveu of the name "feast of booths"; but after the exile it was understood that during this feast the people assembled at Jerusalem were to live in

[^3]booths constructed of branches of trees (Lev. xxiii. 39 sq .; Neh. viii. $14 s q$.). The passage in Nehemiah, describing the celebration of the feast in 444 b.c., serves as a commentary on the post-exilic law in Leviticus, and from it we learn that the use of booths on that occasion had ne foundation in traditional usage, but was based directly on the law, which then for the first timo became generally known. ${ }^{2}$ According to the law in question, the booths were to be a memorial of the wilderness wandering (Lev. xxiii. 43), but of this there is no hint in Denteronomy; and, while it is quite in the style of the later lass to attach a new historical reference to an old name liks "feast of booths," it is certain from Exodus that the feast had originally agricultural and not historical significance. As such it is exactly parallel to the vintage feasts of other ancient nations, e.g., to the Athenian Oschophorian And, in particular, it is noteworthy that in Jndges ix. 27 we find a vintare feast at Shechem among the Canaanites, from whom the Israelites first learned the ways of agricultural life, and from whom so much of the popular religion was copied. To acts of worship nominally addressed to Jehovah, but really to the Canaanite Barlim, Hosea expressly reckons rites celebrated "on all cornfloors" (ix. 1), expressing thanks for divine gifts of corn, wine, and oil (ii. 8 sq .), and in their context these allusions leave no doubt that the prophet refers, in part at least, to autumn feasts, in which Jehovah worship was mingled with Canaanito clements (comp. Wellhausen, Prol. zuer Gesch. Isr., cap. 3, ii.; Eng. trans., p. 92 sq.). These feasts were local in character, but in northern Iscael there was a great autumn feast at the royal sanctuary at Bethel (1 Kings xii. 33), as even in the days of Solomon there was such a feast at Jerusalem (1 Kings viii. 2). In the nature of things the local feasts were the older, and it was the fame of great shrincs that gradually tended to draw worshippers from a distance to temples like those of Jerusalem and Bethel. Finally, the Deuteronomic law of the one sanctuary and the course of events which made that law the practical rule of the remnant of Israel put an end to all local religious feasts, but at the same time obscured the old significance of the festal cycle, and made room for the bistorical interpretation of the celebrations, now concentrated at the temple, which prevailed among the later . Fews (comp. Passover and Pentecost). In their later form all the jearly feasts have exact times and rules. In Deutcronomy the autnmn feast is not yet tied to a day-it could hardly ba so wiile it was still essentially a harvest thanksgiving-but in the priestly legislation it is fixed to commence on the fifteenth day of the seventh month (Lev. zxiii. 34) In Deuteronomy the feast lasts seven days; Lev. zxiii. 36 adds an eighth, and this day nltimately became the most important (John vii. 37).
FIf we accept the conclusion that the autumn festival was originally a vintage fast celebrated in local sanctuaries, the narce "feast of booths" admite of a natural explanation. The Canaanite feast at Shechem and the Helrew feast at Shiloh (Judges xxi. 21) were partly celebrated abroad in the vineyards, and Ilosea also knows such feasts on the open corn-floors. That it was asual to Go forth and live ia booths during the vintage may be concluded from Isa. i. 8; the same practice still prevails at Hebrod (Robinson, Bibl. IRes, ii 81). If it was these booths ereeted among the vineyards that originally gave their name to the feast, we can understand how the book of Nehemiah recognizes the erection of booths within the city of Jerusalem as an inaovation. No doubt at all feasts where there was a great concourse of visitors many would he compelled to live in tents; this seems to have been the case even in old Israel (Hos. xii. 9). But that is quite a different thing from the later observance, in which bnoths or bowers had to bo made and used even by those who lad huases of their awn.

[^4]tables, Mathematical. In any table the results tabulated are termed the "tabular resalts" or "respond. ents," and the corresponding numbers by which the table is entered are termed the "arguments." A table is said to be of single or donble entry according as there are one or two arguments. For example, a table of logarithms is a table of single entry, the numbers being the arguments and the logarithms the tabular results; an ordinary multiplication table is a table of double entry, giving $x y$ as tabular result for $x$ and $y$ as arguments. The intrinsic value of a table may be estimated by the actual amount of time saved by consulting it ; for example, a table of square roots to teu decimals is more valuable than a table of squares, as the extraction of the root would occupy more time than the raultiplication of the number by itself. The value of a 'able does not depend upon the dificulty of calculating it; for, once made, it is made for ever, and as far as the user is concerned the amount of labour devoted to its original construction is immaterial. In some tables the labour required in the construction is the same as if all the tabular results had been calculated separately; but in the majority of instances a table can be formed by expeditions methods which are inapplicable to the calculation of an individual result. This is the case with tables of a continuous quantity, which may frequently be constructed by differences. The most striking instance perhaps is afforded by a factor table or a table of primes; for, if it is required to determine whether a given number is prime or not, the only available method (in the absence of tables) is to divide it by every prime less than its square root or until one is found that divides it without remainder. But to form a table of prime numbers the process is theoretically simple and rapid, for we have only to range all the numbers in a line and strike out every second beginning from two, every third beginning from three, and so on, those that remain being primes. Even when the tabular results are constructed separately, the method of differences or other methods connecting together different tabular results may afford valuable verifications. By having recourse to tables not only does the computer save time and labour but he also obtains the cerfainty of accuracy; in fact, even when the tabular results are so easy to calculate that no time or mental effort would be saved by the use of a table, the certainty of accuracy might make it advantageous to employ it.

The invention of logarithms in 1614, followed immediately by the calculation of logarithmic tables, revolutionized all the methods of calculation; and the original work performed by Briggs and Vlacq in calculating logarithms 260 years ago bas in effect formed a portion of every arithmetical operation that has since been carried out by means of logarithms. And not only has an incredible amount of labour been saved ${ }^{1}$ but a vast namber of calculations and researcbes have been rendered practicable which otherwise would have been quite beyond human rcach. The mathematical process that underlies the tabular method of obtaining a result may be indirect and complicated; for example, the logarithmic method would be quite unsuitable for the multiplication of two numbers if the logarithms had to be calculated specially for the purpose and were not already tabulated for use. The arrangement of a table on the page and all typographical details-such as the shape of the figures, their spacing, the thickness and placing of the rules, the colour and quality of the paper, dec.-are of the highest importance, as the computer has

[^5]to spend hours with his eyes fixed upon the book; and the efforts of eye and brain required in finding the right numbers amidst a mass of figures on a page and in taking them out accurately, when the computer is tired as well as when he is fresh, are far more trying than the mechanical action of simple reading. Moreover, the trouble required by the computer to learn the use of a table need scarcely be considered; the important matter is the time and labour saved by it after he has learned its use. Tables are, as a rule, intended for professional and not amateur nse ; and it is of little moment whether the user who is unfamiliar with a table has to spend ten seconds or a minute in obtaining an isolated result, provided it can be used rapidly and without risk of error by a skilled compater.

In the following descriptions of tables an attempt is made to give an account of all those that a computer of the present day is likely to use in carrying out arithnetical calculations. Tables of merely bibliographical or historical interest are not regarded as coming within the scope of this article, although for special reasons such tables are briefly noticed in some cases. Tables relating to ordinary arithnetical operations are first described, and afterwards an account is given of the most useful and least technical of the more strictly mathematical tables, such as factorials, gamma functions, integrals, Bessel's functions, \&c. It is dificult to clessify the tables described in a perfectly satisfactory manner without prolizity, as many collections contain valuakle sets belongirg to a variety of classes. Nearly all modern $\mathrm{ta}_{\mathrm{a}} \mathrm{h}_{\mathrm{l}}$ les aro stereotyped, and in giving their titles the accorapanyizg date is either that of the original stereotyping or of the tirage in question. In tables that have passed tarough many editions the date given is thzt of the edition described. A much fuller account of general tables pubiished previously to 1872 , by the present writer, is contained in the British Association Report for 1873, Fp. 1-175; and to this the reader is referred.
Tables of Divisors (Factor Tebles) and Tables of Primes.-The Divioow existing factor tables extend to $9,000,000$. In 1811 Chernac pnb-and lisbed at Deventer his Cribrum Arillmeticum, which gives alf the prime prime divisors of every number not divisible by 2,3 , or 5 up to 1,020,000. In 1814-17 Burckhardt published at Paris his Tables des Diviseurs, giving the least divisor of every number not divisible by 2,3 , or 5 up to $3,036,000$. The second million was issued in 1814, the third in 1816, and the first in 1817. The corresyonding tables for the seventh (in 1862), eighth (1863), and ninth (1865) millions were calculated by Dase and issued at Hamburg. Dase died suddenly during the progress of the work, and it was completed by Rosenberg. Dase's calculation was performed at the instigation of Gauss, and be began at $6,000,000$ because the Berlin Acadenn was in possession of a manuscript presented by Crelle extending Burckhardt's tables from $3,000,000$ to $6,000,000$. This manuscript not having been published by 1877, was found on examination to be so inaccurate that the publication was not desirable, and accordingly the three intervening millions were calcolated and published by Jemes Glaisher, the Factor Table for the Fourth Million appearing at Loodon in 1879, and those for the fifth and sixtb millions in 1880 and 1883 respectively (all three millions stereotyped). The tenth million, though calculated by Dase and Rosenberg, has not been published. It is io the possession of the Berlin Academy, baving been presented in 1878. The nine qnarto volumes (Tables des Diviseurs, Paris, 1814-17; Factor Tables, London, 1879-83; Factoren-Tufch2, Hamburg, 1862-65) thus form one uniform table, giving the least divisor of every number not divisible by 2,3 , or 5 , from unity to nioe millions. The arrangement of the restlts on the page, which is due to Burckhardt, is admirable for its clearness and condensation, the least factors for 9000 numbers being given on each page. The tabular portion of each million occupies 112 pages. The first three millions were 1ssued separately, aod also bound in onc volume, but the other six millions are all separate. Burckbardt began with the second million iostead of the first, as Cbernac's factor table for the first million was already in existence. Burckhardt's first million does not supersede Chernac's, as the latter gives all the prime divisors of numbers not divisible by 2,3 , or 5 up to $1,020,000$. It occupies 1020 pages, and Burckhardt found it very accurate ; be detected only thirty-eight errors, of which nioe were due to the author, the remaining twenty-vine having been caused by the slipping of type

In the printing. Tho errata thus discovered are given in the first million. Burckharilt giver but a very brief account of the metbod by whih he constructed his table; and the introduction to Dase's millions merely coosists of Gauss'a letter suggesting their conatruction. The Introduction to the Fourth Blillion (pp. 52) con. ains a full accourt of the metbod of construction and a history of factor tables, with a bibliography of writings on the subject. The Introdnction (py. 103) to the Sixth Afillion tontains an enumeration of primes and a great number of tabies relating to the distribution of primes in the whole nine-millions, portions of which had been published in the Cambridge Philosophical Proceedings and elsewhere. The factor tables which have been deacribed greatly exceed in both extent and accuracy any ethers of the same kind, the argest of which only reaches 403,000 . This is the limit of Felkel'\& Tafel aller einfachen Factoren (Vienna, 1776), a remarkable and extrenely rare book, ${ }^{2}$ nearly all the copies having been destroyed. Vega (Tabule, 1797) gave table showing all the divisors of numbers not divisible by 2,3 , or 5 up to 102,000 , followed by a list of primes from 102,000 to 400,313 . In the earlier editions of this work there are several errors in the list, but these are no doubt corrected in Hulsse's edition (1840). These are the largest and most convenieot tahles after those of Chernac. Salomon (1827) gives a factor table to 102,011, Kibler (Handbuch, 1848) all divisors up to 21,524, and Houël (Tables de Loga ithmcs, 1871) least divisors up to 10,841. Berlow (Tables, 1814) gives the complete resolution of every number up to 10,000 into its factors; for example, correspondung to 4932 re have given $2^{3} \cdot 3^{2} \cdot 197$. Thie table is unique so far as we know. The work also contains a list of primes up to 100,103 . Both these tables are onitted in the stereotyped reprint of 1840. In Rces's Cyclopsdia (1819), article "Prime Numbers," there is a list of primes to 217,219 arranged in decades. The Fourth Sfillion (1879) contains a list of primes up to 30,341 . On the first page of the Second Milllion Burckhardt gives the first nine multiples of the primes to 1423 ; and a smaller table of the same kind, exteudiag only to 313, occurs in Lambert's Supplementa.
Multiplication Tables.-A multiplication table is usually of double entry, the two arguments being the two factors; when so arranged it is frequently called a Pythagorean table. The largest snd most usefut work is Crelle's Rechentafeln (stereotyped, Bremiker's edition, 1864), which gives in one volume all the producta up to $1000 \times 1000$, so arranged that all the multiples of any ono nember appear on the same page. The original cdition was published in 1820 and consisted of two thick octavo volumes. The eecond (stereotyped) edition is a convenient folio volume of 450 pages. Only one other multiplication table of the same extent has appeared, viz., Herwart von Hohenburg's Tabuls Arithmetics Mporөaфaı. ptéews Universales ${ }^{2}$ (Munich, 1610), on which see Napier, vol. xvii. p. 183. The invention of logarithms four years later afforited another means of performing multiplications, and Von Hohenburg's work never becane generally known. The three following tables are for the multiplication of a number by a single digit. (1) Crelle, Erleicherungs. Tafcl fïr jeden, dow zu rechnex hat (Borlia, 1836), a work extendit $⺊$ to 1000 pages, gives the proluct of a number of seven figures by a single digit, by means of a double operation of entry. Each page is divided into two tables: for example, to multiply 9382477 by 7 we tnrn to page S25, and enter the righthand table at line 77, columu 7, where we find 77339; we then enter the left-hend table on the same page at line 93, column 7 , and find 656, so that the product required is 65677339. (2) Bretscbneider, Produktentafcl (Mamburg and Goths, 1841), is somewhat similar to Crelle's table, but sunaller, the nnmber of figures in the multiplicand being five instead of seven. (3) In Landy, $A$ Table of Products (London, 1865), tho product of any five-figure number by a single digit is given by a double arrangement. The extent of the table is the same as that of Bretachncider's, as also is the principle, but the arrangement is diferent, Laundy'a table occupying only 10 pages and Protschneider's 99 pages. Among earlier works may he noticed Gruson, Crosses Einmalcins ron Eins bis Hundertinuscid (Berlin, 1799), -s table of products up to $9 \times 10,000$. Tho author's intention was to extend it to 100,000 , but we believe only the first part was publisbed. In this book there is no condensation or double arrangement; the pages are very large, each containing 125 lincs.
Quarter-Squares.-Nultiplication may be performed by means of a table of single entry in the manner indicated by the formula -

$$
a b=\frac{1}{4}(a+b)^{3}-\frac{1}{4}(a-b)^{2} .
$$

Thus with a table of quarter-squares we can multiply together any two r"smbers by subtracting the quarter-squary of their difference from ihe quarter-square of their sum. The largest table of quartersquares is Leundy, Table of Quarter-Squares of all Numbers up to 100,000 (Londod, 1856). Smaller works are Centnersch wer, Newerfundene Multiplications-und Quadrat-Tafeln (Ber!in, 1825), which extends to 20,000 , and Merpant, Tables Arithmonomiques 1 For information sbout it, sea a paper on "Factor Tables," in Cumb. Phil. froc. vol. 1il. (18is) pp. $99-188$, or tha Introdnction to the Fourth Million. 2 See a payer "On Multiplication is mase of Sibgla Entry," In Phil. Mag.,
(Yannes, 1832), which extends to 40,000. In Morpaut's work the quarter-square is termed the "arithmone." Ludolf, who published in 1690 a table of squaros to 100,000 (see next paragraph), explains in his introduction how his tahle may be used to effect multiplications by means of the above formula ; but the earliest book on quartoraquares is Voisin, Tables des Multiplications, ou logarithmes des nombres entics depuis 1 jusqu'd 20,000 (Paris, 1817). By a logarithm Voison means a quarter-squara, i.e., he calls a a root and ${ }_{4} a^{3}$ its logarithm. On the subject of quarter-squares, \&c., see the paper (already referred to) in Phil. Mag., November 1878.

Squares, Cubcs, de. -The most convenient table for general nse, as well as the most extensive, is Barlow's Tables (Useful Knowledge Society, London, from the stereotyped plates of $18+1$ ), which gives squares, cubes, sqnare roots, cube roots, and reciprocais to $10,000$. The largest table of squares and cubes is Kulik, Tafeln der Quadrat-und Ǩubik-Zahlen (Leipsic, 1848), which gives hoth as far as 100,000 . Two early tables also give squares as far as 100,000 , viz., Maginns, Tabula Tetragonica (Venice, 1592), and Ludolf, Tetragonometria Tabularia (Amsterdam, 1690). Hutton, Tables of Products and Powers of Numbers (London, 1781), gives souares up to 25,400 , cnbes to 10,000 , and the first ten povers of the first hundred numbers. Barlow, Mathomatical Tables (original edition, Loudon, 1814), gives the first ten powers of the first handred numbers. The first nine or ten powers are giveu in Vega, Tabules (1797), and in Hülsse's edition of the same (1840), in Kohler, Handbuck (1848), and in other collections. Fà̀ do Brino, Calcul des Erreurs (Paris, 1869), and Miuller. Vicrstelliae Logarithmen (1844), give sqnares for use in connexion with the mernod of lunt wars res. Small tables occur frequeutly in books intended for engineers and practical men. Drech (Ifessenger of Math., vol. rii., 1878, p. 87) has given to 33 places the cube roots (and the cube roots of the squares) of primes up to 127. Small tables of powers of $2,3,5,7$ occur in various collections. In Vega's Tabulee (1797, sud the subsequent editions, including Hüisse's) the porers of 2, 3, 5 as far as the 45 th, 36 th, and 27 th respectively are given ; they also occur in Köhler's Hard. buch (1848). The first 25 powers of 2, 3, 5, 7 are givon in Salomon, Logurithmische Tafeln (1827). Shanks, Rectification of the Circls (1853), gives powers of 2 np to $2^{\text {r2 }}$.

Triangular Numbers.-E. de Joucourt, De Natura et Preclara Usic Simplicissime Spccici Numeromum Triganalium (Tlie Hague, 1762), contains a table of trianguler nambers ap to 20,000: viz, $\frac{1}{2} n(n+1)$ is given for all nambers from $n=1$ to 20,000 . The table occupies 224 pages.
Reciprocals.-Barlow's Talles give reciprocals up to 10,000 to 9 or 10 places; and they have been carried to ten times this extent by Oakes, Table of the Reciprocals of Numbers from 1 to 100,000 (London, 1865). This gives seven figures of the reciprocal, and is arranged like a table of seven-figure logarithms, differences being added at the side of the page. The reciprocal of a number of five figures is taerefore taken out at ance, and two more figures may be interpolated for as in logarithms. Picarte, La Division reduite d une Addition (Paris, 1861), gives to ten significant figures the reciprocals of the nnmbers from 10,000 to 100,000 , and also the first nine multiples of these reciprocals, Small tables of reciprocals are not common.
Tablesfor the Expression of Vulgar Fractonsus Decinals.-Tables of this kind have been given by Wacherer, Goodwyn, and Gauss. Wucherer, Beyiridge zum allgemeinern Cebrauch der Decimalbrache (Carlsruhe, 1796), gives the decimsl fractions (to 5 places) for all vulgar fractions whose numerator and denominator are each less than 50 ond prime to one another, srranged according to denominairrs. The most extensive sor elaborate tables that have been publ wed are contained in Henry Goodwyn's First Centenary of Tables of all Dccimal Quotients (London, 1816), A Tabular Series of Decimat Quotients (1820), and A Table of the Cirelca arising from the Division of a Unit or any othes Whole Number by all the Integers from 1 to 1024 (1823). The Tabular Serics (1823', running to 153 pages, gives to 3 places the decimal corresponding to every rulgar fraction less than for whose numerator and aerominator do not surpass 1000. The arguments are not arranged according to their numerators or denominstors, bat according to their magnitude, so that the tabular results exhibit a steady increase from 001 ( $=$ roro) to 09989909 ( $=8 \circ \circ \circ^{\circ} \mathrm{F}$ ). The anthor inteuded the table to include alf fractions whose numerator and denominator were each less than 1000, but no more $m$ ever publighed. The Table of Circks (1823) gives all the periods of the circulating decimals that can srise from the division of any integer by another integer less than 1024. Thas for 13 we find 0076923 and $\cdot 153846$, which are the only periods in which the fraction $\frac{x}{13}$ can circulate The table occupies 107 pages, some of the periods being of course very long (e.g., for 1021 ths period contains 1020 figures). Thie First Centena:y (1816) gives the complete periods of the reciprocals of the numbers from 1 to 100. Good Wyn'a tables sre very scarce, bnt as they are cearly unique of their kind they deserve special notice. A second adition of the First Certenary was issued in 1818 with the addition of some of the Tabular Scries, the nnmerator not exceeding 50 and the donomin
nator not excceding 100. A posthumous tablo of Ganas'e, entitled "Tafel zur Vermandlung gemeiner Brúcho mit Neanern nus dom eraten Tausand in Decimalbruche," occure in vol. ii. pp. 419.434 of his Gesammello JVerkc (Gottingen, 1863), and resenblea Goodrryn's Table of Circles. . On this subject seo a paper "On Circulating Decimals, with special referenco to Honry Goodryn's Tuble of Circles and Tabular Scrics of Decimal Quolicnts," in Camb. Phil. Proc, col. jii. (1878), pp. 185-20C, whero is also given a table of tho periods of fractions corresponding to denominators primo to 10 from 1 to 1024 obtamed by counting from Goodwyn'a table. See also tho section on "Circulating Decimals," p. 13 below.

Sexagcsinial und Scxcentcnary Tables. - Originally all calculations wero acxagosimal; and tho relies of the aystem still exist in the divisiou of the demres into 60 minutes and tho minuto into 60 asconos. To facililato interyolation, therefore, in trigonometrical and other tables the following largo sexagusimal tablos were conatructed. John Bernoulli, A Scxceuenary Table (London, 1779), gives st once the forrth torm of eny proportion of which the first term is $600^{\prime \prime}$ and each of the other two is less than $600^{\prime \prime}$; the tabie is of double entry, and may be moro fully described os giving the valne of $\frac{2 y}{600}$ correct to tenths of a second, $z$ and $y$ cach containing a numher of seconds less than 600. Nichacl Taylor, A Scxa. gesimul Table (London, 1780), exhibits at sight the fourth term of sny proportion whero tho first torm is 60 minutes, tho secoud any unmber of minutes less than 60 , and the third any number of minutes and aeconds noder 6$)$ minutes; there is also another tablo in whed tho third term is any absuluto number noder 1000 . Not macb nso zeems to havo been made of these tables, both of which Were pablished by the Commissioners of Longitude. Small tables for the conversion of acxagesimals iuto centesimals and vice versa aro given in a few collections, such as Hulsse's cdition of Vega.

Trignomeirncul Talles (Natural)- Peter Apian published in 1533 a table of sines with tho radius divided decinally. The first complete canon giving all tho six ra*ios of the si les of a right-angled triangle 19 due to Rheticus (1551), who also introduced the semiquadrantal arrangement. Elicticns's canon was calculated for cvery ten minutes to 7 places, and Viets estendad it to evory minute (1579). In 1654 Reinhold published a table of targents to every minutc. The first complete canon publishod in Englanel was by Blunedvilc (1594), although a table of biDes bad appeared four jears earlier. Regiomontanus called his tablo of tangenis (or rather cotangents) tabula focunda on account of its great use; and till the introduction of the word? "tangant" by Finck (acomelriss Robundi Libri XTV., Basel, 1583) a table of tangents was called 2 labula fucunda or canon focundus. Besides "tangent," Finck also introduced the word "secant," the table of secants having previonsly heen called tabula benefica by Manrolycus (1568) and tabula fxenndissima by Vieta

By far the greatest cowputer of pure trigonometrical tables is Georgo Joac̣im Rheticus, whose worl las nover been superseded. तis celebrated ten-decimal canon, tho Opus Paiatinum, was published $\mathrm{b} v$ Valentine Otho at Neustadt in 1596 , and in $1613^{\circ}$ his fifteen-decimal fable of sides by Pitiscus at Frankfort under tho title Thesaurus Mathematicus. The Opus Pajalinum contains a completo ten-decimal trigonometrical canon for every ten acconds of the quadrant, semiquadrantally arranged, with differences for rll the tabular resulte throughout. Sines, cosines, and secants aro given on the left-hand pages in columns beaded, respectively "Perpendiculum," "Basis," "Hypotenusa," and on thio right-hand appear tangents, cosecants, and cotangents in columns headed respactively "Perpendiculum," "Hypotenusa," "Basis." At his death Rheticus left the canon nearly complete, and the trigonomotry was finished and the whole edited by Valentino Oiho; it was named in honour of the elector palatino Frederick JV., Who boro the ex. pense of publication. The Thesaumes of 1613 gives nctural sincs for every ten aeconds throughout the quadrant, to 15 places semi. qnadrentally arranged, with first, aecond, and third differences Natural aines are also given for every sacond from $0^{\circ}$ to $:^{3}$ and from $89^{\circ}$ to $90^{\circ}$, to 15 places, with first and eacond differences. The rescne of the manuscript of this work by Pitiseus forms a striking apisode in the bistory of mathernatical tables. Tho slterations end emandations in the carlier part of the corrected edition of the Opus Palatinum were made by Pitiscus, who bad his snspiciona that Rheticus had himself calculated a ten-sacond tablo of sines to 15 decimal placea; but it could not bo found. Eventually the lost civon was discovered emonmst the papors of Rheticus, Fhich hed passod from Otho to Jamos Christmann on tho death of the former. Amonget these Pitiscus found (1) the ton-eecond table of cines to 15 places, with first, scoond, and third differances iprintod in tho Thesaurus) ; (2) aines for every second of the first and last degrecs of the quadrant, also to 15 places, with first and sccond differences; (3) the commencement of 8 canon of tangonts and sccants, 4 i 4 came numbar of decimal places, for every ton acconds, with first oad socond differonces; (4) a complete minute canon of sines, tariguots, and seconts, alao to 15 decimal places. Theso tables takeu in sonnexian with tio Opus Palatinum give ar idea of the enormous
labours undertaken by Rheticus: lila tahlea not only remnen to this day tho ultimate anthoritios bit formed tho slata when by. Viand calculatod his logarithmic canon. Гitiscus onye tlat lut thilvo Jeara Rbeticus coustantly lial computers at work.
$\Delta$ history of trigowometricai tables by Huttou nis prefixed to all tho carly editious of his Tables of Logarithme, adil forms Trart xix. of lis Mathematical Tracts, rol. i. Il. 2is-306, 1812. A good deal of bibliographical information aliout tho Opuq Palatinum and carlier thigonometrical tablea is given fa Do Slorgan's article "Tables" in the English C'yclopsedia. The irvention of logarithons the year after tho publicatiou of Rheticus'a volumo by Pitiscus changod all tho mothods of calculation ; and it is worthy of note that Napior's original table of 1614 ves a logarithonio canon of aine and not a table of the logarithns of numbers. The logarithmio canon at ouce superseded tho datural canon; and since Pitiscus's time no really extensive tablo of pure trigonometrical functiona has sppeared. In recent jears tho cmploymeut of the arithmometer of Thomas do Colmar has revived the uso of tables of natural trigonometrical functions, it being fould convcuicut for some purpases to cmploy an arithmometer and a natural canon instead of a logarithmic cauon. Junge's Tafel der wi-klichen Lange der Sinus und. Cosinus (Leipsic, 1864) was pnblished with this object. 1. gives natural sines and cosines for every ten seconds of tho quadrant to 6 places. F. M. Clouth, Tables pour lc Calcul des Coordounés Goniometriques (Mainz, n.d.), gives natural sinea and cosines (to 6 places) and their first mine mnltiples (to 4 places) for erery centesimal minute of tho quadrant. Tables of natural functions oecur in many collections, the natural and logarithmic valnes being sometimes given on opposite pagos, suinctimes side by side on the samo pago.

The following works contain tables of trigonometrical functions other than sines, cosines, and tangents, Pasquich, Tabule Loga arilhmico-Trigonomatrice (Leipsic, 1817), contains a table of $\sin ^{3} x$, $\cos ^{2} x, \tan ^{2} x, \cot ^{2} x$ from $x=1^{8}$ to $45^{\circ}$ at intervals of $1^{\prime}$ to 5 places Andrew, Astronomical and Nautical Tablcs (London, 1805), contains a tabla of "squares of natural semichords," \&e., of sid ${ }^{2} \frac{1}{2} x$ from $x=0^{\circ}$ to $120^{\circ}$ at intervals of $10^{\prime \prime}$ to 7 places. This table bas recently been great!y extended by Major-Gederal Hanoyngton in his Havcrsincs, Natural and Logarithmic, uscd in computing Lunar Drstanccs for the Nautical Almanac (London, 1876). Cho namo "laversine," now frequently uscd in works npon navigation, is an abbreviation of "half versed sina"; viz., the haversine of $x$ is equal to $\frac{1}{2}(1-\cos x)$, that is, to $\sin ^{2} \frac{1}{2} x$. The tablo gives logarithmio haversines for every $15^{\prime \prime}$ from $0^{\circ}$ to $180^{\circ}$, and natural haversines for every $10^{\circ}$ from $0^{\circ}$ to $183^{\circ}$, to 7 places, except near the beginning, where tho logarithms aro given to only 5 or 6 laces. The work itself occupies 327 folio pages, and was suggested by Andrew's, a copy of which by chance fell into Hannyngton's hands. Hannyagton recomputed the whole of it by a partly mechanical method, a combination of tro arithmometers being employed. A table of haversinee is nseful for the solution of apherical triangles When two aides and the included angle are given, and in many other problems in spherical trigonometry. Andraw's origind table seems to haro attracted very littlo notice. Hannyngton's Was printed, on tho recommendation of the auperintoudent of the Nautica? Almanac office, at the public cost. Bafore the cal culation of Hannyngton's table Farley'a Natural Versed Sines (London, 1806) Was used in the Nautical Almanac office is com. putime lnoar distances This fine table contains natural veraed sines from $0^{\circ}$ to $125^{\circ}$ at intervals of $10^{\prime \prime}$ to 7 places, with proportional parts, and $\log$ versed sines from $0^{\circ}$ to $135^{\circ}$ at intarvala of $16^{\prime \prime}$ to 7 places. The arguments are elso given in time. The manuscript Was ased in the office for twenty-five years bofore it was printed. Traverse tables, which occur in most colloctions of navigation talles, contam multiples of sines and cosines.

Common or Briggian Logarithms of Niumbers and Trigono metrical Ratios. - For an account of the invention and history of logarithme, see Logarithms (rol. xiv. p. 773) and Napier. The folloming are the fundamental works which contain the reaults of the original caiculations of logarithms of numbers and trigonometrical ratios:-Briggs, Arithmetica Logarithmica (London, 1624), logarithms of pambers from I to 20,000 and from 00,1000 to 100,000 to 14 places, with interscript differances; Vacq, A rithmetica Log. arithmica (Gouds, 1628, also an English edition, London, 1631, the tables being the same), ten-figure logarithms of numbers from 1 to 100,000 , with differencec. also log sines, tangents, and socants for evcry minnte of the quadrant to 10 placea, with interseript difforences: Vlacq, Trigonometria Artificialis (Gonda, 1633), log sines and tangents to every ten reconds of the quadrant to 10 places, with differences, end ten-fgure logarithms of nambers ip to 20,000, with difforonces; Briggs, Trigonomelria Britunnica London, 1633), natural sines to 15 places, tangants and aucants to 10 places, log aines to 14 places, and tangenta to 10 placos, nt intervals of 8 hundredth of a degree from $0^{\circ}$ to ${ }^{\circ} 45^{\circ}$ aith interecript differences for all the functions. In 1799 Vera ruprinted at Leipsic Vlacq's two worke in a aingle folio volume, Thesauru Logaritimorum Completus. The arrangoment of the
$\mathbf{X} \boldsymbol{1} 11$.
table of logrithas of unrabery is more compeadions than in Tlaç, being similar to that of au ordinary seven-figure table, but it is not so ronvenirnt, as mistakes in taking out the differences are more liable to occur: The trigonomatrical canou gives log sines, cosines, tangents, anil cotangents, from $0^{\circ}$ to $2^{\circ}$ at iutervals of one second, to 10 places, withort iliferemes, and for the rest ofthe yuadrant at intervals of ten seconds. The trigonometrical canou is not wholly reprinterl from the Trigonometria Artificialis, as the log-adithus-for every secoud of the first two degrees, which do not oceur in Tacq, wero calculated for the work by Licutenant Dorfmumd. Fera dirated great attention to the detection of errors in Vlacq's logarithons of numbers, and has given several important errata lists. MI. Lelnrt (Annules de CObservaloive de Paris, vol. iv.) has given a full crratal list in Ylacq's and Vega's logarithms of numbers, obtained by comprison with the grest French manuscript Tables du Cadustic (sue Lonalimins, p. 776 ; comp. also Monthin Notises of Roy. Asi. Soc. for May 1872, Jume 1872, March 1873, and 1874, suppl. number). Vega seems not to lave bestowed on the trigonometrical canon anything like the care that lee devoted to the logarithms of numbers, as Gauss ${ }^{1}$ estimates the total of last-figu"e evrors at from 31,983 to 47,746 , most of them only amounting to a mit, but some to os much as 3 or 4. As these errors in the Trigonometria Artificinlis still remain ancorrected, it camot be said that a reliable ten-place logaritlunic trigonometrical canon cxists. The ealculator who has occasion to perform work requiring ten-figure lomarithens of numbers shonhl use Vlaeq's Arithmclica Lognrithmica o[ 1628 , after carefully correcting the errors pointel ont by Vega and Lefort. After Vlaeq, Vena's Theseurns is the next Lest table; and Pineto's Tcbles de Logarithmes Vulfuires ri Dix Décimales, construites d'epre's an nouscau mode (St Petprbburg, 1871), though a tract of ouly 80 pares, may be uscfully employed when Vlaeq and Yegin are unprocurable. l'iueto's werk consists of thrẹe tahles: the first, or ansiliary table, contains a serics of factors by which the numbers whose lomathoms are reguired are to bo multiplied to bring them within the range of table 2 ; it also gives the lorrarithms of the reciprocals of these factors to 12 places. Trable 1 merely gives logarithums to 1000 to 10 places. Tablo 2 rives logarithus from $1,000,000$ to $1,011,000$, with poportional parts to humdredths. The mode of using these tables is as [ollows. If the logarithm cannot le taken ont directly from table 2, a factor $\lambda[$ is 「ound from the anxiliary table by which tha mumer most be maltiplied to briner it within the range of table $\varepsilon$. Then the lomarithm can be taken ont, aud, to neutralize the effect of the multiplication, so far as tho result is concerned, $\log _{0}\left(\frac{1}{d Y}\right)$ must be adjed ; this quantity is therefore given in an adjoining colmm to $X I$ in the auxiliary talele. A similar proredure gives the number answering to any logarithm, another factor (aprosimately the reciprocal of 11) being given, so that in hoth cascs multiplication is uscd. The laborious part of the nork is the multipliention by $M I$; but this is somewhat com. pensated for lyy the ease with which, by means of the proportional parts, the logatithon is taken ont. The factors are 300 in number, ame are chosen so as to minimize the labour, only 25 of the 300 consistug of thre figures all different and not involving 0 or 1. The principle of multiplyurg lig a factor which is subsequently cancelled ly sulbtracting its logaritlom is used also in a tract, containiner only ten pages, published by MM. Namur and Mansion at brussels in 1577 under tlic title Tables de Logaritiomes is 10 décimales jusqu't 434 milliards. IIere a table is given of logarithms of numbers near to $43 f, 294$, and other numbers are bronght within the mange of the table by unltiplication by one or two factors. Tho logarithms of the mmbers near to 434.294 are selected for tabulation beanse their differences commence with the figures 100
.and the prescnce of the zeros in the difference reuders the inter[olation ensy.

If seveu-figure lorgarithms do not give sufficiontly acrurate resnlts, it is uaal to have recourse to ten-figure tables: with one exception, there exist no tables giving 8 or 3 figures. The exception is John Nerrton's Trigonomelria Britannier (London, 1658), which gires logarithms of numbers to 100,000 to 8 plares, and also logr sines $_{0}$ and taugents for every centesimal minute (i.c., the nine-thousandth part of a right angle), aut also $\log$ sines and tangents for the first three derrees of the quadrant to 5 places, the interval being the oue-thonsandth part of a degrec. This table is also unique in that it giv 3 the logarithens of the differences instead of the actnal diferences. The arangement of the parge now miversal in sevenfigure tables-with the tiftli figures running lorizontally aloug the top line of tho jage - is due to Johu Nexton.

As a rule seven-figure lowarithms of numbers are not published scparatuly, us ast tables of lograrithins coutaining both the logarithms of wumbers rud a tricromometrical canon. Babbage's and Saug's lugarithms are exceptional and give logaithns of mmbers only. Bablarge, Table of the Lagarithms of the Satural Numbers firm 1 to $103^{\circ}, n 00$ (London, sterentyped in 1827 ; there are several timges
${ }^{1}$ Sed his "Elnice Bomerkangen 211 V"ean's Thescumis fognrifhmommm." in

of later (lates), is tho bedt for orlinary use. Great pains were aken, to get the maximmm of clearness. The clange of fgure in the niildle of the llock of numbers is marked by a change of type iss the fourth figure, which (with the sole excelitiou of the asterisk) is the best method that lias been used. Copies of the book were printed on paper of different colours-yellow, brown, green, \&c.- as it was considered that black on a white gronnd was a fatiguing combination for the eyc. The tables were also issued with title-pares aud introluctions in otler languages. The book is not very easy to procure now. In 1871 Mr Sang published A Ncw Table of Scven-place Logarillms of all Numbers from 20000 to 200000 (London). In an ordinary table extending from 10,000 to 100,000 the differences near the beginning are so numerous that the proportional parts are either very crowded or some of then omitted; by making the table extend from 20,000 to 200,000 instead of froul 10,000 to 100,000 the elifferences are halved in magnitude, while there are only one-Courth as many in a page. 'rluere is also greater acenracy. A further peculiarity of this tablo is that multiples of the differences, instead of proportional prits, are given at tho side of the page. 'Pypographically the tahle is exceptional, as there are no rules, the nombers being, selarated from the logarithams by reversed commas. This work was to a great cxtent the result of an original calculation; see Edinlurgh Transactions, vol. xxvi. (1871). Mr Sang proposed to pmblish a nine-figuro table from 1 to $1,000,000$, but the reupisite support was not oltainct. Various prapers of Mr Sang's relating to lis logarithmic calculations will be foumd in the Erlinlurgh l'rocrchings subsequent to 1872 . In this connexion refercuce shonld he mate to Abialiam Sharpis table of lowathms of mubers from 1 to 100 and of primes from 100 to 1100 to 61 places, also of mumbers from 999,990 to $1,000,010$ to 63 places. Tlucse first appariel in Grouretry Improvid ... Ly -1. S. Muilumath (London, 1717). They have bsen republished in Slerwin's, Callet's, and the earlier editions of 1lutton's tables. Parlihurst, Astronomical Tablis (New York, 1871), gives logaritlms of mumbers from I to 109 to 102 places. ${ }^{2}$

In many seren-ligure tables of logatithms of numbers the values of $S$ and $T$ are given at the top of the pare, with $V$, the variation of each, for the purpose of deluemg log sines and tangents. $S$ anel $T$ deuoto $\log \frac{\sin x}{2}$ and $\log \frac{\tan x}{x}$ respectively, the arguments leing tho number of seconds denoted by certain numbers (sometimes only the first, sometimes every tonth) in the numher colmm on cach prage. Thus, in Callet's tallics, on the page oul which the first number is $67200, S=\log \frac{\sin 67: 0^{\prime \prime}}{67 \cdot 2}$ and $T=\log \frac{\tan 6720^{\circ}}{6720}$, while the $V$ s are tho variatlons of each for $10^{\prime \prime}$. To find, for example, log $1^{\circ} 52^{\prime} 12^{\prime \prime} \cdot 7$, or lor slu $6732^{\prime \prime} \cdot 7$, we have $S=4.6854980$ and $\log$ $67327=3.8281893$, whence, by adulition, we obtain $8.5136873^{\circ}$; lut $V$ for $10^{\prime \prime}$ is $-2 \cdot 29$, waence the variation for $12^{\prime \prime} \cdot 7$ is -3 , and the log sinc required is 8.5136870 . Taliles of $S$ and $T$ are frequently callet, after thelr luventor, "Delambre's tables." Some sereu-figure tables extend to 100,000 , aud others to 108,000 , the last 8000 logarithms, to 8 places, being given to ensure greater accuracy, as near the beginning of the hombers the diferences are large and the internolations more lahorious and less exact than in the rest of the table. The cight-figure logarithms, however, at the end of a seven-figure talule are liable to orcasion curor; for the computer who is accustomed to three lealing figures, conmore to the block of figures, may fail to notice that in this junt of the table thero are four, and so a fimure (the fourth) is sometines omitted in taking sut th:: Joraritlim. In the ordinary method of arranging a seven-figure table the rlange in the fourth figure, When it occurs in the course of the line, is a somee of frequent error moss it is very clearly indicated. In the earliur tables the change was not marled at all, and the computer had to thecide for himsclf, each time he took ont a logarithm, whether the thind figuse had to loe inereased. In some tables the line is broken where tho change oceurs; but the dislocation of the figures and the corresponding irregularity in the lines are rery awkward. Babbage printe? the fourth figure in small type after a clange. The best method seems to be that of prefixing an asterisk to the fourth fimure of each logarithm after the change, as is rlone in Schrön's and many other modern tables. This is beautifully clicar and the asterisk at onco catches the eje. Shortrede and Sang replace 0 after a change by a molita (resembling a dianond iu a paek of cards). This is very clear in the case of the 0 's, but leaves mumarked the cases in which the fourth figuro is 1 or 2. Bablago printed a subscript point under the last figure of each logarithun that lad been increascd. Schrön used a bar subscript, which,

2 Irgendre (Traits des Fonctions Elliptigues, vol. it., 1226 ) gives a table $\boldsymbol{\alpha}$ nal nral sies to 15 plares, and of log sines to 14 placea, for every $15^{\circ}$ of the qualirant, and also a table of ingarithms of uneven nimplars from 1163 to 1501 , alnh of primes from 1501 to 10.000 to 19 Maces. The latter, which was extracted Trion the Talles du Condasire, is a continnatinn of a talle in Gardiner's Tanfes of Lonnirithms (London, $17+2$; riprinted at Avigunn, 1Fio), which gives

Leing moro obtrusive, is not so satisfactory. In some tables tho increase of the last figure is ouly marked when the figure is increased to a 5 , and then a Roman fivo (v) is used in place of the Arabic figure Hereditary errors in logarithmic tables are considered in two pajers "On the Progress to Accuracy of Logarithmic Tables" aut "On Logaritlmic Ta lles" in Monthly Ninlices of Roy. Ast. Soc. for 1873. Sce also the Monlhly Notices for 1874, p. 248 ; and a praper by Gernerth, Ztsch. f. d. bsterr. Gymn., Heft vi. p. 407.

Passing now to the logarithmic trigonometrical canon, the first great advance after the pulblication of the Trigonometric Arlificialis in 1633 wes made ly Michse] Taylor, Tables of Logarithms (London, 1792), which gives log sinca und tar.gents to every sccond of the quadrant to 7 places. This table contains abont 450 pares with an average musuler of 7750 figures to the nage, so that there are altagether ncarly three millio is and a half of figures. The change in the leadiug figures, when it occurs in a celumn, is not marked at all ; and the table must be used with very great caution. In fart it is advisable to go through the whelo of it, and fill in witl ink tho first 0 after the chancre, as well as make some mark that will cateh the eye at the head of every column containing a clange. The table was calculated by interpolation from tho Trigonomelria Arlificialis to 10 places and then reduced to 7, eo that the last figure should always be correct, Partly oa account of the absence of a mark to denote the clange of figure in the column and nartly on account of the size of the table and a somew hat inconvenicnt arrangeracnt, tho work seems never to liave como into very geueral use. Computers have always preferred Bagay's Noucrelles Tables Astronomiques et Hydrographiques (Paris, 1820), which also contains a complete lorarithanic canen to every second. The clange in tho colamn is very clearly marked by a largo black nuelens, surroundel by a circle, puinted instead of zero. Bagny's work has now beromo very rare. The only other canon to every second that has been published is contained in Shortrele's Logarithmic Tablcs (Edinburgh). This work was oriminally issued io 1844 in ono voluroe, but being dissatisfiod with it Shortrede issued a new eclition in 1848 in two volumes. The first volume contains logarithms of ambers, antilogarithms, \&c., and tho second the trigonometrical canon to cvery second. The volumes are sold separately, and may bo regarded as indcucudent works; they are not cven described on their title-pages as vol. i. and vol. ii. The trironometrical canon is very complete in every respect, tho arguments being given in time as well as in nrc, full proportioual parts being aclderl, \&c. The change of figure in the columo is denoted by a nokta, priuted insteal of 0 where the change occurs.

Of talles in which tho quadront is divided centesimally, the principal are Hobert and Ideler, Nouvclles Tables Trigonométripucs (Berlin, 1799), and Borda and Dclambre, Tables Trigonométrigics Decimales (Paris, 1801). The former give, among other tables, natural and log sines, cosines, tangents, and cotangents, to 7 places, the arguments procecling to $3^{\circ}$ at intervals of $10^{\prime \prime}$ and thence to $50^{\circ}$ at intervals of $1^{\prime}$ (centesimal), and also natural sines and tangents for the first hundied ten-thousandths of a right angle to 10 places. Tha latter gives log sines, cosines, tangents, cotangents, sccants, and cosccauts from $0^{\circ}$ to $3^{\circ}$ at inter vals of $10^{\prime \prime}$ (with full pronortional parts for every second), and thence to $50^{\circ}$ at intervals of $1^{\prime}$ (centesimal) to 7 places. There is also a tahle of $\log$ sines, cosines, tangents, and cotangents from $0^{\prime}$ to $10^{\prime}$ at intervals of $10^{\prime \prime}$ and from $0^{\circ}$ to $50^{\circ}$ at intervals of $10^{\prime}$ (centesimal) to 11 nlaces. Ilobert and ldeler ซiva a natural as well as a lorarithnic canon; but Borda and Delamure give only the latter. Borila and Delambre give sevenfigure logaritlims of nambers to 10,000 , the line being broken when a change of figure talics place in it.

In Brigos's' Trigonometria Britannica of 1633 the degres is livider centesimally, and but for tho appearance in the same yean of Vlaç's Trigonometria Arlificialis, in which the decree is divided sexagesimally, this reform night lave been effected. It is clear that the nost suitable time for effecting such a change was when the natural canon was replaced by the logarithmic canon, and Brims took advantage of this opportunity. He left the degree waaltered, but diviled it centesimally instead of sexagesimally, thus ensuring the advantages of decimal division (a saving of Fork in interpolations, multiplications, \&\&.) with the minimum of change. The French mathematicians at the ent of the 18 th centnry divided the right angle cericesimslly, completely changing the whola aystem, with no apprcciablo advantages over Briggs ${ }^{\text {}}$ s system. In fact the centesimal degree is as arbitrary a unit as the nonagesimal, and it is only the non-centesimal sublivision of the degreo that gives rise to inconvenience. Briges's example was followed by Foe, Oughtred, and other 17 th-century writers; but the centesimal division of the degree seems to have entirely, passed out of nse, till it Ths reantly rovived by Bremiker in his Logarithmischetrigonomelrische Tafeln mit funf Decimalstellen (Berlin, 1872). This little book of 158 pages gives a five-figure canon to every huadredth of a degree with proportional parts, besides logarithms of numbers, addition end sabtraction logarithms, \&c.

Collections of Tables. - For a computer. who requires in ono volume logarithms of numbers and a ton-second logarithmic canon,
perlisps the two bast hooks are Sclirün, Seren-Figure Lonarithms (London, 1865, stereotypert, an English edition of the Genuan wrork pmblished at Bruaswick), and Brulins, A Aew Afanual of Logarithma to Secen Places of Decimals (Lejusic, 1870). Both give logarithms of numbera and a complete ten-second canon to 7 llaces; Brahns also gives lory sincs, cosines, tangents, and cotangents to overy second up to $6^{\circ}$ with moportional parts Scluon contains an inter* polation table, of 75 pages, giving the first 100 multijles of oll numbers from 40 to 420 . The logaritlims of uombers exteud to 108,000 in Schron end to 100.000 in Bruhns Almost equally convenicnt is Bremiker's cdition of Tega's Logarithmic Salles (Berlin, stereotyled ; the English edition Was translated from the fortictl edition of Dr Bremiker's by W. L. F. Fiscber). This book gives a canon to every ten seconds, and for the first five degrees to every second, with logarithms of numbers to 100,000 . All these works give the proportional parts for all tbe diflerences in the lafaritlims of numbers. In Babbage's, Callet's, and many other talues only erery other table of proportional parts is given apar the beginning for rant of space. Schrön, Bruhns, and most modern tables published in Germany have title-pages and introductions in different languages Dupuis, Tables de Logarillimes a sequ Decimales (stereotyped, third tirace, 1868, Paris), is also very convenient, containing a ten-sccoud canon, besides logarithms oi nambers to 100,000 , hyperbolic logarithms of numbers to 100 N , to 7 places, \&c. In this work negative characteristics are juinted throughout in the tables of circular functions, the minus sign being placed ahove the figure; theso are preferahle to the ordinary characteristics that are inercased by 10. This is the only work we know in which negative characteristics ero used. The edges of the parges containing the circular functione are rcd, the rest beine grcy. Dupuis also edited Callet's logarithms in 1862, with which this work must not be confounded. Salomon, Logarithmische Tafeln (Vienna, 1827), contsins a ten-second canon (the intervals being one second for tho fist two degrees), logarithms of nimbers to 108,000 , squares, cubes, square roots, and culve roots to 1000 , a factor table to 102,011 , ten-place Briggian and hyperbolic logarithms of nuubers to 1000 and of primes to 10,333 , and many other useful talles. The work, which is scarce, is a well-printed small quarto volume.

Of collections of gencral tables the most useful and accessible are Hutton, Callet, Verga, and Köhler. Hutton's well-known Mathematical Tables (London) was first issued in 1785, but considerabla additions were nucie in the fifth edition (1811). The tables contain seven-fignre logarithms to 108,000 , and to 1200 to 20 places, soma antilogarithnis to 20 places, hyperbolic logarithms from 1 to 10 at intervals of 01 and to 1200 at intervals of unity to 7 places, logistic logarithms, log sincs and tangents to every second of the first two degrees, and natural and log sines, tangents, secants, and versed sincs for every minute of the quadrant to 7 places. The natural functions orcupy tbe left-hand pages and the logarithmic the right. hand. The first six editions, published in Hutton's lifetime (d. 1823), contain Abraham Sharp'a 61-figt ye logarithma of numbers. Olinthus Gregory, who brought out the 1830 and succceding editions, omitted these tables and Hutton's introdnction, which contains a history of logarithms, the methods of constrncting them, \&e. Callet's Tables Portatives de Logarithmes (stereotyped, Paris) ecems to have been first issucd in 1783, and has sinco passed through a great many editions. In that of 1853 tho contents are seven-figure logarithms to 108,000 , Briggian and hyperbolic logarithma to 48 places of numbers to 100 and of primes to 1027 , log sines and tangents for minutes (centesimal) throughont the quadrant to 7 places, natural and $\log$ sines to 15 places for every ton minutes (centesimal) of the quadrant, log sines and tangents for everv scrond of the tirst fire degrees (sexagesimal) and for every ten seconds of the quadrant (sexagesimal) to 7 places, besidea logistic logarithms, tho first hundred multiples of the modulus to 24 places and the Gist ten to 70 places, and other tables. This is one of the most complete and practically nseful collections of logarithms that. lave been published, and it is peculiar in giving a centesimally divided canon. The size of the page in the editions published in the 19th century is larger than that of tho earlier editions, the type having been reset. Vcan's Tabulæ Logarilhmo-trigonometrice waa first publisled in 1797 in two volumes. The first contains sevenfigure logarithms to $101,000, \log$ sines, \&c., for cvery tenth of a second to $1^{\prime}$, for every second to $1^{\circ} 30^{\prime}$ for every $10^{\circ}$ to $6^{\circ} 3^{\prime}$, and thence at intervals of a minute, aiso natural sines and tangents to every minute, all to 7 places. The second volume gives simpla divisors of all numbers $u p$ to 102,000 , a list of jrimes from 102,000 to 400,313 , hyperbolic logarithms of numbers to 1000 and of primea to 10,000 , to 8 places, $e^{x}$ and $\log _{1} \delta^{x}$ to $x=10 \mathrm{at}$ intervals of 01 to 7 ficrures and 7 places respectively, the first nine powers of the numbers from 1 to 100 , squares and culses to 1000 , legistic lagirithms, binomial theorem coefficients, \&c. Vega also nublished Manuclo Logarithntico-trigonontetricum (Leipsic, 1800), the tables in which are identical with a protion of thoso contained in the first. volura of tha Tabuls. The Tabula went through many cditions, a stercotrped issue being brought out by J. A. Htilsse (Samminng mathematischer Tafeln, Leipsic) in ono volume in 1840. Tho
contents are nearly the same as thosc of the original work, the chicf difference being that a large table of Gaussian logarithms is added. Vega differs from Ilutton and Callet in giving so many useful nonlogarithmic tables, and his collcetion is in many respects comple. mentary to theirs Schulze, Neue und erweitcrte Sammlung logarithmischer, irigonomelrischer, und andercr Tafcln (Berlin, 1778, 2 vols.) is a valuable collection, and contains seven-figure loga. rithm's to $101,000, \log$ sines and tangents to $2^{\circ}$ at intervals of a second, and natural sines, tangeats, and secauts to 7 placea, $\log$ sines and tangents and Napierian $\log$ sines and tangents to 8 places, all for every ten seconds to $4^{\circ}$ and thence for every minute to $45^{\circ}$, besides squares, cubes, square roots, and cube roota to 1000 , binomial theorem coefficients, powers of $e$, and other small tables. Wolfram's Lyperbolic logarithms of numbers below 10,000 to 48 plaees first appeared in this work. Lambert, Supplomenta TabuFarum Logarithmicarum et Trigonometricarum (Lisbon, 1798), coutains a number of usefnl and curious non-logarithmic tables; it bears a general resemblance to the sccond volume of Vega, but eontains numerous other small tables of a more strictly mathematical character. A very usefnl collection of non-logarithmic tables is printed in Barlow's New Mrethematical Tables (London, 1814). It gives squares, cnles, square roots, and cube roots (to 7 places), reciprocals to 9 or 10 places, and resolutions into their prime factors of all aumbers from 1 to 10,000 , the first ten powers of numbers to 100 , foarth and fifth powers of numbers from 100 to 1000 , prime numbers from 1 to 100,103 , cight-place hyperbolit logarithma to 10,000 , tables for the solution of the irreducible caso in cubic equations, \&c. Iu the stereotyped roprint of 1840 only the equares, cubes, square roots, cube roots, and reciprocals aro retained. The first volumo of Shortrede's tablea, in addition to the trigonometrical canon to every second, contaias antilogarithms and Gaussian logarithms. Hassler, Tabula Logarithmica el Trigonometrice (Now York, 1830, stercotyped), gives seven-figure logarithuns to $100,000, \log$ sines and tangents for every second to $1^{\circ}$, and log sines, cosines, tangents, and cotangents from $1^{\circ}$ to $3^{\circ}$ at intervals of $10^{\prime \prime}$ and theace to $45^{\circ}$ at intervals of $30^{\prime \prime}$. Every effort has been made to reduco the size of the tables without loss of distiuctaess, the page being only about $3 \mathrm{~b}_{3}^{-5} 5$ inches. Copies of the work were pablished with the introduction and title-page in different lan. guages. Stanley, Tables of Logarithms (New IIaven, U.S., 1860), gives seven-figure logarithms to 100,000 , and $\log$ siaes, cosines, tangents, cotangents, secants, and cosecauts at intervals of ten seconds to $15^{\circ}$ and thence at intervals of a minute to $45^{\circ}$ to 7 places, besides natural sines and cosines, antilogarithms, and other tables. This colleetion owed its origin to the fact that Hassler's tables were found to be inconveaient owing to the small ness of the type. Luvini, Tables of Logarithms (London, 1866, stereotyped, printed at Turin), gives seven-figure logarithms to 20,040, Briggian and hyperbolic logarithms of primes to 1200 to 20 places, $\log$ siaes and tangents for eaeh sccoad to $9^{\prime}$, at intervals of $10^{\prime \prime}$ to $2^{\circ}$, of $30^{\prime \prime}$ to $9^{\circ}$, of $1^{\prime}$ to $45^{\circ}$ to 7 places, besides squaro and cube roots up to 625 . The book, which is intended for schools, engineers, \&ic., has a peculiar arrangement of the logarithms and proportional parts on the pages. Chambers'a Mathematical Tables (Edinburgh), containing logarithms of numbers to 100,000 , and a canon to every ninute of $\log$ sinea, tansents, and secants and of natural sines to 7 places, besides proportional logarithms and other small tables, is cheap and auitable for seliools, thongh not to be compared as recards matter or typography to the best tables desoribed above. Of six-figure tables Bremiker's Logarithmomem ITT. Decimaliun Nova Tabula Berolinensis (Berlin, 1852) is probably one of the best. It gives logarithms of numbers to 100,000 , with proportional parts, and log sines and tagegets for cvery second to $5^{\circ}$, and beyond this point for every ten seconds, with proportional parts. Hentsch, Lograithmisch-trigonomclrisches Handbuch (Vienna, 1827), gives five-figure logarithms to 10,000, log sines and tangents for every ten seconds to 6 places, natural sines, tangents, secants, and versed sincs for every minute to 7 places, lomarithms of primes to 15,391 , hyperbolic logarithms of numbers to 11,273 to 8 places, least divisors of numbers to 18,277, binomia? theorem coefficients, \&c. Farley's Six-Figure Logeritims (London, stercotyped, 1840) gives six-figure logarithms to 10,000 and $\log$ sines and tangenta for every minnte to 6 places. Of live-figure tables the most convenient is Tables of Logarithms (Usefnl Knowledge Society, London, from tho stercotyped plates of 1839), which were prepared by De Morgan, though they have no name on the title-page. They contain fiveligure logarithims to 10,000 , log sines and tangents to every minute to 5 places, bositers a few smaller tablers Lalante's Tubles do Lognithmes is it five-figure tahle witll nearly the same rontents as De Morran's, first published in 1805. It lias since passerl through many editions, and, ofter being extended from 5 to 7 places, passed throngh several more. Galbraith and llaughton, Manual of Mathemotieal Tables (Londou, 1860), give five-figure logarithas to 10,000 and $\log$ sincs and tancerits for cvery minute, also a small tablo of fraussian logarinhmso Houèl, Tubles de Loycrithmes à Cinq Décimules ( $\Gamma$ aris, 187I), is a very convenient collection of five-figure tibles : besides logarithms of numbers and circular functions, there
are Gaussian logarithms, least divisors of numbers to 10,841, antilogarithms, \&c. The work contains 118 pares of tablcs. The same anthor's Recucil de Formules et de Tables Numérriques (Paris, 1868) contains 19 tables, occupying 62 pages, most of them giving results to 4 places; they relate to very varied subjects, -antilogarithus, Gaussian logarithms, logarithms of $\frac{1+x}{1-x}$, elliptic iutegrals, squares for use in the method of least squares, \& C . Bremiker, Tafel vier. stelliger Logarithmon (Berlia, 1874), gives four-figure logarithms of numbors to 2009, loç sincs, cosines, tangents, and cotangents to $S^{\circ}$ for every hondredth of a degree, and thence to $15^{\circ}$ for evcry tenth of a degree, to 4 places. There aro also Gaussian logainthms, squares from 0.000 to 13,500, antilogarithins, $\& \cdot$. The book coutains 60 pages. Willich, Popular Tables (London, 1853), is a uscful book for an amateur ; it gives Brigmian and hyperbolic logarithms to 1200 to $\widehat{h}$ places, squares, $\& c$. , to 343 , \&c
Hyperbolie of Napicrian Logarithms. -The logarithms invented by Napier and explained by hime in the Dcscriptio (1614) were uot the same as those now called natural or hyperbolic (viz., to base c), and very frequently also Napierian, logarithas. Napicrian logarithms, strictly so called, have eatirely passed out of use and are of purcly historic intercst ; it is therefore sufficient to refer to Logarithms and Napieh, where a full acconnt is given. Apart from the inventor's own publications, the only Napierian tables of importance are coutaincd in Ursinus's Trigonometria (Colognc, 1624-25) and Sclulze's Sammlung (Ecrlin, 1778), tho former being the largest that has been constructel. Logarithas to the base o, where e denotes 2.71828 , were first published by Speidell, New Logarithmes (1619).

The most copious table of hyperbolic logarithms is Dase, Tafol Hyper der naturlichen Logarithmen (Vienna, 1850), which cxtends from 1 bolic to 1000 at intervals of mity and from 1000 to 10,500 at intervals logaof $\cdot 1$ to 7 places, with diffcreaces and proportional parts, arranged rithny as in an ordinary seven-figure table. By adding $\log 10$ to the results the range is from 10,000 to 105,000 at intervals of uuity. The table formed part of the Annals of the I'ienna Observatory for 1851, but scparato copies were printed. The most elaborate table of hyperbolic logarithms is due to Wolfram, who calculated to 48 places the logarithms of all numbers 11p to 2200 , anl-of all primes (also of a great many conposite numbers) between this limit and 10,009 Wolfram's results first appeared in Schulzo's Sammlung (1778). Six logarithms which Wolfram had been prevented from computing by a serious illaess were supplied in tho Berliner Jahrbuch, 1783, 1. 191. The completo table was reproduced in Vega's Thesaurks (1791), when several errors were corrected. Tables of hyperbolio logarithms are contained in the following collcetions:-Callet, all numbers to 100 and primes to 1097 to 48 places; Borda and Delambro (1801), all numbers up to 1200 to 11 places; Salomon (1827), all numbers to 1000 and primes to 10,333 to 10 places; Vega, Tabula (inclutling Hïlsse's edition, 1810), and Köhler (1848), all buabers to 1000 and primes to 10,000 to 8 places; Barlow (1814), all numbers to 10,000 ; Hutton and Willich (1853), all numbers to 1200 to 7 places; Dupuis (1868), all numbers to 1000 to 7 places. Hlutton also gives hyperbolic logarithms from 1 to 10 at intervals of 01 to 7 places. Rees's Cyclopadia (1819), art. "Hyperbolic Logarithms," contains a tahlo of byperbolic logarithms of all numbers up to 10,000 to 8 places.

Tables to convert Eriggian into Ifypertolic Logavithms, and vice Conver versa. -Such tables merely consist of the first hundred (sometimes sion of only the first tan) multiples of the modulus * $4342944819 \ldots$ and Briggig its reciprocal $23025850929 \ldots$ to $5,6,8,10$, or more places. They and are generally to be found in collections of logarithmic talles, but hyperrarely exceed a pago in extent, and are very easy to construct. bolic Schron and Brulns both give the first hundred multiples of the logamodulus and its reciprocal to 10 places, and Bremiker (in his edition rithms of Vega and in his six-figuro tables) aad Dupuis to 7 places. Degen, Tabularum Enncas (Copenlagen, 1821), gives the first hundred multiples of the modulits to 30 places.

Antilogarithins. - In tho ordinary tables of logarithms the natural numbers arc integers, whilo the logarithms are incommensurable. In an antilogarithmio canon the logarithms aro exact quantitics, such as $00001, \cdot 00002, \& c$, and tho corresponding numbers aro incommensurable. The largest and carliest work of this kind is Dodson's Antilogarithmic Canon (London, 1712), which gives numbers to 11 places corresponding to logarithms from 0 to 1 at intervals of $0000 \hat{1}$, arranged like a seven-figuro logarithmic table, with intelseript differmeos and proportional parts at the bottom of the pare. This wolk was the only antilogarithmic canon for more than a century, till in 1844 Shortiede published the first cdition of his tables; in 1819 ho publishel the second edition, and in tho same year Filipowski's tables appeared. Both these works contain seven-figure antilogarithms: Shortredo gives numbers to logarithms from 0 to 1 at intervals of 00001 , with differences and multiples at the top of tho page, ant Filipowski, A Table of Antilogarithms (London, 1849), contains a table of the same exteut, the proportional parts being given to liundiodths.

Adelition and Subtraction, or Gaussian, Logarithms. -The object
of such tables is to give $\log (a \pm b)$ by only one entry when $\log a$ and $\log _{g} l$ are given (see Logarithms, vol. xiv. p. 777). Let

$$
A=\log x, \quad B=\log \left(1+\frac{1}{x}\right), \quad C=\log (1+x)
$$

Leaving out the specimen table in Ieonelli's Theoric des Logarithmes Addilionnels el Deduetifs (Bordenux, 1803), the principal tables are the following. Gauss, in Zach's Monatliche Corrcspondenz (1812), giving $B$ and $C$ for argunent $A$ from 0 to 2 at intervals of 001 , thence to $3 \cdot 10$ at intervals of 01 , and to 5 at intervals of $\cdot 1$, all to 5 places. This table is reprinted in Ganss's IFcrke, vol. iii. p. 244. Matthicssen, Tafcl zur bequesnčn Bcrechnung (Altona, 1818), giving $B$ and $C$ to 7 places for argument $A$ from 0 to 2 at intcrvals of 0001 , thence to 3 at intervals of $\cdot 001$, to 4 at intervals of $\cdot 01$, and to 5 at intervals of $\cdot 1$; tho table is not convenicutly arranged. Petur Gray, Tables and Formnlex (London, 1849, and " Addendum," 1870), giving $C$ for argmment $A$ from 0 to 2 at intervals of 0001 to 6 places, with proportioual parts to lundredths, aud $\log (1-x)$ for argument $A$ from $\overline{3}$ to $\overline{1}$ at intervals of ool nad from $\overline{1}$ to $\overline{1} \cdot 9$ at intervals of 0001 , to 6 places, with juoportional parts. Zceh, Tafein der Additions- und Subtractions.Logarilhonen (I,cipsic, 1849), giving $B$ for argument $A$ from 0 to 2 at intervals of 0001 , thence to 4 at intervals of 001 and to 6 at intervals of 01 ; also $C$ for argument $A$ from 0 to 0003 at intervals of 0000001 , thence to 05 at intervals of 000001 and to "303 at intervals of 00001 , all to 7 places, with proportional parts. These tables are reprinted from Iltilsse's edition of Vega (1849) ; the 1840 edition of Hiilsse's Tega contained a reprint of Gauss's original table. IVittstein, Lugarithmes de Gauss \& Scpt Décimales (Ilanover, 1866), giving $B$ for argument $A$ from 3 to 4 st intervals of $\cdot 1$, from 4 to 6 at iutervals of 01 , from 6 to 8 at intervals of 001 , from 8 to 10 at intervals of 0001 , also from 0 to 4 at the same intervals. In thin landsome work the arrangenent is similar to that in a scren-figuro logarithmic table. Gauss's original five-place table was reprinted in Pasquich, Tabule (Lcjpsic, 1817); Kiohler, Jcrome de le Lande's Tafcln (Leipsic, 1832), and Mandbuch (Leipsic, 1848); nud Galbrath and Hsughton, Manmal (London, 1860). Hovel, Tables de Logarithmes (1871), also gives a small five-place table of Gaussian logarithms, the addition and subtraction logarithms being scparated as in Zech. Modified Gaussian logarithms are given by J. H. T. Müller, Fierstellige Logarithmen (Gotha, 1844), 'viz, a four-placo table of $B$ and $-\log \left(1-\frac{1}{x}\right)$ from $A=0$ to .03 at intervals of 0001 , thenco to 23 at intervals of 001 , to 2 at intervals of 001 , and to 4 at intervals of 1 ; and by Shortrede, Logarithmic Tables (rol. i., 1849), viz., a five-placo table of $B$ and $\log (1+x)$ from $A=5$ to 3 at intervals of $\cdot 1$, from $A=\overline{3}$ to $\overline{2} \cdot 7$ at intervals of 01 , to $1 \cdot 3$ at intervals of 001 , to 3 at intervals of ${ }^{\circ} 01$, and to 5 at intervals of $\cdot 1$. Filipowski's Antilagarithms (1849) contains Ganssian logaritlums arranged in a new way. The principal tablo gives $\log (x+1)$ as tabular rosult for $\log x$ as argunent from 8 to 14 at intervals of 001 to 5 places. Weidenbacb, Tajel um den Logarithmen (Copenhagen, 1829), gives $\log \frac{x+1}{x-1}$ for argunent $A$ from 352 to 2.002 at intervals of 001 , to $3 \cdot 6$ at intervals of $\cdot 01$, and to $5 \cdot 5$ at intervals of $\cdot 1$, to 5 places.

Logistic and Proportional Logarithons. - In mast collections of tables of logarithms a five-place table of loristic logarithms for every second to $1^{\circ}$ is given. Logistic tables give $\log 3600-\log x$ at intervals of a second, $x$ being cxpressed in degrees, minutes, qud scconds; Schulze (1778) and Verma (1797) have them to $x=3600^{\prime \prime}$ and Callet and Ilutton to $x=5280^{\prime \prime}$. Proportional logarithms for every second to $3^{\circ}$ (i.e., $\log 10,800-\log x$ ) form part of acarly all collections of tables relating to navigation, generally. to 4 places, sometimes to 5. Bagay, Tables (1829), gives a five place table, but such are not often to be found in collections of mathematical tables. The same remark applies to tables of proportional loga. rithms for every minute to 24 f , which give to 4 or 5 places the ralucs of $\log 1440-\log x$. The object of a proportional or lomistic table, or a tablo of $\log a-\log x$, is to facilitato tho calculation of proportions in which the third term is a.

Intorpolation Tables. - All tables of proportional parts may bo regarded as interpolation tables. Bremiker, Tafcl der Proportionaltheile (Berlin, 1843), gives proportional parts to lundredtlis of all numbers from 70 to 699. Scliröa, Logarithms, contains an interpolation table giving the first bundred multiples of all numbers from 40 to 410 . Tables of the valnes of binomial theorem coeffiecients, which are required when second and higher orders of differances aro used, aro descrilial belum. Woollıonse, On Infermation, Summation, and the Adjustment of Numerical Tables (London, 1865), contains nine pages of iuterpolation tables. The book congists of papers extracted from vols. xi. aud xii. of the Assurance Magazine.
Dual Logarithms.-This term is used by Mr Oliver. Byrue in his Dual Arithmctic, Young Dinl Arithmetician, Tables of Dusal Logarithms, \&c. (London, 1863.67). A dual number of tho ascend14 g branch is a contiuned product of powers of $1 \cdot 1,1 \cdot 01,1 \cdot 001$. \& c .
takon in order, tho potrers only being expressed ; thus $\downarrow 6,9.7,8$ denotes $(1 \cdot 1)^{6}(1 \cdot 01)^{2}(1 \cdot 001)^{7}(1 \cdot 0001)^{8}$, the mumbers following tho $\downarrow$ being called dual digits. $\Delta$ dual number which lias all lat the last digit zeros is called a dual logatithm; the autliol uses dual logeritlms in which there are seven ciplucrs between the $\downarrow$ and tho logarithms. A dual number of the descending lumely is a courtinued product of powers of $9, \cdot 99$, $\left\{\begin{array}{c}\text { c.: : for instance, }(9)^{3}(\cdot 99)^{2} \text { is }\end{array}\right.$ denoted hy ' 3 ' $2 \uparrow$. Tho Talies, which occupy 112 pages, give dual numbers and logarithms, both of the ascending oud descending branches, and the corresponding natural numbers. Tho author claimed that his tables were superior to thoso of common logarithms.

Constants. -In ncarly all tables of logarithms there is a loge deroted to certain frequently used constants and their logarathmes, such as $\pi, \frac{1}{\pi}, \pi^{2}, \sqrt{2}$. $\Lambda$ specially good collection is printed in Templeton's Nillurright's and Engincer's Peckel Companion (corrected hy S. Mayuard, London, 1871), which gires 58 constants involving $\pi$ aud their logarithins, gencrally to 30 places, and 13 others that may be properly called mathematical. © A good list of constants involving $\pi$ is given in Salomon (I827). A paper by Paucker in Gruncrt's Archiv (vol. i. p. 9) has a number of constants involviag $\pi$ given to a great many places, and Gauss's memoir on the lemniscato function (Werke, vol. iii.) has $c^{-\pi}, e^{-\frac{1}{2} \pi}, e^{-ई \pi}$, \&c., calculated to about 50 places. The quantity $\pi$ bas becn worked out to 707 places (Slaanks, Proc. Roy. Soc., Vol. xxi. p. 319) and Euler's constent to 263 places (Adams, Proc. Roy. Soe., vol. xxvii. p. 88). The velue of the inotulus $M$, calculated by Prof. Adans, is given in Logarithms, vol. xiv. p. 759 . This value is correct to 263 places; but the calculation has since been carricd to 272 1laces (see Adams, Proc. Roy. Soc., vol. xlii. p. 22, 1887).

Tables for the Solution of the Ircducible Case in Culic Equations.- IrrednciLambert, Supplcincuta ( 1 \% 98), rives $\pm\left(x-2^{3}\right)$ from $x=001$ to $1 \cdot 155$ bie enbic at intervals of 001 to 7 places, and Barlow (1814) gives $x^{3}=x$ from equations $x=1$ to 1.1549 at intervals of 0001 to 8 places.

Binomial Theorem Coefficients. -The values of

$$
\frac{x(x-1)}{1.2}, \frac{x(x-1)(x-2)}{1.2 .3}, \ldots \frac{x(x-1) \ldots(x-5)}{1.2 \ldots 6}
$$

from $x=\cdot 01$ to $x=1$ at intervals of $\cdot 01$ to 7 places, are scrviceable for cieuts. use in interpolation by secend and bigher orders of differences. The table queted above occurs in Schalze (1778), Barlow (1814), Yega (1797 and succeeding editions), Hantschl (1827), aud Köhler (1848). Rouse, Dectrinc of Chances (London, io date), gives on a folding sheut $(a+b)^{n}$ for $n=1,2, \ldots 20$. Lambert, Supplomente (1798), has the coefficients of the first 16 terms in $(1+x)^{\frac{1}{2}}$ and $(1-x)^{\frac{1}{2}}$, their accurate values benfor given as decimals. Vega (1597) las a page of tables giving $\frac{1}{2.4}, \frac{1.3}{2.4 .6}, \ldots \frac{1}{2.3}, \ldots$ and similar quantities to 10 places, with their logarithms to 7 places, and a page of this kind occurs in other collcctions. Koluker (1848) gives the valucs of 40 such quantitios.

Figuiale Nambers.-Lambert, Supplomenta. gives $x \frac{x(x+1)}{1}$
Figurato $\frac{x(x+1) \ldots(x+11)}{1,12}$ from $x=1$ to 30 .
Binomial
theorem
coeff.

Trigonenctrical Quadratic Surds.-The surd values of the sines Trigenoof every third degree of the quadrant are given in some tables of metrieal logarithms; c.g., in ITutton's (p. xxxix., ed. 1855), we find quadrati $\sin 3^{\circ}=\frac{1}{8}\left\{\sqrt{ }\left(5+\sqrt{ }(5)+\sqrt{\frac{1}{2}}+\sqrt{\frac{5}{2}}-\sqrt{ }(15+3 \sqrt{ } 5)-\sqrt{\frac{3}{2}}-\sqrt{\frac{1}{2}}\right\} ;\right.$ and surds the dumerical walues of tbe surds $\sqrt{ }(5+\sqrt{ } 5), \sqrt{ }\left(\frac{15}{2}\right)$, \&c., are given to 10 places. These ralucs were cxtcuded to 20 places by Peter Gray, Mcsscirgcr of Math, vol. vi (18i7), p. 105.

Circulating Decimals.-Goodwyu's tables have been described Circulat. above, p. 8. Several others ha:c been published giving the num- iug decibers of digits in the periods of the reciprocals of primes: Burck-mals. lintdt, Tables des Diviscurs du Premier Mlillion (1'ar's, 1814-17), gare one for all primes up to 2,543 and for 22 primes excceding that limit. Desmarcst, Theoric des Nombores (Paris, 1852), included all primes up to 10,000. Reusclilc, Mathomatische Abhandlung, cuthaltend neute zalulontheoretisctue Tabellen (1856), coutains a sinilar table to 15,000 . This Sliauks extended to 60,000 ; the portion from 1 to 30,000 is printed in the Proc. Foy. Soc., vol. xxii. p. 200, and the remainder is preserved in tho archives of the society (Id., xxiii. p. 260 aud xxiv. p. 392). The number of digits in the decimal period of $\frac{1}{p}$ is the same as tho exponcat to which 10 belongs for modulus $p$, so that, whencver the period has $p-1$ digits, 10 is a puimitive root of $p$. Tables of primes liaving a given mumber, $n$, of digits in their periods, i.e., tables of the resolutions of $10^{n-1}$ into factors and, as far as known, into primo factors, havo been given by Loof (in Gruncrt's Archiv, vol. xvi. p. 54 ; reprinted in Nowv. Annalcs, vol. xiv. p. 115) and by Slianks (Proc. Roy. Soc., vol. xxii. p. 381). The former exteuds to $u=60$ and tho latter to $n=100$, but there are gaps in both. Reuschlo's tract also containg, resolutions of $10^{n}-1.2$ For further referencee on circulating decis mals, sве Proc. Camb.'Phil. Soc,, vol. iii. p. 185 (1878).
Pythagorean Triangles.-Right-angled triangles in whish tho
sides and hypothenuso are all rational integers are frenuently termed Pytbagorean triangles, as, for examplo, the trisaglcs 3, 4, 5 and $5,12,13$. Schulze, Sammlung (1778), contains a table of such triangles subject to the condition $\tan \frac{1}{2} \omega>\frac{1}{5}$ ( $\omega$ being one of the acnte angles). About 100 triangles are given, but sonie occur twice. Large tables of right-angled rational triangles wers given by Bretschneider, in Gruncrt's Archiv, vol. i. p. 96 (1841), sad by Sang, Edinburgh Transadions, vol. xxiii. p. 727 (1864). In these the triangles are arranged according to hypothenuses and extend to $1201,1200,49$, and $1105,1073,264$ respectively. Whitworth, in a paper read beforo the Lit. and Phil. Society of Liverpool in 1875, carried his list as far as $2465,2337,784$. See nlso Ratl, "Die retionalen Dreicke," in Gruncri's Archiv, vol. 1vi. p. 188 (1874). Sang's paper also contains a table of triangles having an angle equal to $120^{\circ}$ and their sides integers.

Powers of $\pi$.-Pauckcr, in Grunert's Archiv, vol. i. p. 10, gives $\pi^{-1}$ and $\pi^{\frac{1}{2}}$ to 140 places, and $\pi^{-2}, \pi^{-\frac{1}{2}}, \pi^{\frac{1}{2}}$, $\pi^{\frac{1}{3}}$ to a bout 50 places ; and in Maynard'e list of constauts (sce "Constants," a bove) $\pi^{3}$ is given to 31 places. The first twelve powers of $\pi$ and $\pi^{-1}$ to 22 or more places were printed by Glaisher, Proc. Lond. Mrath. Soc., vol. viii. p. 140 , and the first bundred maltiples of $\pi$ and $\pi^{-1}$ to 12 places by Kulik, Tafel der Quadrat-und Kubile-Zahlen (Leipsic, 1848).

The Series $1^{-n}+2^{-n}+3^{-n}+$ \&c. - Let $S_{n}, 8_{n}, \sigma_{n}$ denote respectively the sums of the series $1^{-n}+2^{-n}+3^{-n}+\& c, 1^{-n}-2^{-n}+3^{-n}-\& c$. , $1^{-n}+3^{-n}+5^{-n}+\& c . \quad L e g e n d r e(T r a i t e ~ d e s ~ F r o u c t i o n s ~ E l l i p t i q u e s, ~$ vol. ii. p. 432) has computed $S_{n}$ to 16 places from $n=1$ to 35 , snd Glaisher (Proc. Lond. Math. Soc., vol. iv. p. 48) has deduced $8_{n}$ and $\sigma_{n}$ for the same arguments and to the samo number of places. Tho latter has also given $S_{n,} S_{n,} \sigma_{n}$ for $n=2,4,6, \ldots 12$ to 22 or mora places (Proc. Lond. Math. Soe., vol. viii. p 140), and the values of $\Sigma_{n}$, where $\Sigma_{n}=2^{-n}+3^{-n}+5^{-n}+\& c$. (prime uumbers only inpolved), for $n=2,4,6, \ldots 36$ to 15 places (Comple Rendu de l'Assoc. Franpaise for 1878, p. 172).

Tables of $e^{x}$ and $e^{-x}$, or Eyperbolic Antilogarithms. -The largest tables are the following. Gudermann, Theoric der potenzial-oder cyklisch-hyperbalischen Functionen (Berlin, 1833), which consists of papars reprinted from vols. viii. and ix. of Crclle's Journal, and gives $\log _{10}$ siob $x, \log _{10} \cosh x$, and $\log _{10} \tanh z$ from $x=2$ to 5 st intervals of "001 to 9 places and from $x=5$ to 12 at intervals of 01 to 10 places. Since siab $x=\frac{1}{2}\left(e^{x}-e^{-x}\right)$ and $\cosh x=\frac{1}{3}\left(e^{x}+e^{-x}\right)$, the values of $e^{x}$ and $e^{-x}$ are deducible at oace by addition and subtraction. Newman, in Canb. Phil. Trans., vol. xiii pp. 145-241, gives values of $e^{-x}$ from $x=0$ to $15 \cdot 349$ at intervals of 001 to 12 places, from $x=15 \cdot 350$ to $17 \cdot 298$ st intervals of 002 , snd from $x=17 \cdot 300$ to 27.635 at intervale of 005 , to 14 places. Glaisher, in Camb. Phil. Trans., vol. xiii. pp. 243-272, gives four tables of $\epsilon^{z^{3}}$, $e^{-x}, \log _{10} e^{x}, \log _{10} e^{-x}$, their ranges heing from $x=001$ to $\cdot 1$ at intervals of 001 , from 01 to 2 at intervals of 01 , from $\cdot 1$ to 10 at intervals of $\cdot 1$, from 1 to 500 at intervals of unity. Vega, Tabula ( 1797 and later edd.), has $\log _{50} e^{8}$ to 7 places and $e^{x}$ to 7 figures from $x=01$ to 10 at intervals of '01. Kohler's Handbuch contains a amall table of $e^{x}$. In Schulze's Sanmanang (1778) $e^{x}$ is givea for $x=1,2,3, \ldots 24$ to 28 or 29 figures and for $x=25,30$, and 60 to 32 or 38 figures; this table is printed in Glaisher's paper (loc. cit.). In Salomon's Tafeln (1827) the values of $e^{n}, e^{\cdot n}, e^{.0 n}, e^{.00 n}, \ldots e^{.000650 n}$, where $n$ has the values $1,2, \ldots 9$, are given to 12 places. Bretschneider, in Grunert's Archiv, iii. p. 33, worked out $e^{x}$ and $e^{-x}$ and also $\sin x$ and $\cos x$ for $x=1,2, \ldots 10$ to 20 places.

Factorials.-The Falues of $\log _{10}(n!)$, where $n$ I denotes 1 . 2.3... $n$, from $n=1$ to 1200 to 18 places, are given by Degen, Tabularum Enneas (Copenhagea, 1824), sud reprinted, to 6 places, at the end of De Morgaz'a article "Probabilities" in tho Encyclopsedia Mictropolitana. Shortrede, Tables (1849, vol. i. ), gives $\log (n!)$ to $n=1000$ to 5 places, and for the srguments ending in 0 to 8 places, Degeu also gives the complements of the logarithims. The first 20 figures of the valnes of $n \times n 1$ and the values of $\log _{10} \frac{1}{n \times n!}$ are computed by Glaisher es far as $n=71$ in the Phil. Trans. for 1870 (p. 370), and the valnes of $\frac{1}{n!}$ to 28 significant figures as $f a r$ as $n=50$ in Camb. Phil. Trans., vol. xiii. p. 246.

Bernoullian Numbers. - The first fifteen Bernoullisn numbers were given by Euler, Inst. Calc. Diff., part ii. ch. $\begin{gathered}\text {. Sixteen more }\end{gathered}$ were calculated hy Rothe, snd the first thirty-one were published by Ohm in Crelle's Journal, vol. xx. p. 11. Prol. J. C. Adsms has calculated the next thirty-one, and a table of the first sixtytwo was published by him ia the Brit. Assoc. Report for 1877 and in Crelle's Journal, vol. 1xxxy. p. 209. The first nine figures of the values of the first 250 Bernoullian unmbers, and their Brjggian logarithms to 10 places, have been printed by Glaisber, Camb. Thil. Trans., vol. xii. p. 884.

Tables of log $\tan \left(\frac{1}{1} n^{\prime}+\frac{1}{1} \phi\right)$. -Gndermenn, Theorio der polenzialoder cyklisch-kyperbolischen Functionen (Berlin, 1833), gives (in 100 pages) $\log \tan \left(\frac{1}{4} \pi+\frac{3}{2} \phi\right)$ for every centesimal minute of the quadrant to 7 places. Another table contains the values of this function, also at intervals of a miaute, from $88^{\circ}$ to $100^{\circ}$ (centesimal) to 11
places. "Legendre, Traill Ire Frmations Elligniques (vol. 11. p. 256). gives the same function for evely half degree (seargesimal) of tha quadraut to 12 places.

Ths Gamma Function. - Legrondre's great table appeared in vol. ii. of his Exscrcicas de Crlcul Intégral (1816), p. 85, sud in vol. ii. of his Traité des Fonctions Ellipliques (1826), T. 489. Log $_{70} \Gamma(x)$ is given from $x=1$ to 2 at iotervala of 001 to 12 places, with differences to the third order. This table io roprinted in full in Sclule. milch, Analytisehe Sizdicn (1848), 1. 183; an obridgment in which tho arguments differ by 01 occurs iu De Morgan, Diff. and Int. Cale., p. 587. The last figures of the valiea onittel are slso supplied, so that tho full table cant bo reprorlued. Avseren-place abridgment (withont differoucea) is published in Pertrand, Calcul Intigral (1870), p. 285, and a six-figure abridgment in Williamson, Iulcgral. C'alculus (1884), p. 169. Ia vol i. of his Ercreices (1811), Legeudre had proviourly puhlished a scven-place table of $\log _{10} \Gamma(x)$, without differences.

Tables conncetch with Ellintic Functions. -Tegendre calculated claborate tables of tha clliptic integrals in vol. ii. of Traits des Fonctions Elliptiques (1826). Denoting tho moulular angle by $\theta$, the amplitude by $\phi$, and the incomplete integral of the sccond kind by $E_{1}^{\prime}(\phi)$ tho tibles are-(1) $\log _{n} E$ a ad $\operatorname{lor}_{r} K$ from $\theta=0^{\circ}$ to $90^{\circ}$ at intervals of $0^{\circ} 1$ to 12 or 14 places, witl dilferences to the thind order; (2) $E_{1}(\phi)$ and $F(\phi)$, the molular angle heing $45^{\circ}$ from $\phi=0^{\circ}$ to $90^{\circ}$ at intervals of $0^{\circ} .5$ to 12 places, with differcuces to the fifth order ; (3) $E_{1}^{\prime}\left(45^{\circ}\right)$ and $F\left(45^{\circ}\right)$ from $\theta=0^{\circ}$ to $90^{\circ}$ at intervals of $1^{\circ}$, with diffcrences to the sixth order, also $E$ nud $K$ for the same arguments, all to 12 ploces; (4) $E_{1}(\phi)$ and $H(\phi)$ for every degree of both the amplitude aud the arguinent to 9 or 10 places. The first three tables had been phblishell previously in vol. iii of the Eecercices de C'ulcol Intégral (1816).

Tables involoing q. - Verhulst, Traite des Fonctions Elliptiqucs Tables (Brussels, 1841), contains a tablo of $\log _{1 v} \log _{10}\left(\frac{1}{q}\right)$ for argunnent $\theta$ iag $\operatorname{iag}$. at intervals of $0^{\circ} \cdot 1$ to 12 or 14 places. Jacubi, ia Crclle's Journal, vol xxvi. p. 93 , gives $\log _{10} q$ from $\theta=0^{\circ}$ to $90^{\circ}$ at intervals of $0^{\circ} \cdot 1$ to 5 places. Moissel, Sammlung mathenatischer Tafcln, i (Iserlohn, 1860), consists of a table of $\log _{30} q$ at intervels of $1^{\prime}$ from $\theta=0^{\circ}$ to $90^{\circ}$ to 8 places. Glaisher, in Month. Nol. Roy. Ast. Sot., vol. xxxvii. p. $372(1877)$, gives $\log _{10} q$ to 10 places and $q$ to 9 places for every degree. In Bertrand, Calcul Infégral (1870), a table of logno from $\theta=0^{\circ}$ to $90^{\circ}$ at intervals of $5^{\prime}$ to 5 places is accompanied by tables of $\log _{10} \sqrt{\frac{2 K}{\pi}}$ and $\log _{10} \log _{10} \frac{1}{7}$ and by abridgments of Legendre's tables of the elliptic integrals. Schlömilch, Vorlesungen der hoheren Analysis (Brunswick, 1879), p. 448, gives a small table of $\log _{10} q$ for every degree to 5 plares.

Legeudrian Cocfficients.-The values of $P^{n}(x)$ for $n=1,2,3, \ldots 7$ Legenfrom $z=0$ to 1 at interrals of 01 are given by Glaisher, in Erit. drian ca Assoc. Rep. for $1879, p p .54-57$. The functions tabulated are $P^{\prime}(r)=x$, efficienta $P^{3}(x)=\frac{1}{2}\left(3 x^{2}-1\right), \quad P^{3}(x)=\frac{1}{2}\left(5 x^{3}-3 x\right), \quad P^{4}(x)=\frac{1}{4}\left(35 x^{4}-30 x^{2}+3\right)$, $P^{6}(x)=\frac{1}{8}\left(63 x^{5}-70 x^{3}+15 x\right), \quad P^{6}(x)=1^{2}\left(231 x^{6}-315 x^{4}+105 x^{3}-5\right)$, $P^{7}(x)=\frac{1}{1}\left(429 x^{7}-693 x^{5}+315 x^{3}-35 x\right)$. The functions orenr in coonexion with the theory of interpolation, the attraction of spheroids, and other physical theories.

Besscl's Functions. - Pessel's originsl tablo appeared at the end Bessel's of his memoir "Untersuchung des planetarischen Theils der func: Stiorungen, welcho ans der Bewegung der Sonne entstehen" (in. Abh. d. Derl. Alad., 1824; reprinted ia vol i. of his Abhandlunger, $\mathrm{\Gamma} .84$ ). It gives $J_{0}(x)$ and $J_{1}(x)$ from $x=0$ to 32 at iatervals of 01. More extensive tables were calculated by Hansen in "Ermittelung der absoluten Storungen in Ellipsea von beliebiger Excentricitat und Neigung" (in Sehriften der Sicrnwarte Secberg, part i, Gotha, 1843). They include sn extension of Bessel's originai tablo to $x=20$, hesides smaller tables of $J_{n}(x)$ for certain values of $n$ as far as $n=28$, all to 7 places. Hansen's table was reproduced by Schlomilch, in Zeilschr. far Math., vol. ii. p. 158, and by Lommel, Studien uber die Bessel'schen Functionen (Lejpsic, 1868), p. 127. Hansen's notation is slightly different from Bessel's; the change amounts to halving each argument. Schlomilch gives tho table in Haasen's form ; Lommel expresses it in Bessel's.

Sine, Cosine, Exponential, and Logarilhm Integrals. -The functions so nsmed are the integrals $\int_{0}^{x} \frac{\sin x}{x} d x, \int_{\infty}^{x} \frac{\cos x}{x} d x, \int_{-\infty}^{x} \frac{e^{x}}{x} d x$ $\int_{0}^{x} \frac{d x}{\log x}$, which are denoted by the fnactional sirns Si $x$, Cix, Ei $x_{1}^{\infty}$ li $x$ respectively. Soldner, Théorie cl Tables d'une Nowvelle Fonctiors Transcendante (Mnnicb, 1809), gave the velues of li $x$ from $x=0$ to 1 at iatervals of 1 to 7 places, and thence at various intervals to 1220 to 5 or more places. This table is reprinted in De Morgan's Diff. and Int. Calc., p. 662. Bretschueider, in Gruneri's, Archic, vol. iii. P. 33, calculated $\mathrm{Ei}( \pm x), \mathrm{Si} x, \mathrm{Ci} x$ for $x=1,2, \ldots 10$ to 20 places, and subsequently (in Schlomilch's Zcitsehrift, vol. vi.) workel out the values of the same functions from $x=0$ to 1 at intervals of -01 and from 1 to 7.5 st intervals of 1 to 10 places. Two tracts by L. Stenberc. Tabula Logrtilhmi Interralis (Malnö. part j. 186 i
and part ii. 1867), give the ralues of li $10^{2}$ from $z=-15$ to 3.5 at intervals of 01 to 18 places. Glaisher, in Phil. Trens., 1870, p. 367, gives $\mathrm{Ei}( \pm x)$, Si $x$, $\mathrm{Ci} x$ from $x=0$ to 1 at intervals of 01 to 18 places, from $x=1$ to 5 at intervals of 1 and tlfence to 15 at intervals of unity, and for $x=20$ to 11 places, besides seven-place tables of Si $x$ and $\mathrm{Ci} x$ and tables of their maximam and miuimum values. See also Bellavitis, "Tavole Numeriche Logaritmo-Integrale" (a paper in Memoirs of the Venetian Institute, 1874). Bessel calculated the ralues of li 1000 , li 10,000 , li 100,000 , li $200,000, \ldots$. $1 \mathrm{i} 600,000$, and li $1,000,000$ (see Abhandlungen, vol. ii. P. 339). In Glaisher, Factor Table for the Sixth 1fillion (1883), § iii, the values of li $x$ are given from $x=0$ to $9,000,000$ at intervals of 50,000 to the ncarest integer.
Values of $\int_{0}^{x_{e}}-x^{3} d x$ and $e^{x^{2}} \int_{0}^{x} e^{-z^{2}} d x$. These functions are employed in researches connected with refractions, theory of errors, conduction of beat, \&c. Let $\int_{0}^{z^{2}} e^{-x^{2}} d x$ and $\int_{z}^{\infty} e^{-x^{2}} d x$ be denoted by Erf $x$ and Eric $x$ respectirely, standing for "error fnaction" and "error function complement," so that Erf $x+$ Erfc $x=\frac{3}{2} \sqrt{ } \pi$ (Phil. Maj., Dec. ISil; it has since been found convenient to transpose ss above the dcfinitions of Erf and Erfc). The tables of the fuactions, and of the functions multiplied by $\varepsilon^{z^{2}}$, are as follows. Kranp, Aualyse des Refractions (Strasburg, 1799), has Erfe $x$ from
 and $\log _{10}\left(2^{2} \operatorname{Erfc} x\right)$ for the same values to 7 places. Bessel, Fundamenta Astrozomix (Königsberg, 1818), has $\log _{10}\left(e^{x^{2}} \operatorname{Erfc} x\right)$ from $x=0$ to 1 at intervals of 01 to 7 places, likewise for argument $\log _{10} x$, the arguments increasiog from 0 to 1 at intcrvals of 01 . Legendre, Trauté des Fonctions Elliptiques (1826), vol ii. p. 520, contains $\Gamma\left(\frac{1}{3}, e^{-x^{2}}\right)$, that is, $2 \operatorname{Erfc} x$ from $x=0$ to $\cdot 5$ at intervals of $\cdot 01$ to 10 places. Encke, Berliner Ast. Jahrbuch for 1834, prints $\frac{2}{\sqrt{ } \pi}$ Erf $x$ from $x=0$ to 2 at intervals of 01 to 7 places and $\frac{2}{\sqrt{\pi}} \operatorname{Erf}(\rho x)$ from$y=0$ to 3.4 at intervals of 01 and thence to 5 at intervals of $\cdot 1$ to 5 places, $\rho$ being 4769360 . Glaisher, in Phil. Mag., December 1871, has calculated Erfe $x$ from $x=3$ to 4.5 at intervals of 01 to 11, 13, or 14 places. Encke's tables and tro of Kramp's were reprinted in tbe Encyclopesdia Metropolitana, art. "Probabilities."
Tables of integrals, not Numerical. - Meyer Hirsch, Integral-
Kln (1810; Eng. trars., 1823), and Minding, Integraltafeln (Berlin, 1849), give values of indefinte integrals and formulx of reduction; both are useful and raluable works. De Haan, Nouvelles Tables d'Integrales Definies (Leyden, 1867), is a quarto volume of 727 pagcs contrining evaluations of definite integrals, arranged in 485 tables. The first edition appeared in vol. iv. of the Transactions of the Amsterlam Academy of Sciences. This, thongh not so full and accurate as the second edition, gives references to the original memoirs in which the different integrals are considered.

Tables relating to the Theory of Numbers. - These are of so technical a character and so nnmerous that a full account cannot be attempted here. The reader is referred to Cayley's paper in the Bril. Assoc. Rhcp. for 1875, where a full description with references is given. Threo tabies mayे, however, be briefly noticed on eccount of their importance and because they form 6eparate volumes: (1) Degen, Canon Pellianus (Copenhagen, 1817), relates to the indeterminate equation $y^{3}-a x^{2}=1$ for values of $a$ from 1 to 1000 . It in fact gives the expression for $\sqrt{ } a$ as a continued fraction; (2) Jacobi, Canon Arithmeticus (Berlin, 1839), is a quarto work containing 240 pages of tables, where we find for escll prime ap to 1000 the numbers corresponding to given indices and the indices corresponding to given numbers, a certain primitive root ( 10 is taken whenever it is a primitive root) of the prime being selected as base; (3) Reuschle, Tafeln complexer Primzahlen, veclche aus Wu raeln der Einheit gebildet sind (Berlin, 1875), includes an enormous mass of results relating to the higher complex theories. A table of $\chi(n)$, where $\chi(n)$ denotes the sum of the complex numbers which have $n$ for the:r norm for primes up to $n=13,000$ (ef. Quatt. Journ., vol. xx. p. 152), has been published since the date of Cayley's report. Some tables that belong to the theory of numbers have been described abore under "Factor Tables" (p. 7).

* BRlliography,-Full bibliographical end historical information relating to tables is collected io Brit. Assoc. Rcp. for 1873, p. 6. The principal works ase: -Heilbronner, ITistoria Natheseos (Leipsic, 1742 ), the aritbmetical portica being at the end; Scheibel, Einleitung sur mathematischen Bücherlienntnios (Bresiau, 1771-84) : Kastner, Geschichle der Nathematic (Gottiageo, 1706.1600), vol. fiii.; Mrrhard, Bibliotheca Mathematiou (Leipsic, 1797-1801), Yoi. Hi.; Pogb, Bibbiotheca Mathematica (Tubingea, 1830), and continustion frold 1830 to 155$\}^{\prime}$ by Solinke (Leipsic and London, 1854); Lalande, Bibliographie Astronomipuc (Paris, 1803), a separato index ou p. 300 . A great deal of accurate information vpon early tablee is given by Delsmbre, Histoire de $t$. Astronomaie Moderne (Paris, 1827), vol. 1.; ; and Nos. ziz. snd IX. of Hutton's Afathematical Tracts (1812). For 3 coinplete list of logaritbmic tables of all kinds fron 1614 to 1862 , see De Fana "Fets over Lngarithnentafels," in Verslapen en Ncdedeclingen der Koning. Aliad, orn IFeteneehampen (Amsterdant, 1562), pt. siv. De Morgan's article "Tables," which aureared Arst in the Penny Cudopzdia, and afterwards with additiona tuthe tip Enplish Cydopedia, gives not ouly a good deal of bibliographical informa. un unt also an account of tables relating to life asouraice and smnuities, natronulical tablea, contwê sial tables, $\Delta \mathrm{C}$.

TABOO (also written Tabu and Talro) is the name given to a sjstem of religious prohibitions which attained its fullest development in Polynesia (from Hawaii to New Zealand ; see rol. xix. p. 426), but of which under different names traces may be discopered in most prarts of the world.

The word "taboo" is common to the different dialects of Polynesia, and is perhaps derived from $t a$, "to mark," and $p u$, an adverb of intensity. The compound wort "taboo" (tapu) would thus originally mean "marked thoroughly." Its ordinary sense is "sacred," It does not, however, imply any moral quality, but only "a connexion with the gods or a separation from ordinary purpeses and exclusivo appropriatiou to persons or things considered sacred; sometimes it means devoted as ky a row." Chiefs who trace their lineage to tho gods are called arii lalns, "chiefs sacred," and a temple is called a vochi laIru, "place sacred." The converse of taboo is woa (in Tonga gnofóa), which means "general" or "common." Thus the rule which forbade women to eat with men, as well as, except on special occasions, to eat any fruits or animals offered in sacrifice to the gods, was called ai tabu, "eating saered"; while the present relaxation of the rule is called ai noa, eating generally, or haviug food in common. Although it was employed for civil as well as religious purposes, the taboo was essentially a religious observance. In Hawaii it could be imposed only by priests; but elsewhere in Polynesia kings and cliefs, and even to a certain extent ordinary individuals, exercised the same power. The strictness with which the taboo was obscrred depended largely on the influence of the perron who inposed it: if he was a great chief it mould not be broken; but a powerful man often set at nouglit the taboo of an inferior.

A taboo might bo general or particular, permanent or Genera temporary. A general taboo applied, e.g., to a whole class and par of animals; a paiticular taboo was confined to one or more ticular ind:viduals of the class. Idols, temples, the persons and names of kings and of members of the royal family, the persons of chiefs and priests, and the property (canoes, houses, clothes, \&c.) of all these classes of persons were always taboo or sacred. By a somewhat arkitrary extension of this principle a chief could render taboo to (i.e., in favour of) himself anything which took his fancy by merely calling it by the name of a part of his person.. Thus, if he said "That axe is my backbone," or "is my head," the axe was his; if heroared out "That canoe! my skull shall be the baler to bale it out," the canoe was lis likewise. The names of chiefs and still more of kings were taboo, and could not be uttered. If the name of a king of Tahiti was a commion word or even resenibled a common word, that word dropped out of use and a new name was substituted for it. Thus in course of time most of the common words in the language underwent considerable modifications or were entirely changed.

Certain foods were permanently taboo to (i.e., in favour of or for the use of) gods and men, bnt were forbididen to women. Thus in Hawaii the flesh of hogs, fowls, turtle, and several hinds of fish, cocoa-nuts, and nearly everything offered in sacrifice were reserved for gods and mon, and could not, except in special cases, be consumed by women. In the Marquesas Islands human flesh was tabooed from women. Sometimes certain fruits, aninuals, and fish were taboo for months together from both men and women. In the Marquesas houses were tabooed against water: nothing was washed in them; no drop of water might be spilled in them. If an island or a district was tabooed, no canou or person might approach it wbile the taboo lasted; if a path was tabooed, no one might walk on it. Seasons generally kept taboo were the approach of a great religious ceremony, the time of preparation for war, and the sickness of chiefs. The time during which they lasted varied from
rears to months or days. "In Hawail there was a tradition of one that lasted thirty years, during which men might not trin their beards, de. A common period was forty days. A taboo was either common or strict. During a common taboo the men were only required to abstain from their orlinary occnpations and to attend morning aud evening praycr. But during a strict tabco every fire and light on the island or in the district was extinguished; no canoe was lannched; no person bathed; no one, except those who had to attend at the temple, was allowed to be seen out of doors; no dog might bark, no pig grunt, no cock crow. Hence at these seasons they tied up the mouths of logs and pigs, and put fowls under a calabash or bandaged their eyes. The taboo was imposed either by proclamation or by fixing certain marks (a pole with a bunch of bamboo leares, a white cloth, \&c.) on the places or things tabooed.
The peualty for the violation of a taboo was either religions or civil. The religious penalty inflicted by the offended atuas or opirits generally took the form of a disease : the offender swelled up aud died, the uotion being that the atua or his emissary (often an infant epirit) had entered into him and devoured bis vitala. Cases are on record in which persons who had unwittingly broken a taboo actually died of terror on discovering their fatal error. Chiefs and priests, however, could in the case of involuntary transgressions perform certain mysticsl ceremoniee which prevented this penalty from taking effect. The ciril penalty for breaking a taboo paried in severity. In Hawaii there were police officers appointed by the king to see that the taboo was observed, and every breach of it wras punished with death, unless the offender had powerful friends iu the persons of priests or chiefs. Elserwhero the punishment was milder; in Fiji (whicl, hovever, is Melanesian) death was rarely inflicted, but the delinquent was robbed and lis gardens despoiled. In New Zealand this judieial robbery wes reduced to a system. No gooner was it known that a man had brokeu a taboo than all his friends and acquaiutances stwarmed down on him and carried off whetever they could lay hands on. Under this system (known as murv) property circulated with great rapidity. If, e.g., a child foll into the fire, the father was robbed of nearly all he possessed. ${ }^{1}$

## Things

 raturallyBesidee the permanent and the artificially created taboos there taboo. This all persons dangerously ill were taboo and were removed from their houses to eheds in the bush; if they remsined in the house and died there the house was tabooed and descrted. Mothers after childhirth were taboo, and so were their new-born children. Women before marriage were noa, and could have as many lovers as they chose; but after marriage they were strictly tabooed to their husbands and from evory one else. One of the strictest taboos was incurred hy all persons who handled the body or bones of a dead person or assisted at his funeral. In Tonga a comnon person who touched a dead chief was tabooed for ten lunar months; a chief who touched a dead chief was tabooed for from three to five nonthe accorliug to the rank of the deceased. Burial grounds were taboo; aud in New Zealand a canoe which had carried a corpse was nover afterwards med, but was drawn on eloore and painted red. Red was the taboo colour in Nerr Zealand; in Hawaii, Tahiti, Tonga, and Samon it was white. In the Marquesas a man tho had elain au enemy was taboo for ten days: be might have no intercourse with his wife and might not meddle with fire; he lad to get eome one else to cook for him. A woman engaged in the prepara. tion of cocoa-nut oil was taboo for five days or nore, during which she might have no intercourse with men. A tabooed person might not eat his food with his hends, but was fed by another person ; if he could get no one to feed him, he had to go down on his knees and pick np his food with his mouth, holding his hands behind him. A chief who was permanently taboo never ate in his own house but always iu the open air, being fed by one of his wives, or taking his food with the help of a fern etalk so as not to touch his head with his hands; food left by him was kept for him in a sacred place; any other person eating of it was supposed to die immediately. A man of any standing could not carry provisions on his back; if he did so they became taboo and were useless to any one but himself. For the taboo was communicated as it were by infection to whatever a tabooed persor or thing touched. This rule applied in its fullest force to the king and queen of Tahiti. Tbe ground they trod on became sacred ; if they entered a house, it became taboo to them and had to be abandoned to them.hy its owner. Hence epecial houses were
${ }^{3}$ The origin of this custom may perhspe be discerned in a castom of the Dieri tribe, Sonth Australia. Among them, if a child meets with an aecident, all its relstions immedistely get thoir heads broken with sticks or boomeranga till the blood flows down their faces, thie surgical operation being supposed to ease the child'e pain (Native Tribes of S. Australia, p. 280).
sot apart for them on their travels, and, except in their bereditary districts, they were alwaye carried on mea's shoulders to provent them tonching the ground. Elsowhere, ss in New Zealand, this rule was not carried out oo etrictly. But even In New Zeslaud the spots on which great chiefs rested during a jolpney becsme tabou und were surrounded with a fence of basket-work. The head and lhair, especially of a chief, were particularly taboo or saered; to touch a man's head was a gross insult. If a chief touched his own head with his fingers he had inumediately to apply them to his nose and enuff up the sanctity which they had abstracted froul his head. The cutting of a chief's hair was a solemu cerconony; the severed locks were collected and buried in a sacred plaio or hung up on a tree. If a drop of a chief's blood fell upou snything, that thing hecame taboo to him, i.e., was his property. If he hreathed on a fire, it became sacred and could nut be used for cooking. In his house no fire could under any circumstances be usel for cookiug: no woman could enter his house before a cortain servich had beou gone through. Whatever a new-born child touched became ts boo to (i.e., in favour of) the child. The law which sejmrated tabooed persons and things from contact with food was esperially strict. Hence a tabooed or sacred person ought not to leave his comb or blanket or anything which had touched his head or back (for the back was also particularly taboo) in a place where food had been cooked; aud in drinking he was eareful not to touch the vessel with hie lands or lips (otherwise the vessel became taboo and could not be ueed by any one else), but to have the liquid shot down his throat form a distance by a second person.

There we:- various ceremonies by which a taboo could le removed. Remove? In Tonga a person who had become taboo by touchinef a chiof or of taboe anything belonging to him could not feed hiuself till he had got rid of the taboo by touching the solee of a euperior chicfs feet with his hands and then rinsing his hands in water, or (if water was ecarce) rubbing them with the juice of the plantain or banana. But, if a man found that he had alrcady (unkuowingly) eaten with tabooed hands, he sat down before a chief, took up the foot of the latter, and pressed it egainst his stomach to counteract the effect of the food inside. In New Zealand a taboo could be taken off by a child or grandchild. The tabooed person touched the child and took driuk or food from ite bands ; the man was theu free, but the caild was tabooed for the rest of the day. A Maori chief who became taboo by touching the sacred head of his child was disinfected, so to apreak, as follows. On the following day (the ceremony could not he performed sooner) he rubbed his hands over with potato or fern root which had been cooked over a sacred fire; this food was then carried to the head of the family in the fonate line, who ato it, whereupon the hands beeame noa. The taboo was removed from a new-born child in a eonewhat similar mauner. The father took the child in his arms and tonched its head, back, \&e., with some fern root which had been roasted over a sacred fire; next morning a similar ceremony was performed on the child by its cldest relstive in the female line; the child was then nor, i.c., freo from taboo. Another mode of removing the taboo was to pass a consecrated piece of wood uver the right shoulder, round the loias, and back agrain over the left shoulder, after which the stick was broken in two and either buried, or burned, or cast into the sea.

Besides the taboos already described there were others which Privat any ono could impose. In New Zcaland, if a man wislied to pre-tabore ecrve his house, crop, garden, or aaything else. he made it taloo; eimilarly he could appropriate a forcst irce or a picce of drift timber, \&c., by tying a mark to it or giving it a chop with his axe. In Samoa for a similar purpose a man would set up a representation of, e.g., a sea pike or a blatk, believing that any one who meddled with property thus protected would he killed by a sea jike or sharls the noxt time he bathed. Somewhat similar to this was what mey be called the village ts boo. In the autumn the kumerc (sweet potato) Sclds belonging to the village were taboo till the crop was gathered, so that no stranger could approach them: and all persons engaged in getting in the crop were taboo, and could therefore for the time engage in no other occupation. Similar taboos were laid on woods during the hunting season and on rivers during the fohiug season.

On looking over the various taboos mentioned above we are tempted to divide them into two general classes.taboos of privilege and taboos of disability. Thus the taboo of chiefs, priests, and temples might be described as a privilege, while the taboo imposed on the sick and on persons who had come in contact with the dead might bo regarded as a disability; and we might say acccordingly that the former rendered persons and things sacred or holy, while the latter rendered them unclean or accursed. But that no such distinction ought to be drawn is clear from the fact that the rules to be observed in the one case and in the other were identical. On the other hand, it is true that the opposition of sacred and accursed, clean and
anclean, which plays so important a part in the later history of religion, did in fact arise by differentiation from the single ront idea of taboo, which includes and reconciles them both and by reference to which alone their history and mutual relation are intelligible.
The ortginal character of the taboo must be looked for not in its civil but in its religious element. It was not the creation of a legislator but the gradual outgrowth of animistic beliefs, to which the ambition and avarice of chiefs and priests afterwards gave an artificial extension. But in serving the cause of avarice and ambition it subserved the progress of civilization, by fostering conceptions of the rights of property and the sanctity of the marriage tie. conceptions which in time grew strong enough to stand by themselves and to fling away the crutch of superstition which in earlier days had been their sole support. For we shall scarcely err in believing that even in advanced societies the moral sentiments, in so far as they are inerely sentiments and are not based on an induction from experience, derive much of their force from an original system of taboo. Thus on the taboo were grafter the golden fruits of law and morality, while the parent stem dwindled slowly into the sour crabs and empty husks of popular superstition on which the swine of moderu society are still content to feed.
It remains to indicate briefly some facts which point to a wide diffusion under various names of customs similar to the taboo. As might have been expected, the taboo is found, though in a less marked form, among the Micronesians, Malays, and Dyaks, all of whom are ethnologically connected with the Polynesians. In Micronesia both the name and the institution occur : the inhabitants of certain islands are forbidden to eat certain animals-and the fruits of certain trees; temples and great chiefs are tabooed from the people; any one who fishes must previously for $t$ wenty-four hours abstain from women; ${ }^{1}$ in conversing with women men are not allowed to use certain words, \&c. Again, the Malays have the custom, though apparently not the name. In Timor and the neighbouring islands the word for taboo is panali (or ponali); and during the long festival which celebrates a successful head-hunt the man who has secured the most heads is pamali; he must not sleep with his wife nor eat from his own hand, but is fed by women. Pamali is a Javanese word, and had originally in Java and Sumatra the sane meaning that it now bears in Timor. In Celebes a mother after childbirth was pamali. Amongst the Dyaks of Borneo the pamali (called by the Land Dyaks porikh) is regularly practised at the planting of rice, harvest home, when the cry of the gazelle is heard behind, in times of sickness, after a death, \&cc. At the harvest home it is observed by the whole tribe, no one being allowed to enter or leave the village. The house where a death has taken place is pamali for twelve days, during which no one may enter it and nothing may be taken out of it. A tabooed Dyak may not bathe, meddle with fire, follow his ordinary occupation, or leave his house. Certain familiesare forbidden to eat the flesh of particular animals, as cattle, goats, and snakes. The taboo is often indicated by a bundle of spears or a rattan. The Motu of New Guinea also have the taboo: a man is tabuoed after handling a corpse. He then keeps apart from his wife; his food is cooked for him by his sister; and he may not touch it with his hands. After three days he bathes and is free. ${ }^{2}$ But the Motu appear to be Malayo-Polynesians, not Melanesians proper.
Howerer, in Melanesia also we find the Howerer, in Melanesia also we find the taboo. It flour-

[^6]ished in Fiji. It is observed in New Caledonia in cases of death, to preserve a crop, \&c. According to the liev. R. H. Codrington, there is this distinction between the Melanesin: and the Polynesian taboo, that for the former there is no supernatural sanction: the man who ireaks a taboo simply pays compensatiou to the person on whose tabooed property he has transgressed. But Mr R. Parki:ison states that in New Britain (now New Pomerania) a person who violates a taboo-mark set on a plantation, tree, \&c., is supposed to be "attacked by sickness and misfortune." To go through the similar customs ohserved by savages all over the world would be endless; we may, however, note that a regular system of taboo is said to exist among some of the wild tribes of the Naga Hills in India, ${ }^{3}$ and that the rules not to touch food with the bands or the head with the hands are observed by tabooed women among one of the Fraser Lake tribes in North America. ${ }^{4}$ In fact some of the most characteristic features of taboo-the prohibition to eat certain foods aud the disabilities entailed by childbirth and by contact with the dcad, together with a variety of reremonies for removing these disabilitieshave been found more or less amongst all primitive races. It is more interesting to mark the traces of such customs among civilized peoples, e.g., Jews, Grecks, and Romans.

Amongst the Jews-(1) the vow of the Nazarite (Num. vi. 1-21) presents the closest resemblance to the Polynesian taboo. The meaning of the word Nazarite is "one separated or consecrated," and this, as vo saw (p. I5), is precisely the meaning of taboo. It is the head of the Nazarite that is especially consecrated (v. 7, "his separation unto God is upon his head "; v. 9, "defile the head of his separation"; v. 11, "shall hallow his head"), and so it was in the taboo. The Nazarite might not partake of certain meats and drinks, nor shave his head, nor touch a dead body,-all rules of taboo. If a person died suddenly beside him, this was said to "defile the head of his separation," and the same effect, expressed in the same language, would apply to a taboocd Polynesian in similar circumstances. Again, the mode of terminating the row of the Nazarite corresponds with the mode of breaking a taboo. He shaved his head at the door of the sanctuary and the priest placed food in his hands, either of which acts would have been a flagrant violation of a Polynesian taboo. (2) Some of the rules for the observance of the Sablath are identical with rules of strict taboo; such are the prohibitions to do any work, to kindle a fire in the house, to cook food, and to go out of doors (Exod. xxxv. 2, 3 ; xvi. 23, 29). The Essenes strictly observed the rules to cook no food and light no fire on the Sabbath (Josephus, Bell. Jud., ii. 8, 9). (3) Any one who touched a dead body was "unclean" for seven days; What he touched became unclean, and could communicate its uncleanness to any other person who touched it. At the end of seven days the unclean person washed his clothes, bathed himself, and was clean (Num. xix. II, I4, 19, 22). In Polynesia, as we have seen, any one who touched a Nead body was taboo; what he touched became taboo, and oould communicate the infection to any one who touched it; and one of the ceremonies for getting rid of the taboo was washing. (4) A Jewish mother after childbirth was unclean (Lev. xii.); a Polynesian mother was taboo. (5) A great many animals were unclean, and could infect with their uncleanness whatever they touched; earthen ressels touched by certain of them were broken. Certain animals were taboo in Polynesia, and utensils which had contracted a taint of taboo were in some cases broken.

Amongst the Greeks a survival, or at least a reminiscence, of a system of taboo is perhaps to wo found in certain applications of the epithets "sacred" and "di-ine" in

[^7]Homer. Thus a king or a chief is sacred (iєp $\eta$ is TY $\lambda_{\epsilon}$
 Oll., vii. 167, viii. 2, むc.) or divine ( ©ios 'Osvaбcús, dec.;
 691); ris chariot is sacred (Il., rvii, 464), and his house is divine (Od., iv. 43). An army is sacred (Od., xxiv. 81), and so are sentinels on duty (Il., x. 56 ; xxiv. 681). This resembles the war-taboo of the Polynesians; on a warlike expedition all Maori warriors are taboo, and the permanent personal taboo of tho chiefs is increased twofold: they are "tabooed an inch thici." The Jews also seem to have had a war-taboo, for when out on the war-path they abstained from women (l Sam. xxi. 4, 5), -a rule strictly observed by Maori warriors on a dangerous expedition. The Dards, who with the kindred Siah Posh Kâfirs on the sonthern slopes of the Hindu Kush-tribes which probably of all Aryan peoples retain a social state most nearly approximating to that of the promitive Aryans-abstain from sexual intcrcourse during the whole of the fighting season, from May to September; and "victory to the clastest" is said to be a maxim of all the fighting tribes from the Hindu Kush to Albania. ${ }^{1}$ The same rule of continence in war is obscrved by some 1ndian tribes of North America. ${ }^{2}$ In Homer a fish is sacred (Il., xvi. 407), and Plato points out that during a campaign the Homeric warriors never ate fish (Rep., $40 \pm$ B). Even in time of peace the men of Homer's day only ate fish when reduced to the verge of starvation (Ocl., iv. 363 sq. ; xii. 3 ? ? sq.). The Siah Posh Kâfirs refuse to eat fish, although their rivers abound in it. ${ }^{3}$ The Hindus of Yedic times appear not to have eaten fish. ${ }^{4}$ It is probable, therefore, that among the early Aryans, as anong primitive peoples in various parts of the world, the eating of fish was tabooed. Again, the threshing-floor, the winnowing-fan, and meal are all sacred (Il., ₹. 499 ; H. Merc., 21, 63 ; Il., xi. 631). Similarly in New Zealand a taboo was cominonly laid on places where farming operations were going on; and among the Basutos, before the corn on the threshing-floor can be touched, a religious ceremony has to be performed, and all "defiled" persons are carefully kept from seeing it. ${ }^{5}$ Although the Homeric folk ate swine, the epithet "divine" commonly applied to a swineleerd in Homer may point to a time when pigs were sacred or tabooed. In Crete pigs were certainly sacred and not eaten (Athenæus, $376 a$ ), and apparently at Pessinus also (Pansanias, vii. 17, 10). Amongst the Jews and Syrians, of course, pigs were tabooed; and it was a moot question with the Greeks whether the Jews abhorred or worshipped pigs (Plut., Qucest. Conv., iv. 5). The pigs kept in the great temple at Hierapolis were neither sacrificed nor eaten; some people thought that they were sacred, others that they were unclean, évay'as (Lucian, De Dca Syria, 54). Here we lave an exact taboo, the ideas of sacreduess and uncleanness being indistinguishable. Similarly by the Ojibways the dog is regarded as "unclean and yet as in some respects holy." ${ }^{0}$ The divergence of the two conceptions is illustrated by the history of the cow among different branches of the Aryan race: the Hindus regard this animal as sacred; the Shin caste among the Dards hold it in abhorrence. ${ }^{7}$ The general word for taboo in Greek is äyos, which occurs in the sense both of "sacredness" and of "pollution"; and the same is true of the adjective $\ddot{a}^{\circ} \gamma \cos$ and of the rare adjective

[^8]ảvayท́s, "tabooed" (Bekker's Ancedota Graca, 212, 32 ; Harpocration, s.v. ávayeis). Usually, however, the Greeks discriminated the two senses, a ayoós being devoted to the sense of "sacred" and $\begin{gathered}\text { evarts } \\ \text { to that of "uncleau" or }\end{gathered}$ "accursed." "To taboo" is $\dot{\alpha} \gamma i\} \epsilon \iota v$; "to observe a taboo",
 or ajıбтcia. The rules of the Greek ajvcía correspond closely to those of the Polynesian taboo, consisting in "purifications, washings, and sprinklings, and in abstaining from mourning for the dead, child-bed, and all pollutions, and in refraining from certain foods," \&c. ${ }^{8}$

Amongst the Romans, who preserved mare traces of primitive barbarism than the Greeks, the flamen dialis was hedged in by a perfect network of taboos. Ho was not sllowed to ride or even touch a horse, nor to look at an army under arms, nor to wear a ring which was not brolien, nor to Lave a knot on any part of his garnients ; no fire, except a sacred fire, could be taken out of his louse; he might not touch or evelu name a goat, a dog, raw meat, beans, and ivy ; he might not walk under a vine; the fect of his bed had to be daubed with mud; his lair could be cut only by a freeman, and his hair and nails when cut had to be buried under a lucky tree; he might not touch a corpse, \&c. His wife, the flaminica, was also subject to taboos :" at certain festivals she might not coinb her hair; if she heard thunder, she was taboo (feriuta) till she had offered an expiatory sacrifice. The similarity of some of these rules to the Polynesian taboo is obvious. The Roman ferie were periods of taboo; no work might be done during them except works of necessity: e.g., an ox might be pulled out of a pit or a tottering roof supported. Any person who mentioned Salus, Scmonia, Seia, Segetia, or Tutilina was tabooed (ferias observabat). ${ }^{9}$ The Latin sacer is exactly "taboo"; for it means either "sacred" or "accursed."

(J. G. FR.)

TABRIZ, Tatris, or TAvriz, a town of Persia, capital of the province of Adarbaijin (Azerbijan, ancient Atropatene), is situated in $38^{\circ} 4^{\prime} \mathrm{N}$. lat. and $46^{\circ} 18^{\prime}$ E. long., more than 4000 feet above the sea, at the eastern end of a wide valley, through which runs a river whose waters irrigate the gardens that encircle the town. In 1812 the walls had a circumference of $3 \frac{1}{4}$ miles. Overlooking the valley on the northeast and east ar bold bare rocks, while to the south rises the more regular peak of Sahand. The town possesses fow buildings of note, and of the extensive ruins but few merit attention. Mounsey in 1866 mentioned the blue mosque; the ark or citadel, containing the palace of the heir-apparent,-a large frowning building near the centre of the town; the Great Maidan, an open square;

[^9]and the bazaars. The mosque, which he ascribes to Stan Abbas, is that of the Turcoman Jahan Shah (1410-1468). Abbas Mirza conserted the citadel into an arsenal. Among the ruins of old Tauris the sepulchre of the Mogul sultan, Ghazan Khán, is no longer to be distinguished, except as part of a huge tumulus. It is situated about 2 miles south-west from the modern town, bat far within the original boundaries. The "spacious arches of stone and other vestiges of departed majesty" with which Porter found it surrounded in 1818 were possibly remains of the college (madrasa) and monastery (zaviya) where Ibn Betuta found shelter during his visit to the locality. In spite of the cholera visitation of 1822 and other occasional ravages of sickness, and the severe cold of winter, the climate of Tabríz is proverbially healthy. Its orchards and fruit gardens have a high repptation, and its running streams make amends for ill-paved and narrovs streets and sorely defective municipal arrangements. General Schindler estimated the population in 1886 at about $170,000,-2$ number agreeing with the latest local census. The same authority states that the city contains 8 tombs of imánizádehs, 318 mosques, 100 public baths, 166 caravanserais, 3922 shops, 28 guard-honses, and 5 Christian (Armenian) churches; but this account must comprise in some of its items more buildings than are actually in use. There are said to be nearly 3000 Armenians in the place.
Tabriz is a city of estensive commorce, a great enporium for tho trade of Persia on the west, and the special mart between Turkey, Russia, and Persia. It possosses an international telegraph station, and the line passes hence to Tiffis and Europe on one side and to Teheran on the other. Subsidiary linos have been constructed to near Astara on tho Caspian ( 136 miles long) and to Saujbulak en the Kurdish frontier ( 125 miles long). Eastrwick in 1860 estimatéd the value of the cxports to Turkey at aboat $£ 600,000$ and to Russia at abont $£ 400,000$, exclusive of smuggling. The chief imports were British, and some Smiss-colonred cotton goods, grey calicoes, and broadcloth, -with miscellaneons हoods from Cermany. In 1881 there mas a marked improvement iu the trade of Tabriz, nainly in increased imports from Constantinople. In 1885 the imports amounted to $£ 721,730$ and the exports to $£ 306,687$. The principal items of the former were cottons from England), woollen cloth (from Austria and Germany), sugar (from France), and tea (from Holland) ; of the later dried fivits (to Russia) snd silk (to France, Anstria, and Switzerland). Thero are lead mines near Tabriz, and cobalt and copper are obtainable from the Sahand.
There is perlaps no city in Persia on which so much bas been recorded by native and foreign writers as Tabriz. Among the former Ibn Batuta, the Arab, and Hamd Ullah, the Persian, are notable. Of the latter may be mentloned Chardin, Porter, Ouseley, Tancoirne, Moricr, Du Pré, Malcolm, Lady Sheil, Eastwick, Mounsey, Schindler, and Madame Dieulafoy (in Tour du Monde, 1833). The name Tabria has been a subject of muck comment and conjecture, hat there is no doubt that it is taken from the ancient name of Tauris. The history of Tabriz is a long and painful record of sieges and conficts, of earthquakes and destruction by natural causes. Of late years it has recovered to some extent its former high position, and is in many respects a worthy rival to the capital.

TACITUS. The famous Roman historian Tacitus, who ranks beyond dispute in the highest place among men of letters of all ages, lived in the latter balf of the first and in the early part of the 2d century of our era, through the reigns of the emperors Nero, Galba, Otho, Vitellius, Vespasian, Titus, Donitian, Nerva, Trajan. All we know of his personal history is from allusions to himself in his own works, and from eleven letters addressed to him by lis rery intimate frieud the younger Pliny. The exact year of his birth is a matter of inference, but it may be approximately fixed near the close of the reign of Claudius, from 52 to 54 A.D. Pliny indeed speaks of Tacitus and himself as being "much of an age" ${ }^{1}$ (propemodum aquales), though himseif born in 61 or 62 , but lic must have been some years junior to his frie ad, who hegan, he tells us, ${ }^{2}$ his official life with a ques torship under Vespasian in i8 or 79 , at which tine he must have
been twenty-five jears of age at least. Of his family and birthplace we know nothing certain; we can infer nothing from his name Cornelius, which was then very widely extended; but the fact of his early promotion seens to point to respectable antecedents, and it may be that his father was one Cornelius Tacitus, who had been a procurator in one of the divisions of Gaul, to whom allusion is made by the elder Pliny in his Natural Itistory (vii. 76). But it is all matter of pure conjecture, as it also is whether his "prenomen" was Publius or Cains. He has come down to us simply as Cornelius Tacitus. The most interesting facts about him to us are that he was an eminent pleader at the Roman bar, that he was an eye: witness of the "reign of terror" during the last three years of Domitian, and that he was the son-in-law of the great and good Julius Agricola, the humane and enlightened governor of Britain. This honourable connexion, which testifies to his high moral character, may very possibly hare accelerated his promotion, which he says ${ }^{3}$ was begun by Vespasian, augmented by Titus, and still further advanced by Domitian, under whom we find him presiding as prextor at the ceieoration of the secular games in 88 , and a member of one of the old priestly colleges, to which good family was an almost indispensable passport. Next year, it seems, he left Rome, and was absent till 93 on some provincial business, and it is possible that in these four years he may have mado the acquaintance of German'y and its peoples. His father-in-law died the year of his rcturn to Fome. In the concluding passage of his Life of Agricola he tells us plainly that he witnessed the judicial murders of many of Rome's best citizens from 93 to 96 , and that being himself a senator he felt almost a guilty complicity in them. "Our hands," he says," dragged Helvidius to prison; we were steeped in Senecio's innocent blood." ${ }^{4}$ With the emperor Nerva's accession his life became bright and prosperous, and so it continued through the reign of Nerva's successor, Trajan, he himself, in the opening passage of his Agricola, describirg this as a "singularly blessed time" (bratissimum seculum); but the bideous reign of terror had stamped itself ineffaceably on his soul, and when he sat down to write his History he could see little but the darkest side of imperialism. To his friend the younger Pliny we are indebted for all we know (and this is but trifing) about his later life. He was adranced to the consulship in 97 , in succession to a highly distinguished man, Virginius Rufus, on whom he delivered in the senate a funeral eulogy. "The good fortune of Virginius," says Pliny, " "was crowned by having the most eloquent of panegyrists." In 99 he was associated with Pliny in the prosecution of a great political offender, Marius Priscus, under whon the provincials of Africa had suffered grievous wrongs. The prosecntion was successful, and we have Pliny's testimony ${ }^{6}$ that Tacitus spoke with his characteristic dignity. Both received a special vote of thanks from the senate for their conduct of the case. Of his remaining years we know nothing, and we may presume that lie devoted them exclusively to literary work. It would seem that ho lived to the close of Trajan's reign, as he seems ${ }^{7}$ to hint at that emperor's extensiou of the empire by his successful Eastern campaigns from 115 to 117. Whether he outlived Trajan is matter of conjecture. It is worth noticing that the emperor Tacitus in the 3 d century claimed descent from him, and directed that ten copies of his works should be made every year and deposited in the public libraries. He also had a tomb built to his memory, which was destroyed by order of Pope Pius V. in the latter part of the 16th century. Tacitus, as we gather from one of Pliny's letters, ${ }^{8}$

had a great reputation during his lifetime. On one occasion a Roman knight, who sat by his side in the circus at the celebration of some games, asked him, "Are you from Italy or from the provinces?" His answer was, "Yon know me from your reading." To which the knight replied, "Are you then Tacitus or Pliny?"

Pliny, as we see clearly from several passages in his letters, had the highost opinion of his friend's ability and worth. He consults him about a schonl which he thinks of cstablishing at Comum (Como), his birthplace, and asks him to look out for suitable teachers and professors. And he pays ${ }^{1}$ him the ligh compliment, "I know that your IFistories will be immortal, and this makes me the more anxious that my name should appear in them."
The following is a list of Tacitus's remaining works, arranged in their probable chronological order, which may be approximately inferred from internal evidence:-(1) tho Diclogue on Orutors, about 76 or 77 ; (2) the Life of Agricolu, 97 or 98 ; (3) the Germany, 98, published probably in 99 ; (4) the Mistories (IIistorix), completed probally by 115 or 116 , the last years of Trajan's reign (be must have been at work on them for many years) ; (5) the Annals, his latest work probably, written in part perhaps along with the Histories, and completed subsequently to Trajan's reign, which he may very well have outlived.

The Dialogie on Orators cliscusses, su the form of a conversation which Tacitus professes to have hard (as a young man) between some eminent men at the Roman har, the canses of the decay of eloquonce under the empice. There aro some interesting remarks in it on the clange for that worso that had taken place in the education of Roman lails.
Tho Life of Agricola, short as it is, has always been considered an almirahle specimen of Liography. The grent man with all his grace and ilignity is hronght vivilly before us, and the sketch we have of the history of our island nuter the Ronans gives a special interest to this little work.
The Gernan", the full title of which is "Coucerning the geograply, the hanners and customs, and the tribes of Germany," deserihes with many suggestive hints tho general character of tho German proples, ami dwells partieularly on their fierco and indepeudent spinit, which the author evidently felt to bo a stapting menace to the cmpire. The geography is its weak poiut; this was no iloubt gathered from vacuo licarsay.
The IIistorics, as originally composal in twelve books, brouglit the history of the cmpire from Gablua in 69 down to the close of Domitian's rien in 97. The first four books, and a suall frayment of the fifth, giving us a very minute accomet of the cyentful year of revolution, 69, aud the brief reigns of Galba, Otho, and Vitellius, are all that remain to us. ln the fragment of the fifth book we have a, curious and interesting account of the Jewish uation, of their character, ellstoms, aud religion, from a cultivatel Roman's point of vicw, which we seo at once was a strongly prejudiced one.
Tho Annals-a title for which there is no ancient authority, nnd which there is no reason for supposing Tacitus gave distinctively to the work-record the history of the cimperors of the Julian liue from Tiberius to Nero, comprising thus a period from 14 A.D. to 68. Of these, nine books hare come down to us eutire ; of book จ., xi., and svi. we have but fragments, aud the whole of the seign of Cains (Caligula), the first sir years of Clandins, and the last three years of Nero are wanting. Out of a periol of fifty-four ycars we thus have the history of forty years.
An attempt has becn mado recently to prove that the Annels are a forgery ly Poggio Braeciolini, an linalian scholar of the 15 th century, but their genuiueness is confirmed by their agreement ? in various minute details with coins and inscriptions discorered since that period. Another important fact has heen brought to light. Ruodolphas, a monk of a monastery at Fulda iu HesseCassel, writing in the 9th century, says that Cornelius Tacitus speaks of the river known to moderns as the Weser as the Visurgis. In the Annals as they have come down to us we find the Visurgis mentioned five times in the first two books, whence we may canclude that a manuscript of theur was in existence in the 9th centrry. Add to this the testimony of Jerome that Tacitus wrote in thirty books the lives of the Cæsars, and the evideare of style, and there cannot be nuch doubt that in the Annals wo have a geuvine work of Tacitus.

## ${ }^{1}$ Epp., vii. 33.

${ }^{2}$ Sco Introduction to vul. i. of Furneaux's elition of the Amanls of Tucitus, Clarendon Presa Series, 1884

Much of the history of the periol described by him, cspecially of the carlier Cresary, must havo becu obscure and locked up with the cmperor's privite papers and memoranda. As we should expect, thero was a vast amonut of floating gossip, which an historian woukd have to sift and utilizo as best he might. Tacitus, as a man of good sucial losition, no doubt had access to tho beet information, aud must have talked matters over with the most elaiucut men of the day. There wore several witers and chrouiclers, whom he occasionally cites but not very often; thero were memoirs of distinguishod lutsous,-thase, for example of the younger Acrippina, of Thbasea, and ITelvidins. There were several collectious of letters, like those of the younger Pliny; a number, too, of funeral oratious; nud tho "acta senatus" and the "acta populi " or "acta cliurna," the lirst a record of procecdings in the scmate, the latter a kind of gazette or journal. Thus there were the materials for history in considerable abundance, and Tacitus Was certainly a man who knew how to turn then to good account. He las given us a striking, and ou the wholo doubtless a true, picture of the cmpire in the 1st contury. Ilo wrote, it may be admitted, with a political bias and a decided turn for satire, but he assurclly wrote with a high aim, and we may nccept his own account of it: "I regarul ${ }^{3}$ it as history's highest function to rescme merit from oblivion, and to hold up as a terror to lase words and actions the rejrobation of posterity." Amid great cvils he recognized the existenco of truly uoble virtues cven in his own derenerate age. Still for tho most part he writes as a mau who felt deeply that the world was altogether "out of joint"; the empiro was iu itself in his viow a huge hunder, aud answerable mote or less directly for all the discases of society, for all the demoralization und corruption of the great word of lome, thongh as to the provinces lie adnits that they wero better off in many ways under the curperors than they hal been in the last days of the repuhlic. lut his political sympathics wero certainly with the old aristocratic and scmatorinu rérime, with the Rome of the Scipics and the Fabii ; for hin the gregtness of his comntry lay in the past, and, thongll he felt hur to be still great, her glory was, ho thonght, decidedly on the wane. Ho was, in fact, a political ideatist, ont conld hardly help spuaking disparagingly of his own day. In his Germeney he dwells ou the contrast betwecu barbarian freedom aud sinnlicity ou the one hand and tho servility and degeneracy of liman life on the other. Yet he hat a strong oud sincero patriotism, which invarially made him minimizo a Roman defent and the umber of lioman slain. There scous to have been a strange tingc, too, of superstitiou abont him, and he could unt divest limself of some belief ${ }^{4}$ in astrology and revelations of the future through oucns and portents, though he held theso wero often misumderstood and misinterpreted by charlatans and innpostors. On the wholo ho appears to have inclined to the philosophical theory of "nccessitarianism," that every man's future is fixel from his birth; but we must not fasten ou him any farticular theory of the would or of the miverse. Sometimes he speaks as a believer in a clivine overuling I'rovidence, and we may say coufidently that with the Epicurean doctrine ho hat no sort of sympathy.
llis style, whatever julgment may be passel on it, is certainly that of a man of genius, and cannot fail to make a deep impression on the studions reader: Tacitean brevity has become proverbial, and with this aro closely allicd an occasional obscurity aud a rhetorical affectation which lis warmest almirers must almit. He has been compared to Calyle, and there are certainly resenublances between the two both in style and tone of thonght. Both affect singularity of expression; both incline to an unhopeful and cynical viev of the worll. Tacitus was probably never a popular anthor; to be understool and appreciated he must be read agaiu and again, or the poiut of some of his acntest remarks will be quite missal. He has been several times translated, but it has always beeu felt that he preseuts rery great, if not insuperable, difficulties to the translator.
Murphy's franslation (a paraphrase we ahouil cell It) is perhaps one of the best known; jt was publishicd early in the present century. On this was based the so-called Oaford translation, published by Bohn in a revised edilion. Tha latest translation is that by Messrs Church and Brodribb. There is on the whole a good French translation by Lollandre. The edllions of Tacitus are very nums. crous. Among more recent editions, the best and mat usefal are Orellits (1859); R1ter's (1864); Nipperdey's (1979); Furneaux's (Annals, 1.-vl.), vol. I., Clarendon Press, 1584.
(W. J. E.)

TACITUS, M. Claudius, Roman emperor from September 25, 275, to April 276, was a native of Interamna (Terni) in Umbria, and was born about the year 200. In the course of his long life he discharged the duties of various civil offices, including that of consul in 273 , with universal respect. Six months after the assassination of Aurelian he was chosen by the senate to succeed him, and the choice was cordially ratified by the army. During his brief reign he set on foot some domestic reforms, and
sought to revive the authority of the senate, but, after a victory over the Alani near the Palus Mrotis, he succumbed to the hardships and fatigues of his new duties at Tyana In Cappadocia. Tacitus, besides being a man of immense wealth (which he bequeathed to the state), had considerable literary culture, and was proud to claim descent from the bistorian, whose works he caused to be transcribed at the public expense and placed in the public libraries.

tadmor. See Palmyra.
TAFILELT, a large oasis in Morocco (see vol. xvi. p. 832). The principal place is Abuam.

TAGANROG, a seaport of southern Russia, on the northern shore of the Sea of Azoff, in the government of Ekaterinoslaff, and nearly 200 miles south-east of its chief town. It is built, principally of wood, on a low cape, and, with its extensive store-houses, exchange, and wholesalo shops, has the aspect of an important commercial city. It is well provided with educational institutions for children, and has a library and a theatre. The imperial palace, where Alexander I. died in 1825, and the Greek monastery (under the patriarch of Jerusalem) are worthy of notice. The advantageous situation of Taganrog was well known as early as the 13th century, when Pisan merchants founded there a colony, Portus Pisanus, which, however, was destined soon to disappear during the great migrations of the Mongols and Turks. An attempt to obtain possessiou of the promontory was made by Peter I., but it was not definitely annexed by the Russians until seventy years aftervards (IT69). Its commercial importance dates from the second half of the present century; in 1870 its population had riscn to 38,000 , and after it had been brought into railway connexion with Kharkoff and Voronezh, and thus with the fertile provinces of south and south-east Russia, the increase was still more rapid, the number reaching 63,025 in 1882;-Greeks, Jews, Armenians, and West-Europeans being important elements. Notwithstanding the disadvantages of its open roadstead, the foreign trade of Taganrog rapidly expanded, the annual value of the exports having recently reached $£ 2,500,000$. The chief article of export being corn, the trade of the city, depending on the crops in south Russia, is subject to great fuctuations. Linseed and other oil-bearing grains are also important articles of commerce, as well as tallow and butter. The imports, which consist chiefly of fruits (dried and fresh), wine, oil, and coffee, are much smaller than the exports; and of the 989 ships ( 499,500 tons) that entered the port in 1885 no fewer than 775 ( 446,500 tons) were in ballast. The coasting trade, chiefly with Rostoff, was represented in the same year by 1321 vessels ( 224,000 tons) entering and 1343 vessels clearing.
Tha roadstead of Taganrog is very shallow, and exposed to winds which cause great variations in the height of the water; it is, more. over, rapidly ailting up. At the quay the depth of water is only 8 So 9 fect, and large ships have to lie 5 to 13 miles from the town.
Taganrog, with the surrounding territory of 137,000 acres, having a population of nearly 30 , 000, living in a dozen villages, constitutes a a eparate township, and, though reckoned to the Rostoff district of Ekaterinoslaff, has a separate governor and administration.

TAGLIACOZZI, Gasparo (1546-1599), a surgeon of wide repute, was born at Bologna in 1546, and studied at that university under Cardan, taking his degree in philosophy and medicine at the age of twenty-four. He was appointed professor of surgery and afterwards of anatomy, and achieved notoriety at least, and the fame of 3 wonderworker - Ye died at Bologna on November 7, 1599.
His principal work is entitled De Curturum Chirurgia per Insitionem Libri Duo (Venice, 1597, fol.); it was reprinted in the following year under the title of Chirurgia Noua de Narium, Aurium, Labiorumque Defectu per Insitionem Cutis ex Humero, arte hactenus omnibus ignsta, sarciendo (F-arkfort, 1598, 8vo).

The latter title sufficiently indicates the art which he professed of repairing nosa, ears, and lips by a apeciea of ingrafting of akin from the arm, that member being kept in apposition with the part to be repaired until auch time as the semi-detached graft had formed ita new vascular connexions. His Latinized name of Taliacotius is well known to the readers of Butler (Hudibras, i. 1), whose ham. orous representation of the nature of the Taliacotian art is, however, in some important particulars inaccurate.

TAGLIONI, Marie (1809-1884), a ballet dancer, was the daughter of Filippo Taglioni, an Italian master of the ballet, and was born at Stockholm 23d April 1809. She was trained by her father, who in his discipline is said to have been pitilessly severe. It was to his care and her own special talent for dancing that she owed her success, for she possessed no remarkable personal attractions. Her first appearance was at Vienna, loth June 1822, in a ballet of which her father was the author, La Récuption d'une jeune nymphe à la cour de Terpsichore. Her success was immediate, and was repeated in the chief towns of Germany. On 23d July 1827 she made her debut at the Opera House, Paris in the Ballet de Sicilien, and aroused a furore of enthusiaem. Her style was entirely new, and may be termed ideal as opposed to the realistic and voluptuous ballet previously in vogue. Among her more remarkable performances were the dancing of the Tyrolienne in Guillaume Tell and of the pas de fascination in Meyerbeer's Robert le Diable. At this period the ballet was a much more important feature in opera than it is now, and in fact with her retirement in 1845 the era of grand ballets may be said to have closed. In 1832 she married Comte Gilbert de Voisins, by whom she had two children. Losing her savings in speculation, she afterwards supported herself in London as a beacher of deportment, especially in connexion with the ceremony of presentation at court. During the last two years of her lifo she stayed with her son at Marseilles, where she died in April 1884. Taglioni is frequently mentioned in the novels of Balzac; and Thackeray, in The Newcomes, says that the young men of that epoch "will never see anvthing so gracefulas Taglioni in La Sylphide."

TAGUS (Span. Tajo, Portug. Tejo), the longest riser of the Iberian Peninsula. Its length is 566 miles, of which 192 are on or within the frontier of Portugal, and the area of its basin, according to Strelbitsky, is 31,864 square miles. The basin is comparatively narrow, and the Tagus, like the other rivers of the Iberian tableland, generally flows in a rather confined valley, often at the bottom of a rocky g.rge at a considerable depth below the general level of the adjacent country. The source of the river is at the beight of 5225 feet above sea-level, on the western slope of the Muela de San Juan, in the south-west of the province of Teruel. Thence it flows at first northwestwards, but, after receiving the Rio Gallo on the right, it flows west, and then south-west or west-south-west, which is its general direction for the rest of its course. The rocky gorges which occur in its course (the principal being where the river is overhung on the right bank by the ancient city of Toledo, and again at the Puente del Arzobispo, near the frontier of Estremadura) all belong to the Spanish section of the river, and in this section the stream is frequently encumbered by sandy shallows or broken by rocky rapids, and is not navigable except for short distances. The Portuguese section has a quieter current, and Villavelha, the highest point to which boats cali ascend, lies within the Portuguese froatier. Regular river-navigation begins only at Abrantes, a few miles below which the Tagus is greatly widened by receiving on its right bank the impetuous Zezere from the Serra da Estrelha. Passing Santarem, the highest point to which the tide ascends, and the limit of navigation for large sailing vessels and steamers. the river divides below Salvaterra into two
arms, called the Tejo Noro (the only ono practicable for ships) and the Mar de l'edro, and these arnis enclose a deltaic formation, a low tract of marshy alluvium known as the Lezirias, traversed by several uatural canals or minor branches of the river. Both these arms enter the upper end of the fine Bay of Lisbou ( $11 \frac{1}{2}$ miles long by about 7 broad), and the Tagus leaves this bay in the form of a channel $4 \frac{1}{2}$ miles long by 2 wide (see vol. xiv. p. 692), communizating with the outan, but having uufortunately a bar at its mouth. On the north side of this channel stands the city of Lisbon. Only slight traces are still to be found of the gold for which the sands of the Tagus were anciently celcbrated.
The narrower part of the Tagus basin lying to the south, the tributaries on the left bank are alnost all mere brooks, most of which dry up in summer. The principal exception is the Rio Zatas or Sorraya, which, rising in the Serra d'Ossa, flows westwards across the plateau of Alerutejo, and joins the Mar de Pedro. The principal tributarics on the right bank, besides the Zezere, are the Jarama, descendiug from the tableland of New Castile a little below Aranjuez, the Alberche and the Tietar, which eollect their head waters from opposite sides of the Sierra lo Gredos, and the Alagon, from the rough and broken sountry between the Sierras de Gredos and Gata.
THHITI ARCIITPELAGO. The eastern Polynesian asland-group generally knoiva as the Society Islands (Isles de lab Suciété, or Tcuili) lies betweon $16^{\circ}$ and $18^{\circ} \mathrm{S}$. lat. and $148^{\circ}$ and $155^{\circ} \mathrm{W}$. long, and stretches for nearly 200 miles in a worth-west and south-east direction; the total area does not exceed 650 square milos, of which 600 fall to Tahitialone. To the east and north-east a channel of only 140 miles in breadth, but over 2000 fathoms in depth, eparates this group froin the great chain of the Low Islands, beyond which the ocean extends unbroken to America. To the west as far as Fiji-the main islands of which group lio between the same degrecs of latitude as those of Tahitithere are 1500 miles of open water. About 300 miles southwest lies C'ook's Archipelago, and at the same distance south are the Austral Islands. To the north, excepting a few coral banks, there is open sea to Hawaii, a distance of 2600 miles.

Tahiti occupies a central position in the Tacific. Sydney lies about 3400 miles to the west and Sau Francisco about as far to the north-north-east. Honolulu, Nounea, and Auckland are each somewhere about 2400 miles away; Panama is at a distance of 4600 miles.

The archipelago consists of eleven islands, which are divided into two clusters-the Leerand and the Windward Islands-by a clear channel of 60 miles in breadth. The Leeward Islands, to which alone the name of Society Islands mas given by Cook, are Tubai or MIotu-iti, a small uninhabited lagoon island, the most northern of the whole archipelago ; Maupiti or Mau-rua-" Doublo Mountain," the most western; Bora-bora (Bola-Bola of the older navigators), or Fáarui ; Tabas; Raiatea or Ulietea (Boenshea's Princessa), the largest island of this cluster, and Hnabine, which approacb each other very closely, and are eacircled by one reef. To the Windward Islands, the Georgian Islands of the carly missionaries, belong Maiaiti or Tapamanu (Wallis's Sir Charles Saunders Island and Boenshea's Pelada) : Mlorea or Eimeo (Wallis's Duke of York Island and Bosnshea's San Domingo); Tahiti-Cook's Otaheiti (probably Quiros's Sagittaria; Wallis's King George's Island, Bougainville's Nouvelle Cythère, and Boenshea's Isla d'Amat), tho most southern and by far the largest of all tue islands; Tetuara or Tetiaroa-"The Distant Sea" (?Quiros's Fugitiva; Bougainville's Umaitia and Boenshea's Tres Hernanos); and Matia or Naitea (ßQuiros's La Dezaua, Wallis's Osnaburg Island, Bougain-
villo's Boudoir and Pic de la Bnudense, and Boenshea's San Cristoval), which is by a degree the most eastern of the archipelago. Bellinghausen, Scilly, and lord llowe (Mopia) are three insignificant clusters of coral islets to the northwest and west, and, like Tubai and Tetuara, are atolls. The leugth of the 'Cetuara recf ring is about six miles; it bears ten palm-covered islets, of which scveral are in habited, and has one narrow boat-passage leading into the lagoon. With the exception just named, the islands, which agree very closely in geological structure, aro mountainous, and present perhaps the most wonderful example of volcanic rocks to be found on the globe. They are formed of trachyte, dolerite, and basalt. There are raised coral beds high up the mountains, and lava occurs in a variety of forms, even in solid flows; but all active voleanic agency las so long ceased that the craters have been almost ontirely obliterated by denudation. Hot springs are unknown, and earthquakes are slight and rare. Nevertheless, under some of these ficers remains of plants and insects of species now living in the islands lave been found,-a proof that the fornation as well as the denudotion of the country is, geologically speaking, recent. Is profite the islands are rugged. A high mountain, usually with very steep peaks, forms the centre, if not the whale island; on all sides steep ridges descend to the sea, or, as is oftener the case, to a considerable belt of flat land. These mountains, excepting some stony crags and cliffs, are clothed with dense forest, the soil being exceptionally fertile. All voyagers agree that for varicd beauty of form and colour the Socicty Islands are unsurpasscd in the Pacific. Innumerable rills, fed by the fleeting cloudy which circle round the high lands, gather in lovely streans, and, after heavy rains, torrents precipitate themselves in grand cascades from the mountain cliffs-a feature so striking as to have attracted the attention of all voyagers, from TVallis downwards. Round most of the islands there is a luxuriant coral growth; but, as the reefs lie at no great distance, and follow the line of the coast, the interisland channels are safer than those of the neighbouring Tuamotus, which exhibit the atoll formation in perbaps its fullest derelopment, and in consequence lave been justly called the "Lou" or "Dangerous Archipelago." Maitea, which rises from the sea as an excecdingly abrupt cone, and Tapamanu appear to be the only islands which have not their fringing and more or less completely encircling barrier-reefs. ${ }^{1}$ The coasts are fairly indented, and, protected by these reefs, which often support a chain of green islets, afford many good harbours and safe anchorages. In this respect the Society Islands have the advantage of most of the Polynesian groups.

The island of Tahiti, in shape not unlike the figue 8, has a total length of 35 miles, a coast-line of 120 , and a super. ficial area of 600 square miles. It is divided into two distinct portions by a short isthmus (Isthmus de Taravao) less than a mile in width, and nowhere more than 50 feet above sea-level. The southern, the peninsula of Tairabu, or Tahiti-iti (Little Tahiti), alone as large as Raiatea (after Tahiti the most important island of the group), measures 12 miles in length by 6 miles in breadth; while the northern, the circular main island of Porionuu, or Tahiti-uni (Great Tahiti), has a length of 23 miles and a width of 20. The whole island is mountainous. A little to the north-west of the centre of Great Talitit the Society Islands attain their greatest altitude. There the doublepeaked Orohena rises to 7340 fcet, and Aorai, its rival, is only a few hundred feet lower. Little Taliti cannot boast of such mountains, but its tower-like peaks are very striking. The flat land of the Talitian coast, extending to a width of several miles-with jits chain of villages, its. ${ }^{1}$ Darwin, Structure of Coral Reefs, London, 1842
fertile gardens, and its belt of palms, sometimes intersected by stream-fed valleys which open on the sea-shore-forms a most pleasing foreground to the grand amphitheatre-like urountain ranges. A good road surrounds the entire island, which is divided into eighteen districts, each under a chief and a municipal council of which be is president. A railroad is in contemplation. By the last census the population of the entire island was 9194 , one-eighth being French and foreigners. The majority of the natives profess the Protestant religion. ${ }^{1}$

The extreme north of the island is formed by Point Venus, to the east of which lies the Bay of Matavai, and some miles still farther east Papeete, the European town and the seat of government. The besutiful harbour, of fair size and depth, is entered by two passages in the reef, Papcete to the north, 7 fathoms in depth, and Taunos to the east, the wider and noro couvenient, though Ghallower. The town, in 1881, had a population of 3224 , helf of whem were French or Frecch half-castes, but at least a dozen different nations were represented is the 800 whites. The little citr is decidedly French in character. "Papeeto is the emporium of trade for the products of the South Sea islands east of $160^{\circ} \mathrm{E}$. long. Small schooners of from 20 to 50 tons burden bring the produce of the rarions groups to Trahiti, whence they are shipped direct for Europe, either by Cape Horn or the Cape of Good Hope, according to the season of the year. These schoozers, of which about twenty fly the Tahitian flag, take back portions of the cargoes of vessels arriving from Europe for sale or barter amongst the islands. The chief exports are cocoa-puts, mother-of-peail, cotton, and some sugar, mainly to Eagland and Germany, rery little to Frasce; and, oranges, trepang (for China), and edible fungus to California." Many whalers formerly visited Papecte harbour, but for some years there has been a steady diminution in their number. In 1845 forty-eight called there, in 1860 five, and none in 1874. Commerce has also in other respects decreased. Three sugar-mill9 with distilleries attached, two cotton manufactories, and a manufactory of cocoa-nnt fibre were at work in
1886 . Oranges and vanilla are profitably 1886. Oranges and vanilla are profitably grown. The timber of the country is hardly nsed, great quantities of Californian pine
being imported.
Oxen and hogs are reared The being imported. Oxen and hogs are reared. The artificial culture of the pearl oyster is beginning to be discussed, but the pearls of the Society lisladd are not to be compared in number or quality to those of the Tuamotus. A good deal of trading in fruit, fibre, ehell, \&c., is carried on with the natives, but still mainly by barter. The corapetition of the Chidese immigrants, of whom in 1886 there were already 400 on Tahiti and Eimeo, is beginning to be keenly felt. The importation of "labour," chiefly for the plantations, from other Polynesian islands was placed under Government control in 1862. The Tahitians themselves prefer handicrafts to agricultural work, and many are employed as artisans ly European masters, Who find them as handy and industrious as their own constrymen, bnt fo: domestic service they show no aptitude. Papeete is in direct sailing communication with San Francisco, and with Sydney by a Governinent ateamer which calls every five months; also with France by Bordeaux steamers which touch on their way te Noumea. ${ }^{3}$
Climate-The seasons are not well defined. Damp is excessive; there is little variation in the weather, which, though hot, is nevertheless not depressing, and the climate for the tropics must be consilared remarkably healthy. The rainfall is largest between Deccrmber and April, b:t there is so much at other times of the jear also that these months hardly deeerve the name of the rainy ecason. Doring this period north-west winds are frequent, continuing at times for weeks, and there are thunderstorms and luurricanes, though they ara not nearly so destructive as in some of the neighbouring islands. During the eight drier and cooler nont ths south east winds (correspondiug with the trades) prevail, but there are southerly winds which bring rain, and even westerly breeres are not unfrequent. The mean temperature for the year is $77^{\circ} \mathrm{F}$; maximum $84^{\circ}$, minimum $69^{\circ}$. The average rainfall froin December to March' ( 4 months) is 29 inches; from April to November ( 8 months), 19 inches. The above observations apply
to the coast ouly to the coast ouly.
Fauna.-Neither the zoology nor the botery of the archipelago has been thoroughly investigated. Mammalians, as in other Polynesian iolands, are restricted to a ferv species of bats (mostly of the genus Pleropus), rats, and mice, none of them peculiar. of domestic animals, the pig and the dog-the former a small breed which quickly disappeared before the stronger European strainswere plontiful even in Wallis's days. The ornithology is very poor as compared with that of the Western Pacific; and, in marked

1 The best chart of Tahitl is that published by the French Government in 1876, and corrected down to 18s1. Morea is fiven on the same sheet.

2 Wallace, Australasia, London, 1884.

- For fuller atatlstlcs, see Notices Coloniales, Puls, 1896, rol. II.
contrast to the isolatcd Hawaiian archipelago, the Society Islands possess no reculiar genera and but few peculiar species. They clain, howcver, a thrnsh, several small parrots of great beauty, doves, pizeons, rails, and a sandpiper. Of this sandpiper, Tringa lencoptera, which, with many of the birds here mentioned, was discovered as far back as Cook's stay in the islands, only one specimen (now in the Leyden museum) is known to exist; and of the rest; their range being often limited to one portion of a small island, several species are (fl.rough the increase in the number of cats, \&c.) threatened with extermination. A jungle-fowl (rar. of Callus bankiva) is found in the mountains, but as donnesticated fowls were abundant, even wher Tahiti was frat discovered by Europeans, these rild birds are doubtless the offspring of tame hirds, probably -imported with the rigs and dogs by Malay vessels. There are no peculiar reptiles, and batrachians are entirely mauting. The lagoons 6 marm with fish of many species. Insects are poor in species, though some of them are indigenous. Crnstaceans and molluscs, on the other hand, aro well represented ; worms, echinoderms, and corals comparatively poorly. A Doteworthy feature of Tahitian conchology is the number of peculiar species belonging to the genus Partula, almost every valley being the habitat of a dis. tinct form. ${ }^{1}$

Flora. - This, theugh luxuriant, is not very rich. Like the zoology, it is much poorer than that of the more westers groups of the Pacific. Mew osideros, Melastoma, and Acacia are the only links which this typically Polynesian region has retained to join it to Australia. Four gesera are peculiar, of which three are claimed by the Composite and Lobeliacer, orders characteristic of Hawaii. It is rich in trees, shrubs, and hardwood plants, poor in the smaller undergrowth. Orchids, including some beautiful specics, and ferns are abundant; but, bere as in Polynesia generally, Rubiaces is the order best represented. Remarkable are the banana thickets, which, chiefly on Tahiti, grow at an altitude of from 3000 to 5000 feet Along the shore-in oome places almost to the extinction of all Dative growth-many exatics have established themselves; and a great variety of fruit-bearing and other useful trees have been successfully introduced in to most of the islands. ${ }^{5}$
Inhabitants. -The Tahitians are a typical Polynesian race, closely connected physically with the Marquesaus and Rarotongans, but widely divided from them is many of their customs. The dialects, also, of the three groups sre different, the Tahitian being perhaps the softest in all Oceania. The women rank with the most beantiful of the Pacific, though the accounts given of them by early voyagers are much exaggerated; aod for general symmetry of form the people are unsurpassed by any race in the world. Even now in its decadence, after generations of drankenness and European disease and vice, grafted on inborn indolence and licentiousness, many tall and robust peoplo ( 6 feet and eren upwards in height) are to be found. The women, as a rule, are small in prc弓ortion to the men. Men and women of good birth can geserally be distinguished by their height and fairness, and of ten, even in carly age, by their enormons corpuleace. The skin varies from a very light olive to a full dark brown. The wawy or curly bair and the expressive eyes are black, or nearly so; the month is large, but well-shaped and set with beautiful teeth; the nose broad (formerly fattened in infancy by artificial means); and the chis well developed. Solong as the rative costume Was retained, the liputa, an oblong piece of bark cloth with a holo in its centre for the head, and the paru, a plain piece of cloth round the loins, were worn alike by men and women of the higher classes. Med of all ranks wore, with or without these, the maro, or $T$ bandage. The women concealed their breasts except in the company of their superiors, when etiquette demaz:ded that inferiors of both sexes should uncover the upper part of the body. The chiefs wore short feather cloaks, zot unlike those of the Hawaiians, and beantiful semicircular breastplates, dexterously interwoven with the black plumage of the frigate bird, with crimson feathers, and with sharks' tecth ; also most elaborate special dresses ss a sign of mournitg. The priests had strange cylindrical hats, made of wicker-work and over a yard in height. Circnmeision, and in both sexes tattooing, were generally practised, and much significance was attached to some of the marks. The houses (vare) were long, low, and oper at ths sides. Honsehold ntensils were fow-plain round wooden dishes, sometimes on legs, cocoa-nut shells, baskets, \&c. Low stools and head-rests were used." Pottery being unkoown, an food was baked in the "pative over" or roasted over the fre. Their chief musical instruments were the nose-flute (viro) -often used as the accompani, ment of song-and the drum (pahu). Of the latter, those kept in the marai were huge elaborately carved hollow cylinders of wood, the upper esd of which was covered with sharks' skin. Cosch. shells (bu) were also used. Tahitian stone adzes, thich are greatly inferior in finish to those of the Hervey Islands, are, like the adzes of eastern Polynesia in gemeral, distinguished from those of western Polynesia by their triangular section and adaptation to a socket.,

[^10]Slings were-perhaps the farourite weapons of the Tahitians; they had also plain spears expanding into a swite blade, and clubs. The bor and arrow seem only to have been used in certain ceremonial games (lecs). Their canoes (vara), from 20 to 70 feet in length, were double or single, and provided with sail and outriggers. They were not well finished, but the high curved sterns. rising sometimes to a height of 20 feet, of those destined to carry the images of their gods, were carved with stranga figures and hung with feathers. ${ }^{\text {? }}$ Connibalism is nnkuown in the Society Islands, though somo ceremonies which were performed in connexion with hnman sacrifices masy possibly be survivals of this practice. The staple food of the islanders consisted of the bread-fruit, the taro-root, the yam, the sweat potato, and in some districts the wild plantain (fei); but they also ate inuch fish (the turtlo was considercd sacred food), as well ss pigs and dogs, though of the latter, as pets, the women were 6o fond as to suckle the puppies sometimes even to the exclusion of their own childron. Popoi was a favonrite dish made of bananas and cocos-nut. Kava (ava), which was prepared in the usual Polynesian manner, was drunk, but in moderate quantities and ouly by the chiefs.

Tahitians were good fisherinen and bold seamen. They steered by the stars, of which they distinguished many constellations. The land was carefully tended and tha fields well irrigated. Three great classes were recognized:-(1) the huiari, of divine origin, which included only the suzerain (arirai), who bore a semi-sacred as woll as a political character, and the reigning chiefs of districts; (2) the bue-raatira, proprietors and cultivators of inherited land, who also built canues, made arms, \&ic.; to these two classes elso belonged the priests (tahora), who were medicine-men as well; (3) the manahrone, fishers, artisans, \&c., and slaves (titi). As wars and infanticide depopulated the island this class gradually acquired land and with it certain privileges. Rank is hereditary and determined by primogeniture, not necessarily in the male line. The firstborn of an arirai received at birth the title of otu; the father, who was the first to pay homage to his own child, then abdicated, and henceforth took up the position of regent. It is easy to sce that, while this custon tended to kecp honours within a family, it may have encoursged the practice of infinticide, which was common in all grades of society when Tahiti was first visited by Enropeans. The age at which the otu's authority became real varied according to lis own abilities and the will of his subjects. Though arbitrary, the power of the arirai was limited by the power of his vassals, the district chiefs (raatiras), who ruled absolutely over their respective districts, and who misht be of as good blood as the arirai himself. The arirsi had a councillor, but was alone responsible for any act. The bi-insular form of Tahiti promoted the independence of the chiefs, and war was rarely declared or an army or fleet despatclied without the raatiras being first sumnoned to council. Withont their favour nothing could be accomplished, for their power over their own people was absolute. The form of goverument was thus strictly feudal in character, but it gradually centralized ioto a monarchy, which, in the person of Pomare 11., the English missionaries greatly helped to regulate and streugthen. The arirai seut his commands by a messenger (vea) whose credentials were a tuft of cocoa-nnt film. This tuft was returned intact as a sign of assent or torn in token of refusal. After the chief the wife ranked first, and then his brother. The arirai was carried on the shoulders of his subjects, and chicfs were not sllowed to feed themselves. Women always ate apart. Their places of worship (marai)-national, local, or private-were square tree-surrounded enclosures. They each had a single entrance, and contained several small courts, within which were honses for the images and atteudant priests. A pyramidal stone structure, on which were the actual altars, stood at the furtlier end of the square. The marais were also used as places of sepulture of chieis, whose embalmed bodies, after being exposed for a time, were buried in a crouching position. Their skulls, however, were kept in the houses of their nearest relations. In tha great marai at Atahura the stone structure was 270 feet long, 94 feet wide, and 50 fcot high, and its summit was reached by a llight of steps, built of hewn coral and basalt. Sacrificial offerings, including human sacrifices, formed a prominent part of Tahitian worship. An eye of the victim was offered to the arirai, and placed within his mouth by the offciating priest. Every houseliold possessed its own guardian spirits ( tii ), but there were several superior divinities, of which, at the berianing of this century, Oro was the most venerated. The images, which are less remarkoble than those of Hawaii, were rough representations of the human form carved in wood. Some were covered from head to foot with small human figures cut in relief; others were mere sticks clothed with feathers. The areoi, a licentious association of strolling players, men and women, which numbered among its ranks the highest chiefs, and practised infanticide, was a special feature of Tahitian society.
The Tahitians are light-hcarted, frivolous, courtcous, and gencr-
1 The masean of the London Missionary Somety and the British Museum contain important colleztions of Tahitian images, dresses, weapons, \&c.
ous; but with these traits are blended deceit, irritability, and crivelty, which formerly reached an unexamuled degree of savage brutality. Their notions of morality were never, according to our ideae, very precise; and their customs, such as the tayo, or exchange of name with the rights which it carricd over the wifo of the giver of the name and all her female relations, seemed to the earlier European observer strangely revolting. It would appear, however, that with the introduction of the vices of civilization such limita. tions as their primitive morality recognized have disappeared and all self-respect has been lost. Especially characteristic were the elaborate costumedances (heivas) performed by women. Besides dancing, the singing of songs (pehe), and the recitation of historical and mythical ballads (ubus), the natives had also a variety of sports and games. During the periodical seasons of rejoicing wrestling (naona), boxing (noto), and spear-throwing (vero patia) matches, with foot and canoe-races, were held; also sham fights and naval reviews. They had several games in which a ball was used, -one, apai, not unlike our bandy, while another, twiraa (played chiefly by women), was a kind of football; but surf-swimming (faahee) was perlaps the most favourite sport with hoth sexes. Kites were known. Cock-fighting (factitoraamoa) was much practised.

Discorery and Exploration.-There is little doubt that the main island and some other members of the group were visited by the Spaniard Pedro Feruandez de Quiros in Fehrnary 1607. They were rediscovered in June 1767 by Wallis in the "Dolphin," who took nnminal possession of Taliti for George I11. and named it after him. In the following year Bongainville visited Tahiti, claimed it as French, and called it La Nouvelle Cythérc. With Tetuara (called by him Umaitia) and Eimeo it makes up the Archipel de Bourbon of his most inaccurate chart. Almost all we know of the early state of the islands is, however, due to Captain Cook's visits in 1769, 1773, 1774, and 1777. The name of Society Islands was given to the Leeward group on lis first poyage in honour of the Royal Society. In 1774 T'ahiti was also visited by two Spanish vessels, which left two priests, who remained for ten months on the island Tha Spaniards named it Isla d'Amat. The islauds were again nneited in 1788 by the "Lady Penrhyn." Bligh in the "Bounty" spent five months on the island in the same year, and it was revisited by that ship after the famous motiny. At this time the leading chief was Pomare, whose family had been pre-ominent in the isiand for more than a century. Aided by sixteen of the "Bounty "mntineers, and armed with guns procured from Bligh and a Swedish vessel, Pomare greatly strengthened his power and brought to a successful close a long struggle with Einueo. In 1791 the "Pandora" carried off fourteen of the "Bounty" mutineers, and from this time forward visits were frequent.

Missions.-7he attempt of the Spauiards in 1774 was followed by the settlement of twenty-five persous bronght in 1797 by the missionary ship "Duff." Though befriended by Pomare I. (who lived till 1805), they had many difficulties, especially from the constant wars, and at length they fled with Poware II. to Eimeo and ultimately to Now South Wales, returning in 1812 when Pomare renounced heathenism. In 1815 he regained his power in Tahiti. For a time the missionaries made good progress, -a pribting press was established (1817), and coffee, cotton, and sugar were planted (1819); but soon there came a serious relapse into heathen practices and imnorality. Pomare II. died of drink in 1824. His successor Pomare III. died in 1827, and was succeeded by his half-sister Aimata, the unfortunste "Queen Pomare." In 1828 a new fanatical sect, the "Mamaia," arose, which gave much trouble to the missions and whose influence is still felt. The leader proclaimed that he was Jesus Christ, and promised to his followers a sensual paradise.

French Annexation.-In 1836 the French Catholic missionaries in slangareva attempted to open a miesion is Tahiti. Queer Pomare, advised by the English missionary and consul Pritchardrefused lier consent, and removed by force two priests who had landed surreptitiously and to whom manyy of the opposition party in the state had rallied. In 1838 a French frigate appeared, under the command of M. Du Petit-Thouars, and extorted from Pomare the right of settlement for Frenchmen of every profession. Other acts of interference followed, and at length, in 1842, Admiral du Petit-Thonars procured the signature of a document placing the islands under French protection, the authority of the queen and chiefs being expressly reserved. In 1843 Petit-Thouara reappeared, and, alleging that the treaty of 1842 had not been duly carried out, deposed the queen and took possession of the islands. His ligh. handed action was not countenanced by the French Government, but, while it professed not to aanction the annexation, it did not retrace the steps taken. Two years were spent in reducing the party in the islands opposed to French rule; an attempt to conquer the western islands failed; and at length, by agreement with England, France promised to return to the plan of a protectorate and leave the western islands to their rightful owners. The London missionaries were replaced by French Protestants, but neither they nor the priests have been very successful, possibly bocause Franch is a compulsory subject in the Government achools. In 188:

Tahiti, includiug Eimeo, was proclaimed a French colony. It is the residence of the governor-general of the Freuch dependencies iff the Pacific.
Esterature. -The following list Includes the zooks which seem most to descive meation: Hawkesworth's Foyages, especially Walis"s Voyage, H.MI.S. TAJAK, TAJIK, or TAUSIK, a term originally occurring in the Pahlavi writings, and explained to mean, first, the Arabs in general, then their descendants born in Persia and elsewhere out of Arabia, and, lastly, the Persians in general and their descendants born in Turkestân and elsewhere out of Persia. Tajak has thus come to be the collective name of all communities of Iranian stock and Persian speech, wherever found in Central Asia. These are co-extensive with the former eastward and northward limits of the Persian eapipire ; but, since the ascendency of the Turki races, they have become the subject element in Turkestan, Afghánistán, Bokhára, Khiva, Kashgaria, while still politically dominant in Badakhshán, Wakhân, Darwáz, Kost, and Karatéghin. In most of these places the Tajaks, with the kindred Galchas, seem to form the bulk of the population, the distinction being that Tajak is apphed rather to the settled and more civilized luwlanders of modern Persian speech, Galcha to the ruder highlanders of Ferghána, Kohistán, Wakhán, dec., who speak cither archaic forms of Persian or dialects intermediate between the Iranian and Sanskritic (Indian) branches of the Aryan linguistic family. The Tajaks are thus a settled Iranian people, agriculturists in the conatry, traders and artisans in the towns, and are essentially "Parsivan," that is, men of Persian speech, -this term, however, being more specially applied to those of Afghánistán. But, although mainly of Iranian stock, with light complexion and regular features, the Tajaks claim Arab descent, regarding the district about Baghdad as their primeval home, and cousidering themselves the descendants of the Arabs who overran Central Asia in the first century of the Flight. At the same time, "it is evident that the ic. sabitants of the greater part of this region (Central Asia) must from an early period have come in contact with the successive waves of Turkish (Tarki) and even Mongol population which b:oke over them; accordingly we find that, ilthough the type is essentially Iranian, it has undergone a certain modification, . . . face, though obriously ?ersimn, is more oblong than that of the Turk, more or less leavy cheeks, thick nose, large mouth, wide forehead, middle height, powerful frame, and broad shoulders, . . . dark hair, but among the Galchas a few fair people are found " (Capt. J. M. Trotter, Bokhara, p. 169). The term Tajak must also be distinguished from Sarte, the latter simply meaning "trader" or "shopkeeper," and being applied indiscriminately to the settled as opposed to the nomad element, and especially to the urban populations, of whatever race, in Central Asia. ${ }^{1}$ The Tajaks are known as Tats on the west side of the Caspian (Baku, Lenkoran, \&c.).

talavera de la Reina, a town of Spain, in the

[^11]province of Toledo, is situatad on the right bank of the Tagus, and on the railway from Madrid to Caceres, some 40 miles below Toledo and 64 miles south-east from Madrid. It was formerly surrounded by a triple circumvallation, portions of which still remain. It bas no buildings of special interest, and its commerce and manufactures are inconsiderable. The population within the municipal limits in 1877 was $10,029$.

Talavera is the birthplace (1536) of Mariana the hisiorian. Wellington overcame a superior French force here on July 27-28, 1809.

TALBOT, FAMILY oF. Apart from its achievements, this is one of the few families in the English aristocracy which traces alike its descent and its surname from the Norman conquerors of England; and it may really be said that there has hardly been a time during the last eight hundred years in which the Talbots have not been of considerable account in public life. Yet in some periods they appear rather as a potential influence, while at certain marked epochs they stand out among the most prominent actors in English history. The name of Richard Talbot occurs in Domesday Book as the holder of nine hides of land in Bedfordshire under Walter Giffard, earl of Buckingham. There is no evidence that he came over to England with the Conqueror hinself ; and, as he did not hold of the king in capite, it is clear that he was not a leader. His son Geoffrey Talbot took part with the empress Maud against King Stephen. But apparently it mas another son Hugh who continued the line; of whom it is recorded that he held the castle of Plessi against Henry I. for Hugh de Gournay, and afterwards became a monk at Beaubec in Normandy. His son Richard obtained from Henry II. the lordship of Linton in Herefordshire, and from Richard I. the custody of Ludlow castle; and his descendants for some generations appear to have been wardens of various castles on the borders of Wales. Under Edward II. a Gilbert Talbot was head of the house, and invaded Scot. land in the king's company, but afterwards took part with Thomas of Lancaster against the king. He, however, was pardoned, and obtained from Edward III. a confirmation of the grant of the manor of Liston and other lands to himself and his heirs.

His son Richard, who had married a daughter of John Comyn of Badenoch, laid claim to certain lands in Scotland in her right, and, when restrained from entering that country by land (Edward IIL. having then made an alliance with King David), he joined in a successful expedition which invaded it by sea in the interests of Edward Baliol. Three years later he was taken prisoner in Scotland, and redeented for 2000 marks, after which the king made him governor of Berwick. He took part also in Edward's wars against France, as did likewise his son Gilbert, who succeeded him, At this time the family possessed lands in the counties of Oxford, Gloucester, Hereford, and Keut, and a little later in Berkshire, Wilts, Salop, and Essex. Another Gilbert Talbot, grandson of the last, claimed to carry the great spurs at the coronation of Henry V., and had a commissiou to receive the submission of Owen Glendower and his adherents. He also distinguished bimself in the invasion of Normandy. He was twice married, his second wife being a Portugueso lady, but he left no male issue, and was succeeded by his brother John, the special hero of the family.

Hitherto the head of the house had borne the aame of Lord Talbot; but this John, after obtaining by marriage the title of Lord Furnivall, was for his distinguished actions created earl of Shrewsbury. He made his name so terrible in France that for several generations afterwards French mothers used to threaten refractory childres that the Talbots would come if they were not quiet (Brown's Venetian Calendar, ii. 75). He rescued Maine from the

## TALBOT

French and took Pontoise ; but his own capture by the Maid of Orleans was what probably discouraged the English most of all in their disasters beyond sea. He was exchanged for an eminent French prisoner and a heary ransom, besides. He served also several times as lieutenant of Ireland, and in 1446 was created earl of Wexford and of Waterford, in addition to the title of Shrewsbury, which hạd been conferred upon him in 1442. He died in 1453, in, an unsuccessful expedition for the recovery of Guienne, which had lately submitted to the French. His son John, Viscount Lisle, was slain along with him in the same fatal battle.

But, besides his martial exploits which live in history, this John claims some attention for his family alliances. His first wife Maud, a granddaughter of Thomas, Lbrd Furnivall, brought him the castle of Sheffield as part of her inheritance, and he was accordingly summoned to parliament in the days of Henry IV. as John Talbot of Hallanshire, otherwise Lord Furnivall, more than thirty years before he was made earl of Shremsbury. The property remained in the hands of his descendants, and became a favourite residence of the family during the whole of the Tudor era; and, but for the death in 1616 of Gilbert, seventh earl of Shrewsbury, without male issue, it has been remarked by Hunter that Sheffield might have remained much longer a centre of feudal magnificence rather than of conmerce and manufactures. The second wife of John, earl of Shrewsbnry, was Margaret, the eldest of three daughters of Richard Beanchamp, earl of Warwick, by his second wife, a daughter of Thomas, Lord Berkeley. By her he obtained a third part of the Berkeley property; and, though she did not become the mother of a line of earls, her eldest son, Joln Talbot, was created Viscount Lisle, and it was he who fell along with his father at the disastrous battle of Chatillon in Gascony. His son Thomas, who inherited the title of Viscount Lisle, was also slain at the early age of twenty-two io a feudal contest with Lord Berkeley, arising out of a dispute as to the possession of Berkeley castle, at Nibley Green, near Wotton-under-Edge, March 20, 1470; and the title was afterwards conferred on Edward Grey, the husband of one of his.two sisters.

John, the second earl of Shrewsbury, was the first earl's son by his first wife. He had beeu knighted at Leicester in 1426 along with the infant king Henry VI., had served in the wars of France, and been made chancellor of Ireland during his father's lifetime, when he was only Lord Talbot. Afterwards he was made lord high treasurer of England, and in 1459 was rewarded for his services to the house of Lancaster with a grant of 100 marks a year out of the lordship of Wakefield, forfeited by Richard, duke of York. But next year he and his brother Christopher were slain at the battle of Northampton, fighting in the caus of Henry VI. His son John succeeded him, and then his grandson George, who fought for Henry VII. at Stoke, and whom King Henry VIII. sent as his lieutenant against the rebels in that most formidable insurrection, the Pilgrimage of Grace. But perbaps the thing which most redounds to his credit is the humanity with which (as related by Carendish) he received the fallen Cardinal Wolsey into his house at Sheffield when he was on his way up to London as a state prisoner, and endeavoured to remove those gloomy anticipatious of his fate which in fact brought on his last illness.

Francis, the fifth earl, took a leading part in the invasions of Scotland under Henry VIII. and Edward VI., and was one of the tro peers who alone opposed the bill for abolshing the pope's jurisdiction under Elizabeth. His son George, who succeeded, was the earl to whom the custody of Nary Stuart was committed, his delicate and
onerous task being rendered all the more difficult for him by the intrigues of his bold, ambitious second wife, Bess of Hardwick, the builder of Chatsworth, who had married three husbands before her union with him. Two sons of this last earl succeeded one another, and the title then devolved, for want of male issue, on the lineal descendants of Sir Gilbert Talbot of Grafton ir Worcestershire, third son of John, the second earl. This Sir Gilbert had fought for Henry VII. at Bosworth, where he was severely wounded, was knighted on the-field, and was throughont one of the first Tudor's most trusted councillors. He fought also at Stoke against the insurgents with Lambert Simnel, was made a knight banneret, governor of Calais, and lord chamberlain.

The ninth earl, George, dèscended from this Gilbert, is not distinguished by any prominent actions. He died unmarried, and his brother, who followed next, was succeeded by his grandson Francis, chiefly memorablo for his unhappy fate. His second wife, a daughter of the carl of Cardigan, was seduced by the duke of Buckingham, whom the outraged husband challenged to a duel. The countess, it is said, was present at the scene, and held Buckingham's horse in the disguise of a page, saw her husband killed, and then clasped her lover in her arms, recciving blood-stains upon her dress from the embrace. Charles, the twelfth earl, son of this unfortunate nobleman, was raised by William III. to the dignity of a duke for his important diplomatic services. His position in those slippery times was altogether exceptional. Abandoning the religion of his ancestors he became a Protestant, was one of the seren who signed the invitation to William of Orange to come over, and was continually consulted by him on state affairs after he becapme king. Yet, being apparently of a very sensitive disposition, he seems to have at times repented what he liad done, and even corresponded with James at St Germain ; yet again, in times of danger, he was as ready as erer to stake his life and fortunes in the service of his country to preserve the new settlement. It was apparently his extreme sensitiveness that caused him to be spoken of as "the king of hearts." In 1694 he was created marquis of Alton and duke of Shrewsbury, but as he left no son these titles died along with him, and the earldom of Shrewsbury divolved on his cousin Gilbert, a Roman Catholic priest.

From this time the direct line of Sir Gilbert Talbot of Grafton began to fail. A nephew three times succeeded to an uncle, and then the title devolved upon a cousin, who died unmarried in 1856. On the death of this cousin the descent of the title was for a short time in dispute, and the lands were claimed for the infant son of the duke of Norfolk under the will of the last earl; but the courts decided that, under a private Act obtained by the duke of Shrewsbury in the sixth year of George I., the title and estates must go together, and the true successor to the earldom was found in Earl Talbot, the head of another line of the descendants of Sir Gilbert Talbot of Grafton, sprung from a second marriage of Sir Gilbert's son, Sir John Talbot of Albrighton. The head of this family in the beginning of the last century was a divine of some mark, who died bishop of Durham in 1730. His son Charles, who filled the office of lord chancellor, was created Baron Talbot of Hensol in Glamorganshire in 1733; and his son again was advanced to the dignity of Earl Talbot in 1761, to which was added that of Baron Dynevor in 1780 . Then succeeded a nephew, who was also created Viscount Ingestre, and assumed by royal licence the surname of Chetwynd before Talbot, from his mother.

The Earl Talbot who successfully claimed the Shrews. bury title (as the eighteenth eárl) was the present earl's
grandfather, and all the titles just mentioned bave been united in his line ever since.
(J. GA.)
talbot, Willay Hemry Fox (1800-1877), a dis. covercr in photography, was the only child of William Davenport Thalbot, of Laycock Alboy, Wilts, and of Lady Elizabeth Fox Strangways, daughter of the second earl of Ilchester. He was born in February 1800, and educated at Harrow and at Trinity College, Cambridge, where he gained the Porson prize in 1820, and graduated as twolfth wrangler in 1821. From 1822 to 1872 he frequently communicated papers to the Royal Society, many of them on mathematical suljects. At an early period ho had begun his optical researches, which were to bave such important results in connexion with photography. To the Edinburgh Journal of Science in $18 \geqslant 6$ he contributed a paper on "Some Experiments on Colcurcd Flane"; to the Quarterly Journal of Science in 1827 a paper on "Monochromatic Light"; and to the Philosophical Magesine a number of papers on chemical subjects, including one on "Chemical Changes of C'lour." Before Daguerre exhibited in 1839 pictures taken by the sun, Talbot had obtained similar success, and as soon as Daguerre's discoveries were whispcred communicated the results of his experiments to the Royal Society (see Photograpiry, vol. xviii. p. 824). In 184] he made known his discovery of the calotype process, but after the discovery of the collodion process by Scott Archer, with whom he Lad a lawsuit in reference to his patent rights, he relinquished this feld of inquiry. For his discoveries, the narrative of which is detailed in his Pencil of Nature (1844), he received in 1842 the medal of the Royal Society. While engaged in his scientific researches he devoted a considerable portion of his tinie to archæology, and this Eeld of inquiry latterly occupied his chief attention. Besides reading papers on these subjects before the Royal Society of Literature and the Society of Diblical Archrology, he published Hermes, or Classical and Antiquerrian Rescar ches (1838-39), and Illustrations of the Antiquity of the Book of Genesis (1839). With Sir flenry Rawlinson and Dr Hincks he shares the honour of having been one of the frst decipherers of the cuneiform inscriptions of Nineveh. He was also the author of English Etymologies (1846). He died at Laycock Abbey, 17 th September 1877.

TALCA, a town of Chili, capital of the province of Talca, is situated on the Claro, a tributary of the Maule, nearly due south of Saxtiage, with which it is connected by rail. The town has a lyceum and some woollen manufactures (especially of "ponchos"). In 1875 the population aumbered 17,496 , and in 1885 about 19,000
Talent. See Numismatics, vel. avii. p. 631.
TALES are, in the usual acceptance of the word, fictitious narratives, long or short, ancient or modern. In this article "tale" is used in a stricter sense, as equivalent to the German "Volks-märchen" or the French "conte pepulaire." Thus understood, popular tales mean the storics handed down by oral tradition from an unkuown antiquity, among savage and civilized peoples. So understood, popular tales are a subject in mythology, and indeed in the general study of the development of man, of which the full interest and importance is scarcely yet recognized. Popular tales won their way into literature, it is true, at a very distant period. The Homeric epics, especially the Odyssey, contain adventures which are manifestly parts of the general human stock of popular narrative. Other examples are found in the Rigreda, and in the myths which were handled by the Greek dramatists. Collections of popular tales, more or less subjected to conscious literary freatment, are found in Sanskrit, as in the work of

Somadeva, whose Kathe Sarit Sigurn, or "Ocean of the Streams of Story," has been translated by Mr l'awney (Calcutta, 1880 ). The Thotasad avip Oae Nicirrs ( 2. er.) are full of popular tales, and popular tales art the stople of the medireval Gesto Romenorum, and of the collectious of Straparola and other Ttalian conteurs. In all these naid similar gatherings the story, long circulatal from woulh to mouth among the pcople, is handled with consciuns art, and little but the gencral outline of plot and chinacter of incident can be regarded as original. Iu the llisturies on Contes du I'emp)s Passé of Perranlt (Elzevir, Amsterdum, 1697; the Parisian cdition is of the same date) we have one of the carliest gatherings of tales which were taken down in their wursery shape as they were told by nurses to children. This at least seems probable, though M. Alfred Maury thinks Perrault drew from literary sources. Pcrrault attributed the conpposition to his son, P'. Darmaucour, at that time a child, and this pretext enabled bim to give his stories in a simple and almost popalar guise. In the dedication signed by the boy, Perrault offers remarks which really do throw a certain light on the origin and characteristics of "märchen." He says, "Ils renferment tous une morale très sensée . . . . et domnent une image de ce qui se passe dans les moindres familles, ou la lonable impatience d'instruire les enfans fait imaginer des histoires dépourvûes de raison pour s'accomoder ì ces mênics enfants, qui n'en ont pas encore." It seems that popular tales in many cases probably owe their origin to the desire of enforcing a moral or practical lesson. It appears that their irrational and "infantile" character-" "d́pourvaes de raison"-is derived from their origin, if not actually among childron, at least among chiidlike peoples, who have not arrived at "raison," that is, at the scientific and modern cenception of the world and of the nature of man.

The success of Perrault's popular talcs brought the genre into literary fashion, and the Comtesse d'Aulncy invented, or in seme cases adapted, "contes," which still retain a great popularity. But the precise and scientific collection of tales from the lips of the people is not much earlier than our century. The chief impulse to the study was given by the brothers Grimm. The first edition of their Kinder-und Haus-Märchen was published in 1812. The English reader will find a very considerable bibliography of popular tales, as known to the Grimms, in Mrs Alfred Hunt's translation, Grimn's Household Tales, with Notes (London, 1884). "How unique was our collection when it first appeared," they exclaim, and now merely to enumerato the books of such traditions would occupy much space. In addition to the märchen of Indo-European peoples, the Grimms became acquainted with some Malay steries, some narratives of Bechuanas, Negroes, American Indians, and Finnish, Esthonian, and Magyar storics. Thus tho Grimms'knowledge of non-European marchen was extremely slight. It enabled then, however, to observe the increase of refinement "in proportion as gentler and more humane manners develop themselves," the monstrositics of Finnish and Red-Indian fancy gradually fading in the narratives of Germans and 1taliaus. The Grimms notice that the evolution of popular narrative resembles the evolution of the art of sculpture, from the South-Sea idel to the frieze of the Parthenon, "from the strongly marked, thin, even ugly, but highly expressive forms of its carliest stages to those which possess external beauty of mould." Since tho Grimme' time our knowledge of the popular tales of nonEuropean races has been greatly cnriched. We possess numbers of North-Auerican. Brazilian, Zulu, Swahili, Eskimo, Samoan, Maori, Kaffir, Malagasy, Bushman, and even Australian märchen, and can study them in comparison with the steries of Hesse, of the West Highlapds of Scotland, of Scandinavia.

While the popular romances of races of all colours must be examined together, another element in this subject is not less important. It had probably been often observed before, but the fact was brought out most vividly by Von Hahn (Griechische und albanesische Märchen, Leıpsic, (1864), that the popular tales of European races turn on the same incidents, and display the same succession of situations, the same characters, and the same plots, as are familiar in the ancient epic literature of Greece, India, Germany, and Scandinavia. The epics are either fully-developed märchen evolved by the literary genius of poets and saga-men, or the märchen are degenerate and broken-down memories of the epics and sagas, or perbaps there may be examples of both proccsses. The second viers, -namely, that the popular tales are, so to speak, the scattered grains of gold of which the epic is the original "pocket" or "placer,"-the belief that the märchen are the detritus of the saga,-was for a long time prevalent. But a variety of arguments enforce the opposite conclusion, namely, that the märchen are essentially earlier in character than the epic, which is the final form to which they have been wrought by the genius of Homer or of some other remote yet cultivated poet. If this view be accepted, the evolution of märchen and of certain myths has passed through the following stages:-
(1) The popular tale, as current annong the uncultivated peoples, such as Iroquois, Zulus, Bushmen, Samoans, Eskimo, and Samoyedes. This tale will reflect the mental condition of rude peoples, and will be full of nonstrous and miraculous events, with an absence of reason proper, as Perrault says, "a ceux qui n'en ont pas encore." At the same time the tale will very probably enforce some moral or practical lesson, and may even appear to have been invented with this yery purpose, for man is everywhere impressed with the importance of conduct.
(2) The same tale-or rather a series of incidents and a plot essentially the same-as it-is discovered surviving in the oral traditions of the illiterate peasantry of European races. Among them the monstrous element, the ferocity of manners observed in the first stage, will be somewhat modified, but will be found most notable among the Slavonic tribes. Nowhere, even in German and Scottish märchen, is it extinct, cannibalism and cruel torture being favourite incidents.
(3) The same plot and incidents as they- exist in the heroic epics and poetry of the cultivated races, such as the Homeric books, the Greek tragedies, the Cyclic poets, the Kalewala of the Finns, certain hymns of the Rigveda, certain legends of the Brahmanas, the story of the Volsungs,-in these a local and almost historical character is given by the introduction of names of known places, and the adventures are attributed to national heroes, -Odysseus, CEdipus, Sigurd, Wainamoinen, Jason, Pururavas, and others. The whole tone and manners are nobler and more refined in proportion as the literary workmanship is more elaborate.

This theory of the origin of popular tales in the fancy of peoples in the savage condition (see Mythology), of their survival as märchen among ine peasantry of IndoEuropean and other civilized races, and of their transfiguration into epics, could only be worked ont after the discovery that savage and civilized popular tales are full of close resemblances. These resemblances, when only known to exist among Indo-European peoples, were explained as part of a common Aryan inberitance, and as the result of a. malady of language. This system, when applied to myths in general, has already been examined (see MyтнoLoay). According to another view, märchen everywhere resemble each other because they all arose in India, and have thence been borrowed and transmitted. For this
theory consult Benfey's Panchatantra and M. Cosquin's Conies de Lorraine (Faris, 1886). In opposition to the Aryan theory, and the theory of borrowing from India, the system which is here advocated regards popular tales as kaleidoscopic arrangements of comparatively few situations and incidents, which again are naturally devised by the early fancy. Among these incidents may be mentioned, first, kinship and intermarriage between man and the lower animals and even inorganic phenomena. Thus a girl is wooed by a frog, pumpkin, goat, or bear, or elephant, in Zulu, Scotch, Walachian, Eskimo, Ojibway, and German marchen. This incident is based on the lack of a sense of difference between man and the things in the world which is prevalent among savages (see Mythology). Other incidents familiar in our nursery tales (such as "Cindereila" and "Puss in Doots") turn on the early belief in metamorphosis, in magic, in friendly or protecting animals (totems or beast manitous). Others depend on the early prevalence of cannibalism (compare Grimm, 47, "The Juniper Tree"). This recurs in the mad song of Gretchen in Foust, concerning which a distinguished student writes, "This ghost of a ballad or rhyme is my earliest remembrance, as crooned by an old East-Lothian nurse." (Compare Chambers's Popular Rhymes of Scolland, 1870, p. 49.) The same legend occurs among the Bechuanas, and is published by Casalis. Yet another incident springs from the taboo on certain actions between husband and wife, producing the story of Cupid and Psyche (see Lang's Custom and Mylh, 1884, p. 64). Once more, the custom which makes the youngest child the heir is illustrated in the märchen of the success, despite the jealousy of the elders, of Cinderella, of the Zulu prince (Callaway's Tales from the Amazulu, pp. 64, 65), and in connfless other märchen. In otaer cases, as in the world-wide märchen corresponding to the Jason epic, we seem in presence of an early romantic invention, -how diffused it is difficult to imagine. Moral lessons, again, are inculcated by the numerous tales which turn on the duty of kind. ness, or on the impossibility of evading fate as announced in proplecy. In opposition to the philological explanation of the story of Edipus as a nature-myth, this theory of a collection of incidents illustrative of moral lessons is admirably set forth in Prof. Cauparetti's Edipo e lo Milologia Comparata (Pisa, I867).

On a general view, then, the stuff of popular tales is a certaia number of incidents and a certain set of cembinations of these incidents. Their strange and irrational character is due to their remote origin in the fancy of men in the savage condition; and their wide distribution is caused, partly perbaps by oral transmission from people to people, but more by the tendency of the early imagination to run everywhere in the same grooves. The narratives, in the ages of heroic poetry, are elevated into epic song, and in the Middle Ages they were even embodied in legends of the saints. This view is maintained at greater length, and with numerous illustrations, in the introduction to Mrs Hunt's translation of Grimm's Kinder-und HausMärchen, and in Cusionn and Myth, already referred to.

A complete bibliography of the literature of popular tales would fill many pages. The reader who is curious about savage popular tales may turn to Theal's Kaffir Folk Lore (2d ed., London, 1886); Callaway's Nursery Tales of the Amazulu (London, 1868); Schooleraft's Algic Researches; Gill's Myths and Talcs of the South Pacific; Petitot's Traditions Indiennes (1886); Shortland's Maori Religion and Mytholomy (London, 1882); The South African FolhLore Record; the Folk Lore Reoord (London, 1879-85, Malagasy stories) ; Rink's Tales and Traditions of the Eskimo; Bleek's Hottentot Tales and Frables (London, 1864); Castrén's Samoyedische Miarchen ; and Leland's Algonqutu Legends (London, 1884). For Europeau tales, the bibliography in the translation of Grimm already referred to may be used, and the Maisonneuve collection, Les Litteratures populaircs may be recommended. The names of

Liebrecht, Köhler, Dasent, Ralston, Nigra, Pitré, Cosquin, Afanasief, Gaidoz, Sébillot, may serve as clues through the enchanted forest of the auisery tales of Europe.
(A. L.)

TALFOURD, Sir Thowas Noox (1795-1854), was at once eminent as a lawyer, as a vriter, and as a member of a brilliant and polished society. $\mathrm{H}_{\theta}$ had the faculty of winning friendships; so sympathetic indeed was his nature that he unconsciously biassed many of the most acute among his acquaintances towards an estimate of his genius as an author-more especially as a dramatist-hardly commensurate with what more impartial criticism has decided to be his just meed of praise. But, though even his most excellent work in literature has now ceased to bo generally cared for, his poetry must always bo interesting to the literary student.

The son of a brewer in good circumstances, Talfourd was born on January 26, 1795, at Doxey, near Stafford (some accounts mention Reading). He received his early education, first at an institution near Hendon, and later at the Reading grammar-school under Dr Valpy. Here, it is said, he acquired his taste for dramatic poctry, presumably uuder the guidance of Dr Valpy. At the age of eighteen the lad was sent to London to study law under Mr Chitty, the special pleader. Early in 1821 be joined the Oxford circuit, having been called to the bar at the Middle Temple in February of that year. When, fourteen years later, he was created a serjeant-at-law, and when again he in 1849 succeeded Mr Justice Coltman as judge of the Court of Commor Pleas, he attained these distinctions more perhaps for the zeal and lahorious care which he invariably displayed in his conduct of the cases confided to him than on account of any brilliance of forensic talent or of any marked intellectual subtlety. A parliamentary life had always had an. attraction for him, and at the general electiou in 1835 he was returned for Reading. This seat be retained for close upon six years, and he was again returned in 1847. In the House of Commons he was no mere ornamental member. Those efforts of his which have most interest for us of later date were made on behalf of the rights of authors, for whose benefit he introduced the International Copyright Bill; his speech on this subject was considered the most telling made in the House during that session. The bill met with strong opposition, but Talfourd had the satisfaction of secing it ultimately pass fato law in 1842, albeit in a greatly modified form.

At the period of his elevation to the bench he was created a lnight, and thenceforward his life was, in the intervals of his professional labours, devoted to scholarly and literary pursuits. From his school days he had entertained dreams of attaining eminence as a writer; and to the last be remained a diligent student of literature, ancient and modern. During his early years in London Talfourd found himself forced to depend-in great measure, at least -upon his literary exertions. He was ąt this period on the staff of the London Magazine, and was an occasioual contributor to the Edinburgh and Quarterly reviews, the New Monthly Magazine, and other periodicals; while, on joining the western circuit, he acted as law reporter to The Times. His legal writings on matters germane to literature are excellent expositions, animated by a lucid and sufficiently telling, if not highly polished, style. Among the best of these are his article "On the Principle of Adrocacy in the Practice of the Bai" (in the Law Magazine, January 1846); his Proposed New Law of Copyright of the Highest Importance to Authors (1838) ; Three Speeches delivered in the House of Commons in Favour of an Extension of Copyright (1840); and his famous Speech for the Defendant in the Prosecution, the Queen v. Moxom, for the Publication of Shelley's Poetical Works (1841).

But Talfourd cannot be said to have gained any position
arnoug men of letters until the production of his tragedy Ion, which was privately printed in 1835, and produced in the following year at Covent Garden theatre. The tragedy was also well received in America, and it met with the honour of reproduction at Sadler's Wells in December 1861. This dramatic poem, its author's masterpiecc, tunis upon the roluntary sacrifice of Ion, king of Argos, in response to the Delphic oracle, which had declared that only with the extinction of the reigning family could the prevailing pestilence incurred by the deeds of that family be removed. As a poem Ion has many high qualities. The blank verse, if lacking the highest excellence, is smooth and musical, and the lines are frequently informed with the spirit of genuine poetry; the character of the high-souled son of the Argive king is finely developed, and the reader is affected throughout by that same sense of the relentless working and potency of destiny which so-markedly distinguishes the writings of the Greek dramatists.

Two years later, at the Haymarket theatre, The Athenian Captive was acted with moderato success. In 1839 Glen. coe, or the Fate of the Macdonalds, was privately printed, and in 1840 it was produced at the Haymarket; but this home drama is indubitably much inferior to his two classic plays. The Castilian ( 1853 ) did not excite a tenth part of the interest called forth by Ion. Before this he had produced various prose writings other than those already referred to,-among them his "Hiśtory of Greek Litera. ture," in the Encyclopædia Metropolitana.

Besides the honour of knighthood and his rarious legal distinctions, Talfourd held the honorary degree of D.C.L. from the university of Oxford. He dieù in court during the performance of his judicial duties, at Stafford. on March 13, 1854.
In addition to the writings above-mentioned, Talfourd was the author of The Letters of Charles Lamb, with a Sketch of his Life (1837); Rccollections of a First Visit to the Alps (1841); Vacation Rambles and Thoughts, comprising recollections of three Contipental tours in the vacations of 1841,1842 , and 1843 ( 2 vols., 1844); and Final Memorials of Charles Lamb (1849-50).

## TALisman. See Amolet.

TALLAGE, or Talilage (from the French tailler, i.e., a part cut out of the whole), appears to have signified at first a tax in general, but became afterwards confined in England to a special form of tax, the assessment upon cities, boroughs, and royal demesnes-in effect, a land tax. Like Scotage (q.v.), tallage was superseded by the subsidy system in the 14 th century. The last occasion on which it was levied appears to be the year 1332. The famous statute of 25 Edw . I. (in some editions of the statutes $34 \mathrm{Edw}. \mathrm{I)}$. De Tallagio non Concedendo, though it is printed among the statutes of the realm, and was cited as a statute in the preamble to the Petition of Right in 1627 , and by the judges in John Hampden's caso in 1637, is probably an imperfect and unauthoritative abstract of the Confirmatio Cartarum. The first section enacts that no tallage or aid shall be imposed or levied by the king and his heirs without the will and assent of the archbishops, bishops, and other prelates, the earlś, barons, knights, burgesses, and other freemen in the kingdom. Tallagium facere was the technical term for rendering accounts in the exchequer, the accounts being originally kept by means of tallies or notched sticks. The tellers (a corruption of talliers) of the exchequer were at one time important financial officers. The system of keeping the national accounts by tallies was abolished by 23 Geo. III. c. 82. the office of teller-by 57 Geo. 'III. c. 84.

Talleyrand de perigord, Charles Maurice (1754-1838), created by Napoleon a prince of the empire under the title of the Ṕrince de Bénévent, was born at Paris on 2d February 1754. His father, who was of a yoninger branch of the princely family of Chalais, was an
officer in the army of Louis $X V$., and his mother, also of noble family, was a member of the royal household at Versailles. An accident in infancy rendered Talleyrand lame for life, and changed his whole carecr. His upbringing was, in accordance with the fashionable heartlessness of the day, entirely left to strangers ; and while a boy he was, in consequence of his lameness, formally deprived by a conscil de famille of his rights of primogeniture, -his younger brother, the Comte d'Archambaud, taking his place; and he was destined for the church. Ho keenly felt the blow, but was powerless to avert it; and he used his enforced profession only as a stepping-stone to his ambition, always despising it, and coolly and defiantly forsaking it when he found it an embarrassment.

When he was removed from the country he was sent to the Collége d'Flarcourt, where he speedily distinguished himself; and in 1770, when sixteen years of age, he became an inmate of the Séminaire de St Sulpice, his education being completed by a course in the Sorbonne. Much as Talleyrand despised the church as a career, be never ceased highly, to appreciate theology as a training, and he publicly testified to its valuo to the statesman and specially to the diplomatist. While achieving distinetion as a student, he carefully cultirated such society as might promote his advancement; and it was in the circle of Madame du Barry that his cynicism and wit, reported by her to the king, gained him the position of abbé. To his arts of manner were added, not only his advantages of birth and scholarship, but a penetrating judgment of men and afiairs, a subtle audacity, and a boundlessly selfish ambition. As early as 1780 we find this abbé malgré lui to have reached the important position of "agent-general" of the French clergy. His ability and his flagrant immorality alike rendered him a marked man, and the latter did not prevent his appointment, in accordance with his father's dying request to the king, as bishop of Autun in January 1789. The clergy of his own diocese immediately elected him a member of tho states-general; and he delivered before his constituents ono of the most remarkable speeches which the crisis produced, containing a sagacious and statesmanlike programme of the reforms which the condition of France demanded. He thus entered the assembly as one of its leaders.

The states-general had hardly met ere Talleyrand's influence was called into play. He successfully urged the clergy to yicld to the demand of the commons that the three estates should meet together; and the nobles could thereafter only follow the example thus set. On the question of the extent of the asscmbly's authority he again sided with the popular leaders. As a financier of great foresight and porver he soon became justly celebrated; and his position in the assembly may be estimated by his appointment as one of a committee of eight to frame the project of a constitution. All his previous successes were, however, eelipsed by the daring with which he attacked the rights and privileges of his own order. He had seconded the proposals that the clergy should give up their tithes and plate for the benefit of the nation, and on loth October 1789 ho himself projosed a scleme whercby the landed property of the church should be confiscated by the state. On 2 d November, after violent deoates, his project was carried, and the old clergy thereafter ranked him as an enemy. But his general popularity so much inereased that he was charged by the national assembly to prepare a written memoir in defence of its labours; and the manifesto, read on February 10, 1590, was received with great approval thronghout the country. On. the 16 h he was elected presicent of the assembly for the usual brief term. On various subjects he was now looked up to as an authority, -on education, on electoral and ecclesiastical
reform, on banking, and on general finance. His career se a diplomatist had not jet begun.

On July 14, 1790, Talleyrand, at the head of 300 clergy, assisted at the fête in the Champ de Mars in commemoration of the fall of the lastille; and publicly blessed the great standard of France. By this time, however, the dispute as to the civil constitution of tie clergy had broken out, the decision of the assembly being resisted by the king, backed by the pope. When in November the king yielded, Talleyrand boldly took the required oath, only two bishops following his example. New bishops were elected by the assombly, and these he, in open defiance of the chpreh, consecrated. In the end of April 1791 he was suspended from his functions and exconmmnicated by the pope. Without a moment's hesitation Talleyrand abandoned his profession, which he never afterwards resumed. He had been false to its vows, and had seandalized it by his shameless life. It was only in the preceding February that he had, in declining nomination for the archbishopric of Paris, felt, indiscrectly enough and contrary to his usual practice, the necessity of writing to the Moniteur a hypocritical confession of his- gambling propensities, stating his gains at 30,000 francs. Although in 1801 the excommunication was recalled, it was nearly half a century after his first act of defiance ere he became personally reconciled to the church, and then only when he was at the point of death.

On purely political lines, however, Talleyrand's career became more and more celebrated. In the beginning of the same month of April 1791, his friend Mirabeau having just died, he was appointed to succeed him as a director of the department of Paris, a position which still further increased his influence in the circles of the metropolis. On the flight of the king in June, Talleyrand leaned at first and cautiously towards the duke of Orleans, but finally declared for a constitutional monarchy with Louis XVI. still on the throne. Ere the constitutional assembly brought its existence to a close on 14 th September, be unfolded before, it his magnificent scheme of national education, which, in the words of Sir Henry Bulwer, "having at one extremity the communal school and at the other the Institute, exists with but slight alterations at this very day." The assembly had voted that none of its members should be members of the new legislative body, so that Talleyrand was free ; besides, events were hurrying on with strango and critical rapidity ; and Talleyrand left France for England, reaching London in the end of January 1792. With this visit his diplomatic career may be said to have begun.

He was not formally aceredited, but had in his pocket an introduction to Lord Grenville by Delessart the foreign minister; the king himself was aware of his mission, the ostensible object of which was to conciliate England. Talleyrand for his part shared tho ulterior views of Narbonne, the minister of war, that it would be for tho advantage of his country to divert its encrgies, which were morbidly directed to its internal troubles, into another clannel, and to precipitate an Austrian war. Although received well in London society, he found the want of official credentials a fatal obstacle to his diplomatic negotiations, and he returned to Paris, whence he was almost immediately again despatched to the English court under much more favourable conditions. He was nominally only attendant with Do Chauvelin, the minister plenipotentiary, but he was really the head of the embassy, and he carricd with him a letter of Louis XVI. to George III. At this time, indced, Talleyrand's relations with Louis were very close, -far closer than he afterwards cared or dared to avow. All, however, was of no avail. The startling course of the Revolution made the English look oskance
apon his mission, and he returaed bafled to Paris, where be arrived shortly before the coup d'état of the 10 th of Angust. But this place, where his mariest manourres were outdone by the rapidity of the popular movements, and where at any turn of affairs he might lose his head, was not to his liking; and by the middle of September he is for the third time in London. It is characteristic of the man-of the dexterity as well as audacity of his intrigue-that he who had but shortly before carried with him a letter of favour from Louis XVI. was, now that royalty was abolished, the bearer of a specific passport"going to London by our orders"-under the hand of Danton. Equally characteristic is the express falsehood with which be opens his negotiations: he writes at once to Lord Grenville, "I have at this time absolutely no kind of mission in England "-he was selling his library and seeking repose. His courtesies were not returned; and, although be succeeded in making friends in certain high quarters, he was, in tho end of January 1794, under the provisions of the Alien Act, ordered to leave England. Fortified with an introduction by Lord Lansdowne to Washington, he sailed for the United States.

A decree of the convention had issued against Talleyrand during his stay in England. He was an émigré. But as the excesses of the period drew to a close the proscription was recalled on the appeal of Chénier, who founded on Talleyrand's relations with Danton and his mission to England in the service of the Revolution! On July 25, 1795 , he arrived at Hamburg, whence he passed to Berlin, and, after a short stay there, to Paris. He mas received.with enthusiasm in the circles of fashion and intrigue. He mould have been eagerly welcomed by any of the political parties as a strength; but the Directory was in power, aad he supported it. Withia the Directory he supported Barras, as against his compeers. He was thus a moderate constitutionalist and in the way of advancement.

During his absence from France he had been elected a member of the Institute. He was now elected its secretary. In this capacity he read before it two memoirs-one on the "commercial relations of the United States with England," and the other "on the advantages of withdrawing from new colonies in present circumstances." These memoirs exhibit Talleyrand at the very maturity of his powers, and aro sufficient to establish his position as one of the most far-seeing and thonghtful statesmen that France ever possessed. The first paper shows how, in spite of the War of Independence, the force of language, race; and interest must in his vies bind England and the States tagether as. natural allies; and it contains that remarkable passage (which once read is never forgotten) in which the civilization of America is described as exbibited in space as well as in time, -as the traveller moves westward from State to State he appears to go backward from age to age. The papers, which were read in April and July of 1797, made his claim to state recognition irresistible, and towards the end of the latter month he was appointed to the post of foreign minister.

He had been carcfully scanning the political situation, and be accurately foresaw that the Directory, which represented no one set of opinions, but only a vaia compound of all, could not stand against unity of policy backed by force, and in the meantime could be manipulated. Thus with a brutal swiftness its personnel becomes changed. Barras with his sluggish moderation remains; but, behind and through hin, it is tho dexterous purpose of Talleyrand that is at work. This is the first characteristic of his administration. "Its second is the ability which ho displays in his communications with tho diplomatic service, in view of the rupture with Englad. Its third is
the shamelessly corrtpt manner in which ho approaches the American ambassadors on the subject of the seizure of certain ships, on the conclusioa of a commercial treaty between England aad the States, putting himself in his public and powerful position at their service, - if the bribe were suitably large. And its fourth is that he is hardly in the chair of office until he has shrewdly selected Bonaparte as the object of his assiduous flatteries, writing to him in semi-confidence, and laying the basis of their future intimacy. But his first term of office was short: the American ambassadors spurned his offer and let his conduct be publicly known, with the result that for this and other reasons he resigned his post. Public opinion was outraged. His official corrnption, however, was not ended, for Talleyrand turned everything into gold ; in his later diplomacy also ho could almays be bought; and this public immorality was but too faithfully reflected in his private life, in which gambling tas his passion and a source of his vast wealth.

Out of office, but still pulling the strings of the Directory, he awaited the arrival of Napoleon in Paris, and it was his hand which was most powerful in shaping the events of the 18 th and 19 th Brumaire- 9 th and 10 th November 1799. He reconciled Siejes to Bonaparte; a majority of the Directory-Sieyès, Ducos, and at last at his persuasion even Barras-resigned; the Directory collapsed, and the consulate was established (see Napoleon and Sieyès). Napoleon was the first and Talleyrand the second man in France.

He was now an absolutist, the whole drift, of his influence being ia the direction of consolidating, under whatever title, the power of Bonaparte. For many years henceforward Talleyrand's career is part of the general history of France. He is soon again foreign minister; and he is acknowledged to have been the ablest diplomatist of an age when diplomacy was a greater power than it has ever been before or since To him falls a full share of responsibility for the kidnapping and murder of the Duc d'Enghiea in March 1804 (sce Savary). He had assisted at the councils when the atrocity was planned, and he wrote to the grand-duke justifying the seizure of the priace while on Baden tertitory. His hend in the matter was of courso concealed. But, when one adrised him to tender his resiguation, he demurely remarked, "If, as you say, Bonaparte has been guilty of a crime, that is no reason why I should bo guilty of a folly." In other and more agreeable directions he had prostrated himself before Napoleon's purposes, approving among other things of the policy of the Concordat :(15th July 1801), and securing thereby the recall of his excommunication. To the pope's grateful brief, which gave him liberty "to administer all civil affairs," he coolly gare a wide interpretation, and he shortly thereafter married. He of course supported and defended first the consulship for life and thea the crowaing of the emperor.

By and by, however, a change comes over his political attitude, and it is not long ere Napoleon detects it. This change we date, with Sainte-Beuve, from the end of January 1809. Before the peace of Tilsit, July 8, 1807, from Jena onwards, he lad personally accompanied the great conqueror ; after it they stood apart, for the statesman saw in those brilliant but ceaseless conquests the prelude to the ruin of his master and his country. He was now prince of Berievento, and he withdrew from the ministry, receiving at his own desire the title of vice-grandelector of the empire. Yet he had not disapproved of the Spanish war; the young princes had even been entrusted to his surveillance at his country house at Valençay", Piut anything might have happened to the einperor in Snain, aud Talleyraud had evidentlv bean calculating the chances
of the future. So at the date stated the explosion occurs, Napoleon pouring upon Talleyrand all the fury of his invective, reproaching him with the affair of the Duc d'Enghien, and clamouring to know where his enormous wealth had come from, -how much he had gained at play or on the stock exchange, and what was the sum of his bribes by foreign powers. Over and over again such scenes are repeated, the burden of the fierce reproaches being always the same; but Talleyrand staads impassive as a statue, remarking once, but not till he is out of the room, and is limping away, "What a pity that such a great man has been so badly brought up!" or sending in, at another time, a resignation, which of course is not accepted. The reproaches of the emperor were only too well founded, his minister having reaped a vast harvest from the smaller powers at the formation of the Rhenish Confederation; it is indeed recorded that Talleyrand once put a figure upon his gains in this department of corruptionthe figure beiog no less than sixty million francs.

It is undonbtedly to his credit, however, that he steadily resisted a warlike policy, and that he was particularly opposed to the Russian invasion. He was occasionally employed in diplomatic negotiations, and was even again offered the post of foreign minister if he would give up that of vice-grand-elector. This offer, which would have placed him at the mercy of Napoleon, he declined, and the breach between the two widened. Before the events of 1814 his hotel had become the centre of anti-Napoleonic intrigue; as the crisis approached he communicated with the allies; when it was at haud be favoured a regency, and appeared anxions that Marie Louise should remain in Paris; and when this was abandoned he carefully arranged a feigned departure himself, but that his carriage should be turned back at the city gates; he did return; and the cmperor Alexander was his guest at the Hôtel Talleyrand! The revolution was his work; and his nominee Louis XVIII. ascended the throne.' For a third time, and again under a new master, he was appointed foreign minister. It would be difficult to overestimate the splendid services which he now rendered to France. . In Paris, on 23d April, the treaty was concluded under which the soldiers of the allies were to leave French soil'; and Talleyrand successfully urged that the territory of France should be the enlarged territory of 1792 , and also that the great art treasures of which so many European cities had been despoiled should remain in Paris. A final treaty of peace between Europe and France was concluded on 30th May, and in September the congress of Vienna assembled. It was the scene of Talleyrand's greatest triumphs. He succeeded aingle-handed in breaking up the confederation of the allies, and in reiatroducing the veice of France into the deliberations of the European powers. Further, on Jamuary 3, 1815 , a secret treaty was concluded between Austria, France, and England.

When Napoleon escaped from Elba and advanced towards Paris, Louis XVIII. retired to Ghent. Although the congress of Vienna was thus broken up, Talleyraad made no haste to follow him thither. He was puzzled, and remained so during the Hundred Days. He despised Louig, and an early approach to Bonaparte was out of the question. .Ho therefore coolly betook himself to Carlsbad, remarking, when an explination was asked for, that the first duty of a diplomatist after a congress was to attend to his liver! Waterloo of course decided him. He appeared at Ghent, and was but coldly received. The foreign powers, however, intervened, conscious after. Vienna of Talleyrand's value ; and, among others, Wellington insisted that the great diplomatist must be taken into the councils of Louis, - with the result that he becaine prime minister at the secund restoration. But his position was one of
extreme difficulty. The king disliked him; there were scenes bordering on violence in the royal presence; the Russian emperor intimated his hostility to him; he shared the odium of having a man like Fouché for a colleague ; Chateaubriand and his party hated and beset him. Fortunately on excuse of a broad and national kind soon presented itself. He oljected to the conditions which the allies were imposing upon France, refused to sign the treaty, and on 24 th September resigned office.

He retired into private life, in which he remained for fifteen years. Ho only spoke in the House of Peers three times during this period,--twice (1821 and 1822) in favour of the liberty of the press, and once (1823) to protest against the Spanish war. But in 1830 , when Charles X.'s reign was evidently imperilled, he again is at the centre of intrigue;-and it is actually at his private but urgent suggestion that Louis Philippe heads the revolution, taking, to begin with, the title of lieutenant-general of the kingdom. Declining the post of foreign minister, he proceeded to London as ambassador, conducting himself and serving his country with his usual corsummate skill. Ho returned crowned with success after the formation of the Quadruple Alliance. In November 1834 he resigned, and quitted public life for ever.

He emerged from his retirement on March 3, 1838, to pronounce before the Institute the éloge of Reinhard, and in so doing to treat of diplomacy in general, and to suggest an indirect but adroit apology for his own career. He was received with unbounded enthusiasm by the élite of French literature and society-Cousin even exclaiming that the cloge was worthy of Voltaire. His last illness, which had by this time shown itself, soon prostrated him. He was visitcd on his death-bed by crowds of celebritics, ibcluding the king. He died on May 17, 1838, at the great age of eighty-four. He is buried at Valençay.

According to his desire, his memoirs under his own hand will not appear till 1890 .
There is a considerable body of anonymous aud untrustworthy literature both in French and English on the subject of this sketch. For the earlier nart of Talleyrand's career, see the general litersture of the Revolution; for the Napoleonic, the general histories, including especially the Alemoirs of the Duc de Rovigo; for the third aud last, slso the general histories, and especially the Correspondence between Talleyrand and Louis XVIII., edited by Pullain (1880; transl. into English, 1881), and the Nemoirs of Guizot. Refercnces abound to the private life of Talleyrand, and on it see also the Histoire Politique et Tie Intime, by G. Touchard-Lafosse (1848), and the Souvenirs Intimes sur MI. de Talleyrand, by Amedée Pichot (1870). The student must be on his guard in perusing most of this last-mentioned literature. For many years the $\vec{H}$ is. toire Politique et Privé, by G. Michaud (1853), stood practically uncorrected, although evidently a studied and bitter attack. The view taken by Louis Blanc in his Dix. Ars (translated into English in 1845) is also quite distorted, and if one wishes to see a completo misreading of Talleyrand's career it can be found in Blanc's tenth chapter of his fifth book. Sir Henry Lytton Bulwer rendered great service by his life of Talleyrand, published in his Historical Characters; and the worth and sccuracy of Bulwer's biography, which was speedily translated into French, has been amply acknowlodged by Sainte-Beuve in his valuable treatiso (lectures) on Talleyrand, published in 1870. Reference should also be made to Mignet, Bastide, and the Memoircs Politiques or Lamartine.
Cation will have to be exercised in reading Talleyrand's autobiography, which will not appear till 1890. The testimony of contemporaries will not be available to check it, and Talleyrand is proved to have presided at the destruction of much documentary evidence implicating himself, e.g., at the moment when the Russian emperor was living at his house.
(T. S.)

TALLIEN, Jean Lambert (1769-1820), the chief leader of the party that overthrew Robespierre, was the son of the mâ̂tre dhôtel of the Marquis de Bercy, and was born in Paris in 1769. The marquis, perceiving the boy's ability, had bin well educated, and got bin a place as a lawyer's clerk. Being much excited by the first events of the Revolution, he gave up his desk to enter a printer's office, and by 1791 he was overscer of the priatiug
topartment of the Moniteur. While thns employed he annceived the idea of the journal-affiche, and from January to. Yay 1791 he placarded a large printed sheet on all the walls of Paris twice a week under the title of the Ami cles Citoyens. This enterprise of his, of which the expenses were defrayed by the Jacobin Club, made him well known to the revolutionary leaders; and he made himself atill more conspicuous in organizing the great "Fête de la Liberte" on April 15, 1792, in honour of the released soldicrs of Chattean-Vienx, with Collot d'Herbois. On July 8, 1792, hie was the apokesman of a deputation of the section of tho Place Royale which demanded from the legislative assembly the reinstatement of Pétion and Manuel, and he was one of the most active popular leadera in the attack upon the Tnileries on 10th Auguist, on which day he was appointed secretary or clerk to the revolutionary commune of Paris. In this capacity he exhibited an almost feverish activity; he perpetually appeared at the bar of the assembly on behalf of the commune; he announced the massacres of September in the prisons in terms of praise and apology; and be sent off the famous circular of 3 d September to the provinces, recommending them to do likewise. At the close of the month he resigned his post on being elected, in apite of his youth, a deputy to the Convention by the department of Seire-et-Oise, and he commenced his legislative career by defending the conduct of the commune during the massacres. He took his seat upon the Monntain, and showed himself one of the most vigorons Jacobins, particularly in his defence of Marat; be voted for the execution of the king, and was elected a member of the. Committee of General Security on January 21, 1793. After a short mission in the westeru provinces he returned to Paris, and took an active part in the coups d'état of 31 st May and 2d June, which resulted in the overthrow of the Girondins. . For the next few months he remained comparatively quiet, but on September 23, 1793, be was sent with Ybabeau on his famous mission to Bordeaux. This was the very month in which the Terror was organized under the superintendence of the Committees of Public Salety and General Security, and Bordeaux was one of the cities selected to feel its full weight. Tallien ahowed himself one of the most vigorous of the proconsuls aent over France to establish the Terror in the provinces; though with but few adherents, he soon awed the great city into quiet, and kept the guillotine constantly employed. It was at this moment that the romance of Tallien's life commenced. Among his prisonera was Theresa, Comtesse de Fontenay, the daughter of the great Spanish banker Cabarrus, the most beautiful and fascinating woman of her time, and Tallien not only spared her life but fell deeply in love with her. She quickly abated the fierceness of his revolutionary ardour, and from the lives ohe saved by her entreaties she received the name of "Our Lady of Pity." This mildness, however, displeased the members of the committees; Tallien was recalled to Paris ; and Madame de Fontenay was imprisoned there. Danton and his friends bad but just fallen, and the members of the committees were hadf afraid to strike again at the moderates, so Tallien was apared for the time, and was even elected president of the Convention on March 24, 1794. But the Terror could not be maintained at the same pitch : Robespierre began to see that he must strike at many of his own colleagues in the committecs if he was to carry out his theories, and Tallien was one of the men condemned with them. They determined to strike first, and on the great day of Thermidor it was Tallien who, urged on by the danger in which his beloved lay, opened the attack upon Robespierre. The movement was onccessful; Ruhespierre end his friends were guillotined; sud the young Tallien, as the leading Thermidorian, was
elected to the Committee of Public Safety. Now came the great months of his career: he showed himself a vigorous Thermidorian; he was instrumental in suppressing the Revolutionary Tribunal and the Jacobin Club; he attacked Carrier and Lebon, the proconsuls of Nantes and Arras; and he fought bravely against the insurgents of Prairial. In all these months he was supported by his Theresa, whom he married on December 26, 1794, and who became the leader of the social life of Paris. His last political achievement was in July 1795, when he was present with Hoche at the destruction of the army of the émigres at Quiberon, and ordered the executions which followed. After the close of the Convention Tallien's political importance came to an end, for, though he sat in the Council of Five Hundred, the moderates attacked him as terrorist, and the extreme party as a renegade. Madame Tallien also got tired of him, and became the mistress of the rich banker Ouvrard. Bonaparte, however, who is said to have been introduced by him to Barras, took him to Egypt in his great expedition of June 1798, and after the capture of Cairo be edited the official journal there, the Décade Égyptienne. But Menou sent him away fron Egypt, and on his passage he was captured by an English cruiser and taken to London, where he had a good receptiva among the Whigs and was well received by Fox. On réturning to France in 1802 he got a divorce from his nufaithful apouse (who eventually married the Prince de Chimay), and was left for some time without employment. At last, through Fouché and Talleyrand, he got the appointment of consul at Alicante, and remained there until he lost the sight of one eye from yellow fever. On returning to Faris he lived on his balf-pay until 1815, when he received the especial favour of not being exiled like the other regicides. His latter days were apent in the direst poverty; he had to sell his books to get bread. He died at Paris on Norember 16, 1820.
Tallis (Tallys, Talye, or Tallisids), Thomas (c. 1515-1585), justly styled "the father of English cathedral music," was born, as nearly as can be ascertained, about the year 1515. Tiue history of his youth is involved in some obscurity ; there seems, howeven but little doubt that, after singing as a chorister at old Saint Paul's under Thomas Mulliner, he obtained a place among the children of the chapel royal. Yis next appointment was that of organist at Waltham abbey, where, on the dissolution of the monastery in $15 \ddagger 0$, be received, in compensation for the loss of his preferment, 20s. for wages and 20 s . for reward. An interesting relic of this period of his career is preserved in the library of the British Museum, in the form of a volume of MS. treatises on music, once belonging to the abbey, on the last page of which appears his autograph, "Thomas Tallys," with the final letter prolonged iuto an elaborate flourish-the only apecimen of his handwriting now known to exist.
Not long after his dismissal from Waltham, Tallis waa appointed a gentleman of the chapel royal; and thenceforward he laboured so zealously for the advancement of his ait that his genius has left an indelible impression upon the English school, which owes more to him than to any other composer of the I6 th century, and in the history of which his name plays a very important part indeed.

One of the earliest compositions by Tallis to which an approximate date can be assigned is the well-known Service in the Dorian Mode, consisting of the Venite, Te Deum, Benedictus, Kyrie, Nicene Creed, Sanctus, Gloria in Excelsis, Magnificat, and Nunc Dimittis, for four voices, together with the Preces, Responses, Paternoster, and Litany, for five, all published for the first time, in the Rev. John Barnard's First Bnok of Selected Chuich IIfusic, in 1641, and reprinted, with the exception of the Venits
XXIII.
and Paternoster, in Boyce's Cathedral M/usic in $1760{ }^{1}$ That thi, work was composed for the purpose of supply. ing a prewing need, after the publication of the second prajer-book of king Edward VE. in 1552 there can be no reasonabie doubt; and its perfect adaptation to its intended purjose is sufficiently proved by the fact that. for n:ore than three hundred years, its claim to occupy the first and bighest place among compositions of its class has becu undisputed. Written in the style known among Italian composers as lo stile famigliare, i.e., in simple counterpoint of the first species, nota contra notam, with no attenpt at ingenious points of imitation, or learned complications of any kind-it adispts itself with equal diguty and clearncss to the expression of the rerbal text it is jutended to illustrate, bringing out the sense of the sumds so plainly that the listener cannot fail to interpret them aright, while its pure rich harmonies tend far moro surdy to the excitement of devotional feeling than the uarvellons combinations by means of which too many of 'I'allis's contemporaries sought to astonish their hearers, while forgetting all the loftier attributes of their art. In this noble quality of self-restraint the Litauy and Responses bear a close analogy to the Improperia and other similar norks of Palestrina, wherein, addressing himself to the heart rather than to the ear, the princeps musica produces tlie most thrilling effects by means which, to the superficial critic, appear almost puerile in their simplicity, white those who are able to look beneath the surface discern in then deptlis of learning such as none but a very highly cultitated inusician can appreciate Of this profound learning Tallis possessed an inexhaustible store; and the rich resources it opened to his genius not only placed his compositions on a level with those produced by the best of his Italian and Flemish contemporaries, but enabled him to raise the English school itself to a height which it hail nerer previously attained, and which, nevertheless, it continued to maintain undiminished untilothe death of its last representative, Orlando Gibbons, in 1625 . Though this school is generally said to have been founded by Dr Tye, there can be no doubt that Tallis was its greatest master, anil that it was indebted to him alone for the infusion of new life and vigour which prevented it from degenerating, as some of the earlier Flemish schools had done, into a mere vehicle for the display of fruitless erudition. Tallis's ingenvity far surpassed that of his most erudite contemporaries; but he never paraded it at the expeuse either of intrinsic beauty or truthfulness of expression. Like every other great musician of the period, he produced occasionally works confessedly intended for no more exalted purpose than the exbibition of his stupendous skill, one of the most remarkable characteristics of which was the apparent ease with which it disposed of difficulties that, to composers of ordinary ability, would have prored insurmountable. In his canon, Misereve nostri, the intricacy of the contrapuntal devices seems little short of miraculous; yet, so smooth and flowing is the effect produced by their dizzy involutions, that no one unacquainted with the secret of their construction would suspect the presence of any unusual element in the composition. In his motet, Spen in "lium non habui, written for forty voices disposed in eight five-part choirs, each singer is intrusted with a part, ?.rreeable and interesting in itself, jet never for a moment interfering with any one of the thirty-nine equally interesting parts with which it is associated. These tours de force, however, though approachable only by the greatest contrapuatists living in an age in which counterpoint

[^12]was cultivated with a success that has never since nezm equalled, serve to illustrate one phase only of Tallis's many-sided genius, which shines with equal brightness in the eight psalm-tunes (one in each of the first eight modes) and unpretending little Treni Creator, printed in 1567 at the end of Archbishop Parker's First Quinquagene of Metrical Psalms, and many other compositions of like simplicity.

In 1575 Tallis and his pupil William Byrd-as great a contrapuntist as himself, though by no means his equal in depth of expression-obtained from Queen Elizabeth royal letters patent granting them the exclusive right of printing music and ruling music-paper for twenty-owe years; and, in virtuc of this privilege, they issued, in the same jear, a joint work, entitled Cuntiones quæ ab argumento Sacrex vocantur, quinque et sex partium, containing sixteen motets by Tallis and eighteen by Byrd, all of the highest decree of excellence. Some of these motets, adapted to English words, are now sung as anthems in the Anglican cathedral service. But no such translations appear to have been made during Tallis's lifetime; and there is strong reason for believing that, though both be and Byrd outwardly conformed to the new religion, and composed music expressly for its use, they remained Catholics at heart to the end of their days.

Tallis's contributions to the Cantiones Sacra were the last of his compositions pablished during his lifetime. He did not, indeed, live to witness the expiration of tles patent, though Byrd survived it and published two more books of Cantiones on his own account in 1589 and $159 I_{4}$ besides numerous other works. Tallis died November 23 1585, and was buried in the parish church at Greenwich, where a quaint rhymed epitaph, preserved by Strype, and reprinted by Burney and IFawkins, recorded the fact that he served in the chapel royal during the reigns of Henry VIII., Edward VI., Mary, aod Elizabeth. This was destroyed with the old church abont 1710; and it was not until about twenty jears ago that a copy was placed in the present building. Portraits, professedly authentic, of Tallis and Byrd were engraved by Vaodergucht in 1730 , for Nicolas Haym's projected History of Mfusic, but never published. One copy only is known to exist.

Not very many morks besides those already mentioned were printed during Tallis's lifetime; but a great number are still pre. served in MS. Unhappily, it is to be fenred that many more were destroyed, in tho 17 th century, during the spoliation of the cathedral libiaries by the Puritans
(W. S. R.)

TALLOW is the solid oil or fat of ruminant animals, but commercially it is almost exclusively obtained from oxen and sheep. The fat is distributed throughout the entire animal structure; but it accumulates in large quantities as "suet" in the body cavity, and it is from such suet that tallow is principally melted or rendered. The various methods by which tallow and other animal fats are separated and purified have been dealt with under Oils (see vol. xvii. p. 743 ). In commerce ox tallow and sheep tallow are generally distinguished from each other, although much nondescript animal fat is aiso found in the market. Ox tallow occurs at ordinary temperatures as a solid hard fat having a yellowish white colour; when fresh and new it has scarcely any taste or smell ; but it soon acquires a distinct odour and readily becomes rancid. The fat is insoluble in cold alcohol, but it dissolves in boiling spirit of $0.822 \mathrm{sp} . \mathrm{gr}$. in chloroform, ether, and the essential oils. The hardness of tallow and its moltingpoint are to some extent affected by the food, age, state of health, dec., of the unimal yielding it, the firmest ox tallow being obtained in certain provinces of Fussia, where for a great part of the year the oxen are fed on hay. New tallow melts at from $42^{\circ} 5$ ta $43^{\circ} \mathrm{C}$., old tallow at $43^{\circ} 5$,
and the melted fat remains liquid till its temperature falls to $33^{\circ}$ or $34^{\circ} \mathrm{C}$ ．Tallow consists of a mixture of two－ thirds of tho solid fats palmitin and stearin，with one－third of the liquid fat olcin．A fluid oil known as tallow oil is obtained from solid tallow by the separation by pressure of the greater part of the olein．To facilitate the separation of the olein，tallow is first melted and just before resolidi－ fying it is mixed with about 10 per cent．of benzeue or petroleum spirit．The mixtura is then allowed to solidify in flat cakes or slabs，which are placed in press bags and piled between iron plates in a hydraulic press．On the application of pressure the olein inixed with the selvent hydrocarbon ${ }^{\text {fllows freely }}$ out，leaving a hard dense cake of stearin and palmitin in the bags．The velatile solvents are subsequently driven off by blowing steam through the oil，which remains a turbid fatty fluid from the proportion of solid fats it carries over with it from the bydraulic press．Tallow oil is a usefui lubricant and a valuable material for fine soap making，but it is not now abundantly prepared．Mutton tallow differs in several respects from that obtained from oxen．It is whiter in colour and harder，and contains only about 30 per cent．of olein． Newly rendered it has little taste or smell，but on exposure it quickly acquires characteristic qualities and becomes rancid．Sweet mutton tallow melts at $46^{\circ}$ and solidifies at $36^{\circ} \mathrm{C}$ ．；when old it does not melt under $49^{\circ}$ ，and be－ comes solid on reaching $44^{\circ}$ or $45^{\circ} \mathrm{C}$ ．It is sparingly soluble in cold ether and in boiling spirit of 0.822 sp．gr．

In early times tallow was a most important candle－making substance，，nd candles made from this material are still consumed in no inconsiderable quantity，but the greater proportion of the supply is now absorbed by the soap trade；thic artificial butter trade which has sprung up since 1872 also takes up large quantitics of sweet tallow．Tallow is further used extensively as a lubricant and in leather dressing，\＆c．It is of course a product of all cattle and aheep－lcaring countries，and it forms an important article of export from the United States，the Argentine Republic，and the Australian colonies．Till within the last quarter of a century Russia supplied nearly all the tallow imported into the United Kingdom；but now the imports from that source are on tlie most mearre scale，although Russian P．Y．C．（pale yellow candle）con－ tinues to represent the finest commercial brand．

TALLOWS，Vegetable．See Oils，vol．xvii．p． 746.
TALMA，Joseph Frunçors（1763－1826），French tragedian，was born at Paris 15 th January 1763．After attending the Mazarin college，he accompanied his father， who was a dentist，to Jondon，where he studied in the hospitals．While in London he took part in some amateur theatricals，and，his talents at ouce attracting notice，a pro－ fessional engagement was offered him．To this，however， his father would not consent，and shortly afterwards he was sent to Pacis，where for some years he was assistant to $\$$ dentist．His predilection for the drama could not be restrained，and on 21st November 1787 he made his début at the Comédie Française in Mahomel．His efforts from the first won appreciation，but for a considerable time ho was restricted to secondary parts．It was in jeune premier parts that he first came prominently into notice，and he attained only gradually to his unrivalled position as the exponent of strong and concentrated passion．In 1791 he and other dissentients founded the Théâtre Français de la rue do Richeiieu，－a name changed in 1792 to Théâtre de la République，where he won his most striking successes． Talma was among the earliest advocates of realism in scenery and costume，being greatly aided in his reforms by bis filiend the painter David．He possessed in perfection the physical gifts fitting him to excel in the highest tragic prorts，an admirably proportioned figure，a striking counten－ ance，and a voice of great beauty and power，which，after he had conquered a certain thickness of utterance，enabled him to acquire a matchless elocution．At first somewhat atilted and monotonous in his manner，he gradually
emancipated binself from all artificial trammels，and became by perfection of art a model of simplicity．Talma enjojed the intimacy of Napoleon，with whom he had an acquaintance before Napeleon attained greatness；and ho was a friend of Chénier，Danton，Camille Desmoulins， and other revolutionists．He mado his last appearance 11th June 1826．and died at Paris 19th October of that jear．
Talina was the suthor of Mémoires de Le Kain，precedes de Riflexians sur cet Actuer et sur l＇drt Theatral，contributed to the Collection des Memoires sur l＇Art Dramalinue：It wes published scparatcly at Paris in 1856 ，under tho titlc Riefexians de Talma sur Le Kain et l＇Art Theatral．See Memoires de J．F．Talma，érits par tui－méne，el recevillis el mis ext ordre sur les papiers de sa jamille． by Alex．Dunas（1856）．

TALMIUD signifies－（1）＂study of and instruction in anything（whether by any one else or by oneself）＂；1（2） ＂learning acquired＂；（3）＂style，system＂：${ }^{3}$ as such it is synonymous with Mishnah in its fifth signification，vol． xri．p． 503 ；（4）＂theory，＂in contradistinction to＂prac－ tice，＂＂－synonymous with Midrash in its fourth significa－ tion，vol．x xi．p． 285 ；（5）such interpretation of the Mosaic law as is apparent on the surface thereof and does not necessitate any further disquisition；${ }^{5}$（6）Boroitho，or the non－canonical Mishnah；${ }^{6}$（7）Gemarr，i．e．，the oldest com－ mentary on the canonical Misinale；（8）the texts of Mish． nah and Gemara combined，－the meaning which is the one most commonly attached to the term Talmud．Although the word Talmud is not to be found in the Bible，there can be littlo doubt that it is a classical Hebrew term，as may be seen by the analogy of Tahămun，＂supplication，＂Tan hum，＂consolation，＂\＆c．

Recensions of the Talmud．－The Talmud exists in two recensions，－the Palestinian，commonly，but by mistake， called Talmud Yerushalmi（sso below），and the Babylonian， correctly called Talmus Babli．The Talmud Yerushalmi embodies the discussions on the Mishnar（q．v．）of hundreds of doctors，living in Palestine，chiefly in Galilee from the end of the $2 d$ till about the middle of the 5 th century，whilst the Babylonian Talmud embodies chiefly the discussions on the same Mishnah of hundreds of doctors living in various places in Babylonia，such as Neharde ${ }^{\circ}$ ，${ }^{8}$
 tho studying of the Law balances them all＂）；Abolh，iv．13，7י7； （＂be circumspect as regards instruction＂）．
 not arrogant on account of his learning＂）；ef．T．B．，Pcsahim，leaf $49 a$ ；

 study prevalent in Babylonia＂）：comp．T．B．，Pesahion，34b，＂ベクココ

${ }^{7}$ See T．B．，Baba Mcsiáa，leaf $33 b$ ，and compare Rashi in loco．
－ 8 The rector of this academy was Shernuel，court physician of Shapur I．，and astronomer．Whilst his friend and fellow－pupil RAB（q．v． they both attended the lectures of the priecipal editor of the Misk． nah）excelled in the other parts of the Jewish law，Shemuel was pre－ eminent in the civil law．On account of this to is repeatedly called in the Talmud both＂Shapur＂（like bis master）and＂Aryokh＂（lion， king，teacher）．To him io duo tho legal principle that＂tho lsw of

Kaphri，${ }^{1}$ Mahuza，${ }^{2}$ Shekhansib，${ }^{3}$ but notably at the two great academies of Sura and Pumbaditha，from about 190 to nearly the end of the 6 th century．The doctors of both recensions，although they primarily discuss the correctness of the text and meaning of tho Mishnah，and what should be the right legal decisiou according to it，do not confine themselves to this．They introduce，as occasion serves， not merely the whole of the oral tradition handed down to their time，and the necessary references to，and interpreta－ tions of，the various laws to be found in the Pentateuch and the other sacred writings，but exhibit also，though only in a fragmentary manner，an almost complete cycle of the profane sciences as current orally and known to them by books composed by Jews and Gentiles．The doctors of both these recensions were and are called Amoraim
 the Mishnic doctors，who were and are called Tannain （ ${ }^{\text {NuTjM }}$ ），i．e．，＂learners，teachers，＂they abstained from inak－ ing new laws unless absolutely compelled by circumstances to do so．${ }^{5}$ These Amaraim stand，on the whole，in the same relation to their Mishnic predecessors as counsel giving a legal opinion，or judges deciding legal cases，stand to the legislature which frames the laws．In these points the doctors of both recensions agree．There are，however， also points of considerable difference between the two Tal－ muds．These are not merely geographical，and so neces－ sarily linguistic，${ }^{6}$ but also material．Whilst the discussions in the Palestinian Talmud are simpie，brief，and to the point，those in the Babylonian Talmud are subtle，long－ winded，and，although always logical，sometimes even far－ fetched．${ }^{7}$ But there is another difference．The Palestinian Talmua，besides containing legal and religious discussions， is a storehouse of history，geography，and archæology，
the civil government is the law，＂i．e．，that except io religions matters the Jew must sulmit to the laws of his country（＇T．B．，Bala Dathra， 54b）．Shemuel and Rab（like Rabbi Yohanan and Rest Lakish， Abayya and Raba，and others），though intimate friends，nevertheless differ on nearly all imagiaable point．s， 8 that when the Talmud wishes to give firmaess to a certain decision or opinion，it naes the phrase： ＂Rab aad Shemuel，\＆c．，both agree．＂

1 The rector of this school was Rab Hisda，the father－in－law of Raba（q．v．）．

2 The rector of this achool was Raba（q．v．）．
${ }^{3}$ The rector of this school was Rah Mnhmon b．Yishak（T．B．，Gittin， 31b，Rashi，catchword SJN），husband of the learned and accomplished Yaltha，the danghter of the resh galutha（T．B．，IIullin，leaf 109b），\＆c．

4 Amora may also mean an interpretcr．The great teachers of the first five centuries had gencrally a man（or several men）at their side， who to the learning requisite to translate the master＇s teaching given in Hebrew，and dilate on it in Aramaic，added a Stentor＇s voice，and could by fascinating speech command the attention of the audience． The first Bubylonian Amorc，i．c．，explainer of the Mishnah，who had su Anora，i．e．，s popular teacher，was Rabbi Shila．The first who is koown to have acted as Amora，i．e．，popular teacher，to sul Amora， i．e．，an explainer of the Mishnah，was the famous Rab（q．v．）．See ＇T．Y．，Berahhoth，iv．1，2，\＆c．；T．B．，Berakhoth，Jeaf $27 b$ ；and T．R．， Yome，leaf 200 （against Rapoport，＂Erekh Millin，s．v．＂Amora＂）．
${ }_{5}$ This certainly was not unfrequently the case，but even then they did $e 0$ only in the spirit of the Tonnaim．
－The Palestinian A moraim，teaching people who understool Greek， had not to explain the Greek terms which frequently occur in the Mish． nah and other works kindred to it．The Babylonian Anoraim，how－ ever，who in common with their hearers were ignorant of Greek，had a oomewhat irregular thougb certainly effective way（received by them traditionally）of explaioing the Greek terms in the Mishnah，\＆c．，by Aramaic etymology．We will give two instances only of this practice：
 T．B．，Baba Mesi＂a，leaf 66b，M他 אלN ן get no payment except from this，＂－evidently＝＂Np אin ins o ＂upon this thou shalt ataed，＂i．e．，＂if l do not pay，this shall aerve as my security＂；compare Rashi on Daba Kamma，11b，catchworl ＂P＇תiפN；（2）＂p＇ת’’ ia evidently the Greek $\delta / \alpha \theta \dot{\eta} \kappa \eta$ ，and is ex－
 stand when I am no more，＂i．e．，＂this is my last will and testa－ ment．＂From T．B．，Baba Bathra，leaf $135 b$（evidently a Babylouian Boroitho），we aee that in T．B．，Baba MEssi＂a，leaf 19a，three worda ＇ทコ コ1תปe ל）have fallen out． 7 Compare p．35，footnote 3.
whilst the Babyloniau Talmud，taking into consideratiou that it is treble ${ }^{8}$ the size of its fellow Talmud，contains less of these．On the other hand，it bestows more care upon the legal and religious points，and，leing the later and the more studied of the two，it is also the more trustworthy．

System of the Taland．－Most people imagine not only that the Talmuds are a pathless wilderness，without so much as grammatical rules in their respective languages，but that the laws laid down in them rest on mere tradition．In reality their languages have strictly grammatical rules（see below under Aids，dc．），and their laws rest on a strictly logical system．The laws in both Talmuds are discussed and argued on philosophical rules，for which it is claimed that they have existed from time inmemorial，and can be traced to the Pentateuch itself．These are－（1）the Seven Rules （שׂע מדות（י），put forth by Hillel（T＇osephto Synhedrin，vii．， last $\S$ ；Siphro，towards the end of the Introduction；$A$ loth de－Rabbi Nathan，xxxvii．）but a great deal older than his time；（2）the Thirteen Rules（שלש עשרה מדות），put forth by R．Yishma＇el（Introduction to Siphro），which can，how－ ever，be traced in nuce to the foregoing＂Seven Rules＂： both these are for the IIalakhah；and（3）there are also the Thirty－two Rules（שלשים וטתים טרות），put forth by R． Eli＇ezer b．R．Yose Haggalili（vol i．of most editions of the Babyloniau Talmud），which are for the Agadah．In additiou，most of the points to which these rules apply are secured by early tradition．It is quite true that by idiosyn． crasy digressions are very frequent both in Talmud and Midrash；but in the Halakhah the digression，however long，invariably ends in coming back to the original cause of the logical combiuation，whilst in the Agadah the digression either comes back to the place from which it started，or else will be found，on examination，to have been introduced for its own sake，and have served its own pur－ pose．As the doctors of Talmud and Midrash are mostly introduced in dialogues，this is the only practical if some－ what uncommon，method．

Division of the Talmud．－The external division of both Talmuds is identical with the divisiou，subdivision，and sub－subdivision of the Mishnah，although there is not aiways Gemara in the one when there is Gemara in the other．${ }^{9}$ This，however，need not be further discussed here， as all on this head is minutely specified in Misunar （q．v．）．Concerning the internal division into Halakhah and Agadah，it ought to be said that the former is more largely represented in the Babylonian Talmud，whilst the latter is more largely and more interestingly given in the Palestinian Talmud．Whole collections of Midrashim now in our hands have constituted（if we may judge from the known to the unknown）part of the Palestinian Talmud，${ }^{10}$ and seem to bave chiefly belonged to those portions of it which have bcen gradually lost．

Purpose．－The Talmud，unlike the Mishnah，contains not only individual decisions，but everything that is necessary for arriving at legal and religious decisions of whatever description these may be，whilst，like the Mishnah，it is not itself a handbook of decisions．This is only in accordance with the nature and spirit of an oral law which delegates the decisions to the Talmudico－speculative capacities of the teachers of every age．Even several of the comparatively few instances in which the words ．．＇＇כ（＂and the

[^13]decision 1．5 according to so and so＂）occur in the Babylonian T＇almud ne alater addition．They belong to the IIalakhoth Gedoloth，${ }^{1}$ and are coasequently，at the earliest，of the Sth reutury，but are probably of even much later date．
Editors．－Tie editorship of the Palestinian Talmud is generally，after Maimonides，${ }^{2}$ ascribed to Rabbi Yohanan （b．Naןl！a）．But this，if literally taken，is a gross mistake， as that teacher（ob．279）died more than a hundred years before the latest $A$ moral（c．450）mentioned in that Talmud． A similar error is made with respect to the editor，or editors of the Babylonian Talnud，whose names are given as Rab Asslii（see liab）（ob．42i）and Rabina（ob．550）， and who lived still much earlier than the last teachers mentioned in that Talnud（Sth century）．But it ought to be remembered that when the ancients speak of editors of books of such a mixed character as the Mish－ nah，the $Z$ ohar，both Talmuds，sc．，they mean the person or persons who gave the first impulse to the collection or redaction of such books．In this sense，certainly，Rabbi Yohanan was the editur of the Palestinian and Mab Asshi and Tabina were the editors of the Babylonian Talmuds． For，whilst the first of the latter pair went more than once tlurough the discussion of the whole Mishnah by the Imorain from 190 to lis time（c．427），the latter supple－ mented the collection down to his own time（550）．As regards the Babylonian Talmud，the Amoraim were succeeded by a new order of men called Saborainn（רבנן ＂סבורא），i．e．，＂opiners，＂who ventured only occasionally to revise and authenticate the sayings of their predecessers． The last of these Saboraim were Rab＇Ina（or Giza）and Rab Simona（c．550－590）．In any case neither the one Talnud nor the other was writtea down，slight private uotes excepted（מללות סתרים），before the close of the 6th century，if then．The apparently insuruountable diff． culty of keeping such vast masses of literature in the head is removed when one takes into consideration that both teacher and studeut had means of help to their memory fully corresponding to the vastness of the literature．In the first place，they had the numbers already occurring in the Mishnah（e．g．，five must not separate the heave－offering or account of the benediction to be recited in connexion with the act；Tereanoth i．1），\＆c．Secondly，they had namies．Since to the sayings of the Talmud were generally attached the names of those who nttered them，saying and name became in the inemory of the student identical．If somebody who had heard a certain saying from somebody， who in his turn bad heard it from somebody else，was mentioned in the Talmud，all other sayings，however unlike these in nature，if they had only the same link of tradition，were recited on the same occasion：e．g．，in the Palestinian Talnud，Megillah iv．1，＂sajs Rabbi Haggai， says Rabbi Shemuel b．Tal Yiṣhak，＂，\＆c．；；T．B．，Berakhoth， leaf $3 b$ ，\＆c．，＂says Rahbi Zerika，says Rabbi Ammi，says． Rabbi Yehoshua ${ }^{\circ}$ b．Levi，＂\＆c．Thirdly，other oral tradi－ tions，which went by the order of the Pentateuch，received in the written Peutateuch rast aids to memory．Fourthly， the Mishnach（althongh itself not written down），by its divisions，subdivisions，and sub－subdivisious，became，in its turn，a mighty aid to memory．Fifthly，as regards the Kalylonian Talmud，there are additional means of aiding meinory in existence，for every now and then one meets with a Arnemosynon（Siman），which strings together the order of suljects（e．g．，T．M．，Berchlhoth，32a，last line）． Both in MSS．and printed editions these Simanim are given in brackets．Rapoport and his followers would have

[^14]us believe that these mnemonc phrases are late muentions， but they have as yet failed to make gond their assertions． See T．B．，Shabbah 104 a，and T．B．，＇Erubin，54b，whero these Simanime are positively mentioned carly in the fth century ：cf．Rashi in loco．

Falue－The value of the Talınuds may be estimated by the fact that they contain the dfishuch in various recen－ sions and a large portion of the contents of Midrashic col－ lections，and in addition comprise a vast anount of Sopheric literature not to be found in the caupnical Mishalh and Agadic matter not to he found in the known Micluckshim， and have thousands of notices on secular knowledge of all kinds．Here，however，the reader ought to be again ro－ minded that，whilst the Babylouian Talnud，the one of much larger extent，contains a great deal more Judwo－ religious matter，the Palestinian Talmud－of much smaller extent－is of much greater value for the historian，the geographer，the nunismatist，and other students．

Vicissitudes of the Talmud．－Whilst the Babylonian． Talmud commanded the attention of a hostile world，and was proscribed，mutilated，${ }^{\circ}$ and condemned，and finally delivered over to the flames ${ }^{4}$ by popes and kings，the Palestinian Talmud suffered still more from one cingle enemy－neglect．${ }^{5}$ Thousands of copies of the former recension were destroyed in the course of time，but，this Talmud being studied in all parts of the world，the few copies surviving became the means of an＇endless supply． Not so as regards the Palestinian Talnud，which found no students，or but few，after the closing（c．450）of the Jewish academies in Palestine；and we have even to thank the enemies of traditional Judaisn，the Karaites，who used it in controversy with their Rabbanite opponents，for the preservation of some copies of it．By degrees the neglect of the book became so great that whole chapters of treatises， whole treatises of orders，and almost two whole orders themselves，disappeared，and are lost to this day．${ }^{6}$
Aids to the Study of lhe Tatmutds．－（a）Lexicons．－The first rank is occupied by lexicons for both Taluuds and Midrashim，and of these that by R．Nathan b．Ychiel of Rome，compiled in the 11th and 12 th centuries，claims the first place．All other lexicone，from Elias Levita，Pliilip Aquinas，Johannes Buxtorf，\＆c．，down to Levy and Jastrow，are more or less bascd upon this grand work called＇Arukh．${ }^{7}$（b）Grammars．－A slight attempt at compiling a
${ }^{3}$ Raymundus Martin（Ramon Martirez），backed up by his teacher Pablo Cristiani（see Ramban），was ons of the first five（or rather sir） mutilators（called censors）of the Talmud and kindred books．See Touron，Histoire des Hommes lllustres de l＇Ordre de Saint Dominigue． i．（Paris，1743，4to）p．492；Jour．Phitol．，xvi． 134.
${ }^{4}$ In the midsurmmer of 1244 twenty－four waggons full of Talmnd copies were burned in France（sea Joumal of Philology，svi．133）． A certain Donin（afterwards called Nicolaus），a converted Jew，by bis accusations against the Talmud，managed that Rabbi Yehiel of Paris＇ had to dispute with bim publicly about its coutents．The disputation took place in the midsummer of 1240；and R．Yehiel cama out of it so victoriously that ouly after four years＇further machinations the Talmud was actually burned．The disputation is printed under the Dama of Disputatio cum Nicolas A． 1252 （！）habita cum Versione Latina in Wagenseil＇s Tela Ignea Satunc（Altdorf，1681，4to）；a less incorrect Hebrew edition cama out in $1873,8 \mathrm{vo}$ ，at Thorn．This event of burning the Taluud called forth three elegies－（1）by $R$ ． Binyamin b，Abrabanı De＇Mausi，hegiuni－g Div תicc，and the refrain of which was הר（see MS． Add．374，Camb．Univ．Lib．，leares $307 a-308 a$ ）；（2）by R．Mifir of Rothenburg（seo Rosk），the beginning of which is どMン （in the Ashkeazic ritual for tha 9th of Ab）；and（3）by H．Abrahau b．Yiṣhak（see Zunz，Zur Gesch．u．Lit．，pp．463－4）．This A bralam b．Yishak is the father of the famous En－bonet Abrara Bederesi（not Bedarshi ；aee Schiller－Szinessy，Cotal．，i．correctiou 5），the author of the Behinoth ${ }^{\text {＇OLam．}}$

7 Rabbenu Nsthan b．Yehiel b．Abraham was，on his father＇s side an＇Anar（y）－and not an＇Akko（1כy＇）as Rapoport，no doubt after Ibn Yahya，writes it in Bikkure Haittim，x． 7 －i．e，of the family ＇Anarim（Dei Mansi，Dei Mausuett，Dei Pirtelli，Dei Pietosi，Dej
grammar，and this only for the Babylonian Talmud，was made by the late learned S．D．Luzzatto．It exists in Italian（Padua，1865）， Gernan by Kruger（Breslan，1873），English by Goldainmer＇（New York，1876），and Hebrew by Lerner（St Petersburg，1880）．Of more value，however，is Noldeke＇s Mandaitic Grammar，although it stands in connexion with the Babylonian Talraud only in an indirect wey．（c）Comntutaries．－Commentaries on the greater por－ tion of the Babylonian Talmud ara extant，by the fanous Rabbenu Hananee］of Kairwan，the teacher of Riph（q．v．），by Rashi（q．v．）， and by the descendants and disciples of this latter conimentator， who composed the Tosaphoth．All these are included in the latest Talinud edition of Vilna．It is asserted by Rabad II．（q．v．）that the whole（B．）Talmud liad been commented on in Arabic．As regards the commentaries cn the Palestinian Talmud，it ought to be said that the Pene Mosheh，\＆．c．，by R．Mosheh Margaliyyoth， and the Korban Hiedaii，\＆c，，by R．David Frankel（the teaclier of Mendelssohn），make more than one commentary on the whole，and they are embodied in the Zintomir edition（1860－67）．（d）Meihod－ ology．－Among the many Introductions to the Babylonian Talmud that of R．Shemuel Haznagid must now be considered the first， not only in time but also in value．There was indoed an earlfer， and perhaps a etill moro valuable one in existence（see SAADIA）， but it 18 now unfortunztely lost．As regards the Palestinian Talmud，the only one in existence is that by the late Z．Frankel （Breslau，1870，8vo）．The Euthor was a most learned man，but somewhat confused in his diction．（s）Translations．－Renderings of isolated treatises of the Babylonian Talmud exist in Latin， Ugolini，Thesaurus，six．，Zebahim and Menahoth，and xגv．， Synhedriu；${ }^{1}$ in French，e．g．，Berakhoth，hy Chiarini（Leipsic，1831，
Umani，Dei Umili），and，on his mother＇a sida，of the Tappuhim，i．e．， De Pomis，to which the celebrated quthor of the Lexicon Semah David belouged．Rabbenu Nathan＇s father and grandfather，like Rubbeuu Nathan himself and his brother＇s descendants，were，no doubt，papal court Jews（ond not linendrapers，as the latest editor of tbe＇Arukh， by misreading and misinterprating the aomewhat hord verses of his author，contrives to show）．This lucrative position furnished them witb ample means not only for their nobla charities to congregational insti－ tationa（a synagague，religious bath，\＆c．），but also with the leiaure aecessary for tha pursuit of Talmudic studies．Rabbenu Nathan was resh kaitah（rector of the Jewish university），and unquestionably the greatest Talmudist，even as he was the poorest Habrew poet，in Italy in the 11th and 12th centuries As regards his teacbers we know four，three of whom he attended，whilst ba atudied and digested the works of the fourth so well that，though personally unknown to one nnother，they may be justly called master and discipla．His 6rst teacher was his own fathar；bis aecond tercher，from whom Rabbenu Nathan no doubt obtained his thorough knowledga of Babylonian habits，was R．Masliah of Sicily，who had been a hearer of the greatest ＂gaon＂of Pumbaditha；his third teacher was R．Mosheh b．Ya．akob b． Slosheh b．Abbun of Nerbonae（or Toulouse；letter known under the name of R．Mosheb Haddarshan）；and the fourth was Rabbenu Han－ aneel of Kairwan．He owed so mach to this teacher that as soon as tha＂A rukh bad appeared most people took it for granted tbat Rabbenu Hananeel had lived at Rome，and accordingly called him＂a man of Rome－＇1sh Romi＇＂；see MS．Brit．Mas．Add．27，201，leaf 73b，and Tosaphoth，passim．（That Rabbenu Gershom，Rabbenu Mosheh＇Diפy， and othera were his teachers，as Rapoport，loc．cit．，asserts，is a fic－ tion．）Rabbenu Nathan，in bis＇A rukih，does not merely explain the foreign（i．e．，Aramaic，Persian，Greek，Latin，and Arabic）words occur－ ring in the Targums，Talmuds，and Midrashim，but the subject－matter alao，and thereby proves himself a donbly useful guide．In this，al． though he had been preceded by no lesa a personaga than the Gaon Semah b．Paltoi（f．870），who also composed such an＇A rulh，Rabbenu Nathan was virtually the first，as the Gaon＇s work hed been early lost．Tho assertion that the fourth of the four men captured by the Spanish admiral（see below，p．39）was R．Nethan Habbabli，that he livad in Narbonne，and that he also composed a similar＇Arukh，rests on a misunderstanding，as the quotation in the Iohusin claarly showa， The passages there given under R．Nathan Habbabli ara taken verbatim from the Arukh of our author（compare the article $\mathcal{V} \sum \mathrm{E}$ ，\＆c．）．That Rome bas been at times called in Jawish writings＂Babel，＂and that consequently Habbabli may mean＂the Roman，＂is clear from tha writings of the New Testament．We will only add here a few words concerning the biblingraphy of the book．Of the＂A rukh exist ao far teu editions，the first of which came out undated，but before or ebout 1480．The seventh edition was enriched by tba physician R．Binyamin Musaphia＇s Musaph，i．e．，Additamenta（Musaphia was a Greek and Latin acholar），and the latest edition by Dr Kobut is now in progress． As regards the MSS．of this remarkabla laxicon the best copies are to be found partly in the University Library，Cambridge（Add．376， which has all the verses of the nutbor and additamenta by R．Shemuel Ibn עDd，and Add．471－72），and partly at the Court Library，Vienns （Cod．cvi． 1 and 2）．The lattar were carried off by Napoleon I，to Paris in 1809，but in 1815 were returned to Vienna．
${ }^{3}$ Varions writers assert that tbere exist many books containing Latio translations of various treatises of the Babylonian Talmud．

8vo）；and in German，c g，Berakhoth，by Rabe（Halle，1777，4tos， regard bcing had also 1 m both to the asme treatise of the Palestinian recension，and again by Pinner（1842）；Baba Mcsi＂$a$ ，by Sammter （1876），both at Berlin and in folio；＂Abodah Zarah，by Ewald （Nuremberg，1856，8vo）；Ta＇anith，by Straschun（Halle，1883）； Dfegillah and Rosh Haschanah，by Rawicz（Frankfort－on－the－Main， 1884 and 1886）．The assertion that the whole ef this Thalmud has breen translated into Spanish has yct to be proved．As regards the Palestinian Talmud，Ugolini＇s Thcsanurus contains the following treatises in Latin ：－Pcsahim（vol．xvii．）；Shckalim，Yoma，Sulikah， Mosh Hasshanah，Ta＇anith，Megillah，Hagigah，Besth，Mo＇cd Kalan （vel．xviii．）；Ma＇ascroth，Maaser Sheni，Hallah，Orlat，Bikikurion （vol．xx．）；Synhedrin，Makkoth（vol．xxv．）；Kiddushin，Sotah， Kethuboth（vol．xxx．）．M．Sohwab（of the Bibliothique Nationale， Paris）lias undertaken a French translation of the entire Palestinian Talmud，which is now in progress；from this Ber Ri／hoth has been trauslated into English（London，1886， 4 to）．
Editions．－The editions of the Palestinian Talnud，iu what was then called its entirety，are only four：－（a）Venice， 1523 ，without any commentary；（b）Cracow， 1609 ，with a short commentary，the text apparently from a different MS．from that used for the editio princeps ；（c）Krotoschin，1866，with a short commentary differing from that of Cracom：these three editions are each comprised in one volunie；（d）the fourth edition came out at 7hitonil；with commentaries by different meц（see Commentarics above）．All theso editions are in folio．Of the editions of iselated treatisea，which are not a few，we will only mention those of Berakhoth（Vienna，1874） and Peah and Demai（Breslau，1875，both in 4 to），witl a new com－ mentary by Z．Frankel．The editions of the Babylonian Talmud are so humerous that they would reiuire soveral entire shcets for enumeration．There is in existence an approximately good treatise on them（see Varim Lectiones，vols．i．and viii．）．We will only name three of the entiro editions：－（1）the editio princeps，Venico， 1520－23，－which，though disfigured by numeroue misprints，was not mutilatel by the censer；（2）the edition of Basel（1578－81）， which omits＇Abodah Zarah altogether，and has a cheering（？）notice in Latin；${ }^{3}$（3）the latest edition，now printing at Vilna，with old commentaries hitherto unpublished．Of isolated treatises，which may be counted by more than hundreds，we will only mention one （the Portuguese of at least Berakhoth），tho existence of which was asserted in the last century（Pahad Yishak，s．v．ヘึクาภПロコ ベコンコ）， then again called in question in our own times，but positively proved by the present writer from an eally work composed at the time when but fow editions of the Talmud existed．It is the Zora Abraham（Camb．MS．Ti．6．50，leaf 59b）．Materiels for the critical editiou of the Babylonian Talmud from an ancient MS．formerly in the monastery of Pfersee，but now in the Royal Library of Munich， and other MSS．and early prints of isolated treatises in varions public and private libraries of Europe，Asia，and Africa，have been collected and are being published by Rabbinovicz．Of this import－ ant work fifteen volumes，containing the following trestises，have already come out：－the whola Serlcr Zeraim（1867）；Besah，Hagigah， Móed K̈atan（1869）；Sukkah，Ta＇anith（1870）；Rosh Hasshanah， Yoma（1871）；＇Erubin（1873）；Pcsahim（1874）；Shabbath（1875）； Mcgillah，Shekalim（1877）；Synhedrin（1878）；Abodah Zarah， Makleoth，Shebuioth，Horayoth，＇Eduyyoth（1879）；Baba Baihra （1881）；Baba Kamina（1882）；Baba Mesi＂a（1883）；Zebahim（1884）； Menahoth（1886）．All these were printed in 8ro and at Munich． except vol．ix．，which came out at Mainz．

Influence of the Talmud．－It must be admitted by every critical student of history that the Talmud has not merely been the means of keeping alive the religious idea among the Jew＇s，but has fornied their strongest bond of union． When，after the fall of the city of Jerusalem and its temple， and the expatriation of the Jews from Palestine，a goodly portion of the Mosaic law lost its application，the Talmud became the spirit which put fresh life into the letter which
Upon examination these books turn out to contain either a transla－ tion ouly of Mishnic treatises with or without excerpta from，and with or without schalia on，Gemara，or disputations wbich introduca omall piaces of Gemara．Tbe utmost they contain is a chapter or two translated from Gemara itself（as，for axample，＂Edzard，Aboda Sara，＂ \＆c．，Hamburg，1705－10 4 to which containg Gemara of the first two Perakim）．
${ }^{2}$ The paging of this has been followed in all subsequent editions．
－Nunc ab omnibus iis quæ contra religionem Christianam facie． bant recogaitum，at juxta mantem Sacri concilii Tridentini expurga－ tum et approbatum，ut non modo citra impietatem verum etiam cnm fructu a nostris legi possit．
＊The notes in the first fourteen volumes go under the name of D＇רפา． 7 7，whilat those of the fifteenth volume have tha title of Dהาבバ 71ゴ，in memory of the late Abrabam Merzbacher，who not merely proved the Mrecenas of this publication during his lifetime， but left a coosiderable sum for its continuation and completion．
had become to a great extent dead Moreover, by the Talmud, the interpretation of which was chiefly in the hands of the academies of Sura and Pumbaditha, the Jews of all the world found, if not a new Jerusalem, at least a new Yabneh (Jamnia), i.e., a place where the old learning was not merely continued, but made to shine with a yet greater eplendour. This fact will be the more readily acknowledged and appreciated when one casts a glance at the miserable religious condition of the Karaites, the so-called Scriptural Jews.

T'ransference of Talmudic L̈earning from the Enst to the West.-There naturally came $\varepsilon$ time when Talmudic learning, if it was to maintain its influence upon the Jews, could not be confined to one spot. We have secn under Rashi (q.v.) that the great emperor of the West (Charlemagne) had been the means, torrards the close of the 8th century, of bringing learned Talmudists not only to Provence but to the north of France and the south of Germany. ${ }^{1}$ But when nearly two hundred years later the academies of vabylonia were threatened with extinction (because of their lacking, from varions causes, the means of subsistence), so that they had to send out members of their body to supplicate the support of their richer brethren in other countries, it providentially happened that the four men whom they sent were taken by a Spanish corsair admiral and sold in four different slave-markets. Rabbi Shemaryah was sold at Alexandria, and was redeemed by the Jews, and great was their astonishment when they recognized in him a most able Talmudist. He became the head of the Cairo community, and one of the most successiul Jewish Talmud teachers Egypt ever had. Rabbi Husshiel was taken to Kairwan, in Africa. There the Jews redeemed him ; and when his great learning was found out he was named the spiritual head of the Jews in that place. From the school which he founded sprang not merely his own son, the famous Rabbenu Hananeel, but also the great Rabbenu Nissim, hath teachers of Ripy (q.v.) Another learned captive, R. Mosheh, was brought to the slave-market of Cordova, the rabbi of which town, a noble and rare example of unsel Gishness, modesty, and love of truth, placed the ragged stranger who had only been ransomed for charity's sake a day or so before at the head of the community instead of himself. The name of the fourth is unknown (see Rabad II., and Yohasin, ed. Cracorr, leaf 125l). Some assert that he was R. Nathan Habbabli, and that he became the teacher of the Jews in Narbonne, but this is a mere conjecture, the truth of which has yet to be proved (see page 37, footnote ${ }^{\circ}$ ). Be this, however, as it may, four great Talmodists, who had come direct from the Babylonian acadcmies, becane the means of bringing Babylonico-Talmudic learning, to places the Jews of which had been dependent on the religious and literary crumbs that fell from the richly-laden tables of Sura and Pumbaditha. Some years afterwerds the former acadcmy was closed, and a short time afterwards the same fate befcll that of Pumbaditha, the sunset of which, if not the noonlight, in the persons of Ilab Sherira Gaon and his son Rab Hai Gaon was even more glorious than that of the sister academy, the last "gaon" of 'which was Rab Shemuel b. Hophni, father-in-law of Rabbenu Har. Meanwhile, however, Talmotic learning had not merely become naturalized, but eventually indigenous in rarious parts of Africa, and part of Europe (Spain, Italy, Provence, the south of Germany, ard the north of Francc). Rabbenu Gcrshom b. Yehudah of Mete and his disciple Rabbenn Tishak of Troyes, Rabberu Ia'akol b. Yakar of Worms, Rabbenu Eliezer Haggadol and his disciple and successor Rabbenu rishak Sezan Leviyyal, Rabbenu Yishak b. Tehudah of Mainz,

[^15] talned her teachers direct fron Irak.

Rabbenu Elyakin of Spires, Rabbenu Nathan b. Yehiel of Rome, and last but not least Rashi himoelf, and his sons-in-law and other disciples, represented Talmudic learning in such perfection as had not been found before as regards the Babylonian Talmud, even in the land of its birth and growth. It was the disciples' disciples of these men who studied and taught in various towns of England within a hundred years ( 1150 ) after the Conquest. When, towards the end of the 13th century and the commencement of the 14th, the Jews were driven out of England (1290) and France (1306), and flocked chiefly to Italy, Greece, Germany, and Poland, the last-named country appropriated the lion's share of Talmudic learuing, so that till within our own centary the rabbis of the clief communities in Hungary, Moravia, Bohemia, and other Austrian states, and in Germany, Holland, England, \&c., had to be fetched from Poland. Talmudic learning, since Mendelssohn and his school arose, threatened to die out not merely among the Jervs in Germany, but also among those of the other countries where the Jews syoke the German tongue in some form or other. Within the last twenty-five years, however, fresh impulse has been given to these studies, not merely among Jewe but also among Christians.
(s. м. s.-s.)

TAM, commonly called Rabbent Tam, more correctly
 known two eminent Rablinic scholars, both named YA'AROB, to whom this epithet was given in allusion to Genesis xxy. 27: "And Jacob was a perfect man" (Ish Tam, 唃 UN). They belonged to the north of Frunce, lived in the 12th century, and avere master and pupil.

1. Ribbenu Ya'akob b. Meir b. Saemuel was, on his mother's side, a grandson of Rashi (g.v.). He was his parents' third son, younger brother of Ribam and Rashbac (q.v.), older brother of Rabbenu Shelomoh of Rameru, ${ }^{2}$ and brother-in-law of Rabbena Shemuel b. Simhah of Vitry the younger ${ }^{3}$ (the reputed author of the Mali:or Fitry, ${ }^{4}$ now apparently lost ${ }^{5}$ ). Fabbenu Than had, like his grandfather Rashi, six teachers:-(1) his own father, (2) his brother Ribam, (3) his brother Rashbam, (4) Rabbenu Ya'akob b. Shimshon, ${ }^{6}$ (5) his grandfather Rashi, ${ }^{7}$ and (6) Rabbenu Yoseph Tobe Elem the younger. ${ }^{8}$ Rabbenu Tham bad at least five children. ${ }^{9}$ The names of three of his sons were Yoseph, ${ }^{10}$ Yislhak, ${ }^{11}$ and Shelomoh. ${ }^{12}$ Rabbenu Tham was unquestionably among Jews the foremost man of his age. For not only was lie the greatest Talmudist after his maternal grandfather's death, but he also added reading wide and varied to a stupendous memory and a marvellou 3

power of comhination, sucl as appeared only again in the last century in the persons of R. Yelonathan Eybenschütz ( 0 ). 176t) and R. Yehezkel Landau (ob. 1793). Let us add that he was a lexicographer, grammarian, and Biblical rommentator of no inean order; that ho was a poet in Hebrew and Aramaic ${ }^{1}$ inferior only to Ibn Gebirol (Avicebron. $q$. 0. .), Mosheh Ibn 'Ezra, and Yehudab Hallevi (and by far greater in this art than the commentator, Abrahanı 1 bn ${ }^{\text {'E Era }}$ ): : that he was held in high esteem by prince and nobles; ${ }^{2}$ and that he was a man of great wealth, with which he generously supported, not merely his own poorer hearers, but other itinerant scholars also. ${ }^{3}$
His works are the following:-
(1) Commentary on Job, and, no donbt, ou other rarts of the Pible (sea Camm. Univ. Lib. MiS. Dd. 8. 53 , leaves $1 b, 4 a, 11 a$, 12b). All these are apprarently now lost. (2) Hakhridioth, i.e., lexical and grainmatical decisions between Ienateen lbo Seruk and Dunash L. Labrat (see Scrher Testuboth Dunizash b. Labrat, Ediuburgh, 1885, $8 \mathbf{0} 0$ ). That these "decisions" are really by Rahbenu Tham is proved by the before-named MS., leaves $10 a$ and $16 a$, where the book is quoted ly an suthor of the 13th century. (3) Sepher Hayyashur (Vienna, 1810, folio). Although this work, in its present forn,1, is the compilation of one of Ralbenu Than'a disciples, R. Yishak b. Durbal ly name (also called Isanc of Russia; see Schiller-Szinessy, Cuttatogue, i. p. 164, and ii. p. 66), not only ia the foundation Rabbenu Tham's (sea Preface), but the contents also are virtually his. Compare the Cambridge MS. Add. 667. 1, passim. (4) The grester part of the Tosaphoth in the Babylonian Talmud are indirectly also by Rablenu Tham ; and he is virtually the first Tosaphist. It is true that liis tather, his brother Kashbam (q.v.), and his nncle Rabbenu Yeluudah b. Nuthan had written Tosaploth before him, and that this kind of literary activity lasted to within the first quarter of the 14 th century. Still, loost and the best of the Tosaphoth now in our hands rest on Rallbenu Tham and his school. (5) Malcor', i.e., a prayer-book, \&c., for the whole year, with Rabbinic ordinances, \&c. See Tosaphoth on T. B., Borukhoth, leaf 37a, catchword DDIza, and Birekhoth Mruhnareun of R. Meir b. Barukh of Rothenburg (Riva di Trento, $1558,8 \mathrm{vo}$ ), leaf $4 \pi$. (6) Pocms. These are partly dilactic and partly liturgical," Of the former kind a specimen will be foumd ("On the Accents," communicated by Halberstam) in Kobak's Yeshurun, v. D. 125 sq. The liturgical poenis, gaviin, are of tivo kinds: (a) such ns have no metre and rhyme only by means of plurals, possessive pronouns, and such like (rliymed prose), and which perfectly resemble most of the productions of the FrancoAslhkenazic school (see, for example, the facsimile in Muller's Cata. logue, Amsterlanin, 1868, 8vo); (b) anch as lave metre and rhyme, and resemble the productions of the Seplaradic seliool, c.g., the one beginniug " 102a). (i) Parious ordinances, \&c., are to be found in later writers (see IIS. Add. 667, in Cambridge, passim, end Teshuboth Maharam, Prague, 1608, folio, \& 1023, \&c. .). Rabbenu Thanı died in 1171 ; see Rashi's Siddur, ii (furneerl) Luzzatto's, then Halberstam's, and now the property of the master of St John's College, Cambridge), leaf $48 a$.
10. Rabbent Tacakob of Orleans, rabbi of London (3). He is often quoted in the Toscphoth (both on the Pentateuch and on the Babylonian Talmud). No independent works of his, however, are extant. He was killed at London in the tumult on the coronation day of Richard Cceur-de-Lion (September 3,1189; Schiller-Szinessy, Catal., i. p. 117).
(s. M. S.-s.)

TAMLAQUA, a borongh of Schuylkill county, Pennsylvania, United States, in a broken, hilly country, upon the

[^16]Little Schuylkill river, 98 miles nearly north of Phidadelphia. It is in the midst of the anthracite coal region, and coal mining is one of its priacipal interests. It is an important railroad centre, upon the Philadelphia and Reading system, being the point of intersection of three main lines and the terminus of several minor branches. The borough had a population of 5960 in 1870 and of 5730 in 1880.

TAMARIND. This name is popularly applied to the pods of a Legnminous tree, which are hard externalls, but within filled with an acid juicy pulp containing sugar and various acids, such as citric and tartaric, in combination with potash. The acid pulp is used as a laxative and a refrigerant, the pods being largely imported both from the East and the West Indies. The tree is now widely distributed in tropical countries, bat it is generally considered that its native country is in eastern tropical Africa, from Abyssinia southward to the Zambesi. Sir Ferdinand von Mueller notes that it is truly wild in tropical Australia. The name (meaning in Arabic "Indian date") shows that it entered inedieval commerce from India, where it is used, not only for its pulp, but Ior its seeds, which are astringent, its leaves, which furnish a yellow or a red dye, and its timber. The tree (Tamazindus indirc, $\mathrm{L}_{\text {. }}$ ) attains a height of 70 to 80 feet, and bears elegant pinnate foliage and purplish or orange veined flowers arranged in terninal clusters. The flower-tube bears at its summit four sepals, but only three petals and three perfect stamens, with indications of six others. The stamens, with the stalked ovary, are curved away from the petals at their base, but are directed towards them at their apices. The antherd and the stigmas are thus brought into such a positiou as to obstruct the passage of an insect attracted ly the brilliantlycoloured petal, the inference of course being that insecta are necessary for the fertilization of the flower.

TAMARISK. The genus Tamurix gives its name to a small group of slrubs or low trees constituting the tamarisk family. The species of tamarisk and of the very closely ailied genus Myricaria grow in salt deserts, by the sea-shore, or in other more or less sterile localities in south temperate, subtropical, and tropical regions of the eastern hemisphere. Their long slender 1 ,ranches Lear very numerous small appressed leaves, in which the evalorating surface is reduced to a minimam. The thowers are minute and numerous, in long clnsters at the ends of the luranches or from the trunk. Each has t-6 free sepal.3, and as many petals springing with the $4-12$ stamens from a fleshy disk. In Tamurix the stamens are free, while in Myricaria they are united into one parcel. The free ovary is onecelled, with basal placentas, and surmounted by $3-5$ styles. The fruit is capsular, and contains numerous seeds, each usually with a long tuft of bairs at one end. The great value of these shrubs or trees lies in their a Lility to withstand the effects of drought and a saline soil, in consequence of which they grow where little else can lourish. It is on this account that the common tanarisk, T. gallice, is planted on our sea-coasts, and affords shelter where none other could be provided. The light feathery appearance of the branches, and the pretty rose-coloured flowers, render it also an elegant and attractive shrub, very different-in character from most others.

Some species produce galls, valued for their tannin, while the astringent bark of others has been valued for medicinal purposes. The ashes of the plant, when grown near the sea, are said to contain soda : but, when cultivated inland or on sweet soil, they are, it is alleged, free from soda.

For tamarisk manna, see Manna, vol. xv. p. 193.
TAMBOFF, one of the largest and moit fertile governments of central Russia, extends from north to south between the basins of the Oka alid the Dor, and las

Vladimir and Nijni-Novgorod on the N., Penza and Saratoff on thie E., the Don Cossacks and Voronezh on the S., Tula and Ryazañ on the W. It consists of an undulating plain intersected by deep ravines and broad valleys, ranging between 450 and 800 feet above sea-level. Chalk and Jurassic deposits, thickly covered by boulder-clay and loess, are widely spread over its surface, concealing the ${ }^{\circ}$ underlying Devonian and Carboniferous deposits. These last appear only in the deeper ravines, and seams of coal lave been noticed at several places. Iron ore (in the north-west), limestone, clay, and gypsum are obtained for building and manufacturing purposes; traces of naphtha have been discovered at Tamboff. The mineral waters of Lipetsk, similar to those of Franzensbad in their alkaline clements, and chalybeate like those of Pyrinont and Spa ${ }_{2}$ are well knowu in Russia. Tamboff is watered by the tributaries of the Oka and the Don. The Oka itself only touches the north-west corner of the government, but its tributaries, the Moksha. and the Tsna, are important channele of traffic The Don also only towches Tamboff, and of ite affluents only the Voronezh and the Khoper and its tributary the Vorona are at all navigable. As a whole, it is only in the north that Tamboff is well watered; in its southern part, which is exposed to the influence of the dry south-eastern winds, the want of moisture is much felt, especially in the district of Borisoglyebsk, which belongs to the dry ateppes of the lower Volga.

The climate is continentel, and, although the average tempere. ture at Tamboff is $42^{\circ} \mathrm{F}$., the winter is comparatively cold (Jannery, $13^{\circ}$; July, $68^{\circ}$ ). The rivers remain frozen for four monthe eud a half. Forests occupy less then one-sixth of the total area, and occur chiefly in the west; in the eouth-east wood is acarce, and atrew is resorted to for fuel. The soil is fertilo throughout; in the north, indeed, it is clayey and sometimes sandy, but the rest of the goveroment is covered with a aheet, 2 to 3 fect in thickness, of the most fertile tchernozem, of such richness, indeed, that in Borisoglyebsk corn-fields which have not bean menured for eighty years still yiald good crops.

Tamboff is one of the densely peopled provinces of Russie. Its population in 1883 reached 2,519,600, and in several districts (Kozloff, Lebedyañ, Lipatsk) there are from 110 to 130 inhsbitants per square mile. It is creat Russian in thic centrel portion, but has a notable admixture of Mondviniana (q.. .) and Mescheriake in the west and north-west, as also of Tsrtare: the Mordiviniane (who ere rapidly becomirig Russified; constitute 4 per cent. of the aggregate population of Tamboff; the Tartars numocr about 20,000, and the Mescheriaks about 4000. Nenconformity is widely apread, although the official figures disclose caly 14,500 Rasko!niks, Notmithstanding a high birth-rate ( 45 in the thousand), the annusl increase of population is but slow ( 0.5 ver ceat. anamally).

The pravailing occupation is egriculture, and in 1883 only 168,200 pereone had their reaidence in towns, which ere mostly thamsolves nothing but large villages of egriculturists living tegether, with a few merchents. More than two-thirds of the area is areble, and of this proportion 58 per cent. belongs to peassut communities, 36 per cent. to privats individuals, and 11 por cent. to the crown. The crops of the years 1883 to 1885 yielded on the average $8,885,000$ quartars of grain (helf being rye, and onc-third oats). Corn is exported to $e$ considerable extent from the eouth, dlthough it is deficient in the north. Homp and linsced ere also cultivated for exportation. The cultivation of tobacco is yearly increasing: 5220 ecres were under this crop in 1885 , end yielded nearly 50,000 cwts. In the samb year 15,950 acres were under beetroot, and yielded . 1,660,000 iwts. Cattle-breeding, thcugt less extensively carried on than formerly, is atill inportent ( $850 \hat{0}, 300$ horess, 399,500 horned cattle, and 1,326,600 sheep in 1883). Excellent breeds of horses are met with, not only on the lerger estates, but also in the herds of the wealthier peasants, those of the Bityug river bning most esteemed. Mannfactures are rejresantad chiefly by distillerics, tallow-malting works, sugar-works, and a few woollencloth mills. The petty trades are not very extensivaly carried on in the villages. Commerce is very brisk, owing to tho large amounts of corn exported, -Kozloff, M orehansk, Tambođt, and Borisoglyebsk baing the chief centres for this traffic, and Lebedyañ for the trado in horees end cettle. Tamboff is rathor hackwerd educationally: in 1883 there were only 629 schools, attonded by 34,739 boye and 5680 girls. The government is divided into twolve districts, the ohief towns of which, with their populations in 1884, are Tamboff (34,000 inhabitants), Borisogly obsk ( 13,000 ), Elatma (7560), Kirz3noff (7770), Kozloff (27,900), Lebodyañ (6250), Lipotsk (15, 860),

Morahansk (21,200), Shetsk (7260), Spassk (5010), Temnikoff (13,700), and Usmañ (8110 in 1880). A distiuctive feature of Tannboff is its vary lerge villages of crown-peasants, a dozen of which have from 5000 to 7000 iuhabitants each. Several of them-like Reskazoro (a great centre of Nonconformity), Atabukhi, Sasovo, lzberdai, ead Arklangelskoye-are important commercial centres.
The region now included in the uorth of the govermment was settled by Russians during the cerliest centuries of the principality of Moscow, but until the end of the 17 th century the fertile tracts to the couth remained too iusecurs for settlers. In the following contury a few immigrants began to coms in fiom the steppe, and lendowners who hed recsived large grants of land as gifte of the czars Liggari to bring their aerfs from ceutra! Russia. ' 'lie popula. tion has very rapidly incrcaeed within tha present century.

TAMBOFF, capital of the above government, 300 miles distent from Moscow, is situated on the Tsas river, and on the railway from Kozloff to Saratoff. It is almost entirely buill of wood, with broad unpaved streets, lined with low houses aurrounded by gardens. It has a small public library, a theatre, and this few cducational institutions which are usual in the chief towns of Russian provinces. Its marnufi ctures are insignificant ; and its trade, in local grais and in cattle purchased in the south and sent to Moscow, is far less impcritant than that of Morshansk or Kozloff. The population in 1884 was 34,000 .
Tamerlane. See Timur.
TAMILS. The word Tamil (properly Tumil) has been identifed with Dravida, the Sanskrit generic appellation for the South Indian peoples and their languages; and the various stages through which the word has passedDramida, Dramila, Damila-have been finally discussed by Bishcp Caldwell in his Comparative Grammar of the Dravidian Langiages ( 2 d ed., 1875 , p. 10 sq.), and the derivation has recently been endorsed by Col. Yule and Dr Burnell in their Glossary. (p. 251b). The identification was first suggested by Dr Graul (Reise nach Ostindien, vol. iii., 1854, p. 349), and then adverted to by Dr G. U. Pope (Tamil Handbook, 1859, Introduction) and Dr Gundert (Malayalma Dictionary, 1872, s.v.). It should, however, be mentioncd that the former prefers now to take the word Tamil to be a corruption of tenmoli, southern speech, in contradistinction to vadugu, the northern, i.e., Telugu language. As in the case of the Kafir, Turkish, Tagala, and other typical languages, the term Tamulic or Tamulian las occasionally been employed as the designation of the whole class of Dravidian peoples and languages, of which it is only the most prominent member. The present article deals with Tamil in its restricted sense only.
The Tamils, taken as the type and representatives of the Dravidian race, do not now, owing to early intermixture with the Aryan immigrants, materially differ in physical character from the other curly-haired indigenous population of 1ndia. They were at one time, on the ground of the general structure of their language, classed with the Mongoloid (Turanian, Scythian) and even the Australian races, but that classification is rejected by all the leading ethnologists. They form, in fact, with the other members of the group, a separate and distinct family, which is of the dolichocephalic class, and comes near the IndoEuropean or Aryan type; while there are scattored remuants of a still carlier population of India (Mundas, Kolarians), whose race characteristics, however, do not so essentially differ from those of the Dravidians as to constitute them a class by thenselves. The Tamils proper are smaller and weaker-built than the Europeans, though more graceful in shape. Their physical appearance is described as fillows:- a pointed and frequently hooked pyramidal nose, with conspicuous nares, more long than round; a marked sinking in of the orbital line, producing a strongly defined orbital ridge; hair and eyes black; the latter, varying from small to middle-sized, lave a peculiar aparkle and a look of calculation ; mouth large, lips thick
and frequently turgid; lower jaw not heavy, its lateral expansion greater than in the Aryan and less than in the Turanian type, giving to the middle part of the face a marked development and breadth, and to the general contour an obtuse oval shape, somewhat bulging at the sides; forehead well-formed, but. receding, inclining to flattish, and seldom high; occiput somewhat projecting; beard considerable, and often strong; colour of skin very dark, frequently approaching to black (Manual of the Administration of the Madras Presidency, Madras, 1885, vol. i., Introd., p. 36 ; see also Caldwell, Comparative Grammar of the Dravidian Languages, 1875, pp. 558-79). The Tamils hare many estimable qualities,-frugality, patience, endurance, politeness,-and they are credited prith astounding memories; their worst vices are said to be lying and lasciviousnebs. Of all the Soutl-Indian tribes they are the least sedentary and the most onterprising. Wherevel money is to be earned, there will Tamils be found, either as merchants or in the lower capacity of domestic servants and labourers. The tea and coffee districts of Ceylon are peopled by about 800,000 ; Tamils serve as coolies in the Mauritius and the West Indies. In Burmah, the Straits, and Siam the se-called Klings are all Tamils (Graul, Reise nach Ostindien, Leipsic. 1855, vol. iv. pp. 113-212).

Languuge.-The area over which Tamil is spoken extends from a few miles north of the city of Madras to the extreme south of the cestern side of the peninsula, throughout the country below the Ghats, from Pulicat to Cape Comorin, and from the Gháts to the Bay of Bengal, including also the southern portion of Travancore on the westeru side of the Ghats and the northern part of Ceylon. According to the census of 1881, the number of Tamil-speaking people throughout the province was 12,413,517, inclusive of 21,992 Yerkalas, 3843 Kurumbas, und 287 Irulas, three tribes speaking rude dialects of the language. To these should be added about 160,000 in the French possessions. But, as of all the Dravidian languages the Tamil shows the greatest tendency to spread, its area becomes ever larger, encroaching on that of the contiguons languages. Tamil is a sister of Malayâlma, Telugu, Canarese, Tulu, Kudagu, Toda, Kôta, Góñ, Ǩhond (Ku), Urâon, Râjmahâl, Keikâdi, and Brahuî, the nine last-naned being uncultivated tongues; and, as it is the oldest, richest, and most inghly organized of the Dravidian languages, it may be looked upon as typical of the family to which it belongs. The one nearest akin to it is Malayâlma, which originally appears to hase been simply a dialect of Tamil, but differs from it now both in pronunciation and in idiom, in the retention of Old-Tamil forms obsolete in the modern language, and in having discarded all personal terminations in the verb, the person being always indicated by the pronoun (F. W. Ellis, Dissertation on the Malayalma Language, p. 2; Gundert, Malayalma Dictionary, Introd. ; Caldwell, Comparative Gir., Introd., p. 23 ; Burnell, Specimens of South Indian Dialects, No. 2, p. 13). Also, the proportion of Sanskrit words in Malayâlma is greater, while in Tamil it is less, than in any other Dravidian tongue. This divergence between the two languages cannot bo traced farther back than about the 10 th century; for, as it appears from the Cochin and Travancore inscriptions, previous to that period both languages were still substantially identical; whereas in the Ramacharitam, the oldest pocm in Malayâlıa, composed probably iu the 13th century, at any rate long before the arrival of the Portuguese and the introduction of the modern character, we see that language already formed. The modern 'Jamil characters originated "in a Brahmanical adaptation of the old Grantla letters correaponding to the eo-callcd Vatteinttu," or round-hand, an
alphabet once in vogue throughout the whole of the Pindyan kingdom, as well as in the South Malabar and Coimbatore districts, and still sparsely used for drawing up conveyances and other legal instruments (F. W. Elhis, Dissertation, p. 3). It is also used by the Mappilas in Tellicherry. The origin of the Vatteluttu itself is atill a controverted question. The late Dr Burnell, the greatest authority on the sulject, has stated his reasons for tracing that character through the Pehlevi to a Semitic sonrce (Elements of South Indian Palxography, 2d ed., 1858, pp. 47-52, and plates zvii. and xxxii.). In the 8tl century the Vatteluttu existed side by side and together with the Grantha, an ancient alphabet still used throughout the Tamil country in writing Sanskrit. During the four or five centuries after the conquest of Madura by the Cholas in the 11th it was gradually superseded in the Tamil country by the modern Tamil, while in Malabar it continmed in general use down to the end of the 17 th century. But the earliest works of Tamil literature, such as the Tolkappiyam and the Kural, were atill written in it. The modern Tamil characters, which have but little changed for the last 500 years, differ from all the other modern Dravidian alphabets both in shape and in their phonetic value. Their angular form is said to be due to the widespread practice of writing with the style resting on the end of the left thumb-nail, while the other alphabets are written with the style resting on the left eide of the thumb.
The Tamil alphabet is sufficiently well adapted for the expression of the twelve vowels of the langugge $\left(a, a, i, \frac{\hat{\delta}}{2}, u, \ell, e, \ell, 0,0, e i, a u\right)$, -tbe occasional sonads of o and $u$, both alort and loug, being covered by the signs for $e, \ell, i, \ell$; bnt it is utterly inadequate for the proper expression of the consonents, inasuuch as the one charseter $k$ hes to do duty also for $k h, g, g h$, and similarly each of tho other surd consanants $\mathrm{ch}, f, t, p$ represents also the remaining three letters oi its respective class. The letter $k$ has, besides, occasionslly the eonnd of $h$, and ch thst of $s$. Esch of the five consodsuts $k, c h, t, t, p$ has ita own nasal. In sddition to the four semivowels, the Tamil possesses a cerebral $t$ and $h$ and has, in common with the Malayalma, retained a liquid $l$, once peculiar to sll the Dravidias languages, the sound of which is 60 dificult to fix graphically, and varies so much in different districts, that it bas been rendered is a dozen different way: (Manual of the Alininistration of the Madras Presidency, vol. ii p. 20 sq ). Fr. Muller is probably correct in spproximating it ts thas of the Bohemisn $\overline{7}$. There is, lastly, a pecularar $n$, differing in function but not in pronunciation from the dental $n$. The thren sibilants and $h$ of Ssaskrit have no place in the Tamil alphabet but ch often does duty ss a sibilant in writing foreign words, auc tho four corresponding letters as well as $j$ and $k$ sh of the Granths alphabot are now frequently called to sid. It is obrious thal many of the Sanskrit words imported into Tamil at various periodr (Csldwell, loc. cit., Introd., pp. 86 sq.) have, in consequence of the incongruity of the Sanskrit and Tamil notation of their respective phonetic systens, assumed disguises under which the originsl is scarcely recognizahle: examples are ulagı (loks), uruvam (rûpa), arıhkiken (arka), arputam (adbhutam), natchattiram (nakshs tram), irudi (rishi), îrkam (dírgbs), arasen (rajann). Besides the Ssnskrit ingredients, which appear but aparsely in the old poetry, Tamil has borroved from Hindustani, Arsbic, and Persian a large nnmber of revenue, political, and judicial terme, and more recenily a good many Englisb words have crept in, such as tiratfi, treaty, pallar, butler, akt, act, kulob, club, kazaraar; goveroor, pinnathodus, pensl code, stikiu, sick, megastiraltu, magistrate. But, as compared with its literary sister languages, it has preserved its Dravidian character singulsrly frce from foreign influence. Of Tamil words which bave found a permanent home in English may be mentioncd curry (kari), mulligatawny (milagu, pepper, and kunkr, cool water), cheroot (suruitu), parıh (parayon).
The laws of elphony (avoiding of hiatas, softening of initial cousonants, contact of final with initial cousonants) are far more comphicated in Tamil than in Sanskrit. But, while they wore rigidly adlered to in the old poetical language (Sen-Tamil), there is a growng tendency to peglect them in the language of the present day (Kodun-Tamil). It is trne the Tamil rules totally differ from tho provailing Sanskrit; still the probability is in favour of a Sanskrit infuence, inasmuch as they appear to follow Sapskrit molels. Thus, irul nikzinda becomes irunitheinan; pon pattiram, porpullirum; rilfit kanden, vilfit kandin; valsirumei, salsirumez, palars landin, yalanrandan. Nouns are divided into high-casto
or personal and low-caste or impersonal, -the former compriaing words for rationsl beings, the latter all the rest. Only in highcaste nouns a distinction botween masculine and feminine is observed in the singular; both bave a common plural, which is indieated by change of a final $n$ (feminine l) into $r$; but the neuter plural termination kal (gal) may be ouperadded in every case. Certain nouns change their base termination before receiving the case affixee, the latter being the same both for singular and plural. They are for the acc. ei, instr. al, social odu (odu, udan), dat. ku, loc. il (idallil, in), abl. ilirundu (inintu), gen. udciya (adu). There is, hesides, a general oblique affix in, which is not only frequently used for the genitive, but may be inserted before any of the above affixes, to some of which the emphatic particlo c may aleo be superadded. In the old poetry there is a atill greater variety of affixes, while there is an option of disjensing with all. $\Delta d j e c t i v e s$, when attributive, precode the noun and are unchangeable; when predicative they follov it and receive verbal affixes. The pronouns of the 1st person are eing. $n d n$ ( $y A n$ ), inflexional base en, plural ndm (yam), infl. nam, including, nangal, infl. cngal, exclading the person sddrossed; of the 2 d person $n$; infl. un (nin, nun), plural nir (niyir, nivir), ningal, infl. um, ungal (num). To each of those forms, inclusive also of the reflexive pronouns tan, tsm, tangal, a place is assigned in the acale of hovorific pro. nouns. As in the domonstrativo pronouns tho forms beginoing with i indicate pearness, those with a distance, and (iu the old poetry) those with of what is between the two, oo the same forms beginaing with $e$ (or $y d$, as in $y a r, d r$, whol) express tho interrogative. The rerb consists of three elements-the ront (generally reducible to one syllable), the tease characteristic, and tho personal affix. There are three original moods, the indicative, imperative, and infinitive (the $2 d$ singular imperative is generally identical with the root), as well as three original tenses, the present, past, and future. The personal affixos are-sing. (1) etn; (2) - $\boldsymbol{a}_{y}$, honorifie © ; (3) masc. - $a n$, fem. -dl, honor. - Ar, neuter -adi6; plural (1) - Cm (- $\left.2 m_{3}-\ell m\right)$; (2) -\{rkal; (3) mase. fens. Arkal, weut. -ana. These affxes serve for all verbs and for each of tho three tenses, except that, in the future, -adu and -ana are replaced by $-\imath / m$ ( $k k u m$ ). It is only in the formation of the tenses that verbs differ, intransitive verbs gonerally indicating the present.by $-k t r-(-k i n r-)$, the past by -d., -nd-, or $\cdot i n$, and the future by $\cdot v=\left(-z_{-}\right)$, and transitive verbs by the corresponding infixes, $-k$ kir $\cdot(-k$ kinr -$),-\ell \cdot(-n d-)$, and $\cdot p p-$; but there are numeraus exceptions and aeemingly anomalous formations. Other tenses and moods are expressed with the aid of special affixes or auxiliary verbs. Czusal verbs are formed by variaus infixes (-ppi-, $-v i-, \cdot \ell u-)$, and the passive by the auxiliary padu, to fall, or by $u n$, to eat, with a noun. The following four pecul. iarities are charactoristic of Tamil :-first, the tenseless negative form of the verb, expressed by the infix $\alpha$, which is elided bafore dissimilar vowels; second, the predicative employnent of two negetipe particles illei and alla, the one denying the existeace or presence, the other denying the quality or essence; third, the use of two sets of participles,-one, called adjective or relative participle, which supplies tho place of a relative clauso, the language possessing no relative pronouns, and an ordiuary adverbial participle or gerund; and, fourth, the practice of giving adjectives a verbal form by means of personal affixes, which form may again be treated as a noun by attaching to it the deciensional terminations, thus: periyns, great ; periyon, we are great ; periydinukku, to us who are great. The old poctry abounds in verbal forms now obsolete. Adjoctives, adverbs, and abstract nouns are derived from verbs by certain affixes. All post-positions were originally cither nouns or vorbal forms. Oratio indirecta is unknown in Tamil, as it is in all the other Indian languages, the gerund enru being used, like iti in Sanskrit, to indicate quotation. The structure of sentences is an exact counterpart of the structure of words, inasmuch as that which qualifies always precedes that which is qualified. Thus the attributive precedes the aubstantive, the substautive precedes the preposition, the adverb precedes the verb, the secondsry clause the primary one, and the verb closes the sentence. Th.s sentence, "Having called the woman who had killed the child, lie askod why ehe had committed such infauticide," runs in Tamil as follows:Kolandelyel ksonrupottavelel alclppittu an un ippadt The child her who hed killed liering cansed to be called, "Thnu why thus ppstita elst.v-attl eeydty enra kittin.
Much as the similarity of the structure of the Tamil and its oister languages to that of the Ugro-Tartar class may hare proved suggestire of the assumption of a family affinity between the two classes, such on affinity, if it exist, must be held to be at least very distant, inasmuch as the assumption receives but the faintest shade of support from an intercomparison of tho radical and leset variable pertion of the respectivo languages.

Literature. -The early existence, in southern India, of peoples, localities, animals, and products the names of whieh, as mentioned in the Old Testament and in Greek and Roman writers, bave been identified with correspond.
ing Dravidian terms goes far to prove the high antiquity, if not of the Tamil Ianguage, at least of sume form of Dravidian speech (Caldwell, loc. cil., Introd., up. 81106; Midras Districl Manual, i., lutrod., p. 13 ! sq.). But practically the earliest extant records of the Tamil language do not ascead higher than the middle of the 8 th century of the Christian era, the grant in possessiou of the Israelites at Cochin being assigned by the late Dr Burnell to about 750 A.D., a period when Malayâlma did not exist yet as a separate language. There is every probability that about the same time a number of Tamil works sprung up , which are mentioned by a writer in the IItb century as representing the old literature (Burncll, luc. cit., ! $] 27$, note). The earlier of these may have been Saiva books; the more prominent of the others were decidedly Jaina. Though traces of a north Indian influence are palpable in all of them that have come down to us (see, e.y., F'. W. Elljs's notes to the Kural), we can at the same tine perceive, as we must certainly appreciate, the desire of the authors to oppose the influence of Jrahmanical writings, and crcate a literature that should rival Sanskrit books and a!peal to the sentiments of the people at larise. But the refinement of the poetical language, as adapted to the genius of Tamil, has been carried to greater excess than in Sanskrit; and this artificial character of the so-callcd High-Tami! is evident from a comparison with the old inscriptions, which are a reflex of the language of the people, and clearly show that Tamil has not undergone any essential change thicse 800 years (Burnell, lac. cil., p. 142). The rules of IIighTamil appear to have becn fixed at a very early date. The Tolkappiyam, the oldest extant Tamil grammar, is assigned by Dr Burnell (On the Ainelra School of Sunstrit Grounmarictus, pp. 8,55 ) to the Sth century (best edition loy C. Y. TAmodaram Pillei, Madras, 1885). The Virasúliyam, another grammar, is of the IIth century. Both have been superseded by the $N$ anuı̂l, of the 15 th century, which has exercised the skill of numerous commentators, and continues to be the leading native authority (English editions in Pope's Third Tamil Grammar, and an abridgment by Lazarus, 1884). The period of the prevalence of the Jainas in the Pandya kingdom, from the 9 th or lotb to the 13 th century, is justly termed the Augustan age of Tamil literature. To its earlier days is assigned the Naladiyâr, an ethical poem on the three objects of existence, which is supposed to have preceded the fiural of Tiruvalluran, the finest poetical production in the whole range of Tamil composition. Tradition, in keeping with the spirit of antagonism to Brabmanical influence, says that its author was a parial priest. It consists of 1330 stanzas on virtue, wealtl, and pleasure. It has often beer. edited, translated, and commented upon; see the introduc. tion to the excellent edition, just publisbed, by the Rev. Dr Pope, in which also a comprehensive account of the peculiarities of High-Tamil will be found. To the Arrei, or Matron, a reputed sister of Tiruvalluvan, but proliably of a later date, two sborter moral poerns, called $A$ tiisudti and Konreivêyndan, are ascribed, whicb are still read in all Tamil schools. Chintamani, an epic of upwards of 3000 stanzas, which colebrates the expluits of a King Jivakan, also belongg to that early Jain period, and so does the Divakaram, the oldest dictionary of classical Tamil. The former is one of the finest poems in the language; but no more than the first and part of the third of its thirteen books have been edited and translated. Kamban's Rimdyanana (about 1100 A.D.) is the only other Tamil epic which comes up to the Chintamani in poetical beanty. The most brilliant of the poetical productions which appeared in the yeriod of the Saiva revival (13th and lith centuries) are two collections of hymns addressed to Siva, the one called Timuâsakam, by Mânikka-Vâsakan, and a later and larger
one called Tivaram, by Sambandhan and two other devotees, Sundaran and Appan. Both these collections have been printed, the former in one, the latter in five volumes. They are rivalied both in religious fervour and in poetical merit by a contemporaneous collection of Vaishnava hymns, the Nelayira-prabandham (also printed at Madras). The third section of it, called Tirwáymoli, or "Words of the Saored Mouth," has lately been published in Telugu character8, with ample commentaries, in ten quartos (Madras, 1875-76). After a period of literary torpor, which lasted nearly two centuries, King Vallabha Deva, better known by his assumed name Ativirarâma Pâṇ̣iyan (second half of the 16 th century), endeavoured to revive the love of poetry by compositions of his own, the most celebrated of which are the Neidadam, a somewhat extravagant imitation of Srî Harsha's Sanskrit Naishadham, and the Verrivêrkei, a collection of sententious maxims. Thongli he had numerous followers, who made this revival the most prolific in the whole history of. Tamil literature, none of the compositions of every kind, mainly translations and bombastic imitations of Sanskrit models, have attained to any fame. An exceptional place, however, is occupied by.certain Tamil sectarians called sittar (i.e., siddhas or sages), whose mystical poems, especially those contained in the Sivavakyam, are said to be of singular beauty. Two poems of high merit, composed at the end of the 17 th century, also deserve favourable notice-the Nitinerivilakkam, an ethical treatise by Kumâragurupara Desikan, and the Prabhulingalilei, a translation from the Canarese of a famous text-book of the Vira-Saiva sect. See the analysis in W. Taylor's Catalogue, vol. ii. p. 837-47.

The modern period, which may be said to date from the beginning of the last century, is ushered in by two great poets, one native and the other foreign. Tayumânavan, a philosopher of the pantheistic achool, composad 1453 stanzas ( $p d d a l$ ) which have a high reputation for sublimity both of sentiment and style; and the Italian Jesuit Joseph Beschi (d. 1742), under tlıe name Viramâmuni, elaborated, on the model of the Chintdmani, a religious epic Tembavani, which, though marred by blemishes of taste, is classed by native critics amang the best productions of their literature. It treats of the history of St Joseph, and has been printed at Pondicherry in three volumes, with a full analysis. English influence has here, as in Bengal and elsewhere in India, greatly tonded to create a healthier tone in literature both as to stylo end sentiment As one of the best Tamil translations of English books in respeci of diction and idiom may be mentioned the Batarydparikal, or "Little Merchants," published by the Vernacular Text Society, Madras. P. Percival'e collection of Tamil Proverbs (3d od., 1875) should also be mentioned. The copper-plate grants, commonly called sasanams, and stone inscriptions in Tamil, many of which have been copied and translated (Archaological Survey of Southern India, vol. iv.; R. Sewell, Lists of the Antiquarian Remains in the Presidency of Mradras, vols. i., ii.), are the only authentic historical records. (See also Sir Walter Elliot's contribution to the Iuternational Numismata Oricntalia, vol. iii. pt. 2.) As early as the time of the Chinese traveller Hwen Tsagg, hooks were written in southern India on talipot leaves, and Albiruni mentions this custom as quite prevalent in his time (1031).. It has not died ont even at the present day, though paper imported from Portugal has, during the last three centuries, occasionally been used. Madras is now the largest depository of Tanil palm-leaf MSS., which have been described in Wilson's Catalogue of the Mackenzie Collection (Calcutta, 1828, 2 vols.), W. Taylor's Catalogue (Madras, 1857, 3 vols.), and Condaswamy Iyer's Catalognc (vol. i., Madras, 1861). The art of printing, however, which was introduced in southern India at an early date, while it has tended to the preservation of many valuable productions of the ancient literature, has also been the means of perpetuating and circulating a deal of literary rubbish ond lasciviousness which would much better have remained in the comparatively safo obscurity of manuscript. Dr Burnell has a nate in bis Elements of South Indian Paleography (2d ed., p. 44), from which it appears that in 1578 Tamil types were cut by Father João de Faria, and that a hundred years later a Tamil and Portnguese dictionary was published at Ambalakkâdu. At present the number of Tamil books (inclusive of newspapers) printed annually far exceads that of the other Dravidian vernaculars put togetber. The earliest Tamil version of the New Teatament was commenced by the Dutch in Caylon in 1688; Fabricius'e translation sppeared at Tranquebar in 1715. Since then many now
translations of the whole Bible have been printed, and eome of them have passed through several editions. The German missionary B. Ziegenbalg was the first to make the study of Tamil possible in Europe by the publication of his Grammatica Damulica, which appeared at Halle in 1716. Some time later the Jesuit father Beschi devoted much time and Iabour to the composition of grammars both of the vulgar and the poetical dialect. The former is treated in his Grammatica Latino-Tamulica, which was written in 1728, but was not printed till eleven years later (Trsnquebar, 1739). It was twice reprinted, and two English translations have been published (1831, 1848). Hia Sen-Tamil Grammar, accessible since 1822 in an English translation by Dr Babington, was printed from his own D1S. (Clavis humaniorum litterarum sublimioris Tamulici idiomatis) at Tranquebar in 1878. This work is especially valuable, as the greater portion of it consiats of a learned and exhaustive traatise on Tarnil prosody and rhatoric. (See, on his other works, Graul's Reise, vol. iv. p. 327.) There are also grammars hy Anderson, Rhenius, Graul (in vol. ii. of his Bibliotheces Tamulica, Leipsic, 1855), Lazarus (Madras, 1878), Pope (4th edition in three parts, London, 1883-5), and Grammaire PrancaiseTamoule, by the Abbe Dupuis, Pondicherri, 1863. The last two are by far the best. The India Office library possesses a MS. dictionary and grammar: "par le Rév. Père Dominique" (Pondicharri, 1843), and a copy of a MS. Tamil-Latin dictionary by the calebrated missionary Schwarz, in which 9000 words are explained. About the like number of words are given in the dictionsry of Fabricius and Breithaupt (Madras, 1779 and 1809). Rottler²s dictionary, the publicaticas of which was commenced in 1834, is a far more ambitious work. But neither it nor Winslow's (1862) come up to the atandard of Tamil scholarship; the Dictionnairs Tamoul-Francais, which appeared at Pondicherri in 2 vols. (185562), is superior to both, just as the Dictionariucm Latino-GallicoTamulicum (ibid., 1846) excala the various English-Tamil diction. aries which have been published at Madras.

(R. R.)

TAMWORTH, a municipal borough and market-town of England, on the borders of Stafiordshire and Warwickshire, chiefly in the former, is situated at the junction of the Tame with the Anker, and on branches of the London and North-Western and Midland Railway lines, 7 miles south-east of Lichfield, 20 north-west of Coventry, and 110 north-west of London. The castle, situated on a height above the Anker near its junction with the Tame, is now chiefly of the Jacobean period, but is enclosed by massive ancient walls. It was long the residence of the Saxon kings, and, after being bestowed on the Marmions by William the Conqueror, remained for many years. an important fortress. Through the female line of the Marmions it has doscended to the Marquis Townshend. Formerly the town was surrounded by a ditch called the King's Dyke, of which some trace still remains. The church of St Editha, originally founded in the 8th century, was rebuilt, after being burned by the Danes, by Edgar, who made it collegiate, but the present building in the Decorated style was erected after a fire in the 14 th century. Since 1870 it has been undergoing restoration at a cost of £10,000. The free grammar school, refounded by Edward VI., was rebuilt in 1677, and again in 1867-68 at a cost' of $£ 3000$. The other public buildings are the swimming bath and boys institute (1885), the town-hall (1701), and the arcade, formerly used as a covered market, but recently obtained by the Salvation Army. The charities include Guy's almshouses, endowed in 1678 by Thomas Guy, founder of Guy's Hospital, London, and the cottage hospital with twenty-one beds. Waterworks have recently been erected at a cost of over $£ 25,000$. On the "moors" burgesses have rights for cattle. Coal, fireclay, and blue and red brick clay are dug in the neighbourhood; and there are also market gardens. The town possesses a clothing factory, paper-mills, and manufactories of small wares. The population of the municipal borough (area

200 acres) in 1871 was 4539 , and in 1881 it was 4891 , that of the parliamentary borough (area 11,602 acres) in the same years being 11,493 and 14,101 . Tamworth ceased to be a parliamentary boraugh in 1885.

Tamworth is situated near the old Roman Watling Street, and occupies the site of a fort which, from the beginning of the 8th century, was the chief royal residence in Mercia. The town, after being burnt by the Danes, was rebuilt and fortified by Ethelfeda, daughter of Alfred the Great. From the reign of Edward the Martyr to that of William Rufus it was a royal mint, and come of the coins struck at Tamworth are still in existence. The torm was incorporated in the 3d year of Elizabeth, from whom it obtained the grant of 3 fair and tho confirmation of various privileges bestowed by Edward 111. The Elizabethan charter was superseded by one conferred by Charles II., which continued to be the governing charter of the towa till the passing of the Municipsl Act. The town, with occasional intermissions, returned members to parlia. ment from the reign of Heary 1. till 1885. Among its more distinguished representatives have boon Thomas Guy and Sir Robert Peel.

TANAGER, a word adapted from the quasi-Latin Tanagra of Linnæus, which again is an adaptation, perhaps with a classical allusion, of Tangara, used by Brisson and Buffon, and said by Marcgrave (Hist. Rer. Nat. Brasilix, p. 214) to be the Brazilian name of certain birds found in that country. From them it has since been extended to a great many others mostly belonging to the southern portion of the New World, now recognized by ornithologists as forming a distinct Family of Oscines, and usually considered to be allied to the Fringillidx (cf. Finch, vol. ix. p. 191); but, as may be inferred from Prof. Parker's remarks in the Zoological Transactions (x. pp. 252, 253, and 267), the Tanagridx are a "feebler" form, and thereby bear out the opinion based on the examination of many types both of Birds and Mammals as to the lower morphological rank of the Neotropical Fauna as a whole (cf. Birds, vol. iii. p. T43).

The Tanagers are a group in which Mr Sclater has for many years interested himself, and his latest treatment of them is contained in the British Muscum Catalogue (xi. pp. 49-307). Therein ho almits the existence of 375 species, which be arranges in 59 genera, forming six Subfamiliss, Procniatine, Euphoniinæ, Tanagrinæ, famprotinx, Phanicophilinse, and Pityline. Theso are of very unequal extent, for, while the first of them consists of but a single species, Procnias tersa, - the position of which may be for several reasons still open to doubt, - the third includes more than 200. Nearly all are birds of emall eize, the largest barely exceeding i Song-Thrush. Most of them are remarkable for their gaudy oolouring, and this is especially the case in those forming the genns called by Mr Sclater, as by most other suthors, Callistc, a term inatinissible through preoccupation, to which the name of Tanagra of right scens to belong, while that which bo names Tanagra should probably be known as Thraupis. The wholo Family is almost confined to the Neotropicsl Region, and there are geveral forms peculiar to the Antilles; but not a tenth of the species reach even southern Mexico, and not a dozen appear in the northern part of that country. Of the genus Pyranga, which has the most northern range of all, three if not four opecies are common summer immigrants to some part or otber of the United States, and two of them, $P$. rubrca and $P$. . stiva, - there known respectively as the Scarlet Tanager and the Summer Redbird,-resch even the Dominion of Cansda, visiting as well, though accidentally, Bermuda. P. æstiva has a westera representativo, P. coopcri, which by some authors is not recognized as a distinct species. The males of all these are clad in glowing red, $P$. rubra having, bowever, the winge sud tail bleck. The remaining species, $P$. ludoviciana, the males of which are nostly yellow snd black, with the head only red, does not a ppear eastward of the Missouri plains, and Lis not so northerly a rango. Another species, $P$. lepuica, has just shewu itself within the limits of the United States. In all these the femalcs are plainly attired; but generally among the Tanagers, however bright may be their coloration, hoth sexcs are nearly slike in plumage. Little has been recorded of the habitg of the epecies of Central or South America, but those of the north have been as closely observed ss the rather retiring nature of the birds renders possible, and it is known that insects, cspecially in the larval condition, and berries afford the greater part of their food. They have a pleasing song, and buill a ohallow nest, in which the eggs, cenerally 3 in number and of a greenish-blue marked with brown aud purplo, are laid.

On a whole the Tanayrids may perhaps be considered
to hold the same relation to the Fringillids as the Icterila do to the Sturnidx and the Mniotiltidæ to the Sylvidæ or Turdidx, in each case the purely New-World Family being the " feebler" type.
(A. N.)

TANCRED (d. 1112), son of the marquis Odo the Good and Emma the sister of Robert Guiscard, one of the most famous heroes of the first crusade. See Crosades, vol. vi. p. 624 sq.

TANCRED, the last Norman king of Sicily, reigned 1189-1194. See Sicily, vol. xxii. p. 26.

TANGANYIKA, a lake in East Central Africa, called Msaga ("tempestuous") by the Wakawendi and Kimana by the Warungu. The meaning of the mame Tanganyka is, according to Cameron, nothing more than "the mixing place." It is the longest freshwater lake in the world being about 75 miles longer than Lake Michigat. Although the Arabs had long known of the existence of the lake, the first Europeans who discovered it wcre Speko and Burton in 1858. It has since been visited by Living* stone, Cameron, Stanley, Thomson, and Hore, who have all added to our knowledge of it. Tanganyika, which is situated some 600 miles as the crow flies from the east coast of Africa, extends from $3^{\circ} 16^{\prime} \mathrm{S}$. Iat. to $8^{\circ} 48^{\prime} \mathrm{S}$. lat., and lies between $29^{\circ} 10^{\prime} \mathrm{E}$. Iong. and $32^{\circ} 30^{\prime} \mathrm{E}$. long. Its length is 420 miles, and its breadth varies from 10 to 50 miles. Its area is 12,650 equare miles, and its altitude may be taken as 2700 feet above sea-level (Cameron, 2710 ; Stanley, 2770; Hore, 2750 ; Popelin, 2665). It has a coast-line of 900 miles in extent. Its greatest depth has not yet been determined, but Hore ctates that a 168 -fathom rope often failed to reach the bottom. Tanganyila may be described as an enormous crevasse. It is bordered on all sides by hills and mountains, some of which rise to from 5000 to 10,000 feet above its waters. The scenery is marked by exceptional grandeur, and is well calculated to impress the traveller. Burton bays:-
"It filled us with armiration, with wonder, and delight. Beyond the ehort foreground of rugged and precipitous hill-fold, down which the footpath painfully zigzzgs, a narrow plot of emerald green shelpes gently towards a riblon of glistening yellow sand, here bordered by sedgy rushes, there clear and cleanly cat by the breaking wavelets. Farther in front etretches an expanse of the lightest, eftest blue, from 30 to 35 miles in breadth, and sprinkled by the east wind with crescents of snowy foam. It is hounded on the other बide by tall snd broken walls of purple bill, flecked and capped with pearly mist, or standing sharply pencilled against the azure sky. To the soath lie high bluff headlands and capes; and as the eyo dilotes it falls on little outlying islets, speckling a sea horizon. Villsges, cultivated lands, the frequent canoes of the fishermen, give a something of Jife, of variety, of movement to the scensry."

Tanganyika is fed by numerous rivers and streamlets which flow from the surrounding hills, the yearly rainfall being about 27 inches, but the rainy seasons vary extremely in different years, altering the ourface area of the lake accordingly. Hore found that between March 1879 and August 1880 the waters had fallen . 10 feet $4 \frac{1}{2}$ inches, as marked by a water-gauge he had erected at Újiji, and he also saw evident signs of the receding of the waters all round the sheres of the lake-belts of dead timber and bleached rock. Some 120 rivers and streams flow into the lake; the most important river is the Malagarasi, near Ujiji. Just below the rapids its width is 500 feet, and the average depth 5 feet. For many years Tanganyika was a riddle to African explorers,-Livingstone, Baker, and others believing that it belonged to the Nile system, and that it was connected with the Albert Nyanza. That this theory is incorrect was proved when Livingstone and Stanley explored the north end of the lake in November 1871, finding no outlet. It was Cameron, in March 1874, who first solved the riddle, and found that the outlet of Tanganyika was the river Lukuga, at about the centre of the western shore of the lake, $5^{\circ} 52^{\prime} 45^{\prime \prime} \mathrm{S}$. lat. In 1876
this outlet was visited by Stanley, who found that there was no apparent outlow, and doubt was thrown upon Cameron's observations, which, however, have been proved to bo correct by Hore, who in 1880 found a strong current setting unequirocally out of the lake. Not ouly so, but he obtained good views of the river, which gradually widens soon after the rapids near the lake are passed. He followed the river to $5^{\circ} 50^{\prime} \mathrm{S}$. lat., and, from an altitude of 1100 feet above the river, he saw it flowing far away to the westward. The question is therefore settled that Lake Tanganyika belongs to the Congo system, but it is only an occasional tributary to that mighty river, its contribution depending upon the rainfall. The lake is subject to frequent storms, especially from the S.S.E. and S.T., lasting sometimes for two or three days, and Jeaving a heavy swell, which proves a great hindrance to navigation. Hore says -"I have never witnessed such wondrous cloud-scenery and majestic effects of thouder and lightuing as on Tanganyika."
The shores and water of the lake abound in animal lifo,-crocodiles, the hipponotamus, otters, aud many kinds of fish being found in its waters. Flocks of waterfowl abound in the river mouths: fulls, divers, berons, kingfishers, eagles, fish-hawks, and black ibis are very numerous. The shores are very fertile, -rice, manioc, kaffre corn, two kinds of ground nuts, maize, uleysi, pumpkins, smeet potatocs, sugar-cane, castor-oil tree, tamariind, cotton, tomato, ${ }_{\text {and }}$ patcucanber growing luxuriantly. The oil palm grows at Ujijii, Urundi, and at the southe end of the lake, tive borassus near the Malagarasi river, the screvw palm in Uguha, and the raphra in aeveral localities. The tzetse fly is found on the shores of the lake from Ujiii round the southern end as far as Ubwari on the west coast. A Inongst the useful timber trees may be noticed the gigantic mbule, the nininga, lignum vitex, and ebony. The pcople inhabiting the counties on the borders of the lake form ten distinct tribes, nith separate national peculiarities ond customs. They live in well-organizell rillares, in which considerable social order is maintainel. They have also learnt, to some extent at any rate, to utilize the products of their country: they work their "wni iron end copper ; salt is prepared for barter ; palm oil is collected; and in some places there are large pottery works. Their fishing industry is extensive, and dried fsh is exported; boathuilding is carried on to a small extent ; cotton cloth is manufactured at several places, and at others the fannous grass or palm-fibre cloth; whilst the dairy farms of Uhha export packages of butter. There are eeveral London Missionary Society stations on Lake Tanganyika, aliso one belonging to the Roman Catholics; and a station of the African International Association is situated at Karema. Ujiji, an Arab town of some importance, stands on the eastern shore of the lake.
TANGIERS, or Tavgier (Tanja), a seaport of Morocco and capital of a pashalik, on the Strait of Gibraltar, about 14 miles to the east of Cape Spartel, stands on two eminences at the north-west extromity of a spacicus bay. The town has a fine appearance from the sea, rising gradually in the form of an amphitheatre, and defended by walls and a castle. The streets, which are unpared, are very narrow and crooked, and the houses, except those occupied by foreign ambassadors or consuls and a few others, are mean. The main thorouglfare is that which leads from the Bab-al-Marsa (Gate of the Port) to the Bab-al-Sok (Gate of the Market Place) ; the sol presents a lively spectacle, especially on Sundays and Thursdays The manufactures of Tangiers are of little importance, consisting chiefly of coarse woollen cloth, mats, and pottery; tanning is also carried on, but the leather, thongh much esteemed in Europe, is inferior to that made in other parts of Morocco. The harbour is a mere roadstead, but it is the best Morocco possesses, and affords good anchorage and shelter to the largest vessels, except during the prevalence of strong winds from the north-west or east. Tangiers Las a large trade with Gibraltar. The climate is temperate and healthy, but the inhabitants often suffer much in summer from deficiency of water-supply. Tangiers, which is the residence of all the foreign ministers ana consuls to the court of Moroceo, has a population estimated at about 20,000 , of whom some 400 are Europeans.

The Roman Tingis, which stood in the immediate vicinity of the site of Tangiers, boastel of great antiquity; under Augustus it became a free city, and Claudius made it a Roman colony and capital of Tingitana. It was held successively by Vandals, Byzantines, and Arabs, and fell into the hands of the Portuguese towards the end of the 15 th century. In 1662 it was made part of the domry of Catherino of Braganza on ber marriage rith Cbarles 11. of England; the English defended it in 1680, but, on account of its expense, dismantled it in 1684 and abandoned it to the Moors, who fortified it anew. It was bombarded by a Spanish flect in 1790 and by the French in 1844.

TANEÄUSER, or TANNHÄUSER, the subject of one of the most famous of old German legends, is represented as a knight who after many manderings comes to the Venusberg. He enters the cave where the Lady Vcnus holds her court, and abandons himself to a life of sensual pleasure. By and by he is overcome by remorse, and, invoking the aid of the Virgin Mary, ho obtains permission to return for a while to the onter world. He then goes as a pilgrim to Rome, and entreats Pope Urban to secure for him the forgiveness of his sins. The pope, who happens to have a rod in his hand, says it is as impossible for him to be pardoned as for the rod to blossom. Tanhäuser therefore departs in despair, and returns to the Lady Venus. In three days the rod begins to put forth green leaves, and the pope sends messengers in all direc tious in search of the penitent; but he is never seeu again. This legend was at one time known in every part of Germany, and as late as 1830 it survived in a popular song at Entlibuch, a version of which was given by Ubland in his Alle hoch- und niederdeutsche Volhssieder. It cau be traced back to the 14th century, but in ite original form seems to have bclonged to the period of Teutonic paganism. According to some legends, the Venus berg is the Hoselberg or Hörselberg, a hill near Eisenacb associated with the Teutonic goddess of the nether world, who was known by various names, such as Hulda, Hilda, and Hel. To this goddess the name of Venus appears to have been transferred. Among the attendants of Hulda was the faithful Eckhart, and in the preface to the Heldenbuch he is said to sit before the Venusberg, and to warn passers-by of the dangers to which they may be exposed if they linger in the neighbourhood. The legend has been reproduced by several modern German poets, and forms the subject of one of Wagner's operas.

In the 13th century, contemporary with Pope Urban IV., there was a Gerınan knight called Tanhäuser, who was well known as a minnesinger at the court of Frederick II., duke of Austria. After Duke Frederick's death Tanhäuser was received at the court of Otho IL, duke of Bavaria; but, being of a restless disposition, and having wasted his fortune, he spent much time in wandering about Germany. He also went as a crusader to the Holy Land. His poems (printed in the second part of the Minnesinger, edited by Von der Hagen) are fresh, lively, and graceful, but lack the ideal tone which marks the writings of the earlier minnesinger. He was much esteemed by the meistersinger, and it is possible that the story of his adventurous life may have been connected with the old legend about the Vennsberg.
See Kornmann, Nons Veneris (1614), and Grässe, Die Sage vomo Ritter Tanhauser, and Der Tanhauser und Ewige Jude; also Zander, Die Tanhäuser Sage und der Miinnesänger Tanhäuser.
TANJORE, a district of British India, in the Madras presidency, lying between $9^{\circ} 50^{\prime}$ and $11^{\circ} 25^{\prime} \mathrm{N} .1 \mathrm{lat}$. and between $78^{\circ} 55^{\prime}$ and $79^{\circ} 55^{\prime}$ E. long., with an area of 3654 square miles. It forms a portion of the Southern Carnatic, and is bounded on the N. by the river Coleroon; which separates it from Trichinopoly and South Arcot districts, on the E. and S.E. by the Bay of Bengal, on the S.TF. by Nadura district, and on the W. by Madura and Trichinopoly and Pudukotta state. Tanjore
is known as the garden of Southern India. It is well watered by an elaborate system of dams, cuts, and canals in connexion with the rivers Canvery and Coleroon, and the soil is exceedingly productive. The delta of the Canfery occupies the flat northern part, which is highly cultivated with rice, dotted over with groves of cocoa-nut trees, and densely populated. Tanjore is a land of temples, many of them being of very carly date. The great temple of Tanjore city is said to be the finest in India; it is of the llth century, and remains in excellent preservation to the present day. The district has a coast-line of 140 miles, but communication with shipping is unsafe, owing to a heary surf which breaks incessantly on the shore. The rainfall, as elsewhere on the Coromandel coast, varies considerably from ycar to year; the mean annual fall, as observed at ten stations for four years, was $47 \cdot 14$ inches. Tanjore is amply provided with means of communication. It is traversed by two branches of the South Indian Railway.
The census of 1881 returned the population of the district at $2,130,383$ (males $1,020,52 \mathrm{~S}$, females $1,103,855$ ), of whom $1,939,421$ were Hindus, 112,058 Johammedans, and 78,255 Christians. Tanjore is the frst district in which Protestant missions began, and new it is eecond only to Tinnevelly in the number of its Christian misaions. These cstahlishments were taken over in 1826 hy the Society for the Propagation of the Gospel, which subsequently founded missions in eeveral parts of the district. The quently number of native Protestants belonging to tha various societies in 1881 was 8255 . Romau Catholic missions in Tanjore dete from the first half of the 17 th century, and the number of native Roman Catholics in 1881 was 67,745 . Five towne have populatious ex. ceeding 10,000 , viz, Tanjore (sce below), Negapatam 53,855 , Comhaconnm 50,099 , Majavarara 23,044 , aud JIunnargudi 19,40 .
Or the total area of the district, reckoned at $2,392,117$ acres, 1,468,500 were returned in 1884-85 as cultivated, aud 149,228 os aral, ahlo for cultivation, while forests covered 21,422 acres. Rice is the stap!e crop, and is raised almost entirely by artificial irrigation; green crops are common; plantain and Letel-vine gardens abeund in the delta, where eugar-cane and tobacco are also cultivated. The chief manufactures are metal wares, silk cloths, carpets, ond pith-work. Imports consist chiefly of cotton piece goods, twist and yarn, metals, timber, and hatel nuts. Rice is by far the most important article of export alike by sea and land. The gress reveune in 1884-85 was $£ 549,982$, the land rielding $£ 389,755$.
The medern history of Tanjore commences with its occupation by the Mahrattas in 1678 under Venkaji, the brother of Sivaji the Great. The Britial first came inte contact with Tanjore by their expedition in 1749 with a view to the restoration of a deposed rajia In this they failed, and a subsequent expeditiou rras bought off. The Blahrattas practically hclil Tanjore until 1799. In October of that jear it was ceded to the East India Comprany in absolnto sovereignty by Rajaí Sharabhoji, pupil of the missionary Schwartz, the company engaging to pay the rajus of Tanjore one-fifth of the net revenne of the territory which was transferred to them, with a further sum of $£ 35,000$. Rajá Sharabhoji retaincd only the capital and a small tract of country aronnd. He died in 1833, and was succeeded by his ren Sivaji, on whose death in 1855 without an heir the house became extinct, the rignts and privileges apiertaining to it ceased, and Tanjore becane British territory.

TANJORE, capital and administrative headquarters of the above district, is situated in $10^{\circ} 47^{\circ} \mathrm{N}$. lat. and $79^{\circ}$ $10^{\prime} 24^{\prime \prime}$ E. long. As the last capital of the ancient Hindu dynasty of the Cholas, and in all ages one of the chief political, literary, and religious centres of the south, the city is full of interesting associations. Its monuments of Indian art and early civilization are of the first importance. Besides its great temple, the city is Iamed for its artistic manufactures, including silk carpets, jewellery, repoussé work, copper wares, \&c. It contained a population in 1881 of 54,745 ( 26,272 males and 28,473 females). The South Indian Railway connects Tanjore with Negapatam, its seaport on the east, and Trichinopoly on the west.

TANNAHILL, ROBERT (17T4-1810), one of the most popular of the successors of Burns in song-writing, was a weaver in Paisley, where he was born in 1774 . He was apprenticed to his father's trade at the age of twelre, in the year of the first publication of the poems of Burns, which quickened the poetic ambition of so many Scottish youths in humble life. The young apprentice studsed and
composed poetry as he drove the shuttle to and fro, with shelf and ink-bottle rigged up on his loom-post. Apart from bis poetry, he had littlo variety in his life. He was shy and reserved, of small and delicate physique, and took little part in the vigorous social life of the tomn, beyond sitting and smoking at a club of local worthies, and occasionally writing humorous verses for their amusement. He had apparently but one love affair, the heroine of which was the original of "Jessie, the Flower of Dunblane." He bade her farewell in indignant rhymes after three years' courtship. The steady routine of his trade was broken only by occasional excursions to Glasgow and the land of Buras, and a year's trial of work at Bolton. He began in 1805 to contribute verses to Glasgow and Paisley periodicals, and published an edition of his pocms by subscription in 1807. Three years later the life of the quiet, gentle, diffident, and despondent poet was brought by his own act to a tragic end. Tannahill's claims to remembrance rest upon half a dozen songs, full of an exquisite feeling for nature, and 8 n happily wedded to music that their wide popularity in Scotland is likely to be enduring. "Loudon's Bonnie Woods and Braes," "Jessie, the Flower of Dunblane," and "Gloomy Winter's Noo Ara" are the best of them.
Tannalill's ceatenary was celebrated with great bonour at Prisley in 1874; and, in au edition by Mr David Semple, published in 1876, there is an exhaustive and minutely les rned account of all that bas been preserved concerning tha poet, his ancestry, and the occasions of his various noerns.

TANNIN, a generic name for a class of vegetable substances which, as the name indicates, are all available for tanning, meaning the conversion of animal hide into leather. Tarnin is widely diffused throughout the vegetable kingdom. An cnumeration of the principal materials which form the commercial sources of the substance mill be found under Leather, vol. xiv. p. 381, and in various special articles referred to from that heading.

Our chemical knowledge on the subject is very limited; and, as long as we know no better, each of the various tanning materials must be viewed as containing a "tannia" of its own kind. ${ }^{1}$ Only a few have as yet been obtained in a state approximating chemical purity. The following characters are common to them all :-
(1) All are colonrless or little-coloured non-volatile solids, solnble in water and in alcohol ; the solution has an astringent tasta.
(2) They colour blue litmus paper feehly red, yet all unite with the alkalies into soluble salta; the solntions of these eagerly absorb oxygen from the ait, with formation of dark-coloured products.
(3) They form insoluble salts with the oxides of lead, zinc, copper, preducible by addition of solution of the tannin to one of the respective acetate.
(4) They form very dark-coloured (green or blne) compounds with ferric oxide, conveniently producible by addition of the tannin to ferric or ferroso-ferric acetate. Ordinary old-fashioned black (gall-nut) ink may be quoted as an illnstration.
(5) Tannin eolutions precipitata gelatine as an insoluble compound, gencrally assumed to be chenically similarto the eubstance of leather.
(6) If a piece of raw hide he placed in a solution of any tannin, it inbibes the latter with formation of Iesther (q.v.).
(7) Aqneous tannin-solutions, if mised with dilute snjphuric acid, ore readily ordized by solution of permanganate of potash, which, being reduced to manganonss salt, loscs its intense violet colour.
Upon the last two propositions Lömenthal has based a convenient mathod for the assaying of tannin materials. A known weight of the substauce to be anelysed (say sumach) is extracted with water, and the extract diluted to a kruwn volume. An aliquot part of the estract is then mixed with a certain proportion of a standard solution of indigo-carmiz and of sulphuric acid, and, after large dilution with mater, standard permanganate is dropped in from a buretto (graduated glass tube) until the colour of the indigo is completely discharged. After deducting the volume of reagent which would have been taken ap by the indige alone, the reat is put down as corresponding to the "permanganate reducers generally." Another measnred volume of the extract is then poured over a eufficient weight of dry shaviags of rew hide, after having been suitably duluted, and the whole is alluwed to stand until the tannin has all passed into the hide. The liquid is then filtored,

[^17]and a measured volume, corresponding to exactly the qnantity of extract used for the assay, tested with permanganste. The volume of reagent ased this time is deducted from that used in the assay as a cerrection. From tho net permanganate the weight of pure gsllotannic acid which it would oxidize is calculsted on the basis of standard experiments, and from this weight the "percentage of tannin" is deduced. The method is purely empirical, and the results are of ne value unless obtained according to a rigorously prescribed mode of procedure. Of individual tannins that of the gall-nuts, known as gallotannic acid, is best kuown. Fer its prepsration (according to Pélouze) powdered gall-nuts are placed in an apparatus for extraction "by displacement," aud in it soaked in a mixtnre of 9 parts of ether and 1 part of water for twenty-four hours. "The liquid is then allowed to drain off, sud the residne washed with aqueous ether. The liquid on standing eeparates into two layers, -a lower heary layer, which contains the tannin, and an upper mors purely ethereal layer, which contains gallic acid and other impurities. The lower layer is drawn off, washed once or twice with ether, and then evaporated to dryness at a gentle heat; the tannin remains as a poreus friable mass of a slightly greyish-yellow colour This is the tannin of the pharmaceutist.

Such tannin is not by any mesns an absolutely nnitary substance. Its solution, if allowed to stsnd in the presence of a ferment which is naturally present in gall-nut extract, or mere readily if hoiled with sulphuric acid, yields a large propertion of gallic acid, which is easily obtained in pure crystsis. According to Strecker, glucose is formed at the same time, whence he viewed tannin as a glucoside (see Sugar). But this is now recegnized as a mistake, since Hugo Schiff showed that pure tannin is only digallic acid, $\mathrm{C}_{14} \mathrm{H}_{10} \mathrm{O}_{9}=$ $2 \mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{5}$ (gallic acid) minus $1 \mathrm{H}_{2} \mathrm{O}$. Pure tannin, according to Schiff, can be obtaned hy dehydrating pure gallic acid by means of chloride of acetyl. The tannin of the Chinese grll-nuts ecems to be identical with gallotsnn:e acid.

Quercitannic Acid. -The tannin of osk bark is certsinly different from gallotannic scid, because it yields no gallic scid when boiled with dilute vitriol. Etti (Jahresb. uiber die Fortschr. der Chemie for 1880, p. 898) prepares it by extracting the powdered bark with dilnte alcehol at s gentle heat, adding ordinary ether to the slcoholic extract, and shaking out the tannin with acetic ether. The acetic ether extract is distilled to recover the solvent, the residue filtered, and the filtrate evaporated to dryness to ohtain the pure (?) tannin as a reddish-white porder of the composition $\mathrm{C}_{17} \mathrm{H}_{26} \mathrm{O}_{90}$ At 130$140^{\circ} \mathrm{C}$. it leses water sud forms phlabaphen, $\mathrm{C}_{34} \mathrm{H}_{30} \mathrm{O}_{17}$, a brown solid insoluble in water but eoluble in solution of the tannin. Quercitsnuic acid forms quite a series of sueh snhydrides: $\mathrm{C}_{34} \mathrm{H}_{30} \mathrm{O}_{17} ; \mathrm{C}_{34} \mathrm{H}_{26} \mathrm{O}_{16} ; \mathrm{C}_{34} \mathrm{H}_{26} \mathrm{O}_{15} ; \mathrm{C}_{84} \mathrm{H}_{24} \mathrm{O}_{14}$. Some, if not all, of these are contained in aqueous oak-bark extract, and they play an important part in its application for tanning. According to Etti, quercitannic acid is a tri-methyl substitution-product of digallic acid, $\mathrm{C}_{14} \mathrm{H}_{10} \mathrm{O}_{2}$ minus 3 H plus $3 \mathrm{CH}_{5}-\mathrm{C}_{17} \mathrm{H}_{15} \mathrm{O}_{9}$.

Besides these two tannins, those of coffee and cachon are the only ones which have bcen obtained in a relatively definito form.

TANNiNG. See Leather.
TANTALUM. A rare element closely allied to Niobitm. See vol. xvii. p. 513.
TANTALUS, a hero of ancient Greek myth and legend. He was a soh of Zeus and Pluto ("Wealth"), and becane the father of Pelops, Proteus, and Niobe. He dwelt in splendour on Mount Sipylus near Smyrna, and was admitted to the table of the gods themselves. But he abused the divine favour by revealing to mankind the secrets he had learned in heaven, or by killing his son Pelops and serving him up to the gods at table. Another story was that he stole nectar and ambrosia from heaven and gare them to men. According to others, Pandareus stole a golden dog which guarded the temple of Zeus in Crete, and gave it to Tantalus to take care of. But, when Pandareus demanded the dog back, Tantalus denied that he had received it. Therefore Zeus turned Pandareus into a stone, and flung down Tantalus with Mount Sipylus on the top of him. The punishment of Tantalus in the lower world was famous. He stood up to his neck in water, which fled from him when he tried, to drink of it; and over his head hung fruits which the wind wafted away whenever he tried to grasp them. From this myth is derived the English word "tantalize." Another story is that a rock hung over his head ready to fall and crush him. The tomb of Tantalus on Mount Sipylus was pointed out in antiquity, and has been in modern times identified by Texier with the great cairn beueath Old Magnesia;
but Prof. W. M. Ramsay anclines to identify it with a remarkable rock-cut tomb beside Magnesia. The story of Tantalus contains a reminiscence of a semi-Greek kingdom which had its seat at Sipylus, the oldest and holiest city of Lydia, and one of the chief birthplaces of early Greek civilization. Of this ancient city the remains are still visible on the northern slope of Mount Sipylus, and abont 4 miles east of Magnesia. They consist of sepulchral mounds, rock-cut tombs, and a small acropolis perched on an almost inaccessible crag which juts out from the nearly perpendicular limestone wall of Mount Sipylus. There was a tradition in antiquity that the city of Tantalus had been swallowed up in a lake on the mountain; but the legend may, as Prof. W. M. Ramsay thinks, have been suggested by the vast ravine which yawns beneath the acropolis. ${ }^{1}$ This acropolis is too small ever to have been the seat of a great empire ; rather, like Pessinus and sther great religious centres of Asia Minor, it may have been "the seat of a priestly suzerainty maintained over the Fiero-donloi [sacred slaves] of the surrounding district." Connected as the city was on the one hand with the sea, and on the other with the capital of the ancient kingdom of Phrygia by means of the "royal road," it was a natural meeting-place for Greek and Oriental culture. A comparison of the art of Phrygia with the early art of Mycenæ and Olympia has fully confirmed the legend which connects the family of Tantalus with the Peloponnesus.

See Pelors, Phriora, and a paper by Prof. W. M. Ramsay in Journal of Hellenic Studies, iii. p. 33 sq.

TAOISML See Lîo-tsze.
TAORMINA (Tauromenium), now an unimportant village of about 3000 iahabitants, is magnificently situated at the edge of a precipitous cliff 900 feet high on the east coast of Sicily, about 32 miles from Messina and the same from Catania. The original city was founded by a tribe of Siculi after the destruction of the neighbouring city of Naxos in 403 b.c. by Dionysius of Syracuse. It was built on the hill of Taurus, whence came the name Tavpopévor (Diod., xiv. 58). In 358 в.c. the city was increased by the settlement of the exiled survivors from Naxos, which was only 3 miles distant ; and hence Pliny (II. N., iii. 8) speaks of Naxos as having been the original name of Tauromenium. Owing to its commanding site, the city has frequently been the scene of important struggles. When with the rest of Sicily it passed into the possession of the Romans, it shared with two other Sicilian cities the privileges of a "civitas feederata." During the Servile War (134-132 в.c.) Tauromenium was occupied by a body of rebel slaves, but was finally taken by the consul Rupilius, and the whole garrison slaughtered. In 36 b.c. it was one of Sextus Pompey's chief strongholas in his war with Augustus, who after his victory established a Roman colony there. Under the empire it was a flourishing city, famed for its wine (Pliny, H. N., ziv. 6) and red mullets (Juv., v. 93). In 902 A.D. it was taken from the Byzantine emperor by the Saracens, who called the place Moezzia. In 1078 it was captured by the Normans. A large number of ancient remains bear witness to its former importance. Fine autonomous silver coins of c. 300 ह.c. exist, with obv. a laureated head of Apollo, and rev. a tripod, with the legend TAYPOMENITAN, and a magistrate's initials AI. The theatre is, next to that at Aspendus (Pamphylia), the best preserved in existence. It is Greek in plan, but the existing structure belongs mostly to the Roman period, and is specially remarkable for the preservation of its lofty scena wall, and two large chambers which form entrance-porches to the cavea. It is oxcavated in an 1 Legends of sabmerged cities and castles are common in different
parte of Earope. It has been suggested that they are confused recolparts of Earope. It has been suggested that they are confused recol-
lections of the sucient villages built on piles in lakes (Wood-Martin, Lake Dwellings of Ireland, p. 28).
elevated peak of rock, and commands one of the most magaificent views in the world, with Mount Etna in the distance. Remains of five piscinæ and a largo bath, popularly called a naunachia, still exist, together with remains of the ancient city wall and that of the arx.
See Sarradifalco, Antichitio di Sicilia, Palermo, 1834-42, vol. v.; Hittorff and Zanth, Architecture Antique de la Sicile, Paris, 1870.

TAPACULO, the nanie ${ }^{1}$ given in Chili to a bird of singular appearance, - the Pieroptochus allicollis of oraitho-logy,- -and, throughout this aeries of articles (Birds, vol. iii. p. 743 ; Ornithology, vol. xviii. p. 40 , et alibi), applied in an extended sense to its allied forms, which are now found to constitute a small Family, Pteroptochidx,

Tapaculo.
welonging to the Tracheophonous division of Passeres, and therefore peculiar to South America. About 20 species, which are disposed by Mr Sclater (Ibis, 1874, pp. 189:06) in $\$$ genera, are believed to belong to this group.

The epecies of the Family first insde known is Seytalopus magellanicus, originally described in 1783 by Latham (Synopasis, 5v. p. 484) a Warblar. Even in 1836 Gould not unnaturally took it for a Wren, when establishing the genus to which it is now referrad ; but somo ten yeara after Johannes Muller found that Scytalopus, together with the trua Tapaculo, which was first described by Kittlitz in 1830, possessed anstomical charactera that removed them far from any position previously assigned to them, and determined their true place as above given. Ia the mean while a kindrad form, Mylactes, also first described in 1830, had been shewn by Eyton to hava aome very exceptional osteological features, and these were found to be also common to Pteroptochus and Seytalopus. In 1860 Prof. Cabanis recognized the Pteroplochidat as a distinct Family, but made it also include Menura (ef. Lyrebind, vol. xv. P. 115), and in 1874 Mr Selater (ut supra) tbought that Alrichia (cf. Scrub-bird, vol, xxi. pp. 554) might belong here. It was Garrod in 1876 and 1877 who finally diveated the Family of these aliens, but, until examples of some of the other genera have been anatomically examined, it may not be safe to sav that they all belong to the Pteroplochide.

The true Tapaculo (P. albicollis) has a general resemblance in plumage to the females of some of the smaller Shrikes (Lanius), and to a cursory observer its akin might

[^18]$p^{\text {ass }}$ for that of one ; but its shortened wings and powerful feet would on closer inspection at once reveal the difference. In life, howcver, its appearance must be wholly unlike, for it rarely flies, hops actively on the ground or among bushes, with its tail erect or turned towards its head, and continually utters various and strauge notes,-some, says Mr Darwin, are " like the cooing of dovea, others like the bubbling of water, and many defy all similes." The "Turco," Mylactes megapodius, is larger, with greatly developed feet and claws, but is very similar in colour and habits. Two more species of Hylactes are known, and one other of Iteroptochus, all of which are peculiar to Chili or Patagonia. The species of Scytalopus are as small as Wrens, mostly of a dark colour, and iahabit parts of Brazil and Colombia, one of them occurring so far northward as Bogota. (A. N.)

## TAPESTRY. See Textiles.

TAPE-WORMS, or CEsTODA, are a group of worms forming one of the three main divisions of the Platyhelminthes, the other two being the Turbellaria (seo Planarians and Nemertines) and I'rematoda (see Trematoda). They have been defined as follows :-"Flat worms withent mouth or alimentary canal, which typically develop by alternation of gencrations, by budding from a gencrally pear-shaped nurse, with which they remain united for a lengthened period as a ribbon-like colony or 'strobila. The individual joints of the colony, i.e., the sexual avimals or 'proglottides,' increase in size and maturity as they are removed farther from their origin by the intercalation of new buds, but are not distinguished in any special way. The nurse, however, known by the name of the 'head' (scolex) is provided with four or two suckers, and usually with curved claw-like hooks. The dorsal and ventral surfaces of the bead are perfectly identical, so that the arrangement of the hooks presents a atrikingly radiate appearance. By means of this apparatus the worms fasten themselves on the intestinal membrane of their hosts, which (except in the case of the otherwise peculiar Archigetes) all belong to the Vertelrata The nurses develop from little round six-hooked embryos in a more or less complicated fashion as so-called 'bladder-worms.' The latter iohabit very diverse, but usually parenchymatous, organs of the higher and lower animals, and are thence passively transferred to the intestine of their subsequent host" (Leuckarit, 1, ${ }^{2}$ p. 270).

Historical Sketch.-Certain forms of Cestodes have been koown from time immemorial. The bydatid cyst is alluded to by early medical writers, and Aristotle speaks of examining the tongue of pigs to ascertain the presence of bladder-worms. By this author and Hippocrates the Cestodes and other flat worms are spoken of as è $\lambda \mu \tau v \theta \varepsilon$ aौarciat, in opposition to the atpogyúdas or "round worms"; the word Trnia (Gr. tavia) does not occur in Greek authors, but is first used by the Romans (Pliny, II. $N$., xi. 33). In the treatises of the Middle Ages the tape-worm figured aa Lumbricus latus, only one species beiog recognized. Felix Plater (23) separated Bothriocephalus from the other humsn tape-worms, and Andry (24) gave it the name Ténia a épine, mistaking the nodular generative organs for vertebre. The appellation Bothriocephalus latus dates from Bremser, 1819 (25). Like other Entozoa, the tape-worms and bladder-worms were supposed to arise by spontaneons generation; it waa found, however, that animal forms atrikiagly like the Entozoa sometimes lived freely. Pallas (19), seeing that the cggs of intestinal worms are expelled from the animats in which they live, and may remain for some time unaltered in water, suggested the hypothesis that the Entozoa agreo with other animals in originating from eggs which can be

2 These figuree refer to the bihliography, pp. 55, 56.
rarried from one animal to another. He also supposed that they reached the liver and other internal organs by means of the blood-stream. Other authorities endeavoured to explain the presence of Entozoa by supposing that they were transmitted from parents to children. Von Siebold (26) in 1838 discovered the six-hooked embryos of Txnia, and came to the conclusion that they could only pass into the fully-formed animal by a kind of metamorphosis. The subject was fully discussed by Eschricht (27), who endearoured to prove that this phenomenon was of common occurrence among the ©Entozoa. Shortly afterwards appeared Steenstrap's famous work upon the alternation of generations (28), which furnished a ready explanation of the isolated facts till then observed regarding the Cestodes. The most important advances in modern times have been due to the introduction of helminthological experiment by Küchenmeister, by means of which the demonstration has been furnished that certain bladder-worms are the larval stages of particular tape-worms. The first of these experiments took place in 1851, when Küchenmeister fed a dog with bladder-worms from the rabbit, and a cat with specimens from the mouse, and succeeded in rearing tapeworms in their intestines (29). Similar investigations on different species have been made by Van Beneden, Leuckart, and others. Of systematic treatises the most important are those of Rudolphi (35), Diesing (20), and Van Beneden (13), while Von Linstow, in addition to numerous scattered papers ( 30,36 ), has given us an invaluable list of bosts with their respective parasites (21).

## Analomy.

In considering the anatomical peculizrities of the Cestoda it will be convenient to describe one particular specics and afterwards to indicate the chief differences presented by other members of the group. For this purpose Tænia saginata, Göze (T. mediocanellata, Küchenmeister), may be selected os a type, as it has been perheps more studied than any other, and is one of the species most commonly found in man; for further details, see Sommer (81).

Dimetaions. - An average specimen of this tape-worm (fig. 1, A) vill measure in a state of moderate coutraction about 500 cm ., sad consist of neavly 1400 segments; of those which immediately follow the head more than 250 will be found within a length of 5 cm ; -hey gradually widen posteriorly, until the widest, which are situated sbout half-way down the chsin, have a bread th of 14 mm . and a length of 6 mm .; whilst the terminal segments measure 5 onm. in breadth by 19 nm . in length.

The head (6g. 1, B) is spheroidal, 1.5 mm . in diameter, a ud besrs on its lateral surface four equidistant suckers, which serve for the sttachment of the whole worm. After death these are generally retracted, but during life they can be protruded and moved in all directions. They are a special development of the musculature of the body-wall, the radial fibres being the most conspicuons. The taperworm now being described is abnormal, inasmuch as the front of its head is not provided with a circlet of hooks; these are well seen, however, in the other common human tape-worm (Tania sotium), which bears a double ring of them, situated around s button-shaped, muscular pad (rostcllum) which forms the apex of the hesd (fig. 1, C). By the varying contraction of the separato parts of this orgsn the hooks may be moved in different directions, and when the xorm is sttaching itself they are first extended directly folwards, and then brought back so as to force the rostellum into the tissues of the host. Esch hook has a brosd bifid base, to which the muscles sre sttached, supporting a long curved point. In Tænia saginata, to the consideration of which we now returu, the rostellum is quite rudimentary, and has been described by earlier authors as a fifth sucker or even as s mouth; it is intereating to note that duriug its incipient stages it bears a number of minute spines homologous with the hooks of other species. "The head contains furthermore the anterior portions of the nervous and excretory aystems. The latter of these consists of an annular vessel placed iminediately below the rostellnm, from which four canals, corresponding to the four suckers, pass backwards: two of these gradually disappear, leaving two which pursue their caurse down the proglottides, in connexion with which they will be egain olluded to, and open at the hinder extremity of the worm by a common pore. The nervous system of the Cestodes was long sought in vain: although some early Investigators described a ganglion, they were unable to give any satisfactory pronf of its existence, this having been first furnished by Schneider. It seems generally to consist of a central ganglion
lying within the hear, from which two cords proceed backwards; these were regarded by Sommer and Lendois as part of the alimentary system. Niemiec (6) has recently given s dẹtailed account of its structure in seversl different species, and its relations have been discussed by Isng (7).

The proglottides arise by a species of budding in the nerrow neck which immediately succeeds thie head; they are separated from each other by grooves. which are at first so shallow and

indistinct that it is impossible to say with certainty where the segmentation really begins. The proglottides which have sttained' sexual maturity sre situated some $30-40 \mathrm{~cm}$. from the head, and measure 1.5 mm . in length by 5 mm , in breadth. The segments, like the head, consist of a solid mass of tissue in which the various orgsus are imbedded. Like the Trematodes, the Cestodes were lonf thought to have no body-cavity or cœlons, and hence were called "parenchymatous" worms. Recently, however, a series of iytercellular spaces has been described by Fraipont (8) as lesding int, the terminal excretory organs, and these spaces lave been inter. preted both by himself sud others ss the homologue of a bodycavity, slthough this opinion has not been allowed to pass unchallenged (seo Pintner, 9). The surface of the body is coverel? by a thin clear homogeneous cuticle, which, according to some suthorities, is perforated by fine closely-set pores. The hooks which have been described above, is well as the amsll spines snd bristles found in certain species, are devclopments of this cuticle. This external covering cannot, according to Leuckart (1, p. 289), be regarded as homologous with the cuticle of other invertebrates; inasmuch as it is not a secretion from a special layer of subjacent cells, but is "the structureless limiting membrane of the connective tissuc substance, and is comparable with the so-called besemento membrane found in the other flat-worms . . . between the nuscular layer and the derma! epitheliom." It is to he observed, however, that this viem has by no means found uuiverssl acceptance (ser

Steudener, 10), aod it is a miori improbable, since the Cestodes (and Trematodes) would thus form an exception to the general rule by whieh ali suinals are clad with an epithelivat derived fiom the embryonic ectoderm. The subcuticular layer is described as consisting of long fusiform rells (probably motlificd connective-tissue cells) disposec perpendirularly to the cuticle. It oeems possible that they are in lircct connexion with tho transverse muscles of the bntly. The matrix of the Cestode borly consists of connective tissnc, the cells composing which are seldom [unvided with a dis. tinct inemhraue, and sometimes can only lie separately distinghished by their nuclei. The layer of muscles (seo below) separates this matrix into a central and a cortical portion. Digtributed in it, and esperially in its cortical portion, are numerous calcareous corpuseles, which are gencrally spheroidal in form, varying up to 0.019 mm . in diameter and concentrically laminated; they contain a large amonnt (oftcu 20 jer cent.) of linge salts, diffinsed through an organir busis, from whirli the salts can he removed with effervescence by the action of acids. 'Thesc corpuscles have been variously interfreted by the oller anthors as emos, or as lymph or blood corpuscles, but the only theories which have been serionsly maintained in modern times are-(1) that they are skeletal (Von Sicbold); (2) that they are excretory (Claparese, Gricsbach); or (3) that they form a rescrve store of calcarous matcrial to be used either in connter. acting the acisl aligestive juices of the host or for the production of egershells (l.cirkait, 1, p. 233).

The musmular system consists of three sets of fibres-longitudinal, tiansversc, aul sagittal. The hirst are the best devcloped, sud rum town the inner part of the cortical laser in the form of strong bands; the seconil set lie inmediately helow them and pass across the holly in the form of two flat muscular plates, which converge towards each other ns they approach the margins of the proglottis; the sagittal muscles rum prinitively straight from one fat surface of the borly to the other, but their direction is mucli modified after the growth of the genital ongans, between the varinus parts of which they lie as isolated bundles; they are the weskest of all the sets. The muscular fibres are non-striated, and when they are fully dereloped no nucleus can be letected in them. They taper towards the extremities, sometimes branching dichotomonsly, and, as above mentioned, a connexion has becu asserted to bo visible between thera and the subcuticular cells.

The excretory system in the proglottides consists of two or four longituinal canals which lio slong their two nsrrow margins (fig. $1, D, e x$.). The origin of these in the head has been already noted, and they pass continuously down the whole worm until they open into a vesicle at the posterior extrenity of the terminal segment. In the hinder part of each proglottis they are connected by a traosverse vessel (fig. 1, D, li.), immediately sbove which a valve is formed by a duplicature of the wall, so that it is impossible to juject the excretory sjetem from behind whilst fluid can be readily forced along it from before backwards. Fraipont has drawn a distinction between ascending and descending canals. Excretory openings have been described by rarious observers in the anterior portion of the worm, near the suckers (Wagencr, 11; Fraipont, 8; Riehm, 12), and, slthough their presence is denied by Pintuer (9), there eeems sufficient evidence to show that they are more generally present than was formerly supposed. A ramifying network of smaller vessels connected with the main trunks just described is fount in the more superficisl parenchyma, snd this in its turn gives off still finer sapillaries which terminato in ciliated funnels. According to Fraipont these open into the intercellular lacune which are the representatives of the colom (see above), whilst Pintner maiotains that the tcrminal funuels are completely closed, and are to be regardell is unicellular glands. The subject, however, is one of axtreme lifficulty and demands forther investigation. It is worthy of notice that each of the thrce eystems of canals above described maintains its proper cliameter throughont, and that no intermediate sizey can bn found. The "plasmatic vascular system" describad by Sommer and Lindois, and regarded by them sa part of the elimentary system, consists partly of some of these delicate canels and paitly of the two cords of the nervous system. The main canals opin prosteriorly into a pulsatile vesicle, at the end of the last proglottis; when, however, some of these have been cast off the opening may be either by a shortened transverse vesicle, as Leuckart (1) naintains to be the case in the nresent species, or by separate openings, one for each canal.

The reprodnctive organs are eerially rcpeated io the proglettides, esch of which contains a complete set of male and female organs (fig. 1, D). The male organs msy be discussed first. The testes ( $\ell_{0}$, . ) are very numerous and scattered throughout the greater part of the proglottis; they are round vesicles ( 015 mm . in diameter) contsining spermatozoa, and attached like berries to the terminal ramifications of the ras deferens (v.d.); these gradually unite, forming larger and larger branches until they reach the main cansl, which runs in a geries of coils transversely bslf way across the joint a little behind its midille, and ends in a common cleaca (cl.), which receires both the male and femsle organe, and is conaected with the outer r.orld by the porus genitalis. The onter por-
tion of the vas las a thickened nuscular wall. nnil this part of it is capable of extrusion aud retraction, thus forming the male sutropuittent organ or "cirrus" (c.p.). The cuticle which lines ali the distal portion of the vas deferens is lere thin and delicate and armed witla serics of minute spines, which are directed backwands (Echencibnthrium) The cirrus in the present species is vary sliort, but in otlier forms its length is somctimes considerable. Tlie protrusion is effected by circular muscles placed around the ent of the vas deferens, while the retraction is brountht about by special longitudinal fibres, lying along the walls of the evaginshle portion.

The female organs may be most conveniently studied by tracing them inwards from the cloaca. The vagina (v.) opens immelliately posterior to the vas deferens, smd like it is lined by a continuation of the external cuticle. Atter passing sbout half way scross the segment it bends backmarils and terminstes in a small cyst, the receptaculnun seminis (fig. $1, E, r . s$.); this reccives and stores up the male fertilizing elements, retaining them until the ova are ripe. From its posterior extremity there passes a thin-wallel canal, wider than the varima ( $f$.), which serves to convey the spermatozoa to the ova, and hence is termed the "fertilizing cansl" (Befruchtungscanal of German authors). It unites with the common oviduct, \& tube formed by the union of the two oviducts ( $0 . d_{j}$ ), and the two together poss backwards into a spherical glandular structure, called from its discoverer "Mehlis's borly" or the shell gland (fig. 1, D and E, sh.g.). Within this apparatus it receives the duct of the yolk.nland (y.g.), and then jissses directly forwards to open into the uterus. The ovaries (ov.) are two in number, situated one on ench side of the middle line of the body; they are fan-shaped, and consist of a system of blind tubules situsted on s'buncheal efferent ditct. The cells of the ovary (primitive eggr) have a ghar]' contour and a large nuclens; the yolk-gland (y.g.) is very similar to the ovaries, behind and between which it is sitnated, but is distinguighed by various histological details (it is called "ovary" by Moniez). The shell-gland, formerly regarded as the ovary, consists of closely compressed uncleated cells, and is provided with small thin ducts opening into fthe narrow internal cavity of the organ. The uterus (ut.), in its early stage of development, is a long straight tube, lying almost in the longitudioal axis of the proglottis, and receiving posteriorly the oviduct after it emerges from the sliell-gland (fig. 1, E, ut.). From whst hes been ssid it will appear that the ova on their way down the common oviduct sre impregnated ss they pass the end of the fertilizing canal, and then receive in succession, first their supply of food-yolk and their shell, during their sojourn in Mehlig's body, sfter which they go forwards into the uterus, where they undergo the first stageg of their development. The nterus assumes a very different ohape as it becomes distended with eggs, which are far too numerous to be contained in a simple otraight tube; snall protubcrances arise from its walls, growiog rapidly and bifurcating here snd there, so, as to produce the complicated branched appesrance seen in fig. $1, F$. As the uterus grows, the male, and later the female, genitnlia degenerste and disappear, and in the proglottides which are rearly to be liberated the only organ visible is the distended uterus. One of the most charscteristic peculisrities in the sexusl system just described is that there is no passage by which the ripe eggs can make their exit from the proglottis; these sre therefore extruded only on its rupture; a very different state of things obtains in the genns Bothriocephalus (see below). Self-impregnation certainly occurs, and is probably the rule; it is obvious that the contrary case can only happen where two individuals lie side by side wifhin the same host. Furthermore, the cirrus has been seen protruded into the vagine of the same joint, and the emission of sperm bas been witnessed (Leuckart, 1; Yan Beneden, 13, p.601).
The eggs are ovoid or spherical, and consist of the kerm.cell (nncleus and protoplasm) with an albuminous enveloping substance, which is gain surrounded by a thin transparent skin. Tho ohell frequeatly presents one or more appendages, probably the sccretion of the shell-gland dramn ont into threads. The structure of the egg has been best studied in Teenia serrata (Van Beneden, 14), where it consists of \& delicate ghell containing a germ-cell, with a quantity of secondary yolk; the former divides into a "granular" cell, which eegmenta no further, and an "embryonic" globe, which agsin divides into a number of cells, of which three are larger and congtitute the "slbuminogenous layer," whilst the remsinder are smaller and form the "embryonic mass," and secrete a delicate ouperficial cuticle, the cell-limits being indistinct. In the embryonic mass from three to five flattencd cells form a chitinogenous layer, and give origin to a sunerficial homogeneons cost, a shell of radislly disposed chitiooid cylinders, and an internal faintly stristed lining, whilst the remaining cells become the six-hooked embryo or proscolex, a superficial layer to which the hooke belong, and a central mass of clesrer cells. When the nreacolex is'mature the originsl egg-ahell sad the albuminogenous layer disappear; and only the chitinoid costs remain.

The proglottides sre cast off by muscular action; the fibres are not continuous between the enccessive segments, so that these are con, nected merely by soft connective tissue, which readily giree way; the
suptoretakes place through the trsnsverse vessel above described, sud, as the hinder margin of the proglottis contracts forcibly when the next one has left it, the transperse vessel gives rise to the rounded vesicle which forms the termination of the excretory system.

## Life-History and Development.

The six-hooked embryo (fig. 1, G) may be conveyed to the inter. mediate host in several ways, but the commonest is for it to be taken intu the slimentary cansl along with food to which it may have allhered, or with water in which it was swimming; the infection may take place either by means of free eggs or by whole proglottides. Iu the latter case the soft tissues are first digested by the gastric juice of the host, and in eitler case the egg-shell is dissolved or rendered so brittle thst the embryo readily escapes hy the movemeuts of its hooks. The proscolex; after spending a longer or shorter time free in the atomach or intestine, procueds to perforate the wall of these organs by means of sctive burrowing motions. Although the embryo of a Tenia has only once been captured in its progress through the wall of the alimentary canal (Raum, 15, p. 28), there cen be no doubt that this is tho route by which it usually proceeds, sud thst its wext locslity is s blood-vessel, rebably some suall branch of the portal vein, in the blood of which it has been found by more than one observer. This would explain the freyuency with which the next stage is found in the liver. There eeems, however, reason to believe that many embryos peaetrate the intestinal wall completely snd reach the body-cavity, in which they can wander freely. When the six-liooked embryo has reached its rcsting-place, which in addition to the liver may be lung, muscles, braid, counective tissue, or eye, it at ouce commences its further development, and in a few days becones visible to the naked cye. Like any other foreigo body, it causes a proliferation of cells, which in due time form a sheath of connective tissue, with a cellular liniog, and smooth like a serous cavity within; this covering, lowever, is not found when the barasite is situated in the brain or the eye. The embryo now growa in size, generally bfcoming aomewhat elougated, and the hooks drop off, Sometimes they can be found lying detached in the councctive-tissue sheath. The central cells enlarge and become clear, and in all the Truise they liquefy, forming a qusntity of fluid which fills the ceutre of the blsdder-worm, At this atage the lerve constitute the so-called "measles" of bcef (that of pork being due to Cysticercus cellulose, the immature stage of Tænia colium); they are ovoid vesicles lying between the muscle fibres and varying in length from 4 to 8 mm , snd being ususlly about 3 nim. in diameter (fig. 2, A). At a poiut on one side of the bladder there applears a emall thickenngg, the meniscus or rudimicut of the future liead; this is soon followed by an invagination of the cuticle (fig. 2, 13). When the rudimentary head thus formed is about 0.2 wni. in length (the hladder being 1.5 mm . in dismeter) the forma. tion of muscles in its walle commences. At four equidistant points pear the bottem of the invaginetion the suckers are developet, and at the lowest part of the cavity the rostellum (and the double circlet of hooks in the armed alecies) is formed. Surrounding the head-rudinicut ou that aurface which is towards the cavity of the bladder is a thin layer, known as the "receptacle." This is best oeen in Cysticercus cellulose, in which there is also a very clarscteristic bend or kink $u$ the pedicle of invagination, which in inost other blanhler-worme remains straight (see fig. 2, C). The rudiments of the vascular system of the bladder bave already sppeared before the formstion of the liead, and now they extend into it es four longitudial vessels, which become connected st the bottom of the invagination by a circular vessel. About this time, too, the cslcarcous corpuscles above described make their appearance. When the looks aud suckers are fully formed, the bead undergoes a process of evagination, so that what was previously a hollow cavity beconcs a solid cylinder, and the houks, which were below the ouckers, come to lie above them. Mature blsdder-worms vary in size from Cystcercus fasciolaris, the size of a pea, to Cysticereus tenuicollis, six inches or more in length.

The development into the adult tape-worm takes place only alter the Cyslicercus bas been awallowed by the permanent or definitive loost. The course of this metamorphosis has beeu followed experimentally, and it has been found that first the bladder and next the neck of the worm are dissolved by the gastric juice. The head ouly is luft ; in the moist warmth of the intestioe its ouckers and rostellunt cxhibit very lively motions, which serve to briug about its sttachment to the intestinal wall. It gradually increases in length, and the formation of segments speedily commences.

The life history of the Cestodes is generally summed up ss consistiog of three different forms:-(1) the proscolex, or six hooked -mbryo, which gives rise to the bladder-worm; (2) the scolex, which dovelops the chain or etrobila by a process of budding; and (3) the proglottis, or sexual animal, which prodoces eggs. Each of these three forms has certain claims to be regerded as a zoological "individual." Vso Beneden (13, Vers Int., p. 251) has laid great atress upon the correspondence between \& Trematode and a ripe proglottis, and it bas been since pointed out that a proglottis may
ullder favorable circumstances (that is, within the intestine) continue to grow after being detached from the pareut chain; it cannot be said, however, that the evidence upon which this rests is quite incontrovertible. Regarded from this point of view the life-bistory

Fio. 2.-Developmeat of Tensa (from Leuckart). A, Cysficercus bovis In beel: pat. alze. B, Invaginated licad of a Cusficercus befora the furmation of tha auckers; $\times 25$. of the tape-worms furnishes an admirable instance of the alternation of geoerations. The individuality of the proglottides, howe ver, slthough maintained by anthorities so eminent as Jeuckart, is by no means universally accepted; a distinction has been drawn between their formation and true budding seen in other animal colonies, such as the Polyzor; and Riehm, in a recent work (12), has pointed out that the casting off of these sexusl segments is in some respects compriable to the detachment of the hectocotylized arm of a Cephalopod, and the formation of new joints to the davelopment of an Oligochretous worm from a few eegments; furthermore, certain organs-for cxample, the nervous and excretory gystems-are continuous throughout the whole chain, and an isolsted proglottis is nnable to maintain its existeuce for more than a very limited period. According to this view, alternation of generations only occurs in Cestodes in forms such as Connurus, where there is a proliferstion of heads in the wall of the bladder. ${ }^{1}$

The Cestode larva corresponding to the stage which lras just beeu described present considerable varistions both in form and atructure, and upon these classifications of the group have been based, and generic names have been given to the different forms; Von Linstow (36) bas, however, pointed out the undesirableness of this, as they sre all parts of the life-history of one genus, Tænia. The nost recent arrangement is that of Villot (16), which is as follows:-
I. The ceudsl blsdder arises from the proscolex by simple growth and atructural modification, without the fornation of any new parts. A larger or smaller quantity of tuid is present, and also a connective-tissue sheath; the bost is a vertebrste. Cysticercus (true bladder-worms), Piestocystis, Canurns, Echinococcus.
11. The caudal bladder ariscs from the proscolex by budding, that is, by the formation of now parts; there is no connective-tissue aleath, and the host is an invertebrate. Cysticercoidei, Leucksrt (a) Csudal bladder formed by endogenons budding; the hesd is ourrounded, not only by the body of the worm sad the caudsl bladder, but also by the blastogen (proscolex). Polycercus (from the earthworm), Monocercus (from the black slug, Arion) (b) Caudsl bladder formed by exogenous budding; the liead is only aurrounded by the body of the worm and the caudal bladder. Cercocystis (from Tenebrio), Staphylocystis, Urocystis, Cryptocystis.

Of these the most important are the first group, and regarding some of them a few words must be added. In the great majority of apecies only one tape-worm bead is prodoced, and such bladderworms constituted the genns Cysticercus of the older heluintho. logists. In certain cases, however, notably is the worm which produces the "staggers" of sheep, numerons heads are formed in the wall of each bladder; such larvi formed the genus Conurus; but apart from their polycephalous condition there are no structurl peculiaritiea calling for apecisl notice. The third variety of bladder.
1 At the mament of golng to presn, Grassi (Zeischr. f. Parasitenk., 11. 1I) makes the important communlcation that Jruig murina ( $=7$, masa) my develop without un Intermedlete host.
worm (Echinococeus) is characterized by the fact that the tape-worm heads are not directly developed in the wall of the bladder itself, but from "brood capsules" which lis in numbers on the inger wall of the bladder.

Development of the Echinococcus. -The amallest bladder yet aecn was reared by Lenckart in the pig, and consisted of a minute protoplasmic mass surcounded by a alructureless cuticle. This cuticle thickens by deposition of new layers as growth proceeds, and the lamination of the cuticle is one of the characteristic peculiarities of the Echinococcus, another being the absence of an excrotory system. At certain points in the parenchyma lining the cyst small warts are noticed (fig. 2, D, a), which enlarge and become hollow; theu the cavity enlarges in a direction opposite to the point of origin, and at the extremity of this hollow suckers and hooks are formed as in the case of Cysticercus described above ( $b, c$ ). No sooner has the development of the first of these reached a certain degree of completeness than others are formed in similar fashion. The first part of the invagination takes place, by which tho future head comes to lie within the brood-capsuls and tle pedicle is no longer hollow but aolid (c) ; the suckers and hooks are, however, still iuveginated, and remain so for a coasiderable period. Seeing that the interior of the brood-capsule is lined with caticle, it corresponds to the outside of the parent cyst, and hence is probably the representative of a provious iavagination. If this bo so then the development of Echinococcus would be quite comparable with that of Cysticcrcus, the ouly difference being that, instead of the head heing an invagivation of the wall of the cyst itself, it is a eecondary invagina. tion, the primary being the brood-capsule. This does not, however, exhaust the peculiarities of the Echinococcus; the form just deacribod, wita a simple cyst and brood-capsules, is common in cattle, and hence goes by the name of Echinococcus vetcrinorum; but cases are frequent, and are the most common in the human aubject, in which the cyst contains daughter-vesicles, differing from those just described in being alerile-giving riso to no heads. These daughter-uladders may originate in threo different waya: (1) from little granular heaps, which are seen between the different layers of the cuticle, and which are probably derived piinarily from the parenchymal layer, -since new layers of cuticle are contioually formed internally, these bladders gradually make their way outwards, until they come to lie externally to the mother-vesicle (Echinocaccus cxagena, Kuhn; E. scalcciparicns, Kïchemmeister); (2) from brood-capsules; (3) from Echinococcus-heads; these last two modes of ouvclepment give rise to vesicles, which are within the nother-vesicle, and produce a form which has been varionsly called Echinococcus, endogcna, Kuhn, E. altricipariens, Küchenmeister, and E. hydatidosus. A very remarkable form is Echinococcus multilocularis, which consists of a number of very small vesicles embedded in a common soft stroma; it is found exclusively in man, and for long was regarded as a forin of alvcolar cancer. The noole of its dovelopment is unknown (for further information, aee Virchow, 17). Compound bladdera occur in man and the ox, whilat other ruminants, swine, and monkeys usnally harbour the simple or exogenous forms. The organs most often affected are liver and lungs. The adult tapo-worm (T. echinococcus) is found in tbe iutestine of the dog, jackal, and wolf, occurring in consiler. ablo numbers between the villi. Its length (fig. 3, A) is at most 5 mm . and it coasista of only threa or four segmenta; the bead has four suckers and a double circlet of books.

## Pathological Effects.

The pathological effects of Cestodes fall naturally into two categories-(1) those due to the adult worm, and (2) those due to the larve or bladder worms.
(1) Those of the first group are in general slight, being confined to the abstraction of a certain amount of nutriment, and to a more or lcss acute feeling of irritation, sometimes amounting even to colic-like pains, in the intestine. There have indeed been many authorities who have maintained that they were beneficial; Jürdens went so far as to describe them as the good angels and unfailing helpers of children, and Schimper records that the Abyssinians consider that they prevent constipation, and only regard them"as disadvantageous when they grow too long. Notwithstanding all this, however. there are not a few cases on record in which aræmia and neurotic, or even mental, diseases have been caused by the malnutrition and irritation which they occasion. ${ }^{1}$

[^19](2) The effects of Cestode larvæ may again be divided into two subdivisions. (a) That due to the invasion and wandering of a large brood of six-hooked embryos has been most successfully studied in cases in which animals have been fed for experimental purposes with fragments of ripe tape-worms; in such instances a train of symptoms has been observed to which the name "acute cestodic tuberculosis" has been given. It is characterized by loss of appetite, fatigue, ruflling of the hair, and fever ; on post-mortem examination it bas been found that the lympbatic systern is in a state of inflammation, while the muscles present the appearance which has already been described. (b) The effects of formed bladder-worms may be summed up as dependent upon the pressure of the growing cyst and the consequent absorption of the surrounding tissues of the host, so that the importance of the results depends almost entirely upon the organ which is affected. Bladder-worms in the brain are, of course, the most frequently fatal, especially when, as is not unfrequently the case, they exert pressure upon the ganglia at its base. Küchenmeister bas collected a considerable number of occurrences of cystic worms in the brain; among these sixteen were not accompanied by pathological symptoms during life; in six others these were slight; twenty-four were cases of epilepsy, six of cramp, fortytwo of paralysis, and twenty-tbree of mental disturbances of varying intensity. Cysticerci in the brain vary greatly in size and form according to the precise situation which they occupy; in its ventricles they have been found as large as a pigcon's egg. In the meshes of the arachnoid the bladder sometincs grows into a remarkably branched structure, which has been called Cysticercus racemosus by Zenker (3). Another peculiar form from the same organ hás ween described by Köberlc (4); it is claracterized by the great length of its head-process ( 2 cm .) , which is coiled up into a regular spiral of sometimes thrce turns, it has received the uane Cysticercus turbinatus, though its specific distinctness is doubtful. The occurrence of Cysticerci in the eye is of special interest, because of the opportunity it affords of observing, by means of the ophthalnuscope, the development of the worm in its natural environment. It seems generally to lie at first below the retima, and is visible as a bluish-white sharply defired body; subsequently the retina is destroyed by the pressure, and the worm falls forward into the ritreous body; sometimes the head may be seen protruding first through the opening; in the chambers of the cye the Cysticercus is almost always free, that is, without a capsule, and swinuming in the fluid, so that its form and motions may be readily and accurately observed. A large number of cases of this affection bave been recorded, principally by Von Graefe in Berlio (5), and in some the bladder as been successfully removed by operation.

The special symptoms of the Echinococcus vary, like those of other bladder-worms, with its situation and size when it grows within cavities with more or less firm limits compression of adjoining vessels and glandular passages often results, producing cedema, varicose veins, congestion of various organs, or even dyspocea, if the parasite occuin the thorax. The liver is its nost frequent seat, and next the lung; but there is scarcely any organ of the body in which it has not been fuund, even the bones being sometimes affected. Since the expanding cyst grows in the direction of least resistance, it has a tendency to pass
Which the first two are the arost reliable. Turpenting may be giver In half-ounce doses along with castor oil, or made up ioto at emulsioe with yolk of egg; while tha malo fera is usually administered in the form of liquid extract (half a drachm to one drachm). Careful scaral should be made in the evacuations for the head or scolex, without that expulsion of which thers is no certain evideace that the parasita hqu been renoved from tho bods.
cowards the surface of organs, and sometimes a sure is effected spontanenusly by its rupturing into the alimentary canal or into some other passage leading to the exterior. Cases in which the cyst opens into the blood-vessels are

Fib. 3.-Varlous Formo of Tape-Werme. A, Tania echinococrus: $\times \mathbf{1 2}$ (from Lenckart). B, Archigetes sieboldi; $\times 60$ (from Leuckatt). C, Echinobolhrium fypus; $\times 10$ (from Van Booeden). D, Caryophylleus mutobilis; $x$ about 5
(from Carus).
almost always suddenly fatal. When the Echinococcus occure near the surface of the body, it may be evacuated by puncture and a cure effected with but little risk.

## Systcmatic Arrangoment of the Cestoda.

The following classification of the Cestodea, based mainly on that of Van Benceden, exhibits the present atate of our knowledge of the group :-

## Class Cestoda.

Family I. Amphilinidx.-Body oval, flattened, with a sucker at the anterior extremity; testes resicular, vas deferens opeuing posteriorly; opary (germarinen) single, yolk glands double, vagins opeoing near the vas deferens, uterus opening nuteriorly; embryo ciliated in front and with ten hooks. Examples: Amphilina, Wagener (ae日 below), Amphiplyches, Wagener.
Family 11. Caryophyllxida_-Body nnsegmented, fat, extended ; head expanded, bilobed, and without hooks; a singla aet of nexual organs in the hinder portion; development probably a aimplified metamorphosia. Example: Caryophyllews mutabilis, from the intestise of Cyprinoid fishes (fig. 3, D).
Family 111. Pscudophyllida.-Head provided with two sucking grooves; proglottides not always well defined; a uterine aperture always present in aldition to the openings of the vas defercoa and vagina ; embryo alroys (?) with a ciliated cont, and eyg-shell with an operculum. Examples: Bolirioccphalus (see below), Triæn ophorus ( - Tricuspidarin), Solenophorks, Schistocephalus, Ligula, Archigctes, and perhaps Duthiersia (sce below).
Family IV. Diphyllidx.-Neck and two snckers armed with liooks. Exampla : Echinobothrium, two apecies known from Selachians, one immature from a mollusc (fig. 3, C).
Family V. Fctrarhynchids.-Head provided with four suckera and four protractile proboscidcs armed with hooks; sexual openings marginal. Example: Telrarhynchus (see below), about ferty apecies known, many only described from immature forms.
Family Yl. Tetraphyllids. - Head with four very mobile and distinct suckers, which are often armed with hooks or clitinous rods; body segmented, proglottides cast off when mature ; sexnal openings margimal.
Subfanily i. Phyllobothrine. - Suckers without hooks or spines. Examples: Echeneibothriun, Ihyllobothrium, Anthobothrium, a fow apecies of cach, all from Elaamobranch fishes.
Subfamily ii Phyllacanthine.- Suckers each with two to four hooks Examples: Caltiobothrium, Onchobothrium Acap-thoboth-uthe, two or three species of cacli genns known Irom Belachiaus.

Fanily VII. Traiadra.-Head furnishad with four auckera and often with a single or donble circlat of hooks; proglottides well-defined and caat off when mature ; yo uterine aperture. Example: Tænia (aee below).
It aems advisable to add a faw details regarding some of the forms alluded to iu the above synopsia.

Amphilina foliacea, deseribed as a Trematodo by Rudolphi, is found in the body-cavity of the sturgeon. A number of uvicellular glands open into the sucker, and are surrounded by the muacles of that organ; the nervous aystem consists of two ganglia, with a commissure, and two lateral nerves; the male organs resembla those of Bothriocephalus, the female those of the Trematodes; the family is generally regarded as furuishing a connecting link between the C'cstoda and Trematoda; see Salensky (18) and Lang (7).

Fio. 4.- Bothriocephalidre. A, A segment of Bothriocephalus latus, sliowing the generativa organs from the ventral surface; ex., oxcretbry vessels; c, clirua; r.p., cirrus pouch; v.d., vas deferene; v.0., vaginal opening; v, veglna; wh.0. ohell-gland; od., culduct; ov., ovary; $y . g, y$ yolk-gland ; y.d., ita duct; uf., utes us; u.0., uterina opening; tha teates are not visible from thils. slde; $\times 23$ from Sommer and Laadols). B, C, marginel end lateral vlewa of tha aaterlor purt of B, cordatua, elrowIng tha cephelic grooves; $\times \delta$ (Irom Leackart). D, Cilated ambryo of B. Iafus ; $\times 00$ (from Leuckert).
Bothriocephatus latus (32) is the most conapicuous example of tho family Pscudophyllidæ; and is, moreover, noteworthy as being the largest tape-worm found in man; its length often reaches 8 to 9 metres, and its extreme breadth 10 to 12 mm . The head bears two grooves, which corrcsposd in position with the flat sides of the body. There are two (more correctly three) genital openings, which are situated, not on the margin bat on the flat aide of the body, on that surface which is usially called the ventral. The most anteriur of these is the raale aperture (fig. 4, A, c.), and immediately behind it is that of the vagina (v.o.), so close that on superficial examination thatwo often aeem to coincide. This vaginal onening, like that of the Tæniadæ, aerves for the intromission of the peois and for the fertilization of the ova, but not for the exit of the ripe eggs; this being provided for by a apecial aperture at the other end of the aterns from that at which the eggs enter it This uterine opening (u.o.) is aituated at a short distance behind the other two. Thie result of this arraagement is that the egga can be evacuatcd without any injury to the proglottis, and consequently their discharge commences before its scparation from tha parent worm and may continue for a long period. The uterns (ut.) itself, owing to its disposition in folled coils, when full of eggs, presents an irregular, round, lobular appearance, which has been compared to a flower or herallic lily. Tho yolk-gland (y.g.) is widely disseminated in the latcral areas of tho segments, and its ducts (y.d.) form a series of branching tubules, first lescribed by Eschricht (27) under the name "yellow dncts." The excretory organs (ex.) differ from those of the Treniadm in that the canals exhibit a reticulate arrangement. The embryo (fig. 4, D) as it leaves the egg is covered with a ciliated mantle, which corresponds to the firm eggshell and associstcd membrane of the cystic taje-worms, and perhaps also to the ciliated envelope of certain Trematore larve (sce Trematoda). This ciliated organism swims freely about in the water, but after a thoo the six-looked proscolex escepes from it. The next stage in its life-history is not yet known, but it has been recently ahown by Braun of Dorpat (33) that at a anbsequent atage it inhabits tha pike and buvbot, and develops into the eexnal adnit when transferred in tha intestine of the human subject. The geographical distribation of Bolhrioecphalus is limited; it has been recerded with certanty in but feur piaces outsido Enrope; while withia that continent the coasts of the Baltic and Switzerland aro
sbe principal localities; it is widely distributed in Russie, ond has been recoricd from Polend, Denmark, Germany, es well as from Fance and Britan, though it is possible that the cases occurring in these latter countries lave been duo to importation.
The genus Ligula has the segmentation obscure or indistinguishable. About six species are known. One is found encapsuled in a monkey, one in the common seal, others in reptiles and teleosteans, Archigeles sieboldi ( $\mathrm{fig} .3, \mathrm{~B}$ ) occura in thio body-cavity of an Oligochætous worm (Tubifex rivelorum); it is about 3 mm . long, and consists of an nval body (scolex), to which is attached a cylin. drical tail (proscolex), bearing et the posterior extremity three pairs of hooks; both these parts are capable of notion. Tbe scolex has eight longitudinal excretory canals, and a terminal vesicle; the ventraly situated genital aperture is the common exit of the vas deferens, the vagina, and a uterus selarate from the latter; the development is direct, and it attains sexual maturity without a chaoge of host. Duthiersia, Perrier (34), contains two species, both from the intestines of varanian lizards. The genus is characterized by the presence of two large compressed frilled suckers, separated by a septum and perforated at their bascs. The proglottides have three genital apertures resembling those of Bothriocephalus.

Fig. 6-Tetrarhynchus A, General vlew of the worm; $\times 4$. B, head ahowing the suckers, probuscides, and excretory canals ; $\times 25$. C $\mathrm{C}_{4}$ portion of a proboscis showing the two forms of hoaks ; highly megnified. (All from Pintner.)

The genus Tetrarhynchus was, a fery years ago, maile the subject of ao elaborate memoir by Pintuer (9), who investigated T. longicollis, V. Ben. The head, in which its most striking anatomical peculiarities are situated, really includes both the head and neck of previous authors (fig. 5, A) ; it is some 9.94 mm . long, but only 0.75 mm . in diameter, and bears at its anterior end two obliquely placed oval disks (fig. 5, B), each of which is perforated towards the apex by two rouod holes through which the four proboscides pro. trude. Each of these disks, norcover, shows traces of a division irto two, a fact which indicates that it is formed by the fusion of two suckers corresponding to those commonly fonnd io tape-worms. The flattening in this genus seems to be in a direction at right angles to that in which it usually takes place. The proboscides, which are the most characteristic orgaus of the gen a, are four in number, and protrude from or cao be retracted into the siterior surface of the bead. Each consists of three parts:-(1) the toothed portion is the most anterior; it is shaped like a long darrow glovefinger, like which it is invaginable; on its external surlace it bears rows of hooks, closely set in diagonal lides (fig. 5, C); there are two forms of these: those which are directed outwards are large triangular hooks, with apices pointing backwards, whilst those situated on that surface of the proboscis which is turned towards the other proboscides are fine, delicate, and curved; between the hooks are fine chitinous bairs; (2) the membranous sheath is firmly attached where the general surface of the body passes over into the toothed portion around the orifice of the invagination ; it consists of a thick homogeneous transparent skin, apparentiy an excretion of cells lining the cavity of the proboscis; (3) the muscular portion in the most posterior of all, and is composed of six layers, remarkable as containing striped nuscular fibres ; throughout all these three portions of the proboscis there extends a retractor muscle. The action of these various structures is not thoroughly understood, but it is probable that the proboseis is pratruded by the action of the last-named muscular sheath, whilst it is retracted, after the relaxation of this, partly by the retractor muscle and partly by the pressure of the surrounding medium.
The family Taniade is usually described es containing only the
one genus Tratia, but, owing to the number and rariety of its species, of which more than 850 have been described, it lins bee subdivided into groups, regarded by different authora as genera or subgenera. The aubjomed arrangent.e. is mainly that of Leuckart It labours muder the disadvantage that its rlief divisions are hased upon the bladder-worm or larral stage, whelh is only known in tha casa of comparatively fer species

1. Cystici (cystic tape-worms). -Head rarely unarmed; nsually provided with a rostellum and with oue or more fowa of hooks; proglattides longish oval when mature; uterus with mediau stent and lateral brauches: the larva has a caudal bladder contrining flud.
2. Cystotznia, Leuckart-The head arnes in the wall of the embryonic blalder.
a. Tenia saginalu, Guze. - Mithout hooks ( - T. nedio. canellata, Kíchenmeister, - genus Taniarhynchus, Weialand).
b. Twnia soliun, limilolphi- Head with a double circlet of hookz.
c. Tania acanthotrius, Weinlend. - Il cad with a triplo circlet of hooks ( - genus Acanthotrias, Weinland).
2 Echinococcifer, Weinland. -The heads arise in special brood-cspsules. Tania echinococeus, V, Siebold.
3. Cystoidei (ordinary tape-worms). -The larva has no distended caudal bladder containing fiuid.
4. Hymenolenis, Weinland. -Troboscis with a single row of Wmall hooks. Ternia aiara, V. Siebold, T. favopructata, Weinland.
5. Dipylidium, Lenckart. -IIcad with seseral rows of hooks, each with a discoilal base; a right and left set of genital organa in eacli joint, the uterus, however, being single and commou to the two. Tania cucumerina, Rodolphi ( $=$ T. elliplica, Batsch).
Hamann (2) has recently proposed a new genus, Ptychophysa, for Truia lineala, Göze, which is defined by the following characters:-(1) the porus genitalis is on the surface and not on the unargin of the joints ; (2) the vaginal opening is anterior to that of the cirras; (3) at a certain period the uterus is convoluted; (1) there is a peculiar shell-gland. In many of these charecters the species shows a resemblance to the Bothrincephutida.

Occurrence in Man.-The Cestodes which in the adult state infest man, with their corresponding arve and temporary hostg, are as follows:-

| Tania saginuta. | Cysticercus bovis. | Ox. |
| :---: | :---: | :---: |
| T. solium. | C. cellulosx. | Pig, man |
| T. nana. | (3) | (?) |
| T. Jlavopunctata. | (3) | (?) |
| T. madagascarimusis. | (?) | (?) |

T. cucuncriza.

Bothriocephatus latus.
$B$. cristatus.
B. cordatis.

Other species, homever, inhabit the human body in their larval coudition; a list of them, with. the corresponding adult forms and permanent hosts, is subjoined :-

| Cysticercus cellulosæ. | Tania soliun. | Man. |
| :--- | :--- | :--- |
| C. acanthotrias. | T. acantholvias (incog.) | (?) |
| C. innuicollis. | T. marginala. | Dog, wolf. |
| Echinococcus. | T. echinococcus. | Dog. |

Phylogeny. -There can be no doubt that the Cestodes and Trematodes are intirately related and lave surung from a common ancestor; there are so many structural peculiarities in which they agree (compare Trematodes), and tliey are connected by so many interinediate forms, that their affinity can admit of no doubt According to Leuckart, the original ancestor of hoth was probably allied to the Planarians, while IIuxley ( $22, \mathrm{pp} .213,676$ ) points out that it is at all events possible that they bave no connexion with free forms iut have always been anenterous, and in fact are nothing but "gigantic mornl), so to speak, which have never jassed through the gastrula stage."

(W. E. HO.)
(W. E. HO.)

TAPIOCA is a farinaceous food substance prepared from cassava starch, the product of the large tuberous roots of the cassava or manioc plant, Manihot utilissima (Jatropha manihot), native of Brazil (see Cassava, vol. v. p. 182, and comp. Arrowroot, vol. ii. p. 631, fig. 6). Cassava starch, being separated from the fibrous and nitrogenous constituents of the roots, is in a moist condition spread upon iron plates, and with constant stirring exposed to such heat as causes a partial rupture of the starch granules, which agglomerate into irregnlar pellets, becoming hard and translucent when cooled. In this partly torrefied condition the starch forms the tapioca of commerce, a light, pleasant, and digestible food, much used in puddings and as a thickener for soups. The French prepare an artificial tapioca from potato starch, mixed with various vegetable substances, for use in soups, \&c., which is found in the market under such names as tapioca. Crecy,tapioca Julienne, \&c., according to the dried vegetables with which the preparations are made.
TAPIR. The general characters of the animals of the $\vec{\theta}$ perissodactyle or odd-toed section of the hoofed manmals are described under Mammalia, vol. xv. p. 427. This oñce numerous group is at present represented by only three rather isolated families, the Horses, Rhinoceroses, and Tapirs. The last of these have retained much more of the original characters of the primitive Ungulates of the Eocene period than the others, and have indeed remained practically almost unchanged since the Miocene period, while almost all other mammalian forms which existed then have either become extinct or undergone extensivo modification. The tapirs constitute the single genus, Tapirus, of the family Tapivida.'
The dentition is $i \frac{3}{3}, c \frac{1}{1}, p \frac{5}{3}, m \frac{5}{3}$; total 42 . Of the upper Incisors, the first and second are nearly equal, with short, broad crowns, the third is large and conical, considerably larger than the true canino, which is separated from it by an interval. Lower incisors diminishing in size from the first to the third; the caninc, which is in contact with the third incisor, large end conical, working against (and behind) the canine-like third npper incisor. In both jaws there is a long interspace between the canines and the contmencement of the teeth of the molar series, which are all in contact. First upper premolar with a _triangular crown, narrow in front owing to the absence of the anterior inner cuap. The other upper premolars and molars all formed on the same plan and of nearly the same size, with four rootg and quadrate crowns, rather wider tranaveraely than from before backwards, each having four cusps, conncted by a pair of transverse ridgea, anterior and posterior. The first lower premolar compressed in front; the others composed of a simple pair of transverse crests, with a small anterior and posterior cingulaf ridge
Skull elevated and coupressed. - Orbit and temporal Cossa widely continnous, there being no trua post-orbital process fron the frontal bone. Anterior narial apertures very largo, and extending high on the face keliveen the orbits; nassl bones short, elevated, triangular, and pointed in front. Vertebra: C 7, D 18, L 5, S 6 , C sbout 12. Limba short and stouto Fore feet with' four toes, having distinct hools: tne frrst is absent, the third the longest. the second and fourth nearly equal, the fifth the shortest and scarcely reaching the ground in the ordinary atanding position. Hind feet with the typical perissodactyle arrangement of three toos, - the middle one being the largest, the two others nearly equal. Nose and upper lip elongated into a fexible, mobile enout or thort proboscis, near the end of which the nostrils are situated. Eyes rather small. Ears of moderate size, ovate, erect. Tail very ghort. Skin thick and but acentily covered with lair.

The existing species of tapir may be grouped into two sections, the distinctive characters of which are only recognizable in the skeleton. (A) With a great anterior
prolongation - of the ossification of the nasal septum (mesethmoid), extending in the adult far beyond the nasal bones, "and supported and embraced at the base by ascending plates from the maxillx (genus Elasmognathus, Gill). Two species, both from Central America, Tapirus Zairdi and T. dowi. The former is found in Mexico, Honduras, Nicaragua, Costa Rica, and Panama; the latter in

American Tepir, from a living specimen in the London Zoologicat Gardens.
Guatemala, Nicaragua, and Costa Rica. (B) With ossifica. tion of the septum not extending farther forward than the nasal bones (Tapirus proper). Three species, T. indicus, the largest of the genus, from the Melay Peninsula (as far north' as Tavoy and Mergui), Sumatra, and Borneo, dis. tinguished by its peculiar coloration, the head, neck, fore and hind limbs being glossy black, and the intermediate part of the "body white ; T.' americanus (1. terrestris, Linn.), the conmon tapir of the forests and lowlands of Brazil and Paraguay; and T. roulini, the Pinchaque tapis of the high regions of the Andes. All the American species are of a nearly uniform dark brown or blackish colour when adult; but it is a curious circumstance that when'young (and in this the Malay species conforms with the others) they are conspicuously marked with spots and longitudinal stripes of white or fawn colour on a darker ground.

The habits of all the kinds of tapirs appear to be very similar. They are solitary, nocturnal, shy, and inoffensive, chiefly frequenting the depths of shady forests and the neighbourhood of water, to which they frequently resort for the purpose of bathing, and in which they often take refuge when pursued They feed on various vegetable substances, as shoots of trees and bushes, buds, and leaves. They are hunted by the natives of the lands in which they live for the sake of their hides and flesh.
The singular fact of the existence of so closely allied animals as the Malayan and the American tapirs in such distant regions of the earth and in no intervening plases is accounted for by what is known of the geological history of the race, for, if we may judge from the some what scanty remains which have been preserved to our times, consisting chiefly of teeth, the tapirs must once have had a very wide distribution. There is no proof of their having lived in the Eocene epoch, but in deposits of Miocene and Pliocene date remains undistinguishable generically and perhaps specifically from the modern tapirs (though named $T_{\text {, }}$, priscus, T. arrernensis, itc.) have been found in France; Germany, and in the red crag of Suffolk. Tapirs appaas
and is separately condensed, the lightest portion passing through a worm condenser. From treatment in close retorts resinous roots yield from 16 to 20 per cent. of tar. with some oil of turpentine and pyroligneous acid.

Wood tar is a serci-fluid substance, of a dark brown or black colour, with a strong pungent odour and a sharp taste. Owing to the presence of acetic (pyroligneous) acid, which is a collateral product, it has an acid reaction : it is soluble in that acid, as mell as in alcohol and the fixed and essential oils, \&c. Tar consists essentially of a misture of homologous hydrocarbons, and by redistillation it can be fractionated into a-series of bodies Laving fixed boiling points. Some varieties of tar have a granular appearance, from the presence of minuto crystals of pyrocatechin, which dissolve and disappear on heating the substance. Pyrocatechin dissolves freely in water, and to it the tar water (liquor picis) of pharmacy probably owes its value.

Crude tar from retorts, when submitted to redistillation, gives off wood spirit (methyl-alcohol), and then acetic (pyroligneous) acid, and finally, on forcing the heat, pitch cil is driyen off. The residuum left in the still hardens into a solid-vitreous mass, which forms the black pitch of commerce. Tar and pitch are most largely used as protective coatings for woodwork and other materials much exposed to water and the weather. Thus tar is of great ralue in connexion with shipbuilding and shipping generally. A considerable quantity is used in manufacturing tarred ropes, and in the "smearing" of highland sheep to afford a protection against the weather. Pitch also is the basis of the Berlin black or Brunswick black used for coating cast-iron goods and for "japanning " preparations.

Coal Tar.-The art of distilling coal for the production of tar was discovered and patented by the earl of Dundonald in 1787, and till the general introduction of coal gas some amount of coal was yearly distilled in Scotland for the production of coal tar. The demand for the substance was limited, it being principally used for coating iron castings and smith work, for making an inferior lamp black, and as a source of a solvent oil. With the extensive use of coal gas the necessity for this separate distillation ceased, and soon tar was produced in the manufacture of gas in quantities that could not be disposed of. It was burned up for heating gas-retorts; it was mixed with coal dust, sawdust, \&c., for making patent fuel; and it was distilled for producing a series of hydrocarbon oils, heavy tar, and pitch; but it was only after the discovery and introduction of "tar-colours" that the substance came for some time to be really valuable. Since that time its price has fluctuated greatly; and in the United Kingdom alone there are now distilled annually about $10,000,000$ tons of coal for gas-making, producing $120,000,000$ gallons of crude tar, - a quantits greatly in excess of the ordinary dcmand.

If wood be distilled slowly at low temperatures, the gases consist chielly of carbonic oxide and carbonic acid, mixed with only very little of carburetted hydrogens, and consequently little luminous on combustion; the watery part of the tar includes relatively much of methyl-alcohol, acetone, and acetic acid; the oily part of the tar (tar proper) has a certain proximate composition characteristic of this mode of distillation. Our present knowledge in regard to this last-named point is very incompleto: of definito species the following have been discovered:-

> (1) Phenol, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}$ (aynongm carbolle acld).
> (2) Cresol, $\left(\mathrm{C}_{6} \mathrm{H}_{4}, \mathrm{CH}_{3}\right) \mathrm{OH}$.
> (3) Phlorol, ( $\left.\mathrm{C}_{6} \mathrm{H}_{4} . \mathrm{OH}\right) \mathrm{C}_{2} \mathrm{H}_{5}$
> (4) Pyrocatechine, $\left(\mathrm{C}_{0} \mathrm{H}_{4}\right)\left(\mathrm{OH}_{2}\right)_{2}$, one of thre isomertdes.
> (5) Guzlacol, $\mathrm{C}_{6} \mathrm{H}_{5}\left\{\begin{array}{l}\mathrm{OH} \\ \mathrm{OH}_{3}\end{array}\right.$, methyl-ester of \$io. 4.
> (6) Homo-pyrocatechine, $\left\{\mathrm{C}_{6} \mathrm{H}_{3}\left(\mathrm{CH}_{3}\right)\right\}(\mathrm{OH})_{2}$.
> (7) Creosol, $\left\{\mathrm{C}_{4} \mathrm{H}_{2}\left(\mathrm{CH}_{3}\right)\right\} \mathrm{OH}_{8}{ }^{\prime}$ methsl-cister of No. 6.

Gennine creosote consists of (1), (2), (5), and (7). In aadition, there aro numberless bodies which still await acientific definition.

If the distillation of rood is carried out at a very high tempera-ture,-if, for instance, the wood is placed in a relatively large retort
proviously branght up to a Dtigntraest heat and kept at ouch temperature, or if the vapours produced at a relatively low temperacure ane piseed, through intensely heated pipes before reaching the condenser (28ttenkoler's method for producing illuminating gas from wood), - the gas produced contains a considerable admixture of luminiferous hydrocarbons, the proportions of metliyl-alcohol, acetone, and ecotic acid get less, and the tar proper assumes more of the character of coal-gas tat (seo below). Similar observations we make in the case of coul. About 1862 Wigan cannel coal used to be distilled industrially at low temperatures to produce "light oils." Schorlemmer examined chose and found them to consist chiefly of "paraffins" (see P"RafFin) from $\mathrm{O}_{5} \mathrm{H}_{12}$ upiwards. A similar result is obtained with ordinary coal, although in its case the "benzols" are morr largely leureosuted. If we distil any kind of coal at high temperatures-i.e. in the way customary for illumin. ating-gas naking-the distillable port of the tar proper consists chiofig of benzcne, $\mathrm{C}_{6} \mathrm{H}_{8}$, and beuisro-derivatives, i.e., benzols, $\mathrm{C}_{6} \mathrm{H}_{6}+2 \mathrm{CH}_{2}$; pheaols, $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{4}$ and homolognes, $\left(\mathrm{C}_{6} \mathrm{H}_{3} .22 \mathrm{CH}_{4}\right)$ OII; amido-bodies, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ (aniline), and homologues; condensed benzols, such as naphthalene, $\mathrm{C}_{20} \mathrm{H}_{8}=2 \mathrm{C}_{6} \mathrm{H}_{6}-\mathrm{C}_{2} \mathrm{H}_{4}$; anthracene, $\mathrm{C}_{14} \mathrm{H}_{10}=3 \mathrm{C}_{6} \mathrm{H}_{8}-\mathrm{C}_{4} \mathrm{H}_{6}$; chrysene, $\mathrm{C}_{18} \mathrm{H}_{12}=4 \mathrm{C}_{6} \mathrm{H}_{6}-\mathrm{C}_{6} \mathrm{H}_{12}$; \&c. The parafinu then become an altogether subordinate feature.

A great and neritorions research of Berthelot's has thrown considerable light on the chemical mechanism of dry distillation. As found by him, even the most complex of the substances named are producible by the interaction upon one another of a fur bedies of very simple constitution, or even one or other of these by the mere action of a high temperature. To give a few examples. Marshgas, $\mathrm{CH}_{4}$, when passed through red-hot tubes, yields olcfines, $\mathrm{C}_{2} \mathrm{H}_{4}$, $\mathrm{C}_{8} \mathrm{H}_{6}, \mathrm{C}_{4} \mathrm{H}_{8}$, \&c., with elimination of hydrogen, $\mathrm{H}_{2}$. The same $\mathrm{CH}_{4}$, if subjected to a spark-current (i.e., local application of intense heat), yields acetylene and hydrogen, $2 \mathrm{CH}_{4}=\mathrm{C}_{2} \mathrm{H}_{2}+3 \mathrm{H}_{2}$, and tho acetylene produced passes partly into beuzeqe, $\mathrm{C}_{6} \mathrm{H}_{6}=3 \mathrm{C}_{2} \mathrm{H}_{8}$. Ethylene, $\mathrm{C}_{2} \mathrm{HI}_{4}$, when passed throngh a porcelain tube kept at a maderato red heat, yields benzene, $\mathrm{C}_{6} \mathrm{H}_{6}$, styrolene $=$ phenylethyleye, $\mathrm{C}_{2} \mathrm{H}_{3} . \mathrm{O}_{6} \mathrm{H}_{5}$, naphthalene, $\mathrm{C}_{10} \mathrm{H}_{8}$, and perhaps also its hydride, $\mathrm{C}_{10} \mathrm{H}_{10}$. Acctylene, qua potential benzene, and ethylene yield styroleae and hydrogen, $\mathrm{C}_{6} \mathrm{H}_{6}+\mathrm{C}_{2} \mathrm{I}_{4}-\mathrm{C}_{6} \mathrm{H}_{5} \cdot \mathrm{C}_{2} \mathrm{H}_{3}+\mathrm{H}_{2}$; and otyroleno plus ethylenc yields hydrogen and naphthaleno, $\mathrm{C}_{10} \mathrm{H}_{6}$.

Benzol at a high temperaturo loses hydrogen, and, so to say, doubles up into di-phenyl, $\mathrm{O}_{22} \mathrm{H}_{10}$; and this latter, when licated with ethylene, yields anthracene, $\mathrm{C}_{14} \mathrm{H}_{10}$, and liydrogen, $\mathrm{C}_{12} \mathrm{H}_{10}+\mathrm{C}_{2} \mathrm{H}_{4}=$ $\mathrm{C}_{14} \mathrm{H}_{10}+2 \mathrm{H}_{2}$. Conversely, hydrogen may, so to say, turn olit its equivalent of a hydrocarbon; thus, for instance, chrysene, $\mathrm{C}_{16} \mathrm{H}_{12}+$ $2 \mathrm{H}_{2}$, yields di-phenyl, $\mathrm{O}_{12} \mathrm{II}_{10},+$ benzenc, $\mathrm{C}_{6} \mathrm{H}_{6}$.

Pyrogenic reactions generally arc reversible; thus, any of the following three equations is correct, whether wo read it from the left to the right or from the right to the left:-

> (1) $\mathrm{C}_{2} \mathrm{H}_{6}$ (ethane), at \& red hest becomes $\mathrm{C}_{2} \mathrm{I}_{1}+\mathrm{H}_{2}$. (2) $\mathrm{C}_{12} \mathrm{H}_{10}+\mathrm{C}_{6} \mathrm{H}_{8}=\mathrm{C}_{18} \mathrm{H}_{12}+2 \mathrm{H}_{2}$. (3) $\mathrm{C}_{14} \mathrm{H}_{10}+2 \mathrm{H}_{2}=2 \mathrm{C}_{6} \mathrm{H}_{6}+\mathrm{C}_{2} \mathrm{H}_{2}$.

Hence no siugle pyrogenic reaction gocs to the end; if it does not, so to eny, cleek its own progress, other secondary reactions set in and do 60 , the general result being that ultimately, but in general slowly, a stato of dyuamic equilibrium is attained in which a set of synthetic reactions on the one land and a set of analytic reactions on the other compensate one another.

Industival Working of Coal Tar. ${ }^{1}$ - Conl tar, as it comes from the gas-works, is uscil for a variety of purposes, such as-(1) for fuel, the tar beiug made into a spray by means of a steam-injecto and the spray kindled; (2) for the preservation of building materials, porous stones, and bricks, \&c.; (3) for making roofing. felt (in 1868, five-sixths of the yono tons of tar produced at the Berlin gas-works was thus utilized ; the case, howercr, is different now) ; (4) for making a low quality of lamp-black. At present, however, most of tho tar produced, in centres of industry at least, is worked up by distillation. The tar as it cones from tho gas. works is allowed to rest in a "pond" nutil tho tar-water (solution elifefly of anmonia and certain ammonia salts) has gone to the top. The tar proper is then pmomped into a large wrought-iron still (of apriglit-cylinder form preferahly) and therein subjected to distillation over a naked fire. A nceessary preliminary, however, is the removal of the unavoidablo remnant of water, which is best effected by cautionsly heating the tar in the still so as to remer it more fluid and enabie the water to riso to the top and then letting the opper stritum run out by an overflow tap at the sido. The distillation is then started. It involves the formation of tro sets of volatile products, namely- (1) combustible gases (including sulphuretted hydrogen and Lisulphide of earbon vapour), which must bo led away to aroid nuisance and danger of fire, and (2) a very complex liquid or semi-liquil distillate. This latter is collected in surcessive fractions, generally in this unanner :-(1) as "first runnings," what comes over at temperatures below $105^{\circ}$ to $110^{\circ} \mathrm{C}$. ; (2) as "liglit oils," at touperatmes between $110^{\circ}$ and $210^{\circ} \mathrm{C}$. ; (3) $99^{* 6}$ carbolic oil," at temperatures between $210^{\circ}$ to $210^{\circ} \mathrm{C}$. ; (4) is
"creosote oil," at temperatures betreen $240^{\circ}$ to $270^{\circ} \mathrm{C}$. ; (b) as anthracene oil, at temperatures above $270^{\circ}$.

In the carlier part of the "first runnings" and light-ail period the condenser must be kept cold ; towarls the end it nubt be kept warm to prevent choking by solidified maphthalcue. In practice, the operator does not go entively by the boiling point, but to a great extent by the specific gravity of the distillate, which, in general, increnses as the boiling point rises. As soon as a drop of the last runnings floats in water (exhibits the specific gravity 1), the "light oil" is sulplosed to be over. That the fractionation is not alirays and everywhere elfected in the same way nceds hardly bo caid. If the manofaeture of earbolic acid is amed at, it is hest (accorling to Lunge) to selcet the fiaction $170^{\circ}$ to $230^{\circ} \mathrm{C}$. for this purpose. Naplithalene boils as high as $217^{\circ}$, yet a dlal gocs into this earbolic-acil iraction. As soon as naphthalene begins to crystallize out largely (on cooling (lown a sumple of (listillate), the carbolic acid may be presumed to bo over. What follows next is put asicle as creosote oil, until, aftor the disalpearance of the naphthaleno, a new solid product, namely, antluacene, lucrms to slow itself. With any tar that contains a remmerative proportion of anthracene, the anthracene oil is the most valuatbe of the products, as the raw material for the making of artificial olizarius.

Supposing tho anthracene to havo been extracted as completcly, as practicable, the residue in the still consists of "hard pitch," a viscid black fluid which on cooling freezes into a fragilu solid. In former times more commonly than bow "soft pitels" used to be produced by leaving wore or less of the anthracone oil aud even creosote oil in the still. At the end of the anthracene stage of the distillation it is as well, if not aecessary, to help tho very high boiling vaponi out of the still by means of superheated stean, and to keep tho romn at $100^{\circ} \mathrm{C}$, to prevent choking. At a German establishment a vacumm is used with great adrantage,

We como now to explain briefly how the scveral fractions are worked up.
The pitch (which wo assume to be "hard pitcl" ") inust be run off hot through a tap at the bottom of the still and led into a low. roofed and well closed-in "house," hecruse it would take firo in the open air. After it las cooled down sulficiently in the "house," the pitch is run into pitch-loles in frent of the loonse and allowed to ficeze there. The depth of pitch in a hole is alonat 12 iuclies. The solid pitch is hacked out with pickaxes and sent into commerce. $A$ sujperior apparatus for tho recovery of the pitch, which prechudes all danger of conflagration and many inconveniences of the ordinary system, lias hcen devised for the Paris gas-works by Regnault. ${ }^{2}$ Lunge found, from inany distillations, that tar from the midland counties yields about 55 per cent. of hard pitch.

Hard pitch is used chiefly for making tho following. (I) Asphatt.-The pitch is fused ip-perhaps in tho still which produed it-with the requisite proportion of creosote and anthraceno oil, previously freed from their valuable components. Suclu asplialt is used for street-lyaing, i.e., filling up the epaces betwecu the paving-stones, and, in admixture with snad and generally more or less of natural asphalt, for tho making of footpaths and floorings generally. In Germany it serves for the makiug of pipes for eonveying reid liquids in works and chemical laboratories, \&c. Endless hemp-raper is soaked in liquefied asphalt and wound spirally around au iron core, previonsly smeared over with soft soap, in about 100 layers. The whole is then exposed to strong pressure while still loot, and is scparated from the core after being allowed to cool. Such pipes stand 'almost any kind of acid, but they must not be used for hot liquids. (2) Varuishes. -The pitclı is dissolved in suitable tar oils, -creosote oil for a lower and light oil for a higher quality. (3) Coke, - In fonnce tines more frequently than now pitch was inade into coke by transferring it to a special flat still and distilling as long as any volatile products caino olf. The coke which remains is a very pure and consequently valuablo fucl. (1) Lamp Blach (as a last resonnce, if no other modo of utilization is practicable). -The pitch is subjected to martial combustion on hot iron plates and the smoke conveyed into chambers to deposit its carbon. The yield is about 40 per cont.

Anthracene Oil. - The oil is allowed to stand cold for a week or so until tho antluaceno has erystallized ont as completely as possible. The mother-litpor is then eliminated, the bulk by means of a filter-press, the rest, at a higher than tlo ordinary temperature, by hydraulic pressure. The crude product inclukes far more than half its weight of impuritics-phenanthrene, parallin, naphthalene, \&c. To remove these as far as possible, tho erumb anthracene is ground up and treated with petroleum spirit (boiling at $70^{\circ}$ to $100^{\circ} \mathrm{C}$.) or coal tar naphtha ( $120^{\circ}$ to $190^{\circ}$ ), in which real anthracene is relatively insoluble. The insoluble prart is seprarated by filtering arrangements and presses (so construeted as to avoid danger of fire), and at last oublimed, mose with tho view of brioging it into a eustomary convenieat form than with tho object of etfecting forther purification. Such final anthraceno may contain 50 to 65 per cent. of pure substance. Tho only reliable method foz

2 It is describer In Lunge's Treatise on the Distillation of Coal Tar, Londun 1882, to which this article is lurgely indebten.
determining its strength is to couvert a known weight into anthraquinone, $\mathrm{C}_{14} \mathrm{H}_{10} \mathrm{O}_{2}$, by boiling it with a glacial acetic acid solution of chromic acid, separating out the quinone by diluting with water, collecting and weighing the product. One part of quinome corresponds to 0.8558 of anthracene.

Creosotc Oil is either used as it is for pickling timber, softening of pitch, \&c., or else redistilled to extract from it what there is of anthracene oil and carbolic acid oil, which are worked up with the respective priocipal quantitics.

Carboic Dil.-Assuming this oil to havo been collected (as it should be if intended for the making of carbolic acid) between $170^{\circ}$ and $230^{\circ}$, the process of extraction is, briefly, as follows. The oil is mixed with a suitable proportion of canstic-sode ley (ascertained by an assay) in an iron vessel at $40^{\circ}$ to $50^{\circ} \mathrm{C}$. Charles Lowe recom! mends loy of 1.34 sp . gr., diluted with water to five times its volume. After settling, the aqueous layer is withdrawn into a lead-lined vessel, and the soda supersaturated by sulphuric acid. Crude carbolic aeid rises to the top as an oil, and is withdrawn to be sold as such or purified. See Carbolio Aoin.

Vaphthatene abounds in the oil left after extraction of the carbolic acid by caustie soda and in the more volatile fractions of the creosete oil. From these it aeparates out (not completely), on standing, in crystals. These are collected, best in a filter-prees, and then subjected to hydraulie pressure to force ont the rest of the mother-liquor. The crude naphthalene thus obtained contains an impurity which causcs it to become red on standing in the air. To remove it, the crude product is mixed with 5 to 10 per cent. of vitriol of at least 1.7 sp . gr., at a moderate heat (addition of a little binoxide of manganese is an improvement, Lunge); it is then washed, first witl water, then with dilute alkali, and lastly again with water, to be ultimately distilled or suhlimed. In the latter case it is obtaiaed in the form of thin colourless plates of great beauty. It fuses at $80^{\circ} \mathrm{C}$. and boils at $217^{\circ} \mathrm{C}$. Naphthalone is nsed largely in the making of certain tar colours, such as Manchester yellow, $\mathrm{C}_{10} \mathrm{H}_{6}\left(\mathrm{NO}_{2}\right)_{2}$, and the beautiful scarlets and crimsons made by the "farbwerke" in Höchst, Germany; theser latter are diazo: compounda derived from $\beta$-naphtliol, $\mathrm{C}_{18} \mathrm{H}_{7}(\mathrm{OH})$. Coal gas, if impregnated at a suitable temperature with nephthalene vapour immediately before issuing from the burner, gains greatly in luminosity. This is the principle of the "albo-carbon " gas lamps.

First Runnings aud Light Oit. -These mgy be said to include all the iodustrially valuable "benzols" (taking "benzol" as a generic term for beuzol or benzene itself and its higher homologues, $\mathrm{C}_{6} \mathrm{H}_{8}, \mathrm{C}_{7} \mathrm{H}_{8}, \mathrm{C}_{8} \mathrm{H}_{10}$, \&c.). As the distiller in most cases does not aim at on actual separation of all the individual benzols from one another, but at the production of certain benzel mixtures demanded by the trade, the mode of working mey assume a great variety of forms; yet the first aim in all cases is the same, being the elimination of all the non-benzol Irom the given oil or olls. For this purpose the light oil is, as a rule, subjected to a preliminary fractionation ovor a naked fire to aplit it up into fractions fit to be worked for (crude) benzol ( $\mathrm{C}_{8} \mathrm{H}_{8}$ and $\mathrm{C}_{7} \mathrm{H}_{8}$ ), for carbolic acid $\left(\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}\right)$, and to be incorporated with the creosote ail respectively; the carbolic acid is extracted, and the creosote-oil part put aside, and thus one or more mixtures of "benzols" are obtained.

The first ruunings contain the bulk of the benzene, $\mathrm{C}_{6} \mathrm{H}_{6}$, and a little of its higher homologues, associated, however, witl bisnl phide of carbon, low-boiling olefines, $\mathrm{C}_{n} \mathrm{H}_{2 n}$, traces of carbolic acid, \&c. To remove theso impurities as far as possible, the oil is thoroughly agitated with concentrated oil of vitriol (which takes up the impurities except the bisulphide of carbon), and the "dirty" acid allowed to settle out. The acid.is then withdrawn as reatly as possible, and the residual oil washed, first with water, then with dilute caustic soda, and, lastly, again with pure water. The washed oil then is subjected to a preliminary fractionation by distillation - ver a paked flame in the "crude benzol still."

The sevoral mixed benzols obtained are subjected finally to a further fractionation in stills worked with stean, to be divided into mixed products known by specifie names in cominerce. But these we cannot possibly consider here. We will rather give an idca of the way in which the soveral chemical species (benzene, toluene, \&c.) are being isolated in a state of approximate purity to meet the demands of the tar-colour industry. To do so even for one named component by means of ordinary stills would require an endless number of fractional distillations. The work is very materially shortened if, as proposed by Mausfield longi ago, we combine the still with an inverted condenser (still-licad, dephlegmator), inserted between the still and the worm, and keep that intermediate condenser at a suitable constant temperature, so that all the less volatile part of the vapour. is jecondensed and sent back to tho still. An excellent apparatus of this kind was constructed and worked successfully by Coupier. His apparatus consists of three parts, viz.:-(1) a still heated by means of a coil of close steam pipes ; (2) a columnar rectifier-" colonnen-apparat" as the Germans call it, which comm micates with the still, and which B divided into many compartmeots by horizontal septaso contrived chat the vapour in nassing from a compartment to the next higher
one must bubble through the liquid condensed there from preceding vaponr, -an overflow pipe, trapped below by condensate, lindering accumulation of the liquid in any compertment beyond a certain level; (3) a constant temperature atill-head, consisting of a succession of communicating riog-बhaped tubes, which are immersed in a bath of .Water or molten parallin kept at a preacribed constant temperature. Only the most volatile part of the vapour aurvives as such in the celumnar rectifier, the degree of its rolatility depending, of course, other things being equal, on the rate at which we distil. This most volatile part suffers partial condensation at the prescribed temperature in the still-head; tlie condensod parts are sent back to compartments of the "colrmn" by pipes bent in to the ebapo of a $U$ at the point where they join the "column," so as to prevent vapour from ontering them. The uncondensed vapour goes to the worm, and is condonsed as usual.
To prepare benzene, the still-head is kept at $60^{\circ}$ to $70^{\circ} \mathrm{C}$. At first a mixture of low-boiling bodies and benzene goes over, which is rejected, but soon pure benzol follows and continues until almost all this component has distilled over. The benzol obtainc.' Boils between $80^{\circ}$ and $82^{\circ} \mathrm{C}$., and consequently is practically pure. In order now to extract the toluene, $\mathrm{C}_{7} \mathrm{H}_{8}$, we raise the temperature of the still-head to $100^{\circ} \mathrm{C}$. A small quantity of a mixture of benzene and toluene follows, which is rejected. After it comes a continuous distillation of almost pure toluene, boiling at $110^{\circ}$ to $112^{\circ} \mathrm{C}$. In a similar manner (relatively) pure xylene, $\mathrm{C}_{8} \mathrm{H}_{10}$, boiling point $137^{\circ}$ to $140^{\circ}$, and tri-methyl-benzene, $\mathrm{C}_{9} \mathrm{H}_{22}$, boiling point $148^{\circ}$ to $150^{\circ}$, can be extracted ancessively; but the process becomes troublesome with anything ahove toluene on account of the high temperatures involved for still and still-head. Coupjer's apparatus is now superseded by other constructions, but they all work on the samo principle, -that of the Coffey still, as ased for the rectifying of spirit of wine.

Pure benzene, tolnene, and xylene are used largely for the manufacture of tar-colours. The following (and other) mixtures are produced directly from the light oil or first runnings:-

| 90 | ..fnitlal boinag polut |  | $82^{\circ} \mathrm{C}$ |
| :---: | :---: | :---: | :---: |
| (2) 80 per cent. benzol. | " | $\cdots$ | 88 |
| (3) "Toluol". | " | " | 100 |
| (4) Carburettlog naphtha | " | " | 108 |
| (5) Solvent naphtha. | " | " | 110 |
| (6) Barning naphtha | ", | , | 138 |

No. 4 serves for enriching coal-ges and adding to its luminiferous power, No. 5 for varnishes, No. 6 for feeding primitive lamps used in the open air, where smoke is no objection.
The following perceutage table for the tar from the Berlin gas. works (given in Chemische Industrie for 1879) gives an idea of the quantitative composition of this most complox material :-

| Benzol (Includilng talool, \&c.)......................... | 0.80 |  |
| :---: | :---: | :---: |
| Higher benzols............................................. | $0 \cdot 60$ |  |
| Crystallized carbolic acld .............................. | $0 \cdot 20$ |  |
| Cresol for disinfecting purposes.................... | 0.30 |  |
| Naphthalene............................................ ...... | 8.70 |  |
| Creosote oll.................................................. |  | 24.00 |
| Anthracene (pure)......................................... |  | $0 \cdot 20$ |
| Pltch ............................................................ |  | 85.00 |
| Water and loss. |  | $18 \cdot 20$ |

TARAI, a British district in the Kumáun division of the lieutenant-governorship of the North-West Provinces and Oudh, India, lying between $28^{\circ} 51^{\prime}$ and $29^{\circ} 30^{\prime} \mathrm{N}$. lat. and $78^{\circ} 46^{\prime}$ and $79^{\circ} 47^{\circ}$ E. long. It contains an area of 938 square miles, and is bounded on the N. by the Khumáun Bhábar, on the E. by Nepal and Pilibhit subdivision of Barcilly district, on the S. by the districts of Bareilly and Moradabada and the native state of Rámpur, and on the W. by Bijnaur. The headquarters of the district are at Naini Tal. Tarai (" moist land") consists of a long narrow strip of country running for about 90 miles east and west along the foot of the Himalayas, with an average breadth of about 12 miles. At its northern edge, where the waterless forest tract of the Bhábar ends, a series of springs burst from the surface, and thesc, increasing and uniting in their progress, form the numerous streams that intersect the Tarai. The Deoha is the great river of the Tarai proper, and is navigable at Pilibhit. Elephants, tigers, bears, leopards, hyænas, and other wild animals are found in the district. The climate is normally bad, but improvement is gradually following the spread of sanitary measures.

According to the census of 1881 the ponulation was 206,993 (113,315 males and 93,678 femalest. Hindus numbered 131,966 and Mohammedans 74,982. The only town with a population exceeding 10,000 is Kásipur, with 14,667 inhabitants. The whole tendency of the population is to agricultural and not to urben lifa.

The total area under crop in 1884-85 was 254,288 acres, of which rice occupied 92,186 acres, wheat 54,627 , and other food grains 80,304 acres. There are no manufactures worthy of note, and the chief trade is the export of grain. The gross revenue in 1884-85 amonnted to $£ 42,048$, the land yielding $£ 35,507$. The Tarai came under British rule at the time (1802) avhen Rohilkhand was ceded to the East India Company. Tho Government is said to hare looked with indifference on this nninviting tract, but since 1831, when the revenue settlements were revised, this reproach has been less deserved. With an improved system of embankments and irrigation in 1851, the formation of the Tarai into a separate district in 1801, and its complete subjection to Kumaiun in 1870, the moral and meterial history of this tract has greatly improved.

TARANTO. See Tarentum.
TARANTULA. The tarantula (Lycosa tarantula) belongs to the mining section of the family Lycosidx or Wolf Spiders. Its cephalothorax is dorsally of a brownish grey colour, whilst the abdomen is more distinctly brown, and marked with either two or three pairs of triangular black spots above the apex of the triangles pointing backwards. One of the most striking specific characteristics of this spider is a large circular black spot which covers the anterior ventral half of the abdomen, the remainder of this surface presenting an ochreous hue. The largest species does not exceed $\frac{3}{4}$ inch in length. The eight eyes are arranged in three transverse rows, the anterior containing four small eyes, while behind this two pairs of larger eyes are arranged in two rows, the eyes of the hindermost row baving between them a wider interval than the first pair.

Tho tarantula is widely distributed in southern Europe, round the shores of the Mediterranean. It accurs throughout Spain and is found in southern France, and extends into Asia. In Italy it is said to be especially common in Apulia, round the town of Taranto, from which place the name of this spider is usually derived. A species has also been described from northern Africa. It is usually to be fonnd in dry pieces of waste land exposed to the sun. It lives in an underground passage, which it digs for itself and lines with its web. These passages are round in section, and sometimes an inch in diameter, and may extend to a depth of a foot or more below the surface. The tube first descends vertically for some inches, then bends at an obtuse angle, becoming vertical again near its closed end. The tarantula takes up its position at the first bend, where it can command the entrance, on the lookout for prey. In some cases the tube is prolonged above the surface of the earth by the formation of a small funnel, built up of fragments of wood and earth, and lined like the walls of the tunnel by the web. The females show considerable maternal care for their offepring, and sometimes sit upon their egg sacs; and the species, although somewhat fierce and combative amongst themselves, are capable of being tamed.

Tarantism. The terentula has given its nsme to one of those dancing manias which overspread Europe during the Middle Ages. The bite of the epider threw the cufferer into $s$ depressed otate of melancholy, accompanied by various nervous disordera. The condition was accompanied by $s_{s}$ increased sencibility to the power of music. The excitement of the nervous eystem amounted in some cases almost to insanity. The symptoms of the patient seem to have varied a good deal with the character of the individusl attacked: the most common were s lividity of the body, icy coldness, great depression, namsea, 6exusl excltement, and loss of sight and hearing. The only masns of arousing the eufferer from the lethsrgy into which he sauk was music. Under the influence of this he awoke ss it were, snd commenced noving rhythmically, then began to dance, and continuon increasing the rapidity of the motion until he fell exhausted to the ground. By this means it was considered that the poison of the tarantula was clistributed through the oyetem and worked out through the okin. If the nueic cessed whilet the patient wes dencing, he st once esnt back into the state of lethargy from which he had been aroused, but when thoroughly exhansted be generally a woke relieved and cured $t$ least for a time. This dencing manis became contsgious: one erson caught it from snother quite independently of the bito if the tarentule, and in thie way whole districte becsme sffected. ?ne of the most Deculiar characteristice wes the sttrection that
bright pieces of metal, or brilliant pieces of colour, exercised over the imagination of the dancers. This was particularly marke in the later history of the disease. Each sufferer apparently admire. one particular hue, the sight of which seemed to cisuse him th greatest rapture. Red was a very general favourite, thongh thi colour threw St Vitus's dancers into a frenzy of rage; green yellow, snd other colours also bàd numerons admirers. Othe colours, on the contrary, they detested, and attempted to destro: articles of the obnoxions shade.

In marked contrast to the effect produced by hydrophobis tarantism appeared to ovoke in its victims an intenso longing fo the sea, into which at times they would precipitate themselves at all times they seemed to prefer the-vicinity of water, sometimea carrying globes of this fluid whilst dancing.

In its origin tarantism appears to have luen contemporaneons with the St Vit:s's dance of Germany. It first appeared towards the end of the 14 th century in Apulis ; thence it spread gradually throughout Italy, and reached its height during the 17 th century, by which time the dancing manias of the North had already died out. It affected not only inhabitants of the country but foreigners visiting it; age appears to have had no aving infuence: children and old people alike commeuced dancing at the sound of the tarantella, hut as a rule women were more susceptible than men. From the 17 th century onwards it has gradually declined, and is now practically unknown, the only relic of it being the graceful dance of southern Italy called the tarsutella. The bite of the tarantula is painful but not dangerous, and the real cause of the phenomens described above must be sought in the temporary epidemic prevalence of an hysterical condition.

The Lycosm carantula is ggured in $\Delta n s$, Sc. Nat., 2d ser., ill. Zoologle, 1835.
TARARE, on the Turdine, a manufacturing town of France, and the second most populous in the department of Rhônc, is 25 miles north-west of Lyons. Within a circle drawa 25 or 30 miles from the town more than 60,000 workmen are employed, and the value of the textile fabrics produced exceeds $£ 600,000$ per annum. Tarlatans are made in 'Tarare on more than 3000 Jacquard looms. The manufacture of Swiss cotton yarns and crochet embroideries was introduced at the end of last century; in the beginning of the 19th figured stuffs, openworks, and zephyrs were first produced. The manufacture of silk plush for hats and machine-made velvets, which was set up a few years ago, now employs 2900 workmen and 500 girls, the latter being engaged in silk throwing and winding. There are, besides, four or five dyeing and printing establishments, and silk looms working for the Lyons trade. An important commerce is carried on in corn, cattle linen, hemp, thread, and leather. In 1886 the population was 11,848 (commune 12,980).
Till 1756, when Simonnet introduced the msnufacture of muelins from Switzerland, Tarare lay unknown among the mountains. On the old castle to which the town owes its origin may be oeen the arms of the family of Albon.

TARASCON, a town of France, ; the department of Bouches-du-Rhône, is situated on the left bank of the Rhone, opposite Beaucaire, with which it is connected by a suspension and a railway bridge. - It is on the Lyons and Marseilles Railway, 156.miles south of the former town. The church of St Martha, built in 1187-97 on the ruins of a Roman temple, rebuilt in 1379-1449, has a Gothic spire, and many isteresting pictures in the interior, which is of fairly pure Pointed architecture. Of the original building there remain a porch, and a side portal with cepitols like those of St Trophimus at Arles. The former leads to the crypt, where are the tombs of St Martha and Louis II., king of Provence. The castle, picturesquely situated on a rock, was begun by Count Louis II. in the I4th century and finished by King Rene of Anjou in the 15 th. It contains a turret stair and a chapel entrance, which are charming examples of 15 thcentury architecture, and fine wooden ceilings. It is now used as a prison. The civil court of the arronassement of Arles is situated at Tarascon, which also possesses a commercial court, a hôtel de ville, and fine carairy barracks. Hats, and the so-called Arles sausages, are made hera The popnlation in 1886 was 6617 (commune 3314)

The tomn wakas up for the fair of Beaucaire and the fête of La Tarasque, the latter in celebration of St Martha's deliverance of the towu from a legendary monster of that name. King Rene presided in 1469, and grand exhibitiona of costume and strange ceremonies take place during the two daya of the featival. Tarascon was originally a settlement of the Massaliots, built on an ialand of the Rhone. The medixval castle, where Pope Urban II. lived in 1096, was built on the ruins of a Romau castrum. The inhabitants of Tarascon preserved the municipal institutiona granted them by the Romans, and of the absolute power claimed by the counts of Provence they only recognized the rights of sovereignty. Tarascon played a bloody part in the White Terror of 1815.

TARAXACUM is the name usually applied in medical practice to the common dandelion (Taraxacum officinale, Wiggers). The DAxDenios ( $q . v$. .) is a plant of the northern bemisphere, extending to the Arctic regions, and is cultivated in India. The preparations chiefly employed are the fluid extract, the preserved juice of the root, or succus, and the solid extract. The dried and roasted root, mixcd with ground coffee, is often sold under the name of dandelion cofiee for use as a beverage. The root is most bitter from March to July, but the milky juice it contains is less abundant in the summer than in the autumn. For this reason, the extract and succus are usually prepared during the months of September and October. After a frost a change takes place in the root, which loses its bitterness to a large extent. In the dried state the root will not keep well, being quickly attacked by insects. Externally it is brown and wrinkled, internally white, with a yellow centre and concentric paler rings. It is 2 inches to a foot long, and about $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter. The juice when first exuded is bitter and neutral, but on exposure to the air soon acquires an acid reaction and a brown tint, coagulating and depositiog a complex substance, to which the name of "leontodonium" has been given. From this deposit a bitter principle, "taraxacin," and an acrid crystalline substance, "taraxacerin," soluble in alcohol," have been obtained, but to which of these the medicinal properties are due is not known. In autumn the root contains about 24 per cent. of inulin, but in summer barely 2 per cent. When the juice bas fermented, mannite is found in it. Taraxacum is chiefly emploged as a stimulant tonic in hepatic disorders. In some cases it acts as a cholagogue and mild aperient, and in others as a diuretic.
The roots of other Composito plants are eemetimes gathered by careless conlectors for dandelion, eappecially that of Leontedon hispidus (L.). The root of this plant is tough when fresh, and rarely exudes any milky juice. The forwers, moriocer. have feathery pappus, while in the dandelion it is simple.
TARBES, a town of France, cheiflieu of the department of Hautes-Pyrienés, is situated in one of the most beautiful plains of France, on the left bank of the Adour, streams from which are conducted through all parts of the town. The lines of railway from Paris to Pierrefite and from Toulouse to Bayonee cross here. Among the many gardens and open spaces for which Tarbes is distinguished is the Massey garden ( 35 acres), given to his native town by a Versailles official of that name, in which his statue faces the towa museum, founded by the collector Achille Jubinal. The varied collections include Roman remains, and specimens of the fauna and flora of the Pyrenees. The architecture of the cathedral is heary and uppleasing, but the cupola of the transept ( 1 tth century), the modern glass in the 12th-century apse, and a rose window of the 13 the ceatury, in the north transept, are worthy of notice. The Carmelite church has an interesting steeple, and there are the ruins of a chapel and cloister, and Roman remains in the garden of the former episcopal palace, ncw occupied by the prefecture. The municipal buildings, with the public library ( 22,000 volumes), the lyceum, the court of justice, and the barracks (which are large and fine) may also be mentioned among the public buildings. The garrison and artillery establishments, the latter associated
with an arsenal and large workshops, nave considerable im. partance. Other industrial establishments are a foundry machine manufactory, felt and woollen factories, and wool and flax spinning mills. Paper, lace, knitted goods, carriages, and leather are also made here, and marble from the Pyrenees is prepared for the market. There are important fairs and markets, particularly for horses, as Tarbes is a well-known centre for a special breed of light horses, its stud being the most important in the south of France. The population of the town was 24,882 in 1886.

Tarbes, a mere vicus in the time of Gregory of Tours, rose into impertance after the destruction of the ancient Aquitanian town of Turba. The seat of the bisholric was transferred to it about the 9 th century, wheu a castle was also built. Rayniond I., towards the middle of the 10th century, rebuilt the town, fortified it, and made it the capital of the county of Bigorre. The English helrl the town from 1360 to 1406 . In 1569 Tarbes was burat by Mentgomery, and the inlabitanta were driven eut. This happened a second time, but in August 1570 the peace of St Germain allowed the inhabitants to return to the grass-grown strcets. Subsenuently Tarbeg was Cour times taken and re-taken, and a number of the inhabitants of Bigorre were forced to take refuge in Spain, bnt in 1594 the menbers of the League were finally expelked. The Englisis, under Wellington, gained a victory over the French near Tarbes in 1814. Théophile Gautier was born here in 1811.

TARENTUM, or Taras, now Taranto, a famous Greek city of southern Italy, situated on the north coast of the bay of the same name, at the entrance of the ooly secure port on the gulf. This port, now called the Mare Piccolo, is a bay 16 miles in circuit, landlocked by a low rocky peniasula. The entrance is so narrow that it is crossed by a bridge of seven arches; it was already bridged in Strabo's time. The modern town, in the province of Lecce, winch is the see of an archbishop and had in 1881 a population of 26,611 , stands on the pevinsula, which is now rather an island, the isthmus connectiog it with the mainland having been cut through for defeoce by Ferdinand I. The ancient citadel occupied the same site, but the city in its best days was much larger, traces of the walls being visible about 2 miles from the gates of the modera town. The remains of antiquity are inconsiderable.
Tarentum was a Spartan colony founded about the close of thö 8th century B. C. (Jerome gives the date 708) to relieve the parent state of a part of its population which did not possess, but claimed to enjoy, full civic rights. Legend representa these Parthenize (se they are called) as Spartans with a stain on their birth, but dhy accounts are neither clear nor consistent, and the facts that under: lie them lare not been cleared up. The Greeks were not the firs settlers on the peninsula : recent excavations have brought to light signis of a pre-Hellenic trading-place, and the name of Taras may bi older than the colony. To the Greeks Taras was a mythical hero, son of Neptune, and he is sometipes confounded with the œcist $0^{\prime}$ the colony, Phalanthus. Situated in a fertile district, especially famous for olives and shcep, with an admirable harbour, great fisheriss, and prosperous manufactures of wool, purple, and potiery Tarentum grew in power and wealth and catended its domair - inland. Even a great defeat by the natives in 473 b.c., wheu more Greeks fell than in any battle known to Herodotus, did not break its prosperity, though it led to a change of goverument from aris: tocracy to democracy. A feud with the Thurians for the distric of the Siris was settled in 432 by the joint foundation of Heraclea ${ }_{5}$ which, however, was regarded as a Tarentioe colony. - In the 4th century Tarentum was the first city of Great Grecce, and its wealth and artistic culture at this tine are amply attested by its rich and aplendid coins; the gold pieces in particular (mainly later than 360) are perhaps the most beautiful ever struck by Greeks (see Nemissiatics, vol. xvii. p. 637). In the second half of the century Tarentum was in constant. war with the Lucanians, and did not hold its ground without tho aid of Spartan and Epirota condeltieri. Then followed war with Rome (281), the cxpedition of Pyrrhua, and at length, in 272, the surrender of the city by its Epirote garrison (see the details in vol. xx. p. 743 sq.). Tareotum retained nominal liberty as an ally of Rome. In the Second Punic War it suffered severely, when it was taken by Hannibal (212), all but the citadel, and retaken and plundered by Firbius (209). After this it fell into great decay, but revired again after receiving s colony in 123 B.c. It remained a considerable scaport, and its, purple, second only to that of Tyre, was stlll valued, but in Strabo'a time it had abrunk nearly to the limits of cbo present town. After the fall of the Western empire it was beld from time to time by

Goths, Lombards, and Sarscens, but was not fiaally wrested from Byzantium till Robert Guiseard took it in 1063.
For special hitereture about Tarentum, see Busolt, Griech. Gesth., 1. 206 sq.
TARES, or Vetches. See Agriculture, vol. i. p. 376.
TARGUM (뇍ำ) in its concrete sense signifies the paraphrastic translation of the Hebrew Scriptures, or parts thereof, into the Aramaic tongue. It has, however, three other meanings:-(1) a translation from any language into another; ${ }^{1}$ (2) an interpretation in any language; ${ }^{2}$ and (3) the Aramaic portions of certain books of the Bible (notahly Daniel and Ezra). ${ }^{3}$

The word is not itself found in the Bible; but the participle methurgam (מְרְ) occurs in Ezr. iv. 7. The noun Targum, a form similar to Talmod (q.v.), occurs for the first time in the Mishnah, both canonical ${ }^{4}$ and noncanonical, ${ }^{5}$-the latter being apparently the older source.

Origin.-Although none of the Targums now in our hands are as old as the Septuacint (q.v.), the public nse of Targums on Sabbaths, festivals, \&c., is very ancient, and indeed their language was for several hundreds of years tho sole one understood by the majority-of the Jews in Palestine and Babylonia. How the Hebrew people of Judæa came so entirely to unlearn their own Hebrew tongue as to stand in need of an Aramaic translation of their Scriptures need not be dwelt on here (see vol. xi. p. 597 and vol. xxi. p. 648). But an important contrast between the Aramaic and Greek versions deserves particular notice. The use of the Septnagint by the Greek-speaking Jews of Alexandria, Asia Minor, and elsewhere caused those who adopted it to forget entirely their own Hebrew tongue. The Aramaic version (Targum), however, springing from a religious necessity, was the cause of revival of the knowledge of Hebrew, which had been nigh forgotten. It is therefore easy to understand why the Jews in general have shown comparatively little attachment to the Septuagint, whilst they ever ardently revered the Aramaic version, even after the instifution of publicly reciting it had ceased. ${ }^{6}$ To this day pions Jews privately prepare themselves every Friday for the lessons of the coming Sabbath by reading the weekly portion twice in the sacred text and once in the Targum (シֵנים מקרא ואחר תרגום).

Former Use of the Targum in Public.-The following rules had to be observed in the reading of the Scriptures at the synagogal service:-
I. As regards the Law (Pentateuch). (1) The private person called to the Law (which cliefly contains halakhic? matter) read ouc verse of it, which the official methurgeman or turgeman (translator) immediately paraphrased ; (2) whilst the reader of the Law was not allowed to take his eye off the written scroll, the methurgeman was forbidlen, not merely to read out of a written Targum, buteveu to look in to the sacred text; ${ }^{8}$ (3) each of these had to wait till the other had quite finished the reading and translation respectively ; (4) one was not allowed to raise his voice in a louder key tlisn the other; (5) a certain mumber of passages, although allowod to be read, were not allowed to be translated; theso were-

## ${ }^{1}$ Hence "תג (Gerouan translation), \&c.

${ }^{2}$ When the word is used in either of these two senses the language Kat, which the traaslation is made, or in which an interpretation is given, must be specified, or otherwisa indicated, e.g., (נ)
 translated), excapt when it is Aramaic, in which case the language 'may be named (as in Ezra 1r. 7) or not (Tosephto, Shabbaih, xiii. [xiv.] 2).
${ }^{3}$ Compare Mishnah, Yadayim, iv. 5 . \$See last note.
8. Siphere (see vol. xvi. . p. 507) on Deuteronany (Pericope Shophetim), Pisko 161.

8 "Let not the Aramaic be lightly esteemed by thee," says the Jerusalem Talnud, "seeing that the Holy One (blessed be He !) has given houour to it in the Pentateuch (Gen. xxxi. 47), in the Prophets (Jer. x. 11), aod in the Hsgiographa (Daa. ii. 4)," (Sotah, vii, 2). Instead of "Arammi" (Aramaic) the Midrash Rabbah on Génesis reads "Parsi" (Persian); the reading here ia "Surai" (Syriac).

J Seo Mishnah, vol. xvi. p. 503.
${ }^{-}$This was done to prevent its being thought that the Targum (the exponent of the oral Law) was to be found in writing in the geatateuch (the exponent of the written Law).
(a) such as might reflect unfarourably on a father of a tribe, or on an eminent tereher (T. B., Megill., 25b, Tosaph., caichword העשע (b) such as might encourage the ignoraut to think that there was some truth in idolstry ; (c) such as might offend decency (Mishnah, Megillah, iv. 10 ; Tosephlo, ibid, 35,37 ; T. Yer., ibid., iv. 10; and T. B., ibid., leaf 25b) ; (d) such as were fixed by the Lord Himself to be read in Hebrew only (as the sacerdotal benediction, Num. vi. 24-26); ${ }^{9}$ (6) the translator wes neither allowed to give a literal tranalation nor to add anything that had no foundation in the Divine word; he had to give the opirit of the letter. ${ }^{10}$
IL. As regards the Prophets. (1) The person called to read the Prophets (which chielly contain agadic master ${ }^{11}$ ) might read three verses, of which the translator, who might be the reader himself, ${ }^{\text {r2 }}$ eought to render the meaning to the best of his ability; (2) the translator was allowed both to read out of a Targum volume and to look also into the book containing the prophetie text; (3) if reader and translator were two different persous they observed the third rule given above for the case of reading the Law; (4) here also certain passages were not sllowed to he translated :-(a) auch as reflected on great men of the Israelite nation; (b) such as offend decency ; (5) any one- sufficiently intelligent might read, and of course paraphrase, the portion from the Prophets.
III. As regards the Hagiographa. The widest range of Jiberty must have been granted botli to reciters and translators, as very scanty mention of any particular provision concerning it is to be found in the Talmuds. The Psalms and the book of Esther are classed together in so far as they may be read end paraphrased even by ten persons (T. B., Meg., 21b). For Job and Lamentations, see below.

Duration of this Practice.-The practice of publicly reciting the Targum continued somewhat later than the last of the geonim. Within the last 400 years of that period, however, the power of this ancient institution began to fluctuate, gradually declined, and finally almost -but not entirely ${ }^{13}$-died out. The causes of this were twofold. One was, that after the Mohammedan conquests Arabic supplanted Aramaic as the vernacular, and the Targums thus became unintelligible to the mass (see Seder Rab 'Amram, i., Warsaw, 1863, leaf 29a), eren as was already the case in the Western world. A second and more important canse, however, was the spread of Karaism, whose criticism of the Rabbinic contents of the Targums provoked the Rabbanites to pay more attention to the etymology and grammar of the Hebrew text of the
${ }^{2}$ The Babylonian Taimnd (Megillah, 25b) Eays that the priestly benediction was not to be recited in Aramaic on account of the phrase "the Lord shall lift up His countensace upon thee," which would appear as if the Lord had been a respecter of persons. In Talmudic times they had apparently, in Babylonia, lost the real reason of the Miahnic prohibition, which is that this benediction is doubly, yea, trably Divinc, being franed in its every word by God Himself, and cau thus only be recited in those very words ( 17 , thus; Num. vi. 23). See Mishnah, Sotah, vii. 2 ; T. Yerushslmi, ibid., and Megillah, iv. 11, and, finally, Bemidbar Rabbah, cap. xi. in medio.
${ }_{10}$ See Tosephlo, Megillah, iv, in fine.
${ }_{11}$ See Midrasi, vol. xvi. p. 285.
12 Thus Jesus (Luke iv. 16-27) no douht read the Haphtarah (prophetic portion) himself, and paraphrased it himself. From this custom of reading and paraphrasiag by one and the sanue person the sermon (กயา7) sprang. The passage in question (1sa. Ixi. 1, \&c.) was resd on tho Sabbath before the New Year (day of memorial).
${ }^{13}$ Long after the institution of publicly reciting the Targum on the Law had generally declined, it was yet retajned in Germany and ltals on certain days of the three high festivals, viz., (a) the seventh day of Passover, (b) the first day of Pentecost, and (c) the last day sttached to the festival of Tabernacles (i.e., הาทก תחロU). The passages so recited were-(a) parts of the lessoa for the day-the song of Moses and the children of Israel, with the introduction; (b) the Decalogue in Exodus; (c) the last portion of Deuteronomy. In the first case the paraphrase was from the three Targums mixed, in the second from the Targum Yonathan with devistions, in the last from the Targurg Orkelos. (These pieces are interspersed with sundry bits of poetry; see Caınb. MS. Add. 374, leaves 169a-171b, 199a-203a, 423b-427b.) Towards the end of the 14 th centory, as regards Passover and Pentecost, thio custom fell into desuetude, but down to our own days some of the congregations of Italy continue the usage of reciting the Targin Onkelos in comexion with the sarration of the death of Moses. This custom, however, is now rapidly dying out. As regards the recitation of the Targum on the Prophets, a smell remnant of the cangregations following the rite of Rome (i.e., the so-called Ilaliani) continue it to this day on the festival of Passover. For the use of the Targam On Pentecost, see Responsa, by R. Meir of Rothenburg (Rosy, g.v. footnote 3), No. 59.

Sible. Thus the Targume, both in their periods of vigour and decay, exercised, directly and indirectly, a salutary influence. In each case the knowledge of Hebrew was promoted; and it advanced so much, that by 1000 A.D. the Jews of Irak, like those of the rest of the world then, and as in our own days, certainly knew the pure Hebrew better than the Aramaic idiom. The same was the case in other Arabic-speaking parts, as Spain, Africa, \&c.,-Yemen then and still forming a solitary exception. ${ }^{1}$

Authorship and Age of the Various Targums.-The Tafrums on the various books of the Bible are not merely by various authors, but also of various ages. They have only one thing in common,--all of them rest on oral traditions, which are hundreds of years older than the earliest form of the written Targums now it our hands We enumerate them according to Biblical order, although that is not necessarily the chronological order in which they were either composed or committed to writing.
I. The Pentatcuch.-(a) There is a complete Targum known as
 even the name of Onkelos havo been for the lest three handred years a crux criticorumi.
Accordiog to the Babylonisn Talmud, Megil., 3 a, "Onkelos (son of Calonicurs, Gill., $56 b$, or of Calonymus, 'Ab. Zar., 11a), the proselyte, composed the Targum on the Pen tateuch (inpop) out of the mouth of R. Eliezer and R. Yehoshua'," who taught in the 1st and 2 d centriies. In the Jerusalem Talmud, Jcç, i. 9 , the same thing is related on the sanne autherities, and alnost in the same morda, of the prosclyte Aquila (Akylas) of Pontus, whose Greek version of the Bille was much ussed by Greek-spoaking Jews down to the time of Justioian (Nov., exlvi. cap. 1).2. There are other parallels between what Tosephoo and the Rabylonisn Talund tell of Onkelos and what the Jerasalem Talmod sind the Midrash tcll of Aquila. Both throw their idolatrous inheritance into the Dead Sca (Tos., Demai, vi. 12; T. Y., Demai, vi. 10), aud both have connaxions with
Roman emperass, Onkelos being sister's son of Titus (Gitin, $56 \downarrow$ ),
 Onkelos, 'Ab. Z., $11 a$, and for Aquila's connexion with Hndrian, T. Y., Hag., ii. 1; Shem. Rabb., xxx.; Epiphanius, De Dfens. el Pond., xiv, sq.). From theso fncts nome (see N. Adlcr, Nethinah lagger, in the Vilna Pent., 1874, Introd.) still argue that Ookelos is but another name for Aquila, and that the Greek translator elso wrote our Targum. This view was long ngo refuted by R. 'Azaryah do' Rossi, ${ }^{3}$ nnd is quite untenable. It is incredible that $\Delta q u i l a$ or any other Greek could have had the mastery of Aramaic and of traditional lore as well as of Hebrew which the Targum displays; and the phrase of T. Y., Ifegil., i. 9 , ", an nntutored person picked out for them Aramaic from the Greek,"," is quite inapplicable to Onkelos, and ought to be taken as referring to the Peshito Syriac, which is admittedly dependent on the LiX. In a Jevisi writing "for them"-set absolutely-means "for the Christians." The view now accepted hy most critics is that the word Onkelos is a Babylonian corruption of Akylas, but that the name "Targum Oakelos," originally meant no more than "Targum in the style of Aquila," $i$.e., bearing to the freer Palestinian Targums a similar relation to that of Aquila's version to the Septuagint. ${ }^{4}$ On this riew there nezer was a real person called Onkelos. . But how Akylas
 could be corruptod into Onkelos has not been sstisfactorily ex. plained ; and, besides the traditions about Onkelos which resemble what is known about Aquila, there ere others, ind these older than
${ }^{1}$ In Yemen the Targum is pablicly recited to this day, and, strange to say, by boya of nine years of age or 80 in turn. See J. Saphir, Eben Sappir, 1. (Lyck, 1866 , 8 vo ) leavea 53b, 61a. Saphir once tald the present writer that a youth, eighteen yeara 0 : age ( $u \ell$ supra, 61b), who carried hls travelliog-bag zad ecrved as his guida over the monntaiaa, Said, i.e., Såadyah, by name and a ahoemaker by trada, could translate to him in Aramaic from inemory any passage Saphir recited in Hebraw.
${ }^{2}$ For the coasexion of Aquila with R. Eliezer and R. Yehoshua', see also Beresh. Rab., flxx.; Bemidb. Rab., viii. end; Kohel. Rab., vii 8.
a I.e., "min Haadummim." The Adunımim are aupposed to bo one of the fonr noble families caried to Rome by Titus.

4 The Jerusalem Talmud repeatedly cites Aquila'a renderings and never names Onkelos. But it does ahow acquaintance with readeriags found in Onkelos (e.g., Megil., iv. 11; cf. Oak. on Exod. xxxii. 35) In the Midrash Rabbah, besides many citations from Aquila, we find ons of Onkeloa by name (in Bem. R., ix in fine; Onk. on Dent. zxxii. 24) and varlous allusions (without name) to renderings found in him. Fo la alao cited byame in the Palestinian Pireke de.R. Elifezer, xuxviii.
eitner Genara, which have no such resemblance, and assign to lim an earlier date, associating him with R. Gamliel the elder, the teacher of St Paul (Toscphto, Shab., vii. [vin.] 18; Hag., iii. 2, 3 ; Kel. Bab. Balh., ii. 4; Mikv., vi. 3; Talmud B., Ab. Zar., Ila; Mas. Semah., vini. init.). The Tohar (ini. leaf $73 a$ of the small ed.) ascribes his being circuincised to Hillel (R. Gamliel's grandfather) and Shammai. These notices, it is true, do not speak of Onkelos as a targumist; and, indead, the Targum beinf a representative pieca of the oral law एas certainly not written down, private notes (nugilloth setharim) excepted, belore the $\lambda$ (ishnah, Tosephto, \&c., i.e., till ebout the end of the 6th or the beginning of the 7th ceutury. But in the opinion of the preseut writer this need not prevent us from recognizing Onkelos as a carrector and compiler of oral Targum in the Ist century. As regards the mane, it may be suggested that Onkelos is a deliberate perversion of Evangelus, a Greck proper name which exactly translates the Jewish (aud especially Babylon-ian-Jewish) name Mebasser. As the Christian writings are called Aven (iniquity, idolatry), and as tho pre- Mi ishnic teacher R. Meir calls tho gospel (vangelion) ongillayon (iniquity of the roll; T. B., Shab., leaf 116, Amst. ed. of 1645), or, by inversion, gilyon-aven (roll of iniquity), the name Evangelus, which suggested associations with the gospel, might be perverted into Onkelos quasi On-keles (iniquity of disgrace). And, while a Balylauian Jew comiug to Palestine might find it convenient to tramsla to his Hebrewname into Evangelus, this good Greek name was enough to suggest in after times that he was of heathen origin and so to facilitate tha confusion with Aquila. The idiom of the Targum Onkelos, which is held to be Palestinian with some Babylonian featrires, points to Babylonia as the country of its final redactor, if to Palestine as its source. It must be remembered that Hillel and other great fountains of Palestinian learning were of Babylonian origia. ${ }^{\circ}$
( $B$ ) Certain Targumic fragments on the Pentateuch go under the nsme of Targum Yerushalmi, or, rather, Palestinian Targum. These are the remeins of a much larger Jcrusalem Targum, once current in Palestine. But, the Palestinian rabbis not having approved of it, perhaps because it accorded in various of its iuterpretations and phrases with intorpretations and phrases to

* Bibtiography of the Targum Di>p:in.- (A) There are very fina MSS. of this Targars at Parma, Oxford, Canbridge (Dd. 11, 26, Add. 446, 1053), the British•Museum, Kissiugen (Ralbiu Bamberger), \&c. (B) A Massoreth on our Targum by an anonymous author, who must hava lived in or before the-12th century, lias been pub-liahed-(1) by Luzzatto (Oşar Nehmad, iv.); (2) by Adler (Vilua edition of the Peatateuch of 1874); aad (3) by Berliaer (with a German translation, \&cc., Leipsic, 18ĩ, 8vo). State of Tcxt. -The Targum text is, taken as a whole, in a very corrupt state The causes of this comuption are many, but chipfly the following:-(1) mistakes ordinarily made by scribes through carelesaness, or ignorance, or beth; (2) the Targumis had passed from cellury to century and from country to comitry without having been written down; (3) when written down they were probably not provided with vowel points at once ; (4) when provided with vowel-points most of them were first provided with Babylonian ior Assyriaii), which afterwards were changed into Palestinian ones; this change was a fertile source of fresh mistalies; (5) the loss of tho general knowledge of the Targumic idiom contingent on the decline and final fall of the institution of publicly reciting the Targum was au additional source from which mistakes arose; (6) conjectural emendations contributed their nuota to the corruption of the text; (7) Buxtorf's emendations founded on the diction of the Biblical Targum (as suggested in the Methurgeman) are a gross mistake, inasmuch as they lack the criticism of history; (8) printers mistakes, increasing in every new edition, have ail but ruined the text. The remedies for this corruption are :-(1) good Targun MSS. in private hands and public libraries, notably in Italy, Germany, and England; (2) Targunt MSS, according to the Babylonico-Assyrian system of punctuation, chiefly preserved in South Arabia, Russia, and England; (3) some early and comparatively gool printed editions; (1) the Massoreth of the Targum.

Value of the Targums. - The idea so long entertained, even by the learned, that these old rersions were valuable chiefly as guides to the original radings of the sacred text must be given up. All of them contain more or less, whether visible at first sight or not, certain paraphrastic clements, which give no absolute security for the exact reading of the pristine Hebrew text But besides their importance as linguistic monmments they have the highest value as historical records-(1) of the exegesis which obtained at the time of their composition, and (2) of the then current manners, thoughts, and aspirations both of the Jews and of the surrounding nations. ${ }^{1}$
(S. M. S. -S.)

TARIFA, a seaport of Spain, in the province of Cadiz, at the extreme south point of the Peninsula, 59 miles southeast from Cadiz and (by land) 21 miles west-south-west from Gibraltar. The town is nearly quadrangular, with narrow crooked streets, and is still surrounded by its old Moorish walls. On its east side, just within these, stands the alcazar. The rocky island in front of the town, con nected with the mainland by a causeway, is strongly fortified, and in some sense commands the Strait of Gibraltar It has a lighthouse, 135 feet high, which has a range of 30 miles. The population within the municipal limits was 12,234 in 1877. Anchovy and tunny fishing is carried on, and there is some coasting trade. The mantufactures (leather sud earthenware) are unimportant. Tbe oranges of Tarifa are famed for their sweetness.

Tarifa is the Julia Joza of Strabo, between Gades and Belon, which, according to that writer, was colonized by Romans and the removed inhabitants of Zelis in Mauretania Tingitana The Julia Transducta or Traducta of coins and of Ptnleny appears to be the eame place. Its present name (Arabic Jazirat Tarlf) is derived from Tarif, the forerumer of Tarik (see vol, xvi. p. 573). After a long siege it was taken from the $\$ 100 r s$ in 1292 by Sancho IV. of Castile, who entrusted it to the keeping of Alouzo Perez Quinquarhoreus (Paris, 1556, 4to), Mercerus (Paris, 1564-65; revised 1657); (6) ou Lamentations, by Alph. Zanı, by Quinquarboreus (Paris, 1549, 4t0), by Ghislerus (Leyd., 1623, fol.), and again by Taylerus (Lond. 1651, 4to) ; on Ecclesiastes, by Ar. Moat., by Scbreckenfucbs (Basel, 1555, 8\%o), aad again by Costus (Leyden, 1554, 4to); (7) on Esther, by Ar. Nont. (1572, folio); (8) Chronicles by Beck from the Erfurt MS. (imperfect, Augsb., 1680-83), and by Wilkins from the Cambridge MS. (Amst. 1715) ; (c) in German(1) on the Fivo Megilloth, by R. Ia'akob b. Shemuel (Breisgau, 153f, 4to); (2) on the Targum Sheni, by David Ottensosser (Sulzbaeh, 1820, 8vo). (D) Commentaries:-(a) in IJebrew-(1) on the Targuna of the Five Megillotb, by R. Elyakim Rutbenburg (Prague, 1018); (2) on Esther alone, by R. Shem"el Makshan (Prague, 1601, 4to); (3) on the same Targum, by Pi. Di sid b. Yehudah Melammed (Cracow, 1644, 4to); on the Targum Sheni, by P. David b. Ya'akob (Prague, 1609, 4to); (b) in Spanish-on Canticles, by F. Mosheh Laniado (Venice, 1619, ito).
R. Yehudah Ibn Koreish fully understood the value of the Targums. See his interesting epistle, addressed to the Jewisb community of Fez, published at Paris (1857. 8vo), under the name o: Epistola de Stzdii Targum Ulitzale. A transiatios of the intro ductory part (by Wetzstein) is given in the L. I. O., iii, col, 22 (reprinted by Dr Berlacer, T. U., p. 163 sq.) 1 $1, n$ Kioreish belonged to the 9th century, aud not, as Berliner says, to the l0th or 11th; por was he a Kiaraite as Graetz (v. 1. 293) halr believes.
de Guzman ; the heroic defeace by the larter, conmenorated in the Romancero, earacd for him the name of Guzman "el Bueno.* It was in the defence of Tarifa that Alfonso X1. gained the battle of Salaio, a short distance to the westward, in 1340 . The place was successfully defended against the French by Gough in 1812.

TARN, a department of southern France, formed in 1790 of the three dioceses of Albi, Castres, and Lavaur, all belonging to the province of Languedoc, lies between $42^{\circ} 23^{\circ}$ and $44^{\circ} 12^{\prime} \mathrm{N}$. lat. and $1^{\circ} 32^{\prime}$ and $2^{\circ} 56^{\prime} \mathrm{E}$ long. It is bounded N. and E. by Aveyron, S.E. by Hérault, S. by Aude, S.W. and W. by Haute-Garonne, N.W. by Tarn-et-Garonne. The slope of the department is from east to west, and its general character is monntainous or hilly; its three principal ranges, the Mountains of Lacaune (peak of Montalet, 4154 feet), the Sidobre, and the Montagne Noire, belonging to the Cevennes, lie on the south-east. The stony and wind-blown slopes of the firstnamed are used for pasturage. The highest point of the range and of the department is the Pic de Montalet ( $415 \frac{1}{2}$ feet) ; several other summits are not much short of this. The granite-strewn plateaus of the Sidobre, from 1600 to 2000 feet high, separate the valley of the Agout from that of the Thore. The Montagne Noire derives its nanse from the forests on its nortlern slope, and some of its peaks are from 3000 to 3500 feet high. The limestone and sandstone foot-hills are clothed with vines and fruit trees, and are broken by deep alluvial valleys of extraordinary fertility. With the exception of a small purtion of the Montagne Noire, which drains into the Aude, the whole department belongs to the basin of the Garonne, -indeed, if the rivulet Giron be excepted, to that of the Tarn, which flows in a westerly direction past Albi, Gaillac, Lisle, and Rabastens, receiving on the left the Agout at St Sulpice. Northern Tarn is drained by the Aveyron and its tributary the Viaur. The eastern portion of the department has the climate of Auvergne, the severest in France, but that of the plain is Girondin. At Albi the mean temperature is $55^{\circ}$, and the rainfall 29.5 inches. The population of the department in 1886 was 358,757 .

Of the total area of 2217 square miles, or $1,418,969$ actes, there are 887,709 acres of arable land, 118,071 of meadows, 118,934 of vineyards, 186,594 under wood, and 52,408 of moorland. 广y last returns there were 11,360 horses, 3280 mules, 5430 asses, 20,550 bulls and oxen, 53,900 cows and heifers, 13,240 calves, 455,500 sheep (wool-clip in 18781209 tons), 87,700 pigs, 5350 goata, and 17,190 bee-bives. In 187837 tons 14 cwt. of silk cocoons were produced. Oxen and sheej are fattened; ewes milk cheese like that of Ronuefort is made; and geese and turkeys are reared. The crops in 1881 were-wheat, $3,429,112$ bushels; meslin, 53,113 ; rye, $1,371,040$; barley, 37,730 ; buckwheat, 8448 ; maize and millet, 1,566,873; nats, 538,422 ; potatoes, $2,554,860$; dry vegetables, 374,715 ; chestnuts, 268,125 ; beetroot, 196,$625 ; 782$ tons of hemp; 476 of flax; $9,676,476$ gallons of wine fonly lalf the quantity of the previous year, owing to the phylloxera). Both conmon and good table wines are produced.
The mineral products include marble, porplyry, granite, lime, inanganese, sulphate of baryta, alum, iron liguite, and tourmaline In 1881335,430 tons of coal were taken from seven pits, and other mines are about to be opened. There are iron, alkaline, thermal, and carbonate of lime springs. The chicf contre for the manafacture of woollen stuffs (in 1875287 mills, 6457 workmen, and 98,615 spindles) and for wool-spmning and weaving ( $\$ 893$ machino and band looms) is at Mazamet (q.v.), but all sorts of woollen and cotton stulls are produced in other localities. Other iudinstrial products are woollen hosiery, cotton, silk, and linen thread, morocco, hats, eartheuware, glass, soap; anl thero are tanneries, distilleries, flour-mills, breweries, dyeworks, sawmills, printing works, and numerous limekilns. In 1881929 tons of steel aud 1947 tons of iron of rarious kints were produced. The Tarn is navigahle for 43 miles; therc are 203 miles of rational roats, 4274 of other roads, and 120 of railway. The department forms tho diocese of Albi, and belon"s to the 16 th corps d'arme (Montpellier), and the court oi appeal is at Toulouse. The chef-lieu is Albi. There are 4 arrondissements (Albi, C'astrcs, Caillac, Lavaur), 35 cantons, and 318 commusies.

TARN-ET-GAllONNE, a department of south-western France, was formed in 1808 of districts formerly belonging to Guienne and Giascony (Quercy, Jomagnc, Armagrace.

Rouergue, ${ }^{,}$Agenaie), with the addition of a small piece of Languedoc. From 1790 to 1808 it was divided between the departments of Lot, Haute-Garonne, Tarn, Aveyron, Gere, and Lot-et-Garonne. Lying between $43^{\circ} 47^{\prime}$ and $44^{\circ} 25^{\prime} \mathrm{N}$. lat. and $0^{\circ} 55^{\prime}$ and $1^{\circ} 58^{\prime}$ E. long., it is bounded on the N. by Lot, on the E. by Aveyron, on the S. by Tarn and Haute-Garonne, and on the W. by Gers and Lot-et-Garonne. The Garonne and its tributary the Tarn unite a few miles below Moissac, and separate the elevated lends to the north, which belong to the Cevennes and the central plateau, from those to the south, which are a continuation of the plateau of Lannemezan. The principal tributary of the Tarn on the right is the Aveyron, the affluents of which run through remarkably parallet valleys from north-east to sonth-west. The general slope of the department is from east to west; the highest point (1634 feet) is on the border of Aveyron, the lowest (164 feet) where the Garonne leaves it. The winter temperature is $37^{\circ} \mathrm{F}$., that of spring and autumn $54^{\circ} \mathrm{F}$., and that of summer $72^{\circ} \mathrm{F}$. Rain falls seldom, but heavily, especially in spring, the annual rainfall being 28.9 inches.
Of a totel area of about 1436 square miles, or 919,265 acres, arable land occuries 552,708 acres, meadows and grass 45,073, vineyards 102,849 , woods 115,429 , moorland and pasturage 41,819 . The raturns in 1883 showed $2,167,000$ bushels of wheat, 35,062 of maslin, 62,975 of rye, 77,000 of barley, 2,722,500 of oats, 759,000 of maize, $1,867,250$ of potatoes, 35,468 tons of beetroot, 172 tons 8 cwt . of colza sced, 399 tons of hemp, 394 tons of flax, 250,788 tons of fodder, 12 tons 15 cwt. of silk cocoons, $20,048,380$ gallons of wine. The live stock in 1881 included 14,336 horses, 1680 mules, 2120 asses, 89,295 cattle of varions descriptions, 116,349 sheep, 1358 goats, 32,375 pigs ; 6347 beehives gave 25 tons 13 cwt. of honey and 8 tons 2 cwt . of wax. There are 57 quarries, employing 426 workmen, where phosphates of lime, lithographic stone, freestone, potters' clay, gypsum, and schist for slating are worked, as are also iron and copper. The manufacturing industry is represented by flour-mills, yarious kinds of silk-mills ( 1317 workmen), and manufactories of linen, wool, and paper. Much fruit is grown, and the principal exports are fresh fiuit, wine, flour, phosphates, lithographic stone. There are 83 miles of waterway, including 48 of canal, 156 miles of national roads, 3515 of other roads, 127 of railway lines, tho centre of which is Montauban. Tarn-et.Garonne is one of the least densely peopled departments of France: in 1886 there wera 214,046 inhabitants, and their number is dccreasing. Except some 10,000 Calvinists, all are Roman Catholics. Tha department forms the diocese of Montauban, and belongs to the jurisdiction of the Toulonse court of appeal and to the district of the 17th corps d'armée (Toulouse). It has 3 arrondissements (Montanban, Moissac, and Castel-Sarrasin), 24 cantons, and 194 communes.
TARNOPOL, a market.town in Galicia, Austria, on the Sereth. It was formerly a fortress, and rendered valuable services to Polish kings, who, in their turn, conferred upon it important privileges. The town enjoys a brisk trade in grain and wine, and has some sugar factories. Its yearly horse fairs are famous throughout the country. The population in 1885 was 27,000 , about half of them Jews.
TARPAULIN is a waterproof sheeting consisting of a stont canvas cloth impregnated and coated with tar. It is employed for covering hatchways and other openings into the holds of vessels, for making covers for railway and other waggons and farm ricks, and generally for protecting bulky goods and structures from weather and damp. Many waterproof compositions other than tar are nsed for similar purposes, the principal ingredients being solutions of india-rubber, gutta-percha, and varions resinous bodies combined with pigments. See Waterproofing.
tarquinji. See Etruria, vol. viii. p. 634.
TARQUINIUS PRISCUS, Lucius, fifth legendary king of Rome, is represented as the son of a Greek refugee who removed from Tarquinii in Etraria to Rome, by the advice of his wife, the prophetess Tanaquil. Appointed guardian to the sons of Ancus Marcius, he slicceeded in supplanting them on the throne on their father's death. It was he who first established the Circus Maximus, built the great cloace, and founded the triple temple on the

Capitol,-the expense of these vast works being defrayed by plunder seized from the Latins and Sabines. Many of the ensigns both of war and of civil office are assigucd to his reign, and he was the first to celebrate a Roman triumph, after the Etruscan fashion, in a robe of purple and gold, and borne on a chariot drawn by four horses. After a reign of thirty-eight years he was assassinated by the contrivance of the sons of Ancus Marcius, but Tanaquil had influence enough to secure the succession to Servius Tullius, his son-in-law. See vol. xx. p. 733.

TARQUINIUS SUPERBUS, Lucios, son of the preceding, and son-in-law of Servins Tullius, immediately succeeded the latter without any of the forns of election, and proceeded at once to repeal the recent reforms in the constitution, seeking to establish a pure despotism in their place. Wars were waged with the Latins and Etruscaus, but the lower classes were deprived of their arms, and employed in erecting monuments of regal magnificence, while the sovereign recruited his armies from his own retainers and from the forces of foreign allies. The completion of the fortress temple on the Capitoline confirmed his authority over the city, and a fortunate marriage of his son to the daughter of Octavius Manilius of Tusculum secured him powerful assistance in the field. His reign was characterized by bloodshed and violence ; the outrage of his son Sextus upon Lucretia precipitated a revolt, which led to the expulsion of the entire family, after Tarquin had reigned twenty-five years. All efforts to force his way back to the throne were vain, and he died a loncly and childless old man at Cumx. See vol. xx. p. 734.

TARRAGONA, a maritime province in the north-east of Spain, with an area of 2451 square miles and a population in 1877 of 330,105 , was formerly part of the province of Catalonia. It is bounded on the S.E. by the Mediterranean, on the N.E. by Barcelona, on the N. by Lerida (the Sierra de Almenar), on the W. by Saragossa and Teruel, and on the S.W. by Castellon-de-Ia-Mlana. The Ebro flows throagh the southern portion of the province, and the other chief strearus are the Gaya and the Francoli. The district, although mountainous, is the richest in Catalonia. The hills are clothed with vineyards, which produce excellent wines, and in the valleys are cultivated all kinds of grain, vegetables, rice, hemp, flax, and silk. Olive, orange, filbert, and almond trees reach great perfection, and the mountains yield rich pastures and timber trees of various kinds. Manufactures are well advanced, and comprise all textile fabrics, soap, leather, and spirits. There are also several potteries and cooperages, and flour, paper, and oil mills. Silver, copper, lead, and barytes are plentiful, and quarries of marble and jasper are worked in the hills. The military government of the province is dependent on the captaincy-general of Catalonia. For administrative purposes the district is divided into eight partidos judiciales, containing 186 ayuntamientos, and returns three senators and eight depaties to the cortes. Besides the capital, the towns in the province with more than 10,000 inhabitants are Reus ( 27,691 ), Tortosa ( 23,808 ), and Valls $(13,256)$.

TARRAGONA, the capital of the above province, is a flourishing seaport, the seat of an archbishopric, at the mouth of the Francoli, 63 miles by rail west-southwest of Barcelona, in $41^{\circ} 10^{\prime} \mathrm{N}$. lat. and $0^{\circ} 20^{\prime}$ E. long., with a population of 23,046 in 1877. The picturesque but badly built older portion of the town stands on the steep slope of a hill 760 feet high, and is still surrounded by walls of Roman (in parts Cyclopean) origin. Below the walls a broad street, the Rambla, divides the upper from the lower town, which has been more regularly built in modern times along the low promontory which stretches out into the Mediterranean. The city is most beautifully situated, and

## ' $\mathrm{A} A-T A B$

gains considerably in effect from its magoificent cathedral, one of the noblest exampies of eariy Spanish art. It is 300 feet in length and 100 feet in breadth, and consisted originally of a nave, aisles; transepts with an octagonal lantern at the crossin $\because$ and an apsidal chancel. Several extericr chapels have been added in later times, and on the south-east stends a 14 th-century steeple raised on a Romanesque tower. The east end was probably begun in 1131 on the ruins of au earlier chnrch, but the main body of the building dates from the end of the 12th century and the first half of the 13 th, and is of transitional char-acter,-the exuberant riclness of the sculptured capitals being admirably kept in snhordination by the Romanesque simplicity of the masses. Considerable changes were introduced at a later date; and the present west end of the nave cannot have been completed till late in the 14th century. On the north-east side is a cloister contemporary with the church, with which it communicates by a very fine doorway. The cloister contains nuch remarkable work, and the tracery of the windows bears interesting marks of Moorish influence. Two other noteworthy churches in the city are San Pablo and Santa Tecla la Vieja, both of the 12th century. The mole, begun in 1491, was chiefly constructed out of the Roman amplitheatre, of which a few rows of seats can still be seen on the sea-shore. The remains of a Roman aqueduct form a picturesque feature in the landscape. The Carcel de Pilatos is said to have been the palace of Augnstus Cæsar; it was partly destroyed by Suchet, and now serves as a prison. The museum contains a collection of the Roman antiquities which are continually being discovered during excavations.

The trade is steadily ivcreasing. During 1885 the ressela cleared amounted to 377,250 tons ( 45,795 tons British, 47,181 French, and 42,617 Swedish and Norwegian). The exports were valued at $£ 1,289,533$ (wine $£ 1,023,847$ ), and the imports at $£ 1,237,012$. The exports were mostly to France, Great Britsin, and the River Plate; the imports were chiefly from Germany, Russia, France, and Sweden. There is communication by rail with Barcelona, Valencia, and Lerida, and by steamer with other porta of Spain.

Tarraco was one of the earliest strongholds of the Romans in Spain, and became a colony (of Julins Cæesar), the capital of Hispania Citerior, and the richest town on the coast. To the Romans the Visigaths under Earic succeeded in 467, but on their expulsion by the Moors in 710 the city was razed to the ground. It was long before the ruins were again inhahited, bat by 1089 , when the Moors were driven out by Raymond IV. of Barcelona, there must have been a certain revival of prosperity, for the primacy, which had been removed to Vich, was in that jear restored to Tarragona. In 1118 a grant of the fief was made to the Norman Kobert Burdet, who converted the town into a frontier fortress against the Moors. In 1705 the city was taken and burned by the English, aud a cen. tury later, after being partly fortified by them, it was captured and sacked by the French in 1811 under Suchet.

TARSHISH. See Phexicla, vol. xviii. p. 806.
TARSUS, now Tarsés, an ancient city in the fertile plain of Cilicia, lay on both sides of the Cydnus, whose cool and swift waters were the pride of the city (Die Clurys., vol. ii. p. 2, Reiske's ed. ; Tita Apollon., i. 7), and bore traffic to and from the port of Rhegma. In the time of Xenophon (Anab., i. 2. 23) Tarsus was already great and flourishing, and was the residence of the vassel king of Cilicia. Its civilization at this time seems to have been mainly Semitic, as was to be expected from the geographical relations of Cilicia, which have generally associated its history with that of Syria. We have coins of Tarsus ( 7 ת) of the Persian period, bearing Aramaic inscriptions; and the deities of the town, known in later times as Heracles, Persens, Apollo, Athena (Dio Cbr., ii. 22), seem to have been akin to those of the Ploenicians and Syrians (see below). The $\cdot$ Semitic infinence was donbtless very ancient ; indeed, the Assyrians invaded Cilicia in the 9 th century b.c., at which date Tarsus is perhaps mentioned on the monuments under the name of Tarzi (Schrader, Seilinschr. und_Gesch., 1878, p. 240 ; the reading is not
certain). Atter Tarsus was Hellenized the citizens learned to boast that they were Argives sprung from the conlpanions of Triptolemus (Strabo, xiv. 5. 12; Dio Chr., ii. 20), and the town became the seat of a famous school of philosophy which mas frequented almost exclusively by natives, but sent forth teachers as far as Ronie itself. ${ }^{1}$ 3iore than one of these philosophers, notably Athenodorus the teacher of Augustus, and Nestor the teacher of Marcellus, held the chief magistracy of the city. Athenodorus and his predecessors were Stoics, but Nestor was an Acadenic (Strabo, xiv. 5. 14), ${ }^{2}$ so that the Platonic philosophy is that with which Paul would probably have come in contact if he gave heed to the Greek wisdom of his native city. Presumably, however, he formed we higher opinion of the culture of Tarsus than did his contemporary Apollonins of Tyana, whose testimony as to the character of the citizens ( Vit. Ap., i. 7) is confirmed by Dio Chrysostom. Tarsus lad made rapid material progress since Cilicia became Roman ( 66 b.c.). It was the capital of a rich province, and bad received freedom from Antony, and from Angustus the dignity of a metropolis and important immunities for its commerce (Dio Chr., ii. 36). The inlabitants were vain, effeminate, and loxurions, more like Phenicians than Greeks. Their sensuous Eastern religion in these golden days of affluence had more attraction for them than the grave philosophy of the Porcly; and the legend supposed to be graven on the statue of Sardanapalus, at the neighbour city of Anchiale, "let us eat and drink, for to morrow we die," which Panl quotes in 1 Cor. xv. 32, might have been the motto of the mass of the townsmen. ${ }^{3}$ At Tarsus the emperor Tacitus died, and Julian was buried. The city was deserted and lay waste duriug the frontier wars of Greeks and Arabs in the first century of Islam: a Moslem general, who saw the ruins, estimated its former population at 100,000 (Beladhori, p. 169). It was rebuilt and settled as a military colony and frontier post by Hárún al-Rashíd in 787 A.D., and became a starting point of forays against the Christians. On such a campaign the caliph Ma'mún died, and was buried at Tarsus (833), having caught a fever, like Alexander the Great, by bathing in the cold Cilician waters. Tarsus was temporarily recovered to Cbristendom by Nicephorns Phocas, and again by the crussters under . Baldwin. Finally it remained in the hands of the Torks.
The Heracles of Tarsus was the Cilician god Sandan. Dio Chrysostom calls him the àpxny's of the Tarsians (ii. 23), and he may be ilentified with the Baal of Tarsus named on the coins alreedy spoken of. He was worshipped by, the periodical erection of "a very fair pyre" (ibid.), a rite presumably ainalogons to that described in the De Dea Syria, ch. 49; and the remarkall, zuin of Dönijk-tash, a vast conrt with massive walls curclosing two lofty plationns of concrete, probably marks the site of his sanctuary (see Perrot and Chipiez, Hist. de l' Art, iv. 536 sq., and Langloiq, Voyage dans la Cilicie, p. 265 sq.). A tradition making Sandan the founder of Tarsus is given by $\Delta$ mmianus (xiv. 8. 3); and, as the Greeks appear to have taken elcments of the myth of Sandan (including the pyre) into their legend of Sardanapulus, this explains the current story that Sardanapalus founded Anchiale and Tarsus in one day (Arrian, ii. 5,2 ; Athen., xii. p. ${ }^{5} 29 \mathrm{sq}$.). On Sandan, see K. O. Mtuller, in lihein. Mhus., 1829, and E. Mryor, in Z. D. M. G., 1877, p. 736 sq. Another account in Anmianus makes Persens the fonnder of Tarsus, aud it aprears from Jio ('hr: that he was almost or quite as much honoured. The foot pinint of Pegasus was shown st Tarsus (Avienus, 1031 sq; ; comp. 1) io, ii. 24); and his rapats (wing?) ras said to have fallon therc (Alex. Molylh. in Steph. Byz., s.v,). This worship reappears at Joppia. Apmllo "with the trident" had a secred sword at Tarsus, which conld be cleansed only by the water of the Cydnns (Plut., Def. Orac., 41), and is probably the same as the harpe sliown on coins of Hadriari's time ; if so, he is presumably a differentiated form of Perseus. ${ }^{1}$ To Strabo's list must be added Zeno, the successor of Chrysilius.
${ }^{2}$ Lucian, Macrob., 21, makes him a Stoic and teacher of Tiberius.
3 Athenæus, v. p. 215, tells of an Epicurean philosopher, Lysias, who, becoming priest of Heracles, lecame tyrant of the city, taxiug the rich to provide Largesses. for the poor. A The fact is probable, tha date quite uncertain.

The worship of Athena may be connected with the etatement of Athenodorus (the famous philosopher of Tarsus) that the ancient name of the city was Parthenia (Fr. Hist. Gr., iii. 487); Abydenus in Eusb., Chron., p. 35, ed. Schöne) ascribes the foundation of her tomple with its brazen columns and of the city itself to Sennacherib. Thus with the Baal of Tyre there was worshipped an unmarried goddess, as in so many shrines of Syria and Asia Minor. Dio Chr., ii. 2, speaks also of Titans as lords of the city. The reference is to Jspetus (Japhet?), grandfather of Cydnus (Athenodorns, ut sup.).

TARTAGLIA, Niccold (c. 1500-1557), a self-taught mathematician, was born at Brescia about 1500. His father, Michele Fontana, was a postal messenger between Brescia and the neighbouring towns, who, dying in 1506, left two sons and a daughter to the care of their penniless mother. Niccold's childhood was accordingly passed under the stress of dire poverty, and was marked by a cruel misfortune. During the sack of Brescia in 1512 ho was, in the cathedral where he lad vainly sought a refuge, horribly mutilated by some infuriated French soldiers. His skull was laid open in three places, his palate cloven, both jawhones fraetured. Yet he recovered with no further assistance than-his mother's patient care. He, however, long continued to stammer in his speech, whence the nickname, adopted by himself, of "Tartaglia." His edueation remains a mystery. Save for the barest rudiments of reading and writing, he tells us that he had no master; yet we find him at Verona in 1521 an esteemed teacher of mathematics. In 1534 he transferred his residence to Venice, and was there met by Antonio del Fiore with a challenge to one of the intellectual duels then customary. Del Fiore relied on his possession of an undivulged formula by Scipione del Ferro for the solution of a particular case of cubic equations. But Tartaglia had attained in 1530 a similar result, which he now, in February 1535 , greatly extended. His consequent triumph over his adversary gave him a. high reputation, aud his house became the resort of the learned of all grades and nations. The mystery in which he chose to shroud his metbod of dealing with cubic equations promised him a highly effective weapon in future contests, as well as leisure to perfect, before publishing, the coveted rules. But in 1539 Cardan enticed him to Milan, and there, by unremitting solicitations, proeured from him the rude verses in which he had enshrined hls discovery (see Alarbra, vol. i. p. 513). The Milanese physician's breach of his oath of seerecy gave rise to a bitter and lifelong quarrel, the most conspicuous incident in which was a public disputation at Milan, August 10, 1548, at which Cardan shrank from appearing. In 1548 Tartaglia accepted a situation as professor of Euclid at Brescia, but returned to Venice at the end of eighteen months. He died at Venice December 13, 1557. Aerid and emulous in disposition, he incurred abundant enmities; yet his honesty, uprightness, and the morality of his life remain unimpeached. He was keen-witted, diligent, and ingenious, and by his discoveries in the solution of equations helped to initiate the rapid progress of modern mathematics.
Tartaglia's first printed work, entitled Nova Sceientia (Venice, 1537), dealt with the theory and practico of gunnery, to which his attention laal been drawn in 1531 by the question of a bombardier at Verona as to the elevation giving the greatest rango. He easily found it to be $45^{\circ}$ (true only in vacuo), but failed to demonstrate the correctness of his intuition. Indeed, be never shook off the erroncous ideas of his time regarding the paths of projectiles, further than to see that no part of them could be a straight line. He meverthcless in augurated the scientific treatment of the subject, and his propositions reappeared in most lallistical treatises down to Blondel's in 1683. Tho publication of the Aora Scientia was determined by the menacing attitude of Soliman II. Unless in the interests of Christendon, Tartaclia regarded it as a crime to promote arts of destruction. Inquiries rendered lawful by necessity were, however, resumed in his Qucsiti ct Invensioni Divicrsc, a collection of the sutlor's replies to questions addressel to him by parsone of the most varied conditions, published in 1546, with a oedation to Heary VIll. of England. Problems in artillery
occupy two out of nine books; the sixth treats of fortification ; the ninth gives several examples of the solution of equations of the third degree. His last years were full of activity. He published in 1551 Regola Generale per sollevare ogni affondata Nave, intitolata la Travagliata Invenzione (an allusion to his personal troubles at Brescia), setting forth a method for saising sunken abips, and describing the diving-bell, then little known in western Europe. He pursued the subject in Ragionamenti sopra la Travagliata Invenzione (May 1551), adding a table of specific gravities. Of his largest work, entitled General I'rattato di Numeri e Misure, two parts appeared at Venice in 1556 , the remaining four posthumously in 1560. This is a comprehensive mathematical treatise, including arithmetic, feometry, mensuration, and algebra as far as quadratic equations. He designed to embody the results of his original investigations in a separate form; but his Algelra Nova remained unwritten. He published the first Italian translation of Euclid (1543) and the earliest version from the Greek of some of the principal works of Archimedes (1543). Thesc included the tract De Insidentibus Aqua, of which his Latin now holds the place of the lost Greek text. An Italian version of it is appended to his Ragioncenenti. Tartacrlia was the first Italian writer on fortification, and claimed the invention of the gunner's quadrant.

- Tartaglia's own account of his early life is contained in hia Quesiti, lib. vi, p. 74. See also Bittantía Discurso di Niccolo Tartaglia, Lrescia, 1871, Bnoncompagni, Mhorno ad un Tes?amento inedito di M. Tartagiza, Silan, 1881; Libl, Hist. des Sciences diathematiques, t. iii. P. 149: Montucia, /hist. des srath., vol. ${ }^{\circ}$ p. 567; Marle, Mist. des Sciences, t. H. p. 24.: Hankel, Zur Gesch. e. Bath., 1874, were ; rasslated ine enalish by Lucar in 1588 and into Freach by kiefel in 1845 , were iranslated into English by Lucar in 1588, and into French by Rleffel in 1845. Thos. Salusbury published (London, 1564 ) nn English version of his Travagizata Invenzione, And a selection irom his wimings appeared at Venice in 1606 with the
title Opere del Famosissimo Niccolo Tartagha, 1 vol, 8vo.
TARTAN is a worsted cloth woven. with alternate stripes or bands of coloured warp and weft, so as to form a chequered pattern in which the colours alternate in "scts" of definite width and sequence. The weaving of particoloured and striped cleth cannot be claimed as peculiar to any special race or country, for indeed such checks are the simplest ornamental form into which dyed yarns can be combined in the loom. But the term tartan is specially applied to the variegated cloth used for the principal portions of the distinctive costume of the Highlanders of Scotland. For this costume, and the tartan of which it is composed, great antiquity is claimed, and it is asserted that the numerous clans into which the Highland population were divided had each from time to time a special tartan by which it was distinguished. After the rebellion of 1745 various Acts of Parliament were passed for disarming the Scottish Highlanders aud for prohibitiug the use of the Highland dress in Scotland, under severe penalties. These Acts remained nominally in force till 1782, when they were formally repealed, and since that time clan tartan las, with varying fluctuations of fashion, been a highly popular article of dress, by no means confined in ịts use to Scotland alone; and many new and imaginary " sets" have been invented by manufacturers, with the result of introducing comfusion in the heraldry of tartans, and of throwing donlt on tho reality of the distinctive "sets" which at one time nudoubtedly were more or less recognized as the badge of various clans. The manufacture has long been carried on at Bannockburn, in the neighbourlood of Stirling, and it still conitinues to be a feature of the local industries there.

Undoubtedly the term tartan was known, and the material was woven, "of one or two colours for the poor and moro varied for the rich." as early as the middle of tho 15 th century. In the accounts of John, bishop of Glasgow, treasurcr to King James Ill. in 1471 , there occurs, with other mention of the material, the following:-"Ane elne and ane halve of blue Tortane to loue his gowne of cloth of Gold." It is here obvious" that the term is not restricted to particoloured chequered texturcs. ${ }^{1}$ In 1538 accounts wore innirred for a lighland dress for King Janes V. on the occasion of a hunting excursion in the Hlighlands, in which there are charges for "variant cullorit velvet," for "ane schort Heland coit," and for "Heland tartane to le hose to the kinge's grace." Bishop Lesley, in his Dc Origine, Moribus, et Rcbus Gcstis Scotornm, published in 1578, says of the ancient and still used dress of ihe Highlanders and islanders, "all, both noble and common people, wore mantles oi one sort (except that the nobles preferred those of several colonis):" George Buchanan, in his Rerum stoticarum
${ }^{1}$ Neither so is it in the French tiretaine or in the Spanisb diritana

Historia (1582), as translatel hy Monypenny (1612), says of the Highlanders, "they delight in marlect clothes, specially that have any long stripes of sundiy colours; they love chiefy purple and blue. Their predecessors used short mantles or plaids of divera colours sundry wejs divided; and amongst some the same custom is observed to this day." A hint of clan tartan distinctions is given by Martin in his Western Isles of Scolland (1703), which work also contains a minte description of the dress of the Highlanders and the manufacture of tartan. "Every isle," he observes, "differs from each other in their fancy of making plaids, as to the stripes in breadth and colours. This humour is as different through the mainland of the Hizhlands, in so far that they who have secn those places is able at the first view of a man's plaid to guess the place of his residence."
See W. and A. Smith, Tortans of the Clans of Scotland, 1850; J. Sobleski Stuart, 「estiarium Scoticum, 1842 ; R. R. M1'lan, Clans of the Scottish Highlands, 1815-46; J. Grant. Tartans of the Clans of Scotiand, Edinburgh, 1855.
rARTARIC ACID, in its ordinary acceptation, refers to one acid, $\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{H}_{2}$, which occurs in most acid fruit juices, in association generally with malic or citric, or both. Grape-juice owes its sourness almost entirely to acid tartrate of potash. While the juice ferments into wine, the greater part of the acid tartrate separates out, along with tartrate of lime, colouring matter, and othcr impurities, as a hard crust adhering to the sides of the cask. Such impure acid tartrate of potash is known commercially as "argol." It was known to the Greeks as $\tau \rho v \xi$, to the Romans as frex: vini. The alchemists from the 11th century called it fartarus, which name has survived in familiar chemical parlance to this day. The true constitution of tartarus vini was discovered by Scheele in 1769. He was the first to isolate the acid from its acid potash salt by a method which is still used for its industrial extraction.

Manufacture.-Crude tartar (10 to 14 corts.) is placed in a tank, and dissolved in sufficient water with the help of steam. The surplus acid is then neutralized by addition of powdered chalk, and precipitated as lime salt:-

$$
2\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{8}\right) \mathrm{KH}=\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{K}_{2}+\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{8}\right) \mathrm{H}_{2}
$$

$$
\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{H}_{2}+\mathrm{CaCO}_{3}-\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{8}\right) \mathrm{Ca}+\mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2} .
$$

The other half of the tartaric acid which remains dissolved as normal potash salt is then precipitated in the same form by addition of chloride of calcium :-

$$
\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{K}_{2}+\mathrm{CaCl}_{2}=2 \mathrm{KCl}+\left(\mathrm{C}_{4} \mathrm{H}_{3} \mathrm{O}_{6}\right) \mathrm{Ca} .
$$

The tartrate of lime precipitate is collected, washed, and decomposed by an cacess of sulphuric acid at $75^{\circ} \mathrm{C}$ : :-

$$
\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{Ca}+\mathrm{H}_{2} \mathrm{SO}_{4}=\mathrm{CaSO}_{4}+\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{H}_{2} .
$$

The sulpbate of lime is removed by decanting and filtering, and the acid solution evaporated in leaden pans to a sufficient degree to deposit crystals on standing in the cold. The crystals are purified by redissolving them in hot water, decolorizing the solution with animal charcoal, and causing the acid to crystallize a second time after addition of sulphuric acid, which promotes the formation of large crystals. The crystals contain a little sulphuric acid and a trace of lead; if intended for internal use, they must be recrystallized from pure water.

Tartaric acid forms hard colourless transparent monoclinic prisms of 1.764 spec. grav., casily solublo in cold and abundantly in hot water. It has a strong but agreeable sour taste. At $15^{\circ} \mathrm{C} .100$ parts of water dissolve 138 parts of the acid, 100 of alcohol (absolute) $20 \cdot 4$, and 100 of ether 0.39 . It fuses at $135^{\circ} \mathrm{C}$. and passes into an amorphous modification known as meta-tartaric acid; when heated more strongly it loses water, and passes into the forms of anhydrides. At ligh tempcratures it is decomposed with formation of charcoal and volatile products, which smell pretty much like those formed from sugar in the same circumstances. Most oxidizing agents produce formic from the aqueous avid Poiling with oxide of silver and excess of caustic alkali produces oxalate.

Tartaric acid is used largely in callco printing as a discnarge. In pharmacy and households it serves, conjointly with bicarbomate of soda or potash, for the extem-
poraneous preparation of effervescing drinks. The socalled Gernan effervescing powders are a combination of weighed-out doses of tartaric acid and of bicarbonate of soda. In the so-callcd "seltzogenes" (glass apparatus in which carbonic acid is produced in one compartment, to be forced by its own pressure into a mass of water, wine, \&e, in the other) the gas is similarly produced.

Tartrates.-The acird potash sall, $\left(\mathrm{C}_{4} \mathrm{II}_{4} \mathrm{O}_{8}\right) \mathrm{H} \mathrm{K}$, "cream of tartar," is preparcel from crule tartar (argol) ly dissolving it in hot water, filtering off what remains of tartrate of lime and other mpurities, and allowiug the filtrate to crystallize. The crystals are generally contaminated with a little of the lime-salt, for the removal of which the lest methol is to treat the powdered crystals with cold dilnte hydrochlnric acid and then wash then with cold water by displacement. The lime passca into the filtrate. Cream of tartar forms small colourless liard crystals which dissolve in olout 200 parts of cold and in 15 parts of beiling water. In alcohol the salt is cren less soluhle than in water.
The normal (neistral) potash sell, ( $\left.\mathrm{C}_{4} \mathrm{I}_{4} \mathrm{O}_{6}\right) \mathrm{K}_{2}+\frac{1}{2} \mathrm{H}_{2} \mathrm{O}$, is prepared by dissolving powdered cream of tartar in hot solution of carbonate of potash until a neutral or slightly alkaline solution is preduced. The salt, bcing extremely solnble in water, does not crystallize very readily. In former times the carbonate of potash required used to be made by igniting one half of the cream of tartar to be operated upon in a cruciblc. Hence the name of tartarus tartarisalus, which ia still familiar in plarnacy. The salt is used onedicinally, and also for remoring free acid from excessively sour wine by formation of relatively insoluble bitartrate (Liebig's method).
Rochelle salt, $\left(\mathrm{C}_{8} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{KNa}+4 \mathrm{H}_{2} \mathrm{O}$, is prepared by not quite neutralizing hot solution of carbonate of soda with powdered cream of tartar. The (filtered) hot solution deposits on cooling magnificeut crystals, readily soluble in water, though less so than the unmixed potash salt. Rochelle salt is used as a mild purgetive The so-called Seidlitz powders are effervesciag powdera with a considerable addition of Rochelle salt to the bicarbonate.

The normal tartrates of lime, baryte, \&c., are insolublo precipitates producible by double decompositions.

Tartar emelic, $\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{K}(\mathrm{SbO})+\frac{1}{2} \mathrm{H}_{2} \mathrm{O}$, is produced by boiling 4 parts of oxide of antiniony, $\mathrm{Sb}_{2} \mathrm{O}_{3}$ and 5 of powdered cream of tartar with 50 of water for about an hour. The filtered selution, on cooling, deposita crystals of the ebove composition seluble in 15 parts of cold and 2.8 of boiling bet water. The crystals generelly exhibit the appearance of tetrahedra; yet they ere rhembio prisms combined with pyramids. The process geing on in the formation of the salt is easily understood if we remember that $\mathrm{Sb}_{2} \mathrm{O}_{3}$ often acts on aqueous acids $s s$ if it were the monoxide, (SbO) ${ }_{2} \mathrm{O}$, of a radical (SbO) antimonyl. (SbO) ${ }_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{O}$ is equivalent to $2(\mathrm{SbO}) \mathrm{OH}$, and

$$
\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{KH}+\mathrm{OH}(\mathrm{SbO})=\mathrm{H}_{2} \mathrm{O}+\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{K}(\mathrm{SbO}) .
$$

Tartar emetic has long had a standing in medicine. In doses of 1-3 grains it acts as a powerful emetic; very small dobes (of to $\frac{1}{10}$ grain) induce perspiration. Large doscs preduce poisenous effects.
Analysis.-Tartaric acid is characterized chiefly by the relative insolubility of it 3 acid potash salt. To produce it from a solution of a neutral tarirate, add acetic acid and acetato of potash, and stir vigereusly; the salt gradually separates out as a crystallino precipitate. Neutral tartrate solutions, with chloride of celcium, give a precipitate of tartrate of lime, which is at first amorpbous, and in tbis condition dissolves pretty readily in excess of reagent or tartrate, but in general re-separates in the crystallipe form (the undissolved tartrate likerise becemes crystalline) on standing.
Anhydrides. - Tartaric acid, when kept at $135^{\circ}$, fuses and becomes' meta-tartaric acid without change of weight, and on continued appli.' cation of $140-150^{\circ} \mathrm{C}$., ditartrylic acid, $\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{O}_{21}=2 \mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{8}-\mathrm{H}_{2} \mathrm{O}$; and at $180^{\circ}$ tartrelic acid, $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{10}=2 \mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{6}-2 \mathrm{H}_{2} \mathrm{O}$, is produced. All these three acids ferm salta of their own, which, however, tend to become tartrates in the presence of water. At $180^{\circ}$ real tartario anhydride (like tartrelic, $\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{O}_{20}=2 \mathrm{C}_{3} \mathrm{H}_{4} \mathrm{O}_{5}$ ) is produced, in addition to tartrelic acid, as an infustble jellewish mass, inseluble in water and in ether. By continued contact with water it is converted finaliy into tartaric acid solutiou.
Isomeric Modifcations. - Among theso racemic acid hes long been known as an occasional bye-product in the manufacture of tartario acil. It used to be believed that racemic acid is present rendy formed in certain grape-juices, and thus comes to make its appearance occasionally; but it is well known new that the bulk of it at any rate is produced from what was originally tartaric acid, by the centinued action of high temperatures and water. Racemic acid is almost identical with tartaric acid; the only purely chemical point of difference is that correspending salts of the tro sclds often crystallize with different proportions of water. The two acils, heverer, are easily distinguished by their action on polarized light (see Pozarity, vol. xix. p. 314). A solution of tartaric acid turns the plane of polarization to the right; racemic acid is, in thie eense.
optically inactive. These leng-knewn farts led lasteur to the discovery of the true rulations of the two acids. If the double incemate, $\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\right) \mathrm{Na}^{2}\left(\mathrm{~N}_{4}\right)$, is allewed to crystallize alowly, two kinds of crystals are protluced, both beariug hemiedric faces, but dilfering from each other in tlie situation of these, exactly as tho right hand difers from the loft. Pasteur separated the two linds of crystals, and found that one kind is ilentical with the ordiuary (dextro-) tartrate of seda and ammonia, while the other contains a now kind of tartaric acid, which ho called levo-tartaric acid hecanse it turns the plave of polarization to the left. Erlual veights of the two acids, when dissolved separately in water and mixed, unite, with perceptible evolution of heat, into optically neutral racemic acid. Pacemic acil, then, is levo- and dextro-tartaric minted (loosely) into one molecule. There are a mumber of optically inactive tartaric acida, not susceptible of decouposition in the se'.av as which racemic acid is.
(W. D.)

I aRTARS (more correctly Tatars, but Tartars is the form generally current), a name given to nearly three millon inhabitants of the Russian empire, chietly Mosleu and of Turkish origin. The majority-in Enropean Rus ia-are remnants of the Mongul invasion of the 13th centiry (ses Mionaols), while those who inhabit Siberia are survivals of the once much more nunerous Turkish population of the Ural-Altaic region, mised to some extent with Finnish and Samoyedic stems, as also with Mongols. The name is derived from that of the Ta-ta Mougols, who in the 5th century inhabited the northeastern Gobi, and, after subjugation in the 9th century by the Tungus Kidañs, migrated southward, there founding the Mongolian empire nuder Jenghiz Kitan ( $q . v$. ). Under the leaderslip of his grandson (Batu) they moved westwards, driving with them many stems of the Turkish UralAltaians towards the plains of Russia. The ethnographical features of the present Tartar inhabitants of European Russia, as well as their language, show that they contain no admixture (or very little) of Mongolian blood, but belong to the Turkish branch of the Ural-Altaic stock, necessitating the conclusion that only Batu, his warriors, and a limited number of his followers were Mongolians, while the great bulk of the 13th-century invaders were Turks. On the Volga they mingled with remnants of the old Bulgarian Turkish empire, and elsewhere with Finnish stems, as well as with remnants of the ancient Italian and Greek colonies in Crimea and Caucasians in Caucasus. The name of Tatars, or Tartars, given to the invaders, was afterwards extended so as to include different stems of the same Turkish branch in Siberia, and even the bulk of the then little known inhabitants of the high plateau of Asia and its north-western slopes, which was described under the general name of Tartary. This last name has almost disappeared from geographical literature, but the name Tartars, io the above limited sense, remaios in full use.

The present Tartar inhabitanta of the Russian empire iorm three large groups, - those of European Russia and Poland, those of Cancasus, and those of Siberia. The discrimination of the sefarate stems included under the name is atill far from completion. The following subdivisions, however, may be regarded as established. (1) The liazañ T'artais, descendanta of the Kiptclaks settled on the Volga in the 13th century, where thoy mingled with survivors of the Bulgar Turks and partly with Finnish Etens. Thcy number ahout half a million in tho gnvernment of Kazañ, about 100,000 in each of the govermments of Ufa, Samara, and Simbirsk, and abont 300,000 in Tyatisa, Saratoli, Tamboff, Penza, Nijni-Novgorod, Perm, and Orenburg; some 15,000 belonging to the same stem havo migratal to Ryazan, or have been settled os prisoners in the 16 th and ITth centurios in Lithmania (Vilna, Grodno, and Podolia); and there are some 2000 in St Petersburg. In Poland they constitute 1 per cent. of the population of the rlistrict of Plock. The Kazan T'artars speak a purc Turkish dialect; they are mitlde-sized, broad. shoulilered, and stroag, and mostly have black eyes, a straighit nose, and salient cheek boaes. They are Mohammedans; polygamy is practiscd only by the wealthier classes and is a waning institution. Eacellont agioculturista and garleners, very laborious, and loaving a good reputation for honesty, they live on the best terms with their Russian peacant ncirhboura. It may be ndderl that, aecorrling to M. Iuférnff (Etule ह́lhoz. sur les Bachたirs, 1881), those Bashkirs who live between the Kiama, Ural, apd Volga are not of Finnish origin, hut in virtue of their bistory, language, authronological features.
and custoun must be regerded as Tartare. (2) The Astrakhan Tartart (about 10,000) are, with the Dlengol Kalmucka, all that now remains of the ouce so powerful Astraklian empire. They also are agriculturista and gardencrs; while sone 12,000 Kundrovsk Tartars still continue the momadic life of their ancestora. (3) I'he Crinıean Tartars, who occup,iel the Crimea in the 13th century, have preserved the name of thic leader, Nogai. During tho 15 th, $1 \$$ th, and 17 th centuries they constituted a riel empire, which prospered until it fell umler Turkish rule, when it had to auffer much from the wars fought between Turkey and Russia for the prossession of the peninsula. The war of 1853 nnd the laws of $1860-63$ and 1874 caused an exodus of the Crimean Tartars; they abandoned their odmilably irrigated fiella and gardens and moved to 'I'urkey, so that now their number falls below 100,000. These of the south coast, mixed nith Greeks and Italians, aro well known for their skill in garclening, their honesty, and tbeir lahorious habits, as well as for their fine features, presenting the Tartar typo at its best. The monntain lartars closely resemble theso of Cuncesiss, while these of the steppes-the Nogais-are decillally of a mixell origin from Turks and Mougolians.

The 'lartars of C'aucasus, who inhabit the rlpee" Fuhañ, the ateppes of the lower Kuma and the Kura, ami the Araxes, numbir about 1,350,000. Of these ( $f$ ) the Nogais on the Kinma slow traces of an iatimate nixture with Kaluncks. They are nomads, suluniting thenselves by cattle-hreding and fiahing; fuv are arimiturists. (5) The Karatchais ( 18,500 ) in tho upper valleys alont Elburz Jive by agrienlture. (6) 'The monntain Tantara (about 850,000), divided into many tribes and of an origin still nuluterminel, are scattered thoughont the provincca of Baku, Erivan, Tillis, Kınais, Jathcatan, and jurtly also of Batum. They are cortainly of a mixed origin, and present a variety of othnolorical ty jes, all the roore so as all who aro neither Armenians nor Kussians, nor belong to auy clistinct Cancasian tribe, are often called Tartar's. As a ritle they are well built and little helind their Caucasian brethren. They are celebratel for their excellence as gardeners, arricultwists, catlietentlers, aud artisans. Althongh most fervent Shititus, they aro on very good terus both with their Sumite and witly their lknssian veighbours. Polygany is rare with them, anl their womeu go to work unveiled.
Tho Siberiau Tartars, mostly mixed with Finnislı atems, ars the most dificult to classify. They occupy three diatinet regions,-strip runuing west to east from Tobolak to Tomsk, the Altai and its apurs, and Soutlı Yeniseisk. They origiuated in the agglo. merations of Turkisl! stems which in the region north of the Altai succecled the Ug:0-Samoycdic civilization (sce Sibenia), and reached a relatircly high degree of culture between the 4 th and the 8 th centuries, but were subuned and enslaved by tha Mongols. In the meautime the following subrlivisjons of the Siberinn Tartars may be arcepited. (7) The Barabs Tartars, who tako their weme from one of their stems (Barama), number about 50,000 in tho government of Tobolsk aud ahout 5000 in Tomsk. After a strennons resistance to Russian conquest, and much suffering at a later period from Kirghiz and Kalmuck raids, they now live by agriculture, either in separate villages or along with Russiuns. (8) The Tcholym or Tchulym Tartars on the Teholyin and both the rivers Yus apeak a Turkish language with many Nongoliun and Yakut words, antl aro more like Mongols tlian Turka. In last century they pail a tribute for 2550 arbaletes, but they now are rapidly hecomiug fuscl with Rucsians. (9) The Abakau or Minusinsk Tartars occhipied the steppes on the Abakan and Yus in the 17 tl century, after the withdrawal of tbe Kirglizea, and represent a mixture with K nibals iwhom Castrén considers as partly of Ostiak and partly Sanoycdic origind and Beltirs-also of Finnish origin. Their langusge is also mixed. They are known under the name of Sagais, who numbered 11,720 in 1864, and are the purer Turkish sten of the Mlinusinsk Tartars, Roibals, and Kyzyl or Red Tartars. Fornaerly; Shamanists, they now are, nominally at least, adherents of the Greek Orthodox Church, and support thensclves mostly by cattle breeding. Agriculture is a preading but slowly among them; they still prefer to plunder the atores of hulbs of Lilium Martagon, Pronia, ank Ervthonirm Dens canis laid up by the steppe monse (Ifus socialis). The Soyotes, or Soyons, of the Sayan Mountains, who aro Finns mixed with Turks, the Uryankhes of north-west Mongolia, who are of Turkish origio but follow Buddhism, and the Karagasses, aiso of Turkish origin but mucl like the Kirghizes, and reduced now tc a few lusulreds, are akin to the above. (10) The, Tartars of the northern slopes of the Altai (nearly 20,000 in number) are of Fianish origin. They comprise some hundreda of Kumandintses, the Loherl Tartars, the Tchernevyie or Black. Foreat Tartars, and the Shors (11,000), descenlaata of the Jiluzaetsk or Iron-Smith Tartars. They are chiefly huaters, passionately lov. ing their taiga, or wild foresta, and have maintained their Shaman religion and tribal organization into suoks. They live partly also on cedor-nuts and honey collected in the forests. Their dress is that of their former rulers, the Kalmucks, and their language contains many Mongolian words. (Il) The Altai Tartars, or "Altaians"." comprise-(a) the Mountain Kalmucke (12,0noj, io whom this name
has been giveu-by mistalic, and who have nothing in common with the Falmucks except their dress and mole of life, while they speak a Turkish dialect, and (b) the Teleutes, or Teleughites (5800), a remainder of a formerly numerons and warlike nation who have migrated from the monntains to the lowlands, where they now live along with Russian peasants.

Finally, there are a number of Tartars in Turkestan and Central Asia. Without including under this name the. Sarts and the Kuramintses of Turkestan, still less the Kirghiz-Kazaks, it may be reckoned that thace are still ucarly 30,000 survivors of the Uigurs in the valley of the Ili, about linlija, and in tbe Khami oasis.

As is evident from the above, although the name Tartars eriginated in an indiscriminate application of the werd to the Turkish and Mongolian stems which invaded Europo six centuries ago, and its gradual extension to the Turkish stenns mixed with Mongolian or Finnish blood in Siberia, it still represents an aggregate of characters which warrant at least a provisional use of this genetic name, if those to whom it is given are properly subdivided. It embodies stems which, although widely distinct, still have some common ethnographical and philological features, besides being to some extent of like origin and history.
The litcrature of the subject is very extensive, and biblographleal indexes may be found in the Geographical Dicfionary of $P$. Semenoff, appended to the articles devoted respectively to the names giren sbove, as miso in the yearly Indczes by M. Mezhoff. Eexides the well-known works of Castren, which are a very rich source of informatlog on the subject, Schlefner (St Petersburg academy of science), Donner. Ahlgsist, and other explorers of the Ural-Altsians, as also those of the fussion historlana Solovieff, Kustomaroff, Bestuzheft-Riumin, Schapoff, zod llovalokiy, the followiog containing valuasle information may be mentloned:- the publications nf the Russlan Geograplical Society and Its brenches; the Russian Efnographicheskiy Soornik; the Ievestia of the Bloscow coclety of the amateur's of natural aclence; the works of the Rosslan ethnographical congresses: Kostroffa rescarches on the Siberlan Tartars in the memoins of the Siberian branch of the geogr. coe.; Radlaffs Reise durch teen Allai, 4 us Sibirien; " Plicturesque Russis, (Jvopisnaya Rossiya); Semenoff ond Potanin's "Supplements" to Rifter's Asien; Ilarkavi's reporl to the coneressat Kazaf ; Hortakhai's "\#ist. of Crimean Tatars," In Tyestnik Ebropy, 1866 sod 1867; "Katchinsk

TARTARUS,' in the Iliad (viii. 13 sq., 481), is a dark underground prisou with iron gates, as far below Hades as earth is below heaven, whither Cronus and the Titans were thrust down by Zeus (vol. xxi. p. 321 ), and to which the sovereign of Olympus threatens to consign other gods who may disobey his behests. Later writers make Tartarus the place of punishment of the wicked after death : Æoeas, in his visit to the abode of the shades, comes to a point where the road divides, the branch to the right leading to Elysium and that on the left to the prison-house of Tartarus, girt about by a triple wall, with the fiery Pllegethon as a moat, and guarded by the fury Tisiphone (En., vi. 540 sq.). Tartarus is personified as the son of Ether and Ge, and father of the giants Typhoeus and Echidna.

TARTINI, Gioseppe (1692-1770), violinist, composer, and musical theorist, was born at Pirano, April 12, 1692, and in early life studied, with equal want of success, for the church, the law courts, and the profession of arms. His life as a young man was wild and irregular, and bis temper extremely violent and impulsive. His unfitness for an ecclesiastical career was manifest; and, after failing in jurisprudence, he crowned his improprieties by clandestinely marrying the niece of Cardinal Cornaro, archbishop of Padua. Though the family of Tartini had been legally ennobled, the cardinal resented the marriage as a disgraceful mésalliance, and denounced it so violeatly that the unhappy bridegroom, thinking his life in danger, fled for safety to a monastery at Assisi, where, calmed by the soothing infucace of the religious life, his character underwent a complete change. Docile and obedient, as he had before been passionate and headstrong, he studied the theory of music under Padre Boemo, the organist of the monastery, and, without any assistance whatever, taught himself to play the violin in so masterly a style that his performances in the church became the wooder of the neighbourhood. For more than two years his identity remained undiscovered, but one day the wind blew aside a curtain behind which be was playing, and one of his hearers recognized him and betrayed his retreat to the cardioal, who, hearing of his changed character, readnitted him to favour and restored him to his wife.

Tartini next removed to Venice, where the fine violin-
playing of Veracini cxcited his admiration and prompted him to repair, by the aid of good instruction, the shortcomings of his own self-tauglit method. - After this he studied for some time at Ancona; and here, about 1714 , he made the curious acoustical discovery on which his fame as a theorist chiefly rests. He observed that, when two notes are sounded together on the violin with sufficient intensity, a third sound, distinct from bath, is simultaneously produced. For the production of this "third sound," as he called it, Tartini failed to account on strict mathematical principles. When the two primary notes form an impure consonance, the "third sound" of Tartini (now known as a difference tone of the first order) is accompanied by beats due to the presence of different toaes of higher orders, the existence of which, unknown of course to Tartini, has been established by Helmholtz. Tartini made his observations the basis of a theoretical system which he set forth in lis Trattalo di Musica, secondo la verce scienzia dell' Armonia (Padua, 1754) and Dei Principij dell' Amonia Musicale (Padua, 1767). In 1721 be returned to Padna, where he was appointed solo violinist at the church of San Antonio. From 1723 to 1726 he acted as conductor of Count Kinsky's private band, but afterwards returned to his old post at Padua, where he died on February 16, 1770.
Tartini's compositions are very numerous, and faithfully illustrate his passionate and masterly style of execution, which surpassed in brilliancy and refined taste that of all his contemporaries. He frequently headed his pieces with an explanatory poctical motto. such as "Onibra cara," or "Volgete il riso in pianto o mie pupillc." Concerning that known as $1 l$ Trillo del Diavolo, or The Deril's Sonata, he told a curions story to Lalande, in 1766. He dreamed that the devil had hecome his slave, and that he one day asleed him if he could play tho violin. The devil replied that he beliercl he could pick out a tune, and thereupon lie playcd.a sonata so exquisite that Tartini thouglit he had never heard any music to equal it. On awaking, he tried to note down the composition, bat succeeded very inperfectly, though the resulting Devil's Sonala is one of his best and inost celebrated productions.
Besides the theoretical works we have mentioned, Tartini wroto a Trattato delle Appogiature, posthumously printed in French. and an unpublished work, Delle Ragioni o delle Proporaioni, the MS. of which has been lost.

TARUDANT. See Morocco, vol. xyi. p. 834.
TASHKEND, or Tasheent, one of the largest and most important cities of Central Asia, now the capital of Russian Turkestan, is situated in the valley of the T'chirtchik, some 50 miles above its junction with the Syr-Daria, in $41^{\circ} 20^{\prime} \mathrm{N}$. lat. and $69^{\circ} 18^{\prime} \mathrm{E}$. long. The city, formerly enclosed by walls which are now ruinous, is surrounded by rich gardens, and its houses are buried among the fruit and other trees which grow all along the numberless ramifications of the irrigation canals. The buildings, which are of stone and sun-dried bricks, are mostly low, on account of the earthquakes which frequently disturb the region. Like all old cities of Asia, Tashkend is șubdivided into sections (yurts), which are characterized by the special trades carried on in each. Asiatic Taslakend in 1871 had 78,130 inhabitants, mostly Sarts ( 75,176 ), with a few Uzbegs, Kirghizes, Jews, Kussians, and Germans. A depression in the south-east is occupied by Russian Tashkend, dating from 1865, which has clean, broad streets lined with poplars, the low nicc-looking houses being surrounded by gardens. In 1875 its population, exclusive of the military, was 4860 , mostly Russians. It has a public library containing a rich collection of works on Central Asia, an observatory, a museum, two gymnasia, a seminary, and the buildings occupied by the administra. tion. A branch of the Rissian Geographical Society has been opened at Tashkend, and its publications, as also those of the statistical committee and the Turkestan Gazefie, contain most valuable information about Turkestan. According to the most recent estimates, the population of

Tashkend, with its suburbs, is reckened at 100,000 . In consequence of the chequered histery of the town (see Turkestan), few old bnildings have been preserved, and only the madrasah Beklar Bek, with its fifty students, and the graves of Sheikh Zenedjin-baba and Zenghi-ata are worthy of mention. The former is four centuries old, and that of Zenghi-ata, a saint held in high veneration throughout Central Asia, yearly attracts thousands of jilgrius.
A variety of petty trades are carried on in numerons simall work. shops, -weaving and dyeing of eottons and the manufacture of small brass and iron wares, of harness, and espccially of beots, being the chief. Most of the inhabitants are also engaged in raising corn. xice, oil-plants, cetton, wine, and lacerne, and in gardening. Tho trade of 'Inslikeud has lost ite former inportance, but corn, cattle, silk, cotton, and fruits are still cxported, and all kinds of manafactured wares are imported from the countries to the south.
TASMAN, Abel Janszen (c. 1602-1659), a distinguished Dutch navigator, bern at Hooru, North Holland, prebably in 1602 or 1603. He is known to have made two important royages of discovery in the Pacific and Southern Oceans; only of the second of them have we a full account. In June 1639 Tas: nan, along with Matthew Quast, was despatched by Van Diemen, governorgeneral of the Dutch East Indics, on a vowage to the Western Pacific, which was fist directed to the Pbilipyine Islands; part of the coast of Luzon was explored. Sailing east and north Tasmian and Quast tenched at several of the Benin Islands, which they were probably the first to discover. Sailing still farther north, in quest of what were then known as the "islands of gold and silver," they reached the latitude of $38^{\circ} 40^{\prime} \mathrm{N}$., about 600 iniles east of Japan, and continued east for other 300 miles en the parailel without discovering anything. On October 15 the navigators decided to return, and, after tonching at Japan, anchored at Taiwan-fu, Formosa, November 21. After this, Tasman was engaged in operations in the Indian seas until 1612, when he sct out on his first great expedition. ${ }^{1}$ Several Dutch navigaters had already discovered varieus portions of the west coast of Australia, and the Dutcl East India Cempany were anxious to obtain a more accurate and extended survey of that land. Sailing from Batavia on Angust 14, 1642, with two vessels, the "Hcemskirls" and "Zeehaan," Tasman on November 24 sighted the land to which he gave the name of Van Diemen, in honour of the governer-general, but which is now named Tasmania. He doubled the land, which he evidently did net know was an island; and, running up Storm Lay, anchored on Decemher 1 iu the bay to which he gave the name of Frederick Henry. There he sct up a post on which he hoisted the Dutch flag. Quittiug Tan Dicmen's Land on December 5, Tasinan steered castwards with a rague idca of reaching the Solomon Islands, and on December 13 he discovered a. "high monntainous country," which he called "Staatenland" (New Zcaland). Cruising along the west coast of the South Island, he anchered on the 18 th in $40^{\circ} 50^{\prime} \mathrm{S}$. lat., at the cutrance of a " wide opening," which he teok to be a "fine bay," but which was no doubt Couk's Strait. He gave the name of Moordenaars (Massacre) Bay to the bay, at which he attempted to land, and where scveral of his men were killed by the natives. Leaving New Zealand, and pursuing an irregnlarly north direction, but never coining in sight of Australia, he discoverch, on January 21, 1643 , two islands belonging to the Friendly group, to which he gave the names of Miblellurg (Eova) and Ansterdam (Tongatabur). After discovering sevcral other islands in the Friendly group and their neighbourhood, Tasman stecred north and west, reaching the neighbourleod of New Britain on March 22. On the 24th he

[^20]passed Morghen Isiands, and, sailing round New Ireland and along the north coast of New Guinea, he cleared the straits between New Guinea and Jilolo, arriving at Batavia on June 15 , after a ten menths' voyage. ${ }^{2}$ The materials for an account of Tasman's inportant second voyage in 1644 are extremely scanty; they consist of Tasman's own chart and some fragmentary notes by Burgomaster Witsen in his work (1705) on the migrations of the human race (translated in Dalrymple's collection). Further information as to authorities ${ }^{3}$ will be found in Mr R. H. Major's Hakluyt Society volume on Eurly Voyages to Australia. where also will be feund the "Instructions" given te Tasman for his voyage to New Cuinea. He is instructed to obtain a thorouch knowledge of Staten and Van Diemen's Land, and "whether New Guinea is a continent with the great Kuidland, or separated by chamels and islands," and also "whether the new Van Diemen's Land is the same continent with these two great countries or with one of them." In this royage Tasman had three ressels under his command. His discoveries were confined to the nerth and north-west coasts of Australia, and his chart gives the soundings for the whole of this line of coast. He discovered the Gulf of Carpentaria, and established the continuity of the north-west coast of the land designated generally "the great known south continent," as far south as about the 22 d degree. The fullest details as to maps of the voyage and other anthorities will be found in Mr Majer's Hakluyt Society volnme referred to above. Tasman rightly ranks as one of the greatest navigaters of the 17 th ecntury. He died at Batavia in October 1659.
For personal details, see paper on Tasman by Ch. M. Dozy in Dijdragen tot de Taal., Land-, en Volkenkunde van NederlundschIndië, 5th series, vol. ii. p. 308.
TASMANIA, formerly Van Diemen's Land, is a compact island, forming a British colony, which lies to the south of Anstralia, in the Southern Ocean. It has an area of 24,600 square miles (about three-fourths of the size of Ireland), and some fifty islets belong to it. Most of these lie between it and the southern shore of Victeria, in Bass's Strait. It is a land of mountain and flood, with picturesque scenery. The centre is a mass of hills, generally covered with forest, with large lakes nearly 4000 feet above the sea; and this high land is continued to the west and nerth-west, while southward are other elevations. Ben Lomond in the cast rises to a height of 5020 feet; in the north-west are Dry's Bluff ( 4257 feet) and Quamby ( 4000 ); while westward are Cradle (5069), Hugel (4700), Prenchman's Cap ( 4760 ), and Bischoff (2500). Wellington, near Hobart, is 4170 feet. Anong the rivers flowing nerthward to Bass's Strait are the Trmar, Inglis, Cam, Emu, Blyth, Forth, Don, Mersey, Piper, and Ringarooma. The Macquarie, receiving the Elizabeth and Lake, falls into the Sonth Esk, which unites with the North Esk to form the Tamar at Launceston. Westward, falling into the ocean, are the Hellyer, Artlur, and Pieman. The liing and Gordon gain Macquarie Harbour ; the Davey and Spring, Port Davey. The central and seuthern districts are drained by the Derwent from Lake St Clair,-its tributaries being the Nive, Dee, Clyde, Ouse, and Jordan. The Huen falls into D'Entrecastcanx Channel. The chief mountain lakes

[^21]TASMANIA
PLATEI.

are the Great Lake ( 50 miles in circuit), Sorell, St Clair, Crescent, and Echo. The colony is divided into eighteen counties. The principal towns are Hobart, the capital; on the Derwent, with a population of 21,118 in 1881 (25,044 in 1886), and Launceston (12,752 in 1881; 19,379 in 1886), at the bead of the Tamar. The rugged western half of the island has only a few small settlements, while the eastern country is increasing in population on account of the mines.

Climate.-This small colony has a far greater range of climate than can be experieuced throughout the Australian continent. The eastern side is dry ; the western is very 'wet. Tin and gold miners are partially arrested in their ;work during summer from want of water in the north-east. Dense forests and impracticable scrubs result in the west from deposition of a bundred or more inches of rain in the year, whilo other parts to the east occasionally suffer from drought. Tasmania does not escape the summer $v$ isit of an Australian hot wind. Hobart and Launceston, being near the sea, have greater equability of temperature, with rare frosts. The mean temperature of Hobart is $54^{\circ}$, of Waratah in the north-west $44^{\circ}$. Hobart averages 22 inches of rain, less than Melbourne, Sydney, and Brisbane. Inland, in the settled parts, cold is severe in winter, but only for a short period. The wooded north-west shore has no cold and no excessive heat, but plenty of showers. Up in the lake country the climate rather resembles the Highlands of Scotland. On the west and southern coasts the winds are usually strong, and often tempestuous.

Like New Zealand, Tasmania is very bealthy. No miasma is retained in its forests. Rheumatism and colds may prevail, but little fever or dysentery occurs. Perhaps no part of the world can show relatively so many aged people. Children generally display the robustness of English village life. As a retreat for Australians, Tasmania in the summer has strong claims. Cool and strengthening airs, magnificent forest solitudes, and secluded fern-tree vales may be enjoyed along with all the comforts of modern civilization.

Geology. - The comparatively recent connexion of Tas. mania with Victoria is evidenced not less by rocks than by flora and fauna. The granitic islands of Bass's Strait are as so many stepping-stones across, a depression having converted the loftier districts into islands. The want of similarity, however, between the tufted-haired Tasmanians and their Australian neighbours would indicate that the disruption took place before the advent of the younger race on the northern side. While doubts exist as to the presence of rocks older than the Silurian, a Palæozoic floor exists north, east, south, and west, though often thrown up into irregular ranges, sometimes over 5000 feet, by igneous irruptions. Convulsions have distinguished the bistory of the little island from one end to the other. Not only is granite in all its varieties very prevalent, but there is an immense amount of metamorplism in different directions. Then, at another period, not merely porphyries, but basalts and greenstones, were widespread in their ravages. They consumsed or deranged beds of coal, and overflowed enormous tracts. Earthquakes were busy, and tremendous deluges denuded great areas to depths of thousands of feet, leaving mountains of Primary rock, with peaked or platean summits of basalt or greenstone. There are prismatic walls several hundreds of feet in height, and 4000 feet above the sea-level; as at Mount Wellington, looking down upon "ploughed fields" of greenstone blocks. Still, unlike Victoria, there are not the extinct craters to tell the tale of more modern lava flows. The lake district, up to over 4000 feet, is a tangled mass of granitic and metamorphic rocks. Quartz is so common a feature that the western storm-bound cliffs reflect a white light to passing ships; *hile mica, talcose, dolerite, and siliceous schists are
common over the island. Contorted slate and the tesselated pavement of Tasman's Peninsula are effects of that transmuting period. Granite is strong at eastern and northern points, at western localities, in the interior, and in the straits. Greenstone is exhibited southward in enormous fields, as well as in the western and lake districts, and alternates often with basalt. Silicified trees are seen standing upright in the floor of igneous rock. The Prim ary rocks have more casts of former life than fossils in ordinary condition. The Hobart clay-slate abounds in Fenestella or lace coral, and trilobites occur in limestone. Slate is abundant on the north-west coast, the South Esk, and westward. New Red Sandstone near Hobart is marked by the presence of salt-beds. The Carboniferous formations are not much exhibited on the western half of the island, but are prominent along the Mersey and other northern rivers. The southern fields are torn by igneous invaders. Anthracitic forms are conspicuous on Tasman's Peninsula. Inland, on the eastern side, the formations spread from near Hobart northward for scores of miles, and even to a thousand feet in thickness. The Fingal and Ben Lomond north-eastern districts are remarkably favoured with Carboniferous sandstones and crinoidal limestones, bearing excellent seams, and like strata are noticed in islands off the east coast. Carbonaceous non-coal-bearing, beds by the Mersey are 500 feet thick. Tertiary rocks are not extensive, save in the breccia and coarse sandstone south of Launceston, over Norfolk plains, and along some river valleys. Alluvial gold deposits beloug mainly to the Pliocene formations,- -the ancieut Primaries containing the auriferous quartz reins. Greenstone and basalt belong to various periods, the latter being specially apparent in the Tertiary epoch. Travertine, near Hobart and Richmond, is from freshwater actiou. The Pleistocene development was claracterized by overwhelming denuding forces. Raised beaches are noticed along some of the larger rivers, and westerly moraines would imply a greater elevation of the country formerly. Caves and recent beds exhibit marsupial forms analogous to existing ones. Not far from Deloraine are limestone caves, with passages two miles in extent. The density and intricacy of the island scrubs have interfered with the investigation of its geology.
Minecrats.-Tasmania has failed to take a very inportant position as a gold producer. Still, when the crushing of 1300 tons in one mine produced $£ 11,528$, ?dventurers may well be hopeful. From Beaconsfield mine, west of the Tamar, gold was obtained to the value of $£ 615,330$ from July 1878 to Jannary 1, 1887. In 1885 there were five districts under commissioners of mines. Westward, gold is found from Arthur river to Point Hibbs; north-westward, from Blyth river to Cape Grim. . In the north-east are Scottsdale, Ringarooma, Mount Victoria, and Waterhonse fields; east, Fingal and St George river. Arsenic and silver are found with gold in the north-east; and iron, arsenic, copper, and lead with it at Beaconsfield. For 1885 the gold export was 37,498 oz, worth $£ 141,319$. Silver occurs at Pengnin, Monnt Ramsey, and Waratah (Muant Bischoff), combined with lead. Copper is met with at Mount Maurice, \&c., but not in paying quantities. Bismuth at Mount Ramsey is rich, but the country is difficult to reach. Antimony, zinc, manganese, copper, plumbago, and galena are known west of the Tamar, where also asbestos in serpentine hills is plentiful. Tin is well distribnted in Tasmanian granite. Mount Bischoff, in the scrubby, rocky, damp west, has the richest lodes; other mines are in the north-cast and west. In ten years the prodnct came to two and a half million pounds sterling. Bischof district in 1885 gave 2871 tons of ore, much being found in hage blocks. Want of water in the north east prevents much hy draulic working. An thracito coal is pretty abundant at Port Arthur. Near Hobart are werkings of poor quality. Around Ben Lomond are bituminous seams, but difficult of access. Fingal district has coal equal to that of Newcastle, with a seam of 14 feet, but carriage is difficult. ${ }^{1}$ 'ersey river coal mines yiolded 60,000 tons in the course of over a dozen years. Iron was worked near the Tamar, but did uot pay, excess of clironium making it brittle; its stecl was very malleable: All varieties of iron ores are known. Hebart freestone is largely exported to othcr colonies. Tasmanite or dysodile in the Merseg district is an inflammable resinous suiostance. During 1884 thers
were raised $41,240 \mathrm{oz}$. of gold, 5461 tons of tin, and 5334 tons of coal. The total exnort of gold and tin during the five years 1880 to 1885 was of the value of $£ 2,591,320$, -being $£ 642,230$ more than for the ten years preceding. The oxport of tin averaged $79,682 \mathrm{cwt}$. Agriculture. - The island has not a large area fit for cultivation. A great part is very mountainous; and densa serubs, with beary furesis, are imperiments to the farmer. The west side is too wet, stormy, and sterile for settlement. Almost all the farms lie in the line between Hohart and Launceston and between Launceston and Circular Head. The climate being cooler and moister than in most prits of Australia, the productious are of an English charactcr, hops, barlej, and onts being freely raised. Cropping land for many successive years rith wheat has lessened the produce of what mas fertile country, as little manure had been used. In later times there has heen a great improvenent in agriculture. For some time Tasnaanian growery did well, supnlying Anstralia and New Zealand wish flour, potatoes, and fruit; but, as their customers became in there turn producers, the old narkets failed in all but apples and otone fruit. Fresh and preserved fruit, with jams, together with excellent hops, continue to afford the islauders a good trade. In 1885-86 there were 417,777 acres in eultivation; in crop, 144,761; in grasses, 181,208. Wheat occupied 30,266 aeres, barley 6833, oats 29,247, pease 7147, potatoes 11,073, hay 41,693, turnips 3680 , and gardens and orchards 8198.

So large a part of the island is covered with thicket, rock, and marsh thot it appears less pastoral than eastern Australia The total number of sheep in 1886 amounted to $1,648,627$, the horses to 28,610 , and the cattle to 138,642 . Of $16,778,000$ acres only 4,403,888 have been sold or granted.

Flora. -This differs but little from that of south-eastern Anstralia, with which it was formerly conuected. Over a thousand apecies are represented. The eucalypts are gums, atringy bark, box, peppermint, ironrood, \&c. Tbs celobrated bluo gum (Eucalyptus Globulus), so eagerly sought for pestilential places io southern Europe, Africa, and America, flourishes best in the southern districts of the island. For shipbuilding purposes the timber, which grows to a large size, is much prized. Acacias are abundant, and manna trees are very productive. Sassafras (Atherosperma mos. chata) is a tall and handsome tree. Pines are numerous. Tha Huon pine (Dacrydium cuprcssinum), whose satin-like wood is so sought efter, flourishes in Hoon and Gordon river districts. The colery pine is a Phyllocladius, and the pencil cedar an Athrotaxis. The pepper tree is Tasmania fragrans. The Myrtaceas are noble trees. The lakes cider trea is E'ucalyptus resinifera, whose treaclelike sap was formerly msde into a drink by bushinen. Xanthorroas or grass trees throw up a flowering spike. The charming red flowers of the Tasmanisn tulip tree (Telopea) are seen from a grest distrace on the sides of mountains. The so-called rice plant, with rica-like grains on a stalk, is the grass Richea. Of Borenia, Epacris, and Orch is thero are numerons species. The Blandfordia, a Liliaceous plant, has a head of brifliant crimson flowera. The Casuarina, Exocarpus, Banlesio, and tree fern resemble those of Australia. Tasmanian evergreen forests are very aromatic. At one tima the islend had an extensive timber trade with Sydney, Melbourne, and Adelaide, and it still exports $£ 50,000$ to $£ 80,000$ worth annually of planks, shingles, paling \&c.

Fauna. - Animal life in Tasmanis is similar to that in Anstralia. The dingo or dog of the latter is wanting; and the Tasmanian devil and tiger, or molf, aro peculiar to the sland. The Marsupials include the Macropus or kangaroo, Didelphys or opossum, Petaurus or flying phalanger, Perameles or bandicoot, Hypsiprymines or kangaroo rat, Phascolomys or wombat; while of Ifonotremata there are the Echidna or porcupine anteater and the duck-billed platypus. The marsupisl tiger or Tasmanian wolf (Thylacinus cynocephalus), 5 feet long, is yellowish brown, with several stripes across the back, having short stiff hair and very short legs (see vol. xv. p, 380). Tery ferv of these nocturnal carnivores are now alive to trouble flocks. The tiger cat of the colonists, with weasel lega, white apots, snd nocturnal habits, is a Jarge species of the untameable pative cats. The devil 'Dasyumus or Sarcophilus ursinus) is black, with white bands on oeck and haunches. Tha covering of this savage but covardly little pight-prowler is a sort of short hair, not for. The tail is thick, snd the bull-dog mouth is formidable. Among the birds of the island ara the eagle, hawk, petrel, owl, finch, peewit, diamond bird, firetsil, robin, emu-wren, crow, swallow, magpie, blackcan, goatsucker, quail, ground dova, jay, narrot lark, mountain thrush, cuckoo, wattlobird, whistling duck, horeybird, Capa Barreo goose, penguin duck, waterhen, enipe, albatross, and laughing jackass. Snakes are pretty plentiful in serubs; the lizards aru harmless. Insects, though similar to Australian ones, ara far less troublesomo; many are to be sdmired for their great besuty.

Fisheries. - In the eally years of occupation the island was the resort of whalere from tha United Kingdom, the United States, and Erence. Both sperm and black oil, with whalobone, were important articles of export till tha retreat of the whales to other sess. Seal. ing was carried on auccossfully for many years in Bass'e Streit. ontil the sesls were utterly destroyed. There has recsutly been a
revival of whaling, the product of the island fisbery for 1885 being £12,600. The bays contain some cxcellent fish, much esteemed in the neighbouring colonies, particulatly the trumpeter, found on the southern side of the island. Of nearly 200 sorts of fishes a third can be considered good for food. The outer fisheries extrad to 16 miles from shore, being from 20 to 80 fathoms deep. The species include the trumpeter (Latris, found up to 60 it weight), the "salmon " of the ofd sectlers (Arripis), the flathead (Platycephalus), tresally (Neptonemus), garfish (Hemurhamphus), barracouta and kingfish (both Thyrsite's). There are thirteen sorts of perch, and five of bream. The anclovy is migratory. English mackerel have been scen off the east coast; and some of the herrings are much like the English. Rock cod and bull-kelp cod are favourites. Mud oyaters are nearly worked out; artiticial oyster-beds are being formed. Euglish trout (Salmo fario) are more certainly found than the true saluon (Salno salar); the last are doubtful, thougls num. bers have beeu raised in hatcheries on tha Derwent. Among freshwater fish are a so-called freshmater herring (Prototroctes), various kinds of what the old settlers called trout (Galaxias), blackfish (Gadopsis), aml fine perch.

Commerce. - Soon after the colony was founded thera was a great trade iu whale onl, as well as in the oil and skins of seals. When this declined, merchants did well in the exportation of breadstuffs, fruits, and vegetables to the ueighbouring and more recently estab. lished colonies, not less than to New South Wales. Timber was also freely sent to nlaces less favoured with-forests or too busy with other employments. When the trade with England in oil fell off, the export in wool and then of metals succeeded. Tasmanio has now an active commerce with Victoria, but has a competitor rather than a customer in New Zealand. Tho shippiog during 1885 was 342,745 tons inward, 335,061 outward. The imports for that year came to $£ 1,757,486$; the exports to $£ 1,313,693$. Of the exports, $£ 1,299,011$ were of Tasmanian products and manu-factures,-including wool, £260,480; tin, £357,587; gold, £141,319; fruit, $£ 105,363$. The baaks of the colony at the eud of 1885 shorved assets $£ 3,754,226$ and liabilities $£ 3,814,631$. The saviogs banks early in 1886 declared $£ 455,774$ to the credit of depositors. Attempts hare been recently mau'e to draw Tasmania into eloser commereial and fiscal relations with Victoria.
Manufactures. - Numerous industries are practised, though not to the extent of exportation, excepting from the working of 28 tanneries, 62 sawmills, 33 breweries, 7 manufactories of jam, and a rising wool factory.
Roads and Railuizys. - No colony, for its area, was ever so favoured with excellent roads as Tasmania has been. There arb now about 5000 miles of good roads. The priocipal line of reilvay is toat from Hobart to Launceston. Altogether, 260 iniles of railway were open in 1887.
Post-Office. - In early years letters were carried by runners on foot across the island. In 1885 there were 246 post offices, and the telegraph had 1579 miles of wire A submarine line connects Tasmania with Victoria.

Administration. - l'he governor is appointed by the British crown. The legislative council has eighteen members, and the assembly thirty-six. The revenue for 1885-86 was £571,396, the expeaditure $£ 585,766$. The public debt, contracted for publio works, amounts to three and a third millions. The customa provided $£ 276,100$. The official machinery is as extensive as for a colony with seven or eight times the population.

Edication. - At first tha state made grants in aid to schools established by private persons and religious denominations, but ultimately, ss in Victoria and New Zealand, education was mada secular and compulsory, roligions teaching being out of school hours, or depondent on Sunday schools, which are to be found all over tho island. There are 204 public scliools, maintained out of a fund of $£ 32,793$. In eight grammar and collegiate sehools a higher standard of instruction is reached. Tbe degree of Associate of Arts is conferred on deserviug scholars in the atate schools; and exhibitions (up to $£ 200$ a year for four years) euable pupila to study at the higher schools or colonial or European universities, No state grant is now made for the support of any religious denomination.

Population. - The whites have entirely displaced the blacks. Outrages and cruelties led to conflicts; and now tha last individual of tha tribes hss passed away. There are, howover, some halfcastes on islands in the Straits. The colonists in Tasmania are more concentrated than in other settlements. In 1818 there were 2320 men, 432 romen, and only 489 children. At the census of 1881 the population numbered 115,705 (61,162 males, 54,543 females) ; in 1886 it was estimated at 133,791. The birthe in 1886 sveraged $34^{\circ} 6$ per thousand, the deaths $15 \cdot 2$.

History. -The Duteh navigator TAsMAN (q.v.) sighted the island November 24, 1642, and narned it Van Diemen's Land, aftor the Dutch gorernor of Java. He took possegsion at Frederick Henry Bay in the name of the stadtholdtr of Holland, and then passed on to the discovery of New Zealend. The French Captain Mariou in 1772 came to blows with the netives. Cantain Cook was at

Adventure Bay, to the south, in 1777. His companion, Captain Fnrneanx, bad entered tha bay four years previously, assuring Cook that Van Diemen'a Land was joinoll to New Holland. Admiral Bruni d'Eutrecastenux, with the uaturalist La Billariliere, entered the Detwent, calling it North River, in 1792. Two years after, Captain H:yes namel it Derwent. Mr Bass anl Licutenant Flinders passoll through Bass's Strait, and first sailed round the island, in 1798. The high terms in which they spoke of Sullivan's cove, at the mouth of the Derwent, afterwards led to tho sestloment of Hobart there. "Tha Freach discovery ships, "Geagraphs" and "Naturalisto," under Commodore Baudin, were off the coast in 1801-2. The island was settled from Sydney. A small party was sent to the Derwent, under Licutenant Dowen, in 1803, and another to Port Dalrymple next year under Coloacl Paterson, who was ren:oved to Launceston in 1806. Captain Collins, who had been sent with a largo mumer of convicts from England to form a penal colony in Port Phillip, thonght proper to remove thence after three moutlis, and establish liniself at Hobart Town, February 1804. The carly days were trying, from want of supplies and of good government ; and confiets arose with the natives, which led to the celchrated Black War. In 1830 nearly all the settlers, with 4000 solliers and artocl constables, attempted to drive the aborigines into a peninsula, but canght only one lad. Mr George Rabinson afterwards succeeded in indacine the few hunted ones to surrender and bo taken to Flinders Island. Deaths rapidy followed. The last man dici in 1862, tha last female in 1872 . Bushrangiug was common for years in this scrubly land. The colony was aubject to Now South Wales till 1825, when independence was declared. On free acttlers being permitted to go to Van Diemen'a Lavd, they endeavoured to get frecdom of the press, trial by jury, and a popular form of rulo. After long struggles, the liberties they sought for were gralually granted. A respousibla goverament was the last boon received. Oppressed by the number of convicts thrown into the country, the free inhabitants petitionel again avd again for the cessation of transportation, which was evertually allowed. Among the governors was Sir John Franklin, of polar celebrity. The first newsinpur, The Derwent Star, came out in 1810. Literatura advanced from that humbla begiming. At first the Governneent entircly supported achouls and churches, and for many years state aid was affordect to the Churcin of England, Presbyterion, Wesleyan, and Roman Catholic charcles, but this ail is now withdrawn. The islanl poving too small for a large population, uumbers swarmed off to tho neighbourity settlemens'\%, and Port Philip, now Victoria, received its first inhabitants from Tasmania. Though not so prospcrons as Victoria, the little island enjoys an amount of easo aud confort which few, if any, settlenents elsewhere hara been known to experience.
(J. BO.)

TASSIE, JAMEs (1735-1799), gem-engraver and modeller, was born of lumble parentage at Pollokshars, near Glasgow, in 1735. During his earlier years he worked as a stone-mason, but, having visited Glasgow on a fairholiday, and seen the collection of paintings brought together in that city by Robert and Andrew Foulis, the celebrated printers, he was seized with an irresistible desire to become an artist. He remorcd to Glasgow, attended the academy which lad been established there by the brothers Foulis, and, applying hinsself to drawing with indomitable perscverance, seconded by great natural aptitude, he eventually became one of the most distinguished pupils of the school. When his traiuing was completed he visited Dublin in search of commissions, and there becane acquainted with Dr Quin, who had been experimenting, as an amateur, in initating antique engraved gems in coloured pastes. He engagce Tassie as an assistant, and together they perfected the discovery of a vitreous paste composition, styled "enamel," a substance adinirably adapted, by its hardness and beauty of texture, for the formation of gems and medallions. Dr Quin encouraged his assistant to try his fertune in London, and thither be repaired in 1;66. At first he had a hard struggle to make his way, for he was modest and diffident in the extreme, and without influential introductions to a mateurs and collectors. But he worked on steadily with the greatest care and accuracy, scrupulously destroying ${ }_{a} l l$ impressions of his gems which were in the slightest degree inferior or defective. Gradually the beauty and artistic claracter of his productions came to be known. He received a commission from the empress of Russia for a collection of about 15,000 examples; ail the richest
cabinets in Europe were thrown open to him for purposes of study and reproduction; and his copies were frequently sold by iraudulent dealers as the original gems. He exhibited in the Royal Academy from 1769 to 1791. In 1775 he published the first catalogue of his works, a thin pamphlet detailing 2856 items. This was followed in 1791 by a large catalogue, in two volumes quarto, with illustrations etched by David Allan, and descriptive text in English and French by Rudolph Eric Raspe, F.S.A., enumerating nearly 16,000 pieces Materials exist in MIS., in the possession of a descendant of Tassie's, for a list of moro than 3000 further items.

In addition to his impressions from antıque gems, Tassie executed many large profile medallion portraits of his contemporaries, and these form the most original and definitely artistic class of his works. They were modelled in wax from the life or from drawings done from the life, and-when this was impossible-from other authentic sources. They were then cast in white enamel paste, the whole medallion being sometimes executed in this material; while in other cases the head only appears in enamel, relieved against a background of ground-glass tinted of a subdued colour by paper placed behind. His first large enamel portrait was that of John Dolbon, son of Sir William Dolbon, Bart., modelled in 1793 or 1794; and the series possesses great historic interest, as well as artistic value, including as it does, portraits of Adam Snith, Sir Henry Raeburu, Drs James Beattie, Blair, Black, and Cullen, and many other celebrated men of the latter half of the 18th century.

At the time of bis death, in 1799, the collection of Tassie's works numbered about 20,000 pieces. (J. M. а.)

TASSIE, Willians (1777-1860), gem-engraver and r. deller, nephew of the above, was born in London on the 4th of December 1777. He succeeded to the business of his uncle, to whose collection of casts and medallions he added largely. His portrait of Pitt, in particular, was very popuar, and circulated widely. When the Shakespeare Gallery, formed by Alderman Boydel was disposed of by lottery in 1805, William Tassie was the winner of the prize, and in the same year he sold the pictures by auction for a sum of over $£ 6000$. He died at Kensington on the 26 th of October 1860, and bequeathed to the Board of Manufactures, Edinburgh, bn extensive and valuable collection of casts and medallions by his uncle nnd himself, along with portraits of James Tassie and his wife by David Allan, and a series of water-colour studies br George Sanders from pictures of the Dutch and Flemish $\varepsilon$ hools.
( s , M. o.)
TASSO, Torquato (1544-1595), who ranks with Dante, Petrarch, and Ariosto among the first four poets of Italy, was the son of Beruardo Tasso, a nobleman of Bergano, and his wife Porzia de Rossi. He was born at Sorrento in 1544. His father bad for many years been secretary in the service of the prince of Salerno, and his mother was closely connected with the most illustrious Neapolitan families. The prince of Salerno came into collision with the Spanish Government of Naples, was outlawed, and was deprived of his hereditary fiefs in this disaster of his patren Tasso's father shared. He was proclaimed a rebel to the state, together with his son Torquato, and his patrimony was sequestered. These things happened during the boy's childhood. In 1552 he was living with his mother and his only sister Cornelie at Naples, pursuing hiseducation under the Jesuits, who hac recently opened a school there. The precocity of intellect and the religious fervour of the boy attracted general admiration. At the age of eight he was already famous. Soon after this date he joined his father, who then resided in great indigence, an exile and witteut occupaticn, in.

Rome. News reached them in 1556 that Porzia Tasso had died suddenly and mysteriously at Naples. Her husband was firmly convinced that she had been poisoned by her brotber with the object of getting control over her property. As it subsequently happened, Porzia's estate never descended to her son ; and the daughter Cornelia married below her birth, at the instigation of her maternal relatives. Tasso's father was a poet by predilection and a professional courtier of some distinction. In those days an Italian gentleman of modest fortunes had no congenial sphere of society or occupation outside the courts of petty ecclesiastical and secular princes. When, therefore, an opening at the court of Urbino offered in 1557, Bernardo Tasso gladly accepted it. The young Torquato, a bandsome and brilliant lad, became the companion in sports and studies of Francesco Maria della Rovere, heir to the dukedom of Urbino. The fate whick condenned him for life to be a poet and a courtier like his father was sealed by this early entrance into princely palaces. At Urbino a society of cultivated men pursued the æesthetical and literary studies which were then in vogue. Bernardo Tasso read cantos of his Amadigi to the duchess and her ladies, or discussed the merits of Homer and Virgil, Trissino and Ariosto, with the duke's librarians and secretaries. Torquato grew up in an atmosphere of refined luxury and somewhat pedantic criticisn, both of which gave a permanent tone to his claracter. At Venice, whither his father went to superintend the printing of the Amadigi, these influences continued. He found himself the pet and prodigy of a distinguished literary circle. But Bernardo had suffered in his own career so seriously from addiction to the Muses and a prince that he now determined on a lucrative profession for his son. Torquato was sent to study law at Padua. Instead of applying himself to law, the young man bestowed all his attention upon philosophy and poetry. Before the end of 1562 he had prolluced a narrative poem called Rinaldo, which was meant to combine the regularity of the Virgilian with the attractions of the romantic epic In the attainment of this object, and in all the minor qualities of style and handling, Rinaldo showed such marked originality that its author was proclaimed the most promising poet of his time. The flattered father allowed it to be printed; and, after a short period of study at Bologna, he consented to his son's entering the service of Cardinal Luigi d'Este. In 1565, then, Torquato for the first time set foot in that castle at Ferrara which was destined for him to be the scene of so many glories and such cruel sufferings. After the publication of Rinaldo he had expressed his views upon the epic in some Discourses on the Art of Poetry, which committed him to a distinct theory and gained for him the additional celebrity of a philosophical critic. The age was nothing if not critical ; but it may be esteemed a misfortune for the future author of the Gerusalemme that he should have started with pronounced opinions upon art. Essentially a poet of impulse and instinct, he was hampered in production by his own rules.
The five years between 1565 and 1570 seem to have been the happiest of Tasso's life, although his father's death in 1569 caused his affectionate nature profound pain. Young, handsome, accomplished in all the exercises of a well-bred gentleman, accustomed to the society of the great and learned, illustrious by his published works in verse and prose, he became the idol of the most brilliant court in Italy. The princesses Lucrezia and Leonora d'Este, both unmarried, both his seniors by about ten years, took him under their protection. He was admitted to their familiarity, and there is some reason to think that zeither of them was indifferent to him persorally. Of the celebrated story of his love for Leonora this is not the
place to speak. It is enough at prcsent to observe that he owed much to the constant kindness of both sisters. In 1570 he travelled to Paris with the cardinal. Frankness of speech and a certain habitual want of tact cansed a disagreement with his worldly patron. He left France next year, and took service under Duke Alfonso II. of Ferrara. The most important events in Tasso's biography during the following four years are the publication of the Aminta in 1573 and the completion of the Gerusalenme Liberata in 1574. The Aminta is a pastoral drana of very simple plot, but of exquisite lyrical charm. It appeared at the critical moment when modern music, under Palestrina's impulse, was becoming the main art of Italy. The honeyed melodies and sensuous melancholy of Aminta exactly suited and interpreted the spirit of its age. We may regard it as the most decisively important of Tasso's compositions, for its influence, in opera and cantata, was felt tbrough two successive centuries. The Gerusalemme Liberata occupies a larger space in the history of European literature, and is a more considerable work. Yet the commanding qualities of this epic poem, those which revealed Tasso's individuality, and which made it inmediately pass into the rank of classics, beloved by the people no less than by persons of culture, are akin to the lyrical graces of Aminta. It was finished in Tasso's thirty-first year; and when the MS. lay before him the best part of his life was over, his best work had been already accomplished. Troubles immediately began to gather round him. Instead of having the courage to obey his own instinct, and to publish the Gerusalemme as he had conceived it, he yielded to the critical scrupulosity which formed a secondary feature of his character. The poem was sent in manuscript to several literary men of eminence, Tasso expressing his willingness to hear their strictures and to adopt their suggestions unless he could convert them to his own views. The result was that each of these candid friends, while expressing in general high admiration for the epic, took some exception to its plot, its title, its moral tone, its episodes, or its diction, in detail. One wished it to be more regularly classical ; another wanted more romance. One hinted that the Inquisition would not tolerate its supernatural machinery ; another demanded the excision of its most charming passages-the loves of Armida, Clorinda, and Erminia. Tasso had to defend himself against all these ineptitudes and pedantries, and to accominodate his practice to the theories be had rashly expressed. As is the Rinaldo, so also in the Jerusalem Delivered, he aimed at ennobling the Italian epic style by preserving strict unity of plot and heightening poetic diction. He chose Virgil for his model, took the first crusade for subject, infused the fervour of religion into his conception of the hero Godfrey. But his own natural bias was for romance. In spite of the poet's ingenuity and indnstry the stately main theme evinced less spontaneity of genius than the romantic episodes with which, as also in Rinaldo, he adorned it. Godfrey, a mixture of pious Æneas and Tridentine Catholicism, is not the real hero of the Gerusalemme. Fiery and passionate Rinaldo, Ruggiero, melancholy impulsive Tancredi, and the chivalrous Saracens with whom they clash in love and war, divide our interest and divert it from Goffredo. On Armida, beautiful witch, sent forth by the infernal senate to sow discord in the Christian camp, turns the action of the epic. She is converted to the true faith by her adoration for a crusadiag knight, and quits the scene with a phrase of the Virgin Mary on her lips. Brave Clorinda, donning armour like Marfisa, fighting in duel with her devoted lover, and receiving baptism from his hands in her pathetic death; Erminia seeking refage in the shepherd's hut,-these lovely pagan women, so touching is
their sorrows, so romantic in their adventures, so tender in their emotions, rivet our attention, while we skip the battles, religious ceremonies, conclaves, and stratagems of the campaign. The truth is that Tasso's great invention as an artist was the poetry of sentiment. Sentiment, not sentimentality, gives value to what is immortal in the Gerusalemne. It was a new thing in the 16 th century, something concordant with a growing feeling for woman and with the ascendant art of music. This sentiment, refined, noble, natural, stecped in melancholy, exquisitely graceful, pathetically touching, breathes throughout the episodes of the Gerusalemme, find metrical expression in the languishing cadcnce of its mellifluous verse, and sustains the ideal life of those seductive heroines whose names were familiar as honsehold words to all Europe in the 17 th and 18 th centuries.

Tasso's self-chosen critics were not men to admit what the public has since accepted as incontrovertible. They vaguely felt that a great and beautiful romantic poem was embedded in a dull and not very correct epic. In their uneasiness they suggested every course but the right one, which was to publish the Gerusalemme without further dispute. Tasso, already overworked by his precocious studies, by exciting court-life and exbansting literary industry, now grew almost mad with worry. His health began to fail him. He complaiued of headache, suffered from malarious fevers, and wished to leave Ferrara. The Gerusalemme was laid in manuscript upon a shelf. He opened negotiations with the court of Florence for an exchange of service. This irritated the duke of Ferrara. Alfonso hated nothing more than his courtiers leaiving him for a rival duchy. He thought, moreover, that, if Tasso were allowed to go, the Medici would get the coveted dedication of that already famous epic. Therefore he bore with the poet's humours, and so contrived that the latter should have no excuse for quitting Ferrara. Meanwhile, through the years-1575, 1576, 1577, Tasso's health grew worse. Jealousy inspired the courtiers to calumniate and insult him. His irritable and suspicions temper, vain and sensitive to slights, rendered him only too easy a prey to their malevolence. He became the subject of delusions,thought that his servants betrayed his confidence, fancied the had been denounced to the Inquisition, expected daily to be poisoned. In the autumn of 1576 he quarrelled with a Ferrarese gentleman, Maddalo, who had talked too freely. about some love affair; in the summer of 1577 he drew bis knife upon a servant in the presence of Lacrezia d'Este, duchess of Urbino. For thie excess he was arrested; but the duke relessed him, and took him for change of air to hie country seat of Belriguardo. What happened there is not known. Some biographers have surmised that a compromising liaizon with Leonors d'Este came to light, and that Tasso agreed to feign madness in order to cover her bonour. But of this there is no proof. It is only certain that from Belriguardo he returned to a Franciscan convent at Ferrara, for the express parpose of attending to his health. There the dread of being murdered by the duke took firm hold on his mind. He escaped at the end of July, disguised himself as a peasant, and went on foot to his sister at Sorrerto.

The truth seems to be that Tasso, after the beginning of 1575, became the victim of a mental malady, which, without amounting to actusi insanity, rendered him fantastical and insupportable, a misery to himself and a cause of anxiety to his patrons. There is no evidence whatsoever that this state of thinge was due to an overwhelming passion for Leonora. The dake, instead of acting like a
 epd =ni s.rmpathetic man, as egotistical as a princeling of that ags ras wint to be. But to Tasse he whe never
cruel,--hard and unintelligent perbaps, but far irata being that monster of ferocity which has been painted. The subsequent history of his connexion with the poet, over which we may pass rapidly, will corroborate this vicw. While at Sorrento, Tasso hankered after Ferrara. The court-made man could not breathe freely outside its charmed circle. He wrote humbly requesting to bo taken. back. Alfonso consented, provided Tasso would agree the undergo a medical course of treatment for his melancholy. When he returned, which he did with alacrity under those conditions, he was well received by the ducal family. AlI might have gone well if his old maladies had not rerived. Scene followed scene of irritability, moodiness, suspicion, wounded vanity, and violent outbursts. In the summer of 1578 he ran away again; travelled through Mantua, Padua, Venice, Urbino, Lombardy. In September he reached the gates of Turin on foot, and was courteously entertained by the duke of Savoy. Wherever he went, "wandering like the world's rejected guest," he met with the honour due to his illustrious name. Great folk opened their houses to him gladly, partly in compassion, partly in admiration of his genius. But he soon wearied of their society, and wore their kindness out by his querulous peevishness. It seemed, moreover, that life was intolerable to him outside Ferrara. Accordingly he once more opened negotiations with the duke ; and in February 1579 he again set foot in the castle. Alfonso was about to contract his third marriage, this time with a princess of the house of Mantus. He had na children; and, unless he got an heir, there was a probability that his state would fall, as it did subsequently, to the Holy Sie. The nuptial festivals, on the eve of which Tasso arrived, were not therefore the occesion of great rejoicing to the elderly bridegroom. As à forlorn hope he had to wed a third wife ; but his heart was not engaged and his expectations were far from-sanguine. Tasso, preoccapied as always with his own sorrows and his own sense of dignity, made no allowance. for the traubles of his master. Rooms below his rank, he thought, had been assigned him. The princesses did not want to see him. The duke was engaged. Without exercising common patience; or giving his old friends the benefit of a doubt, he broke into terms of open abuse, behaved like a lunatic, and was sent off without ceremony to the madhouse of St Anna. This happened in March 1579; and there he remained until July 1586. Duke Alfonso's long-sufferance at last had given way. He firmly believed that Tasso was insane, and he felt that if he were so St Anna was the safest place for bim. Tasso had put himself in the wrong by his intemperate conduct, but far more by that incomprehensible yearning, after the Ferrarese court which made him return to it again and yet again. It would be pleasant to assume that an unconquerable love for Leonora led him beck. Unfortunately, there is no proof of this. His relations to her sister Lucrezia were not less intimate and affectionate than to Leonora. The lyrice he addressed to numerous ladies are not less respectful and less passionate than those which bear her name. Had he compromised her honour, the duke would certainly hare had him murdered. Custom demanded this retalistion, and aociety approved of it. If therefore Tasso really cherished a secret lifelong devotion to Leonora, it remaine buried in impenetrable mystery. He did certainly not bebave like a loyal lover, for both when be returned to Ferrara in 1578 and in 1579 he showed no capacity for curbing his peerish humours in the hope of access to her eociety.

It was no douibt very irksoms for a man of Tasso's pheasure-loring, restless, and self-conscious spirit to be kept for more than seven years in confinement. Yet we must weigh the facts of the case rather than the fancies which
hape been indulged regarding them. - After the first few months of his incarceration he obtained spacious apartments, received the visits of friends, went abroad attended by responsible persons of his acquaintance, and corresponded freely with whomsoever he chose to address. |The letters written from St Anna to the princes and cities of Italy, to warm well-wishers, and to men of the highest reputation in the world of art and 'learning, form our most valuable source of information, not only on his then condition, but also on his temperament at large. It is singular that he spoke always respectfully, even affectionately, of the duke. Some critics have attempted to make it appear that he was hypocritically kissing the hand which had chastised him, with the view of being released from prison. But no one who has impartially considered the whole tone and tenor of his epistles will adopt this opinion. What emerges clearly from them is that he laboured under a serious mental disease, and that he was conscious of it. He complains that his disorder at times amounted to frenzy, after which his memory was weakened and his intellectual faculties enfeebled. He saw visions and heard phantom voices. Puck-like spirits made away with his books and papers. The old dread of poison, the old terror of the Inquisition, returued with greater violence. His bodily condition grew gradually worse; and, though he does not seem to have suffered from acute attacks of illness, the intellectual and physical constitution of the man wa's ont of gear. Mcanwhile he coccupied his uneasy leisure with copious compositions. The mass of his prose dialogues on philosophical and ethical themes, which is very considerable, we owe to the years of imprisonment in St Anna. Except for occasional odes or bonnets-some written at request and only rhetorically interesting, a few inspired by his keen sense of suffering and therefore poignant-he neglected poetry. Rut everything which fell from his pen during this period was carefully preserved by the Italians, who, while they regarded him as a lunatic, somewhat illogically scrambled for the very offscourings of his wit. Nor can it be said that society was wrong. Tasso had proved himself an impracticable human being; but he remained a man of genius, the most interesting personality in Italy. Long ago his papers had been sequestered. Now, in the year 1580, he heard that part of the Gerusalemmee was being published without his permission and without his corrections. Next year the whole poem was given to the world, and in the following six montlis seven editions issued from the press. The prisoner of St Anna had no control over his editors; and from the masterpiece which placed him on the level of Petrarch and Ariosto he never derived one penny of pecuniary profit. A rival poet at the court of Ferrara undertook to revise and re-edit his lyrics in 1582. This was Battista Guarini; and Tasso, in his cell, had to allow odes and sonnets, poems of personal feeling, occasional pieces of compliment, to be collected and emended, without lifting a voice in the matter. A few years later, in 1585, two Florentine pedants of the Declia Crusca academy declared war against the Gerusalemme. They loaded it with insults, which seem to thoso who read their pamphlets now mere parodies of criticism. Yct Tasso felt bound to reply; and he did so with a modoration and urbanity which prove him to have been not only in full possession of his reasoning faculties, but a gentlefnan of noble manners also. Certainly the Listory of Tasso's incarceration at St Anna is one to make us pause and wonder. The man, like Hamlet, was distraught through ill-acconmodation to his circumstances and his age ; brain-sick he was undonbtedly; and this is the duke of Furrara's justification for the treatment he endured. In the prison he bore hiaself pathotically, jcevishly, but never ignobly. We ehowed a singular
indifference to the fate of his great poem, a rare magnanimity in dealing with its detiactors. His own personal distress, that terrible malaise of imperfect insanity, absorbed him. What remained over, untouched by the malady, unoppressed by his consciousness thereof, displayed a swcet and gravely-toned humanity. The oddest thing about his life in prison is that he was always trying to place his two nephews, the sons of his sister Coroclia, in court-service. One of them he attached to the duke of Mantua, the other to the duke of Parma. After all his father's and bis own lessons of life, he had not learned that the court was to be shunned like. Circe by an honest man. In estimating Duke Alfonso's share of blame, this wifful idealization of the court by Tasso must be taken into account. That man is not a tyrant's victim who moves heaven and earth to place his sister's sons, with tyrants.

In 1586 Tasso left St Anna at the solucitation of Vincenzo Gonzaga, prince of Mantua. He followed his young deliverer to the city by the Mincio, basked awhile in liberty and courtly pleasures, enjoyed a splendid reception from his paternal town of Bergamo, and produced a meritorious tragcdy called Torrismondo. But only a few months had passed when he grew discoutented. Vincenzo Gonzaga, succeeding to his father's dukedom of Mantua, had scanty leisure to bestow upon the poet. Tasso felt neglected. In the autumn of 1587 we find hinn journeying through Bologna and Loreto to Rome, and taking up his quarters there with an old friend, Scipione Gonzaga, now patriarch of Jerusaiem. Next year he wandered off to Naples, where he wrote a dull poein on Monte Oliveto. In 1589 he returned to Rome, and took up his quarters again with the patriarch of Jerusalem. The servants found him insufferable, and turned him out of doors. He fell ill, and went to a hospital. The patriarch in 1590 again received hinı. But Tasso's restless spirit drove him forth to Florence. The Florentines said, "Actum est de" eo." Rome once more, then Mantua, then Florence, then Rome, then Naples, then Rome, then Naples-such is the weary record of the jears 1590-94. We have to study' a yeritable Odyssey of malady, indigence, and misfortune: To Tasso everything came amiss. He had the palaces of princes, cardinals, patriarchs, nay popes, always open to him. Yet be could rest in none. To rest would bave been so easy, had he possessed the temperament of Bernior of Horace. But he was out of joint with the world. No sensuous comforts, no tranquillity of living, soothed his vexed soul. Gradually, in spite of all ventration for the sacer vates, he made himself the laughing-stock and bore of Italy.
His health grew ever feebler and his genius dimmer. In 1592 be gave to the public a revised version of the Gerusalemme. It was called the Gerusalemme Conquistata. All that made the poem of his early manhood charming he rigidly erased. The versification was degraded the heavier eloments of the plot underwent a dull rhetorical development. During the same year a prosaic cumposition in Italian blank verse, called Le Sette Giornate, sary the light. Nobody reads it now. We only mention it as one of Tasso's dotages-a dreary amplification of the first chapter of Genesis.
It is singular that just in these years, when mental disorder, physical weakness, and decay of 'inspiration seemed dooming Tasso to oblivion, his old age was cheered with brighter rays of hope. Clement VIII: jascended the papal chair in 1592. He and his nephew, Cardinal Aldobrandini of St Giorgio, determined to befriend our poet. In 1594 they invited him to Rome. There he was to assume the crown of hays, as Petrarch bad assumed jit; on the Capitol. Lean and worn out with siekness, ready to
totter into the tomb, where rest might possioly oe found, Tasso reached Rome in November. The ceremony of his coronation was deferred because Cardinal Aldobrandini bad fallon ill. But tha pope assigned him a pension; and, under the pressure of pontifical remonstrance, Prince Avellino, who held Tasso's maternal estate, agreed to discharge a portion of his claims by payment of a yearly rent-charge. At no time since Tasso left St Anna had the heavens apparently so smiled upon him. Capitolian honours and money were now at-his disposal." Yet this good fortune came too late. . It seemed as though fate had decided that this man, in all his weakness of character and pathetic grace of genius, should win the stern fame of martyrdom. Both laurel wreath and wealth must be withdrawn from him. Before the crown was worn or the pensions paid he ascended to the convent of .St Onofrio, on a stormy lst day of April in 1595. Seeing a cardinal's coach toil up the steep Trasteverine Hill, those good monks came to the door to greet it. From the carriage stepped Tasso, the Odysseus of many wanderings and miseries, the singer of sweetest strains still rocal, and told the prior he was come to die with him.

In St Onofrio he died, on the 25th of April of that year 1595. He was just past fifty-one; and the last twenty years of his existence had been practically and artistically ineffectual. At the age of thirty-one the Gerusalemme, as we have it, was accomplished. The world too was already ringing with the music of $A$ minta. More than this Tasso had not to give to literature. But those succeeding years of derangament, exile, imprisonment, poverty, and hope deferred endear the man to ns. Elegiac and querulous as he must always appear, we yet love Tasso better because be suffered through nearly a quarter of a century of slow decline and unexplained misfortunc.
Taken altogether, the best complete edition of Tasso's writings is that of Rosini (Piss), in 33 vols. The prose works (in 2 vols., Florence, Le Monnier, 1875) and the lettors (in 5 vols., same pub. lishers, 1853) have been admirably cdited by Cesare Guasti. This edition of Tasso's Letters forms by far the most valuable source for bis biography. No student can, however, omit to use the romantic memoir attributcd to Tasso's friend Marchese Mlanso (printed in Rosini's edition of 'Tasso's works above cited), and the important Vita di Torguato Tasso by Serassi (Bergamo, 1790). To give anything like a complete account of more recent critical and biographical Tasso literature is impossible within the limits of this article.
(J. A. S.)

TASSONI, Alessandro, Italian poet, was a native of Modena, where he was born in 1565 , and where he died in 1635. From 1599 till 1608 he was secretary to Cardinal Ascanio Colonna, and in this capacity saw some diplomatic service ; he was afterwards employed for some time in similar occupations by Charles Emmanuel, duke of Savoy. His best-known literary work is a burlesque epic entitled La Secchia Rapita, or "The Rape of the Bucket" (1622), the reference being to a raid of the Modenese upon the people of Bologna in 1325, when a bucket was carried off as a trophy. As in Butler's Hudibras, many of the personal and local allusions in this poem are now very obscure, and are apt to scem somewhat pointless to the general reader, but, in spite of Voltaire's contempt, it cannot be neglected by any systematic student of Italian literaturé (compare vol. xii. p. 512). Other characteristic works of Tassoni are his Pensieri Diversi (1612), in which he treats philosophical, literary, historical, and scientific questions with unusual freedon, and his Considerazioni sopra il Petrarcha (1609), a piece of criticism showing great independence of traditional views.

TASTE is the sensation referred to tne mouth wheo certain soluble substances are brought into contact with the mocous membrane of that cavity. The sense is located almost entirely in the tongue. Three distinct sensations are referable to the tongue - (1) taste, (2) touch, and (3)
temperature. The yosterior part of its surface, whero there is a $\Lambda$-shaped group of large papillæ, called circnmvallate papillæ, supplied by the glosso-pharyngeal nerre, and the tip and margins of the tongue, covered with fliform (touch) papillæ and fungiform papille, are the chief localities where taste is manifested, but it also exists in the glosso-palatine arch and the lateral part of the soft palate. The middle of the tongue and the surface of the hard palate are devoid of taste. The terminal organs of taste consist of peculiar bodies named taste-bulbs or tastegoblets, discovered by Schwalbe and Lovèn in 1867. They can be most easily demonstrated in the papilla foliatx, large oval prominences found on each side near the base of the tongue in the rabbit. Each papilla consists of a series of laminæ or folds, in the sides of which the tastebodies are readily displayed in a transverse section. Tastebodies are also found on the lateral aspects of the circumvallate panillæ (see fig. 1), in the fungiform papillæ, in the

F10. 1.-Transversa section of a circumpallate papilla: W, the papilla: $\boldsymbol{v}$, $\boldsymbol{v}$, the wall in aection; $R, R$, the circolar alit or fossa; $R, R$, the taste-balbs in posi. 2lon; $N, N$, the nerves. The figures are from Landols and Stirling ${ }^{\prime \prime}$ Fhysiology.
papillæ of the soft palate and uvula, the under surface of the epiglottis, the upper part of the posterior surface ol the epiglottis, the inner aides of the arytenoid cartilages, and even in the vocal cords.

The taste-bulbs are minute oval bodies, somewhat like an old-fashioned Florence flask, about $\frac{1}{300}$ inch in length by $\frac{1}{800}$ in breadth. Each consists of two sets of cells,-an outer set, nucleated, fusiform, bent like the staves of a barrel, and arranged side by side so as to leave a small opening at

 barrel), called the gustatory cell.
pore; and an inner set, five to ten in number, lying ia the centre, pointed at the end neat the gustatory pore, and branched at the other extremity. The branched ends are continuous with non-medullated nerve fibres from the gustatory nerve. These taste-bodies are found in immense numbers: as many as 1760 have been counted on one circumvallate papilla in the ox. They are absent in reptiles and birds. F. E. Schultze states that they exist in the mouth of the tadpole, whilst the tongue of the frog is covered with epithelium resembling that of the gustatory bodics. Leydig has described organs having a similar structure in the skins of freshwater fishes and the tadpole: these may possibly be widely distributed taste-organs." The proofs that these aro the terminal organs of taste rest on careful ohservations which have shown (1) that taste is only experienced when the sapid substanco is allowed to come into contact with the taste-body, and that the sease

## T A T-. T A '

is absent or much weakened in those areas of mucous membrane where these are deficient; (2) that they are most abundant where the sense is most acute ; and (3) that section of the glosso-plaryngeal nerve which is known to be distributed to the areas of mucous membrane where taste is present is followed by degeneration of the tastebodies. At the same time it cannot be asserted that they are absolutely essential to taste, as we can hardly suppose that those animals which have no special taste-bodies are deyoid of the sense.

Taste is no doubt closely allied to smell; hence in invertebrates organs are found that may be referred to either of the senses (see Smell). Tastes have rien variously classified. One of the most useful classifications is into sweet, bitter, acid, and saline tastes. To excite the sensation, substances must be soluble in the fluid of the mouth. Insoluble substances, when brought into contact with the tongue, give rise to feelings of touch or of temperature, but excite no taste. The specific mode of action of sapid substances is quite unknown. The extent of surface acted on increases the massiveness of the sensation, whilst the intensity is affected by the degree of concentration of the solution of the sapid substance. If solutions of various substances are gradually diluted with water until no taste is experienced, Valentine found that the sensations of taste disappeared in the following ordersyrup, sugar, common salt, aloes, quinine, sulphuric acid; and Camerer found that the taste of quinine still continued although diluted with twenty times more water than common salt. Von Vintschgau found that the time required to excite taste after the sapid substance was placed on the tongue varied. Thus saline matters are tasted most rapidly ( 17 second), then sweet, acid, and bitter ( 258 second). This is probably due to the activity of diffusion of the substance. No relation between the chemical constitution of the substance and the nature of the taste excited by it has yet been discovered, and there are many curious examples of substances of very different chemical constitutions having similar tastes. For example, sugar, acetate of lead, and the vapour of chloroform have all a sweetish taste. A temperature of from $50^{\circ}$ to $90^{\circ}$ F. is the most favourable to the sense, water above or below this temperature either masking or temporarily paralysing it. Taste is often associated with emell, giving rise to a sensation of flavour, and we are frequently in the habit of confounding the one sensation with the other. Chloroform excites taste alone. whilst garlic, asafutida, and vanilla excite only smell fhis is illustrated by the familiar experiment of blindfolding a person and touching the tongue successively with slices of an apple and of an onion. In these circumstances the one cannot be distinguished from the other when the nose is firmly closed. No doubt also experience aids in detecting slight differences of taste by suggesting to the mind what may be expected ; it is not easy, for instance, to distinguish the tastes of red and white wine when the eyes are blindfolded. Taste may bo educated to a remarkable extent; and careful observation-along with the practice of avoiding all substances having a very pronounced taste or having an irritating effect-enables tea-tasters and winetasters to detect slight differences of taste, more especially when combined with odour so as to produce flavour, which svould be quite inappreciable to an ordinary palate. . As to the action of electrical currents on taste, observers have arrived at uncertain results. So long ago as 1752 Sulzer stated that a consfant current caused, more especially at the moments of opening and of closing the current, a sensation of acidity at the anode ( + pole) and of alkalinity at the katode (- pole). This is in all probability due to electrolysis, the decomposition products exciting the taste-
bodies. Grünhagen found that rapidly interrupted current fail to excite the sense ; Von Vintschgau, who has directed much attention to the sense of taste, says that when the tip of his tongue is traversed by a current theze is only a tactile sensation. Again Hönigschmied, on the contrary, found that a current excited the metallic or acid taste at the anode placed on the tip of the tongue, whilst the alkaline taste of the katode was absent. The writer of this article has found that this is the experience of most persons examined by him.

Disease of the tongue causing unnatural dryness may interfere with taste. Substances circulating in the blood may give rise to subjective sensations of taste Thus santonine, morphia, and biliary products (as in jaundice) usually cause a bitter sensation, whilst the sufferer from diabetes is distressed by a persistent sweetish taste. The insane frequently have subjective tastes, which are real to the patient, and frequently cause much distress. In such cases, the sensation is excited by changes in the taste-centres of the brain. Increase in the sense of taste is called hypergensia, diminution of it hypogensia, and its entire loss ageusia. hare cases occur whero there is a subjective taste not associated with insanity nor with the circulation of any known sweetish matters in the blood, possibly caused by irritation of the gustatory nerves or by changes in the nerve centres.

As to the comparative anatomy of tho tougue, sco Owen's Com. parative Anatomy and Physiology of Vertebrates (London, 1863). For a full a acount of the pliy siology of tasto, oce Yon Vintschgau: articlo "Gcschmackssinn," in Hermann's Handbuch der Physiologic, vol. iii. part ii.

TATE, Naifos (1653-1715), poot-laureate, was born in 1652 in Dublin, and was educated at Trinity College there. He aftcrwards removed to London, and adopted literature as a profession, sncceeding Shadwell as poetlaureate in 1692. Ho died within the precincts of the Mint, Southwark (whither he had taken refngo froni his debtors), August 12, 1715.
His namo is atill remenbered in connoxion with the $\mathrm{S}^{\circ}$ eto Version of the Psalms of Datid, which, in conjunction with Nicholas Brade (g.v.), he publishach in 1696 (see Hysiss, vol. xii p. 590). Tate was also the author of some ten dramatic pieces (sce Diogr. Dranatica, i. 703) and a great number of pooms, including ons ontitled The Innocent Epicurc, or The Art of Angling (1697).

TATIAN, one of the earliest Christian apologists, whose personality and work had an important influence on the history of the church duriug the period of the Antonines. He was by birth an Assyrian (according to Zahn of Sem. itic descent), but received a Greek education, and, after acquiring a very extensive knowledge of Greek literature, began to travel about the Roman empire as a wandering teacher or "sophist." But his inquiring disposition and his earnest spirit remained unsatisfied alike with the religions and the philosophies he encountered, while the doings of men, their greed for amusement and pleasure, their vanity and treachery, disgusted him. In this temper, about 150 A.D., he reached Rome, where the Old Testament fell into his hands, and at the same time he came into closer :elations with the Christians; their firm faith, chaste morals, fearless courage, and close fellowship deeply impressed him, and in the end the spectacle of their life and their monotheistic doctrine founded upon prophetic revelation completely conquered him. Henceforward the whole unchristian world, with all its philosophy and culture, presented itself to him as mere darkness and the deception of demons, but the "barbarian philosophy" (for so he calied Christianity) as the wisdom of God. He became a convert, and soon afterwards (153-153) wrote (most probably in Greece, where he stayed for some time) his Oratio ad Gracos, which gained lim great repute
alnong the Christians, and is still extant. This discourse is distinguished from the other apologies of that century hy the brusqueness with which its author repudiates the culture of the Greeks; his scorn, however, does not forget to a vail itself of the resources of Greek philosophy and rletoric. His polemic often reminds the reader of the Cynics and of such scoffers as Lucian ; his view of things, howerer, is very different from that of the last-named writer, for with Tatian the "barbarian philosophy," oo behalf of which he speaks, which teaches a moootheistic cosmology and inculcates rigid asceticism and renunciation of the world, is indisputably certain. In many details, and even in the general outline of his philosophy, Tatian the Christian continued without knowing it to be a Platonizing philosopher; but that he had undergone a radical change is shown by lis views of history and civilization, his faith in one living God, his conviction that truth is contained nowhere else than in the Christian Scriptures, his attitude of trust towards the Logos, made man in Jesus Cbrist, aud finally by his earnest and world-forsaking expectation of judgnent to come. The Oratio, which is polemical rather than apologetic in its character, has a special importance in the 0 history of Christian dogma, inasmuch as it gives an elaborated exposition of the doctrine of the Logos; it was also read by subsequent writers, as, for exanple, by Julius Africanus, for its chronological data. Tatian was the first apologist to undertake, on behalf of Christianity, a work of the class which afterwards developed into the numerous "world-histories" written from the Christian point of view. Tatian's diction is often rough, harsh, and abrupt, his sentences involved and inelegant. He has the art, indeed, of expressing himself with uncommon freedom and independence, and can put things also in a very graphic way, but at the same time he is a careless stylist, or rather, as an apostate from the Greek view of things, he has tried to accentuate his breach with classical traditions by elaborate carelessness and deliberate eccentricity.

Tatian soon returned from Greece to Rome, and came into close relations with the famous apologist Justin, whom he reverenced greatly. He himself established a school, to which the afterwards celebrated ecclesiastical writer Rhodon belonged for a time. So loug as Justin lived (i.e., till 166) Tatian's doctrines excited no feelings of offence in the Christian community, although even in his Oratio there are germs of questionable and unorthodos views. These germs, however, he continued to develop until about 172 ; and, as about this very time the Roman church became severely opposed to everything Gnostic and heretical, a rupture was inevitable; the date of the breach is given by Eusebius (doubtless 'following Julius Africanus) as having been 172. But the teaching of Tatian had really become open to challeage. He drew a distinction between the supreme God and the demiurge, coosiderais the latter to be good in his natuie iodeed, bul quite a subordinate being; he accepted the doctrine of a pariety of æons; be utterly rejected marriage and the use of animal food; he denied the blessedness of Adam; he began to abandon the allegorical interpretation of the Scriptures and to see genuine difficulties and contradictions in them; he sought to demonstrate from the epistles of Paul the indispensableness of the most rigid asceticism; but indeed all his "heresies" (and he has also been charged with docetism) have their explanation in this desire of his to establish a theoretical basis for his doctrine of the Christian duty of complete world-renunciation. He joined the "Encratites," a sect which indeed had existed before this time, but which received new life from his presence. Of his numerous writings belonging to this period nothing hias survived the hostility which sought their repression
 $\sigma \omega \tau i \bar{\rho} a$ катартוб,woù, \&c.) and one or two very interesting fragments in the works of Clement of Alexandria, Origen, and Jerome. Clement of Alexandria seems personally tc have known Tatian, and even to have been his pupil for a time. Soon Tatian began also to be assailed in writing by the teachers of the church, and to be set aside as a very prodigy among heretics, and as a man who united the errors of Marcion with those of Valentine. Musanus, Rhodon, Irenæus, the author of the Muratorian fragment (see below), Tertullian, Hippolytus, Clement of Alexandria and Origen all took part in refuting him.
Towards the end of his life, or perlaps even between 152 and 172, Tatian went from Rome to Nesopotamia, aud there-probably in. Edessa-wrought a great deal. It is probable that he was in Rome about the year 172, but whether he died there or in his native country is not ascertained. It is very possible that in Syria, where ecclesiastical matters had not been developed so far as in the West, the doctrines of Tatian met with toleration within the Christian communities, but neither of this can we be certain. ${ }^{1}$ But this we do know, that a a work of Tatian's not yet mentioned, the Diatessaron, held its ground in the Syrian churches and even in ecclesiastical use for two whole centuries.
The Diatessaron is a gospel very freety and boldly constructed by Tatian out of tha four Gospels known to us. It cannot have heen produced during his latter years, for all traces of dualism are absent. On the other hand, however, it exhibits certain peculiarities of the theology of its compiler. Probably one would not be far wrong in assigning it to the first years of the reign of Marcus Aurelius. It was written by Tatian in Greek, not in Syriac as Zahn has tried to make out; this is shown-(1) by the title, it being known even among the Syrians as Diatessaron; (2) by a few Greek frayments which still survive; (3) by the Latin redaation which it received in tha 6 th century; (4) by its rejcction in the Muratorian fragment-for that the word " m -tia- -i ," carelessly corrected hy the transcriber, stood originally "tatiani" may be regarded as certain. ${ }^{2}$ In estimating the work scholars were formerly entirely dependent on certain meagre notices in Euse bius, Theodoret, Ephraem Syrus, Epiphanius, and tha later Syrians, ${ }^{3}$ but we bave recently becoma possessed of large portions of it, and are now in a position to form for ourselves an idea of its character and plan. In 1877 there waa published ${ }^{4}$ a Latin translation, by Aucher the Mechitarist, of Ephraem's gospel commentary, which had been preserved in Armenian, and it then became apparent that Ephraem bad taken the Diatessaron as his basis.. This led to further research.' Recognizing with other scholars that other Syrian writers also, down to the middle of the 4th century, had used the Diatessaron (Theodoret tells us that in bis diucese alone ba caused more than 300 copies to be withdrawn from n99), Zahn uudertook the labo. rious task of restoring the work with the help of Ephraem's commentary and other aources.a In details much of what Zahn has given as belonging to the text of the Diatessaron remains problem. atical, --in particular he has not been sufficiently careful in his exarnination of the work of Aphraates, - but in all the main points his restoration has been successful. The rediscovery of such a work is in a variety of ways of the very highest importance for the early history of Christianity. (1) It is of interest for the history of the canon. It showa that in Tatian's time there was still no recognized New Testament canon, and that tha texts of the Gospels were not regarded as inspired. He could not possibly have treated them with such freedom bad they been held to be otherwise. But the ecclesiastical use made of his work in Syria shows that Tatian intended it for the church, and, as we are informed further by Eusebins that Tatian also edited the Pauline epistles, we are entitled to couclude that, like Marcion, be .wished to frame a special New Testament canon. (2) It is of importance for the Gospels as we now have them. We learn fron the Diatessaron that about 160 A.D. our four Gospels lad already taken a place of prominence ir the clurch and that no others bad done so; that in Irarticular the Fourth .Gospel had taken a fised place alongside of the three

[^22]synoprics. (3) As regards the text of the Gospets, we can conclude from the Dinlessaron that the texts of our Gusjels about the year 160 already ran essentially as we now read then, but that intentional changes were not watiting about the middle of the 2 d century. I'hus, for cxample, T'atian in his Gospel according to liatthew found nothing ahont the "church" and about the building of the church upon l'etcr the rock. These sentences therefore are very probably of lister interpolation. (4) It is of importance for the light it throws on 'Tatian's Christianity. The Syriac translation of the Diatessaron still falls withiu the 2 d centmy, but Zahn was mistaken in assuming it to presuppose a prior Syriac translation of the separate Gospels the so-called Syrus Curetoriams); Bacthgen' has shown the latter to be the later. It was only gradually that the "evangelium der Getrennten" superseded thie "evangelium der Gemischten."

The best cultions of the Oratio ad Griecos are those of Worth (Oxford, 1:00), M1. Hanus (Paris, 1742, and Oito (Jena, 1851 ). See Danitel, Tatian der APologet, 15si; Zahn, Tatian's Diatessaron. (A. HA.)

TATIUS, Achilles. See Romance, vol. xx. p. 635 sq.
TAULER, Johann (c. 1300-1361), was born about the year 1300 in Strasburg, where his father was a wealthy burgher. It is probable that he entered the Dominican convent in his native city about the year 1313, while Meister Eckhart was still professor of theology 11312 1320) in the monastery school. From Strasourg he went to the Dominican college of Cologne, and some believe that his superiors sent him a few years later to St James's College, Paris. After his theological education was finished he returned to Strasburg. In 1324 the pope placed under an interdict these parts of Germany, including Strasburg, which supported the excommunicated emperor Louis of Bavaria. It was one of the privileges of the Dominican and Franciscan orders to be allowed to perform religious services when the secular and all other regular clergy were silenced by an interdict. The Dominican order, however, had taken the side of Frederick, and in most places refused to say mass ; but in Strasburg they remained in the deserted city, kept their churches open, and administered to the citizens the consolations of religion. It is supposed that this conduct of the Strasburg Dominicans was due to the influence of Tauler. In 1339 the heads of the order interfered, and commanded the monks to close their churches. The town council in return banished the Dominicans from the city. Tauler, with some of "his brethren, found refuge in Basel, although that city, like Sirasburg, sided with the emperor. During these years Basel was the headquarters of the "Friends of God" (Gottesfreunde, see Mysticism, vol. xvii. p. 133), and Tauler was brought into intimate relations with the members of that pious mystical fellowship. He returned to Strasburg probably in the year 1346. It is somewhat difficult to trace his later life. The Black Death came to Strasburg in 1348 , and it is more than probable that, when the city was deserted by all who could leave it, Tauler remained at his post, encouraging by sermons and personal risitations his terror-stricken fellow-citizens. His correspondence with distinguished members of the Goltesfreunde, especially with Margaretha Ebner, and the fame of his preaching and other work in Strasburg, had made him known throughout a wide circle of pious people. He seems to hare made preaching journeys, in the later years of his life, to Cologne and to other places iu the Khineland. He died in the year 1361.

[^23]It is somewhat difficult to form an estimate of the religions life and opinions of Tauler. For many yuas the chief inodern authority upon the subject was the late Prof. ('. Sclamilt of Strasburg, whose views had been introfncad into Enerland in Miss Winkworth's book upon 'Tauler. According to Schanidt, 'Tunler's religious lite divides into two parts, before and alter what may be called his sccoml conversion. In the fist period Ecklart rules his religions life; in the second he is under the infuence of the mysterions "Friend of God in the Oberland," Whem Schmidt asserts to be Kicholas of Basel. Denifle doubts the historical character of this elisode and the genuineness of the book, while Preger admits the fact of the convcrisiou, but refuscs to ilentify the mysterious stranger with Nicholas of Basel.
It is still more difficult to determine the grecise nature of the theological ppinions of Tauler. Denitle maintains that the only genuine remains of Tauler are the eighty Well-known Scrmons included in the carliest edition and four others in two manuscripts, all of which bear Tauler's mame; Preger seems inclined to admit in addition the S'mons in the account of "lauler's conversion; both critics exclude the famous Buok of Spuribual Porcrity. Scinuidt, on the other hand, while almitting the anthenticity of oll the above-named sermous, calls the Book of Spiritual Poveriy Tauler's masterpiece.

If we take the Semons by themselves, then Tauler's teachers in theology were the Psendo-Dionysius, Angustine, Gregory, Bennand, the two abbots of St Victor, Thomas Aquinas, and, above all, Theodoric of Freiburg and Meister Eckhart. His theology will represent the purest and lighest tylueof German mysticism (see Mrstucrsu), and, by insisting upon persunal relationship to God, freedom from thic thiallom of authority, and the worthlessucss of nere good works without the renewal of the inward life, will represent a tendency in theology which founcl full expression in the reformation of the 16 the century. If, ou the other hand, the Book: of Spiritual Povcrly be included among the genuine writings of Tauler, then undoubtedly his views have nore distinct connesiou with that doctrine of the appropriation of the benefits of Christ's work of redemptiou by an inilatio Christi finding expression in a life of evangelical poverty which is such a characteristic of the religious lite of the century to which he belonged. The problen is a very difficult one, and it may be questioned whether we aro yet in a position to solve it. Denifle is mudoubtedly correct in his statement that we need critical texts of 14 th-century mystical writers, and that very great uncertainty exists with reference to the authons of the individual mystical writings of that feriod. It may be added that it is vcry probable, when the organization and method of work among the "Friends of God" are taken into consideration, that many mystical books of devotion were the work, not of ane, but of severdi authors, and that the condstions of the problem concerning tho authenticity of Tauler's writings are not unlike those which exist among the books and tracts ascribed to Wicklilfe. This at all events may be safely asscrted, that Tauler's sermons are anong the noblest in the German language. They are not so emotional as Suse's, nor so speculative as Eckhart's, but they are intensely practical, and touch on all sides the deeper 1 broblems of the moral aud spiritual life.
Tauler's Sermons were printed first at Lelpsic in 1498, and reprinted with additions frum Ecklart an! uthers at Basel ( $1521,1.52$ ) and at Cologno ( 1513 ). There is a recent editlon by Jullis Hamberger, Frankfort. 1864. See Denifle, Das Buch von geisticher Armuth, 1877; Carl Schmat. TAUNTON, a municipal borou-u and market-town of Somerset, England, is situated in the beautiful and fertule vale of Taunton Dene, on the river Tone, on the Taunton and Bridgwater Canal, and on several branches of the Great Western liailway, 45 miles south-sonth-west of Bristol, 31 north-east of Exeter, and 163 west-south-west of London. The river is crossed by a stone bridge of three arches. The town is well built, the three main streets being wide and regular, and mceting in a triangular space in the centre called the Parade, where there is a market cross. The castle, now occupied by the museun of the Somerset Archeological and Natural History Sociciy, is reputed to have been founded by Ine, king of the TVest Saxons. The earliest portion of the present building w'as erected by Walter Giffard, bishop of Winchester, in the tine of Henry I., but the whole building was repaired in 1496, and an embattled gateway erected by Bishop Langton The church of St Mary Magdalene, a spacious building with double aisles both north and south of the nave is chiefly Perpendicular. but has remains of Normau work in
the chancel arch, and of Eary English in the north aisles and transepts. It possesses one of the finest of the sharacteristic towers of Somerset, but only a facsimile reproduction (erected 1857-63) of the old one. There are still some remains of the Augustinian priory founded by Bishop Giffard, and there are also two mudern convents. Taunton is an irpportant centre of education, the principal institutions being the grammar school (founded in 1522 by Richard Fox, bishop of Winchester), Huish's schools, the Independent college (1841), and the Wesleyan collegiate iostitution (1847). The other principal public buildings are the old market-house, the assenbly rooms, the new market in the Ionic style, and the shire lall in the Elizabethan style, opened in 1858 at a cost of $£ 28,000$. The charitable iostitutions include the Taunton and Somerset hospital (opened in 1809 and extended in 1850 and 1873), the eye infirmary (1816), Gray's almshouses and chapel (1635), St Saviour's home for boys (1870), and the servants' training home (1882). The town possesses manufactories of silk, collars and cuffs, and gloves, iron and brass foundries, coach-building works, and breweries. . There is also a considerable agricultural trade. The population of the municipal and parliamentary borough (area 1249 acres) in 1881 was 16,614 . The population of the same area in 1871 was 15,466 .
Taunton las played a prominent part dûring the troubled periods of English history. Various Roman remains prove it to have been occupied by the Romans; but it first obtained historical notice when Ine, king of the West-Saxons, made it the border fortress of lis kingdom. It takes the name Taunton, or Thoneton, from its situation on the Tone or Thonc. The castle was razed by Ethelburg after oxpelliog Edbricht, king of the South-Saxons. About the time of William the Conqueror the town and castle were granted to the bishop of Winchester, and for many years the castle was the bishop's principal residcace. In the reign of William it possessed a mint. in 1497 the town ond castle were seized by the impostor Perlkin Warbeck. Tauaton was mado the seat of the suffragaa see of Taunton and Bridgwater in 1538, but, on the desth of William Fincl, the first bisbop, in 1559, the Act had no further operation in reference to Taunton. Like the o ther towns of Somarset, Taunton was strongly Puritan in its sympathies. Situated at a point where the main roads of the conaty met, it was during the Civil War almost coustantly in a state of siege by one or other of the rival parties. Having been garrisoned by the Parlianeutary forces, it was captured by the Royalists in the sumnier of $16 \pm 3$, but on 8 th July 1644 it was, after a long siege, taken by Blake, who held it witli heroic pertinacity till reliered by Fairfax on the 11th May 1645, and agaio after it was invested by 10,000 troops under Goring till the siege was fimally raised on the 3d July. Still constant to its Puritan traditions, Taunton welcomed Soamouth in 1685 with acclanation, and he was proclaimed king there on the 20th June, the naidens of the town presenting him with a standard. As a consequeace, Tauuton was made the chief example of the fearful vengeance of Jiffreys, who, at the assizes held in the casile. coudemned no fewer than 134 inhabitants of the town and neighbourhood to death, and a much larger number to transportation. Taunton obtained a municipal clanter from Charles I. in 1627, which was revoked in 1660. A second charter, granted by Clarles I1. in 1677, was permitted to lapse in 1792 oming to the corporation allowing a majority of their number to die withont filling up the vacancies, From this time uatil it again received municipal government, 17 th April 1877, it was under the care of two bailiff appointed at the zeurt leet of the lord of the manor. Formerly tho town returucd two members to parliament, but in 1885 the number was reduced to one.
See Toulmin's Sistory of Taunton, cdited by Sarnge, 189?; and several papers in the Procecdings of the Someliset Alchixollogical Society or 18 is?

TAUNTON, a city of the Unived States, the county seat of Bristol county, Massachusetts, lies some 31 miles nearly south from Boston. The town proper, sometimes called Taunton Green, stands on the right bank of the Taunton river, at the head of narigation, about 17 miles above its mouth. The entire area enclosed within the coiporate limits is 37 square miles. Taunton is traversed by the main line of the Old Colony Railway, which conaects it with Boston and Fall River, Mass., and Providence, R.I. Owing to its situation and its connexions by rail and sea, Taunton bas become a supply point for the
greater part or south-eastern Massachusetts. The pnpula: tion of the city was 18,629 in 1870, 31,213 in 1880, and 23,674 in 1885 , showing an increase somewhat in excess of that of the State at large. Fully one-fourth of the population are of foreign bitth, and the proportion is increasing. The State lunatic asylum is in Taunton. The leading industries are the manufacture of cotton goods, iron and steel products (particularly locomotives, machinery, nails and spikes), and silver-plated table ware. Taunton as incorporated as a town in 1639, and received a city chartef in 1864.
TAURIDA, a government of southern Russia, includes the peninsula of Crimea (q.v.) and a tract of mainland situated between the lower Dnieper and the consts of the Black Sea and the Sea of Azoff, and is bounded by these two seas on the S., while it has on the N. 'the governments of Kherson and Ekaterinoslaff. The area is 24,540 square miles, of which 6990 square miles belong to the Crimea; its continental part consists of a gently undulating steppe of black earth, with only a few patches of salt clay on the banks of the Sivash or Putrid Sea, and sands in the lower course of the Dnieper. It is watered by the Dnieper, which flows along the frontier for 150 miles, and by two small rivers, the Molotchnaya and Berda. Many sinall lakes and ponds occur in the north, especially among the Dnieper sands, as well as on the Kinburn peninsula, at the mouth of the Dnieper, where salt is made. There are no forests except the artificial plantations in the colonies of the Mennonites. The climate is continental, and resembles that of central Crimea and Kherson. The population- in 1883 was 940,530 ( 247,780 in Crimea). The continental portion, although less mixed than that of the peninsula. consists of Russians (Great, Little, and White Russians), who constitate 83 per cent. of the population, Germans (11 per cent.), Bulgarians ( 5 per cent.), and Jews ( 1 per cent.). Agriculture ond cattle-breeding are the leading foccupatiens. Wheat is the chief product, and by the Germaus and Russian Nooconformists on the Molotchnaya agriculture is carried to a high degree of perfection. In 1882 there were within the government 356,270 herses, 485,800 cattle, and $3,985,300$ slieep (2, 891,700 merinos). Salt is made both on the mainland and in the Crimiea, and the fisheries aloog the coast supply au export trade. Manufactures are insigoificant, but there is a brisk cxpart trado in grain, salt, fish, wool, and tallov. The main centres of trade are the Kakhorka port, on the Daieper, Berdyansk on the Sea of Azoff, and tbe seaports of Enpatoria, Sebastopol, Sudak; and Theorlosia. The government is divided into cight districts, the chicf towns of which (with populations in 1881) are Sinferopol ( 29,030 ), enpital of the goveriment, Eupatoria $(13,420)$, and Theodosia ( 10.800 ) in Crimea, und Aleshki ( $(915$ ), Berdyansk ( 18,180 ), Helitoppl $(13,310)$, Perekop ( 4280 ), and Yalta ( 3000 ) on the continent. Several villages, such as Bolshoy Tokinak ( 8000 ) and Andreevka ( 7300 ), liave eacl. a population of more than 5000 .

TAURUS. See Asfa Mivor, vol. ii. p. 704-5.
Tavernier, Jean Baptiste ( $1605-1689$ ), the celebrated traveller and pioneer of French trade with India, was born (1605) at Paris, where his father Gabriel and uncle Melchior, Protestants from Antwerp, pursued with reputation and success the profession of geographers and engravers. The conversations he heard in his father's housc inspired Jean Baptiste with an early desire to travcl, and in his sixteentl year he had already visited England, the Low Countries, and Germany; and seen something of war with the imperialist Colonel Hans Brenser, whom he met at Nuremberg. Four and a lalf jears in the household of Brenner's uncle, the viceroy of Hungary (1634-29), and a briefer connexion in 1629 with the duke of liethel and his father the duke of Nevers, princo of Mantua, gave him the habit of courts, which was invaluable to him in lator years, and at the defence of Mantaa in 1629, and in Cer. many in the following ycar with Colonel Walter Butler (afterwards notorious through the death of TVallensteio)
he gained some military experience. When he left Butler to view the diet of Ratisbon in 1630, he had seen Italy, Switzerland, Germany, Poland, and Hungary, as well as France, England, and the Low Countries, and spoke the principal languages of these regions. He was now eager to visit the East, and at-Ratisbon he found the opportunity to join two French fathers, M. de Chapes and M. de St Lieban, who had received a mission to the Levant. In their company he reached Constantinople carly in 1631, and here he spent eleven months, and then procecded by Tokat, Erzermm, and Erivan to Persia. His farthest point in this tirst journey was Ispalian; he returned by Baghdad, Aleppo, Alexandretta, Malta, and Italy, and was agaiu in Paris in 1633. Of the next five years of his life nothing is known with certainty, but it is probable that it was during this period that he became controiler of the honsebold of the duke of Orleans. In September 1638 he began a second journey (1638-43) by Aleppo to Persia and thence to India as far as Agra and Golconda. His visit to the court of the Great Mogul and to the famons diamond mines was, of course, connected with the plans realized more fully in his later voyages, in which Tavernier travelled as a merchant of the lighest rank, trading in costly jewels and other precious wares, and finding his chief customers among the greatest princes of the East. The second journey was followed up by four others. In lis third journey (16+3-49) he went as far as Java and returned lyy the Cape; but his relations with the Dutsh proved not wholly satisfactory, and a long lawsuit on his return yielded but imperfect redress. In his last three journeys ( $1651-55,1657-62,1664-68$ ) he did not proceed beyond India. The details of these voyages need not detaia us bere, and indeed are often obscure: but they completed an extraordinary knowledge of the routes of overland Eastern trade, and brought the now famous merchant into close and friendly communication with the greatest Oriental potentates. They also secured for him a large fortune and great reputation at home. He was presented to Louis XIY", "in whose service he had travelled sixty thousand leagues by land," received letters of nobility (16th Febraary 1669), and in the following year purchased the barony of Aubonne, near Geneva. In 1062 he had married Nadeleine Goisse, daughter of a Parisian jeweller.
Thus settled in ease and aflluence, Tarernier occupied himself, as it would seem at the desire of the king, in publishing the account of bis journeys. He had neither the equipment nor the tastes of a scientific traveller, but in all that referred to eommerce his knowledge was vast and could not fail to be of much public service. He set to work thsrefore with the aid of Samuel Chappuzeau, a Freuch Protestant littérateur, and produced a Fonvelle Relation de l'Intérieur du Séruil du Gvand S'eigneur (4to, Paris, 1675), based on two risits to Constantinople in his first and sixt' journeys. This was foilowed by Le Si.. Toyages de J. B. Tacermier (2 vols, 4to, Paris, 1676) and hy a supplementary Recucil de Plusienrss Relatoons (4to, Paris, 1679), in which he was assisted by a certain La Chapelie. This last contains an account of Japan, gatleered from merchants and others, and one of Tong-king, derived from the olservations of his brother Janiel, who had shared his second voyage and settled at Batavia; it centained also a violent attack on the agents of the 1)natch East India Company, at whoso hands Tavernier had suffered more than one wrong. This attack was elaborately answered in Dutch by H. van Quellenburgh (Tindicia Bataricæ, Anist., 1684), but made more noise because Arrauid drew from it some inaterial unfa vourable to Protestantism for bis Apoloyie poru. Les Cutheliqurs (1601), and so brought on the travelier a ferocious onslauglit in Jurieu's Esprit de
M. Arnuald (1684). Taverner made no reply to Jurieu; he was in fact engaged in weightier matters, for in 1684 he travelied to Berlin at the invitation of the Great Elector, who coummissioned hinn to organize an Eastern trading cont-pany,-a project never realized. The closing years of Tavernief's life are obscure ; the time was not favourable for a Protestant, and it has even been supposed that he passed some time in the Bastille. What is certain is that he left Taris for Switzerland in 1687, that in 1689 he passed through Copenhagen on his way to Persia through Minscovy, and that in the same year he died at Moscow. It appears that he had still business relations in the East, and that the neglect of these by his nephew, to whom they were intrusted, had determined the indefatigable old man to a fresh journey.

Tavernier's travels, though often reprinted and translated, havo two defects . tho anthor uses other men's nuterial without dis. tinguishing it from his own observations; and the namative is much confused by his plan of often deserting the ehromological order and giving instead notes from various jomsmeys about cestain routes. The latter defect, it is true, while it embarrasses the biograplier, is hardly a blemish in riew of the object of the writer, who sounght mainly to furnish a guide to other merchants. A careful attenurt to disentanglo the tbread of a life still in many parts obscure has been made by Charles Joret, Jcan Eaptiste T'avernic, d'umis des Docriments Nozicarex, 880, Paris, 1886, where tho literature of the subject is fully given.

TAYIRA, a seaport of Portugal, in the province of Algarves, at the month of the Seca, 21 miles east-north-east of Faro. It is regularly built, and has an alcazar, used as an official residence, besides other public buildings. It has sardine and tunny fisheries, and carries on a considerable coasting trade. Excellent fruit is grown in the neighbourhood. The population in 1878 was 11,459 .
TAVISTCCK, a town of Devonshire, England, is finely situated in the valley of the Tavy, on the western border of Dartmoor, and on the South Devon Railway, 15 miles north of Plymonth, 14 soutl-east of Launceston, and 213 west-south west of London. The town has been greatly improved since 1845 , chiefly at the expense of the duke of Bedford, by the constrnction of a system of sewage and the erection of many new dwellings suitable for the working classes There are some remains (including a portion in the square, now used as a public library established in 1799) of the magnificent abbey of Sts Mary and Rumon, first fourded in 961 by Orgar, earl of Devon. After destructior by the Danes in 997 it was restored, and among its famous abbots were Lyfirg, friend of Canute, and Aldred, who crowred Harold II. and William, and died archbishop of York. The abbey church was rebnilt in 1285, and the greater part of the abley in 1457-58. The church of St Eustachius possesses a lofty tower supported on four open arches. Among the principal public buildings are the guildhall (1848), the corn market (1838), the market bnildings ( $18: 8$ ), and the rew hall for concerts and public entertainments. Near the town is Kelly College, opened in 1877, founded by Admiral Benedictus Marwood Kelly, with a preference for the founder's kin. Mines of copper, manganese, lead, silver, and tin are in the neigbbourhood, and the town possesses a considerable trade in cattle and corn, as well as a brewery. The population of the township in 1881 wâs 6914 . The parliamentary borough (area 11,450 acres), which bad a population in 1871 of 7725 and in 1881 of 6879 , was merged in the county in 1885.
The town owes its origin to the foundation of the abbey in 961 . From Henry 1. the abbots obtained the entire jurisdiction of tho hundred of Thevistock, with a weekly market. A school for Saxon literature wes estabilished by the monks, which flourished till the Reformation. The Royalists were quartered at Tavistock after the cefeat of the Parlismentarians on Bradock Down in 1643, and Charles 1. visited it on his way to Cornwall. It returned memburs to parliament from the time of Edward I. till 1885, among its representatives haring heen John Pym, the great opposer of the policy of Charlcs 1 ., and William, Lord Russell, bebeaded in the
reign of Charles II. Among the famous natives of Tavistock ore Sir Joln Glanville, judge under Jannes I., William Brown, the author cf Britannia's Pastorals, and Sir Francis Drake, of whom a colossal statue by Boekm was preseuted to the town by tho duke of Bedford in 1883.
TAVOY, a British district in the Tenasserim division of Barmah, lying between $13^{\circ} 15^{\prime}$ and $15^{\circ} 11^{\circ} \mathrm{N}$. lat. and between $97^{\circ} 48^{\prime}$ and $98^{\circ} 44^{\prime}$ E. long. It has an area of 7200 square miles, and is bounded on the N. by Ainherst district, E. by the Yoma Mountains, S. by Mergui district, and W. by the Bay of Bengal. The district is enclosed by mountains on three sides, viz., the main chain of the Yomas on the east, rising in places to 5000 feet, which, with its densely wooded spurs, forns an almost inplassable barrier between British and Siamese territory ; the Nwahlabe in the centre, which takes its name from its loftiest peak ( 5000 feet) ; and a third range, under the name of Thinmaw, between the $N$ wahlabe and the seacoast. The chief rivers are the Tenasserim and Tavoy, the former being formed by the junction of two streams whick unite near Mift-ta; for the greater part of its course it is dangereus to navigation. The Tavoy is navigable for vessels of any burden. It is interspersed with many islands, and with its numerous sualler tributaries affords easy and rapid commanication over the country. The clinate is on the whole pleasant. The rainfall averages about 190 inches a year.
The census of 1881 returned the population of Tavory at 84,988 (males 41,785 , Semales 43,263 ), of whioni 82,187 wero Buddhists, 828 wero Mohamniedans, and 1365 were Christians. The headquarters and capital is Tavoy town, which is situated on the left Lank of the 1 iver of the same rame, and contained a pepulation of 13,372 in 1881. Of the total area, only 83,740 acres are (1885-86) cultivated. Rico is the principal product: the betel-nut is cxtensively grown for home consumption ; and the district is larticularly rich in fruit trecs. With its only port difficult of access, and with no means of internal communication, the trade of Taroy district has always been small and almest entirely confinod to Stam and the Straits Settlements. The principal imports are p:ece goods and other cotton manufactures, raw silk, tea, crockery, wines and spirits, metals, and previsions The cr ief manufactures are salt and earthen pots. Tie gross revenue of the district in $1885-86$ was $\{20,235$, of which tho lani contributed $£ 12,663$. Tavoy was lianded over to tlie Britishl at the cml of the first Burmese war in 1824 A revolt broke out in 1829, healed by Mousg Da, the former goveruor, which was at once quelled, and since then the district has remained in undisturled possession of the Eritish.

## TAWING. See Leather.

TATATION. With regard to laxes in general Adam Smith lays down four maxims which tave been briefly described as the maxims of equality, certants. conrentence, and cconomy. The treatment of the generai principles of taxation by subsequent writers consists in the main of the development ard criticism of these celebrated canons.

Equality of Taxution.-The suljoined passage from Adam Snith contains the gerns of several distinct theories of what constitutes just or equa! taxation:-
"The snlujects of every state ought te contribnte tomards the support of its goverument as nearly as possible in proportion to theil respectivo abilities, that is, in proportion to the revenue whicis they respectively enjoy under the protection of the state The expense of gorernment to the individuals of a great wation is like the expense of management to the joint teanats of a great estate, who are all olliged to contribute in proportion to their respective interests in the estate. In the observation or neglect of this maxim con ists what is callce the equality or inequality of taxation. Every tax, it must be observed once for all, which fallis fually upoul ne only of the three sorts of reveune above.mentioned [viz., rent, wages, profits) is necessarily nnequal in so far as it does not atfect the other two. In the following exasination of differeut taxes I shall seldon take much further notice of this sort of inequality, bat slaall in most cases confine my observations to that incquality wlich is occasioned by a particnlar tax falling unequally mpout that partienlar sort of priviste revenue whicl: is affected by it ", The first sentence implies (a) that every Gevernment has the right to exact contributions for its suppert from all its subjects. According to this view. the right of taxation is
derived directly from the conception of sovereignty. It was the determination to insist on this principle whick. led to the retention of the 3 d . per id duty en tea, thar "figment of a tax, that peppercern rent," which lost the British their American colonies. The Americans opposed tc this absolnte doctrine the maxim that taxation onght to bc coincident with representation,-that only those whe ebared in the powers shonld have the burdens of geveramert. Il the latter opinion is strictly construed it would follon that all taxes on articles of cniversal consumption are urjuat except in a country where all who have the natural have also the legal capacity of roting. The doctrine of sovereignty as the basis c: taxation, pushed to its legical extreme, results in the maxim that a Government should impase snch taxes as are "most easily assessed and collected, and are at the sane time most conducive to the public interests" (M"Culloch). Just as a general leoks to the efficiency of his army as a whole, and is prepared to sacrifice any pertion if necessary, so, it may be said, the state should net regard the particular interests of individuals, but should ratber consider the wation as an organism, or, to adopt older phraseology, a leviathan. So far as the political existence of a state is concerned, this view seens to meet with general acquiescence even in modern times, when patriotism is often classed amongst the doubtful virtues, but no ideal of a perfect state has yet met with such acceptance in any nation as to reader popular a complete neglect of private interests.

Accordingly, a second basis of taxation (b) is found ir the expansion of the term "abilities" used by Adan. Smith, which leads to the position that taxes oughi to be levied so as to involve equality of sucrifice on the part of the contributors. This is the ideai of taxation which advocated by Mill and Farcett. "Equality of taxation, as a maxim of politics," says the former, "means equality of sacrifice. It means the apportioning the contribution of each person towards the expenses of government, so that he shall feel neither more nor less inconvenience from his share of the payment than every other person experi. ences fren: his." IIt is admitted that this standard cannot be completely ralized, but it is thought to furnish a proper foundation of remission in some cases and of pro portional increase of taxation in others. It is generally on this ground that it is proposed to leave incornes belor a certair: anount untaxed,-a rlan which, so far as direct taxes are concerned, las been adopted in the United Kingdom. It is clear, however, that any taxes on commodities in general use must infringe this canen, whilst the distinction between "necessaries" and "luxuries," as Adan Smith peinted out, is difficult to draw in comnumities advancing in civilization; and certaialy a considerable portinn of the taxes on stimnlants is, as a matter of fact, derived from persons whose incomes are below what is generally considered a reasonable minimuta for the standard of couffort, and such persons would prob. ably consider enfereed abstinence a greater sacrisice thar, the payment of a direct tax. It is also principally on the ground of equality of sacrifice that the proposal for graduated or progressive tasation rests. It is argued tbat a person with $£ 10,000$ a year can pay 10 per cent. (for example) as easily as a person with $£ 1000$ can pay 5 per cent. It is to be observed that the principle of equality of sacrifice regards the payment of taxcs as duty imposed on the subjects of a state incependently of the advantages they may derive indıvidually from the exjenditure of the amount levied.
A third basis of taxation, however, is found in the principle (c) that taxes ougbt to be considered as payment for raluable services rendered by the state to indivicuais. and this seems to be tbe position Adom Smith had in vi:
in introducing the clause "under the protection of the state," and in comparing the individuals of a great nation to the joint tenants of a great estate. It is easy to show, as Mill does, that, if protection is taken in its narrowest signification, as a matter of fact the poor need more protection than the rich, but the argnment becomes more plausible, and more consonant with the general teaching of Mill, if stress is laid on the protection and assistance afforded by the state in the process of acquisition of individual fortunes-a; view of taxation sometimes called the social dividend theory (cf. Walker, Helferich). It is really on this ground that Mill proposes that the "unearned increment" from land should be taken by the state, and, as has often been pointed out, "unearned increments" are by no means confined to land. JVithout much exaggeration the state may be regarded as a partner in all industrial undertakings, and is therefore eotitled to a share in the proceeds. In a somerwhat similar manner, poor rates, education rates, \&c., have been regarded as of the nature of insurance paid by the rich against the carelessaess of the poor. The priaciple under consideration has becu generally applied in cases in which the service readered by the state and the benefit accruing to individuals are easily discovered and estimated, especially in connexion with local taxation.

The object of taxation is in general to provide the state with an adequate revenue, but in all cases the indirect effects are important, and somctimes provision of revenue is considered of sccondary importance. Accordingly it has been maintained ( $d$ ) that the state ought to use its powers of taxation for the promotion of various social ends. Adam Smith remarks that "it bas for some time past bcen the poliey of Great Britain to discourage the consumption of spirituous liquors, on account of their supposed tendency to ruin the health and corrupt the morals of the common people," and in our own times the falling off in the revenue from alcobolic drinks often furnishes a subject for appareat congratulation in "budget" speeches. German writers with socialistic tendencies (e.g., Wagner) have emphasized this social point of taxation; and Mill, although disapproving of graduated taxation of income, adrocated the imposition of extremely hcary succession duties, with the object of promoting a better distribution of national wealth and compelling individuals to rely on themselves. Many rations again have inposed duties on. imports with the view of protecting and encouraging home industries, and most of the import duties levied in England before the great reforms of Peel were of this nature. Accordingly, both theoretically and .practic-lly, the promotion of social or moral ends may be considered as a fourth basis of taxation. It is worth noticing that in early times the fines received in the courts of justice were an important source of revenue.

Whatever basis of taxation be adopted, the elementary principle of justice noticed in the conclusion of A. Smith's first canon must be considered. If it is just to tax A, it is just to tax B under precisely similar circumstances. Thus stated, the principle seems almost formal, but for practical purposes small differences in cireumstances may be neglected, and it is clear that in any great nation the taspayers may be arranged in a. limited number of groups, within each of which the constituent individuals may be regarded as similarly situated. A tax on rent, or wages, or profits would be obviously unequal if those in one place or employment were taxed while those in another were left free. The practical difficulty is to discover what cases may fairly be regarded as similar, especially if equality of sacrifice be taken as the ideal.

As a matter of fact, in every civilized community a complex system of taxation is adopted, the diferent parts
of whieh rest in different degrees upon the various principles just noticed. Some taxes are jnstified on the grounds of their coaveaience to the sovereign porer, and others are increased or diminished in certain cases in accordance with the principle of equality of sacrifice; some are regarded as payments for services readered by the state, others partake of the dature of sumptuary regulations or are approved on various social or moral grounds; and sometimes the imposition of one productive tax involves, on the ground of simple equality, the adoption of similar taxes which are hardly worth collecting.
Tho remaining canons of Adan Smith are partly, like the first, ethical in cbaracter partly purely economic. Of the second-the cavon of certainty-Adam Smith remarks :"The time of payment, the manner of payment, the, quantity to be paid, ought all to be clear and plain to the contributor and to every other person [on the ground of the otherwise arbitrary powers which are given to the taxgatberer] . . . The certainty of what each individual ought to pay is in taxation a matter of so great importance that a very considerable degree of inequality, it appears, I belicve, from the experience of all nations, is not near so great an evil as a very small degree of uncertainty." Perhaps the best example of the infringement of this canon is furnished by the taxes levied from the miserable provincials ly their Roman governors.
The third rule-the canon of convenience-which enjoins that "every tax ought to be levied at the time or in the nanner to which it is most likely to be convenient for the contributor to pay it," may be justificd, not mercly on general grounds of good government, but also on the special coonomic ground of the increase in the productiveness of taxes which satisfy the condition. It has been found possible to raise a considerable revenue by taxes on commodities, the payments of which by the consumers are made in insensible portions, when it would have becu impossible to collect the sane amount by direct taxation at comparatively long intervals Taxation is in this respect like bleadiag.
The fourth rule-the canon of economy-states as its general principle that "every tax ought to lo so contriscd as both to take out and to keep out of the pockets of the people as little as possible over and above what it brings into the public treasury of the state." Taxcs inay, according to Adam Smith, break this rule by requiring a large number of officials for their collection, by restraint of trade and production, by encouraging smuggling, and by causing unnecessary vexation; "and, though vexation is not, strictly speaking, expense, it is certainly equiralent to the expense at which every man would be willing to redeem himself from it." On smuggling Adam Simith else where remarks that "to pretend to have any scruple about buying smuggled goods would in most countries bo regarded as one of those pedantic pieces of hypocrisy which serve only to expose the person who affects to practive them to the suspicion of being a greater knave than bis neighbours." It may be observed that in practical politics it is generally taken for granted that a tax which can be evaded will be evaded, and indirect methods of taxation are to a great extent devices by which possibilities of evasion are restricted.
To these general rules of taxation explicitly given by Adam Smith, the following may be added, nost of which, are implied in different passages of lis treatment of taxation, but have been expounded and emphasized by subse. quent writers. A coavenient summary is given by Hel. ferich in Schönberg's Handbutch der Politischen Oekonomie (vol. ii. p. 138). (a) A given amount of revenue is. as a rule, both from the point of view of the Government and its subjeets, more couveniently raised from a small number
of very productive taxes than from a larger number with smaller returns per unit. This was one of the principal finaneial reforms advocated by Adan Sinith with reference to the custons duties, and has been carricd out in the United Kingdom by Sir Robert Pcel and his successors. The inextricable confusion of the customs duties levied before these reforms were effected can only be realized by those who study the details of the? istory of taxation. A similar process of simplification has been partially applied to the direct taxes, but in many cases (esprecially in local taxation) the rule is more honoured in the breach than in the observance. (b) A good system of taxation ought to provide for a self acting increase in the revenue in proportion as the population and the consequent deroands for governmental expenditure increase. It has been found by experience that an old tax causos less inconvenience than a new tax of smaller amount, a fact which is so striking in some cases as to have given rise to the saymg that an old tax is no tax. (c) Those taxes are best which yield a steady and calculable return, instead of a return fluetuating in eharacter and difficult to estimate. (d) Those taxes are best which in case of need can be most conveniently increased in amount. It is this characteristic of the incone tax which renders it so popular with chancellors of the exclequer, and it was partly on this ground that Mr Gladstone substituted a tax on beer for the tax on malt. (e) Regard must always be paid to the real ineidence of tazation, and care taken that the real burden of the tax falls on those aimed at by the legislature. No part of the theory or practice of taxation has giren rise to so much controversy as the incidence of particular taxes, a subject indeed of so much difficulty and importance as to ocsury the greater portion of the treatment by systematic "riters.
Incidence of Taxation.-Taxes are generally divided inso direct and indirect. A direct tax is defined by Mill as, one "demanded from the very persons who it is in. fended or desired should pay it." Others (e.g., M ${ }^{\prime}$ Culloch) letine it as a tax taken directly from income or capital. In the former definition non-transferable taxes on expenditure would be included (e.g., a tax on livery servants), but not in the latter. Mill's definition has been generally adopted (e.g., by Wagner, in the German Hancluuch, vol. ii. p. 152); but in any case the most important direet taxes practically are those levied on income or capital directly, and the nost important indireet the customs and excise duties. In examining the iacidence of taxation the - order oi arrangement adopted by Adam Smith seems best. He disensses separately taxes on the three great species of income,-rent, profits, and wages (appending to the articles on the first two an examination of tares upon the capital value of land, bouses, and stock), and taxes intended to fall indifferently upon every species of revenue, viz., capitation taxes and taxes upon consumable commodities.
Taxes on Rent.- What is commonly known as rent consists in general of two parts, which may be termed economic rent and profit rent. Eeonomic rent arises from the superiority of advantage of any source in the production of a certain amonnt of utility over the least prodnctive source which the conditions of demand and supply (including transmission to market) render it possible to employ. Thus, in the production of food, some lands have an advantage in fertility or situation; again, in furnishing amenities of accommodation or facilities for business, some houses have from their situation a sinnilar advantage; and again, different processes in the arts and manufactures are superior to others (giving rise to patents). In all these cases where the amont of the 'superior sources is limited (naturally or artificially), and recourse must be made to inferior suurces of supply, economic rent is oaid for the
superior advantage Any tax imposed on this syectes of revenne falls on the owner. If levied in the first instanec from the lessee, he will pay so mueh less rent, and any nen taxes imposed during the eurrency of leases onglit, il intended to fall on the owner, to be taken directly from him. It may be assumed othat every owner of a superion source has exacted the highest price obtainable for its use, so that he cannot transfer the tax to the tenaut, no through the tenant to the coustumer. If, for example, $\varepsilon$ tax is inposed ote the economic rent of agricultural land the landlord cannot exact it from the temant (for if the temant could afford nore rent, why under competition was he not forced to do so before?) nor from the consumer ol the produce, for the price is obviously determined inde pendently of rent. Siinilarly a tax on the ground rent of houses, if it be assumed that the land is nseless for other purposes, mûst fall on the owners; although a certain portion will be transferred to the occupier if the landlord could use it otherwise and escape the tax (cf. Alill, bk. v ch. iii. §6) Taxes on economic rent of various kinds, se heary as to absorb the whole amount, lave been advocated by some theorists on grounds noticed under Adaus Smith's: first canon. It is said they would impose no burden on the state as a whole, that they would not affect production or accumulation, and even that the substitution of the state for private owners-who are simply nati consumere fruges-would really increase the wealth and power of the mation by compecling these unprodnctive consumers to work, and by lightening the pressure of taxation on industry. It is, bowever, obvious that the confiscation of rent would, seeing that land has for generations been it the circle of exchangenile commodities, strike at the root= of the institution of private property. Apart from this general objection, there would in the case of agricultural land be gieat difficulty in selarating economic from profil. rent, and any exceptional tax on the latter would obviously tend to cleeck agricultural improvements.

Taxes on Profits.-Profits; as commonly used, is a term embracing three elements which, from an economic and financial point of view, are quite distinct in character, viz, interest (pure and simple), insurance against risk, and earnings of management. The interest on capital in any industrial area, lent on the same security, tends to equality If, then, a tax is imposed on interest in every form, the incidence in the first place will be on the owners of capital. But two indirect consequences will follow. (I) As Adam Smith remarks, "the proprietor of stock is properly a citizen of the world, and is not necessarily attached to any particular comitry. He would be apt to abandon the country in which he was exposed to a vexations inquisition in order to be assessed to a burdensome tax, and would remove his stock to some other country, where he could either carry on his business or cujoy his fortune more at his ease." In this case the ultimate result would be that the country in which the tax was imposed would possess less eapital, and thus would yield a liigher rate of interest sufficient to counterbalance the burden of the tax (2) The tax wonld tend to cheek the accumulation of capital within the country, so far as the interest received is a cause of aceumulation, with the same ultimate result as in the former case. It must, however, be observed that the rate of interest is only one of the causes affecting the accumulation of capital.

A tax on some particuiar form or interest (security still being supposed perfect), for example on mortgages on land, would obviously fall on the berrowers. In the samo way a tar on that part of the profit rent of houses rhich is interest on capital tends to fall on the occupier. In gene ral, however, the security is more or less imperfect, and the insurance against risk is allowed for in the rate of
interest charged on borrowed capital. Thus a tax which took equal percentages from all species of interest would be in part a tax on insurance against risk, and the tendency must be for snch a tax to fall on the borrowers of capital. Suppose at any time a perfect security yields 3 per cent. and one with greater risk 6 per cent., then 3 per cent. represents the estimated value of the insurance against risk. A tax which reduces the net yield on the first to 2 per cent. would reduce the net yield on the latter to 4 per cent. In order, then, for the insurance against rists to remain the same, the rate yielded by the latter must rise from 6 to $7 \frac{1}{2}$ per cent. It follows, then, that a tax levied on all forms of interest (no allowance being made for risk) would tend to check investinent in proportion as risk was involved, and would thus check industrial enterprise. This result would follow even although the rate of interest on perfect security, owing to the causes mentioued abore, were raised in proportion to the tax.
A tax on that part of profits known as earnings of management would, if imposed generally, fall in tho first instance on the entreprenears or employers of capital, and with similar indirect consequences to those just noticed in regard to interest. Capital would tend to flow abroad, and accumulation would be checked, since in general the employers of capital are also to a large extent the owners. So far as profits, in this sense, are of the nature of rent (a view recently advocated as regards all profits by Prof. Walker), a tax on profits would be analogous to a tax on rent. If the differences in the net advantages of different methods of employing capital are supposed to remain constant (according to Prof. Marshall's view of earnings of management), a proportional tax on profits must be in part transferred to the consumers of the articles produced, in the same way as a tax on interest with risk was shown to fall on the borrower. It will be seen from this general survey that the incidence and effects of a tax on profits (taking the term in its common acceptation without analysis) are extremely difficult to determine, and the practical difficulty is still greater than the theoretical. For, as M'Culloch and others have shown, profits are always fluctuating and dificult to estimate. So great, for example, is this difficulty felt to be as regards farmers' profits that in the income tax it is assumed that such profits bear a certain proportion to the rent paid for land on a purely empirical rule, which may bappen to hit the mark in a majority of cases, but is much more likely to be unequal and unjust in its operation.

A tax on some particular form of profits (as distinct from a general tax on profits) will, it is generally said, fall on the consumer of the article produced, on the ground of the teadence of profits to equality. This view will be noticed below under taxes on consumable commodities.

T'axes on Capitai.-In early English histō̃y taxes upon capital of a very simple kind played an important part. A grant, for example, of certain fractional parts of movables, commencing with the famous Saladin tithe (on both rent and movables in 1188, and gradually setting dorn to a fifteenth for the counties and a tenth for the towns, prevailed for more than three centuries. In 1334 a fifteenth and tenth was fixed at a certain sum for each township, and after this date a grant of one or more "fifteenths and teaths" meant simply a grant according to the scale then fixed (Dowell, rol. iii. p. 75). But in our own times taxes on capital are levied principally when mroperty changes hands, and may be divided, as they are by Adam Smith, according as they are levied when property passes (a) from the dead to the living, (b) from the jiving to the living.

It is obvious, as regards incidence, that taxes of the
first class (a) are the most direct of all taxes, in the sense that they cannot be transferred to other persons by the beneficiaries. The principal difficulties connected with the "death duties," as they are often called, arise in connexion with the canon of equality of taxation. Opinion is still divided on the proportions which ought to be paid by personal and real estate respcctively, as well as on the advisability of the taxes being made progressive according to the value of the property, and there are still greater difficulties in connexion with life interests in settled pro perty. Mill was strongly in favour of making the death duties very heavy and also graduated. "I conceive," he says (Pol. Econ., bk. v. ch. ii. § 3), "that inheritances and legacies exceeding a certain amount are highly proper subjects for taxation, and that the revenue from these should be made as great as it can be made without giving rise to evasions by donation during life, or concealment of property, such as it would be impossible adequately to check. The principle of graduation, that is, of levying a larger percentage on a larger sum, though its application to general taxation would be in my opinion objectionable, seens to me both just and expedient as applied to legacy and inberitance duties." The principal objections urged against such taxation are, that a stimulus. would be given to personal extrapagance and a check placed on accumulation, and that in consequence indirect production would be lessened, partly by want of capital and partly by the check placed on production on a large scale. As regards the want of capital, apart from the check placed on saving, there would be a tendency to send it abroad. A heavy tax on large capitalsat home will place a premium on investments abroad, in which erasion would be easy. Perhaps, with the present rate of accumulation, tho objection may be made light of, as it is by Mill; but the second, if less ohvious, is more inpportant. All our great staple manufactures are necessarily conducted on a large scale, and in many respects also large agricultural capitals are most productive. In manufactures, as a rule, the larger the scale of operations the more extended will be the division of labour in prodnction, and the greater the facilities for ready sale in foreign markets. Of all the causes which contribute to our commercial prosperity, perhaps the most important is the large scale on which our operations are conducted. We are able to employ machinery where the foreigner, working on a smalles scale, is obliged to use manual labour. There can be little doubt that graduated taxation, even on the modified form proposed by Miil, would tend to check production on a large scale. Indirectly it might artificialiy foster joint-stock compauies. (b) Taxes on the transference of property frou the living to the living cannot, as Adam Smith points out, be very easily taken directly, as such transactions for the most part actually are or might be secret. This has led to the invention of stamp and regis. tration duties. The penalty of invalidity attaching to unstamped documents of various kinds has proved a very effective ceterrent to evasion. A tax on sales will vary in its incidence according to the nature of the commodity and the degree of competition or monopoly (cf. HJ. Sidgwick's Principles of Pol. Econ., bk. ii. ch. x.). The most important case is that of taxes on the transfer of land. Theoretically it seems that, just as the farmer who takes land on rent offers more or less rent according to the burdens imposed on the land by rates, \&c., so the purchaser of land will consider any expenses connccted with its acquisition as part of the capital value, and thus any taxes on transfer will really fall on the sellers. If, lowerer, the taxes are imposed in such a way as to fall less heavily of land wheu sold in larser than in sumald
quantities, it is clear that the tendency will be for the differential pertion of the tax at least to fall on ths purchaser of a small amount; and practically at present this feature is cbaracteristic of the English system. A tax on the transfer of stocks and shares is generally held to fall on the seller, as in case of repeal he would obtain so much mere; but in this case the same cousiderations apply as in the case of interest noticed above. Acurieus example of legal evasion is furnished by time-bargains; and the inposition of the tax direstly on the contracts of sale, instead of as at present on the actual transfer, has been strongly urged.

Taxes on Wages.- It is clear that the treatment of taxes on wages will depend on the general view taken of the determination of the rate of wages. Adam Smith appears to lay undue strass on the price of provisions, and to think that in most cases taves on wages must fall on the employer of labour (bk. v. ch. ii. art. iii.). There seems, hewever, to be no sufficient reason why a tax on labour should be transferred to the employer, excent in the case where the wages are really at a ininimum below which the supply of efficient labour could net be kept up. Even in this case, as Prof. Walker shows, there would probably be a degradation of labour tefore the rise in wages was effected. Certaialy no practical statesman at the present time weuld venture to propose a direct tax on wages, under the idea that it would be transferred to the employer. Jn Germany it was found necessary to abandon the system, owing to the hardship inficted on the poor. At any rate, in all cases in which the rate of wages is above the "necessary" minimum, a tax on wages must fall on the labourer. $\Lambda$ differential tax on seme particular species of employment would, unless it partook of the nature of a monopoly, tend to fall on the consumer of the article produced or the person who enjoys the service rendered. In every case, speaking generally, the incidence of the tax will depend on the conditions of the demand and supply of the labour in question, and no further analysis can be given without entering into the general principles governing wages. See Wages.

Capitation taxes are chiefly of interest historically, as illustrated in England by the poll-tases imposed at various times. The income tax as at present levied is in reality not a single nuiform tax, as mght at first sight anpear, but a tax on the various species of rent, interest, profits, and wages. The anomalies which arise from practically taking income as uniform bave often been pointed out and acknowledged, but the autherity of Mr Gladstone may be quoted in support of the view that the practical difficuities in the way of a readjustment more in accordance with theoretical principles are insuperable. The objections noted above to a graduated property tax apply, mutatis mutandis, to a graduated income tax, which appears, bewever, to find increasing faveur on the Continent. A full discussion of the anomalies of the inceme tax would involve a repetition of the analysis of the taxes on the varions species cf income.

Taxes on Commodities.-The general principles applicable in this rase are that, where production takes place under free competition, the tax will, owing to the tendency of profits to equality, be transferred to the consumer, but thet, when the article is practically monopolized, a tax must tall on the menopelist, on the assumption that he has already fixed such a price fer the article as mill, considering the law of demand and the expenses of production, yield him a maximum revenue. The practical difficulties connected with the assumption of equality of prefits have been well exposed by Cliffe Lesiie (Financial Reform: Cobden Club Essays, 2d series, 1871-72).

The incidence of export and impert daties is peculiarly Nifficult to ascertain even theeretically. The prevailing
opinion that an import duiv necessarily falls on thes consumer of the import necessarily involves as its counter part the position that an expert duty must fall on tiue consumer of the expert. If the latter view is upheld it is curious that expert duties find such little favour with practical statesmen. It is clear, however, that the real incidence of expert and import duties will depend partly on the conditions of production in various countries, partly on the variations in demand due to changes in price, partly on the indirect influence on the general balance of trade, and partly on the pessibility of using substitntes for the article taxed (cf. H. Sidgwick's Principles of Pol. Econ., bk. iii. ch. v.; Cournot, Revue Sommaire des Doctrines E'conomiques, sects. 5 and 6). A fuller examination is not possible in the limits assigned to this article. In con. clusion, it may be pointed out that a thorough investigation of the general principles of taxation must presuppose the principles of political philosophy, whilst a full inquiry inte the incidence of particular species of taxes must pre suppose the principles of political economy. (J. s. N†.)

TAXIDERMY, the art of preserving the integument together with the scales, feathers, or fur, of animals Little is known of the beginnings of the practice of the "stuffing" or "setting up" of animals for ernament or for scientific purpeses; and it is highly probable, from what we gather from old works of travel or natural histery, that the art is not more than some three hundred years old. Il was practised in England towards the end of the 17th century, as is proved by the Sloane collection, which in 1725 formed the nucleus of the collection of natural history now lodged in the galleries at Sonth Kensington.

It was not until the middle of last century that any treatise devoted to the principles of the then little under stood art was published in France, Réaumur's treatise (1749) being probably the first. This was fellowed al intervals by others in France and Germany, until the be ginning of the present century, when the English begat to move in the matter, and several works were published, notably these by E. Deneran, ${ }^{1}$ W. Swainson, ${ }^{2}$ Capt. Thornas Brown, ${ }^{3}$ and others. These works, bowever, are now in adequate ; and since the Great Exhibition of 1851, when the Germans and French taught British taxidermists the rudiments of scientific treatment of natural objects, several works have appeared upon the subject frem the pens of Amerizan and Euglish authors, such as J. H. Batty, ${ }^{4}$ R Ward, ${ }^{5}$ and Mentagu Browne. ${ }^{6}$

The first principle governing the art is that, after the sporimen has been procured, in as fresh and clean a state as may be, it should have the skin stripped from the bedy in such a manner as not to disturb the scales if a fish or a reptile, the feathers if a bird, or the fur or hair if a mammal. To do this correctly requires a small stock of tools, as well as a great amount of patience and perseverance. The appliances comprise several sharp knives (some pointed and some obtuse), a pair of scissors, a pair of pliers, a pair of nippers or "cutting-pliers," some tow, waduing, needles and thread, also a "stuffing-iron," some crooked awls, a pair of fine long flat-nosed pliers, and a camel-hair brush. The preservative compeund is often the original (Béceeur's) "arsenical soap," made by cutting up and boiling 2 tb of white soap, to which 12 oz . of salt of tartar and 4 oz . of powdered lime (or whiting) are added

[^24]
## T A X I D E R. M Y

when dissolved; to this mixture, when tuarly cold, 2 fb of powdered arscnic and 5 oz . of camplor (the latter previously triturated in a mortar with spirits of wine) are added. The mixture is put away in small jars or pote for use. Like all arsenical preparations, this is exceediagly dangerous in the hands of unskilled persons, often causing shortness of breath, sores, brittleness of the nails, and other symptoms ; and, as arsenic is really no protection against the attacks of inseets, an efficient substitute has been invented by Browne, composed of 1 th of white curd soap and 3 th of whiting bailed together, to which is added, whilst hot, $1 \frac{1}{2}$ oz of chloride of lime, and, when cold, 1 oz. of tucture of musk. This mixture is perfectly safe to use when cold although when hot the fumes should not be inhaled, ,wing to the chlorine given off), and is spoken of as doing ts work efficiently. Solutions of corrosive sublimate, often recommended, are, even if efficient, dangerous in the extreme. Powders consisting of tannin, pepper, camphor, and burnt alum are sometimes used for "making skins," but they dry them too rapidly for the purposes of " mounting." Mammals are best preserved by a mixture of 1 tib of burnt alum to $\frac{1}{4}$ ib of saltpetre; this, when intimately mixed, should be well rubbed into the skin. Fishes and reptiles, when not cast and modelled, are best preserved in rectified spirits of wine; but this, when economy is desired, cas be replaced by "Möller's solution" (bichromate of potash 2 oz , sulphate of soda 1 oz ., distilled water 3 pints) or by a nearly saturated solution of chloride of zinc. The cleaning of feathers and furs is performed by rubbing them lightly with wadding soaked in benzoline, afterwards dusting on plaster of Paris. which is beaten out, when dry, with a bunch of feathers.
The preparation and mounting of bird epecimens, the objects most usuafly aelected by the amateur, are parformed in the following manner. The epecimen to be operated npon ehould have its nostrils and throat closed by plugs of cotton wool or tow; both wing-bones should be broken close to the body, and the hird laid upon a table on its back; and, as birds-espocially white-breasted voes-should eeldom, if ever, be opened on the breast, an incision should be made in the skin noder the wing on the side most damased, from which the thigh protrudes when pushed up slightly; this is cut through at its junction with the body, when the knifo ie gentiy used to soparate the skin from this, uatil the wiog-bono is been on the open side. This is then cut through by ecissors, and by careful manipulation the elkin is further freed from the back and breast antil tho neck can be cut off. The other sido now remains to be dealt with; from this tho wing is cut by travelling downwards, tho remaining leg is cut amay, eod yery careful skinning over the stomach and upon the lower back brings the operator to the tail, which is cut off, leaving a small portion of the bone (the caecyx) in the skin. Tho Eody now falls off, a ad nothiog remains in the skia but the neck and head. To slik these ont properly without unduly atretching the integumcut, is a task trying to the patieace, but it can be accomplished by gradually working the $6 k i o$ away from the back of the head forward, taliog care to svoid cutting the eycs or the oyelids, but, by cautious managemeot, to cut the memliranous skin over those parts, so that the eyes aro easily extracted from the orbits without lursting. The ekin ehould be freed down pearly to the beak, and then the back of tho head, with neck attached, should be cut off, the breins oxtracted, all the flesh cleared from the skull and from the hones of the wings, legs, and tail, the skin painted with the preservetive, aod ultimately turned into its proper position. When "skins" only are to he made for the cabinet, it is suffecient to fill the head and ner.k with chopped tow, the body with a false one made of tere, lightly packed or loose according to tho genius of the preparer, to sew up the skin of the stomach, and to place a band of paper lightly pinned around the body over the breast and wings, and allow it to romain in a warm rosition, freo from dust, for several days or weeks, according to the eizo of the specimen. It should then bel labelled with namo, sox, locality, and date, and put away pith iosect porder around it.
When, howerer, the specimen is to be "monnted," the operations shonld be carried up to the point of returning the skin, and then a false body of tightly wrapped tow is made upon a wire pointed at its urper end. This is inserted through the incision under the wing, the pointed end going up the neck and through the ekull to the outside. When the imitation body rests within the skin, pointed wires are thirust through the solos of the feet, up
the skin of the back of the legs, and are finally clenched in the body. Wires aro also thrust into the butts of tho wings, foisow. ing the skin of the aoder surfaco, and also clonched through into the bmiy. A stand or perch is provided, and the bird, being fixed upin this, is, after the oyes have been inserted, arrangod in the uost natural attitude which the skill of the taxulermist can give it.

Mammals are cut along the stomach from uearly the middlo to the broast, and are skinned by working out tho hand legs first, cutting them off under tho skin at the junction of the fensur with the tibia, and carcfully stripping the skin otl the lowe twack atad front until the tail is reached, the flesh 8 nd booes of wlich are pulled out of the skin, leaving the operator free to folloa cas ug tise back and chest nutil the fore legs are reached, which are cut off in like manner. The neck and head aro skiuned out down to the inner edges of the lips and nose, grest care being exerciscd not to cnt the outer portions of the ears, the eyelids, the uuse, or tho lips. The flesh being cleased off, and the brain and eyes extractcu, the okull ghould adhere to the skin by the inner edges of the lips. All the flesli should he trimneal from the bones of the logs. The head, being slaped, where the flesh was remored, hy tow and clay, is returasd into the okin. A long wire of sufficient strongth is tightly bound with tow, making a long, narrow body, throumh which wires are thrust by the skio of the soles of the fcet. The leg wires and bowes being wrapped with tow and clay into shape, the points of the wires are pushed through the tow body and clenched. They and the body are then beot into the desired position, and modelled up by the addition of more tow and clay, untib the contours of the natural body are imitated, when the stomach is sewn up. A board is provided apon which to fix the specimen, artificial eycs are inserted, the lips, nose, and eyelids fixed by means of pins or "peedle-points," and tlie specimen is then placel in a warm situstion to dry.

Reptules, wheo small, have their skin removed by cutting away the attachment of the skull to the cervical vertebres, and by turning the decepitated trunk out at the mouth by delicato manipulation. When large, they are cut along their modian line, and treated in the same manner as mammals.

Fishes, after being covered ou their best side with paper or rouslin to protect the seales, are cut along the of her side from the tail to the gills, and are skinned out by removiug "cutlets," as large as is possible without cracking the skin, which, indeed, sbould be kept damp during work. After being cured with a pre servative, they are flled with sawdnst or dry plaster of Paris, sewn up, turned over on a board, the fins pinned out, and the month adjusted, aud, when perfectly dry, the plaster may bo shaken out.

A new school of taxidermists, with new methods, whose aim is to combine knowledge of anatomy and modelling with taxidermic technique, are now coming to the front and the neat gencration will discard all processes of "stuffing" in farour of modelling. Within the limits of an article dike the present it is impossible to do more than glance at the intricate processes involved in this. In the case of mammals, after the skin has been completel: removed, even to the toes, a copy is made of the body, posed as in life, and from this an aceurate representation of form, inciuding delineation of muscles, \&c., is built up in light materials; the model is then covered with the skin, which is damped, and pinned in to follow every depression and prominence; the study is then suffered to dry; and, models baring been made, in the case of large animals, of the mucous membrane of the jaws, palate, tongue, and lips, these are truthfully reproduced in a plastic naterial. The ordinary glass eyes are discarded, and hollow globes, specially made, are hand-painted from nature, and are fixed in the head so as to convey the exact expression which the pose of the body demands. Birds, if of any size, can be modelled in like manner, and fishes are treated by a nearly identical process, being finally coloured as in a "still lile" painting.

To give a life-like representation. attention is also paid to artistic "monoting." By the is meant the surrounding of speeimens with arppropriate accessories, and it is well exemplified by the new work shown in the natural history museum at South Kensington, where, for example, birds are arranged as in a state of nature, feeding or flying to their young, sitting on their eggs, swimming in miniature nools, or preening their feathers whilst perched lovingly side by side, and surroundeo by exquisitely modelled.

## T A X - T A Y

foliage and Howers. This, with correct modelling of the specimens, which, excent in rare instauces, is not guite so striking in the new groups, indicates the future of the art, the hope of which lies in the better education of taxidermists as designers, artists, and modellers.

TAXlla. See Rawal Pindi.
TAY, Tue, the longest river in Scotland, has its sourco on the worthera side of Ben Lui, on the borders of Argyll,hire and Perthshire, being known in its earlier courso as th: 2 Filtan, and, after forming Loch Dochart, as tho Dochart, until satering Loch Tay, 25 miles from its scurce, at an elevaticn above eca-level of 553 fect. Its course through Perth:shire is described in the article on that county. Its total length to the town of Perth is about 95 miles, and it drains a total area of ahout 2400 square miles, while its estuary extends for about other 25 miles. The navigation of the estuary is somewhat impeded by aandbanks. The only important port is Dundce, but vessels of 100 tons can pass up to l'erth, the river being tidal to 2 miles above is The salmon fisheries on the river and its estuary aro anone the most valuable in Scotland. A railway bridge over tha Tay at Jundee, designed by Sir Thomas Bouch (see Bradocs, vol. iv. p. 346 ), was opened for traffic 31st Jlay 1878 , but was blown down during the crossing of a passenger train 28th December 1879. Somo distance to the west a new bridgic, designed hy W. H. Barlow, was commenced in 1882, and was opened for general traftic 20 th Juno 1887.

TAYLOR, Bayard (1825-1878), one of the most prolific among American authors, was born it Kennett Square in Chester county, Pennsylrania, on January 25, 1825. Tho son of a well-to-do farmer, he received his early instruction in an academy at West Choster, and, later, at Unionvilic. At the age of seventeen he was apprenticed to a printer in West Chester. A little volume, published in $18+\frac{1}{4}$ under the title Ximena, or the Battle of the Sierva Morena, and other Porms, brought its author a little cash and indirectly it did him better service as the means of his introduction to The New York Tribune. With the moncy thus obtaiaed, and with an advance made to him on account of soma journalistic work to bo done in Europe, "J. B. Taylor" (as he had op to this time signed himself, thnugh he bore no other Christian name than Bayard) set eail for the East. The young poet spent a happy time :n roanlog through certain districts of England, France, Gernany, and Italy; that ho was a born traveller is evident from tho fact that this pedestriau tour of almost two years cost him only £100. The graphic accounts which be sent from Europo to The Nero Tork Tribune, The Satuday Evening I'ost, and The United Stales Gazette wero so highly appreciated that on Taylor's retura to America be mas advised to throw his articles into book form. In 1816, accordingly, appeared his Viers Afoot, or Europe seen with Knapsack and Staff. This pleasant book had considerable popularity, and its author now found himsolf a recognized man of letters; moreover, Ногасө Greeley, then editor of the Tribune, placed Taylor on tho staff of that journal, thus securing him a certain if a inollonate income. His next journey, made when the goldfever was at its beight, was to Califoraia, as correspondent for the Trilune: fron this expedition be returned by way of Mlexico, and. seeing his opportuoity, published (1850) a highly aucecssful book of travels, entitled Eldorado. or Ademtures in the Puth of Empire. Ten thousand copics wero said to have been sold in America, and thirts thousand in Great Fritain, within a fortnight from the date of issue. Bayard Taylor alnays coosidered himself native to tho East, and it was with great delight that in 1851 ho found binself on the banks of the Nile. He ascended as fart $13^{\circ} 30^{\circ}$ N. lat., and stored his memory with count-
less sights and delights, to many of which he afterwards gave expression in metrical form. From England, towards the end of 1852, he sailed for Calcutta, proceeding thence to China, where he joined the expedition of Commodoro Perry to Japan. Tho results of theso jouraeys (hesides his poetical memorials, to which referenco will bo afterwards made) were $\Delta$ Jouney to Central Africa, or Life and Landscapes from Eigypl to the Negro Kingdoms of the. Nile (1854) ; The Land of the Saracens, or Picturs of Palestine, Asia Minor, Sicity. and Spain (1854); and 4 Visit 10 India, China, und Japan ine the Iear 1853 (1855). On his return ( $185 t$ ) from these various journeyings le entered, with marked success, upon the carcer of a public lecturer, delivering addresses in every town of importanco from Naine to Wisconsin. After two years' experience of this lucrative profession, he again started on his travels, on this occasien for northern Europe, his special object being tho study of Swedish liîo, language, and literature Tho most noteworthy result was the long narrative poom Lars, but his "Swedish Letters" to the Tribune were also republished, under the title Norkerne Travel (1857). In October 1857 lie married Naria Hansen, the daughter of the well known German astronomer. The ensuing winter mas spent in Gircece. In 1859 Taylor cnce more traversed the whole extent of the western American gold region, the primary caliss of the journey lying in an invitation to lecture at San Francísco. About thrco years later be cotered the diplomatic service as secretary of legation at St Petersburg, and the following year (1863) became chargé d'affaires at the Russian capital. In 1864 he returned to the United States and resumed his active literary labours, and it was at this period that Mamah Thurston, the first of his four novels, was published. This book had a moderate success, but neither in it nor in its successors did Bayard Taylor betray any special talent as a norelist: some of hiz characters are faithful studies from life, and he could describe rell the aspects of nature,-but a good deal more than this is necessary for the creation of noteworthy romances. In 1874 he went to Iceland, to take part in tho centennial celebration which was held in that year. In June 1878 he was accredited United States minister at Berlin. Notmithstanding the resistless passion for travel which had always possessed him, Bayard Taylor was (when not actually en route) sedentary in his babits, especially in the Iater years of his lifo ; and at Berlin ho aggravated a constitutional liver affection by too sedulous devotion to literary studics and pursuits, in the intervals of leisure from his diplomatic duties. His death occurred on the 17 th of December, only a few months after his arrival in Berlin.

The main drawback to the widespresd acceptance of Bayard Taylor's poetry as a whole is its porpetual difuseness. His incst ambitious productions-his Masque of the Gods (1872), Prince Deukalion (1877), The Pichure of St John (1865), Lars (1873), and The Prophict (1874)-are marred by a ceaseless eflort to overstrain his powicr. Lars is the least likely of his longer poems to aurviro any length of time: it lacks the grandiose eloquence and impressive "adjuncts" of the Masque or Prince Deukalion, irlile in tbeme and treatment it is, ot most, only sedately agrecable. The Poents of the Oricnt contains his most genuinely satisfactory poetic writings. But probably long after even the most familiar of the pocma just mentioned havo ceased to be popular, when even the Vicus Afoot and Eldoralo po longer bold tha attention of the numerous publis interested in rivilly parrated experiences of travel, Bayard Teyler will be remenabered by lis poctic and execllent translation of Fisust. Taylor felt, iu all truth, "tbo tornent and the ecstagy of verse "; but, of a critical friend has writteu of him, "his natura was 6 ardent, yo full-blooded, that slight and commor sensations intoricated him, and he estimated their effect, and his power to transmit it to others, bejond the true velue.". Ho felt lifo as perlaps only tho poetic temperament cau experionce the beauty of tho world; eingle worde thus became for him so charged with poatry that ha overlooked the fact that to most peoplo these were, aimply in themselrea, mera abstract terms-sunshine, sea, spring, morning, night, and ao forth. Thus a otauza baving absolutely nothing original or ntriking or even poetic in it would, because
born of him, seem to be poetry unadulterate: to his mind, each line, each word, was charged with delightiful significance, thereforo -so he felt--would be so also to the synupathetic reader. Ho had, from the carliest period at which be began to compose, a distinct lyrical faculty: so keen indeed was his car that he became two insistently haunted by the music of others, pre-eminently of Tennysun. But he liad often a true and fine note of his own. His best short poems are "The Metempsychosis of the Pine" and the well-known Bedonin love-song, tho latter a stirring lynic that ought assuredly to endure. In his eritical essays Bayard Taylor had himself in no inconsiderable degree what be wrote of as "that pure pootic insight which is the vital spinit of criticism.' The most valuable of these prose dissertations are the Studics in German Literature.

TAYLOR, Brook (1685-1731), a distinguished mathematician of Newton's school, was the son of John Taylor, of Bifrons House, Kent, by Olivia, daughter of Sir Nicholas Tempest, Bart., of Durham, and was born at Edmonton in Middlesex, Angust 18, 1685 . He entered St John's College, Cambridge, as a fellow-commoner in 1701, and took degrces of LL.B. and LL.D. respectively in 1709 and 1714. Having studied mathematics with applause under Machin and Killl, he obtained in 1708 a remarkable solution of the problem of the "centre of oscillation," which, Lowever, remaining unpublished until May 1714 (Ihi.. Trans., vol. xxviii. p. 11), his claim to priority was unjustly disputed by John Bernoulli Taylor's Methodus Incrementoram Directa et Inversa (Loudon, 1715) added a new branch to the higher mathematies, now designated the "calculus of finite differences." Among other ingenious applications, he used it to determine the form of novement of a vilurating string, by him first successfully reduced to mechanical principles. The same work contained (p. 23) the celebrated formula known as "Taylor's theorem." It is of extensive use in almost every analytical inquiry; but its. full importance remained unrecognized until pointed out in 1772 (Berlin Memoirs) by Lagrange, who later termed it "le principal fondement du calcul différentiel."

In his essay on Linew Perspective (Loudon, 17J5) Taylor set forth the true principles of the art with much originality, and in a more general form than any of his predecessors. The little work suffered, however, from the brevity and obscurity which affected most of his writings, and needed the elucidation bestowed on it in the treatises of Joshua Kirby (1754) and Daniel Fournier (1761).

Taylor was elected a fellow of the Royal Society carly in 1712, sat in the same year on the committee for adjudicating the claims of Newton and Leibnitz, and acted as secretary to the society Jantary $13,1711,10$ October 21, 1718. During a visit to Paris in 1716 he made acquaintance with Bossuet and the Comte de Caylus, and knit a warm friendship with Bolingbroke, whom he visited at La Souree in 1720 From 1715 his studies took a philosophical and religious bent. He corresponded, in that year, with the Conte de Montmort on the subject of Malebranche's tenets; and unfinished treatises, "On tho Jewish Sacrifices" and "On the Lawfulness of Enfing Blood," written on his return from Aix-la-Chapelle in 1719, were afterwards found among his papers. His marriage in 1721 with Miss Brydges of Nallington, Surrey, led to an estrangement from his father, a person of somewhat morose temper, which terminated in 1723 alter the death of the lady in giving birth to a son. The ensuing two years were spent by him with his family at Bifrons, and in 1725 be maried, with the paternal approuation, Saletta, danghter of Mr Sawbridge of Olantigh, Kent, who, by a strange fatality, died also in childbed in 1730 ; in this case, however, the infant, a daughter, survived. Weighed down by repeated sorrows, Taylor's fragile health gave way; he fell into a decline, died 1) ecember 29, 1731, at Semerset House, and was buried at St Ann's. Soho. By his father's deaill in 1729 he
nad inherited the Bifrons estate. Socially as well as intellectually gifted, he possessed a handsome person and engaging manners, and was accomplished to an unconmon degrec in music and paiuting. As a mathematician, he was the only Englishman after Newton and Cotes capable of holding his own with the Bernoullis; but a great part of the effect of his demonstrations was lost through his failure to express his ideas fully and clearly.
A posthunous work entitled Contempratio Philusophica was printed for private cirenlation in 1793 by his grandson, Sir William Young, Bart., prefaced by a life of the author, and with an appendix containing letters addressed to him by Polingbroke, Bossuct, \&u. Severai short papers by him were published in Phil. Traise, vols. xxvii. to xxxii., incluling accounts of somu interesting experineents in magnetisno and capillary attraction. He issued in 1719 an improved version of his work on perspective, with the title Xcho Principles of Linerr Perspective, revised ly Colson in 1719, and printed agziu, with portrait and life of the author, in 1811. A French trauslation appeared in $37 \overline{5} 3$ at Lyons. Taylor wave (dfe. thodus Inerementorm, p. 108) the first satisfactory insestigation ed astronomical refraction.
 Phys. Astronomy, p. ग77; Suliie, Hist. des Seccuces, vil. p. 23il.
TAYLOR, Sir Henry ( $1800-1886$ ), poet and colerial statesman, was born October 18, 1800, at Bishop. Wid dleham, in the county of Dirhan. His ancestors bad beeu small landowners for kome generations, and both his studious father, who late in life cmerged for a time /fom a recluse existence to make an efficient secretary to t, e Poor Law Commission, and his original warm-hearted fother were interesting persons. His mother dicd while ic was yet an infant, and he was chiefly educated by his fatber, who, finding him less quick and deening him less intel ligent than his two elder brothers, allowed him $t 0$ go to sea as a midshipman. Eight months summeri up bis naval career: it had taken much less to dughst him with it. After obtaining his discharge he was appointed to a clerkship, in the storekeeper's office, and liad scarcely entered upon his duties ere he was attacked by typhus fever, which carried off both his brothers, theu living with him in Jondon. In threc or four years more his uffice was abolished while he was on duty in the West Indies. On his return he found his father happily marred to a lady whose interest and sympathy proved of priceless value to him. Through her he became acquainted with her cousin Isabellit Fenwick, the neighbour and intipate friend of Wordsworth, who introluced him to Wordsworth and Southey. Under these influcuces he lest his carly admiration for Byron, whose school, whatever its merits, ho at least was in no way calculated to adorn, and his intel. lectual powers developed rapidly. In October 1822 an article from his pen on Moore's Mrish Mefulters appeared in the Quarterly Revitew. A year later he departed for London to seek his fortune as a man of letters, and met with such mpid success, though not precisely in this capacity, as has but rarely attended au unknown young man. He became editor of the London Mlayazine, to which be bad already contributed, and in January 1821 obtained, through the influence of Sir Jlenry Holland, an appointment in the Colonial Office, insurigg him, not only an ample salary, but considerable influence in this depart ment of public affairs. The gencrnl standard of the office was probably at that time low; at all events Taylor was immediately entrusted with the preparation of conlidential state papers, and his opinion soon exercised an important influence on the decisions of the secretary of state. He visited Wordsworth and Southey, travelled on the Continent with the latter, and at the same time, mainly through his friend and official colleague, the Hou. Hyde Villiers, became intimate with it very different set, the younger followers of Bentham, without, bowever, atop,ting their opinions, -"young men," he aIterwards reminded

Stuart Mill, "who every one aaid would be rained by their independence, but who cinded by obtaning all their hearts' desires, except one who fell by the way." The reference is to Hyde Yilliers, who died prematurely, and for whose sister, afterwards Lady Theresa Lewis, Taylor was an unsuccessful suitor. He actively promoted the emancipation of the slaves in 1833, and became an intimate ally of Sir James Stephen, theno counsel to the Colonial Office, afterwards uuder-secretary, by whom the Act of Emanclpation was principally framed. His first drama, Israc Comnenus, was published anonymonsly in 1827. Though highly praised by Southey, it made little impression on the public. Philip van Artevelde, the snbject of which had been recommended to him by Southey, was begun in 1828, published in 1834, and, aided by a laudatory criticism from Lockhart's pen, achieved extraordinary snccess. Edwin the Fair (1842) was less warmly received. In the interim he had married (1839) the daughter of his former chief Lord Monteagle, and, in conjunction with Stephen, had taken a leading part in the abolition of negro apprenticeship in the West Indies. The Stutesuan, a volume of essays suggested by his official position, had been published in 1836, and about the same time he had written in the Quarterly the friendly advertisements of Wordsworth and Southey, sulsequently published under the somewhat misleading title of Notes frome Books. In 1847 he was offered the under-secretaryship of state, which he declined. Notes fron Life and The Eve of the Conquest appeared in this year, aud Notes, from Books in 1849. An experiment in romantic comedy, The l'irgin Widow, afterwards entitled A Sicilian Summer, was published in 1850. "The pleasantest play I had mitten," says the author ; " and I never could tell why people would not be pleased with it." His last dramatic work was $S t$ Clement's Eve, published in 1862. In 1869 he rras made K.C.M.G. He retired from the Colonial Office in 18i2, though continuing to be consulted by Government. His last days were spent at Bournemouth in the enjoyment of oniversal respect ; and the public, to whom he had hitherto been an-alnost impersonal existence, becane familiarized with the extreme picturesqueness of his appearance in old age, as represented in the photographs of his friend Mrs Cameron. He died on March 27, 1886.
Sur Heury Taylor is pre-eniueutly the statesuan awong Eoglish poets. When he can speak poetically in this claracter he is impressive, almost great; whea he deals with the more prosaic aspects of poliey he is digoificd and weighty, without being altogether a poet, wheu lis theme is entirely nn relatell to the eonduct of public affairs or private life he is usually little noore than an gecomplished man of letters. An exception must he made for the interesting character of Elena in Philip van Artevelde, and for Artevelde's early love explerience, which reproduces and transfigures the writer's own. The circuustance of Philip venh Artevelde beiog to a great extent the velicle of his own ideas and feelings explains its great superiority to his other works. It is suljective as well as objective, and to a certain exteat lyrical io feeliog, though not in foral. Though more elaborate thaa auy of his other dramas, it seems to suell less of the lamp. He Las thoroughly jdentified himself with his hero, and the ooly fault to be found with this nolle picture of a cousummate leader and statesiman is the absence of the shadow required for a tragic portrait. The blame allotted to Aitevelde is folt to he merely couventioual, and the delioeation of uniforn excellence becomes monotouous. The hero of Edwein The Fuir, Dunstan, the ecclesiastical statesnan, the man of two worlds, is less sympathetic to the author and less attractive to the reader. The chazacter is perertheless a fine psychological atudy, and the play is full of historieal if not of dramatic interest. Isacce Comuenus is more Elizabethan io tone than lis other dramas. Coinnenus is like a preliminary sketeh for Yan Artevelde; and the picture of ihe Byzantive court and peoplo is exccedingly lively. The idea of the revival of romantic comedy in The Virgin Widon is exeellent, but the play lacks the humour which might have made it a success. The length of the speeches, even, when not set speccles, is a drawback to all these dramas. Taylor's lyrical work is in general laboriously artificial. It is therefore extraordinary that he slould have produced two songs ("Quoth tongue of neither
mald nor wife" and "If I wad the wings of a dove") whith it would hardly be an exaggeration to call worthy of Slakespuare. His character as au essayist repeats his character as a drannatist. The essays published nuder the title of The Statesmanz oceupy a peculiar place in literature. They bave serions fuults, especially the too obvious initation of Bacon, but they ueverthe less are origiaal in their 1 10int of viev, and their wisdon is the result of a differeut kind of observation from that which qualifies the bulk of essayists on human life. When writing as one of these Taylor is less removed from the commonplaee, though wany of his remarks are admirable. As a literary critic le seenis nnable to get beyond Wordsworth aud the select circle of peets admired by the latter. His essays on Wordsworth did much to digpei the conveutional prejodices of the day, but will not adrance the atudy of the poet where his greatuess is already recognized. His strietures on Byron and Sleelley are narrow and not a little presumptuous. Presump. tion, iodeed, the last fanlt to have been expected in so grave ond measured a writer, is one of those of which he uncst freely accuses hiunself in the autobiography published a year before his death. It is not other vise apparent io this highly interesting book, which, sioning a little by the egotisnı pardonable io a poet and the garrulity uatural to a veteran, is in the main a pleasiug and faillf ful picture of an aspiring youth, an active maturity, and a bappy aud honoured oll age.
(1. G.)

TAYLOR, Isaac (1787-1865), a voluminous writer ou philosophical and theological suljects, was born at Lavenham, Suffolk, in 1787, and was trained by his father to be an artist, but early adopted literature as a profession. From 1824, the year of his marriage, he lived a husy but uneventful life at Ongar, in the parish of Stanfond Pivers, Essex, where he died on June 28, 1865.
He early became a contributor to the Eclectic Revicro, when it was conducted by Robert Hall and Jolu Foster, and in 1892 he published a small volune cntitled Elements of Thought 'Clis was followed by a translatiou of Theophrastus with origioal etcliings, a History of the Transmission of Ancicit Books to DIDdern Tumes, Menoirs and Correspondence of Jane Taylor (his zister, who died in 1821), and a trauslation of Herodotus. None of these works attaiued very great popularity; but in 1829 le published anooymously a work bearing upoa the religious and political problems of the day, eutitled The Natural History of Enthusiusin, which was eagerly read and speedily ran through eight or nine editious. The sucess of this publication encouraged himito produce, also anony. mously, The Natural History of Fanaticism, Spiritual Despotisisn, Scturilay Evening, and The Physical Thcory of A nother Life, all of which conmanded a large circulation. Among his subsequent works may be mentioned Ancient Christianity, , series of dissertations in reply to the "Tracts for the Tines," a volume eutitled The Restorction of Belicf, and a courso of lcetures on The Svirit of Hebrow Poctry.
TAYLOR, Jeremy (1613-1667), was a native of Camtridge, and was baptized on the 15th August 1613. His father, Nathaniel, though a barber, was a man of some education, respected by his tormsmen, and lineally descended from Dr Rowland Taylor, Cranmer's claplain, who suffered martyrdom under Mary. Jeremy, after passing through the grammar school, was entered at Caius College as a sizar in 1626, eighteen months after Milton lad entered Clirist's, and while George Herbert was public orator and Edmund Waller and Thomas Fuller were undergraduates of the university. He was elected a fellow of his college in 1633, but the best evidence of his diligence as a student is the enormous learning of which he showed so easy a command in after years. Accepting the invitation of Risden, a fellow-student, to-supply his place for a short time as lecturer in St Paul's, he at once attracted attention by his remarkable eloquence as well as by his handsome face and youthful appcarauce. Archbishop Laud, ever on the outlook for men of capacity, sent for Taylor to preach before him at Lambeth, and, discern. ing that his genius was worth fostering, dismissed him from the overpressure of the metropolis to the quiet of a fellowship in All Souls, Oxford, and at the same time, by making him one of his own chaplains, showed his desire to keep him in permanent connexion with himself. At Oxford Chillingworth was then busy with his great work, the Religion of Protestants, and it is possible that by intercourse with him Taylor's mind may have beea turned
towards the liberal movement of his age. After two years in Oxford, in March 1638 be was presented by Juxon, bishop of London, to the reetory of Uppingham, in Rutlandshire. In the autumn of the same year ho was appointed to preach in St DIary's on the auniversary of tho Gunpordor Plot, and apparently used the oceasion to clear himself of a suspieion, whieh, however, haunted him throngh life, of a seeret leaning to the Romish communion. This suspicion seems to have arisen chiefly from his intimacy with Christopher Davenport, better known as Franeis a Saneta Clara, a learned Franeiscan friar who became chaplain to Queen Henristta; but it may lave been strengthened by his known connexion with Laud, as well as by his aseetic habits and ritualistie propensities. Hore scrious consequences followed his attachment to the Royalist eause, when in $\mathbf{1 0 4 2}$ the livings of the loyal clergy were sequestered by deeree of parliament. The author of Epiccopracy A ssertecl aguinst the Aerians and Arephati Nern and Old, ineffective as that work seems in the light of modern research, could seareely hope to retain his parish. Along with Fuller, Chillingworth, and others, he found temporary refuge with the king at Oxford. His two little boys must have been eared for by friends, for his wife, Ploebe Langsdale, whom he had married the year after his settlement at Uppingham, had died with ber third child in that disastrous year 1642 .

During the next fifteen years 'Taylor's movements are not easily traced. Sometimes he appears with the king, from whom at his last interview he received, in token of his regard, his watch and some jewels which had ornamented the ebony case in which he kept his Bible. He is supposed to be the Dr Taylor who was taken prisoner with other Royalists while besieging Cardigan castle. In $16 \leq 6$ lie is found in partnership with two other deprived elergvmen keeping a sehool at Newton Hall, in the parish of Llanvihangel. It was while resident here that be attracted the friendship of one of his kindest .patrons, Richard Vaughan, earl of Carbery, whose hospitable mansion, Golden Grovo, is immortalized in the title of Taylor's still popular manual of devotion, and whose ecuntess had the greater distinetion of being the original of tha "Lady" in Milton's Comus. It was also while resident in Tales that Taylor married his second wife, Joanna Bridges, who was generally understood to be a nacural daughter of Charles I., and who orned a good estate, though probably impoverished by Parliamentarian exactions, at Mandiaan, in Carmarthenshire. From time to time he appears in London in the company of his friend Evelyn, at whose table he met sucb men as Boyle, Berkeley, and Wilkius. Thrice he was imprisoned: in 16.53-4 for a well-intended but injudicious preface to his Golden Grove; again in Chepstow castle, from Nay to Oetober 1655, on what charge does not appear; and a third time in tho Tower in 1657-8, on account of the indiscretion of his publisher, Royston, who bad adorned his "Coliection of Offiees" with a print representing Christ in the attitude of prayer. This unsettled life, with its interruptions, harassments, and privations, would seem rather to bave stimulated than to lave stiuted the productiveness of his genius. In 1647 appeared his most important work, The Liberty of Prophesying, and in the following year the complete edition of his Apolony for Authorized and Set Forms of Liturgy ayainst the I'retence of the Spirit, as well as his Life of Chirist, or the Great Excmplar, a book whicb at once won a popularity it still in large nieasure retains. Then followed in rapid suecession tho Twenty-seven Sermons, "for the summer half-year," and the Twently-five "for the winter half year," IFoly Living, [Holy Dying, a controversial treatise on the Real Presence, the Golden Grove, and the Unum Necesarium, whieh by
its Pelagianism gave great offence. During these years be was also busy with his Ductor Dubitantium (pablished in 1660), which be intended to be the standard manual of easuistry and ethics for the Christian people.

In 16.58 settlement was at length reached through the kind offees of the earl of Carbery, who obtained for Taylor a lectureship in Lisburn. At first he de. lined a post in which the duty was to be shared with a l'resbyterian, or, as he expressed it, "where a Presbyterian and myself shall be like Castor and Pollux, the one up and the other dorn," and to which also a very neagre salary was attached. He was, however, induced to take it, and found, near his patron's mansion on Lough Neagl, so congenial a retirement that even after he was raised tn a bishopric he continued to make it his home. At the Restoration, instead of being recalled to England, as be probably expeeted and certainly desired, he was appointel to the see of Down and Connor, to which was shorty added the small and adjacent diocese of Dromore He was also made a member of the Irish privy council and vice-chancellor of the university of Dublin. Nono of these honours were sinecures. Of the unirersity he writes. "I found all things in a perfect disorder . . . a heap of men and boys, but no body of a college, no cne member, either fellow or scholar, having any legal title to his place, but thrust in by tyranny or chance." Accordingly he sut himself vigorously to the task of framing and enforeing regulations for the admission and conduct of mewhers of the university, and also of establishing lectureshins. Ilis episcopal labours were still more arduous There were. at the date of the Tiestoration, about seventy Presligterian ministers in the north of Ireland, and most of these were from the west of Seotland, and were inblucd with the dilike of Episeopacy which distinguished the Covenanting party. No wonder that Taylor, Whiting to the duke of Ormonde shortly after his consecration, should have said, "I perceive myself thrown into a place of torment." His letters perhaps somewhat exaggerate the danger in which be lived, but there is no doubt that his authority was resisted and his overtures rejected His writings al-o were ransacked for matter of aceusation acgainst him, "a committee of Seoteb spiders being appointed to sec if they ean gather or make poison out of them." Here, then, nas Taylor's opportunity for exenplifying the wiso toleration he had in other days inculeated. These Preshyterians had, like bimself, suffered under Cromwe!! for their loyalty, and might lave been expeeted to evoke his sympathy; but the new bishop, had nething to offer them but the bare alternative-submission to episcopal ordination and jurisdiction or dejrivation. Conseguently in his first visita. tion, be deelared thirty-six churehes vacant; and of these foreible possession was taken hy his orders. At the same time many of tho gentry were won by his undorbted sincerity and devotedness as well as by bis eloquence. With the Romanist element of the population he was less successful. Ignorant of the English languace, and firmly attached to their ancestral forms of wor:hip, they were yet compelled to attend a service they considered profane, conducted in a language they conld not understand. As Heber says, "No !!art of the administration of Ireland by the English crown has been more extraordinary and incre unfortunate than the system pursued for the introduction of the lieformed religion." At the instance of the Irish bishops Taylor undertook his last great work, the Dissuasive from /'opery (in two parts. 1664 and 1667), but, as he himself seemed partly conseious, he might have more effectually gained his end by adopting the inctlivds of Trssher and Bedell, and inducing his elerge to acouire the Trish tongue.

Nor were domestic sorrows awanting in thest later scars

In 1661 te buried, at Lisburn, Edward, the only surviving son of his second marriage. His oldest son, au olficer in the army, was killed in a duel; and his secoud son, Charles, intended for the church, left Trinity College aud became companion and secretary to the duke of Buckiugham, at whose house he died. The day after his son's funeral Taylor sickened, and, after a ten days' illuess, he died at Lisburn on the 13th August 1667, in the fifty-fifth year of his life and the seventh of his episcopate.
Taylor's fame has been maiutaiued by the popularity of his sermoos and devotional writings rather tban by his iulluence as a theologian or his importance as an ecclesiastic. His mind was neither seientific nor speenlative, and he was attracted rather to questions of casnistry than to the deeper problems of fiure theology. His wide realing and capacious nemory enabled liin to carry iu his mind the materials of a sound historical theology, but these materials were unsilterl ly criticism. His inmmense learuing served hinn rather as a storehouse of illustrations, or as an aruoury out of which he could choose the fittest weaplou for discomfiting an oproment, than as a quarry furnishing him with material for buikling up a completely designed and enduring edifice of systennatized truth. Iodeed, be had very limited faith in the human mind as an instrument of truth. "Theology," he says, "is rather a diviue life than a divine knowledge." His great plea for toleration is based ou the inpossibility of erecting theolocy into a demonstrable science. "It is impossible all shoull be of one mind. Aud what is impossible to be done is not necessary it slould be done.' Differences of opiniou there must be; but "heresy is not an error of the understanding but an error of the will." His aim in life was practical ; his interests were in men rather than in ideas, and his sympathies were evoked ratlier by the experieuces of indiviluals than by great moveinents. Of a decidelly poetic temperament, fervil and mobile in feeliog, and of a prolific fancy, he had also tho sense and wit that come of varied contact with men. All his zifts were made available for influencing other nifn by his easy command of a style rarely matched in dignity and colour. With all tho majesty and stately elaboration and musical rhythm of Milton's finest prose, Taylor's style is relieved and brightened by in aslonishing variety of felicitous illustrations, rauging froin the most homely and terse to the most dignified and elaborate. His seruens especially abound in quotations and allusions, which have tho air of syoutaneously susgesting themselves, but which must sometimes have bafled his hearers. This seeming pedantry is, lonever, atowed for hy the clear practical aim of his sermons, the nohlte illeal lie keens before his bearers, and the skill with which he landles spiritual experience and uyses incentives to virtuc. But, throngh all his gorgeons eloruence and genial interest in lumunu uature, thicre breaks from time to time some dead and lahoured irrelevaucy, the growth of his training in sclolastic dialectics; for. "like some other writers of the 17th century he seems alwost to have two minils, - one tender, sweet, luxuriunt to excess, the other laral, subtle, formal, proue to definition and logomacly.'
The first collected edition of his works was published by Bishop Heber (with a life) in 1822, reissued after careful revision by Charles Pago Eden, 1852-61.
(M. D.)

TAYLOR, JoHn (1580-1654), commonly called "The Water Poet," was born at Gloucester in Augnst 1580 Of his parentage and early boyhood very little is known, and that little is mainly to be gleaned from various scattered personal allusions in the numerous short writings of this prolific wit and rhynister. After fulfilling his apprenticeship to a waterman, he seems to have served (1596) in the Teet under the earl of Essex, and to have been present at the naval attack upoo Cadiz. On his return to England be took uy the trade of Thames waterman, and for a time at any rate was a collector of the dues exacted by the reutenant of the Torver on all wines destined for fondon. The title of " Water Poet," which he owes to his occupation ou the river, is a misnomer. Taylor was no poet, though he could string rhymes together with facility; his wit, Which was vigorous and vulgar, found lest expressiou in gollicking prose. He shows a lroad sense of rough fun, occasionally of humour ; but for the most part his comicalities would now meet with scanty appreciation. He lad a very good opinion of himself, his writings, and his importance; and it was he himself who set forth that he wes the "king's water poet" and the "queen's waterman." His literary perfurnances can most easily and most
satistacturily he studied in the hardsome qnarto, centaining all his proluctions, tdited by Mr C. Elindley, and published in 18.72. His" "works," sixty-three in number, first appeared in one large volune-unw a rarity souglit after by collectors-in 1630. He delighted in eccentric freaks, calculated in uarration to astound both the sober countryfolk and the somewhat sceptical Londoners. Thus, with a companion as feather-brained as himself, he once started on a voyarfe from Londou to Queenshorough in a paper loat, with two stockfisl tied to two canes for oars ; before the journey's ent was reached the frail boat collapsed, as might have been expected, though a qualified success finally met Taylor's efforts. The spinit of the bargee was in him, aud le delighted in rough give-and-take; a rude lampoon was one of his favourite verbal weapous. Thus Thomas Coryat, the author of Comlitips, baving excited the literary waterman's ridjcule, was rewarded with a ludicrous dedication in the prollaction entitled Taylor's Travels in Germanie; again, the "water puet" indulged in abusive satire to his leart's content in an "effusion" which he called $A$ lircksey- Wiasey, or a Lervy Come-Theony-a literary castigation which he inflicted upoo those subscribers' to a certain "work" of his who omitted to substantiate their promises. This production was entitled The Penuiless I'ilgrimage, or the Moneyless Percurbulution of Johu Traylor, and consisted of an account of its author's pedestrian tour from J.ondon to Edinburgh; and to this work some sixteen liundred persons are said to lave promised their support. Another wasering veuture was a journey to Prague, where he is said to have been received and entertaiued by the sheen of Doheinia in 1620. Two years later Taylor made "a very merry, wherry ferry voyage, or Yorke for my money," and in the ensuing year another water-journey, which he subseguently described in prose and verse as $A$ Nru Discovery by Sut with a IIherry from London to Sulishury. At the outbreak of the Civil War 'Taylor forsook the river and retired to Oxford, where he tempted fort une by keeping a pullicbouse. His sympathies were wholly with the Royalists, -the Roysterists, as he called them once; and, when the town surrendered, the "water poet" returned to London and kept a public-house under the sign of The Crown, in Phœnix Alley, Long Acre. He incurred some odium from his loyal observance of the king's death in the placement above his door of the sign of The Mourning Crown, and he was forced to take the latter down. With claracteristic readiness he substituted for it his own portrait, with some doggerel lines underneath. It was here that in December 1654 lie died, and in the neiglubouring charchyard of St Martin's-in-the-Fields his remaius were laid.
At the most, 'Taylor can only be called an amusiug and vulgarly clever pamphleteer; he wrote nothing wortly of remembrance save by the historian of the period io which he lived, by the autiquary, and by the enthusiastic student of thic many stragorling little by ways of literature.

TAYLOR, Tom (1817-1880), dramatist and art critic, was born at Sunclerland in 1817 . After attending school there, and studying for two sessions at Glasgow unirersitr, he in 1837 entered Trinity College, Cambridge, of which he became a fellow. Subsequently he held for two years the professorship of English literature at University College, London. He was called to the bar (Middle Temple) in November 1845, and went on the nortbern circuit until, in 1850, he became assistant secretary of the Board of Health. On the reconstruction of the board in 1854 he was made secretary, and on its atulition his services were transferred to the Local Government Act Office, a department of the Home Office created by the Sanitary Act of 1866. In his very early years Tom Taylor showed a predilection for the drama, and was in the habit of performing dramatic pieces along with a number of children in a loft
ever a brewer's stable. His first dramatic composition was a rhymed fairy tale or extravaganza, written in conjunction with Albert Smith and Clarles Kenny, and performed in 1846: From this time he wrote for the stage continuonsly till the close of his life, his dramatic compositions or adaptations numbering in all over 100, amongst the best known of which are Still Water Runs Deep, Victins, the Contested Election, the Overland Route, the Ticket of Leave Mann, Anne Boleyn, and Joan of Arc. He may perhaps be regarded as the first dramatist of his time, so far as general appreciation goes; and, if his chief concern was the constrnction of a popular acting play, his dramas possess at the same time considerable literary excellence, while the characters are clearly and consistently drawn, and the dialogue is natural, yet nervous and pointed. In his blank verse historical dramas, such as Anne Boleyn and Joan of Arc, be was not so successful. Taylor was also a very frequent contributor to the light magazine literature of the day. In 1872 he withdrew from puolic life, and, on the death of Shirley Brooks in 1873, he became editor of Punch. He occasionally appcared with success in amateur theatricals, more especially in the character of Adam in As You Like It and of Jasper in A Sheep in Wolf's Clothing. He had some talent for painting, and for many years was art critic to the Times. He died at Lavender Sweep, Wandsworth, 12th July 1880.
Apart from the drama, his chief contributions to literature are his biographies of paiuters, viz, Autobiography of B. R. Haydon (1853); Autobiography and Corrcspondence of C. R. Leslic, R.A. (1859); and Life and Timcs of Sir Joshua Reynolds (1865), which had been left in a very incomplete state by Mr Leslie. His Historical Dramas appeared in one volunie in 1877. He also edited, with a memorial preface, Pen Sketches from a Vanished Hand, selected from Papers of the late Mortimer Collins.

TAYLOR, Zachary ( $1784-1850$ ), prosident of the United States, was born in Orange county, Virginia, November 24, 1784 . He entered the army as lientenant in 1808, and rose to the rank of major jn the war with Great Britain which followed. At the outbreak of the Mexican War he was in command of the American forces in Louisiana and Texas, and was directed to make the advance into the disputed territory which brought on the war. Beating the Mexicans in two battles, he followed them into Mexico, and there defeated Santa Anna in the crowning battle of his campaign, Buena Vista (1847). Dissatisfied with his treatment by the administration, he resigned and retorned to the United States, where the Whig party nominated him and elected him president (1848). The struggle over the question of the admission of slavery to the territory taken from Mexico occupied his term of office, and he died at Washington, July 9, 1850.

TCHERKASY (Polish Czerkasy), a district town of Russia, in the government of Kieff, and 190 miles by rail to the south-east of Kieff, on the right bank of the Dnieper. It is poorly built, mostly of wood; the population has rapidly increased lately, and has doubled since 1846, reaching 15,740 in 1883. There are now two gymnasiums for boys and girls, and several lower schools. The inhabitants (Little Russian) are mostly employed in agriculture and gardening. There is a brisk export trade in corn, refined sugar, tobacco, salt, and timber ; raw sugar and manufactured goods are imported, principally by Jewish merchants.
Tcherkasy, formerly Tcherkassk, was an important town of the Ukraine in the 15th century, and remained so, under Polish rule, until the revolt of Hmelnitski, when it became free. When West Ukraine was taken again by Polanil, most of its inhabitants migrated to the left bank of the Dnieper. It was annexed by Russia in 1795 .

TCHERNIGOFF, a government of Little Russia, on the left bank of the Dnieper, bounded by Moghileff and Smolensk on the N., Orel and Kursk on the E., Poltava on the S., and Kieff and Minsk on the W., has an area of 20,233 square miles. Its surface is an undulating. plano, 650 to 750 feet high in the north, and from 370 to 600 feet in the south, deeply grooved by ravines and the valleys of the rivers. In the north, "beyond the Desna," about one-third of the area is under wood (which is rapidly disappearing), and marshes occnr along the conrses of the rivers; while to the south of the Desna the soil is dry, sometimes sandy, and assumes the characters of a stcppeland as one proceeds southward. Chalk deposits prevail in the north, and Eocene in the south. The goverument is watered by the Dnieper (which forms its western boundary for 178 miles) and its tributaries the Soj and the Desna. The latter, which flows through Tchernigoff for nearly 350 miles, is navigable, and timber is brought down its tribntäries. Corn, linseed, timber, brandy, hemp, and sugar are shipped on the Dnieper, Soj, and Desna, and salt imported. The climate is much colder in the woody tracts of the north than in the south; the average yearly temperature at the town of Tchernigoff is $44^{\circ}{ }^{\circ}$ (January, $23^{\circ}$; July, $68^{\circ} 5$ ).
The population, which is rapidly increasing, reached $1,996,250$ in 1883. It is chiefly Little Russian ( $85 \cdot 6$ per cent.); Great Russians ( 6.1 per cent.), mostly Raskolniks, and White Rnssians ( 5.6 per cent.) inhabit the northern districts. Jews have spread rapidly since last century, and now number more than 45,000 . There are, besides, some 20,000 Germans as well as Greeks at Nyczhin. Agriculture is the principal occupation; in the north, however, many of the inhabitants are enggged in the timber trade and various domestic industries. Catelle-breeding. is carried on in the central districts, and there were in 1883 572,200 horses, 515,300 cattle, and 948,000 sheep. Beet is extensively cultivated, and in 1884 2 nillion cwts. of beet-root were delivered to the thirteen sugarworks within the gevernment. The culture of tobacce is also increasing, upwards of $500,000 \mathrm{cmts}$. being produced annually. Hemp is widely cultivated in the north, and the milder climate of the sonth encourages gardening. Bee-keeping is extensively earried on by the Raskolniks. Tar, pitch, and a large variety of wooden manufactures are largely produced in the forest districts, as a.so are woven fabrics, felts, and leather wares. Limestone, grindstones, china-clay, and building stone are quarried. Mannfactures have begun to develep rapidly of late; by 1881 their yearly production reached $£ 1,340,000$ ( $£ 860,000$ from sugar-works and distilleries). Trade is active, especially since the opening of the railway between Kieff and Kursk, which runs through Tchernigoff. The government is divided into fifteen districts, the chief towns (with populations in 1885) being Tchernigoff (19,000), Borzma (13,700), Glukhoff ( 16,450 ), Gorodnya ( 3550 ), Konotop ( 16,420 ), Kozelets (4430), Krolevets ( 9190 ), Mglin (10, 880), Novgorod-Syeversk (8020), Novozybk off (11,920), Nyezhin (43,020), Oster (3550), Sosnits3 (5650), Starodub (23,890 in 1880), and Surazh (3770). A number of unimportant towns ( 14 posads and 49 myestech $k i$ ) possess muni. cipal institutions.

TCHERNIGOFF, capital of the above government, stands on the right bank of the Desna, nearly half a mile from the river, 476 miles from Moscow. Far removed from the great channels of trade, its sole importance is as an administrative centre. Its honses are poorly bnilt, and the streets are unpaved. The population ( 19,000 in 1885, one-third being Jews) is almost stationary. The ruins of its fortress, and the old cathedrals of Preobrazhenie and Borisoglebsk, founded in the 11 th and 12 th centuries, bear witness to the former importance of the town. Numerous graves scattered about, and now partly explored, speak of the battles which caused its decay.
Tchernigoff is known to have existed before the introduction of Christisnity into Russis. In 907 it is mentioned in the treaty. of Oleg as next to Kieff, and in the 11th century it became the capital of the principality of Syeversk and an important commercial city. Tbe Mongolian invasion put an end to its growth. Lithnania annexed it in the 14th century, but it was soon seized by Poland, Which beld it ontil the 17 tT century. The great rising in 1648 rendered it independent nutil 1654, when the Cossacks accepted the protectorate of the czars of Mescow. In 1686 it was definitely annexed to Rustia

TCHERNOMORSK, a gevernment of Caucasia, Russia, consisting of a narrew strip of land betwcen the main Caucasus chain and the Black Sea, formerly inhabited by the Adyghe mountaineers of Caucasus. This strip, protected by the mountains from the cold winds of the north; is in respect of climate one of the most favoured parts of the Black Sea littoral. Owing to extensive emigrations of its inhabitants to Turkey since the Russian conquest of 1864 , it is very thinly peopled, the population numbering but 25,980 , mostly Russians, on an area of 2824 square miles. The steep slopes of the Caucasus, whose summits range from 2000 to 10,000 feet, are furrowed by narrow gorges, and bear a luxuriant vegetation. The wild vinea relic of former gardens-grows freely in the forests, which are almost impassable on account of the underwood and decaying trees. The moistness of the atmosphere contributes to the spread of the Caucasian fever, which is characteristic of the littoral. Notwithstanding the proximity of the mountains to the sea, a road is now being constructed along the coast,-for military reasons.

Agriculture is carriod on, but only in the south,-gardening and the culture of the rine and tobacco being the chief occupations besides fishing and hunting. Some manufactures are rising up at Novorossiysk (3330 inhabitants) and 'Anapa (5350), the two prin. cipal towns, which also have some foreign trade. The rogion is a separate province under a military governor residing at Novorossiysk, where a new harbour is being constructed.

TCHISTOPOL, a district town of Russia, in the government of Kazain, 90 miles to the south-east of that fown, on the left bank of the Kama Before 1781 it was a mere village (Tchistoye Pole), founded by runaway eerfs ; at present it is extending rapidly and becoming an industrial town, with flour-mills, distilleries, and a few cotton-mills. The merchants carry on a brisk trade in corn brought in from the fertile tracts of Ufa, and shipped down the Kama; manufactured wares are imported. The popalation in 1883 was 18,200 .

TCHITA, capital of Transbaikalia, Eastern Siberia, stands 585 miles east of Irkutsk, on the Tchita river, half a mile above its junction with the Ingoda. It was founded in 1851 ; and military considerations led to the selection of this very small village to be the capital of Transeaikalia. Steamers on the Amur and Shilka do not penetrate so far as the upper Ingoda; they usually stay at Sryetensk, 320 miles distant. But the military supplies sent every year from Transbaikalia to the Amur region usually start from Tchita, - the forest-covered hills on the banks of the Ingoda supplying material for the construction of the barges (from 100 to 200 in number) on which these sup)plies are carried as soen as the melting of the snows in the mountains temporarily raises the water in the river to a sufficient height. Tchita is built of wood, with unpaved strcets and wide open spaces. The dryness of the Buriat steppe close by prevents snow from accumulating to any depth, even when the cold is extreme; the merchandise accordingly which is forwarded from Irkutsk to the Nertchinsk district is brought to Tchita on carts, and is there loaded on sledges for the continuation of the journey down the frozen rivers. The population of Tchita in 1883 was 12,600 . The inhabitants support themselves by agriculture, by trade in furs, cattle, hides, and tallow, which are bought from the Buriats, and in all kind of manufactured wares imported from Russia and Western Siberia.

TEA. This important food auxiliary, now in daily use as a beverage by probably one-half of the population of the world, is prepared from the leaves of one or more plants belonging to the natural order Ternströmiacex. The order includes the well-known ornamental genus of shrubs Camellia, to which indeed the tea-plants are so closely allied that by many systematic writers they are
included in the same genas. The tea-plants have been cultivated in China for at least a thousand years.

As is commonly the case with plants which have been long under cultivation, there is much doubt as to specific distinctions among the varieties of tea. Under the name of Thea sinensis, Linnæus originally described tea as a singlo species; but with fuller knowledge of the Chinese plants he established two species, Thea Bohea and Thea viridis, and it was assumed that the former was the source of black teas, while Thec viridis was held to yield the green varieties. In 1843, however, Mr Robert Fortune found that, although the two varieties of the plant exist in different parts of China, black and green tea are mado indiffereutly from the leaves of the same plant. The teaplant is cultivated in China as an evergreen sbrub, which grows to a beight of trom 3 to 5 feet. The stem is bushy, with numerous and very leafy branches; the leaves are alternate, large elliptical, obtusely serrated, veined, and placed on short channelled foot-stalks. The calyx is small, smooth, and divided into five obtuse sepals. The flowers are white, axillary, and slightly fragrant, often

F1a. 1.-Tea-Plant (Thea sinensis).
two or three together on separate pedicels. The corolla has from five to nine petals, cohering at the base. The filaments are short, numerous, and inserted at the base of the corolla; the anthers are large and yellow, the style trifid, and the capsules three-celled and three-sceded.

The viridis varieties are hardier, and possess larger and brighter green leaves than belong to the Bohea variety. No strictly wild tea-plants have been discovered in China, but an indigenous tea-tree (Thea assamica) is found in Assam, which botanists now incline to regard as the parent species of all cultivated varicties. It differs in many respects from the Chinese plants. The indigenous Assam tea-plant is a tres attaining a hoight of from 15 to 20 feet, growing in the midst of dense moist jungle and in shady sheltered situations, Its leaves vary considerably in size, form, and venation, being usually amooth, thick, and leathery, lanceolate, ovate lanceulate, or oblong lanceolate. They are varionsly dotted with pellucid cells containing essential oil, and the number of such cells shown by the leaf is held to be an indication of the quality of tea it will yield. The leaf of the Chinese plant never exceeds 4 inches in length, while that of the Assam tree reache

9 inches and upwards. The Chinese plant is hardy, and capable of thriving under many different conditions of climate and situation; while the indigenous plant is tender and difficult of cultivation, requiring for its success a close, hot, moist, and equable climate. The characteristic venation of the leaf of the Chinese tea-plant is delineated in fig. 2. In minute structure the leaf presents highly characteristic appearances. The under side of the young leaf is densely covered with fino onecclled thick-walled hairs, about 1 mm . in length and 015 mm . in thickness. These hairs eutirely disappear with inereasing age. The structure of the epidermis of the under side of the leaf, with its contorted cells, is represented ( $\times 160$ ) in fig. 3 . A further characteristic feature of the cellular structure of the tea-leaf is the abundance, especially in grown leaves, of large, branching, thickwalled, smooth cells (idioblasts), which, although they occur in other leaves, are not found in such as are likely to be confounded with or substituted for tea. The minute structure of the leaf in section is illustrated in fig. 4.

The cultivated varietios of tea,
 being comparatively hardy, possess an adaptability to climate excelled among food plants only by the wheat. The limits of actual tea cultivation extend from $39^{\circ} \mathrm{N}$. lat. is Japan, through the tropics, to Java, Australia, Natal, and Brazil in the southern hemisphere. The tea-plant will even live in the open air in the sonth of England, and withstand some

amount of frost, when it receives sufficient summer beat to hardén its wood. But comparatively few regions are suited for practical ter-growiag.

A rich and exuberant growth of the plants is a first essential of successful tea cultivation.. This is only obtainable in warm, moist, and comparatively equable climates, where rains are frequent and copious. The climate indeed which favours tropical profusion of jungle growth-still steaming heat-is that mos: favourable for the cultivation of tea, and such climate, unfortunately, is most prejudicial to the health of Europeans. It was formerly supposed that comparatively temperate latitudes and steep sloping ground afforded the most farourable situations for teaplanting, and much of the disaster which attended the early stages of the tea enterprise in India is traceable to this erroneous conception. Tea thrives best in light friable
scils of good depth, through which water percolates freely. the plant being specially impatient of marshy situations and stagnant water. Undulating well-watered tracts, where the rain escapes freely, yet without washing away the soil, are the most valuable for tea gardens. As a matter of fact, many of the Indian plantations are established on hill-sides, after the example of known districts in China,

Fio. 4,-Section through Tea-Leaf. where hill slopes and odd corners are commonly occupied with tea-plants.

According to Chinese legend, the virtues of tea (cha, pronounced in the Amoy dialect té, whence the English name) were discovered by the mythical emperor Chinnung, 2737 в.c., to whom all agricultural and medicinal knowledge is traced. It is doubtfully referred to in the book of ancient poems edited by Confucius, all of which are previous in date to 550 B.C. A tradition exists in China that a knowledge of tea travelled eastward to and in China, having been introduced 543 A.D. by Bodhidharma, an ascetic who came from India on a missionary expedition, but that legend is also mixed with mythica! and supernatural details. But it is quite certain, from the historical narrative of Lo Yu, who lived in tle Tang dynasty (618906 A.D.), that tea was already used as a beverage in the 6 th century, and that during the 8 th century its use had become so common that a tax was levied on its consumption in the 14th year of Tih Tsung (793). The use of tea in China in the middle of the 9 th century is known from Arab sources (Reinaud, Relation des Voyages, 1845, p. 40). From China a knowledge of tea was carried into Japan, and there the cultivation was established about the beginning of the 13 th century. Seed was brought from Ching by the priest Miyoye, and planted first in the south island, Kiushiu, whence the cultivation spread northwards till it reached the high limit of $39^{\circ} \mathrm{N}$. To the south tea cultivation also spread into Tong-king and Cochin China, but the product in these regions is of inferior quality. Till well into the 19 th century it may be said that China and Japan were the only two tea-producing countries, and that the product reached the Western markets only through the narrowest channels and under most oppressive restrictions.

In the year 1826 the Dutch succeeded in establishing tea gardens in Java. At an early period the East India Company of Great Britain, as the principal trade intermediary between China and Europe, became deeply interested in the question of tea cultivation in their Eastern possessions. In 1788 Sir Joseph Banks, at the request of the directors, drew up a memoir on the cultivation of economic plants in Bengal, in which he gave special prominence to tea, pointing out the regions most favourable for its cultivation. About the year 1820 Mr David Scott, one of the Company's servants, sent toleutta from tho district of luch Behar and Rangpur-the very district indicated by Sir Joseph Banks as favourable for tea-growing-certain Ieaves, with a statement that they were said to belong to the wild tea-plant. The leaves were submitted to Dr Wallieh, Government botanist at Calcutta, who pronounced them to belong to a species of Camellia, and no result followed on Mr Scott's communication. These very leaves ultimately came into the herbarinm of the Linnean Society of London, and bave authoritatively been pronounced to belong to the indigenous $\Lambda$ ssam teaplant. Dr Wallich's attribution of this and other specimens
subsequently sent in to the genus Camellia, although scientifically defensible, unfortunately diverted attention from the significance of the discovery. It was not till $183 \pm$ that, overcome by the insistance of Captain Francis Jenkins, who maintained and proved that, called by the name Cumellic or not, the leaves belonged to a tea-plant, Dr Wallich admitted "the fact of the genuine tea-plant being a native of our territories in Upper Assam as incontrovertibly proved." In the meantinie a committee had been formed by Lord William Bentinck, the governorgeneral, for the introduction of tea culture into India, and an official had already been sent to the tea districts of China to procure seed and skilled Chinese workmen to conduct operations in the Himalayan regions. The discovery and reports of Captain Jenkins led to the investigation of the capacities of $A$ ssam as a tea-growing country by Lord William Bentinck's committee. Evidence of the abundant existence of the indigenons tea tree was obtained; and the directors of the East India Company resolved to institute an experimental establishment in Assam for cultivating and manufacturing tea, leaving the industry to be developed by private enterprise should its practicability be demonstrated. In 1836 there was sent to London 1 lb of tea made from indigenous leaves; in 1837 5 H of Assam tea was seut; in 1838 the quantity sent was twelve small boxes, and ninety-five boxes reached Loudon in 1839. In January 1840 the Assam Company was formed, and thenceforward the cultivation of tea in India was carried on as a private commercial undertaking. The tea districts of India include, in the order of their priority, Assam, Delra Dun, Kumann, Darjiling, Cachar, Kangra, Hazaribagh, Chittagong, Tarai, and the Nilgiris (MIadras).

Attempts were repeatedly made to introduce tea culture in Ceylon, under both Dutch and British authority. No permanent success was attained till about 1876, when the disastrous effects of the coffee-leaf disease induced planters to give serious attention to tea. Since that period the tea industry has developed in Ceglon with marvellons rapidity, and it has every frospect of taking the first rank among Singalese productions. Tea-planting has also been successfully established in Natal. But beyond the regions above enumerated the industry has never taken root. It bas been tried in the West Indies, the Sonthern States of America, Brazil, Anstralia, and the south of Europe ; but cheap labour is a sine qua non of success. Tea can be picked in China and the British East Indies for two or three pence a day of wages, and it is on such exceedingly moderate outlay that the margin of profit depends.

Tea is more or less cultirated for local consumption in all provinces of China except the extreme notth, but the regions from which it is exported are embraeed within the provinces in the south-cast-Kwang-tung, Fuh-keen, lieang-se, Che-keang, Keangsu, anll Gan-hwuy. Black-tea uanufactire beiongs to the more southerly portion of these regions, the green-tea comntry lying to the north. The methods emploved in cultivatiug the plants and ta making tea in China differ widely in various districts, and the teas retained for native use-especially the high-class fancy teas which are -never seen abroad, and would probably not bear ex-portation-undergo special manipulatiou. The teas exported are of three principal classes-black tea, green tea, and brick tea.

In cultivation, the young plants are not realy for picking till they are three, years old, by which time they should be well astablished, throwing out young shoots or "finshes" with vigour and profusion. It is these tender shoots, with leaf-buds aud expanding leaves, which alone are gathered for tea manufacture, and the younger the leaf-bud the better is the quality of the tea. According to Chinese statements there are four gatherings of leaves in the year. The first is made early in April, when the young leaf-buds are just unfolding, and these, covered below with their fine silky hairs, are taken for making pekoe or young hyson. The second gathering takes place about the beginuing of May, another in July, aud the fourth in August and September. On each succeeding occasion the product is less fragrant and raluable, and the final gathering is aaid to consist of large leaves of little value. These statements do not, however, accord with Indian experience.

The folloming bricf outline of the Chinese tea-making processes is given by Mr Ball (Cultization end Manufacture of Tea):-
"The leares of lack tea are exposed to the sun and sir on circular traye and treated as hay, during whisch an incipicne anceliarlne fermentatlon iv supposed to take place in conjunction with a volatile oil. Varrous modntcations of farour are thus produced by the management of this fermenration; a loss of pannin takes place by the conversion of part of the tannic acit into sugar. Doring this change the leaves become flaccid, and slightity tinged or spened with rel or brovn colouring matter, and give ont a peculiar odour, approximating ro, or, as some think, dentjeal with. the odour of tea. A certaln change in this odour s carcfulty warcied by the workmen, this being an indication that the rwasting must not bo delayed. It is not necessary to wait till the leores ave spotted with red. They
 ean be cxpressed from the leaves in the act of rolling. jimally, they are dried in sieves pliced over n charcoal fire in drying tubes, during which the leares aro necasionally talsen from the firc, and surned until completely dried. It is in this last stage of the process that the leaves tum black, though this cliange of colour is inainly dite to thic pacecse of manlpulation previously to rossting, and not to the uction of heat."
"The leares of green tea arc roasted also In an lron ressel, hat as soon as gathered, without any previous manipulation, all heating or fermentallon of the lespes being ssudlously avoisled; they uro then rolled is black tea, and finally dried in the same vessel in which they have beeo roasted, by constantly stiming and mosing them aboat. They are also fanned to hasten ernporaton, and the drying and formation of the peculiar characteristic colour of this iea, which it
gradnaily acquires in this process, and which resembles thic bioom on somo graduail
fruts."

The colour of genuine green tea is entirely due to the rapil drying of the fresh leares, whieh prevents the chlorophyll from undergoing any alteration. The greeu tea sent out of China is almost invariably faced or glazed with artificial colouring matter, priucipally with a powdered mixture of gypsum and Prnssian blue.

The names distinguishing commercial qualities of tea are almost eutirely of Chinese origin. Iu general they indicate a gradation of qualities from the fine and delicate product of the young leaf. bud ap to the hard and woody expanded and partly-grown leaf. The following list represeats the ordinary series of qualities, beginuing with the finest:-
Black: Tca.-Flowery pekoe, orange pekoe, pekoe, pekoe souchong, souchong, congon, bohea.
Grecn Tca.-Gumpowder. imperial, byson, young hyson, hyson skin, caper.

Of these names, pelioe is derived from pak-ho (wbite hairs), tho pekoes showing the fine downy tips of the young buds; souchong is from siaou-chung, little plant or sort; congon (hung-fu), labour; bobea (uru-i), the mountaius in Ful-been, the centre of the black-tea country; and hyson (yii-tsien), before the rains, or tu-chun, flourishing spring. Mlany other names occur in the trade denoting teas of special qualities or districts, such as oelong (black dragon) and twankay, from the district of that name in the province of Feangsu. Seented teas also-form a special class of Clinese produce. In scentiug the fimisherl tea, either black or green is intimately intermixed with odoriferous flowers and leftin a heap till the tea is fully impregnated with the odour, when the qwo substances are separated by sifting, and the tea so scented is immediately packed and excluded from the air.

Brick tea is the speeial form in which tea is prepared for use throughout the vast traets of Central Asia. It is made prineipally from broken leares, stalks, and fraginents of large learcs, conipressed into blocks of various sizes. The bricks are of rarious degrecs of compression, some being lightly squcezed into a loose mass and served up in cowhide bars, while others form compact resomant cakes, in which all trace of the original leaf structure is lost, with gilt characters impressed in their surface. Lrick toa is much in demaid over an area greater than the whole of Europe, amel by many tribes, it is stewed with milk, salt, and butter or other fat and eaten as a vegetable. The Pussian factors establishacl in Hoo-pilh prepare two sizes of brick tea, which they send ofl in great quantities throngli the lialgan Gate of the Great Wall.
Under European supervision the cultivation and especially the manufacture of tea have in India undergone remarkabic improvements. Indeed, the traditional and empinical teaching and proeesses of Clina proved a most serious stumblingblock to the progress of the tea industry under Western anspices. The tea plants now, cultivated in India are of three principal classes-the indigenous Assam, the Clinese, and a hy brid between the taro. 1:y much crossing aud intermixture the gradations from one extreme to the other are almout impercentible. The best qualities of hlack teas are inade from indigenous and high-class hybrid lilants, luat these are comparatively thuler and rexuire a close humid elimate. Tho hardiness of the Chinese plants is their most innortant clanaretur, for, favomably sitnated, the Assam plant gives a larger yi $1 / d$ of delicate young leaf during the season than any other.

In farourable circumstances thie" tea-plant "flushes" or sende forth a fresh rrep of teader youns shoots from twenty to whentyfive times in the course of its growing and pieking scason of about wine months. The averane annual yield per juant is very variahle; but mas be stated at about one-firth of a ith of finishod tea; and, as each acre of a garden holds 1500 to 1600 maturo flants, the yifld per ocre may be from 300 to 350 th pice annum. The diagram (fig. 5) from Col. Moncy's valuable jractical treatise on tho C'ultio
oation and Manufacture of Tca illustrates the method in which a Aush or shoot is picked, and the portions which go to make special classes of tea. The lines in the diagram show the points at which the shoot may be picked, and it is important that the lowest leaf taken should be 60 nipped off as to leave the bud in its axil aninjured on the branch, as from it the uext flush will then develop. The three leaves at the growing point $(a, b, c)$ yield peloe, and the whole shoot down to and including $f$ gives pekoo-souchong. Ia the order of their age, the individual leaves manufacture into a flowery pekoe, $b$ orange pekoe, $c$ pekoe, $d$ pekoe bouchong, e souchong, and fcongou. Were the flush further developed another

Fig. 5.-Mode of Picking Tea
leaf might be taken, which wonld be classed as bohea, but that is not a quality recognized by Indian growera. It is not, however, the practice to pick or treat leaves separately, the whole flush being manipulated together, and the tea is only separatcd into qualities by sifting after the nanufacturing processes have been completed.

The manufacture of black tea is found to be an essentially simple matter. Many of the processes employed by the Chinese are quite superfluous, and eeveral of the manual operations which bulk largely in the Chinese manufacture, it is found, can with advantage be supplanterl by mechauical agencr. The whole object of the black-tea manufacturer is to ferment, roll, and dry the leaf, and for that purpose the leaves undergo-(I) withering, (2) rolling, (3) fermenting, and (4) fring or dholing. Between the fermenting and the firing operations it is desirable to expose the leaves to the direct sunlight for an hour or thereby. This cannot alwaye be done, as it is impossible to keep the fermented leaves after they have attained their proper state; nevertheless the best result is always attained in bright weather, when it is possiblo to expose the fermented leaves to the sun.

The fresh leaves from the garden, as they are brought in Eo the factory, are withered by being spread evenly over square wickerwork trays-leaf challanies-thickly or thinly as the weather is bot or cool. Thus they are left exposed to the air till they become quite soft sud flaccid, folding together when pressed in the hand into a clammy inass without crackling or rebound. In cloudy or rainy weather it becomes uecessary to wither by machine, acting on the leaves with artificially dried and heated air. Withering is a preliminary to rolling, in which the flaccid and velvety leaves are kneaded, twisted, and rolled back and forward over a table till the whole comes into a mashy coadition by the exudation of juice. While in Chinese ter-making that juice is squeezed out of the leaves, in India it is most carefully lapped up and absorbed in the spongy mass. In band-rolling as much as can be worked betweeu two hands is operated on, and passed from man to man along the table till fully worked, when it is made up into a compressed ball and so put aside for fermenting. This procese is the distinguisbing featare of black-tea making, and on its sufficient accomplishment depends much of the character and quality of the tea made. The piogress of the fermentation must be carefully watched, and at the point when by the colour it is known to be sufficiently advanced the tea is in favourable weather sunned by exposure, thinly epread out to the sunlight for about an hocr. It is immediately thereufter fird, either by the fumes of burning charcoal or by a current of dried and heated air from ono of the numerous machines non in use. With this single firing the process is completed, and the tea so finished is sifted by machinery into commercial qualities according to the size of the leaf.
For the entire range of manufacturing operations nnmerons forms of machinery and mechanical devices bave been adapted and intro. duced 11 Indian gardens, so that, apart from picking the leaves, tea-making las becoue practically a factory industry.
The manufacture of green tea is comparatively little prosecuted in ludia. In Europe the demand bas greatly fallen away, and, thongh the consumption is considerable in the United States, the zapply is principally drawn from Japan, where its preparation is
extensively practised. The manufacture as carried on in the Norin Western Provinces resolves itself into a rapid rolling and drying of the leaf. Withont permitting the leaves to wither after gathering, they are, if free from moisture, at once hy exposure to e brisk heat oweated and aoftened for rolling. They are then without delay rolled as in black-tea manufacture, next spread out in the suu till they take a blackish tinge, then again rolled, and this rolling and exposure may be repeated yot a third time. When the rolling i: completed the tea is placed in a highly heated pan, in which it is otirred about briskly till the whole mass becomes too hot to be worked by hand. Then it is tightly packed in a strong canvas bag, in which it is besten by a heavy flat stick to consolidate it, and in this condition left for a night. Next day it is fired off iu a pan, beginning with a high heat, which is gradually reduced during the nine hours or thereby of the operation, an incessant atirring and tossing being kept np the whole time. During this firing oll the green colour of the tea is developed; and Indian green tea never owes any of its colour to "facing" with foreign substances.
The qualities of a sample of tea and its commercial value can only with accuracy be determined by actual infusion and trial by a skilled tea-taster. Certain general and extermal appearances which indicate the class of a tea are obvious enomgh, out, although a pekoe may be readily distinguished from a souchong, the souchong of certain planters or districts may be more valuahle than other pekoes. While it is impossible to defne the conditious which determine the commercial value of an ordinary black tea, Col. Money lays down the following rules: the darker the liquer the atronger the tea, and the nearer the approach of the infused leaf to a uniform salmony brown the purer the flavour. Black tea of good quality should in infusion yield a clear bright brown liquor emitting a subdued fragrance, and in tasto it ehould be mild, bland, and sweetish, with an agreeable astringency. Green tea yields a light-coloured liquor of high fregrance, but thrn, sharp, and somewhat rasping in taste as compared with black tea.

The chemical components of tea leaves are essential oil, theine tannin, boheic acid, quercetin, quercitannic acid, gallic acid, oxal c acid, gum, chlorophyll, resin, wax, albuminoids, colouring matterg, cellulose, and mineral ash. Of these the first three-essential ail, theine, and tannin-are of importance in the infused beverage. The esseutial oil, on which the flavour of tea depends, is present to the extent of from 0.5 to 1 per cent. Theine $\left(\mathrm{C}_{6} \mathrm{H}_{30} \mathrm{~N}_{4} \mathrm{O}_{2}\right)$ is an alkaloid identical with the caffene obtained from coffee, and it is remarkable that the same substance is yielded by the mate or Paraguayan tea and the guarana of South America, and ly the kola nut of Ceutral Africa. The theobromine of cocoa is also closely allied to theine, and the characteristic components of the extract of meat similatly show certain points of contact with these stimulent bodies. 'lo the tamin of tea jufusions is due what is known as the strength of the tea. Prof. Dittmar has recently examined a number of China amd Indian teas in regard to the proportions of theine and tamiu in their infusions and to the dependence of these proportions on the time of infusion. Tlee general result was that Chinese tea yields more theine and less tanuin than Indian tea, and that in both cases 10 minutes' infusion extracte practically all the theine. Loncer infusion adds only to the tannin that passes into the oolution, and, ss excess of tannin impedes diges. tion, prolonged infusion is burtfinl and onght to be avoided.
The quantitative compositiou of tea is of course subject to great variation. The analyses by Mul. der giveu in the accompanying table furnish a general iden of the pioportion of constitnents.
A series of investigations into a large number of teas has been carried out by Mr G. W. Wigner (Pharm. Jour., 3d 6eries, vi. 261, 281, 402). In tea as imported he found large proportions of moisture which could be expelled on exposure to a temperature of

|  | Hyson. Green. | Congon. Black. |
| :---: | :---: | :---: |
| Volatile oil | 0.79 | $0 \cdot 60$ |
| Chloropbyll ........ | 2-22 | 1.84 |
| Wax. | 0.28 | $0 \cdot 00$ |
| Resin.. | $2 \cdot 22$ | 3.64 |
| Gum. | 8.56 | $7 \cdot 28$ |
| Tannin | 17.80 | 12.88 |

| Extractive matter. | 22.80 | $21 \cdot 36$ |
| Colouring matter... | 23.60 | $13 \cdot 12$ |
| Alburacs. | $3 \cdot 00$ | $2 \cdot 80$ |
| Woody fib | $17 \times 08$ | $28 \cdot 32$ |
|  | $98.78{ }^{2}$ | $98.30^{2}$ | $212^{\circ} \mathrm{F}$. In a range of thirty-five samples the average moisture wss equal to 7.67 por cont., the lowest-in a Chinese young bysonbeing 4.84, while in several congous it exceeded 10 per cent. Tho ash in sixty-seveu specimens of ordinary and special (rindried) teas he found to average 5.78 per cent., the maximum being 7.02 and the minimum $5 \cdot 17$; and of that ash $54 \cdot 50$ per cent. was soluble in water. The propurtion of extractive substances ju twenty four teas varied from 26.15 in a congou to 44.85 in Moyume young hyson. The total average nitrogen from sixty green teas, slightly faced, was $3 \cdot 76$, from sixty black teas $3 \cdot 26$, from six Assam tcas $3 \cdot 64$, and from exhausted leaves 3.80 per cent.

So long as the Western world remained almoet exclusively
1 Tha theine la certainly understated; more recent observera obtain from 1 : 8 to 3 per cent., and occadionally more.
0,2 The mineral ealts (ash) partly included In these totals amonntel to $5 \cdot 85$ and 5.21 respectively
depeadent on China for its tea supply, adulteration was rampant and multiform in the trade. Especially among green and fancy teas there was ecarcely such a thing as an unsophisticated sample to be obtained. The Chinese were also expert in fabricating in artificial gunpowder-appropriately known as "Ite tea,"-which conaisted of the sweepings of tea warehouses artfully made np with a paste of rice water. Paddy husks and many kinds of leaves faced with China clay, boapstone, catechu, and black lead also found their way abundantly into tea. On the European side, exhausted leaver were again dried, impregaated with catechu and gum, and faced up to do duty os fresh tea, and the leaves of numerous plants -sloe-thorn, hewthors, willow, beech, plane, Epilobium angustifolium, \&c.-were freely worked up as tea. $\Lambda$ dalterated tea is now, however, comparatively rare, largely owing ta the watchfulness of the customs authorities. Moreover, as it is ncarly as cheap to make tea from the leaves of the tea-plant as from those of any ather herb, thero is not much incentive to substitute the false for the real.

At a very early period in the European history of tea the probable effects of its use an the health and morala of the population attracted jealous attention, and a great deal was written, mostly in 3 hostile sense, on the subject. In 1678 wo find Mr Henry Savile writing to his uncle, Mr Secretary Coventry, in oharp reproof of certain frionds of his "who call for tea, instead of pipes and bottles after diuner, - a hase unworthy Iucian practice, which I must cver adnire your most Christian family for not admitting." And he adds, with an andible sigh, "the truth ia, all nations are srowing so wicked as to have some of these filthy customs!" Some of the writers, however, although resolute for its baoishment from tho caddy, were willing to give it a place in tho medicine chost. "Among many otlier novelties," saye a medical writer in 1722 , "there is one which seems to be particularly the cause of the Lypochondriac disorders, and is menorally known by the nanie of thea, or tea. It is a drug which of late years has very much iosinuated itself, as well into our diet as regales and entertainnents, though its occupation is not less destructive to the animal economy than opium, or some other drugs which we have at present learned to avoid. "i Dr Lettsom was the first medical writer who gave the public a ressonable and scicatific account of the plant; but eren he let the fear of its aluse ran away with his judrment, assertiug that "the first rise of this pernicious custom [that of drinking 日pirits to excess] is often owing to the wealness and debility of the system brought on by the daily habit of drinking tea; the trembling hand secks a temporary reliof in some cordial, in orler to refresh and excite again the enfeebled eystem, whereby such parsous almost necessarily fall iuto a hahit of intomperance." ${ }^{2}$ Jodas Haaway (Essay on Tca, 1756) was among its most vigorous assailants. "Men," be says, " seem to have lost their stature and comeliness, and women their leanty . . . . . What Shakespeare ascribes to the concealment of "love is in this age more frequently occasioned by the use of tea. "To thesa complaints echoes were not wanting, but after a while the tea-drinkers had it all their owr way. In the meantime, however, tea was not without its apulogists. To say nothing of our own familiar poets and esseyists, its praises have been sung by Herrichen and by Fraacius in Greok verses, by Pecklin in Latin opigrame, by Pierre Pctit in a Latin poom of five huadred lines, and by a German. versifier, who colebrates, in a fashion of his awn, its "burial and bappy resurrectiou." ${ }^{\text {" Huet, bishop of Avraaches, has also paid his graceful }}$ tributo to a stimulaut to which, probably, no scholar was ever more indebted, and which be continued to enjoy at the are of minety. Dr Johnson draws his own portrait as "a hardened and shameless tea-driaker, who for twenty years diluted his meals with only the infusion of this fascinating plant; whose keitle had bearcely time to cool; who with tea amused the ovening, with tca solaced the midnight, and with tea welcomed the morning."

Authoritice are not yet by any means sgreed as ta the exact physiological inflence and value of tea. The very striking fect that theise is preeissly the characteristic constituent of coffee, maté, guarana, and the kolannt, all cubstances eagerly sought after iu dificrent quarters of the giobe, serves to show that the alkaloid satisfies come craving of the human oystem, al though what its effect is has not yet been certainly determined. The quantity of theine ousnured even by the most zardened tea-drinker is exceedingly ninute, and thero are not wanting authorities who assert that it is pr, tically inert, an assertion surely contradicted by the general instinct of the race. What is indisputable about tea drinking is that it forms an agreeablo merns of imbibing the proportion of sater neccos31) in horuan nutrition, which, beiug taken hot, com-

[^25]municates to the system a diffused warm glow. Further, as used by Westeru commuities, it is a medium of taking, in the form of sugar and cream, no iuconsiderable amouut of real uutriment. The other effects of tea are more a matter of general impression than of ascertained acientific reality. Its virtues have nowhere been better summarized than by the earliest Chinese writer on the subject, tho above-mentioned Lo Yu, who saya, "It tempers the spirits and harmonizes the mind, dispels lassitude and relieves fatigue, awakens thaught and prevents drowsiness, lightens or refreshes the body, and clears the perceptive faculties." The gentle exhilaration which accompanies the moderate use of tes is not followed by the depression which aucceeds the use of alcoholic stionuli. Experience has ploved that it bustains the frame mader severe mascular os mental exercise without causing eubsequent exhaustion and collapse Tea is frequently found to be beneficial to sufferers from nervou. headache, and it counteracts to some exteat the effects of aicoho. and of opiates. Taken in excess it produces cerebral excitement, elceplcesness, and general nervous irritability. The tannin contained in ifs infusions also interferes with the flow of the saliva, diminishes the digestive activity of the stomach, and impedes the action of the bowels. In this view the large quantity of strong tea used by the poor-and especially by the sedentary poor, -while eerving to blunt the keen tooth of sunger, must work incalculable havac with the digestive and nervous eystems of the consumers.

It is a remarkable fact that no mention of tea is made by Marcs Polo, and that no knowledge of the substance oppears to liave reached Europe till after the establishment of intercourse between Portagal and China in 151\%. The Portuguese, however, did little towards the introduction of the herb into Europe, and it was not till the Dutch established thomselves at Bantam early in the 17 th century that these adventurers learned from the Chinese the habit of tea drinkiog aud brought it to Europe.

The earliest mention of tca by on Englishman is probably that contained in a letter from Mr Wickham, an agent of the East India Company, written from Firando in Japan, on the 27 th June 1615 , to Mr Eaton, another officer of the company, resident at Macao, and asking for "a pot of the best sort of chaw." How the com. mission was exccuted does not appcar, but in Mr Eaton' subse. quent accounts of expenditure occurs this item-"three silver porringers to drink chaw in.

It was not till the middle of the century that the Engliob beran to use tea, and they also received their supplies from Java till in 1686 they were driven out of the island by the Dutch. At first the price of tea in England ranged from $£ 6$ to $£ 10$ per 15 . In the Nercurias Politicus, No. 435, of September 1658, the following advertisement occura:-"That excellent and by all Physitians approved China Driuk called by the Chineans Tcha, by othes nations Tay, celias Tre, is sold at the Sultaness Head, a coplec-bouse in Sweetinga Reats, by the Royal Exchange, Loudon." Thomas Garway, the first Englizh tea dealer, and founder of the well-knowiu coffee-house, "Garrabay's," in a curious broadsheet, An Exact Description of the Grouth, Quality, and Virtues of the Laff Tea, issued in 1653 or 1600 , writes, "in respect of its scarceness and dearucss, it hath been only used as a resalia in high treatments and enter tainments, and presents made thereof to princes and grandeas," In that year he purchascd a quatity of the rare and much-prized commodity, and offered it to the public, in tho lcaf, at fixed prices vary. ing from 15 s . to 50 s . tho 10 , accordiag to quality, and also in the infusion, "made according to the directions of the most knowing merchants and travellers iuto those eastern countries." In 1060 an Act of the first parliament of the Restoration imposed a tax on "every gallon of chocolate, 日lerbet, and tea, made and cold, to be paid by the maker thereof, eightpence" (12 Car. II. c. 23).
Pepye's often-quoted mention of the fact that an the 25 th September 1660, "I did sund for a cup of tee, a China driuk, of waich I never had drank before, ${ }^{3}$ proves the novelty of tee in Englead at that date. In 1664 wo find that the East India Company presented the king with 2 th and 2 oz. of "thea," which cost 40s. per f , and two years afterwards with another parcel containing $22 \frac{8}{4} \mathrm{lb}$, for which the directors paid 60s, per tb. Both parcels alpear to have been purchesed on the Continent. Not until 1677 is the Company recorded to have taken any steps for the importation of tea. The order then given to their agents was for "teas of the best kind to the amount of 100 dollars." But their instruc. tions were coosiderably exceeded, for the quantity imported in 1678 was 4713 iJ, a quantity which seems to have glutted the market for several years. The angale of the Company reeord that, in Febraary 1684, tho directors wrote thus to Madras:-"In regard thea is grown to be a commodity here, and we have occasion to make presents therein to our great friends at conrt, we would have you to send os yearly five or aix canisters of the very best and freshest thea." Until the Revolation no duty was laid on tea other than that lavied on the iofusion as oold in the coffee-housea By 1 Vivilliam and Mary c. 6 , a duty of 5 s. per th and 5 per cent. on the value was ioposed. For eeveral years the quantities im yorted were very amall, and consisted exclusively of the finer sorts. I'ho furst dircet purchacs in China was maje at Amuy, the teas
previously obtained by the Company's factors having been purchased in Madras and Sumt, whither it was lrouglit lyy. Chinese junks after the expulsion of tho Dritish from Jovn. During the closing ycars of the coutury the amonnt brought orer secms to have been, on the averaye, alont $20,000 \mathrm{tt}$ a $y$ car. The instructions of 1700 directed the supereargoes to senct home 300 tubs of the finer green teas anrl 80 tubs of bolien. In 1703 orders were given for "75,000 1h. Singlo (green), 10,000 it jmprrial, and 20,000 lb bohea." The average price of tea at this perioul was 16 . per lt.

Duriner the 100 yerss from 1710 to 1810 the aggregate sale of tea by the l'ast Imilia Company amounted to $750,219,016 \mathrm{tb}$, worth $£ 129,804,595$, of whech $116,470,675 \mathrm{H}$ was re-cxported. The duties during that contury (excentiner a poriod of eleren years, 1784-95, when they were only $12 \frac{1}{2} p^{3 e r}$ cent.) were excessive, amounting to ahont 200 per ecut. on the value of common teas. The results of so enormons it thx wero the creation of a gigantic smuegling trade, extensive athlteration of imported teas, and mneh fabrication of counterfeit tea within tho comentry. Probably the duty-paid tea did not rimesent more than half what was consumed wnler the name of tea. The following table exbibits the priacipal facts connectel with the thate during tho period of the Company's monopoly, which terminatcal on the 2 ed of April 1834, when the trade whs thrown opien to all, the prices quoted being those of goed qualities in the Company's warchouse or in bond:-

The progressive increase in the consumption of tea in the United Kingelom during 50 years from 1836 till 1886 is instructively shown in the accompanying diagram constrveted by Mlessrs J. C. Sillar ant Co., of Lomlon. The totted line represents the average monthly consumption in encly year; the fluctuations in price of foon samid congou aro thaced by the black line; and the years in which rectuced chstoms duty came into operation are indicated along the base. From 1860 onwarls the ainonnt of Indian tea cutered for lome consumption is shown in monthly average by a black column. This column brings ont the remarkable fact that the Intion tea consumad in the Unitel Kiagdom in a year now exceeds the total

consumption of all kinds in 1860, and is more than double the whole quantity used fifty years ago.

The following table sloows the growth of the British tea trade for five years cuding 1885 :-

|  | India. | Ceyton. | China, | Hong <br> Kung. | $\begin{gathered} \text { Total } \\ \text { imperts. } \end{gathered}$ | Home Consumpilon. |

The consunption of tea in the United Fingdom per head was in 1840 1 22 th, which increased in 1850 to 9.86 tb ; is 1860 it reached 2.67 tt , in 18703.81 tb , in 18504.06 tt , and now ( 1887 ) it is about 5 It .

Moxt to the United liingtom, the greatest tea-mporting nation is the United States, Notwithstanding that tea has from 1873 been duty free duty 25 cents per th in 1870, 17.72 in 1871, and 15 in 1872), the habit of ten drinking does not grow in America as it is tomen to do in the British Isles, as is shown by the accompraying table. Of the $72,104,956 \mathrm{It}$ of tea imported into the United States in the year onded June 1885, $35,895,835$ tb was Chinese, $32,156,032$

| Year ending <br> 30th Junc. | ib entered ior <br> Consumption. | Per Head. |
| :---: | ---: | :---: |
| 1870 | $40,812,189$ | 1.06 |
| 1571 | $46,972,789$ | 1.19 |
| 18,12 | $34,224,494$ | 0.84 |
| 1873 | $106,423,570$ | 2.55 |

| 1893 | $70,711,225$ | 1.31 |
| 1884 | $65,774,234$ | $1 \cdot 18$ |
| 1885 | $69,820,172$ | 1.22 |

3,540,148 to came from England. Nearly 6,000,000 th was reexpater:, principally in Canada.

Next to the Euglish, the Dutch are the greatest consumers of tea outside of China; and the only other considerable tea-using nation 1s Russin. Tho following table rives the amount of tea iunported in the feary $185 \pm$ by the prinerpal tea-drinking comntries:-

| Russia | $35,600,000$ 古 $=$ | -43 tt jer head. |  |
| :---: | :---: | :---: | :---: |
| Holland | 3,900,000 $\quad=$ | $\cdot 91$ |  |
| Demmark. | §20,000 , = | - 01 |  |
| New South Wales. | 8,437,981 ${ }^{\text {, }}=$ | $9 \cdot 15$ | ,', |
| $V \mathrm{~V}$ torin. | 11,521,205 $\quad=$ | 11.99 | " |
| Sunth Anstralia | 2,229,993 ${ }^{\text {, }}=$ | $7 \cdot 00$ |  |
| Queenslant........... | 2,757,277 , | $8 \cdot 75$ |  |
| Cate of Goot Hope... | 1,295,042 $\quad=$ | $5 \cdot 00$ | " |

By this table the Anstraliau colonists come out as the most inveterato tea-drinkers in the work. The quantity received by Holland in 1854 was $2,250,000$ Jh less than the imports of $1883^{\circ}$, bitt tho average of recent times has been $4,500,000 \mathrm{Ht}$.

The yuantity consumed in China has been estimated as high as 2000 millions of pounds annually, being at the rate of a littlo nore thau 5 It per henl of the popnlation; and, considering the teadrinking labits of the poople, the estimate is by no means extravagint. In this light it nay be safe to affirm that the amonnt of tea used yearly thronghout the world reaches the gigantic totn] of 2500 millions of pounds.
Bibliography.-The frerature of tea is revy copions but much seattered. TEAK ${ }^{3}$ may justly be called the most valuable of all known timbers. For use in tropical countries it has no equal, and for certain purposes* it is preferable to otler woods in temperate climates also. Its price is higher than that of any other timber, except mahogany. ${ }^{2}$ Great efforts Late been made to find substitutes, but no timber has been brought to market in sufficient quanfities combining the miany valuable qualities which teak possesses.

The first good Ggure and description of the tree was given by Rheede. ${ }^{3}$ The younger Linnaus called it Tectona yrandis. It is a large decituous tree, of the natural order Verbenacer, with a tall straight stem, a spreading crown, the branchiets four-sided, with large quadrangular pith. It is a native of the two Indian peninsulas, and is also

found in the Philippine Islands, Jara, and other islands of the Malay Archipelago. In India proper its northern limit is $24^{\circ} 40^{\prime}$ on the west side of the Aravalli Hills, and in the centre near Jhansi, in $25^{\circ} 30^{\prime} \mathrm{N}$. lat. In Burmah it extends to the Mogoung district, in lat. $25^{\circ} 10^{\prime}$. In Bengal or Assam it is not indigenous, but plantations have been formed in Assam as far as the 27 th parallel. In the Punjab it is grown in gardens to the 32d.
Teak requires a tropical climate, and the most important forests are found in the moister districts of India, where dusiog the summer montlis heavy rains are brought by the south-west monsoon; the winter months being rainless. In the interior of the Indian peninsula, where the mean annual rainfall is less than 30 incles, no teak is found, and it thrives best with a mean annual fall of more than 50

[^26]inches. The mear annual temperature which suts it best lies between $75^{\circ}$ and $81^{\circ}$ Fahr. Near the coast the tree is absent, and the most valuable forests are on low hills up to 3000 feet. It grows on a great variety of soils, but there is one indispensable condition-perfect drainage or a dry subsoil. On level ground, with deep alluvial soil, tcak does not often form regularly shaped stems, probably because the subsoil drainage is imperfect.

During the dry scason the tree is lealless ; in hot localities tho leaves fall in January, but in moist places the tree renains green till March. At the end of the dry season, when the first monsoon rains fall, the fresh foliage comes out. The leares, which staud olposite, are from I] to 2 feet in length and from 6 to 12 inches in breadth On coppice shoots tho leaves are much larger, and not rarely from 2 to 3 feet long. In shape they somewhat rescinble those of the tobacco plant, but their substance is hard and the surface rougl. The small white flowers are fery numerous, on large erect cross-branched panicles, which terminate the branches. They appear during the rains, genarally in July and August. and the seed ripens in January and February. On the east side of the Indian peninsula, the teak flowers during the rains in October and Novcmber. In Java the forests are leafless in Septenber while duriag March and April, after the rains have commenced, they are clothed with foliage and the flowers open. During the rainy season tho trec 's readily recognized at a considerablo distance by the whitish fower panicles, which overtop the green foliage, and during the dry season the feathery seed-bearing panicles distinguish it from ail other irces. The small oily seeds are eיpelosed in a hard bony 1-4 celled nut, which is surroundied by a thick covering, consisting of a dense felt of natted hairs. The fruit is enclosed by the colarged membranous calyx, in appearance like an irreguiarly plaited or crumpled blacder. The tree seeds freely every ycar, but its spread by means of selfsomn seed is impeded by the forest fires of tho dry season, which in India generally occur in March and April, after the seeds hare ripened and have partly fallen. Of the seeds wnich escape, numbers are washed down tho bills by the first heavy rains of the monsoon. These collect in the ralleys, and it is here that groupz of seedlings and young trees are frequently found. A portion of the seed remains on the tree; this falls gradually after the rains hare commenced, and thus escapes the fires of the hot season. The germination of the sced is slow and uncertain; a large amount of noisture is needed to saturato the spongy covering; many seeds do not germinate until the eecond or third year, and many do not come up at all.

The bark of the stem is about half an inch thick, grey or brownish grey; the saprood white; the heartwood of the green tree has a pleasant and strong aromatic fragrance and a beautiful golden-yellow colour, which on seasoning soon darkens into bromra, mottled with darker streaks. The timber retains its aromatic fragrance to a great age. On a transserse section the mood is marked by large pores, which are more numerous and larger in the spring wood, or the inner belt of each annual ting, whilo they are less numerous and smaller in the autumn wood or outer lelt. In this manner the grorth of each successive jear is marked in the wood, and the age of a tree may be determined by counting the annual rings.

The principal value of teak timber for use in warn countries is its extraordinary durability. In India and in Durmela beams of the wood in good preservation are often found in buildings aeveral centuries old, and instances are known of teaik beams having Iasted more than a thousand.years.* Being one of the few Jndian timbers

[^27]which are really durable, teak has almays been used for buildings, particularly for temples, and in India it has been the chief timber cmplayed for shipbuilding. When iron commenced to he extensircly use, for the last-mamed purpose, it was supposed that the demand for teak would decrease. T'his, however, has not been the case, for the wood is still very largely used for the backing of irouiluds and for lecks of large vessels. It is also used for furniture, for door and window frames, for the construction of railway earriages, and for many other purposes. White ants eat the sapwool, but rarely attack the heartwood of teak. It is not, however, proof against the borings of the terelo, from whose attacks the teak piles of the wharves in the Rangoon river bave to be protected by a shoasthing of metal.
Once seasoned, teak timber does not split, crack, shrink, or Ther its shape. In these qualities it is superior to most timbers. I 1 contact with iron, neither the iron nor the teak suffers, and in this respect it is far superior to oak. It is not very hard, is easily worked, and takes a beantiful polish. It las great elasticity and strength, and is not very heavy. The averago weicht of perfectly seasoned wood fluctuates between 38 aud 46 th per culic foot. ${ }^{2}$ Its weight, therefore, is a little less than that of English oak. Green teak timber, however, is heavier than water, and unless thoronghly seasoned it camot be floated. In Burmah, therefore, where the rivers are used to float the timber to the seaports, a peculiar mode of seasoniog teak hy girdling has been practised from time immemorial. Girdling consists in making a deep circular cut through bark and sap into the leartwood, so as e, mpletely to sever communication between bark and sapwood above and below the cut. In teak, as in oak and other trees with well-marked heartwood, the circulation of the sap only takes place in the sapwool, and the girdleal tree therefore dies after a few days if the operation has been effectually performed. But if even the smallest band of sapwood is left connecting the outer layers of wood above and below the girdle, the tree is not killed, and of ten recovers completcly. The girdled tree is allowed to stand one or two years, and longer if a very large-aized tree. Being exposed to the wind and to the action of the sun, the timber of a girdled tree scasons more rapidly and more completely than that of a tree felled green. The teak produced in the presidencies of Madras and Bombay and in the Central Provinces is as a rule felled green, and even when dry it generally is a little beavier than the timber from Burmah. ${ }^{2}$ For a long time to come, the rivers of Burmah nad Siam will continue to afford the most convenient and most economical routes for the transport of timber. Indeed the forests drained by the Salwin and its fecders are not likely ever to be worked otherwise than an the present plan, under which the logs are floated singly orer the rapids and are caught and rafted lower Jown, at the kyodan or rope station, 70 miles above Mnulmain.

As already mentioned, teakwood contains an aromatic oil, which gives it a peculiarly pleasant smell and an oily surface when fresh cut. To this ail may probably with justice be ascribed its great durability. In Burmanoil is extracted from the timber on a small scale, for medicinal purposes, by filling an earthen pot, which is placed inverted upon another, with chips of wood, and putting fire round it, ufon which the oil runs down into the lower vessel.

Accorling to the colour and texture of the wood, several varieties of teak are distinguished in India, Burmah, and Java; in the timber trade, however, these distinctions are of no importance. Teak as well as other trees, when standing isolated, forms side branches far lown the stem, and the wood of such trees is more knotty and wary, and generally heavier and darker-coloured than the timber of trees which hare grown close together in a dense forest. Apart from the manner in which the tree had grown up in the forest, soil, elevation, and climate bave a great influence upon the grain and tho mechanical qualities of teak as of other timbers. Most of the larger logs brought to market have an irregular crack or hollow in the centre, which commences at tha butt and oftell runs up a long way. There is little doubt that this is generally due to the action of the fires, which scorcb and of ten destroy the luark of young trees. Such external injuries are apt to induce decay in the wood. Moreover, most teak seedlings which come up naturally are cut down to the ground by the fires of the hot season;
preservation and showed the peculiar structure of teak timber in a very marked manner. They had been in the building for 500 years (Indian Forester, vol. vii. p. 260). In the wall of a palace of the Persian kings near Baghdad, which was pillaged in the 7th century, two Americans found in 1811 pieces of Indian teak which were perfectly sound (Ouseley, Travels in Various Countries of the East, vol. ii. p. 250, note 67). In the old cave temples of Salsette and elsewhere in western India pieces of teak have been found in good preservation which must have been more than 2000 years.old.

1 At 44.8 th per cubic foot a load of 50 eubic feet weighs a ton ( 2210 tb ), heoce in the Eurmah ports a ton of teak timber is taken as equivalent to a load of 50 cubic feet.

2 It has been erroncously stated that the tree in Burmah is tapped for its wid before felling.
some are killed, but many sprout again daring the rains, and this is generally repeatud year after year, until a sapling is produced strong enough to outlive the fire. Such snplings have a very larga pith, which dries up, causing a hollow in the heart. Or a piece of the old shoot killed by the fire is enclosed by the new mood, and this also is apt to gire rise to a hollow.

The leaves of the teak tree contain a red dye, which in Malabar was formenly used to dye silk and cotton. Nintives of Burmah use the leaves as plates, to wrap up parcels, and for thatching.
In its youth the tree grows with extreme rapidity. Two-yearold seedling\% on good soil are 5 to 10 feet bigh, and instances of moie rapid growth are not uncommon. In the plantations which lave been made since 1856 in Burmah, the teak has on gooll soil attaiced an average height of 60 feet in 15 years, with a girth, breast high, of 19 inches. This is between $16^{\circ}$ aml $18^{\circ} \mathrm{N}$. lat., with a mean annuar temperature of $78^{\circ} \mathrm{F}$. and a rainfall of 100 inches. In the Burmah plantations it is estimated that the tree will, under farourable circumstances, attain a diameter of 24 ioches (girtb 72 inches) at the age of 80 . Timber of that size is marketable, but the timber of the natural forests which is at present brought to market in Burmah has grown much more slowly, the chief reason being the ammal forest fires, which harden and intpoverish the soil. In the natural forests of Burnah and India teak timber with a diameter of 24 inches is never less than 100 and often more than 200 years old. In future, the timber grown in luantations and in forests noder regular management may be expected to grow much faster; and there is no ground for anticipating that rapidly grown timber will be less valuable than that of slow growth, which is at present bronght to market.
Like the other trees of the dry leciluous forest, teak does not attain any extraordinary size. The trees are not generally more than 100 to 150 feet nigh, even under the most favourable circumstances, and stems more than 100 feet to the first branch are not often found. Exceptionally tall trees were measured in 1861 in the Gwaythay forest in Pegu, east of the Sitang river, on goeiss. The stems liad 106 to 114 feet to the first branclr, with a girth, at 6 feet off the ground, from 7 to 16 feet. Larger girths, up to 25 feet, are not uncommon.
The teak tree does not usually form pure forests. It is asso. ciated with bamboes and a great variety of other trees, which have little market ralue, and, as a rule, thrives best in such company. Hence in the plantations established in Burmah, the alject has been to raise forests of teak mixed with bauboos and other trees.

Most of the teak timber produced is consumerl in India. The produce of the magnificent forests of Travancore, Cochin, the JIadras wresidency, Coorg, Nysore, Bombay, Berar, and the Central Provinces is all so consumed. Formerly there was a considerable export from the ports of the western coast, - Maluhar, Kanara, Surat, and Broach, - but the country at present requires all the teak which its forests can produce; indeed the demand is in excess of the supply, and large quantities are imported from Burmah to Calcutta, ITadras, Bombay, and other ludian ports Small quantities are still e.ported from the ports of the western coast to Arabia and the coast of Africa. The cbief export is from Burmah, pridcipally from Rangoon and Maulmain. Of the other teak-prodncing countries, Java exports a little; there have also been exporis from Saigon; and since 1882 Eankok has sent considerable quantities to Europe. But the Burmah coast is the cbief source of supply at prosent. Rangoon bas for a very long time been an important place for shipbuilding, teak being the chief timber* used : between 1786 and 1825111 European vessels were built at Rangoon, aggregating 35,000 tons. At the same time timber was exported, and, when the nl?or. was taken by the British in 1852, teak was the chief article of export. Jlaulmain became British territory at the close of the first Burmese war in 1826. At that time the place was a large fishing village, and it was mainly througb the expert of teak timber and the shipbuilding trade that it attained its present importance. From 1829 to 1841 upwards of 50,000 loads of teak tiniber were exported, and, in addition, 68 vessels were built during that period, aggregating 15,680 tons, and estimated to have required for their construction 24,000 loads of teak tiuber. The forests from which Blaulmain first derived ita suppliea are situated on the Attaran river, a feeder of the Salwin. In 1836, however, timber began to come dewn from more distant forests, and in 1841 one-fourth only of the supply was brought from the Attaran forests.

The increase in the export of timber from the Burmah ports was slow at first, but has gone on ranidly since Rangoon became a British port. Siuce that time the timber brought to the Burmah ports has come from the following sources:-(I) from the forests in the British coast provinces, Pegu and Tenasserim ; (2) from the forests in the former kinglom of Burmah, floated to Rangoon down the Sitang and Irrawaldy rivers; (3) from the forests in the Shan states formerly tributary to Burmah, from the Karenai coantry, and from Siam, which is all floated to Maulmain by the Salwin river. Since 1856 the increase of the supply derived from these three sources has been large, as will be appareat from the following
averages for the eight years $1856-57$ to $1863-64$ and for the two years 183き－84 and 1884－85：－

|  | $\begin{gathered} 1856-7 \text { to } \\ 1863-4 . \end{gathered}$ | $\begin{aligned} & 1883-4, \\ & 1884-5 . \end{aligned}$ |

Of the quantities exported，between 38,000 and 65,000 loads ${ }^{1}$ have gone beyond India during this period，the balance having been sent to Calcutta，Bombay，and other Indian ports．The quantitics here stated do pat include the timber consumed in Upper Burmah， nor that brought from the forests draincd by the Menam and Mekhong rivers on the east side of the lndo－Chinese Peninsula，nor the teak produced in Java and the other ialands of the Nalay Archipelago，and in the extensive forests of the western peninsnla of India．No data are yet available for a precise catimate；but the total amonnt yielded by these forests，and consumed locally or exported，appears to be not less than 500,000 loads or tons a year．

In British India a large potion of tho teak－producing tracts have since 1856 been placed uuder conservancy management，and similar mensures will doubtless bo extended to the forests in Upper Burmah，now annexcd to the British empire，as well as to the forests of the feudatory uative states．In British India，the area of state forests demareated in order to loo permonently con－ ocrved ${ }^{2}$ was in 1885 （in round figures） 33,000 square miles，and the teak－producing tracts included in this area may be estimated to cover about 12，000 square miles，or $7,680,000$ acrew．Large additions will be made to this area，especially in Upper Burnah． Of teak plantations，12，000 acres have－been formod is Burmah， 563 acres in Coorg， 3436 at Nilamour in \＄lalabar，and about 2000 acres in other districts．There are good grounds for estimating the future yield of plantations at the rate of 50 cubic fect fone ton）per acre annnally．The natural fon sts will，in their preseut impoverished condition，not furnish more ：han one cubic foot per acre anmually，but，as protection against fire is gradually exteud－ ing，the proportion of teak is everywbere being increased by cultural operations in the forests，and the effect of these messures will eventually manifest itself by a considerable increase in the yield． In their present condition，the natural forests demarcated in India up to 1887 may be cxpected to yield 150,000 tons a ycar，while the produce of the plantations will eventually add 18,000 tous more．The teak forests in Java were surveyed in 1871 ，and their area was found to be 2250 Equare miles，while the plantations in that island in 1880 amounted to 24,710 acres．These figures will eerve to show that，if the system commenced in India and Java is maintained，there is no reasnn to apprehend a diminntion of the teak supply．
（D．BR．）
TEAL（OId English Tele），a word of uneertain origin， but doubtless cognate with the Dutel Tuling（formerly Talingh and Telingh），and this apparently with the Seandi－ navian Atteling－And（Brünnieh，Ornithol．Borealis，p．18） and Atling，which it seems impossible not to conneet with the Scottish Atteile or sitteal，to be found in many old records，though this last word（however it be spelt）is generally used in conjunction with Teal，as if to mean a different kind of bird；and commentators have shewn a marvellous ineptitude io surmising what that bird was．

The Teal is the Auas crecca of Linnrus，and the smallest of the European Anatidæ，ns well as one of the most abundant and highly esteemed for the table．It breeds in many parts of the British Islands，making its nest in places rery like those chosen hy the Wild Duck，$A$ ．boscas；but there is no doubt that by far the greater number of those that are taken in decoys，or are shot，during the autuma and winter are of foreign origin．While the female pre－ aents the usual inconspicuons mottled pluange of the same sex in most species of $A$ natinx，the male is one of the handsomest of his kind．His deep chestnnt head and throat are diversifid on either side by a line of buff，which，springing from the gape，runs upward to the eye，in front of which it forms a fork，one prong passing backward above and the other below，enclosing a dark glossj－green patch，and both losing themselves in the clongnted feathers of tho

[^28]hind－head and nape．The back and sides of tho body apper to be grey，an effect produced by delicate transverse pencillinga ot black on a dull white ground．The outer lanceolate scapulars have one－half of their nobs pure white，forming a conspicuous stripe along the sido of the back．The breast is of a palo salmon or peach－blossom colour，eacly feather in front bearing a roundish dark spot，but these spots lessen in number and size lower down，and ths warm tint passes into white on tho belly．The tail－coverts above and below aro velvety black，but those at the side are palc orange．

The Teal inhabits alnost tho whole of Europe and Asia，－from Iceland to Japan，一in winter visiting Northern Africa and India． It accasionally ocenta on the western shores of the Atlantic；but its place in North America is taken by its representative， $\mathcal{A}$ ． carolinensis，the male of which is easily to be recognized by the absenco of the upper butf line on the side of the head and of the white scapular stripe，whilc he presents a whitish crescentic bar on the sides of the lower rock just in front of the wings．

Speeies more or less allied to these two are found in most other parts of the world，and among such species are some（for instance，the A．gibberifions of the Australian Region and the $A$ ．eatoni of Kerguelen Island）in which the male wears almost the same inconspicuous plumage as the female．But the determination of the birds which should Lo teclunically considered＂Teal：，＂and belong to the subgenus Neftium（generally misspelt Nettion），as distinguished from other groups of Anatinx，is a task not yet successfully attempted，and much confusion has been caused by associating with them such specics as the Garganey（vol，x．p．80）and its allies of the group Quer－ quedula．Others again have not yet been diseriminated from the Wroeons．（q．r．），the Pintail－Ducks，Dafila，or even from the typical form of Anas（ef．Duck，vol．vii．p． 505），into each of which subgenera the Teals，Nettium， seem to pass without any great break．In ordinary talk ＂Teal＂seems to stand for any Duck－like bird of small size，and in that sense the word is ofter applied to the members of the genus Nettopus，though systematists will have it that they are properly Geese．In the same loose sense the word is often applied to the two most beautiful of the Family Anatidx，belonging to the genus EXx （commonly misspelt $A i x$ ）－the Carolina Duek of North Ameriea，$E$ ．sponsa（not to be confounded with the abore－ named Anas carolinensis or Nettium curclinense），and the Mandarin－Duck of China，尼．gulericulata．Hardly less showy than these are the two species of the subgenus Euretta，－the Faleated Duck，E．falcata，and the Baikal Teal，E．formosa，－both from castern Asia，but occasionally appcaring in Europe．Some British authors have referred to the latter of these well－marked speeies certain Ducks that from time to time occur，but they are doubtless hybrids， though the secret of their parentage may be unknown；and in this way a so－ealled Bimaculated Duek，Anas bimaculata， was for many years erroneously admitted as a good species to the British list，but of late this has been properly discarded．
（A．ल．）
TECHNICAL EDUCATION．The special education， the objeet of which is to train persons in the arts and sciences that underlio the practice of some trade or pro－ fession，is technical education．Selools in which this training is provided are known as technical schools．In its widest sense，techuical education embraces all kinds of instruction that have direct reference to the eareer a person is following or preparing to follow；but it is usual and convenient to restrict the term to the special traising which helps to qualify a person to engage in some branch of productive industry．This education may consist of the explanation of the processes concerned in production， or of instruction in art or seience in its relation to in． dustry，but it may also include the aequisition of the manual skill which production neeessitates．The term techoieal，as applied to edueation，arose from the necessity of finding a word to indieato the special training which was needed in consequence of the altered conditions of
production during the present century. Whilst the changed conditions of production, coissequent mainly on the application of steam power to machinery, demanded a sjuecial training for those who were to be engaged in productive industry, the prevalent system of education was not adapted to the requirements of these persons, and schools were wanted in which the necessary instruction could bo obtained. Other circhmstances resulting mainly from the application of steam power to machinery have remdered techrical education necessary. Production on $a$ !arge scale led to a great extension of the principle of the division of labour, in consequence of which it was found economical to keep a man constantly engaged at the same kind of work, since the more the practised it the quicker and more skilful he became. "Thus employed, the workman learned little or nothing of the.process of the mauufacture at which he assisted, or of other departments of the work thao the particular one in which he was engaged, and his only opportunity of acquiring such knowledge was outside the workshop or factory in a technical school. The economy effected by the division of labour ied to the extension of the principle to other industries than those in which machincry is largely employed. There are many trades in which manual skill is as necessary now as ever, but even in these the methods of instruction prevailing under the system of apprenticeship are now almost obsolete.
In many industries, including trades it which machinery is not as yet extensively employed, production on a large scale has increased the demand for unskilled labour, numbers of hands being required to prepare the work to be finished by a few artisans. Lapidity of exccution is attained by keeping a workonao at the same work, which after a time he succeeds in mechanically performing, and continues to do uutil some machine is invented to take his place. In most trades, as formerly practised, the master employed a few apprentices who assisted hiru in his work, and who learnt from him to understand the details of their craft, so that, when the term of their apprenticeship was over, they were competent to practise as journeymen. But now the master has neither time nor opportuoity to instruct young lads, and the old relation of master and apprentice is clanged into that of capitalist and workman. In consequence of these alicred relations between employer and employed, there is an acknowledged want of properly trained workmen in a number of trades in which skilful hand work is still needed ; and in these trades a demand has arisen for techuical schools, or some other substitute for apprenticeship, as a meaus of suit. ably training workmen and foremen. The ever-incrcasing competition in production has led to the employncut, in many trades, of childres to do work of a mechanical kind requiring little skill; but, whilst thus enuployed, these young people have little opportunity of learning those parts of their trade in which skill and special knowledge are needed ; aud when they are grown up, and seek higher wages, they are dismissed to make room for other children. Numbers of young men are thes thrown upou the labour inarket, competent to do nothing more that children's work, and to earn children's wages, and knowing no trade to which they can apply their hands. To remedy this, hy creating sone substitute for the old apprenticeshiy, is one of the objects of a system of technical education.
A complete system of technical education should provide necessary instruction for the different classes of persons engaged in productive industry. It is usual to divide these persons into three classes:-(1) workmen or journeymen ; (2) foremen or overseers; (3) managers or masters.
The industries in which they are employed may be grouped under four heads:-(1) those involving the use of extensive machinery, such as iron and steel manufacture,
machine making, the textile industries, and some of the chemical trades: (2) those which mainly require tho use of hand tools, as calinet-making, brick-work, plumLing, and tailoring; (3) those depending on artistic skill, an wool and stone carving, metal-chasing, decorative work, and industrial designing gencrally ; ( $\ddagger$ ) agriculture in all its branches. These industries will be reforred to as manufactures, laadicrafts, art industries, and agriculture. The foregoing classification comprises grouns which necessarily, to some extent, overlap one another. Every factory contaius a carpenter's and suith's shop, and' handicraftsmen of group (2) are required in every manufacturing concern. Whilst the industries in which hand labour is oxelusively employed are becoming fewer and fewer, there are many trades which, owing to the frecqueut invention of labour saring appliances, are passing gradually from the class of Landicrafts to that of manufactures. in these trades, of which watch and clock making and boot and shoo making may be taken as examples, there is still a demand for grods largely if not entirely prodnced by hand work, In such trades, owing to tho absence of facilities for instruction in the ordinary slopls, there is a want of skilled hand labour which there is an iucreasing difficulty in satisfying, and to supply this want technical schools of different kinds have been established. Then, again, there are many lranches of manufacturing industry which greatly dejend for their success upon the designer's art, and it is neccessary that tho industrial designer should possess a knowledge of the processes of the manufacture in which his designs will be utilized, as well as of the properties and capabilities of the material to which they will be applicd. Indeed, it is the possession of this knowledge which mainly distinguishes the industrial designer from the ordinary artist, To determine the best training for such designers is one of the problems of tecinical education. There are many trades, too, in which the liandicraftsman and the designer should be united. This is the case in such industries as mood-engraving, metal-chasing, and silversmith's work. In these and other trades the true artisau is the artist and handicraftsman combined.
In order to reconcile some of the diferent views which are held as to the objects of technical education, it is necessary to keep in inind the broad distinction, above referred to, between the conditions of production on a large scale, as in those iudustries in whicly goods are manufactured by the use of extensive labour-saring machinery, and in those trades in which hand work is chiefly employed. Nuch of the diversity of opinion regarding the oljects of technical education is due to the difference of standpoint from which the problen is regarded. The volume of the trade and comraerce of 3ritain depends mainly on the progress of its mannfacturing industries. It is these which chiefly affect the exprorts and imports. The aim of manufacturers is to produce cheaper and Letter goods than cau be 1 roduced by other manufacturers at home or abroad; and technical education is ralualle to them, in so far as it enables them to do so. But the artisan engaged iu hand industries looks to teclmical education for the means by which lie may aceurire a knowledge of the principles of his trade, which the alsence of the systern of alprenticeship prevents hin from acnuiring in the slop. Hence the artisau and the manufacturer approach the consideration of the question from different sides. To the spinner or weaver who almost exclusively employs nomeu to tend his machincry, or to the manufacturing chemist whose workpeople are little more than labourers employed in carrying to and fro materials, knowing little or nothing of the scientific principles underlying the complicated processes in which they are engaged, the technical educstion of the workpeople may seemi to
be a matter of little moment. What such manufacturers require are the services of a few skilled engineers, artistic designers, or scientific chemists. From the manufacturer's point of view, thercfore, technical instruction is not so much needed for the hands he employs in his work as for the heads that direct it. But in trades in which machinery plays a subsidiary part, technieal teaching supplies the place of that instruction which, in former times, the master gave to his apprentice, and the workman looks to it to supply him with the knowledge of the principles and practice of lis trade, on the acquisition of which his individual success greatly depends. In the former class of industries, teclinical education is needed mainly for the training of managers ; in the latter, for the training of workmen. Hence has arisen a double cry,-for the teaching of art and of the higher branches of science, with a view to their application to manufacturing industry, and for the teaching of trades, and of the scientific facts which help to explain the processes and methods connected with the practice of these trades. This double cry has led to the establishment of technical universities and of trade schools.

Owing to the conditions under which manufacturing Industry is now carried on, it is difficult to select competent foremen from the rank and fie of the workmen. The ordinary hands gain a very limited and circumscrived acquaintance with the details, of the manufacture in which they are engaged, and have little oppostunity of acquiring that general knowledge of various departments of work, and of the structure of the machinery in use, which is essential to the foreman or overscer. It is in evening technical classes that this supplementary instruction, which it is the workman's iaterest to acquire and the master's to encourage, can be ohtained. The history of invention shows how frequently impertant improvements in machinery are made by the workman or minder in charge of it, and adds weight to the arguments already adduced for giving technical instruction to persons of all grades employed in manufacturing industry. To these advantages of technical education, as affecting the worksuen themselves as well as the progress of the industry in which they are engaged, must be added the general improvernent in the character of the work produced, resulting from the superior and better-trained intelligence of those who have had the benefit of sucb instruction.

In order that the different classes of persons who are to be engaged in productive industry may receive a fitting preparatory training, the programme of elementary and secondary as well as of the higher educution must be organized with reference to their special requirements. If the demand for technical instruction is to be fully satisfied, a great part of our existing system of education must be reconstructed, and the training provided in our several schools must be made a more fitting preparation for industrial work than it is at present.

Schools in which the course of instruction is not specialized with a view to any particular industry, but is so arranged as to form a general preparation for manufacturing or otaer trade pursnits, are often spoken of as professional, technical, or trade schools ; but such schools must he distinguished from apprenticeship schools, the object of which is to teach trades. Of the former class of schools there are excellent examples in the different countries of Europe as well as in the United States, and sone few bave recently been establisbed in the United Kiugdom. Of the latter class the best examples are found in France and Austria. The study of these schools, and of the means of providing filting education for the different classes of producers, may be simplified by a statement of the following propnsitions:-

1. The ordinary education of all persons who are likely to be engaged in productive industry should be determined by the general requirements of their fnture work. This proposition affects the curriculum of all schools in which different classes of producers are to be trained, i.e., of primary, secondary, and higher schools, and involves the consideration of the extent to which, in such schools, modern languages, science, draving, and manual instruction should take the place of literary and classical studies.
2. Special schools on classes should be established ( $a$ ) for instruction in art, and in those sciences which serve to explain the processes of productive industry, inclnding agriculture, manufactures, and engineering, as well as in the application of art and science to these departments of industry; (b) for the teaching of, and in certain cases for practice io, various handicrafts or tradex
3. The special schools should be adapted to the requirements of the different grades of workers, and to the different kinds of work in which they are or are likely to be engaged.

A survey of the technical schools in different conntries shors how these different requirements are met. Owing to the complexity of the problem, a complete or an ideal system of technical education is nowhere to be found. Schools have been established to meet local and present wants, and the greatest rariety exists in the attempts that have been made to establish schools in accordance with the foregoing propositions.

1. Workmen. - Many attempts hare been made to provide a substitute for apprenticesbin, but hitherto with no great success. Two classes of workpeople bave to be considered-(1) thoss engaged in inanufacturing industries, and (2) those engaged in handicraft industries. The education of all classes of workpeople begins in the public elementary schools; and, in vicw of the finture occupation of the children, it may bo taken for grantel that primary instruction should be practical, and should include drawing and clementary scieuce, with some anount of manal training for boys, and with needlework, cookery, and domestic economy for giris. In nearly every country of Europe, and in the United Siates, primary instruction includes drawing, in addition to reading, writing, and reckoning. In Emgland this is not yet the case, drawing being taught in very few schools outside of the jurisuliction of the London school board. In France, Belgium, llolland, and Swedeu handicraft instruction is generally included in the curriculum of elementary schools. Rudimentary science is also tanght in nearly all the primary schools of Europe. Modelling is tanght both to byys aud girls in many Continental schools; and io Sweden "slojd," or elementary woodwork, in whicl: simple and useful articlos are constructed with the fewest possible tools is taught with cousiderable success to children of both seres.
In Germany and Switzerland there exists an excellent system of eveniug continuation schools, kuown as Fortvitdungs- or Ergænz-unyju-Schulen, in which the iustruction of the children who leave school before fourtcen, aud of those who leave at tbat aree, is conthued. In most of these schools draving *is taught with special reference to local industries. In Eugland an attempt is boing made to attract children to cvening schools by means of recreativo classes. These classes are inteuded to continuo the child's gencral education, and to supplement it by sonie amount of practical teaching betwecn the timo that he leares the clementary school and is prepared to take arlvantage of cvening techuical instruction. The training of most vorkpeople, and of nearly all those who are engaged in manufacturing indinstry, consists of -(1) primary teaching in elementary schnols; (2) practice ia the factory or slop; (3) eveuing technical instruction.
It all the principal towns throughout Europe evcning clessee have been established for teaching drawing, painting, and designing, and the elements of science in their application to special industries. On the Continent these classes are mainly supported by the municipalities, by the chambers of commerce, hy industrial or trade societies, by county boards, and in some cascs by the fees of the pupils. They receive little or no support from the statu. They are well attended by work peoplo of an grades, who are cucouraged by their employers to profit by these opportanities of instruction. In England evening tochnical instruction is roore systematically organized than in any other country. It is under the dircction of the committee of the council of euncation known as tha Science and Art Departmeat, aud of the Ciry and Guilds as London lnstitute for the advancement of technical educstion, as institute founded and supported bv the corborstiou and bo a liram
number of the livery companies of London. The department cncourages instructiou in pure scielloe aod iu art; the institute in the application of science, and to some extent of art also, to different trades.
Both the department and the institute make grants on behalf of properly recristered teachers on the results of the examination of their pup.ls. The directory of the department contrins a detailed gyllabus of the twenty-five different subjects on the teaching of which grants are paid, aud in the programme of the iustitute are fouml syllabuses of iuseruction in the technology of fifty different trade subjects. In the evening classes organized by the department, as mell as in those in connexion with the institute, the workman or forem, 2 engaged in any manufacturing industry has the oplortunity, ? payment of a very small fee, of studying art in all its brancles, science theoretically and practically, and the teclinology of any particular industry, Provided his early edication Enahles hiun to take adrantage of this instruction, ho better system las been ststested of enabling workmen, whilst earoiog wages at an early are, to aequire mamual skill by contionons practice, and at the same time to gain a knowledge of the priuciples of science conuected with their work and explanatory of the processes of the manufacture in which they are engaged.

For those engaged iu handicraft trades this eveuing mastraction is equally valuable, and in many jurts of Europe there exist evening trate schools in which the worknan is able to supplement the "scctional" mactice he aerquires in the ghop by more general practice in other branches of his trade. In Vieuna, for example, and in other parts of Austria, there are found practical evening classes for carpenters, turners, joiners, metal-workers, and others; and similar classes, some of which are subsidized by the City aad Guilds lostitute, have recently bcen established in Euglaud. Thoonghout Europe schools for weaving, with practical work at tiu loom and pattern designing, lave existed for many years.
'Co provide a training more like the old systens of apprenticeship, sehools have been established io mauy parts of Europe which are knowu as $\quad$ rofessional, trade, or apprenticeship schools (ecoles professionclles, écoles des apprentis, Fachseluien). The object is to train workmen : anll the pupils, after completing their course of instruetion in such a school, are supposed to lave learnt a trade. The school is the substitute for the siop. In such a school the pupils have the alvantago of being taught their trade systematically and leisurely, and production is made sabsidiary to instruction. Under such an artificial system of production, the pupil is less likely to actuire excellenco of worknauship and smartness of habit than in the mercantile shop, under the strain of severe competition. Moreuver, the cost of manteuance of these schools renders it impossible to look to then as a general substitute for a!prenticeship. By sending into the labour market, however, a fev highly-trathed workmen, who are absorbed in various vorks and exert a beneficial influence on other workmen, these schools serve a useful purpose. Schools of this kind have been tried with more or leis success iu different countries. In Paris there is the well-kuown Ficole Diderot for tho trainiog of mechanies, fitters, smitlss, sc. ; and similar schools lave been established in other parts of france. A furuiture-trade school of the same category has recently hee: opened in Pais, and for mauy years a society of Chyistian lưthren have directed a large school in which several elifferent trades hare been taught. In this establishment, situated in the Rue Vangirard, all the secular and geueral instruction is given gratnitonsly ly the brothers, and an the several shops attaclicd to the school skilled workmen aro enn-loyed, who instruct the pupil apprentices. and utilize their labour. This bystem combinics many of the advautages of shop work and school work, but it lepends financially for its success upon the religious shirit which actuates its promoters and supporters. The Artaue Bchool, near Dublin, is conducted on sornewhat similar pricciples, but is intendea for a lower class of children. In Anstria, particularly in the rural districts, there are pumerous schools for the training of corpeuters, joincis, tumers, cabiuetuakers, workers in stone and miable, in silver and other metals, \&c. Scliools of the same class are fonnd in Gemnany, Italy, and elsewhere. It is only in certain cases, however, that apprenticeshij, schools can be said to satisfactorily answer tho purpose for which they hare been established. Whero a new industry, especially in rural districts, has to be created; where decaying industries ueed to be revived, where machinery is superseding hand rork, and, owing to the demands for ordinary liands, there is a dearth of skilled workmen ; where through the effects of competition and other causes the trade is carried on under conditions in which competent worknen cannot be properly trained in the ordinary shop,-in these cases, and in various art industries, an apprenticeship school may preve to be the best means of trainiug workmen, and of advancing particular trades. Generally, an apprenticesbip school should be Jooked upon as a temporary expedient, as a form of relief applied at tho birth or duriug any temporary depression cf a particular industry. The proper training school for workmen is the factory or shop.

Foremen. - The forman bust be familiar with the vanoma
branches of work he is to overlook, and the training which the workman receives in the factory or shop affords him but scanty opportunities of obtaining this general knowledge. The foreman needs also a generally superior education. How then are foresen to be trained? The problem is somewhat easier thau that of training workmen, because the number required is fewer. The valiety of schools in Europe devoted to this purpose is very great. There are three distioct ways in which foremen are being trained.
(a) The eveniug technical classes in Britain and on the Continent offer to ambitions workmen ao opportunity of aequiring a know. ledge of other departmeots of the trade than those in which they are eugagel, as well as of the scientific principles unterlying their work. These classes serve the double purpose of improving the workpeople and of aftording a means of discovering those who are best fitted to occupy higher posts.
(b) Spceial schools liave been established for the training of foremen. There are many trade echools of this kinel in which selected hoys are reccived after learing the elementary school. The best known are those at Chalons, Aix, Nevers, Ancers, and Lille in Franec. These schools are intended for the trainiug of formen in engincering trades. Z'liey aro state institutions, in which practical nechanical work in the shops is supplemented by theoretioal instruction. The first of these schools was founded in 1803. The course lasts three years, and the number of ctudents in cach school inust not exceel three hundred. The students, spend from six to seven hours a rlay in the workslop, and are trained as fitters, founders, smiths, and pattern-makers. As in all such schools, salcable goorls are produced, but, as production is subordinated to instrnction, the school does not hind itself to deliver work ot a given date, and therefore does not compete with any loamufacturiog establisliment. The students on learing these schools are conpetent at ouce to undertake the duties of foremen, managers, er dranghtsmen. At Komotau, Steyr, Klagenfurt, Ferlach, snd many other places schools have been established on somewhat eimilar principles. In Germany there are special schools for the training of foremen in the building trade, whien are chicfly frequented in tho winter, and numerous schools are found in all parts of the Contioent for the trainng of weavers. At W"interther in Switzerland a school has been established the main purpose of which is the training of forenieo. Io ltaly there are numerous techaical institutes, the objcet of which is to train young men for iutermediato posts in industrial works. In the United States the manual training schools, the mumber of which is rapidly increasing, have somewhat similar objects. In London, the Finsbury technical college of the City and Guilds of London Institnta has a day department, the main purpose of which is the training of youths as foremen, works managers, \&c.; but in this school, as well as in those last mentioned, the character of the iustruction deriatus considerably from that given in Freuch schools, and aims lather at preparing youths to learn, than at teaching them, their tiadc.
(c) A third method adopted for the training of foremen is by $\in \mathrm{z}$ couraging selected childreu of the ordinary elcmentary schools to continue their education in schools of a ligher grade of a technical character. It is thought that, by developing to a higher degree the iutelligence and skill of those children who show aptitude for scientific and practical work, they will be able, wheu they enter the sl:op, to lcarn their trade more quickly and more thoroughly, and to acquire that general knowlealge of their work, and to exhibit those special aptitudes, which may qualify them for the position of foreman or manager. The education fiven in these schools, althonglı having direct reference to the futire career of the pupil, is disciplinary in character, and consists of the subjects of primary instruction furtler pursucd, -of drawing, modelliug, science, mathematics, and inannal exercises. The curriculum is varied to some extent according to local requirements, the technology of the staple industries forming in many cases part of the instructiou. Such schonls, under varied forms, have been established in most Continental countries, some of the best exaniples of them being fonnd iu Paris, Lyons, Kheims, Rolen, and in otler towns of France. The want of similar schools in Britain has been frequently pointed out. Ooe of the oldest of these schocls is the Ecole Martiniere at Lyons. The school was founded in 1820 by a bequest from Major-General Martin, who had fought against the English under Tippoo Sahib. In this school, in which the education is gratuitous, as in nearly all the higher elementary schools of France, instruction is given in drawing, modelling, chemistry, mechanics, and physics, in the working of wood and iron, and in German and English in addition to the subjects of an ordinary school education. Surveying is also taught to some of the pupils, and the instruction generally is of a rery practical character. The students visit factories uuder the guidance of the masters, and ou their return they write out full descriptions of their visits. The school hours are from seven till eleved in the moruing and from 000 till seven in the aftertion. The boys from this school rapidly obtain places in the comnercial and industrial houses of Lyons, and mauy of them, after a time, succeed in obtaining high positions. A very similat school, on more modern lines, has heon established at Rhei us and
is accommodated in a buildinc especially adapted to the purpose. In this school instruction is lirected towards the staple industries of the district, namely, weaving, dyeing, and engiveering. There are many other similar schools in France, the object of wbich is to give the children of artisans and small shopkeepers a higher practical education in order to fit them to occupy the posts of foremen, overseers, and superior clerks in manufacturing and commercial firms. A large nunber of poor childreu showing talent are sclected from the primary schools and receive scholarships; and the objection sometimes urged against the establishment of higher elementary schools, - that the better elasses only are able to benefit by them-is thas obriated. In Germany the real-schools in which Latin is not tanght, known as Ohnclatein Realschulcn, nave very nearly the sanie objects as the ligher elementary schools of France. The instruction in these German schools is not yet so practical as in the schools of France. Drawing is always well taught, and the schools generally contain good chemical laboratories, as well as collectious of physical apparatus and museums. From the children of these schools the ranks of forcmen are largely recruited. They receive no special trade instruction, but the general trainiag is so arranged as to yualify then for ligher posts in industrial works. The cost of this higher education seldom excceds £3 per annum. In Bararia it is two shillings a month. In most of these schools, as well as in the chief intermediate commercial schools, the exit certificate exempts a lad from two of the thre years' compulsory military service, and this remmation, to which nothing corresponds in England, is an iuceutive to parents to allow their children to receive higher instruction, which operates rery forcibly in largely increasing the number of well-educated youths in Germany. In these opportmities for highor education England is still very deficient, and the complaint is generally lieard of the difficulties of obtaining competent formen.
3. Masters. - The best special schools for the training of future masters, managers, engineers, manufacturers, aml industrial chem. ists are in Germany, and are known as technical highty schools or polytechnic schools. Schools of a similar character are found in other conntries, and in Encland the facilities for higher technical edncation lave within the last few years greatly inıproved.

In Germany the polytechnic or techuische Hochsclucle is an institution of university type in which the education has special reference to industrial purposes. In many respects the teaching coibeides with that given in the universities. The chief distinction consists in the arrangement of courses of instraction in the several departments, in the admission of students having a non-classical preliminary training, and in the absence of certain faculties fonnd in the university and the addition of others. It is not correct to say that the polytechnic is a professional school as distingrnished from the university ; for the faculties of law, medicine, and theology give to the university as distinctly a professional character as the facnlty of engincering gives to the polytechnic. Nor can it be said that the suientitic studies at the miversities are less practical than at the polytechnic. For, whilst workshops for instructio: in the use of tools are found in very few of the nolytechuic schools, the laboratories, for the practical study of chemistry and pliysics, are perhaps better fitted and under more eminent professors at some of the German universities than at the polytechnic schools. At the same time, engineers of every description, arehitects, and bnillers, besides a great number of manufacturigg chemists, find in the polytechuic the scientificand teclinical training which the lawyer or physician, and iu many cases the industrial chemist, secks in the university.

In some of the large cities-in Berlin, Vienna, aud Munich, for instance-the university and polyteclnic coexist ; and in certain cases, in which a very special training is required to fit a youth for his career, the German stndent, after speuding three or four years at a polytecluic school, passes on to another institution, such as a dyeing school, in which lis studies are further specialized with a view to his future work.

Taking the technical high school of Munich as a type of other similar iustitutions, we fund the cost of the building and of the various collections it contains to have amounted to nearly $£ 200,000$, and the annual cost of maintenance to bo about $£ 20,000$. The iustitution consists of six schools:-(1) the general ; (2) the civil engineering; (3) the building; (4) the mechanical engineering; (5) the industrial chemical ; and (6) the agricultural. A department for electrical techmology is now being built. In other institutions there are arelitectural, pharmaceutical, and mining schools. The programme of the Munich school gives a list of about 180 different courses of instruction distributed over the several dejartments. A separate professor is engaged to lecture on that particular subject with which he is specially conversant, and the number of such professors attached to a polytechnic school is very large. In the engineering department there are six or seven distinct courses of lectures under the direction of thirteen professors. The largest and most recently constructed of all these institutions is the polytechnic school of Berlin, which was completed in 1884 at a cost of about $£ 450,000$. In Fiance tha institutions in which the highest techni-
cal instrmetiou is giveu are concentrated in the capital. There are a large number of provincial colleges where the edncation is soncwhat more practical, but where the mathematical and scientifie teaching is not earried to sa ligh a noint (tbe Ecole Centrale at Lyons, the Ecolo des Mineurs at St Etienue, and the Institut du Nord at Lille, \&c.). The École Centrale of Paris, in which the majority of Freuch engineers who are not employed in the Governneut service are trained, is a rare instance of an institution for higher technical instruction which is self-supportiug and iudependent of Government aid.

In Switzerland tho federal polytechuce of Zurich is similar to the polytechaic schools of Germany and Austria. Italy has thres superior technical institutes, - one at Milan, one at Turin, and one at Naples, in which technical education is given on the same lines as in Geman polytechnic schools. Ifolland has an excellent institution at Delft, which was opened in 1864; and in Russia the imperial techuical school at Moscow is a ligh-class engineering school, in which the theoretical studies are supplemented, to a greater exteut than in the Germau schools, by worksbop practice.

In some of the German schools the fees charged vary according to the number of lectures and to the number of hours of practical work which the student takes per week. Thus at Munich the entrance fee for each student is 10 s , aud the lecture fee is 2 s .6 d . for each honr's lecture [per week, including the use of materials. At Zurich the cost of a student in a cl:emical department, including laboratory practice, does not exceed $£ 12$ per aunum, and in other departments it does not exceed $£ 4$ per annum. At Dolft the student pays about $£ 16$ per aunum for a complete course.

In England there is a growing tendency to associate technical with university edncation. This is maialy owing to the fact that the colleges which have recently becn established to give university education are poorly endowed, aml have found it uecessary to attract students by mectiog the increasing demand for technical iustruction. Jost of the provincial colleges niay indeed be regarded as technical schools with a literary side. Iu order that they may provide university education in addition to sound techoical instrnction, it is necessary that they should be placed on a sound and satisfactory footing by means of state endowment. Of the more recently erected English colleges, the Owens College at Manchester is the most important, combiuing the faculties of a German university with those of a polytechaic school. The Yorkshire College, Leeds, possesses a special school for the teaching of weaving and dyeing. Other somewhat similar institutions are found in Birminghan, Neweastle, Sheffield, Nottinghann, Dundee, Cardiff, and elsewhere. "The university of Edinhurgh has a good school of chemistry, physics, and engineering, and the university of Glasgow has been long distinguished for the excellence of its physical laboratories. In University College and King's College, London, the metropolis possesses two institutious each of which may be likeued to a university and a polytechuic combined. In the university of Cambridge there are mechanical worksliops in conaexiou with the chair of engincering. The Royal School of Mines and the normal scbools of science and art in Sonth Kensiugton are the only technical institutions in England supported by state aid. 'Ilso central iustitution in Londou has more in common with the German polytechuic school than any other iostitution in Britain. This school is designed for the technical teachiog of engineers, architects, master builders, and industrial chemists. It was built at a cost of $£ 100,000$, and is maiutained by an annual grant from the City and Guilds of London Institute of $£ 10,000$, in addition to the studeuts' fees.

Such is a linef outline of the means provided for the techuical education of masters in different parts of Europe. It will be seen from the foregoing statement that efforts are now being made to bring Britain move nearly on a level with other conatries iu the provision of those kinds of instructiou which are best adapted to the differput classes of prolucers. But as yet only a beginning has been made, and in England technical students can be counted by hundreds, whilst those of Germany are aumbered by thousands.

For further information the meader is referred to the Report of the royal commissioners on technical instructiou, publisbed in 1884.

TEETH. See Mammalia, vol. xv. p. 349 ; Draestive Organs, vol. vii. p. 232; Irohy ; and Dentistry.

TEGEA, one of the chief cities of Arcadia, of which its territory occupied the south-eastern corner, being bounded on the S. by Laconia, on the E. by Cynuria and Argolis, on the $N$. by the territory of Mantinea, and on the W . by Mænalia. Its legendary founder was Tcgeates, son of Lycaon. Like many other cities of ancient Greece, Tegea was formed by the union of a population which had previously lived dispersed in villages: The people were divided into four tribes, - the Clareotis, Hippothoetis, Apolloniatis, and Athaneatis Tegea offercd a stubborn
resistance to the encroachments of Lacedrmon, and on more than one occasion defeated its ambitious ucighbour. About 560 b.c., howerer, the Lacedrmonians found the bones of Orestes in Terea and conveyed them to Sparta; and henceforward Spartan valour, backed by this powerful fetich, proved too much for the merely carnal weapons of Tegea. At Platæa ( -179 B.c.) 3000 Tegeans fought the good fight of frecdom, and were the first to enter the breach which the Athenians had made in the Persian redoubt. Petween the Persian and Peloponnesian Wars hostilities again broke out between Tegea and Sparta, in tho course of which Tegea was twice defeated. However, in the Peloponnesian War (431-404), and afterwards in the Corinthian War (395-387), Tegea sided with Sparta. But after tho battle of Leuctra ( 371 ), when the star of Sparta began to decline, Tegea concluded an alliance with the victorions Thebans, and fought on their side against Sparta at the great battle of Mantinea (362). In the Macedonian period Tegea joined the Etolian League, but Cleomenes, king of Sparta, haring won it over to his side, the city was besieged and taken by Antigonus Doson, king of Macedonia, the ally of the Achrann League (222). In 218 the city was retaken, except the acropolis, by the Lacedæmonians under Lycurgus. After the defeat of Machanidas, tyrant of Sparta, by Philopœmen in 207, Tegea passed into the hands of the Achran League. In the time of Strabo it was the only town of any importance in Arcadia. In the $2 d$ century it was visited by Pausanias, who has left a fairly full deseription of it (viii. 45-53).

Of its buildings much the most famous was the great temple of Athene Alea, which bad often afforded sanctuary to fugitives from Sparta. The old templa was burned down in 394 b.c., and Pausanius speaks of the newer templa as by far the finest and largest in the Peloponnesus (that of Zeus at Olympia, however, occupied nearly double the area). The architect was Scopas; and, as the recent German excavations have proved, the temple was a Doric peripteros, with six columns at each end and fourteen at each sida. Of the columns which Pausanias mentions in addition to tha Doric, the Corinthian may have stood in the prouaos and posticum, the lonic in "tha interior of the templa" (for $\begin{gathered}\text { krebs we }\end{gathered}$ should probably read evvos in Pausanius, viii. 45, 5). The ancient imaga of Athene Alea was carricd off by Augustus, and placed at the entrance to his new forum at Rome. The statues of Esculapius and Health, which in Pausanias's time stood on the two sides of the imaga of the goddess at Tegea, were by Scopas. On tha front pediment of the temple was sculptured the hunt of the Calydonian boar, on the back pediment the combat between Telephus and Achilles. Somo flagments of theso pedimental sculptures (comprising the head of the boar and two human heads, one helmetel) have beer discovered; and, as they are the only existing sculptures which can be referred with some certainty to the hand of Scopas himself, they are of the highest importance for the history of art. The site of the temple, at the modera village of Piali, was partially excavated under the auspices of the German archeological iustitute in 1879 and 1882 . It appears that the foundations of the temple measured $49-90$ metres (nearly 164 feet) by 21.30 ( 70 feet). As Tegca stood on a plain surrounded by mountains and liable to inundations, its site las been covered by an alluvial soil which has been favourable to the preservation of the ruins, and a thorough excavation might yield important results.

TEGNER, E~AIAS (1782-1846), the most celebrated of Swedish writers, was born November 13, 1782, at Kyrkerud in Wermland. His father was a pastor, and his grandparents on buth sides wero peasants. His father, whose name had been Esaias Lueasson, took the surname of Tegnerus-altered by his fifth son, the poet, to Tegner -from the hamlet of Tegnaby in Smalland, where he was born. In 1799 Tegnér, hitherto educated in the country, entered the university of Lund, where he graduated in philosophy in 1802, and continued as tutor until 1810 , when he was elected Greek lecturer. In 1812 he was named professor, and continued to work as a lecturer in Luud until 1824, when he was made bishop of Wexiö. At

Wexiö he remained until his death, twenty-two years later. Tegner's early poons bave little merit. He was cumparatively slow in derelopment. His first great success. was a dithyrambic war-song for the army of 1808 , which stirred every. Swedislı heart. In 1811 his patriotic poem Svea won the great prize of the Swedish Acadeny, and made him famous. In the same year was founded in Stockholm the Cothıc League (Götiska förbundel), a sort of club of young and patriotic men of letters, of whon Tegnér quickly became the chief. The club published a magazine, cntitled ldunce, in which it printed a great deal of excellent poetry, and ventilated its views, particularly as regards the study of old lcclandic literature and history. Tegner, Geijer, Afzclius, and Nicander became the most. famous members of the Gothic League. Of the very numerons poems written by Tegnér in the little room at Lund which is now slown to visitors as the Tegner museum, the majority are short, and even occasional lyrics. His celebrated Song to the Sun dates from 1817. He completed three poems of a more ambitions character, on which his fame chiefly rests. Of these, two, the romance of Axel and the delicately-chiselled idyl of Nattvardsbarnen ("The First Communion," 1820), translated by Longfellow. take a secondary place in comparison with Tegnér's masterpiece, of world-wide fame. In 1820 he published in Iduna certain fragments of an epic or cycle of epical picces, on which he was then working, Frithiofssaga or the Story of Fritbiof. In 1822 he published five more cantos, and in 1825 the entire poem. Before it was completed it was famous throughout Europe; the aged Goethe took up his pen to commend to his countrymen this "alte, kräftige, gigantisch-barbarische Diehtart," and desired Amalie von Imhoff to translate it into German. This romantic paraphrase of an ancient saga was composed in twenty-four cantos, all differing in verse form, modelled somewhat, it is only fair to say, on an earlier Danish masterpiece, the Helge of Ochlenschläger. Frithiofsatga is the best known of all Swedish productrons; it is said to have been translated nineteen times into English, eightcen times into Cerman, and once at least into every European language. It is far from satisfying the demands of more recent antiquarian research, but it still is allowed to give the freshest existing impression, in imaginatire form, of life in carly Scandinavio. In later years Tegnér began, but left unfinished, two important epical poems, Gerda and hronbruden. The period of thepublication of Frithiofssaga (1825) was the critical epoch of his carcer. It made him one of the most famous poets of Europe; it transferred him from his study in Lund to the bishop's palace in Wexiö ; it marked the first breakdown of his health, which had hitherto been excellent; and it witnessed a singular moral crisis in the inner history of the poct, about which moch has been written, but of which little is known. Tegnér was at this time passionately in love with a certain beautiful Euphrosyne Palm, the wife of a town-councillor in Lund, and this unfortunate passion, while it inspired much of his finest poctry, turned the poct's blood to gall. From this time forward the heartlessness of woman is one of Tegnér's principal themes. It is a remarkable sign of the condition of Sweden at that time that a man not in boly orders, and so little in possession of the religious temperament as Tegnér, should be offered and shonld accept a bishop's crozier. He did not hesitate in accepting it: it was a great bouour; he was foor; and he was anxious to get away from Lund. No sooner, however, had he begun to study for his new duties than he began to regret the step he had taken. It was nevertheless too late to go back, and Tegnér made a respectable bishop. as long as his health lasted. But he became moody and melancholy; as early,
as 1836 he complained of fiery heats in his brain, and in 1810, during a visit to Stockholm, be suddenly became insane. He was sent to an asylum in Schleswig, and carly - in 1841 he was cured, and able to return to Wexiö. It was during his convalescence in Schleswig that he wrote Kronbruder. He wrote no more of importance; in 1843 he had a stroke of apoplexy, and on the 2 d of November 1846 he died in Wexiö. From 1819 he lad been a member of the Swedish Academy, where he was succeeded by his biographer and best initator Böttiger. In prose T'egnér wrote letters, which have been collected, and which are considered the best of their kind in the Swedish language. As a poet he mill scarcely be preferred to Betlman or to Runeberg by Swedish verse amateurs, but he still exceeds these and all other writers in popularity.
See Böttiger, Teckning af Tegners Lefnad; Georg Brandes, Esaias Tegner; Thomander, Tankar och Löjcn. (E. W. G.)
teherant, or, more properly, Tehran (lat. $35^{\circ} 40^{\prime} \mathrm{N}$., long. $51^{\circ} 25^{\prime}$ E.), for abont a century the recognized capital of Persia, has little to distinguish it, in general outward appearance, from other large cities of the country, though in quite recent years Parisian streets or boulevards, and even Western architecture for single houses, in the midst of mud-brick palaces or plain mud hovels, have been incongruously introduced. Formerly a kind of polygon some 4 miles in circumference-with its mcan "shahr panah" or wall, its clumsy and uneven ditch, and its six gates, two facing north, two south, one east, and one west, -Teheran has now been extended to an outer ditch and wall, thrown out on each side beyond the ancient limit. The bazaars are good, though hardly of the first class; the caravanserais deserve honourable mention; and the telegraph and arsenal are respectable institutions. The streets are for the most part narrow and wrotchedly paved. The "Ark," or citadel, contains the royal and better description of public buildings, and connecting its encircling wall with the city gates are four principal thoroughfares, of which the parallel avenues from the Násiriya and Daulat entrances are the more notable. Between these tryo gates, in a parallelogram extending from one to the other and including both, is the gas-lighted Tôp Maidan, or "Place des Canons," in the centre of which is a large reservoir. European professors are to be found in the king's college, where some 250 students, more or less, are taught mathematics, engineering military tactics, music, telegraphy, painting, together with the Arabic, Eng'ish, French, and Russian languages. Among the not rery remarkable mosques-to some of which madrasahe, or colleges, are attached-may be specially mentioned the Masjid-i-Sbah, or king's mosque, with its handsome enamelled front, and the Masjid-i-Mádar-i-Shah, or mosque of the king's mother. Water is freely supplied to the town by means of the underground canals, or kanats, from the near mountain ranges. Public baths abound, but the Europeans use those of the Armenian and not of the Mohammedan community. The British legation stands in a handsome garden of great size, in which are placed the houses of the secretaries, which resemble English villas. In the summer season the representatives of Western powers and other Europeans move out to the slope of the mountain range north of Teheran,-the' British residents to Gulhal, a village about 7 miles from the city. A prominent feature in the landscape at Gulhak and the neighbouring summer quarters, as at Teheran itself, is Demavend, the noblest and most graceful of Persian mountains.

The present population of Teheran may be taken at 160,000 at most. According to a late authority (Bassett, 1887) the European inhabitants are reckoned at about 100 only; the Jerrs number some 2500 ; and there are 150 Czbrs or Parsis, a sorry remant of the old fire-
worshippers. In 18ia there were said to be 100 Armenians, maialy traders and artisans. In 1872 there were but four legations in Teheran-those of Eugland, France, Russia, and Turkey. Since that year representatives hare been added from Holland, Austria, Germany, and the United States. The French have summer quarters at Tejrish and the Russians at Zargandab, at no great distance from the English Gullak.

Morier supposes Teheran to be the Tahors of the Theodosian Tables, and recognizes it also in the account of the journey of the Castilian ambassadors to Tinur. Porter, too, relates that in 1637 the secretary of the Holstcin ambassadors mentions Teheran as "one of the towns which enjoy the privilege of naintaining no soldicrs." Again, in the 17 th century, it was visited by Pictro della Vallo and by Sir Thomas Heroert, - the latter spelling it "Tyronn." Most writers affirn that Tcheran, though not of recent origin, can barely be held of repute till Agha Muhammad made it bis residence in about 1788, taking to himself the title of shah, as first of the Fajar kings, in 1796. Yet there is eridence that in the previous century it was a royal resort, if nothing more, in Herbert's statement that "the Toune is most heautified by a vast garden of the kinss, suecinct with a great towered mud-wall larger than the circuit of the city." Du Pre (who visited it in 1808) states that it had been pillaged and nearly destroyed by the Afghans, -evidently at their invasion of Persia in 172s. Since Agha Muhammad's time Tcheran has been the usual seat of the Kojar dynasty, a circumstance to be attributed to the political adrantages of its geographical position.
See, besides the atthoritles cited, Telegraph and Travel (1574); Dr Wills's Land of the Lion and Sin (18S3); and Mr Bassett's Land of the Inams (18S7).
TEHUANTEPEC, an isthmus in Mexico, comprising the western extremities of the states of Vera Crnz ano Oajaca, and limited eastrards by the states of Tabasco and Chiapas, thus lying between $16^{\circ}$ and $18^{\circ} \mathrm{N} .1 \mathrm{lat}$. and $91^{\circ}$ and $95^{\circ}$ W. long. Between the Bay of Campeche on the north or Atlantic side and that of Tehuantepec on the sonth or Pacific side the distance in a bee line is only 125 miles. Here also the Sierra Madre falls rapidly from over 5000 fect in Chiapas to about 730 feet in the ridge skirting the Pacific coast, and leaving the rest of this district someWhat level, with a rise from the Atlantic of not more than 60 feet in the mile except at the Chivela Pass, where for S miles the gradients are about 116 feet per mile.
This favourable condition of the relief, combined with a relatively heal thy climate subject only to dangerous insect pests in summer, has naturally attracted attention to the Tehuantepee isthmus, as offering peculiar adrantages for interoceanic communication either by a navigable canal, a railway, or a ship railway. A first conces: sion was made in 1841 by the Mexican Government to Don José de Garay, who Jad the land surveyed with a view to a canal, but who, after the war with the United States, surrendered his rights to Mr P. A. Hargous of New York. The company then organized to give effect to the Garay grant caused a fresh survey for a railway to be made in 1851, under the direction of the late General J. G. Barnard. But nothing came of this or of another railway project in 1857, when a third surrey was executed, under the direction of Col. W. II. Sidell. Then the "Tehuantepee Railway Comprany," formed it 1870 in New York, and reorganized in 1879, obtained a concession from the Mexican Government to construct the "Tehuantepec Railway"; but, after a few miles were made, the work was suspended, and in 1882 the Government contracted with privato individuals for the completion of the line, which was to be 190 miles long, and to run from the mouth of the Goatzacoalcos (Coatzacoalcos) river on the Atlantic to the port of Salina Cruz on the Pacific. The work was carried to Dinatitlan, a distance of 25 miles, in 1884, and was to have been completed in 1885; but since then onerations appear to have been suspended for want of neans. A Teluantepec ship railway is also projected, as it is cxpected that most of the trade betreen the Atlantic and Pacific coasts of the United States will be attracted to this route, which shortens the distance betreen New Yorls and San Francisco by 1477 miles, and between New Orleans and the same place by 2334 miles, as compared with that by the Panama railway and future canal.
Tehuantepee, the town which gives its name to the istlimus, hay, and neighbouring lagoon, stands on the river Tehnantepec, 15 miles above its mouth on the Pacifc, where it develops a shallow and somewhat exposed harhour. Of the population, estimated at 14,000 , a large number are civilized and industrious Indians engaged in cotton-weaving and on the salt-works. Indigo is grown in the district, and there are productive pearl-fisheries in the bay. Amongst the exports are cochineal and a purple dye extracted from a shellifish abounding on the coast.

TEIGNMOUTH, a seaport and market town of England, in Devonshire, consisting of the parishes of East and West Teignmonth, and situated on the English Channel, at the mouth of the Teign and on the Great Westera Railway, 14 miles sonth of Exeter and 209 west-southwest of London. It is somewhat irregularly built, partly on a projecting peninsula and partly on the acclivities rising behind the river. The Teign is crossed by a bridge 1671 feet in length, built of wood and iron in 1824. St Michael's church, in East Teignmonth, erected in 1822-23 in the Decorated style, was enlarged in 1875. The other buildings include St Scholastica's abbey (erected for Benedictine puns in 1862), the East Devon and Teignmouth club-house, the mechanics' institute (1840), the temperance hàll (1879), the sailors' home (1881), the baths (1883), and the public market (1883). There are two commodious
quays and a pier 600 feet in length. Fine pipe and potters' clay (from Kingsteignton) is shipped to Stafordshire. Coal and culm are imported, and there is also a trade with Newfoundland. Fishing is extensively carried on. The town, which is not incorporated, was formerly governed by portreeves. It now forms an urban sanitary district, which was extended on 29th September 1881. The population of the former area ( 1238 acres) in 1871 was 6751 , and in 1881 it was 7120 ; that of the extended area (2347 acres) in 1881 was 8496.

Teignmouth is of very ancient origin. It received a grant of a maikel from Henry III. East Teignmouth was formerly called Teignmouth Regis, and West Teignmouth, Teignmouth Episcopi,the mauor having belonged to the see of Exeter until alienated by Bishon Vesey. Toignmouth was burned by French pirates in 1340 , and was again dovastated by the French on 26th June 1690.

# TELEGRAPH 

TTELEGRAPH (from $\tau \hat{\eta} \lambda \epsilon$ and $\gamma$ рá申 $\omega$ ) signifies an instrument to write at a distance. The term is specifically applied to apparatus for communicating intelligence to a distance in unwritten sigas addressed to the eye or ear, and has only recently had application to those wonderful combinations of inanimate matter which literally write at a distance the intelligence committed to them. The chief object of the present article is to explain the principles and practice of the electric telegraph, and we shall allude to other telegraphic systems only to illustrate the general principles of signalling.

A word expressing an idea may, according to a prearranged plan of signalling, be communicated by voice, by trumpet calls, by gun fire, by gesture or dumb signs, by lamp signals, by flags, by semaphore, or by electric telegraph. The simplest system of word-signalling hitherto practised is that of the nautical flag telegraph, in which each hoist represents a word by a combination of four flags in four distinct positions (see Signals, Naval). If $n$ denote the number of flags, supposed all different, out of which the four to be sent up may be selected, the number of different ideas which can be expressed by a single hoist is $n(n-1)(n-2)(n-3)$, since there are $n$ varieties out of which the flag for each of the four positions may be independently chosen. To commit to memory so great a number of combirations, which amount to 358,800 if $n=26$, would be a vain effort ; the operators on each side must therefore have constant recourse to a dictionary, or code, as it is called. For the sake of convenient reference each flag is called by the name of a letter of the alphabet, and all that the operator has to bear in mind is the letter by which each flag is designated. Sometimes the words to be expressed are spelled out by means of the flags as in ordinary language; but, as in most words there are more than four letters, as scarcely any two consecutive words are spelled with four or less than four letters, and as more than four flags at a time cannot be conveniently used, the system of alphabetic signalling frequently requircs the use of two hoists for a word, and scarcely ever has the advantage of expressing two words by one hoist. $\mathrm{I}_{\mathrm{t}}$, is therefore much more tedious than code signalling in Line nautical telegraph.

In point of simplicity spoken words may be considered is almosi on a par with the nantical telegraph, siace each word is in reality spoken and heard almost as a single atterance. Next in order comes the system of spelling out words letter by letter, in which-instead of, as in the nantical telegraph, 358.800 single symbgls to express the same number of ideas - 26 distinct symbols are used to express by their combinations any number whatever of
distinct ideas. Next again to this may be ranked the system by which several distinct successive signals are used to express a letter, and letters thus communicated by compound signals are combined into words according to the ordinary method of language. It is to this last class that nearly all practical systems of electro-telegraphic signalling bolong. But some of the earliest and latest proposals for electric telegraphs are founded on the idea of making a single signal represent a single letter of the alphabet; as instances we may name those early forms in which separate conductors were used for the different letters; a method suggested by Professor W. Thomson ${ }^{1}$ in 1858 is which different strengths of current were to be employed to indicate the letters; and the various forms of printing telegraph now in use.

## I. Historical Sketch of Early Telegraphs.

Although the history of practical electric telegraphy does not include a period of more than half a century, the idea of using electricity for telegraphic purposes is much older. It was suggested ágain and again as each new discovery in electricity and magnetism seemed to reader it more feasible. Thus the discovery of Stephen Gray and of Wheeler that the electrical influence of a charged Leyden jar may be conveyed to a distance by means of an insulated wire gave rise to various proposals, of which perhaps the earliest was that in an anonymous letter ${ }^{2}$ to the Scots Magazine (vol. xv. p. 73, 1753), in which the use of as many insulated conductors as there are letters in the alphabet was suggested. Each wire was to be used for the transmission of one letter only, and the message was to be sent by charging the proper wires in succession and received by observing the movements of small pieces of paper marked with the letters of the alphabet and placed under the cnds of the wires. A very interesting modification was also proposed in the same letter, viz., to attach to the end of each wire a small light ball which when charged would be attracted towards an adjacent bell and strike it. Some twenty years later Le Sage proposed a similar method, in which each conductor was to bo attached to a pith ball electroscope. An important advance on this was proposed in 1797 by Lomond, ${ }^{9}$ who used orly one line of wire and an alphabet of motions. Besidee these we have in the samo period the spark telegraph of Reiser, of Don Silva, and of Cavallo, the pith ball telegraph of Ronalds, and several

[^29]others. Next came the discovery of Galvani and of Volta, and as a consequence a fresh set of proposals, in which voltaic electricity was to be used. The discovery by Nicholson and Carlisle of the decomplosition of water and the subsequent researches of Dary on the decomposition of the solutions of salts by the voltaic current were turned to account in the water voltameter telegraph of Sommering and the modification of it proposed by Schweigger, and.in a similar method proposed by Cose, in which a solution of salts was substituted for water. Then came the discovery by Romagnesi and by Oersted of the action of the galvanic current on a magnet. The application of this to telegraphic purposes was suggested by Laplace and taken up by Ampere, and afterwards by Triboaillet and by Schilling, whose work forms the foundation of much of modern telegraphy. Faraday's discovery of the induced current produced by passing a magnet through a helix of wire forming part of a closed circuit was laid hold of in the telegraph of Gauss and Weber, and this application was at the request of Gauss taken up by Steinheil, who brought it to considerable perfection. Steinheil communicated to the Göttingen Academy of Sciences in Septernber 1838 an account of his telegraph, which had been constructed about the middle of the preceding year. The currents were produced by a magneto-electric machine resembling that of Clarke. The receiving apparatus consisted of a multiplier, in the centre of which were pivoted one or two magnetic needles, which either indicated the message by the movement of an index or by striking two bells of different tone or recorded it by making ink dots on a ribbon of paper. Among other workers about this time we may mention Masson, Bréguet, Davy, Deval, Billon, Soudalot, and Vorsselman who proposed to use the physiological effects of electricity in working an electric telegraph. ${ }^{1}$
Steinheil appears to have been anticipated in the matter of a recording telegraph by Morse of America, who in 1835 constructed a rude morking model of an instrument; this within a few years was so perfected that with some modification in detail it has been largely used ever since (see below). In 1836 Cooke, to whom the idea appears to have been suggested by Schilling's method, invented a telegraph in which an alphabet was worked out by the single and combined movement of three needles. Subsequently, in conjunction with Wheatstone, he introduced another form, in which five vertical indes needles, each worked by a separate multiplier, were made to point out the letters on a dial. Two needles were acted upon at the same time, and the letter at the point of intersection of the direction of the indexes was read. This telegraph required six wires, and was shortlyafterwards displaced by the single-needle system, still to a large extent used on railway and other less important circuits. The single-needle instrument is a vertical needle galvanoscope worked by a battery and reversing key, the motions to right and left of one end of the indes corresponding to the dashes and dots of the Morse alphabet. To increase the speed of working, two single-needle instruments were sometimes used (double-needle telegraph). This system required two lines of wire, and, along with all multiple-wire systems, soon passed out of uss. Similar instruments to the single and double needle ones of Cooke and Wheatstone were about the same time invented by the Rev. H. Highton and his brother Edward Highton, and were used for a considerable time on some of the railway lines in England. Another series of instruments, introdtuced by Cooke and Wheatstone in 1840, and generally known as "Wheatstone's step-by-step letter-showing" or

[^30]"A B C instruments," were worked out with great ingenuity of detail by Wheatstone in Great Britain and by Bréguet and others in France. They are still largely used for private wires, but are being rapidly displaced by the telephone. ${ }^{2}$ Wheatstone also described and to some extent worked out an interesting modification of his step-by-step instrument, the object of which was to produce a letter-printing telegraph. But it never came into use; some years later, however, an instrument embodying the same principle, although differing greatly in mechanical detail, was brought into use by Royal E. House of Vermont, U.S., and was very successfully worked on some of the American telegraph lines till 1860, after which it was gradually displaced by the Phelps combination telegraph. The House instrument is not now in use, but various modifications of it are still employed for private lines and for stock telegraphs, such as Calahan's and the universal stock telegraphs, Phelps's stock printer, Gray's automatic printer for private lines, Siemens's and Phelps's automatic type printers, \&c. (see infra, pp. 120-121).

## II. General Description of Electric Telegraphs for Land and Sea.

The first requisite for electro-telegraphic communication between two localities is an insulated conductor extending from one to the other. This, with proper apparatus' for originating electric currents at one end and for discovering the effects produced by them at the other end, constitutes an electric telegraph. Faraday's term "electrode," literally a way for electricity to travel along, might be well applied to designate the insulated conductor along which the electric messenger is despatched. It is, however, more commonly and familiarly called "the wire" or "the line."
The apparatus for generating the electric action at one end is commonly called the transmitting apparatus or instrument, or the sending apparatus or instrument, or sometimes simply the transmitter or sender. The apparatus used at the other end of the line to render the effects of this action perceptible to any of the senses-eye, ear, or taste, all of which have been used in actual telegraphic signalling-is called the receiving apparatus or instrument.
In the aerial or overground system of land telegraphs the main line consists generally of a "galvanized" iron wire from one-sixth to a quarter of an inch in diameter, stretched through the air from pole to pole, at a sufficient height above the ground for security. The supports or insulators, as they are called, by which it is attached to the poles are of very different form and arrangement in different telegraphs, but consist essentially of a stem of glass, porcelain, coarse earthenware, or other non-conducting substance, protected by an overhanging screen or roof. One end of the stem is firmly attached to the pole, and the other bears the wire. The best idea of a single telegraphic insulator may be got from a common umbrofec. with its stem of insulating substance attached upright to the top of a pole and bearing the wire supported in a notch on the top outside. The umbrella may be either of the same substance as the stem-all glass or all glazed earthenware, for instance-or of a stronger material, such as iron, with an insulating stem fitted to it to support it belor. Very good insulators may be made of continuous glass; but well-glazed porcelain is more generally used, or rathér earthenware, which is cheaper, less brittle, and less hygroscopic, and insulates well as long as the glazing is sufficient to prevent the porous substance within from absorbing moisture.
One of the best forms-Varley's dou'vie cup insulator
${ }^{2}$ For the different forms. see Prescott's Electricity and the Elcinere Telegraph, pp. 562-602.
-is shown in fig. 1. It consists of two distinct cups ( $c$, C), which are moulded and fired separately, and afterwards cemented together. The double cup gives great security against loss of insulation due to cracks exteuding through the insulator, and also gives a high surface insulation. An iron bolt (b) cemented into the centre of the inner cup is used for fixing the insulator to the pole or bracket.

In the underground system the main line generally consists of a copper wire, or a thin strand of copper wires, covered with a continuous coating of gutta percha, india-rubber, or some equivalent insulating substance, served with tarred tape and encloscd in earthenware, iron, or lead pipes laid below the surface of the ground. This system is largely used for street and tunnel work, and to a considerable extent,
 especially in Germany, for ordinary lines. Fio. 1. - Varley's Each tube generally contains a number of double cup insula. wires, which are either laid up into a cable tor, one-fourth full and covered with a serving of tarred tape or hemp before being drawn into the tube, or - as is more commonly the case in the United Kingdom-simply laid together in a parallel group and tied at intervals with binders, which are remored as the wires are drawn into the tube. On some long underground lines in Germany the insulated wires are laid up into a cable, served with jute or hemp, and sheathed with a continuous covering of iron wires, precisely similar to the submarine cables described below. The cable is laid in a deep trench and coated with bitumen. This form of cable is easily laid, and if properly manufactured is likely to be very durable.

Sulmarine Cables.-A submarine cable (figs. 2-4), as nsually manufactured at present, consists of a core $a$ in the centre of which is a strand of copper wires varying in weight for different cables betweea 70 and 400 而 to the mile. The stranded form was suggested by Prof. W. Thomson at a meeting of the Philosophical Society of Glas gow in 1854, because its greater flexibility renders it less likely to damage the
 insulating envelopo during Fios, 2-4,-Sections of three types of submarine cables, the manipula- mediate type. Fig. Type of shore ond. Fig. s.-linterthe manipula- mediato type. Fig. t.-Deep sea type.
tion of the cable. The central conductor is covered with several continuous coatings of gutta percha, the total weight of which also varies between 70 and 800 Zb to the mile. With a light core the weight of the gutta percha generally exceeds that of the copper. While in some
heavy cores the copper is beavier. The different coatings of gutta percha and of the conductor are usually scparated by a thin coating of Chatterton's compound (a mixture of gutta percha, resiu, and Stockholm tar), in order to make them adhere firmly together. This practice bas recently been departed from by Messrs Siemens Erothers, who have succeeded by an improved process of manufacture in getting perfect adhesion without the use of the compound. The coro is served with a thick coating of wet jute, yarn, or bemp ( $h$ ), forming a soft bed for the sheath, which consists of soft iron, or of homogeneous iron, wires of the best quality. The sheathing wires are usually covercd with one or two servings of tarred canvas tape $(t)$, or of tarred hemp, laid on alternately with coatings of a mixture of asphaltum and tar. The weight of the iron sheath varies greatly according to the depth of the water, the nature of the sea bottom, the prevalence of currents, and so on, Fig. 2 shows the intermediate type again sheathed with a heary armour to resist wear in the shallow water near shore. In many cases a still heavier type is used for the first mile or two from shore, and several intermediate types are often introduced, tapering gradually to the thin deepwater type. Captain S. Trot and Mr F. A. Hamilton havo proposed ${ }^{1}$ to abandon the iron sheath and substitute a strong double serving of hemp, laid on in such a way as to prevent twisting when the cable is under tension. This suggestion, which is a revival with some modifications of an old idea, is, however, still in the experimental stage.

We will now describe very briefly a few of the most important processes in the manufacture and submergenco of submarine cables.
In manufacturing a cable (fig. 5) the cepper strand is passed Their through a vessel A containing melted Chatterion's compeund, then manuthrough the cylinder C , in rhich a quantity of gutta percha, puri- facture. fied by гереated washtion, and by filtering warm by a steamthrough, a coating of
ing in hot water, by. masticathrough wire gauze filters, is kept jackct. As the wire is pulled

Which is regulated by the dis $D$, is pressed ont of the cylinder by applying the requisite pressure to the piston $P$. The nemly coatcal wire is passed throngh a long trough $T$, containing cold water, until it is sufficiently cold to allow it to be safely round on a bob$\operatorname{lin} \mathrm{B}^{\prime}$. This operation completed, the wire is wound from the bobbin $B^{\prime}$ on to anather, and at the same time carefully examined for air-holes or other flaws, all of which are eliminated. The coated wire is treated in the same way as the copper strand, the die D, or anothez of the same size, being placed at the back of the cyliader and a larger one substituted at the front. A second coating is then laid on, and after it passes throngh a similar process of examination a third coating is applied, and so on nntil the requisite number is completed. The finished core changes rapidly in its electric qualities at first, and is generally kept for a stated interval of time before being subjected to the specifed tests. It is then placed in a tank of water and kept at a certain fixed temperature, nsually $75^{\circ}$ Fahr, until it assmmes approximately a constant electrical otete. Its conductor and dielectric resistanco and its electrostatic capacity are then measured. These tests are generally repeatcd at another temperature, say $50^{\circ} \mathrm{Fahr}$., for the purpose of obtainiog at the same time greater certainty of the conddness of the core and the rate of pariation of the conductor and dielectric resistances with temperature. Should these tests prove satisfactory the core is served with jute yarn, coiled in watertight tanks, aod surrounded with salt water. Tbe insulation is a gain tested, and if no fault is discovered the served core is passed through the sheathing machine, and the iron sheath and the outer covering are laid on. Ae the cable is sheathed it is stored in large water-tinht tanks and kept at a nearly nniform temperature by
means of water.
The cable is now transferred te a cable ship, pravided with water- Snbree tight tanka aimilar to those used in the factory for atoring it. The siru tanke are nearly cylindrical in form and have a truncated cons

[^31]fixed in tho centre, os shown at $C$, fig. 6. The cable is carefully coiled inte the tanks in horizontal flakes, each of which is begun st the outside of the tank and coiled towards the centre. The different
the friction between the cable and the grouvd is sufficient the cable will either break or he left in a Jong span ready to break at some future time. It is impertant to observe that the risk is in mo way obviated by the iocrcasing slsch paid out, except in 60 far as the amount of sliding which the strength of the cable is able to produce at the points of contact with the ground may be thereby increased. The speed of the ship must therefore be so regulated
F10. B.-Diegrani of cable tank and paying out apparatus of submarine cable.
cals are prevented from adhering by a coating of whitewash, and the end of each nautical mile in carefully marked for future reference. After the cable has beon again sabjected to the proper electrical tests and found to be in perfect coudition, the ohip is taken to the place where the shore end is to be landed. A oufficicnt length of cable to resch the shore or the cable-house is paid overboard and coiled on a raft or rafte, or on the deck of a steam-launch, iu order to be connected with the shore. The end is taken into the testing room in the cable-house and the conduetor connected with the testing instrumenta, and, ehould the electrical tests continue gatisfactory, the ship is put on the proper course and ateams slowly ahead, paying out the cable over her stern. The cable must not bo everstrsined in the process of submersion, and must be paid out at the proper rate to give the requisite slack. This ievolve日 the intro. duction of machinery for measuring and controlling the speed at which it leaves the ship and for measuring the pull on the cable. The essential parts of this apparatus are shown in fig. 6. The lower oude of the cable in the tank $T$ is taken to the testing room, 60 that continuous tests for electrical condition can be made. The upper end is passed over a guiding quadrant $Q$ te a bet of wheels or fixed quadrants $1,2,3, \ldots$ then to the paying-ont drum $P$, from it to the dynamometer $D$, and finally to the stern pulley, over which it passes into the sea. The wheels 1, 2, 3, ... are 60 arranged that $2,4,6, \ldots$ can be raised or lewered bo as to give the cable less or more bend es it passes between them, while $1,3,5, \ldots$ are furnished with brakes. The whole system prevides the mcans of giving sufficient back-pull to the cable to make it grip the drum P, round which it passes eeversl times to prevent slipping. On the same chaft with $P$ is fixed a brake-wheel furnished with a pewerful brake B , by the proper msnipulation of which the epced of paying out is regulated, the pull on the cable bcing at the same time observed by means of $D$. The shaft of $P$ can be readily put in gear with a powerful engine for the purpose of hauling back the cable should it be found necessary to do oo. The length paid out and the rate of paying ont are obtained approximately from the number of turns mado by the drum $P$ and its rate of turning. This is checked by the mile marks, the known pesition of the joints, \&c., 8.0 they pass. The speed of the ship can be roughly cstimated from the speed of the engines; it is more accurately obtained by one or other ct the various forms of log, or it may be measared by paying out continuously a steel wire over a measuring wheel. The average speed is obtaincd very accurately from selar and stellar observations for the position of the ship. The differeace between the speed of the slip and the rate of paring out gives the amount of slack. The amount of slack varies in different cases between three and ten per cent, but some is always allowed, so that the cable may easily edapt itself to inequalities of the bottom and may be moreresdily lifted for repairs. But the mere paying ont of oufficient sleck is not a gearanteo that the cablo will slways lio closely along the bettom or be free from spans. Whilst it is being paid out the pertion between the surface of the water and the bettom of the sea lies slong s straight line, the compenent of the weight at right angles to its length being supported by the frictional resistance to siviking in the water. If, then, the opeed of the ship be $v$, the rate of paying out $x$, the angle of immersion $i$, the depth of the water $h$, the weight per unit length of the cable 20 , the pull on the cable et the surface $P$, and $A, B$ constants, we have-
\[

$$
\begin{equation*}
\mathrm{P}=h\left\{v-\frac{\mathrm{A}}{\sin i} f(u-v \cos i)\right\} \tag{a}
\end{equation*}
$$

\]

and $\quad 2 \cos i=B f(v \sin i) \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots$ where $f$ stands for "function." The factors $A f(u-v \cos i)$ and $\mathrm{Bf}(v \sin i)$ give the frictional resistance to sinking, per unit longth of the cable, in the direction of the length and transverse to the leagth respectively. ${ }^{2}$ It is evident from equation $(\beta)$ that the angle of immersion depends solely on the speed of the ship; henco in laying a cable on an irregular bottom it is of great inn. pertance that the epeed should be sufficiently low. This may be illustrated very simply as follows:-вnppose a a (fig. 7) to be the surface of the sea, $b c$ the bottom, and $c c$ the straight line made by the cablo; then, if a hill $H$, which is at any part steepor than the inclination of the cable, is passed over, the cable tonches it at seme point $t$ before it touches the part immediately below $t$, and if

1 See Sir W. Thomsod, Mathematical and Physioal Papere, vol. Ii. n. 105.
that the angle of immersion is as great as the inclimation of the steepest alope passed over. Uader ordinary circumstances the angle of immersion $i$ varies between six aad nine degrees. ${ }^{\text {a }}$

Fig. 7.
Qualities of a Telegraph Tine. The efficiency of the telegraph depends on three qualities of the main line-(1) its coaducting quality, (2) its insulation, and (3) its electrostatic capacity.

1. The conducting quality of a wire or other elongated portion of Coaduct? matter is measured by the quantity of electricity which it allows to ing flow through it when a stated "electrometive force," or "difference quality; of electric potentials," is maintained between its two ends. It may be most naturslly, and is in point of fact generally, expressed in terms of resistance to transmission, regarded as a quality inverse to that of conducting power, and expressed numcrically by the reciprocal of the measure of the conducting power. An independent explanation and defnition of the clectrical resistance of a conductor may be given 6 follows:--the electrical resistance of a conductor is measured by the amount of electromotive ferce, or difference of poteatials, which must be maintained between its ends to produco. a stated strength of electric current through it.
2. The true measure of the ingalation of a body is the resistance Insuls to conduction offered by its supports. The reciprocal of this, or the tion. conducting pewer of the supports, uneasures the defectiveness of the insulation. Since no substance yet known is absolutely a nonconductor of electricity, perfect iasulation is impossible. If, however, the supports on which a telegraph wire resta present, on each part and on the whole, 60 great a rcsistance to electric conduction as to allew only a small portion of the electricity sent in, in the actual working, st oneend to escape by lateral conduction, instead of passing through the line and producing effect st the other end; the insulation is as good as need be fer the mode of working adopted. With the good insulation attained in a submarine line, round every part of which the gutta percha is free from flaws, no telegraphic operation completed within a second of time can be sensibly influenced by lateral conduction. A charge communicated to a wire thus insulated nnder water, at the temperature of the seabottom, is so well held that, after thirity minutes, not so much as half of it is found to bsvo esceped. From this, according to the familiar "compound interest" problem, it sppears that the loss must be at the rate of less than five per cent. per two minutes.
3. In 1849 Werner Siemens proved that "when a current is sent Electrothrough a submerged cable a quantity of electricity is retained in static charge along the whele surface, being distributed in proportion capacity. to the tension of each point,"-that is to say, to the difference of potentials between the conductor at any point and the earth beside it. In 1854 Faraday showed the effect of this "electrostatic cliarge" on signals sent through great lengths of snbmerged wire, bringing to light msny remarkable phenomens end pointing out the "inductive" embarrassment to be expected in werking long submsrine telegraphs. In letters ${ }^{3}$ to Prefesser Stokes in INevember and December of the same year, Prof. W. Themson gare the mathematical theory of these phenemons, with formuls and diagrams of curves, containing the elements of synthetical investigation for every possible case of practical operstions. Some of the results of this theory are given at the end of the present article. The conductor of a submarine cable has a pery large electrostatic capacity in comparison with that of a land tolegraph wire in conseqnence of the induction, ss of a Leyden phial, which takes place acress its gutta percha coat, between it and its moist outer surface, which may be regarded as perfectly connected with tho earth, -that is to say, at the same potential as the earth. The mathematical expressions for the abselute electrostatic capacity C, per unit of length, in the two cases sro as follows.

Let $\mathbf{D}=$ diameter of the inner conductor, suppesed to be that of $a$ circular cross section, or of s circle inappreciably less than one circumscribed sbout the strand which constitutes a modern submarine
${ }^{3}$ For detalls of cable manafacture and inging consult Douglas's Telegraph Electric Telegraph Cables, London, 1878.
Electric Gelegraph Cables, London, 1878.
conductor; $D^{\prime}=$ outer dismeter of the insulating cost; $I=$ specific inductive capacity of the gutta percha or other substance constituting the insulating cost. Thén

$$
C=\frac{I}{2 \log _{a} D^{\prime} / D}
$$

In the case of a single wire of circular section, diameter $D$, undisturbed by the presence of othere, snd aupported st a constant height $h$ above the earth by poles so far spart as not to influcnca its capacity sensibly -

$$
C=\frac{1}{2 \log _{6} 4 h / D}
$$

Exsmple 1. In s submarine cable in which $\mathrm{D}^{\prime}=\mathrm{I}$ centimètre ; $D=0.4$ centimètre ; and $I=3.2$ -

$$
\mathrm{C}=\frac{\mathrm{I}}{2 \log _{8} \mathrm{D}^{\prime} / \mathrm{D}}=\frac{3 \cdot 2 \times 4343}{2 \times \cdot 3979}=\mathrm{I} \cdot 75
$$

Example 2. In a land line is which $\mathrm{D}=0.6$ centimètro and $h=600$ centimètres-

$$
\mathrm{C}=\frac{1}{2 \log , 4 h / \mathrm{D}}=\frac{\cdot 4343}{7 \cdot 204}=\frac{1}{16 \cdot 6^{\circ}}
$$

The capacity, therefore, is in this case less than one-twenty-ninth of that of the submarine cable of example 1 for the same length.

## Telegraph Testing.

Standards of Measurement.-A brief consideration of the standards according to which the electrical qualities referred to in the last section are measured, and the measurements to he described in this section are mode, will render, the statements of those qualities and quautities more definite. A complete and uuiversally comparable system of standards for physical measurements can bo obtained by adopting arbitrarily as fundamental units thoso of length, mass, snd time, snd expressing in terms of these in a properly defined msnner the units of all the other quantities. The units now sdopted all over the world for electrical measurements take the centimetre as the unit of length, the gramme as the wnit of mass, sod the mean solar second as the unit of time. There are two systems in use, the electrostatic and the electromagnetic. In the former the rmutual forces exertad by two bodies, each charged with static electricity, sre taken as the starting-peint, and in the latter the mutual forces exerted betreen a current of electricity and a magnet. The units sccording to these two syetems sre definitely related; but as wa deal in the present srticle with the electromagnetic system (We give the following brief account of it only.

The dyne or unit force is that ferce which, acting on a gramme 'of matter, free to more, imparts to it a velocity of I centimetre per second. Unit quantity of magnetism or unit magnetic pole is that quantity of magnetism which, when plsced st a distance of 1 centimètre from an equal and similar quantity of magnetism or a msgnetic pole, repels it with unit ferce. Unit magnetic field is a field which, when a unit quentity of magnetism or a unit magnetic pole is plsced in it, is acted on by unit force. Unit current is $s$ current which, when made to flow reund a circle of unit radius, produces a magnetic field of $2 \pi$ unite intensity st the centre of the circle, or acts of s unit quantity of magnetism placed st the centre of the circle with $2 \pi$ units of force. Unit quantity of electricity is the quantity conveyed by the unit current in one second. Unit difference of potential is the difference of potential between the ends of a condnctor of unit length when it is plsced with its length at right sngles to the direction of force in s unit magnetic field and kept moving with a velocity of 1 centimetre per second in the dircction st right angles to its own length and to the direction of the magnetic force. Unit eledromotive force is produced in a closed circuit if any unit of its length is held in the manuer, and moved in the direction snd with the velocity, described in the last section. Unit resistance is the resistance which, when acted on by unit electromotive force, tranemits unit current. Unit capacily is the capscity of a body which requires unit quantity of electricity to raise ita potential by unity. The units sbove specified aro generally referred to as the absolute C.G.S. electromagnotic units of the different quantities. In practice their magnitudes were found inconvenient, and certain multiples snd submultiples of them have been sdopted as the prsctical units of measurement: thus the shm is equsl to $10^{9}$ C.G.S. units of resistance; the volt is equal to $10^{9} \mathrm{C} . \mathrm{G} . \mathrm{S}$. units of electromotive force ; the ampere is equsl to $10^{-1}$ C.G.S. units of current; the coulomb is equal to $10^{-1}$ C.G.S. nnits of quantity; the farad is the capscity which is charged to a Folt by \& coulomb, snd is equal to $10^{-9}$ C.G.S. units of capacity ; tha microfarad is the millionth part of the farad, and is equal to $10^{-15} \mathrm{C} . \mathrm{G} . \mathrm{S}$. anits of capacity.
We are here chiefly concerned with the units of electromotive force, resistance, and capacity. No universally recognized standard of electromotive force has jet been established, but the want has been to a great extent eqpplied by the potential galvanometers, electrostatic voltmeters, atandsrd cells, and other instruments devised by Sir W. Thomson and others. The work of Lord Reyleigh, Dr. Fleming, snd other experimenters on the Clark and Daniell standard colls has ohown conclusively that an electromotive ferce
can be reproduced with certainty within ona-testh per cent. of sccurscy by mesns of either of theso cells. Specimens of the standsrd unit of resistance, or ohn, made of an slloy of platiuun and silver, or of plstinum snd iridium, have been constructed, and can be relied on, if properly taken care of, to remain very nearly sccurate from year to year. Similar specimens of the standard unit of capacity or microfsrad which remain very nearly constant have been successfully produced. For a fuller trestment of this subject sud of the methods of determining the different units, see Electricity, vel. viii. p. 40 sq. ${ }^{1}$
Telegraph line testing consists mostly of comparisons of the resistance of the conductor snd the insulator with sets of stendard resistances, sud of comparisens of the inductive capscity of the line or cable with standard coulensers of known capacity. When, as is sometimes the case, the streugth of the current Howing through the line or through a particular instrument is to be determined, it is measured by an electrodynsmometer, or by a current galvanometer, properly constructed for indicating currents in absoluto messure. In the sbsence of such an instrument it msy be obtained accurately by the use of a standard galranometer in a knewn or determined magnetic field, or, taking advantage of Farsdsy's discovery of the electro-chemical equivalents, by messuring the smount of silver or of copper deposited by the current when it is made to pass through an electrolytic cell ; or the electromotive forca per unit resistance of the circuit may be determined by the use of standard resistances and a standard cell. Space does uot sllow us to do more than eimply refer to these methods, the first two at least of Thich involve accurste snd somewhat difficult experimental work. ${ }^{2}$
Measurement of Wire Resistance.-(1) By Wheatstone's bridge. ${ }^{9}$ Measure earth, $a$ snd $b$ known resistances, earth, $a$ snd $b$ known resistances, G \& galvs ometer, $K$ a siugle lever key, $\mathrm{K}_{1}$ a reversing key, and B a battery. Put the zinc pole of the battery to the line and adjust the resistance $x$ until the galvanometer $G$ shows no deflexion when $\mathrm{K}_{1}$ is depressed. Wo then have, assuming no electromotive
 force in the line, $l=a x_{1} / b$. Next put the copper pole to the line and repeat the test, and suppose in this case $l=a x_{2} / b$; if these $t$ wo values
of $l$ nearly agree the true value may be taken as $2 a x_{2} x_{2} b\left(x_{1}+x_{2}\right)$ of $l$ nearly agree the true value may be taken as $2 a x_{2} x_{2} / b\left(x_{1}+x_{2}\right)$. The effect of an electromotive force in the line itself is nearly eliminated
(2) Let the battery B (fig. 9) be connected through the keys $\mathrm{K}_{1}$ and $K$ and the galvanometer $G$ with the line $l$, which has its distant end to the earth ss before; shunt the galvanometer by a shunt $s$ antil s convenient deflexion is obtsined, and then take as quickly as possible a series of readings with zinc and copper alternately to the line. Next substitute for $l$ a set of resistance coils and vary the resistance until the same series of readings is obtained. The resistance introduced for the reproduction of each resding indicates the apparent resistance of the line wheu that reading was taken. The readings will generally differ because of the existence of a varisble electrometive force in the line. If, however, the difference is not very great, the harmenic mean of the srithmecic mean of the

3 See A. Gray, Absolute Measurements in Electricity and Maonetism, I884. 74; also T. Gray, Phil. Afag. November 18s6. The following quotation p. 27, the art. Teleorapa in the sth ed. of the Ency. Brit. Ghows how comparatively recent is the introdnction of a nything like absolute messurement in telegraph testing:-"The nrdinary test for insulation consists in appent in telegraph battery, with one pole to earth and the other through a pelvanome a galranic the line of telegraph of which the remote end is kept insulated tion of the whole line were perfect, the galvanometer needle wonld insulszero; but, when looked for with a battery of snitable power and a galvanomet of suitable sensibility, indicetions of a current ere slways found, alvanometer very short length of very perfectly insulsted line thst is tested. The shisolnto measure of the strength of this corrent divided by the absolute measure of the electromntive force of the battery gives an absolute messnre for the insulation of the cable. No tolegraphic testing onght in future to be accep the insulation partment of telegraphic business which has not this definite cheracter, elthough it is nnly within the last jear that convenient instruments for working in absolute
measure have been introduced at all, snd the whnle eyster of eng measure have been introduced at all, snd the whole eystem of abeolnte roeasureeystematically for the first time in 1859 , in cxperiments by Prof $F$ in practice $\$$ For this theory. seo Electaicity, vol. vili. p. 44.
resistances, when zinc and copper were respectively to the line, will give nearly the true resistance. Since the deflexions are reproduced by substituting resistances for the line, the galvanometer zero may be off the cale to one side, and hence the total deflexion, and therefore the sensi. bility, may be made very considerable. In this case the reversing key K is reguired for keeping the de-

## lexion in the same direc

tion. With a perfectly insulated battery this can be accomplished by putting the galvanometer between the battery and the key K; but the orrangement shown is safer. The most suitable galvano. meter for these tests is a dead-beat mirror galvanometer with a long enough suspension to prevent error from the viscosity of the fibre. Such an iostrument is much to be preferred to the astatic form, especially when variable esrth-currents are present.
(3) A highly sensitive modification of method (2) is obtaired by the use of a differential galvacometer, one coll of which is joined in circuit with the standard resistances and the other coil with the line. The resistances are then adjusted to balance, or to give no permanent deflexion when the battery circuit is closed. Several balances with pasitive and negative currents must be taken and the results combined as indicated above.
(4) Wheo an electrometer is employed for testiug insulation, as described below, it may be used for the wire resistance also either by substitutiog it for the galvanometer in Wheatstone's bridge method (fig. 8, G) or by that shown io fig. 10 . One pole of the battery B is joined to the line through the reversing key K and the resistance R , the other pole being to the earth. The electrometer El is then applied to the two ends of $\mathbf{R}$ and to the ead of $l$ and the earth alteraately and the relative deflexion

noted. The deflexions should be as nearly as possible equal; that is, $R$ should be as nesrly as possible equel to $l$. The form of reversing key shown at $\mathrm{K}_{1}$ is convenient for this test, as it allows the comparisons to be made quickly; and, as the readings can be always taken to the same side of zero, the whole length of the scale is available for each deflexion. The key consists of two ordinary front and back stop single lever keys fixed together by au insulating piece $i$ at such a distance apart that the cootact stops $a, b$ and $c, d$ are at the corners of a square. Suppose one pole of the battery put to the line and the resistance R adjusted until no change of deflexion is obtained by depressing $\mathrm{K}_{1}$; then R is eqnal to $l$ if thero is no earth disturbance. Then put the other pole of the battery to the line; tarn the levers of $K$ through $90^{\circ}$ round the pivot $p$; and repeat the adjustment of $R$ for a second determination of $l$. Repeat these measurements several times and combine the results in the manner described in method (2). If $R$ is not mado equal to If the resistances are in the ratio of the correspoading deflexions.

Measurement of Insulator Resistance. - (1) In the direct deflexion methed the connexions are the same as those shown in fig. 9 , except that the distant eod of the lino is insulated. Very great care mast be taken that the galvanometer and all the connexions between it and the end of the line are so well iosulated that no seosible part of the observed deflexion is due to leakage through them. In making the test, first earth the line for five minutes; then, with the galvanometer ehort-circuited, apply the rioc pole of the battery to the line ; at the end of from thirty seconds to a minute, depeading on the length and capacity of the line, remove the short-circuit plugs and record the deflexion at the end of overy ten or fifteen secouds during the whole time (usually from ten to twenty minutes) the tast is contioued. Again earth the line for an interval equal to that during which the battery was applied; theo apply the copper pole of the battery and repeat the readings as before. Using the deflexions as ordinates and the corresponding times as abscisse, construct a emooth curve for both the zioc and the copper test. The galranometer constant divided by the mean ordinate of these carves at any time gives the insalation at that time. To determine the galvanometer constant, substitute a high resistance $R$, say one megohm, for the line, and shunt the galvanometer with a shunt 6. If the deflexion under these circumstances is $d$ and $G$ is the galvanometer resistance, the constant is

$$
\mathrm{C}=\mathrm{R} d \frac{\mathrm{G}+s}{s}
$$

(2) The olectrometer method is only applicable to linee of considerable iudactive capacity, but is particularly well suited for cable testing. The battery $\mathbf{B}$ (fig. 11 ) is comnected through a refersing key $\mathbb{E}$, to the eads of the resistance slide $a b$, one end of
which is put to earth. The slide generally consists either of 10 or 100 equal resistances, amounting in the aggregate to from 10,000 to 100,000 ohms. The cable can be counected by means of the reversing key $K$ to either pair of quadrants of the electrometer $E l$, the slider $s$ being at the same time put to the other pair. To determine the constant of the electrometer, con. nect the earth wire with the cable terminal and the slider with contact 1 , and observe the deflexion; this should be the same for both
 directions of the curreat through the slide; its value multiplied by 10 , when the slide is made up of ten coils, gives the value in scale divisions of the full difference of potential between the ends of the lide. Thia number added to the zero reading of the electrometer is called the inferred acro. To find the insulation of the cable, remove the wire $w$, put in the short circuit plug $p$, move the slider to contact 10 , and, the distant end of the cable being insulated, opnly by means of $\mathrm{K}_{1}$ the zinc pole of the battery to the cable and the copper pole to the earth. Allow sufficient time for the cable to charge-say one mioute for a cable of 2000 knots- then remove the short-circuit plug snd take readings every fifteen or thirty seconds. The difference of these readings from zero gives the fall of potential of the cablo due to discharge through the insulating coat. Next earth the cable at both ends for a time equal to the duration of the last test, and after reversing $K$ put the copper pole of the battery to the cable and the zinc pole to the earth and take another series of readings. Subtract these readings from the inferred zero, and, using the differences as ordinates and the correspondiag times as abscissx, draw two curves. To find the insulation of the cable at any iaterval $\ell$ after the battery was applied, draw a tangent to the curve at the point corresponding to that time and produce it to cut the axis of the ordinates. Let $D_{1}$ be the ordinate to the point of iutersection, and $D$ the ordinate at the time $t$; then, if $C$ be the capacity of the cable in microfarads and I its insulation in megohms,

$$
\mathrm{I}=\frac{t \mathrm{D}}{\mathrm{C}\left(\mathrm{D}_{1}-\mathrm{D}\right)}
$$

If the difference between the reading and the iuferred zero at the times $l$ and $t_{1}$ be $D$ and $D_{1}$, the insulation is given by the equation

$$
\mathrm{I}=\frac{-4343\left(t_{1}-t\right)}{\mathrm{C} \log \mathrm{D} / \mathrm{D}_{1}}
$$

when $t_{1}-t$ is reckoned in seconds. This latter is the formula commonly uscd; it gives the insulation at come time in the interval between the two observations; the exact time depends on the rate of "absorption" of the cable.

The advantages of the electrometer method of testing cables are the comparative steadiness of the needle during earth-current disturbances, its high sensibility for the detection of small iotermittent faults, and the fact that simultareous tests can be taken from both ends of the cable. In order to test from both ends simaltaneously one or other of the following methods may bo adopted. Call tho ends of the cable $A$ and $B$, and suppose the operator at $A$ is to begin the test. The operator at $B$ joins the copper pale to the earth and the zinc pole to the line, and leaves the slider of his slide resistance at the earth end of the alide. Then, at a time previously arranged, he watches until he sees the electrometer begin to indicate a charge in the cable, and moves the slider along the slide so as to keep the electrometer near zero. As soon as the olectrometer ceases to indicate increase of charge he ceases to move the slider and begins to record the deflexions at regular intervals, the first reading being taken as zero. The other method is to leave the slider permavently to earth and keep the electrometer so insensitive that the deflexion is always within the limits of the scale. Observe the time at which the electrometer begins to be deflected, and from that time onward take readings every thirty secouds during the time of the test. The mean of the readiogs taken at beth ends, reduced to the same sensibility, should be used for calculating the insulation. This method not only eliminates the effects of earthcurrent disturbance out also throws light on the nature and dis. tribution of such disturbances.

When an electrometer is not available and the line is too much diaturbed for good testa to be obtained by the galvanometer method, the following procedare may be adopted. Join the battery and the galvanometer in series with the cable as for the direct deflexion test. Short-circuit the galvanometer and charge the cable for one minute. Insulate the cable for fifteen seconds; then break the short circuit of the galvanometer; again apply the battery, and take the deflexion procuced by the charge. Keep the batterv on the cable for fiftern seconds, and during that time take if possibio the direct deflexion reading two or three times. Again insulate for
fiften secouds and repat the above rcadings ; and continue tho samo cycle of oporations for the whole time of the test. After earthing the cable for the proper interval repeat the above test with the other pole of the battery to the cable. To reduce the charge readings to absolute measure, find the dellexiou of the gal. vanometor noodlo due to the charge of a condenser of $n$ microfarads capacity by the testing hattery; let $d$ bo this deflexion. Then the dotlexion that would be obtained by charging the whole cesble would bo $C \mathscr{L} / n$, and, if D bo ony one of the deflexions during the test, $\mathrm{D}_{n} / \mathrm{Cd}$ is the fraction of the whole charge which-has been lost in the fiftecu secouds immodiately preceding this charge ; thus

$$
I=\frac{4343 \times 15}{C \log \frac{\mathrm{C}^{3} d^{2}}{\mathrm{C}^{2} d^{2}-n^{2} \mathrm{D}}}
$$

The method just described takes advantaga in a somewhat imperfect manner of both the direct deflexion and the eloctrometer test; but the galvanometer should have such a long period that the whole of the charge can take place before the needle is eensibly moved from its zero position, and that the vibration of the needle unust not be damped to any great extent, -a condition which rendera the instrument unsuitable for direct deflexion testing.

The points with regard to the cable which should be particularly attended to when testing for insulation are-the continuity of the insulation all through the test, that is, there should be no eign of a breakdown for ever so short a time; the rate of polarization with positive and negative current is always the same in a perfoct cable, but is seldom so when a fault exists ; the absolute insulation with both eurrents shouid also be the same if the cable is perfect, but is never so for any length of time when 8 fault exists. If the insulatious show any sign of being defective great caro must be taken utt to apply a powerful battery to the cable, unlass the object is to increase or "breals down" the fault. The resistance of a fanlt is generally diminished by applying the zinc pole of the battery to the cable and increased by applying the copper pole; but if tho fault is small it sometimes happens that both currents increaso the resistance. Even a very powerful battery may in ench a case fail to increase the fault.

Capacity Tests-The arrangement of the connexions for Thomson's capacity test are shown in fig. 12. 4 woll-insulatel battery 13 is connected through a reversing key $\mathrm{K}_{1}$, to the clide resistance $a b$, and by means of a key I $a$ can bo put to a standard condenser $C$ and $\delta$ to the cable, or tho condenser and tho cable can be connected together and then both put to carth through the galranometer $\mathbf{G}$ by closing the key $\mathrm{K}_{\mathrm{p}}$ Any point in the ro-
sistance $a b$ can be put sistance $a b$ can be put the slider s. Suppase

the middle point put to the earth, then C and L will be charged to eqnal potentials but of opposite sign. If the connexions to the slide are broken and $C$ is joined to $I_{\text {s }}$ the resulting charge will be saro when the capaclty $C$ is equal to the capacity $L$, and when $\mathrm{K}_{\text {, }}$ is closed no current will fow through $G$. Similarly, if $\alpha s$ is to $s b$ as $L$ is to $C$ the resulting charge is zero. Hence when, after jointog $C$ to $L_{,}$, no deflexion is shown on $G$ when $K_{2}$ is closed -

$$
\mathrm{L}=\mathrm{C} \frac{a s}{s b}
$$

A modification of this test has beon suggested by Mr John Gott. The condenser $C$ is joined in series with the cable and one end of the slide is put to earth. The galvanometer $G$ is joined from the end of the cablo to the slider 8 and the position of the latter, which gives no deflexion, is found by successive trials, the cable being discharged and recharged between the trinils, A small condonses in the galvanometor circult is an adrantage, as it allows several adjustmonts to be made witbout discharging the cable. The most suitebla instrument, however, is an electrometor, as it allows the adjustment to be made at onco.

The capacities of condensers may be compared by charging or discharging them through a galvanometer and comparing the deflexions, or, as in De Sauty's mothod, by substituting them for two sides of a Wheatatone's bridge and finding the ratio of the resistances in the other two sides; then, with the galvanometer circuit closed, the battery circuit can be closed without producing any deflexion. The galranometer circuit must join the condensers at the same points as the bridge resiatances. These methods are quite unsuited for telegraph-line testing becanse of the resistance and the inductive retardation of the line.

Tests of a Submerged Cablo.-During the submergence of a cable
is necessary to provids the means of knowing at every instant
whethor it continues in perfect electrical coudition, so that should any fault dovelop it can bo at once detected and further paying ont atopped until it is removed. It is also of great importance that tho ship and shore should bo in telcgraphic communication with. each other. The arrangements made for these purposes by different electricians vary considerably; but the general principle will be gathered from fig. 13, which includes all that is absolutely neccessary for the purpose. The principal testing station is always on board the ship, and from it all the testing operations both on board and on ehore are regulated. Roferring first to tlie arrangements on board, B is the testing battery, K the testing key, and $G$ the teating galvano. meter; $\mathrm{B}_{1}$ is the sig.
 battery, $\mathrm{K}_{2}$ the key, and $\mathrm{G}_{1}$ the galvanometer; R is a resistance box and E the earth-plate-the ohip's side in this case. The battery B is connected through the key K , the resistance $\mathrm{R}_{\text {, }}$, and the galvanometer G to the cable, as for direct deflexion testing. The shore end of the cable is at the same time connected to one set of plates of a highly insulated condenser $\mathrm{C}_{\mathrm{r}}$ and (although this mey be omitted) to one pair of quadrants of an electrometer El. The other pair of plateg of the condenser are put to earth through the eigoalling key $\mathrm{K}_{1}$. It is convenient also to have a second condenser C , on shore, the capacity of which can be readily varied, so arranged that its capacity can be udded to that of $C_{1}$ by depressing the key $K$, and again discharged through a.galvanometer $G$ by releasing the key. The operations are then conducted as follows. The insulation is measured on board ship, alternately with positive and negative currents of from ten to fifteen minutes' duration, by observing the deflexion on the galvanometer $G$; and the reading at the end of ewh minute, or oftener, is recorded in a diary. The continuity of the conductor is tested at short intervals-say every five minutesby the observer on shoro depressing the key $K$ and thus adding the capacity of C to tho cablo. This gives a sudden deflexion on the galvanometer $G$ on board, and at the same time showe thist the conductor is continuous and that the observer on shore is attending to his duties, When the shore key K is released, the dischargo through $G$ is indicated by a throw deflexion, the amount of which is recorded in the diary and shows the potential to which the ehore end of the abble is kept charged. When the elegctrometer $E 7$ is used, a continnous test of the poteutial at the shore end is obtained, and the development of a fault in tho cable is at once indicated. It is convenient for this purpose to dispense with the charge in the electrometer jar and needle and connect the needle to the pair of quadrants wbich are joned to the cable. The deflexion is then proportional to the square of the potential and is always to one side of zero, so that the whole range of the scale is availablo for the deflesion. The tosts for wiro-resistance and capacity are practically the eame as those already described. They are in osdinsry circnmstances of much less importance than the insulation testa. The wire rosistance test is of groat value, however, for giving a close estimate of the temperaturo of the submerged cahle, and hence for giving the means of comparing the tests of the submerged cable with those of the cable previous to submersion. In laying short lengths of cable the shore station may be dispensed with and capacity tests relied on for coutinuity. Communication betreen ship and shore is carried on by means of the keys $K_{1}, K_{1}$, the galvanometes $\mathrm{G}_{1}$, and the batteries $\mathrm{B}_{1}, \mathrm{~B}_{1}$. The signalling key on board the ebiF adds or cubtracts the electromotive force of the battery $B_{2}$ from the testing battery, and hence varies the potentinl of the cable. This is shown on shore by the partial charge or discharge of $C_{F}$ passing through the galvanometer $G_{1}$ and is interpreted in accordance witb the single needle alphabet in the ordinary way. In a similas manner the signalling key on shore varies the charge of $\mathrm{C}_{y}$, and eo causes slight variations of the testing-cusecut on board the ship, which are read on the galvanometer $\mathrm{G}_{1}$ and interpreted in the same way. The testing is usually suspencled during the signalling; but if the mossage is long an insulation reading is taken every few minutes according to pre-arrangement.

The galvanometers used at sea require to be constructed so that the rolling of the ship does not deflect tho needle, either on account of its inertia and the action of gravity, or of the relative changes in the position of the ship's magnetism. The best form of marine galvanometer consists of two short bobbins of fine silk-covered wire placed ead to end, about an eighth of an inch apart, and having their axes in the same line, with a very light mirror, carrring cemented to its back one or more small magnets suspended between the two bobbins in such a way that the centre of the mirror is in their common axis. The mirior and magnet system weighe from ono-half to one grain. It is euspended as eloown in fige 14 by a
single silk fibre $f$, which passes throigb tae centre of inertio of tho mirror and needle system $m$ and is fixed at one end directly to the frame $F$ and at the other end to a light spring s. The frame $F$ is made thin eoough to slide into the opening between the two bobbing, so that the mirror can be easily taken out for adjustment when necessary. So long as the suspending fibre passes through the centre of inertia of $m$ it is clear that no motion of translation of $F$ can produce rotation of the mirror. When the instrument requires to be highly seasitive, as for testing purposes, it is shielded from the ection of the ship's and the earth's magnetism by enclosing it in a massire iron case. For signalling purposes the controlling magoet is arianged to produce at the ucedle a field so strong
 that the effect of variations of external mag-

F10. 14.-Marino galveno. meter. netism is insppreciable.

Testing for Faults. - Numcrons methods have been proposed for the localization of faulto in telegraph lines, some of a complex character and adapted to the cases of faults of a kind which fortunately seldom, if ever, occur. Wo give here a brief outline of the tests for the cases of most common occarrence.

For the determination of the nosition of a complete rupture with the conductor insulated both the insulation and the capacity tests are theoretically applicable. The insulation of a line of uniform type and material is inversely as its length; hence if a piece is broken of the insulation is increased. If I be the total insulation before ruptures, $I_{1}$ the insulation of one section after ruptrure, and $l$ the total length of the line, the length of the section is $l / / I_{3}$ : Unfortuastely it is difficult to obtain the necessary accuracy in insulation testing on account of the great infuence of earth-currents on the result; but apart from this there is always some ancertainty, especially in cables, as to the iosulation at tho break. For cables a fairly reliable test can be obtained from the capacity even when the insulation at the fault is somerhat imperfect, if it be sufficient to hold the greater part of tho charge for a ferr seconds, siace the amount of loss in any short interval can be estimated by a separato test. The capacity of a uniform cable is inversely as its length; hence, if $C$ be the total capacity of the perfect cahle and $C_{1}$ the capacity of one section, the length of that section is $l \mathrm{C}_{2} / \mathrm{C}$. Whenas is almost always the case-the cable is not quite aniform in electrical quality and in temperature, a table or a curve ahowing the wire resistance, the insulation, and the capacity up to any point from either end should be kept for reference.

It is oot at all uncommon in cables for one side of a fractiare to be partially insulated throngh the condnctor uot breaking exactly at the same point as the insulator. In this case, however, the other ond will be iu most cases almost perfectly earthed and the position of the fault can be very nearly deternined by the wire-
resistance test. When both ends are partially insnlated it is very difficult to obtain a near approach to the position of the fanlt because of the uncertainty as to which side of the break offers the greatest resistance. A frst approximation is obtained by finding the wire resistance from both ends and subtracting the total wire resistance of the cable from the sum of these. This gires the sum of tho resistances at the fracture, and half of this, if it is not too great, subtracted from the resistance of either section gives an approximation to the resistance of that section ap to the break. If, however, the resistance at the fracture is comparable to the total wire resistance of the cable, this method is useless. An approxch to the solution of the difficulty can be obtained from capacity tests, the cable being discharged through different resistances at tho testing end. But the procedure is very uncertain and difficult, and a full discussion of it would take more space than can bs afforded here. The resistance at a fault can sometimes be greatly diminished by repeated application alternately of the positive and negative poles of a powerful battery to the cable, hat this should never be resorted to if it can possibly be aroided. The direct deflexion method of taking wire resistance is most auitable for these tests. The resistance ocoms to diminish gradually after tho battery is epplied uatil it reaches a minimum value, after which it again increases. This maximum deflexion should be taken as indicating most nearly the trus wire resistance up to the fracture.

IVhen ithe fault is a partial earth without fraeture, and both ends of the cabla are arailable-as in factory testing, or when a socond well-insulated cable can be used-the most eatisfactory uncthod is the loop test. In this the two sections of the cable form two sides of the V"heatstone's bridge; one pole of tho battery is put to the juuction of the other two sides and the other pole to earth, -that is, practically to the fault. The ratio of the resistances in the bridge when balance is obtained gives the ratio of the resistances of the two eections of the cable, or the ratio of the resistance of one section to the resistance of tho other section plas \$he resistance of the sccond cable. The total resistance of the
cable being known, it is easy to determino the position of the fault: When the fault has a high resistance it is ncceseary to make a correction for the want of perfect insulation is the sound part of the cable. When both ends of the cable are not available, measure the potential at the testing end and the resistance between that end and the earth, and simultaneously measure, by means of a slide resistance and zero galvanometer or by means of a quadrant electrometer, the potential at the distant end. Then, if $V$ be the potential at the testing ead, $v$ the potential at the distant end, and $K$ the resistance measared, the troe resistance of the fault is $R(1-v / V)$. Another simple, although less perfect method, may be mentioned. Measure the resistance between both ends and the earth and subtract frem the snm the true wire resistanco of the cable; the differeace is twice the resistance of the fault. The imperfection of this method, and indeed of any which involves two observations not made simnl. tancously, lies in the variable character of the resistance of a fault.

## III. Modery Telegrapis.

The code of signals introduced by Morse is still emplojed in the United States and Canada, and the international codo in vogue in Europe differs only sliglitly from it. Currents in one direction onl are used, and different combinations of from one to four long and short coutacts form the lottcrs, while the numerals are represented by groups of five signals, and punctnation and other apecial aigns by groups of six and sometimes more. The iustruments ased for land telegraphs on this system are of two types,-" sounders," which indicate by sound, and "recorders," which record the eigoals.
(1) Recorders vary in details of construction, but all have the same object, namely, to record the intervals during which the current is epplied to the line. In the earlier forms of instrument the record vas made by embessing lines on a ribbon of paper by means of a slarp stile fixed to one cud of a lever, which carried at the other end the amnature of an electromagnet This metbod of recording is still largely employed in America, and certainly has the advantage of simplicity. The form of instrument almost universally used in Europe makes the record in ink, and hence is sometimes called the "ink-writer." This method has the advantage of distinctaess, and so is less trying to the ejes of the operators. The action of the instrument will be understood from the annexed sketch(fig. $\begin{array}{ll}\text { 15). Sup- } \\ \text { pose } & \text { s to }\end{array}$ be a strip of paper mhich is beingpulled towards
the left by the left by
means of two rollers $r_{1}$ aud $\pi_{2}$ moved by a train of mechanism. Uaderneath the roller $r_{1}$ a small wheel $i$ is kept turning by the samo mechanism, and has ita lower edge in contact with the surface of ink in the ink-well wo. When a current is sent through the magnet $m$, the armature $a$ is
attracted and the lever $l$ lifts the

Fio. 15.-Morse ink-writer, one-fourth ink-wheel $i$ into contact with th Whk-wheel $i$ into contact with the paper, against tise oariace. of length of which depends on the speed of the mechanism and the time the curreat flows. As the speed of the mechanism is nearly constant, the relative leggths of the marks depend only on the durstion of the current. In this wey the letters of the alphabet, or auy other understood signs, are indicated by groups of long and ehort marks, commouly called "dashes" gnd "dots."
(2) Operators who use the record- $F$ ing instrumont soon learn to read the message by the click of tho armature against its stop, and as this is a less reading, and leaves the hands and eyes free to write, the sound is usually preferred. Thus, when it is not necessary to keep a copy, a much simpler instrument may be cmployed and the message read by sound. The earliest successful form was Bright's bell sounder, which consisted of two bells of distinet touo or pitch, ors of which was sounded when tho current was sent in one direction and the other when it was reversed.: This instrument was capable of giving very cousiderable speed, but it Was more complicated than
510. 16.-Marse sounder, one-fourth sall size. ouly of an clectromagnet, with its armature lever arranged to atop
against an anvil or screw $\bar{b}$ (fig. 16) in such a way as to give a dis. tinct and somewhat loud sound. Dots and dashes are distinguished by the interval between the sounds of the instrument in precisaly tha same way as thay are distinguiahed when reading from the recorder by aound. The form of sounder commonly used in England is shown in fig. 16 ; it is one of the simplest possibla instruments, is easily adjusted to the currant by tightening or slackening the spring $s$, and is very little liable to get out of order.
Another and in some respecta a simpler method of recording is to use a chemically prepared ribbon of paper. Suppose, for inatance, tha paper ribbon to be soaked in a solution of iodide of potassinm and a light contact spring made to presa continu. ously on its surface as it is pulled forward by the mechanism. Then, if a current is sent from the epring to the rollar through the paper, a brown mark will ba mada by the spring due to the liberatiou of iodine. This was the principle of the chemical telegraph proposed by Edward Davy in 1838 and of that proposed by Bain in 1846. It gives a ready means of recording on the Morse plan at a high rate of speed, and Bain's telegraph was successfully worked for soma years in America. Several ingenious applications of his method have been proposed, as, for axample, the copying telegraph of Bakewell and of Cras, by means of which a telegram may he transmitted in the aender's own handwriting; the pantelegraph of Caselli ; the autographic telegraphs of Meyer, Lenoir, Sawyer, and others; and the autographic typo-talegraph of Bonalli. The priuciple of action of thesa instruments is this. Suppose two motallic cylinders, one at the sending and the other at the receiving station, to be kept ravolving synchrouonsly, and suppose the axis of each to be threaded with a fine screw so that as it revolves rapidly it has a slow side motion. Wrap round the cylinder at the sending statiou a ribbon oí tinfoil, or paper covered with a conducting coating, on which the message is written in varnish or soma other insulating substance. Suppose also a ribbon of paper which has been soaked in iodide of potasaium to be wrapped round tha cylinder at the receiving station. Cause a stila, as in the Bain telegraph, to press on each cylinder sad eet it in motion. It is evident that so long 'as the stile at the sending end prasses on the clean foil the stile at the receiving end will continua to make a brown mark, but that when it passes over the rarnish the mark will be interrupted. In this way, as the two cylinders revolve and move sideways, the series of interruptions made at the receiving end form an exact copy of the varnish marks at the sending ead. These instruments are at present but little used.
It has been fond pessible to make the Morsa ink-writer so sensitive that it cen record oignals sent over land lines of several hundred miles in length vary much faster than they can be transmitted by hand, and this has led to the adoption of automatic mathods of transmission. One was proposed by Bain as early as 1846, but it did not coma into nise. That now amployed is, however, practically 'a development of his idea. It consista in punching, by means of "a puncher," a series of holes in a strip of paper in such a way that, when the strip is seut through another instrument, called the "transmitter," the holes cause the circuit to be closed at the proper times and for the proper proportionate intervals for the message to be correctly printed by the receiving iustrument or recorder. The most euccessful apparatus of this kind is that devised by Wheatstoue; others have been introdnced by Sicmens and Halske, Garnier, Humaston, Siemens, and Little.

In Wheatstone's automatic appar cus three levers are placed sido by aide, each acting on a set of omall punches and on mechanism for feeding the paper forward a step after eack. operation of the levers. The punches are arranged as shown in fig. 17, and the levera are adjusted bo that the laft-hand ona mores $a, b, c$ and punches a row of holea across the paper (group 1 in the figure), the middle one moves $b$ only and punches

a centre hole ( 2 in the figure), while the right-land one movea $\alpha, b$, $d_{1} e$ and punches four holes ( 3 and 4 in the figure). Tha whole of this operation reprasents a dot and a dash or the letter "a." The side rowe of holes only are uscd for tranamitting the messaga, the centre row being required for feading forward the paper in the transmitter. The perforation of the paper when done by hand is usually performed by means of small mallats, but at the central telograph office in London the kayo are only used for opening air-valves, the actual punching being dono by pnoumatic pressura. In this way aaveral thicknesses of papar can ba perforated at the sama time, which is a great conveniance for press work, since copias of the same message have often to be transmitted to several newspapers at the same time. The mode of asing the paper ribbon for the transmission of the message is illustrated in fig. 18. An abonito beam E is rocked np and down rapidly by a train of machanism and moves the cranka $A$ and $B$ by means of two matal pins $p, p$. A and $B$ are in metallic contact with each other through the springs $s, s$, and they carry two light vertical
rods $\mathrm{M}_{1} \mathrm{M}_{1}$, the one as much in front of the other as there is apace between two successive holes in the perforated ribbon. To the other ends of $A, B$ rods $H, H_{1}$ are loosely hinged, their ends passing loosely through holes in the ends of the bar $P$, which is fixed to the divided disk D . By means of two collars $\mathrm{K}, \mathrm{K}_{1}$ and the wheel W, the disk $D$ is made to oscillata in unison with the beam $E$ The cranks $C$ and $C_{1}$ are connected with the polcs of the sending

battery B. The operation is as follews. The paper ribbon R is moved forward by its centre row of holes at the proper speed above the upper enda of the rods $\mathrm{M}, \mathrm{M}_{1}$; should there be no hole in tha ribbou it pushes tha crank $A$ or $B$ out of contact with the pins $p, p^{\prime}$ and prevents a current passing to the line. Should, however, a row of holes, like group I ahove, be perforated, the rod $M_{1}$ will first be allowed to pass through the paper and copper will be put to the line; at the next half stroke of the beam, M will pass through, and as the disk $D$ reverses the battery zinc will be put to the line. Thua for a dot first a positive aud tljen a negative current are sent to the line, the effect of the positive current continuing during the time required for the paper to travel the space hetween two boles. Again, suppose groups 3 and 4 to be puncherl. The first part will be, as before, copper to the line; at the next half stroke of the beam M will not pass through, as there is no hole in the paper; but at the third half atroke it passes through and zine is put to the line. Thus for a dash'the interval between the positiva and the negative current is equal to the time the paper takes to travel over twice the apace between two successive holes. Hence for sending both a dot and a dash reverse currents of short duration are sent through the line, but the interval between the reversal is three times as great for the dash as for the dot. In the receiving instrument the electromagnet is so construlcted that the armature, if pulled into any position by either current, remains in that position, whether the current continues to flow or not, until a reverse current is mada to act on the magnet. For the dot the armature is deflected hy the first current, the ink-wheel heing brought into con. tact with the paper and after a short interval pulled back by the reverse current. In the case of the dash the ink-wheel is brought into contact with the paper by the first current as before and is pulled back by the reverse current after three times the interval. Tha armatura acts on an inking diak on the principlo dascribed above, aave only that the disk is supplied with ink from a groove in a second wheel, or which it rolla: the grooved wheel is kept turning with one edge in contact with ink in an ink-well. By this method of transmission the battery is alwaya to the line for the same interval of time, and alternately with opposite poles, so that the effect of electrostatic induction is reduced to a minimum. Through the instrumentality of this method as many es 400 words per minuta have lately been transmitted by Mr Preece between London and Newcastle, a distance of 278 miles.

The first considerable improvenient on the House type-printer, referred to above, was made by D. E. Hughes of Kentucky in 1855, In tha Hughes instrument (see fig. 19) two trains of clockwork mechanism, one at each end of the line, are kept moving synchronously by powerful spring governors. Each instrument is provided with a key-board, resembling that of a small piano, the key levers of which communicate with \& circular row, $R$, of vertical pins. A horizontal arm A fixed to a vertical ahaft in gear with the mechanism sweeps over these pins at the rate of from one to two turns per eecond. When a key is depressed, slightly raising one of the pins, the battery is put to the line for a ahort time at that part of the ravolution by means of a sledge $S$ carried hy the horizontal arm. The current thus aent to the line may ba made either to act directly on tha printing instrument or to close a local circuit by means of a relay. For aimplicity we will supposa direct action. The current then passes through the coils of a powerful electromagnet $M$, which relieves the printing mechanism. The electromagnet consista of two coils each containing a aoft iroth cora of the same length as the coil. Thesa cores rest on the ends of tha two arma of a powerful horsa-shoa permanent magnet, and thus become atrongly polarized by induction. A aoft iron armature is placed across the free ends of the eoft iron cores and is pulled by a strong apring, the tension
of which is adjusted 60 as to be nearly equsl to the magnatic attraction. The carrent is eent in the proper direction to diminish the power of the magnet and allow the spring to preponderate. A rery po xarful action is thus obtained by means of a very small current, the actual work being done by motive-power in the instrument itself. After the letter ia printed the mechanism short-circuits the magnet and replaces the armature automatically. The printing action is as follows. The type-ribel W is carried round cortinu:

"American combination printing telegraph," because it entbolicd part of Hnglieg's and part of House's instruments. With this modified form somewhat greater speed was obtaiucd, lut it tuas found difficult to drive, requiring the nse of stean or some such motive-power. In a subsequent modification introduced in 1875 8n electromotor is applied to drive the printing mechanisuu. This allows a eborter train and stronger wheelwork to bo uscl, sccures moro certain action, and iuvolves less risk of derangument. Hughes's form was taken up ly the French Goverpment in 1860, ant is atill rery largely in use in France.
Stock and privato line telegraplas constitute an important class of instinments, of which Laws's "gold indicator," introduced in 1866, may be taken as the forernnner. A brief elescription of Calahan's stock telegraph, introluecd in 1867, will give a general idea of the action of this class of instrumenta. The printing mechauisin cousists of two typcwheels, on the edge of one of which are the letters of the slphabet and on thi edge of the other the numerals from 1 to 9 sud fractions by eightlis up to unity. The type-wheels are placed sife by sille, but can be turued independently of each other. Beneath them a platen is carried on one zud of a lever, whose other end is attached to the arinature of au electiomagnet. Between the platen and the Wheels a ribbon of paper broad enough to cover the edges of both wheels is passed. The instrumeut is rorked by three lines of wire, one for driring each
ously by the clockmork, to which it is attached through a friction aleeve which allowa it to be stopped, and puslied backward or forward without atopping the mechanion. Another slaft carrying three came is arranged so as to be locked into gear with the wheel. work when the armature leaves the poles of the inagnet. Tho cans then come into action in rotation; the first moves the adjustment lever, shown to the left of W in the figure, which pushes a wedgeshaped picce into the teath of the type-wheel and adjusta it exactly to the proper position for printing; the second cam presses the paper against the type ; the third mores forward the paper' ; a fourth cam replaces the armature of the magnet and relieves the ram shaft, leaving the instrument rcady to reeeive another letter. The whole of this operation occupies only a emall fraction of a secoud. By means of the adjustment lerer or "corrector" $l$ every error in syuchronism decidedly less than half the space from letter to letter is parfectly corrected each time an impression is made. Thus, during the time the receiving instrusoent at one station is in use, ita typa. wheel is kept in perfect agreement with the sending wheel at the other atation ; sad, if the electric action keeps time, a wrong letter cannot be printed unless the rate of tho clockmork is at fault by some such amount as one or tro per cent. If the two wheels are allowed to run a long time without the electric maintenance of agreement, they will be found more or less at variance, es the pieces of clock work, however good, caunot be parfect. Au' that is neceasary to bring them in to agreement agaiu is to etrike several times the key corresponding to a prearranged adjnstment signalthat corresponding to the dot type, for instanco. The receiver knowa (sccording to the regulated system of working) that it is adjustment, not message, that is being sent; and he turns his type-wheel by hand till it prints dots. He then aignals back "O.K." "All correct !") end is ready to receive the messagc. If by any accident hia type-wheel gets on a wrong letter in the course of a message, he disturbs the sender (who all the time seea the effect of his sending printed before his own eyes) by sending back a few currenta on him ; he receives dota by way of acknowledgment, end resets his type-wheel to print correctly. This ayatem of telegraphic printing has a great advantage over the step-by-step eyster in using continuous instesd of intermittent currents, and so avoiding the uecessity for the rapidly acting elactric sacapement, which, however skil. fully planned and executed, is always liable to failure when worked too rapidly. In Hughea's instrument almost perfect accursey and certainty bare been ettained ; and in actual practice it has proved to be decidedly superior to sll provious type-printing telegraphs, not only in speed and accuracy, but in lesa lisbility to mechanical derangement from wear and tear and from accident. It involvea many novel features: the receiving electromsgnet is of peculiar construction and remarkshle efficiency ; the tranemitting apparatus has a contrivance to prevent nnintentional repetitions of a letter through the operator holding his finger too long on a key; the type-wheal has a lock for each station, to be opened by its own key, one of the letter keys of suy of the instruments in the circuit. This instrument was for some years extensively used in the United States, antil ouperseded by G. Mi. Phelps's modification of it, known as the
type-wheel and oue for printing and feeding the paper forward. The movement of the type-rheel is accomplished by ao escapement acted on by closiug and opening the circuit of an electromagnet. For the conveniance of the sender the transmitting iustruicent is made in the form of tro dials, each resembling the dial of su A B C instrument, round the edge of one of which letters are printed, and round the other thenumerala and fractions. Mechanism is provided for opening and closigg the circuit, ao that by turning a handle (fixed to an axis passing through the centre of the dial) until an index attached to it points to the letter which is to bo printed, the type-wheel of the receiving instrument is in the proper position to print that letter, aud this is accomplished ty depressing a key and closing the third circuit The printing magnet then raises the platen aud pressea the paper against the type. Supposo direct United Statca telegraph stock is to be reported end the price is $9 \frac{3}{8}$. The operator turns the index on the letter dial to $\mathbf{D}$ and presses the priutug key; he next turns the index to period aud again pressas the priuting key; be then turns in succession to U , to period, to S , to period, and printa these; than he turns the index on the figure dial to 9 and prints it, lastly to $\frac{z}{b}$ and to period, and printa them. The quotation then rcads on the paper ribbon D. Ư. S. 9 ?

Various modifications of this instrument heva since been introduced. In one form, the "universal etock printer," two lines of mire are required, and both type-wheels are driven by one wire, the printing magnet being made to change the action from one wheel to the other when the wheels are brought into a particular position. In another, "Phelps's stock printer," only one lize of wire is required, a polarized armature leing used for moring the type-whegla and an ordinary neutral armature for the printing. The rapid reversals which work the polarized armature do not last long earough to move the printing lever, but when a pause is made the printing mechanism is relieved and a letter printed. This instrument is aimilar in principle to the House spparatus and is capable of working at a considerable speed. ${ }^{1}$
Cowper'e writing telegrsph is designed to record the mesgage in' written characters; its arrangement is as folloms:-Two lines of wire are connected, one with each of two small reaistance slides, Which are placed in such 8 wey that the sliders move in the same plane but in directions at right angles to each other. A pen placed et the point of intersection of the lines of motion of the two sliders is connected with them in such a may that, when it is mored, as in the act of writing, each slider takes np that component of the motion which is in the direction in which it is free to more. The eliders thus vary the resistance in the line circuits hy an am ount proportional to the motion of the pen, and when a battery is kept joined in the circuit the corrent raries in the same way. The current is passed through the coils of two electromamets at the receiving end, each capable of gising motion to a pencil in one line, at right sagles to the direction of motion of the other. When the pen at the sending end is moved as in the act of writing a messaga 1 For these and other type-printing instruments, see Prescott's Elechriciov and the Electric Telegraph.
the pencil at the receiving end moves in a corresponding manner on account of the variations of the current, and in this way it writes the message on a slip of paper moving beneath its point.

Methods of Working Telegraph Circuits.-(1) The arrangement on the open circuit syetem for single-current working is shown in fig. 20 , in which $L_{1}$ represents the line, $G$ a simple form of galrauoscope, nsed simply to show that the currents are going to line when the message is being transmitted, $K$ the transmitting key, B the battery, I the receiving instrument, and $E$ the earthplate. The complete circuit is from the
 plate E throngh the instrument I , the key K , and the galvanoscope $G$ to the line $L_{1}$, then through the corresponding instruments to the carth-plate $\mathbf{E}$ at the other end, and back through the earth to the plate E. The earth is always, except for some special reason, used as a seturn, because it offers little resistance and sares the expense and the risk of failure of the return wire. The earth-plate E ought to be buried in moist earth or in water. In towns the water and gas pipe systems form excellent earth-plates. It will be observed thst the circuit is not in this case actually open; the meaning of the expression "open circuit" is "no battery to line." Under normal circumstances the instruments at both ends are ready to receive, both ends of the line being to earth through the receiving instruments. A signal is sent by depressing the key K , and so changing the contact from $a$ to $b$, and thas putting the battery to line. On circuits where the traffic is emall it is usual to make one wire serve several stations. The connexions at an intermediate or wayside station are shown at $W$. S is a switch, consisting of three blocks of brass fixed to an insulating base. W may be made the terminal station of $\mathrm{I}_{1}$ by inserting plug 3, and of $\mathrm{L}_{2}$ by inserting plug 2, or the instruments may bo cut out of circuit by inserting plug 1. In ordinary circumstances the messages from all stations are sent through the whole line, and thus the operstor at any station may transmit, if the line is free, by manipulating his key. The greatest inconvenience of this system arises from the varying strength and resistance of tho betteries used at the different stations. As, however, delicate recording instruments are seldom required on such circuits little difficulty is experienced.
(2) The connexions for positive and negative current or singleneedle working on open cirenit aro shown in fig. 21, in which all the letters hare the same meanings as before. Bat N is a single necdleinstra. ment, and $K$ is a reversing key. The levers 1 and $2 \square$

the stops $a$ when the line is free; hence the line is to earth at hoth ends. But, if lever 1 is depressed, one pole of the batiery is put to line; if 2 is depressed, the other pole is put to the line. In this way the meedles of the receiving instrument may be made to turn to either left or right; and, if we call a motion to the left a dot and a motion to the right a dash, the Morse alphahet may be read from these motions. The connexions for wayside stations are illnstrated at $W$, and will be readily naderstood from the description giren under single-current working above.
(3) When the line consists in wholo or in part of undergrouud or submarine cable the capacity canses a very considerable diminu. tion in the speed of working. This is to some oxtent got over by putting the earth connexion in of the battery and using donble the number of cells, as shown in fig. 22. The stop $\alpha$ of the key K is

connected
Fig. 22.
through a switch $S$ with one pole of the battery $B$, and the stop $b$ in tho usnal wny with the other pole. Suppose the acm $c$ of the switch $S$ to be in contact with 2 ; then when the key is mani-
pulated it sends alternately positive and negative currents into the line. If the positive is called the signalling curreut, the line will be charged positively each time a signal is sent; butas soon as the signal is completed a negative charge is communicated to the line, thns hasteuing the discharge and the return of the relay lever to its insulatcd stop. This method of workirg has been already referred to in connexion with Wheststone's automatic systern.

The connexions for single-current working on this system are Closed illustrated in fig. 23. It differs from the open circuit in only requir- circait ing one battery (although, as in the figure, half of it is often placed at each end), in having the receiving instrument between the line and the key, and in having the battery continuously to the line. The battery is kept to the line by the bar $c$, which short-circuits the keys. When signals are to he sont from either station the operator tnrns the bar $e$ out of
 contact with the stop $b$, and then operates precisely as in open circuit sending. This system is more expensive than the open circuit system, as the battery is always at work; but it offers some ad. vantages on circuits where there are a number of intermediate stations, as the circuit is under a constant electromotive force and has the same resistance no matter which station is sending or receiving. The arrangement at a wayside station is shown at W. When the circuit is long and contains a large number of stations, the sending battery is sometimes divided among them in order to give grester uniformity of current along the line. When only one battery is used the current at the distant end may be considerably affected by the leakage to earth along the line.

In working long circuits with ordinary instruments inconven- Relay iently high battery power is required in order-to send sufficient working current to prodace the signsle. In such cases it is usual to employ a local bsttery to produce the signals and to close the local battery circuit by mcans of a delicate circuit-closing apparatus calied a relay, which is a very delicate clectromagnetic key having its lever attached to the armature of tho magnet. The arrangement at a station morked by relay is ohown in fig. 24 , where $L$ is the line of wire, joined throngh the key K to one end of the coil of the relay magnet $R$, the other end of which is put to earth. When a current passes throngh $R$ the armature $A$ is attracted and the local circuit is closed throngh the armature st $b$. The local hattery $\mathrm{B}_{1}$ then sends a current through tho instrament I and records the signal.
 In the form of reloy indicated in the figure the armature is held. against the etop $a$ by a spring S . In some cases-as, for example, in Siomens's polarized relay, ehown in fig. 25 -the armature $\alpha$ is put in contact through the pivot $\pi_{2}$ with one pole $N$ of a permanent magnet $m$, the other pole s of which is fixed to the yolk $y$ of a horse-shoe electromagnet M. The armature is placed between the poles of the electromagnet, a little nearer one pole than the other, so that the magnetic attraction holds the contact lever against the insulated stop without the aid of a epring. This form of relay only answers to currents in one direction, but it is capable of giving great sensibility, and for some purposes - for instance, in some methods of quadruplex working-its directional
 polarized relay. character is au advantage.

Translation.-In a precisely similar manner a relay may be made to rc-transmit automatically the message over another line, or, what is the same thing, over a oontinuation of the same line when the whole length is too great for direct working. It is not usual in practice to emplay the delicate receiviug relay for re-transmitting the message, bat it is made to work a coarser instrument, which takes the place of the sounder, or, it may be, the sounder itself, in the local circuit. It is clear that one receiving relay may be used to work a number of re-transmitting keys in the same local circuit, and hence to distribute a message eimultaneously over a number of branch lincs from a central station.

Duplex, Quadruplex, and Multiple Telegraphy.-Duples telegraphy consists in the simultaneous transmission of two messages.
-ne is each direction, over the same wire. The solution of this problem was attempted by Gintl of Vionns in 1853 and in the following year by Frischon and by Siemens and Halske. Within a few yoars several methods had been proposed by different inventors, but nene were at first very successful, not from any fault in the principle, but becanse the effect of electrostatic capacity of the line was left out of account in the early arrangemants. The first to introduce a really good proctical syatem of duplex telegraphy, in which this difficulty mas safficiently overcome for land lino purposes, was J. B. Stearns of Boston (Mass.) In order that the line between two stations $S_{1}$ and $S_{2}$ may be worked on the duplex eystem it is essential that the roceiving instrument at $S_{1}$ shall not be acted on by the currents sent into the line at $S_{1}$, and similarly that the currents sent into the line at $\mathrm{S}_{2}$ shall not act on the receiving instrument at $S_{2}$, whilo at the 8 me time these currents must act on the instrument at $S_{2}$ and $S_{1}$ respectively. The two mothods most commonly $e^{-}$oyed aro the following.
(1) In fig. 26 B is the bending battery, $\mathrm{B}_{1}$ a resistance equal to that of the vattery, $R$ a set of resistauco coils, and $C$ e condenser. Suppose the key at station $S_{1}$ to be depressed; then a cur. rent flows into the line throagh circuit 1, and to earth through circuit 2. Now, if both these curronts pass, as indicated in the fig. ure, round the electromagnet of the receiving instru.
 ment, lut in opposite directions, and if thair strengths are properly adjusted, no offect will bo produced on that instrument. At station $\mathrm{S}_{3}$ horever, the current llows to earth, partly through circuit 1 and partly through circuit 2, but in the same direction round the coils of the receiving instrument. Hence, if the current is strong enough, the receiving iustrument at $\mathrm{S}_{2}$ will be set in action. Similarly the depression of the key at $\mathrm{S}_{2}$ can be made to produce a signal at $S_{1}$ and yet have no effect on the instrument at $S_{2}$. The aecessary and sufficient condition is that the currents in circuits 1 and 2 at the sending station shall at all times bear a certain fixed ratio to each other, depending on the coils of the receiving instruncint at that station. If for simplicity we suppose the resistance of the line to be constant and not to be affected by the trans mitting apparatus, and to be of zero electrostatic capacity, the fixed ratio may be obtained by odjusting $R$ in the auxiliary circuit 2. In actual practice the line has capacity, and this is compensated for by supplying to $R$ from the condensor $C$ capacity cquivalent to that of the line. O should be of such a forn that the capacity in the circuit can be varied, and it must have the same inductive retardation as the line; that is to eay, the capecity mast be distribnted along the resistance $R$ in a manner equiralent to that in which tho capacity of the line is distributed along its resistance. A rough approximation to this adjustment will answer the purpose for ordinary land line working, but for subinarine cable work a very accarata adjustment is necessary. In order that the manipulation of the key may not affect the resistance of the line, the resistance betwean the point $D$ and $E$ should be as nearly as possible the same far all positions of the key. This implies that the keys shall not at any tima break circuit, nor make contact on both the front and the back stops for mors than an instant, for an instantaneous break of the circuit would affect the signals boing received from the other station. The principle o. the "continuity preserving key," used for daplex working, will be ondarstoud from the figure. So long as the kpy is not depressed the line is kopt to earth through the resistance $\mathrm{B}_{1}$; when the key is pushed down it suddenly changes to the battery $B$, being at the ransition in contact with both $B$ and $B_{1}$ This produces very little disturbance, becanse the key is moving quickly at that part of its stroke, and the resistance of the lias and receiving instrument is generally much higber than that of $\mathrm{B}_{1^{\circ}}$. This is called the "differential method." The principle was first enunciated by Frischen; but its present condition is the result of the labours of a large number of experimenters, ainong whom may be mentioned Siomens and Halske, Stark, Edlund, Gintl, Nyström, Preece, Nedden, Farmer, Maren, Winter, Stearns, and Muirhead.
(2) The second mathod to which mo may here rofer 19 known as the "brilge method "from the cimilarity of the arrangement (see fig. 27) to that of the Mheatstone bridre. Instead of gending the currents in the tro branches of the divided circuit $D P$ and $D Q$ throagh the tro coils of a differentially wound relay or receiving instrument, as in Frischen's method, two resistances $a$ Lud $b$ are inserted and the iustruments ato joined batweon $P$ and $Q$. It is claar that if the difference of potential between $P$ and $Q$ is nonaffected by closing the sendiag key $K$ no change of current will take place in the instroment circuit. The relative poteutial of $\mathbf{P}$ and Q is net
affected ly the manipulation of 5 if the resistance $\alpha$ is to that of $b$ as the resistance of $L$ is to that of $R$; hence that is the arrange ment used. The sams remar!ss with'regard to retardation ang

capacity that were made when describing the differential mether apply here also Oue very great advantage in this method is that the instrument used betreen $P$ and $Q$ may be of any ordinary form.

Most important cables, buch as those of the Eastern Telegraph Company and the parious Atlantic cables, are worked duplex on Muirhead's plan. What may bo called a mechanical mothod of duplexing a cable was deacribed by Sit W. Thomeon in a pateat takeu out by him in 1858. In this, as in the ordinary methods, a differentially wound receiving instrument was used, one coil being connected with the cable and the other mith the earth; but it difererl from other mothods in requining no "artificial" or model cable The compensation was to be obtsined by working the slides of a resistance slide included in the circuit of the compensating coil, either by the sending key or by clockwork reliered by the key, 60 as to rary the resistance in that circuit according to any lam which might be requirad to prevent the receiving instrument being aflected by the no ${ }^{+}$wing current. Four years later Varley patented his model cable, which was the first near approach to a successful colution of the duplex problem on the principle now adopted. It was not, however, a sufficiently perfect representation of a laid cahle to serre for daplexing cablee of more than a few handred miler in length. ${ }^{1}$

By an interesting modifcation of the bridge method, which has been applied with excellent results by Dr Mluirhead to submarine work, condensers are substituted for $a$ and $b$, ors being also placed in the circuit betweon $P$ and $Q$. In this case no curreut flowe from the battery through the line or instrumente, the whole action being inductive. As we Lave already stated, the distribruion of the capacity along the resistance $\mathbf{R}$ must is oubmarine cable work he made to correspond very accurately with the distribution of the capacity along the resistance of the cable. This is accomplished by Dr Muirhead in the following manner. One side of a sheet of paraffined paper is covered with a sheet of conducting substance, say tinfoil, and over the other cide narrow strips of the eame substance are arranged gridironwise to form a continnous circuit along the strip. The breadth and thickness of the strip and the thick. ness of the parafined paper are adjusted so that the relative resist ance and capacity of this arrangement are the same as tbose of thie cable with which it is intended to be used. A large number of such sheets are prepared and placed together, one over the other, the end of the strip of the first sheet being connected with the beginning of the strip of the second, and so on to the last sheet, the whole represeuting the conductor of the cable. In the asme way all the conducting sheots on the other side of the paper are connected together and form the earth-plats of this artificial cable, thas represeuting the sea. The leakage through the insulator of the cable is compensated for by connecting high resistances betreen different points of the strip conducter and the earth coating. Faults or any other irregularity in the cable may be represented by putting resistances of the proper kind into the artificial lino. This system of doplexing cables las proved remarkably successful.

Quadraplex telegraphy consists in the eimultaneons transmission of tro messages from each end of the line. Tho only now problem introduced is the simultaneeus transmission of two messages in the same direction; this jo sometimes called "diplex transmission" The solntion of this problem was attempted by Dr J. B. Stark of Fionna in 1855, and during the next tan years it was workod at by Bosscha, Kramer, Maron, Schaak, Schreder, Wartmann, and othere. The first to attain success was Edison, and his method with some modifications is still used. Oze of the latest arrangements is shown in fig. 28,8 brief description of which will iodicate the general principle involved. $\mathrm{K}_{1}$ and $\mathrm{K}_{2}$ are two transmitting keys the pature of which will be understood from the jllustration; $\mathcal{B}_{7}$ and $\mathrm{h}_{2}$ are two differentially wound polarized relays, both of which aro supposed to respond to positive currents and to be held agrinst pressed a current, which for convenienco we call - 4, flows to the tine; this is sufficient to overcome the pull of the spring T in the relay $\mathrm{R}_{3}$ (the receiving instruments are supposed to be at the other end of the line), and hence the levers of both relays are held against their back-stops. When $\mathrm{K}_{1}$ is depressed a current -1 is sent to the line, and, this being too weak to overcome the spring $T$, the lever 1 See De shuty, Journ Sor Tch Enge, vol. ii., 2578.
of $R_{1}$ moves into centact with the ansiliary lever $l$ and closes the circuit of the sounder $\mathrm{S}_{1}$. When $\mathrm{K}_{2}$ only is depressed a current +4 is sent to the line. This acts ou both relays, but is powerful eneugh to overcome the polins pull of the so to move the lever $l$ and break the circrit of the sounder $S_{1}$ before it has time to act. Thus $\mathrm{K}_{2}$ acts on the sonnder $S_{2}$ but not on the sounder $S_{1}$. When beth keys are depressed a current +1 is sent iuto the line. This is sufficient to move the lever of $\mathrm{R}_{1}$ into con. tact with $l$ but not to overceme the pull of $T_{1}$, and hence the circuit of scunder $S_{1}$ is closed; it is also sufficient to move the lever of $\mathrm{R}_{2}$ and close the circuit of $\mathbb{S}_{2}$. When therefore both keys are down the sounders $S_{1}$ and $S_{2}$ at the other end of the line are both cet in action; the first responds to $K_{1}$ and the secand to $\mathrm{K}_{2}$. Thus all the conditions for the cimultaneous transmission of two messages are provided for. It is not necessary to enter again into the question of continuity at the different positions of the keys. The figure illustrates how this diplox system may be duplexed, and hence how quadruplex working can be obtained. It is only necessary to wind the coils of the relay magnets differentially, when, by means of a precisoly similar arrangement to that used for simple duplex, the instruments at the sending station are left unaffected by the outgoing currents, but are affected by the incoming currents. The method here indicated is on the differential principle; but it is scarcely necessary to say that the bridge method is equally applicable. \& combination of the bridge and the differential methods hass been used by Prescett and Smith, and possesses some advantages in certain cases. It is impossible in this article to go into the great variety of detall in arrangement and method with which it is possible to ebtain grood results.
The several methods that have been proposed for the transmission of a number of messages in one direction ou the same wire are reducible to two classes. In one the time which a revelving centact slider takes to make one revolution is divided inte as many intervals as there are sete of sonding and receiving instruments on the line, and by means of it the current is closed through the different sets of apparatus in saccession. This implies the synWhronous movement of the revolving sliders at the two ends of the cine. In a cense this may be said to be simultaneous trausmission: all the messages are being sent at the same time, but the progress of any one message is slower than it would be if it alone was occupying the whqle line in the ordinary way. The method possosses some advantages when the line is capable of being werked at a higher speed than a single operator can attain, or when one of the stations can advantageously bo used as a distributing station; for in that case one set of apparatus may be used as an automatic distributor. Multiple telegraphy on this plan was proposed by Themson in 185s. 1 A very complete set of apparatus for the purpose was shern by Meyer at the Vlenna exhibition of 1873.2 Delaunay's multiple telegraph is the most recent develepment of the system, and bas been lately adoptod on some circuits in Great Britain. ${ }^{8}$

In the other class there are joined to the tre ends of the line of wire a number of branch circuits, in each of which a set of transmitting and receiving apparatus is included. In the circuit, betr een the line and each of the sending keys, an electromagnetic vibrator is placed se as to open and close the circuit a great number of timos during each signal. The vibrators in the key circuits at one end of the line have all different and, if possible, relatively incommensurable periods. The receivers at the other end of the line consist of a corresponding set of electromagnotic vibrators, mounted on resenators and baring exactly the same ribrational periods as these in the key circuits at the sending end. When any one of the keys is manipulated the currents sent into the line have such a pulsatery character that they only affect the recoiver, which is capable of vibrating freely in unison with those pulsations. When a number of keys are manipulated at the same time the receivers analyse the resultant wave, each picking out its ewn componeut, thus separating the different messages. The "harmenic telegraph" of Mr Elisha Gray of America is a good example of this class.

Working of Submarine Cables.-The arrangement of the apparatus for riorking some of the most recent cables is shomn in fig. 29. The cable is supposed to be worked duplex; but, if $S, C_{1}, C_{2}$, and $A C$ are removed and the key cennected directly with $\mathrm{C}_{3}$, the arrangement for simplex working is obtained. The apparatus consiste of a sending battery B, a reversing transmitting key K , a slide of small

## I Tel. Journ., September 1996.

resistance $S$, three condensers $C_{1}, C_{9}, C_{8}$, an articicial cahlo $A U_{1}$, the receiving instruments I and $G$, and one or more resistances $R$ for adjusting the leakage current. The peculiar censtruction of AC has beon already referred to. The cenductor of the cable is practically insulated, as the cendensers in the bridge have a very high
resistance; hence no appreciable current ever flews into or out of tive line. Two receiving instrumente, a siphon recorder and a mirror galvenometor, are shown; one only is absolutely necessary, but it is couvenient.
to have the
 galvanemeter ready, 60 that in case of eccident to the recorder it may be at once switched into circuit by the switch s. When one of the levers of K is depressed, the condenser $\mathrm{C}_{3}$ and the cablo, and the condenser $\mathrm{C}_{3}$ and the artificial cable, are simultaneously charged in series; but, if the capacity of $\mathrm{C}_{1}$ bears the same proportion to the capacity of the cable as the capacity of $\mathrm{C}_{2}$ bears to the capacity of the artificial cable, and if the other adjustments are proporly made, no charge will bo communicated to $\mathrm{C}_{3}$. After a very shert interval of time, the length of which depends on the inductive retardation of the cable, the condeusers correspouding to $\mathrm{C}_{1}$ and $\mathrm{C}_{8}$ at the other end begin to be clarged from the cable, and bince the charge of $\mathrm{O}_{3}$ passes through the receiving instrument I or G the signal is recorded. The charging of $\mathrm{C}_{3}$ at the receiving end will take place, no matter what is the absolute potential of the condensers, consequently the incoming siguals are not affected by these which are being transmitted from that end. In actual practice the recoiring instrument is so sensitive that the difference of potential between the twe coatings of the condenser $\mathrm{C}_{3}$ produced by the incoming signal is only a very emall fraction of the potential of the battery B. When the key is relieved the condensers and cables at once bogin to return to zero notential, and if the key is depressed and relieved sereral times in rapid succession the cablr is divided into sections of varying potential, which travel rapidly towards the receiving end, and indicate their arrival there by producing corresponding fluctuations in the charge of the condenser $\mathrm{C}_{3}$. All cables of any great length are werked by reverse currents, the single needle alphabot being used : that is to say, curreuts in onc direction indicate dots and in the other direction dashes.
The following descriptions of the mirror galvanometer and the siphon recorder are, with some slight alteration, taken from a lecture delivered by Sir W. Thomson before the Institution of Engineers and Shipbuilders in Scotland. ${ }^{4}$
(1) The instrument first used for receiving signals through a long submarine cable (the ohort-lived 1858 Atlantic cable) was the miror galrace galvanometer, ${ }^{\text {b }}$ which consisted of a small mirror with four light meter. magnets attached to its back (weighing in all less than half a grain), suspended by means of a single bilk fibre within the hollow of a bobbin of fine wire,-a suitable controlling magnet beiug place adjacent to the apparatus. The action of the instrument is as follows. On the passage of a current of electricity through the fine "ire coil the suspended magnets with the mirtor attached tend to take np a position at right angles to the plane of the cril, and are defiected to one side or the other according as the current is in one direction or the other. Deflexions to one side are iuterpreted as dots and to the other side as dashes, and the messages are transmitted in accordance with the international Morse code of signals. (2) The spark recorder in come respects foreshadowed the xore Spark perfect instrument-the siphon recorder-which was introduced recordes some years later. Its action was as follows. To an indicator, ouitably supported, a to-and-fre metion was given by the electromagnetic actions due to the electric currents constituting the signals. The indicater was connected with a Ruhmkorff coil on other equivalent apparatus, designed to cause a continual succcossion of sparks to pass between the indicator and a metal plate cituated beneath it zad baring a plane surface parsllel to its line of motion. Orer the surface of the plate and betwe in it and the indicator there was passed, at a regularly uniform speed, in a direction perpendicular to the line of motion of the indicator, a material capable of being acted on physically by the aparks, either through their chomical action, their heat, or their perforating force. The record of the signals given by this instrument was an undulating line of fine perforations or spots, and the character and succession of thundulations were used to interpret the siguals desired to be sent.
(3) The latest form of receiving instrument for long scbmarine Siphon cables is the siphon recorder, for which Sir W. Thomsen obtained recorden

4 See his Mathematical and Physieal Papers, vol. 1i. p. 168
5 For a description of the mirror galvanometer, see art, Gaxparonerrer, fol
x p. 506 g .
his first patent in 1867. Within the three succeeding years great improvements were effected on it, and the instrument has since that date been exclusively employed in morking most of the more important submarine cables of the world,-indeed all except theze on which the mirror galvenometer method is in nse. In the siphon recorder (see fig. 30) the indicator consists of a light rectangular signal coil of fine wire, suspended between the poles of tro powerful electromagnets M, Mi so as to be free to move abont its longer axis, which is verti. cal, and so joined that the electric aignal currents through the cable pass through it. A fine glass siphon tube is suspended with freedom to more in only ono degree, and is connected with the sig. nal-coil and moves with it. The short leg of the siphon tabe dips into an in sulated ink-bottlo, so that the ink it contains becomes electrified, while the
 long leg has its open end at a very emall distance from a brass table, placed with its ourface parallel to the plane in which the mouth of the leg moves, snd over which \& slip of paper may be passed at a uniform rate, as in the spark recorder. The ink is electrified by s small induction electrical machine Eplaced on the top of the instrument; this causes it to fall in very minute drops from the open end of the siphon tube apon the brass table or the paper elip passing over it. When therefore the eignal-coil moves in obedience to the electric sigual currents passed through it, the motion communicated to the siphon is recorded on the moving elip of paper by a wavy line of ink-marks very close together. The interpretation of the signals is according to the Morse code, -the dot and dash being represented by deflexions of the line of dots to one side or other of the centre line of the psper. A very mach simpler form of siphon recorder has been de vised and brought into use within the last ferm years. Instead of the electromagnets, bandles of long bar. marnets of вquare eection and made up of equare bars of glass. hard steel are used. They are supported vertically on a castiron socket, and on the upper end of each is fitted a soft iron shoe, ehaped to concentrate the lines of force and thas produce a strong magnetic feld in the space within which the signal-coilis suspended. Instruments of this kind have been made to work both with and withont electrification of the ink.
Without electríi.

cation the instrument (see fig. 31) is very simple and compact, and capable of doing good work on cables 500 or 600 miles long. When conatructed for electrification of the ink they are svailable for much greater lengths, but for cables such as the Atlantic the original form is atill used. The strongest magnetic field hitherto obtained by permanent magnets (of glass-herd steel) is about 3000 C.G.S. With the electromagnets used in the original form of eiphon recorder a magnetic field of sbout or over 5000 C.G.S. is easily obtanned. Fig. 32 shows a facsimile of part of a message received and recorded by a siphon recorder, such as that of fig. 30 , from one of the Eastern Telegraph Company's cables about 830 miles long.
(4) The sutomatic curb sender $\begin{aligned} \\ \text { as designed by Sir Wr. Thouson }\end{aligned}$ for the purpose of diminishing the cffect of inductive einbarrassment in long cables. In ordinary hand-sending the end of the cable is put to one or the other pole of the battery and to carth alternately, the relative tinne during which it is to battery and to eartb deponding to a great extent on the operator. By the auto.

Fia. 32.-Facsimito of siphon rccorder messañ.
matic curb sender the cable is put to one or the other pole of the battery and then to the reverse pole for definite proportionsta times during each signal The cable is thas charged first positively and then negatively, or vece versa, for each signal. This method not only facilitates the discharge of the cable, and so accelerates the return of the index of the receiving instrnment to zero, but provides the mesns of sending positive snd negative curreuts into the cable at the proper times and for the proper intervals. The action of the instrument is regulated, like that of Wheatstone's automatic transmitter, by a perforsted elip of paper. The arrangement of the perforations and the method of using the paper slip are, however, quite different. The paper is fed forward by a ceutral row of holes, which are therefore continuous. The dots and dashes of the message are represented by the side rows of holes; but the two currents required for a dot are produced wholly by cne hole on one side and those for a dash by one hole on the other eide. The perforated elip is exactly similsr to the message written by the siphon tecorder, the gide holes occupying the same relative positione as the loops to one eide or other of the central line in the record. As the side holes resch a certain point in their passage throngh the instrument they sllow the end of one or the other of two levers to fall; the other end of the lever lifts a light contact apring, forming one lever of a reversing key, and makes electrical connexion betreen the bsttery and another set of springs, which also form the levers of a reversing key. The spring is held up, by a fange on the edgo of a revolving theel passing under it, during the time required by the paper to sdvance through the distance between two central holes. During this interval the current is reversed at the proper time by a pair of adjustabla cams fixed to the samo epindle as the flanged wheel. This method of transmission has been fonnd quite successful, though it has not been brought into use, as handsending bas hitherto proved sufficient for the work required.
Speed of Signalling. -The mathemstical theory of the speed of telegraphic signalling was given in a paper on "The Theory of the Electric Telegraph " communicated by Sir W. Thomson ${ }^{1}$ to the Roysl Society in 1855. He shows that, if $k$ be the wire resistance, $c$ the capacity per unit length, and $l$ the total length of the line, the carrent at the receiving end st any time $t$ after the application of the battery at the sending end is given by the equation

$$
\mathrm{C}_{\varepsilon}=\mathrm{C}\left\{1-2\left(\epsilon-\epsilon^{4}+\epsilon^{9}-\epsilon^{18}+8 c_{c}\right)\right\},
$$

Where C is the maximum current which the battery is capable of maintaining throngh the line, and $\epsilon$ is equal to $\left(\frac{3}{3}\right)^{\frac{1}{a}}$ when $a$ is equal to $k c^{2} \log _{a}\left(\frac{3}{3}\right) / \pi^{3}$. The number 参 is quite arbitrary; it is chosen becsuse it makes a nearly equal to the time reqnired for the current to become sensible at one end of the line after the battery has been
applied to the other end. The number $10^{\frac{1}{20}}$, which is more convenient for calculation and which does not differ greatly from ${ }^{3}$, was oubsequently adopted by Sir W. Thomson, and also by Professor Jenkin. ${ }^{2}$ The eqnation may be written
which shows plainly how the current is affected by the length, the resistance, and the capacity of the line.
It is evident from this equation that a finite time is required after the battery has been applied at the sending end for the current to become eensible at the receiviug end, the interval being practically equal to $a$, snd also that for similar actions the intervals between operations for one line must be to tie corresponding intervals for sinother line dircetly ss the values of $a$ or of $k c l^{2}$ for the two lincs. We $e \in$, therefore, that for lines of the same type, worked in the same manner, the eneed of working will be invereely as the square of the length of the line, or, if the type varies, inversely as the product $K Q$, where $K$ is the total resistance snd $Q$ the total capacity

[^32]of the line. The ister ai a must not bo confonnder mith the time required for each sighu: it is a measme of the slomuess of transmission ; but the number of signals which can be received in a given time, on any one line, depends on the method of working and on the sensibility of the instruments employed. The ratios of the number of signals which can be sent orer different lines in a stated time are the aarse as the ratios of the values of $a$ for these lines. The value of $a$ for the different Atlantic cables varies between a Ofth and a quarter of a second, and, as the time required for the current to reach 90 per cent. of its maximum value is ten times $a$, an instrument which requires as much as 90 per cent. of the full current to produce a signal and a fall to 50 per cent. between the signals could ouly receive about one signal every two seconds or between one and two words per minute. The instrments actually used attain to a speed of about twenty times this; but they are capable of showing distinctly a current of a ten-thousandth, or even less, of the maximum current. The value of a for ordinary land lines is very small, probably not exceeding the five-thousendth part of a second for a circuit 500 miles in length. The current,
thercfore, rises almost to ita full valus for each signal when the time of contact is as small as the five-hundrenth part of a second, or, on the Wheatstone instrnment, when the speed is about 500 pords per unimite. There is, however, a very aensible increase in the effective resistance of the circuit, especially when iron wire is used, wlen signals are sent as rapidly as 100 per second, so that higher battery power is required for fast than for slow rates of speed. The difficulty in working land lines at rates up to 300 , or even more, mords per minute is not to any serious extent electrical, but io in great aueasure due to material and magnetic inertia in the receiving instrumenta. Altliongh land lines can be morkerl at a very high syeed when the whole of the wire is insulated on poles, the rate is greatly diminished if a length of underground or of submarine cable is included in the circuit. In practice also the speed depends greatly on the position of the cable in the circuit; for exaniple, the actual speed from Dublin to Loudon, according to Mr Preece, is about twice as great as that fromi London to Dublin. Mr Culley states that the greatest effect is produced when the rahle is in the middle of the circnit.
(T. GRu)

TEl EMETER, or Rangefinder. This is an instrument nsed in modern warfare to deternine the distance or range to an enemy's position, in order that correct elevations may be given to guns or rifles directed against it. Telemeters have been made on three distinct principles, and classifed as acoustic, optical, and trigonometrical respectively.

Aconstic lelemeters record the time which elapses between sceing the flash or smoke and hearing the report of a gun, rifle, or shell, the range being given in gards as "the time in seconds $\times 36 t^{\circ} 6$." The Boulenge telemeter is the best known of this class. It consists of a graduated glass tube filled with liquid and containing a small metal traveller. At the flash the instrument is brought to a vertical pooition, and the traveller starts from.zero; at the detonation it is turned to a horizontal position and the traveller stops. The objections to the acoustic telemeter are that the rate of transmission of sound in air is affected by wind and other local conditions and that the instrument cannot be used until firing has conmenced.

Optical or perspective telemeters determine the distance to any point by observing the size of some object of known dimensions, as seen in a graduated telescope. Porro's telemeter, Elliott's telescope, and Nordenfelt's macrometer illustrate the principle. The chief defect of the systerii is that the objects mast comveniently observedmen and horses - vary considerably in size, so that the assumption of a constant dimension may be productive of error.

Trigonometrical telemeters shorten the ordinary methods of surveying by adapting them to military purposes They are of two kinds,-field rangefinders and rangefinders for coast batteries.
(1) Field rungefinder's exist in great variety, aud differ from one another bnth in the trigonometrical methods pursued and in the mechanical pecrliarities exdibited. The following are the common solutions of what is technically called "the range-finding triangle,"-i.e., a triangle in which $O$ (fig. 1) is the object the distance to which is required, $A O B$ an acute angle, and $A B$ the base, - $O$ being visible both from $A$ and $B$. (i.) Where the base is a fixed length and the angles are variable.-A fixed base is rarely adopted except when the base forms part of the instrument, the angles being observed by powerful telescopes. The range is nsually read
 in yards by the assistance of verniers, extreme perfection of mechanism being uecessary. Many ingenious instruments of the kind have been devised, but none have as yet proved satisfactory. With a fixed base the accuracy diminishes as the range increases. (ii.) Where the base and the angles afe variable.-The base angles are generally olserved by instruments of the theodolite type, and the
base is actually measured or found by means of a snb-loase. The range is obtained by table or calculating scale. The Nolan rangefinder, which was the first telemeter used by the British artillery, was of this kind. (iii.) Where one base angle is a right angle, the other angles and base being variable.-The instrument used is generally double-reflecting of the sextant type, - the base being found as in (ii.) The most perfect example is the Wratkin rangefinder, used
 set in a steel arm, which is worked by a movalble collar on a graduated bar, and this again is moved by the turning of a graduated cylinder. O (fig. 3) being the object, the observer sets up a picket at $A$, and with the instrument at zero (the horizon glass being inclined $45^{\circ}$ to the index glass) finds the right angle at the point $C$. A sab-base $A B$ of 6 yards is then set off, and (with glasses set parallel and the sliding collar at 6) the observer reflects B upon A by turning the cylinder, which is thus made to record the base AC in yards. This reading being set on the graduated bar by moving the sliding collar, the observer proceeds to $A$, and from there reflects C upon O , which causes the range to be given in yards on the cylinder. In this

Fig. 3. operation the position of the sliding collar regulates the movement of the steel bar so that the number of turns of the cylinder is always a true measure of the range OC, whatever the length of the base AC. (iv.) Where the angles are fixed and the base is a measure of the range. The base points are determined by the use of prisms or 01 mirrors reflecting the particular angles adopted. The base is measured or found by a subsidiary triangle, and muitiplied by a constant to give the range. The Weldon rangefinder, recently issned to the British infantry, is on this principle. It consists of three prisms, and is generally used as follows. O (fig. 4) being the object and D a convenient distant point, the observer makes with the first prism the right angle OAD. He then retires in the direc. tion DA till the second prism records the angle $O B D=1$
$88^{\circ} 51^{\prime} 15^{\prime \prime}$, when the range $=50 \times \mathrm{AB}$. If it is inconvenient to measure $A B$, the observer can retire from $B$ in the line OB until the third prism records the ar - le $\mathrm{OCA}=7 \underline{I}^{\circ} 53^{\prime} 15^{\prime \prime \prime}$, when the range $=200 \times$ BC. The prisms must be-held in the plane of the objects and looked into at the same point. This rangefinder is tery simple and portable, but is frequently inapplimable on hilly or broken ground, and does not possess great accuracy.

The merits of different field rangefinders depend mainly upon the Fra. 4.-Weldon rangehalance of advantages they offer finder. with respect to accuracy, suitability to variety of ground, simplicity, portability, and durability, these conditions being of a more or. less conflicting character. The following are recognized principles:-(1) the naked eye cannot with certainty appreciate less than one minute difference of angle, therefore telcscopic power is necessary in proportion as the base is short compared with the range; (2) telescopes of high power cannot be steadied by hand alone ; (3) the longer the base the more inconrenient are any restrictions as to its length or direction ; (4) it is a disadvantage to be compelled to traverse the line joining base points; (5) the longest base which it is convenient to measure by hand is that length of
measuring line which can be stretched tight in a high wind.
(2) Rangefinders for Coust Buteries.-Rangefinding is less adapted to the requirements of coast defence than "position finding,"-a method which furnishes every gun with its proper training aud elevation so that it can be fired without sighting the target. Rangefinders are, however, somctimes employed. The most worthy of notice is the Watkin depression rangefinder used by the British artillery in coast batteries. The instrument resembles in principle the Watkin field rangefinder, the height above the sea-level being a vertical base. The range is found by observiag the angle of depression to the object. This is done by a powerful cross-wire telescope, which forms part of the instrument. The fastest steamer can be continuously follorred, and even the successive grazes of shot and shell can be observed. The instrument is levelled upon a tripod stand. When necessary, it finds its exact height in feet above the water-level in any state of tide by reference to a datum distance, and it records the range in yards automatically on a graduated cy linder. An interesting contrivance combining $\ddagger$ clemeter and gun-sight, applicable to guns in permanent emplacements over non-tidal waters, has been tried in Itsly. By means of a cam the hindsight of the gun is always maintained in the position necessary to give the proper elevation in firing, so that it only remains to make the sights cover the target.
(A. W. w.*)

## TELEPEONE

TTELFPHONY is the art of reproducing sounds at a distance from their source. The term was first used by Philip Reis of Friedrichsdorf, in a lecture delivered before the Physical Society of Frankfort in 1861. ${ }^{2}$ But, although this lecture and Reis's subsequent work received considerable notice, little progress was made until the subject was taken up between 1874 and 1876 by Alezander Graham Bell, a native of Edinburgh, then resident in Boston, Mass. Bell, like Reis, employed electricity for the reproduction of sounds; but he attacked the problem in a totally different manner. This will be better understood if we consider shortly on what the chief characteristics of sound depend (compare Acoustics).

The sensation of sound is produced by rapid fluctuations in the pressure of the atmosphere on the tympanum of the car. It the fluctuations are irregular and non-periodic, the sound is called a noise; if they are cyclic and follow a regulac and sufficiently rapid periodic law, the sound is musical. In connexion with the present subject it is important to notice the three characteristics of a musical sound, namely, pitch, loudness, and quality. The pitch of a musical scrud depends on the number of cycles passed through by the fluctuations of the pressure per unit of time; the louduess depends on the amount or the amplitude of the flucuation in each cycle; the quality depends on the form or the nature of the fluctuation in each cycle. The necessary cundition for a successful system of telephony is the abilisy to reprod ce these characteristics.

## I. History.

In 1831 Wheatitone by his "magic lyre" experiment showed ${ }^{2}$ that, when tie sounding-boards of two musical instruments are cormected together by a rod of pine wood, a tune played on one will be faithfully reproduced by the other. This only answers, however, for telephoning musical ronuds to short cistances. Another and somerwhat

[^33]similar example is furnishel by what has been variously Mechan. designated as the "string," "toy," "Iovers," and "meckan- ical teleical "telephone. Two disks of thin metal, or two stretched phone. membranes, each furnished with a mouthpiece, are connected together by a thin string or wire attached at each end to the centres of the membranes. A good example may be made with tro cylindrical tin cups; the bottoms form the membranes and the cups the mouthieces. When the connecting string is held taut and sounds, such es those of ordinary speech, are produced in front of one of the membranes, pulses corresponding to the fluctuations of the atmospheric pressure are transmitted along the string and communicated to the other membrane, which in its tura communicates them to the air, thus reproducing the sound. In both these examples all the three characteristics-pitch, relative intensity, and quality-of sound are reproduced.

Let us now.return to the development of the application Pase's of electricity to telephony. In July 1837 Dr C. G. Page disof Salem, Mass., drew attention to the sound given out by covers. an electromagnet at the instant $\pi$ hen the electric circuit is closed or broken, and in Octoler of the same year he discussed, in a short article ${ }^{3}$ entitled "Galvanic Music," the musical note produced by rapidly revolving the armature of an clectromagnet in frout of the joles. Experiments hearing on this subject were subsequently made by a great number of investigators. ${ }^{4}$ Page's discovery is of considerable importance in connexion with the theory of action of various forms of telephone, and was a very important feature in the early attempts by Reis to transmit music and speech. On

[^34]26th Aagust 1854 there appeared in L'Illusiration (Paris) an interesting article by Charles Bourseul on the electric transmission of speech. ${ }^{1}$ The writer recommended the use of a flexible plate at the source of sound, which would vibrate in response to the varying pressure of the air, and thus open and close an electric circuit, and of a similar plate at the recciving station, which would be acted on electromagnetically and thus give out as many pulsations as there are breaks in the current. These suggestions were to some extent an anticipation of the work of Reis; but the conditions to be fulfilled before the sounds given out at the receiving station can be similar in pitch, quality, and relative intensity to those produced at the transmitting station are not stated, and do not seem to have been appreciated.

In Reis's lecture an apparatus was described which has given rise to much discussion as to priority in the intention of the telephone. The instrument was described in over fifty publications ${ }^{2}$ in various countries, and was trell known to physicists previous to Bell's introduction of the electric telephone as a competitor with the electric telegraph. Reis caused a membrane to open and close an electric circuit at each vibration, thus transmitting as many electric pulses through the circuit as there were vibrations in the sound. These electric pulses were made to act on an electromagnet at the receiving station, which, in accordance with Page's discovery, gave out a sound of a pitch corresponding to the number of times it was magnetized or demagnetized per second. Reis's object was to reproduce at a distance not only music but also human speech; but that he did not wholly succeed is clear from the following extract from his lecture: "Hitnerto it has not been possible to reproduce human speech with sufficient distinctness. The consonants are for the most part reprodaced pretty distinctly, but not the vowels as yet in an equal degree." Considering the time at which he wrote, Reis seems to have understood very well the nature of the vibrations he had to reproduce, but he failed to comprehend how they could be reproduced by electricity. His fundamental idea-the interruption of the current-was a fatal mistake, which was not at the time properly understood. The suggestion of Bourseul and the experiments of Reis are founded on the idea that a succession of currents, corresponding in number to the successive undulations of the pressure on the membrane of the transmitting instrument, could reproduce at the receiving station sounds of the same character as those produced at the sending station. Neither of them seemed to recognize anything as important except pitch and amplitude, and Reis thought the amplitude was to some extent obtained by the varying length of contact in the transmittiog instrument. This might possibly be to a small extent true; but, considering the small capacity of the circuits he used and the nature of his receiving instrument, it is hardly probable that duration of contact sensibly influenced the result. The quality of the sounds was to some extent also reproduced; but, judging from the results of recent telephone investigation, it is highly probable that this was due, not to the varying duration, but to the varying firmness of the contact. Since the effect of the degree of contact has, through the researches of Bell, Berliner, Edison, Hughes, Elisha Gray, and others, become generally understood, it has become easy to make instruments very similar to those of Reis;

[^35]and even his instruments, with slight modincation, can be made to speak fairly well. The accidental transmission of words by Reis, the occasional recognition of the woice of a singer, and other instances of the trausmission of quality were no doubt due to this element, the existence of or the necessity for which was never, so far as tho present writer knows, hinted at by Reis.

The next worker at the telephone, and the one to whom the present great commercial importance of the instrument is due, was Bell. His aim was the production, by means of the undulations of pressure on a membrane caused by sound, of an electric current the strength of which should at every instant vary directly as the pressure varied. ${ }^{3}$. His first idea seems to have been to employ the vibrations of the current in an electric circuit, produced by moving the armature of an electromagnet included in the circuit ncarer to or farther from the poles of the magnet. He proposed to make the armature partake of the vibrations of the atmosphere either by converting it into a suitable vibrator or by controlling its vibrations by a stretched membrane of parchment. In the early trials the armature had the, form of a hinged lever of iron carrying a stud at one end, Which pressed against the centre of a stretched membrane. The experiments with this form were not successful, and, with the view of making the moving parts as light as possible, he substituted for the comparatively heavy lever armature a small piece of clock spring, about the size of a sixpence, glued to the centre of the diaphragm. The magnet was mounted with its end carrying the coil opposite, and rery close to, the centre of the piece of clock spring. This answered sufficiently well to prove the feasibility of the plan, and subsequent experiments were directed to the discovery of the best form and arrangement of the parts. An increase in the size of the iron disk attached to the nembrane augmented both the loudness and the distinctness of the sounds, and this finally led to the adoption of the thin iron disk now in use, whicls is supported round its edge, and acts as both membrane and armature. Again, the form of the opening or mouthpiece in front of the membrane exercised considerable influence on the efficiency of the instrument, and it was ultimately ascertained that a small central opening, with a thin air space extending across the face of the membrane, was best. It was also found that comparatively small magnets were sufficient, and that there was no particular virtue in the closed circuit and electromagnet, but that a small permanent magnet having one pole in contact with the end of the coro of a short electromagnet, the coil of which was in cirsuit with the line, but which had no permanent current flowing through it, answered the purpose quite as well. ${ }^{4}$ In fact the effect of keeping a permanent current flowing, through the line and the coils of the electromagnet was to keep the core of the electro-magnet magnetized. This seems to have been almost simultaneously pointed out by Bell and others who were working in conjunction with him and by Professor Dolbear. Many experiments were made for ascertaining the best length of wire to nse in the coil of the transmitting and the receiving instrument; but this is clearly a question dependent to a large extent on the nature of the line and the system of working adopted.

After Bell's success a large number of experimenters entered the field, and an almost endless variety of modifications have been described. But few possess any real merit, and almost none have any essentially new principle. ${ }^{5}$

[^36]A telephone transmitter and a receiver on a novel plan were patented in July 1877 by Edison, shortly after the introduction of Bell's instruments. The receiver was based un the change of friction produced by the passage of an electric current through the point of contact of certain substances in relative motion. In one form a dram, mounted in an axis and covered by a band of paper soaked in at solution of caustic potash, is turned under a spring the end of which is in contact through a platinum point with the paper. The spring is attached to the centre of a diaphragm in such a way that, when the drum is turned, the friction between the point of the spring and the paper defiects the diaphragm. The current from the line is made to pass through the spring and paper to the cylinder. Now it had been previously shown by Edison that, when a curreut is made to pass through an arrangement like that just described, tho friction between the paper and the spriug is greatly diminished. Hence, when the undulating telephonic currents are made to pass through the apparatus, the constant variation of the friction of the spring causes the deflexions of the diaphragm to vary in unison with the variation of the electric currents, and sounds are given out corresponding in pitch, and also to some extent in quality, with the sounds produced at the transmitting station. A cylinder of chalk was used in some of Edison's later experiments with this receiver. The transmitter is illustrated (see fig. 10) and described (p. 132) below.

Experiments very similar to these of Edison were made by Elisha Gray of Boston, Mass., and described by him in papers communicated to the American Electrical Society in 1875 and 1878. In these experiments the electric current passed through the fingers of the operator's hand, which thus took the place of the spring. in Edison's apparatus. The diaphragm was itself used as the rubbing surface, and it was either mounted and rotated or the fingers were moved over it. When the current passed, the friction was felt to increase, and the effect of sending a rapidly undulating current through the arrangement was to produce a sound. The application of this apparatus to the transmission of music is described by Gray. ${ }^{1}$
Olbear's In another form of telephone, brought prominently forward by Professor Dolbear, ${ }^{2}$ the effects are produced by electrostatic instead of electromagnetic forces, as in the Bell telephone. Sir W. Thomson observed in $1863^{3}$ that when a condenser is charged or discharged a sharp click is heard, and a similar observation was mado by Cromwell F. Varley, who proposed to make use of it in a telegraphic receiving instrument. ${ }^{4}$ In Dolbear's instrument one plate of a condenser is a flezible diaphragm, connected with the telephone line in such a way that the varying electric potential produced by the action of the transmitting telephone causes an increased or diminished charge in the condenser. This alteration of chargo causes a corresponding change in the mutual attraction of the plates of the condenser; hence the ficxuble plate is made to copy the vibrations of the diaphragm of the transmitter. It is obvious that this apparatus may be used either as a transmitter or as a receiver, but that the effects must under ordinary circumstances be in either case extremely feeble.

In the Reis instruments the transmitter and receiver are separate parts, which are not interchangeable. The Bell telephone can be used eithcr as a transmitter or as a

[^37]receiver. The Edison recerver and the Dolbear condenser were only intended to be used as receiving instruments.

It was very early recognized-and, indeed, is mentioned in the first patents of Bell, and in a caveat filed by Elisha Gray in the United States patent office only some two hours after Bell's application for a patent-that sounds and spoken words might be transmittcd to a distance by causing the vibrations of a diaphragm to vary the resistance in the circuit. Both Bell and Gray proposed to do this by introducing a column of liquid into the circuit, the length or the resistance of which could be varied by causing the vibrations of the diaphragm to vary the depth of immersion of a light rod fixed to it and dipping into the liquid (see figs. 8, 9 below). This idea has been perhaps the most fruitful of any modification of telephonic apparatus introduced.
On 4th April 1877 Mr Emile Berliner filed a caveat in the United States patent office, in which he stated that, on the principle of the variation with pressure of the resistance at the contact of two conductors, he had made as instrument which could be used as a telephone transmitter, and that, in consequence of the mutual forces between the two parts of the current on the tro sides of the point of contact, the instrument was capable of acting as a receiver. The caveat was illustrated by a sketch showing a diaphragm with a metal patch in the centre, against which a metal knob was lightly pressed by an adjusting screw. This seems to have been the first transmitter in which it was proposed to use the resistance at the contact or two conductors.

Almost simultaneously with Berliner, Edison conceived Edison's the idea of using a variable resistance transuitter. ${ }^{5}$ Ho microproposed to introduce into the circuit a cell containing $\begin{gathered}\text { phone } \\ \text { trans- }\end{gathered}$ carbon powder, the pressure on which could be varied by mitter the vibrations of a diaphragm. He sometimes held the carbon powder against the diaphragm in a small shallow cell (froin a quarter to half an inch in diameter and about an eighth of an inch deep), and sometimes he used what he describes as a fluff, that is, a little brush of silk fibre with plumbago rubbed into it. In another form the plumbago powder was worked into a button cemented together with syrup and other substances. - In the specification of the patent applied for on 21st July 1877 he showed a sketch of an instrument which consisted of a diaphragm. with a small platinum patch in the centre for an electrode. against which a hard point, made of plumbago powder cermented together with india-rubber and vulcanized, was pressed by a long spring, the pressure of the carbon against the platinum diss being adjusted by a straining screrr near the bass of the spring. Subsequently he filed an application for a patent in which various forms of springs and weights assisted in maintaining the contacts and otherwise improved the instrument.

In the early part of 1878 Professor Hughes, whilo en- Hughes'a gaged in experiments upon a Bell telephone in an electric microcircuit, discovered that a peculiar noise was produced when- thone ever two hard electrodes, such as two wires, were drawn across each other, or were made to touch each other with a variable degree of firmness. Acting upon this discovery, he constructed an instrument which he called a microphone, ${ }^{\frac{1}{6}}$ and which consisted essentially (sce fig. 11) of two hard carbon electrodes placed in contact, with a current passing through the point of contact and a telephone included in tho same circuit. One of the electrodes was attached to a sounding board capable of being vibrated by soundwaves, and the other was heid either by springs or weights

[^38]in delicate contact with it. When the sounding board was epoken to or subjected to soxnd-waves, the mechanical resistanco of the loose electrode, due to its weight, or the epring, or both, served to vary the pressure at the contact, and this gave to the current a form corresponding to the sound-waves, and it was therefore capable of being used as a speaking-telephone transmitter. ${ }^{1}$ The best transmitters now in use are modifications of Hughes's apparatus. A microphonic apparatus very similar to it is described in the specification of a German patent taken out by Robert Lutdge on 12th January 1878. In this patent the action of the microphone is also described. ${ }^{2}$

The next transmitter of note, introduced by Mr Francis Blake, U.S. (see fig. 13 below), although it does not, like the first microphones, embody anything intrinsically new, is one of the most perfect and convenient forms of microphone. It is at present almost universally used in the United States.

It appears to be pretty well established that carbon in one form or another is the best material for one or both of the contacts of a microphone transmitter. When both the contacts are of carbon and the surfaces have considerable area, say from a quarter to half an inch in diameter, the sounds are loud, but have a tendency to harshness. When, as in the Blake transmitter, one of the contacts is a piece of polished gas carbon and the other a small sphere of platinum about the twentieth of an inch in diameter, the articulation is clear, but less loud. For most purposed, however, the increased clearness more than compensates for the diminished loudness. Many transmitters in actual use-as, for instance, the "Gower," largely employed in the United Kingdom-have a number of contacts. Some of these when properly adjusted are both loud and clear in their action. Although the Blake instrument is most in vogue in America, in the United Kingdom and on the Continent multiple contact microphoues have found more favour. Carbon powder instruments have been to some extent used, and in one or two cases-as, for example, the Hunnings transmitter-with considerable success. The fault in most of them is the tendency of the powder to "pack," which causes the instrument to rapidly lose sensibility. In the Hunnings transmitter this difficulty is to a large extent overcome by the use of a coarse granular powder in a somewhat large cell (about an inch in diameter and from one-eighth to one-fourth of an inch deep). The front face of the cell is a piece of platinum foil, which serves both as an electrode and as a diaphragm. The cell is placed either on edge or in an inclined position when in use, the action being precisely similar to that in other transmitters. In addition to its freedom from packing, the carbon, in consequence of the inclined position of the cell, is also less liable to fall a way from the electrode and break the circuit. Some packing of the powder, however, does occur, and several modifications have been proposed by Blake and others for making the sound vibrations stir the powder and keep it loose. Good results appear to have been got by placing the cell mouth downwards, the carbon powder lying on the platinum foil, and by forming the upper electrode either of wire gauze or of a perforated plata completely immersed in the powder. The sound vibrations are conveyed to the bottom of the cell by a bent tube communicating with a mouthpiece. Instruments of this class are very loud-speaking, and therefore very serviceable for long or disturbed circuits.
The radiophone is an instrument proposed by A. G. Bell

[^39]and Sumner Tainter in 1880 for utilizing radiant energh such as light or radiant heat, for the transmission of sound. The apparatus forms a telephone transmitter of a particularly interesting kind. In the earlier papers describing it and the eaperiments which led to its invention it is called photophone, hecause at that time the effects were supposed to be wholly due to light. Afterwards, in order to avoid ambiguity, Bell changed the name to radiophone and sug. gested that, to distinguish between instruments depending on the different kinds of radiation, the names photophone, thermophone, \&cc., should be employed. He also proposed the name spectrophone for an application of this instrument to spectrum investigation. ${ }^{3}$ The apparatus is founded on the discovery, made by Mr May while carrying out experiments on selenium for Mr Willoughby Smith, that when selenium is exposed to light its electrical resistance is very different from what it is in the dark. This discovery led to a great many interesting experiments by other investigators. ${ }^{4}$ In thinking over this discovery in 1878 Bell conceived the idea that, if a beam of light proceeding from one station could be made to fall on a selenium plate at another station, and if its intensity could be varied by the roice of a speaker, then by connecting a telephone and a battery in circuit with the selenium plate the words spoker at the distant station would be heard in the telephone. This was found to be the case. At first, to vary the intensity of the beam, it was passed through a small opening, the width of which could be varied by the vibrations of a diaphragm against which the speech was directed. But better results were afterwards obtained when the diaphragm formed a mirror from which the beam of light was reflected. The spreading of the beam, due to the vibrations of the mirror diaphragm, served to vary its intensity 'see fig. 18 below).

Edison's phonograph (see fig. 19 below) is an instrument Fdison't whose action somewhat zesembles that of a telephone trans- phonomitter and which has been much talked of in regard to its ${ }^{\text {graph }}$ possible applications in telephony. It was invented shortly after the introduction of the telephone for the purpose of recording sounds, and was included in some of Edison's telephone patents as a means of working a telephone transmitter, and thus telephoning sounds which had been previonsly recorded on the phonograph sheets.

## II. Telephomo Instriments.

One of the best-known forms of the Reis telephone is ohown in fig. 1. The tranamitter consists of a boz A, provided with a mouthpiece M. In the top of the box a round hole is cut and across it a mombrane $S$ of hog's bladder is stretchod. A thin strip of platinum $p$ fixed to the hox at one side of the hole and extend.

Fio. 1.-Reis's telephone. ing to the centre of the memhrane, oupports at that point one foot of a light metal tripod egf. One of the feet, $e$ or $f$, rests in a cup centaining mercury, which is in metallic connexioa with the terminal $b$, while

[^40]the end of the strip $p$ is similarly in connexion with the terminal $a$. The receiver consists of an electromarnet made up of a magnotizing coil H, with a strut knittiDg needle for a core. When in use these two instrumer* sre joined in circuit with a battery B, Bo that under ordinary circumstances a contidumis current is Howing through the line. Suppose a sound is then produced in front of the mouthpicce M, the successive varistions in the pressure of the air are communicated to the inside of the box, and canes the nembrane to vibrate in unison with the sound Reis's theory of tho action of the instrument was that at each outward impulse of the membrave the point $g$ would be thrown out of contact with the plate underpesth it and would thus break the circuit. Tbere wouid consequently result as many breaks in the circuit as there were vibrations in the sound, and, in conformity with Page's discovery, the electromagnetic receiver would give out a rapid succession of beats, which weuld tagether form a continuous sound of the same pitch as that to which the transmitter was subjected.

Fig. 2 shows the first telephone made by Bell for transmittung speech. It consisted of a wooden frame $F$, to one side of which a tube T was fixed; over the end of the tube a neembrane $M$ was stretched taut by a etretching ring R. To the opposite side of the frame and with its axis in line with that of the tube $T$ wass fixed an electromagnet $H$, snd between the membrase M and the end of the electromagnet a hinged arms. ture A was arranged in such a way that its motions rould be controlled hy the membrane. The instrument was joised in circuit with battery and another aimilar iostrument placed at a distance. A contipuous current was made to flow through the circuit,
 which kept the electromagnet magnetized. Bell reasoned thus: wlren words are spoken in front of the tube T the membrane will be eet in vibration and with it the armsture A, sed the vibration of the armature in frout of the electromagnet will iuduce variations in the line current ; their magnitude will he proportional to the amplitude, and their frequency to the frequency, of the vibrations of the armature ; in fact, the difference betircen the actual and the average current in the circuit will be at each instaut proportional to the rato of motion of the armature. It follows from this that the armsture and membrane of the distant instrument should have induced in them a motion precisely similar to thst of the membrane of the transmitter. This telephone was made in June 1875, but wss put aside after trial as unsatisfactory on sccount of the feebleness of the sounds it produced; since then, bowerer, a successful telephone has beeu made on preciscly the same plan es that here indicated.

The next form tried is shown in fig. 3. It is very similar except in constructive details to the first; the hinged armature, however, is omitted, its place being taken by a emall iron disk A fixed to the ccatre of the diaphragm. D. The electromagnet $H$ is, as before, placed so as to have the centre of the soft iron core Copposite to the centre of the disk, and the theory according to which it Fio 3.-Bell's second teleplione; one-ifth null size. was expected to act is the same. The resulte obiained with this instrument were much more satisfactory; indeed it was with one precisely like that shown in the figure that the remarkable results of the Philadelnhia exhibition in 1870 were obtained. A perspective and a sectional view of the receiving instrument used along with that shown in fig. 3 are illustrated in figg. 4 and 5. It consisted of an ircn cylindrical bor $B$, throagh the axis of which a rod of coft iron $C$ was passed to form the core of 9n electromagnet, hasing the magnetizing belix H wound on the upper half of its length. Across the top of the box a thin disk $D$ of soft iron was fixed, tho core $C$ being just clear of the disk when the steongest current is fowing through the helix. In the perspective view the cist is pemoved, showing the end of the core.

These instruments are interesting, not only becanse they may be considered the first resily successful speaking telephones, but because they are of the same form as those brought to Great Britain in 1876 by Sir W. Thomson, and exhibited before the British Associstion at Glasgow in that jear.

Fig. 6 ehows one of the earliest forms brought into commercial nsc. On each pole of a somewhat largo horse-shoe permaneot magnet

Fio. 6.- Bell's unultiple pole telephone (1877); one-hif iull size.
Ma short coil E with a soft iron core mas fixed This is one of the early forms of permanent magnet telephones, of which there were at that time several, including a hand telephone very simlar to that shown in fig. 7. In another form, introduced about the end of 1877, the emall magnctizing coils and soft iron cores were fixed on the side and opposite the poles of the horseshoe magnet, and the diaphragn was placed wit its plane parallel to that of the magnet. The diaphragm in these telephoues was of thin sheet iron and a little over 4 inches in diameter.
The form of telephone now slmost universally in use is shows in Bell: fig. 7. It was introduced in December 1877 snd consists of a com-hand pound permanent magnet M , fitted into the centre of a teletube of vulcanite
or "hard rubber" or "hard rubber"
and carryingatone end ashort elcetromagnet, the coil of which through its terminsls $t, t$ is iucluded in the cir-
 cuitwen the instrument is in use. In front of tbe electromagnet with its plane normsl to the axis of the magnet, is fixed a thin soft iron disk about $1 \frac{8}{4}$ inches in diameter, which has its cover cut to a convenient shape to form a mouthpicce. This telephone acts well either as a transmitter or as a rccciver ; but for the former purpose it is now seldom used on eccount of the great advances which have beeu made in "microphone" transmitters.
It has been stated that Bell and Elisha Gray almost simultane- Bell's ously suggested the nse of a column of liquid to vary the resistance liquid
in the circuit. The form of iostrument proposed by the former and said to bave been exluibited at the Pliladelphia exhihition is shown in fig. 8. It consists of a speaking tube or mouthpiece M, across the lower end of which a unembrane D is stretched. To the centre of the membrane a light rod R , made of metsl or of carbon, is fixed with its length at right sagles to the plane of the membrane. Uniler the lower end of $R$ a small metallic vessel C is eupported on a threaded rod, working in a nut fixed to the sole F , so tbat its height 10ay be readily adjusied. Suppose C to be filled with water or sny other con-

Fio. 8.- Rell's liquind transmitter. Fio. 9.-Elisha Gray'e liquid transmitter. ancting liquid, sud the rod $R$ to bo of metal. $C$ is raised until the liquid just touches the point of the rod, when adrsotage is taken of the change of contact resistance with the greater or less immersion of R during the vibration of D Good results were obtained with mercury as the liquid and with a rod of carbon.
The arrangement proposed by Elishs Gray is almost identical in form with Bell's. The only differeace beems to be that Gray in. tended the rod $R$ (fg. 9) to reach near to the bottom of the vessel B or to the end of another rod, a prolongation of $b$, projecting up from the bottom. The variation of the current was produced by the variation of the distance between the ends of the rod caused by the vibrations of the diaphragm. This plan was not tried until after the euccess of Bell's expleriments was known, snd when it was
tried the results did not prove encouraging. - Indeed the variations of the resistance which can be produced in this way must be excessively emall, naless the liquid hes a very high specific resistance, the distance between the eads is very small, and the eides of the $r$ ds are prevented by 80 insulating covering from interfering with the results. Neither of these traosmitters has any great merit as such, but they ehow that both Bell and Gray clearly recognized the principle oa which successful transmission of the different forms of sound, including speech, could be accomplished.
The first successful microphone transmitter was Edison'e. An early form of it (fig. 10) somewhat resembles Bell'e hand telcphone in excell of insulating its bottom a flatecrew G ; on the layer of carbon top of that a thin D, and above cover of the cell, position by a coatre of this the diaphragm hand telephone, is hold in M. The varying pressure duced near it, causes correpressure on the carbon similarvaristionsin its elecwhen the instrument is incuit through which a curtioos io the pressure on the sponding undulations in

two rectangular pieces of gher with their phanes at right angles to each other. D forms the base, and to B two smsll blocks of carbon C, C are attached. Between these a light rod material is supported or in C, C. To the blocks are counected for the purthe instrument in ao electric terial which Hughes found the carbon blocks and rod metallized by heating it to reduess and pluaging it while hot into mercury. If this microphone is joined in circuit with a telephooe and a small battery, say one or two small Daniell cells, the ribration pros dnced by a fly walking on
 the base D can be distinctly heard in the telephone. The sarno apparatus will also act as a microphone transmitter, but the sonnds are apt to be harsh. A better form for this purpose is shomn in fig. 12. In this a light pencil of carbon $M$ is pivoted at $h$ and has one end resting on two blocks of 6 carbon $c, c_{3}$, the lower one being fixed to the base. The pressure of ML on the carbon block is regulated by a opring s. .This arrangemenf is en-
 closed io a box of then wood, against which the sound is directed. It is canable of acting well as a transmitter, and especially in 'a modified form used by Hughes as a microphone receiver. The lower block $c$ is then attached to the centre of a vertical diaphragm and against it the sounds are directed.

The Blake transmitter, which is perhaps most wideny rised of all, is a simple modification of the Hughes instrument last dcscribed. It consista (fig. 13) of a frame $F$, to which is attsched a disphragm D of thin sheet iron; in froot of this is a cover M, M provided with a suitable cavity for directing the cound-waves against the diaphragm. The microphonic arrangement consists of a spring $S$, about the hundredth of an ioch thick and the eighth of an inch broad, fixed st one end to a lever $L$, and carrying at its free extremity a brass hlock $W$. In one side of $W$ a small disk $C$ of gas carbon is inserted, resting on the hemispherical end of a small platianm pin K, about the twentieth of an inch in diameter, held in position by a thin epring A. The pressure of the carbon on the platinum point can be adjusted by the ecrew $N$, which turns the lever about the flexible joint G. The electrical connexions of the instrument as arranged for actual use are also illustrated in the figure. The curreat circnit gots through $\mathrm{S}_{1} \mathrm{~W}, \mathrm{C}, \mathrm{K}, \mathrm{A}$, and the
primary circuit of the induction coil I to the battery $B_{\text {, }}$ and thence to $S$ agaio. This forms a locsl circuit at the transmitting station. The line of circuit pesses through the eecondary of the induction

Fio. 13.-Blake's transmilter.
coil I to the line, from that to the telephone $T$ at the receiving station, and then either to earth or lack to the induction coil by a return line of wire.

## Telephonic Circuits.

The lines used for telephone purposes are, generally speaking; Teles Bo far as erection, mode of inculation, and so on are concerned, much phon the same as those used for ordinery telegraphs. In towns where winad a very large number of wires radiate from one centre or exchange, as it is called, where thick wires are unsightly, and where it is often necessary to provide for long epans, a comparatively thin wire of etrong msterial is employed. For this reason various bronzes, such es silicon, aluminium, \&c., have come to be extensively used for making wires for telephons lines. They are made from shout tho twentieth to the thirtieth of an inch in diameter, and are found to wear well in the somewhat mixed atmosphere of a town; and owing to their lightness and considerable tensile strength it is com. paratively essy to erect them and keep them iu order. The majn objection to them is the high electrical resistance they oppose to the current. The lines on a town exchange system are not, however, as a rule, so long as to make this objection of great importance. But loog lines, such as those extending between towns some miles spart, should be made of pure copper wire hard drann. It has lately been found possible to draw copper so hard as to be almost equal to bronze in strength, and yet to retain about three times the electric conductivity of that substance. Copper and bronze wires posscss great, advantages for telephonic purposes over the iron wires employed in telegraph lioes, in that they offer a much lower effective resistance to the rapidly undulating aod ioternittent currents produced by telephonic transmitters. The electric resistance opposed by a wire to the passage of such a current is always greater than that opposed to a steady current, and this difference is much more marked when the wire is of magnetic material like iron. This increased resistance rises in proportion to the rapidity of the undula. tions of the current; consequently high notes are more resisted than low notes. Besides this variahle resistance, telephouy has to contend with "self-ioduction" (see Electricity, vol. viii. p. 76 sq.) of the current on itself, and this is by 110 means uaimportant, especially on long circuits. ${ }^{1}$ The marked difference betweea iron and copper for loog circuits is plaialy shown by the fact that Rysselberg and others have spokeo clearly to a distance of over 1000 miles through a copper wire insulated on poles, whereas Preece could not work a similer line of juron wire between London and Manchester.

The electrostatic capacity of the line (see Telearapy, p. 115 above) is also diminished by the use of thio wires of highly conductingmaterial. They should all if possibie be erected oo poles at a considcrable beight above the earth. It is not practicable to work an ordiaary undergroond line through more than 20 miles, and cable telephony through distances of over 100 miles may in the present state of ecience be put down as en impossibility,
Another element of great importance in connexion with telephone Roy. Soc papers by Prof. Hughes, Procs Soc. Tel. Eng., vol. xv. p. 6, and Proc. Journ, vol. zviii. p. 321 gnd vol. 大ix.
 See aloo Prof. Chrystal on the "Differential Telephone," in Trans. Rog. Soce Edinb., Vol and. Pp. 609-696'

Cines, which in most cases does not require to be attended to in ordinary telegraph circuits, is the iaduction from one line to another (see Electuicity, vol. viii. p. 76 sq.). When two lines hsving, as in ordinary telegraphy, an earth connexion at each end run for any great distance, say a aile or more, parallel to each other on the same supports, a conversation which is being carried on through ode of them can be overheard by means of the telephones on the other. This is due to the fact that, when a current is ouddenly set up in one closed circuit, it induces an instantaneous current in any other closed circait which is near to it. This induced current not only destroys the privacy of the circuit in question buc also lowers its efficiency. The mischief is even greater when telegraph and telephone lines run elong the asme route supported on the same poles, because the strong intermittent currents sent through tclegraph wires, and the irreguler manaer in which the intermittences follow each other, induce a series of such powerful secondary currents in the telephone lises that the noise heard in the telephene is often sufficient, when the line is a mile or two long, to drown all speech. In the case of parallel teleplone lines the best, if net the only, cure is to use return wires, and arrange them so that the currents induced in the outgoing wire shall he neutralized by the corresponding current induced in the incoming wire. For mixed telegraph and telephone circuits various methods have been proposed ; but the most generally approved plan is to lisve return wires. For circuits worked wholly on the return principle the main thing to be attended to is the symmetrical arrangement of the wites, so that the outgoing and incoming wires may be subjected to the same influence. This is nearly provided for by ruuuing them in such s way that they may be all supposed to lie on the surface of a cylinder io lines parallel to its axis, tho two wires at the opposite ends of a diameter being alwayg used for the same circuit. When more than four wires form the group complete compensation is not obtained in this way, becsuse the curreut is alweys atromger near the transmittiog end of the line than near the receiving ead, on account of the very sensible effect of the capacity end tlıe leaksye of the line. It is therefore best to arrange the wires in grelups of four -that is, in pairs of circuits-and run them so as to form spiral lines round an exial line equidistant from each of the four wires. Any pair of wires forming a circuit which runs parallel to other Wires can be arranged so as to lo very nearly free from induction by interchanging their position relatively to the other wires st short distances along the line. Care must. however, be taken, when moro than one group of feur or when more then one peir are run, thot the compensation produced by the twisted arrangement of oue set, or of the interchanges of the wires in the differeut paire, is not spoiled by the tristing or interchauging of another aet or pair. Telephone lines running parallel to telcraraph lines should be formed into one or mere groups, each being run on the twist plan so as to eliminate as completely as possible the effect of the telegraph signals; the smali residual effect of the telephone signals is of comperatively little importrace in such a case. A twisted cable of telephone wire may, when cach circuit is formed by dismetrically opposite wires, be placed in the same tube witto similar cables emplojed for talegroph purposes. Tho central wire of the cable may be used either as a telegraph line or as a telephone line having an earth return. Another method is to use powerful telephone transuitters and insensitive receivers; that is to say, make the telephone currents 60 powerful that the telegraphic ioduced currenta will bo 6 mall in comparison, and use zeceivers so insensitive as to suit such currents. One of the main obstacles in the wey of this method et present is the difficulty of getting strong telephonic curreats, for even tho best transmitters are not jet aufficiently porrerful, and there is, besides, a decided taudency towards a loss of quality in the sound when the transmitter is made powerful. A third method is to render the telecraplic current comparatively hermless by taking away the endenncss of the intermittences. This is quile prosible because the number of currents sent per second, even ou fast woriking circuite, is not such as to produce a high musicsl noto. If, then, the curreuts be made in some way to rise slowly to their full atreagth aad foll a gain elowly to zero the diaphragm of the receiving instrunent, instead of ahowing the sudden rise and suddeu fall as at present, would move so elowly beckwards and forwards that the car would rot be disturbed by the sonnd. Perhaps the simplest rey to accomplish this is to place an electromagnet in the circuit of the tolograph line at the seuding station, fer the self-induction of the msgnet coil prevents the current assuning its otreagth ouddenly. But on telegraph circuits where speed is of great importance this method cannot be followed owing to the retardstion of the telegraph Eirnale and the cousequent loss of speed thereby occasioned.

An ingenious application of the method of componsation just indicated has beep made by Ryssel berg, who has used not only wires carried on the same poles as the telegraph but even the tolegrsph lines themselves for telephone parposed. The arrangemont of his system is shown in fig. 14, where $L$ and $J_{1}$ represent two telegraph lines. Betweeu tliese, at each eml, are inserted two condensers $\mathrm{O}_{1}, \mathrm{C}_{2}$ and a telephone $T$, torether with transinitters, \&c., so that, $\mathrm{O}_{1}, \mathrm{C}_{2}$ and a telephone , inposing the telegraph instruments rewoved, the two wires would
be an ordisary telephone circuit worked through condensers. The telegraph apparatus consists of an ordinary rectiver $R$, seading battery B, and key K, together with a condenser $C$, inserted between the earth and the line terminal of the key, and two electromagnetic indacters E, E'. When the key is de. retarded by the electro. dense- C, which has to fact additionsl electrosending end of the line.
 further retarded by the Fig. 14. heace the condenser $C_{1}$ becomes charged so cradusily that $\mathrm{E}^{2}$; little disturbance is noticesble in the telephone T. The condensers $C_{1}, C_{2}$ prevent leakage from one line to the other, but have eufficient capacity to allow the telephooe to act as if it were in a metallic circuit.

## The Working of Telephone Circhits.

The method first employed for working a telephone line was extremely gimple. A single line of wire, like an ordinary telegraph line, hed a Bell telephone included in it at each end and the eads were put to earth. Werds spoken to the telephone at one end could be heard by holding the telephone to the ear at the other. To obviate the inconveniedce of placing the telephone to the mouth and the ear alternately, two telephones were commonly used at each end, joined either parallel to cach other or in series. The contrivance mest generally alopted for calling attention is the call bell, rung either by a small magneto-electric machine or by a battery. The telephoue wes switched out of circuit whed not iu use and the bell put in its place, an ordinary key being used for puttiog the battery in circait to make the signal. This arrangement is still employed, a hook being attached to the owitch lever so thet tho mere hauging up of the telephode puts the bell in circuit. In some ceses, when the bell is rung by a magneto machine, the coil of the machine is automatically cut out of circuit when it is not in action, but the turning of the handle movee a centrifugs] arrangement by which it is thrown in.

At first it was usual to employ the eame instrument both as trane- Workh mitter and as receiver, and to join it in the direct circuit. But it with Was aoon fonnd that the microphone transmitter could ooly be used microto advantage in this way when the total resistance of the circuit, phome exclusive of the microphona, was small compared with the resistance $e$ of the microphone,-that is, on very ehort lines worked with low resiatance telephones. The transmitter on Iong and high resistance lines worked better by joining indirectly in a loçal circuit, in the manner ehown in fig. 13, the microphone, a battery, and the primery of an induction coil, and putting the line in circuit with the secondary of the induction coil, which acted as the traosmitter. The resistance of the microphone can thus be made a large fraction of the total resistance of the circuit in which it is placed; hence, by using considerable currents, amall varistiono in its resistance can be made to induce somewhat powerful currents in the line wire. The requisite energy is derived from the battery. If there are other resistances in the circuit it is, in some cases, better to join it as a ehuat to the primary circuit of the induction coil. It may even prove advantageous to insert resistances in the circuit, increase the battery power, and join the microphone as here indicated, because in this way powerful currents can be obtained in the line withoat the harshnees which is apt to be produced by the variations of a strong current passing through the microphone.

Iranslation from one line to auother, or from one eection to Tram another of the same line, is effected by putting the primary of an tion. induction coil in the place of the receiving telephone, the secondary being in circuit with the second line or section. Thie plan is useful where the same message is to be sent to different "places at once (distributed), and is sometimes used for trasslating from a doubla wire to a single wire system. Probably a better plen is to work a microphone by the membrane of the receiving telephone, and retransmit the message, taking new energy from a second battery. ${ }^{1}$ When the indaction coil arrangement is used for translating from a double to a single wire circuit, or vice versa, it is necessary to make the indaction coil suit the circuits, so that either coil may be used as primary, according to the end from which the message is sent. Every thing else being similar, the resistances of the coils ehould be in nearly the same ratio as the resistances of the lines in which they are placed.

In a large town it is ncither practicable nor desirable to connect each suhscriber direcily with all the other subscribers, bence s syetem of "exchangee" has beeu adopted. An exchange is a central station to which wires are bronght from the different subscribers, any two of whom can be putin telephonic communication mith eacb $\frac{\text { other when the proper pairs of wires are joined together in the ex. }}{1 \text { Bea Thombon and Bonston, Tel Journ., 15tb } \Delta \text { Lgust } 18 \text { is. }}$
change. The srrangement is illustrated in fig. 15, where C represents sn exchange from which wires radiate to the points $a, b, c, d, \ldots$ Suppose $a$ wishes to epcals to $d$; he communicates his wish to au attendant at $O$, who first calls $d$, and then connects 6 to 1 , making the circuit continuous from $a$ to $d$. Tho arrangements at the ex- a phange for facilitating connexions vary coneiderably, but ars similar in principle to the awitch boards used in telegraphy. Each of the

Fio. 15.-Telephone crehange. wires is first brought to an indicator and then to a sot of torminals arranged in sn orderly manner on a board, tho number of the terminal for any one wire weing the eame as the number under the shutter of the indicator in that wire circuit. In many cases the terminals take the form of spring clips, which connect the line to earth, and under which a thin piece of metal, covered with iusulating material on one eide and called a "jack," can be readily inserted for connecting that circuit with sny other. A piece of flexible wire cord, carrying a jack at each end, forms a ready and common mediurn of connexion ; hut in many cases the switch board is arranged with cross atrips of metal so that by inserting a jack into the terminals of the two wires they can'bs both conuected to the same strip of metal and therefore togsther. In large exchanges one switch hoard of moderate size is not eufficient, and eo a number are fitted, being connected together by several conductore, in order that no interroption may ensue in consequonce of these being all oecupied. A line on one board is connected with one on another board by joining the terminal of the first to ons of the conductors connecting the two bosrds by a jack-cord, and then by another jack-cord connecting that conductor to the terminal of the other line. Thus different owitch boards may be lookod upon as sepirsto exshanges, connected together by a number of trunk wires aftor the manner described below.

In a large eystem it is much more convensent and economical to have oxchanges in the various districts, snd connert these with a central exchange by a sufficient number of truak lines. A eubseriber in ons district wishing to speak to a subscriber in another calls the exchange in his own district and is put in communication by the attendant stationed there with the central exchange. The sttendant at the central exchangs puts the subscriber in communication with the district he requires, and the attendant there calls the other subscriber and joins the two eubscribers' lines together. In some cases neighbouring district exchanges have, besides a common means of communication through the central sxchange, an independent connexion. These arrangements are diagrammatically

Fro. 10.-Telophone district ezchances.
illustrated in fig. 16, wliers 1, 2, 3, 4, 5, 6 represcnt district exchanges and $C$ the contral exchange ; districts 3 and 4 and 4 and 5 are supposed to have independent connexions.

An arrangement was proposed about two years ago by Mr D. Sinclair of the Glasgow telephone exchange for allowing small district exchanges to be worked by the attendante at the central exchange. ${ }^{1}$ The two exchanges are connected by a trunk line and from the district exchange wires are led to the differcat subscribere. Thess wires are in the normal state of matters connected, with contact plates, over which an arm joined to the trunk wire can be made to travel. Suppose the contral exchange wishcs to apeak to any one of the oubscribers, the arm is made to travel round, by currents efnt from the exchango through an electromaguetic step by step arrangement, until if comes in contact with the proper plate, ufter which the eubscriber is called in the ordinary way. Wben one enbscriber belonging to the district exchange wishes to speak to another in the ssme district, he rings the bell in the ordionry way, and this operation disconnects all other aubscribers and puts hin in connexion throngh the trunk line with the central ex-

1 Bee Proc. Phil. Soc. of Glasgow, vol. xvil. p. 38.,
clange. The sttendant there sscertains to whom it is that ho wiohes to speak, snd by moving round the contact arm puts the two subscribers lines in contact.

The indicator, or annunciator as it is sometimes called, is shown in fig. 17. It consiets of an electromagnet $M$, which on a current being sent through it pulls down the asmature $\alpha$, relieves the catch $c$, and allows the ehutter $\alpha$ to "fall down, exposing a plate $p$, on the front of which the number of ths subscriber is printed. When the exchange is called, the shutter $d$ is dropped, the attendant connects the line leading
 to the exchanga table with the terminal corrosponding to the indicator, and finds who is wanted; then he calle that subscriber, makes the through connexiou, and puts up the shutter. When the subscribers have finished, both call the exchange or, as it is commonly put, "ring off"; this drops both shatters and eerves as the eigusl that they have finished speaking.
The principle of transmitting sonnd by the radiophone will he Racioonderstood from fig. 18. M represents a mirror, frem which a phone beam cf light is reflected through the lens $l$ to s sscond mirror $m$, snd $m$ forns a diaphragm against the back of which the sound vibrations eent through the tube $t$ are made to impinge. The beam of limht, sfter being reflected from $n$, passcs through the lower lens $l$, and thence as a nearly parsilcl beam to the parabolic reflector R . photophonic receiver $P$, supposed in this case to ha s spiral of selenium wire wound on the surface of a cylinder,

Fio. 18. - Bell's radiopt 万ne. is placed st the focus of the reflector so that the beam of light from $m$ is concentrated on it. In circuit with tha receiver Pa battery $B$ and s telephone $T$ are included and through the circuit a feeble clectric current flowe continuously. The photophonic receiver should be placed 50 as to recerve as little light as possitle from any other source than the mirror $3 n$. Words spoksn through the tube $t$ make the mirror $n$ vibrate, ,o that the beam of light reflected from it becomes mors or less spread. The lens $l$ is then unable to bring the beam into parallelism, and the intensity of the reflexions from $R$ to $P$ is varied, therefors slso the current through the coil of the telephone, which in consequence gives out a sound. The amount of spreading of the beam bcing proportional to the intensity of the vibrations of $m$, and this agsin proportional to the intensity of the sounds, the sounds heard in the telephone are similar to those produced at the end of $t$. Theoretically the receiver may be at any distancs from the transmitter, but considerable difficulty arises if the distance is grest.

One of the simplest forms of the phenograph is shown in fig. 19. Phono It consists of a rigid epiadls $S$ scrowed for about one-third of its graple. length, and fitted to work smoothly but tightly in the frams $f, f$, which is sccurely attached to a sole plate P . On the spindle a drum D is fixed, the axis of which coincides accarately with that of the spindle. On the surface of the drum \& acrew is
 sams pitch as that on the spindle. $\Delta$ fly.wheel $W$ is fixed to one end of the spindle, and is provided with s handle $H$, by which the spindle and drum can be conveniently turned. One of the bearings has either a screw thread cut along it, or is fitted with one or more studs which work easily, but without ohake, in the screw thread. When the spindle is turned, it receives a trans. verse motion, and a point fixed relatively to the sole plate $P$ and touching the drum traces out a spiral on its surface, exactly coinciding with the screw thread cut on it. A moutbiece M, liks that of a telephone transmitter, provided with a diaphragm of parchment or similar substance, is monnted on a lever, which is pivoted at $h$ and provided with a set screw $b$. A blunt needle point is either fixed to the centre of the diapbragm or carried by a light epring in such a way as to press on the centre of the diaphragm with the ncedle point projecting outwards. To use the instrument, the drum $D$ is covered with a sheet of somewhat stiff tinfoil, and the mouthpiece is adjusted as ehown in the figure, with the weedle point over the hollow part of the tinfoil, and fixed by the set acrev to make a slight indentation in it. The drum io then turnod and words spoken in eomowhst loud and clear tone in front of the
monthpiece. The vibrations of the diaphragm cause the needle point to make indentations more or less deep, according to the intensity of the saund, in the surface of the tinfoil. If the mouthpiece is then raised, the drum turned back to its original position, the
mouthplect rowered so that the point rests on the groove march it previously made, and the drum sgain turned, the diaphragm, scted on by the needle point passing over the indentation, will give out the same words which were spoken to it.
(T. GR.)

## TELESCOPE

TIHE telescope is an optical instrument employed to view or discover distant objects, ${ }^{1}$ The fundamental optical pribciples inrolved in its construction have already been dealt with in the articles Light and Ortics, and these should be first perused by the reader.

## History.

The credit of the discorery of the telescope has been a fruitful subject of discussion. Thus, because Democritus announced that the milky way is composed of vast multitudes of stars, it has been maintained that ho could only have been led to form such an opinion from actual examination of the heavens with a telescope. Other passages from the Greek and Latin authors have similarly been cited to prove that the telescope was known to the ancients. But, as has been remarked by Dr Robert Grant (History of Physical Astronomy, p. 515), we are no more warranted in drawing so important a conclusion from casual remarks, however sagacious, than we should be justified in stating that Seneca was in possession of the discoveries of Newton because he predicted that comets would one day be found to revolve in periodic orbits. Molyneux, in his Dioptrica Nova, p. 256, declares his opinion that Roger Bacon (who died c. 1234) "did perfectly well understand all kinds of optic glasses, and knew likewise the method of combining them so as to compose some such instrument as our telescope." He cites a passage from Bacon's Opus DIajus, p. 377 of Jebb's edition, 1733, translated as follows:-
"Greater things than these may be performed by refracted vision. For it is easy to understand by the canons above mentioned that the greatest objects may appear exceedingly emall, and the contrary, also that the most remote objects may appear just at hand, and the converse ; for we can give such figures to transparent bodies, aud dispose them in such order with respect to the eye and the objects, that the raye shall be refracted and bent towards any place we please, so that we shall see the object near at hend or at any dis. tence under any angle we pleasa. And thas from an incredible distance we may read the smallest letters, and may number the emallest particles of dust and asnd, by reason of the greatness of the angle under which we see them. .. Thus slso the sun, moon, and stars may be made to descend hither in appearance, andoto be visible over the heads of our enemies, and many things of the like sort, which persons unaoquainted with such things would refuse to believe."
Molyneux also cites from Bacon's Epistola ad Parisięnsem, "Of the Secrets of Art and Nature," chap. 5 :-
"Glasses or diaphanous bodies may bo so formed that the most remoto ohjects insy appear just at hand, end the contrary, во that we may read the smallest lotters et 80 incrediblo distance, and may number things, though never eo small, and may make the atars slso appear as near as we please."
These passages certainly prove that Bacon had very nearly, if not perfectly, arrived at theoretical proof of the possibility of constructing a telescope and a microscope; but his writings give no account of the trial of an actual telescopo, nor any detailed results of the application of a telescope to an examination of the heavens. It has been pointed out by Dr Smith, in his Complete System of Optics, that Bacon imagines some effects of telescopes which caunot be perforned by them, and his conclusion is that Bacon never actually looked through a telescope.

Giambattista della Porta, in his Mfagia Naturalis, printed in 1558 , makes the following remarkable statement:-

[^41]"If you do hut know frow to join the two (viz., the concare and the conrex glasses) rightly together, you will see both remote and near objects larger than they otherwise appear, and withal very distinct."
Wolfus infers from this passage that its author was the first actual constructor of a telescope, and it appears not improbable that by happy accident Porta really did make some primitive form of telescope which excited the wonder of his friends. Here, howerer, his interest in the matter appears to have ceased, and he was unable either to appreciate the importance of his discovery or to describe the means by which the object was attained. Kepler, who examined Porta's account of his concare and convex lenses by desire of his patron the emperor Rudolph, declared that it was perfectly unintelligible. Poggendorff (Gesch. der Physik, p. 134) throws considerable doubt on the originality of Porta's statement.

Thomas Digges, in his Stratioticus, p. 359, published in Leonard 1579, states that his father, Leonard Digges,
samong other curious practices had a method of discovering by perspective glasses set at due angles all objects pretty far distant that the sun shone upon, which lay in the country round about," and that this was by the help of a manuscript book of Roger Bacon of Oxford, who he conceived was the only man besides his father who knew it. There is also the following passage in the Pantometria (bk. i. chap. 21) of Leonard Digges ${ }^{2}$ (originally published by his son Thomas in 1571, and again in 1591):-
"Marrellous are the conclusions that may be performed by glasses concaro snd contex, of circular and parabolic forms, using for multiplication of beams sometime tho aid of glasses transparent, which, by fraction, should unite or dissipate the images or figures presented by the reflection of other."
He then describes the effects of magnification from a combination of lenses or mirrors, adding :-
"But of these conclusions I minde not here to intreate, having at large in a volume ${ }^{3}$ by itselfe opened the miraculous eflects of perspective glasses."
It is impossible to discredit the significance of these quotations, for the works in which they occur were published more than twenty jears before the original date claimed for the discovery of the telescopo in Holland.

That Roger Bacon had tolerably clear ideas as to the practical possibility of constructing telescopes, and that Leonard Digges had access to some unpublished IISS. of Bacon, and by their aid constructed some form of telescope, seem to be obvious inferences from the preceding evidence. But it is quito certain that previous to 1600 the telescope was unknown, except possibly to individuals Who failed to see its practical importance, and who confined its use to "curious practices" or to demonstrations of "natural magic." The practical discovery of the instrument was certainly made in Holland about 1608, but the credit of the original invention has been claimed on behalf of three individuals, Hans Lippershey and Zacharias Jansen, spectacle-makers in Middelburg, and James Metius of Alkmaar (brother of Adrian Metius the mathematician).
Descartes, in his treatiso on Dioptrics (1637), attributes the discovery to Metius "ahout thirty jears ago," whilst Schyralus de Rheita, a Capuchin friar, in his Oculus Enoch el Eliw (Antwerp, 1645), gives the credit to Lippershey about 1609. Peter Borel, plysician to the king of Franco, published ot The Hague, in 1655, a work De Vero Teleccopii Inventore. Zu was assisted in its preparation by William Borel, Dutch envoy at the court of France, and the latter declares, $8 s$ the result of patient investigation, that ${ }^{2}$ He died about 1570 . His son slludes to his untimely death in ihe preface to the Pantomelria.

There is no further trace of this volume.

Jansen and his father were the real inventors of the telescope in 1610, and that Lippershoy only mado a telescope after hints accidentally communicated to him of the details of Jansen's invention. But the zost trustrorthy information on the auhject is to be got from the researches of Van Svinden. ${ }^{1}$ Briefiy gummarized, this eridence is as follows. In the library of the university of Leyden, amongst the MSS, of Huygens there is an original copy of a document (dated 17th October 1608) addressed to the states-general by Jacob Andrianzoon (the same individual who is called James Metiue by Descartes), petitioning for the exclusive right of a日lling an instrument of his invention by which distant objects appear an instrument of distinct. Ho states that ha had discovered the instrument by accident when engaged in making experiments, and had so far perfected it that distant objects wero made as risiblo and distinct by his instrument as could be done with the one which had been lately offered to the states by a citizen and opectaclomaker of Middelburg. Among the Acts of the states-general preaerved in the Government archives at The Hague, Van Swinden found that on 2d October 1603 the assembly of the atates took into consideration the petition of Hans Lippershey, spectacle-maker, a native of Wesel and an inhabitant of Middelburg, inventor of an instrument for seeing at a distance. On 4th October a committes was appointed to test the instrument, and on the 6th of the same month the assembly agreed to give Lippershay 900 forins for his instrument. Further, on the 15 th December of the same year they examined an instrument invented hy Lippershoy at thair request to seo with both eyes, and gave him orders to executo two similar instruments at 900 fiorins each; but, as many other persons had knowledge of this new invention to see at a distance, they did not deem it expedient to grant him an exclusive privilege to aell auch instruments. The dntes of these documents dispose effectually of Borel'a gtatement that Lippershey horrowed the ideas of Jansen in 1610. They also prove that, whilst Metius was in possession of a telescope, with which he may have experimented, about the time when Lippershey presented his application for patent rights, yot the makes no pretension that Lippershey borroved the invartion from him. The conclusion is that Lippershey ras the first person who independently invented the telescope, and at the amatima made the instrument known to the world. The common atory is that Lippershey, happeniag one day, whilst holding a spectacle-lons in either hand, to direct them towards the ateeple of a neighbouring church, was astonished, on looking through tho nearer lens, to find that the weathercock appoared nearer and more distinct. He fitted the lenses in a tube, in order to adjust and preserve their relatipo distances, and thus constructed his first tolescope. But doubt may be threwn on this traditional account owing to the further statement that the image of the weathercock so viewed was geen turned npside down All the oriminal Dutch telescopes were composed of a convex and a coucave lens, and telescopes so couatructed do not invert. The inverting telescopa, composed of two convex lenses, was a later invention ; gtill it is not impossible that the original experiment was made with two conver lenses.

Telescopes seem to have been made in Holland in considerable numbers soon after the date of their invention, and rapidly found their way over Europe. Sirturus, in his De Telescopio (1618), states that "a Frenchman proceeded to Milan in the month of May 1609 and offered a telescope for sale to Count di Fuentes"; and Lorenzi Pigorna writes, ${ }^{2}$ under date 31st August 1609, that "Galileo had been appointed lecturer at Padua for life on account of a perspective like the one which was sent from Flanders to Cardinal Borghese." Simon Marius, the German astronomer, appears to have made astronomical observations in 1609 with a telescope which he procured from Hollaud, and Professor Rigaud of Oxford found from the MSS. of Harriot, the mathematician, that he had been making astronomical observations with a Dutch telescope as early as July 1609. Galileo, in his Nuncius Sidereus, states that, happening to be in Venice about the month of May 1609, he heard that a Belgian had invented a perspective instrument by means of which distant objects appeared nearer and larger, and that he discovered its construction by considering the effects of refraction. In his Saggiatore Galileo otates that he solved the problem of the construction of a telescope the first night after his return to Padua from Venice, and made his first telescope next day by fitting a convex lens in one extremity of a leaden tube and a concare lens in the other one. A few

[^42]days afterwards, having succeeded in making a better telescope than the first, be took it to Venice, where he communicated the details of his invention to the public, and presented the instrument itself to the doge Leonardo Donato, sitting in full council. The senate, in return, settled him for life in his lectureship at Padua and doubled his salary, which was previously 500 florins, and which then became treble that which any of his predecessors had enjoyed. Galileo may thus claim to have invented the telescope independently, but not till he had heard that others had done so. In fact the time was ripe; and, as often happens in similar circumstauces, only a hint was necessary to complete the latent chain of thought. Galileo devoted all his time to improving and perfecting the telescope. Knowing the theory of his instrument, and possossed of much practical skill, coupled with unweariod patience, he conquered the difficulties of grinding and polishing the lenses, and soon succeeded in producing telescopes of greatly increased power. His first telescope magnified three diameters; but he soon made instruments which magnified eight diameters, and finally one that magnified thirty-three diameters. ${ }^{8}$ With this last instrument he discopered in 1610 the satellites of Jupiter, and soon afterwards the spots on the sun, the phases of Venus, and the hills and valleys on the moon. He demonstrated the rotation of the satellites of Jupiter round the planet, and gave rough predictions of their confgurations, proved the rotation of the sun on its axis, established the general truth of the Copernican system as compared with that of Ptolemy, and fairly routed the fanciful dogmas of the philosophers. These brilliant achievements, together with the immenso improvement of the instrument under the hands of Galileo, overshadowed in a great degree the credit due to the original discoverer, and led to the universal adoption of the name of the Galilean telescope for the form of the instrument invented by Lippershey.

Kepler first explained the theory and some of the practical advantages of a telescope constructed of two conver lenses in his Catoperics (1611). The first person who actually constructed a telescope of this form was Father Scheiner, who gives a description of it in his Rosa Ursina (1630). William Gascoigne was the first who practically appreciated the chief advantages of the form of telescope suggested by Kepler, viz., the visibility of the image of a distant object simultaneously with that of a small material object placed in the common focus of the two lenses. This led to his invention of the micrometer and his application of telescopic sights to astronomical instruments of precision (see Microneter, vol. xvi. p. 242). But it was not till about the middle of the 17 th century that Kepler's telescope came into general use, and then, not so much because of the advantages pointed out by Cascoigne, but because its feld of view was much larger than in the Galilean telescope. The first powerful telescopes of this construction were made by Huygens, after much labour, in which he was assisted by Lis brother. With one of these, of 12 -feet focal length, he discovered the brightest of Saturn's satellites (Titan) in 1655, and in 1659 he published his Systema Saturnium, in which was given for the first time a true explanation of Saturn's ring, founded on observations made with the same instrument. The sharpness of image in Kepler's telescope is very inferior to that of the Galilean irstrument, so that when a high magnifying power is required it becomes essential to increase the focal length. Cassini discovered Saturn's fifth satellito (Rhea) in 1672 with a telescope of 35 feet, and the third and fourth satellites in 1684 with telescopes made by Campani of 100 and 136 feet focal length. Huygens states that he and his brother

[^43]Aade object-glasses of 170 and 210 feet focal length, ana he presented ene of 123 feet to the Royal Society of London. Auzout and others are said to have made telescopes of from 300 to 600 feet focus, but it does not appear that they were ever able to use them in practical observations. Bradley, on 27 th December 1722 , actually measured the diameter of Venus with a telescope whose object-glass had a focal length of $212 \frac{1}{4}$ feet. In these very long telescopes no tube was employed, and they were consequently termed aerial telescopes. Huygens contrived some ingenious arrangements for directing such telescopes towards any object visible in the heavens, -the focal adjustment and centring of the eye-piece being preserved by a braced rod connecting the object-glass and eye-piece. Other conrivances for the same purpose are described by La Hire 'Mém. de l'Acad., 1715) and by Hartsoeker (Miscel. Berol., rol. i. p. 261). Telescopes of sucl great length were naturllly difficult to use, and must have taxed to the utmost the skill and patience of the observers. One cannot but pay a passing tribute of admiration to the men who, with such troublesome tools, achieved such results.
-Until Newton's discovery of the different refrangibility of light of different colours, it was generally supposed that object-glasses of telescopes were subject to no other errors than those which arose from the spherical figure of their surfaces, and the efforts of opticians were chiefly directed to the construction of lenses of other forms of curvature. James Gregory, in his Optica Promota (1663), discusses the forms of images of objects produced by lenses and mirrors, and shows that when the surfaces of the lenses or mirrors are portions of spheres the images are curves concare towards the objective, but if the curves of the surfaces are conic sections the spherical aberration is corrected. He was well aware of the failures of all attempts to perfect telescopes by eroploying lenses of various forms of curvature, and accordingly proposed the form of reflecting telescope which bears bis name. But Gregory, accordjng to his omn confession, had no practical skill; he could find no optician capable of realizing his ideas, and after some fruitless attempts was obliged to abandon ail hope of bringing his telescopo into practical use. Newton was the first to constrcet a reflecting telescope. When in 1666 he made his discovery of the different refrangibility of light of different colours, he soon perceived that tho faults of the refracting telescope were due much more to this cause than to the spherical figure of the lenses. He over-hastily concluded from some rough experiments (Optics, bi. i. pt. ii. prop. 3) "that all refracting substances diverged the prismatic colours in a constant proportion to their mean refraction "; and he drew the natural conclusion "that refraction could not be produced without colour," and therefore "that no improvement could be expected from the refracting telescope" (Treatise on Optics, p. 112). But, having ascertained by experiment that for all colours of light the angle of incidence is equal to the angle of reflexion, he turned his atlention to the construction of reflecting telescopes. After much experiment he selected an alloy of tin and copper as the most suitable material for his specula, and he devised means for grinding and polishing them. He did not attempt the formation of a parabolic figure on account of the probable mechanical difficulties, and he had besides satisfied himself that the chromatic and not the spherical aberration formed the chief faults of previous telescopes. Newton's first telescope so far realized his expectations that he could see with its aid the satellites of Jupiter and the horns of Venus. Encouraged by this success, he made a second telescope of $6 \frac{1}{3}$-inches focal length, with a magnifying power of 38 diameters, which be presented to the Royal Society of London in December 1671. A third form of reflecting telescope was devised in 1672 by Cassegrain
(Journal des Sçavans, 1672). No further practical advauc appears to have been made in the design or construction of the instrument till the year 1723, when John Hadley (besi known as the inventor of the sextant) presented to the Royal Society a reflecting telescope of the Newtonian construction, with a inetallic speculum of 6 -inches aperture and $62 \frac{5}{8}$-inches focal length, having eye-pieces magnifying up to 230 diameters. The instrument.was exarmined by Pound and Bradley, the former of whom reported upon it in Phil. Trans., 1723 , No. 378, p. 382. After remarking that Newton's telescope "had lain neglected these fifty years," they stated that Hadley had sufficiently shown "that this noble invention does not consist in bare theory." They compared its performance with that of the object-glass of 123-feet focal length presented to the Royal Society by, Huygens, and found that Hadley's reflector
"will bear euch a charge as to make it magnify the object as many times as the latter with its due charge, and that it representa objects as distinct, though not altogether so clear and bright. Notwithstanding this difference in the brightness of the objects, we were able with this reflecting telescope to see whatever we have hitherto discovered with the Hugenian, particularly the transits of Jupiter's satellites and their shadows over his disk, the black list in Saturn'e ring, and the edge of his shadow cast on his ring. We have also seen with it several times the five satellites of Saturn, in viewing of which this telescope had the advantage of the Hugenian at the time when we compared them; for, being in summer, and the Hugenian telescope being managed without a tube, the twilight prevented us from seeing in this some of these small objects which at the eame time we could discern with the reflecting telescope."
Bradley and Molyneux, haring been instructed by Hadley in his methods of polishing specula, succeeded in producing some telescopes of considerable power, one of which had a focal length of 8 feet; and, Molyneux having communicated these methods to Scarlet and Hearn, two London opticians, the manufacture of telescopes as a matter of business was commenced by them (Smith's Optics, bk. iii. ch. 1). But it was reserved for James Short of Edinburgh to givo James practical effect to Gregory's original idea. Born at Edin- Sbort burgh in 1710 and originally educated for the church, Short attracted the attention of Maclaurin, professor of mathematics at the university, who permitted him about 1732 to make use of his rooms in the college buildings for experiments in the construction of telescopes. In Short's first telescopes the specula were of glass, as suggested by Gregory, but he afterwards used metallic specula only, and succeeded in giving to them true parabolic and elliptic figures. Short then adopted telescope-making as his profession, which he practised first in Edinburgh and afterwards in London. All Short's telescopes were of the Gregorian form, and zome of them retain even to the present day their original high polish and sharp definition. Short died in London in 1768 , having realized a considerable fortune by the exercise of his profession.

The historical sequence of events now brings us to thè discovery of the achromatic telescope. The first person who succeeded in making achromatic refracting telescopes seems to have been Chester Moor Hall, a gentleman of Essex. He argued that the different humours of the human eye so refract rays of hght as so produce an image on the retina which is free from colour, and he reasonably argued that It might be possible to produce a like result by combining lenses composed of different refracting media ${ }^{1}$ After devoting some time to the inquiry he found that by combining lenses formed of diffcrent kinds of glass the effect of the unequal refrangibility of light was corrected, and in 1733 he succeeded in constructing telescopes which exhibited objects free from colour. One of these instruments of only 20 -inches focal length had an aperture of $2 \frac{1}{2}$ inches. Hall was a man of independent
${ }^{1}$ The same argument was employed by Gregory more than fifty .years previously, but had been followed by no practical result. The lens of the human eye is not achromatic (see LicHT, vol. xiv. p. 601).'
XXIII. - 18

# TELESOUP L 

means, and seems to have been careless of fame: at least he took no trouble to communicate his invention to the world. At a trial in Westminster Hall about the patent rights granted to Dollond (Watkin v. Dollond), Hall was admitted to be the first inventor of the achromatic telescope; but it was ruled by Lord Mansfield that "it was not the person who locked his invention in his scrutoire that ought to profit for such invention, but he who brought it forth for the benefit of mankind." ${ }^{2}$ In 1747 Euler communicated to the Berlin Academy of Sciences a memoir in which he endeaveured to prove the possibility of correcting both the chromatic and the spherical abcrration of an object-glass. Like Gregory and Hall, he argued that, since the various humours of the human eye were so combined as to produce a perfect image, it should be possible by suitable combinations of lenses of different refracting media to construct a perfect object-glass. Adopting a hypothetical law of the dispersion of differently coloured rays of light, he proved analytically the possibility of constructing an achromatic object-glass composed of lenses of glass and water. But all his efforts to produce an actual objectglass of this construction were fruitlcss, -a failure which he attributed solely to the difficulty of procuring lenses worked precisely to the requisite curves (Mem. Acad. Berlin, 1753). Dollond admitted the accuracy of Euler's analysis, but. disputed his hypothesis on the grounds that it was purely a theoretical assumption, that the theory was opposed to the results of Newton's experiments on the refrangibility of light, and that it was impossible to dotermine a plysical law from analytical reasoning alene (Phil. Trans., 1753, p. 289). In 1754 Euler communicated to the Berlin Academy a further memoir, in which, starting from the hypothesis that light consists of vibrations excited in an elastic fluid by luminous bodies, and that the difference of colour of light is due to the greater or less frequency of these vibrations in a given time, he deduced his previous results. He did not doubt the accuracy of Newton's experiments quoted by Doliond, because he asserted that the differenco bctween the law deduced by Newton and that which he assumed would not be rendered sensible by such an experiment. ${ }^{3}$ Dollond did not reply to this memoir, but soon afterwards he received an abstract of a Klingen. memoir by Klingenstierna, the Swedish mathematician and etierna. astronomer, which led liim to doubt the accuracy of the results deduced by Newton on the dispersion of refracted light. Klingenstierna showed from purely geometrical considerations, fully appreciated by Dollond, that the results of Newton's experiments could not be brought into harmony with other nniversally accepted facts of refraction.

[^44]Like a practical man, Dollond at once put his deubts to the Dollond test of experiment, confirmed the conclusions of Klingenstierna, discovered "a difference far beyond his hopes in the refractive qualities of differont kinds of glass with respect to their divergency of colours," and was thus rapidly led to tho construction of object-glasses in which first the chromatic and afterwards the spherical aberration were corrected (Phil. Trans., 1758, p. 733).
We have thus followed somewhat minutely the history of the gradual process by which Dollond arrived independently at his invention of the refracting telescope, because it has been asserted that he borrowed the idea from others. Montucla, in his Histoire des Mathématiques (pp. 448-449), gives the following footnote, communicated to him by Lalande:-
"Ce fut Chestermonhall" (an obvions misprint for Chester Moor Hall) "qui, vers 1750, eut l'idée des lunettes achromatiques. Il s'adressoit ì Ayscough, ${ }^{4}$ qui faisoit travaillir Bass. Dollond ayant ou besoin de Bass pour un verre que demandoit le duc d'Yorck, Bass luif fit voir dn crown-glass et du fint-glass. Hall donna une lunetto ì Ayscouglh, qui la montra à plusieurs personnes; il en donna la construction à Bird, qui n'en tint pas compte. Dollond en profita. Dans le procès qu'il y eut entre Dollond et Watkin, au banc du roi, ccla fut pronvé ; mais Dollond gagna, parce qu'il étoit lo premier qui eatt fait connoitre les lunettes achromatiques."
It is clearly established that Hall was the first inventor of the achromatic telescope; but Dollond did not borrew the invention from Hall without acknowledgment in the manner suggested by Lalande. His discovery was beyond question an independent one. The whole history of his researches proves how fully he was aware of the conditions necessary for the attainment of achromatism in refracting telescopes, and he may be well excused if he so long placed implicit reliance on the accuracy of experiments made by so illustrious a philosopher as Newton. His writings sufficiently show that but for this confidence he would have arrived sooner at a discovery for which his mind was fully prepared. It is, besides, impossible to read Dollond's memoir (Phil. T'ranis., 1758, p. 733) without being impressed with the fact that it is a truthful account, not only of the successive steps by which he independently arrived at his discovery, but also of the logical processes by which these steps were successively suggested to his mind.

The triple object-glass, consisting of a combination of two convex lenses of crown glass with a concave flint lens between them, was introduced in 1765 by Peter, son of John Dollond, and many excellent telescopes of this kind were made by him.

The limits of this article do not permit a further detailed historical statement of the various steps by which the powers of the telescope were developed. Indeed, in its practical form the principle ofo the instrument has remaincd unchanged from the time of the Dollonds to tho present day; and the history of its development may be summed up as consisting not in new optical discoveries but in utilizing new appliances for figuring and polishing, improved material for specula and lenses, more refined means of testing, and more perfect and convenient methods of mounting. About the year 1774 William Herschel, then a teacher of music in Bath, began to occupy his leisure hours with the construction of specula, and finally devoted himself entirely to their construction and use. In 1778 he had selected the chef dowere of some 400 specula which he made for the celebrated instrument of 7 -feet focal length with which his early brilliant astronomical discoveries were made. In 1783 he completed his reflector of $18 \frac{7}{10}$-inches aperture and 20 -feet focns, and in 1789 his great reflector of 4 -fest aperture and 40 -feet focal length. The fame of these instruments was rapidly spread by the brilliant discoveries which their maker's genius and perso-

- Ayscough was an aptician in Ludgate Hill, London.
verance accomplished by their aid. The reflecting telescope became the only available tool of the astronomer when great light grasp was requisite, as the difficulty of procuring disks of glass (especially of flint glass) of suitable purity and homogencity limited the dimensions of the achromatic telescope. It was in vain that the French Academy of Sciences offered prizes for perfect disks of optical fint glass. Some of the best chemists and most enterprising glass-manufacturers exerted their utmost efforts without succeeding in producing perfect disks of more than $3 \frac{1}{2}$ inches in diameter. All the larger disks were crossed by strix, or were otherwise deficient in the necessary homogeneity and purity.

Pierre Louis Guinand, a bumble watchmaker living near Chaux de Fond in Neuchatel, Switzerland, was the first who succeeded in making marked progress in the manufacture of optical fint glass. After making preliminary experiments extending over seven years (178490 ), and nothing daunted by their comparative want of success, he erected a furnace near Les Brenets, and devoted most of his slender earnings (then derived from making the bells, or rather gongs, of repeating watches) to the fulfilment of his ambition. His persistency, courage, and self-denial recall forcibly the story of Palissy. In 1805 he joined the optical establishment of Fraunhofer and Utzschneider and remained with them about nine years. During this period extensive experiments were instituted with remarkable success. It is said that the disks for the Dorpat refractor $29 \cdot 6$ inches aperture, with which the observations of Wilhelm Struve were made) were manufactared during this period, though the complete instrument was not delivered till 1823. Fraunhofer had, however, profited so fully by the suggestions of Guinand, and had probably also so far improved on the original methods, that he afterwards succeeded in producing still larger objectglasses. After Fraunhofer's death in 1826 his successors Merz and Mahler carried out saccessfully the methods handed down to them by Guinand and Fraunhofer, and produced sonie large and excellent telescopes, which are hereafter mentioned. Meanwhile Guinand, having returned to his native country in 1814, resumed there the manufacture of disks of optical glass, discovered a method of removing striz by breaking and reuniting the portions by heat, when the glass was in a plastic state, and eventnally produced perfect disks up to 18 inches in diameter. Most of these he disposed of to Lerebours and Secretan, opticians in Paris, by both of whom some fine object-glasses were made. ${ }^{1}$ Guinand commnnicated his secrets to his sons before his death in 1823. About 1829 Bontemps entered into partnership with one of the sons, and another son carried on his father's manufacture in partnership with his mother. The latter firm was succeeded by Danget of Soleure, whose exhibits of optical glass excited so much attention at the London exhibition of 1851. About 1848 Bontemps joined the firm of Chance Brothers of Birmingbam, and thus carried the secret of Guinand's methods to England. It is not a little remarkable that the only firms in the world by whom large disks of optical glass have been produced trace their success to information derived more or less directly from Guinand. MMI. Feil of Paris, who are direct descendants of Guinapnd, and Messrs Chance Brothers of Birmingham are at the present time the only makers of optical glass in disks of larger- diameter than 20 inches.

## Jistroments, de.

We now proceed to give an account of the methods and principles of construction of the varions kinds of telescopes,

[^45]and to describe in detail special typical instruments, which, owing to the work accomplished by their aid or the practical advances exemplified in their ronstruction, appear most worthy of resord or study.

## Refracting Telescope.

In its simplest form the telescope consists of a convex objectlens capable of forning an image of a distant object and of an eye. lens, concave or convex, by which the image so formed is magnified. When the axis of the eye-lens coincides with that of the ob-ject-glass, and the focal point of the eye-Iena is coincident with the principal
 focus of the object-lens, parallel raye incident apon the object-glass will emerge from the eye-piece as parallel rays. These, falling in turn on the lens of the human eye, are converged by it and form an image on the retina. ${ }^{3}$ Fig. 1 ahows the course of the raye when the eye-lens is coavex (or positive), fig. 2 when the eyelens is concave (or negative). The former represents Kepler's,
 the latter Lippershey's or the Galilean telescope. The magnifying power obviously depeads on the proportion of the focal length of the object-lens to that of the eye-lens, that is,
magnifying power $=F / e_{\text {, }}$
Where $F$ is the focal length of the object-lens and $e$ that of the eye-lens. Also the diameter of the pencil of parallel rays emerging Megaity from the eye-lens is to the diameter of the object-lens inversely as ing the magnifying power of the teleacope. Heace one of the best power. methods of determining the magnifying power of a telescope is to measure the diameter of the emergent pencil of rays, after the teleacopo has been adjusted to focus upon a star, and to divide the diameter of the object-glass by the diameter of the emergent peacil. If we desire to utilize all the parallel raye which fall upon an objectglass it is necessary that the full peacil of emerging rays should enter the observer's eye. Assuming with Sir William Herschel that the normal pupil of the eye diatende to one-fifth of an inch in diameter when viewing faint objecta, we obtain the rule that the nitimum magnifying power which can be efficiently employed is five times the diameter of the object-glass expressed in inches. The defects of the Galilean and Ecpler telescopee are due to the chromatic and spherical aberration of the simple lenses of which they aro comprosed (see Optics, vol. Xvii. p. 802 sq.). The substitution of a positive or negative eye-piece for the aimple convex or concave eje-lens, and of an achromatic object-glass for the simple object-lens, transforma these early forma into the modern achromatic telescope. The Galilean telescope with a concave eye-lens instead of an eye-picee still survives ss the modern opera-glass, on account of its shorter length. but the object-glass and eye-lens are achromatic combinations.
The principles of an achromatic combinstion of prisms or lenses Achrohave been explained in Lig日t (vol. xiv. pp. 692, 595) snd further matic developed in Optics (vol. xvii. p. 804 sq.). As a lens may be re-objectgarded as built up of a series of thin slices of prisms, divided from glass. each other by planes parallel to the axia of the lens, it will be seen that, if a priam perfectly achromatic for raye of two definite wavelengths, aud approximstely achromatic for all rays, can be constructed by combining two prisms of different kiods of glass, all that is required to produce an object-glass with similar small chromatic errors is to combine a convex lens of crown glass and a concave one of fint glass as in fig. 3, their surfaces being of such curvatures as to form a series of imaginary prisms (such as we have supposed an object-glass to consist on through any one of which all kinds of light lalling on the object-glass parallel to its axis will be refracted very nearly to a common focua F. Accordingly any pro-

[^46]posed object-glass can be tested as regards its optical conditions by "tracing a ray," i.e., calculating the point at which, after refraction through the two lenses, the ray so traced will cut their common axis. For the analytical solution of this problem it
is necessary to assume that the adjacent surfaces of the supt posed infioitely numerons prisms form together some continuous

## Fiz. 3.

curved surface, which practically is nearly spherical. But the actual differences between the curves which may be required in certain. conditions for producing a perfect lens differ so slightly from true spherical surfaces that it is impossible by any previously designed mechanical process to predict whether the resulting tigure will be that of a sphere or some other curve very nearly that of a sphere. The mathematician, therefore, who discusses the subject is compelled to adopt spherical curves as the basis of his calcula. tion." On this assumption we may then trace a ray rigidly through any snpposed object-glass as follows. Let $\mathrm{A}, \mathrm{B}, \mathrm{A}^{-}, \mathrm{B}^{\prime}$ be respectively the poiats where the refracted ray produced wonld intersect the optical axis after refraction at the first, second, third, and fourth refracting surfaces respectively; also let $a$ be the first angle of incidence, $\mu$ and $\mu^{\prime}$ the refractive indexes for the crown and fint lens respectirely for a ray of the wave-length whose course is to be traced, $r$ and $s$ the first and second radii for the crown lens, $r^{\prime}$ and $s^{\prime}$ the first and second radii for the flint lens, $a, \beta, a^{\prime}, \beta^{\prime}, a^{\prime}$, and $b^{\prime}$ auxiliary angles, $d$ the thickness of the crown lens, $d^{\prime}$ the thickness of the fint leos, $\Delta$ tho distance between the second and third enrfaces. Then for the intersect after refraction at the first surface

$$
\begin{aligned}
\sin a & =\frac{1}{\mu} \sin \alpha ; \\
(A) & =a-a ; A=\frac{r \cdot \sin a}{\sin (A)}+r ;
\end{aligned}
$$

for the intersect after refraction at the second surface

$$
\begin{aligned}
& \sin b=\frac{A+s-d}{s} \sin (A) \\
& \sin \beta=\mu \cdot \sin b
\end{aligned}
$$

$$
(B)=(A)+\beta-b ; B=\frac{s \sin \beta}{\sin (B)}-s ;
$$

for the intersect after refraction at the third surface

$$
\begin{aligned}
\sin a^{\prime} & =-\left(B-r^{\prime}-\Delta\right)^{\sin (B)} \frac{r^{\prime}}{} \\
\sin a^{\prime} & =\frac{1}{\mu^{\prime}} \sin a^{\prime} ; \\
\left(A^{\prime}\right) & =(B)+a^{\prime}-a^{\prime} ; A^{\prime}=r-r^{\prime} \cdot \frac{\sin a}{\sin \left(A^{\prime}\right)} ;
\end{aligned}
$$

for the intersect after refraction at the fourth surface'

$$
\begin{aligned}
\sin b^{\prime} & =-\left(\Lambda^{\prime}+s^{\prime}-d^{\prime}\right) \sin \frac{\left(\Lambda^{\prime}\right)}{s^{\prime}} ; \\
\sin \beta^{\prime} & =\mu^{\prime} \sin b^{\prime} ; \\
\left(B^{\prime}\right) & =\left(\mathrm{A}^{\prime}\right) \cdot \dot{r} b^{\prime}-\beta^{\prime} ; \mathrm{B}^{\prime}=-s-s^{\prime} \cdot \frac{\sin \beta^{\prime}}{\sin \left(\overline{\left.\mathrm{B}^{\prime}\right)}\right.} .
\end{aligned}
$$

The computation is very much simplified when we consider the angle of incidence to bo very small-i.c., the point of incidence very near the optical axis, viz.,

$$
\begin{aligned}
& \frac{r}{\mathrm{~A}}=\frac{\mu-1}{\mu} ; \frac{\delta}{1 \mathrm{~s}}=\stackrel{\mu s}{\Lambda-l}+\mu-1 \\
& \frac{r^{\prime}}{\mathrm{A}^{\prime}}=\frac{r^{\prime}}{\mu^{\prime}(\mathrm{B}-\Delta)}+\frac{\mu^{\prime}-1}{\mu^{\prime}} ; \overline{\mathrm{B}^{\prime}}=\frac{\mu^{\prime} s^{\prime}}{\mathrm{A}^{\prime}-d^{\prime}}+\mu^{\prime}-1
\end{aligned}
$$

By means of these formulæ we can compute $B^{\prime}$ (the point where a ray, entering the first surface of the object-glass, will intersect the optical axis) for any angle of incidence $=a$, when for a ray of that wave-length the indexes of refraction are known for the glass of which the lenses are composed, if the radii of curvature of the lenses are als. known. The most perfect object-glass would be one in which the value of ' $B^{\prime}$ is the same for two rays of the two selected wave-lengths, through whatever portion of the object-glass they may pasa. This, however, is a condition which cannot be mathematically satisfied with spherical surfaces. It is of conrse possible to find values of the four unknown quantities $r, s, r^{\prime}$, and $s^{\prime}$ such that four conditions shall be satisfied. The ordinary approxi. mate method is to find such values of the radii that $B^{\prime}$ is the same for rays of two different wave-lengths when the incident rays are near the axis, and for mean rays which enter near the margin of the lens; but of course this solution is indeterminate, and only becomes rigid when two radii are assumed. Thus, for any crown lens of any radii of curvature it is possible to find a flint lens to satisfy these conditions. The rigid solution becomes one of successive approximation to such fous conditions as the computer miay
consider most desirable. Herschel adrocates satisfying the terms depending on the secood power of the aberration, klingel that the refiractions of the rays should be as small as possible; or we may make it a coodition that tha second and third surfaces sball bave the same radius, so that the snrfaces may be cemented together. The fourth condition is of course the desired focal length. But for all practical Iurposes it is sufficient to have placed the reader in a position to test the optical cooditions of any combinations that may be proposed, and to refer him to the works mentioned in the subjoined note ${ }^{1}$; for, in fact Practics the construction of object-glasses on papcr is of far higher interest method as a mathematical exercise than as a practical matter. By a slight of coradeparture from the spherical figure - a departure so minute that putatio there are no mechonical means sufficiently delicate to measure it witll certainty - the optician may fail to realize true spherical surfaces, and thus on the one hand miss the fine definition which his calculation led him to expert, or on the other hand convert an object-glass which with splerical curves wonld have large spherical aberration into one perfectly corrected in this respect. Having, therefore, for particular kinds of glass ascertained a good general form of object-glass, it becomes only neccssary for the optician to perform an approximate calculation of the curva. tures requisite to produce correction of the chromatic abcrration, and to trust to the process of final figuring for correction of the fiual splierical and chromatic aberration, It fortunately happens that in the rigid equations the terms which express the thickness and distance apart of the leases involve only the focal distances of central rays, and have but a small influence on the ratios of the aberrations of the lenses ; and, further, they affect chiefly the focal length of the lens, and have a very small influence on the chromatic aberration. Tlus in the preliminary computation the optician may neglect the thickness of the lenses and employ the simple approximate formulæ given under OpTICs, vol. xvii. p. $804-$

$$
\begin{gathered}
\begin{array}{c}
\delta \mu \\
\mu-1 \\
\cdot \\
f^{1}+ \\
\frac{1}{\mu^{\prime}}-1 \\
\frac{\delta \mu^{\prime}}{\mathbf{F}^{\prime}} \\
=\frac{1}{f^{\prime}}+\frac{1}{f^{\prime \prime}}
\end{array},=0
\end{gathered}
$$

where $\frac{\delta \mu}{\mu-1}$ and $\frac{\delta \mu^{\prime}}{\mu^{\prime}-1}$ are the dispersive powers of tho two kitds of glass for the two rays which he desirca to unite, $f$ and $f^{\prime}$ the corresponding focal lengtlis of the two lenses, and $\mathbf{F}$ the focal ledgth of the combination. The focal lengths of the two lenses which secure the cooditions of achromatism having been thus computed, the radii of curvature may bo computed far either lens hy tho nsual formula (seo Liaht, vol. xiv. p. 593)-

$$
\frac{1}{f}=(\mu-1)\left(\frac{1}{r}-\frac{1}{s}\right)
$$

In the last expression, where $r$ and $s$ correspond to the radii of curvature, the optician has an iofinite range of choice. He will of conrse select such a proportion of $r$ to $s$ as experience or moro clahorate calculation has shown to be favourable. In the form of object-glass recommended hy Sir Johu Herschel, as fulfilling the most favourable conditions for correction of a spherical aberration for parallel as well as nearly parallel rays, the required curvatures for the exterior sufaces of the crown and the flint lens were found to vary very slightly for a considerable range of the ratio of the dispersive powers of the crown aud the flint glass. Assuming $\mu$ (the mean index of refraction) to be 1.542 for crown glass and $1 \cdot 585$ for dint glass, Herschel proved that, if the radii io question are taken to be 6.72 for the crown lens and $14 \cdot 20$ for the flint lens (supposing the focal length of the desired combination to be 10 ), we bave only to compute the radii of the second and third surfacea 1757; D'Alembert, Dica, St Petersburg, 1 T67-71; Clairaut, Nem, de l'Acall. by meane of the above aimple formalæ and the measured dispersive and refractive power of the glass of the lenses. (The method of determining $\mu$, \&c., is givea under Optics, vol. zvii. p. 800.) The form generally adopted (see fig. 4) in the best modern object-glasses is extremely simple, viz., an equi-convex crown lens and a flint lens whore first ourface has the asme radius of curvature as the aurfaces
 of the crown lens - this radius depending on the focal length which it is deaired to give to the object-glass. . Since in order to fulfil the conditions of achromatism the focal lengtlis of the two lenses have to be proportional to their diapersive nowera (for the raya which it is desired to unite), and as in the two descriptiona of glass in question the dispersion of flint glass for C to rays between $F$ and $G$ is very nearly twice tbat of crown glass, the posterior surface of the fint lens becomea nearly a plane. The final correction for achromatism is made, if necessary, by departing alightly from a plane in the curvature of the last surface of the fint lens, aud the final correction for apherical aberration in the figuring of the ourfaces. In a lecture delivered at the lioyal Institution on 2d April 1886 Sir Howard Grubb, optician, of Dublin, said:
"A truly spherical curva is tha exception, not the ruls. When I tell you that a sensibla differenca in correction for spherical aberration can be mada by hall an hour's polishing, correspondlag probably to a differenca In tha frst place of dechasis in radu of the curves, you will sea that it ls practically not necessary to eater upon any calculstion for spherical aberration. FVa know a bout what form givea an approximate correction ; wa adhere nearly to that, and the rest la doas by fignring of tha aurface. To 1 lustrste what I mean. 1 would be quite willing to uodertake to alter the curves of the crown or fiat lena of any of my objectives by a very larga quantity, increasing ona and decressing tha other an as to atill satisfy tha coaditiona of achromatism, but introlucing theoretically a large amount of positive or negativa apherical aberration, and yet to niska out of tha altered lena an object-glass perfectly corrected for spharical aberration. . I raby remark that it is cometimes poasibla to maka a better objectlve by deviatiog from the curves whlch giva a true correction for apherical aberration, sad correcting that aberration by figuring, rather than by atrictly adhering to the theoratical curves."

When an object-glass is designed for use as an ordinary telescope it is usual to select for the rays of different colour to be united those near $C$ and those between $F$ and $G$, aince rays of lower and higher re. frangibility produce a com. paratively faiot impression on the aense of sight. In such a telescope of any considerable aperture the image of a bright atar at focus is surrounded by a halo of hluish or violetcaloured light,-a defect which is nnavoidable in an object-glass composed of a crown and flint lens on account of the irrationality of their apectra (Lioht, vol. xiv. p. 592). There aeems to be no doubt that differerit eyes are differently impressed by rays of different wave-length. 1 Thus two observers will often have different opinions as to the chromatic corrections of the saine object-glass: the observer whose eye is abnormally sensitive to violet light will pronounce the chromatic aberration over. corrected in an object-glass which another will consider perfect in this respect, and vice versa. Probably it is partly owing to this canse that the object-glasses of different makers ahow syatematic differences in their colour correction. An exccedingly aenaitive method of testing this correction devised by Professor Stokes is given nader Optics, vol. zvii. p. 804. Another method, due to Professor Harkness and first carried out by Dr Vogel, is the following. Place behind the eye-piece a direct vision prisin (cf. OpTics, p. 801). The imsge of a siar in the field will then be converted into a narrow spectrum, which, if there were no chromatic aberration, would when focased be represented by a fanat coloured atraight line, uniformly aharp asd narrow. But in on ordinary object-glass only two points in the spectrim can be perfectly focused aimultaneouely; therefore all its other parts are sprcad out, forming a coloured band of variable breadth. If we focus on the brightest part of the apectrum, both 2 8ee Abney and Feeting. Bakertan Lectura, Phil Trans., 1888; also Photooraphic Neurs; May 1886, p. 882.,
its extreme ends become spread out into a more or less trampetahaped form, enabling the observer to noto the range of the apectrum over which precise defipition can be expected. The amount of this extension will depend in some degree on the form of the object-glass, but much more (if the achromatism is fairly well corracted) on the irrationality of the apectra of the glass of which the lenses are composed. If wo then focus, for erample, on the $C$ line, we shall have the band of light contracted at $S$ and at auother point (probably between $F$ and $G$ ), widening to a slighty trumpet-shaped form below $C$, and markedly ao above $G$. This second point of greatest contraction gives the wave-length of the ray which has the same focus as C. If the telescope has a focuaing scale, we can also measure directly in this way the change of focus for rays of different colours. The chromatic aberration will be best corrected for the raya of minimum focas, and this minimam focus should for an ordinary telescope correapond with the brighteat part of the spectrum, viz., with rays between $D$ and $\mathrm{E}_{6} \quad A$ comparison of the chromatic correction of object-glasses by different makers is given by Dr Vogel (Monatsber. der Berliner Akad., April 1880), obtained in the manner just described. The tele. scopes compared are-

| Frsunhofer | Berlia | 0.243 | 41931 | 27.8 |

Fig. 6, taken from the above-quoted paper, affords most interesting information as to the colour-correction of these three typlcal object-glasses. The curves of the diagram ahow the variation of the focal point for rays of different wave-lengtha in the case of each object-glass. It will be seen that Fraunhofer has united the rays about C with those of wave-length 525 millionths millimetres, Grubb with those about wave-length 494 , and Schröder aboust wave. length 463. The object glasses of Grubb and Schröder are com.

FIg. $\delta$.
posed of modern glass, which is comparatively coloursess, whilst Fraunhofer'e glass is decidedly green in colour. The minimum focus in Franhofer'a teleacope is placed near D (rather at wave-lougth 585), because the absorption of the blae and violet rays of the spectrum by the fint lene readers the brighteat part of the apectrum less blue than in an objective composed of modern glass by Chance or Feil, which is nearly colourless. This circumatance enabled Fraunhofer to apply a very large over-correction for colour, - that is, to unite as perfectly as possible tbe red and central part of the apectrum, and to leave the outstanding violet rays to be in grest part absorbed by the colour of the glass. The colonr-correotions in the object-glasses of Grubb and Schröder are very different in character. In Grubb'a object-glass the minimum focus is for rays of wave-length about 545, that of Schröder's is sbout wave-length 533, which appears to prove that Grubb's eye is more eonalive to
red and Schröder's to blue light, - Alsc Grubb's object-glass unites the red rays very closoly with the brightest part of the spectrum, snd leaves the blue sud violet rays ontstanding. Schroder, on the other band, leaves the red rays outstanding in order to unite the rays between D and $F$ more closely. The conclusion is that to Grubb'a eyo the red rays would be obtrusively prominent in Schröder'a telescope, and that he would pronounce the object-glass under-corrected; whilst Schröder'a eye would find the ontstanding violet rays too promineut in Grubbis telescope, and pronouoce it over-corrected. The absolute amount of light in the seccndary spectrum in viewing the same object depends, cateris paribus, upon the square of the aperture; therefore telescopes of large aperture have to bo made of gleater proportional focal length than those of small aperture, in order to diminish the secondary spectrum. Figs, a, $\beta, \gamma, \delta$ in the diagram give the form of the epcetrum of a star in Schröder's telescope for various adjustments of the focus; figs. $a^{\prime}$ and $\gamma^{\prime}$ give the corresponding forms for Fraunhofer's telescope. Fig. a represents the eye-piece focused for the brightest part of the spectrum; fig. $\beta$ when the red rays and those near Ha aro simultaneously focusxd; fig. $\gamma$ when the extremo red rays are in focus, the corresponding focus being a little below H $\gamma$; fig. $\delta$ when focused on $\mathrm{H} \gamma$.

When a telescope is to be constructed for photographic purposes the aim should be to unite, as perfectly as possible, the rays near that portion of the apectrum which act most powerfully on the photcgraphic plate to bo employed. This latter point has been dotermined for the various photographic processes by Captain Abney. ${ }^{3}$ The results are shows graphically in fig. 6 for the processes practi-
 cally employed at present in astronomical photography.

Flg. 6.
To unite the rays near $G$ or $H$ the angle of the flint prism mnst be diminished ; that is, the focal length of the flint lens must be lengtboed as compared with that of an object-glass of similar constraction saited for oye observations; and the rays of greatest photographie action can be united more perfectly than the visible rays.

If an object-glass is composed of three lenses of different kinds of glass it is thecretically possible to nnite three instead of two points of the apectrum, besides improving the correcticn for spherical aberration. The most important practical applications of such a system have been-(1) the tiple object-glass of John Dellond; (2) the application of a convex crewn glass in front of an ordinary object-glass io order to alter its chrematic correction from that best suited for eye observations to that best suited for photographic observation. John Dollond'a abject-glass is generally described as a concave flint lens between two crown lenses. If tho crown lenses are of similar glass, there is no gain as to the correction of the secondary enectrum ; it becomcs only possible to correct the epherical aberration more perfectly. "Very few telescopes with tripla object-glasses hsvo been mado since the days of John Dollond. But the great and detrimental obtrusiveness of the secondary spectrum in the large object-glasses of the present day can be diminished in no other way, unless very extreme focal lengths are adopted, or some Dew kinds of glass that can be prodnced in large disks are discovered, in which the irrationality of their spectra is less, and in which' also there is the necessary difference in the

1 Proc. BRoy. Soc., vol. 퍼니. Pp. 164-188.
relation batween refractive index and dispersive powel. The cost of a triple object-glass would of course be at least 50 per cent. greater than that of a doable object-glass; but, on the other hand, the extreme focal length necessury for large object-glssses might be considerably reduced. Thus the cost saved by a less heary mounting and a smaller observatory and domo might conuterbalance to aome extent, if not entirely, the additional cost of the triple objectglass. Dr Schröder has constructed for the present writer an exquisite triple.object-glass (three different kinds of glass) of 3 -inclies aperture and only 18 -inches focal length. Its performance with its highest eye-piece of $\frac{1}{\text { a }}$-inch focus (power 72 ) is most admirable. It would probably be impossible to construct iarge telescopes approaching such ehort focal length, but there is no donbt that a large triple object-glass of 10 or 12 apertures focrs would have an enormous advantage in colour correction, and proiably in aplerical aberraticn, over a double object-glass of the same aperture and much greater focal length. One peculiarity of sucis a triple object-glass is thet three points in the spectrum can bave the same focus, and therefore the point of minimum focus may for the best chromatic adjustment not quite correspond with the focal point for the brightest part of the spectrum ; but, obviously, the rays of the whole visible spectrum may thus be brought to intersect the axis much more uearly at the same point There will probalily be a far wider adoption of the triple object-glass in the future, especially as the greater intrinsic brilliancy of the image in shortfocus telescopes is a matter of high importance in tho spectroscopic and photographic processes of modern astronomy. On the subject of triple object-glasses the reader is referred to an admirable paper by Professor C. S. Hastings (Amer. Journal of Science and Arts for Decem ${ }^{2}$ er 1879, p. 429), which exhiblts the results to bo got, from combiuations of difforent existing kinds of glass.

The folloviog table exhibits the excess of the focus for any ray over the true focus, the unit being roveod of the focal length, in -I. the actual results of Dr Vogel's observations on three existing object-glasses already quoted, but each reduced to comparison with its tius or minimum focus; IL. the theoretically best possible results from a doublo object-glass consisting of Feil's crown 1218 and Feil'o flint 1237, as computed by Hastings; III. the theoretical results of fcur different triple object-glasses, capable of practical construction, of which details are given by Hastings

Prof. Hastings's first condition in these compuitations is that the radius of curvature of none of the surfaces shall exceed one. $f$ fteenth of the focal length. He also neglects the thickness and distance apart of the lenses, since these affect chiefly the focal length, but do not very materially affect the difference of the foci for different rays. The expression for the focal lagth $F$ is then

$$
\phi=\left(\mu^{\prime}-1\right)\left(\frac{1}{r_{1}}+\frac{1}{r_{2}}\right)+\left(\mu^{\prime \prime}-1\right)\left(\frac{1}{r_{3}}+\frac{1}{r_{4}}\right)+\left(\mu^{\prime \prime \prime}-1\right)\left(\frac{1}{r_{5}}+\frac{1}{r_{6}}\right),
$$

Where $\phi=\frac{1}{\mathbf{F}^{\prime}}, \mu^{\prime}, \mu^{\prime \prime}, \mu^{\prime \prime \prime}$ are the indexes of refraction for the three kinds of glass, and $r_{3} r_{23} \ldots r_{6}$ the radii of curvalure for the six enccessive surfaces. Writing this in the form

$$
\phi=\left(\mu^{\prime}-1\right) A+\left(\mu^{\prime \prime}-1\right) B+\left(\mu^{\prime \prime}-1\right) C
$$

We may call $\mathrm{A}, \mathrm{B}$, and C the curvature sums of the first, second, and third lenses respectively. The problem then is to find, for existing specimens of glass, valnes of $A, B$, and $C$ no ono of which shall exceed 30 when $\phi=1$, and which shall make $\phi$ independent of the wave-length of the light transmitted. The resulting values of $\Delta$, B , and C for the first combination (marked "Hastings 1 ") are

$$
\stackrel{A}{2} 47026 \quad 7.20827 \quad-8.35472
$$

the curvatures are therefore very moderate and perfectly practicable. The constants for the glass of the first and sccond lenses havo.been. determined by the author with great accuracy (see Amer. Jour., vol. xv. p. 273). The third glass is Fraonhofer's flint 13 [Hastings 4 misprinted y in his tablo, in Amer. Jour., vol. xviii p. 131), for which the canstants are given in Schumacher's Astron Abhandlung fur 182s. If this glass can bo rejroduced in large disks, as no doubt it could be, wo have the meaus of making an object-glass very superior to any in existence and equally available for eje and photographic observation. Such an object-glass could be mode of inach shorter proportional focus thsn is usual or possibls in donblo object-glasses, not only because of the absence of secondary spectrum but also from tha command afforded over the epherical aberration

Oy aix profacce, After satisfying the coaditione of focal length, the ársi power of the spherical aberration, and two conditious of achromatism, wa have still two available arbitrary couditions, which may be that $r_{2}=r_{8}$ aud $r_{4}=r_{5}$

If thess lead to coarabient forms, as seems likely in the case in point, the whole may constitute a cemented lens; thus tha loss of light at the interior surfaces may be eliminsted, and the final perfecting of the epharical aberration be left to the figuring of the surfaces.

In some recent larga double object-glasses, especially those of Alvan Clark, it has beeu usual to leave a apace betwaen the crown and the 日int lens sufficient to afford access, through apartures in the cell, for cleaning the inner crowa and fint surfaces, withoat risk of disturbing the lenses and their centring. ${ }^{1}$ If in fig. 3 we imagias the lenses to be considerably separated and through both lenars trace a ray entering the crown lens parallel to and at some distance from the axis, we shall find that the effect of the separation is to diminish the power of the flint lens, and therefore to change tha character of the chromatic aberration. Thus an objectglass over-corrected for colour can ba improved in this respect by increasing the distance between the lenses. It bas been angerested that a telescope cau be made suitable for both eys cbservation and photograpbic jurposes if means are provided for ilu-easing the distance between the lenses without risk of dersnging the ceatring When the telescops is to be employed for photography. Lut the great change that would be pecessary in such a case cannot bs brought about consistently with preservation of the perfection of the corrections for spherical aberration. ${ }^{3}$

Any account of the achromatic olject-glass woold be incomplete without reference to the labours of the Rev. W. Vernon Harcourt and Prof. Stokes. Experiments in the production of optical glass were instituted by the former in 1834 ; and specimeus, axhihited at the meating of the British Association at Cambridge io 1802, were plsced in the hands of Prof. Stokes, who determined the optical constants of the numerous specimens of glass which Harcourt produced, and indicated from thess results the direction in which fresh experiments should he undertaken. It was discovered that titanic acid exteuds the bloe end of the spectrum more than carreepoads to the dispersive power of the glass, whilat boracic acid has the opposite effect (licport Bril. Assoc., 1871, p. 38). At a meeting of the British Association at Belfast in 1874 a telescope was exhibited whose ohject-glass was constructed from Harcourt' glass by Sir Howard Grubb of Dublin The following is Prof. Stokes"a completa and concise sccount of it.
"The original lotentlon was to construct tha objective of a phosphatle glass contalning \& auitable percentage of titanic acld, achromstized by a glass of terborate of lead. (The percentage of titanic scid was so chosen that there shonld be no frationality of dispersion between the titanle glass and the terborate.) As the curvature of the coavez lens would be rather severe if tas whole coovex power wera thrown lato a slagle leus, it was intended to nse two lenses of thls glass, one In frunt and one behad, with the concave torborate of lead placed betweer them. It wes fonnd theit, provided not mara than abont one-third of the convex power wera thrown behind, tha adiaceot arfaces might be msde to fit, consisteotly with the condition of destroying the apherical as well as the chromstic aborratloa. Thie would reader it possible to cement the glasseg, and thereby protect the terborate, which was rather lishle to tarnish. At the tima of Mr Harcourt'e death two disks of the titanic glass had been prepared which it was hoped would bo good eaough for employmeot, as aleo two disks of terbarate. These were placed In Mr Grubb's badds. On polishlog, one of the titanle disks wes foued to be too badly etriated to be employed ; the other was pretty falr. As it would have required rather severe curvatare of the first surface sud su uusual convexity of the last to throw the whole convex power ioto the first lona, using a inere aball of glass to protect the terborate, Profeasor Stokes thought It more prudent to glass to protect the terborate, frofeasor stokes thought it more prudent to glass lens, though at the eacrifice of an absolute destractlon of becondary disglass lens, though at the sscritice of an absobute destraction of eccondary disjnst baraly perceptible. Of the terborato diske, the less atriated bsppened to be allghtly muddy, from some accident in the preparation; bot, as this elgulfed leas than the atrie, Mr Gruhb deemed It better to employ this dak. The tele-
 scope exhibited to the meetlog was of about 2 - -nchea apert urs and 23 -Inches focal leogth, snd was provided with an object-glass of the ordinary klud, by Which the other could be replaced, for contrasting the performance. When the teleacope was tarned on to \& chimney seea against the sky or other anits ble oblect, and half the oblect.glass covered by a screen Fith ita edga parallel to the edgas of the object, In the case of the ordinsry nbjective vivid green and porple were secn abuut tha two edges, wheresa with the Earconrt objective there was barely any perceptible colour, It was not of courae to be expected that the perforinence of the telescope aboold be good, on account of the diff culty of preparing glass free from strix, but it was quite sumclent to allow the possibility of destroyling the eecondary colour."
An experiment to determins whether the substitution of titania acid for a portion of the silica in ordinary crown glass would have as effect similar to that which had been ubserved in the phosphatic series of glasses (viz, whilst somewhat raising the dispersive power, to prodace a separation of the colours at the blue as compared with the red and of the spectrum, to en extent ordinarily belonging only to glass of much highet dispersive power) was carricd oat by Mr Hopkinson at the glass works of Messrs Chaace of Birmingbam; but it proved unfortuastely in this combination that, a hilst the

2 Thls arrangement siso helps to equalize the temperatures of the lepses with each other and with the outer elr
2 Qulte recently Pror. Stakea has engrested thist to adapt a telescope to elther photagraplic or teleacoplc purposes at plessure the crown lena should In reverslble as well as changeeble se to distance with reapect to the filnt In thla way doahtless the chromatic and apherical ciberration could be pro-
dispersive power weq increasea, as in the phosphatic glasses, the bloo end of the epectruxa, as compared with the red ead, was not spread out more than in ordinary glass of like dispersive power (leport Brit. Assoc., 1875 , p. 26). It is to be hoped, howerer, that makers of optical glass will not relas their efforts till astronomers ehall be able to obtain refracting telescopes in which the eecondary spectrum is mearly if not quite eliminated. Abbs's dew optical glass ${ }^{8}$ laarls ons to beliave tbat this hope will soon be realized.

The addition of a conves crown lens in frout of the ordinary object-glass, to diminish the colour-correction and change the minimum focus from that for rays betweea $D$ and $E$ to that for rays near G, was first made by Rutherford of New York. In this way he alterad bis telescope from one suited for eja ohservations to 000 in the best chromntic adjustmeot for photographic work The chromatic effect is the same as increasing the convexity of the crown lens, and by proper proportioning of the two radii of corvaturs it hecomes possible elso to couserve, and eren to further perfect, the destruction of epherical aberration The great objectglass of 36 -inches alverture, now (1887) uader construction for tho Lick ohservatory by Messrs Clarko of Boston (Mass.) is to be pres vided with an additional crown lens for this purposo."
The problcm of making a perfectly achromatio object-plass has Blairy been solved by Dr Blair (Edin. Trans, vol iií p. $5 S$ ) by employ-achroing fluid medis, and he actually constructed an object-gluss con-matic sisting of a plaoo-conver lens and a meniscus lens, both of crora faid ob glass with thoir convoxities turued towards each other, the space jectbatwsen the lenses being filled with hjdrochloric acid. Unfortu. glasses. nately aach combinations are practically useless, not only on accornt of uneroidable leekage, bot also because currente ara eet up in fuid leases by chenges of temperatare, which correspood in effect with want of homogeneity in the flint lews in an ordinary object-glass.

## Eyo-Picces.

The îrst aubstitute for the eingle leas of the Galilean and Kepler Eye telescoper was the componad eye-piece iavented hy Rheita. Behind pieces. the convex ese-lens of the Kepler telescope ha applied a second short telescope, zotesisting of two convex lenses, their distance being the sam of ther focal lengths. The principal effect was to erect the inverted image, and thus to constitute the simplest form of the day eje-piece, or common terrestrial telescope. The neat improve. ment was the Hnygenian eye-piece, which consists of two conver lenser (ses fig. 7),-the "field-lens," thet next the object-glass, having its focal leggth to that of the "eje-lers"es 3 to 1 ; the distance between them is twice the focal length of the latter, the combination being so placed as to form the visibla imogo heli-way between the two. This eye-piece is achromatic in :he sense in Which an eye-piece is said to bo so: a colcurless imege seen through it does not appear bordered with coloured sringes, as is the case with a single lsns or Rheita'a eye-piece. This is not becanse, as in the achromatic object-glass, all the ceutral coloured rays aro collceted in one focus, which in the case of an eye-piece is a matter of comparatively small consequence, bot becanse it possesses the same magnifying porsar for rays of all colours on an object of sensible angular diameter, so as not to form overlapping coloured pictures of it on tho retina. This condition it is which furnishes the "equation of achromaticity" of an eje-piace. An expression for the maglifying power of a teleacope provided with a ccrtain byo-piece is formed in general terms which involvo the focal leogth of its lences, their distonces from each othar, and their refractivo indexes; and, this being mede to vary by the variation of the last-mentioned elementa only, the variation is equated to zcro. The algcbraic working, which eveo for a two-glass eya-piece is a little complex, is given in E. Lloyd's Treatise on Light and Vision (London, 1831), and in an elaborate paper by Littrow in the fourth volume of the Trans. Roy. Astron. Soc. (p. 590). From the former we extract the following proposition: An eye-gless of two lenses of the same medinm is achrometic when the interval hetween the lenses is an arithmetical mesn between their focal length, - a condition which the Muygenion construction evidently satisfies, The rationale of this is obvions, independently of algebraio anslysis, by inspection of the course of the raye io ing. 7, where $\mathrm{AC}, \mathrm{BD}$ are the lensce, PQ the image Which would bs formsd by the object-glass alone, $p q$ thst really formed by tha action of the feld-glass. Tho object-glass boing aupposed achromatic, a ray of white light, as OC, going to form the image of a point $Q$, will be refrac ad by the feld-gless at $O$ tomards the corresponding point $q$ of the new imace, but not as a

single white ray; it will be seperated jnto conoured rays, following different courses. The red rey Cr being less refrected will fall on * point $r$ of the eje-glass more remote from its centre $B$ than

Fio. 7.-Huggentan eye-piece.
the violet rey $C v$, and (the prismaticity of the lens increasing from the centre outwerds) will in proportion by the second transmission be more bent aside tlan the violet, and thns a compensstion is effected, and the two rays finslly emerge parallel, their exact parallelism boing secured by the proportion of their focal lengths. The Huygenian eje-piece possesses also other important adrantages. The total deflexion of the light, to prodace the magnifying power, is equally divided between the two glasses, - the most favourable condition for diminishing that distortion which is always perceived in looking obliquely through s lens; and the field of view is greatly enlarged in proportion to the size of the eye-lens, being such as would require, to prodnce the same magnifying porver, 8 single lens of the much greater semi-diameter $b d$, found by drawing $Q b$ parallel to $q B$ and erecting $b d$. The inconvenience of this oye-piece (whence it is improperly termed a negative eye-piece) is that the image, being formed between its lenses, undergoes a certsin amount of distortion by the field-glass, owing to which equal linear portions of it do not correspond precisely to equal angular measures of the distant object. Equal parts of a micrometer applied at the place of the image, so as to be seen at the same time through the eye-lens, will not correspond to precisely equal angular interCommor vals. The common astronomical or positive eye-piece, described or posi- by Ramsden (Phil. Trans., 1783), consists of two plano-convex tive eye lenses of eqnal lengths, having their convexities turned towards piece. each other and eeparated by two-thirds of the focal length of either, as in fig. 8. This combination is placed behind the image PQ

Yormed by the object-glass, st a distance $A P$ equal to one-fourth of the focal length of A. The first or field-glass, therefore, forms an enlarged image $\dot{p} q$, at a distance one-third of that focal length which places it in the focus of the eye-glass. This eye-piece is not properly achromatic, but its spherical sberration is much less than in any of the other constructions, and it has the advantage of giving a flat field of view, requiring no change of focus to ace the
turned towards each other. (3) For an erecting eje-piece of four lenses the first and fourth (reckoned from the object-glass towards the eye) shonld be crossed lenses of focal length 3 , the radii of their eurfaces 1:6, with their convex surfaces towards each.other. The second lens should be a meniscus of focal length 4, the radii of its surfaces $25: 11$, and its convexity towards the eye. The third lens ehould-be plano-convex, of focal length 4, its plane side towards the eje. The distance of the centre of the second lens from that of the first $=4$; that of the third from the second $=6$; snd that of the fourth from the third $=5 \cdot 13$. If a bright object appears jellicw or a dark one blae at the edge farthest from the centre of the felf, the third and fourth lenses most be together pushed inwards towirds the second lens.

In many telescopes constructed specially for star observation only the object-glass is over-corrected for colour and under-corected for spherical sberration ; both these errors may sometimes be nearly eliminated by a properly constructed Hoygenian eye-piece (see Miososcope, vol. xvi. pp. 266-267). But, rinen a telescope is to be used over a considerable range of figld fur micrometric measurements, it is obvions that the spherical sberretion should bo corrected by the object-glass slone. It is possible, howevrr, to improve the appearance of objects somewhet in a telescope in which the chromatic sberration is over-corrscted by employing an evo-pieco somembat nnder-corrected for colour, and vice versa; but the ouly sstisfactory plan is to have both object-glass and eye-piese as free as possible from both chromatic and spherical sberration.' In order to secure this, or a very large field of view, many forms of eye-piece Lave been devised. Achrumstic combinations have been enbetituted in some cases for the field-lens, in others for the eye-lens, in others for both simple lenses of the Ramsden eye-piece. The best of these combinations which the present writer has teated and Which practically fulfil all requireraents of the astronomer are due to Dr Hugo Schröder, to whom k.e is indebted for izformation as H. Schro to their construction. Fig. 10 represents Schröder's high power der's to ther construction. His

Fio. 10.-Schrörer's high power eye-pleca.
eye-piece, which is admirably suited for micrometer work, not only because there are only two reflecting surfaces in the triple lens of which it is composed, but also because there is a comparatively large distance between the lens and the micrometer web when the latter is in focus. This coudition is essentisl when it is desired to get the best bright illamination of the wires in a dark field (see Micrometer, vol. svi. p. 248). The triple lens is composed of s dense fluid plano-convez lens between two lenses of soft crown glass. The radii of curvature aro-

## Fio. 9.-Erecting or terrestrisl eye-puece.

centre and borders of the field with equal distinctness. The erecting or terrestrial eye-piece was invented by Dollond. The principle of its construction will be understood from fig. 9. It is convenient for telescopes of ordinary use, becanse it presents a non-inverted image to the eje, although st some sacrifice of light and definition.

For an acconnt of the theory of the chromatic and spherical aberration of eye-pieces by Sir George B. Airy, see Trans. Phil. Soc. Camb., vol. ii p. 243 ind vol iii p. 61. The sathor's conclosions are the following. (1) To secure the greatest distinctness with an eye-piece of the Huygenian type, the field-lens should be s meniscus of focal length 3 , the radil of its surfaces $11: 4$, and its convexity towards the object-glass; the eye-lens should be a double convex of focal length 1 , the radii of its surfaces $1: 6$, and its more conver side towards the field-lens. The distance of the lenses shoold be 2. There should be a perforated diaphragm at distance 1 from the eye-lens. If a bright object appears yellow or a dark one blue ot the edge farthest from the centre of the field, the lenses must be brought a little nearer together. (2) For an eyepiece of Ramsden's type the two lenses shonld be plano-convex, of focal longth 8, placed st distance 2, their convex surfaces being

Dr O. Schröder's aplanatic efe-piece. The glass emplofed is der's Danget's crown ( Cb$)_{1}$ ) snd liint $\left(\mathrm{Fb}_{1}\right)$. The refiactive power of crown splanatts is 1.5126 for $D_{\text {, }}$ that of flint 1.6405 ; the dispersive power of both eyekinds of glass is $9: 588$.

The distance between the plane eurfaces is $22 \cdot 57 \mathrm{~mm}$. This form of eyo-piece has been employed by Schönfeld in his southern "Durchmusterung," and Dr Schröder has made one for the present writer which gives a perfect field $44^{\circ}$ in diameter on the telescope of 18 inches focal length and 34 inches aperture already referred to.

## Refiecting Telescope.

The following are the various forms of reflecting telescopes. The Gregorian telescope is represented in fig. 12. AA and BB are

concave mirrors having a common axis and their concaritiea facing each otber. The focue of $A$ for parallel rays is at $F$, that of $B$ for parallel raye at $f$-between B and F . Parallel rays falling on AA converge ot $F$, where an image is formed; the raye are then reflected from $B$ and converge at $P$, where a second and more enlarged tmage is formed. Gregory himself showed that, if the large mirror were a segment of a paraboloid of revolution whose focus is $F$, and the small mirror an ellipsoid of revolution whose foci are $F$ end $P$ respectiruly, the resulting inage will be plane and undistorted. The irage formed at $P$ is viewed through the eye-piece at $E$, which may be of the Huygenian or Rameden type. The focal adjustment is accomplished by the screw S , which acts on a slide carrying an arm to which the mirror B is attached. The practical difficulty of cbastructing Gregorian telescopes of good defining quality is very considerable, because if spherical mirrors are employed their aberrations tend to increase each other, and it is extremely difficult to give a true elliptio figure to the necessarily deep concarity of the emall speculam. Short appears to have systematically conquered this difficulty, and his Gregorian telescopes attained great celebrity. The use of the Gregorian form is, liowever, practically abandoned in the present day. The magnifying power of the relescope is $=\frac{\mathrm{F}+f}{e+x}$, where F and $f$ are respectively the focsl lengthe of the large and the small mirror, o the focal length of the eye-piece, and $x$ the distancel between the principal fooi of the two mirrore ( $=$ F $f$ in the diagram) when the instrument is in edjustment for viewing distant objects. The images are erect.
The Cassegrain telescope differs from the Gregorian only in the substitution of a conver hyperbolic mirror for a concave elliptical mirror as the small speculum. This form has two distinct advantages: (1) if spherical mirrors are employed their aberrations have a teidency to correct each othor; (2) the instrument is shorter than the Gregorian, ceteris paribus, by twice the focal length of the small mirror. Fewer telescopee have been made of this than perhaps of any other form of reflector; but in comparatively recent yeara the Cassegrain has acquired importance from the fact of its adoption for the great Melbourne teleecope. The magnifying power is compated by the same formula as in the case of the Gregorian teleecope.

The Newtonian telescope is represented in fig. 13. AA is a concave mirror whobe ezis is aca. Parallel rays falling on AA converge on the plane mirror $B B$, and are thence reflected at right angles to the axis, forming an
image in the focus of the eye-piece E.
The burface
 The magnifying power is $=F / \rho_{\text {. }}$. This form is omployed in the construction of moot modern reflecting telescopes. A glass prism of total reflexion is sometimes substituted for the plane mirror.

The Herschelian or front view reflector is represented in fig. 14. $\Lambda \Delta$ is a concave parabolic mirror, whose aris ac is inclined to the arie of the tube ab 50 that the image of an object in the focus of
the mirror may be viewed by an eye-piece at $E$, the angle bac being equal to the angle caE. This form was edopted by the elder

Herschel to avold the loss of light from reflexion in the small mirror of the Newtonian tclescope. It has sereral disadvantages. (1) The upper part of the obserrer's head must necessarily obstruct scme of the rays which would otherwise fall on the large mirror; but when a telescope of very large aperture is employed the loss of light thus occasioned is comparatively insignificant. Moreover, disturbance of the air in front of the telescope is created by heat from the observer's head and body, and this is fatal to the best definition. To avoid the latter drawback Sir John Herschel (Ency. Brit., 8th ed, art. "Telescope," vol. xxi. p. 128) suggested the employment of a emall right-angled prism of total reflexion placed close to the eyelens of the eye-piece, to permit the observer to view the inage by looking in a direction at right angles to the eye-piece, and therefore at right angles to tho tube. (2) In consequence of the tilting of the mirror aberration is created, and this increases rapidly with increasec tilting. The construction is thus limited to telescopes in which the proportion of aperture to focal length is not too great. In Herschel's 40 -feet tclescope the proportion was 1 to 10 , and the construction would hardly be applicable to modern telescopes, in which the proportion often rises to 1 to 5 or 6 . Yet, when exceed: ingly faint cbjects have to be observed, this form of telescope has great advantages. Herschel found that some objects which he discovered with such an instrument could not cven be seen when the same telescope was used in the Newtonian form. The front view telescope, however, has hardly beed at all employed except by the Hersclicls. But at the same time none but the Herschels bave swept the whole sky for the discovery of faint nebulx ; and probably no other astronomers have worked for 60 many hours on end for so many nights as they did, and they emphasize. the easy position of the observer in using this form of instrument.

## Constraction of Object-Oln יess.

The first point is the selection of glass disks of suitable quality. Testro The-requisites are (1) general transparency and freedom from object mechanical defects, such es specks, air-bubbles, \&c.; (2) homogeneity; glassem (3) freedom from internal strain. The disk being roughly polished on the sides, faulte of the first class are easily detected by inspection. In order to secure the maximure of light grasp for aperture it is desirable that the glass should be as coloarless as possible; if the roughly polished disk is lais upon white paper the amount of discoloration can be readily estimated by comparing the colour of the sheet as seen directly with that eeen through the glass. Fraunhofer's glase was far from colourless, Dollond's more coloured still; and we have shown that, for purposes when extreme light grasp is not an object, the less transparency of such glass to the blue raye of the spectrum affords adrantages for a better correction of the chromatic aberration of rays in the brighter part of the apectrum. The emount of light excluded by specks, air-bubbles, or even ecratches is quite insignificant; but these blemishes create diffraction phenomena and ecattered light in the field, which are very injurious to the performance of the instrument, especially when faint objects are searched for in the neighbourhood of brighter ones. It is essential for a telescope lens that the glass should be perfectly homogeneous ; that is, the refractive index must be identical for every part of the disk. This can be teated with extreme delicacy by grinding the disk into the form of a lens and testing it by Töppler'e method, ${ }^{1}$ deccribed under Optice (vol. xvii. p. 805). If the disk is intended for a concave lens and is already so thin that It becomes undesirable to make it thinner at the edges by convert ing it, in the first place, into a conver lens, it may be tested by placing one of its surfaces in contact with and at right anglee to the axis of a crown lens of known perfection, and testing tins com. bination by Toppler's method. If a glass disk is not properly annealed-that is, if it has been too quickly cooled, so that the outer shell has hardened before the inner portion-the fioally solidified mass must be in a state of tension, like that of "Ropert's drops." Unless cooled very gradually an optical diak would fly to pieces, but a very mach smaller defect in the annealing process would be fatal for refined optical parposes. Changee of temperature would produce changee of curvature, and the lens would also change it Form when successive portions of the strained outer ghell were removed in the process of grinding and potishing. Fortunatoly
defects in aunealing are very easily detected by means of the polari. scope. The polished disk is placed in light reflected from a polarizing surface, such as a sheet of glass blackened at the back, and examined with a Nicol's prism as an analyser. If the bright riugs and black cross (see LiGHT, vol. xiv. p. 613) are visible the disk is unfit for use ; but, since few diska are so perfectly annealed as not to show a trace of the black cross, euch as show it in no marked degree may be safely employcd. Perfect annealing has now become the most difficult portion of the art of making optical glass, and arge disks (nore particularly of crown glass) are rejected by the ptician more frequently for defects in annealing than for any other ause.

The disks having been selected, their refractive and dispersive powers determined, and the radii of curvature computed, it remains to convert the disks into lenses with surfaces of the required curvature, and to complete the object-glass. The work consists of five distinct operations-(I) rough grinding by a revolving tool supplied with sand and water; (2) fine grinding with emery; (3) polishing with oxide of iron, rouge, or putty powder, the grinder being faced with fine cloth, eatio, paper, or-best of all-pitch; (4) centring ; (5) figuring and testing. These processes are essentially of a technical character, and can only be familiar to those who practise the grt. The details would bo out of place here, but are well described in a lecture delivered by Sir Howard Grubb at the Royal Institetion, 6th April 1886, and printed iu Nature, 27th May 1886.

## Construction of Specula.

The composition of metallic specula in the present day differs of
lity alloys have been suggested, solee incliding silver, nickel, zinc, or arsenic; but that which has practically been found best is an alloy of four equivalents of copper to one of tin, or the following proportions by weight:-copper 252, tin 117.8 . Such speculum metal is exceedingly hard and brittle, takes a fine white polish, and when protected from damp has little liability to tarnish. The process of casting and annealing, in the case of the epecula of the great Melbourno telescope, was admirably descrihed by Dr Robinson in Phil. Trans, 1869 , vol. clix. p. 135. Shaping, polishing, and figuring of specula are accomplished by methods and tools preciscly similar to those employed in the construction of lenses. The reflecting surface is first ground to a spherical form, the parabolic figure being given in the final procesa by regulating the size of the pitch squares and the etroke of tho polishing machine. The process of testing is identical with that of an object-glass.
Soon after Liebig's discovery of a process for depositing a film of pure metallic silver upon glass from a salt of silver in solution, Stcinheil (Gaz. Univ. d'Augsburg, 24th March 1856), and later, independently, Foucault (Comptes Rendus, vol. xliv., February 1857), proposed to employ glass for the specula of telescopes, the reflect. ing surface of the glass speculum to be covered with silver by Liebig's process. These cilver-on-glass specula are now the rivals of the achromatic telescope, and it is not probable that many teleecopes with metal specula will be made in the future. The best speculum metal and the greatest care are no guarantee of freedom from tarnish, and, if such a wirror is much exposed, as it must be in the hands of an active observer, frequent repolishing will be necessary. This involves refiguring, which is the most delicate and costly process of all. Every time, thercfore, that a epeculum is repolished, the future quality of the instrument is at stake; its focal length will probably be altered, and thus the valne of the constants of the micrometer also have to be redetermined. Partly for these reasons the reflecting telescope with metallic mirror has never been a favourito with the professional astronomer, and has found little employment out of England. In England, in the hands of the Herschels, Rosse, Lassell, and De la Rue it has done splendid service, but in all these cases the astronomer and the instrument-maker were one. The silver-on-glass mirror has the enormous edvantage that it can be resilvered with little tronble, at amall expense, and without danger of changing the figure. Its chief work has been done in the hands of Draper and Common, who were the engineors, if not the actual constructors, of their own instruments. Glass is lighter, stiffer, less costly, and easier to work then speculun metal. The silvered mirrons have also some advantage in light grasp over those of epecnlure metal, though, a perture for aperture, the former are inferior to the modern object-glass. Comparisons of light grasp derived from small. fresi, carefully silvered surfaces are sometimes given which lead to illusory results, and from such experiments Foucaul claimed superiority for the silvered epeculum over the object-glass. But the prescat writer has found from experience and careful comparison that a bilvered mirror of 12 -inches aperture mounted as a Newtonian telescope (with a silvered plane for the small mirror), when the surfaces are in fair average condition, is equal in light grasp to a furst-rate refractor of 10 -inches apesture, or area for arca as 2:3. This ratio will become more eyual for larger sizes on account of the additional Hickness ut larger object-glasses and the consequeat additional ab-
morption of light in transuission.

## Mounting of T'clescopes.

The proper mounting of a telescope is hardly of less importance Mount than ita optical perfection. Freedom from tremor, ease and deli-ing of cacy of movement, facility of directing the ingtrument to any teledesired point in the heavens, are the primary qualifications. Our scopes limits forbid an historical account of the earlier endeavonrs to fulfil these ends by means of motions in altitude and azimuth, nor can we do more than refcr to mountiags such as those employed by the Ilerschels, or those designed by Lord Rosse to overcome the engineering difficulties of mounting his huge telescope of 6 feet aperture. Both are abundantly illustrated in most popular works on astronomy, and it seems sufficicnt to refer the reader to the original degcriptions. ${ }^{1}$
We pass, therefore, directly to the equatorial telescope, the instrument par cxcellence of the modern extra-meridian astronomer, and relegate to the article Transir Circle ( $q . v$. ) a description of those mountings io which the telescope is simply a refined eubstitute for the sights or pinules of the old astronomers. The equatorial in its simplest form consista of an axis parallel to the earth's axis, called the "polar axis"; a second axis, at right angles to this, called the "declination axis"; and a telescope fixed at right angles to the latter. In fig. 15 AA is the nolar axis; the telescopo is attached to the end of the declination axis; the latter rotatce in bearings attached v to the polar axiz, and concealed by the telescope itself. The telescope is counter. poised by a weight attached to the oppasite end of the The lower pivot of the polar axis rests on a cup bearing at
 C , the upper pivot upon a strong metal casting MIM, attached to a 日toae pier S. A vertical plane passing through AA is therefore in the meridian, and, when the declination axis is horizontal, the telescope mores in the plane of the meridian by rotation on the declination axis only. Thus, if a graduated circle BB is attached to the declination axis, toget her with the necessary microscopes or verniers V,V for reading it (seo Transit Circle), so arranged that when the telescope is turned on the declination axis till it is parallel to $A A$ the vemier reads $0^{\circ}$ or $90^{\circ}$, and when at right aagles to AA $90^{\circ}$ or $0^{\circ}$, then we cen employ the readings of this circle to measure the polar distance or declination of sny star seen in the telcecope, and these readings will also be true (apart from the effects of atmospheric refraction) if we rotate the instrument through any angle on the axis AA. Thus one important attribute of an equatorially mounted telescope is that, if it is directed to any fixed star, it will follow the diurnal motion of that star from rising to setting by rotation of the polar axis only. If we further attach to the polar axis a graduated circle. DD, called the "hour circle", of which the microscone or vernier $R$ reads $0^{\mathrm{h}}$ when the declination axis is horizontal, WB can obvionsly read off the hour angle from the meridian of any star to which the telescope may be directed at the instant of observation. If the local sidereal time of the observation is kuown, the right ascension of the star becomes known by adding the observed hour angle to the sidereal time if the star is yest of the meridian, or subtracting it if east of the meridian. Sirce the equatorial is unsuitable for such observations when great tccuracy is required (see Transit Circle), the declination and hour circles of an equatorial are employed not for determination of the right ascensions and declinations of celestial objects, but for directing the telescope with ease aod certanty to any object situated in a known position, and which may or may not he visihle to the naaided eye, or to define approximately the position of an unknown object. Further, by cansing the hour circle, and with it the polar axia, to rotate by clockwork or some other mechanical contrivance at the same angular velocity as the earth on its axis. but in the opposite direction, the telescopo will antomatically follow a star from rising to setting.
Eyuatorial mountings may te divided into five types. (A) The pivots or bearings of the polar axis are placed at its extremities. The declination axis rests on bearings attached to opposite sides of the polar axis. The telescope is attached to one end of the declina* tion axis, and counterpoised by a weight at the other end, as in fig. 15. (B) The polar axis is supported as in type $A$; the telescope is placed between the bearings of the decliation axis and is mounted symmatrically with respent to the polar axis; zo counterpoise is therefore requisite. (C) The declination axis is mounted on the prolongation of tlee npper pivot of the polar axis; the telescope is placed at one end of the declination axis and counterpoised by a weight at the other and. (D) The declination axis

- Herschel, Phil. Trans, 1i95, vol. Lxxav. p. \$47; Rosse, Phil. Trans., 1840,
is mounted on a forked piece or other similar contrivance attached to a prolongation of the apper pirot of the polar axis; the telescope is mounted between the pivots of the declinstion nxis. (E) The eye-piece of the telescope is placed in the upper pivot of the polar axis; s portion or the whole of the axis of the teleacope tnbe coincides with the polar axis. Mountings of types A snd B -that is, with a long polar axis supported at both ends-are often salled the "English monating," sad types C and D , in which the leclination exis is placed on the extension of the upper pivot of the polsr axis, are called the "Germsn mountiug," from the first employment of type $C$ by Frannhofer. A description of some of the best examples of each type will illustrate their relative adventages or peculiarities.
Fig. 15 may be taken as a practical exsmple of the earlier equs. torials as made by Troughton in England and afterwards by Gambey for various Continental observatories. In the Phil. Trans. for 1824 (part 3, pp. 1-412) will be foand s description by Sir John Herschel snd Sir James South of the equatorial telescope which they employed in their measurements of double stars. The polar axis was similar in shape to that of fig. 15 sad was composed of sheets of tinned iron. In Smyth's celebrated Bedford tolescope the polsr axis was of mahogany. Probably the best example of this ty'pe of mounting applicd to a refractor is that made by the elder Cooke of York for Mr Fletcher of Tarmbank; the polar axis is of cast iron sad the monating very satisfactory and convenient, but unfortunately no detailed description hss been published. In recent years no noteworthy refractors have been mounted on this plan; but type A has been chosen by Grubb for the great Melbourne reflector, with msrked ingenuity of
adaptation to the yeculiar requirements of the case. Tig. 16 shows the whole instrument on a small scale, sad fig. 17 represents part of it on a larger scale, the upper part of the tube and polar axis being omitted. The figures show the telescope directed to the pole, the hour circle being set $6^{\mathrm{b}}$ from the meridian. The polar axis consists of a bollow
 cone $C$ (fig. 17) of csst iron Fio. 16.-Melbourne refiector. bolted to s hollow csst-1ron cube H , to the lower side of which thetsched s short steel axis carrying the driving sector EF sud the hour circle $R$, snd terminating in the lower pivot of the polar exis. This pivot $a$ is terminsted by a piece of chilled cast iron polished flat on its lower face, which face rerolves in contact with a piece of bell metal, fist on its apper snd partly spherical on its lower side, bearing in s correspondingly shaped snaulus, formed to receive it in the cast-iron block which is sttached to the pier. This srrangement enables the bell-metal coshion to take its own position when the direction of the polar sxis is slightly clanged in process of sdjustment. The pressure of the pirot on
its besrings, in the direction st right sngles to the polsr axis, is relieved by the sector $A$, which is forcod up by the acrew $d$ acting through laminm of steel springs. The end pressure of a npon its

Fio. 17.-Section of Melbourne reflector.
bearings is relieved by s weight. The friction of the upper pivot is relieved by a sector pressed up against it by the sction of two weighta In this wsy, although the moving part of the telcscope weighs 18, 170 Ib , it can be turned with a pressure of $12 \frac{1}{3} \%$, scting ats radius of 20 feet. The driving sector EF is 5 feet in radius; its circulsr rim is sccurately toothed to fit a squara threaded endless screw $E$, which is turned by the driving clock. A toothed wheel attached to H and acted on by a pinion connected with a hand-wheel sfforda an easy mans of setting the instrument in lioar sugle, or moviag the telescope quickly in right ascension. The telescope is clsmped by iron bands to the strong cast-iron cradle, which is cast with sad forms one extremity of the declias.

tion sxis. The counterpoise $U$ is attached to the other extremity. There is sa elegant arrangenient for diminishing the friction of the declinstion axis, which our limits do not permit us to deacribe, snd the means for clamping and giving slow motion in declinstion do not require specisl notice. The reader is referred for 8 fuller degcription to Phil. Trans., 1869, pp. 127-161. The telescope is of the Cassegrsin form, the mirror hsfing \& 4 -feet aperture snd $30 \frac{1}{2}$-feet focal length.

The best existing examples of type B are Airy's equatorial at Greenwich, the equatorial st Liverpool (slso designed by Airy), and the photogrsphic equatorisl recently erected at the Paris observatory. The polar axis of the Greenwich equstorial consists of six iron tubes arranged so as to form two triangular brsced beams coonected by very strong elliptical wheels of cast iron, which carry the upper and lower pivots of the polar axis. These tubes are ahown in section at the points T, fig. 18 , which represents s section through the declination axis in the plsae of the equator when the telescope is directed to a star at the equator (for the general srrangement of the mounting, see fig. 19). The driving circle is 6 feet in diameter, and turne freely on the lower pivot of the polar aris, under the action of the driving clock. The hour circle is graduated on the driving circle, and may be set to show sidereal time during

io. 18.-Greenwich equatorial. The whole of a night's work; thus the observer, in order to direct the instrument on s particnlar object, liss only to set an index connected rith the polar axis to the star's right ascension apon the hour circle, without the trouble of computing the hour angle at the instant of observation. This convenient arrangement was first introduced by Airy. The whole mounting is very massive, but very inconvenient to nse when a great many different objects have to be exsmined on the same aight; but on acconnt of its freedom from tremor and the excellence of its driving clock it should be very auitable for prolonged study of s single object or for long photographic exposures ${ }^{3}$ Quite recently Sir Howard Grubb has signed a contract to make a telescope of 28-inches sperture and s-feet focal length, ${ }^{2}$ which is to be substituted for the present tele18 seo by Merz \& Son of 12 -inches aperture and 18 -fect focus. Fig. 10 is engraved from a photograph of the model of the original polar aris. The model was prepared to illustrate the manner in which the new telescope is to be-mouated, sad we sre indebted for the picture 1 See the datailed acconnt in Greenwich Observations. 1868.

2 This ohject-gleas will have the ehortest proportional focal leneth of any yet constructed of sperture excceding in Inches. The following table gives the focal length in epertures of the largest existing refractors:-

Fienns telescope (Gruhb) 27 -ioches a perture, focal length 15.5 in pertures $\begin{array}{lllll}\text { Yienns } \\ \text { Tashington } & \text { " } & \text { (Clark) } & 20 & \text { " } \\ \text { Pulkowa } & \text { (Clark) } & 30 & \text { " } & \text { " } \\ & & 150 & 180 & \end{array}$
to the kindnees of Mr Christia, astronomer royal. The object-glass will be actually outside the dome when the telescope is pointed near the zenith or near the horizon. The dew-cap, not shown in the model, will be alwajs outside the dome. and it is not impossibla

that this arrangement may be favonrable to good definition, except in case of high wind. When the telescope is not in use the dewcap slides backwards on four rails parallel to the axis of the telescope, and the whole is housad in the pasition obown in fig. 19. The spectroscope is used at right angles to the telescope tube, a right-angled prism of total reflexion being interposed in the converging cone of rays near the focus. This prism can be turned $180^{\circ}$ and sn eye-piece inserted on the opposite side from the spectroscope for observations near the zenith or horizon, otherwise the eye end would be too near the floor or northern pier. ${ }^{1}$

A'figure of the new photographic telescope erected at the Paris observatory may be seen in Nature, 13th May 1886. The objectgless is by MM. Paul and Prosper Henry, the mounting by M. Gautier. Here Airy's braced tubes are replaced by bollow metal beams of triangular shape (as for the Liverpool equatorial). The honr circle has two toothed circles cut upon it, one acted apon by a acrew attached to tho pier and driven by the clock, the other by a eecond screw attached to the polar sxis, which can be turned very slowly by a handle in the observer's band. Thus a very slow movement can be given to the telescope in right ascension, independertly of the clock. Slow motion in declination can be communicated by a screw acting on a long arm, which can be clamped at pleasure to the polar axis by a convenient bandle. An oblong metallic box, fitted with pivots, whose bearings are sttached to the triangular beams, forms the tube for two parallel telescopes; these are separated throughout their length by a metallic diaphragm. The chromatic aberration of the object-glass of oue of these telescopes is corrected for photographic rays, and the image formed bvit is received on a highly eensitive photographic plate. The oraer telescope is corrected for visual raye and its imege is formed on the plane of the spider lines of a filar micrometer. The peculiar form of the tube is eminently suited for rigid preservation of the relative parallelism of the axes of the two telescopes, so that, if a certala selected star is retained in bisection by two intersecting wires in the micrometer, by means of the driviug clock, added by emall corrections given by the observer in right ascension and declikation (required on account of irregularity in the clock movement, orror in astronomical adjustment of the polar axis, or changes in the atar's apparent place produced by refraction), the image of a star will continue on the same spot of the photographic plate during the whole time of exposure. Exquisite photographs of star elustars, double atars, the moon, and planets have been obtained by MM. Henry, and they are the most eloquent testimony to the optical perfection of the object-glass and the efficiency of the mounting. They show also that we ore entering upon a new era in practical astronomy, in which photography is destined to play a loading part. The Henry photogrophic object-glass is of $13 \cdot 4$-inches uparture and only 10 spertures in focal length. The "guiding talescope" is of $9 \frac{1}{2}$-inches sperture and nearly 12 -feet focus. The photepraphic object-glass, notwithstanding its amall proportional foeal leagth, covers field of $2 \frac{1}{2}^{\circ}$ in diameter with perfect precision.

Nany more telescopes heve been male of type $C$ than of any

[^47]other, and it is now almost exclusively employed for the monnting of modern refractors. Its essential features are (1) a comparatively ohort polar axis and (2) a cross-head attached to the extension of the upper of the derefractor, first equavided with hour circle

axis in order to relieve the brass, wbich is ecrewed to a the declination axis; the dewhich is attached to its opclamp the instrument in H is a weight acting on a wheels $k$ (one only eeen axis in order to relieve the friction of that pivot

on its bearing. The counterpoise W balances the tube about the polar axis. M, M are counterpoise weights which act on ievers $i n, m$, whose fulcra are universal joints at $n$ attached to the cradle. These weights scrve to counterpoise the longer end of the tube and to check its flexure. $Q Q$ is the finder, a small telescope whose axis is parallel to the great telescope; having a low magnifying power and a largo field of view, it serves to direct the large telescopo to any object seen in the eky, which otherwise would be difficult to find in the comparatively limited field of the large telescope. The stand TTT is of oak. The instrument is described in detail by Struve (Beschrcibung des auf der Sternucarte zu Dorpas befindlichen grossen Refractors von Fraunhofer, Dorpat, 1825, fol.) The instrument was an enormous advance upon all previous telescopes for micrometric researcb. In the bands of Struve results were obtained by it khich in combined quality and quantity had never before been reached in micrometric research. Its success was such that the type of Frannhofer's telescope became etereotyped for many years not only by his successors but throughout Germany. When twelve years afterwards Struve ordered the 15 -inch refractor for the onew observatory at Pulkowa, the only important change made by Fraunhofer'e successors was, at Struve's suggeation, the eubstitution of a etone pier for the wooden stand in the original instrument.

Both the Dorpat and the Pulkowa refractor are defective in rigidity, especially in right ascension. The declination circle is most inconvenient of access, and slow motion in declinstion can only be effected when the instrument is clamped by a long and inconvenient handle, so that practically clamping in declinstion wes not employed. The slow motion in right ascension is defectiva being accomplished :- tise Dorpe: refractor by changing the rate
of the clock, and in the Pulkowa refractor by a handle which when used affects very iojuriously the rate of the clock for the time being. Struve's skill as an observer was such that he used to complete the bisection on the fixed wire of the micrometer by a pressure of the finger on the side of the tubs, - a method of proved efficiency in sucb hands, but plainly indicative of the want of rigidity in the instrument and of the deficiency of the slow motions (see Micrometer, vol. xvi. p. 245). The driving circle is also much too emall, so that a very slight mechanical freedom of the screw in the teeth involves a large angular frecdom of the telescope in right ascension, whilst its position at the lower end of a too weak polar axis tends to create instability in right ascension from torsion of that axis. Strange to say, the wooden tube has till very recently retained its place in German mountings.

About 1840 a great advance was made in the right direction by the Repsolds of Hamburg in the equatorial mounting of the Oxford heliometer. The driving circle was greatly increased in diameter, and placed at the upper end of the polar axis, and both the polar axis and the declination axis were made much atronger in propor :tion to the mass of the instrument they were destined to carry. (A figure of this instrument is given in the Oxford Observations for 1850.) About 1850 Thomas Cooke of York began his career as a maker of equa. German tescopes, and gavo a represents a typica equatorial of his design. A etrong cast-iron pillar is substituted for Fraunhofer's stand. On the semi-cylindrical top of the pillar rests the cast-iron box AA, which contains at its opper and lower extremities the bearings of the polar axis. Its mode of connexion with the pillar permits the inclination of the box to be changed for adjustment of the inclination of the polar axis. The strong cross-head C, supporting the bearings of tho keclination axis, is of cast iron, bolted to a flange on the upper pivot of the polar axis. Fraunhofer's cradle and wooden tubo are abolished, and in their place is a es cast-iron cylindri. aal tube D, flanged st both ends aud also at the point where it is bolted to a corresponding flange on the end of the declination axis, all three flanges being cast in one piece with the central tube; the rest of the tube consists of two slightly tapered brass cylinders bolted by strong flanges to the central tube D. The handle F clamps the arm. H to the cross-head $C$ at pleasure, and slow motion in declination is commonicated by the handes st $E$ and $G$. Two circles at $K$ and M are atlached to the

Fig. 21.-Cooka's equatoris. urper part of the polar axis. To one of these motion is communicated by the tangent acrev at M (turned by the clock N) acting on teeth cut at the edge of the circle. The other is a graduated bour circle read by two opposite microscopes, one of which is seen at P. The endless cord hanging down and holding a sliding ring at $Q$ is employed to give slow motion in right ascension, in some iustruments by moving the frame of the driving ecrew in the direction of the axis of the scren; in others by moving differential wheels which accelcrate or retard the velocity of rotatiou of the driving bcrew without affecting the rate of the clock. The declination circle RR is attached to the farther end of the declination axis and is inconvenient of access. Cooke's stand is admirable for its symmetry and simplicity of design, its just apportioning of strength, and a general rigidity with suitability of means to ends.
It is not a little curions that the obvious improvement of transferring the declination circle as well as the declination clamp to the telescone end of the declination axis was bo long delayed; we can ascribe the delay only to a desire to retain the declination circle as part of the counterpoise. We believe that the first important cquatorials in which the declination axis was read from the eje end were the 15 -inch by Grabb and the 6 -inch by Cooke, made for the observetory of Lord Crawford (then Lerd Liudsay) at Dun Echt (Aberleenshire) about 1873. The plan is now almost univereally dontad. Telescopes of sncls dimenvions can be convenioutly
directed to any object by the circles mithont the observer being under the necessity to climb a special ladder. But When mach larger instruments are required the hour circle becomes insccessible from the floor, and meane have to be devised for read. ing both circles from the eye end. This was first accomplished by Grubb in the great refractor of 27-inches aperture which he constracted for the Vienna observatory, represented in section in fig. 22. The observer's eye is applied to the emall telescopo E, which (by means of prisms numbered 1,2 , 3,4) views the vernier attached to the cross-head simultaneously with the hour circle attached to the upper end of the polar axis. Light to illuminate the vernier and circle is thrown from the lamp the prisms 6 and 5. Prism 1 is in the axis of the declination circle and always

Fio. 22.-Grubb's 2"-inch refractor (Vienna).
reflects rays along that axis, whatever the position of the telescope may bo, whilst the prisms $2,3,4,5$, snd 6 are attaclied to the crosshead and therefore preserve their relative positions to each other. Through the eye-piece of the bent ${ }^{1}$ telescope $\mathrm{E}^{\prime}$ another hour circle attached to the lower end of the polar axis can be seen; thus \&n assistant is able to direct the telescope by a handle at H to any desired hour angle. A sliglit rotatory motion of the telescopis $\mathbf{E}$ on its axis euables the remier of the declination circle to be jead through prism 3. The leading features of this fine instrurnent represent those of all Grubb's large telescones. The mode of ro lieving the friction of the declina. tion axis is similar to that entployed in the Melbourno relescope and in the accomnt of the Vienna telescope publishod by Grubb. The end fric. tion of the polar axis is relieved by a ring

Tre must condense further degcription into critical remarks on a fow typical modern instruments.
(1) Telescopes of Moderale Size for Micrometrue Research only. -

In the bent telescope refracting prisma are employed st the cormars change the direction of the raye.

Fig. 23 showe the mounting of the 8 -inch refractor, of 9 .feet focal longth, at the private observatory of Dr Engelmann, Leipsic. The bbject-glass is by Messre Clark of Cambridge, Mass., the mounting by the Repsolds of Hamburg. The declination circle reads from the eje end, and four handles for clamping and alow motion in right ascension and declination are aituated near the observer'e hands. The tube is of sheet steel, light, stiff, and froe from tromor. The eyo end carries the micrometer with an illuminsting apparatus similar to that proviously described under Micrometer, vol. xvi. p. 246 sq ., figs. 16, 17, 20, and 21. The lamp near the eyo ond illuminates the field or the wires at plessure, as well as the position circle of the micrometcr and the declination circle; a eeparate lamp illuminates the hour circle. An excellont festure (see fig. 24) is the short distance between the eyo-piece and the declination axis, so that the observer has to follow the eye end in a comparatively small circle; another good point is
 the flattening of the cast-iron centre-piece of the tube so that the flange of the declination axis is attached as near to the axis of the telescope tube as is consistent with free passage of the cone of rays from the object-glass. For purposes of micrometric research with the ordinary micrometer this instrument is the mostelegant, eatisfactory, and useful that we know, as was shown by the exceedingly accurate observations of the minor planets Victoria and Sappho for eolar parsllax, by Galle's method (see Parallax, rol. xviii. p. 249), made by Dr Engelmann in 1882. The substitution of small incandesceat electric lamps for the oil lamps would be an improvement

Fio. 24.-Dr Engelmano's 8-Inch
(2) Telescopes of Moderate Size for General Purposes.-The modern equatorial ehould for general purposes bo capable of carrying spectroscopes of considerable weight, so that the strength of the axis and the rigidity of the instrument generally have to be considerably increased. Grubb has realized our ideas of what such an instrument ehould be in an equatorisl of 6 -inches sporture which he has recently made for the royal observatory at the Cape of Good Hope. The principal features are its great strength and rigidity, with special precautions to ensure preservation of the instrumental declination. The observations of Victoria and Sappho in 1882 revealed the great deficiency of most modern equatorials in this respect. That is to say, if a star uear the meridian is first made to run along the measuring web of the micrometer, the clockwork then set in action, and the star brought back to the centre of the field by the slow-motion handle in right ascension, it will be found that the perfection of the bisection is no longer preserved. Thus at most observatories the measures of difference of declination when the clockwork was employed were far inferior to those made with the telescope at rest. The reason seems to be that in most equatorials the lower pivot is cylindrical, and onters an ordinary cylindrical bearing which cannot be a perfect fit. Also the crosshead, telescope, counterpoise, \&c., generally together overbalapce the polar axis about the upper bearing, so that the lower pivot presses upwards in its bearing, and its rotation, under the action of the clock or slow motion coupled with the friction of the surfaces, gives rise to a emall rolling freedom which creates the orrors in question. In this telescope the lower pivat is of oteel, made slightly conical, and carefully ground to fit a long conical bearing, in which it would work very tightly, or even jam, but for arring pressure brought to bear on its lower hardened flat end, which relieves the greater part of the thrust ; and the polar axis is accurately balanced about its upper bearing by a weight at the lower end of the poler axis, so that the thrust ie exactly in the axis of the cone. The apper pivat ( 4 inches in diazeter) ia also of steel, finished with the same care as that of a transit circle, so that the telescope rotates with the precision of a meridian instrument: Unusual rigidity has also been given to the declination clamping arms, and the new slom motion in declination is by far the best yet contrived ; it is a recent invention of Grubli's, and is de-
scribed below in his own words. The eye ond, suitable for heary epectroecopes, \&cc., is fitted to the butt end of the telescops by bayonet joints and tightening ecrewo, eo that it can be exchanged for a micrometric eye end with almost as little trouble as the exchanging of an eye-piece. The illumination of the circles and the micrometer is by electric incandescent lamps. The instrument may be adjusted to any latitude and is probably the most practical and serviceable equatorial made. The subjoined description of the new slow motion in declination is takon from Proc. R. Dubl. Soc., 1886, p. 107.
"The elow motion arrangcments usually nsed in equatorials are of either of two forms, Viz., (c) an endlese acrew working into a bector or portion of a toothed circle of long radic a, or (b) a screw appiying or puahing directly aome other form of apring having a conaiderahla range of motion. The orst (g) possesses the disadvantage th $t$, however carefully made, it ie impossible it is quite fres from 'loss' or 'ha ik lash'; and consequently the position of the talaacope is not perfectly determinata in declination, which fault is incon. venlent when delfcato measur.s are required. The seoond (b) bea practically no 'back lash; as apring keeps the arm in perfect conthe disadvantare that, whatever rance of motion whatever range or motion is FB -
quared, the apring mnet ba quired, the spring minet be capehis of working throngh the asmarange; consequently stronger in action et one end of the rance than the other or thes it be mado very long indead in which rasaly long indeed, in which case its action is uncertain and unpleasant. To remedy these defects the author [Grubb] hes devised the following, tages of both :-ABCD (fig. 25) is a portion of the arms
 cradle, on which is planted the block (b), forming the bearing of the screw. The nut ( $n$ ) is in tha form of a ball working in a bocket on the extremity of the clamp.arm EFG. A ahort stif apring ( N ) is attached to thla clamp-arm, bearing, not directly againat any part of othcr arm, but against end of a second and or sate pich as ene main acrew, the hut or wbich (ce) ja toothed on edge, and works into a whecl of equal siza ( $p p$ ) on main berew. The point of thja aecond screw, therafore, advances as much in one direction as the frame $A B C D$ is carried in other, according as the milied head is turned ; and consequently the point of the gerew does not sensihly vary in ite position with respect to the clamp-arm EFG. A chort atil epring can therefore be need, and the disadvantage above mentioned disappears.'
This form of slow motion could be applied with advantage to the right ascension also, and probably to the separation of the segments of heliometers.
(3) Of large equatorials we name first the great refractor at Large Washington of 26 -inches aperture and $32 \frac{1}{2}$ feet focal length ${ }^{1}$ Tbe equamounting appears to be unworthy of the well-known excellence oi toriala, the object-glass. To illuminate the micrometer an assistant is Wash. required to hold a lamp in his hand. No convenient means are ington provided for illuminating the declination axis; and in order to telaacop point the telescope in declination the following elaborate process has to be performed:-
"The instrument is brought into the meridian and set by the obaerver within a degree by means of coarse divisions painted on the edge of the declination circle. These divisions ara rendered visible by lighting one or two of the gas burners or the dome, and viewed by the astronomer with an opera.glass. Then an assiatant mounts by a ladder to a high platiorm and bolds a gas lamp near the vernier, and the fne zetting is accomplished by the observer aested in th observing charr, the declination clamp and slow-motion serew being convenient to his hand " (TV ashington Observations, 1974, Appendix 1., p. 33).
The polar and declination axes are of steel, only 7 inches in diameter at tho thickest point, sad the driving arc, which is far too small, is placed at the lower ead of this slender axis. There must thus be considerable liability to tremor in right ascension. However well the instrument may act in specially practised hands with an excelleut Clark's micrometer (art. Micrometer, vol. xvi. p. 245), the instrument must be considered wanting in the rigidity and convenience which a modern equatorial should possess. In his official report on the inatrumenta of European observatories Nowcomb defends the want of solidity and convenience of this instrument as compared with the Vienaa telcscope, becauso its emaller axes (notwithstanding Grubb's anti-friction arrangements) permit it to turn more easily and the mounting to be of far eimpler design. But at the time of Newcamb'e visit the Vienna telescope had not been bronght into work, and cannot have been in proper working order if the motion in declination was so stiff as he describes it, at least when the preseat writer tested the instrument in Dublin that. motion was surprisingly essy.

The great Pulkowa refractor (Sg. 26) erected in 1885 is of 30 inches aperture and 45 -feet focal length. The object-glass is by Clark, the mounting by the Repsolds. The tube is cylindrical, of riveted ateel plate, graduated in thickness from the coatry to its extremities, and bolted by very powerful flanges to a strong short cast-iron central tube, in which, as in Dr Eagelmann'e telescope (fig. 23), the attachment to the flange of the declination axis is placed as close as it can be to the axis of the tube withont inter-

1 Described and flgured in the Washinaton Observetions, 1874. Apra. L
fering with raya converging from the object-glass to any point in the field of riaw. A now featurs in this iastrument is the plat form at the lower end of the polar axis, where an assistant can viow the hour circle by one cye-pieco and the declination circle by another (lookiag up the perforated polar axis), and where he cana also set the telescope to any hour angle by one whecl, or to any declination by a aecond, with the greatest ease. The observer at the oyo end can also read off the hour and declination circles and connunicate quick or alow motions to the
telescope both in right ascension and declina. telescope both in right ascension and declination by cosveuiently placed bandlea. The eye end freseots au appoarance too cornplicated to bo figured hera; it has a micrometer and its illumination for the position circle, a micrometer bead, and a briglit or dark field,' clamps in right asceasion and declination and quick and slow motion in the snme, a finder, nicicroscepes

time and driven by a galvanic current from the aidereal clock, and counter weights which can bo removed when a epectroecope or other heary applianco is added. All these, although making up an ap-
paraotly complicated apparatue, are conveniently arranged, and are paratly complicated apparatue, are conveniently arranged, and are all necessary for the quick and eaay working of ao large an instrument. We have the authority of Otto Struve
for stating that in practice they are all that can by for stating that in practice they are all that can bs desired. There is in this instrument a remarkably
elogant method of relieving the friction or the polar axis. Let AA (fig. 27) be a aection of the polar axis; it is then easy to adjust the weight $P$ of the circlee, \&c., sttached to its lower ead so that the centrs of gravity $X$ of the whole moving parts of the instrumeut shall be in the vertical (VV) of a liue passing through the apex of tho hollowed flange $p q$ at $q$, which flange forms part of the polar axis. If Iovva wheel $W$ is forced up against $q$ with a pressure equal to the weight of the moving part of
the
instrument the instrument, the whols weight
 of tha moving Fis. 27. part would rest upon W in unatable equilibrium ; or if a pressure R , less than W, is cmployed, we have the end friction on the lower bearing removed to an extent $=R$ sin $\phi$, and the friction on the bearings of the upper pirot rezoroved to the extent of $F \cos \phi$, where $\phi$ is the latitude of the place. The wheel W is therefore mounted on a guided rod, which is forced upwards by auitable levers and weights, and this relief of pressurg is precisoly proportional to the pressure on the respective beariogs. The Repoelde find it unnecessary to reliave the friction of the declination axis.
Fig. 28 ahows ths equatorial mpunting which Grubb designed for the great object-glass of 36 -inches aperture that Messrs Clark lave corapleted for the Lick trustees, and which may be supposed to cxpress Grubb'a lateat ideas as to the znounting for a very large telescope. The Repsolds have a large driving circle at the upper end of the polar axis, thas avoiding torsion of the polar axis at the exponse of greatly increased length of the cross-head. Grubb

[^48]hy emploging a driving arc gets the tolescopa much closer to tho polar axis with an increased radius for driving, a, ha he makes the polar axis a very large hollow ateel or cast-iroo cylinder in which torsion is insansible. Both Grubb and the Repsolds neem to think that for tho tube of the telescopp all necesasyry rigididy caa
be attained with cylindrical tubee of be attained with cylindrical tubee of riveted eteel, the thickness of tha auccesaive sheots of which diminieh from the cen tre-piece outwards without making

## Fio. 28.-Grabb'e mouating for the Lick object.glase.

arrangermants for giving access to the eye end and for following its diurnal motion have liitherto proved a source of difficulty. The tryeelling atages of the new Pulkewa telescope are the most manageabls and practical that have yet been contrived, but even they leave much to be desired. For energetic work the atandiag position is bast, provided that the eye-piece is situated at the precise height above tho stage which is most convenient for the obeerver, and that the altitude of the observed object is not greater than $60^{\circ}$. For alditudes abore $60^{\circ}$ a mall chair with a back, the top of which is stuffed for the head to rest upon, is tha biet seat, provided that the observer's eye cen bs kept at the hight of the eya-piece. Accordingly Grubb has suggeeted the following plan for the observatery at Mount Hamilton, Califoroia, which is to cover the Lick telescope. The whole floor, 70 feet in dismeter, is to be raised or lowered ly water-power under control of the observer by means of electric keys, which act on a secondary piece of mechanism, that in turn worlse the valves and reversing gear of the water-engines. Other water-engines, aimilarly connected with keys at the observer's hands, rotate the dome and perform the quick motiona in right asceasion and declination. ${ }^{3}$ By this arrangement a large instrument can be worsed with perfect facility and comfort. There is only one other plan, that of suspending the observer's chair to the eye end, so that his eys is ncar the centre of motion of the chair. This is quite practicable for a 36 iach teleacope, and -one observer, with the nccessary guiding keja at hand, could easily work a telescope and dome of the largest dimeneions as quickly and with more ease than he could one of 1.0 or 12 inches a perture. Probably a nervoue astronomer would profer a solid floor to work upon, as in Grubb's proposal; in the latter case the quickest working can only be accomplislied by tro persons, one seated on the platform at the foot of the polar axis and doing the rough aettiag in right ascension and declination, the other meanwhilg adjusting the beight of the floor and the azirnuth of the dome opening.
In very larga equatorials there must ba in existing methods con. Proponed sidarabla inconvenience from the extended widlb of the epparatus facilities at the eyg end. Were wo called upon to design a great refractor for using wo ahould abolish all auch apparatus and provide the observer large with a fow conveniently placed small handles or keys for electrical teleconnaxions, and we ehould perform all motions of the telescops whatsoover by electromotors. Thers is no form of energy ao conrenient for the aatronomer. It provides by incandesceat lamps the most auitablo light for hie purpose, perfectly constant, giving off littlo heat, and unaffected by wind; and such a light can be placed whers required without tbe aid of reffectors or aay complicated apparatue, and ite intensity can be regulated with ease and pracision by changing the resistance of the conductors. Moreover the electromotora cain be as powerful or as delicate as wo please, and can be placed in the most convecient or suitable positions. The energy of a 5-herse-power ateam-engine working for tea hours can be atored in accumulators of no incoovenient dimensions ready for use as required during a whole weak or aven a month, and can be brought iato action in forco equiraleat to several horse. power to raise or lower the floor or turn the dome, or to perform, alow motiona. requiring no greater energy than that exercied by the finger and thumb, or to illuminato a lamp of zar or candlepower. There would be no limit to the rigidity which could be given to such a telescope, as great eass of motion would not bave

to be considered, and we should abolish all complicated antl-friction apparatus for the declination axis, retaining it only for the polar axis to save wear in tha teeth of the driving arc. Finally, instead of making the finder a ahert telescope attached to the eye end of the instrument, we should give it a focal length equal to that of the great object-glass, attaching the cell of its object-glass rigidly to the cell of the large object-glass and its eye end to the butt end of the main telescope, in order to aecure the utmost rigidity in the relations of the axes of the two tele. acopes. Such a finder would correapeud in efficiency to that of the Henry photographic telescope, and would be a railable as a guiding telescope in photographic worl, or for keeping a star exactly on the slit of a apectroscope.
The first important in. atruments of type D were Mr Lasseli's refiectors, the largest of which, and the last, is represented in fig. ${ }^{29 .}$ The polar ontly rigid, but

Fia. 29.-Lassell'e refiector.
forks which carry the pivots of the contral cracie are elements of instability, especially when the instrument is directed to an object of considerable hour angle. There is practical confession of this instability in the cross-bracing which connects the two forks, and which must be remeved if the telescope is pointed to an object between the zenith and the elovated pole.
The best exampla of type $D$ is the reflecting telascope of 36 -inches aperture designed by Mr. A. A. Common, with which his exquisite photegraphs of nebulx, \&c., were made. The principal preliminary conditions which be laid down as necessary were the follomingl :(1) no tuhe properly zo called, to aroid air-currents in the tube; (2) no mass of motal either beloin or at the aide of the ling joining tho large aud emall mirrors, to avoid currents from pessible difference of tempera. ture between the mass of metal and the surroundin air; (3) an equatorial mounting capable of direction to any fart of the visible hea. vens and of continned observation past the moridian withont reversal; (4) an efficient means of aupporting the mirrer without flezure; (5) driving clock; circles to find or identifyan object, and motions taken to oye end; (6) a mounting whec will give the greatest amonnt of steadiness with the least amount of friction. Fig. 30 is a section of the instrument in the plane of the meridian. $\mathrm{DD}_{1}$ is a cast-iron bellow cylinder, accurately bored out, attached to a atrong basa block. $\mathrm{D}_{3}$ is a cover bolted on the bottom of this cylinder, in the centre of which is a tapering ateel pin $\mathrm{D}_{2}$, which enters a correspending hole in the bottom of the polar axis $E$, and aervea as the lewer pivot of
the polar axis. The cylindrical part of the polar axis is accarately turned to a diameter ona eighth of an inch lesa than the outer cylinder, and the otherwise severe friction on the pin $\mathrm{D}_{3}$ ia relieved by filling in the space between D and E with merenry, so far as aufficient nearly to fleat the whele meving part of the telescope. The apper elbew-shaped part of the polar axis $\mathrm{E}_{2}$ is flanged and belted to the lewcr part. In the section at right angles to that eshibited in fig. 30 this elbow-shaped part is T-shaped, and tho cross of the $T$ is bered to receive the declination axis; and, as the elbow puts the pelar axis considerably out of balance, the $T$-shaped head is carried forward of the axial line abont 11 inehes, so that the whole meight of the telescopa above just restores the balance. Two beavy weights $X, X$ counterpoise the eye end $F$ with the four braced tubes T, T which support it. B is the declination circle. It is impessible to describe this fine instrument adequately within our limits; we mention as specially worthy of study the methed of supporting the mirror aud the eminently ingenions and practical form of the observatery, and refer the reader to Common's illustrated account of the instrument in Ifem. R. A.S., vol. xlvi. pp. 173-182.

There is alse an admirable mounting of type D designed by Lord Rosse" Rosse for his 3 -foot reflector at Birr Castle, described by him in 3 -foot Phil. Trans., vol clxxi. p. 153. The instrument is planned on mountthe broad lines of Lassell'a telescope (fig. 29), but the badly planned img. and weak fork of the latter is replaced by a thoroughly rigid bent fork made of boiler plate a quarter of an inch thick, firmly riveted to angle iron of $2 \frac{1}{3} \times 2 \frac{1}{4} \times \frac{\pi}{18}$ inch scantling along each angle, the. whole, as we have proved by trial, being exceedingly rigid. It would be an impropement to adopt Mr Common's plan of putting the declination axis a little out of the line of prolongation of the polar axis, and thus dispense with the counter-meight; and wo should prefer hollow steel tubce with push and pull bracing rather than the angle iren reds and bracing which form the tube.

In the Proccedings of the Reyal Dublin Seciety (vol. ii. p. 362) Type E Grulb describes a "siderostatic telescope," which forms a good elementary example of type E . In fig. 31 TT is the tubs of a telo- Grabb's scope of 4 -inches apertore, which is mounted to rotate sideroabout its axis, the latter forming the polar axis. MM etatic is a plane mirror reflecting rays from a star $S$ to the telescope objcct-glass, so that its image can be riewed from the cye-piece at E . The star is retained in the field by (1) $T$ tho clock C . Stare of different declination can bo in different hour angles by rotating the tube npon ite axis. The instrument in European
latitudes cannot command a view of tho heavena batween the elevated pole and the zenith unless the distance $O G$ is made exccedingly great; cren then only a limited range beyond the zenith is possible. The instrument is pri-
 resulting advantage is that the obeerver may bo in complete darkness and
his cbservations aje not interrupted by tion.
In Comptes Loowy E Rendus for the equator. year 1883, vol inal coude
xcvi pp. 735-741, M. Loewy gives an account of an instrument Thich ho calls an "equatorial coudé," designed (1) to attain greater atability and ao to measure larger angles than is generally possible with the ordinary equatorial; (2) to enable a aingle astronomer to point the telescope and make observations in any part of the sky Withont changing his position ; (3) to abolish the naual expensive dome, and to aubstitute a corcred ahed on wheels (which can be ran back at pleasure), learing the telescope in the open air, the obaerver alone being abeltered. These conditions are fuffilled in the manner shown in fig. 32. EP is the polar axis, retatiog on bearings at E and $P$. The object-glass is at $O$, the eye-pieco at E . There is a plano mirror at M , which reflects raya converging from the object-glass to the eye-piece at E , $A$ eecond mirror N , placed at $45^{\circ}$ to the optical axis of the object-gless, reflects raye frem a star at the pole; but by retating the bux whi contains this mirrer on the axis of its supporting tube T a star of any declination can be observed, and by combining this motion with retation of the polar axis tho astronomer aeated at E is able to view any object whatever in the visible heavens, except those situated between $10^{\mathrm{h}}$ and $12^{\mathrm{h}}$ bour

2ngle. An hour circle attached to EP and a deolination circle attached to the hox containing the mirror $N$, both of which can be read or set from E, complete the essentials of the instrument. Its mechanical details present no great difficulty, and are most conveniently arranged. But we entertain - grave doubts as to the practical value of the

Fio. 32.-Loewy's coudé equatorial. rument, not on mechanical, but on opetical grounds. There mnst be a certain loss of light from two additional reflexions; but that could be tolerated for the sake of other advantages, provided that the mirrors conld be made sufficiently perfect optical planes. A few jears ago it was very difficult to obtain an optically perfect plane 6 inches in diameter, and having obtained it there remained the futher difficulty of mounting it so that in all positions it should be free from flexure. By making the mirrors of silvered glass, one-fourth of their diameter in thickness, MM. Henry have not only succeeded in mounting them with all neceseary rigidity free from flexure but have given them optically true plane surfaces, notrithstanding their large diameters, viz., II and $15 \cdot 7$ inches. The present-writer tested the equatorial coude on double stars at the Paris observatory in 1884, and his last doubts as to the practical value of the instrument were dispelled. He has never seen mora perfect optical definition in any of the many telescopes be has employed, and certainly never mocasnred a celestial object in such favourable conditions of physical comfort. The easy position of the observer, the convenient position of the handles far quick and slow motion, and the absoluta rigidity of the mountiug leave little to be desired. In future instruments the object-glass will be placed outside the mirror N , so that both the silvered mirrors will bs protected from exposure to the outer air, and probably will retain the brilliancy of their surfaces for a long period.

## Adjustment of the Equatorial.

## adjust

Let us take the usual casa, that of an equatorial of type $C$.
py means of an azimuth compass, or, better, by the shadow of a pumb line at apparent noon, lay down a meridian line on the upper aurface of the stone pier, or other fonndation, previausly built for the instrument. (2) Employ this meridian line to set up the instrument and with it the polar axis approximately in the azimuth of the meridian, which can bo tested by stretching a wire through the centres of the bearings of the polar axis, and dropping a plumb line from the extremities of the wire upon the meridian line. If this is carefully done when the azimuth adjustment is near the middle of its range all desirable accuracy in this preliminary desideratum will be sccured. (3) Place the polar axis approximately at the altitude of the pole. This is rery easily doue for an instrument in which the polar axis is cylindrical or is encased in a box with an upper side parallel to tlat axis \{as in Grubb's or Cooke's equatorials). Prepare a right-angled triangle of wood of which the acute angles represent the latitude and co-latitude of the placa. Lay the hypothenuse of this triangle upon the line of the instrument parallel to the polar axis (or the wire of operation 2) with the angle equal to the co-latitude next to the elevated pole, and change the inclination of the polar axis till a mason's level placed on the side of the triangle opposite to the angle of the latitude shors the side. in question to be horizontal. (4) Adjust the movable microneter web to coincidence with the axis of the position circle by bisecting the image of a distant object and reading the number of revolutions or fractions of a revolution at two different readings of the position circle $180^{\circ}$ a part. The mean of these two readings is the reading for coincidence with the axis of the position circle. Set the micrometer to this mean. (5) Adjust the polar axis more caactly to the required altitude as follows. Point the telescope to a well-known star not far from the equator and ncar the meridian, ind turn the position circle so that the image of the star by the diurnal motion runs along the web. Read the declinstion circle. Now reverse the telescope to the other side of the polar axis and lisect the same star again, and again read the declination circle. The mean of the two readings is the star's instrumental apparent declination; the difference of the two readings is twice the index crror. To eliminata this latter it is only necessary to shift the vernier of the declination circle by the screws provided for the purpose, without unclamping in declination, till the circle reads the star's instrumental apparent declination. This being done, select another star near the meridian and compute its a pparent dechination (allowing for refraction). Set the telescope to this computed reading and clamp in declination; then cause an assistant to
change the altitude of the polar axis (hy the screw for the purpose) till the star is bisected by the micrometer wirc. (6) Sclect any convenient known ster about six hours from the meridian; comfuta its apparent declination (allowing for refraction) ; and set the telescope to this reading in declination. Cause the assistant to turn the slow motion in azimuth till the image of the star is bisected by the micrometer web. (7) Repeat operation 5 and mako final corrections if necessary: (8) Repeat operation 6 with stars both east and west of the meridian, and readjust azimuth if necassary. (9) Turn the position circle of the microneter $90^{\circ}$; place the declination axis nearly horizontal ; clamp the telescope in right ascension; and observe the time of transit of a known star acress the web of tha micrometer. Compute the true hour angle of tha star from the known error of the micrometer and the star's right ascension, and set the vernier so that the hour circle slall read the computed hour angle. By these means, with a previously prepared programme, the writer has frequently completely adjusted an equatorial in less than an hour, so far as operations 4 to 9 wera concerned.
There still remain two instrumental errors of the stand. (1) The line joining the optical centre of the lens with the axis of rotation of the position circle may not be at right angles to the declination axis, (2) The declination axis may not bo st right angles to the polar axis. In modern equatorials it is usual to leave these adjustments to the maker, as to leave thern to the astronomer would be incompatible with the greatest stability of the instrument. In a good instrument these errors will certainly be extremels small and hare no influence on its efficiency for practical purposes. The methods for determining their amount are given 24 most works on practical astronomy. ${ }^{1}$
There remain two important optical adjustments which must has very carefully atteaded to, viz., the centring of the lenses of this object-glass relatire to each otlier and the centring of the axis of the object-glass relative to that of the eye-piece. The former consisto in placing the lenses of the object-glass so that the centres of curvature of their surfaces shall lie in one straight line, which lina is the axis of tha object-glass. This operation is so delicate and requires such special experience and ckill that it should be left to the maker of the object-glass. An elegant method of testing this adjustment was given by Wollaston in Phil. Trans., $1822, \mathrm{p} .32$. If the object. glass itself is perfectly centred, the test of the centring of its axis with that of the eye-piece is very easy: are the diffraction rings
 which surround the image of
 a bright star shown as in fig. 33 , er is there flore, that is, are the rings extended on one side as in fig. 34! If the latter is the case, that side of the object-glass towards which the flare is directed is too far from the eje-piece, and should be brought owards it by the appropriata screws or cther sweans provided by the maker. In a good objectglass perfectly centred, on a night of ateady defimition, a bright star in focus should appear as in fig. 33.

A useful apparatus for the adjustment of centring is a small telescope (Gg. 35) whose axis is in the centre of and at right angles to a flat pieca of brass in the shape of an equilateral triangle fitted with screws at the three angles. To use this instrument, place the points of the ecrews on the object-glass as in fig. 36 , so that two angles of the triangle are in contact with the inner edge of the cell of the object-glass, and adjnat the ecrew a so that the cross-wires iu the common focus of the objectglass and eye-piece of the small telescope coincide with the image of tha cross-wires of the micro. meter of the telescopa which mark the axis of rotation of the position circle. Now, kceping the same angles of the brass triangle in con. tact with the cell, more tha small centring telescope round the cir. cumference of the object-glass and
 partura from coincidence. Correct Fios. 35, 36.-Apparatas for a.ljus. this departure half by the screw a ment of centring ia a small telescope of the small centring telescope and half by the centring screws of tha object-glass. The adjustment is perfect when tho ceutring telescope can bo moved round tha whole periphery of tha object-glass in the abovo manner whilst it cross-wires continue to bisect tho cross-wires of the micrometer o! 1 Chauvenet, Practical and Spheriral Astronomy, vol, ji. pp. S.9.3., : Brapnoy Spherical Astranamu, D. 45 ; snd Lowms, Praclical As'ronomy, rp, 28
the telescope. If after this adjustment has been perfected the diffraction rings are still not circular round the images of etars, the fault is in the centring of the lenses of the object-glass with respect to each other, and the object-glass should be scnt to the maker for rectification.

## Driving Clock:

Tho means employed to cause an equatorial telescope to follow the diurnal motion of a etar obviously must not resemble the intermittent motion of an ordinary clock. Numerous devices have been contrived for producing uniform motion. But the limits of this article will only allow us to refer briefly to a few of those most cammanly in use. Fig. 37 represents Fraun. hofer's governor. $\mathrm{On}^{\prime}$ its axis $C$ is a piniou driven by a train of wheels. The axis carries an arm BB, at the extremities of which, attached by aprings $f, f^{\prime}$, are the weights $\mathrm{D}, \mathrm{D}^{\prime}$. When theae weights ac\&nire a certain velocity of rotation the centrifugal force is sufficient

Fio. 37.-Fiaunhofer'a govermor. to cause the weighte to fly out and rub against the inside of the cylinder AA, aud their velocity is checked. Instead of a cylinder, The balls may rub against the inside of a hollow cone, and by raising or lomering the axis C the contact of the weights with the cone may bo mode to take placo whon tho balls have slightly greater or less

velocity, and thus the rate of the clock is regalated. A mach better arrangement is a modification of Watt's governor, employed by Grubb and Caoke. The governor balls $g$, $g$ (fig. 38) repose on the points $h_{,} h$ of the arm KK till they reach their normal velocity, when they fly outwards and bring the point $S$ (tipped with leather) into contact with the friction plate $p$. These clocks are simplo in construction and act very well. Newcomb in the Washington equatorial has employed a long suspended conical pendulum ; when this pendulum in the least exceeds its normal velocity (that is, its
normal departure from the vertical) it estallishes an electrical contact which brings friction to bear, and thus reduces the power applied to the pendulum. There is occasional tendency to elliptical motion, and the clack is otherwise troublesame. In the Ropsoldss driving clock of the 30 -inch Pulkowa refractor the conical pendulum is reversed, being a heavy weight at the top of a vertical steel rod, kept in conical rotation by a pin at its upper end, which enters a slot in a revolving arm. The rod is in fact a spring of such a form as to cause the revolutions to be nearly or perfectly isochronous whatever the angle of the cone of motion; the clock is therefore, within limits, independent of the power applied to it or the force to be overcome.
Many forms of air-fans have been suggested; probably the best is the modification of Foucault's proposed by Hilger (see Monthly Notices R. A.S., vol. zlvi. p. 155), which is ohown in fig. 39 . E is the axis of rotation; C and D are fans that are pulled towards the spindle E by chronometer springs in the bores $A$ and $B$. The fans fly out symmetrically when the velocity exceeds 25 or 30 revolutions per eecond; the increased resiatance of the air thus produced checks the velocity of rotation. By means of the small weighis $\mathrm{W}, \mathrm{W}$ attached to arms on the fans Hilger states that it is possible to adjust this governor so that it shall erca lose by an increase of the driving weight.

For the most refined worl none of these governoss cian ba said to be perfect; none would be eren tolerable as a clock for astronomical time-keeping purposes. It is possible that the elaborate Greenwich driving clock may give better results, but its construction is too complicated to be frequently repeated (see, for a description of it, the Greenwich Obscrvations for 1868). The only way in which aearly perfect uniform motion can be realized is to control it in some way from a swinging pendulum. This is done
 Foucault'a air-fan. in Bond's spring governor ${ }^{1}$ and by Grubb, the latter emploging the arm of a romontoir train connected with a dead-beat escapement to bring friction to bear on a revolving plate connceted with the axis of his governor (see fig. 38). The best existing driving clock is probably that at Lord Crarford's observatory at Dun Echt. ${ }^{2}$ An account of its performance is given by Mr Copeland in Viertsl. jahrsschr. astron. Gesellsch., 16 Jahrg., p. 305. In this clock gain of a hundredth of a second, or even less, introduces increased friction on the revolving disk during the next second, or uatil the gain has beca corrected. A still more perfect clock could probably be mado on a similar plan by abolishing the clock weight and making the origin of power an electromotor, the current being cut off in a Way similar to that io the Dun Echt clock if the clock of continuous mation gets in advance of the ordinary clock.

For information on clock work of equatoriala and telescope mountinga generally, see Konkoly's Practische Anlcitung wur Anstcllung astron. Beobachtungdn.
(D. GI.)

TELESPHORUS, bishop of Rame from about 128 till âbout 137, succeeded Sixtus I. and was followed by Hyginus. Eusebius in his History gives the date of the martyrdom of Telesphorus as the first year of Antoninus Pius (138) and in his Chronicle as the eightecnth year of Hadrian (135).

TELFORD, Thomas (1757-1834), civil engineer, was the son of a shepherd in Eskdale, Dumfriesshire, and was born in the valley of the Megget, 9 th August 1757. From early childhood he was employed as a herd, occasionally attending the parish school of Westerkirk, where his quickness and diligence helped to make up for his lack of opportunity. On being apprenticed, at the age of fifteen, to a stone mason at Langholm, he found leisure not only to gain an acquaintance with Latin, French, and German, but to gratify his literary tastes by a wide variety of reading. In his early manhood be was much given to
the writing of verse: a poem of some length on Eskdale appeared in 1784 in the Poetical Museum, published at Hawick ; under the signature of "Eskdale Taın" he coutributed verses to Ruddiman's Weekly Magazine; and he addressed an epistle in rhyme to Burns, which was published in Currie's Life of the poet. But these poetical effusions were of comparatively littlo value. In 1780 Telfora weut to Edinburgh, where he was employed in the erection of houses in the "new" town, and occupied much of his spare time in learning architectural drawing. Two years later he proceeded to London, finding employment in the erection of Somerset House. Having in 1784 supcrintended the erection of a honse for the commissioner at Portsmouth dockyard, he next repaired the castle of

[^49]Sir W. Pulteney, member for Sbrewsbury, who conceived such a high opinion of bis talents that he got him made surveyor of public works for the county of Salop. His earliest bridge was that across the Severn at Montford, finished in 1792. In the following year be was appointed engineer of the Ellesmere Canal, which led to his being employed for the chief canals subsequently constructed in Great Britain, including the Caledonian (1804), the Gloucester and Berkeley (1818), the Grand Trunk (1822), the Macclesfied (1824), and the Birmingham and Liverpool Junction (1825). He was consulted in 1806 by the king of Sweden regarding the construction of the Gotha Canal between Lake Wener and the Baltic, and, his plans having been adopted, he visited the country in 1810 to superintend some of the more important excavations. In 1803 be had been appointed engineer for the construction of 920 miles of roads in the Highlands of Scotland, a great part through very difficult country. Of the numerous bridges built in this line of roads mention may be specially mado of that across the Tay at Dunkeld. Subsequently he parfected the road communication between London and Srotland and the northern towns of England. An undertaking of equal magnitude and importance with that in the Highlands of Scotland was a system of roads through the more inaccessible parts of Wales, which involved the erection of the magnificent suspension bridge across the Menai Straits, begun in 1820, and the Conway bridge, besun in 1822. For the Austrian Gorernment Telford built the Polish road from Warsaw to Brest. While the fame of Telford rests chiefly on his road and canal engineering, and the erection of the numerous bridges and aqueducts which this involved, he also did good work in harbour construction. In 1790 he was employed by the British Fishery Society to inspect the harbours on the north-east coast of Scotland ; and, besides constructing the important fishing harbour at Pulteneytown, Wick, he greatly improved those at the other principal fishing stations. His important works of this kind were, however, his improvement of the barbours at Aberdeen and Dundee, and the construction of the St Katherine's docks at London. In 1828-30 he drained the north level of the eastern Fen district, an arca of 48,000 acres. The erection of the Dean Bridge, Edinburgb, and of the Broomielaw Bridge, Glasgow, and the improvement (1833-34) ; Dover harbour were the principal achievements of his later years. He died on 2d Stptember 1834, and was buried in Westminster Abbey.
Telford was nover married. For twenty-one years ho lived at the Salopian coffee house, afterwards the Ship Hotel, Charing Choss. He was a fellow of the Royal Sociaties of London and of Eltinhurgh, and was annually elected president of the Institution of Ciril Engineers from its commencement. He received the Swedish order of knighthood "of Gustavus Vasa."
isee Telford's Menairs, written by hlmself and edited by Join Rlckman (1\{38); also Emfles: s Lives of the Engineers.
TELL. The story of William Tell's skill in shooting at and striking the apple which had been placed on the head of his little son by order of Gessler, the tyrannical Austrian bailiff of Uri, is so closely bound up with the leg:ndary history of tirg origin of the Swiss Confederation that they must be considered together. Both appear first in the 15th century, probabiy as results of the war for tho Toggenburg inheritance (1436-50); for the intense ha' red of Austria, greatly increased by her support of the claims of Zurich, favoured the circulation of stories which assumed that Swiss freedom was of immemorial antiquity, while, as the war was largely a struggle between the civic and rural elements in the Confederation, the notion that the (rural) Schwyzers were of Scandinavian descent at once separated them from and raised them above the German inhabitants of the towns.

The Tell story is first found in a ballad the first nine stanzas of which (containine the story) were ccrtainly
vritten before 1474. There is no mention made of the names of the bailiff or of his master, or of the hat placed on a pole. Tell is called "the first Confederate," and his feat is treated as the real and only reason why the Confederation was formed and the tyrants driven out of the land. It is probably to this ballad that Melchior Russ of Lucerne (who began his Chronicle in 1482) refers when, in his account (from Justinger) of the evil deeds of the bailifis in the Forest districts, he excuses himself from giring the story. He goes on to narrate how Tell, irritatec by his treatment, stırred up his friends against the governo, who seized and bound him and was conveying him by boas to his castle on the Lake of Lucerne, when a storm arosa, and Tell, by reason of his great bodily strength, was, after being unbound, given charge of the redter on his promise to bring the boat safely to land. Hu suers it tuswards a shelf of rock, called in Russ's time Tell's Platte, sp.ings on shore, shoots the bailiff dead with his crossbow, and goes back to Uri, where he stirs up the great strife which ended in the battle of Morgarten. In these two accounta, which form the basis of the Uri rersion of the origin of the Confederation, it is Tell and Tell only who is the actor and the leader. We first hear of the cruelties of Austrian bailiffs in the Forest districts in the Bernese Chronicle of Conrad Justinger (1420). No names or details are given, and the dates are different in the two recensions of the Chronicle as "olden days before Bern was founded" (i.e., before 1191) and 1260. Several details, but only one name, are added in the De Nobilitate et Rusticitate Dialogus (clp. 33) of Felix Hemmerlin, a canon of Zurich, who wrote it after 1451 and before 1454 ; in this last year he was imprisoned by the Schwyzers, whom be had repeatediy insulted and attacked in his books. 'According to him, the men of Schwyz and of Unterwalden were the first to rise, those of Uri following suit much later. But neither Justinger nor Hemmerlin makes any allusion to Tell or his feat.

The Tell story and the "atrocities" story are first found combined in a M.S. known as the White Book of Sarnen. They are contained in a short chronicle written between 1467 and 1476 , probably about 1470 , and based on oral tradition. Many details are given of the oppressions of the bailiffs: we bear of Gessler, of the meeting of Stonpacher of Schwyz, Fürst of Uri, and a man of Nidwald at the Rütli,--in fact, the usual version of the legend. To give an instance of tyranny in Uri, the author tells us the story of the refusal of "der Thall" to do reverence to the hat placed on a pole, of his feat of skill, and of his shooting the bailift, Gessler, from behind a bush in the "hollow way " near Küssnacht. Tell is represented as being one of those who swore at the Rütli to drive out the oppressors; but the narrative of his doings is merely one incident in the geueral movement which began quite independently of him. The chronology is rery confused, but the events are placed after Rudolph's election to the empire in 1273. This is the only account in which Tell is called "der Thall," which name be bimself explains by saying, "If I were sharp (voitzig) I should be called something else and not der Tall," i.e., the simpleton or slow-witted man. The only other known instances of the Uri version of the legend relating to the origis of the Confederation are the Latin hexameters of Glareanus (1515), in which Tell is compared to Brutus as "assertor patrix, vindex ultorque tyrannam," and the Urnerspiel (composed in 1511-12), a play acted in Uri, in which Russ's version is followed, though the bailiff, wbo is unnamed, but announces that he has been sent by Albert of Austria, is slain in the "bollow way." Tell is the chief of the Rütli leaguers, and it is his deed which is the immediate occasion of the rising against the oppressors, which is datcd in 1296. Mutius
(1540) is the latest writer who, in his description of the origin of the Confederation, does not mention Tell and his act. The two storics are now firmly bound together; the version contained in the White Book is the accepted one, though small adilitions in names and dates are often made.

The task of filling up gaps, smoothing away inconsistencies, rounding of the tale, was accomplished by Giles Tschodi ( $q . v$. ), whose recension was adopted, with a few alterations, by Von Mïller in his Itistory of the Confederation (1780). In the final recension of T'schudi's Chronicle (1734-36), which, however, differs in many particulars from the original draft still prcserved at Zurich, we are told how Albert of Austria, with the view of depriving the Forest lands of their ancient freedom, sent bailiffs (among them Gessler) to Uri and Schwyz, who committed many tyrannical acts, so that finally on 8th November 1307, at the Riütli, Werner von Stauffacher of Schwyz, Walter Fürst of Uri, Arnold von Melchthal in Unterwalden, each with ten companions, among whom was William Tell, resolved on a rising to expel the oppressors, which was fixed for New Year's day 1308. A few days later (November 18) the Tell incident takes place (described according to the White Book version), and on the appointed date the general rising. Tschudi thus finally settled the date, which had before varied from 1260 to 1334 . He utterly distorts the real historical relations of the Three Lands, though he brings in many real historical names, their owners being made to perform historically impossible acts, and introduces many small additions and corrections into the story as he had received it In particular, while in his first deaft he speaks of the bailiff as Gryssler-the usual name up to his time, except in the White Book and in Stumpfi's Chronicle of 1548 -in his final recension te calls him Gessler, knowing that this was a real name. Later writers added a few more particulars,-that Tell lived at Bürglen and fought at Morgarten (1598), that be was the son-inlaw of Fürst and had two sons (early 18th century), \&c. Johannes von Müller gave a vivid description of the oath at the Riitli by the three (Tell not being counted in), and threw Tschudi's version into a literary form, adding one or two names and adopting that of Hermann for Gessler, calling him of "Bruneck." Schiller's play gave the tale a world-wide renown.

The story was, on the ground of want of evidence, regarded as suspicious by Guilliman in a private letter of 1607, and doubts were expressed by the brothers Iselin (1727 and 1754) and by Voltaire (1754) ; but it was not till 1760 that the legend was definitely attacked, on the ground of its similarity to the story of Tokko (see below), in an anonymous pamphlet by Freudenberger, a Bernese pastor. This caused great stir; it was publicly burnt by order of the Government of Uri, and many more or less forged proofs and documents were produced in favour of Tell. The researches of J. E. Kopp ${ }^{1}$ first cleared up the real early history of the league, and overthrew the legends of the White Book and Tschudi. Since then many writers have worked in the same direction. Vischer (1867) has carefully traced out the successive steps in the growth of the legend, and Rochholz (1877) has worked out the real history of Gessler as shown in authentic documents. The general result has been to show that a mythological marksman and an impossibie bailiff bearing the name of a real family lave been joined with confused and distorted reminiscences of the events of 1245-47, in which the names of many real persons have been inserted and many unputhenticated acts attributed to them.
The story of the skilful marksman who succeeds in striking some s:nall ofject placed on the head of a man or child is very widely

Toowments for the Distory of the Forleral Allinnaces. 1835 and

spread: we find it in Denmark (Tokko), Norway (two versions), Iceland, Holstein, on the Rhine, and in Englaud (William of Cloudesley). How it came to be localized in Uri we do not know; possibly, throngh the story of the Scandinavian colonization of Schwyz, the tale was fitted to some real local hero.

The alleged proofs of the existence of a real William Tell in Uri in the 14 th century break down hopelessly. (1) The entries in the parish registers are forged. (2) As to the Tell chapels-(a) that iu the "hollow way" near Kiissnacht was not known to Melchior Russ and is first mentioned by Tschudi (1570). (b) Tbat on Tell's Platte is alse first mentioned in Tschudi. The document which alleges that the chapel was built by order of a "landsgemeinde" held in 1388, at which 114 men were present who had been porsonally acquainted with Tell, was never hcard of till 1759. The procession in boats to the place where the chapel stands may be very old, but is not connected with Tell till about 1582. (c) The chapel at Buirglen is known to have been founded in 1582. Other documents and statements in support of the Tell story have even less claim to credit. It has been pointed out above that with two exceptions the bailiff is always called Gryssler or Grissler, and it was I'sclndi who popularized the name of Gessler, though Grissler occurs as late at 1765 . Now Gessler is the name of a real family, the history of which from 1250 to 1513 has been worked our by Rochholz, wbo shows in detail that no nember ever played the part attributed to the bailiff in the legend, or could have done so, aud that the Gesslers conld not have owned or dwelt at the castle of Küssnacht; nor could they have been called Von Bruneck.

In the Urnerspiel the name of the bailiff's servant who guarded the hat on the pole is given as Heintz Vögely, and we know that Friedrich Vogeli was the mame of one of the chief military officers of Peter von Hagenhach, who from 1469 to 1474 administered for Charles the Bold, duke of Burgundy, the lands (Alsace, \&c.) pledged to him by Sigismund of Hapsburg. Now Hagenbach is known to have committed many cruelties like those attributed to the bailiffs in the legend, and it has been plausibly conjectured that his case has really given rise to these stories, especially when we find that the Confederates had a hand in his capture and-execution, that in a document of 1358 Hagenbachs and Gesslers appear side by side as witnesses, and that the Hagenbachs had frequent trans actions with the Hapsburgs and their vassals.
Among the vast number of books and pamphlets on the Tell etory, the two most to be recommended are W. Vischer, Die Sage von der Befreiung der Wald. staitt, Leipsic, 1867, and E. L. Rochholz, Tell und Gessler, with a volume of dacuments 1250-1513, Heilbronn, 1877. Convenient summaries of the controversy will be found in any modern book on $\$$ wiss history, and mare particnlarly in Q. von Wyss, Ueber d. Gesch. d. drei Lànder-Uri, Schwyz, u. Unterwalden -in den Jahren 1\$12.1315, Zurich, 1858 ; Alf Huber, Die Wraldställe bis zur festen Begriundung ihrer Eidgenossenschaft, mit einem Anhange über die geschicht. liche Steliung des With. Tell, Innsbruck, 1861 ; Albert Rilliet, Les Origines de la Confederation Suisse, Histoire el Ligende, Gene va, 1869.
(W. A. B. C.)

TELLER, Wilhelm Abraham (1734-1804), was the son of the Leipsic clergyman, Romanus Teller, who edited the earlier volumes of the Englisches Bibelwert (in 19 vols., 1749-70), an adaptation for German readers of the exegetical works of Willet, Ainsworth, Patrick, Poole, Henry, and others. Teller was born at Leipsic on 9th January 1734, and studied philosophy and theolagy in the university there. Anongst the men whose influence mainly determined his theological position and line of work was J. A. Ernesti. 'His writings present rationalism in its course of development from Biblical supernaturalism to the borders of deistical naturalism. His first learned production was a Latin translation of Kennicott's Dissertation on the State of the Printed Hebrew Text of the Old Testament (1756), which was followed the next year by an essay in which he expounded lis own critical principles. In 1761 he was appointed pastor and professor of theolegy in the university of Helmstädt. Here he pursued his exegetical, theological, and historical researches, the results of which appeared in his Lehrbuch des christlichen Glaubens (1764). This work threw the entire theological world into commotion, as much by the novelty of its method as by the beterodoxy of its matter, end more by its omissions than by its positive teaching, though everywhere the author seeks to put theological doctrines in a decidedly modern form. In consequence of the storm of indignation the book provoked. Teller eagerly accepted an invitation from the Prussian cultus minister to the post of prebendary of Köln on the Spree, with a seat in the Berlin consistory (1767). Here he found himself in the company of the rationat:istic theologians of Prussia-Sack, Spalding, and
ethers-and became one of the leaders of the rationalistic party, and one of the chief contributors to Nicolai's Allgemeine Deutsele Bibliothek. Teller was not long in making use of his freer position in Berlin. In 1772 appeared the most popular of his books, Wörterbuch zum Neuen Testument ( 6 th ed., 1805). The object of this work is to recast the language aud ideas of the New Testament and give them the form of 18tb-century illuminism. This Heb. xiii. 8 signifies the permanence of Christ's teaching, and, as the New Testament has no word for Christianity, "Christ" may mean sometimes His person and at others His doctrine or the Christian religion ; Col. i. 15 signifies the priarity of Christ to all other Christians. By this lexicon Teller lad put himself amongst the most advanced rationalists, and his opponents charged him with the design of overthrowing positive Christianity altogether. The edict of Wöllner (1788), and Teller's manly action as consistorialrath in defiance of $i t$, led the Prussian Government to pass upon hin the sentence of suspensian for three months, with forfeiture of his stipend. He was not, however, to be moved by such means, and (1792) issued his work Die Religion der Yollkonmeneren, an exposition of his theological position, in which he advocated at length the idea, subsequently often urged, of "the perfectibility of Christianity,"-that is, of the ultimate transformation of Christianity into a schenue of simple morality, with a complete rejection of all specifica!ly Christian ideas and methods. This book represents the culminating point of German illuminism, and is seprrated by a long process of develapment from the anthor's Lehrluch. Teller died on 9 th December 1804. [n aldition to the above works bo wrote Anleitung zur Religion illerhaupt und zum Allgemeinen des Christenthums iusbesondere (1792) ; and; besides his contributions to the Allgemeine Deutsche Bibliothek, he edited a papular and practically useful Mrogazin für Prediger (1792-1801).

TELLeZ, Gabriel (c. 1570-I648), Spanish dran atist, better known as Tirso de Molina (bis nom de plune), was born about the year I570, and about 1613 entered the order of the Brothers of Charity at Toledo. In 1645 he became prier of the nonastery of the order at Soria, There he died in 1648.
Hise dramatic works are said to have numbered nearly 300 , but of these only a small proportion are now extant. A selectiou of the best of, them was edited by Hartzenbusch in 1839.42 (Madrid, 12 vols.). See Drasa, vol. vii. p. 421 , add Spanisn Litcrature, vol. xxii. p. 359.
TELLICHERRI, a seaport town of India, in Malabar district of Madras, situated in $11^{\circ} 44^{\circ} 53^{\prime \prime} \mathrm{N}$. lat. and $75^{\circ} 31^{\prime} 38^{\prime \prime}$ E. long. It is a healthy and picturesque town, built upon a group of wooded hills runing down to the sea, and is protected by a natural breakwater of rock. The town with its suburbs occupies about 5 square miles, and was at one time defended by a strong mid wall. Tho citadel or castle still stands to the north of the town. The East India Company established a factory hero in 1683 for the pepper and cardamom trado. For two years (1780-82) the town withstood a siege by Hyder's general Sardár Khín, and ir the subsequent wàrs with Mysore Tellicherri was the base of operations for the ascent of the Gbáts from the west coast. In 1881 the population was 26,410 .

TEMESVAR, a royal frea city and capital of the county of Temes, is the chief town of soutb-eastern Ilungary It lies on the narigahle Bega, Canal and the river Tega, in $45^{\circ} 47^{\prime} \mathrm{N}$. lat and $21^{\circ} 14^{\prime} \mathrm{E}$. lans. The innes towa is
fortified and separated from the suburhs by a glacis, now partly converted into a park. Temesvár is the scat of the Roman Catholic bishop of Csanád and of a Greek bisholv as also of several Government departments of great ins partance, and of one of the fifteen army corps of the Austrian-Hungarian army. The majority of the inhalitants follow industrial and commercial pursuits, and carry on a brisk trade in grain, flour, spirits, fruits, flax, and Lemp with the neighbouring districts and with Roumania and Servia, by means of the Arad-Tenesvar and tho Austrian-Hungarian State Railvays, $a_{0}$ well as by the Réga Canal and by road. The town possesses many charitable and educational establishments, and is a favourite place of residence on account of its neatness and cleanliness. It has been lighted by electricity since 1883. Among tho build ings specially worthy of notice are some fine old churches, a new theatre, and a synagogue in the Byzantine style. Temesvár played an important part in the Turkish wars and in that of 1848-49. The population was 37,500 in 1886.
temphinck, Konrad Jacob (1778-1857), kecper of the Leyden museum of natural history, was especially distinguished as an ornithologist, and was the author of many magnificently illistra+ed systematic' works. Sce Ornithology, vol. xviii. p. 1 I sq.

TEMPE. Seo Thessaly.
TEMPERA, or Distemper, ${ }^{1}$ is a method of painting in which solid pigments are employed, mixed with a water medium ${ }^{2}$ in which some kind of gum or gelatinous substance is dissolved to prevent the colours frem scaling off. Termpera is called in Italy "fresoo a scceo," as distinguished from "fresco buono," or true fresco, painted on freshly laid patches of stucco. The peculiarities of true fresco are described in vol. ix. p. 769 sq . The disadvantages of tempera painting are that it will not bear exposure to the weather; the pigments merely lie on the surface and do not sink into the stucco, as is the case with true fresco pigments; moreover, the medium used, being soluble in water, will not stand the rain. Its advantages are that the painter can work at leisure, and can also transier or sketch his whole design on the dry finished surface ; while in fresco work each portion of the design is hidden piece. meal as each nev patch of stucco is applied (see Raphafl, vol. xx. p. 279). Another important point is that a far greater variety of pigments can be used in tempera painting, as thev are not subjected to the caustic action of wet lime. Lasily, tempera painting can be applied to ary substance, such as dry plaster, wood, stone, terracot a a, velium, and paper. ${ }^{3}$ Various media have been used for tempera work, such as the glutinous sap of the fig and other trees, various gums which are soluble in water, and size made by boiling down fish-bones, parchment, and animals' hoofs. In more recent times a mixture of egg and vinegar has been found to make a good medium, especially when it is desirable to apply the colours in considerable body or impasto. Painting in tempera is probably the oldest method of all, and was used in ancient Egypt very largely, as can bo seen by au examination of the many existing examples on papyrus or wood and stona thinly coated with a skin of fine plaster (gesso). Other ancient examples have been found in Babylan and Ninerch, and for internal work it appears to have been much enployed by the Greeks. To some extent tempera was used by the Romans, though in most cases a combination of fresco and encaustic (hot wax) was employed for their inural decoration (see vol. xvii. p. 42).

F For some account of tempera painting in classicat and medixva" limes, seo Mirmal Decoration, vol. xvii. pp. 39.47
${ }^{9}$ Heace it ored to be called " water-work"; sce Shakespeare, $H_{\varepsilon}$ 'e :1., part ii., act ii. sc. 1
${ }^{3}$ Miniatures and illumivated letters in medixval MSS. were paista 1 with vory tinely asound colours mincd with a templera nuedium.

In medirval times, from the 6th century in the Byzantium of Justinian down to the 14th century, most painting, whether on walls or panels, was executed in tempera, though in many ceses it appears to have been the custom to put in the coloured ground in true fresco, and, when that was dry, paint on it the complete picture with a tempera medium. This was the method used in the Byzantine wall-paintings in_the churches of Thessalonica, Mount Athos, and elsewhere. A similar practice exister in England and other northern countries, ${ }^{1}$ as in the very complete series of paintings on the walls and vault of the chancel of Kempley church, Gloucestershire, dating from about 1100. Most commonly, however, in England as in France and Germany the whole painting was done in tempera, the finished surface of the plaster being first covered with a wash of old slaked lime or whitening. As a rule every inch of stone, whether carved, moulded, or plain, in the cathedrals and other churches of medixval France, England, and other countries was covered with this thin coating of white, and then elaborately decorated with tempera painting. In those rare cases where want of money prevented the application of colour the stone-work of the interior received the coat of white, so that at any future time the colouring might be added, and also because the feeling of the Middle Ages evidently was that hare stone inside a building had an unfinished and uncomfortable look, ${ }^{2}$ and was quite as unsuitable in a richly decorated and furnished cathedral as it would now bo considered in a lady's drawing-room. The additional splendour gained by the use of minute patterns stamped in gesso, thinly laid over the surface of the stone, is descrileil in Mural Decoration, vol. xvii. p. 47 ; see also fig. 17.

Temperr in Italy.-For panel and canvas paintings tempera continued in use till nearly the end of the 15 th century, when the Flemish method of oil painting gradually took its place. In many cases with panel pictures of the latter part of the 15 th century it is now difficult, if not impossible, to be sure whether they were rainted in tempera or in oil, either because both methods were com-bined-the picture being begun in tempera and finished with oil glazings-or because an oil varnish has been laid over the tempera pictures, and so the pigments hare absorbed oil out of the varnish and have thus practically become associated with an oil medium. In some cases slight peculiarities of brush-work bear witness to one medium or the other; lut these appearances are often deceptive, and any real certainty on the point is unattainable. The round panel of the Madonna and St Joseph by Michelangelo may be mentioned as an exanple of these doubtful cases.

In the main the earlier tempera easel pictures were jainted on wood,-pear, joplar, or walnut being commonly used; but a fev painters preferred in some cases to use canvas. ${ }^{8}$ The National Gallery of London possesses a very beautiful example of this, 一the Entombment, attril,uted to Van der Weyden (see Schools of Painteng, vol. zxi. p. 438, fig. 29), which is most delicately and yet powerfully painted on linen without any priming. Usually Loth panels and canvas were prepared for tempera by being covered with a fine priming or coating of gesso (plaster). Some later painters used marble dust ; others unfortunately used white lead, which has since blackened through the absorytion of gases from the air.

[^50]In the case of wall paintings, loth ten rera and fresco ${ }^{4}$ were used together, -the proportion of fresco work being gradually increased. In the 13th and most of the 14 th. century little more than the groundwork of the picture was painted in fresco, though this varied according to this custom of each painter. In the 15th century increastd technical skill and rapidity of execntion allowed much more complete work to be done in fresco, till at last nothing but a few finishing touches were done in tempera. Fur this, exceptional certainty of touch and speed of executicn were required, and some weaker painters never attainel to a very complete mastery over the fresco 1 rocess. Tle brilliant series of wall paintings by Pinturicchio in the cathedral library at Siena contain a very large proportisn of tempera work, in spite of which they are still iu a wonderful state of preservation. Raphael's rapill advance in the mastery of fresco-work is clearly shown in his paintings in the Vatican stanze, each one of which is carried to a furthir stage in true fresco than the preceding. Thus the earliest painting of the series (the Disputa) is very largely executed in tempera, while some of the later ones ale nearly completed in fresco, and show the most perfect skill in that difficult process. Michelangelo was specially rimarkable for his great power in fresco, and carried his Sistine paintings to a very advanced stage before touching them with tempera. Sad to say, what tempera finishing touches he did apply have mostly been scraper off during the many cleanings and repairs that these works hare undergone; and the same misfortune has happened to a large number of other important pictures. Tempera was specially used for paintings on canvas which were intended to be hung like tapestry, as, for example, the fine 15th-century series at Rheims and Mantegna's Triumph of Julius Cæsar at Hampton Court. ${ }^{5}$ It was also much used for large cartoons, such as Raphael's tapestry designs, now in the South Kensington Museum. After the first half of the 16 th century the increasing use of oil painting, assisted by the artistic decadence of the age, caused the gradual disuse of both fresco and tempera.

A third process, often used during the earlier Middle Ages, was a sort of compromise between tempera and fresco. A finished stucco surface was prepared as for ordinary tempera, hut before each day's painting the plaster $\pi$ as soaked with water, so that the pigments, laid on to the wet plaster, to some extent sank below the surface, though without penetrating as deeply as they would on nenly mixed stucco.
( 3. ․ . і. .)
TEMPERANCE SOCIETIES. ${ }^{8}$ The modern temperance movement may be said to date from the publication at Philadelphia, iu 1785, of Dr Benjamin Rush's essay on "The Effects of Ardent Spirits on the Human Body and Mind," $w$ hich was republished in the Gentleman's Magazine of 1786 , and had a wide circulation. The distinction which he draws between distilled and fermented liquors has, however, no foundation in fact, the difference being one of degree anil not of kind. In 1808 Dr Lyman Beecher and Dr B. J. Clark, both readers of Rush, took action, and the result of the nork of the latter was the formation of What is Leliered to be the first modern temperance society. It was formed in Greenfield, Saratoga county, New York, as an anti-spirits association, and still remains a teetotal society. This example was soon followed elsewhere, the early societies all restricting their scope io advocacy of moderation in the use of distilled liquors, and placing no inluibition upon fermented drinks. One society had a

[^51]byelaw requiring any member who became intoxicated to treat all the other members. The work made further progress when the American Temperance Society was founded in 1826. Three years later Prof. John Edgar of Belfast called attention to the need for similar work in Ireland; and John Dunlop nearly at the same time organized a temperance seciety in Glasgow. In 1830 the first English temperance society was founded at Bradford. The habitual use of fermented liquers in England was a prolific source of drunkenness, and the evil was greatly increased by the passing of the Beer Act in October 1830. Hence some of the reformers began to abstain from all forms of alcohol. This new departure found its leader in Joseph Livesey of Preston, a man of singular zeal and benevolence, who with six others signed a pledge of total abstinence on 1st September 1832. The reformers were soon divided over the fierce "battle of the pledges." Some were willing to pledge themselves to abstain, but not to refrain from previding alcoholic drink for their visitors. After the formation of the distinctive total abstinence organizations, the moderation societies died of inanition. It should be mentioned here that the Society of Bible Christians, founded at Salford in 1809, adopted the rule of abstinence from flesh meat and intoxicants, and that a number of the "radical reformers" were abstainers from a desine to diminish the public revenue, which they regarded as devoted to wrong purposes by the Government of the day. In Ireland Father Theobald Nathew became president of the Total Abstinence Society in Cork in 1838, and the "pledge" was taken from his hands by crowds; before he died in 1850 between three and four million persons are said to have received it from him in the course of his journeys. J. S. Buckingham secured the appointment of a committee of the House of Commons, which sat in June 1834, to inquire into drunkenness. The adjective "teetotal" was first used in September 1833 by Fichard Turner, a reformed drunkard, to express the theroughgoing principle of total abstinence, but whether he coined the word, or whether it was merely a stuttering pronunciation of "total," or an old dialect werd has been disputed; Prof. Skeat (Etym. Dict., s.v. "Teetotal") believes it is an emphasized form of "total," formed on the principle of reduplication. The early teetotallers were earnest missionarics. Iu consequence of their efforts societies and leagues multiplied, periodicals were established, and, notwithstanding many failures and apparent retrogressions, the temperance movement progressed. One of the chief forms of thrift amongst the artisan ciass was that of the friendly society, the meetings of which were usually held at thie public-house, large sums being spent (sometimes by rule) on liquor. In 1835 the Independent Order of Rechabites was formed at Salford, and has since had a prosperous career as a workingclass insurance company on temperance principles. The Sons of Temperance and the Total Abstinent Sons of the Phenix are similar organizations. The sickness and death-rate ariong members of these bodies is much below that of the ordinary friendly societies. The beneficial effect of abstincuce upon health and longevity is shown by the experience of the United Kingdom Temperance Provident Institution, the example of which has led several large insurance comparies to add a special section for teetotallers. The statistics of these offices show that the mortality of the ordinary insured is considerably heavier than that of the abstainers. A vehement controversy arose at an early period as to the uss of sacramental wine, and the nature of the mines mentioned in Scripture was discussed in innumerable pamphlets. The result has been that in a number of cases the wine now used for sacramental purposes is understood to ho wutet
mented. The cosmopolitan character of the movement was shown by the meeting of the World's Temperance Convention at London in 1846. The Scotch United Presbyterian Abstinence Society, originated in 1845, was one of the first of the church societies; and there are now few, if any, religious denominations either in England or America in which such organizations are wholly wanting. The Church of England Temperance Society has twe sections, one pledged to the temperate use of intoxicants and the other to total abstinence This method of organizing has found imitators. The enactment of the Maine Liquor Law in America in 1851 (see vol. xv. p. 299) led to the formation, in 1853, of the United Kingdom Alliance, which has for its object the suppression of the liquor trafic by legislation, and with a view to this suggests that a power of local vete should be placed in the hands of the ratepayers. This proposal took parliamentary form in the Permissive Bill of Sir Wilfrid Lawson, which was ultimately withdrawn and replaced by a "local option" resolution, which has been thrice affirwed by the House of Commons. Temperance hotels, temperance cafés, British workmen public-houses, cocoa houses, coffee palaces, tectotal clubs, have arisen in many places as social aids of the temperance movement.

In 1868 the Good Templar order was introduced into England from the United States, where it had come into existence several years earlier. In England it made rapic progress, until it was seriously checked by a dispute arising out of the Negre question; but the two sections have again reunited (1887). Good Templary is the freemasonry of temperance, with ritual, passwords, grips, icc., closely modelled on those of the old secret societies. It has had a remarkable extension in Great Britain, the United States, the British colonies, and in Scandinavia, its aggregate membership now reaching over 623,000 . One of its results has been the foundation of a temperance orphanage at Sunbury-on-Thames. Side by side with the general movement there has been a special movement against the use of alcohol as medicine, and the tendency of medical teaching now favours at least restriction of its use as a therapeutic agent. The London Temperance Hospital for the non-alcoholic treatment of disease was opened in October 1873. The impertance of training the young was early recognized by the leaders of temperance reformation, and the labours of Dr R. B. Grindrod of Manchester and Mrs Carlile of Dublin led to the formation of bands of hope, which are now found in connexion with many places of worship. The juvenile temples of the Good Templar order alsn work in the same direction. The Woman's Christian Temperance Union, founded in the United States in 1874, is one of the latest forms of terperance activity. A branch was organized in Great Britain in 1876; and in 1883 the World's Women's Temperance Union came inte existence.

The temperance morement has now, branched ont into a manlitude of organizations in the United Kíngdom, of which the Rail. way Temperance Union, the post-office temperance societies, and associations connected with the army and nary are types. Tho organizatious of a wore gencral character are tho United Eingdom Alliance, which is very active in the dissemination of teetotal doctrines generally, the National Temperance League, the Scottish Temperance League, tho British Tcmperance League, the Scottish Permissive Bill Association, the Irish Temperanco League, and tho Irish Association for the Prevention of Intemperance. There are also large district and county societies. Next to theso ceme tha secret orders, of which the Rechabites, Sons of Temperance, Sins of -the Phoenix are large bencfit societies. The Independent Ordir of Good Templars is non-beneficiary, and seaks in its "lodges" to provide social attractions, and at the same time to train the mem. bers in temperanco work; it is probably the largest voluntary association in the world. There are societics in connexion with the varions religious bodies, of which the Church of England Evuperanco Society, the Catholic League of the Cross, tho Daptist Thtal Abatinence Society, are promincat instanecs.

The oldest organization in America is the Sons of Temperance (1842), now numbering; about 80,000 members. The Indepeudent Order of Good 'Templars (1851) is the largest, its membership epproaching 100,000. Both these, as also the Royal Templars of Temperance (1877) and the Templars of Honour and Temperance (1845), are mutual benefit societies. The Woman'e Christian Temperance Union, the National T'emperance Socicty and Pub. Lication House (New York), and the National Prohibition Party gre octive in clucational work. The Woman'e Christian Temperence Union is the outgrowth of "the Women's Crusade" (1872), a femarkable uprising among the women of Olio and Pennsylvania against the liquor traffic. The organization was effected in 1874, and has since spread throughout the United States, its memberhip now (1887) uumbering 207,000. Its influence las been sidely felt in legislatures and in elections in which prohibitory lawe have been voted upon. With the exception of the Church Temperance Society of tho Protestant Episcopal Church, which bas the "double basis," all the temperance societies of the United States are based on the dactrine of total abstinence; and, with the additional exception of the Father Mather Total Abstinence Bocieties of the Roman Catholic Church, they all odvocate the principle of prohibition. Amendments embodying this idea have been inserted in the State constitutions (by popular vote) of Maine, Kansas, and Rhode Island. In Vermont and Iowa the legislature has enacted statutory prohibition, which is still in force. In other States local prohibition prevaila to a large extect, chiefly in Georgia, Mississippi, Massachusetts, Tennessee, Kcntucky, ond Arkansas.
Bibliography.-The literature of the subject is very extensive and' may most conveniently be classed under the following headd (1) Hisfory: P. T. Winskill, History of the Temperance Reformation; One Hundred Years of Tem. perance (Now York, 1880゙); Dorchester, Liquor Problem in all Ages (New York) ; Willard, woman and Temperanco (Hartford); Sbaw, Great Temperance Reforms (Toronto). (2) Theolony: Dawson Burna and F. R. Lees, Temperance Bible Commentary; J. Snith, The Church and the Temperance Reformation; bamson, Divino Laro as to Wincs (Philalel phia). (3) GENERal: A. Gustafaon, The Foundation of Death; R. B. Grindrod, Our Nation"s Vice; D. Burns, Basts of the T'emperance Reformation; Grindrod, Dacchus; B. Parsons, Anti-Bacchus; Powell, Bacchus Dethroned; Baker, The Curse of Britain ; J. Dunlop, Philosophy of Drinking Usagcs (1839): The Political Prohilitiontst (New York, 1887) ; Pitman, Alcohol and the State (New York). (4) Political Economit F. R. Lees, Argument for the Protibitiont of the Ltquor Traffc; W. Hoyle, Our National Resources; Hargreaves, Our IFasted Resources (Nivew York). (5) Science: J. Livesey, The Mlalt Liquor Lecture; P. Burne, Tetoteller's Companion; W. B. Carpenter, Physiology of Temperance cind Total Abstincuce; A. A. Reade, Study and Stimulanls; Miller, Alcohcl, its Place and Pover: Id., Nephalism; B. W. Richardson, Cantor Lectures on Alcohol; Hargreaves, Alcohol and Science (New York). (6) Fiotions : novels and tales embodying teetotal principles have been written by Mrs Henry Wood, Mrs H. B. Stowe, Mrs. C. L. Balfonr, Mr Jobn Zabberton, Mr Edward Jenkins, Mrs 8. C. Hall, Mrs Eilis, and many others. (7) Periodioals: the temperance periodicals isaued in Great Britain now number about fifty.

TEMPLAPS, Knights. Perhaps the most renowned of the three great military orders founded in the 12 th century for the defence of the Latin kingdom of Jerusalem is that of the Knights Templars (pauperes commilitones Christi templique Salomonici), though abolished long before its rivals. It differed from the Hospitallers and the Teutonic Knights in having been a military order from its very origin, inas much as its earliest menbers banded themselves together for the express purpose of giving armed protection to the numerous pilgrims who, after the first crusade, flocked to Jerusalem and the other sacred sites in the Hoiy Land. Walter Map has preserved the legendary story of their first arhievements, from which it would appear that their earliest efforts were confined to the immediate neighbourhood of Jerusalem; and the memory of their original aim may perhaps be traced from fifty to seventy years later, when they condncted Henry of Saxony from their own quarters on Jount Moriah to the banks of Jordan, or when on the fall of the Doly City (1187) they protected the vanguard of the Cbristians on its way from Jerusalem to Tripoli. The three orders were distinguished from each other wy their garb. The Hospitallers wore black mantles with white crosses, the Templars white mantles with a red cross, the Teutonic Knjghts white mantles with a black cross. ${ }^{1}$
'he Templars almost from their foundation had their quarters in the palace of the Latin kings, which had been the mosque of Nount Noriab. This palace was also known as Solomon's temple, and it was from this tentplum Salomonis that the Templars took their name.

About the year 1118 a Burgundian knight, Hngh de
? William of Tyre, xi. c. 7, viil. 3. xviii. 3-6: James de Vitry, IIist. Hieros. 60-67.

Paganis, bound himself and eight comrades by a vow to $\mathrm{t}_{136}$ patriarch of Jerusalem to guard the public roads, to live as regular canons, and to fight, for the King of Heaven in chastity, obedience, and self-denial. Baldwin [I. grantod them quarters on Mount Moriah and recommended their cause to St Bernard. Under his patronage the papal legat ${ }^{\text {a }}$ Matthew, bishop of St Albano, presided at the conncil of Troyes in Jannary 1128 for the purpose of drawing ul or confirming the statutes of the new order. The seventy-twa statutes then drawn up met with the approval of Pope Honorius II. and the patriarch of Jerusalem, and became the groundwork of the later and more elaborate "Regle" du Temple." Long before St Bernard's death (1153) the new order was established in almost every kingdom of Iatin Christendom. IIenry I. granted them lands in Normandy. They seem to have been settled in Castile by 1129 , in Bochelle by 1131, in Languedoc by 1136, at Rome by 1138 , in Brittany by 1141, and in Germany at perhars a still earlier date. Alphonso I. of Aragon and Navarre, if we may trust the Spanish historians, bequeatled them the third of his kingdom (Mariana, x. c. 9). Raymond Berengar, count of Barcelona, and Alphonso's successor in Aragon, whose father had been admitted to the order, granted them the strong castle of Monçon (1143), and established a new chivalry in imitation of theirs. Louis VII. in the latter years of his reign gave them a piece of marsh land outside Paris, which in later times became known as the Temple, and was the headquarters of the order in Europe. Stephen of England granted them the manors of Cressing and Witham in Essex, and his wife Matilda that of Cowley, near Oxford. Eugenius III., Louis VII., and 130 brethren were present at the Paris chapter (1147) when Bernard de Balliol granted the order 15 librates of land near Hitchin; and the list of English Lonefactors under Stephen and Henry II. includes the noble names of Ferrers, Harcourt, Hastings, Lacy, Clare, Pere, and Mówbray.

After the council of Troyes Hugh de Paganis came to England and induced a number of English knights to follow him to the Holy Land. Amongst these was Fulk, count of Anjou, who would thus secm to have been a Templar before assuming the crown of Jerusalem in 1131." Hugh Easly de Paganis died about the jear 1136 and was succeeded by Robert de Craon, who is said to have been Anselm's nephew. Everard de Barris, the third master, was conspicuous in the second crusade. In the disastrous march from Laodicea to Attalia his troops alone kept up even the show of discipline; and their success prompted Louis VII. to regulate his whole army after the model of the Templar knights. In the French king's distress for money the Templars lent him large sums, ranging from 2000 silver marks to 30,000 solidi. When Conrad III. of Germany reached Jerusalem he was entertainedat their palace (Easter 1148); and in the summer of the same year they took part in the unsuccessful siege of Damascus. The failure of this expedition was ascribed by a contemporary writer to their treachery, -a charge to which Conrad would not assent. This is the first note of the accusations which from this time were of constant recurrence. ${ }^{2}$

Henceforward for 140 years the bistory of the Tempfars is the history of the Crusades (q.v.). In 1149 the Templars were appointed to guard the fortress of Guza, the last Christian stronghold on the way towards Egypt. Four years later the new master, Bernard de Tremelai, and forty of his followers, bursting into Ascalon, wero surrounded by the Saracens and cut off to a single man. William of Tyre has preserved the scandal of the ding when he bints that they met a merited fate in their eage:ness to possess themselves of the city treasure. Next year
the rumour went avroad that they had sold a noble balf. converted Egyptian prince, whe had fallen into their hands, to chains and certain death for 60,000 aurei. In 1166 Amáric, the Latin king of Jerusalem, hanged twelve Templars on a charge of betraying a fortress beyond the fordan to an emir of Núr al-Dín of Damascus. The military power of Núr al-Din (1145-1173) was a standing menace to the Christian settlements in the East. Edessa kad fallen to the prowess of his father (1144-45); Damascus was conquered by the son (1153), who four years earlier had carried his depredations almost to the walls of Antioch, and in 1157 laid siege to the Christian town of Paneas near the sources of the Jordan. In the disastrons fight that followed for the safety of the fortress of the Hospitallers, Bertrand de Blanquefort, the master of the Templars, and Odo de St Amand, one of his successors, were taken prisoners. Bertrand was released later when Manuel was preparing to march against Núr al-Dín. The Templars do not seem to have opposed Amalric's early expeditions against Egypt. It was Geoffrey Fulcher, the Templar correspondent of Louis VII., who brought back (1167) to Jerusalem the glowing accounts of the splendour of the caliph's court ai Cairo with which Gibbon has enlivened his great work. Nor was the order less active at the northern limits of the Latin kingdom. Two English Templars, Gilbert de Lacy and Robert Mansel, "qui Galensibus præerat," starting from Antioch, surprised Núr alDin in the neighbourhood of Tripoli and put him barefooted to flight. But jealousy or honour led the Templars to oppose Amalric's Egyptian expedition of 1168; and the wisdom of their advice became apparent when the renewed discord on the Nile led to the conquest of Egypt by Asad al-Din Shirkúh, and thus indirectly to the accession of Saladin, in 1169. In 1170 they beat Saladin back from their frontier fortress of Gaza; and seven years later they shared in Baldwin IT.'s great victory at Ascalon.

Meanwhile Saladin had possessed himself of Emesa and Damascus (1174-75), and, as he was already lord of Egypt, his power hemmed in the Latin kingdom on every side. In July 1173 Amalric was succeeded by his son Baldwin IV., a boy of twelve. Raymond III., count of Tripoli, a man suspected of being in league with the Saracens, was appointed regent, although in 1176 the masters of the Templars and the Iospitallers united in offering this office to the nemly arrived Philip of Flanders. The construction of the Templar fortress at Jacob's ford on the upper Jordan led to a fresh Saracen invasion and the disastrous battle of Paneas (1179), from which the young king and the Holy Cross escaped with difficulty, while Odo de St Amand, the grand-master, was carried away captive and never returned.

During Odo's mastership the Old Man of the Mountains sent to Amalric offering to accept the Christian faith if released from the tribute he had paid to the Templars since (according to the reckoning of M. Defrémery) somewhere about 1149 . The Templars murdered the envoys on their return (c. 1172). Amalric demanded that the offenders should be given up for justice. Odo refused to yield the chief culprit, though he was well knom, and invoked the protection of the pope. Amalric had to vindicate his right by force of arms at Sidon, and died while preparing to take stronger measures. The connexion between the Templars and the Old Man was still vital eighty years later when the two grand-masters rebuked the insolence of the Assassin envoys in the presence of Louis IX. Odo de St Amand was succeeded hy Arnold de Torroge, who died at Verona on his way to implore European succour for the Holy Land. The power of Saladin was now (118t) increasing daily ; Baldwin IV. was a leper, and his realm was a prey to riral factions. There were two ciaimants
for the guardianship of the state,-Raymond "III. of Tripoli and Guy de Lusignan, who in 1180 had married Sibylla, sister of the young king. Baldwin inclined to the former, against the patriarch and Arnold de Torroge.

There is something Homeric in the story of the fall of the Latiu kingdom as related by the historians of the next century. A French knight, Gerard de Riderfort or Bideford, coming to the East in quest of fortune, attached himself to the service of Raymond of Tripoli, looking for the hand of some wealthy widow in reward. But on his claiming the hand of the lady of Botron he was met with arcfusal. Angered at this, Gerard enrolled himself among the Templars, biding his time for revenge, and was elected grand-master on the death of Arnold. Baldwin IV. died (1185), leaving the throne to his young nephew Baldwin V., the son of Sibylla, under the guardianship of Raymond, Whose office was not of long duration, as the little king died in September 1186. This was Gerard's opportunity. The Templars carried the body of their dead overeign to Jerusalem for burial ; and then, unknown to the barons of the realn, Gerard and the patriarch crowned Sibylla and her lusband Guy. The coronation of Guy was the triumph of Reginald of Clâtillon, once prince of Antioch, and Saladin's deadliest foe. It was at the same time the overthrow of Raymond's ambition ; and both Latin and Arabic writers are agreed that the Christian count and the Mohammedan sultan now entered into an alliance. To break this friendship and so save the kingdom, the two grand-masters were sent north to make terms with Raymond. But the rash valour of the Templars provoked a hopeless contest with 7000 Saracens. The grand-master of the Hospitallers was slain ; but Gerard made his escape with three knights to Nazareth (Ist May 1187). In this emergency Raymond became reconciled with Guy; and Gerard placed the temple treasures of Henry II, at his king's disposal. Once more it was the Templars' rashness that led to the disastrous battle of Hittin (4th July). Gerard and the king fell into the hands of Saladin, but were released about a year later; Raymond of Tripoli made his escape through treachery or fortune; and 230 Templars fell in or after the battle, for the fght was scarcely over before Saladin ordered all the Templars and Hospitallers to be murdered in cold blood. One after another the Christian fortresses of Palestine fell into the hands of Saladin. Jerusalem surrendered on 2d-3d Octo- Fall oll ber 1187 , and the treasures of the temple coffers wero Jero; used to purchase the redemption of the poorer Christians, part of whom the Templar warriors guarded on their sad march from the Holy City to Tripoli. Part of their wealth was expended by Conrad of Montferrat in the defence of Tyre; but, when this prince refused to admit Guy to his city, both the Templars and the Hospitallers from the neighbouring parts flocked to the banner of their released king and accompanied him to the siege of Acre (22d August 1189). In his company they bore their part in the two years' siege and the terrible famine of 1190-91; and their grand-master died in the great battie of 4 th October -1189, refusing to survive the slaughter of his brethren.

On the fall of Acre Philip Augustus established himself in the palace of the Templars, whe are, however, stated to have sympathized with Richard. This king sold them the island of Cyprus for 100,000 besants ; but, unable to pay the purchase money, they transferred the debt and the principality to Guy of Lusignan. The English king consulted them before deciding on any great military movement; and in June 1192 they advocated the bold plan of an advance on Egypt rather than on Jerusalem. In the disputes for the Latin kingdom of the East the Templars secm to hare supported Guy, inl, like Richard, were credited with haring bad 3 hand in the murder of Conrad
of Montferrat (April 1192). It was in the disguise of a Templar and in a Templar galley that Richard left the Holy Land. When Acre was recovered, the Templars, like the Hospitallers, received their own quarters in the town, which from this time became the centre of the order. On the death of Henry of Champagne (1197) they retoed the election of Raoul de Tabarie; after the death of his successor Amalric they refused to renew the truce with Saladin's brother, Saif al-Din, and led au expedition against the Saracens before the arrival of the new king, Joln de Brienne, at whose coronation in 1210 William de Chartres, the grand-master, was present. Seven years later, with the aid of Walter de Avennis and of the Tentonic Knights, they commenced the building of their fortress of Castle Pilgrim, near Acre, on a rocky promontory washed by the Mediterranean on every side except the east. This wonderful structure, whose ruins are still to loe seen, was fortified with a strong wall, founded on the substructure of a yet more extensive one running from sea to sea, and was flanked by lofty towers of hage squared stones. Within was a spring of pure water, besides fishןonds, salt-mines, woods, pastures, orchards, and all things fittel to furnislı an abode in which the Templars might await the day of their restoration to Jerusaleri.
It was from this castle that in May 1218 the fifth crusade started for the expedition against Egypt. The Templars were the heroes of the siege of Jamietta, at which William de Chartres was slain. "First to attack and last to retreat," they saved the Christian army front annihilation on 29th August 1219; and when the city surrendered (5th November) the only one of its treuty-eight towers that had begun to give way had been shaken by their engines. On the other hand, it was largely owing to their objections that John de Brienne refused the sultan's offer to restore Jerusalem and Palestine.
From the very first the Templars seem to lave been opposed to Frederick $\Pi$., and when he landed at Acre ( 7 th September 1228) they refused to march under the banuers of an excommunicated man, and would only accompany his host from Acre to Joppa in a separate body. They were accused of notifying Frederick's intended pilgrimage to the Jordan to the sultan, and they were certainly opposed to Frederick's ten Jears' peace with Al-Kámil, the snltan of Egypt, and refused to be present at his coronation in Jerusalem. Frederick was not slow to avenge himself: he left Jerusalem abruptly, publicly insulted the grand-master, demanded the surrender of their fortresses, and even laid siege to Castle Pilgrim. He left Acre on 3d May 1229, and on landing in Apulia gave orders to seize the estates of the order and chase all its members from the land.

Long before the expiration of Frederich's peace Europe was preparing for a fresh crusade against the now divided realm of the Ayyulids. Theobald of Navarre and his crusaders reached Palestine about August 1239. The Templars shared in the great defeat near Jafia, an engagement which their temerity bad done much to proroke ( 13 th November 1239). If the king ever accepted the overtures of Salih of Damasulus, he was supporting the policy of Hermann of Perigerd, 'the grand-master, who towards the summer of 1244 wrote a triumphant letter to England, telling how he had engaged this sultan and Nassir of Kerak to make an alliance against the sulton of Egypt and restore the whole of Palestine from the Jordan to the sea. Theobald, however, before leaving the Holy Land (27th September 1240), sigued a ten years' truce with Salib of Egypt. The Hospitallers seem to have been won over to his view, and when Richard of Cornwall arrived (11th Oclober) he had to decide between the two rival orders and their opposing policies. After soms hesi-
tation he concluded a treaty with the sultan of Egypt, much to the annoyance of the Templars, who openly mocked his efforts. On his departure the three orders came to open discord: the Templars laid siege to the Hospitallers in Acre and drove ont the Tentonic Knights "in contumeliam imperatoris." They were successful on all sides. The negotiations with Darrascus' and Kerak were reopened, and in 1244 Hermann of Perigord wrote to the princes of Europe that after a "silet ce of fifty-six years the divine mysteries wonld once more be celebrated in the Holy City."

It was in this momest of danger that the sultan of Babylon called in the harLarons Khárizmians, whom the Mongol invasions had driven from their native lands. These savages, entering from the north, flowed like a tide past the newly built and impregnable Templar fortress of Safcd, swept down on Jerusalem, and annihilated the Christian army near Gaza on St Luke's day (18th October) 1244. From this blow the Latin kingdom of the East never recovered ; 600 knights took part in the battle ; the whole army of the Templars, 300 in number, was present, but only 18 survived, and of 200 Hospitallers ouly 16. The masters of both orders were slain or taken prisoners. Despite the admirable valour of the Templars, their policy harl proved the ruin of the land. Jerusalem was lost to Christendom for ever; and, though the Kharizmians melted away in the course of the next three years, they left the country so weak that all the acquisitions of Theobald and Richard fell an easy prey to the sultan of Babylon.

Recognizing the fact that the true way to Jerusalem Louis lay through Egypt, Louis IX. led his host to the banks IX.'s of the Nile, being accompanied by the Templars. Their cruside master, William de Sonnac, attempted in vain to restrain the rash adrance of the connt of Artois at the battle of Mansúra (8th Fehruary 1250), which only three Templars survived. St Louis, when captured a few weeks later, oryed his speedy release to the generosity with which the order advanced his ransom-money. Shortly after his departure from Acre (April 1254) they consented to an eleven jears' truce with the sultans of Egjpt and Damascus.

A new enemy was now threatening Mohammedan and Christian alike. For a time the llongol advance may have been welcomed by tho Christian cities, as one after another tho Mohammedan principalities of the north fell before the new invaders. But this new danger stimulated the encrgies of Egjpt, which under the Nameluke Bes-Sucbars (see vol. vii. P. 755 ) encroached year after year on the cesses of scanty remains of the Latin kingdom. The great Frankislu Reybara lords, fearing that all was inst, made haste to sell their lands to the Templars and Mospitallers before quitting Palestine for ever. In 1260 the former purchased Sidon and Beaufort ; next year the Hospitallers purchased Arsuf. In 1267, by a skilful adaptation of the banners of both orders, Beybars nearly surprised Antioch. The Tcmplar fortress of Safed surrendered with its garrison of 600 knights, all of whom preferred death to apostasy (June 1266). Beaufort fell in April 1268, Antioch six weeks later; and, though the two orders still made occasional brilliant dashes from their Acre stronghold, such as that to Ascalon in 1261 and that with Prince Edward of England to destroy Kakun in 12T1, they became so enfecbled as to welcome the treaty which secured them the plain of Acre and a free road to Nazareth as the result of the English crusade of 1272.

But, though weak against external foes, the Templars were strong enough for internal warfare. In 1277 they espoused the guarrel of the bishop of Tripoli, formerly a member of the order, against his nephew Bohemond, prince of Antioch and Tripoli, and commenced a war which lasted three years. In 1276 their conduct drove Hugh TII., kiug
of Cyprus and Jerusalem, from Acre to Tyre. In the ensuing year, when Mary of Antioch had sold her claim to the crown to Charles of Anjou, they welcomed this prince's lieutenant to Acre and succeeded for the moment in forcing the knights of that city to do homage to the new king. Thirteen years later ( 26 th April 1290) Tripoli fell, and next year Acre, after a siege of six weeks, at the close of which (16th May) William de Beaujeu, the grand-master, was slain. The few surviving Templars elected a new master, and, forcing their way to the seashore, sailed for Cyprus, which now became the headquarters of the order. A futile attempt against Alexandria in 1300 and an unsuccessful effort to form a nevv settlement at Tortosa about the same time (1300-2) are the closing acts of their long career in the western parts of Asia.

For nore than a hundred years the Templars had been one of the wealthiest and most influential factors in European politics. If we confine our attention to the East, we realize but a small part of their enorinous power. Two Templars mere appointed guardians of the disputed castles on the betrothal of Prince Henry of England and the French princess in 1161. Other Teniplars were almoners of Henry III. of Eugland and of Philip IV. of France. One grand-master was godfather to a daughter of Louis IX. ; another, despite the prohibition of the order, is said to have been godfather to a child of Philip IV. They are reported to have reckoned a pope (Innocent III.) among their nembers and to bare refused admission to a king and his nepherr (Philip IV.). They wero summoned to the great councils of the church, such as the Lateran of 1215 and the J.fons council of 1274 . Frederick II.'s persecution of their order was one of the main causes of his exconmunication in 1239; and his last will enjoined the restoration of their estates. Their property was scattered over every country of Christendom, from Denmark to Spain, from Irelaud to Cyprus. Before the middle of the 13 th century Matthew Paris reckons their manors at 9000 , Alberic of Trois-Fontaines at 7050, whereas the rival order of St John had barely half the latter number. Some fifty years earlier their iucome from Armenia alone was 20,000 bosants. Both in Paris and in London their houses were used as strongholds for the royal treasure. In the London temple Hubert de Burgh and the Poitevin favourites of Henry III. stored their wealth; and the same building was used as a bank into which the dobtors of the foreign usurers paid their dues. From the English Templars Henry III. borrowed the purchase money of Oléron in 1235; from the French Templars Philip IV. exacted the dowry of his daughter Isabella on her marriage with Edward II. To Louis IX. they lent a great part of his ransom, and to Edward I. of England no less than 25,000 livres Tournois, of which they remitted four-fifths. James de Molai, the last grand-master, came to France in 1306 with 150,000 gold florins and ten horse-loads of silver. In the Spanish peninsula they occupied a peculiar position, and more than one ling of Aragou is said to have been brought up under their discipline.

Such were the power and mealth of the Templars at the time when Philip IV. of France accuserl them of heresy and worse offences, had them arrested (13th October 1307), and forced them to confess by tortures of the most excruciating kinds. Five years later (26th May 1312) the order was suppressed by decree of the council of Vienne and its goods transferred to the hospital of St John.

The order consisted of (1) knights, (2) chsplains, and (3) men-6tarms (armigeri, clientes, snd servientes). The knights were eithor bound for life or for a fized periorl, and were the only members entitled to weer the white mantle. Married brethren were admitted; but no woman might enter the order. Each knight might keep threa horses and one man-at-arms, who, like his master, might be bound for life or only for s time. Like Augustinisn canons,
they were to attend daily services; but the soldier outwearied mith his nightly duties might on certain conditions absent himself from matins with the master's consent. Two regular meals were allowed for each day; lut to these might he slded, at the master'e discretion, a light collation towards sunset. Meat might be eaten thrico a week; and on other days there was to be a choice of regetablo fare so as to suit tho tenderest stomach. Brethren were to eat by couples, each keeping an eye on hie fellow to see that he dill not practise an undue austerity. Wino was served at evcry meal, and at thase times silence was strictly enjoined that the words of Holy Writ might be heard with the closest attention. Special care was to be taken of aged and ailing members. Every brother owed tho most absolute obedienco to the master of the order, and was to go wherever his superior bade him without delay, "as if commanded by God." All undue display in arms or harncss was forbidden. Parti-coloured garmeuts were forbidden; black or dusky-brown (burellus) ras to be worn by all except the knights. All garments were to be made of rool; but from Easter to All Souls a linen shirt might be snbstituted for one of wool. The hair was to be worn short, and a rough beard became one of the distinguishing marks of the order. Hunting and hawking were nulawful; sud the very allusion to the follies or secular schievements of earlier life was forbidden. A lion, however, being the type of the evil one, was legitimate prey. Strict watch was kept on the iucomings aud outgoings of every brother, except when he went out by night to visit the Sepulchre of our Lord. No letter, eveu from the nearest relative, might be opened except in the master's presence; nor was any member to feel sanoyance if he saw his relative's gift trausicrred at the master'e bidding to aome other brother. The bretliron wore to sleep in separate beds in shirts and breeches, rith a light slways burning in the dormitory. Those who lacked a mattress might place a piece of carpet on the floor; bnt all luxury was discouraged. The order recognized two governing bodies, -tho first, a meetiug for ordinary lusiness, to which only the riser members were summoned ; the second, one for extraondinary affairs, such as the grantiug of lands or the reception of new members, on which occasions the master might summon the whole community. Even at these last assemblies the master seems to have decided on the final action (c. 59). A term of probation was assigned to each candidate before admission; snd a special clause discouraged the reception of boys before they were of su age to bear arms. Lastly, the bretluren of the Temple were exhorted to shun the kiss of every woman, whether maid or widow, mother, aunt, or bister.
The general spirit of the Templar statutes remained nasltered Admints to the ond, though the increasing wealth of the order gave rise to tration. a number of additional rules. The grand-master nas almaye head of the eociety; his instructions were biuding on every member, and the very lawe were at his discretion. . But he could not declare war, alienste the society's estates, or even admit a nember withont the consent of his chapter. He was elected by thirteen brothcrs, chosen by a peculiar method of co-optation, and all, if possible, belonging to different nations. Next to him in dignity came the seneschal, on whom the duties of the absent master devolved. The marshal had charge of the steeds ond accoutrements; he also commanded the knights and men-et-arms, the latter of whom scem in time of war to have been at the disposal of the turconolier. The commander of the kingdom guarded the treasure-housc, to which eren the grand-master might not havo a key; the comnander of the city of Jerusalem had charge of tho True Cross in timo of war. There were twolre or perhaps more commanders or preceptors of the difierent provinces and Eingdoms of Europe and Asia, Jerusalem (kingdom and city), Acre, Tripoli, Antioch, France, England, Poitou, Aragon, Portugal, Apulia, and Hungary. No European preceptor could cross the $6 e a$ without the grand-master's leave; but all ought to be present at the election to this office. The privileges and duties of every member were strictly prescribed, from the number of horses he might ride and the smount of food ha micht est to the colour of his clothes. The order eeems to have owned a fleet, part of which, if not all, Wes under the a uthority of the commander of the kingdom. Besides the knights sud men-atarms, the society reckoned chaplains in its ranks; and it was the babit of confossion to these priesto that seems to have atirred the Wrath of the Dominicans and the Franciscaue, who played a very conspicuous part in the overthrow of the order, especially in England. For grievous offences, auch as desertion to the Saracens, heresy; or losing the gonfalon, a Templar might be expelled (perdre la maison) for minor offences, such as disobedience or lowering the banner in battle, he suffered a temporary degradetion (perdre son abit). By a motash agreerment the Templars snd Hospitallers, despite their of the rival order ; and the Templar cot off in battle and defeat from all hope of rejoining his own rauks might rally to the cross Ef St John. As Acre was the besdquarters of the order in the East, en Peris was its centre in the West (Matt. Paris, 8.478 ). every member before admission must declare himself free of debt, bound of body, and aftimated to no other religious sociaty; he must also take \& row of obedience and chastity, at the same time re-
nouncing his privato property and dedicating his future life to the Holy Land. The order prided itself specially on the splendour of its religions cervices, the abundance of its alms, and its reckless valour for the Cliristian faith. At the time of its suppression it was calcnlated to number 15,000 members. Three ILSS. of its ancient statutes, written in Old French, are still extant at Dijon, at Paris, and at Rome. Of these the first was transcribed about 1200 , the last two from 1250 to 1300 . They have bcen published by DI. Maillard de Chambure (Paris, 1840).
A scheme for the union of the three great military orders into one had received the sanction of Gregory $X$. and Lonis IX., of Nicholas IV. and Boniface VIII. The recovery of the Holy Land was the dream of the last pope's highest ambition; and when he died a prisoner in the hands of Philip IV. of France this king coutinued to advocate the plan for his own purposes. llis gold or influence secured the election of Clement V. as pope(5th Jone 1305). According to a slightly later tradition, before consenting to the new pope's appointment he exacted from him an oath to assist in carrying out six propositions, one of which he wonld not disclose as yet. This sixth condition, if it ever existed, must have been the suppression of the Templars; and, whether false or true, Villani's story emplasizes a popular and almost contemporary pinion. It is known that Philip was urging Clement in this direction before the latter's coronation at Lyons on 14th November 1305, and all throngh the two succeeding years. On 6th June 1306 the pope summoned the grand-master from Cyprus to Fiance. James de Molai obeyed the call, and, heaning of tho charges against his order, demanded a prompt investigation. In this demand he was supported by thi leading Templars of the realm. Clement, who disbelieved the accusations, fenced with the question. But, though only a rery short time previously Philip had spoken of his special love for the order, and though it had sheltered him from the fury of the Paris mob in 1306, be was now determined on its destruction. Its wealth would fill the royal coffers, and the rumours of the day afforded a ready engine for its overthrow.

For perhans half a century there had been strange stories circulating as to the secret rites practised by the order at its midnight neetings. It was said that on his initiation each member had to disavow his belief in God and Christ, to spit upon the crucifix, to submit to indecent ceremonies, and to swear never to reveal tho secrets of the society or disobey the mandates of a grand-master, who claimed full power of absolntion. When the mass was celebrated the consecrating words "Hoc est corpus" were omitted; on Good Friday the holy cross was trampled under foot; and the Christian duty of almsgiving had ceased to be observed. Even the vaunted chastity of the order towards women had, it was said, been turned into a sanction for more horrible offences. These evil practices were part of the secret statute law of an order which in its nightly assemblies worshipped hidcous four-footed figures, - a cat or a calf. In England the rery children at their play bade one another beware of a Templar's kisses. Stranger storics yet were rife in this country and gravely reported before bishops and priests, -of children slain by their fathers because they chanced to witness the nightly orgies of the society; of one prior's being spinted away at every meeting of the general chapter ; of the great preceptor's declaring that a single hair of a Saracen's beard was worth more than the whole body of a Christian man. In France they were said to roast their illegitimate children and smear their idols with the burning fat.
For nearly two years Philip waited for Clement to fulfil his bargain. A certain Templar from the prisons of Toulouse now offered to put the king in possession of a secret that would be worth a realm. Acting on the evidence of this informer, Philip issued orders (14th September 1307) for the arrcst of all the Templars in France on the night of Fridity, 13th October. He seems to have written to the neighbouring princes urging them to act in the same way. James de Molai was seized with sixty of his brethien in Paris. On Saturday they were brought before the university of Paris to hear the enumeration of their crimes; and on Sunday the Paris mob was gathered in tho royal gardens, where preachers were inveighing against the iniquities of the order. The inquisitors began their work at once; and inhuman tortures forced the most horrible avowals from the lips of many. In Paris alone thirty-six Templars died under torture. ${ }^{1}$ Of -40 Templars examined at Paris between 19th October and 24th November 1307, the experience of some of whom extended over nearly half a century, there is hardly one who did not admit the dishonouring of the crucifix at his reception. $Y$ cry many confessed to other charges, even of the morst description. Clement V., although he suspended the inquisitors' powers on 27 th October (Loiseleur, 159), before the end of the next month Mrote to Edward II. to arrest all the English Templars, who were accordingly seized on 10 th January 1308. About the same time they were arrested in Sicily (24th January) and in Cyprus (27th Mlay). As Clement did not move fast enough, Philip went to Poitiers with 700 armed men, and the pope was at his mercy. It was agreed that the prisoners, their lands, and their money should bo nominally placed in the hands of Clement's commissioners. The power of
the inquisitors was restored (5th July) ; and the property forfeited was to be deroted to the recovery of the Holy Land. Clement now gave orders for fresh diocesan inquiries into the guilt of the Templars. He liad already heard the confessions of seventy-two at Poitiers (29th June to 1st July). The grand-master and the three precepiors were re-examined at Chinon, and renewed their old confessions (20th August). Lastly, the hull Regnans in Colo summoned a great comncil at Vienne for 1st October 1310, when the question of the guilt of the order might be considered. The diocesan councils were only empowered to inquire in to the conduct of individuals.
The trial began on 11th April 1310. On 23d April Reginald de Pruino protested against the unfairness of the proceedings. On Tucsday, 12 th May, fifty-four Templars were burnt by order of the archbishop of Sens, and a few days later four more. Next day the terror spread (19th May). Forty-sin Templars withdrew their defence and the commissioners decided (30th May) to adjourn till November. Tho second examination lasted from 18th December 1310 to 5th June 1311. Neanwhile (c. April 1311) Clement and Plilip had come to terms. The pope condemned the Templars. The council of Vienne met in October 1311. A discussion arose as to whether the Templars shonld be heard in their own defence. Clement, it is said, broke up the session to avoid compliance; and When seven Templars offered themselves as deputies for the defence lee had them cast into prison. Towards the beginning of March Plilip came to Vienne, and he was seated at the pope's right hand Wlien that pontiff delivered his sermon against the Templars (3d April 1312), whose order had just been abolished, not at the gencral council, but in private consistory (22d March). On 2d May 1312 he pulbished the bull Ad Providam, transferring the goods of the society, except for the Kingloms of Castile, Aragon, Portugal, and Majorca, to the linights of St John. The order was never formally pronounced ginilty of the crimes laid to its charge; its aholition was distinctly, in the terms of Clement's bull Considerantes Dudum, "nou per modum definitive sententiæ, cum cam super hoc secundum inquisitiones et processus super his habitos nou possemus fcure de jure sed per vian provisionis et ordinationis apostolicæ" (6th Mlay 1312).

The individual members of the order seem to have been left io the judgment of provincial councils. They were divided into threo classes, - (1) those who confessed at once ; (2) those who persisted in denial of the charges; (3) those who, having confessed at first, withdrew their confessions later on the plea that they had been extracted by torture. The penalties for the three classes were respectively (1) penitence, (2) perpetual imprisonment, (3) death by fire. The cases of the grand-master, the visitor of Frauce, aud the masters of Aquitaine and Normandy were reserved for the pope's decision. Early in 1314 they were forced to make a public confession in Notre Dame, and had already been condemned to perpetual imprisonment when tlie grand-master and the preceptor of Normandy publicly proclaimed their entire innocence. The king, withont consulting the church, had them burnt "in the little island" of the Seine "betreen the Augustinians and the royal garden."

The opinion that the monstrous charges brought against the Questios Templars were false and tho confessions were only extracted'by of their torture is supported by the general results of the investigation (in guilt ur almost every country outside France), as we have them collected in irco. Raynouard, Labbe, and Du Puy. In Castile, where the king flungervea them into prison, they were acquittcd at the conncil of Salamanca. In $A r a g o n$, where they held out for a time in their fortresses against the royal power, the council of Tarragona proclaimed in their favour (4th Norember 1312). In Portugal the commissioners reportod that there were no grounds for accusation. At DIainz the council pronounced the order blameless. At Treves, at Dlcssina, and at Bologna, in Romagna and in Cyprus, they were either acquitted or no evidence was forthconing against them. At the council of Ravenna the question as to whether torture should be used was ansmered in the negatire except by two Dominicans; all the Templars were absolred,-even those who had confessed through fear of torture being pronounced innoeent (18th June 1310). Six Templars were examined at Floreuce, and their evidence is for its length the most remarkable of all that is still extant. Roughly speaking, they confoss with the most elaborate detail to every charge, - even the most loathsome ; and the perusal of their eridence induces a constant suspicion that their answers werc practically dictated to them in the process of the examination or invented by the witnesses themselves. ${ }^{2}$ In England, where perhal ${ }^{3}$ tortura was not used, out of eighty Templars examined only four confessed to the cliarge of denying Christ, and of these four tro were apostate knights. But some English Templars would only guarantee the purity of their omn country. That in England as elsewhere the charges were held to be not absolittely proved scems evident from the form of confession to be used before absolution, in which the Templars acknowledge themselves to be defamed ia the matter of certain articles that they cannot purge themselves. In Enspland nearly all the worst evidence comes at second or thind
hand or through the depositions of Franciscans and Dominicaus, Yet it can hardly be doubted that the "spuitio super crucem" did form a part of the initiation ceremony. Even the English Templars admitted that the statutes of the order were one and the same all the world over ; and there is no setting aside the consistent evidence of almost every French Templar as to his guilt in this matter. Of the other charges the most revolting may have originated in the abuse and misinterpretation of a licence primarily intended for military emergencies. Such at least is the form it aeems to take in the evidence of John Senand (ap. Mich., ii. p. 137). A debased mind might misiuterpret this concession and translato it into coarser words, till (this part of the initiatiou ceremony being probably conducted in private, as, most certainly, was the spitting on the cross) there might be two formularies current in the order, of which the second was plainly immoral, whereas the first was perfectly harmless unless coupled with a sous-entindre. So too with regard to the spuitio. One Templar says plainly that he took it for a joke,-pro trufa; Qthers regarded it as an imitation of St Peter'e denial ; a modern writer has suggested that the custom was intonded ss a symbol of sbsolute obedience (ap. Mich., ii. 260). There is little doubt that most menhers looked upon the ceremony with disgust. Somo salved their consciences by the excuse that they were denyiug Jesus and not Christ ; another when shown the crucifix denied his belief in the painted figure. Nearly all declared that they had spst near hut not upon tho cross, and denied Christ "yon corde sed ose." Den who could thus play with their own consciences at their initiation might well, when their lives were in peril, clothe a falsehood in the garb of truth by denying "spuitio super crucem" instead of confessing to "spuitio juxta crucem."

The other clarges stand upon в somewhat sineilar footing. The power of lay absolution might easily be developed out of the harmless words with which the master or preceptor dismissed his chspter. The cordnle which Templars were accused of wearing in honour of their idol take a very different appearance as the "zones of chastity" or "helt of Nazareth" worn in accordance with St Bernard's precent. With regard to the charge of idolatry the evidence is rery conflictiug. In France and at Florence a large proportion of the members confessed to indecent kissing (oscula inhonesta) at their initiation ; but hardly a single English Templar admitted the charge, and one French witness suggested an almost ludicrous explanation of the rumour. Here also a simple ceremony of respect or humiliation seems to have been expanded into one of shamelessness; but the evidence is too strong to admit of ita being explained away, at least in France.

Not a few witnesses confessed that they had been called upon to declare Christ a felse prophet, who suffered for His own sins and not for the race, and to belitre only in a superior God of the heavens (Deum coli superiorem). One Florence witness admits that the idol was worshipped as God and Saviour. It was this head, according to one of the witnesses, that could make the order rich and cause the earth to hud and the trees to blossom. A Carcassonne Templar spoke of the idol (Raynouard, 241) as a friend of God, who converses with God when be wishes. On such evidence M. Loiselour holds that the Templars were members of a secret religion, which combined the heretical teachings of the Bogomilians and the Luciferians. The former, "the friends of God," believed in a Supreme Deity, whose eldest son Satanael was the creator of our world after bis revolt against his father, and whose younger eon Jesus was made man to counteract the evil deeds of his brother. They did not venerate the cross, regarding it as the instrument of Christ's passion. The Luciferians, on the other hand, worshipped the eldest son, who had power over all the riches of this world. M. Loiseleur. has shown eome remerkable coincidences, verbal and otherwise, between the creed of these two sects and that of the Templars, who, according to him, borrowed from the former their belief in the Supreme Deity and from the latter their devotien to the God of this carth. It seems, however, doubtful whether he is justified in combining the several items of such scattered evidence into a complete doctrinal aystem. His argument might be turned against himself; for, if these heresies were so widely spread in mediæral Europe, are they not for that reason those most likely to be sscribed to an unpopular order?
On the wholo it may perhaps be sdmitted that the charges of "spuitio" and "osculatio inhonesta" were current, st least sporadically, for fifty years before the euppression of the order. ${ }^{1}$ They may have become more gencral in the time of Thomas Beraud, the grand-master (who died 1273 ), according to the evidence of the preceptor of Aquitaine. On the death of William de Beaujeu (1291) there were two rivals for the office of grand-master, - Hugh de Peraud, the visitor of France, हnd James de Molai. The latter in 1291, at a general chepter, had declared his intention of extirpating certain practices in the order of which he did not approve ${ }^{2}$; while, if we may trust the Freach witnesses, the most vigorous initiator according to the new method was Hugh de Persud. This exactly fits in with the sccount ${ }^{3}$ that the errors were introduced after

[^52]Willis.m de Beanjeu'e death. In other words, it is probable that the perty of Hugh de Pcraud between 1290 and 1307 made a desperate effort to enforce the new ceremonies and the new doctrines throughout France and England. The custom of "spuitio," at all.events, was very ancient, and Hugh de Peraud devoted his energies to the propagation of the "osculatio inhonesta." This would explain the omission of all allusion to the latter ceremony when the English Templars were absolved; for they wonld not confess to a practice of which they were innocent. This theory likewise goes a long way towards interpreting both the confession and the denial of James de Molal and the gencral acquittal of the Templars in aearly all the councils outside France.
(T. A. A.)

TEMPLE. The templo is an institution common to religions of natural growth which have reached a certain stage, and in most languages bears a name expressing that it is the bouse or palace erected by men as a habitation for their ${ }^{\text {god }}{ }^{4}$ (Greek, vaós; Hebrew, kēk kel, "place," or beth cilohim, "house of God"; Latin, xdes sacrax). In this conuexion the term "house of God" has quite a different sense from that which we connect with it when we apply. it to a Christian place of worship. A temple is not a meeting-place for worshippers; for many ancient temples were open only to priests, and as a general rule the altar, which was the true place of worship, stood not within the house but before the door. The temple is the dwelling-house of the deity to which it is consecrated, whose presence is marked by a statue or other sacred symbol; and in it his sacred treasures, the gifts and tribute of his worshippers, are kept, under the charge of his attendants or priests. Again, a temple implies a sanctuary; but a sanctuary or holy spot does not necessarily contain a temple. A piece of land may be reserved for the deity without a dwelling-house being erected to him upon it, and a sacred tree, stone, or altar, with the holy precinct surrounding it, may be_recognized as a place where the worshipper can meet his god and present his offerings, although no temple is attached. Indeed the conception of a holy place, separated from profane use, is older than the beginnings of architecture ; and natural objects of worship, such as trees and stones, which need no artificial protection or offcial keeper, are older than images enshrined under roofs and protected by walls and doors. All antique religion is essentially allar-worship (see Sacrifices), and for ritual purposes the altar always continued to be the true centre of the sanctuary. But the altar is only a modification of the sacred stona (comp. PrissT, vol. xix. p. 726), and it has already been obserred that, even in later times, the chief altac of a sanctuary stood outside the tempile. In the oldest and most primitive forms of religion the sacred stone is at once the place where gifts are offered and the material sign of the presence of the deity; thus the temple with its image belongs to a later development, in which the significance of the eacred stone is divided between the altar outside the door and the idol, or its equivalent, within. But in many very ancient sanctuaries the place of a temple is taken by a natural or artificial grotto (e.g, the Phenician Astarte grottoes, the grotto of Cynthus in Delos), or else the temple is built 'orer a subterranean opening (as at Delphi) ; and, while this may be in part explained as connected with the cult of telluric deities, or the worship of the dead, it seems not unreasonable, to think that in their origin care temples may date back to the time when cares were commonly used as human habitations; that the altar in front of the temple had its prototype in altars at the mouths of sacred cares, which wcre approached with holy fear and not entered by ordinary worshippers, and that thus some of the main features of the ancient temple were fixed from the first by the analogy

- Tomplum properly denotes a spot inangarated for the observation of anspices by the augurs. Bnt it Rome most edes sucra were also templa, and so the terms came to be used as bynonymous.
of more primitive sanctuaries. The influence of the cave temple seems at least to be undeniable in that wide pread type of eanctuary in which, besides the court for the worshippers and an outer chamber, there was a dark and mysterious inner room, an adytum or Holy of Holies. This type is-found in Egypt (see Architecture, vol. ii. p. 388 and plate VII.), among the Semites, as in the temple at Jerusalem and in that of Hierapolis (De Dea Syr., § 31), and also among the Greeks and Romans. In Greece the adytum was not a universal feature, though large temples usually had an antechamber as well as the cella or proper chamber of the god. Bnt, where an oracle was given, or mysteries were celebrated, an adytum was always found, and one of its names was $\mu^{\prime}$ ' $\gamma a \rho o v$, which seems to be a transcription of a Semitic word for a cave (meghara). Certain adyta in Greece were actually subterranean; and the association of oracles with caves is well known.

The architectural features and plan of temples in various parts of the world have beon illustrated at length in the article Architecture, and need not detain us here, but somo further notice of the successive temples at Jerusalem is cailed for by the unique interest of the subject, while a glance at the topographical problems connected with this holy site is necessary to supplement the article Jertsalem.

1. The Temple of Solomon.-There were temples among the Hebrews before the time of Solomon, whether private, !like that of Micah (Judges xvii. 5), or public, like that of Shiloh, where the ark was housed for a time (see Tabernacle). In this, as in other matters, the Israelites must have learned from the Canaanites, who had large temples in the time of the Judges. The "hold" (vault?) of the temple of El-Berith at Shechem was tile place of refuge for a thousand men (Judges ix. 46 sq. ), and at Gaza there was a vast temple with a roof supported on two middle pillars (Judges xvi. 29). Solomon's enterprise was not therefore absolutely novel, and in point of size his temple can hardly have surpassed those just mentioned. But his subjects were much behind the Canaanites and Philistines in the constructive arts, and as Solomon had to call in the aid of Tyrian craftsnen it cannot be questioned that the design was derived from Tyrian architecture. The general plan, iudeed, of the house or " palace" (hēkal) of Jehovah, with an adytum (debir, E.V. "oracle"), an outer chamber, and an altar before the door, is, as we have seen, common to many countrics, especially in temples which had an oracle, as was the case with Solomon's temple, built to contain the ark. But all the distinctive features are Plœenician, or at least characteristic of the northern Semites, of whose art the Phoenicians were then the leading exponents. For the general arrangements the temple of Hierapolis (Mabbūg), described by Lucian, offers a complete parallel. Like that of Solomon, it faced the past, and had two celle and a pronaos. The interior was enriched with gold work. Before the door stood a brazen gltar within a walled court. Tho walled court is a constant feature in the Phœenician and Syrian temples, known to us from their remains or from coins, ${ }^{1}$ and the golden decorations, the portico, and the brazen altar appear in the ancient temple of Byblus and in other Phœenician shrines (C.I.S., Nos. 2, 143). The chief motives in the internal decoration of Sclomon's temple were tho palm tree and the cherub. The former is one of the commonest Phonician symbols, and the Phœnician associations of the latter are clear from Ezek. xxviii. The cherub, in fact, is ooly a variety of the sphine, and the way in which the palm and winged animal figures were combined in
[^53]Phoenician decoration is shown in a fragment of alabaster preserved in the Louvre and here figured (fig. 1) after Perrot (op. cit., iii. 131). Two cherubs with outstretched wings stood in the adytum to form a baldachin over the ark. Baldachins over the image or symbol of the deity existed in other temples of the northern Semites (Donaldson, op.cit., pp. 73, 76 sq., 99), and in many Phocnician works of art (e.g., on the stele of Byblus) the figure or symbol of adeity is overshadowed by the winged disk (an Assyrian symbol of godhead) arranged as a sort of
 canopy (Ménant, Glyptique Oriental, ii. 231, 233).
The adytum of the temple was a cube of 20 cubits each way; the outer chamber was of the same breadth, but 40 cubits long and 30 high. ${ }^{2}$ The portico was of the breadth of the main building and 10 cubits deep. That the two chambers were separated by a solid wall and not by a mere wooden partition may be taken as certain if, with Stade, we understand 1 Kings vi. 31 to say that the doorway of the adytum was pentagonal, i.e., that instead of a horizontal lintel a rude arch of two blocks was introduced to distribute the pressure of the superincumbent wall. In this case it is not likely that the exterior walls of the adytum were carried up to a height of 30 cubits, so as to allow of a continuous roof. The reduction of the dimensions to English feet is approximately determined by the Siloam inscription, which gives a round number of 1200 cubits for a measured length of 1760 feet. The Hebrew cubit, therefore, was the short cubit of antiquity, and for practical purposes may be taken as equal to the Greek cubit of 18 inches, used by Josephus for the measurements of Herod's temple. Thus the roof-beams of the temple had a span of 30 feet, a length sufficient to make it probable that the wooden pillars spoken of in 1 Kings x. 12 (comp. 2 Kings xviii. 16) were employed to support them. The roof of the temple at Gaza rested on pillars, as te have seen, and wooden pillars seem to have been used within the temple at Colgus (Cesnola, Cyprus, p. 139), which was smaller than that of Jerusalem. A peculiar feature in Solomen's temple was that all its sides except the front were surrounded by three stories (each 5 cubits high) of small chambers, 5 cubits wide on the ground floor, 6 on the first floor, and 7 on the second, the increasing breadth being evidently got by reducing the thickness of the walls by 1 cubit at each floor. ${ }^{3}$ Thus, allowing for tho walls, the external measurements of the house cannot have been much less than 45 cubits by 90 . The aspect of the façade can only be conjecturally determined. Several Phœenician temples, known from coims, show on their façade a highpitched gable (Byblus, Tripolis), and that of Tripolis has also a flat-roofed wing on each side of the gable and portico, which would answer to the ends of the side chambers in

[^54] text is not slways sound. Cp. Stade'e essay in Z. f. ATliche Wiss., 1883, p. 129 sy.
$s$ In ouch ornañ chambers the winding stair (1 Kings vi. 8) can bardly have been more than a vertical post with footholis nailed to it (Prof. J. H. Middleton).
ear temple. But perhaps the closest analogy to the frontispiece of Solomon's temple is the often-citcd one of the temple at Paphos, of which a representation from a coin is annexed (ng. 2). Here the portico between the side wings is flanked by two slender towers, and in the end of the have above the door there are equare-topped windows. Solomon's iemple had "windows of beams" (or "with horizontal liniels") "framed in," which, as Professor J. H. Middleton observes, is
 naturally explained on the analogy of the windows betreer the beams in the wooden gables of Coptic churches. This is the obvious position of openings for light in buildings the type of which was derived from mooden constructions, and we know that the oldest Phœnician temples were, at least in great part, of wood (Utica; Pliny, H.N., svi. 79 ; comp. Jos., C. Ap., i. 17, 18, and Solomon's house of the forest of Lebanon). That Solomon's temple had towers cannot be proved, for the beight of the porch is not given in Kings, and the 120 eubits of 2 Chron. iii. 4 is obviously an excessive figure, due to a mistake of the writer or of a copyist. But the fact that in Ezekiel's ideal temple the door-posts of the porch are 5 cubits broad unakes the existcnce of slender turrets like those of Paphos un each side of the portal probable. Another feature of Solomon's temple is exactly reproduced at Paphos. On each side of the door the coin shows a fantastic pillar atandinf ${ }^{\text {freee. Solowon erected two such pillars of bronze, }}$ 18 cubits nigh (1 Kings vii. 15 sq .), with capitals of "lily work," i.e., adorned with lotus flowers, like the Phœnician capital from Cyprus figured by Perrot (op. cit., p. 116). Such twin pillars or twin etelæ in stone are of constant occurrence in Phænician sacred art, and are still familiar to us as the Pillars of Hercules. In Solomon's temple both the oracle and the outer cella had folding doors. In the second and third temples the innor door was replaced by a vail ( $p \overline{\mathrm{a}}$ oolheth), and a vail also hung before the outer door (Mal. i. $10 ; 1$ Mac. i. 22 , iจ. $51 ; B . J .$, จ. $5, \S 4$ sq.). The Chronicler ( 2 Chron. iii. 14) introduces a vail in the first temple. This feature also seems to be common to the temple with other Semitic shrines (comp. C.I.S., No. 86, פכ, Assyt. parakku. Syriac prakke, "shrines," and the Kaaba at 1Iecca). ${ }^{\text {I }}$
The temple had an inner court of its own (1 Kings vi. 36), but the outer or great court ( 1 Kings vii, 12) was the court of the palace as well as of the eanctuary. Details as to the position of the courts and buildings must be reserved till we speak of the site, but it may be noticed that Jer. xxxvi. 10 speaks of the "higher court," to which the "nerr gate" of the temple belonged. This new gate io the higher court can hardly be different from the "higher gate" built by Jotham ( 2 Kiugs ET. 35), or from the "higher gate" of Benjamin, which, in Jer. xx. 2, is not the city gate of that name, but a gate "in" (not "by" as E.V.) "the house of the Lord." From jits name this gate must have been on the nerth side or at the aorth-east angle of the temple area, so that the ground rose to the aorth or north-east. The upper court may be merely the upper par" of the great coart ncar the "higher gate" leading to the palace (2 Chron exiii. 20), or may be the same as the "nnw court" of 2 Chron. Ex .5 . But ode capaot be sure that the Chronicler is not transferring to Jehoshaphat's time a nem court of the second temple. We know, however, that the kings of Jadah made from time to time considerablo changes in and about the temple.
2. The Temple of Zerubbabel.-After the captivity an altar of etone took the place of the brazen altar, or rather perhaps of the altar of Ahaz ( 2 Kings xvi. 10 sq .). The altar was erected immediately after the return (Ezra iii.

[^55]2); but the rcbuilding of the temple was long delayed, and the work was not completed till 520 b.c. (see Hagadi). It was much infcrior to the first temple in magnificence, though not perhaps in size (Haggai ii. 3). The proposed breadth of 60 cubits and height of 60 cubits spoken of in Ezra vi. 3 would indeed imply that it was larger than the first temple, but in vier of the testimony of Haggai (loc. cit.) it seems unlikely that these dimensions were realized by Zerubbabel.

The first temple resembled other temples of antiquity in being built to contain a visible symbol of the preseuce of the deity, namely, the ark, which stood in the inner chamber. In the second temple the adytum was empty, but the idea that the Godhead was locally present in it still found expression in the continuance of the altar service, in the table of showbread (a sort of continual lectisternium) that stood in the outer chamber, and above all in the annual ritual of the day of atonement, when the high priest entered the Holy of Holies to sprinkle the blood of the expiatory sacrifice on behalf of the people. Not only in this point but in all others the ritual of the second temple was dominated by the idea of priestly mediation, and the stated sacrifices of the priests on behalf of the people, which replaced the old stated oblations of the kings, became the main feature of the altar service. The first temple was primarily the royal chapel, and the lings did as they pleased in it ; the second temple was the sanctuary of the pricsts, whose chief now became the temporal as well.as the spiritual head of the people. In the time of Ezekiel not only laymen but uncircumcised foreigners entered the sanctuary and acted as servants in the sacred offices (Ezek zliv. 7); in the second temple the laity were anxiously kept at a distance from the holy things, and even part of the court around the altar was fenced off by a barrier, which only the priests were allowed to cross (Joseph., Ant., xiii. 13, §5). Being no longer hemmed in by the royal buildings, as the first templo had been (Ezek xliii. 8), its precincts could be expanded to suit the necessities of the enormous host of ministers of various ranks demanded by the growing complexity of the ritual, which, in matters of music and the like, was immensely developed as time went on (comp. Psalms). Herod's temple, rith the dependent buildings, was a little city enclosed in its own fortifications. But long bcíore his time the temple was a sort of priestly citadel, the fortress as well as the sanctuary of the hierocracy; and the sacred offerings which flowed to Jerusalcm from Jews in all parts of the world were lavishly cxpended on enlarging and strengthening it (Jos.; B.J., v. 5, § I). The name of Simon II. (c. 200 b.c.) is associated in Ecclus. 1. 1 §2. with important works of fortification on the circuit of the temple. Twice ruined in the wars with the Seleucids, these bulwarks were twice rebuilt, by Judas and Jonathan Maccabæus (1 Mac. vi. 7 ; Jos., Ant., xiii. 5, § 11). The works were further strengthened by Simon (1 Mac. ziii. 52), and at the time of Pompey's siege ( 63 b.c.) constitutci an almost impregnable fastness, strengthened on its weakest or northern side by great towers and a deep ditch (Ant., xiv. 4, §2). Twenty-six jears later the temple was again besieged by 'Herod, who, attackitg, like Pompey, from the north, had to force three lines of defence,-the city wall and the outer'and inner temple (Ant., xiv. 16, § 2).
Of tho temple as it was in the Greek or the Hasmonean period we have two descriptions by Hellenistic Jews, Pseudo-A ristrens (comp. Septvaant) and Pecudo-Hecatæus (Jos,., C. Ap, i. 22). 1n such a matter we may auspect even notorious literary fergers of carelessness and exaggeration rather than uf absolute ontrath. Preude Aristras describes the temple as aurrounded by a triple circuit of walls more than 70 cubits high, and as further protected by the adjoining Acra, which overlooked the place of sacrifice Comparing the account of Herod's siege, we may perhaps take the third circuit to be the wall of the town, which is rcpresented as lying below the
temple on the same hill. The upper city ou the western hill is Ignored, which seems to show that the account was written before the Hasmonean period (comp. Jerusalem, vol. xili. p. 641), as has bcen argued on other grounds in Septuagint. The Acra, which is often mentioned in the history of the Maccabee wars, seems to have been on the same site as the Baris or castle of the Hasponean priest-princes, where they put on their priestly robes beforo doing sacrifice (Ant., Xv. 11, 8). That the Baris was close to the temple appears both from this circumstance and from the fact that Antigonus wes charged with setting fire to tho porticoes of the temple during the siege by Herod (Ant., xiv. 16, § 2), -an accusation which woald have had no pleusibility unless the destruction of the porticrea had been useful to isolate the castle. Pseudo-Hecatwus gives the temple precincts a length of 500 feet end a breadth of 100 cubits. The explanation of these numbers will appeer in the sequel.
3. The Temple of Herod.-In the eighteenth year of his reign (20-19 B.c.) Herod the Great began to rebuild the temple and its precincts from the foundation, doubling the old area (Añt., xy. 11; Bell. Jud., i. 21). The works included the reconstruction, on the old site, of the Baris, which now received the name of Antouia, and is generally reckoned by Josephus as forming part of the templo precincts. Apart from the Antonia, the temple area formed a quadrangular plateau supported by retaining walls of great height and strength, and surrounded by porticoes. Three of the porticoes were double walks, 30 cubits broad, with monolith pillars 25 cubits high, and cedar roofs; the fourth or southern portico (the Stoa Basilica) had four rows of Corinthian pillars and three walks, respectively 30,45 , and 30 cubits in breadth. The middle walk was twice the height of the aisles, and the latter were 50 feet high. As regards the size of this enclosure, we sre told by Josephus that the Stoa Basilica was a stadium or 600 feet long (Ant., $5 \mathrm{x} .11, \S 5$ ); and in Ant., sx. $9, \S 7$, the same length is assigned to the castern colonnade, which was known as Solomon's Porch (comp. John x. 23; Acts iii. 11 and v .12 ), because it, and it alone, rested on an ancient snbstructure held to be the work of Solomon. The whole circuit of the porticoes was therefore 4 stadia, ${ }_{1}{ }^{1}$ or with the Antonia 6 stadia (B.J., マ. $\bar{b}, \S 2$ ). The Antonia lay on the north eide (Ant., xv. 11, § 4) and communicated ly stairs with the north and west porticoes at the north-west angle of the enclosure. Fergusson and others suppose that it touched the temple only at this angle, thence stretching porth and west. But in this case the Antonia, which, as wo shall seo below, lay just north of Wilson's arch, would pave been built over the hollow of the Tyropeen valley, a : 1 pposition absurd in itself and inconsistent with B.J., $\nabla$. 5 § 8 , which says that it stood on ac cliff. Again, the tower 70 culits ligh that stood at tho south-east angle of the Antonia overlooked the whole temple, just as we know from Pseudo-Aristrus that the old Acra overlooked the altar. But, if the south-east anglo of the Antonia had been, as Fergusson supposes, at the north-west angle of the temple porticoes, the view from the tower would have been intercepted by the lofty porch in front of the Holy Place. The Antonia, thercfore, had its sonth face along part of the north face of the templo enclosure, and to gain a circuit of 6 stadia for temple and Antonia together we must assign to the latter the length of a stadium from north to south. This is not too mneh, for Josephus describes it as a little town in itself (B.J., v. 5, § 8).

The Antonia, the porticoes, and the space immediately within them (the outer court, or, as modern writers call it, the court of the Gentiles) were not holy ground. But in

[^56]the middle of the enclosure there was a platform rased 15 cubits above the court of the Gentiles and fenced off by a barrier, with inscriptions, one of which still exists (Palestine E. F. Quarterly Statement, 1871, p. 132), forbidding aliens to pass on pain of death. The platform was approached by steps on all sides but the rest (B.J., $\nabla$. $1, \S 5$, and $5, \S 2$ ), and was surrounded by a wall, rising 25 cubits above the iuner level, and pierced by four gates on the north side and as many on the south. On the west there was no gate, but on the east-that is, in front of the fane-there mere two, one within the other, for the eastern end of the platform was walled off to form a separate court for the women, at a somewhat lower level. One of the northern and one of the southern gates belonged to the court of the women, hut it was also entered directly from the east by a very splendid gate of Corinthian brass, much more costly than the others, though they were overlaid with silver and gold. An enormons gate, 40 cubits wids and 50 high (gate Nicanor), connected the women's court with the higher part of the platform, or court of the men of Israel. The beautiful gate of Acts iii. 2 is variously identified with the first or second of these eastern portals. The walls of the platiorm were liued within with chambers, in front of which ran a splendid colonnado; and the gateways were connected with the colonnade by small lofty halls (exedra), which from without had a tower-like aspect. It is doubtful whether all the gates had exedra; but, on the other liand, there was such a hall also at the west end where no gate opened. In the court of the men-i.e., in the upper and western part of the platform just describedstood the fane or temple proper raised tweive steps above the court. For the ground plan of the Holy Place and the Holy of Holies the ancient dimensions of Solomon's temple were preserved, and the external size demanded by the scale of the surroundings was gained by increasing their height, placing a lofty second story above them, making their walls and those of the surrounding chambers (corresponding to the chambers in the first temple) enormously thick, and placing at the front or east end a porch 100 cubits wide and 100 cubits high. The open doorway of this porch was overlaid with gold, as was also the door oi the fane and the wall round it. To the ornament of the entrance belonged also a golden vine with clusters of grapes as lig as a man. In front of the fane beneath the steps was the great altar of stone, 50 (or, according to the Middoth, 32) cubits square and 15 high; it was ascended by a flight of steps from the south. The part of the court round the fane and the altar was fenced off for the use of the priests and other Israelites were admitted only when the sacrincial ititual required the presence of the sacrificc:
Besides the descriptions in Josephus, we have for Herod'e tomple a mass of details and measurements in the Mishnic treatise Middoth. Josephus was himself a priest, whilo the Mishuah nas not written till a century after the destruction of the temple, though it usee traditions that go back to Levites who had served in the temple. The two sources liffer in many measurements, ond the Middoth appears to be possessed of detailed traditions only for the inner temple. The state of the evidence is not such as to allow a plan of the temple to be formed with erchitectural precision. The above account rests alinost entirely on Josephus, who, apart from certain exaggerations in detail, gives a satisfsctory general account, such as could be written from memory without notes and drewings.

Herod's gigantic and costly structures were still in building, forty-six years after their commencement, when our Lord began His ministry (John ii. 20), and the works were not completed till the procuratorship of Albinus (6264 A.D.). In 66 the great revolt against Rome broke out, and in August 70 Jerusalem was taken by Titus and the temple perished in a great conflagration. ${ }^{3}$
${ }^{2}$ On 10 Ab ; but Jewish tradition celebrates $\theta \mathrm{Ab}$ as the day of the destruction of the temple.
4. Topography. - It is not disputed that the site of the temple lay within the great Haram platform (see Jerusalens), now a Moslem holy place, and it is generally agreed also that the south-west corner of that platform is the south-west corner of Herod's outer plateau, parts of the southern and western retaining walls being confidently ascribed by experts to his age. But if Herod's temple (excluding the Antonia) was only 600 feet square it can have occupied but a small part of the Haram area, which measures about 1500 feet from north to south and 922 feet along the south wall. Moreover, the highest part of the hill, where the Dome of the Rock now stands, must have been outside and north of the temple enclosure. But this affords no good reason to doubt the accuracy of Josephus's measurements in a matter in which his memory could hardly fail him, and where his tendency would be rather to exaggerate than to diminish. There is no evidence that the eastern wall of the Haram is as old os Herod, much less as old as Solomon; for the supposed Phœenician letters found on stones belonging to it are not letters at all, and may be of any date. ${ }^{1}$ Moreover, there are various evidences of later building about the east wall of the Haram ; the so-called Golden Gate is certainly a later construction, and Justinian's church rested on now substructures to the south and east (Procopius, De AEd., v. 6), which implies an extension eastward of the old platform. And this is contirmed by the fact that in the neighbourhood of the south-east angle the platform does not rest on sclid substructures such as Josephus speaks of, but on the vaults known as Solomon's stables. Again, though the temple of Solomon lay above the town, there is no evidence that it was on the very top of the hill; on the contrary, buildings of the dimensions given in 1 Kings might have been placed on the hill-top without the need for such great substructures as are spoken of in 1 Kings vii. 10 ; and we have seen in speaking of tho courts of the first temple that the ground appears to have risen to the north, the upper court being on that side. ${ }^{2}$
If we accept the measurements of Josephna we have to bresk mith medieval tradition, both Moslem and Christian, which associates the Sakhre or rock under the dome on the top of the hill with the sacred site of the Jewe. So much weight has been laid on this circlumstance by writers of eminence that it is necessary here to go into some particalars and show that earlier tradition goes quite the other way. It is a Talmudic legend that in the Holy of Holies the place of the logt ark was taken by a stone called the "foundetion stone." Further this stone fras identifed with Jacol's stone at Bethel (comp. Rashi on Gen. xxviii and Breithaupt's notes). Both Mohsmmedans and Christians transferred these legends to the Sakhra, which the former accordingly venerated as "a gate of heaven" (Ibn 'Abd Rabbih, 'Ǐkd, iii. 369). Mohemmeden eourecs enable us to trace back this identificatiou to the Moslem Jew Wahb ibn Monahbih, who enriched Iolam with so many Jowish fables aud died a. contury after Jerusalem was taken by the Arabs (Ts bari, i. 571 sq. ; Ibn al-Fakih, p. 97 sq.). Eutychius, on the other hand, Fho is the first Christian writer to apply the Jewish legend to the Moelom Sakhra, avers that the tradition was communicated to 'Omar by the Christian patriarch Sophronins on the taking of Jerusalem, and guided the caliph in the choics of a site for his mosque. Entychius wrote nearly three bundred years after this ovent ; and, thongh it is known from earlier authorities (Arculphus, Theophanes) that the first Moslem mosque was built on what was pointed out as the site of the temple, it is cqually certain, and was known to Kuty chins himself, that that mosque lay to the south of the Sakhrs (Eutyohius, ii. 289), which was not embraced in thie precincts of the Moslom sanctuary till the reign of "Abd al-Maliks. Who bilit the dome, es an inseription with the dato 691 still testifies (IVid., p. 3 . 355 ). This is confirmed by the excellent Arabian historian Ion Wadih (ii. 311). 'Abd al-Malik's motive was political, as both historians attest ; Mrecca being in the hands of a rival, he resolved to set op

[^57]another place of pilgrimage to eupplant the Kaiba, and recommended it to the faithful as the point from which the Prophet made his miraculous ascent from Jerusalcm to heaven (Ibn Wadib, ut supra). There is nothing of the Jewish legend here; that, as we have seen, Was suppled by Wahb in the neat generation, and on his foundation there grew up a mass of other fables for which it is enough to refer to lbu al-Fakih, p. 93 sq . From all this it may be taken as certain that at the time of "Omar it was towards the seuth.west angle of the Haram, on the site of the original mosque, that tradition eupposed the temple to have stood; indeed Eutychius is guilty of self-contradiction when be first says that Sophrovius indicated the Sakhra to 'Omar as the site on which to build his mosque, and then adds that it was not part of the Moslem sanctuary till a generation later. Finally, the extension of the Haram to the north 80 as to bring the Dome of the Rock in to the centre of the sacred area was the work of 'Abd sl-Malik's son Walid (Eutychius, ii. 373)
Thus far we have met with nothing but confrmation of Josephus's measurements and the site they imply; but there are other topographical indications which supply confirmation more decisive. And first let us compare what is related of the outer gates of Herod's temple with existing remains. On the north was the gate Tadi of the Mishnah, which Josephus mentions only incidentally. This, like the gate Shushan on the east, which he does not mention at all, must have been of minor importance; the chief accesses were necessarily from the lower city to the south and the upper city to the west beyond the Tyropeon valley. The south wall, says Josephus, had gates in the middle (Ant., xv. 11, 5). The Mishnah names them the two gates of Huldah, which may mean "tunnel (weaselhole) gates." There is a double gate in the substructure of the south wall, 350 feet from the south-west angle, and from it a double tunnel leads up to the platform. This double gate exactly fits Josephus's description. There is also a triple gate, 600 feet from the south-west angle, which those who suppose the wall to have been more than 600 feet long regard as the second Huldah gate. But this view does not give us two gates in the middle of the wall, especially as the old wall cannot have enclosed Solomon's stables. Iu the west side the Mishnah places one gate (Kiponus), while Josephus reeognizes four. But these accounts are at once reconciled if we accept Josephus's measurements. For of his four gates the most southerly is necessariiy the one which opened on a flight of steps descending and then reascending across the Tyropeon to the upper city opposite. Now at the south-west corner of the platform there are still remains of a great arch (Robinson's arch), which must have belonged to a bridge connecting the upper city with the south portico of the temple. Thus one of the four gates is fixed. The second gate led to Herod's palace (at the exireme north of the upper city) by means of an embankment crossing the Tyropœon (Ant., xv. 11, § 5). Comparing B. J., ii. 16, § 3, vi. $6, \S 2$, and $\nabla .4, \S 2$, we see that the embankment also carried the city wall (the so-called first wall). Of this approach there are remains at Wilson's arch, 600 feet north of Robinson's arch ${ }^{3}$; thus, if Josephus's measurements are correct, the two westeru accesses were at the extreme ends of the western portico. Josephus's other two gates led to the suburbs outside the first wall, and therefore lay north of Wilson's arch, and were not gates of the temple enclosure proper but of the Antonia, which Josephus habitually reckons as part of the outer temple. ${ }^{4}$ Of them the Mishnah would naturally take no account, and as naturally it would neglect the gate that led to the palace as being not a public entrance. But further,

[^58]according to Josephus's account of the whole circumference of the temple with Antonia, the latter extended a stadium north of the north-west angle of the temple portico, i.e., 600 feet north of Wilson's arch; and, if we measure off this distance on a plan of the rock contours and then draw a line at right angles to represent the north face of the Antonia, we find that this line runs across the narrowest part of the saddle from which the temple bill is assailable. The breadth of the Antonia from east to west cannot have been more than about 300 fcet if, as is to be presumed, the gate Tadi was opposite the twir gates of Huldah; but with this breadth it would entirely cover the dangerous saddle.

Every attempt to reconstruct the area and situation of the temple as it was before Herod must be more or less conjectural, and an analysis of the possibilities would take up so much space that it seems better simply to offer a plan which appears to satisfy the main conditions of the problem.

A. Temple. B, B, B. lnner court. C, C, C. Great court. D, E. Porches of the king's house. F. Palacs of Solomon. G. Great tower of prison court. H. House of the forest of Lelanon. J. Water gate. I. North court. L, L, L. Naw space taken in ly Herod. MNPQ. Herod's enclosure. NP. Solomon's portico. PQ. Stoa Basilica or royal portico. P. Triple gate. Q. Rolinson'e arch. R. Double gate (Huldah gates). M. Wilson's arch.
According to this plan the area of the temple enclosure was doubled by Herod, his additions leing in the parts where the work of leveling up was heaviest, and where neither the convenience of norshippers nor reasons of defence called on earlier builders to extend the plateau. It is certain that the substructures of the south-west angle, raised to a dizzy height above the Tyropeoon, are Herod's (Ant., xr. 11, § 5), and Josephus also speaks of an extension to the north (B.J., v. $5, \frac{8}{} 1$ ). But, on the other hand, the Baris already adjoined the temple, a condition which is satisfied ly giving the older north court K (corresponding to the new court of Chronicles, and perhaps also to the upper court of the frst temple) a length from east to west of 300 feet and a breadth from north to south of 150 . The old east face of the plateau is, as Josephus says, 600 feet long, but this length was gained after the time of Nehemiab by taking in the site of the armoury or house
of the forest of Lebanon (H) and the street in front of the water gate (J). For the proof that the water gate stood at a re-entrant angle between the retaining walls of the armoury aud the palace and faced east as shown in the plan reference must be made to an article in the Journal of Philology (vol. xvi.). The rocky boss between these two walls was in Nehemiah's time surrounded by an outwork, which to the north joined the wall of Ophel,--that is, of the swelling mass of hill which lies out to the northeast (f the palace. From the lower city (south of the Haram area) a stair near the wall led up to the plateau H (Neh. iii. 19 ; xii. 37). The armoury was 150 feet long and 75 broad ; the plan allows the same dimensions for the open space within the water gate. The great court C, C, C is arranged in accordance with 1 Kings vii. 12, in such a way that it is at once the court of the palace and that of the temple, enclosing the inner court B. The dimensions of the inner court are not giren in 1 Kings, but as the temple was twice the size of the tabernacle the court was probably also double the court of the tabernacle. This gives a length of 300 feet and a breadth of 150 , as in the plan. The part of the court in front of the temple is 150 feet squarc, which agrees with the dimensions given in Ezel. xl. 23, 27. The great court is a square of 300 feet. This gives room on the east face for two porches D and E leading to the palace and each 75 feet long. Both porches are described in 1 Kings vii. 6, 8, and the dimensions of one are given. It is also expressly stated that the porch was before (i.e., on the east side of) the pillars that decorated its front, and that it led into the inner court of the palace, so that the arrangement in the plan is fully justified. In the time of Jeremiah (xxxviii. 14) there were three entries from the palace to the temple; the third was probably into the north court, the palace having been extended northwards. It is evident that before the time of Herod the palace had disappeared. It was on a lower level than the temple, and when it was cleared away the great substructures on the line PE stood out as the boundary of Solomon's building. North of E the substructures were less considerable, the rock at the north.end of this porch leing but 20 feet under the present level of the plateau. In Herod's time, as can be seen at Robinson's arch, the level of the plateau was the same as at present ( 2420 feet), but in older times there was a fall between the upper and lower court, and K was probably 10 feet above C, C, C. In that case D was on the natural level of the ground, while (unless the great court was on two levels) E stood on a retaining wall 10 feet high at the north end of the porch and nearly twice as lofty at the south end. The plan shows the temple thrown out on very lofty substructures, so as to be practically inaccessible on all sides and ovcrhang the Tyropœon in the most striking way. ${ }^{1}$ The whole group of buildings formed a complete defence to the city of David on its northern or vulnerable side. It will be observed that in Herod's temple the Huldah gates at $R$ led directly to the altar, the position of which seems never to have been changed, and also that the plan explains the statement of Hecatrus that the temple was 150 feet broad. His length of 500 feet from east to west is 50 feet too much unless he includes some remains of the old palace. The Baris is shown as standing on the south-west corner of the existing platform of the Dome of the Rock.

A word may be said in conclusion on the ancient line of wall to the west of the temple, which, as has been shown from Neh. iii. in the article Jerusalem, ran along the eastern side of the Tyropœon. A bridge connected the temple with the upper city in the time of the later Hasmoneans, and, as the palace (on the site of Herod's palace)

[^59]ard the Baris were the points which it was most important to connect, it no doubt corresponded to the northern bridge already spoken of, at Wilson's arch M. But at that date it must have led, not directly to the temple, but to a lower point on the slope south of the Baris. In Nehemiah's time there was no bridge, but the gate of Ephraim probably corresponded to the east end of the bridge near the southwest angle of the Baris. In that case the wall, as is natural, ran close under the western substructures of the temple and probably served as a buttress to them ia the part of its course south of the gate of Ephraim, which in Neh. xii. 38 is called "the broad wall." The throne of the Persian governor, beside the gate of Ephraim (sco JerusaLEM, vol. xiii. p. 640), stood so close to the Baris that we may conclude that there was alraady a castle on its site, held for the great king. The position assigned to the gate of Ephraim, which, according to 2 Kings xiv. 13, was 600 feet from the corner gate, where the north wall of the city joined the west wall, suits the fact that a line drawn east and west 600 feet north of Wilson's arch coincides with the line of scarped rock marked on the plan. Here, therefore, the old north wall ran, with the great fosse filled up by Pompey. T'his wall figures also in Herod's siege, but seems to have been destroyed by him.
Litcrature. - The Jiterature of the subject is immense. The results of modern surveys and diggings are given in the Palestine Exploration Fund volume on Jerusalem (London, 1884) and in the accompanying Allas. Of other books it may suffice to name $\mathrm{D}_{2}$ Vogué, Le Temple de Jerusalem (fol., Paris, 1864); Fergusson, Topography of Jerusalem (8vo, London, 1847); Id., The Temples of the Jewos (4to, London, 1878) ; Thrupp, Antient Jerusalern (8vo, Cambridge, 1855) ; Lewia, The Siege of Jerusalem by Titus (8vo, London, 1803); and Perrot and Chipiez, Histoire de l'Art (Paris, 1887).
(W. R. S.)

TEMPLE, Sir William (1628-1699), English statesman, diplomatist, and author, was born in London in 1628. He came of an old English family, but of the vounger branch of it, which had for some time been settled in Ireland. He was the eldest son of Sir John Temple, master of the rolls in that country. His mother was Mary Hammond, sister of a well-known Tory divine. Temple received a liberal education, calculated to produce that moderation of judgment for which he was afterwards remarkable. He was first a pupil of his uncle Dr Hammond, after which he went to the grammar-school at Bishop Stortford, and then to the Puritan college of Emmanuel at Cambridge, where he came under the influence of Cudworth. At the commencement of the civil troubles his father embraced the popular causo and was deprived of his office. Coming to England, ho sat in the Long larliaraent as member for Chichester, and was one of the recalcitrant members turned out by Colonel Pride. Before this event happened his son had left Cambridge, without taking a degree, and in 1647 started to travel abroad. In the Isle of Wight, while on his way to France, he fell in with Dorothy Osbornc, and won her affections. Her father, Sir Peter Osborne, was governor of Guernscy and a Royalist. Her family were naturally opposed to the match, and threw difficulties in the way, which hindered its consummation for seven years. During this period Temple travelled in France, Spain, Holikad, and other countries, gaining knowledge of the world and kecping up a constant correspondence with his betrothed. At length, apparently in 1654 , the difficulties were surmounted and the marriage took place. In 1655 Temple and his wife went to Ireland. The next five years were spent in the house of Sir John Temple, who had made his peace with Cromwell, and had resumed his official position. His son took no part in politics, but lived the lifo of a student and a country gentleman.

The accession of Charles II. rescued Temple, like many others, from obscurity. In 1600 he sat in the conventiou
parliament at Dublin as member for Carlow, and he represented the samo county along with his father in the regular parliament that followed. After a short visit to England in 1661, as commissioner from the Irish parlia ment, he finally removed thither in 1663 . There he attached himself to Arlington, secretary of state, and two years later received his first employment abroad. It was in March 1665 that the disastrous war with the United Netherlands began. Charles II. was anzious to obtain allies, especially as Louis XIV. was taking up a hostile attitude. At this juncture the bishop of Münster sent an envoy to England, offering to attack the Dutch if the English Government would supply the means. Temple was sent over to negotiate a treaty, and in this business gavo evidence not only of the diplomatic skill but of the peculiar candour and frankness for which he was afterwards so distinguished. He was successful in making the treaty, but it was rendered ineffectual by the declaration of war by France, the threats of Louis, and the doubledealing of the prelate, who, after recciving a great part of the subsidy, made a separate peace with the Netherlands. As a reward for his services Temple was created a baronet, and in October 1665 became the English representative at the viceregal court at Brussels. While the war continued, Temple's duties consisted chiefly in cultivating good relations with Spain, which was a neutral in the quarrel between England and the Dutch, but was threatened by the claims of Louis XIV. on the Spanish Netherlands. Louis's designs became apparent in the apring of 1667, when he marched an army into Flanders. This event was one of those which led to the peace of Breda, and to the subsequent negotiations, which are Temple's chief title to fame. The French conquests were made at the expense of Spain, but were almost equally dangerous to the United Netherlands, whose independence would have been forfeited had Louis succeeded in annexing Flanders. Whilo the French were taking town after town, Temple made a journey into Holland and visited De Witt. The friendship established and the community of views discovered during this interview facilitated the subsequent negotiations. Templo had for some time pressed on his Government the necessity of stopping the French advance, and had pointed out the way to do so, but it was not till Decomber 1667 that he received instructions to act as he had suggested. He at once set out for The Hague, and in January 1668 a treaty was made between England and the United Netherlands, which, being joined shortly afterwards by Sweden, became known as the Triple Alliance. It was a defensive treaty, made against the encroachments of France. Whether we regard the skill and celerity with which tho negotiations were conducted or the results of the treaty, the transaction reflects great credit on Temple. The French king was checked in midcareer, and, without a blow being struck, was obliged to surrender almost all his conquests. Pepys records puhlic opinion on the treaty by saying that it was "the only good public thing that hath been done since the kin's came into England."

Unfortunately the policy thus indicated was but shortlived. In taking up a hostile attitude towards France Charles's object had apparently been only to raise his price. Louis took the hint, increased his offers, and two years later the secret trcaty of Dover reversed the policy of the Triple Alliance. Meanwhile Temple had developed the good understanding with the Dutch by contracting a commercial treaty with them (February 1668), and had acted as English plenipotentiary at Aix la-Chapelle, where peace between France and Spain was made in May 1668. Shortly afterwards he was approinted arobassador at The Eague. Ifere the livel for two years on qood terms both with De

Witt and with the young, prince of Orange, afterwards William III. The treaty of Dover led to Temple's recall; but the plot was not jet ripe, and Temple nominally held his post for another year. He perceired, however, that his day was over and retired to his house at Sheen. In June 1671 he received his formal dismissal. The war with the Netherlands broke out next year, and was alrnost as discreditable to England as that of 1665. Want of success and the growing strength of the opposition in parliament forced Charles to make peace, and Temple was brought out of his retirement to carry through the change of front. After a negotiation of three days, carried on through the medium of the Spanish ambassador, the treaty of TWestminster was made (February 1674). As a recognition of his services Tenple was now offered the ennbassy to Spain. This he declined, as well as the offer of a far more important post, that of secretary of state, but accepted instead a renewal of his embasiy to The Hague, whither he went in July 1674. In the March following he was nominated ambassador to the congress at Nimeguen; but, owing to the tortuousness of Charles's dealings, it was not till July 1676 that he entered that town. The negotiations dragged on for two yeais longer, for Charles was still receiving money from France, and English mediation was no more than a ruse. In the summer of 1677 Temple was summoned to England and received a second offer of the secretaryship of state, which he again declined. In the autumn of the same year he had the satisfaction of removing the last difficulties which hindered the marriage of Willian and Mary, an event which seemed to complete the work of 1668 and 1674 . Louis still remaining obstinate in his demands, Teuple was comnissioned in July 1678 to make an alliance with the states, with the object of compelling France to come to terms. This treaty was instrumental in bringing about the general pacification which was concluded in January 1679.
This was Temple's last appearance in the field of diplomacy; but his public life was not yet over. A third offer of the secretaryship was made to him; but, unwilling as ever to mix himself up with faction and intrigue, he again declined. He did not, however, withdraw from politics ; on the contrary, he was for a short tine niore prominent than ever. The state was passing through a grave crisis. Political passion was embittered by religious fanaticism. Parliament was agitated by the popish plot, and was pressing on the Exclusion Bill. The root of all the mischief lay in the irresponsibility of the cabinet to parliament and its complete subservience to the crown. To remedy this, Temple brought forward his plan for a reform of the privy council. This bods was to consist of thirty members, half of whom were to be the chief officers of the crown, the other half being persons of importance, lords and commoners, chosen without reference to party, Special care was taken to selcct men of wealth, which Temple considered as the chief source of political influence. By the advice of this council the king promised to act. The parliament, it was supposed, would trust such a body, and would cease to dictate to the crown. The scheme was accepted by the king, but was a failure from the outset. Intended to combine the advantages of a parliament and a council, it created a board which nas neither the one nor the other. The conduct of affairs fell at once into the hands of a junta of four, of whom Temple was at first one, and the king violated his promise by dissolving parliament without asking the advice of the council. Temple retired in disgust to his villa at Sheen, and appeared only occasionally at the council, where he soon ceased to exercise any influence. In 1680 he was nominated ambassador to Spain, but stayed in England in order to take his seat in parlizment as member for the university of Cambridge.

He took no part in the dehates on the great question of the day, and acting on the king's advice declined to sit in the parliament of 1681. Early in that year his name was struck off the list of the council, and henceforward he disappeared from public life. He continued to live at Sheen till 1686, when he handed over his estate there to his son, the only survivor of seven children, and retired to Moor Park in Surrey. When William III. came to the throne Temple was pressed to take office, but refused. His son becamo secretary at war, but committed suicide immediately after"ards. Sir Willian, though occasionally consulted by the king, took no further part in public affairs, but occupied himself in literature, gardening, and other pursuits. It should not be omitted that Swift lived with him as secretary during the last ten years (with one short interval) of his life. Temple died at Moor Park on 27th January 1699.

Templo's literary works are mostly political, and are of considerable inportance. Among them may be mentioned An Essay ons the Present State and Seltlement of Sreland (1668); The Empirc, Siveden, \&ic., a survey of the different Governments of Europe and their relations to England (1671); Observations upon the Uniled Provinces (1672); Essay upon the Original and Nature of Government (16:2); Essay upon the Advancement of Trade in Ireland (1673). Some of these were published in the first part of his 3 liscellanea (1679). In the samo year apparently his Poems were privately printed. In 1683 he hegan to write his Menoirs. The first part, extending from 1665 to 1671, he destroyed unpublished; tho second, from 1672 to 10 ór9, was published without lisa authority in 1691 ; the third, from 1679 to 1681 , was published by Swift in 1709. In 1692 he published the second part of his Miscellanea, containing annong other subjects the essay Upon the Ancient and Afodern Leurning, which is remarkable only as having giren rise to the famous controversy on the "Letters of Phalaris." His Introduction to the Hislory of England, a short sketch of English history to 1087, was published in 1695. Several collections of his letters were published by Swift and others after his deatl.

His fame rests, however, far more on his diplomatic triumplis than on his literary work. His connexion with domestic affairs was slight and unsuccessful. He was debarred both by his virtues and his defects, -hy his impartiality, his honesty, and his want of ambition,-from taking an active part in the disgraceful politics of his time. But in the foreign relations of his country he was intimately concerned for a period of fourteen years, and in all that is praiservarthy in them ho had a principal hand. He cannot be called great, but he will be remembered as one of the ablest negotiators that England has produced, and as a public servant who, in an unprincipled age and in circumstances peculiarly ofeu to corruption, preserved a blamcless record.

See Live and Works of Sir Mrilliam Temple, 2 vols. fol., 1720; 2 d ed., with Lifo by Laly Giffard, 1731 ; a more completo edition, including the Lellers, was published in 4 vols. 8vo, 1814 : Burnet, History of his own Time; Courtenay, Memoirs of the Life, \&c., of Sir IFilliant Temple, 2 vols., $1 \$ 30$; Macsulay, Essay on Sic William Temple.

## TENAN'T. See Landlord and Tenant.

TENASSERIM, a division of the province of British Burmah, lying between $9^{\circ} 30^{\prime}$ and $19^{\circ} 30^{\prime}$ N. lat. and $95^{\circ} 50^{\prime}$ and $99^{\circ} 30^{\prime}$ E. long. It has an area of 46,730 square miles and comprises the seven districts of Moulmein town, Amherst, Tavoy, Mergui, Shwagyin, Toungoo, and Salvin, which formed the tract south of Pegu conquered from Burmah in 1826, and were for many years generally known as the Teuasserim provinces. The southern extremity of the division approaches the insular region of Malaysia, and it is fringed along its entire western coast by a number of islands, forming in the north the Moscos and in the south the Mergui Archipelago. The eastern frontier is formed by a mountain range 5000 feet high, which acts as a water-parting between the Tenasserim and the Siamese river systems.

The population of the dirision in 1881 was 825,741 (437,900 males and 387,841 females). By religion Hindus numbered 23,145, Mohanmedans 24,786, Christiana 28,315, Budhhists 698,304 , and Nat warshippers 51,160. The cultived area in 1885-86 waa returned at 729,251 acres. The gross revenue in the same year mas $£ 184, \geq 62$, of which the land-tax yielded $£ 107,631$.
TENBY, a municipal and parliamentary borough aisi watering-place of Pembrokeshire, South Wales, is fine! situated on a long and narrow promontory of limestone rock, wathud on three sides by the sea, on the west side of

Carmarthen Bay, and on a branch of the South Tales Railway, 10 miles east of Pembroke and 274 west of London (by rail). Its chief attractions as a watering-place are its picturesque appearance, its antiquarian remains, its equable and salubrious climate, and its wide stretch of firm sands." There are considerable remains of the old fortifications of the town, dating originally from the Norman Conquest, and repaired by Elizabeth, whose initials with the date 1588 are inscribed on a stone near the fine south-west gate, which with the south-west and north-west walls is in very good preservation. The remains of the castle on a lofty rock at the extremity of the promontory include the keep, a circular bastion overhanging the cliffs, and portions of the outer wall. Within the grounds, which are laid out in walks, there is a local museum; and on the summit of the hill is the Welsh memorial to the Prince Consort, a statue of Sicilian marble (1865). Opposite the castle, about 100 yards distant and accessible on foot at low water, is St Catherine's Island, on which is a strong fort begun in 1868 , forming one of the land defences of Pembroke dockyard. The parish church of St Mary is a large and beautiful building, showing every variety of style from the Norman of the 12 th to the Tudor of the late 16 th century; it has a massive tower with a spirerising to a height of 15,2 feet. In the north aisle are some medirval altar tombs and in the south aisle one of the early Tudor period. The fisheries of Tenby, for which the place was noted at a very early period, are still of importance. The trade of the port is inconsiderable. Steamers, however, ply to Bristol, Cardiff, Ilfracombe, and Weston-superMare. In the neighbourhood there are extensive limestone quarries. The population of the municipal and parliamentary borough (area 640 acres) in 1871 was 3810 , and in 1881 it was. 4750 . In summer it is augmented by more than a half.

Tenby has the same derivation as Denbigh in North Weles. Anciently it was called Dynbych-y-Pyocod, the "precipice of fishes." The importance of the town dates from the eettlement of the Flemings in the reiga of Henry I. In 1150 Cadell, eldest oon of Rhys ab Gryffith, was slain by the people of Tenby, in revenge for which the castle was taken and the town derastated by his two brothers Meredith and Rhys. During the Wars of the Roses the fortifications were restored and streugthened by Jaspar, earl of Pembroke. They were again greatly strengthened by Elizabeth in apprehension of the landing of the Spaniards. At the beginning of the Civil War the town and castle were garrisoned for the king, but in 1644 it surrendered to the Parliamentarians after a viege of three days. Its privileges were extended by Hanphrey, duke of Gloucester, who made the maygr on independent justice, and by Henry IV., Henry VI., Elizabeth, and Charles I. It is now governed by the Municipal Act, and the corporation are the sanitary euthority. Since the 27th of Henry VIII. it has formed part of the Pembroke district of boroughs for parliementary representation.

TENCH, the Tinca tinca of naturalists, is one of the commonest and most widely spread freshwater fishes of Europe. It is generally distributed in ail suitable localities throughout England, but is limited to a few lakes and ponds in the south of Scotland and in Ireland. As the tench is of comparatively uncommon occurrence in unenclosed waters, its place among the indigenous fishes of Great Britain has been denied, and it has been supposed to have been introduced from the Continent. In central Europe, however, where it is undoubtedly indigenous, it thrives best in enclosed, preserved waters, with a clayey or muddy bottom and with an abundant vegetation; it avoids clear waters with stony ground, and is altogether absent from rapid streams. The tench belongs to the family of carps (Cyprinidx), and is distinguished from the other members of that family by its very small scales, which are deeply embedded in a thick skin, whose surface is as slippery as that of an eel. All the fins hare a rounded outline; the short dorsal fin is without a spine, but the
males possess a rery thick and flattened outer ray in tne ventral fins. The mouth is rather narrow and provided at each corner with a very small barbel. Tench if kept in suitable waters are extremely prolific, and as they grow within a few years to a weight of 3 or 4 Bb , and are then fit for the table, they may be profitably introduced

Tench (Tinea linca).
into ponds which are already stocked with other fishes, such as carp and pike. They live on small animals or soft vegetable substances, which they root up from the ground. The albino variety especially, which is known as the "golden tench," can be recommended for ornamental waters, as its bright orange colours render it visible for some distance below the surface of the water. This variety, which seems to have been originally bred in Silesia, is not less wellflavoured than the normally coloured tench, and grows to the same size, viz., to 6 and even 8 焐.

## TENDER. See Pafment.

TENERIFFE. See Canary Islands, vol. iv. p. 798.
TENIERS, David (1610-1690), the jounger, a Flemish painter, almost ranking in celebrity with Rubens and Van Dyck, was born in Antwerp on 15 th December 1610. His father, David Teniers the elder (1582-1649), whose style he followed with a vastly superior power of conception, had been a pupil of Elsheimer in Rome and of Rubens in Antwerp. Besides these influences, we can also distinctly trace that of Adrian Brouwer at the outset of his career. Although the young painter's general system of ten reminds us of Rubens, several of his works also betray a vivid recollection of Brouwer in type as well as general arrangement. There is no evidence, however, that either Rubens or Brouwer interfered in any way with Teniers's cducation, and Smith may be correct in supposing that the admiration which Brouwer's pictures at one time excited alone tempted the younger artist to imitate them. The only trace of personal relations having existed between Teniers and Rubens is the fact that the ward of the latter, Anne Breughel, the daughter of John (Velvet) Breughel, married Teniers in 1637. Admitted as a "master" in the guild of St Luke in 1632, Teniers had even before this made the public acquainted with his works. The Berlin museum possesses a group of ladies and gentlemen dated 1630. No special signature positively distinguishes these first productions from those of his father, and we do not think it correct to admit with some writers that he first painted religious subjects. Dr Bode, in a most remarkable study of Brouwer and his works, expresses the opinion that Teniers's earliest pictures are those found under the signature "Tenier" (with the omission of the final $s$ ). Tenier is in reality a. Flemish version of a thoroughly Walloon name, "Taisnier," which the painter's grandfather, a mercer, brought with him when he came from Ath in 1558, and Bode's supposition is greatly strengthened by the circumstance that not only David the elder but his brothor Abraham and his four sons were all inscribed as "Tenier" in the ledgers of the Antwerp guild of St Luke. Some really first-rate works-the Prodigal Son and a group of Topers in the Munich gallery, as well as a party of gentlemen and ladies at dinner, termed the Five Senses ia tha

Brussels museum - with the abore signature are remarkable instances of the perfection attained by the artist when be may be supposed to have been scarcely twenty. His touch is of the rarest delicacy, his colour st once gay and barmonious. Both Tragen and Smith express the opinion that the works painted from 1645 to 1650 speak most righly of the master's alilitics. We may venture to add that a considerable number of earlier productions would have been sufficient to immortalize his name. He was little over thirty when the Antwerp guild of St George enabled him to psint the marvellous pitture which ultimately found its way to the Hernitage Gallery in St Petersburg, -the Jubilee Meeting of the Civic Guards, in honour of their old commander, Godfrey Sneyders. Correct to the minutest detail, yet striking in effect, the scene, under the rays of a glorious sunshine, displays an astonishing amount of acquired knowledge and natural good taste. This painting, one of forty among many of the master's earlier and Later productions, ${ }^{1}$ leads us to mention another work of the same year (1643), now in the National Gallery, London (No. 952), an equally leautiful repetition of which, dated 1646, belongs to the duke of Bedford. A hundied and fifty figures are resting after a pilgrimage to some holy shrine or some miraculous well. The hungry travellers are waiting for the meal which is leing prepared for them in several hrage caldrons. Truth in physiognomy, distribution of groups, the beantifnl effect of light and shade, command our warmest admiration. A work like this, says Waagen, stamps its author as the greatest among painters of his class. That, however, a subject of the kind should have becn accepted as a "feast" (see the National Gallery Catalogue) may tend to prove how little, from the first, Teniers thought of dramatizing. Frankness in expression snd freedom in attitude certainly guided his preference in the choice of a model, and we may even suppose him to have occasionally exaggerated both. He seems anxious to have it known that, far from indulging in the coarse amusements of the boors he is fond of painting, he himself lives in good style, looks like a gentleman, and behaves as such. He never secms tired of showing the turrets of his chateau of Perck, and in the midst of rustic merry-makings we often see his family and himself received cap in hand by the joyous peasants. We may also observe that he has a certain number of farourite models, the constant recurrence of which is a special feature of his works. We even meet them in a series of life-size portrait-like figures in the Doria Pamphili Gallery in Rome, ${ }^{2}$ as well as in a picture belonging to Mr H. R. Hughes, and the man here represented as a fishmonger is unmistskably the painter's brother, Abraham Teniers, judging from the portrait Edelinck has left us of this artist.

Teniers was chosen ly the common council of Autwerp to preside over the guild of painters in 1644. 'The archduke Leopold $\Pi$ illiam, who had assumed the government of the Spanish Netherlands, being a great lover of art, employed Teniers not ouly as a painter but as keeper of the collection of pictures he was then forming. With the rank and title of "syyuds de camara," Teniers took up his abode in Brussels shortly after 1647. Lmmense sums were spent in the scquisition of paintings for the archduke. A number of valuable works of the Italisn masters, now in the Belvedere in Vienna, came from Leopold's galle, y after Laving belonged to Charles I and the duke of Buckingham. De Bie (1661) states that Teniers was some time in London, collecting pictures for the duke of Fuensaldaña, then acting as Leopold's lieutenant in the Netherlaede. Psintings in

[^60]Madrid, Munich, Vienna, and Brussels have enabled art critics to form an opinion of what the imperial residence was at the time of Leopold, who is represented as conducted by Teniers and admiring some recent acquisition. No picture in the gallery is omitted, every one being inscribed with a number and the name of its author, so that the ensemble of these paintings might serve as an illustrated inventory of the collection. ${ }^{8}$ Still more interesting is a canras, now in the Munich gallery, where we see Teniers at work in a room of the palace, with an old peasant as a model and several gentlemen looking on. When Leopold returned to Vienna, Teniers's task ceased; in fact, the pictures also travelled to Austria, and a Flemish priest, himself a first-rate flower painter, Van der Baren, became keeper of the archducsl gallery. Teniers nevertheless remained in high favour with the new governorgeneral, Don Juan, a natural son of Philip IV. The prince was his pupil, and De Bie tells us he took the likeness of the paiuter's son. Honoured as one of the greatest painters in Europe, Teniers seens to have made himself extremely miserable through his aristocrstic leanings. Shortly after the death of his wife in 1656 he married Isabelia de Fren, daughter of the secretary of the council of Brabsnt, snd strove his utmost to prove his right to armorial bearings. In a petition to the king he reminded him that the honour of knighthood had been bestowed upon Rubens and Van Dyck. The king at last declared his readiness to grant the reqnest, but on the express condition that Teniers should give up selling his pictures. The condition was not complied with ; but it may perhaps account for the master's activity in fasour of the foundation in Antwerp of an academy of fine arts to which artists alone should be sdmitted, inhereas the venersble guild of. St Luke made no difference between art and handicraft : carvers, gilders, bookbinders, stood on an even footing with painters and sculptors, however great their talent. ${ }^{4}$ There were great rejoicings in Antwerp when, on 26th January 1663, Teniers came from Brussels with the royal charter of the scedemy, the existence of which was due entirely to his personal initiative.

Teniers died in Brussels on 25th April 1690.5 A picture in the Munich gallery (No. 906), dated 1680, represents him as an alchemist, oppressed with a burden of age bey ond his years. From this date we hear more of his doings as a picture-dealer than as a painter, which most probably gave birth to the legend of his having given himself out as deceased in order to get higher prices for his works. David, his eldest son, a painter of talent and reputation, died in 1685. One of this third Teniers's pictures-St Dominic Kneeling before the Blessed Virgin, dated 1666 - is still to be found in the church at Perck. As well as his father, he contriluted many patterns to the celobrsted Brussels tapestry looms. Cornelis, the painter's daughter, married John Ersamus Quellin, a well-known artist (1634-1715).
Smith's Catalogue Raisonne gives descriptions of over 700 paintings eccepted es original productions of Teniers. Few artists ever worked with greater ease, and eome of his emaller pictures-landgcapes with figures-have been termed "afternoons." not from their subjecta, but from the time spent in producing them. The museums in Madrid, St Petersburg, Tienna. Mnnich. Dresden. Paris, London, and Brusele have more than 200 pictures hy Teniera In the United Kingdom 150 masy be found in privare hands sud many of her examples are to be met with in private collectiono throughout Europe. Although the apirit of many of these works

[^61]is as a whole marrellous, their conscientiousness must be regarded as questionable. Especially in the later productions we often detect a lack of earnestness and of the calm and concentrated study of nature which alone prevent expression from degenerating into grimace in situations like those generally depicted by Teniers. His education, and still more his real and assumed position in society, to a great degree account for this. Brouwer knew moro of taverns; Oatade was more thoroughly at home in cottages and humble dwellings; Teniers throughout triumphs in broad daylight, and, though many of hia interiors may be justly termed masterpieces, they acldom equal his open-air acencs, where he has, without constraint, given full play to the bright resources of his luminous palettc. In this respect, as in many others, he almost invariably suggests comparisons with Watteau. Equally sparkling and equally joyous, both seem to live in an almost ideal world, where toil, disease, and poverty may exist, but to be acon forgotteu, and where sunshine seems everlasting. But his subjects taken from the Gospels or sacred legend are absurd. An admirable picture in the Lourre showa Peter Denying his Master, next to a table where soldiers sre smoking and having a game at cards, He likes going back to aubjects illustrated two centuries before by Jerome Basch-the Temptation of St Anthons, the Rich Man in Hell, incantations, and witches-for the simple purpose of assembling the most comic apparitions. His villagers drink, play bowle, dance, and sing; they seldam quarrel or fight, and, if they do, seen to be shamming. His powers certainly declined with adrancing age; the works of 1654 begin to look hasty. But this much may bo said of Teniers, thst no other painter ahows a more enviable ability to render a conception to his own and other people's satisfaction. His works Lave a technical freshness, a straightforwardness in means and intent, which make the study of therm most delightful; as Sir Joshua Reynolds says, they are worthy of the closest attention of any painter who desires to excel in the mechanical knowledge of his art.

As an etcher Teniers compares very unfavourably with Ostade, Cornelis, Bega, and Dusart. More than 500 platesavere made from his pictures; and, if it be true that Louis XIV. judged his "baboons" (magots) unworthy of a place in the royal collections, they found admirable engravers in France - Le Bas and his scholars-and passionate admirers. The duke of Bedford's admirable specimen was sold for 18,030 livres ( $£ 1860$ ) in 1768. The Prodigal Son, now in the Louvre, fetched 30,000 livres ( $£ 3095$ ) in 1776. Smith's highest estimates have long sinco been greatly exceeded. The Archers in St Petersburg he gives as warth £2000. The Belgian Government gave $£ 5000$ in 1867 for the Village Pastoral of 1652 , which is now in the Brussels museum; and a picture of the Prodigal Son, scarcely 16 by 28 inches, fetched $£ 5280$ in 1876.

Although Van Tilborgh, who was a scholar of Teniers in Brnssels, follorred his style with aome auccess, and later painters often excelled in figure-painting on a small scale, Tenicrs cannot be said to have formed a school. Properly speaking, he is the last representative of the great Flemish traditions of the 17th century.

TEnimber. See Timor Ladt.
TENISON, Thomas (1636-1715), archbishop of Canterbury, was the son of Rev. John Tenison, rector of Mundsley, Norfolk, by Mary, daughter of Thomas Dowson of Cottenham, Cambridgeshire, where he was born on 29th September 1636. He was educated at the free school, Norwich, whence he entered Corpus Christi College, Camhridge, as a scholar on Archbishop Parker's foundation. He graduated B.A. in 1657, M.A. in 1660 , was chosen fellow in 1662, and became B.D. in 1667. For a short time be studied medicine, but in 1659 was privately ordained. In 1667 he was presented to the living of Holywell-cumNeedingworth, Huntingdonshire, by the earl of Manchester, to whose son he had been tutor, and in 1670 to that of St Peter's Mancroft, Norwich. In 1680 he received the degree of D.D., and was presented by Charles II. to the important cure of Sc Martin's-in-the-Fields. Tenison, according to Burnet, "endowed schools, set up a public library, and kept many curates to assist kim in his indefatigable labours." Being a strenuous opponent of the Church of Rome, and "Whitehall lying within that parish, be stood as in the front of the battle all King James's reign."

In 1678, in a Discourse of Idolatry, he had endeavoured to fasten the practices of heathenish idolatry on the Church of Rome, and in a sermon which be published in 1681 on Discretion in Giving Alins was attacked by Andrew Pulton, head of the Jesuits in the Savoy. Tenison's reputation as an enemy of Catholicism led the duke of Monmouth to send for him before bis cxecution in 1685, when Bishops Kcn and Turner refused to administer the Eucharist ; but, although Tenison spoke to him in ".a softer and less peremptory manner" than the two bishops, he was, like them, not satisfied with the sufficiency of Monmouth's penitence. Under William, Tenison was in 1689 named a member of the ecclesiastical commission appointed to prepare matters towards a reconciliation of the Dissenters, the revision of the liturgy being specially entrusted to him. A sermon which he preached on the commission was published the samo year. He appears to have been better satisfied with the religious sentiments of Nell Gwynn on the approach of death than with those of the duke of Monmouth, for in 1691 he preached her funeral sermon, in which he rcpresented her as truly penitent, - a charitable judgment which did not meet with universai approval. The general liberality of Tenison's religious views commended him to the favour of William, and, after being made bishop of Lincoln in 1691, he was promoted to the primacy in December 1694. He attended Mary during her last illness and preached her funeral sermon.in Westminster Abbey. When William in 1695 went to take command of the army in the Netherlands, Tevison was appointed one of the seven lords justices to whom his authority was delegated. Along with Burnet he attended Willian on his deathbed, and it was from their hands that he received the Eucharist. He crowned Queen Anne, but during her reign was not in much favour at court. He was a commissioner for the Union in 1706. A strong supporter of the Hanoverian succession, he was one of the three officers of state to whom on the death of Anne was entrusted the duty of appointing a regent till the arrival of George I., whom be crowned on 31st October 1714. Tenison died at London on 14 th December of the following year. Besides the sermons and tracts above mentioned, and various others on different points of the Popish controversy, Tenison was the author of The Creed of $M r$ Hobbes examined (1670) and Baconia, or Certain Genuine Remains of Lord Bacon (1679).
The Memoirs of the Life and Times of the Most Rev. Futher in God, Dr Thomas Tenison, late Archbishop of Canterbury, appeared without date not long after his death. See also Burnet's History of his own Time and Macaulay's History of England.

TENNANT, William (1784-1848), author of Anster Fair, was born in 1781 at Anstruther in Fifeshire, the birthplace of two other contemporary Scottish worthies, Thomas Chalmers and John Goodsir. He was lame from childhood, like his more famous contemporaries Byron and Scott, and this probably determined his father, who was a smali merchant and farmer, to educate him for a scto'arly career. But the paternal means failed before he had completed his curriculum at St Andrews, and he was obliged to return home and act for some eight years of his carly manhood as clerk to ono of his brothers, a corn-factor. The corn-factor's clerk, homever, under the impulse of a genius for language and a strong delight in literatur, besides Greek and Latin and Hebrew, mastered, during his leisure, Italian and German, and not only read, but set himself to imitate, Ariosto and Wieland. And, strange to say, this poor youth, in a remote country town, anticipated the fashion of mock-heroic verse, which was set for England by "the ingenious brothers Whistlecraft," and which gave Byron the hint for his Don Juan. Anster Fair, a fantastic poem in ollava rima, amazingly fluent, brimming over with
high spirits, rich almost to excess in diction and fanciful imagery, was written by Tennant in 1811, when his brother's business had failed and he did not know where to look for employment. Its publication in 1812 brought the poct into notice, and employment was found for him as schoolmaster of the parish of Dinino, near St Andrews. From this he was promoted ( 188 3) to the school of Lasswade, near Edinburgh; from that (1819) to a mastership in Dollar academy; from that (1831), by Lord Jeffrey, who had written an admiring review of Anster Fair, to the professorship of Oriental languages in St Andrews. Tencant never fulfilled the promise of his first poem, which reads as if it bad been dashed off in a fit of careless and happy inspiration, and never flags in its humorous glee from the first stanza to the last. The Thane of Fife (1822), in which he essayed the same vein, evidently cost him more pains, shows the same high reach of humorous imagination, and is indeed, as he claimed for it, "bold in its style and rare, fantastic, and sublime." But the subject was more remote from general interest; the mock-epic machinery, with all his wealth of grotesque description, was too far-fetched for the popular taste; and the poem fell flat. A third poem, in the Scatch dialect, Papistry Stormed (1827), though full of the most spirited description, was also in a vein of humour that found few sympathizers. He wrote also two historical dramas, Cardinal Beaton (1823) and John Baliol (1825). His last published work was a series of Hebrevo Dramas (1845), founded on incidents in Bible history. He died near Dollar, on 15th Tebriary 1848.
$\Delta$ Memoir of Tennant by M. F. Conolly was pablished in 1861.
TENNENT, Sir James Eyerson (1794-1869), English politician and traveller, the third son of William Emerson, a merchant of Belfast, was born there on 7th April 1794. He was educated at Trinity College, Dublin, of which he became LL.D. After travelling in Greece, where he made the acquaintanco of Lord Byron, whose sentiments in regard to the Greek cause he fully shared, he studied for the bar and was called at Lincoln's Inn in 1831. He published a. Picture of Greece (1826), Letters from the LIgean (1829), and a History of Modern Greece (1830). On his marriage to the daughter and heiress of Willia.m Tennent, a wealthy merchant at Belfast, he adopted by royal licence the name of his wife in addition to his own. He entered parliament in 1832 as member for Belfast. In 1841 he became secretary to the India Board, and in 1845 he was knighted and appointed colonial secretary of Ceylon, where he remained till 1850. The result of his residence there appeared in Christianity in ${ }^{\bullet}$ Ceylon (1850) and Ceylon, Physicai, Historical, and Topographical (2 vols., 1859). On his return he becamé member for Lisburn, and under Lord Derby was secretary to the Poor Law Board from February to November 1852. From then till 1867 he was permanent secretary to the Board of Trade, and on his retirement he received a baronetcy from Lord Palmerston. In his early years his political views had a Radical tinge $\theta_{2}$ and, although be subsequently joined the Tories, his Cunservatiom was of a mild type. He withdrew from the Whige elong with Lord Stanley and Sir James Graham, and afterwards adhered to Peel. He died in London on 6th August 1869.
Besides the books above mentioned, he wrote Belgium in 1840 (1841) and Wine, its Duties and Taxation (1855), and was a contributnr to magazines and a frequent correspondent of Notes and Queries.

TENNESSEE, one of the United States of North America, the third added (June 1796) to the original thirteen, its predecessors having been Vermont (1791) and Tontucky (1792). Tennessee is bounded on the E. by the Unaka Mountains, which divide it from North Carolina, to the S by the line of lat. $35^{\circ} \mathrm{N}$., dividing it from Gaorgia,

Alabama, and Mississippi; on the W. by the Misisisipp river, dividing it from Arkansas and Missouri ; and on the N. by a line which erroneous surveys have caused to vary greatly from the intended boundary,-the line of lat. $36^{\circ}$ $30^{\prime} \mathrm{N}$.-the variations all being measured to the north of that parallel. The actual boundary commences at the north-east corner of the State 7 miles north of $36^{\circ} 30^{\prime}$, and continues at that distance as far as the frontier of Virginia and Kentucky, where it diminishes to 5 miles; thence to about its intersection with $86^{\circ} 30^{\prime}$ W. it increases to 11 miles; thence a deflexion southwards to a point about 2 miles from. the Cumberland reduces it to 10 miles; there it suddenly shoots north again to 12 miles, which distance is increased to $12 \frac{1}{2}$ by the time it strikes the Tennessee; on the other side of that river it becomes very nearly coincident with the normal $36^{\circ} 30^{\prime}$; and to that line it adheres with very slight aberrations until it strikes the Mississippi. The eastern boundary has one deviation from the stipulated line: it runs along the culminating ridge of the Unakas till within 26 miles of the Georgia frontier, when it turns due south, giving to Tennessee a triangular piece of territory which should belong to North Carolina. The area of the State was 41,750 square miles in 1880 . Its extreme length is 432 miles and its width 109.

Configuration and Geology.-Commencing at the eastern frontier, the State of Tennessee is divided into several districts, having distinct characteristics and separated by well-marked natural boundaries, whose general direction from north-east to south-west corresponds with the trend of the main valleys (see the geological sketoh map inserted on pl. II.).

1. The mountain region of East Tennessee is a long narrow belt of very irregular surface, comprised between the Unaka Range and a disjointed chain of lower mountains, the principal of which are called the Chilhowee Range, and the whole of which may be considered as constituting the secondary mountain system of the State. The intervening space is occupied by broken masses forming hills, mountains, and valleys, some ${ }^{-1}$ parallel to the principal ranges, some crossing the space at right angles to them. This region varies in width from 28 miles to about 7. All the rocks of this region and the next to it belong to what constitute in England the Silurian and Cambrian systems, the former being found in the western and the latter in the eastern part of the district. It has been contended that some metamorphic rocks near the crest of the mountains belong to the Archaic (Huronian and Laurentian) system ; but the preponderance of geological opinion now assigns them to the same formations ws the neighbouring rocks, the difference in structure being dne to metamorphic action. - The lowest of these, called in Tennessee the Ocoee group, is believed to be cooval with the Potsdam group of the Armerican system,-the Lower Silurian and perhaps the Upper Cambrian of the British Isles. It consists chiefly of slates and conglomerates, with the sandstones of the Chilhowee group above. Above these last are the Knox dolomite group, with its shales and limestone more separated from the other two groups and perhaps not exactly corresponding to any other recognized formations. The crystalline metamorphic rocks are mainly syenitic and micaceous gneiss, with micaceous, horablendic, and talcose schists. .Occasional small dykes of diorite, greenstone, and basalt traverse these rocks, sometimes interstratified, but oftener breaking through thim.
2. The rocks of the first division are tilted at very high angles; those of the second division, the eastern ralley of the Tennessee, are fractured and distorted at nearly every conceivable angle, and, in consequence, it is the edges of the uplifted strata which here form the surfar:. The strate invo been eatson awhy to form vallejer, il loft standing as.

ridges, giving the whole tract a deeply channelled character, the ridges consisting of sandstone and dolomite and the valleys of friable achists. These all trend in the prevalent direction of the Appalachian upheaval, from north-east to south-west. The rivers take the same directions, except when they break through transverse fissures in the ridges, or work round their terminations where they give way to the outcropping of other rocks; in these cases the current runs at right angles to their prevalent direction. All these formations belong to the Silurian period, the oldest cropping out to the eastward, the later members appearing to the westward. In some spots the Subcarboniferous rocks which once covered the entire valley have escaped the erosive action which swept the rest away. The whole disirict is a valley of denudation which has been excavated by the Tennessee and its-tributaries, -some breaking through the Unaka barrier, and others descending from Virginia along the longitudinal valleys above described.
3. Rising in a steep elevation at from 800 to 1200 feet above the average level of the eastern valley of the Tennessee is the plateau popularly called the Cumberland Mountain. This mass, superincumbent on the Silurian system, consists of four very distinctly marked formations, -(i.) the Devonian black shale, (ii.) the Subcarboniferons silicious beds, (iii.) the Mountain Limestone, (iv.) the Coalmeasures. These can easily be distinguished one above another on the face of the eastern escarpment; but on the western aide the first two extend in a wide plain far beyond the base of the plateau, constituting the fourth district. The Mountain Limestone is shaly at the bottom, and more solid at the top, where it abounds in silicious concretions. The Coal-measures consist of thick slabs of sandstone and conglomerate with the seams of coal interstratified between them. In its southern portion the plateau is divided longitudinally by the narrow valley of the Sequatchie river, which cuts deep into the subjacent Silurian beds. The portion east of this valley, known as Walden's Ridge, has its strata much disturbed and tilted, conformably with the Silurian rocks below; the western portion, on the contrary, has all its strata nearly horizontal. This formation, averaging about 40 miles in width, is divided by a stratum of conglomerate 80 feet thick into the upper and lower Coal-measures, the former of which are much the more productive, but cover a less area, large portions of it having been carried away by denudation. These coal-seams are believed to average an aggregate thickness of 8 feet and to cover an area of 5000 square miles.

4, 5, 6. The Subcarboniferous area, the central basin, and the western valley of the Tennessee can best be considered together. They conaist of the Subcarboniferous silicious beds, together with the basins formed by their erosion. On the western face of the Carboniferous belt the Mountain Limestone has been carried amay with the harder rocks of the Coal-measures above it, but the underlying silicious beds have resisted all erosive forces and are spread out over an extended area on both sides of the Mississippi. In Tennessee they form a margin round the central basin and are styled by local geologists the "highland rim." They consist of two strata, a lower one distinguished by the absence of lime and iron, and an upper one which contains both these materials in abundance. Both members consist mainly of a peculiar gravel, formed of silicious concretions embedded in a stiff retentive clay. The upper stratum has in addition considerable horizontal beds of limestone ; it contains abundant fossils of a large coral, Lithostrotion canadense, by which it is easily recognized, is very fertile, and possesses inexhaustible beds of limonite. The lower stratum is destitute of both fossils and minerals and is of but little account for agriculture. Excavated from this formation is the central valley of

Tennessee (No. 5), surrounded on all sides by an escarpment of about 200 feet in depth, by which descent is made from the "rim" into the valley. All the members of the Silurian period, except the three lowest, are represented in this valley, which has been formed by the erosive action of the rivers within its borders: its higher strata were carried off northwards by the Cumberland and its tributaries, westward by the Duck, and southward by the Elk, the last two being tributaries of the Tennessee. A channel of erosion along the lower portion of the Duck river connects this valley with another (No. 6) much narrower-the western valley of the Tennessee-where again the Silurian beds have been reached by the removal of the Subcarboniferous formations above them. Again, south of the main basin, the portion drained by the Elk is nearly separated from the rest by a number of detached hills of the Subcarboniferous formation, marking the watershed which divides the headwaters of the Elk from those of the Duck.

7, 8, 9, 10. A little west of the Tennessee river the Palæozoic rocks disappear under the Cretaceous formations (No. 7), and these in their turn are covered successively by the Tertiary, Quaternary, and recent formations (Nos. 8,9 , and 10 ). The tract of ground covered by these four formations constitutes the Mississippi slope of western Tennessee, all of whose rivers run westward and discharge into the Mississippi. The dip of the strata is very slight, and the surface inclines with a very gentle slope.

In general terms, the territory embraced in Tennessee may be described as a great mountain chain on the east, from the foot of which extends a gently inclined plane, interrupted by an elevation, the Cumberland or Carboniferous plateau, and a depression, the central valley.

Rivers. -The Cumberland and the Tennessee are the principal River channels of inland navigation, while the Mississippi, washing the whole western fronticr of the State, is its outlet to the Gulf of Mexico. The headwaters and embouchure of the Cumberlend are in Kentucky, but much the greater part of its navigable stream is in Tennessee. From its confluence. with the Ohio, at Smithland, Kentucky, to N sshville, a distance of 200 miles, it is generally navigable for eight months in the year, and during high water it is sometimes accessible to light-draft ateamboats more than 300 miles further. The Tennessee rises in Virginia, crosses east Tenneesee in a south-western direction, and enters Alabama a little above Bridgeport; in that State it assumes successively a westerly and a northerly direction, and then re-enters Tennessee and crosses the State northwards to its confluence with the Ohio et Paducah, Kentucky. Its navigsble waters are divided by obstructions into three portions, - (1) from the mouth to Florence, Alabama, 800 miles, where navigation is arrested by the Muscle ehosls; (2) thence through Alabama, shout 100 miles, when the river breake through the Cumberland Meuntain; and (3) from Chattanooga to Kingston. ahout 100 miles further.

Agriculture. - In 1880 the number of farms was 165,650 , embrac. ing $8,496,556$ acres of improved land, valued at $\$ 266,749,837$. The principal productions are Indian corn, wheat, oats, cotton, tobacce, potatoes, pea-nuts, and hsy, particulare of which for different years are shown in the following table:-

| Product. | 1860. | 1870. | 1880. | 1834. |
| :---: | :---: | :---: | :---: | :---: |
| lndisa corn | 52,089,928 bush. | 41,848,014 bush. | 82, 764, 429 busb. | 86, 723,000 busb. |
| Whest | 5,459,208 . | 6,188,916 | 7,331,858 " | 9,820,000 " |
| Osts ...... | 2,207,814 208,404 balies. | 1,618,815 bäles. | 4,722,190 balles. | , 315,807 hal'es. |
| Tobseco | 43,448,097 th. | 21,465,452 D. | 29,385,052 tb. | 31, $892,000 \mathrm{Ib}$. |
| Potatoes | 8,786,677 bush. | 2, 330,020 bush. | 8,724,382 bnsh. | 2,800,000 bush. |
| Hay | 143,499 tons. | 116,582 tons. | 188,698 tons. | 217,916 tons. |

In $18841,250,000$ brehels of pes-nuts were prodnced, as against 800,000 in 1883. In recent years considerahle attention has been given to the cultivation of fruit and vegetables.

The live stock statistics in different jears are ohown in the table which follows next :-

| Yesr. | Horses. | Cattie. | Sneep. | Pigs: | Mules and Asses. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1880 | 290,882 | 764,782 | 573, 317 | 2,547,321 | 128,845 102085 |
| 1870 | 247,254 | ${ }^{643,696}$ | 820,783 | 1,828,890 |  |
| 1850 | 266,119 | 783,674 | 672,789 | 2,180,495 | 178,499 |
| 1885 | 288,604 | S01,828 | 603,780 | 2,122,646 | 187,208 |

TXTII. - 23

Mincrals. - The chief minerals found in the State are coal, iron, copper, zinc, lesd, and manganese. Of coal the output was 494,491 tons in 1880 and $1,100,000$ tons in 188,5 ; in the latter year there were slso 268,400 tons of coke. In 1880 there were produced 89,933 tons of iron ore ( 326,040 tons in 1885), 153,880 th of copper ingots, and 792,621 cmhic feet of marble and limestone. Of zine 17,415 tons were produced in 1884. Besides the minarels slresdy mentioned, Tennessee fields millstone grit, hydranlic rock, barytes, fire-clay, gold, sod patroleum.

Manufactures. -Since 1875 the manofactarlng indnstries of the State have grown immensely. From 1880 to 1885 the number of establishmente increased from 4326 to 4425 , the capital invested from $\$ 20,002,845$ to $\$ 40,703,850$, and the vslue of the manofactured products from $\$ 37,074,886$ to $\$ 75,216,211$. In 1880 cotton was mannfactured in the Stste to the ralne of $\$ 934,014$ (in 1885 to $\$ 2,719,768$ ), carriages and waggons $\$ 1,253,721$, flour and gristmill products $\$ 10,784,804$, foundry and machine-shop products $\$ 1,191,531$, iron and steel $\$ 2,274,203$, leather $\$ 2,051,087$, lumber $\$ 4,015,310$, and cotton-eeed oil, cotton seed, and cake to the value of $\$ 1,235,000$.
Population, The popaistion of the State, which in 1860 wss $1,109,801$ and in $18701,258,520$, was in $18801,542,359$ (males 169,277, females 773,082). Of this last total 403,151 were Negroes. [n 1887 the total population was estimated to nomber about $1,800,000$, giving a density of 43 inhsbitanta to the sqnare mile, to against 36.9 in 1880. The growth of the orincipal cities is hown by the following table:-

|  | 1870. | 1880. |  | 1970. | 1880 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Memphls. | 40,220 | 03,592 | Kn | 8,882 |  |
| Castarooga ... | 25,805 | 43,350 12,982 | Jackson |  | 6,377 |

The considerable declino in the popalation of Memphis is accoanted for by two epidemics of yellow fever in 1878 and 1878 (eee Memphis). Chsttanooga is still increasing at a very rapid rate in consequence of the vast development of the mineral resources of east Tennessee. Knoxville is also growing from the same cause, bat not eo rapidly as Chattanooga.

Education. - Provision for common school edncstion was made before the Cinil War, but was limited to white children. A State bank was established for the purpose of regulating the currency, and a portion of its capital was reserved as a school fund ; its profits were slso to be used for school parposes. The fund on which interest is now paid is $\$ 2,512,500$. A bill is now (1887) before the State legislature to increase the permanent State fand to $\$ 5,000,000$. Besides this, the proceeds of a tax of 15 per cent. on property and a poll tax of $\$ 1$ per annum are applied to the same parpose. Moreorer, each county has the power of imposing a school tax on its people, and msny incorporate cities and towns sdd etill farther to it by special taxes within their limits. All children between six and twenty. one (eighteen until 1885) are entitled to free edncation in the public ochools. In 1875 the school population numbered 426,612, of whom there were 199,058 pupils enrolled. In 1886 the corresponding figares were 609,028 and 373,877 , and in $1887.623,450$ and 383,537 . Besides the common schools numerous privste achools exist. Higher education is provided for in soreral institutions, such as Vanderbilt oniversity (Methodist) at Nashrille, the university of the South (Episcopalian) st Sewanee or Cumberland Mountain, the south-western Presbyterian university at Clarksville, and others; the university of Tennessee at Knoxville is supported by State grants, and is not under the direction of any one denominstion. Many smaller establishments entitled universities exist in rarions parts of the State.

Administration, de. -The legislative and execntive functions of government sre carried on by a governor, a State senste, and a honse. of representatives, whose respective duties and prerogatives correspond almost exactly to those of the president, senate, and fepresentatives of the United Ststes. Both the senators (33) and the fepresentatives (99) sre elected for two years. The president of the penste, who is elected by the senators, succeads as gorernor in case af the death of the elected governor during his term of office. The governor has the power of veto on the Acts of the legislature. In case of its exercise, the Act is returned to the legislature, when, if it passes by a constitutional majority in both houses, it becomes lsw in spite of the veto.

The judiciary administration is carried on by courts of four designations, -the county criminal courts, the circnit courts, the chancary courts, and the supreme court of the State. The county conrts consist of the magistrates, who assemble at the connty sest four times a year to transact county busiuess. They elect a chairman ont of their own body, who by virtue of such election becomes the financial agent of the county. In counties large enough to justify it, a county judge is elected, who exercises criminal jurisdiution. There are foarteen circuit courts, esch having jurisdiction a several oounties ; in these all common-law cases are adjudicated, excent in those counties where there is a criminal judge. There
are elaven chancery dirisions, for esch of which a chancellor 19 elected, who tries all rases in equity in his division. All these judges ara elected for eight years. The judges of the supreme court, five in nuinber, are elected by the people at large, but not more than two can be taken from any one of three divisions of the State viz, the eastern, middle, and western. Their jurisdiction is purelr appellate: they revise the decisions of the other courts. and their decisions are final, excapt where s question sriess as to the inter pretation of the United States constitution.
History. - At the time of its first settlement and occapation by Europesns Tennessee wss part of the territory granted to the colony of North Carolins by Charles II. It was then, however, a hypothetical claim, the boundaries of which were chiefly determined by $35^{\circ} 30^{\circ}$ and $35^{\circ} \mathrm{N}$. lat. The eastern boundory of North Carolina Wrs the Atlantic Ocean; on the other side the western territory extended according to one theory to the Mississippi, according to another theory to the Pacific Ocesn. When the Engliah settlers began to cross the Appalachisn chsin, they found the Freuch estab lished on the Mississippi and its tribataries,- the Ohio, the Ten nessee, and the Comberland. Thie Spanich clairo of an indefinite extension of their possessions in Florida was also a constant menace to the adrances of the earliest English colonists in the direction of South Carolins sad Georgia. The most important effort of transmontane colonization by the British prior to 1760 was the establishment of Fort Loudon on the Little Tennessee river in 1756 or 1757. But in 1760 this post was captured by the Cherokees and its garrison massacred; and the same fate befell a number of colonists who had eettled between Fort Chissel (on New River. Virginis) snd Fort Loudon. Early. in 1761 Colonel Grat completely routed the Cherokees and compelled their French and Spang ish allies to withdraw to Louisians and Georgis.

Eight years later the stream of emigration began to set westwards, mainly by two routeg, of which one led through Cumberland Gap to the palley of the Cumberland river, whilst ths other followed the course of the Tennessee round the soathern border of the Cumberland platean into the western Tennessee valley. A body of emigrants from Virginia aettled on the banks of the river Holston, in what is now Hawkins county, and formed the aucleus of s rapidly increasing colony, which was msinly recruited from Virgiria snd North Carolina. The chief settlements were on the Watsuga river, extending thence to the Nolichucky, both tribataries of the Tennessee. The colonists adopted a code of laws for themselves based apon those of Virginia, and entrusted their execu. tion to a bench of five magistrstes. Their first trouble related to the title to their lands. They aupposed themselves to be settling in Virginis ; but they were really in North Carolina, and therefore outside of the territory which had been ceded to the British crown by the eix uations of Indians. A further obstecle wss a roysl pra. clamation dated nine years before forbidding privsto persona to purchase titles from the Indians. Though the Cherokees had nc Ionger fired babitation in the country, they still claimed the whole valley for hnnting grounds. The dilemms was solved by a lesse negotisted for eight years. The next difficulty arose with the British Government in alliance with the hostile Indians. But out of these tronbles the colonies on the Watauga, Holston, and Nolichucky emerged as a populous and poweriul community.

When it $\pi$ ss proposed to liquidate the debts incurred by both the States and the Federsl Government for war expenses by the sale of public lands, an Act of Cession wrs passed in 1,84 by the North Carolina legislature ceding their lands west of the mountains, inclnd ing those of the Watanga settlers, to the Federal Goverument. But in the following year the North Carolins legislature repealed the Act of Cession, and the whole matter was thus indefinitely poatponed. The Watanga community now declared itseff independent of North Carolina ; that State had relinquished its sovereignty over them and the Federal Corernment had not accepted it. At this time the transmontane territory consisted of Washington, Sullivsn, and Greene counties. It also embraced all the settlements on the Curnberlsnd, comprising the existing counties of Davidson, Sumner Montgomery, Robertson, and Williamson. Davidson county had been organized by the influenco of James Robertson (one of the eatliest arrivals from North Carolina, in 1769), who had moved to the site of the future city of Nashville. But Davidson county took no part in thesa proceedings. The Stata organized by the seceding counties in August 1784 T8s called the State of Franklin; its constituent counties returned to their allegiance to North Carolina on 1st March 1788. A second Act of Cession was passed in 1790, by which the defunct State of Franklin became part of the territory of the United States south of the Ohio, including what now constitutes Kentucky and Tennessee. The northern portion became a State, under the name of Kentucky, in 1722, and the southern portion took rank as the State of Tennessee in 1796, being received into the Union the,same year. The settlement of middle Tennessee wss mach retarded so long as the path of access to it from east Tennessee was throngh Cumberland Gap and down the Ohio. The broader route round the south of the Cumberland plateau by the Temnessee river tras too unsafe for general use on account of tho
powerful Indian tribes-the Creeks and the Cherokees. This obstacle was finally removed by General Jackson's crushing defeat of the Creeks in 1814, and a large cessiou of their territory.
The position of Tennessee during the Civil War was the eame as that of the other middle and southern States. While secession was in agitation, it refused to secede; but when actual hostilities commenced it joined the Southern confederacy. Even then, however, west and middle Tennessee eympathized with the South, whilst eastern Tennessee sided with the North. Each division sent very large contingents to the army which it faroured. A large portion of the State was, during the later yeare of the war, iu the occupation of the Northern army, and many great battles were fought on its soil, notably those of Fort Donelson, Murfreesborough (Stone River), Franklin, and Nashville. - Tenncssee suffered more from the exhaustion attendant on the close of the war, and from the rigorous government which accompanied the period of reconstruction, than any other State except Virginia.

IENNIS. This, the oldest, perhaps, of all existing ball-games, is at once the most difficult to learn, on account of the intricacy of its laws, and the most interesting when learnt; because of the great variety of its combinations, and the diffeulty of solving rapidly the problems which are constantly presented to the player. It derives an additional claim to attention from numberless historical asseciations. Of the origin of tennis it is not possible to speak with certainty; but it may be confidently assumed that it sprang frem some very simple spert. It first appeared in Europe in the Middle Ages, when we find it played in open courts, in the parks or ditches of the feudal castles of France and Italy. It was at first the pastime of kings and nobles, but afterwards became popular with all classes. The French seem to have berrowed it from the Italians, and to have contributed some of its refinements ; and the English took it from the French. Though mentioned in the Arthurian romances, the game was certainly not known in England in the time of Arthur. The name tennis is supposed to be derived from the exclamation "Tenez!"employed by early French players in serving the ball. In Italy the game is called "giuoco della palla"; in France, "jeu de paume," which also means the tennis court; in Germany it is called by the generic title of "Ballspiel"; in Spain, "juego al ble" or "jugar al ble." It is clear from the French name that the ball was originally struck with the palm of the hand. This was afterwards protected by a glove, as is still the practice in the

Plan of ternis court. $A, D$, walls on each side of dcdans; $d, d$, gallery walls ; $h$, grille wall: lan of ternis court. $A, D_{1}$, walls on each side of dcdans $; d, d$, gallery walls ; $h$, grille wall;
$f$, net post ; $g, g$, gallery post ; $v, v$, first galleries ; $y, y$, secoud galleries ; $x, x$, last galleries;

$4,5,6$, marl chaees.
which a sloping reof, called the penthouse, reaches to the outer wall. The surrounding passage thus enclosed (not shown in plan) is 7 feet wide. Opposite to the long penthouse is the main wall, in which there is at one point a projection called the tambour, $E$, which deflects the ball across the court. In the inner wall, below the penthouse, there are several openings, the one at the end, on the service side, being called the dedans, $B$, the others the galleries. At the further cnd of the court is the grille, a square opening adjacent to the main wall. Across the court, halfway between the two ends, is stretched a net $n$, 3 feet high in the middle and 5 feet at the sides. The game may be played by two, or by three, or by four players, one against one, one against twe, or two against two. At the commencement the playcrs toss or "spin" a racket, to decide which shall serve first, calling "rough " (for the knotted side) or "smooth." The party which wins the "spin" has the cheice of the service or the "first stroke," the latter term meaning the return of the scrvice. The server then begins at the "dedans" end of the court, technically called the "service side," pitches the ball in the air, and strikes it with his racket so that it shall drop on the side penthouse or on the wall above it, and then from the penthouse upon the floor on the other side of the net (called the "hazard side"), within the "service court" bounded by the "service line" $x$ and the "pass line " $p$. If he fail to do this, a "fault" is called, or a "pass" if the ball has gone beyond the pass line. If he serves a second fault, his adversary scorcs a point, called a "stroke." A pass counts for nething, but annuls a previous fault. ${ }^{1}$ It now becomes the duty of the adversary, called the "striker-out," to return the ball by striking it with his racket in such a manner that it shall pass back over the net to the service side. The server must now strike it again and return it to the hazard side and the olaver Whe first returns the ball inte the net or "out of court" (i.e., to the roof, or above the play line on the malls) leses the stroke, which is scored to his antagonist. But, if a player fail or refuse to strike the ball in the air (a "volley") or on its first bound and before it touches the
floor floor a second time, then, except on the hazard side bcyond the service line, a "chase" is made or reckoncd on the floor, accerding to the lines on or between which the ball has dropped the second time. This chase is a stroke in abeyance. When onc has been made it is called by the marker, but does not affect the score until one of the players has scored 40, when they change sides, and the player who has allowed the chase to be made must then
endeavour to win it, $i, e$, , to place the $\frac{\text { In }}{\text { In }}$ Ine Nanchester Club this law ( 8 ) bas been wisely abolighed

Basque country. Upen the glove strings and cross-strings were next stretched, to give a faster impulse; and the addition of a short handle made an easy transition to the racket! In the time of Henry VII, the hand still sometimes met the racket, even in the royal court at Windsor.
One of the first improvements in the game censisted in the building of closcd courts, first with walls, then with walls and roof. It is still played in the open air in some places in France, and "pallone," a rude and violent variety of the game, is yet seen in Italy. There are twenty-seven courts in England and one in Dublin.

As now played, tennis in France is virtually the same as in England, though there are a few differences of detail. The court is rectangular (see the annesed plan). An inner vall rums round three sides, to the height of 7 feet, from
ball returned by him better, i.e., nearer to the end wall, than the point at which the chase was marked. As often as his adversary returns his stroke, he must again endeavour to do this, until he succeeds or fails. If he succeed, he scores the stroke; if not, it is scored to his adversary. If two chases have been made at any stage of the score, eren at the beginning of a game, then the players must change sides and play for the chases, as above described. A player who succeeds in sending the ball into the grille, the dedans, or the last division of the gallery-called the "winning gallery "—on the hazard side, scores at all times a stroke. The minutire of the game and the mode of scoring cannot be more succinctly described than in the annexed laws. ${ }^{\text {. }}$

## Lawz.

## Single-Handed Game.

1. The balls shall be not less than $2 \ddagger \mathrm{in}$. and not more than $2 \frac{1}{8}$ in. in diameter, and shall be not less than $2 \frac{1}{2} \mathrm{oz}$ and not more than $2 \frac{8}{8}$ oz. in weight.

Note.-There is no restriction as to the shape or alze of the racketa
2. (a) The choice of sides st the beginning of the first set ie determined by a spin.
(b) In subsequent sets of a eeries, the players shall begin each set on the side on which they finished the set before it.
3. The ball served must be etruck with tho racket, sad may be delivered from any part of the service side.
4. The ball served must touch the service penthouse before touching eny other part of tho court, ezcept the rest of the side penthouse snd the service wsll ; snd it must drop in the eervice conrt or on one of the lines which bound it.
5. The eervice is good,
(a) if the ball served touch in its descent any part of the service penthouse so as to rise sgain from it, or
(b) if the ball served strike the service wall snd afterwarde touch in its descent any part of the service penthouse, oven thongh it do not rise again from it, or
(c) if the ball served drop in the winaing gallery.
6. A faglt may not be returned.
7. A pass may not bo returned ; but a bsll sorved, which has not gone scross the pass line on the penthouss, may be volleyed, sithough if untouched it might have dropped in the pass court. If a pass touch the striker-out, or if a service before it has dropped touch him when standing with both feet in the pass court, and not having attempted to etrike the ball, it is still counted a pass
8. A pass annuls a previous fanit.
9. If the striker-ont declare himsolf not ready for a service, and have made no attempt to return it, that service is counted for nothing, thoogh it he s fault. It annals a previo is fsult. The striker-out, having beer asked if he is teady, and having declared himsolf ready, may not similarly refuse a second seivice.
10. The server continues to serve until two chases be made, or one chase when the score of either player is at forty or advantage (see law 25). The players then change sides, the server becoming striker-out and the striker-out becoming server.
11. The return is good if the ball in play be atruck with the racket so that it pass the net without tonching a gallery post or anything fized or lying in an opening on the side from which it is struck, and without going out of court.
12. The return is not good,
(a) if not in accordance with the terms of law 11, or
(b) if the ball be struck more than once, or be not definitely etruck, or
(c) if the ball in play, hsving passed the net, come back and drop on the side from which it was etruck, unless it should have touched a gallery post or anything fixed or lying in sn opening on that side of the court which is opposite to the etriker.
13. A boll which is no longer in plsy msy not be returned.

14 The server wins a stroke (escept as provided in law 9),
(a) if a good eervice enter the winning gallery or the grille, or
(b) if the etriker-out fail to return a good sertice (except When it makes a chase; see laws 17-19), or
(c) if the striker-out fail to return the ball in play (except When it makes a chase; cee laws 17-19), or
(d) if he himself return the ball in play oo that it enter the winning gar ry or grille, or fall on or beyond the service line, or
(b) if he serve or return the ball in play so thst it drop or fsll upon a ball or other object which is on or beyond the eervice line, or

[^62](f) if he win a chase (see lam 20), or
(g) if the striker-out lose a ctroke (bee lsw 16).
15. The etriker-out wins a stroke (except as provided in lsw 9),
(a) if the server serve two cobsecutive faults (except as provided in law 81 (b)), or
(b) if the server fail to return the ball in play (except whon it makes a chaee ; bee lawe 17-19), or
(c) if he himself return the bsll in play so that it enter the dedans, or
(d) if he win a chase, or
(e) if the server lose s stroke (see law 16).
16. Either player loses s atroke,
(a) if he lose a chase (see lsw 21),
(b) if the ball in plsy (except as provided in law 7) toach him or snything which he wears or carries, except his racket in the act of returning the ball, or
(e) if he touch or strike the ball in plsy with his racket more than once, or do not definitely strike it.
17. When a ball in play on either side of the net, not being that on which the striker is standing,
(a) falls on sny part of the floor, except on or heyond the service line, or
(b) enters say gallery, except the winning gallery, or
(c) touches $s$ gallery post,
it is marked s chase
(a) at that line on the floor on which it fell, or
$(\beta)$ better or worse than thst line on the floor which is nearest to the point at which it fell, or
( $\gamma$ ) at that gallery the post of which it touched,
except as provided in laws 18 and 19.
Note (a).-A ball in play which tonches thie net post and drops on the slde opposite to the striker is marked a chase at the line on the side on which it drops. Note (b). - A ball in play which enters a gallery is marked a chaee at that gallery which it enters, notwithstanding that it may have touched an adjacent gallery post without touching the floor in the interifo.
Note (c). The gallery lines on the floor correspond and are equivalent to the galleries of which they bear the names.
18. When a ball in play
(a) drops or falls in the net, on the side opposite to the striker, or
(b) drops on the floor, on the side opposite to the striker, and, hounding over the net, falle on that side of it from which it was struck, whether it touch the net in its bound or not,
it is marked a chase st the line on the side opposite to the striker.
19. When a ball in play drops or fells upon a ball or other object which is on the floor (except when it is on or beyond the service line ; see lsw 14 (e)), it is marked a chase at the point at which that ball or other object wss when the bsll in play dropped or foll apor it.
20. Either player wins a chase,
(a) if he cerve or return the ball so that it enter a winning opening, or
(b) if he serve or return the ball so that it fall better than the chase for which he played, or enter a gallery or tonch a gallery post hetter thsn the gallery or the gallery line at which the chase was for which he played, or
(c) if he serve or return the ball so that it drop or fsll apoo a ball or other object which is at a point on the floor botter than that at which, or at the gallory corresponding to which, the chase was for which he plsyed, or
(d) if his sntagonist fail to return the ball in play, except when it falls worse then the chase in queation.
21. Either player loses a chase,
(a) if he fail to return the ball in play, except when it falle Worse than the chase in question, or
(b) if he return the hall in play so that it fall worse then the chase, or enter a gallery or tonch a gallery post worse thsn the gallery or the gallery line at which the chase tras for which he played, or
(c) if he return the hall in play eo that it drop or fsll npon a ball or other object which is at a point on the floor worse than that at which the chase was for which he played.
22. Whens ball in play
(a) falls at a point on the floor neither better nor woree than that at which, or at the gallery correspondiag to which, the cbese was for which the striker plsyed, or
(b) enters that gallery or the gallery corresponding to that gallery line, or tonches the post of that gallery, or falls on the gallery line corresponding to that gallery, at which the chase was for which the striker played, or
(c) drops or falls upon a hall or other object which is at a point on the floor neither better nor worse than that at which, or at the gallery corresponding to which, the chase was for which the striker played,
it is marked chees-off: it is not scored as a stroke won by either player ; the chase is annalled, and the atriker has not to play for it again.
23. As soon as two chases are marked, or one chase when the score of either player is at ferty or advantage (see law 25), the players change sides. The player who made the first chase now defends it, while the other playe to min it ; and 80 with the second chase, except when only one has been marked.
24. If by an error three chases have been marked, or two chases when the acore of either player is at forty or edvantage (see law 25), the last chase in each case is annulled.
25. On either player winning his first etroke, the score is called fifteen for that player ; on either player winning his second stroke, the acore is called thirty for that player; on either player winning his third stroke, the score is called forty for that player; and the fourth stroke won by either player is ecored game for that player, except as below.

1. both players have won three strokes, the acore is called deuce, and the next stroke won by either player is scored advantage for that player. If the same player win the following stroke, he wins the gamo; if be lose the following stroke, the score is again called deuce; and so on, until either player win the two strokes immediately following the score of deuce when the game is scored for that player.
2. The player who first wins six games wins a set, except as below.

If both players win fire games, the score is called games all, and the next game won by either plajer is scored advantage game for that player. If tha same player win the following game, he wins tho set; if he lose the following game, the score is again called ganies all; and so on, until either player win the twn games immediately following the score of games all, when he wins the set.
Note.-Players often agreo not to play advantage sets, bnt to declda the aat by ona gatna after arriving at the acore of games all.
27. Every chase is marked, and every stroke scored, by the marker, who is entitled to consult the dedans when he is in doubt. A player who is dissatisfied with the marker's decision is entitled to appeal to the dedans. A majority of the dedans confirms or reverses the marker's decision. An appeal mnst be made before a recommencement of play.
Note.-The dedans shouid dot giva a dectsion unasked on a question of marking a chasa or atroke, but may, and abould, correct inaccurata scoring of chases, strokes, games, or sets.

## Three-Handed and Four-Handed Games, sometimes called Doubie Games.

28. The partners serve and strike-out in alternate games, unless it shall have been previously agreed to the contrary.
Note.-It is unually, but not always, agreed that the atriker-out may leave to hia partner elach services as pass hun.
The former laws apply to these as well es to single games, the advantafes and disadvantages attaching to a single player under the former laws here attaching to a pair of players.
odds.
29. (a) $A$ bisque or a half-bisque may not be taken after the oervice hay been delivered.
(b) T'ao server may not take a bisque after a fault; but the striker-out may do so.
Note.- $A$ bisque is a stroke which may be claimed by the reciplent of odds et any tima during a set. aubject to the provisions of lawa 29 and 90.
30. A player who wishes to take a bisque or a half-bisque, there being a chase or two chases marked, may take it either before or after changing sides; but he may not, after changing sides, go back to take it.
31. (a) When the odds of round services are giren, the ball eerved by the giver of the adds must tonch the grille pent. house after touching the service penthonse and hefore dropping in the servic:3 court or on one of the lines which bound it.
(b) Neither faults nor failure in complying with the above condition are counted against the giver of the odds; but the recipient of the odds may dectine to return such services as do not touch hoth the pentheuses; it, however, he attempt and fail to return eny such service, it is counted against him.
32. Half-court: the players having agreed into which half-conrt on each side of the net the giver of the odds shall play, tho latter loses a stroke if "he ball returned by him drop in either of the other half-courts.

But a ball retirned by the giver of the odds which
(a) drope on the half-court line, or
(b) drop in his half-court and touches the dedans post before falling or
(c) drops in his half-court and falls in the dedans, even though on the other side of the dedans post, or
(d) tounhes the dedans post before dropping,
is counted \& $r$ the giver of the odds.
And a retrim baasted against eny wall by the giver of the odds Which
ie) drops in his half-court, or
( $f$ ) drops on the half-court line, or
(g) touches the dedans post before dropping, or
(h) touches any penthouse, battery, or wall before drop. ping in his half-court, dropping on the half-court line, or touching the dedans post,
is also counted for the giver of the odds.
Nole.-It is, of course, evident thst the giver of thesa edds may make chase, or win a chasa or a stroke, with a bail wbich drups in hia half-court, or on the balf court Ine, but falla In tha other half-court.
33. When the odds of "touch no walls" or "touch no eide walls" are given, a ball returned by the giver of the odds which on falling makes a nick is counted for the atriker.

## Directions to the Sfarker.

It is the duty of the marker
to call the faults, and the passes;
to call the strokes, when won, or when he is asked to do so ;
to call the games and sets at the end of each, or when asked to do eo ;
to mark the chases, when made ;
to call the chases when there are twe in the order in which they were made, or the chase when there is one with the score at forty or adrantage; and then
to direct the-players to change sides;
to call the chase or chases egain, in order as above, when the players have changed sides, and each chase as a player has to play for it ;
not to call play or noi play in doubtful cases before the conclusion of the rest, unless asked to do so ;
to decido all doubtful and disputed strokes, subject to an appeal to the dedans;
to warn the players of any balls lying on the floor in their way, or to their danger or disadvantage, and to remove all such balls;
to collect the balls into the ball-basket ; and
to keep the ball-troughs constantly replenished in the dedans and last gallery, and the latter especially in three-handed and four-handed games. (J, MA*.)
TENNIS, Lawn. Lawn-tennis is a modern adaptation of the first principle of tennis, in the simplest form, to a ball-game played on grass with rackets. The balls are of india-rubber, hollow, and covered with white cloth. The rackets are lighter and broader than those used at tennis. The court for the single-handed game, one player against one, is shown in fig. 1 , that for. the three or four-handed game in fig. 2. The dimensions of the courts, the size

Lawn-tennis courts. Fig. 1, for single game; fig. 之, for double gsme. and weight of the balls, the mode of scoring, and other details are giren in the laws of the game (see below). The only requisites for the game are the balls, rackets, net and posts, and a hard level surface of grass. It may be, and often is, played upon surfaces of wood, asphalt, cement, gravel, or other substance. The grass requires constant mowing, rolling, and in dry weather watering, to keep it
in order. In the winter months it should be sedulously weeded, sown where necessary, and swept and rolled whenever the weather permits.

The choice of sides depends upon a toss or spin of a racket, as in tennis. The winner chooses the service or the preferable side, as he pleases. The server begins the game by striking the ball with his racket so that it passes (without touching) over the net, which is hung across the court from the posts A, A. The ball served must drop in the space which is diagonally opposite to him ou the other side of the net, -a space bounded by the net, the side line, the half-court line, and the service line. His adversary, called the "striker-out," must return the ball before it touches the ground a second time; and the server must similarly return it again; and so on, until one or other player fails to return it over the net so that it shall drop on the ground anywhere on the side of the oct furthest from him, and within or upon any of the lines which bound that space, technically called his adversary's court. When one player thus fails, he loses a stroke, which the other is deemed to win, and it is added to the score of the latter. The score is kept as at tennis, but there are no chases.

Activity and condition have great value in lawn-tennis, though there is room for much skill in placing the ball in the corners with hard, low strokes, and in intercepting and returning the ball by the volley while in the air, before it reaches the ground. But in matches temper, enduranco, and quickness of movement count for very much.

Lavn-tennis, in one form or another, has been played for many centuries ont-of-doors. The present variety of the game ras first introdnced, in a form which was soon shown to be impracticable, about the year 1874. It was then taken up by the All England Club at Wimbledon, who in 1877 remodelled the eize and shape of the court, and the laws, and altered the system of scoring to that which obtains in the parent game. Therenpen, with the consent of the M.C.C. at Lord'e, whe lent the anthority of their name to the movement, the code of laws which now prevails, and has been occasionally amended only in a few dotails, was promulgated by the All England Club. The championship of the game, which is open to gentlemen amateurs only, was instituted at Wimbledon by the A.E.C. in 1877. A lady's championship snd a champienship for pairs (gentlemen) hàve also been instituted, and am annually competed for on the groands of the A. E.C. st Wimbledon. Lawntennis, in the short time which has elapsed since its introduction, has achieved immense popularity. Prize-meetings are held annually at Bath, Cheltenham, Dablin, Edinburgh, Manchester, Liverpool, and many other places in the United Kingdom ; the game is also played with as great enthusiasm in the United States, Canada, Australia, and India. In all those conntries prize-meetings ere held and championships aro institated.

## Laws. 1 <br> Sirgle-Handed Game.

1. For the aingle-hsnded game the coart is 27 feet In width sud is feet in lensth. It is divided across the middie by a uat, the ends of which are attisched to the tops of two posts $\Delta$ and $\mathbf{A}$ (see fig. 1), Which atand 8 feet outside the court on each side. Tha height of the net is 3 feet 8 Inches at the posts sud 3 feet et the centre. At each end of the court, parallel to tha net, and at a distanoce of 99 feet from it, are drawn the base lines CD and EF, the extremities of Fhich are convected by the side lines CE and DF. Half-way between the side linea, and parallel to tham, is drawn tha half-court line $O H$, dividing tha space on each side of the net lnto two eqnal parts, called the right and left courts. On each aide of the net, at \& distance of 21 feet from it, and parallel to 1 t , sre drawn the service lines XX and YY.
2. The halls shall be not less than of inches nor more than $2, \frac{1}{8}$ Inches in diameter, and net less than $1 \frac{7}{5} \mathrm{oz}$. nor mors than 2 ez . in weight.
3. In matches where umpires are appointed their decision shall be final: bot where a referee is appointed an appeal ahall lle to him froin the decision of ay umpire on a question of law.
4. The choics of sides and the right of serving daring the first game ahall be decided by toss, provided that, if the winner of the toss chooss the right to serve, the other player ehall have the chole日 of sides, and vice versa.
5. The players shall stand on opposite sides of the net. The player who Arst delivers the ball shall be called the server, the other the striker-out.
delivers the ball shall $\begin{gathered}\text {. At the end of the first game the striker-ont ahall become server and tha }\end{gathered}$ server shsll become atriker-out; snd ao on aiternately in the subseqnont games of the set.
6. The server shall stand trith one foot beyond (i.e., further from the net than) the base lne, and with the other foot upan tha base line, and shall de.
 degert.
7. The ball served must drop within the service line, half-court line, and side liue of the court vihish is diagenslly opposite to that from which it was side liue of the court vihish is
eerved, or npon any ench lina.

Frinied of nermiszor of the Dli Eaglatd La wn-Tranan Cill
9. It is a fanit if the eervice be delivered from the wroug coturt, or if the server do not atand as directed in law 7 , or if the ball aerved drop in the net or beyond the service lioe, or if it drop ont of court or in the wrong court; it is not a fault if the aerver's foet which ta heyond the base line do not touch the ground at the memant at which the bervice is dellvered.
10. A farlt may not ba takan.
11. After \& fault, the server shall airve again from the same conrt from which oe served that fanlt, nuless it was a fault becanse served from the wrong courth 12. A fanlt may not be claimed after the next bervice has been delivered.
18. The aervice may not be volleyed, i.e., taken before it toaches the ground. 14. The asryer shall not serye until the atriker-out is resdy. If the latter attempt to retarn the cervice, he ehall ba deemed to be ready.
15. A hall is in play from the moment at which it is delivered in service (unless a fault) until it has boen vollayed by the striker-cut in his first atroke, or bas dropped in the net or out of court, or has touched either of the players or anything that he wears or carriea, except his racket in the act of striking, or bas been etruck by either of the players with his racket more than once con secutively, or has been vollezed before it has passed over the net, or has failed to pass over the net before its first bound (except as provided in law 17), or has tonched the ground trice consecutivaly on either side of the net, though the second time may bave been ont of cosrt.
18. It is a let if the ball served touch the net, provided the service be otherwise good, or if a sarvice or falt be delivered when the atriker-out is not ready, or if either player be prevented by an accideri beynud his cootrol from serving or retarning the ball in play. In case of a let, the service or stroke counte for nothing, and the server ohall serve acain
17. It is a good retarn although the ball touch the net, or, having passed ontside either post, drop on or within any of the linea which bound the court into which it is returned
18. Tha server wins a stroke if the striker-ont volley the aervice, or fail to return the service or tha ball in play (except in the case of a let), or return the service or ball in play ae that it drop outside sny of the lines which bound his opponeat'a court, or otherwisa lose a stroke, as provided by lav 20.
19. The striker-out wios a stroke if the server aerve two consecntive fanlts, or fail to return tha ball io play (ercept in the case of a lat), or return the ball In play eo that it drop outside any of the linea which bound hia opponent's court, or otherwise lose a stroke, as provided by law 20.
20. Either player loses a stroke if the ball in play touch bito or anything that he wears or carries, except his racket in the act of striking, or if ho tonch or atrike the ball in play with his racket mors than once consecutively, or if he tonch the bet or any of its supperts while the ball is in play, or if he volley the ball before it has passed the pet.
21. On either player winning his first stroke, the score is called 15 for that player; on either player minning his eccond stroke, the score is called so for that player; on sither player winning bis third stroke, the scors is called 40 for that player; and the fourth stroke won by either player is acored gate for that piayer, except as below.

If both playere have won three strokes, tha score is called deace; and the next atroke won by either plajer is scored advantage for that plajer. If the same player win the next etroke, he wins the garne ; if he lase the nert atroke, the score is amin called deuce; and so on until either player win the two strekes immediately following the score of dence, when the pame is scored for that player.
22. The flayer who first wios six chmes wing a set, except as below.

If both players win five games, the acore is called games all; and the next game won by either player is ecored advantaga game for that player. If the aatoe player win tha next game, he wins the set; if he lose the next
game, the score is again called gsmes all ; anu so on until either player game, the score is again called gsmes all : anu so on ubtil either player win the two g
Note.- Playera may agree not to play advantege sets, but to decide the set by one game after arriving at the score of games all
22. The players shall change sides at the end of every set ; but the umpire, on appesi from aither party befors the toss for choice, may direct the players to change aides at the oad of every gane if in his opinion cither side have a distinct advantage, owing to the sua, Find, or any other sccidental cause; bot, If the appeal be mado after a match has bcen began, the umpire may only direct tha players to change aides at the end of every gatne of the odd and concluding set.
24. When a saries of sats is played, the player who was server in the last game of one aot shall be etriker-ont in the first game of the next.

## Odds.

25. A bisqua fa ene atroke, which may be claimed by the receiver of the odd: at any time during a set, except as below.

A bisqua may not be taken after the service has been delivered.
The erver may not take a bisque after a favit; but the striker-ont may do ao.
26. One or more blaques may be givea in augrentation or diminntion of ther odds.
27. Half-ifteen is one stroke given st the beginning of the second and every subsequeat alternate gatne of a set,
28. Fifteen is one strake given at the beginning of every game of a set.
29. Half-thirty ia one stroke given at the beginning of the first game, two atrokes at the beginning of the eecond game ; and so on, alternately, in all the ubseqnent grzaes of 8 sat.
30. Thirty ia two strokes given at the beginning of every game of a set.
31. Half-forty is two strokes given at the beginning of the first game, three strokes at the beginning of the second game; and so on, alternately, in all the subseqnent games of a aet.
3. Forty is thres strokes given at the beginning of every game of a aet.
33. Half-court: the players having agreed into which conrt the giver of the odds shall play, the latter loses a stroke if the ball, returned by him, drop outside any of the lines which bound that court.

## Three-Handed and Four-Handed Games.

34. The above lawe shall apply to the three-banded and forr-hauded gamee, except as below
idth. With three-handed and four-handed games the court is 38 leet in o them, Winin the side lines, at a distance of $4 \frac{1}{4}$ feet from them, sud parallel to them, are drawn the service side lines 1 K and LM. The service lines ard not drawn beyond the pointe $\mathrm{I}, \mathrm{K}, \mathrm{K}$, and M , towards the side lines. In othey
respects, the conrt is sirmilar to that which is described in law 1 . respects, the conrt is aimilar to that which is described in law 1.
S6. In the three-handed game the singla player shall serve in avery altanaty ${ }_{\text {gis. }}$ In the four-hauded game, the pair who have the right to acrve in the first game may decide which partner ahall do so, and the opposing pair msy decide aimilarly for the second gsme. The partaer of the player who eerved in the first game shall serve in the third; and the partner of the player who eerved in the eecood game shail serve in the fourth; and 80 on in the bame order in al; the subsequent kabies of a set.

3a. The players shall take the service alternately throughout esch game. No plujer shall receive or return a service delivered to his partace. The order of scrvice sad of striking-out ouce arranged ehall not be altered, ner suan.
S9. The ball served mast drop Within the eervice line, half-court line, sad aervice side line of the court which ls diagonslly opposite to thst from which it was served, or upon bay such line.
40. It is a fsult if the ball serred do not drep as provided in ?sw 39 , or if it tonch the e日rver's partner or anything that he weare er carriee.
41. If a player serve ont of his turn, the umplre, ss вoon as the mistake is discovered by himself or by one of the players, ahall direct the player to serve who ought to have eerved; but all strokes ecored and any fault berved befors Who onght to have served; but all strokes ecored and any fault aerved before
such discovery ehsll be reckoned. If a game shall have been completed before
 ouch discovery, then partner of the player who served out of his turn ; snd so on in regular by the pa
rotation.
(J. MA*.)

TENT. A tent is a portable habitation or place of shelter consisting in its simplest form of a covering of some textile substance stretched over a framework of cords and poles, or of wooden rods, and fastened tightly to the ground by pegs. Throughout the greater part of the interior of Asia the pastoral tribes have of necessity ever been dwellers in tents,--the scantiness of water, the consequent frequent failure of herbage, and the violent extremes of seasons compelling a wandering life. Tents have also been used in all ages by armies in campaign.. In ancient Assyrian sculptures discovered by Layard at Nineveh the forms of tent and tent-furnishings are, similar to those which still provail in the East, and it appears that then as now it was a custom to pitch tents within the walls of a city. The ordinary family tent of the Arab nomads of modern times is a comparatively spacious ridged structure, averaging from 20 to 25 feet in length, but sometimes reaching as much as 40 feet. Its covering consists of a thick felt of black goat hair (cp. Cant. i. 5), or sometimes of alternate stripes of black and white disposed horizostally. The ridge or roof is supported by nine poles (avamid) disposed in sets of three, the central set heing loftier than those at each end, whereby a slope outward is formed which belps to carry off rain. The average height inside at the centre is 7 feet and at the sides 5 feet, and the cloths at the side are so attached that they can easily be removed, the sheltered end being always kept open. Internally the tent is separated by a partition into two sections, that reserved for the women containing the cooking utensils and food. The jourt or tent of the Kirghiz of Central Asia is a very capacious and substantial structure, consisting of a wooden frame for sides, radiating ribs for roof, and a wooden door. The sides are made up of sections of laths, which expand and contract in lozenges, on the priaciple of lazy tongs, and to their upper extremities ribs are lashed at regular intervals. Over this framework a heavy covering of felt is thrown, which is either weighted down with stones or. when necessary, stitched together.

In Western countries tents are used chiefly in military encampments, by travellers and explorers, and for temporary ceremonial occasions and public gatherings. The material of which they are composed is commonly a light linen canvas or navy duck; but for tents of small size stout cotton canras is employed, being light, strong, elastic, and sufficiently waterproof. These tents vary in size from a low-pitched covering, under which a couple of men can with difficulty creep, ap to spacious marquees, in which herticultural and agricultural shows are held, and which can accommodate thousands of persons.
The marquee is distinguished from the tent by being a ridged struecture, devoted to show and social uses; but the humblest tent mqde-the tente d'abri or shelter tent of the French armyis also ridged in form. The texte d'abri affords sleeping accommodation for six men, and consists of a rope stretched over three low poles and fixed into the ground. Four separate squares of canras buttoned together are thromn over the rope and pegged to the ground on each side so as to form a low ridge. Two other squares are used for covering the ends, being thrown over the slanting rope ends by which the poles are pegged to the ground. Each of the six men nsing the fent carries ene of the squares of canvas hesidea his quota of the poles, rope, and peegs. The Gipsics and travelling tinkers of Englanc' have an equally unpre-
tentious tent, which consists of a framework of hazel rods bent so as to form a series of low ridges, the ends heing stuck iuto the ground, and over this frame blanketg or other coverings are thrown and pegged down. The siinplest, but at the same time the least convenient, of ordinary tents is the conical, consisting of a central pole with ropes and canvas radiating from it in an unbroken slopa to the greund. This form, however, covers much ground in propertion to the accommodation it affords, as the space round the circumference is of little value. A tent, thercfore, which has sides or a fall is a much more couvenient structure. The counterpart of the conical is the pyramidal tent, the forr equal eides sloping to the ground ; and this form with a fall or sides makes the square tent, which is both couvenient in shape and firm in structuro. Small tents are also made, modified from the $\Delta$ rab ferm, with a central pole and two lewer lateral poles. In the umbrella tent the roof is supported by a set of ribs which radiate from the pole, precisely as the ribs of an umbrella spread out from the stick. In the balloon expansion tent, invented in 1877 by Captain Newburgh Stevart, R.N., the use of tent pole, pegs, and ropes is entirely avoided, the canvas being eupported by light ribs of elastic mood resting on the ground, and the structure is kept taut by hauling ropes descending from the apes and secured by a holdfast driven into the groond. When from the nature of the sarface sucl fastening cannot he obtained, a heavy weight of any kind bung to the hauling rope is suffcient to moor the tent, and except in stormy weatber the weight may be hung high np, thus leaving the whole interior of the tent clear. As forther provision against stress of weather there are four iren holdfasts at the sides, which may he skecwered into the ground by long iron pins. Captain Stewart claims that his tent possesses much greater stahility and capacity than the ordinary army tent, that it is mnch more easily and expeditiously pitched and taken down, and that it is very mucb lighter. In the latter iraportant respect he calcnlates that by the adoption of his pattern a regiment at present carrying eighty tents of the Indian service pattern would save no less than twenty tons of transport.

TEPLITZ, or Töplitz, one of the most frequented watering-places in the north of Bohemia, is picturesquely situated about 30 miles south of Dresden, in the plain of the Biela, which separates the Erzgebirge from the Bohemian Mittelgebirge. The main interest of the little town centres in the bathing seasou, which reaches its height in August ; and the arrangements for the convenience end amusement of visitors are very complete. There is a large curhaus, and numerous handsome bathhouses are situated both in Teplitz and in the immediately adjoining village of Schönau. The environs are laid ont in pretty and shady gardens and promenades, the finest being in the park which surrounds the château of Prince Clary, the superior of the town. The other chief buildings are the Roman Catholic and Protestant churches, the Jewish synagogue with a conspicuous dome, and the theatre. The saline-alkaline springs of Teplitz, ten to twelve in number, ranging in temperature from $90^{\circ}$ to $117^{\circ}$ Falr., are classed among what are called "indifferent" waters. Used until lately almost exclusively for bathing, they are prescribed for gout, rheumatism, and some scrofulous affections, and their reputed efficacy in alleviating the effects of gun-shot wounds had gained for Teplitz the sobriquet of "the warriors' bath." Military laths are maintained in the town by the Governments of Austria, Trusia, and Saxony, and there are also bath-houses for the poor. Teplitz is much visited for the after-cure, after Carlshad and similar spas. The number of patients in 1883 was 6000 and the passing visituzs were almost as numerous. The presence of a bed of lignite in the neighbourhood has encouraged the industrial development of Tcplitz, which carries on manufactures of cotton and woollen goods, india-rubber, chomicals, hardware, \&cc. In 1880 the unitcd population of Teplitz and Schöuau wa 16,750.
The thermal eprings are fabled to havo been discovered as early as 762 , but the first autlientic mention of the baths occurs in the 36 th century. The town is mentioned in the 12 th century, the name heing derived from a Slavonic word meaning "warm bath ${ }^{\text {S }}$ Teplitz figures in the history of Wallenstein, and is also interest. ing as the spot where the ruonarclis of Austria, Russis, and Prussis first signed the triple alliance asainst Napoleon in 1513. It is a
curious fact that on the day if the earthquake at Lisbon (1st November 1775) the main spring at Teplitz ceased to flow for some minutes.
TERAMO, a town of Italy, capital of the province of Teramo (formerly Abruzzo Ulteriore I.) and an episcopal see, stands on the left bank of the Tordino where it is joined by the Vezzola, 12 miles from the coast and 876 feet above sea-level. It is connected by a branch line with Giulianova on the railway from Ancona to Brindisi. The picturesque valley of the Tordino is here dominated by the peaks of the Gran Sasso d'Italia ( 9522 feet). The town is traversed by one straight wide street with large houses, but for the most part it consists of narrow dirty lanes; the modern suburbs are good. The cathedral (1317-55) has been greatly modernized ; the church of San Agostino is in the later Gothlc style. The antiquities include remains of a gateway, a theatre, and baths, as well as numerous inscriptions There are manufactures of wool and silk, and of straw hats and pottery. The population of the town in 1881 was 8634 , with its suburbs 13,988 (commune, 20,309 ).
Teremo is the ancient Interamua Pretutiana, capital of the Pratutii. In the Middle Ages it was known as Aprutium (whence Abruzzo); the intermcdiate form of the present name was Teramne.
TERAPHIM (תרפים), a Hebrew word found only in the plural, which the Authorized Version sometimes simply transcribes (Judges xvii. 5, xviii. 14 sq.; Hosea iii. 4), but elsewhere translates by "images" (Gen. xxxi. 19 and often elsewhere), "image" (1 Sam. xix. 13), "idols" (Zech. x. 2), "idolatry" ( 1 Sam. xv. 23) The etymology of the word 'is quite obscure (see Gesenius, Thesaurus, p. 1519 sq.), but it appears that the teraphim were a kind of idols (Gen. xxxi. 30), with something of a human figure ( 1 Sam . xix. 13); and, though their use was condemned by the prophets ( 1 Sam. xv. 23 ; cp. 2 Kings ixiii. 24), they were long commonly used in popular worship, both domestic (1 Sam. xix. 13, in the house of David and Michal) and public (Judges xviii.). They are associated with the ephod, which in this connexion seenss to mean a plated image, and Hosea speaks of ephod and teraphim as essential elements in the religious usages of northern Israel. Like the ephod, they were specially associated with divination, and in particular with the sacred lot (Zech. x. 2; Ezek. xxi. 21 [26]) From the last passage it appears that teraphim were used by the Babylonians as well as by the Hebrews. These statements and references cover all that is known about the teraphim ; the fables of the rabbins are collected in Buxtorf, Lex. T'almud., 2660 sq .
terburg, Gerard ( $1608-1681$ ), sulject painter, was born in 1608, at Zwolle, in the province of Overyssel, Holland. His father, also an artist, sent him to study in Rome, where he adopted a style distinguished by great finish and accuracy. He practised for a time in Paris with much success, visited England, it is said, and then returned to Holland. In 1648 he was at Münster during the meeting of the congress which ratified the treaty of peace between the Spaniards and the Dutch, and executed his celebrated little picture, painted upon copper, of the assembled plenipotentiaries,-a work which, along with the Guitar Lesson, now represents the master in the national collection in London. At this time Terburg was invited to visit Madrid, where he received employment and the honour of knighthood from Philip IV. It is said that, in consequence of an intrigue, he was obliged to return to Holland. He seems to have resided for a time in Hearlem ; but he finally settled in Deventer, where he became a member of the town council, as which he appears in the portrait now in the gallery of The Hague. संख died ar Deventer in 1681.
Terburg is exccllent as a portrais painter, bat still greater as a oauter or genre subjects. He depicts with admirable trutl, the
life of the wealthy and cultured classes of his time, and his work is free from any touch of the grossness which finds so large a place in Dutch art. His figures are well drawn and expressive in attitude; his colouring is clear and rich; but his best skill lies in his unequalled readering of texture io draperies, which is aeen to advantage in such pictures as the Letter in the Dutch royal collection, and in tbe Paternal Advice (known as the Satin Gown)engraved by Wille-which exists in various repetitions at Berlin and Amsterdam, and io the Bridgewater Gallery. Terburg's works are rare ; only about eighty have been catalogued.

TERCEIRA. See Azores, vol. iii. p. 171.
TEREDO, a genus of Lamellibranchiate Mollusea, of the order Isomya, sub-order Sinupallia, family Pholadacea (see Mollusca, vol. xvi. p. 685) The animals included in this genus are commonly' known as "ship-worms," and are notorious for the destruction which they cause in ships' timbers, the woodwork of harbours, and piles or other wood immersed for a long period in the sea. They inhabit long cylindrical holes, which they excavate in the wood, and usually occur in great numbers, crowded together so that often only a very thin film remains between the adjacent burrows. Each burrow is lined with a layer of calcareous substance secreted by the mollusc; this lining is not usually complete, but stops short a little distance from the inner end of the burrow, where the boring process continues to take place. In some burrows, however, the lining is complete, either because the animal has reached its full size or because some cause prevents it continuing its tunnel; in such cases the calcareous tube has a hemispherical termination. The burrows are usually driven in the direction of the grain of the wood, but not invariably so. When a knot or nail or the tube of a neighbour is reached, the course of the burrow is altered so as to bend round the obstruction. One burrow is never found to break into another.

The adult Teredo, when removed from its burrow and calcareous tube, is from a fetw inches to 3 feet in length, according to the species to which it belongs, and is cylindrical and worm-like in appearance. The anterior end, which lies at the bottom of the burrow, is somewhat enlarged and bears a pair of shells or valves, which are not connected by the usual ligament, bat are widely separated dorsally. The valves are triangular in shape and very concave on the side which is in contact with the animal. In front their edges are widely separated, and the mantle tube, which is elsewhere closed, has here a slight median aperture, through which the short sucker-like foot can be protruded. The next portion of the body behind the shell-bearing part is naked, except for the shelly lining of the burrow, which is secreted by this part. Anteriorly this portion contains part of the hody proper; posteriorly it forms a tube divided internally by a horizontal partition into two chambers. In the lower chamber are the elongated gill plates, which have the typical lamellibranchiate structure. In the upper chamber anteriorly is the rectum. A thick muscular ring terminates this region of the body, and bears two calcareous plates shaped like spades or battledores. The expanded parts of these plates are free and project backwards; the handle is fixed in a deep socket or pit lined by epidermis. These calcareous plates are called pallets (Fr. palmules). Behind the pallets the tubbular body bifurcates, forming two siphons similar to those of other Lamellibranchs; the siphons can be contracted or expanded within wide limits of length. The principal organs of the body-stomach, heart, generative organs, and nephridia-are situated in the anterior part of the body, forming a visceral mass, which extends some distance behind the valves. The heart is above the intestine and not perforated by it. The two valves are connected by an anterior adductor muscle.

From its resemblance to Pholas, Teredo is placed by conchologists in the family Pholadider, emeng the Isomya; but it is still unde-
cided which part of the body corresponds to the posterior adductor. According to Quatrefages, it is a muscular band passing transtersely between the handles of the pallets. His discussion of this point is connected with another, namely, the nature of the long tubular portion of the body behind the valres. Deshayes limits the axtent of the mantle to the part covered by the shell, snd considera all the rest of the animal as formed by the siphons; the branchix and part of the other viscers in this view are contained in the siphons. Quatrefages argues that the siphons commence at the point where their retractor muscles are inserted, namely, at the muscular ring corresponding to the pallets. This reasoning is plausible; but it is difficult to accept the view that the retractor muscles of the aiphons and the posterior adductor muscle are so closely connected as Quatrefages thinks; in other Isomya the retractors of the siphons and the posterior adductor are distinct and separate. Deshayes believes thes the single adductor between the valves results from the fusion of the two muscles usually separate. Jeffreys belisves that the posterior adductor is really present between the posterior parts of the valves; but the opinion of a conchologist on a question of morphology is not of very great weight. In other Isomya the visceral (paristo-splanchnic) ganglia are attached to the rentral surface of the posterior adductor. In Tercdo these ganglia are situated at the posterior end of the body proper, some distance behind the shells, and immediately behind the generative organ. It is hers probably that the rudiment of the posterior adductor, if it exists, is to be sought ; or, if it does not exist, it is here that it originally was placed.
It is evident that the anatomy of Teredo has not yet been in. vestigated from the point of view of modern morphology; bnt as far as can be judged at present the body proper oxtends back some distance behind the shells, to the posterior limit of the visceral mass. The part between this and the pallets is a tubular prolonga. tion of the mantle chamber containing the axtended gill laminæ, and beyond the pallets are the separate siphons. Besides ths visceral ganglia a cerebral and a pedal pair are present. The stomach is provided with a large crystalline style. Ths function of the pallets is to form an operculum to the calcsreous tube when the siphons are withdrawn into it. In soms species the external or narrowser and of the calcareous tube is provided with transverse laminæ projecting into the lumen; and in some the oxteraal aperture is divided by a horizontal partition into two, one for each siphon.

The Teredo, according to Quatrefages, is direcions, though Gwyn, Jeffreys believes it to be hermaphrodite. As in the case of the oyster, the ova ars retained in the branchial chamber during the early stages of their development. The segmentation of the ovum is unequal, and leads to the formation of a gastrula by apibole. By the growth of a preoral lobe provided with a ring of cilia, and by the formation of a mouth and an anus, the trochosphere stage is reached. A pair of thin shells then appear on the sides of the larve, connected by a hinge on the dorsal median line, and the foot grows out bstween mouth and anus. By the time the larra "swarm," or leave the branchial cavity of the parent to live for a time as frecswimming pelagic larve, the valves of the shell have grown so large as to cover the whols of the body when the velnm is retracted; the foot is also long, cylindrical, sad flexible, and can be protruded far beyond the shell. The valves of the ehell at this stage are hemiapherical in shape, so that the whole larva when its organs are retracted is contained in a globular case.
Concerning the later changes of the larva and the mothod by which it bores into wood nothing or little is known from direct observation. Much has been written about the boring of this and other marine animals, but even yet the matter cannot be eaid to be satisfactorily elncidated. Osler, in a paper in Phil. Trans., 1826, argued that the Teredo bores by means of itsshells, fixing itself by the surface of the foot, which it uses as a sucker, and then rasping the wood with the rough front edges of the shell-walves. This view was-founded on the similarity of the arrangement of the shells and mnscles in Teredo to those occurring in Pholas, in which the msthod of boring described was actually observed. W. Thompson, in a paper in the Edinb. New Phil. Journ., 1835, snpported the Fiew that the excavation is due to the action of a eolvent secreted from the eurface of the animal. Albany Hancock, sgain (Ann. and Mrag. Nat. Hist., vol. Iv.), thinks that the excavating power of Teredo is dus to silicions particles embedded in the anterior portion of the integument, in front of the valves. But the actual existence of either silicious particles or acid secretion has been denied by others. Jeffreys believes that the foot is the organ by which the animal burrows. In the larger number of Lamellibranchs the fort is doubtless a burrowing organ, and it is difficult to see how the limpet hollows out the rock to which it is attached if not by means of the snrfacs of its foot. At the sams time it is difficult to explain how the soft muscular foot can penstrate into hard wood. The process is of course slow, and Jeffreys supposes that particles are detached one by one from the moistened surface to which the foot is applied. In any case the valves are covered by an epidermis, which could scarcelv be there if they wers used in burrowing.

Teredo grows and burrows at an extremely rapid rate: spawning takes place in the spring sud summer, and before the end of the year the animals are adult and their burrows of large size. Quatrefages relates that at Guipuzcos (N. Spain) a ferry-boat was sunk accidentally in the spring, and was raised four months afterwards, When its timbers were slready rendered nseless by T. pedicellata, -How long the animals live is not accurately known, but Quatro. fages found that they nearly all perished in the winter. This cannot be generslly the cass, as the size of the tubes varies so greatly. In Holland their greatest rarages are mads in July and August. Iron ships have nothing to fear from their sttacks, and the copper sheathing now almost universally used protects wooden hulls. A great deal of loss is, however, cansed by Tercdo in harbour works and shipping stages, and ths embankments in Holland are continnally injured by it. The most effcisnt protection is afforded by large-headed nails driven in in close proximity. Soaking wood is creasots is not a certain eafeguard; Jeffreys. fonnd at Christiania in 1863 that a large number of harbour piles previously aoaked in creasots had beon completely destroysd by T. navalis. Cosl tar and the silicate of lims, used for coating stonework, have been soggested as protective coverings, but they do not seem to bavo been adequately tested.

Species of Toredo occur. in all seas. The animal was known to the ancients and is mentioned by Theophrastus, Pling, snd Ovid. In 1715 it is mentioned by Valisnieri, in 1720 by Deslandes. In 1733 great attention was drawn to it on account of the discovery that the wooden dykes of Holland were being rapidly destroyed by ship-worms, and that the country was in danger of inundation Thres treatises were published concerning the animal, by P. Massust, J. Rousset, and Godfrey Slllius. The work of the last-mamed, which was the best, described the anatomy of the creature and showed that its affinities were with bivalve molluses. Tho truth of Sellins's view was not grasped by Linnæus, who placed Tcredo together with Serpula in ths genus Dentalium; but its proper position was re-established by Cuvier and Lamarck. Adansor, unaware of the work of Sellins, in 1757 believed himself to bs the first to discover the molluscan affinities of Teredo. It will not be necessary to give here a definition of the genns taken from any gystematist; it will be sufficient to point out that the long cylindrical body with its two small anterior polygonal valves, the absence of a ligament and aceessory valves, the muscular ring into which are inserted the calcareous pallets, and the continnows calcareous tabe lining the hole bored by the animal are the diagnostic features.
Jeffrsys, in his British Conchology, gives the following species as British:-Teredo norvegica, Spengler; T. navalis, Linn.; T. pedicellata, Quatrefages; T. megotara, Hanley. T. norvegica occurs chiefly on the west coast of Great Britain. It was taken by Thompson at Portpatrick in Wigtownshire, and occurred in Jefreys's time in abnndance at Milford Haven. This species has been described by Gmelin and a nnmber of British authors ss T. navalis, Lina. It is distinguished by having the base of the pallets siroplo, not forked, and the tube semi-concsmereted at its narrower posterior and. The length does not usually dacceed a foot. It is the T. navium of Sellius. T. navalis has been identified from tha figures of Sellins, to which Linnaus referred; Sellius called it $T$. marina. It occurs on all the western snd southern coasts of Europe, from Christiania to the Black Sea, and is the species which canses so much damage to the Dutch embankments. The pallets of this speciea are omall and forked, and the stalk is cylindrical. The tubs is simpls and not chambered at its narrow end. $T$. pedicellata was originally discovered by Quatrefages in the Bay of Los Pasages on the north cosst of Spain; it has also been found in the Channel Islands, at Tonlon, in Provence, and in Algeria. In T. megotara the tube is simple and the pallets like those of $T$. norvegica; it occurs at Shetland and Wick, and also on the western shore of the Atlantic, where its rangs extends from Massachusetts to South Carolina. T. malleolus, Turton, and T. bipinnata, Turton, belong to the West Indies, but are often drifted in floating timber to the coasts of Europe. Other occasional pisitants to the British shores are T. excavata, bipartita, spatha, fusticulus, cucullata, and fimbriata. Thess were described by Gwyn Jeffrsys in Ann. and Mag. Nat. Hist., 1860. T. fimbriata is stated to be a nativo of Vancouper's Island. A kind of ship-worm, the Nausitora dunlopi of Perceval Wright, has been discorered in India, 70 miles from the sea, in a stream of perfectly fresh water, namely, the river Kumar, one of the branches of the Ganges. T. corniformis, Lam, is found burrewing in the busks of cocoa-nuts and other woody fruits floating in the tropical seas its tubes are estremely crooked and contorted for want of space. Fossil wood and palm.fruits of Sheppey and Brabant are pierced in the same way.

Twenty-four fossil species have been recognized in the Lias and succeeding beds of Europe and the United States. The sub-genus Teredina, Lam., is a fossil of the Eocene of Great Britain and France.

TEREK (Russ. Terskaya oblast), a Russian government of Caucasia, situated to the north of the main Caucasus chain. It is bounded by Starropol on the N., by the Caspian Sea and Daghestan on the E., by Tifis and Kutais on the S., and by Tchernomorsk and Kuban on the W. It has an area of 23,548 square miles. From Nt Elburz to Kazbek the southern boundary coincides with the main snow-covered range of the Caucasus and thus includes its highest peaks ; further east it follows a sinuous line so as to embrace the secondary chains and their ramifications. Nearly one-third of the area is occupied by hilly tracts, the remainder being undulating and flat land belonging to the depression of the Terek; one-half of this last, on the left bank of the river, is occupied by sandy deserts, salt clay steppes, and arid stretches unsuited for cultivation. Granites, syenites, diorites, and Palæozoic schists constitute the nucleus of the Caucasus mountains ; Jurassic and Cretaceous formations rise to great heights in the secondary chains; and a series of Tertiary formations, covered by Quaternary deposits, cover a wide area in the prairies and steppes. A group of mineral springs occura about PyatiGORSK ( $q \cdot v$. .
The climate is continental. The mean annual temperatures are $49^{\circ} \cdot 8$ Fahr. at Pyatigorsk ( 1850 feet above the eea ; January $39^{\circ}$, Jaly $70^{\circ}$ ) and $47^{\circ} \cdot 7$ at Vtadikavkaz ( 2230 ft ; January $23^{\circ}$, July $69^{\circ}$ ), but frosts a few degrees below zero are not uncommon. The mountain slopes rececive an ahundance of rain ( 37 in.), but the steppes suffer much from drought (rainfall between 10 and 20 in.). Nearly the whole of the government belongs to the drainage area of the Terek, but the north-west corner is watared by the upper tributaries of the Kuma. The Terek rises at the height of obout 8000 feet in the glaciers of the Kazbek on the southern slope of the main chain of the Cancasus,* hich it pierces by the Darial gorge to the south of Vradikavkaz after having received several dons or etreams (Res, Guzel, Fiag, Ar). In 53 miles it descends neerly 6000 feet. A few miles above Vtadikavkaz it is 2068 feet above sea.level, at Mozdok 441 feet, and it is 29 feet below the Black Sea at Kizlyar. From Vładikavkaz it pursues a north-easterly direction before taking its eastward courso; it seems most proboble that at a recent cpoch (Post-Plicrene) it joined the Kuma and perhaps the Manytch instead of flowing into the Caspian. In the lower part of its course it fows a a a higher level than that of the neighbouring plains, and is kept in its bed by dams. Inundations are frequent and cause great destruction. The delta begios $2 \ddagger$ Duborka ( 50 miles from the Caspisn), and at this part the river frequently changes its bed. The Old̀ Terelk is no longer uavigahle, the chief current being directed northwards into the New Terek Several canals made by the Cossacks supply water for the irrigation of the neighbouring fields. Its chief tributaries are the Sunja on the right, and the Tcherekh, the Baksan, and the Malka, in its apper course, on the left. The population of the government in 1884 was 615,660 ; of 608,500 inhabitants returned in 1883, 238,230 were Little and Great Russians, 1230 Georgians, 18,500 Armenians 4300 Germans, 2570 Poles, 4780 Jers, 23,630 Ossets, 194,430 Tchetchens and Ingushis, 72, 160 Kabardians, 9130 mountaincers of the Avarín stem, 25,360 . Kumyks, $1 \pi i 0$ Tatass, 6270 Nogais, 2470 Kalmucks, and 1620 Persians. Out of these 239,500 were reckoned as belonging to the Greek Orthodox Church, 336,460 were Mussulmans, 17,730 Gregorian Anmenians, and tho remainder Protestants, Catholirs, and Jers. Owing to the great fertility of the soil in the well-watered districts, agriculture is the chief occupation. In 1882 the crops, slthoughi below the average, yielded 967,000 quarters of corn, 268,000 bushels of potatoes, $6,750,000$ gallons of wine, and tobacco to the value of \&18,000. Cattlo breeding is extensively carried on in the steppes, snd there were in the same year 118,630 horses, 582,800 cattle, and 1,220, 400 sheep ; murrains, however, are frequent, and cause great loss, Manufactures occupy only 3371 persons, and their yearly production hardiy reaches $£ 300,000$ in value. Petty, trades are rapidly spreading in the villages. Trade suffirs from want of good roads. Tho railway from Russia to the Caucasus has not yet (1887) got beyond Vtadikavkaz. The unilitary and other chief roads have an aggregate of only 1300 miles. The exports are limited to corn, wine, cattle, and some raw produce.

The government is divided into six districts, the chief towns of which, with their populations in 1883, were Vtadikavkaz (32,340), the capital, Georriersts ( 4250 ), Groznyi ( 6280 ), Eizlyar ( 8780 ), Mozdok (8380), and Pyatigorak (11.120).

TERENCE. P. Terentins Afer ( 185 ?-159 b.c.) holds a unique position among Roman writers. No writer in any literature has gained so great a reputation who has contented himself with so limited a function. He lays no claim to the position of an original artist painting from life or commenting on the results of his own observation. His art has no relation to his own time or to the country in which he lived. The chief source of interest in the fragmentary remains of Nævius, Ennius, Pacuvius, Accius, and Lucilius is their relation to the national and moral spirit of the age in which they were written. Plautus, though, like Terence, he takes the first sketch of his plots, scenes, and characters from the Attic stage, is yet a true representative of his time, a genuine Italian, writing before the genius of Italy had lcarnerl the restraints of Greek art. The whole aim of Terence was to present a faithful copy of the life, manners, modes of thought and expression which had been dramn from reality a century before his time by the writers of the Nexv Comedy of Athens. The nearest parallel to his literary position may be found in the aim which Virgil puts before himself in his Bucolics. He does not seek in that poem to draw Italian peasants from the life, but to bring back the shepherds of Theocritus on Italian scenes. Yet the result obtained by Virgil is different. - The charm of his pastorals is the Italian sentiment which pervades them. His shepherds are not the shepherds of Theocritus, nor are they in any sense true to life. The extraordinary result obtained by Terence is that, while he has left no trace in any of his comedies of one sketching from the life by which he was surrounded, there is perhaps no more truthful, natural. and delicate delineator of human nature, in its ordinary and more level moods, within the whole range of classical literature. His permanent position in literature is due, no doubt, to the art and genius of Menander, whose creations he has perpetuated, as a fine engraver may perpetuate the spirit of a great painter whose works have perished. But no mere copyist or verbal translator could have attained that result, Though without claims to creative originality; Terence must have had not only critical genius, to enable him fully to appreciate and identify himself with his originals, but artistic genius of a high and puio type. The importance of his position in Roman literature consists in this, that he was the first writer who set before himself a high ideal of artistic perfection, and was the first to realize that perfection in style, form, and consistency of conception and execution. Living in the interval between Ennius and Lucilius, whose original forco and genius survive only in rude and inartistic fragments, he produced six plays, which have not only reached our time in the form in which they were given to the world, but have been read in the most critical and exacting literary epochs, and still may be read without any feeling of the need of making allowance for the rudeness of a new and undeveloped art.

While his great gift to Roman literature is that he first. made it artistic, that he imparted to "rude Latium" the sense of elegance, consistency, and moderation, his gift to the world is that through him it possesses a living image of the Greek society in the 3d century B.c., presented in the purest Latin idiom. Yet Terence had no affnity by birth either with the Greek race or with the people of Latium. He was more distinctly a foreigner than any of the great classical writers of Rome. He lived at the meeting-point of three distinct civilizations,- the mature, or rather decaying, civilization of Greece, of which Athens was still the centre; that of Carthage, which was so soon to pass away and leave scarcely any vestige of itself; and the nascent civilization of Italy, in which all other modes were soon to be absorbed. Terence was by birth a Pbæenician.
and was thus perhaps a fitter medium of connexion between the genius of Greece and that of Italy than if he had been a pure Greek or a pure Italian; just as in modern times the Jewish type of genius is sometimes found more detached from national peculiarities, and thus more capable of reproducing a cosmopolitan type of character than the genius of men belonging to the other races of Europe.
Our knowledge of the life of Terence is derived chiefly from a fragmert of the lost work of Suetonius, De Viris Illustribus, preserved in the commentary of Donatus. Confirmation of some of the statements contained in the Life is obtained from later writers and speakers, and also from the prologues to the different plays, which at the same time throw light on the literary and personal relations of the poct. These prologues were among the original sources of Suetonius; but he quotes or refers to the works of various grammarians and antiquariansPorcius Licinus, Volcatius Sedigitus, Santra, Nepos, Fenestella, Q. Cosconius-as his authorities. The first two lived within a generation or two of the death of Terence, and the first of them shows a distinct animus against him and his patrons. But, notwithstanding the abundance of authorities, there is uncertainty as to both the date of his birth and the place and manner of his death. The doubt as to the former arises from the discrepancy of the MSS. His last play, the Adelphi, was exhibited in 160 b.c. Shortly after its production he went to Greece, being then, according to the best MSS., in his twenty-fifth ("nondum quintum atque vicesimum egressus ${ }^{1}$ annum"), according to inferior MSS., in his thirty-fifth year. This uncertainty is increased by a discrepancy between the authorities quoted by Suetonius. Cornelius Nepos is quoted for the statement that he was about the same age as Scipio (born 185 x.c.) and Lælius, while Fenestella, an antiquarian of the later Augustan period, represented him as older. As the authority of the MSS. ceincides with that of the older record, the year 185 b.c. may be taken as the most probable date of his birth. In the case of an author drawing originally from life, it might seem improbable that he should have written six comedies, во true in their apprehension and delineation of various phases of human nature, betwern the ages of nineteen and twenty-five. But the case of an imitative artist, reproducing impressions derived from literature, is different; and the circumstances of Terence's arigin and early life may well have developed in him a precocity of talent. His acknowledged intimacy with Scrpio and Lelius and the general belief that they assisted him in the composition of his plays are more in accordapee with the statement that he was about their own age than that he was ten years older. Terence, accordingly, more even than Catullus, Tibullus, or Lucan, is to be ranked among those poets who are the "inheritors of unfulfilled renown." He is said to have been born at "'arthage, brought to Rome as a slave, and carefully edurated in the house of M. Terentius Lucanus, by whor, he was soon emancipated. A difficulty was felt in arcient times as to how he originally became a slave, as t' 1 ere was no war between Rome and Carthage between "he Second and Third Punic Wars, and no commercial re'ations between Africa and Italy till after the destruction of Carthage. But there was no doubt as to his Phœeni an origin. He was admitted into the intimacy of yrung men of the best families, such as Scipio, Lælius, and Furius Philus, and he enjoyed the favour of older mer of literary distinction and official position, such as C. Sr-lpicius Gallus, Q. Fabius Labeo, and M. Popillius. He is said to have owed the favour of the great as much to his personal gifts.and graces as to his literary distinction;

[^63]and in one of his prologues he declares it to be his ambition, while not offending the many, to please the "boni."
Terence's earliest play was the Andria, exhibited in 166 B.c., when the poet could have been only about the age of ninetcen. A pretty, but probably apocryphal, story is told of ,his having read the play, before its exhibition, to Cæcilins (who, after the death of Plautus, ranked as the foremost comic poet), and of the generous admiration of it manifested by Cæcilius. A similar instance of the recognition of rising genius by a poet whose own day was past is found in the account given of the risit of Accius, on his journey to Asia, to the vetcran Pacuvius. The next play exhibited by Terence was the Hecyra, first produced in 165, but withdrawn in consequence of the bad reception which it met with, and afterwards reproduced in 160. The Heauton-timoroumenos appeared in 163, the Eunuchus and Phormio in 161, and the Adelphi in 160 at the funeral games of L. Æmilius Paulus.

After bringing out these plays Terence sailed for Greece, either to escape from the suspicion of publishing the works of others as his own, or from the desire to obtain a more intimate knowledge of that Greck life which had hitherto been known to him only in literature, and which it was his professed aim to reproduce in his comedies. The latter is the more probable motive, and we recognize in this the first instance of that impulse to visit the scencs familiar to them through literature which afterwards acted on many of the great writers of Rome. From this voyage to $G$ reece Terence never returned. According to one account he was lost at sea, according to another he died at Stymphalus in Arcadia, and according to a third at Leucadia, from grief at the loss by shipwreck of his baggage, containing a number of new plays which he had translated from Menander. The old grammarian quoted by Suetonius states that he was ruined in fortune through his intimacy with his noble friends. Another account speaks of him as having left behind him property consisting of gardens, to the extent of twenty acres, close to the Appian Way. It is further stated that his daughter was so well provided for that she married a Roman knight.
The tone of the prologues to Terence's plays is for the most part apologetic, and indicates a great sensitiveness to criticism. He constantly speaks of the malevolence and detraction of an older poet, whose name is said to have been Luscius Lavinius or Lanuvinus. The chief charge which his detractor brings against him is that of contaminatio, the combining in. one play of scenes out of different Greek plays. Terence justifies his practice by that of the older poets, Nævius, Plautus, Ennius, whose careless freedom he follows in preference to the "obscura diligentia" of his detractor. He recriminates upon his adversary as one who, by his literal adherence to his original, had turned good Greek plays into bad Latin ones. He justifies himsclf from the charge of plagiarizing from Plautus and Nævius. In another prologue he contrasts his own treatment of his subjects with the sensational extravagance of others. He meets the charge of receiving assistance in the composition of his plays by claiming, as a great honour, the favour which he enjoyed with those whe were the favourites of the Roman people.

We learn from these prologues that the best Roman literature was ceasing to be popular, and had come to rely on the patronage of the great. A consequence of this change of circumstances was that comedy was no longer national in character and sentiment, but had become imi. tative and artistic. The life which Terence represents is that of a well-to-do-citizon class whose interests are commonplace, but whose modes of thought and speech are refined, humane, and intelligent. His characters are finely delineated and discriminated rather than boldlv conceived
as they are in Plautus. Delicate irony and pointed epigram take the place of broad humour. Love, in the form of pathetic sentiment rather than of irregular passion, is the chief motive of his pieces. His great characteristics are humanity and urbanity, and to this may be attributed the attraction which he had for the two chief representatives of these qualities in Roman literature, - Cicero and Horace. It was through the comedies of Terence that the finer influences of the Epicurean philosophy-the friendliness, the tolerance, the consideration for the feelings of others, inferiors as well as equals, inculcated by that philosophy-entered into Roman life and literature. The dissolving influence of that school on the severer personal morality of the older Roman republic also entered into Roman life through the same medium. But it was a great gain to the strong but rude Roman character to learn, as it could from every line of Terence, lessons not only of courtesy and social amenity but of genuine sympathy and consideration
Terence's pre-eminence in art was recognized by the critics of the Augustan age:

## "Vincere Cæcilins gravitate, Terentius arte."

The art of bis comedies consists in the clearness and glmplicity with which the situation is presented and developed, and in the consistency and moderation with which his varions characters play their part. But bis great attraction to both ancient and modern writers has been the purity and charm of his style, whether employed in narrative or dialogue. This charm he derived from his familiarity with the purest Latin idiom, as it was habitually used in the intimate infercourse of the best Roman families, and also with the purest At!in? idiom, as, it had been written and spoken a century before his own time. The fine Attic flavour is more perceptible in his Latin than in the Greek of his contemporaries. He makes no claim to the creative exuberance of Plautus, but he is entirely free from his extravagance and mannerisms. The superiority of his atyle over that of Lucilius, who wrote his eatires a generation later, is almost immeasurable. The best judges and the greatest masters of atyle in the best period of Roman literature were his chief admirers in ancient times. Cicero frequently reproduces his expressions, applies passages in his playe to his orn circumstances, and refers to his personages as typical representations of character. ${ }^{1}$ Julius Cæsar characterizes him as "puri sermonis amator." Horace, so depreciatory in general of the older literature, ghows his appreciation of Terence by the frequent reproduction in his Satircs and is his Odes of his language and his pbilosophy of life. Quintilian applies to his writings the epithet "elegantissima," and in that comnexion refers to the belief that they were the work of Scipio Africanus. His works were studied and learned by heart by the great Latin writers of the Reuaissance, such as Erasmus and Molanchthon; and Casaubon, in his anxiety tbat his son should write a pure Latin atyle, inculcates on him the constant study of Terence. Montaigne applies to him the phrase of Horace:

## "Liqułdus puroque simillimus amni."

He speaks of "his fine expression, elegancy, and quaintness," and adds, "bo does so possess the soul with his graces tbat wo forget those of his fable."3 It is among the French, the great masters of the prose of refined couversation, that his merits have been most appreciated in modern times. Sainte-Beuve, in his Nouveaux Lundis, devotes to him two papers of delicate and admiring criticism. He quotes Fénelon and Addison, "deux esprits polis ct doux, de la même famille littéraire," as expressing their admiration for the inimitable beauty and naturalness of ono of his scenes. Fénelon is said to have pleferred him even to Molière. Sainte-Beuve calls Terence the bond of union between Roman urbanity and the Atticism of the Greeks, and adds that it was in the 17 th century, wheu French literature was most truly Attic, that he was most appreciated. M. Joubert is quoted ${ }^{s}$ as applying to him the words" Le miel attiqno est sur ses lévres; on croîrait aisément qu'il naquit sur $l_{0}$ mont Hymotte.
The most famous edition of Terence is that of Bentley, pnblished in 1726. More recent editions are those of Parry, in the Bibliotheca, Classica, and of W. Wagner. The text has been edited by A. Flickeisen in the Teubner series of clasaics. A number of editions of the seperate playe have been published recently both in England and in Germany.
(W. Y. S.)

TERESA, St. See Theresa, St.
TERLIZZI, a town of Italy, in the province of Bari, and 20 miles west from that town, stands in the midst of a fertile plain. It has a castle which at one time was

[^64]very strong and occasionally resorted to by the emperor Frederick II. and afterwards by the Aragonese sovereigns. The walls and towers of the town still remain, but the fosse has been turned into boulevards. Terlizzi has a considerable trade, chiefly in the wine and fruit of the district. The population of the towu in 1881 was 20,442 (commune, 20,592).
TERM (from the Latin terminus) in English law is used in two senses, the idea common to both being that of a limited and certain period of time.
(1) It denotes (or rather did denote) a fixed time during which the courts are open for legal proceedings. Terms in this sense affected only what used to bo called the superior courts, -that is, the Queen's Bench, Common Pleas, and Ezachequer. They were originally the leisure seasons of the year which were not occupied by great feasts or fasts of the church or by agriculture. Their origin is no doubt to be traced back to the legislation of the early Christian emperors, the principle being adopted in England through the influence of ecclesiastical judges, and still surviving in the universities and Inns of Court. Terms were regulated by many Acts of parliament, the effect of whieh was to confine to a comparatively short period the time during which the courts could sit in banco, -that is, for the decision of questions of law as distinguished from the decision of questions of fact. There were four terms, Hilary, Easter, Trinity, and Michaelmas, the average duration of each being about three weeks. All legislation on the subject previous to 1873 is now merely of historical interest, for by the Judicature Act of that jear the division of the year into terms was abolished so far as related to the administration of justice.
(2) It denotes the time during which an interest in an estate for life or for years is enjoyed, also the interest itself, because such an interest must determine at a definite time If the interest be for life, it is an estate of freehold; if for years, only a personal interest in real estate, and so personalty, even though the length of the term-for instance, 1000 years-may far exceed in duration any possible life estate. A term of years is of two kinds, -the first that created by an ordinary lease reserving a rent, as of a house or a building lease; the second that created by a settlement or a will, usually without rent reserved, for the purpose of securing payment of money, such as portions to younger children, by the owner of the land. Both kinds have been considerably affected by recent legislation. For instance, the Conveyancing Act, 1881, enables a mortgagor or mortgagee in possession to make certain leases. Before I845 provision was always made in conveyances for keeping on foot a term to attend the inheritance, as it was called,- that is, for assigning the remainder of a term to trustees for the protection of the owner of the property against rent-charges or other incumbrances created subsequently to the term, although the term had been satisfied,-that is, the purpose for which the term had been created had been fulfilled. By 8 and 9 Vict. c. 112 the assignment of satisfied terms was rendered unnecessary. The Conveyancing Acts, 1881 and 1882 , give power to enlarge the unexpired residue of a long term in certain cases into the fee simple.

In Scotland terms are the days at which rent or interest is payable. They are either legal or conventional : the legal are Whitsunday and Martinmas ; the conventional are fixed by agreement between the parties. A recent Act (44 and 45 Vict. c. 39) makes uniform the law as to removal terms in burghs. Terms as times of court sittings were defined by 6 Anne c. 53 , which fixed four termsMartinmas, Candlemas, Whitsuntide, and Lammas-for the now obsolete Court of Exchequer. By 19 and 20 Vict. c. 56, s. 26, the winter and summer sittings of the Court of Session are to be held to correspond with the Exchequer terms.

Termini, or Termini Imerese (Thermæ Himerenses), a town on the north coast of Sicily, at the mouth of a river of the same name, in the province of Palermo, and

23 miles east-south-east of that torm. None of its modern buildings are of any speciai interest; in the Piano de San Giovanni above the town the substructure of a Roman villa has been excavated, and there are also traces of an amphitheatre. Termini is one of the busiest provincial towns of Sicily; the surrounding district being exceedingly fertile and the harbour good, there is a considerable export trade in grain, fruit, tartar, and other products. The macaroni of Termini is in high repute. The tunny and sardine fisheries are extensive, and there is a school of narigation. The warm saline springs ( $110^{\circ}$ Fahr.), sung by Pindar, are still largely resorted to, there being - well-appointed bath establishment, founded by Ferdinand. I. The population of the town in 1881 was 22,370 , with its suburbs 22,733 (commune, 23,148 ).
For the ancient history of Termini see Himera. The castle of Tornini, which Robert of Naples besieged in vain in 1338, was destroyed in 1860 .

## TERMITES. See Ant, vol. ii. p. 99.

## TERMONDE, See Dendermonde.

TERN (Norsk Tærne, Tenne, or Tende; Swedish Türna; Dutch Stern ${ }^{1}$ ), the name now applied generally to a group of sea-birds, the Sternince of modern ornithology, but, according to Selby, properly belonging, at least in the Farne Islands, to the species known by the book-name of Sandwich Tern, all the others being those called Sea-Swallows -a name still most commonly given to the whole group throaghout Britain from their long wings, forked tail, and marine habit. In Willughby's Ornithologia (1676), however, the word Tern is used for more than one species, and, though it does not appear in the older English dictionaries, it may well have been from early timcs as general a name as it is now.
Setting aside those which are but occasional risitors to the British [slands, six species of Terns may be regarded as indigenous, thiough of them one hss ceased from ordinarily breeding in the United Kiugdom, whils a second has become so rare and regularly appears in so few places thst mention of them must for prudence sake be svoided. This last is the heautiful Roseate Tern, Sterna dougalti; the other is the Black Tern, Hytrochelidon nigra, belonging to a genus in which the toes sre only half-webbed, of small size and dark leaden-grey plumage. It is without doubt the Sterna of Turner, and in former days was sbundant in mauy parts of the fen country, ${ }^{2}$ to say nothing of other districts. Though nearly all its ancient abodes have been drained, and for its purposes sterilized these many yesrs past, not a spring comes hut it shows itself in small companies in the eastern counties of England, evidently seeking a breedingplace. All around the coast the diminution in the numbers of the remsining species of Terns within the Iast 50 years is no less deplorable than demonstrable.

The Sandwich Tern, S. scondvicensis or S. cantiact-named from the placo of its discovery, though it has long since ceased to inhabit thst neighhourhood-is the largest of the British species, equalling in size the smaller Gulls and having a dark-coloured bill tipped with yellow, and dark legs. Through persecution it has been extorminsted in all its southern bannts, and is become much sesrcer in those to which it still resorts. It was, however, never so abundant as its sussller congeners, the so-called Common and the Aretic Tern, -two species that are so nearly alike as to bo leyond discrimination on the wing by an ordinary observer, and oven in the hand require a somewhat close exsmination. ${ }^{8}$ The former of these has
" "Starn" was used in Norfolk in the 19th century as a name for the bird commonly known as the Black Tern, thus confirming Turner, who, in 1544, describes whet seems to have been the same species an "nostrati lingus sterna sppollata." In st least one instance the word has been confounded with ons of the old forms of the modern Stahlino (vol. xxii. p. 457). To Turner'a name, repeatod by Gesner and other suthors, we owe the introduction by Linnzus of Stcrna into ecientific nomanclature. "Ikstern" is another Dutch form of the word.
${ }^{2}$ It was known there 8 Carr-Swallow, Carr-Crow (corrupted into "Scarecrow"), snd Blue Dar (qu. = Daw?).
${ }^{8}$ Linnæus's diagnosis of his Sterna hirundo points to his heving had BA "Arctic" Tern before him ; but it is certain that be did not suspect that epreific sppellstion (already used by other writera for the "Common" Tern) to cover \& second apecies. Some modern authorities disregard his name as being insufficiently definite, and much is to be *aid for thia viow of the csse. Undoubtedly "hirundo" has now been used co indiscrimisately for one species or the other as to causo consasion, whleh is perhsps best avoided by sdopting the epithets of Nau-
the more southern range, snd often affects inland situations, wirl the latter, though by no means limited to the Arctic circlo, is widely distributed over the north and mostly resorts to the sea. coast. Yet there are locslities where, as on the Farne Islands, both meot snd breed, without occupying stations spart. The minute diagnosis of these two species cannot be briefly given. It nins! suffice here to atate that the most certain difference, as it is the most easily recognizable, is to he found in the tarsus, which in the Arctic Tern is a quarter of sn inch shorter than in its kinsmen. The remaining nativo species is the Lesser Tern, S. minula, oue of the eraallest of the genus and readily to be distinguished by its permanently white forehead. All ths species already mentioned, excopt the Black Tern, have much the same general celorationthe adults in summer plumago wearing a black cap aud having the upper parts of the body and wings of a nore or less pale grey, while they are mostly lighter. benesth. They generally breed in association, often in the closest proximity-their nests, containing 3 eggs at most, being made on the shingle or among herbage. The joung are hatched clothed in variegated down, and remain in the rest for some time. At this season the parents are almost regardless of human presencerand expose themselves freely.

At lesst half-a-dozen other species have heen recorded as occurring in British waters, and among them the Caspian Tern, S. caspia, which is one of the largest of the genus and of wide listribution, though not breeding nearer to the shores of England than on Sy!t and its neighbouring islands, whieh still afford lodging for a few pairs. Another, the Gull-billed Tern, S. anglica, has also been not unfrequently shot in England. All theso species are now re. cognized, though the contrary was once maintained, as inhalitants of North America, and many go much further.
An excellent synopsis of the Sub-family Sterninze has been given by Mr Howard Saunders in the Zoological Proceedings (1876, pp. 638-672). He recognizes 5 genera, -Hydrochelidon (with 3 species), Sterna (with 38), Nenia, a very aberrant form consistiug of but one species, the Inca Tern, peculiar to the western coast of South America, and Gygis, composed of 2 species of purely white birds and restricted to the southern hemisphere; his fifth genus is Anous, to which belong the various species of NoDDy (vol. xvii. p. 531). Oten confounded with these last are the two species called in books Sooty Terns (S. fuliginosa and S. anxstheta), but by sailors "Egg-birds" or "Wide awakes" from their cry. These crowd at certain seasons in innumerable multitude to certain, islands within the tropics, where they breed, and the wonderful assemblage at present known as "Wide-awake fair" on the island of Ascension has been more or less fully described from very ancient times. Dampier in his royage to New Holland in 1699 particnlarly described and figured the Sooty Tern (Voyages, iii. p. 142), discriminating it from the Noddy, from which it had not before been distinguished. (A. N.)

TERNATE, a small island in the East Indian Archipelago, off the west coast of Jilolo ( $q \cdot v$. ), in $0^{\circ} 48^{\prime} \mathrm{N}$. lat. and $127^{\circ} 19^{\prime}$ E. long. It is mearly circular in form, with an area of about 25 square miles, and consists almost entirely of a very remarkable volcano ( 5600 fect) formed of three superimposed cones. Frequent and destructive eruptions lave taken place. Cocoa-nuts, sago, tobacco, cotton, sulphur, and saltpetre are the chief productions of the island. The clove, which had been extirpated by the early Dutch rulers to enhance its value by restricting its cultivation to the Banda Fslands, Araboyna, \&c., is beginning again to be grown, as also is the nutmeg. The inhabitants are nearly all Mohammedan Malays. The town of Ternate, with a population of about 9000 , is the seat of a native sultan and of a Dutch resident; the harbour is commanded by a fort. The residency, which includes a part of the eastern coast of Celebes (see Celebes), the grcater part of Jilolo, and numerous smaller islands, has an area of 26,900 square miles and a population estimated at about 290.000 .
$\operatorname{mann}$ ( 1 sis, $1819, \mathrm{pp} .184 \overline{7}, 1818$ ), who, acting on snd confirmugg the discovery of Nitzsch (who first detected the apecific difference), cslled the southern species $S$. fuviatilis and the northern S. macruma Temminck's nsme S. arctica spplied to the latter a year later hes bee most generally nsed for it, notwitlirtanding.

TERNI, a town of Italy, in the province of Perugia, is situated in the fertile valley of the Nera, between two branches of that river, about 5 miles below the point where it is joined by the Velino. It has a station, threequarters of a mile off. on the railway line between Rome and Ancona, 69 miles to the north of the former city and 19 sonth by west from Spoleto. Terni is an episcopal see, and the seat of a sub-prefecture and a chamber of commerce. Its public buildings include the cathedral (17th century), the church of S. Francesco (partly dating from the 13th century), a gymoasium, and a theatre. Terni manufactures leather and cloth, and has some trade in wine and silk. For the traveller its chief intarest lies in its antiquities (remains of an amphitheatre of the time of Tiberius, a temple, a theatre, baths. and numerons inscriptions) and in the proximity of the falls of Velino (Cascate delle Marmore). Alike in volume and in beauty these take a very high place among European waterfalls; the cataract has a total descent of about 650 feet, in three leaps of 65,330 , and 190 feet respectively. They owo their origin to $\mathrm{M}^{\prime}$. Curius Dentatus, who in 272 b.o. first opened an artificial channel by which the greater part of the Lacus Velinus in the valley below Reate was drained. The population of the town in 1881 was 9415 , with its suburbs 10,371 (commune, 15,853).
Terni is the ancicnt Interamna ("inter amnes"), origivally belonging to Umbria and founded, sccording to a local tradition, in the year 672 a.o. It early became a flourishing mnnicipinm, and it did not permanently sufficr through being portioned out among his soldiers hy Snlla. Its inhabitants had frequent litizations and dispntes with their neighbours at Reate in connexion with the regulation of the Velinus, the waters of which ere so strongly impreguated with carbonate of lime that hy their deposits they tend to block up their own channel. The first interlerence with $j$ ts natural course was that of $M^{\prime}$. Curius Dentatus already referred to. In 54 B.o. the people of Reate appealed to Cicero to plead their cause in an arbitration which had been appointed by the Roman senate to settle disputes about the river, and in comnexion with this he made a personal inspection of Lake Yelinus and its outlets. In the time of tiberius there was a project for regulating the river and its outlets from the lake, against which the citizens of Interamna and Reate energetically and encecssfully protested (Tac., Ain., i. 79). Similar questions arose as the river formed fresh deposits during the Middle Ages and during the 15 th and 16 th centuries. A branch of the Via Flaminia passed from Narnia to Fornm Flaminii, and is given instead of the direct line in the Antonine and Jermsalem itineraries. The emperor Tacitus and his brother Florianns were probably natives of Interamna, which also has been claimed as the birthplace of Tacitus the historian, but with less reason. Terni was the scene of the defeat of the Neapolitans by the French on 27 th November 1798.

TERPANDER, a Lesbiau poet and musician, settled in Sparta about the end of the Second Messenian Tar ( 668 в.c.). According to some accounts, he was invited thither by command of the Delphian oracle to compose the differences which had arisen between different classes in the state. His innovations in music were considered to have inaugurated a new cra of musical art in Greece; but we are very imp,erfectly informed as to their nature. On the strength of a fragment (No. 5 in Bergk), which may or may not be genuine, - "rejecting the four-toned song, we will sing to thee new hymns with the seyen-voiced lyre," Strabo says that he increased the number of strings in the lyre from foar to seven; others take the fragment to mean that he developed the citharedic nomos (sung to the accompaniment of the cithara or lyre) by making the divisions of the ode seven instead of four. We possess six short fragments of poetry in the Dorian dialect bearing the name of Terpander. They are from hymns to the gods Zeus, Apollo, Apollo and the Muses, the Dioscuri, \&c., and are written in a slow spondaic movement or in dactyls. They present no remarkable features and are probably spurious.
Bergk, Poeta Lyrici Greci, iii. (4th ed.) pp. 7.12, Leipsic, 1882.
TERRACINA, a town of Italy, in the province of Rome, and about 60 miles to the south-east of that city, at the
south-east extrenity of the Pontine marohes, where the Monti Lepini (see Italy, vol. xiii. p. 438, and Latium) descend into the sea. The ancient town (Volscian Ansur, Roman Tarracina) stood on the white hillside ("inpositun! eaxis late candentibus Anxur "), along the foot of which, by the seashore, ran the Via Appia. The modern town stands mainly on the level ground. The most conspicuors building is the cathedral, which is believed to occupy the site of a temple of Jupiter Anxurus; it is enriched both externally and internally with beautiful old columus and Roman mosaics. Above the town, on the summit of the cliff, are the remains of a palace of Theodoric (c. 500), afterwards a medieval castle. The ancient harbour, constructed by Antoninus Pius and once very important, is now silted up; a new mole affords shelter to coasting vessels. Fishing is carried on, and there is some trade in the produce of the district. The population of the town in 1881 was 6294 (commune, 8572).

Anxur finally became Roman in 400 b.c., and a colony was established there in 329. Its strategic position early gave it milijtary importance ; and its pleasent situation and its mincral waters Jed many Romans to build villas and seek seaside quarters there.

TERRA-COTTA. ${ }^{1}$ Strictly speaking this name is Mensapplicable to all objects made of baked clay, from the ing. rudest brick to the finest piece of pottery, but it usually has a more limited meaning, to denote fictile objects which do not come under the head of pottery, such as statnettes and busts; and in its architectural use it specially implies the finer sorts of decorative clay-work, to the exclusion of common building bricks. In ancient times, especially among the Greels and Romans, terracotta rwas employed for an immense variety of purposes, from the commonest objects of everyday use to the most elaborato and ambitious works of art, such as colossal statues and groups. Though the natural colour and surface of the burut clay are generally very pleasing in tone and texture, it seems to have been universally the custom in classical times to cover the terra-cotta completely with a thin white coating, which formed an absorbint ground for the further application of colour. For internal work, except in rare instances, these colours were mixed with a tempera medium, and applied after the clay had been fired. They were therefore not true ceramic colours; and pigments of great sariety and brilliance could be employed, as they had not to undergo the severe ordeal of the kiln. For external work, such as that shown in fig. 5, only earth pigments such as ochres aud lime wers used, and the colours were fired.
No branch of archreology has during the last dozen Greek years or so developed so rapidly as that of Greek terra- figures cotta figures; on this noost fascinating subject an aston- licfs. ishingly large mass of literature has been published in Germany and France. ${ }^{?}$. The discovery of this new world of Greek art began practically in 1873 , with the first excavations in the tombs of Tanagra, a Bceotian torn on the high road from Athens to the north, which brought to light a number of very beautiful terra-cotta statuettes. ${ }^{3}$ Subsequent excavations at Corinth, Smyrna, Cyme, Tarentum, the Cyrenaica, and many other places also yielded a vast number of terra-cotta figures of various dates and styles. By far the greater number belong to the second half of. the 4th century B.C.; but examples of an earlier

[^65]Sate are not wanting, not only of figures in the round, but also of reliefs, which appear to have been largely used for the decoration of the flat surfaces of walls and friezes. The earliest of all date from a quite prehistoric period, and are mostly small idol-like figures of the rudest possible form, having an almost shapeless trunk with stick-like projections for the limbs, and the breasts and eyes roughly indicated by round dots. They are usually decorated with coarse stripes or cheques in ochre colours. Examples of these have been found at Hissarlik (Troad), in Cyprus and other islands, and in the citadel of Tiryns in 1884-85 by Dr Schliemann and Dr Dörpfeld. Later but still very archaic figures, 2 or 3 inches high, have been exhumed in many parts of the Fgean Islands; some of these are stiff seated figures of deities, - links between Oriental and Hellenic art, like the statues of the Sacred Way at Branchidæ (south of Miletus). Comparatively few specimens exist of the best period of Greek art-the 5th century. ${ }^{1}$ A relicf in the Lourre (about 18 by 12 inches) with a pierced background, dating from the first half of the 5th century, represents two female mourners at a sepulchral stele,-one standing and the other seated; under the foot of the latter is inscribed AAEKTP. On the other side of the stele are two youths (the Dioscuri) standing by a horse. The whole design is simple, but very graceful, and the modelling is skilfully treated in very low relief. The colouring-blue, red, white, and dark brown-is well preserved. This relief was pressed in a mould, and was fontended to be attached to a wall, probably that of a tomb, as a rotive offering to the dead. ${ }^{2}$

In most cases the terra-cotta figures and reliefs occur In or close by tombs, but it is only in comparatively rare fnstances that the subjects represented have any reference to death. Another large class have been found in the vicinity of temples, and are probably votive offerings, such as the small statuettes of horses from the acropolis of-Athens, now in the Lourre. In other cases, as at Halicarnassus, great quantities of small figures were buried under a temple, probably to purify the site, as was done in Egspt under the later dynasties, when many hundred figures of bronze were sometimes buried under one building. Owing to the fact that the statuettes found scattered in and round sombs have frequently their heads broken off, Pottier and Reinach have suggested that they were brought as offerings to the dead and their heads were broken off by the mourners at the side of the tomb. Rayet believes that this practice was a sort of survival of the custom of sacrificing female and boy slaves at the tombs of the dead. In many cases, however, the figures are intact, and it is probable that many of the tombs were broken open and rifled long ago, which would explain the mutilated and scattered condition of the figures. The tombs of Tanagra have yielded by far the richest finds of these figures, the specimens being very remarkable for their beauty. These exquisite statuettes do not (in most cases) represent deities or heroic personages, but the homely every-day life of the Greeks, treated with great simplicity and evident realizm: they are in plastic art what in painting would be called genre, ${ }^{3}$ and in their strong human

[^66]interest and naturalistic pathos bring us in closer contact with the life and personalities of the past than any more' ambitious style of art could possibly do. Moreover, they prove more clearly even than the great plastic works in bronze and marble how deeply a feeling for beauty and a knowledge of art must have penetrated the whole mass of the people. Their immense number shows that they must have been far from costly, within the reach of every one, and certainly not the production of any famous eculptors. Nevertheless, sketchy as they are in treatment and often faulty in detail, they are in pose, in motive, and in general effect works of the highest beauty, full of the most inimitable grace, and evidently the production of men in whom the best qualities of the sculptor were innate by a sort of natural birthright. Several small figures from Myrina (Mysia) have the artist's name inscribed on them ; but signatures of this sort are rare. ${ }^{4}$

It is impossible to describe the many subjects treated. Only a fetw examples can be mentioned. Among single figures the most frequent are those of girls standing or seated in an immense rariety cí pose, and with plertiful drapery arranged in countless methods, showing the great taste with which a
 Greek lady could Fio. 1. - Statuette of a girl and infant Eras dispose the folds of from Tanagre (St Petershurg.) her ample pallium, whether it hung in graceful loops or was wound closely round the figure or formed a hood-like reil over the head. In some the lady holds a leaf-shaped

Fİ. 2.-Aphrodite and cupids. The pendant hung round the neck of Aphrodite is gilt. (South Kensington Museum.)
fan, or is looking in a circular mirror, or holds a ball ready for the game. Many have a strange broad hat, probably of straw, which does not fit on the head, but must hape
been fastened by a pin to the hair or veil. One very beautiful motive is that of a girl playing with an infant Eros, who flies to her for shelter, and is received with welcome half tinged with dread. Fig. 1 shows a very lovely statuette of this kind, now in the Hermitage Palace. A favourite subject is taken from a game in which one girl carries her playmate on her back,-a motive which, though difficult to treat in sculpture, is managed very gracefully in terra-cotta. Other very lovely groups are Aphrodite suckling the baby Eros, or with more than one cupid hovering round her. A very beautiful example (see fig. 2) occurs in the South Kensington Museum (from the Castellani sale). It represents a half-nude figure of Aphrodite reclining on a couch, with two cupids behind holding up a veil, which was colcured blue to form a background to the creamy white of Aphrodite's body.

The Tanagra and other figures are all formed of thin pieces of soft clay pressed into a mould, usually formed in two halves and then stuck together; and they are made hollow so as not to warp and crack in the firing; and have a hole at the back for the escape of moisture during that process. The head is solid and was formed in a separate mould, as were also any accessories, such as fans or mirrors, and arms if they extend away from the body. Replicas of the same figure are often varied by having different heads or accessories; three or four examples have been found from the same mould. After the whole was put together it was usually touched up and finished with modelling tools. The colour was applied after baking: a coating of creamy white lime or chalk all over served as the flesh tint and also as a good ground for the other colours. The hair of the females is always of a rich auburn red, such as the Venetians were so fond of painting in the 16 th century; blue was touched on the eyes and crimson on the lips. Drapery, if not white, was usually rose-colour or blue, often with a fringe or bands of gold on the border. Necklaces, earrings, and other ornaments were generally gilt, the gold leaf being applied over a slightly raised surface of slip, as on the Greek vases. Similar examples have been found in tombs at Thebes, at Thespix, and round Athens. Some of the Attica figures are covered, not with the usual non-ceramic colours, but with a real white enamel, the vitrified surface of which is very often slightly decomposed; further coloured decoration was in some cases added over this enamel.
A number of places in the west of Asia Minor have yielded large quantities of terra-cotta figures, very similar in size and technique to those of Tanagra, but belonging for the most part to quite a different school of sculpture. Unlike the Tanagra figures, which are rather pictorial in style and deal with genre subjects, those from Ṡmyrna, Cyme, Myrina, and other places in Asia Minor are thoroughly sculpturesque in design, and are frequently miniature reproductions of large statues or groups (see fig. 3). Many of them stand on moulded pedestals, while the Tanagra figures have only a thin slab of clay as a base. The average size of both classes is from 6 to 10 inches high. Very elaborate groups with three or four figures often occur. Dionysiac and Bacchanal subjects are frequently chosen, or scenes from sacred mythology, such as
the labours of Heracles. ${ }^{1}$ These also mostly date from the 4 th century b.c., and the statuettes often appear to be copies from sculpture of the school of Praxiteles or Scopas. One instance is the fine nude figure of Eros as a youth leaning against a cippus, holding a bronze arrow in his hand, in the collection of M. de Branteghem, now in Rome. ${ }^{2}$ The whole of it was gilt, r. hich was frequently the case with the Asia Minor statuettes, but rarely so in those of Tanagra. ${ }^{3}$ A very beautiful figure of a winged Victory in the same collection (from the Castellani sale) presents the same motive as the colossal Victory of Samothrace (in the Louvre) ; it supplies the missing right hand, which in the terra-cotta contains a bunch of roses. The drapery of this figure is blue, mottled, or shot with gold. Other figures, from their heights being arranged in even gradations, seem to be copies from some large pedimental sculpture. Unfortunately little is yet known of the various fabriques of these Asia Minor figures, as in most cases their provenance is very doubtful. ${ }^{4}$ The Lecuyer collection possessed some groups with several fignres forming important compositions. One of these shows two female mourners at a tomb, and a warrior clad in full armour with his horse. The most remarkable group (see fig. 4) is that of a soul led by Hermes Psycho-

Fra. 4. - A eoul about to enter Charon'e bark. (Prince Liechtenstein'e collection, Vienns; formarly in the Lecuyer collection.)
pompus to the bark of Charon, who is represented as a bent aged man. Hermes, a graceful nude figure, gently urges the shrinking soul-a draped female figure-to the boat, at the brink of the rush-grown Styx. The whole scene is imagined with much tender grace and real pathos, though not highly finished in its details. One of the most important terra-cotta figures yet discovered has recently been brought to England from Smyrna. It is a very beautiful copy of the Diadumenos of Polycletus, which in the details of its modelling reproduces some. characteristics of the later school of Praxiteles. The forearms and the legs below the knee are lost ; but in breadth

[^67]of modelling and grandeur of style this little figure, which was ondy about 14 inches bigh when perfect, has the effect of a much larger statue, and it is a real masterpiece of Cireek, plastic art. ${ }^{1}$ In the neighbourhoul of Smyrna aud Elhesus a large number of caricature figures have been exhumed, some of which are modelled with a wonderful feeling for humour. ${ }^{2}$ These strange figures have attenuated limbs, large heads, flapping ears, and google eyes. Some play on musical instruments; others reprezent actors ; and one in the De Branteghem collection is a caricature of a discoholus in almost the attitude of 1 syron's selebrated statue.
A sery different class of statuettes has recently come to light in the Cyrenaica, on the northern coast of Africa. Many of these are nude female dancers wearing an elaborate stephanos-like head-dress. They are realistic in modelling and rery ungraceful in pose, - a striking contrast to the exquisite taste of the Tanagra and most of the Asia Minor figures. Recent excavations in the tombs of Corinth Lave produced a large number of fine terracottas, ranging iu date over a very long period. Another and artistically very perfect class of figures is being ding up from anong the tombs of Tarentum. Some of these belong to the finest period of Greek art, prohably about 400 b.c., and others are even earlier. Many are not statuettes, but merely small busts of heroic style, and of the highest sculpturesque beanty. They are certainly not portraits, and do not.appear to represent deities. It has been suggested that they are idealized representations of ancestors, whose commemoration, in some places, formed an important cult ; but their real meaving must for the present remain uncertain. Many thousand votive figures and reliefs in clay lave been found within the temeni of the temples of the Clithonian deities at Tareutum and elsewhere. It seems to have been customary for the priests periodically to clear out of the temples the broken or too numerous offerings which were then buried withiu the enclosure ; whole series arranged chronologically in groups have been discovered buried in separate holes.
In.addition to statnettes and reliefs, terra-cotta was used by the Greeks for various minor ornamental purposes. Delicately moulded necklaces and pendants for ears were stamped out in clay and then thickly covered with gold leaf; this produced a very rich effect at a small cost; many fine examples are preserved in the Louvre. Children's toys, such as miniature horses and chariots, and dolls with movable limbs of terra-cotta fastened with wooden pegs, occur iu many tombs.
On a larger scale terra-cotta was adapted by the Greeks to important architectural ornamentation. Many fine examples have been found at Olympia and among the ruined temples of Selinus. In some cases the main cornices of the building were simply blocked out square in stone, and then covered with moulded plaques of terracotta, carefully formed to fit on and round the angles of the block. The large cymatium which forms the upper member of the cornice is curred upwards, so as to prevent the rain water from dripping all along the edge ; and at intervals it is pierced by ornamental clay pipes, which project like a mediæval gargoyle. In some examples from Selinus the cymatium is pierced with a beautiful open pattern of lotus leaf (see fig. 5). The greatest care was taken in fitting these applied mouldings where each plaque joined the next, and especially in making them fit closely on to the stone blocks, in which rebates were cut to receive each plaque. The whole surface of

[^68]the terra-cotta is covered, with elaborate painted orna ments of great beauty, in ochre colours applied on a white ground, as in the case of the statuettes. These beautiful temple decorations are well illustrated by Dörpfeld and

F10. 5.- Cornice enrichments of painted terra-cotta from Selinno. This section shows the careful wey in which the terre-cotta is fitced on to the stone; the colours are red and brown ochre and cream-white.
others in Die Temoendung von Terra-cotten, Berlin, 1881. Though no complete examples of terra-cotta statuary now exist, it is certain that the Greeks produced it on a large scale and of the highest class of workmanship. Pliny (H.N., xxxv. 36) mentions that certain statues of Hercules Dusagetes and the Nine Muses were "opera figlina," executed by the painter Zeuxis. These were brought from Athens by M. Fulvius Nobilior, and placed in the temple of Hercules Musagetes, which adjoined the Porticus Octaviæ in the Campus Martins of Rome. Other and earlier examples of clay statues are mentioned by Pausanias.

Among the Etruscans the use of clay for important sculp- Etresem. ture was very frequent,--painted terra-cotta or bronze almost excluding marble and stone. An important example was the clay quadriga on the pediment of the temple of Capitoline Jupiter, which, according to one legend, was brought from Veii by Tarquinius Superbus. This existed till the destruction of the temple by fire in 83 в.c., and was considered one of the seven precious relics on which the safety of the Roman state depended. The great statue of Jupiter in the central cella of this triple temple was also of terra-cotta, and was said to be the work of an Etruscan sculptor from Fregenæ. Vitruvius mentions "signa fictilia" as being specially Etruscan. Many other statues in the early temples of Rome were made of the same material. Among the existing specimens of Etruscan terra-cotta the chief are large sarcophagi, with recumbent portrait effigies of the deceased on the top, the whole being of clay, decorated with painting. Fine examples exist in the Louvre and the British Museum; a good specimen from the latter collection is figured in vol. viii., plate VIII, The Museo Gregoriano in the Vatican possesses some wery beautiful friezes of a later date-about the 4 th century B.c.- When native Etruscan art had been replaced by that of Greece. These friezes are very rich and elaborate, with heads and scroll foliage in very salient relief Some of them have at intervals cleverly moulded heads of satyrs, painted a brilliant crimson. ${ }^{3}$

Another very elaborato application of terra-cotta is shown in the numerous large asci, covered with statuettes, which are found in the tombs of Canosa (Canusium), Cales, and
${ }^{3}$ The use of this strongly glowing red is almost peculiar to Hellenio Italy; the other colours used there were much the same is those of Greece itself. The same magnificent crimson often occurs on cenochore, moulded into the form of satyra' heads, which are found in the tombs of Magna Grecia
many parts of Magna Grecia. The statuettes are 80 me . what similar in style and colouring to the Tanagra figures, and date from about the same period (4th century B.c.), but are not equal to them as works of art; they are also usually crowded together in a somewhat awkward manner. ${ }^{1}$ The British Museum is specially rich in these elaborate terra-cottas; few of the colours used appear to be true ceramic pigments.

As in other branches of art, the Romans closely copied the Greeks in their wide application of terra-cotta for etatues, reliefs, and architectural ornaments. A large number of beautiful Greco-Roman reliefs exist, many having designs evidently copied from earlier Greek sculpture. Berlin, the Louvre, the British Museum, and many places in Italy possess fine colleotions. Friezes with beautiful reliefs 12 to 18 inches deep often occur, little inferior in execution to the earlier Greek work. Many subjects of great interest are represented: a very fine plaque iu the Lourre has the scene of Orestes taking refuge at the sacred omphalos at Delphi, which is represented as a conical stone about 3 feet high, hung round with ornamental festoons made of gold. ${ }^{2}$ These terra-cottas belong to the early period of the empire; in the 2 d century A.D. thay became much coarser and less Greek in style, like all the sculpture of that time. A plaque in the Louvre, which represents a chariot-race in the circus, bears its maker's stamp, L.S.ER. At the end of the first and in the early part of the $2 d$ century A.D. the use of terri-cotta for architectual adornment was carried to a high point of perfection in Rome. Many buildings of this period have the most elaborato dccora: tion moulded in clay and fitted together with wonderful neatness. Not only enriched cornices and friezes were made of terra-cotta, but even Corinthian columus with their elaborate acanthus capjtals. In all cases the whole surface appears to bave been covered with a thin coating of "opus albariun" and then decorated with colours and even gold. The best existing $\omega$ examples in Ronio are theo Amphitheatrum Jastrense, many tombs on the Tia Latina, and the barracks of the VIIth colort of the guards (vigiles) in the Trastevere. But few examples exist of the large Roman terra-cotta sculpture ; the best are some seated femalo figures from' tombs, smail life-size, in the Capitoline museum, -works of great beauty and very akilfully fired without cracks or warping. The British Mu-i acum also contains fine speci- Fio. 6.-Terra-cotta statue of the mens of terra-cotta sculpture Muse Urania, 1st cenţury A.D. on a large scale, cspecially
 the torso of a nude male figure (Hercules), some terminal figures of Bacchus, and a beautiful statue of Urania (see fig. 6).

[^69]In the 14 th and more especially in the 15 th century terra-cotta was adapted in various parts of Europe to in most magnificent and elaborate architectural purposes. In Germany the mark of Brandenburg is specially rich in terra-cotta work ${ }^{3}$ The church of St Catherine in the town of Brandenburg is decorated in the most lavish way with delicate tracery and elaborate string-courses and cornices, enriched with foliage, all modelled in clay; the town-hall is another instance of the same use of terra-cotta. At Tangermuinde, the church of St Stephen and other build ings of the beginning of the 15 th century are wonderful ex. amples of this method of decoration ; the north door of St Stephen's especially is a masterpiece of rich and effective. moulding. In northern Italy this use of terra-cotta was carried to an equally high point of perfection. ${ }^{4}$. The western façade of the cathedral of Monza is a work of the most wonderful richness and minute elaboration, wholly executed in clay, in the latter part of the 14 th century. The cathedral of Crema, the communal buildings of Piacenza, and S. Maria delle Grazie in Milan are striking examples of the extreme splendour of effect that can bs obtained by terra-cotta mork. The Certosa near Pavi¢ has a most gorgeous specimen of the early part of the 16 th century; the two cloisters are especially magnificent. Pavia itself is very rich in terra-cotta decoration, especially the ducal palace and the churches of S. Francesco and S. Maria del Carmine. Some delicate work exists among the mediæral buildirgs of Rome, dating from the 14th and 16 th century, as, for example, the rich cornices on the south aisle of S. Maria in Ara Cceli, c. 1300; the front of S. Cosimato in Trastevere, built c. 1490 ; and a once very magnificent houso, near the Via di Tordinone, which dated from the 14 th century. The most important application of terra-cotta in medieval Italy was to statuary-reliefs, busts, and even groups of many life-sized figures-during the 15th and 16 th centuries, Mucb of the Elorentine terra-cotta sculpture of the 15 tb century is among the most beautiful plastic work the world has ever seen, especially that by Jacopo della Quercia, Donatello, and tbe sculptors of the nextgenerction. ${ }^{5}$ For life, spirit,
 and realistic truth, combined with sculpturesque breadth, these pieces are masterpieces of invention and manipulation. The portrait busts art perfect models of iconic sculpture (see fig. 7). In som respects the use of burat clay for sculpture has greal advantages over that of marble: the soft clay is easily and rapidly moulded into form while the sculptor's thought is fresh in his mind, and thus terra-cottad often possess a spirit and vigour which can hardly bi reproduced in the laboriously finished marble These

[^70]qualities are specially remarkable in the best works of the Della Robbia family (see Robbis). In the 16 th century a more realistic style was introduced, and this was heightened by the custom of painting the figures in oil colours. Many very clever groups of this class were produced by Ambrogio Eippa (Caradosso) for S. Satiro at Milan and by Guido Mazzoni and Begarelli (1479-1565) for churches in Modena. These terra-cotta sculptures are unpleasing in colour and far too pictorial in style; but those of Begarelli were enthusiastically admired by Michelangelo. ${ }^{1}$ Much fine terra-cotta work mas produced in France during the 16 th century, partly under Italian influence,-many sculptors from northern and central Italy having settled in France, especially under the patronage of Francis I. In the same century a similar Italian influence prevailed largely throughout Spain, and very ciever works mere produced there, remarkable for their vivid realism and deceptive pictorial style. In England the elaborate use of terra-cotta did not come into rogue till the early part of the 16 th century, and then only in certain counties. Essex possesses the finest examples, such as those of the manor house of Layer Marney, built in the reign of Heary VIII. The richly moulded windows and battlemente of this house are very un-English in style, and it seems probable that all the terra-cotta decorations were made in Holland or Flanders. A richly decorated terra-cotta tomb with recumbent effigy exists in the church of Layer Marney; and in the collegiate church of Wymondham in Norfolk there are very large and elaborate sedilia mith lofty canopied niches, all of clay, which appear to be of the same date and fabrique as the Essex examples. Most of the terracotta sculpture in England, such as that by Torrigiano, of which fragments exist in Westminster Abbey, the colossal heads of the Cesars at Hampton Court, and the recumbent effigy in the Chapel of the Rolls, ${ }^{2}$ were the work of Italian oculptors, mostly from Florence, who were invited to England in the reigns of Henry VII. and Henry VIII.

Of late years terra-cotta for architectural purposes has been employed for some very important buildings in London, such as the natural history museum at South Kensington, the Albert Hall, and the front of the other museum in the Exhibition Road. The durability of wellfired clay, its dense testure, pleasant colour, and smooth surface make it specially suitable to an atmosphere laden with acids and soot as is that of London. The surface resists decomposition, and affiords little hold to the minute particles of carbon. The great improvements which have been made in the manufacture of terra-cotta will probably lead to its more extensive use. The great difficulty is to retain the sharpness of impression given by the mould, and abore all to aroid the uneven shrinkage and warping which is so liable to take place when it is fired in large pieces. Any want of truth in the lines of a long cornice becomes painfully apparent, and each moulded llock of a door or windor-jamb must fit accurately on to the next one, or else the line of moulding becomes broken and irregular. Terracotta is now made of many different colours, a rich red and a warm ochre or cream colour being the most pleasant to the eye. In order to avoid defects it is necessary that the clay should contain a large proportion of powdered silica, and that the whole mass should be thoroughly homogeneous. The method by. which these ends are secured is much the same as that employed in the making of pottery (see vol, xix. p. 642 sq .).

The most important public collections are in the Lourre, the British Museum, the maseums of Berlin snd Athens, snd a fow fine specimens exist in the Sonth Kensington Mnseum. The oplendid Sabouroff collection is now in the Hermitage Pslace at St Peters-

[^71]barg. Many muscums in Italy-such as thoso st Florence, Perugia, Capua, Rome, and other places-contain many examples from Etruria and Magna Grecia. A large nomher of the finest of the Tanegra fgures and the like are in privste hands; some sre illustrated in the Forks mentioned in the following list; that of Prince Liechtenstein at Vienns is one of the finest.s

terranova, or Terrantota, \& seaport town of Sicily, on a hill at the mouth of the Terranora, in the prorince of Caltanisetta, and $41 \frac{1}{2}$ miles east-south-east from Girgenti. It contains a castle and several large churches, but has little to interest the traveller. Thourf the harbour is poor, there is a considerable trade in corn, wine, fruit, sulphur, and soda. Cloth is manufactured to a small extent. The population of the towin in 1881 was 16,440, that of the commune 17,173. In and near Terranova are the remains of the ancient Grit (q.v.). The modern town owes its origin to the emperor Frederick II.
terrapin. See Tortoise.
TERRE HAUTE, a city of the United States, in Harrison township, Vigo county (of which it is the county seat), in the western part of Indiana. It is situated in $39^{\circ} 27^{\circ}$ N. lat. and $87^{\circ} 54^{\prime}$ W. long., at a height of 492 feet above the sea, upon the east bank of the Wabash river, 186 miles nearly south of Chicago and 73 miles west-south-west of Indianapolis. The city stands apon level ground, about 60 feet abore the ordinary surface of the river. It is regularly laid out, with wide streets, lined with shade trees; its principal buildings are the State normal school and the Polytechnic -Institute. Six great railroad lines pass through Terre Haute, connecting it directly with the cities of the Mississippi ralley. This fact, together with its proximity to the coal-mines or Clay county, has greatly promoted its growth as a manufacturing centre. It had in 1880 a population of 26,042 , as against 16,103 in 1870 .
TERSTEEGEN, Gereard (169-1769), German religlous writer, was born at Mörs in Rhenish Prussia on 25th November 1697. After being cducated at the gymnasium of his native town, he pursued for some years the calling of a ribbon-maker. In 1728 le withdren from all secular pursuits and gare hiraself ontirely to religious work. His writings include a collection of hymns (Blumengärtlein, 1 1̌29; last edition, Stuttgart, 1868), a volume of Gebete, and another of Briefe. He died at Mühlheim in Rhenish Prussia on 3d April 1769." See Hyans, vol. xii. p. 588.
tertiaries. See Franciscans, vol. ix. p. 700.

[^72]TERTULLIAN, whose full name was Quintus Septinfus Florevs Tertuluanus, is the earliest and after Augustine the greatest of the ancient church writers of the West. Before him the whole Christian literature in the Latin language consisted of a translation of the Bible, the Octavius of Minucius Felix-an apologetic treatise written in the Ciceronian style for the higher circles of society, and with no evident effect for the church as a whole-and a list of the books recognized as canonical (the so-called Muratorian fragment). Whether Victor the Roman bishop and Apollonius the Roman senator ever really made an appearance as Latin authors is quite uncercain. Tertullian in fact created Christian Latin literatcre; one might almost say that that literature sprang from him full-grown, alike in form and substance, as Athene from the head of Zeus. Cypriau polished the language that Tertullian lad made, sifted the thoughts he had given out, rounded them off, and turned them into current coin, but he never ceased to be aware of his dependence on 'Tertullian, whom lie designated as $\kappa a \tau^{\prime}$ ' $\bar{\xi} \xi \circ \times \dot{\eta}^{v} v$ his master (Jer., De Vir. Ill., 53). Augustine, again, stood on the shoulders of Tertullian and Cyprian ; and thcse three North Africans are the fathers of the Western churches.

Tertullian's place in universal history is determined by (1) his intellectual and spiritual endowments, (2) his moral force and evangelical fervour, (3) the course of his personal developraent, (4) the circumstances of the time in the midst of which he worked.
(1) Tertullian was a man of great originality and genius, characterized by the deepest pathos, the liveliest fancy, and the most penetrating keennesś, and was endowed with ability to appropriate and make use of all the methods of observation and speculation, and with the readiest wit. His writings in tone and character are always alike "rich in thought and destitute of form, passionate and hairsplitting, eloquent and pithy in expression, energetic and condensed to the point of obscurity." His style has been characterized with jnstice as darl and resplendent like ebony. His eloquence was of the vehement order ; but it wins hearers and readers by the strength of its passion, the energy of its truth, the pregnancy and elegance of its expression, just as much as it repels them by its heat without light, its sophistical argumentations, and its elaborate hair-splittings. Though he is wanting in moderation and in luminous warmth, lis tones are by no means almays harsh; and as an author he ever aspired with longing after humility and love and patience, though his whole life was lived in the atmosphere of conflict. Tertullian both as a man and as a writer had much in common with the apostle Paul.
(2) In spite of all the contradictions in which he inralved himself as a thinker and as a teacher, Tertullian was a compact ethical personality. What he was he was with his whole being. Once a Christian, he was determined to be so with all his soul, and to shake himself Iree of all half ineasures and compromises with the world. It is not difficult to lay one's finger upon very many obliquities, self-deceptions, and sophisms in Tertullian in matters of detail, for he struggled for years to reconcile things that were in themselves irreconcilable; yet in each case the perversities and sophisms were rather the outcome of peculiarly difficult circumstances in which he stood. It is easy to convict him of having failed to control the glowing passion that was in him. He is often outrageously unjust in the substance of what he says, and in manner harsh to cynicism, scornful to gruesomeness; but in no battle that be fought was he ever actuated by selfish interests. What he did was really done for the Gospel, as he understood it, with all the faculties of his soul. "But he understood the Gospsi as being primarily an assured
hope and a holy law, at fear of the Judge who can cast into hell and as an inflexible rule of faith and of discipline. Of the glorious liberty of the children of God he had nothing but a mere presentiment; he looked for it only in the world beyond the grave, and under the power of the Gospel he counted as loss all the world could give. He well understood the meaning of Christ's saying that He came not into the world to bring peace, but, a sword: in a period when a lax spirit of conformity to the world had seized the churches he maintained the "vigor evangelicus" not merely against the Gnostics but_ against opportunists and a worldly-wise clergy. Among all the fathers of the first three centuries Tertullian has given the most powerful expression to the terrible earnestness of the Gospel.
(3) The course of Tertullian's personal development fitted him in an altogether remarkable degree to be a teacher of the church. Born at Carthage of good family -his father was a "centurio consularis"-he received a first-rate education both in Latin and in Greek. He was able to spcak and write Greek, and gives evidence of familiarity alike :zith dits prose and with its poetry; and his excellent memory-though he himself complains about it-enabled him always to bring in at the right place an appropriate, often brilliant, quotation or some historical allusion. The old historians, from Herodotus to Tacitus, were familiar to him, and the accuracy of his historical knowledge is astonishing. He studied with earnest zeal the Greek philosophers; Plato in particular, and the writings of the Stoics, he had fully at command, and his treatise De Anima shows that he himself was able to investigate and discuss philosophical problems. From the philosophers he had been led to the medical writers, whose treatises plainly had a place in his working library. But no portion of this rich store of miscellaneous knowledge has left its characteristic impress on his writings; this influence was reserved for his legal training. His father, whose military spirit reveals itself in the whole bearing of Tertullian, to whom Christianity was above everything a "militia," had intended him for the law. He studied in Carthage, probably also in Rome, where, according to Eusebius, he enjoyed the reputation of being one of the most eminent jurists. This statement derives confirmation from the Digest, where references are made to two works, De Cástrensi Peculio and Quæstionum Libri VIII., of a Roman jurist named Tertullian, who must have flourished about 180 A.D. In point of fact the quendam advocate never disappeared in the Christian presbyter. This was at once his strength and his weakness: his strength, for as a professional pleader he had learned how to deal with an adversary sccording to the rules of the art-to pull to pieces his theses, to reduce lim $a d$ absurdum, and to show the defects and contradictions of his statements,-and was specially qualified to expose the irregularities in the proceedings taken by the state against the Christians; but it was also his weakness, for it was responsible for his litigiousness, his often doubtful shifts and artifices, his sophisms and argumentationes ad hominem, his fallacies and surprises. At Rome in mature manhood Tertullian became a Christian, under what circumstances we do not know, and forthwith he bent himself with all his energy to tho study of Scripture and-of Christian literature. Not only was he master of the contents of the Bible: he also read carefully the works of Hermas, Justin, Tatian, Miltiades, Melito, Irenæus, Proculus, Clement, as well as many Gnostic treatises, the writings of Marcion in particular. In apologetics his principal master was Justin, and in theology proper and in the controversy with the Gnostics, Irenæus. As a thinker he was not original, and even as a theologian he has produced but few new schemes of doctrine, excent his doctrine of sin His snecial gift lay
in the pow to make what had been traditionally received impressive, wive to it its proper form, and to gain for it new currency. From Rome Tertullian visited Greece and perhaps aisu Asja Minor; at any rate 'we know that he had temporary relations with the chürches there. He was consequently placed in a position in which he could check the doctrine and practice of the Roman Church. Thus equipped with knowledge and experience, he returned to Carthage and there laid the foundation of Latin Christian iiterature. At first, after his conversion, he wrote Greek, but by and by Latin almost exclusively. The elements of this Christian Latin lang age may be enumerated as follows :-(i.) it had its origin, no in the literary language of Rome as developed by Cicero, but in the language of the people as we find it in Plautus and Terence; (ii.) it bas an African complesion; (iii.) it is strongly influenced by Greek, particularly through the Latin tra slation of the Septuagirit and of the New Testament, besides being sprinkled with a large number of Greek words derived from the Script- es or from the Greek liturgiss ; (iv.) it bears the stamp of the Gnostic style and contains also some military expressions; ( $\stackrel{\text {. ) }}{ }$ it ortes something to the original creative power of Tertullian. As for his theology, its leading factors were-(i.) the teachings of the apologists; (iii.) the philosophy of the Stoics ; (iii.) the rule of faith, interpreted in an anti-Gnostic sense, as he had received it from the Church of Rome ; (iv.) the Soteriological theology of Melito and Irenæus; (r.) the substance of the utterances of the Montanist prophets (in the closing decades of his life). This analysis does not disclose, nor indeed is it possible to discover, what was the determining element for Tertullian; in fact he was under the dominion of more than one ruling principle, and he felt himself bound by several mutually opposing authorities. It was his desire to anite the enthusiasm of primitive Christianity with intolligent thought, the original demands of the Gospel with every letter of the Scriptures and with the practice of the Roman Church, the sayings of the Paraclete with the authority of the bishops, the law of the churches with the freedom of the inspired, the rigid diseipline of the Montanist with all the utterances of the New Testament and with the arrangements of a church seeking to set itself up within the world. At this task he toiled for years, involved in contradictions which it took all the finished skill of the jurist to conceal from him for a time. At last he felt compelled to break off from the church for which he had lived and fought; but the breash could not clear him from the contradictions in which he found himself entangled. Not only did the great chasm between the old Christianity, to which his soul clung, and the Christianity of the Scriptures as juristically and philosophically interpreted remain unbridged; he also clung fast, in spite of his separation from the Catholic church, to his position that the church possesses the true doctrine, that the bishops per successionem are the repositories of the grace of the teaching office, and so forth. The growing violence of his latest works is to be accounted for, not only by his burning indignation against the everadvancing secularization of the Catholic church, but also by the incompatibility between the authoritics which he recognized and yet was not able to reconcile. After having done battle with heathens, Jews, Marcionites, Gnostics, Monarchians, and the Catholics, he died an old man, carrying with him to the grave the last remains of primitive Christianity in the West, but at the same time in conflict with himself.
(4) What has just been said brings out very clearly how important in their bearing on Tertullian's development were the circumstances of the age in which he laboured. Hie activity as a Christian falls between 190 and 220,
a period of very great noment in the history of the Catholic church; for within it the struggle with Gnosticism was brought to a victorious close, the New Testament established a firm footing within the churches, the "apostolic" rules which thenceforward regulated all the affairs of the church were called into existence, and the ecclesiastical priesthood came to be developed. Within this period also falls that evangelical and legal reaction against the political and secular tendencies of the church which is known as Montanism. The same Tertullian who had fortified the Catholic church against Gnosticism was none the less anxious to protect it from becoming a political organization. Being unable to reconcile incompatibles, he broke with the church and became the most powerful representative of Montanism in the West.

Although Tertullian's extant works are both pumerous and copious, our knowledge of his life is rery rague. He cannot have been born much later than about 150 . His activity as a jurist io Rome must fall within the period of Comnodus; for there is no indication in his writings that he was in Rome in the time of Marcus Aurelius, and many passages seem to preclude the supposition. The date of his conversion to Christianity is quite nncertain; there is much in farour of the years between 190 aod 195. How loog he remained in Rome after becoming a Christian, whether be had attained any office in the church before leaving Rome, what was the date of his risit to Greece, -on these points also we remain in ignorance. It is certaiu that he was settled in Carthage in the second half of 197, the date of his writing his Apologeticus and (shortly afterwards) his two books Ad Nationes; we also know that le becatoe a presbyter in Carthage and was married. His recognition of the Montanistic prophecy in Plirygia as a work of God took place in 202-203, at the time when a new persecution broke out. For the next five years it was his constant endeavour to secure the victory for Montanism within the church; but in this he became involved more and more deeply in controversy with the majority of the church in Carthage and especially with its clergy, which had the support of the clergy of Rome. As Jerome writes (De Vir. Ill., 53): "Usque ad mediarn ætatem presbyter fuit ecclesiæ Africanæ, invidia postea et contnmeliis clericorum Romanæ ecclesix ad Montani dogna delapsus." Ou his breach with the Catholic church, prohably in 207-208, he became the head of a amall Montanist community in Carthage. In this position he continued to labour, to write, and to assail the lax Catholics and their clergy ontil at least the time of Bishop Calixtus in the reign of Elagabalus. The year of his death is uncertain. Jerome (ut sup.) says: "Fertur vixisse usque ad decrepitam ætatem." That he returned at last to the bosom of the Catholic church is a mere legend, the motive of thich is obvious; his adherents after his death continued to maintain thernselves as a small community in Carthage. Although he had left the church, his earlier writings continued to be extensively read; sod in the 4th century his works, along with those of Cyprian, were the principal reading of Western Christians, until they mere superseded by those of Jerome, Ambrose, Augustine, and Gregory. Jerome has included him in his catalogue of 'Christiau "viri illustres," but only as a Catholic to whom reference should he made with caution. ${ }^{1}$
The works of Tertullian, on the chronology of which a great deal has been writteu, and which for the most part do not admit of being dated with perfect certainty, fall into three classes, -the apologetic, the polemical theological, and the ascetic. Aod in point of time also three periods can be readily diatinguished, the years 202-203 and 207-208 constituting the divisions. Some of the things he krote have unfortunately disappeared,-in particular the De Spcctaculis, De Baptismo, and De Virginibus Velandis in Greek; his rorks in Latin on the same subjects bave survived.
I. IV'orkis dating from before 202.203.-To this class helong the Apologeticus (197) and the two books Ad Nationcs, De Spectaculis, De Idololatria, De Cultu Feminarum Libri II., De Testimonio Anime (written soon after the Apologeticus), Ad Martyres (perhaps the earliest of all), De Baptismo Hareticorum (now lost), De Baptismo, De Fenitentia, De Oratione (the last three written for catechumens), De Patientia, Ad Uxorem Libri II., De Prescriptione Hareticorum, and Adv. Marcionem (in its first form). The Apologeticus, which in the 3d century was translated into Greek, is the weightiest work in defence of Christianity of the first two centuries. Respecting its relation to the Octavius of Minucius Felir much has been written; to the present writer it seems unquestionable that Tertullian'e work was the later. Of Ereat moment also is the De Prescriptione Herficorum, in which the jurist is more clearly heard than the Christian. The De Spectaculis and De Idololatria show that Tertullian was alresdy in a certain bense a Montanist

[^73] Comrronit, 24.
before he formally went over to that creod; on the other hand, his De Panitentia proves that his earlier views on church discipline were much more tolerant than his later. To learn something of his Christian temper we must read the De Oratione and the De Patientia. The De Baptismo is of special interest from the arehæological point of view.
II. Works voritten between 202-203 and 207-208.-De Virginibus Velandis, De Corona Militis, De Fuga in Persecutione, De Exhortalione Castitatis, Scorpiace adv. Gnosticos (?), Adversus. Hermogenem, De Censu Arime adv. Hermogenem (lost), Adv. Valentinianas, Adv. Apelleiacos (lost), De Paradiso (lost), De Fato (lost), De Anima, De Carne Christi, Dc Resurrectione Carnis, and De Spe Fidelium (lost), were all written after Tertullian had recognized the prophetic claims of the Montanists, but before he had left the church.
III. Works later than 207-208. - To this period belong the five books Adv. Marcionem, his main anti-Gnostic work (in the third form-the first of the five was written in 207-20s), Ad Scapulam (a memorial to the governor, written soon after 211), Die Pallio (possibly this ought to be classed among the earliest writings), Adv. Praxean (his principal work against the Monarchians), and Adv. Judxos. The latest extant morks of Tertullian (all after 217) are his controrersial mritings against the laxity of the Catholics, full of the bitterest attaclos, especially quon Caliztus, the bishop of Rome ; theso aro De Mfonogamia, De Jejunio, De Pudivitia, and De Eestasi Libri VII. (lost). The arguments against the genaincness of some of the above writings do not seem to the present rriter to have weight. It is uncertain whether Tertullian was the author of the Acta Perpetuse et Felicitatis.

Lileralure.-A thoroughly aleqnate edition of the works of Tertullian and a fnll acconnt of his fortunes as a writer are still desiderata; the best edition at present is thst of Oehler ( 8 vols, Leipsic, 1853). The editio princeps is by Pamelius (15i\%), De 1a Barro (1550), Rigaltius (103i), Semler (1770-i1), Oberthiur
 (1750), Leopold ( 1839 sq.), and Nigne (1811). The Vienns Academy is about to
publish an edition by Reiferscheid. There are Germsn translations by Besnard publisb an edition by Reinerschen English translation appeara in Clark's Ante(1837) and Kellner (1852), and an English franslation appears in Clarks ante-
Nicene Treological Library. Sepsrate treatises of Tertullian hava often been Nicene Theological lited, the Apologeticus by Havercamp (1718), Oehler (1si3), and Kayser (1So5); edited, -the Apologeticus by Havercamp (1718), Oehler (1sis), and kayser (15o5); the $A d$ Nationes by Godofredns (1635); the De Spectaculis by Klussmann (1877);
the De Testinon io Arimex by Lindner (1862); the De Pallio by Salmasius (1855); the De Testimonio Arimas Murter, \&c. Tbe testimoniea of the church fathers other minor writings by Hurter, ec. Cyprian, Eusebius, Jerome, aod Vinceut of (the most important being those of Cyprian, Eusebius
The older studies on Tertullina by Lo Nourry, Tillemont, Dupio, Allix, Cave, Ceillier, Mosheim, Ceutntr, Sermler, Noesselt, are to some extent reproduced In vol. iii. of Oehler'a edition. Among the more modern contributiona to the snbject may be mentioned those of Neaoder (Antignosticus: Geist des Tertul. lians, Berlin, 1525), Boh=inger (Dic Kirehe Chisti in Biographicn, vol. iii., od ed., 1875), Monler (Patrologie, vol, i., 1840, pp. 701-789), Kaye (Eocles. Hist. of the ed and $3 a$ Centurics, illustroted from the writiugs of Tertullian, 3d ed., 1845), Coenen (Comment. de Tertull., Utrecht, 1825), Hesselberg (Teriullian:'s Lehre, pt. i., Dorpat, 1848), Ebert (Gesch. d. Christh. Lit., 1874), Freppel (Tertullien, Paris, 1S64), Hanck (Tertullian's Leten u. Schrißer, 1si7), Alzog (Potrologie, 3d ed., 1sit) ; seo also the manuals of church history, history of dogme (e.g.,
 Eomao literature (Tenfel), of Christian philosophy (Ritter, Steckl, Erdmann, Deberweg). Compara also Deutinger, Ccist d. Christl. Ueberlieferung, vol. i.

TERUDANT, or Tasudant. See Morocco. vol. ivi. p. 834.

TERUEL, a prorince of Spain, forming part of the ancient kingdom of Aragon, is bounded on the N. by Zaragoza, on the E. by Tarragona, on the S. by Castellon de la Plana and Valencia, on the S.TV. by Cuenca, and on the W. by Guadalajara, and has an area of 2363 square miles. It is intersected from east to west by the mountain chains of Albarracin and Gudar, from which sereral offsets diverge on either side. The loftiest summit is the Muela do San Juan ( 5280 feet), which is covered with snow for a great part of the year. These sierras gire rise to several large rivers, the principal being the Tagns, the Guadalaviar, the Jiloca, and the Guadalope. Notwithstanding the fertile character of the plains and an abundance of mineral wealth, the trade of the province is unimportant, and civilization in a backward state, owing to the lack of means of transport, the want of enterprise, and imperfect communication with the onter world. The chief products are corn, wine, oil, cheese, fruits, timber, flax, hemp, silk, wool, and saffron, together with cattle, shcep, and swine; while in the busier centres some slight manufacture of coarse cloth, paper, leather, soap, pottery, and esparto goods is carried on. The population of the prorince in 1877 was 249,000 .

TERUEL, the capital and most important town of the above prorince, is situated on the left bank of the Guadalariar, 142 miles east of Madrid, and on the high road from Calatayud to Valencia. It is an ancient walled city, fast falling into decay, with narrow gloomy streets and crumbling mediæval houses. Some of the numerous churches are worth seeing, with their paintiugs by the rarely known 17th-century artist Antonio Visquert, as is also the great aqueduct of 140 arches, raised $1555-60$ by Pierre Bedel, a French architect. In the cloisters of San Pedro lie the remains of the celebrated "lovers of Teruel," Juan de Marcilla and Isabella de Segura, whose pathetic story has formed the subject of numerous dramas and poems by Perez de Montalban, Yaque de Salas, Hartzenbusch, and others. The cathedral is Churrigueresque. Terucl was raised to the dignity of a see in 1577, the bishop being suffragan of Zaragoza. The popuiation of the city in 1877 was 9482.

TESCHEN (Polish Cieszyn), the chief town of a duchy in Austrian Silesıa, is situated on the Ulsa, a tributary of the Oder, 34 miles south-east of Troppa. It combines both Polish and German peculiarities ir the style of its buildings, and contains fire churches, the most interesting of which are the parish church, which formerly belonged
to a Dominican monastery, and the Gnadenkirche, one of the Protestant churches built in terms of the treaty of Altranstädt in 1706 . The only relic of the ancient castle is a square tower, dating from the 12 th century. The manufacturing industry of the town is slight, and, since the construction of the railway via Oderberg, Teschen has lost much of the trade formerly commanded by its position near the borders of Silesia, Hungary, Moravia, and Galicia. A flax dressing and spinning factory, a large brewery, and several furniture factories are the chief industrial establishments in the town. The population in 1880 was $13,004$.
It was at Tescben that Maria Theresa and Joseph II. aigaed the peace which put an end to the war of Bavarian auccession in 1779. The duchy of Teschen wes formerly a more or less dircet apanage of the Bohemian crown. For some time it bore the uame of SaxeTeschen (Sachsen-Teschen), owing to the fact that Prince Albort of Saxony, who married an archduchess of Austria, received it as part of his wife's dowry. Prince Albert bequeathed it in 1822 to the emperor of Austria, who bestowed it on the archduke Albert.

TEST ACTS. The principle that none but persons professing the established religion were eligible for public em. ployment was adopted by the legislatures of both England and Scotland soon after the Reformation. In England the Acts of Supremacy and Uniformity and the sovere penalties denounced against recusants, whether Roman Catholic or Nonconformist, were affirmations of this principle. The Act of 7 Jac. I. c. 2 provided that all such as were naturalized or restored in blood should receive the sacrament of the Lord's Supper. It was not, however, until the reign of Charles II. that actual receiving of the communion of the Church of England was made a condition precedent to the holding of public offices. The earliest imposition of this test was by the Corporation Act of 1661 (13 Car. II. st. 2, c. 1), enacting that, besides taking the oath of allegiance and supremacy and subscribing a declaration against the Solemn League and Covenant, all members of corporations were within one year after election to receive the sacrament of tho Lord's Supper according to the rites of the Church of England. This Act was followed by the Test Act of 1672 (25 Car. II. c. 2). The immediate cause of the Test Act (the full title of which is "An Act for preventing dangers which may happen from popish recusants ") was the king's declaration of indulgence, dispensing with laws inflicting disabilities on Nonconformists. This Act enforced upon all persons filling any office, civil or military, the obligation of taking the oaths of supremacy and allegiance and subscribing a declaration against transubstantiation, and also of receiving the sacrament within three months after admittance to office. The Act did not extend to peers; but in 1078 30 Car. II. st. 2 enacted that all peers and mambers of the House of Commons should make a declaration against transubstantiation, invocation of saints, and the sacrifice of the mass, - a special exception being made in favour of the duke of York. The provisions of the Test Act were violated by both Charles IL. and James II. on the ground of the dispensing power claimed by the Stuart kings. In a well-known case of Godden \%. Hales (11 State Trials, 1166), an action for penalties under the 'Test Act brought against an officer in the army, the judges decided in favour of the dispensing power,-a power finally abolished by the Bill of Rights. After a considerable number of amendmente and partial repeals by the legislature of the Acts of 1661, 1672, and 1678, and of Acts of indeunity to protect persons unde: certain circumstances from penalties incurred under the Test Aci, the nccessity of receiving the sacrament as a qualification for office was abolished by 9 Geo. IV. c. 17, and all Acts requiring the taking of oaths and declarations against transubstantiation, \&c., were repealed by the Roman Catholic Relief Ace of 1820 ( 10 Ge .
IV. c. 7.). This general repeal has been followed by the special repeal of the Corporation Act by the Promissory Oaths Act, 1871 ( 34 and 35 Viet. c. 48), of the Test Act by the Statute Law Revision Act, 1863, and of the Act of 1678 by 29 and 30 Vict. c. 19. Religious tests remained in the English universities until 1871. To be a member of the Church of England was a necessary condition precedent for holding most university or college offices by the Act of Uniformity of 1662, and such offices were not affected by the Toleration Act of 1688 and the Roman Catholic Relief Act of 1829. In 1871 the University Tests Act abolished subscriptions to the articles of the Church of England, all declarations and oaths respecting religious belief, and all compulsory attendance at public worship in the nniversities of Oxford, Cambridge, and Durham. There is an excepticl. confining to persons in hely orders of the Church of Eagland degrees in divinity and positions restricted to persons in holy orders, such as the divinity and Hebrew professorships.

Scolland.-A religious test was imposed immediately after the Reformation. By 1667, c. 9, no oul was to be appointed to a public office or to be a notary who did not profess the Reforned religion. The Scotch Test Act was 1681, c. 0 , rescinded by 1690, c. 7 . Renunciation of popery was to be nade by persons emplosed in edncation ( 1700, c. 3). A motion to add, after the 18 th article of union, an exemption of Scotsmen from the sacramental test in the United Eingdom was uegatived by the Scottish parliament. A similar fato a waited a proposal that while a sacrarnental test was in force in England all persons in public ollice in Scotland should subscribo their adhesion to the Pre:byteriau Church gorcrameut. By 1707, c. 6 , all professors, principals, regents, masters, or others bearing office in any university, college, or school in Scotland rere to pro. fess and subscribe to the Confession of Faith. All persons were to be free of any oath or test contrary to or inconsistent with the Protestant religion and Presbyterian Church government. The reception of the communion was never a part of the test in Scotland as in England and Irelaud. The necessity for subscription to the Confession of Faith by persons holding a university office (other then that of principal or professor of theology) was removed by 16 and 17 Vict. c. 89 . The Act provides that in place of subscription every person appointed to a university ofice is to subscribe a declaration eccording to the form in the Act, promising not to teach any opinions opposed to the divine acthority of Scripture or to the Confession of Faith, and to do nothing to the prejudice of the Church of Scotland or its doctrines and privileges.
Ireland. - An oath of allegiance was required by the Irish Act of Supremacy (2 Eliz. c. 1). The English Aet of 8 Will. and M. c. 2 substituted other oaths and enforced in addition from peers, mom. bers of the Hoase of Commons, bishops, barristcr3, attorneys, and othere a declaration against transubstantiatiou, invocation of the Virgin Mary and the saints, and the sacrifice of the mass. By the Irish Act of 2 Anne c. 6 overy person admitted to any office, civil or military, was to take and oubscribe the oaths of allegiance, supremacy, and abjuration, to subscribe the declaration against transulstantiation, \&cc., and to receive the Lord's Supper according to the usage of the Church of Ireland. English legislation on the subject of oaths and declarations was adopted in Ireland by Yelverton's Act, 21 and 22 Geo. III. c. 48, §3 (Ir.). These provisions were all repealed by the Promissory Oaths Act, 1871. The Roman Catholic Relief Act of 1793 ( 33 Geo . III. c. 21, Ir.) excepted Trinity Colloge, Dublin, from its provisions, and tests existed in Dublin university until 1873. They wero abolished as far as regarded certain scientific professurships in 1867 by 30 Vict. c. 9 , and were finally abolished for the whole university by the Uni versity of Dublio Tests Act, 1873 , except as to professors of and lecturers in divinity.

United Slates.-By art. 6 of the constitution, "no religious test aluall ever be required as a qualification to any office or public trust under the United States." A similar provision is generally included in the State constitutions.

## TESTAMENT. See WILL. <br> TESTIMONY. See Evidence.

TETANUS (frum Gr. TEive, I stretch), a disorder of the nervous system, consisting in an increased reflex excitability of the spinal cord and manifesting itself by painful tonic spasm of the voluntary musnles throughont the body. Tho disease shows itself under various conditions. It occasionally occurs, particularly in tropical countries, without apparent cause, and has thus been known to affect numbers of persons simultancously (idiopathic letarius).

It is sometimes observed in new-born children (trismus neonatorum) and in parturient women (puerperal tetanus). But by far the greater number of cases occur in connexion with a wound or other injury, more especially in the extremities, probably implicating some of the peripheral nerves. Certain forms of injury, as punctured, lacerated, and gunshot wounds, are more liable to be followed by tetanus than others. In many cases the liability bears no proportion to the extent of the wound. Exposure to cold after injury is an important exciting cause. The symptoms of tetanus in its most usual forms generally appear during the healing process of a wound, but occasionally they arise after cicatrization is completed. Sometimes they are preceded by appearances of irritation in the wound or its neighbourhood, but this is exceptional. The earliest indications of the disease usually show themselves, no matter where the wound is sitnated, by stiffness about the muscles of the jaw, causing difficulty in opening the mouth, which soon increases to lockjaw or trismus. This is accompanied by spasm in neighbouring muscles, and the drawn features and exposed teeth give to the countenance the peculiar expression known as risus sardonicus. The rigidity extends to the muscles of the neck, back, chest, abdomen, and extremities, and the body frequently assumes a bent attitude, either backward (opisthotonos), forward (emprusthotonos), or laterally (pleurosthotonos). This general muscular rigidity, which at first is not constant but occasionally undergoes relaxation, is accompanied by frequently recurring convulsive seizures, which are readily excited by the slightest irritation, such as from a draught of cool air, a bright light, the closing of a door, \&c. In such attacks there is great suffering and the expression of the face is indicative of agony; and the function of respiration may be seriously involved and asphyxia threaten or actually take place. The temperature of the body sometimes rises to a high degree. The attack is usually acute and after a few days either passes off or, as is more frequent, terminates fatally, either by asphyxia from tonic spasm of the respiratory muscles or from exhaustion consequent on the violence of the symptoms together with the absence of sleep. Throughout the whole course of the disease the mind is clear. In idiopathic tetanus the symptoms are less severe, the course more chronic, and recoveries more common than in those which depend upon a wound or injury. The puerperal form, with symptoms which differ in no way from those described, is rare and occurs either after parturition or after abortion. Tetanus in new-born children, also a rare form, usuallv chows itself a day or two after birth by obvious difficulty in the acts of sucking and swallowing; by the supervention of trismus, together with tonic contraction of the muscles of the limbs and body, sometimes accompanied by convulsive seizures; and by a peculiar low whining cry, seldom absent and very caracteristic. Various opinions have been held as to the cause of this form of tetanus, some referring it to the wound produced by severance of the umbilies. cord, others to pressure upon the bones of the head in parturition, dc. It has not yet been satisfactorily explained. Although sometimes recovered from, it is usually fatal.

The symptoms of poisoning by strychnine bear a strong resemblance to those of tetanus. They are, however, more acute and develop in connexion with something which has been taken; further, the absence of a wound and the fact that the spasm affects the muscles of the extremities first, and not those of the jaws, as in tetanus, serve to establish the diagnosis. In Hidrophobia (q.v.), which in certain of its symptoms resembles tetanus, the absence of trismus, the dread of water, and the violent spasms on attempting to drink, together with the history of the case, readily caable a distinction to be made. Various other forms of
nervous disease accompanied by tetanic symptoms, such as cerebro-spinal meningitis, hysteria in some forms, \&c., may be still more clearly distinguished from true tetanus.

The pathology of tetanus is referred to in the article Pathology (vol. xyiii. p. 391). No constant changes are observed in the body after death from tetanus. The most common are great dilatation of the blood-vessels of the spinal cord and sometimes evidence of inflammatory action, but these are probably the effects of the symptoms rather than their causo.

For the treatment of tetanus many remedies have been employed. Where a source of irritation in or about a wound can be made out, it ought to be dealt with by the surgeon. Of medicinal agents those which diminish the reflex excitability of the spinal cord and relax the spasm are to be recommended. But it is not safe to employ all substances which produce these effects. Thus tobacco and its active principle nicotine act powerfully in this way, but they are attended with danger from theil poisonous properties, and the same may be said of curari, conium, calabar bean, \&c., all of which have been used in tetanus. Opium carefully administercd sumetimes produces a markedly beneficial effect, as does also Indian hemp. Chloroform or ether inkalation greatly mitigates the severity of the spasm. Chloral hydrate and bromide of potassium or ammonium are among the most useful agents which can be employed, and they may be given separately or, still better, in combination. As adjuvants, the warm bath, the absence of all noise and excitement, and the maintenance of the strength by appropriate nutriment should not be neglected.

TETRARCH ( $\tau \epsilon \tau \rho a ́ \rho \chi \eta$ ), the ruler of $\approx$ tetrarchy ( $\tau \in \tau \rho a \rho \chi i a$ ), that is, in the original sense of the word. of one quarter of a region. The title of tetrarch is familiar from the New Testament as borne by certain princes of the petty dynasties which the Romans allowed to exercise a dependent sovereignty within the province of Syria. In this application it has lost its original precise sense, and means only the ruler of part of a divided kingdom, or of a region too narrow to support a higher title. After the death of Herod the Great ( 4 B.C.) his realm was shared among his thrce sons: the chief part, including Judæa, Samaria, and Idumea, fell to Archelaus (Matt. ii. 22), with the title of ethnarch; Philip received the north-east of the reaim, and was called tetrarch; and Galilee was given to Herod Antipas, who bore the same title (Luke iii. I). These three sovereignties were reunited under Herod Agrippa from 41 to 44 A.D. Another tetrarchy is mentioned in Luke iii. 1, viz., that of Lysanias in the little district of Abilene, near Damascus, in the Falley of the Barada. An inscription of this Lysanias is given in $C$. I. Gr., 4521 .

See Reцan, Jím do 厄Acad., xxvi. 2 (1870), p. 49 sq.
TETUAN (Tettúwin), a town of Morocco, about 23 miles south-south-west from Ceuta and 44 south-east from Tangiers, is picturesquely situated about 9 miles inland on the steep slope of a hill, behind which rise the bold Rif Mountains. It is surrounded by walls flanked with towers, and has on the summit of the hill a castle whick is the residence of the governor. The streets are narrow, unpaved, and dirty, and with fer exceptions the houses are poor. Scme of the numerous mosques, bowever, are bandsome. The principal manufactures are gun-barrels, coarse woolien cloths, and woollen and silk sashes. The harbour of Tetuan, at the mouth of the Martil, allows only small vessels to cross the bar, and the roadstead is much exposed to the east. There is some export trade in cattle, grain, fruit, leather, and wool, principally to Gibraltar The population of Tetuan is estimated ar about 20,000 (5000 Jems).

Tetuen is said to have been founded in 1492 by refugees from Grinada. Is was taken by storm on 4th Fehruary 1860 by the Spaniards under O'Donnell, but restored to Morocco when veace ras coocluded.

TEUTONES, or Teuton, a powerful German tribe, first appearing in history along with the Cimbri (q.v.). They are again mentioned at a later period by Pliny (H.N., xxxvii. 11) and others as inhabiting a district in the northwest of Germany to the north of the Elbe. The name of Teutones was never employed either by the Germans themselves or by the Romans as a general name for the whole German nation.

- teutonic languages. See Germany (vol. x. p. 514 sq.) ; also. English Language, Goths (rol. x. p. 852 sq.), Scandinavian Languages, Frisians. and Holland (vol. xii. p. 84 sq.).
teutonic Order, The, or Teutonig Kinights of St Mary's Hospital at Jerusalem (Deutscher Orden, Duntane Ritter, Orden der Ritter des Hospitales St Marien zu Jerusalem), is one of the three great military and religious orders to which the crusades gave birth. Its name is derived from. a German hospital founded at Jerusalem in 1128, which disappeared on the capiure of the Holy City by the Saracens in 1187. The pity excited in the minds of some German merchants by the sufferings of the Christian soldiers at the siege of Acre in 1190 induced them to revive the work of this society under a somewhat different form ; and eight or nine years later the society, as thus resuscitated, was converted into a military order. Like the two other military orders, the Teutenic orde - adopted the Augustine rule of life; and, in addition to the ordinary monastic vows, the members laid upon themselves the special obligations of tending sick and wounded pilgrims and of fighting the pagans. Frederick, duke of Swabia, took the young order under his protection, and it soon received charters from the pope and emperor, entitling it to the same privileges as the Templars and Knights of St John. Whatever was the case at first, the members of the order were ultimately required to be Germans of honourable birth. Priest brothers were introduced about 1220, and afterwards half-brothers, like the freres servants d'armes of the other orders, who did not require to be of noble birth, and might, to some extent, continue their ordinary secular occupations. The distinguishing garb of the order consisted of a white mantie with a black cross.

Almost at once a rich strean of benefactions of all kinds began to flow into the coffers of the order, which gradually acquired extensive territories in Palestine and also in Germany and other parts of Europe. Its first seat was at Acre, and the first grand-master was a Rhenish knight named Herman Walpot of Bassenheim. The order rose to great power and influence under Herman von Salza (q.v.), who held the office of grand-master from about 1210 to 1239 , and enjoyed the fullest confidence of both emperor and pope. He was also keen enough to see the hopelessness of the attempt to expel the Mohammedans from the Holy Land, and eagerly hailed the opportunity of transferring the activity of the order to another sphere which was afforded by the invitation to undertake a crusade against the heathen Prussians. The successful progress of this crusade, the aggrandizement thereby accruing to the order, and its subsequent decline have already been narrated in the article Prussia (vol. xx. pp. 5.6). Soon after the beginnag of the struggle, in 1237, the Teutonic order absorbed the order of the Brothers of the Sword, a union which brought Courland, Semgallen, and Livonia to swell its territories. In 1291, when Acre, the last stronghold of the Franks in Palestine, fell the order removed its beadquarters to Venice - but, when its centre of gravity
became so obviously shifted to the extensive territories won from the Prussians, the seat of government was transferred (1309) to Mariesporg (q.v.) on the Vistula, where a splendid castle was erected for the grand-masters. The grand-mastership of Weinrich von Kniprode (1351-82) is the most prosperous period in the history of the order. Its territorial possessions far exceeded those attained by .either of the rival orders, stretching from the Oder. on the west to the Gulf of Finland on the east, and containing a population of two to three million souls. .Its government at first was excellent, and for a time it may be said to have played the leading rôle in the political history of northern'Europe. Wherever the order spread, Christianity and German national life were introduced. Its revenues were very large, and its ranks were kept full by hosts of aspirants to a share in its pious and lucrative crusades.

So long as the order maintained its own high standard all went well with it. But its internal decay was synchronous with external events that wruld alone have been extremely perilous. The union of Poland and Lithuania in 1386 raised up a jealous neighbour, whose power it was wellnigh impossible in the long run to resist, while the nominal conversion of the latter to Christianity struck at the root of the order's prosperity by depriviog it of its missiou. When there were no more heathens within reach to convert and despoil, the chief attraction to outsiders to join its ranks disappeared. After the conversion of Prussig into a secular duchy the Teutonic order still continued to exist as an ecclesiastical organization, possessing eleven bailiwicks in different parts of Europe, with a total area of 850 square miles and 88,000 inhabitants. The headquarters were fixed at Mergentheim in Swabia. Its political importance was of. course now a thing of the past, and the scattered position of the bailiwicks only emphasized its weakness. In 1801 the bailiwicks to the west of the Rhine were absorbed by France, and in 1809 the order was entirely suppressed by Napoleon, its lands going to the secular principalities within which they lay. In 1840 the order was resuscitated in Austria, where it now exists as a semi-religious knighthood, presided over by a royal archduke. Of late it has been doing something towards justifying its existence and connecting itself with its past history by engaging in the ambulance service in time of war. The bailiwick of Utrecht, which survived the decree of Napoleon, also still exists, but the Dutch representatives of the order have become Protestants. The jewel of the order consists of a black and white cross, surmounted by a helmet with three feathers.
The complete organizetion of the Teutoric order included a grand-master (hochmeister), provincial masters (landmeister) for the greater providces, and commanders (komturren) for the smaller dis-, tricts and costles. The power of these officers was not, however, absolute The grand-master co-opcrated with a chapter consisting of the provincial masters and five other important functionaries, winie the provincial masters in turn lad to consult with the council formed by the knight commanders. The privilegee enjoyed by the order in its palmp daye were of the most extensive nature, and its relations to both church and etato were often of a most exceptional nature.
See Voigt, Gesch. d. Deutschen Ritterordiens (1857-59): E.ohmeyer, Gesch. v. Osi* u. West-Preussen (vol. 1., Gotha, 1831); and E. Strehlise, Tabulas Ordinis Thestonicí (Berlin, 1869).
TEWKESBURT, an ancient borough and market-town of Gloucestershire, England, is situated in a fine pastoral valley at the junction of the Severn and the Upper Avon, and on the Midland and Great Western Railways, 15 miles south of Worccster and 126 north-west of London. It has three principal streets, which era regularly built and well paved. The Sevcrn is cressed by an iron bridge with a flattened arch of 170 feet span, erecte? - Tisors in 1824. Of the great Benedictine abbey, one of the richea foundations in England, refounded and enlarged by Sir XXIII. - 26

Robert Fitz-Hanoon in the 12th century on the site of the ancient hermitage and Saxon monastery, there only remain the gate and part of the cloisters. The abbey church, consecrated in 1125, is a magnificent specimen of Early Norman. This elaborate cruciform building consists of nave and side aisles, with transepts united by a grand central tower richly arcaded. The choir terminates in an apse and is surrounded by an ambulatory. One of the most remarkable features of the buiiding is the unique western front, the central part of which is accupied by one Fast arch extending from the ground to the roof. Originally it was filled in with Norman windows, but these were remeved in the 14th century, when the whole building underwent restoration in tho Middle Decorated style, of which it is one of the finest existing examples. The nare was refilled by tracery windows, and stone groining was substituted for the carved wooden ceiling, a like transformation taking place in the transepts. The old Norman columns in the choir still exist; but above them rises a grand superstructure of Decorated work. The elegant clerestory windows are of the 14 th century, with stained glass of the same date. The ambuiatery was rebuilt some distance farther out, and from it projected a beautiful series of chapels. The elaborate tombs include those of Sir Robert Fitz-Hamon, the De Spensers, Alan prior of Canterbury, Sir Guy de Brien, and the vault of George duke of Clarence (murdered in the Tomer) and his wife Isabella. Edward, prince of. Wales, slain after the battle of Terkesbury (1471) by the Yorkists, is also buried in the church, which las undergone an extensive process of restoration under the direction of Sir Gilbert Scott. In the High Street there are several anciont timbered and gabled houses. Remains of an ancient wall have been discovered adjoining the town. The principal modern buildings are the town-hall, the philharmonic laall, and the corn exchange. There is a free grammar-school and a number of charities, including the dispensary, the rural hospital, and Queen Mary's, Barnes's, Richardson's, and Russell's almshouses. Formerly Temkesbury had a woollea trade and an important mustard manufacture, but it is now chiefly dependent on its agricultural trade. The population of the municipal berough (area, 2619 acres) in 1871 was 5409 , and in 18815100.
The tomn is supposed to derive its name from Theoc, a Saxon monk, who founded a hermitage bero in the end of the 7 th century, which was changed into a monastery by tho duke of Mercia in 715, and rebuilt by Sir Robert Fitz-Hamon in 1302. On the death of Fitz-Hamon in 1147 the manor passed to the De Clares, who became merged in the $\mathrm{D}_{\ominus}$ Spensers, they in turn in tho Beanchanps, and the Beanchamps in the Nerides. At Towlesbury took place, 4th May 1471, the battle between the Yorkista and Lancastrians which placed the crown on the head of Edward IV. During the Civil War the town was occupied by the Parliamentarians, who were driven out by the Royaliste ; but it was surprised and captured by the former in 1644 , after which it remained in their possession. Towkesbury was first incorporated by Elizabeth in 1574, and when James I. sold the manor to the corporation in 1609 he grantod it a new charter with extended privileges. This being lost during the Civil War, a new charter was granted by Charles II. Between 1692 and 1698 the town was without a corporation, but a new cbaiter was granted by William 1II., Tlich remained the govern. ing charter until the passing of tho Mun:cipal Act. Until 1s67. Tewkesbury returned two members to the Honse of Commons; from 1867 to 1885 it returned ono; and in 1885 it became merged in the north or Terkesbury division of cilouacestershire.
 caited by H. R. Luard, 189.1 .

TEXAS, the largest in area and tho elerenth in populaion of the United States of America, is bounded by the Gulf of Mexico on tho S.E., by Louisiana and Arkansas on the E., by Arkansas and the lindian Territory on the N., the latter extending north of its northern prolongation (the Panhandlo), by Now Mcxico on the TV. and N. of its westers prolongation (tho trans-Pcoos region), and by diecaco on the S.W. Its area in 1850 was 262,290 squarə
miles, or one-eleventh (ncarly 9 per cent.) of the entire area of the United States. The extreme length is 740 miles, the breadth 825 , and the coast line 400 miles. The boundaries, as recognized by the United States Government, ${ }^{1}$ are--the Gulf of Mexico from the Rio Grande to the Sabine river, the Sabine river to $32^{\circ} \mathrm{N}$. lat., thence the meridian of $94^{\circ} 10^{\prime}$ to the Red river of Lovisiana, thence following that river west to its intersection with the 100 th meridian, thence north to lat. $36^{\circ} 30^{\prime}$; thence west to $103^{\circ}$ W. long., thence south to lat. $32^{\circ}$, thence west to its intersection with the Rio Grande, which river constitutes the soutli-western border of the State to the Gulf of Mexico.

The surface featurcs are exceedingly varicd, the prevailing eloments being steppes or treeless plains in the north-mest, mountains west of the Pecos river, forests in the east, marshes adjacent to the coast, low prairies in the south-east, and a combination of prairies and broken hills, interspersed with forest growth and thickets of tall shrubs (chaparral), in the centre. These regions are classified as follows (seo map below). (1) The coast plain is the direct geographical and geological continuation of the otleer States which border ou the Gulf of Mexico. It includes all the country cast of a line concentric with the coast, dramn from Texarkana in the north-east corner of the State to near Larcdo on the Rio Grande. The general direction of its slope, in common with that of the rest of the State, is from north-west to south-cast. Its altitude rangea up to 500 feet. The immediate coast strip is newly made marshland; west of this and north of the Colorado rirer are forests ; and to tha south of it the country is mostly a plain. (2) The black prairie region succecds the coast plain on the rest. Its western border is sharply defined frorn the Red river to the Rio Grande, beginning at Denison, passing through or near the citics of Sherman, Dallas, TVaco, Austio, and San Antonio, and then deflected west. Ward to Eacle Pass. It is a gently undu. lating prairie, corcred with a rich black soil, and raries in altitude from 300 to 700 feet.
 (3) The central region extends from the black prairie region on the cast to the eastern escarpment of the great plains on the north-mest and the trans. Pecos mountains ou the south-west. This is tho only region of Texas rhich is not the direct continuation of the physical features of some ad. joining political division. A great rariety of conditions is embraced within its bounds. In its north-eastern part are two long belts of stunted forest (the Cross Timbers), extending from the Red river to the Brazos, and separated by a prairie 50 miles in width. This is the most fertile partion of the entire region. West of this sub-region and north of the Colorado is a broken, arid country (the Coal-measures), having a sandy, pebbly soil, covered with a seattered growth of vegetation. West of this, between the 100 th meridian and the escarpment of the plains, is the gypsum conntry, consisting of the so-called "red beds" of the western United Stateg, accompanied by massive deposits of gypsum and other salts. This country is nuch sculptured by erosion, and in places resembles the "bad lands" of the upper Missouri country. There are also extensive intervals of prairie here. Near the centre, in the countice of San Saba, Mason, and Liano, is a rough, semi-mountainous area of older formations. The soutbern half of tho central region is a broken country of white limestone formation, semi-tropical in climate, and covered with scraggy vegetation, its pbysical features graduatind into those of northcrin Mesico. Ting south-western part is a rolling plain, entircly destitnte of streams. Throughout the region, at intervals of many miles, low, truacated hills (buttes) occur, represcating the remains of limestone formations now being rapidly croded. The region, as a whole, is poorly watered. It is best adapted for cattle and sheep raising, and is tho chicf locality of those indnstries in Tcxas. 'Jhe altitude varies fion 700 to 2500 fect. (4) The plains region is the portion of tho Stato west ef the 101st meridian and morth of tho thisty-sccond parallel,

The State does not recognizo tho South Fork oi the led river as the northero boundary, but iosists upon tha North Fork; it also elaims tho 100 th meridino ns laid down npon Mellish'a map ( 100 miles cast of the true meridian) as the castern bonter of tho l'anhaude.
commonly known es the "Staked Plain" (Llano Estacado). It is the direct oouthern continuation and termination of the great plains of the North American continent which extend along the eastern slope of the Rocky Mountains from British America to the Rio Pecas. The eastern edge is well rarked by a steep escarpment, which, in consequence of destructive erosion, is constantly receding to the westward. The surface is smooth, and utterly devoid of forest growth or atreams of water. But there are many small ponds or lakes, and in the southern part these are saline. The soil is light, rich, and prous, and is covered with a good growth of grass. Until a few years ago this region was totally unperpled, but many portions of it are now (1887) used for grazing purposes, water being secured by means of wells or artificially constructed reservoirs. The altitude ranges from 2500 to 4000 feet. (5) The trans-Pecos or mountainous region west of the Pecos river is composed of numerous mountain peaks and ranges, with interrening valleys of many miles in width. It is poorly watered, and the population outside the immediate Rio Grande valley is very sparse. The general level of the country is from 3000 to 5000 feet.

The rivera are separable intocseleral sub-systerns. The Rio Grande snd the Arkansas, constituting the north and south limits of the Texas drainage system, with their respective tributaries, the Pccos and the Canadian, originate in a limited district of northern New Mexico and Colerado, and ultimately reach the sea at pointa a thousand miles apart. The Canadian and the Pecos have cut deep cañons throuch the Llano Estacado. The former continues eastward through Indian Territory, aud the latter southward, joining the Rio Grande between $101^{\circ}$ and $102^{\circ} \mathrm{W}$. long. on the southern border of the State. The Rio Grande aud the Pecos receive no tributaries of importance in Texas, but ore constant in their flow. The next and most important group cowprises the Red, the Brazos, and the Colorado, all of which originate aloug the cestern border of the Llano. They traverse similar regiona, and have a general resemblance in character of sediment, irregularity of flow, velocity, and topography of drainage basins. Their brackish water is principally derived from the sudden precipitation of rainfall along the gypsiferous escarpments of the Llano. Its volume is ordinarily small, the flow often ceasing entirely west of the black prairie region. There are periodic freshets, however, which suldenly swell the volume to enormous proportions. These freahets, ladeu with the rich red loam of the plains, usually reach the lower inhabited sections of the State in periods of drought, and are termed "red rises." Much of this sediment is deposited upon the food plana of the lower valleys, and by this process the wost valuable sngar and cotton lands of the coast plain here been built up. Ancther important group consists of the Sabine, the Trinity, the San Jíqrcos, the Guadalupe, and the Nuecea, most of which have their origin near the western border of the black prairie ragion. These atreams have a greater volume and are more constant in flow than any others, and are usually without deep cañons or wide bottoms. Many of them, especially those south of Austin, have their origin from large springas situated along the foot of the escarpment line extending from Austin southwestward. Another oubsidiary system of streams originatea in the narrow Quaternary region along the coast, within the district of the greatest rainfall. These streams bre tidai, and sometimes navigable towards their mouths. Most of them are locally known as bayous. In general, the rivers of Texas are not adapted for irrigation or navigation. Neither do they afford much available water power porth of Austin.
The entire geologic series, with q ferw exceptions, is represented in Texss. The earlier Palæozoic rocks, including the pre-Cambrian (Kemeenawian; A in accompanying geological map), the Yotsdam (oc), snd the Ordovician (oc), up to the Trenton, underlie the State, but are only exposed in two limited districts. The first of these is in the counties of Mason, Llano, Burnet, and San Saba in the central region; the other is in the disturbed mountainous portion of the trana-Pecos region. The Cambriau was deposited horizontally upon the upturned Feweenamian, and the Ordorician appeara to rest conformably upon the Cambrian (Potsdaur) ; but there was a continentsl elevation of the whole region, probably commencing at the close of the Trenton epoch, which continued until the beginning of the Coal-messure epoch, for the Upper Silurian, Deronisn, and sub-Carboniferous are absent, and the earlier rocks are disturbed. These earlier Palæozoic sedimenta present no marked stratigraphical or palæontological differences from the same formations throughert the continent, and thus show the widely distributed uniformity of conditions which then existed. At the commencement of the Carboniferous period, however, thet marked difference oi faunal, lithological, and stratigraphical features began which distinguishes the eynehronoue deposits of the later formations of the western and eastern portions of the United States. The Texas region has been the transition ground, and hence all the geologic deposits, beginning with the Carboniferous, have two faces, dependent upon their geographical position east of west of $100^{\circ} \mathrm{W}$. long, and representing the sediments either of interior continental basing or of the, waters of the Atlantie duriug alternating periods of submergence and emergence.

The Carboniferous rocks, and most of the sacceeding formations, aro exposed in two widely geparated portions of the Siate, with entirely different lithological and faunal aspects. The mutual relations of these series have never been traced The first occurs in the central region hetween $97^{\circ}$ and $100^{\circ} \mathrm{W}$. long., north of the Colorado river, and consists of clays, sandstones, conglomerates,
limestones, and coal seams of prorkable thickness. It is the south. limestones, and coal seams of roorkable thickness. It is the southWestern prolongation and termination of the Coal-measures of the

eastern United Statea. These rocks, although in general similar to them, differ in some respects from those of the same fermation further east, ond also exhilit a few resemblances to the strictly marine Carboniferous of the Rocky Mountain region ( $\left(\mathrm{K}^{2}\right)$. To the other series belonga the traus-Pecos Carboniferons ( $\kappa^{1}$ ). Altl ough this is of the same gcologic age as the eastern Coal-mean:ures, it is a purely marine deposit of limestones and sandstones, and is barren of vagetable remains. It is exposed along the Guadalupe and other mountains of the trana-Pecos region, forming the most eastern outcrops of the non-ceal-bearing Carboniferous of the west. The study of the areal clistribution aud relation of the strata interrening between the Carboniferous and the fully-identifed Cretaccous in Texas has not heen begun. The Permian, Triassic, and Jurassic, if they exist, liave not been clearly diagnosed, although these names have been applied to the series of rocks west of the contral Carboniferous region. The thickness of the sedimenta belonging to theso undetermined atrata is very great. They are mostly unfossiliferous, and the presence of stratified gypsum and other salts indicates that they were laid down in sn interior basin cut off from oceanic waters and were too bighly concentrated for the existence of molluscan life. Certain of these deposits, known as "red beds" or "Jura-Tnes" (JT), cxtend beneath the Lleno Estacado, across New Mexico, and into Arizona. The Cretacenus is by far the most conspiccous and exteasire of the geologic formations of the State. It once cuvered the entire territory, but has beer eroded awsy in many pleces west of the black prairio region, exposing the older formations, and is covered to the east of that region by mere recent deposita. From the fact that the lowest member of the series is found resting direct? ? upon the pre-Cambrian in Llano county, the Carboniferous in Lampssas and the counties northward, the Silurian in the traus-Pecos region, and the Jura-Trias beds in the plains region, it is evident that ila beginning marked a period of contimental submergeace, and that this submergence, from the great thickness of pelagic sedimente in it, was long continued. The lowest member of the serica, the oldest known of the Amcrican Cretaceous, is unknown elsemhere in the United States, and its peculiar features give individuality to the central remion. This member (cx), which may be called the Texas group, is the equiralent of tho Neocomian of Europe, aud msny of its iossils are conmon to Europe and America It is not exposed east of the cintral region, except (probably) in the salines of Louisiana. There was a great elevation of this deep-sea formation at ita close, as is attested by the shallow water sediments of later groups deposited unconformably upon it. The Jiddle (cc, cs ${ }^{1}$ ) and the Upper Cretareous ( $\mathrm{cs}^{2}$ and $\mathrm{cs}^{2}$ ) are also well exposed. The black prairie reginn is nnder* lain by the middle and upper groups of the marino Cretaceous characteristic of the other Gulf States and known ss the Rotten Limestone (cs ${ }^{1}$ ) and Ripley (cs ${ }^{1}$ ) groups. The Cretaccous groups of the Racky Mountain region extend into Texas, and are exposer isi the trans-Pecos region and along the lower Rio Grande. The

Tertiary formations，so far as recognized，are parely marine，and， like the marine Upper Cretaceoue of the black prairie region，are the direct geographical continnation of the formations of the other Gulf States．They occupy the coast plain，in bands approximately concentric with the ehore of the Gulf of Moxico，and represent the sediments of its reccding waters．Tho alleged occurrence of the fresh－water Miocene，the Loup river group（ $M$ ），upon the Llano Estacado has not been demonstrated．Quaternary（Q）and．other recent allnvial deposits occur along the coast and the upper terraces of the three oldcr river eystems as far west as the eastem border of the central region．This is attested by the character of the de－ posits，accompanied by well－authenticated remains of the elephant and mastodon．These Quateruary soils are mostly the redenosited detritus of the strata of the eastcra escarpment of tre Llano Estacado，which is carried down by the＂red rises．＂The surface festures of the central region are the result of sub－aerial denudation． The black prairio is protected from this destructive erosive process by the tenacious character of its eoil；and the coast plain is covered by a luxnriant forcst growth，and is constantly extending eastward by the recession of the shore line．The final cmergence of the State began in Middle Cretaceoue time，and was connected with the same movements that bronght op the Rocky Mountain eystem．The strata of Texas，excopt the Palæozoic groups，are soft，and yield readily to disintegration．A fow cruptive sheets are found in the trans－Pecos region and along the lower Rio Grande，being remnants of the eastem edge of the great eruptive area of the Rocky Moun－ tain region．Granitic masses occur，as extrusions from the pre： Cambrian，in the central and trans－Pecos Palæozoic deposits．
The eastern ranges of the Rocky Mountain system are deflected towards the Gulf of Mexico after passing south of $33^{\circ} \mathrm{N}$ ．lat．，and take a south－easterly course through Texas into Mexico，the trend of their axes being generally parallel to the direction of the Rio Grande and its principal tributaries．The only true mountains in Texas are situated weet of the Pecos，with the exception of a ferr foot－hills（lomitas）which re－cnter the State from Mexico near Eagle Pass and follow the river to an undetermined point below Laredo．The principal ranges are the Guadalupe，Limpia，Chinali， Los Chisos，Organ，and Franklin Mountains．They are composed of older rocks，in most placcs；the later formations have been washed a may，except whare protected by eruptive flows．The most eastern and northern of these mountaios are usually the highest． Gnadalupe Teak is 9000 feet；Limpia Peak and the crest of the Chinalis，from 3500 to 8000 feet；Eagle Mountains， 7000 ；and the intervening valleys from 3500 to 5000 feet．The low buttes of the central region are miscalled mountaina upon most maps． There are seversl well－defined escarpments extending for long distances，approximately north and south The step of the first of these，from Austin to Eagle Pass，is from 200 to 500 feet high，and is the result of an clevation at the close of the early Cretaceous period．Near the 100th meridian another eacarpment occurb，and along the eastern and sonthern borders of the Staked Plain still another．The western part of the coast plain has a few low hills． The rest of the State has no motable prominences．

The mineral rcsources of Texas have not been mapped or studied， and hence the State ranks last in mineral products．The trans－ Pecos region is rich in silver and lead ores；but the State owne the mineral rights of ncarly all the land，ano has hitherto declined to open them to development．Only one miue is worked here．Silver and gold have also bcen discovcred and mined in Llano aud Mason connties，but without ouccessful results．Gold occurs throughout the marine limestones of the lowest（Texas）group of the Cretaceons， but not in eufficient quantity for profitable extraction．Rich but not abundant copper ores occur in the drift of the gypsum country． Iron ore is found in the Tertiary of eastcrm Texas，and is profitably reduced in a few charcoal furnaces by tho aid of convict labour． At present these are remote from coal and suitable means of trans． portation．Magnetic iron ore occurs iu the pre－Cambrian rocks of Mason county，and recent analysce show it to be equal in quality to the best Swedish ores．It is in great abundance，but remote from means of transportation and fuel．Ores of iron（sphæro－siderite） occur in the central Carboniferous formation，but their commercial value is unknown．The non－metals occur in great abundance in different portions of the State，lncluding salt，gypsum，magncsium eulphate，natural cements，kaolin，and other clays．The unutilized beds of massive gypsum are，with the exception of those of the Sahara and the Andes，the purcst and most extensive in the world． Salt is gathered from lacustral deposits or mined at El Paso， Colorado City，and along the lower Gulf coast for local use．The coals of the central Carboniferous area have been rorked to some extent，but are generally of inferior quality，having from 50 to 70 per cent．of ash．Very recent discoveries of better quality have been reported．Tertiary fibrous lignite，of light epecific gravity，is found in great abundance all along the junction of the coast piain and black prairie regions．It is worked to a omall extent，but has no commercial value．The most important coal area is the eemi－bituminous lignite belt of the trans－Pecos and lower Rio Grande regions，rhich is the dircct geographical continuation of
the late Cretaceous coals of New Mexico and Colorado．It is worked at Eagle Pass and Santa Toma，near Laredo．The beanti－ ful marbles and other oraamental stones of the State are untouched， with the exception of the Llano county granite．

The amount and regularity of the rainfall decreases inland，the mean annual varying from 52.3 inches at Galveston to 13 at El Paso in the extreme west and 23 at Mobcetie in the extreme north． The subjoined table gives the mean temperature and rainfall of certain representative localities ：－

The coast plain and the black prairie regions have abundant rain－ fall for agricultural purposes．It decreases，however，to the west， and varics greatly in different ycars，sometimes being ample；but in 1885.86 it did not average 10 inches．The precipitation is also rery sudden，seldoni lasting more than a ferv minutce at a time． Only 52 per cent．of the 20 inches of rainfall in the central region and west of it falls in the agricultural scason，one－half being in summer and the remainder in autumn，so that it is equivalent to only 15 inches in regions where the rainfall，occurs in more pro－ pitious seasons．This condition is，howercr，especially favourable for grazing．There are few statistics of the plains region ；but the rainfall along its castern escarpment is slichtly greater and nore regular than that of the central region．The temperature varics greatly thronghont the State，both in extremes and means．Fort Ringgold on the lower Rio Grande is the hottest point in the United Statea，except Key West，Fla．Its mean tcmpcrature is $73.4^{\circ}$ Fahr．； that of El I＇aso is $63^{\circ}$ ，and of Mobectio $546^{\circ}$ ．The prevalent winds are southerly and south－easterly，and blow constantly across the State，without which its summere would be unendurable．The Rio Grande valléy is not subject to frosts．Snow seldom falle south of Galveston aud Austin．In the Panhandle the winters are severe．

The arborcal flora of Lonisiana and Arkansas extends into north－ eastern Texas，conformable with the coast plain，where，immediately south of the Colorado river tho great pine belt of the Atlantic and Gulf coasts terminates．The Hora of the great plains regiorr， principally consisting of nutritious grasses，enters the north－western portion of the Statc and extends south to the 32 d parallel and east to the lolst meridian．The peculiar plants of the Rocky Moun－ tain plateaus renetrate into the trans－Pecos region，while the north Dlexican dora is found along the Rio Grande．The central region is a transition ground whero these floras find representation gencrally in detcriorated and dwarfed species．In the coast plain occur the long and short lcaf pine，with many speciea of oak and lickory．The black mairie revion is dostitute of trees，except scattercd individuals of lire oak and the mesquite bush（Prosopis glandulosa）．The broad river valleys of this region，however，are well－timbered with pecan，cypress，cottonwood，and several speciea of oak，and lave a vigorous growth of smeller shrubs．West of the black prairie region the dwarfed，stunted trecs are of little value except for fuel．The river valleys have the same character of trecs as further cast，but the rocky highlands are covcred with scraggy bushes（chaparral）of oak，juniper，and cedar．The summits of the Guadslnpe ond Limpia rangea，in the trans－Pecos region，are clothed with forests of the yellow（Pinus ponderosa），flexible（ $P$ ． fexilis），and nut pine（ $P$ ．cdulis），all of which attain great size． Many smaller trees grow on these mountains．The volleys and several of the ranges in tlie last－named region，however，are desti－ tute of trees．The entire Rio Grande valley，from El Pase to Brownsville，grows many epecies of cactus and other prickly，cori－ aceous shrubs．The grassea of the State are especially numerous in species，and are found most luxuriantly on the praries of the lowe

cosst the central, sel the plane regions. The lunber supply of the Siate comes entirely from the east Texas pins forests. The cedar, juniper, and mesquite are only utilized for fuel and fencing. Tho black bear (Ursus americanus), panther (Felis concolor), and lynx (Felis rufa) are common to all parts of the State. The bison, wild horse, prongbuck (Antilocapra americana), cojote (Canis latrans), grey wolf (C. lupus), eastern prairie dog (Cynomys ludovicianus), snd the lesser Mammalia of the great Rocky Moun. tain plains constituta the fauna of the north-western part of the Elate, reaching iuto the western part of the central region. Their sonthern limit is approximately the 31at parallel. The highest ranges of the trans-Pecos region possess the unique avian and mammalian fauna of the Rocky Mountaine, including the blacktailed or mule deer (Cariacus macrotis) and Rocky Mountain sheep, with a few Mexican species. The lower valleys have a mingling of the Mexican, Rocky Mountain, and great plain faunas. Along the ralley of the Rio Granda, and extending northward in places, the subtropical fauna is Mexican, including the peccary (Dicotyles corquatus), armsdillo (Dasypus peba), jaguar (Felis onca), and ocelot (Felis pardalis). Among the birds are the scissor-tail (Milvulus forficatus), Mexican eagle (Polyborus cherivay), chaparral cock (Geococcyx viaticas), and numerous other unique forme. The fanna of the humid wooded coast plain is tho couth-western continuation and termination of that of the South Atlantic and Gulf States, with slight rariations, and includes the Virginia deer (Crriacus leucurus), raccoon (Procyon lotor), opossum (Didelphys aurginiana), alligator, \&c. The black prainie region limits the last naned fanna en the west, except in its wooded river bottoms. The ceutral region possesses representatives of the great plsins, Rocky Mountain, Mexican, and Louisiana §aunas, but none of them cross it into other regions. It is a true transitional ground of most of the fsunas of all temperate North America, east of the Pacific slope.
The totsl population in 1880 was 1,591,749 (837,840 males and 753,909 females), and in 1887 it was estimated to have risen to 2,415,000, giving 9.2 inhabitants to the square mile. Of the population in 1880 I, 477,133 were natives of the United States and 114,616 foreign born. There tere 393,384 Negroes, 136 Chinese, 992 Indians, and 43,000 civilized aborigines (Mexicans). Of the entire population 522,133 parsous mere engaged in occupations as follows :-in agriculturs (including stock-raising), 359,317 ( 68.8 per cent.) ; in law, medicine, and other professions, 97,651 ( 18.7 per cent.) ; in trade and transportation, 34,909 ( 6.7 per cent.) ; in manufacturing and mining, 30,346 ( 6.8 per cent.). At the same dato there rere 3153 prisoners, 2276 idiots, 1564 insane, 533 paupers, 1375 blind, and 771 deaf. 13.9 per cent. of the native whites, 24.7 of the foreigners, and $75 \cdot 4$ of the Negroes-or 29.7 per cent. of the entire populstion-wero unsble to read or write. The population of Texas has iucreased more rapidly than that of any State in the Union except Kansas. The following table shows the increase for the past ferw decades:-

| 镸 | Anglo- American. | $\begin{gathered} \text { IVegro } \\ \text { neeceut. } \end{gathered}$ | Mexican <br> Aborig'a nescent | $\underbrace{\text { İRna }}_{\text {In- }}$ | Euro- | Aalf atic. | $\begin{aligned} & \text { Total } \\ & \text { Popula- } \\ & \text { tion. } \end{aligned}$ | $\begin{gathered} \text { Per } \\ \text { cent.la. } \\ \text { creaee. } \end{gathered}$ |

84 per cent. of the total population of the State is found east of tha central region-the black prairie region (northern half) being the most densely populated, and tha coast plain nest. Betmeen 1880 and 1887 thera was a large flow of population into the trans-Pecos and plains regions, and during the last two years mentioned a decrease in the central region. The population consists priacipally of whita natives of the southern United States, except in the counties of Brazog; Fort Bend, Harrison, Marion, Moore, and Washington, where it is of Negro raca; in the counties of Fayatte, Colorado, Guadalupe, Comal, and Gillespie, where it is German ; and along the Rio Grande, where it is Mexican.
Of the United States Texas now ranks first in the production of cotton and cattle, second in sugar, sheep, mules, and horses, eighth in rica and pigs. The esstern third of tha State, containing 80 per cent. of the entire population, is agricultural ; tha remainder is pastoral. The chief crops are cotton and Indian corn; wheat is grown in the northern part of tha black prairie and eastern part of the central regions, sugar in the lower bottom lands of the Brazos and tha Colorado, rice on tha coast. The chief vegatable products for 1880 were-cotton, 805,284 bales; Indian corn, $29,065,172$ bushels :
wheat, $2,567,737$; oats, $4,893,359$; sweet potatoes, $1,460,079$; Irish potatoes, 228,832 ; barlay, 72,786 ; Iye, 25,399 ; sugar, 4951 hogsheads; molasses, 810,605 gallons; hay, 59,699 tons; tobscco, 221,283 pounds; rice, 62,152 pounds; orchard products, to the value of $\$ 876,844$. The total value of thes producta was $\$ 63,076,311$. Since 1882 the quantity of cotton produced annually has exceeded $2,000,000$ bales, of 500 pounds each. In 1880 there were 174,184 farms in the State, with an aggregate of $12,650,314$ acres of im . proved land. The farms are usually of large eize, and garden, orchard, and dairy products are entirely eecondary to plantation crops. The southern part of the coast plain and the rest of tha State west of the black prairie region are peculiarly adapted to pastoral purauits, which are entirely separated from agricultural the cattle and sheep being allowed to rosm at large, or enclosed in enormons pastures, where they subsist without other food or shelter than nature affords. In 1880 there were in the State$4,084,605$ cattle, $2,411,633$ oheep, $1,950,371$. pigs, 805,606 horses, and 132,447 mules and asses. The sheep walks are more particu larly confined to the southern half of the central region, includin: the lower Rio Grande valley.
The exports are cottou, wool, sad hides, most of which sre Com. shipped from Galveston or sent overland hy rail. The chief im- mero ports are manufactured articles used in the State, also coal and railway material. Apart from a small retail trade along the border, thera are no exports to the adjoining States. The principal sesport and commercial city is Galveston. Tlee mileage in railways has increased from 1048 in 1872 to 5974 in 1882, and to 7034 in 1886.
The founders of the State made liberal provision, by grauts of Educe land and revenue, for public education, but their intentions have tioa not been carried out by subsequent legislation. Texas occupies the anomalous position of having the best school fund and the poorest school system in the Tinited States. The public free school system proper consists of two normal schools for the preparation of teachers and numerous district schools, open for four months in the year. In most of the cities the State fund is supplemented by local taxation, and excelleut schools are maintained. In 1886 there were 489,795 children within school age, and the cost of the mainteuance of the whole syatem was $\$ 2,362,226$. There are no echools for secondary education, escept the high schools of a few cities. Tho State university is at Austin ; it is abundantly endowed with lands, but does not receive the full benefit of ita revennes. There is also a State agricultural aud mechsnical college, but technical training is made secondary.

The State government differs samerlat fiom those of the rest of Admus the Union, orving to the fact that it has had to sdapt itself to the tration administration of the great public demain, by which most of the public institutious are supported and worke of interual improvement accomplished, and hecause much of the attention of the Govern10ent has been pecessarily diverted to the protection of its extensive frontier. The executire gorernment consists of a gorernor, comptroller, treasurer, conımissioner of the general land office, and superintendent of education, elected biennislly, with an attorney. general and a secretary of state, sypointed by the gorernor. The judiciary consists of two courls of final appeal, one for criminal, the other for civil business ; forty itinersnt higher courta for the trial of pensl offences and rivil suite; couris for misdemeanours and minor ciril cases in each county; sud iunumerable justices courts for first hesrings. The legislsture consists of 32 serfators elected for four years, and 115 inelubers of the house of representatives elected for tro yearb. It is resiricled by the constitution to biensial sessious of ninety days each. The State is divided into thirtern congressional snd forty judicial election districts. It is also divided iuto 232 counties, 75 of which have no population, or insufficient population to be organized. Each county is divided into four commissioners' preciucts and a rariging number of achool, election, and justices' precincts. The State las always maintained a corps of troops, formerly for protection against Indisns, but now for preserving order in the unorganized counties. It has institutions for the hlind, deaf and dumb, and insane. The prison system is far euperior to that of the other southern States, bat still very imperfect. The bonded debt of the State on 1st January 1887 was $\$ 4,237,730$, and its taxable wealth $\$ 600,000,000$. The aggregate debt of all the counties and cities was $\$ 7,000,000$. The homestead and exemption laws are unusually liberal to the deltor.

The upper Rio Grande valley was visited in 1580.83 by the Spaniards, who ostablished missions among the bettled Indians dear El Paso aud Santa Fé. The first white settlement was mado by La Salle at Lavaca, on the coast, in 1685 . The country was inhabited by Indians of various tribes, both eavage and agricultural, most of whom ara now extinct, except tha so-called "Mexican" population of the Rio Grands. From 1583 to 1794 many missions wera established by Roman Catholic missionaries among the Indians, wha were completely alienated from their original language, relis gion, domestic habits, and tribal relations. After the purchase of Louisiana from the French in 1803 Anglo-American adventurere began to cross into Tezas from the United States. In 1821, when Maxico threw off tha Spanish yoke, Texas and Coaluila constituted
a state of the republic. It was shortly 3 fter this that the first American colonists were permitted to enter the territory under Government patronage. Within ten years over 20,000 had setfled between the Sabine and the Colorado. In 1830 the Mexican Government placed them under military rule, from which, with accompanying impositions, originated the war of Texsu Independenco. The Anglo-Americans were assisted by voluntecrs from the United States, and the war was terminated by the defeat of the Mexicans under General Sauta Anna at San Jacinto, 21st A pril 1836. From 1837 to 1845 Texas was an independent republic. It was admitted to the United States on 29th December 1845, in spite of the protests of Mexico, and a war with that country immediately ensued. The new State sold to the United States Government for $\$ 10,000,000$ all the territory west and north of the present boundaries between the headwaters of the Rio Grande and the Arkansas. But it reserved the control and disposal of the puhlic lands within its borders, which have proved a magnificent source of revenue, and also the right to divide into fire states, should future growth and development justify it. By a small majority the State seceded from the Union in 1861. In 1868 a new constitution mas adopted, and the State readmitted into the Union. In 1874 the Kiowa and Comanche Indians, who had prevented the settlement of the central and plains regions from the earliest times, were subjugated.

(R. T. H.)

TEXTILES. ${ }^{1}$ This word is applied to all fabrics which are woven in a loom, of whatever material they may be made, and whether the woven stuff be plain or figured. The simplest and earliest process of wearing was managed thus. The ground of the future stuff was formed by a number of parallel strings called the warp, having their npper ends attached to a horizontal beam and drawn taut by weights hung from their lower ends. In the early Greek loom each warp thread had a separate weight (see fig. 1). On the number of the warp strings the fineness and width of the stuff depended. The strings of the veeft were interlaced at right angles to those of the warp, and the combination of the two formed the woven stuff or web. The weft was so called from its being "wafted" in and out of the waro; it is also often called the woof, though more correctly trie woof is the same as the web or finished stuff. The threads of the weit were wound round a sort of bobbin on a pirot which was made to revolve inside a hollow boat-shaped piece of wood pointed at both ends so as to pass easily between the threads of the warp. This is called the shuttle. The thread passed out through a hole in the side of the shuttle, the inner pirot revolving as the thread was delivered between the strings of the warp. In order to make the weft interlace in the warp some of the upright strings were pulled forward out of the general plane in which the warp hung; this was done in the simplest way by a reed, which divided the threads into two sets called leaves and thus formed an opening called the shred, through which the shuttle could pass, as shown in fig. 1. Another way, applicable to more complicated ornamental weaving, was to have a series of threads, attached to the warp at right angles, so that the weaver could pull any of the warp threads a way from the rest, thus allowing the shuttle to pass in front of or behind any special warp strings. By a very simple mechanical contrivance these threads were worked by a foot treadle, thus leaving the weaver's hands free to manage the shuttle. ${ }^{2}$ In the

[^74]simplest sort of weaving first one and then the other halt of the warp threads were pulled forward, and so a plain regularly interlaced stuff was woven. The next stage was to make a cloth with coloured stripes, by using successively two shuttles containing different-coloured threads In a chequered cloth the warp was mado of two-coloured threads stretched in successive bands, and the cruss stripes of the weft were woven in by the two shuttles. To form a more complicated pattern the weft must not cross the warp alternately: the design is formed by either the warp or the weft predominating on the surface in certain places. In all cases each thread of the weft must be driven home to its place after each stroke of the shuttle. In the carliest times this was done by beating the weft with a wooden sword-shaped implement ${ }^{3}$ introduced between the strings of the warp; but later a heavy comb-shaped tool was used, ${ }^{4}$ the teeth of which passed between the warp and drove home at one blow a longer length of the weft. An upright loom such as has been described is shown clearly in some of the wall paintings from Thebes, dating about 1600 b.c. and in other earlier ones from Beni-Hasan. A rery similar loom is represented on a Greek vaso of the 5 th century b.c., with a picture of Penelope and the never-finishod piece of stuff (see fig. 1). In this interesting

Fio. 1. - Penelope's 100 m , from a Greek rase of the 5th century b.c. The standing figure is that of Telemachus. ${ }^{5}$
painting the upper band has simple geometrical ornaments, such as occur on archaic Greek vases; the next has figures of winged men and gryphons. This sort of loom is still used in Scandinavian countries for tapestry. ${ }^{6}$ Another form has the warp threads stretched, not upright, but horizentally, -an arrangement which is more convenient for working treadles. These two forms are called in French "la haute lisse" and "la basse lisse,"-the high and the low loom. The general principle is the same in both. Fig. 2 shows a simple form of the "basse lisse," such as was used throughout the Middle Ages, except in Iceland and in Scandinavia. ${ }^{7}$ The clay whorls, or pierced cones, decorated with simplo painting, which hare been found in countless numbers on the sites of Troy, Mycenæ. and other prehistoric cities, were probably used to strair the thread as it mas being spun on the distaff. ${ }^{8}$ Other

[^75]hearier ones were employed to streten the strings of the warp; this method must have been rery inconvenient, as the whole warp could swing to and fro, A very obvious improvement, introduced in some countries at an early date, was to have a second beam, round which the lower ends of the warp could be wound.
In Scandinavian countries the use of weights continued till modern times. Ir the fateloom of the sagas these weights are heroes'skulls, while the shuttle is a sword.

Some simple form of wearing zeems to have been practised by prehistoric man at a very early stage of development. Fig. 3 shows an example of coarse flaxen stuff from the lake-dwellings of Switzerland, dating from the
 Fic. 2.-Nediæval low-warp loom, from a cut by Jost Amman; middle of the 16 th century. Stone Age. Wool appears to have been the first substance used, as no skill is required to prepare it for spinning. Weaving was specially the duty of women, ond even in the Middle Ages in Europe it ras, in some countries, considered a specially feminine employment. ${ }^{1}$ An early Christian sarcophagus in the Lateran has a symbolical relief representing God condemning the futare world to labour, -tillage for the man and wearing for the woman:-He gives ears of corn to Adam and a sheep to Eve.

The Egyptians were

Fia. 3. - Frehistoric (Stons Age) fazen stuff, from a lake-dwalljag in Switzerland. famed for the beauty of their woven stuffs, and almost incredible stories are related of the fineness of their linen, such as a pallium sent by King Amasis to the Spartans, which, Herodotus (iii. 47) says, was mado of yarn containing no less than 360 thrcads; the figures woven on this were partly of cutton and partly of gold thread. Herodotus also mentions a wonderful pallium sent by the same king to the shrine of Athene at Lindus. Ferv examples of the fine and richly ornamented sorts of Egyptian stuffs now exist, though we hare immense quantities of the coarse linen in which mummies were wrapped. This, though coarse, is closely woven, and usually has in every inch many more threads to the warp than to the weft. ${ }^{2}$ A few fragments of Egyptian cloth of the XVIIIth Dynasty have been found with a border of coloured bands, the blue of which is indigo and the red cxtract of Kermes

[^76](q.v.). In Egypt linen was specially employed for religious purposes, such as pricstly and royal restments, because it barbours dirt less than wool or cotton, which were also worn by the Egyptians, and it was used to bandage mummies, because it was thought not to engender worms. Though priests were allowed to wear outer garments of wool, they were obliged to put them off before entering a sacred place.

The Phcenicians were celebrated for their weaving, as for their skill in other aris. Their purple linen, dyed with the murex, was spectally ralued; Tyre and Sidon were the chief places where this was made. Babylou Carthage, Sardis, Miletus, and Alexandria were all famo seats of textile manufacture in the time of Herodotus.

Though no specimens of Assyrian textiles remain, some notion of their richness of ornament and the styles of their patterns may be gained from the minute representations of rich dresses worn by kings and other important personages in the sculptured wall-reliefs from Nineveh which are now in the British Museum. ${ }^{\text {S }}$ The stuffs worn by Asur-banipal are most elaborate in design, being covered with delicate geometrical patterns and diapers, with borders of lotus and other flowers treated with great decorative skill. A large marble slab from the same palace is covered with an elaborate textile pattern in low relief, and is evidently a faithful copy of an Assyrian carpet. Still more magnificent stuffs are represented as being worn by Assyrian captives on the enamelled wall-tiles from Rameses II.'s palace ( 14 th century в.c.) at Tel al-Ýhhúdiya (see Pottery, vol. xix. p. 603); the woven patterns are most minutely reproduced in their different colours, and the design, special to Assyria, of the sacred tree between two guardian beasts, is clearly represented, though on the most minute scale.

Uur knowledge of Greek textiles, in the almost com-Greas plete absence of any existing specimens, ${ }^{4}$ is chiefly derived from the descriptions of various classical authors. One indication of the patterns commonly used at au early period is giren by the desigus on much of the archaic Greek pottery, which clearly has ornament derived from textile sources. Vol. xix. p. 607, fig. 16, shows examples of these; simple bands, chequers, and zigzags rould naturally be the first steps towards more elaborate patterns, Again, recent excarations at Orchomenus and Tiryns bave brought to light examples of ceiling and wall decoration the motives of which are obriously derived from textile patterns. A stone ceiling at Orchomenus has in relief a carpet-like pattern, and the painted wall-stucco of the Tiryns palace has many varieties of coarse but effective textile ornament. The poems of Homer are full of descriptions of woren stuffs of the inost magnificent materials and design, used both for dresses ${ }^{5}$ and for tapestry hang. ings. ${ }^{6}$ In later times the most important examples of rich woven work of which wo havo any record were certain peploi made to corer or shade the statues of the deities

[^77]at Athens, Olympia, Delphi, and other famous shrines. ${ }^{1}$ Euripides (Ion, 1141-1162) gives a glowing description of a peplos which belonged to the temple of Apollo at Delphi, on which was depicted the firmament of heaven, with Apollo Helios in his chariot, surrounded by the, chief stars and constellations. At Athens a new peplos, ornamented with the battle of the gods and the giants, was woven for the gold and ivory statue of Athene in the Parthenon every fifth year, and was solemnly carried in procession at the greater Panathenæa. Similarly at Olympia a new peplos was woven by sixteen women, and displayed every fifth year at the Olympian games in honour of Hera. It appears probable that these magnificent peploi were not used as garments, which would have partly concealed the splendour of Phidias's gold and ivory statues, out were suspended over them like a mediæval baldacchino. "ery possibly, however, most of the elaborate work on them ras embroidery done by the needle, and not loom or textile work.
The Romans under the late republic and the empire possessed immense stores of the most magnificent textiles of every description, such as the splendid collection of tapestry which Rome inherited along with the other art treasures of Attalus II. of Pergamum ( $2 d$ cent. B.c.). A very costly cloth of gold was called by the Romans "attalica," after Attalus. The C. Cestius who died about the middle of the 1st century B.c., and who is buried in the existing pyramid in Rome, left orders in his will that his body was to be wrapped in certain attalica; but, as this was forbidden by a sumptuary law, his heirs sold the gold stuff and with the proceeds had two colossal bronze statues made, which were set outside the tomb. The feet of one of these have been found with an inscribed pedestal recording the above-mentioned facts. The size of the statue shows that the attalica must have been worth a very great sum. Examples of large prices given by Romans for woven stuff's are recorded by Pliny (H.N., viii. 48): Metellus Scipio bought some bangings from Babylon for 800,000 sesterces, and other similar stuffs were bought by Nero for four millions of sesterces (about £3360). Costly tapestry from Babylon is mentioned by Plautus (Stich., II., ii. 54), Silius Italicus (xiv. 658), and Martial (xiv. 150). Virgil (Geor., iii. 25) mentions woven tapestries with figures of Britons being used at theatrical shows: "Purpurea intexti tollant aulæa Britanni.". Other tapestries with scenes from the story of Theseus and Ariadne are inentioned by Catullus (Argon., xlvi. 267). ${ }^{2}$ On a very remarkable example of late Roman stuff found at Sitten (Sion) in Switzerland is woven a graceful figure of a nymph seated on a sea-monster, among scroll-work of foliated ornament, purely classical in design. ${ }^{3}$ A large quantity of very remarkable woven stuffs has recently been found in tombs at Ekhmin (Panopolis) in Middle Egypt. More than 300 pieces have been hought for the South Kensington Museum. They are of various dates, apparently ranging from the 4th to the 6 th or 7 th century A.D. The earliest are of purely classical style: some have badly designed but very decorative figures of pagan deities, with their names in Greek -e.g. Hermes and Apollo; others have figures driving chariots drawn by two centaurs, or marine gods, or long bands of animals-bears, lions, stags, ducks, and many others. Chese are used to decorate linen tunics or pieces of stuff about 2 feet square The later examples appear to be Coptio vestments of various shapes, and are decor-

[^78]ated with rude figures of St George and other Orienial saints, each with a nimbus. These ornaments are done by true tapestry weaving, the weft pattern being in brilliantly coloured wools on a flaxen warp. In some cases the colours, especially the magnificent reds and blues, are as bright as if they were new. Though in all cases the figure drawing is rude, the decorative value is very great.

From the 6th to the 13th century Byzantium became the capital of all the industrial arts, and in none is its influence more obvious than in that of weaving There the arts of ancient Greece and of old Rome met and were fused with the artistic notions of ancient Egypt, Assyria, Persia, and Asia Minor, and this combination produced a fresh and very active art spirit, which for many centuries dominated the whole civilized world. As regards weaving, this new development was strengthened by the introduction of silk into Europe in the reign of Justinian, and many specimens of early silk fabrics have lasted down to the present time, partly through their being safe against moths. The silken stuffs found in the tombs of Charlemagne and other kings, though perhaps not themselves as early as the 6th century, show one class of design used in Byzantium in the time of Justinian. Some of these combine the figure-subjects of ancient Rome with the stronger decorative beauty of the East. Chariot races in the circus, consuls and emperors enthroned in state, gladiatorial fights with lions, and other classical subjects occur, arranged in medallions or wreaths, set in close rows, so as to fill up the ground. Again, mixed with these classical scenes are designs of purely Assyrian origin, such as the sacred tree between two guardian beasts, closely resembling the designs of 2000 в.c. The manufacture of these rich fabrics was carried on, not only in Byzantium, but also in many towns of Greece proper, such as Athens, Thebes, and Corinth, all of hat which were spetheir silk textiles. During the same time, the 6th to the 12th century, Baghdad, Damascus, Ispahan, and many other towns in Persia and Syria were producing woven stuffs of the richest materials and designs; names of reigning caliphs are sometimes mingled with Arabicsentences from the Koran and other sacred books, which are introduced freelyamong the intricate pat-
 terns with the most

Fla. 4.-Persian damask in silk and gold, (Souih Kensington Museum.) richly decorative effect. By this means some existing specimens of the 8 th to the 10 th century can be dated. Fig. 4 shows a 16 th-century example of the finest Persian damask in silk and gold,-a masterpiece of textile design.

According to the usual story, Roger of Sicily, who in 1147 made a successful raid on the shores of Attica and took Athens, Thebes, and Corinth, carried off as prisoners a number of Greek weavers, whom he settled at Palermo and made the founders of the royal factory for silk wear. ing. This story is doubtful, for the Saracenic inhabitants of Sicily had apparently been producing fine silken stuf's
long before the 12 th century. In part, however, the story may be true; certainly an impetus was given to the weaving industry of Palermo in the 12 th century, and for about two centuries Sicily became the chief seat in Europe for the production of the finest woven stuffs. A large number of examples of these beautiful fabrics still exist, showing an immense variety of designs, all of which are imagined with the highest decorative skill, - perfect masterpieces of textile art, combining freedom of invention and grace of drawing with that olight amount of mechanical stiffness which is specially suited to the requirements of the 160 m . One of the earliest existing specimens, which shows the existence of the fabrique before the time of Roger I., is a piece of silk stuff in which the body of St Cuthbert at Durham was wrapped when his relics wero translated in 1104 ; this mas found at the opening of his grave in 1827, and is now preserved in Durham catliedral library. The figures woven on it show an interesting combination of Western and Oriental art. Birds and conventional arnaments of purely Eastern style are mingled with designs taken from late Toman mosaics, -the whole being blended with great skill into a highly decorative pattern. ${ }^{1}$ The Sicilian silks of the 12th to the 1 th century were mostly used for ecclesiastical restments, altar frontals, and the like; and the fact that examples have survived in almost all countries of Europe shows how important and far-reaching a trade in them must once have been carried on. The favourite designs were the sun breaking through a cloud from whence rays of light are issuing, or conventionally treated ships, fountains, islands, castles, and an immense variety of birds and beasts, such as swans, mallards, eagles, lions, cheetahs, hounds, giraffes, antelopes, and others. Some specimons have siren-like female forms, with floating hair, casting nets, leaning down from palm trees, or issuing from shells. Others, rather later in style, have winged angel-like figures. In many cases the Assyrian sacred tree and its guardian beasts occur, and very frequently borders with sham Arabic letters are intro duced,-a surviva! of the time when real sentences were woven into the fabrics of Persia and Egypt, probably intended as a visible sign that tho stuff was the genuine product of Saracenic looms. All these are perfect masterpieces of tex. Fig. F.-Sicilian silk हtafi of the 13 th century, tile art, and have
 never since been rivalled either in beauty of design or in skilful use of gold and colours. Fig. 5 shows a characteristic example; another copied from a painting is given under Moral Decoration, vol. xvii. p. 46, fig. 15.

In the 14 th century the chief centre of fine silk weaving was transferred from Palermo to Lucca, Florence, Milan, Venice, and other towns in northern Italy, and a different class of design, less rich in fancy, but scarcely less beautiful in effect, came into vogue. The designs of these 14 th and

[^79]15 th century textiles were chiefly conventional adaptation of natural foliage and flowers, arranged with great beauty of line and wealth of decorative effect; among the most beautiful is scroll-work of vines with graceful curving lines of leaf and tendril. An cytremely rich design, largely employed throughout the 15 th century, was made from the artichoke plant, ${ }^{2}$ and was especially used for the rich "cut" velvets of Genca, Florence, and Venice, in which the pattern is formed in relief by pilo raised above pile, mixed with gold ${ }^{5}$ (see fig. 6 and vol. xvii. p. 46, fig. 14). At this time Venice contained a large number of Ori

ental craftsinen in all the industrial arts, and very beautiful stuffs were woven there with designe of mingled Oriental and Italian style, probably the work of Mohammedan weavers (see fig. 7).

F1a. 7.-Silk stuff of Oriental desiga, woren et Veaice in the 15 th century. (South Keasington Museum.)
In all these Oriental, Sicilian, and early litalian stuffs gold thread is used in a very lavish and effectivo way. It was made very skilfully, the richest effect being produced with little metal by thickly gilding fine rellum skins with gold leaf; the rellum was then cut into very thin strips

[^80]and wound round a thread of silk or hemp so closely as to look like a solid gold wire. In and since the 15 th century gold thread has been made by twisting a thin ribbon of gilt silver round a silken core. In this way much less gold is required, as the silver ribbon is gilded before being drawn out to its Gnal thinness, and it is thus liable to tarnish, owing to the partial exposure of the silver surface. In classical times attalica and other gold stuffs were made of solid gold wire beaten out with the hammer. ${ }^{1}$ Masses of this fine gold wire ${ }^{2}$ have been found in the tombs of Egypt, Greece, and Etruria, the metal having lasted long after all the rest of the stuff had crumbled into dust. In 1544 the grave of the wife of Honorius was opened and 36 \# of gold thread taken out of it and melted.

Throughout the Middle Ages cloth of gold was largely cmployed for ecclesiastical and royal purposes. In some cases the whole of the visible surface was formed of gold thread, producing the utmost splendour of effect. Westminster Abbey still possesses a magnificent gold cope of the 15 th century, in almost perfect brilliauce of preservation. In the 13 th and 14 th centuries Cyprus and Lucca were specially famed for their gold stuffs, and the royal inventories of France and England show that the kings possessed stores of this to an immense value. The enormous sum of $£ 11$ a yard ${ }^{3}$ is recorded to have been riven for a "cloth of estate" in the prirate accounts of Heary VII. This was a cloth to hang orer the royal ihrone, and must have been unusually mide, as other cloth if gold at the same time was bought for 38 s . the yard. †arious names were at different times giren to textiles which were whally or in pait woren in gold, such as -iclatoun (a word of obscure origin), bundelin (from Baliak or Baghdad), nak, and tissue. ${ }^{4}$ Samile or examite ( $\ddagger \xi$ нítot) was so called because the weft threads were only jaught and looped at every sixtb tbreat of the warp, lying loosely over the intermediate part. Mediaral samite was sometimes made of gold; if of silk it was a rariety of satin: called satin of si3: Modern satin usually bas its weft looped in less closely-suin of eight or ten.

Although throughout tise Middlo Ages ile finer stuffs used in England were to a great extent the product of foreign looms, there was no lack of native textiles, many of which were of great beanty. In the use of the needle the women of England were especially skilful, and rich English embroideries were much exported, eren into Italy, from the 12 th to 1 lie 144 h century, ${ }^{5}$ and were esteemed more bighly tlan the productions of any other country. Two fine examples of early English silk and gold needle-work-a stole and maniple with the inscription Aclffed fieri precepit: pio episcopo Fridestuno-are preserred in the Durham Jibrary. Fridestan became bishop of Winchester in 905 . Other examples of native textiles have been found in the coffins of many ecclesiastics in England. Some interesting fragments are preserved in the chapterhouse of Worcester cathedral ; the ground is of silk, and the pattern, of conrentional scroll foliage, is a characteristic example of 13 th-century design. Pictures in English MSS. show that the low loom was mainly used,-this being the most convenient for ordinary weaving. ${ }^{6}$ England

1 The process of making wire by drawing it through conical apertures iu a steel plate is snid to have been first invented at Nuremberg in the 14 th century.
\& The Museo Gregoriano (Vatican) contains examples from Etruscan tombs. ${ }^{3}$ Equal to quite $£ 50$ of modern money.

4 Hence thin paper laid between the folds of these rich stuffs to protect theia was called tissue paper.
${ }_{5}$ The celebrated cope in Pienza cathedral. which once belonged to Pius TI. (Piccolowini). is a magnificent example of English needlework of the 15 th century.
"Among Chaucer's pilsrims are included "A webbe. a dyer, and a Lapisser." "the first a low-loom wearer, "the hast a weaver of tapestry on the high loom.
was specially celebrated for its wool and woollen stuffs, and even at the present day English wool is used for the Govelin tapestries ; in the 15 th and 16 th centuries it was largely imported into Flanders. In the 14 th century Bath produced the finest woollen cloth, and that of Worcester was equally celebrated; in the 15 th century the production of woollen stuff was a great source of wealth to Norwich and other tomns in the eastern counties. A special sort of woollen yarn took its name from Worstead in Norfolk, where it was made ; it had a closer and harder twist than most woollen thread, and thus could be mado up into cloth of special fineness, which was used for chasubles and other vestments, as is recorded in the inventories of York, Exeter, and other cathedrals.

Old English Names for Textiles.-A large number of uames for Old different sorts of textiles occur in old English writings, many of Englisi them derived from the name of the place where the stulf was nade names or exported. Bucleram was a woven cloth of much richness, highly prized, probably quite unlike what we now mean by the word. Damask or damas got its name from Damascus. Fustian, from Fostat (Old Cairo), was a cheaper stuff made of linen and cotton mixed. Muslin, from Mosul, was a fine cotton stuff. Cloth of Tars (Tarsus) is often mentioned, usually meaning a purple cloth. Camoca or comak (Arah. kankha, frorn Chinese kimkha, "brocade") was another richly decorated Oriental stuff. Cendal or sandal and syndonus were fine silk stuffs. Taifeta was made of silk or linen of very thin substanco. Satin (from Low Lat. seta) was a glossy silk stuff made like samite. Fclect (from It. velluto, "shaggy") had a silk weft woven so as to form a raised pile, the encts of which were cut or shaved off to one even level; hence it is also called in Italy raso. Diaper, "jasper-like" (Ital. diaspro), was not only used to denote a regular geometrical pattern, but in some cases means also a special sort of linen or silk. Phrases such as "silk of brydges" (Bruges), "silk dornex," from Dorneck in Flanders, and "slseets of raynes" (Rheims) eften occur. A large number of other similar names are to be met with in mediæval writings. ${ }^{7}$.

Space will not allow a description of the textile work in Other each separate country. That of Italy and the East was mediar by far the most important throughout the Middle Ages. and Even Chinese textiles of gold and silk were imported into the west of Europe, and were sometimes used for ecclesiastical purposes. Mediæval vestments of Chinese stuff still exist, the shape and added borders of which show that they date from as early. as the 14 th century. These fabrics exactly rescmble in design and workmanship some which are woven in China at the present day. A very interesting survival of the medirval style of weaving exists in Swedez and other Scandinavian countries. Articles of dress, counterpanes, table-covers, and the like are woven by the peasantry in a simple, highly decorative way, with

Fio. 8.-Invian hill loom, as still used.
patterns which hare altered little during the last three or four centuries. Theugh coarse in texture, many of these are of great artistic beauty; nothing but an occasional use

7 The most extraordinary speliing often occurs in lists of textiles in medirval documents, especially in the case of foreign names. Thus we find in the Bury Wills (printed by the Camden Socicty) "fuschar in Appules;" meaning Naples fastlan, and many similar blunders.
of harsh colours shows any sign of decadence of style. Strong marks of Oriental influence are visible in these fine patterns, but the method of weaving is purely native, "probably very like what the edicts of Lonis IX. eall "tapisserie nostrez." Very beautiful fabrics are still produced in India, old designs being followed, and woven in the simplest form of loom. Fig. 8 shows an example of a modern Indian loom used by the hill weavers. In sueh looms the richest materials, such as gold and silk, and the most elaborate patterns are woven, often by travelling weavers who can set op their whole apparatus in a very short time.

## Cakpets.

Carpet weaving was essentially an Oriental art, and was the natural product of a dry mudless country, where little furniture was used and the shoes were removed on entering a building. Till the 16 th century carpets were almost unknown in France and England, except for royal personages and for the sanctuaries of cathedrals and important churches. In the latter case they were usually laid in front of the high altar, and thus carried on to the floor the richness of colour which ornamented the walls and vault. Jriental carpets frequently occur in cathedral inventories among the other rich treasures of fureign or native make which adorned the building. They were first employed in England for domestic purposes by Queen Eleanor of Castile and her suite, in the latter part of the 13th century. In the palaces of Spain they were introduced much earlier, owing to the presence of the Moors iu southern Spain. In many cases they were used for wall bangings, and the smaller ones to cover tables and other furniture, as is represented in many 15 th-century Italian pictures. Though few examples of Oriental carpets exist sarlier in date than the 15 th century, yet the manufacture nas carried on in the highest state of perfection centuries bofore. An example of the 14 th century is preserved in a private collection at Vienna; it was originally made as Q hanging for the Kaaba at ${ }^{\text {' Mecca. }}{ }^{1}$ These beautiful Criental pile carpets are among the most perfect producdions of the weaver's art, and till the 16 th century were masterpieces of design and splendour of colour. Usually they were woven of wool or of camels' or goats' hair, with a separate warp and weft of flax; but many magnificent carpets were also made of silk mixed with gold thread. This extravaganee of luxury produced an effect, at least as regards the use of silk, but little superior to that of fine wool or camel's hair, as the special beauty of the silken gloss is seen on the sides, not on the ends of the silk thread. Pile carpets are woven in a very different way from ordinary textiles: short tufts of wool or sillk are knotteif on the warp so that the ends of the threads which form the pattern project, and these are cut down by shears to a uniform surface, thus forming a sort of textile mosaic. Each row is firmly fixed by a shoot of linen weft-thread thrown across the web, and then carefully beaten down with the batten.
Various classes of ornament occur in these magnificent Oriental carpets; one variety has stiff geometrical patterns, the motives of which appear to be taken from mosaics or tiles. Another and still more beautiful sort, manufactured especially at Ispahan (see fig. 9), has elaborate flowing designs of flower forms, sometimes mixed with figures of cheetahs, lions, antelopes, and birds, in a few cases combined with human figures. Mr W. Morris, in his valuable lecture on textils fabries (London, 1884), traces three stages of design, 一first, a pure flowing style, closely resembling the early stucco mural reliefs of Cairo; secondly, a similar style blended with animal forms ; and thirdly, a parely
${ }^{1}$ See Karabacek, Die persische vadelmalerei Susandschird aud veutr. Monatseh. f. d. Orient, 1884, p. 48. with cut.
foral style, flowing in its lincs and very fautastic and ingenious in its patterns; this last he thinks belongs 4

about the time of Shah Abbas, and lasted from about 1550 to 1650 ,-the culminating period of Oriental art. ${ }^{2}$ Since then there has been a distinct degradation of style, though in many cases older patterns have been worked from and very perfect work produced. At the present day the influence of European taste is rapidly destroying this survival of the best class of design, and especially is introducing the most harsh and discordant colouring in place of the glorious rich hues of the earlier Oriental wieavers.

Though no existing specimens can be pointed out, it appears probable that the "tapisseric Saracenois" of Louis IX.'s edicts (1226-12i0) refers to pilo earpets, made by French weavers after the Oriental fashion. ${ }^{3}$ The same edicts for the regulation of the textile industry mention two other classes of manufacture, "tapisserie à la haute lisse," i.e., what we call tapestry, and "tapisscrie nostrez," "native stuff," prohably resembling the coarse but effective patterned fabrics for aprons and dresses which are still woven by the peasantry near liome, in the Abruzzi monmtains, and elsewhere in Italy, and in Scandinavia.

## Tapestry.

The making of tapestry (Gk. тánrs), like the weaving of pile carpets, differs from ordinary fabric iu that no risible weft is thrown completely across the loom, but the

[^81]design is formed by short stitches knotted across the warp with a wooden needle called a broach. It is a sort of link between textile work and embroidery, from which it differs in having its stitches applied, not to a finished web, but to the stretched strings of a warp. ${ }^{2}$ It is made on a high loom, and the whole process, though requiring much skill, is mechanically of the simplest kind. It is very probable that many of the noven hangings used in ancient Egypt, Greece, and other countries were true tapestry; but little is known on this point. Till after the 12 th century, in porthern Europe', embroidery seems to have served the place of tapestry, as, for exauple, in the wrongly named Bayeux tapestry (see vol. viii. p. 162) ; while in the south of Europe and in Oriental countries its place was supplied by the rich silken textiles and pile carpets mentioned above.
In the 14th century tapestry began to be largely made, especially in Flanders, where the craft of weaving became yery important at an early time. The designs on the very few existing samples of 14 th-century tapestry closely resemble these of contemporary wall painting. A characteristic early specimen in the Louvre has rows of medallions, each containing a scene from the life of St Martin, with two or three figures treated in a very simply decorative way. The spaces between the circles are filled up with a stiff geometrical ornament. To the end of the 14 th century belongs the magnificent tapestry in Angers cathedral, on which are represented scenes from the Apocalypse ; these were made at Arras, the chief seat of the tapestry manufacture, both for quantity and quality. Hence the name arras. (Italian arazzi) came to mean any sort of tapestry, wherever it was mado. Another magnificent series of arras work is preserved in Rheims cathedral, with designs from the history of Clovis ; these date from the middle of the 15 th century. In the 14 th century Flanders produced enormous quantities of woven stuffs. At that time twentyseven streets were occupied by the weavers of Ghent ; in 1382 there were 50,000 weavers in Louvain ; and at Ypres there is said to have been a still larger number. From about 1450 to 1500 was the golden age for tapestry, especially in Bruges and Arras, where large quantities of the most magnificent historical pieces were woven from designs supplied by painters of the Van Eyck school. The Flemish tapestries of that time are perfect models of textile art, rich in celour, strong in decorative effect, graceful in drawing and composition, and arranged with consummate skill to suit the exigencies of the loom and the æsthetic requirements of wall decoration. A very beautiful example of this class exists at Hampten Court, hung in the dark under the gallery in the great hall,-a striking contrast to the clever but artistically degraded tapestries of half a century later, which hang round the main walls of the hall. Other fine examples exist in the Cluny, Bern, and other museums, and especially in Madrid ${ }^{2}$-in the royal collection and in that of the duke of Alva-and elsemhere in Spain. Though very' rich and varied in effect, the tapestry of the best period usually is woven with not more thand twenty different tints of wool, -half tints and gradations being got hy hatching one colour into another. In the 16 th century about sixty colours were principally employed in the still fine but rapidly deteriorating tapestry

[^82]of that period; and in the laborious but artistically worth. less productions of the Gobelin factory more than 14,000 differently tinted wools are now used.

In the 16th century the art began to decline; very slight symptoms of decadence are visible in the beautiful tapestries with Petrarch's Triumphs in the South Kensington Museum, -most gorgeous pieces of textile art, of the richest decorative effect. These were worked very soon after 1500 (see fig. 10). The influence of Raphael and his school succeeded

Fig. 10.-Figure of Lucretia from the Triumph of Chastity, woven at Brussels about 1507. Her dress is an Italian velvet, eimilar in style to that shown in fig. 6.
that of the 15 th-century Flemish painters, and was utterly destructive of true art value in tapestry. Raphael's cartoons, fine as they are in composition, are designed without the least reference to textile requirements, and are merely large pictures, which the weavers had to copy as best they might. This new style, which reduced the art to a fceble copyism of painting, gave the death-blow to the production of really fine tapestry. Brussels became the chief place for the manufacture after the taking of Arras by Louis XI. in 1477, and its wearers with wonderful skili imitated any sort of painting that was put before them. Cartoons were drawn by several of Raphael's pupils, such as Giulio Romano and Giovami da Udine, and by Mabuse, Michiel Coxcie, Bernard van Orley, and other Italianized Flemish painters.
In 1539 Francis I. founded a factory for tapestry at Fontainebleau, and soon after other high looms were set up, in Paris, examples from which still exist and show a rapid degradation of style. In 1603 a new factory was started in Paris under royal patronage, in the workshop of a family of dyers named Gobelin, after whom the new factory was named (see Gobelin). The Gobelin lonms were first workch by weavers from Flanders. whic soon_ taught the
mysteries of the craft to a number of French workmen． Cartoons were supplied by Simon Vouet and other distin－ guished French painters．In the reign of Louis XIV．a great impulse was given to the factory，and from 1667 the whole establishment became the property of the crown． Louis XIV．＇s minister，Colbert，did much to encourage this and other industries．Charles Le Brun the painter was made director of the works，and a number of artists prepared the cartoons under his supervision．In the 18 th century Coypel，Jouvenet，Boucher，Watteau，and many other popular painters made designs，often of great size and elaboration，for the Gobelin looms，but all in the very worst possible taste ；these include large series of sacred， mythological，and historical subjects，landscapes，sea－pieces， and even portraits，－the last being perhaps the most ridicu－ loas misuse of the textile art that could possibly be in－ vented．Other tapestry looms were worked in the 18th century at Aubusson，Felletin，and other places in France．

High－warp looms appear to have been worked in England in the 15 th century，though by far the greater part of the rich stores of tapestry in this country came from Flanders． One very beautiful example of English work of this time exists in St Mary＇s Hall at Coventry；it represents the marriage of Henry VI．Part of another series with the marriage of Heary VII．is preserved in a house in Cornwall． In the latter part of the 15 th and the first half of the 16 th century enormous sums were spent by the rich in England on Flemish tapestry Cardinal Wolsey＇s private accounts and inventories，which still exist，${ }^{1}$ give an astonishing picture of the wealth which he lavished on the adornment of his palace at Hampton Court．In 1522 he bought 132 large pieces of Brussels tapestry，woven with Scriptural eubjects，and mostly made to order，so as to fit exactly the tarious wall spaces He also bought large quantities of costly Oriental carpets．In the inventories are enumerated ＂foot carpets，＂＂table carpets，＂and＂window carpets，＂ ＂hanging peces，＂．＂borders with arms，＂and＂window peces，＂the last being strips of tapestry woven in narroviv lengths to fit the sills and jambs of windows．Among the ＂wall peces，＂in addition to the numerous sacred subjects， are mentioned mythological scenes，romances，historical pieces，and＂langings of verdures，＂the last being decor－ ative work in which trees and foliage formed the main design，with accessory figures of hunting，hawking，and the like．The catalogue of Wolsey＇s linen napery is no less sumptuous and abundant；bo possessed an immense quantity of finest linen for sheets and＂board－cloths＂ （table－cloths），mostly patterned with＂damaske diaper＂or ＂paned losinge－wise．＂This example of the wealth of textile work possessed by one rich prelate will give some notion of what England and other countries possessed in the 16 th century．

In the reign of James I，tapestry looms were sct up at Mortlake，and the industry was carried on during the fol－ Iowing reign under the direction of the painter Francis Crane．Charles I．introduced skilled weavers from Ouden－ arde in Belgium，and the whole existing series of cartoons by Raphael were copied on the Mortlake looms．${ }^{2}$ Most of the Mortlake tapestry has distinct marks，such as the shield of St George with F．C．（F．Crane）Some pieces are inscribed＂Car．Re．Reg．Mortl．＂（Carolus rex regnans）． Though closcd during the Commonwealth，the Mortlake fabrique was again worked after the Restoration until the death of Crane in 1703 ．In the 18 th century tapestry was woven on a small scale in Soho and at Fulham，and kithin recent years a new royal fabrique has been estab－ listed at Windsor，where very costly and skilful weaving in the pictorial Gobelin style is carried on．The only ${ }^{1}$ See Law，Hampton Court Palace，London， 1885.
＊See Rapasel，vol．xx．p． 280.
modern tapestry which has any of the merits of the best old productions is that made on a small scale by Mr Willian Morris at Merton Abbey（Surrey），where work of the higb－ est beauty has been produced．Unfortunately，however， the inodern taste for feeble imitations of oil paintings has as yet shown little appreciation of this revival of the true textile art．
As in England，by far the greater part of the tapestry used in Italy was a Flemish import．But in the 16th century，under the patronage of the dukes of Fcrrara， tapestry loons were set up in Ferrara；these were，how－ ever，worked by Flernish weavers，and closely resemble contemporary tapestry woven at Brussels．Othcr fabriques were established in Florence by the Medici princes，and continued to be worked till the end of the 17 th century． Factories for tapestry existcd also at Venice，Turin，and other northern cities，but the industry was purely an exotic， and never attained to any great importance．Since the pontificate of Clenent XI．，in 1702，${ }^{3}$ a papal factory for tapestry has existed in Rome，and is still carried on in the Vatican．The papal looms have produced a large number of most costly and elaborato copies of celcbrated paintings， executed with wonderful skill，but utterlv worthless as works of art．
The South Kensington Museum possesses the best and most Collec illustrative collection of woven fabrics of various dates．The church tions of St Mary at Dantzic has a magnificent collection of early textilcs， mostly used for vestments ；these are well illustrated by Hinz，Dis Schatzkammer der Marien－Kïrche zu Dantziq，1870．Fine examples of carly tapestry exist in the cathedrals of Rheims，Bruges，Tournay， Angers，Beaurais，Air，Sens，and in the church of St leieny at Rheims．Other fine collections aro preserved in the Louvre，the Cluny Museun，at Chartres，Amiens，Dijon，Orleans，Auxcrre， Nancy，Bern，Brusccls，Munich，Bcrin，Dresden，Vienna，and Nuremberg．＇In Italy tho richicst colleetions（nustly of later tapestry）aro those of tho Vatican，the Pitti，the Bargello，Palazzo del Tè at Mantua，Turin（royal palace），Milas：\｛royal palace），Como （eathedral），and the museum of Naples．Tha Spanish collections have been already mentioned．In England，besiles the South Kensington Museum，fine tapestries exist in the palaces of Windsor and Hampton Court．Those formerly in the House of Lords were destruyed in the firc of 1834 ．St Mary＇s Hall at Coventry contains the finest examples of the 15th century．
Literofure．－Ey far the best work for its well－chosen coloured illustrations is that of Fisclilhacl，Tex：ile Frabries，English ed．，18S3；sec alsoDupont－Auberville， Liornemert tles tissus，Raris，1S75．77；Michel，Recherches sur la fubrication des étofes，Faria， 1852 （a very valuable work）；Jubioal，Anciennes topisseries，l＇aris， 1855－53：Do Roochaud，Le pepplos d＇Athené，Paris， 1872 ；Id．，Ia topisserie，Paris， 1855；Muntz，Loz taziscerie dans i＇ontignith，Paris，187s：＇Lessing，Arodeles do topis Orientaux，Paris， 1579 ；Id．，Ancient Oriental Carpels，London， $1 \mathrm{s79}$ ；Vin． ceut Robinson，Driental Corpets，London， 1882 （the illustrations are better than the text）；Lady Alford，Needlework ns Art，London， 1886 （deals partly with textiles）Though few works treat of the gencral history of texthles，a very lange nunber exist about tapestry wcaving．Tbe chiel are－Depping，Risleo ments sur les nrts．．．au XIIIme sidcle，Paris，1837；De Montault，Topisserio de lo cath．© Angers，Paris， 18 G3；De Farcy on the ealhic subject， 1875 ；Barraud， Top．de las cult．de Beouvais，Beauvais， 1853 ：Ruck，Tcstite Febrics，S．K．M． London， 18 io ：Bock，Cal．des lissus，\＆c．，au Musce Germar．，Nurumberg， 1800 Givelet，Toiles brodees de Reims，Rheinıs， 1883 ；Louis Paris，Tap．de la ville dé Reines，Rheims，1813；Loriquet，Tap．He Notre Dame de Reims，Rheims，LNi心； Reins，Rheims，18s3；Loriquet，Tap．He Nore Dame de Reims，Rheims， Tap．d＂Arccs evant le XVme sidcle，Paris， 1879 ；Proyart，Recherches sur les top

TEZA，or Tizi．See Morocco，vol．zvi．p． 834.

[^83]thackeray, William Marepeace (1811-1863), one of the greatest of English authors and novelists, son of Richmond Thackeray (Mrs Richmond Thackeray was born Miss Becher), and grandson of W. R. Thackeray of Hadley, Middlesex, was born at Calcutta on July 18, 1811. Both his father and grandfather had been Indian civil servants. His mother, who was only nineteen at the date of his birth, was left a widow in 1816, and afterwards married Major Henry Carmichael Smyth. Thackeray himself was sent home to England from India as a child, and went to Charterhouse, since his time removed to Godalming from its ancient sito near Smithfield. Anthony Trollope, in his book on Thackeray in the English Men of Letters series, quotes a letter mritten to him about Thackeray's school-days by Mr G. S. Venables. "He came to school young," Mr Venables wrote, "a pretty, gentle, and rather timid boy." This accords with the fact that all through Thackeray's writings the student may find traces of the sensitiveness which often belongs to the creative mind, and which, in the boy who does not understand its méaning and its possible power is apt to assume the guise of a shy disposition. To this very matter Mr Venables tersely refers in a later passage of the letter quoted by Trollope: "When I lnew him better, in later years, I thought I could recognize the sensitive nature which he had as a boy." Another illustration is found in the statement, which will be recognized as oxact by all readers of Thackeray, that "his change of retrospective feeling about his school-days was very characteristic. Iu his earlier books he always spoke of the Charterhouse as Slaughter House and Smithfield. As he becanie famous and prosperous his memory softened, and Slaughter House was changed into Grey Friars, where Colone「 Newcome eaded his life." Even in the earlier references the bitterness which has often been so falsely read into Thackeray is rot to be found. In " Mr and Mrs Frank Berry" (Men's Wires) there is a description of a Slaughter-House fight, following on an incideut almost identical with that used in F'anity Foir for the fight between Dobbin and Cuff. In both cases the brutality of school life, as it then was, is very fully recognized and described, but not to the exclusion of the chivalry which goes alongside with it. In the first chapter of "Mr and Mrs Frank Berry, "Berry himself and Old Hawkins both have a touch of the heroic. In the story which forms part of Men's Wives the bully whom Berry gallantly challenges is beaten, and one hears no more of him. In Fanity Fair Cuff the swaggerer is beaten in a similar way, but regains his pepularity by one well-timed stroke of magnanimity, and afterwards shows the truest kindness to his conqueror.

In Februarv 1829 Thackeray went to Trinity College, Cambridge, aud in that year contributed some engaging lines on Timbuctoo, the subject for the prize poem, to a little university paper called The Snob, the title of which he afterwards ntilized in the famous Snob Papers. The first stanza has become tolerably well known, but is worth quoting as an early instance of the direct comic force afterwards employed by the author in verse and prose burlesques :-

> In Africa-a quarter of the world-
> Ments skins aro thack; their hair is crisp and curled; And somewhere thero, unk iom to public view, A mighty city lies. called Timbuctoo.

One other passage at least in The Snob, in the form of a skit on a paragraph of fashionable intelligence, seems to bear traces of Thackeray's handiwork. At Cambridge James Spedding, Monckton Milnes (Lord Houghton), Edward Fitzgerald, W. H. Thompson (afterwards master of Trinity), and other distinguished persons were among his friends. In 1830 he leit Canbridge without taking a degree, and went to Weimar and to Paris. His risit to Weimar bore fruit in the sketches of life at a small

German court which appear in Fitz-Boodle's Confessions and in Vanity Fair. In 1832 be came of age, and inherited a sum which Trollope's book describes as amounting to about five hundred a year. The money was soon lost,-some in an Indian bank, some in two newspapers which in Lovel the Widower are referred to under one name as The Museum, in connexion with which our friends Honeyman and Sherrick of The Nevcomes are brisfy brought in. His first regular literary employment after the loss of his patrimony was on Fraser's $^{3}$ Magazine, in which in 1837-38 appeared The History of Mr Samuel Titmarsh and the Great Hoggariy Diamond, a work filled with instances of the wit, lumour, satire, pathos, which found a more ordered if not a fresher expression in his later and longer works. For freshness, indeed, and for a fine perception which enables the author to perform among other feats that of keeping up throughout the story the curious simplicity of its supposed narrator's character, the Greett Hoggarty Diamond can scarce be surpassed. The characters, from Lady Drum, Lady. Fauny, Lady Jane, : and Edmund Preston down to Brough, his daughter, Mrs Roundhand, Gus Hoskins, and, by no means least, Sarmuel Titmarsh's pious aunt with her store of "Rosolio," are living; the book is crammed with honest fun; and, for pure pathos, the death of the child, and the meeting of the husband and wife orer the empty cradle (a scene illustrated by the author himself with that suggestion of truth which no shortcoming in drawing could spoil), stands, if not alone in its own line, at least in the company of very few such scenes in English fiction. The Great Hoggarty Diamond, oddly enough, met with the fate that afterwards befell one of Lever's best stories which appeared in a periodical week by week, -it had to be cut short at the bidding of the editor. In the same year in which it appeared Thackeray married Isabella, daughter of Colonel Matthew Shawe. Of the daughters born of the marriage, one, Mrs Richmond Ritchie, has earned distiuction as a novelist. Mrs Thackeray, to quote Trollope, "became ill and trer mind failed her," and Thackeray thereupon "became as it were a widower till the end of his days." In 1840 came out The Paris Sketch Book. Much of it had been written and published at an earlier date, and in the earlier writings there are some very curious divagations in criticism. The book contains also a striking story of card-sharping, afterwards worked up and put into Altamont's mouth in Pendennis, and a very 'powerful sketch of a gambler's death and obsequies. Three years before, in 1837, Thackeray had begun, in Fraser, the Yellowplush Papers, with their strange touches of humour, satire, tragedy (in one scene, the closing one of the history of Mr Deuceace), and their sublimation of fantastic bad spelling (M'Arony for macaroni is one of the typical touches of this) ; and this was followed by Catherine, a strong story, and too disagreeable perhaps for its purpose, founded closely on the actual career of a criminal named Catherine Hayes, and intended to counteract the then growing practice of making ruffians and barlots prominent characters in fiction. There soon followed Fitz-Boodle's Confessions and Professions, including the series Jeen's Wives, already referred to ; and, slightly before these, The Shabby Genteel Story, a work interrupted by Thackeray's domestic affiction and afterwards republished as an introduction to The $A d$ ventures of Plitip, which took up the course of the original story many years after the supposed date of its catastrophe. In 18.43, and for some ten years onwards according to Trollope, Thackeray was writing for Punch, and the list of his contributions included among many others the celebrated Snob Papers and the Ballads of Policeman .X. In 1843 also came out the Srish Sketch Book, and in 1844 the account of the journey From Cornhill ta Grand Criro.
in which was published the exeelient poem of The White Squall. In 1844 there began in Fiviser the Memoirs of Burry Lyndon, called in the magazine The Luck of Borry Lyndon, a Romance of the Last Century. Barry Lyndon has, with a very great difference in treatment, some resemblance to Smollett's Count Fathom:- the bero, that is to say, is or becomes a most intolerable scoundrel, who is magnificently uriconscions of his own inequity. The age and pressure of the time depicted are canthe with amazing verisimilitude, and in the boyish carecr of l3arry Lyndon there are fine touches of a wild clivalry, simplicity, and generosity, which iningle naturally with the worse qualities that, under the influence of abontinable training, afterwards corrupt his wholo mind and eareer. The man is so infatnated with and so blind to his own roguery, he has so mueh dash and daring, and is on occasions so infamously treated, that it is not easy to look upon him as an entireiy retestable villain until, towards the end of his course, he becomes wholly lost in brutish debauchery and cruelty. IIis latter career is founded on that of Andrew Robinson Stoney Bowes, who inarried the widow of Joha, ninth earl of Strathmore. There is also no doubt a touch of Casanova in Barry Lyndon's claracter. Besides the contributions to /'unch specially referred to, there should bo noticed I'moll's I'rize Sovelists, containing some brilliant parodies of Edward Lytton Bulwer, Lever, Mr D'Israeli (in Corlingsly, perhap's the most perfect of the scries), and others. Among minor but admirable works of the same period are lound $A$ Legend of the Thine (a burlesque of the great Dumas's Othon listcher), brought out in a periodical of George Cruikshank's, Cox's Diary (on which las been founded a well-known Duteh comedy, Janus Tulp), and the Futal Rools. This is the mest fitting moment for mentioning also Rebecca and Rowence which towers, not only over Thackeray's other ber'esques. excelient as they are, but over every other buriesque of the kind ever written. Its taste, its wit, its pathos, its humour, are exmatchable; and it contains some of the hest songs of a partucuiar kind aver written-songs worthy indeed to rank with Pearock's best. In 1846 was published, by Messrs Bradbury and Evans, the first of twenty-four numbers of Panily Futr, the work which first placed Thackeray in his proper position before the public as a novelist and writer of the Grst rank, It was completed in 1848 , theu Thackeray was thirty-seven years old; and in the same jear Abrabam Hayward paid a tribute to the author's powers in the Edinburgh Revino. It is probable that on $I^{\text {ranity }}$ Fair lise been largely based the foolish cry, now heard less and less frequently, about Thackeray's cyoicism, a cry which he himself, with his keen knowledge of men, foresaw and provided agaiost, amply enough as one might have thonght, at the end of the eighth chapter, in a passage whict is perbaps the best commentary cever written on the autbor's method. He las explained how he wishes to describo mon and womoll as they actually are, goud, bad, and indifferent, and to clain a privilege -

[^84]too thick, in the sense that the villains were too villainous, the good people too goody-croody, tho best and completest answer to that can be found by any oue who chooses to read the work with care. Ostorne is, and is meant to be, a poor enough creature, but be is an eminently human being, and one whose poorness of claracter is developed as ho allows bad influences to tell upoo his ranity and folly. The good in him is fully rccognized, and comes out in tho beantiful passage describing lis larewell to Amelic on the ove of Waterino, in which' passage may be also found a Eufficient enongh answer to the statement that Amelia is ebsolutely insipid and uninteresting. So with the companinn picture of Rawdon Crawley's farewell to Becky: who that reads it can resist sympathy, in spite of Rawdon's vices and shady shifts for a living, with his siouple bravery and devotion to his wife? As for Becky, a character that has since been imitated a host of times, there is certainly not much to be said in hor defence. We know of her, to be sure, that slie thorght she mould have found it easy to be good if she had beea rich, and wo know also what happered when Rawdon, released without her koowledge froin a spunging-house, surprised ber alone with and singing to Lord Steyne in the house in May Fair. After a gross insult trom Steyne, "Rawdon Crawley, springing out, scized him by the neckeloth, until Steyne, almost strangicd, writhed and bent under bis arm. "You lie, you dog,' sand Rawdon ; 'you lie, you coward and villain!' And be struck the peer twice over the face with his open hand, and tlung him bleeding to the ground. It was all done before Rehecca could interpose. She stood there trembling before him. She admired her busband, strong, brave, and victorious." This admiration is, as Thackeray himse!f thought it, the capital tonch in a sceno which is as powerfnl as any Thackeray over wrote-as powerful, indeed, as any in English fiction. Its \{all merit, it may be noted in passing, has been curiousiy secented by an imitation of it in M. Daudet's Fromont Jeune et Risler Aíné. As 'to the extent of the miserable Beczy's guilt in the Steyne matter, on that Thackeray leares it practieally open to the reader to form what conelusion he will. Tbere is, it should be added, a distinet touch of good in Beeky's conduct to Amelia at Ostend in tho lnst clapter of the book, and those who think that too little punishment is meted out to the brilliant adventuress in the end may remember this to her "redit. It is supreme art in the treatment of her character that makes the reader understand and feel ber attractiveness, though he knows her extraordinarily evil qualities; and in this no writer subsequent to Thackeray who has tried to depict one of the genus Beeky Sharp has even faintly succeeded. Among the minor characters there is not one-and this is not almays tho case even with Thackeray's chief figures-who is incompletely or inconsistently depicted; end no one who wishes to fully understand and appreciate the book can afford to miss a word of it.

Vanity Fair was followed by Pendennis, Esmond, and The Nevcomes, which appeared respectively in 1850,1852 , and 1854. It night be moro easy to pick holes critically in Pendennis than in Vanity Fair. Pendeonis himself, alter his boyish passion and university eseaprades, has disagreeable touches of flabbiness and worldliness; and the important episode of his relations with Fanny Rolton, which Thackeray could never have treated otherwise than delicately, is so lightly and tersely handled that it is a little vagua even to those who read between the lines; the fial aanouncement that those relations have been innocent can senreely be said to bo led up to, and one can hardly see why it should havo been so long delayed. This does not of course affeet the value of the book as a pieture of middle and upper class life of the time, the time when Vauxhall still existed, and the haunt for suppers and songe
which Thackeray in this book called the Back Kitchen, and it is a picture filled with striking figures. In some of these, motably in that of Foker, Thackeray went, it is supposed, very close to actual life for his material, and in that particular case with a most agreeable result. As for the two umbre of the marquis of Steyne, it is difficult to believe that they were intended as caricatures from two well-known persons. If they were, for once Thackeray's hand forgot its cunning. Here, as in Vanity Fair, the heroism has been found a little insipid; and there may be good ground for finding Laura Pendennis dull, though she has a spirit of her own. In later books she becomes, what Thackeray's people very seldom are, a tiresome as well as an uninviting person. Costigan is unique, and so is Major Pendennis, a type which, allowing for differences of period and manners, will exist as long as society does, and which has been seized and depicted by Thackeray as by no other novelist. His two encounters, from both of which he comes out victorious, one with Costigan in the tirst, the other with Morgan in the second volume, are admirable touches of genius. In opposition to the worldliness of the major, with which Pendennis does not escape being tainted, we have Warrington, whose nobility of nature has come unscathed through a severe trial, and whe, a thorough gentleman if a rough one, is really the guardiau of Pendennis's career. There is, it should be noted, a characteristic and acknowledged confusion in the plot of Pendennis, which will not spoil any intelligent reader's pleasure.
Probably most readers of The Newcomes (1854) to whom the book is mentioned think first of the grand, chivalrous, and simple figure of Colonel Newcome, who stands out in the relief of ahmost ideal beauty of character against the crowd of more or less imperfect and more or less base personages who move through the novel. At the sane time, to say, as has been said, that this book "is full of satire from the first to the last page" is to convey an impression which is by no ineans just. There is plenty of kindliness in the treatment of the young men who, like Clive Newcome himself and Lord Kew, possess no very shining virtue beyond that of being honourable gentlemen ; in the character of J. J. Ridley there is much tenderness and pathos; and no one can help liking the Bohemian F. B., and looking tolerantly on his failings. It may be that both the fiendish temper of Mrs Mackenzie and the sufferings she inflicts on the Colonel are too closely insisted on; but it must be remembered that this heightens the singular pathos of the closing scenes of the Colonel's life. It has seemed convenient to take The Nerucomes after Pendennis, because Pendennis and his wife reappear in this book as in the Adventures of Philip; but Esmond (1852) was written and published before The Nexcomes. To sore studerts Esmond seams and will seem Thackeray's capital work. It las not been rivalled, and only a few times approached by Mr Besant, as a romance reproducing with unfailing intercst and accuracy the figures, manners, and phrases of a past time, and it is full of beautiful toucles of character. But Beatrix, upon whom so much hinges, is an unpleasing character, although one understands fully why men were captivated by her insolent beauty and ,srilliancy; and there is some truth in Thackcray's own :a ing, that "Esmond was a prig." Apart from this, the atory is, like the illusion of a past time in the narrative, so complete in all its details, so harmoniously worked out, that there is little room for criticism. As to Esmond's marriage with the lady whom he has served and loved as a boy, that is a matter for individual judgment Beatrix, it has been indicated above, is wonderfully drawn; and not the least wouderful thing about her is her reappearance as the jaded, battered, worldly, not altogether unkindly, Baroness in The Virginians. It was just what Beatrix
must have come $t \mathrm{n}$, and the degradation is handled witla the lightest and finest tonch.
In 1851 Thackeray had written The English Humourists of the Eighteenth Century, delifered as a series of lectures at Willis's Rooms in the same year, and re-delivered in the United States in 1852 and I853, as was afterwards the series called The Four Georges. Both sets were written for the purposes of lecturing. In 1857 Thackeray stood unsuccessfully as a parliamentary candidate for Oxford against Mr Cardwell, and in the same year appeared the first number of The Tirginians, a sequel to Esmond. This is a most unequal work,-inferior, as sequels are apt to be, to Esmond as an historical romance, less compact and coherent, prone to divagation and desultoriness, yet charming enougls in its lifelikeness, in the wit and wisdom of its reflexions, and, as has been said, in its portrait of Beatrix grown old. The last number of The Virginians came out in 1859, and in the same year Thackeray undertook the editorship of the Cornhill Magazine. This was a task which, as readers of his Roundabout paper "Thorns in the Cushion" will remember, the kindliness and seusitiveness of his disposition made irksome. to him, and he resigned the editorship in April 1862, though he contnnued to write for the magazino until he died. In the Cornhall appeared from his pen LoveI the Widover, previously written, with different names for some of the personages, in dramatic form; The Adventures of Philip; the Rorndabout Papers; and the story, unhappily never finished, called Denis Ducul. Lovel the Widower?, changed from the dramatic to the narrative form, remains a piece of high comedy in whicl the characters are indicated rather than fully worked out, with a bold and practised touch. It contains some refereuces to Thackeray's early and unfortunate newspaper speculations, and it was provided by the author with illustrations which as in others of his books have a value which is entirely their own in furnishing, as it were, a far completer commentary on the letterpress than could have been given by any dranghtsman, however perspicacious and finished, who approached the pictorial representation of the characters from the outside. To the general statement thus indicated an exception should be made in the case of Doyle's illustrations to The Vercomes and to Relreced and Rovena. On the other laud, not even Doyle could have matched the fun and spirit of Thackeray's own illustrations to another burlesque story, one of his best, The Rose and the Ring. The Ronndabout l'apers, a small storehouse of some of Thackeray's best qualities as an essayist, came out in the Cormhill Mragazine simultaneously with Lovel the IFidozer and with The Adventures of Philip. Among them is one differing in form from the rest, called The ATotch one the Axe-a Story ì la Mode. It is an almost perfect specimen of the author's genius for burlesque story-telling; but it contains an odd instance, which a careful reader will not fail to discover, of the odd habit of inaccuracy of which Thackeray limself was conscious. The Adrentures of Philip is, as has been before said, in the nature of a sequel to or a completion of A Shabby Genteel Story. As with the other direct sequel, it is a sork of great inequality. It contains scenes of humnur, pathos, satire, which rank with Thackeray's best work; some old friends fronu others of the novels make brief but pleasant reappearances in its pages; there are fine sketches of journalistic, artistic, and diplomatic life, and the scene from the lastnamed in Paris is inimitable. The Little Sister is altogether delightful; the Twysden family are terribly true and vastly diverting; the minor characters, among whom old Ridley, J. J.'s father, should be mentioned, are wonderfully hit off; nor did Thackeray ever write a better scene than that of the quarrel between Bunch, Baynes, and 31 'Whirter in the Paris dension. Philip himself is impos-
sible：one cannot say that the character is ill－drawn－it is not drawn at all．It is an entirely different personage in different chapters；and it has here and there a very un－ ［leasant tonch which must have come of rapid writing． let so adınirable are many parts of the book that it can－ not be left out of the list of Thackeray＇s most considerable works．Denis Duval，which reached only three numbers， promised to be a first－rate work，more or less in the Esmond manner．The anthor died while it was in progress，on the day before Christmas day 1863．He was buried in Kensal Green，and a bust by Marochetti was put up to his memory in Westminster Abbey．

Little Las vet Leen said of Thackeray＇s performances in poetry．They formed a small but not the least significant part of his life＇s work．The grace and the apparent spou－ taneity of his versification are beyond question．Sonte of the more serious efforts，such as The Chronicle of the Drum （1841），are full of power，and instinct with trne poetic feeling．Both the balt－humorous half－pathetic ballads and the wholly extravagant ones must be classed with the best work in that kind；and the translations from Béranger are as good as verse iranslations can be．He had the true poetic instinct，and proved it by writing poetry which equalled his prose in grace and feeling．

It is not pecessary to discuss the precise place which Thackeray will in fnture hold，in respect to his immediate contemporaries．What seems absolutely certain is that the force and variety of his genius and art will always hold for him a place as one of the greatest of English novelists and essayists，and，it should be added，as by no means the least of English critics．
（W．H．P．）
THALBERG，Siorsmoxd（1812－1871），a celebrated pianist and composer for his instrument，was born at Geneva in 1812 （May 5 or January 7）．In 1822 he was taken to Vienna，where，under the watchful care of Count Dietrichstein，his education was completed．There is some doubt as to the masters under whom he studied；but it is certain that he received instruction from Hommel，and perhaps also from Czerny，and that be took lessons in com－ position from Sechter．He made his first appearance as a pianist at Prince Metternich＇s in 1826，and published his first composition－a Funtasia on Airs from＂Euryanthe＂ －in 1829，but it was not until 1830 that he mas first fairly introduced to the public，with such brilliant success that from that time formard his only rival was Liszz．In 1834 he was appointed＂kammervirtuos＂to the emperor of Austria． He first appeared in Paris in 1837；and in 1838 he came to England，astonishing his hearers with the novel effects prodnced in his Variations on Goul Save the Queen，while he charmed them with bis delicate tonch and the purity of his expression．Thenceiormard his career was a succession of trinmphs．In order to disprove the popular idea that he conld execute no music but his own，he played Beet－ hoven＇s Concerto in $C$ minor（op．37）at the London Wednesday Concerts，held in 1846－47 at Exeter Hall， with a keen intelligence which proved his power of inter． preting the works of the groat masters to be at least on a level with his wonderful Lechnique．Besides his pianoforte compositions，which are almost innumerable，Thalberg pro－ duced two operas，－Cristina，which proved a complete failure，and Florinda，which fared but little better at Her Majesty＇s Theatre in 1851．He played in London for the tast time in 1863 ，and afterwards retired to his estate near Naples．He died at Naples，April 27， 1811.

THALES of Niletos（640－546 B．c．），son of Examyus and Cleobuline，is universally recognized as the founder of Greek geometry，astronomy，and philosophy． He is said by Herodotus and others to have been of Phœnisian oxtraction，but the more common acconnt（see Diogenes Laertius）is that he was a native Milesian of
nolle birth．Zeller thinks that his auccstors belouged to the Caunean tribe in Biwotia，who wero intermingled with the Ioniaus of Asia Minor，and thas recouciles the con－ flicting statements．The nationality of Thales is certainly Greek and not Phonician．The high estimation in which he was held by his coutemporaries is shown by the place he occupied as clief of the seven＂wise men＂of Greece； and in later times amongst the ancients his fame was quite remarkable．It is well known that this uame（oo申ós）was given on account of practical ability；and in accordance with this we find that Thales had been occupied with civil affairs，and indeed several instances of his political sagacity have been handed down．Of these the inost remarkalle is the adrice，prased by Herodotus，which he gave to his fellow－conntrymen＂before Ionia was ruined，＇－＂that the Ionians should constitute one general council in Teos，as the most central of the twelve cities，and that the remaining cities should nevertheless be governed as independent states＂（Herod．，i．170）．It is probable， however，that in the case of Thales the aprellation＂wise man，＂which was given to him and to the other six in the archonship of Daınasius（ 586 b．c．），${ }^{1}$ was conferred on him not only on account of his political sagacity，but also for his scientific eminence（Plut．，Solon，c．3）．To about the same time must be referred his celebrated prediction of the eclipse of the sun，which took place on May 28， 585 в．c． This erent，which was of the highest importance，has given rise to much discussion．The account of it as given by Herodotus（i．74）contains two statements：－（1）the fact that the eclipse did actually take place during a battle between the Medes and the Lydians，that it was a total eclipse（Herodotus calls it a＂night battle＂），that it cansed a cessation of hostilities and led to a lasting peace between the contending nations；（2）that Thales had foretold the celipse to the Ionians，and fixed the year in which it actually did take place．Various dates－ranging from 625 B．C．to 583．B．C．－have been assigned by different chrono－ logists to this eclipse；but，since the inrestigations of Airy，${ }^{2}$ Hind，${ }^{3}$ and Zech，${ }^{4}$ the date determined by them （May 28,585 B．c．）has been generally accepted．This date agrees nearly with that given by Pliny（H．N．，ii． 12）．The second part of the statement of Herodotus－the reality of the prediction by Thales－has been frequently called in question，chiefly on the ground that，in order to predict a solar eclipse with any chance of success，one should have the command of certain astronomical facts which were not known until the $3 d$ century B．c．，and then merely approximately，and only employed with that object in the following century by Hipparchus．The question， however，is not whether Thales could predict the eclipse of the sun with any chance of success－much less whether he could state beforehand at what places the eclipsc mould be visible，as some hare erroneously supposed，and which of course would have been quite impossible for him to do， but simply whether he foretold that there would be a solar eclipse in that year，as stated by Herodotus．Now as to this there is quite a remarkable unanimity in the testi－ mony of the ancients，and the evidence is of the strongest Find，ascending to Herodotus，and，according to the account of Diogenes Laertins，cven to Xenophanes，who was an Ionian，and not much later than Thales．Further，

[^85]we know that in the 8th censury B.0. there were obser. vatories in most of the large cities in the valley of the Euphrates, and that professional astronomers regulanly took observations of the heavons, copies of which were sent to the king of Assyria; and from a cunciforia inscription found in the palace of Scunaciacrib at Nineveh, the text of which is given by George Smiti, ${ }^{1}$ we learn that at that time the epachs of eclipses of both sun and moon were predicted as possible-probably by means of the cycle of 223 lunations or Chaldæan Saros ~and that observations were made accoraingly.

The wonderful fame of Thales amongst the ancients must have been in great part due to this achievement, which seems, moreover, to bave been one of the chief causes that excited emongst the Hellenes the love of science which ever afterwards characterized them. Thales seems not to have left any writings behiad him, though as to this there appears to be some doubt (see Diog. Laer., i. 23). Many anecdotes, emusing rather than instructive, are related of him, which have been handed down by Diogenes Laertius and other writers. From some of them it would appear that be was engaged in trade, which is indeed expressly stated by Plutarch (Solon, c. 2). It is probable that in the pursuit of commerce he was led to visit Egypt. Of the fact that Thales visited Egypt, and there became acquainted with geometry, there is aburdant evidence. Hieronymus of Rhodes (ap. Diog. Laer., i. 27) says, "he never had any teacher except during the time when he went to Egypt and associated with the priests." "

But the characteristic feature of the work of Thales was that to the knowledge thus acquired he added the capital creation of the geametry of lines, which was essentielly abstract in its character. The only geometry known to the Egyptian priests was that of surfaces, together with a sketch of that of solids, $\theta_{\text {s }}$ geometry consisting of some simple quadratures and elementary cubatures, which tbey had obtained empirically. Thales, on the other hand, introduced abstract geometry, the object of which is to establisin precise relations between the different parts of a figure, so that some of them could be found by means of others in \& manner strictly rigorous. This was a phenomenon quite new in the world, and due, in fact, to the abstract spirit of the Greeks.

The following discoveries in geometry are attributed to Thales :(1) the circle is bigected by its diameter (Procl., op. cit., p. 157) ; (2) the angles at the bass of an isosceles triangie are equal (1d., p. 250), (3) when two strsight lines cut each ather the vertically opposito ar.mes are equal (1d., p. 299); (4) the angle in a semicircle is a right angle; ${ }^{3}$ (5) the theorem Euclid i. 26 is referred to Thales by Eudemus (Procl., op. cit., p. 352). Two a pplicetinns of geometry tn the solution of practical problems are also attributed to him :(1) the determination of the distance of a ship at sea, for which he made use of the last theorem; (2) the determination of the height of a pyramid by means of the length of its shadow: according to Hieronymus of Rhodes (Diog. Laert., i. 27) and Pliny ( $N . H_{0}$, xxxyi. 12), the shedow was meesured at the hour of the day when a man's shadots is the same length as himself. Plutarch, however, states the method in a form requiring the knowledge of Euclid vi. 4, but without the restriction as to the hour of the day (Sept. Sap. Conviv., 2). Further, we learn from Diogenes Laertius (i. 25) that he perfected the things relating to the scalene triangle and the theory of lines. Proclus, too, in his summary of the bistory of geometry before Euclid, which he probably derived from Eudemns of Phodes, saye that Thales, haring visited Egypt, first brought the knowledge of geometry into Greece, that he discovered many

[^86]things himself, and comannicated tio eeginrings of meny to his auccessors, zome of whul ha atternpted in $n$ more abstract mannes (ka0orusútepor) and some in a mo:3 intuitional or sensible manner

From thess indications it is no doubt dificult to determine what Thales brought from Egypt and what was due to his own invention. This diđicuity has, however, been lessened since the translationend publication of the papyrus Rhind by Eisenlohr; ${ }^{8}$ and it is now generally admitted that, in the distinction mado in the last pessage quoted above from Procius, reference is made to the tro
 Egypt or arrived at in an Egeptian nıanner, while käodıcútepov indicates the discorories which he medo in accordance with the Greek spirit. To the former belong the theorems (1), (2), and (3), and to the latter especially the theorem (4), and also, probably, his solution of the two prectical problems. We infer, then, [1] that Thalee must have known the theorem that the sum of the three angles of a triangle are equal to two right angles. This inference is made from (4) taken elong with (12). No doubt we are informed by Proclus, on the authority of Eudemus, that the theorem Euclid i. 32 was first proved in a general way by the Pytha goresns (see Pytuagosa3, vol. $\mathrm{zx} . \mathrm{p} .140$ ) ; but, on the other hand, we learid from Geminus that the ancient geometere observed the equality to two right angics in each kind of triangle-in the equilatoral first, then in the isosceles, and lastly in the scalene (Ápoll, Conica, ed. Halleius, p. 9), and it is plain that the geometers older than the Pythagorcans can be no other than Thales and his achool. The theorem, then, seems to have been arrived at by induction, end may have been suggested by the contemplation of floors or walls covered with tiles of the form of equilateral triauglea, or squares, or hexagons. [2] We sce also in the theorem (4) the hirst trace of the important conception of geometrical loci, which we, therefore, attribute to Thales. It is worth noticing that it was in this manner that thio remarkable property of the circle, with which, in fact, abstract geometry Tas inaugurated, presented itself to the imeginatioz of Dante :-

## "O Eo del mezzo cerchfo far si pooto Triangol st, ch'uu retio <br> Triangol st, ch'uu retto non avesse."-Par, c. xy. 101.

[3] Thales discovered the theorem that the sides of equisngular triangles are proportional. 'The knowledge of this theorem is dis. tinctly attributed to Thales by Plutarch, and it wes probably made use of also in his determination of the dratasca of a ship at sea.
Lct us now consider the importance of the wark of Thales. I. In a scientific point of view: (a) we see, in the first place, that by his treo theorems he founded the geometry of lines, which has ever since remained the principal part of geometry ; (b) he may, in the second place, be fairly considered to have laid the foundation of algebra, for his first theorem establishes an equation in the true sense of the mord, while the second institutes a proportion. ${ }^{8}$ II. In a philosophic point of viem: we see that in these tro theorems of Thales the first type of a natural law, i.e., the expression of a fixed dependence between differtnt quantities, or, in enother form, the disentanglement of constancy in the midst of variety-has decisively arisen. ${ }^{6}$ III. Lastly, in a practical point of viere: Thales furnished the first example of an opplication of theoretical geometry to practice, ${ }^{7}$ and laid the foundation of an important branch of the same-the measurement of heights and distances. For the further progress of geometry see PyTracoras.

As to the astronomical knowledge of Thales we have the following notices:-(1) besides the prediction of the solar eclipse, Eudemus attributes to him the discorery that the circuit of the sun between the solstices is not always uniform $;_{;}^{8}$ (2) he called the last dify of the month the thirtieth (Diog. Laert., i. 24); (3) he divided the year into 365 days (Id., i. 27); (1) he detormined the diameter of the sun to be the 720 th part of the zodiac ;9 (5) he appears to have pointed out the constellation of the Lesser Bear to his countrymen, and instructed them to steer by it [as nearer the pole] instead of tho Great Bear (Callimachue ap. Diog. Laert., i. 23 ;. cf. Aratus, Phenomena, $\nabla .30$ sq.). Other discoverics in astronomy are attributed to Thales, but on authoritics which are not trustWorthy. He did not know, for exannle, that " the earth is spherical," as is erroneously stated by Plutarch (Placita, iii. 10); on tho contrary, he conceired it to be a flat disk, and in this supposition he was followed by most of his successors in the Ionian schools, including Anaxagoras. The doctrine of the sphericity of the earth,

Ths is thio received interpretation of the. passage in Diogenes Lsertius, i. 24 (see Wolf, Cesch. der Astron., p. 169), where $\sigma \in \lambda \eta$ palou
 who attribates to Thales, then old, the discorery: "quictiens sol mag. citudice eus circulum quem pemseat metiatir."
for which the researches of Anazimander had propared the way, ${ }^{2}$ was io fact ono of the great discoveries of Pythagoras, was taught by Parmenides, wha was connected with the Pythagoreans, and remained for a long time the exclusive property of tha Italian schools. ${ }^{2}$

Whilst in virtue of his political sagecity and intellectual ominenca Thales held a place in the traditional list of the wise men, on the atrength of the disintcrested love of knowledge which appeared in his physical epeculations he ras accounted a "philosopher" ( $\phi c \lambda \delta-$ gaфns). His "philosophy" is usually ammmed up in tha dogma "xater is the principle, or the clement, of things"; but, as the technical terms" principle" (apxý) and "olement" ( $\sigma$ тoıxєiov) had not jat come into use, it may ba conjectured that the phrase " all things are water" ( $\pi \alpha \nu \tau a$ " $\delta \omega \rho \rho$ '̇ $\sigma \tau \ell$ ) more cxactly represents his teaching. Writings which bora his name wara axtant in sntiquity; but, as Aristotle, when ha spazks of Thales's dactrine, always dependa upon tradition, there can be little doubt that they ware forgerics.

From Aristotle we learn (1) that Thales found in water the origin of things; (2) that he conceived the earth to flost npon a sea of the elomental.fluid; (3) that he supposed all things to be full of gods; (4) that in virtas of the attraction exercised by the magnet he attributed to it a aoul. Hare our information ends. Aristotie's auggestion that Thales was led to his fundamontal dogma by observation of the part which moisture plays in the production and the maintenance of life, and Simplicius's, that the impressibility and the biuding power of weter' were perhsps also in his thoughts, ara by admission purely conjectural. Simplicius'a further buggestion that Thales, conceived the element to be modified by thinning and thickening is plainly inconsistent with the atatement of Theopbrastus that the bypothesis in question was peculiar to Anaximenes. Tha assertioo preserved by Stohwns that Tinales racognized, together with the matarial element "water," "mind," which penotrates it and sets it in motion, is refuted by the precise testimony of Aristotla, who declares that the early physicists did not distingryish the moving, cause from the material cause, and that before Inermotimus and' Anaxagoras no ona postulated a creative intelligence.

It wonld seem, then, that Thales sought amid the varicty of things a single materisl causa; that he found such a cause in one of tha forms of matter most familiar to him, Damely, water, and accordingly regarded eartll and all that it coabhns as water variously metamorphosed; and that, asking himaelf no questions about the manner of its transformstion, he was content "to aee in the furces of natura present deities" (Zeller).
The doctrine of Thales was interpreted and developed in the conrse of three succeeding generations. First, Anaximander choso for what he called his "principle" ( $\dot{a} \rho \mathfrak{\eta}$ ), not water, but a corporeal alement intermediate between fre and air on the one hand and water and earth on the other. Next, Anaximenes, preferring air, resolved-its transformations into proceases of thinning and thickening. Lastly, Heraclitus asserted tho claima of fire, which ha conceived to modify itself, not occasionally, but perpetually. Thus Thales recognized change, but wes not careful to explain it; Anaximander attribnted to chango two directions; Anaximenes coneeived the two sorts of changa as rarefaction and condeasation; Heraclitus, perceiving that, if, as his predecessors had tacitly assumed, change was oceasional, the interference of a moving causo was necessary, made change perpetual. But all four agreed in tracing the varicty of things to a singla material eause, corporeal, cadowed with qualities, and capablo of self-transformation. A now departure was taken by the Eleatic Parmenides (oce vol. xriii. p. 315), who, expressly noting that, when Thales and his successora attributad to the supposed element changing qualities, they were untrue to the priaciple of monism, required that the superficial plurality of nature shonid be strictly distinguished from its fundsmental woity. Hence, whereas Thales and his auceessors had confoundeif the Ooe, the element, and the Many, its modifications, the One and the Not-One or Many became with Parmonides matters for aeparate investigation. In this way two lines of ioquiry originated. On the one haorl Empedocles and Anaxagoras, abandoniof the pursuit of the One, gava themsclves to tha scientific study of the Maay; on the other ZeDo, abandowiag the pursuit of the Many, gave himself to the dialcetical study of the Oue. Both successions were doomed to failuro; and the result
 until Plato, returning to Parmacnides, declared the study of the Oue and tha Many, jointly regarded, to ba the truo affico of philoaophy. Thus, meagre and futile as the doctrine of Thales was, all the Greek schools, with the aolitary exception of that of Pythagoras, took their origin from it. Not in aame ouly, but also in faet, Thalea, the first of the Ionian physicists, was tho fouader of the philosophy of Greece.
${ }^{2}$ In likening the earth to a cylinder Aoaximander recogoized its eircular figure in one direction.

THALLIUM, one of the rarer clements of chemistry. Its discovery is one of the outcomes of Bunsen and Kirchhof's method of spectruns analysis. When Crookes, in 1861, applied this method to the flue-duse produced in the roasting of a certain kind of pyrites he observed in its spectrum a green line foreign to all then known spectra, and concluded that his substance must contain a new element, to which be gave the name of thallium, from oa $\lambda \lambda$ ós, a green twig. Crookes presumed that his thallium was something of the order of sulphur, selenium, or tellurium ; but Lamy, who anticipated him in isolating the nerr element, found it to be a metal Our present knowledge of the chemistry of thallium is based chiefly upon the labours of Crookes.

The chemical character of thallium presents striking peculiaritics. Dumas once called it the "ornithorkynchus paradoxus of metals." As an elementary substance, it is very similar in its mechanical and physical propertics to lead; like lead it forms an almost insoluble chloride and an insoluble iodide. But the hydroxide of thallium, in most of its properties, comes very close to those of the alikali metals; it is strongly basirous, forms an insoluble cliloroplatinate, and an alum strikingly similar to the corresponding potassium compounds. Yet, unlike potassium or lead, it forms a feebly basic sesquioxide similar to manganic oxide, $\mathrm{Mn}_{2} \mathrm{O}_{3}$.

Traces of thallium exist in many kinds of pyrites, as used for vitriol-making. The only known mineral of which it forms an essential component is the "crookesits" of Skrikerum, Smâland, Sweden, which, according to Nordenskiold, contains 33.3 of selenium, $45 \cdot 8$ of copper, 3.7 of silver, and $17 \cdot 2$ of thallium in 100 parts. Crookesite, however, is scarce. The best raw materials for the preparation of thallium are the flue-dusts produced industrially in the roasting of thalliferous pyrites and the "chamber muds" accumulating in vitriol-chambers wrought with suclb pyrites; in botb it is frequently associated with Selenture (q.v.). The flue-dust from the pyrites of Theux, Dear Spa (Belgium), according to Böttcher, contains 0.5 to 0.75 per cent. of thallium; that of the pyrites of Meggen, according to Carstanjen, as much as $3.5^{\circ}$ per cent.; while that of the pyrites of Ruhrort yielded 1 per cent. of the pure chloride to Gunning.

For the extraction of the metal from charmher mud, the latter is boiled with water, which extracts the thallium as $\mathrm{Tl}_{2} \mathrm{SO}_{4}$. From the filtered solution the thallium is precipitated by addition of hydrochioric acid, as TlCl , along, io general, with more or less of chloride of lead. The mixed chlorides are boiled down to dryness with oil of vitriol to convert them into sulplates, which are thea separated by boiling water, which dissolvas only the thallium salt. From the filtered solution the thallium ie recovered, as anch. by means of pure metallic zinc, or by electrolysis. Tha (s]proxiroateiy pure) metallic sponge obtained is washed, made compact hy compression, fused is a porcelain crucibla in an atmosphere of hydro. gea, and cast into sticks. Methods for the fieal puritication of tho metal will casily ha dednced from whai followa.

The metal is bluish white; it is extremely enft but almoat deroid of tanacity and clasticity. Its specifie gravity is 11.80 . It fuses at $290^{\circ} \mathrm{C}$; at a white heat it boils and ean be distilled in hydrogen gas. When heated io air it is readily oxidized. with formation of a reddish or violet rapour. When exposed to the air it resdily draws a film of oxide; the tarnished metal when plunged into water reassumos its metallic lastre he oxide film being quickly dissolved. When kept in contzet with mater and air it is gradually converted into hydroxide, $\mathrm{T}_{2} \mathrm{OH}_{2} \mathrm{O}$ or TlOll.

This hydrate, T1OH, most eonveniently prepared by decompos"ng the solution of tha sulphata with baryta water, crystallizes from its
solution in long yellow needles, TlOF or $\mathrm{TlOH}+\mathrm{H}_{2} \mathrm{O}$, which dissolve readily in water, forming an inteusely alkaline solution, which acts as a caustic, like, for instance, potash.loy, and like it grecdily absorbs carbonic acid from the atmosphere. But, unlike the alkalics, it readily loses its water at $100^{\circ} \mathrm{C}$. and even at the ordinary temperature, to pass into the state of anhydrous $\mathrm{Tl}_{2} \mathrm{O}$, which is hlack or black-violet.

The chloride, TlCl , is readily obtained from the solution of any thallous salt (c.g., the sulphate), by addition of hydrochloric acid, as a white precipitate similar in apmearance to chloride of silver, like which it turns violet in the light and fuses below redoess into a (yellow) liquid which freczes into a llorn-like flexible mass. The specific gravity of this "horn" thallium, as one might call it, is 7.02 . One part of the precipitated chloride dissolves at $0^{\circ} \mathrm{C}$. in 500 parts of water, and in 70 parta at $100^{\circ} \mathrm{C}$. It is less soluble is lilute hydrochloric acid. Carhonate of soda solution dissolves jt pretty freely.
Tho iodinc, TlI, is a yellow precipitate, which requires 16,000 parts of cold water and still more of solution of iodide of potassium for its solution.
The chloroplatinute, $\mathrm{PtCl}_{6} \mathrm{Tl}_{5}$, readily obtainable from thalloussalt solutions by addition of chloride of platinum $\left(\mathrm{PtCl}_{6} \mathrm{H}_{2}\right)$, is a yellow precipitate soluble in no less than 15,600 parts of cold water.

The carbonate, $\mathrm{Tl}_{2} \mathrm{CO}_{3}$, comes closer to the litbium compound than to any other ordinary carbonate. It formas resplendent monoclinic. prisms, soluble at $18^{\circ} \mathrm{C}$. in $19 \cdot 1$ and at $100^{\circ}$ in 4.46 parta of water. A stable bicarbouate, $\mathrm{T} 1 \mathrm{HCO}_{3}$, does exist.
The sulphate, $\mathrm{T}_{2} \mathrm{SO}_{4}$, forms rhombic prisms isomorphous with $\mathrm{K}_{2} \mathrm{SO}_{4}$. It dissolves at $18^{\circ} \mathrm{C}$. in $20^{\circ} 8$ and at $101^{\circ}$ in $5^{\circ} 2$ parts of water. It unites with vitriol into an acid salt, $\mathrm{TlHSO}_{4}+3 \mathrm{H}_{2} \mathrm{O}$, and witlı sulphate of alumina into an "alum," $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3} \mathrm{Tl}_{2} \mathrm{SO}_{4}+$ $24 \mathrm{H}_{2} \mathrm{O}$.

Thallic salts are related to thallous pretty much as manganic are to manganous. Tho chloride, $\mathrm{TlCl}_{3}$, is obtained as a solution by passing chlorine into a suspension of thallous chloride in water. The solution, when craporated in racuo, deposits colourless crystals, $\mathrm{TlCl}_{3}+\mathrm{HL}_{2} \mathrm{O}$. For the oxide, if chlorine be passed into a solution of thallous chloride in carbonate of soda a brown precipitate is produced, which, after drying, has the composition $\mathrm{Tl}_{2} \mathrm{O}_{3}+\mathrm{H}_{2} \mathrm{O}$. When heated with strong hydrochloric acid it evolves chlorine and yields WCl; when heated with oil of vitriol it yields oxygen gas and thallous sulphate. Thallic sul phate, however, does exist, -in crystals, $\mathrm{Tl}_{2}\left(\mathrm{SO}_{4}\right)_{3}+7 \mathrm{II}_{2} \mathrm{O}$, soluble in dilute sulpluric acid, but decomposeri by water, with precipitition of hydrated $\mathrm{T}_{2} \mathrm{O}_{3}$.

Inalysis. - All thallium compounds volatile or liable to dissociation at the teinperature of the flame of a Bunsen lamp impart to such flame an intense green colour.' The spectrum consists of only one line, which, of coursc, has a definite position in the spectrum, and consequently is easily identified, -a most delicate test.

From solutions containing it as thallous salt thometal is casily precipitated as chloride, iodide, or chloroplatinate by the corresponding reagents (see supra). Sulphuretted hydrogen, in the presence of free mineral acid, givea no preciuitate; sulphide of ammonitan, from neutral solutions, precipitates $\mathrm{TI}_{2} \mathrm{~S}$ as a dark brown or black precipitate, insoluble in cxcess of reagent. Thallic aalts are easily reduced to thallous by meana of solution of sulphurous acid, and thus rendered amenable to the above reactions.

The atomic weight of thallinm was determined very carefully by Crookes. $H_{0}$ found it $\mathrm{Tl}=204 \cdot 2,-\mathrm{O}$ being 16.
(W. D.)

THAMES, the most important river in Great Britain, has its source in severai streams on, the Gloucestershire border, the main one having its rise in the parish of Coates, 3 miles south-west of Cirencester. The upper part of the river, until the junction with the Thame near Dorchester, is generally called the Isis, a usage to which Camden perhaps gave currency, who derives the word Tamesis or Chames from the junction of the names of the two rivers, the Thame and Isis. The total length of the river from Thames Head to London Bridge is 170 miles, and to Sheerness 228 miles. It drains an area of 6100 miles. It becomes navigable 24 niles from its source, near Lechlade, its waters having been greatly augmented by the junction of the Colne, Leach, and Churn; here also is the junction with the Thames and Severn Canal. The height of its source above sea-level is 370 feet, and that of the stream at Lechlade 250 feet, the average fall between Lechlade and London Bridge ( 146 miles) being 21 inches per mile. The course is remarkably equable throughout. Above Teddington, 19 miles from London Bridge, the tidal wave may be said to cease, and thence up to Lechlade navigation is carried on by the aid of locks. A small steamer
plies as high as Oxford. While at Lechlade the daily flow of the ordinary summer level is about 100 million gallons, the flow at Teddington is about 380 million gallons. There are seven hours of ebb tide and five hours of flow tide. From the Nore to London Bridge, a distance of 40 miles, the tidal wave travels in two hours, and in other two hours it reaches Teddington. The width of the river at Teddington is 250 feet, and at London Bridge the width at high tide is 800 feet, the deptl being 30 feet, while at low tide the width is 650 feet and the depth 12 feet Large barges can ascend the river 150 miles above London Bridge, vessels of 200 tons as high as the bridge, and of 400 tons to the Pool, below which, at Irongate and St Katherine's wharf, deep-sea steamer navigation commences, while vessels of any tonnage can come as high as Deptford.

The Tinames leaves the Gloucestershire and Wiltshire border near Buscot, after which it separates successively Berks and Oxford, Berks and Bucks, Middlesex and Surrey, and, finally, at its estuary, Essex and Kent. Below Lechlade it has a winding course, passing near Farringdon and Bampton. After receiving the Windrush, it passes near the grounda of Blenbeim, whence it receives from the left the Evenlode, and at Oxford it receives from the left the Cherwell. It then floms in a sontherly direction to Abingulon, where it receives on the right the Ock from the valley of the White Horse, and has a junction with the Wilts and Berks Canal. Turning in an easterly direction it is joined, abont a mile after passing Dorchester, by its principal afluent the Thame. Thence, through an opening of the Chiltern Hills, it passes Bensington, and turns southwards by Wallingford and Reading, where it receives the Kennet from the right. It then benda northward to Henley, eastward to Great Marlow, and southward to Maidenhead, where it reccives from the right the Loddon. Winding in a south-easterly direction it passes Eton, Windsor, Datchet. Staines, and Chertsey, recciving at Staines the Colne from the left. Flowing through the gronnds of Hampton Conrt it reaches Kingston and Teddington, where its bulk is iocreased by the tidal ware. From Richmond, where it receives the Mole, it begina to pass the villas and suburbs of London. At Gravesend, 27 miles below London, it has a width of half a mile, and at the Nore lighthouse, 50 milea below London Bridge, the estuary widens to nearly 10 miles. In the tidal reaches the principal affluents of the Thames are the Mole at Richmond, the Brent at Brentford, the Wandle at Wandsworth, the Lea at Blackwal1, the Roding at Barking Creek, the Ingre bourne at Rainham, and the Medray at Sheerness. The land adjoining the river is greatly subject to floods, and from above London there were in ancient times wide stretches of marsh land covered by shallow lagoons. The embankments below London Bridge date possibly from the time of the Romana, but their origin is the aubject of much dispute (see Losidon, vol. xiv. p. 840). Between London Bridge and Chelsea the bed of the river has been altered artificially, and flooding is prevented by a marine wall (see LoNDon, vol. xiv. p. 823). The Thames occupies the bel of a nuch larger prehistoric river, the gravcls of which adjoin its hanks at a considerable distance.

The scenery, thoush scarcely to be called picturesque, and in a certain sease monotonous, has a pcculiar charm from the richness of its sylvan beauty and its pleasant alteruation of hill and dale. The number of islands that occur in the course of the river add to its interest, and afford convenient seclusion for the erection of boathouses and tents. . The Thamea vies with the Tyne as the pribcipal river for boat-racing in England, and of course greatly surpasses the latter river as regards amateur boat-racing, the principal fixtures in which are the Oxford and Cambridge boat race and the Henley, regatta. The river affords about one balf of tbe water supply of London, and is the principal outlet for its sewage. It is uuder the sovernment of conservators, originally constituted in 1857, but their duties have becn extended by several subsequent Acts.

of the Thames. of the Thames.
THANA; or Tannah, a district in Bombay presidency, India, with an area of 4243 square miles, lying between $18^{\circ} 42^{\prime}$ and $20^{\circ} 20^{\prime} \mathrm{N}$. lat. and $72^{\circ} 45^{\prime}$ and $73^{\circ} 48^{\prime}$ E. long. It extends along the coast for 105 miles, with a breadth or 50 miles, and is confined between the Sahyádri Gháts on the E. and the sea on the W., while on tle N. it is bounded by the Portuguese territory of Daman and by Surat district, and on the S. by Kolaba and Poona districts. The district is well watered and wooded, and, except in the north-east, is a low-lying rice tract broken by hills. The spurs of the Gháts form health resorts: the two mosk
conspicuous bills are Mátheran and Tungar. Most of the hills wera once fortified, but the forts built on them are now dilapidated and useless. The only rivers of any imporlance are the Vaitarna and the Ulhas, the former oeing navigahle to a distance of about 20 miles from its mouth ; the latter is also navigable in parts for small craft. There are no lakes; but the Vehár and the Tulsi, formed artificially, supply Bombay city with water. The forests, lying chiefly in the northern half of the district, occupy i664 square miles, or about 40 per cent. of the total area. The average annual rainfall exceeds 90 inches.
In 1881 tha population of Thána was returned at 908,548 (males 468,236 , females 440,312 ) ; Hindus numbered 806,805 , Mohsm. medans 42,391 , and Christians 39,545 . The district has seven towns with pepulations exceeding 10, 000, namely, Bandra ( 14,987 ), Thana (sea below), Bhiwandi ( 13,837 ), Falyan (12,910), Bassein ( 10,357 ), Panvel ( 10,351 ), Uran ( 10,149 ). The area under cultivation in 1885-86 was 1,002, 448 acres, and 768,057 ramained uncultivated. The total area of crops was 522,810 actes, including 5835 twica cropped. Rice is by far the most important prodact, and occupied 324,680 acres; it is also the chief article of export. Sugar-cansand plantains are cultivated largely, as wall as mangoas and cocos-nuts. In 1885-86 the gross revenus of the district was $£ 245,182$, the land yiclding $£ 130,409$. The territory comprised in tha district of Thána formed part of the dominions of the peshwá, and was annexed by the British in 1818 on tho ovarthrow of Baji ráo. Since then the operations to put down the Koli robhers, which extended over aaveral years, hava been tho only cause of aerious trouble, and lately, in 1874 and 1877, therawera a number of gang robberies which wera suppressed, but not without difficulty.
THÁNA, chief town of the above district and a station on the Great Indian Peninsula Railway, lies 20 miles northeast of Bombay city, in $19^{\circ} 11^{\prime} 30^{\prime \prime} \mathrm{N}$. lat. and $73^{\circ} 1^{\prime} 30^{\prime \prime}$ E. long., and in 1881 had a population of 14,456 (males 7856, females 6600). It is a manicipal town and a port, and contains a civil hospital and post-office.

THAPSACUS. See Mesopotamia, vel. xvi. p. 49.
thar and Párkar, or Thur and Pareer, a district in the east of Sind, Bombay presidency, India, with an area of 12,729 square miles. It lies between $24^{\circ} 13$ and $26^{\circ} 15^{\prime} \mathrm{N}$. lat. and between $68^{\circ} 51^{\prime}$ and $71^{\circ} 8^{\prime}$ E. long., and is bounded on the N. by Khaipur state, on the E. by the states of Jaisalmir, Malani, and Jodhpur, on the W. by Hyderabad district, and on the $S$. by the Runn of Cutch. The district is divided into two portions. The western part, called the "Pat," is watered by the Eastern Nara and the Mithrau canals, which constitute the sole water-system of the district, and the presence of water has created a quantity of jungle and marsh; the other part, called the "Thar," is a desert tract of relling sand-hills, runring north-east and south-west, composed of a fine but slightly coherent sand. To the south-east of Thar is Parkar, where there are ranges of rocky hills, rising to 350 feet above the surrounding level, and open plains of stiff clay. The Parkar portion of the district contains the ruins of several old temples; one of these is a Jain temple, which contained an idol of great sanctity and repute, known under the name of Gorcha. The climate is subject to considerable extremes in temperature, being excessively hot in the summer and very cold in winter, the cold increasing as the sand-hills are approached.
The census of 1881 returned tho population at 203,344 (males 112,400, females 90,944 ); Hindus numbered 43,755 , Mohammedans 102,924 , and Christions only 14 . Umarkot, the birth. place of Akbar, is the chief tomn, with a pepratation of 2828. The chief prodacts of tha district are rice, joir, bajri, cotton, and oil aceds. It is estimated that only 45 per cent. of the arabla area is under cultivation. The exports are chiefly rice, wheat, oil-seeds, cattle, goats, and sheep; tha imports consist of cotton, metals, dried fruits, plece goods, sugar, and tobacco. The manufacturea are chiefly blankets, camel sadules, and coarse cetton cloth. The imperial revenus in 1885-80 amounted to $£ 44,313$, of which tho land supplicd $£ 32,927$.

Vasy little is known of the aarly history of tho district. The

Soda Rajputs, said to be descendants of Parmar Soda, are supposed to have coms into this part of Sind about 1226, when they qqickly displaced the rulers of the country, though, according to other authorities, they did not conquer the country from the Sumras the dominant race, before tha beginning of the 16 th century. The local dynasty of the Sodes succumbed to the Kalhoras about 1750 , eincs which period the district has been subject more or less to Sind. The Talpur mirs succeeded the Kalhoras, and built a number of forts to overame tha people, who were lawless and addicted to robbery. On the British conquest of Sind in 1843 the greater part of the district was mads over to Cutch; and in 1856 it was wholly incorporated in the province of Sind. In 1859 a roballion broke out, which was quickly sappressed.

THARRAWADDY, a district in the Pegu division of Burmah, with an area of 2014 square miles. It lies between $17^{\circ} 30^{\prime}$ and $18^{\circ} 40^{\prime} \mathrm{N}$. lat. and between $95^{\circ} 20^{\circ}$ and $96^{\circ} 10^{\prime}$ E. long., and is bounded on the N. by Prome, on the E. by the Pegu Yoma range, on the S. by Hanthawaddy, and on the W. by Henzada. The Pegu Yoma range separates Tharrawaddy from Toungú district, and forms the water-parting between the rivers Irrawaddy and Sittang; there are also many small elevations. The Irrawaddy, which traverses the district for 46 miles, is the principal navigable.river. Another important river is the Hlaing, which runs through the district from north to south, receiving from the east, through numerous channels, the drainage of the Pegu Yoma Mountains, which fertilizes the plain on its eastern bank. There are twenty-three teak forests and four fuel reserves in the district, covering an area of 817 square miles. Among the wild animals generally found in the mountains are the alephant, rhinoceros, bison, and various kinds of feathered game.
In 1881 the popolation was returned at 278,155 (males 143,413, femkles 134,742), of whom 1985 were Hindus, 1110 were Mobam. medans, 270,552 were Buddhists, whilst Christians and ahorigines nambered 2363 and 2135 respectively. The aran ander cultivation in 1885-86 comprised 323,542 acres, and that available for cultivation 186,002 acres; forests occupied 364,524 acres. Tha chief products of the district ara rice, sesamurn, tobacco, engar-cana, cotton, and fruits. The gross revenus of Tharrawaddy in 1885-86 was $£ 85,254$, of which the land yielded $£ 51,523$. The history of the district is identical with that of Henzada (q.v.). Tharramaddy was formed in 1878 out of that portion of Henzada lying east of tha Irrawaddy. Its headquarters are at Thoon-tshay, on tha atream of the same name.

THASOS, an island in the north of the Egean Sea, off the coast of Thrace, $3+$ miles distant from the plain of the river Nestus (now the Kara-Su). The island was colonized at an early date by Phœnicians, attracted probably by its gold mines; they founded a temple of Hercules, which still existed in the time of Herodotus. Thasus, son of Phcenix, is said to have been the loader of the Phenicians, and to have giver his name to the island. In 720 or 708 b.c. Thasos received a Greek•colony from Paros. In a war which the Parian colonists waged with the Saians, a Thracian tribe, the poet Archilochus threw away his shield. The Greeks extended their power to the mainland, where they owned gold mines which were even more waluable than those on the island. From these sources the Thasians drew great wealth, their annual revenues amounting to 200 or even 300 talents. Herodotus, who visited Thasos, says that the best mines on the island were those which had been opened by the Phcenicians on the east side of the island, facing Samothrace. After the capture of Miletus ( 49.4 b.c.) Histiæus laid siege to Thasos. The attack failed, but, warned by the danger, the Thasians employed their revenues to build war ships and strengthen their fortifications. This excited the suspicions of the Persians, and Darius compelled thera to surrender their ships and pull down their walls. After the defeat of Xerses the Thasians joined the Greek confederacy ; but afterwards (in 467,465 , or 464 , according to different calculations), on account of a difference abcut the mines and marts on the mainland, they revolted. The Athenians defeaterl
them by sea, and, after a siego that lasted more than two yerrs, took the capital, Thasos, and compelled the Thasiane to destroy their walls, surrender their ships, pay an indemnity and an annual contribution, and resign their possessions on the mainland. In 411 B.c., at the time of the oligarchical revolution at Athens, Thasos again revolted from Athens and received a Lacedmmonian governor ; but in 407 the partisans of Lacedrmon were expelled, and the Atbenians under Thrasybulus were admitted. After the battle of Aegospotami ( $\ddagger 05$ B.C.): Thasos again fell into the hands of the Lacedemonians ; but the Athenians mnst have recorered it, for it formed one of the subjects of dispute between them and Philip of Macedouia. In the embroilment between Philip III. of Macedonia and the Romans, Thasos subinitted to Philip, but received its freedom at the hands of the Romans after the battle of Cynoscephalx ( 197 B.c.), and it was still a "free "state in the time of Pliny. Thasos, the capital, stood on the north side of the island, and had two harbours, one of which was closed. Archilochus described Thasos as "an ass's backbone crowned with wild wood," and the description still suits the mountainous island with its forests of fir. The highest mountain, Ipsario, is 3428 feet high. Besides its gold mines, the wine, nuts, snd marble of Thasos were well known in antiquity. The mines and marble quarries are no longer worked ; and tho chief exports are now fir timber for shipbuilding, olive oil, boney, and wax. The imports consist of mannfactured goods, beasts of burden, and corn, for the island is too mountainous to grow enough corn for the inhabitants.

In 1858 the population, distributed in ten villages, was estimated at 10,000. The people are Greek Christians, and do not differ in appearance from the inhabitants of the other Greek islands. The villages are mostly situated at aome distence from the sea; for the island suffored from pirates up to a time within living memory. In the early part of this century sentinels stood on duty night end day, and at a signel of alarm the whole population, including the Turkish aga himsolf, used to hido in the woods. For a description of the island and its remains of antiquity, seo A. Conze, Rcise auf den Inseln des thrakischen Mecres, Hanover, 1860.

THAYETMYO, a district in the Irrawaddy division of Burmah, having an area of 2397 squsre miles, and lying between $18^{\circ} 50^{\circ}$ and $19^{\circ} 30^{\prime} \mathrm{N}$. lat. and between $94^{\circ} 30^{\circ}$ and $95^{\circ} 50^{\circ} \mathrm{E}$. long. It is bounded on the N . by the newly acquired territory of Burmah, on the E. by Toungu district, on the S. by Prome, and on the W. by Sandoway. On the west is the Arakan Yoma range, and on the east the Pegu Yoma; and the face of the country, where it does not rise into mountains, is everywhere broken by low ranges of hills, many of which are barren and destitute of all vegetation. The greater part of the district is wooded, and the Yomas east and west are covered with forests now mostly preserved. The chief river is the Irrawaddy, which traverses Thayetnyo from north to south. The country is well drained; the drainage finds its way to the Irra. waddy by three inain streams (the Pwon, Ma-htún, and Ma.dc) on the west, and by two (the Kye-nee and Bhwotlay) on the east. Several salt and hot springs occur in many localities of the district; petroleum is also found, and extensive lime quarries exist a few miles south of Thajetmyo. The principal wild animals are leopards, vild cats, barking decr, elephants, rhinoceroses, tigers, black besrs, and wild hogs. Silrer phessants and partridges are found in large numbers, especially in the mountains.

In 1881 the number of inlabitants in the district was 169,560 (males $87,30 \mathrm{~S}$, femoles 82,252); Hindus numbered 2620 , Mohammedans 1861, Christians 2349, and Buddhists 148,629 . The chief town is Thayetmyo, with a population (1881) of 16,097 ; it is situated in $19^{\circ} 18^{\prime} 43^{\prime \prime} \mathrm{N}$. lat. and $95^{\circ} 15^{\prime} 40^{\prime \prime} \mathrm{E}$. long., on the right bauk of tho Irrawaddy. Of the total arca of $1,534,080$ acres, only 108,167 werc unter cultivation in $1885-8 G ; 547,631$ were avail. able for cultuation: and forests occupied 256,256 acres. Tho chief yroducts are rice, cotton, oil seculs. and :obacco; cutch is also very
whondant, and the manuracture of the dye-stuff is carried on extenoively. Coal has recently been found in the district, and earth oilwells exist, but neither coal nor oil has yet been extracted in any quantity. Tbe revenue of the district in 1885-86 mas returned at $\dot{£} 6,702$, of which the land contributed $£ 10,482$. On the aunexation of Pegu by the British in 1852-53, Thayetmyo was formed into a subdirision of Promo district; and in 1870 it was erceted into a separato jurisdiction and placed undor a depnty-commissioner.
 The iuvention of a building specially devised for dramatic representations was due to the Athemians (sce Drama). At first representations at the Dionysiac festivals were held on temporary wooden platforms ; an accident, however, which occurred in 500 B.C. induced the Athenians to begin the construction of a permanent building. This first theatre was not completed till 340 B.c., and during the interval a large umber of theatres, designed on the same model, had been erected iu many towns of Greece and Asia Minor, though in some cases, as at Sparta, they were used for assemblies of the people and dances rather than for drsmatic performances. The great Dionysiac theatre at Athens was placed in the Lenxum, an enclosure sacred to Dionysus, and its auditorium is scooped out of the rock at the base of the Acropolis on its south-est side. A similar position on the slope of a hill was always chosen by the Greeks, and it was not till the lst century B.c. that theatres were built by the Romans on a level site.

Fio. 1.-Plan of tha Theatre at Myra,
Fig. I shows the plan of the existing theatre at Myra, in the south-enst of Lycia, which, though late in date, is built after the old Greek model. ${ }^{1}$ The seats for the audience are arranged in concentric ticrs, rising like steps one above the other (seo fig. 2) ; theso mainly rest on a cavity excavated in the hill-side, and the whole space occupied by the spectators was called the кoìdov (Lat.cavea). About half-way up the slope is an encirc-
 ling passage ( $\delta$ cáYou $\alpha$, prxcirctio). Flights of steps divide the seats into wedge-shaped blochs (кєркiঠぇs, cunci). At the highest level behind the top row of seats ran a colounade, forming a covered passage with a gallery at the top. Rows of niches were formacd in the back wall of this, and also sometimes in the low wall encircling the $\delta$ óasw $\mu a$; in these niches a series of large bronzo jars (ineia) were set: they werc intended to catch and repent the reverberation of the voices from the stage. Virruvius (iii. 5) gives
${ }^{3}$ See Texier and Pullan, Asia Minor, Londou, 1805.
olaborato directions for the construction of these rases, which were to be tuned in a chromatic scale; ${ }^{1}$ he mentions their use by the Gireelss, but says he knows of no Roman theatre which possessed these vases, the real utility of which is very problematical. ${ }^{2}$ The segmental fioor space in a Greek theatre was called the ópxígт $\rho a$ (orchestra), and was occupied by the chorus; in the centre of this was the Dupéd $\eta$, a platforn slightly raised on steps, in the middle of which was an altar to Dionysus. The stage ( $\pi \rho \rho \sigma$ кípiov, proscenium was a narrow platform, raised 3 to 5 feet above the orchestra, with which it communicated by stairs, so that the chorus could move from one place to the other; tie central part of the stage, where the principal actors usually stood, was the doyciov (pulpitum). The stage was also connected with a chamber under it (imorкiviou) by a dight of stairs called $\chi$ apóvot клípakes, by which ghosts ascended." At the back of the stage was a lofty wall, which usually reached to the level of the colonaade behind
 which were three doors leading into the stage from the actors dressing-rooms behind it. ${ }^{3}$ This wall was usually decorated with three orders of columns and entablatures, forming an architectural façade, which represented a palace or temple, before which the action of the play was supposed to take place. Other morable wooden ecenery was in some cases added in front of the permanent scena; or curtains with woven or embroidered figures were hung against it to form a background to the actors ( $\pi$ apa\#ย่тaбнa or aủ̉aia, aulsa or siparium). More elaborate painted scenes were also used, but, according to Aristotle (Poet., iv. 16), not before the time of Sophocles. Various kiods of machinery mere used, such as the $\mu \eta \chi$ वarn, to suspend in the air an actor who was playing the part of a god descending from heaven; ${ }^{4}$ and the $\beta$ pootetor, an apparatus to imitate thunder by stones roiled in metal jars, prolably in the ghost-chamber under the atage. Women were not excluded from the Greek tragic drama, but appear to have sat by themselves in the upper roms of seats (Athenæus, zii. 534). ${ }^{5}$ At least in late times the chiof priestesses of Athens occupied marble thrones in the $\pi \rho o \varepsilon \delta \rho i \alpha$ or front row.

The ramains of the Dionysiac theatre at Athens, the prototype of all later theatres, were excavated in 1862, When the proscenium, orchestra, and lower rows of seats were found in a fair state of preservation. It must have held 30,000 people: the cavea reaches from the foot of the Acropolis hill to close under the upper circuit wall. The rock-cut cavern, which was faced with the choragic monument to Tlurasyllus ( 320 b.c.), seems to have opened behind the highest row of soats; the face of the rock is here scarped to a curve concentric with the lines of seats. The most interesting discovery was that of a row of 67 marble thrones in the front row, each inscribed with the name of one of the chief Athenian priests or with that of a secular official. ${ }^{6}$ The cavea was divided into 13 cunei;

[^87]a law wall separated the auditorium from the orchestra. The front or "riser" of the stage is decorated with fine rclicis of deitics on largo marble slabs. These existing features are mostly restorations of the time of Hadrian, but the reliefs themselves are of much carlier date. The floor of the orchestra is very late, formed of roughly laid slabs of stonc, with a large central lozenge in marble, which may mark the limits of tho thymele, and is apparently part of an earlicr pavement.

The position of the monysiac theatre, with many of the chief temples of Athens in sight, and with its glorious view of Mount Hymettus, the blue waters of the Egean Sca, and the islands of Salamis and Egrina, should not bo forgotten in reading the dramas of the great tragedians, with their impassioned appeals to the glories of nature and their allusions to the protective uresence of the divine patrons of Attica

Outside Athens the largest Greek theatres wero those at Magalopolis (Paus., viii. 32), Cnidus, Syracuse, Argos, and Epidaurus. By the end of the 4 th century B.c. every important Hellenic city possessed its theatre, and new ones were built or old ones restored throughont the wholo period of homan docaiuation. The most perfect existing example is that at Aspendus in Pamphylia, ${ }^{7}$ a building of the 2d cuntury of our era, in which the early Greek model has been closely followed. Aspendus is the only place where the whole scena with its three orders of columns is still standing, and every row of seats exists in almost perfect condition. In this theatre the whole interior appears to have been covered by an awning, ${ }^{8}$ supported along the top, of the scena by wooden poles set in rows of perforated corbels like those on the Colosseum in Rome. The earlier Greek theatres were probably unsheltered from the sum. Next to Aspendus, tho theatre of Tauromenium, in Sicily (see Taormina), is tho best preserved, at least as far as regards the scena and the upper gallery round the carea. That at Myra, in Lycia (fig. 1). is also in good preservation.

The Roman Theutre.-In $\mathrm{t}_{1}$ a main the theatres of the Romans were copied closely frc a those of the Greeks, but in the Greek theatre the orchestra occupied more than a semicircle, while the Romans raado it exactly half a circlo. The accompanyiag diagrams (see fig. 3) show the principlo on which the plan of each was set out. ${ }^{9}$ The Romans also introduced another important change, in many cases constructing theatres on a level site, not scooped out of a hillside as iu the caso of Hellenic theatrcs.
 This necessitated an Fic. 3-Disgram to show the Principle oo which claborato arrange- the Plans of the Greek and Roman Theatre were ment of substrac-
tures, with raking ranlts to carry the seats of the carea, and also an additional risible façade with tiers of arches following the semicirclo of the auditorium. The design universally adopted for this appears to have been tiers, usually three in number, of open arches, with intermediate

[^88]engaged columns, each tier being of a different order, as is still to be seen in the remains of the theatre of Marcellus in Rome. 1 The development of the use of the stone arch, and still more the use of concrete for forming vaults, enabled the Romans to erect their theatres on any site. Those in Rome were placed in the level plain of the Campus Martius.
During the Republican period the erection of permanent theatres with seats for the spectators was thought to savour of Greek luxury and to be unworthy of the stern simplicity of the Roman citizens. Thus in 154 b.c. Scipio Nasica induced the senate to demolish the first stone theatre which bad been begun by C. Cassius Longinus ("tanquam inutile et nociturum publicis moribus," Liv., Epit., 48). Even in 55 r.c., when Pompey began the theatre of which remains still exist in Rome, he thought it wise to place a sbrine to Venus Victrix at the top of the carea, as a sort of excuse for having stone seats below itthe seats theoretically serving as steps to reach the temple. This theatre, which was completed in 52 b.c., is spoken of by Vitruvius as "the stone theatre"par excellence: it is said in the Regionary catalogues to have held 10,000 people. It was also used as an amphitheatre for the bloody shows in which the Romans took greater pleasure than in the purer intellectual enjoyment of the drama. At its inauguration 500 lions and 20 elephants vere killed by gladiators. Near it two other theatres were erected, one begun by Julius Cæsar and finished by Augustus in 13 b.C., under the name of his nepherw Marcellus, ${ }^{2}$ and anotier built about the same date by Cornelius Balbus \{Suet., Aug., 29; Pliny, H. N., xxxvi. 16). Scanty re: mains exist of this last theatre, but the ruins of the theatre of Marcellus are among the most imposing of the buildings of ancient Rome.

A long account is given by Pliny ( $H . N_{\text {., xxxvi. } 2}$ and 24) of a most magnificent temporary theatre built by the medile M. Emilius Scaurus in 58 b.c. It is said to have beld the incredible number of 80,000 people, and was a work of the most costly splendour. Still less credible is the account which Pliny gives ( $H . N .$, xxxvi. 24) of two mooden theatres built by C. Curio in 50 r.o., which were made to revolve on pivots, so that the two together could form an amphitheatre in the afternoon, after baving been used as two separate theatres in the morning.

In some cases the Romans built two theatres close together, one for the Greek and the other for the Latin drama, as is the case at Hadrian's magnificent villa near Tivoli. The two theatres at Pompeii are still mell preserved, and all Roman provincial tomns of any importance seegn to bave possessed at least one theatre, designed with the semicircular orchestra after the Roman fashion (see fig. 3). The theatres built under the Roman rule in Hellenic cities seem, on the other hand, to bave been usually constructed on the old Greek model, probably because they were designed by Greek architects. This is the case at Tauromenium, Aspendus, and Myra see (fig. 1). An important exception to this rule is the still wellpreserved theatre of Herodes Atticus, at the south-rest angle of the Athenian Acropolis, which has a semicircular rrchestra. It was built in the reigu of Hadrian by Herodes Atticus, ${ }^{3}$ a very wealthy Greek, who spent enormous sums in beautifying the city of Athens; ho called it the Regillum, after his wife Regilla. Its cavea,

[^89]which is excavated in the rock, held about 6000 people it was connected with the great Dionysiac theatre by a long and lofty porticus or stoa, of which considerable remains still exist, probably a late restoration of the stoa built by Eumenes II. of Pergamum. In the Roman theatre the "orchestra." was occupied, not by the chorus, but by senators and other persons of rank (Vitr., iii. 6). ${ }^{4}$ The Romans used scenery and stage effects of more elaboration thau was the custom in Greece. Vitruvius (iii. 7) mentions three sorts of movable scenery:-(1) for the tragic drama, façades with columns represent ing public buildings ; (2) for comic plays, private houses with practicable windows and balconies; ${ }^{5}$ and (3) for the satyric drama, rustic scenes, with mountains, caverns, and trees.

The Modern Theatre.-During the Middle Ages mıracle plays with sacred scenes were the favourite kind of drama; no special buildings were erected for these, as they were represented either in churches or in temporary booths. In the l6th century the revival of the seculaip drama, which, in the reign of Elizabeth, formed so im . portant a part of the literature of England, was carried on. in tents, wooden sheds, or courtyards of inns, mostly by strolling actors of a very low class. It was not till towards the close of the century that a permanent building was constructed and licensed for dramatic representations, under the management of Shakespeare and Burbage. ${ }^{\circ}$ In

[^90] position.
${ }^{5}$ These are ahown on Greco-Roman vaaes of the latest type, witb paintings of burlesque parodies of mythological stories.
6 The first building specially erected in London for dramatic purposes was built in $1576-77$ by the actor James Burbage, who was originally a carpenter by trade. It was constructed of timber, and stood in Holywell Lade, Shoreditch, till 1598, Fhen it was pulled down; it was known as "The Theatre" par excellence. Of almost equally early date was the "Curtain" theatre, also in Shoreditch; many explanations of its name have been given, but the real one appears to be that it was so called from the plot of ground, known as "The Curten," on which it stood. It probably continued in use till the general closing of theatres by order of the parliament in 1642.
The "Glabe" theatre, famous for its assacistion. with Shakespeare, was luilt by James Burbage, who nsed the materials of "The Theatre," in the year 1598. Its site was in Southwark, in a district called "The Baokside," near the old "Bear Gardens." It was an octagooal structure of wood, with lath and plaster between the main framework. It was burot in 1613 , rebuilt, and finally pulled down and its site bnilt over in 1644. Its name was derived from its siga of Atlas aupparting the glabe. Near it were two less important theatres, "The Rose," opened in 1592 by Henslowe, and "The Swan," opened in I 598 and probably owncd also by Heoslowe; like the Globe, it was an actaronal woad-and-plaster building.

The "Blackfriars" theatre, another of the Burbages ventures, was built in 1596 (not 1576, as stated by Collier, Hist. of Dramatic Potry and Annals of the Stage, new ed., 1879, vol. i. p. 287), near the old Dominican friary. :The "Fortune" theatre was built by Edward Alleyn, the great rival of the Burbages, in 1599-1600, at a total cost, including the site, of $£ 1320$. It stoad between Whitecroas Streat and Golding Lane. It existed as lato as 1819, when a drawing of it was giveo by Wilkinson (Londina illustrata, 1819). The "Real Bull ${ }^{\circ}$ theatre was prabably originally the galleried court of an inn. which was adapted for dramatic purposes towards the close of Elizabeth"s reigo. Other early theatres were the "Hope" or "Paris Garden" theatre, the "Whitefriars" and "Salisbury Caurt" theatrcs, and the "Newington" theatre. A curious panoramic view of London, ergraved by Visscher in I616, showa the Globe, the Hope, and the Swan theatres.
The play of the first English theatres appears to have had no cannexion with those of classical times, as was the case in Itsly: it was evidently produced in an almost accidental way by the early custom ci erecting a temporary platform or stage in the middle of the open court yard of ay inn, in which the galleries all round the court formed boxes for the chief spectators, while the poorer part of the audience stool is the count on $a_{1}$ ] sides of the central stage. Something similar to this arrangement, nnsuitable though it now seems, was reproduce oven in buildings, such as the Globe, the Fortune, and the Swan, which were specially designed for the drama. In these and other early theatres there was i central platforin for the stage, furroundal ${ }^{3}$ y seats except sa oye aide, where there was a "green-room" or
the 16 th and 17 th centuries a favourite kiud of theatrical. representation was in the form of "masques," with" processions of grotesquely attired actors and temporary scenic effects of great splendour and mechanical ingenuity. In the reigns of James I. and Charles I. Ben Jonson and the architect Inigo Jones worked tagether in the production of these "masques," Jonson writing the words and Inigo Jones devising the scenic effects, the latter being very costly and complicated, with gorgeous buildings, landscapes, and clouds or mountains, which opened to display mimic deities, thrown into relief by coloured lights. These masques were a form of opera, in which Ben Jonson's words were set to music. Ben Jonson received no more for his libretto than Inigo Jones did for his scenic devices, and was not unnaturally anuoyed at the secondary place which he was made to occupy: he therefore revenged himselt by writing severe satires on Inigo Jones and the system which placed the literary and mechanical parts of the opera on the same footing. In an autograph MS. which still exists this satirical line occurs-" Painting and carpentry are the soul of masque" (see Cunningham, Life of Inigo Jones, London, 1848).
In Italy, during the 16th century, the drama occupied a more important position, and several theatres were erected, professedly on the model of the classic theatre of Vitruvius. One of these, the Teatro Olimpico at Vicenza, still exists; it was designed by Palladio, but was not completed till 1584 , four years after his death. It has an architectural scena, with various orders of columns, rows of statues in miches, and the three doors of the classic theatre, but the whole is painted with strong perspective effects which are very unclassical in spirit. Scamozzi, Palladio's pupil, who completed the Teatro Olimpico, built another pseudo-classical theatre in 1588 at Sabbionetta for the duke Vespasiano Gonzaga, but this does not now exist.
In France the miracle play developed into the secular drama rather earlier than in England. In the reign of Louis XI., about 1467, the "Brothers of the Passion" had a theatre which was partly religious and partly satirical. In the 16 th century Catherine de' Medici is said to have spent incredible sums on the dresses and scenery for the representation of the Italian ballet; and in the middle of the 17 tha century the regular opera-was introduced at Paris.

At the end of the 18th century the theatres of San Carlo at Naples, La Scala at Milan, and La Fenice at Venice were the finest in Europe; all these have been rebuilt in the present century, but have been eclipsed by the theatres of Paris, St Petersburg, and other capitals, both in size and architectural splendour.

[^91]- In the modern theatre the auditorium has changed comparatively little, except that the stalls have gradually encroached upou 3nd almost absorbed the pit. The arrangement of the boxes, stalls, balcony, and gallery are teo well known to need description. Few people, have, however, any notion of the immease size and extreme complication of the space and machinery behind the proaceninm, of which the visible stage occupies but a very small propertion. The stage-floor slopes upwards a way frem the audience, so that it may appear deeper than it really is by diminishing the foreshertening. ${ }^{1}$ Its extent behind the most distant plane of scenery is naually quite as great as that which the audience sees. In addition to this extensien of the visible stage there are thrce other enermous epaces filled with the machinery to werk the acenery.
(1) Of these the first consists of the "wings" (Fr. coulisses), a series of chambers or platforms on each side of the stage, arranged many steries high, and reaching to more than deuble the height of the prescenium.
(2) The "dock" or under-space (Fr. dessous), extending under the whole area of the stage floor, and about equal in height to the proscenium, is divided into three or four stories by successive fleors, and contains long rows of immense windlasses (Fr. gril) for raising and lewering scenery, and also an elaberate arrangement of lifts by which acters can suddenly appear or venish threugh the stage floor. A very ingenious device called the "star trap," invented by an English mecharician (Fr. trappe Anglaise), allows an actor to vanish through the floor without eny opening in it being visible. This is dene by making the trap door of thin boards (semething like a venetian blind) fixed on to flexible bands of steel ; the weight of the actor makes these open in the middle and let him through, while the steel springs close the opening as soon as they are released. The whole movement is so rapid that the actor seems to sink through the solid floor. ${ }^{2}$ In all mechanical appliances for theatrical purposes England is far abead of other countries, many of which have adopted English methods.
(3) The third space, and the largest of all, is that ahove the proscenium-the "fies" (Fr. dessus or cintre), extending over the whole of the stage, and reaching sometimes to nearly double the leight of the prosceninm. This also is divided into many floors, and contains rows of great windlasses, by which sceuery can be hoisted up out of sight, withont folding or bending it. All these three parts of the building are filled with a complicated but most orderly scries of ropes, lifts, and machinery of every sort, of whicly it is impossible here to give a detailed description.
The old method of fixing scenery was to slide it in tro halves from the wings in grooves formed in the stage floor: these are no longer used, as much more realistic cffects can be gained by supporting scencry from the top; or by building it un with supports of its own, so that, iastead of a series of painted planes set parallel to the stage front, castles, cathedrals, or even wholo streets are actually built upon the stage, and give striking effects of real perspective.
A rapidly gromiog teadency now exists to increase the mechanical perfection of the theatre. The cxtended use of iron instead of wood for the stage floor and the various nachiucs haa been a great gain in space and rapidity of working. It is polv considered a great object to drop the curtain as seldom as possible, and even the Grand Opera House of Paris is now left far behind in the modera competition for mechanical perfection, though from an architectural point of view it is the most magnificont and costly of all cxisting boild. ings of its kiod. Sea fig. 4.
The latest improvement to prevent delay between the F10. 4.-Plan of the Grand Opera Mouse In scenes has been introduced in
 the Madison Square theatre A, Audtiory. B, Stage. C, Grand S:aircase. in New York city, which has H, Greai Saloou. E, Royal Eur two elages, one above the Green-room.
other. During the performance of a sceze the second stage floor in

[^92]bsing prepared in the under-space, with all its scenery fixed, and When the curtain falls the first stage rises into the upper regions and the second floor goes up to take its placc. Thesu floors are accurately balanced by heary counterpoise weights, so that the whole of these enormous masses aro moved with comparatively little force.

On the whole, for magnificence of effect and mechanical ingenuity the great London pantomimes are unrivalled. Their transforma. tion-scenes are marvels of the mechanist's skill, and are often devised with very high artistic talent. Unhappily much danger and suffering have often to be nndergone by the women who act the part of fairies and the like, suspended ligh in the air by almast invisible surporty, and by the young children who have to squeeze themselves in to pasteboard shells representing insects or reptiles.
In addition to the above-mentioned parts of the theatre, which are reserved for the mechanical working of the performance, much space is occupied by the "green-room" for the actors, and rows of dressing-rooms. An imniense deal of storage room is also required, and some of the Parisian theatres have large magazines for this purpose in the suburbs. In many cases also the atelier for the scene painters is far removed from the theatre, and thos far better space and lighting for the work con be provided. Fig. 5 show the plan of the Drury Lane theatre, in many respects the best arranged in London.

The painting of theatrical scenery has frequently been the work of artists of very bigh talent, such as laphael in Rome, Watteau, Bouicher, and Servandoni in France, and Stanfiold in England. Paintings of very high artistic merit and wonderfully decoratiro effect are now produced for theatrical purposes, especially in France, Germany, and England. ${ }^{1}$ In England especially great historical and antiquarian knowledge are brought to the aid of this branch of art. The landscapes in particular are sometimes works of great beanty, and very beantiful effects of lako scenery with trees and mountains rellected in the water are got by setting great sheets of plate glass over Fig. 5.-Pian of Drury Lane Theotre: the stage floor, slightly inclined, so
 that a real reffexion is thrown by the A. Stage. B, Saloon between the landscape painted on the scene be. Chief Staircases. C, Entrance Hall. hind. Another ingenious device, used by Wagner at Baircuth and Also in Englaud for magical scenes, was to form a thin and semitransparent curtain of vapour, which was seut up by a perforated steam-pipe concealed in a groove in the stage.

The various methods of lighting used are an important item 1u the production of striking effects. The old system of a row of "foot-lights," with their unfleasant upward shadow, is now almost obsolete. Dip candles were used till 1720, when moulded candles were introduced into French theatres. The next improvement was the lamp of MI. Argand, with its circular wick. In 1822 gas was first used in a Parisian theatre, next came the oxyhydrogen lime light, used for special effects, and now electric lighting is rapidly superseding all other kinds.

The old way of producing lightning was to blow lycopodium or powdered resin with bellows through a flame, and this is still used in realistic effects of conflagrations. Moro effective lightning is now made by flashing the electric light behind a scene painted with clouds, in which a zigzag aperture has been cut out and filled with a transparent substance. Thunder is made by shaking large sheets of iron, by rolling cannon balls above the ceiling of the anditorium, and by clapping together a series of planks strung together on tro ropes. Wind is imitated by a machine with a cogged cylinder, which revolves against coarse cloth tightly stretched. The sound of rain is produced by shaking parched peas in a metal cylinder.

The orchestra is now usually arranged either below or above the proscenium, so that the musicians aro not visible. The prompter is placed at one side, in the wings, so as to avoid the disfigurement of the hood-like hox which formerly used to cut the front line of the stage into two halves. This is, however, less convenient for the actors.

Till the middle of the present century little trouble or expense was laid out on dresses and aocessories. Certain conventional costumes, made of cheap stuff, were used for each part, with but little regard to historical correctncss. Armour and weapons were

[^93]made of pasteboard covered with metal foil, and stage jewellery was made of small cup-like jrieces of tin formed with many facets. Now, however, no tromble or expense is spared to get the costumes ond various properties archæologically correct : real jewels and the richest stuffs are often used for the dresses, as well as real furniture of tho most costly sort for the furnishing of the scenic rooms. $\Lambda$ s much as $£ 20,000$ is sometimes spent before the play can be presented. All this splendour and realism is very hostile to the true interests of the drama ; maguificent scenery and costly accessories are expected by the audience, rather than good acting. In some scenes, such as the ball in the first act of Romeo and Julict, as recently represented at the Lyceum, the words and acting of the chief performers were almost lost in the general bustle and splendour of the scene. Frequently, too, the noise of setting up some elaborate scene behind alnost drowns the voices of the actors iu front of the drop scene.

Another serious cause of the present low state of acting in England is the fact that a popular play sometimes runs for several hundred nights without a break, thus reducing the performers to the condition of machines. The modern system of expending large sums on dresses and decoration maturally prevents that frequent change of subject which is so desirable, and which in France is provided for by the rules of the Théatro Français, whero acting of a very high order of merit still survives.

The present system, aided by the cnormous size to which Londor. has unhappily grown, has completely changed the character of the audience. Instead of an audieuce largely composed of habilués, who by their constint attendance at tlie theatre had gained some knowledge of what acting onght to bc , and were prepared to show their disgust at clap-trap or ranting, we have now practically a fresh and ignorant audience every night, who, by their applause of what is worst and their coldness to real refiuement of acting, do much to lower the dramatic standard and demoralize the actors.

## Law Relating to Theatres,

The regulation of the theatre by legislation can be traced back to the time of the lower empire, in which it depended almost wholly upon constitutions of Theodosins and Valentinian, incorporated in the 'Theodosian Code (tit. xv. 5, 6, 7), and a century later to a large extent adopted by Justinian. In the whole of this law there is an evident attempt at a compromise between the doc. trines of Christianity and the old Roman love of public.spectacles of all kinds. It deals less with theatrical representations proper than with gladiatorial contests and chariot races. ${ }^{2}$ Tho Theodosiau Code provided that the sacraments were not to be administered to actors save where death was imminent,' and only on condition that the calling should be renounced in case of recovery. Daugliters of actors were not to be forced to go on the stage, provided that they lived an honest life. An actress was to be allowed to quit the stage in order to become a nun. There were also numerous sumptuary regulations as to the dress of actors. None of the law which has been mentioned so far was adopted by Justinian, but what follows was incorporated in Cod. xi. 40 ("De Spectaculis et Scenicis"), which consists entirely of extracts from the Theodosian Code of a very miscellaneous nature. Provision was made for the oxhibition of public games and theatrical spectacles by magistrates, practically confining them to exhibiting in their own cities. Statues of actors were not to be placed in the public streets, but only in the proscenium of a theatre. A governor of a province was entitled to take the money raised for public gaines for the purpose of 1rpairing the city walls, provided that he gave eecurity for afterwards celebrating the games as usual. In Cod. iii. 12, 1 I ("De Feriis") is a constitution of Leo and Anthemius forbidding dramatic representations on Sunday. The Digest (iii. 2) classed all who acted for hire ("omnes propter pecuniam in scenam prodeuntes ") as infamous persons, and as such debarred them from filling public oftices. A mere contract to perform, not fulfilled, did not, however, carry infamy with it. By the 51st of the Novclle actresses could retire from the stage withont incurring a penalty, even if they had given sureties or taken an oath.

In England, as in other countries of western Europe, theatrlcal legislation was of comparatively recent introduction. Such legislation was unnecessary as long as the theatre was under the control of the church and actors under its protection (see Drama). The earliest regulations were therefore, as might be expected, made by the church rather than by the state. The ccclesiastical ordinances were directed chiefly against the desecration of churches, thongh they sometimes extended to forbidding attendance of the faithful as spectators at plays of a harmless kind. ${ }^{3}$ Sacrawents and Christian ${ }^{9}$ The word ludi seems sometimes to inclade, sometiraes to exclude, dramatle performances. Its meaning in a particular instance depends on the context. 8 A large number of such ordinauces will be found cited in Prynne, Listrio. mastix: Bossuet, Jfoximes et Replexions sur la Comedic; Majana, De Spectaculis
Smith, Dictionary of Christian Antizuilues, arts. "Actors" and "Thearte.:-
burial were denied by the canou law to actors, whose gaing, said St Thornas, were aequired cex turpi causa. ${ }^{2}$ The same law forbade plays to be scted by the clergy, even under the plea of custom, as (n Christmas week, and follorred the Code of Justinian in enjoining the clergy not to consert with actors or be present at plays (seo the Decretals of Gregory, iii. 1, 12, and 15, "De Yita ot Honestate Clericorum "). As lately as 1603 canon lexxviii. of the tanons of the Church of Englavd cnacted that churchwardens were not to suffer plays in churches, chapels, or churchyards.

The Reformation marks the period of transition from the ecclesiastical to the non-ecclesiastical authority over the drama. Precautions began to be taken by the crown and the lepislature against the acting of uvauthorized plays, by unautherized persons, and in anauthorized places, and the acting of plays objectionable to the Government on political or other grounds. The protection of the church being withdramb, persons not enrolled in a fixed company or in possession of a licence from the croma or justices were liable to screre penalties as vagrants. The history of the legisiation on this subject is very curious. An Act of the year 1572 (14 Eliz. c. 5) cascted that "all fencers, bearrards, common players of interludes, and minstrels (not belongiog to any barou of this realm, or to any other honourable person of greater degree)," wandering ahroad without the licence of two justices at the least, were subjccet "to be grievously whipped and burned through the gristle of the right ear with a hot iron of the compass of an inch about." This statute was superseded by 39 Eliz. c. 4, nuder which the panish. ment of the strolling player is less severe, and thero is mo mention of justices. The jurisdiction of justices over the theatre disappears from legislation from that time until 1788 . In 39 Eliz. c. 4 there is a remarkable exception in favour of persons licensed by Dutton of Dutton in Cheshire, in accordance with his clsim to liberty and jurisdiction in Cheshire and Chester, established in favour of his sncestor by proceedings in quo warranto in 1499 . The stricter werding of this Act as to the licence seems to show that the licence had been abused, perhaps that in some cases privileges had been assumed without authority. In 14 Eliz.c. 5 the privileges of a plaver attached by service of a voble or licencc from justices, in the later Act only by service of a noble, and this was to be attested utder his hand and arms. The spirit of the Acts of Elizabeth frequently appears in later legislation, and the unanthorized player was a ragabond as lately as the lagrant Act of 1744, which was 1sw till 1824. He is not named in the Vagrant Act of 1824 The Theatre Act of 1737 口arrowed the defiuition of a player of ioterludes, for the purposes of punishment as a ragabond, to niean a person acting interludes, \&c., in a place where be had no legal settlement.

Before the Restoration there were privileged places as well as privileged persons, e.g., the court, the universities, and the inos of court. With the Restoration privilege became practically con. fned to the theatres in the possession of those companies (or their representatives) established by the letters patent of Charles II. in 1662 (see Drasa). In spite of the patents other and nuprivileged theatres gradually arose. In 1735 Sir John Barnard introduced a bill "to restrain the number of playhouses for playing of interludes, and for the better regulation of common playcrs." On Walpole's rishing to add a clause giring parliamentary sanction to the juris. diction of the lord chamberlain, the mover withdrew the bill. In 1737 Walpole introduced a bill of his own for the same purpose, thero being then six theatres io London. The immediate conse of the bill is said to have been the production of a politieal cxtravaganza of Fielding's, The Golden Rump. The bill passed, and the Act of 10 Geo. 1I. c. 28 regulated the theatre for more than a century. Its effect was to make it impossible to establish any theatre except in the city of Westminster, and in places where tho king should in person reside, avd during such residence only. The Act did not confine the prerogative within the city of Westminster, but as a matter of policy it was not exereised in farour of the non; privileged theatres, except those where the "legitimate drama" was not performed. The legitimate drama was thus confinell to Corent Garden, Drury Lane, and the Haymarket from 1737 to 1543. In the prorioces patent theatres were established at Bath b." 8 Geo. III. c. 10, at Liverpool by 11 Geo. III. c. 16, and at Bristol by 18 Geo . III. c. 8 , the Act of 1737 being in each caso repealcd pro tanto. The acting of plays at the universities was forbidden by 10 Geo. II. c. 19. It is not a little remarkable that the universitics, once possessing nousual dramatic privileges, should not only have lost those privileges, but have io addition become suhject to epecial disabilities. The restrictions upon the crama were found very inconvenient in the large towns, especially in these which did not possess patent theatres, In one direction tho diffeulty was met by the lord chamberlain granting annual licences for performances of operas, pantomimes, and other spectacles not regarded as legitimate drama. In another direction relief was giren by the Act of
1788 ( 28 Geo. III. e. 30), under which licences for occasional per. 1788 ( 28 Geo. 11I. e. 30), under which licences for occasional per-

- For this reason it appears to hare been the custom in France for actors to be married onder ths name of musicians. See Hist Parlementare de la Revolu

forraances cight be granted ia general or quarter sessions for a poriod of not more thao sixty days. The rights of patent theatres were preserved by the prohibition to grant such a liceuce to auy theatre within 8 miles of a patent theatre. During this period (1737-1843) there were several decisions of the courts which confirmed the operation of the Act of 1737 as creating a monopoly. The exclusire rights of the patcot theatres wero also recogaized in the Music Hall Act of 1752 , and io private Acts dealing with Covent Garden and Drury lane, end regulating the rights of Tarties, the application of charitsble funds, \&c. (sce $16 \mathrm{Geo}$. . III. cc. 13,31 ; 50 Geo. III. c. cexiv; 52 Geo. Ill. c. xix; 1 Geo. IV. c. 1x.). The results of theatrical monopoly were beocficisl neither to the puilic dor to the momolists themselves. In 1832 a sulect committee of the House of Commons recommended the legal recognition of "stage-right" and the abolition of theatrical monopoly. The recommendations of the report as to stage-right were carried ont immediately by Bulwer Lytton's Act, 3 and 4 Will. IV. c. 15 (see Copyriglit). But it was not till 1843 that the present Theatre Act, 6 and 7 Yicl. c. 68 , was passed, a previous hill on the samo lines larving been rejected by the House of Lords. The Act of 1843 insugurated a more liberal policy, and there is now complete "free trade" in thestres, subject to the conditions imposed by the Act. The grewth of theatres since that time lias been enormous. In 1885 there were forty six licensed under the Act in London, Liverpool coming next with ten. Nor does the extension seem to have been attended with the social dangers anticipated by some of the witnesses before the commuttee of 1832.

The suppression of objectionable plays was the ground of many early statutes and proclamations. While the religious drania was dying out, the theatre was used as a vchicle for enforcing religions and political viers not always as orthodos es those of a miracle play. Thus the Act of 34 and 35 II en. V111. c. 1 made it crininal to play in an interlade contrary to the orthodox faith declared, or to be declared, by that monarch. Profanity in theatres seems to have been a cryiog cvil of the time. The first business of the Goverument of Elward VI. was to pass an Act reciting that the most holy and blessed sacranuent was named in plays by such rite and unsecmly mords as Christian ears alid abhor to hear rehcursed, and inflictiog fine and imprisonment upod any person adrisedly contemning, despising, or reviling the said most blessed sacrament (1 Eds. V1. c. 1). A proclanation of the same king in 1540 forbade the aeting of iuterlurles in English on account of their dealing with sacred subjects. In 1556 tho council called attention to certain lewd persons in the livcry of Sir F. Leke representing plays and interludes reffecting unon the queen and ber consort aid the formalities of the mass. The same queen forbade the recurrence of such a representation as the mask riven ly Sir Thomas Pope in honour of tho princess Elizabeth at Hatfield, for she "misliked these follies." By the Act of Uniformity, 1 Eliz. c. 2, it was made an offence punishable by a fioe of a bundred marks to speak anything in the derogation, depraving, or despising of the Book of Common Prayer in any interlades or plays. In 1605 "An Act to restrain the Abuscs of Players" made it an ofence punishable by a five of $£ 10$ to jestingly or profanely speals or use certaio sacred names in any stage play, interlude, slow, may-game, or pageant ( 3 Jac .1 . c. 21). In consequence of the appearance of players in the characters of the king of Spain and Goddomar, an ordinance of James I. forbade the representation on the stage of any living Christiau king The star chamber in 1614 fincd Sir John Yorka for representing a Catholic drama in lis house. The first Act of the reign of Charles I. forbade acting on Sunday (sce Susiday). Puritan opposition to the theatre culminated in the ordinance of the Long Parliament (seo vol, vii. p. 43.1). After the RestoraLion there are few royal proclamations or ordinances, the necessary jurisdiction being exercised almost entirely by parlizment and the lord chamberlain. One of the few post-Restoration royal procla. mations is that of February 25, 1665, restraining any but the company of the Duke of I'ork's theatre from entering at the attiriDg house of the theatre.
Preventive censorship of the rama by an officer of state dates from the reigo of Elizabeth, and is perliaps the only ciample of censorship of the press still existing io the United lingdom (see Press Laws). Such a censorship is not unkDorrn in other countries, and it seems to havo existed cren in renublican Rome, if ode may judge from Horace's line,-

Quad neque lo ede soneot certanta Judtec Tarpa."
The master of the revels appears to hare been the dramatic censor from 1545 to 1624 , when he was auperseded by the lord chamber. lain. In some cases the superrision was put into comraission. Thus with Til口ey, the master of the revils in 1531, were associated by order of the priry council a divine and a statesman. In other cases it was delegated, as to Daniel the poct by warrant in 1603. The proposal to give statatory anthority to the jurisdiction of the lord chamberlain led, as has been already stated, to the mithuraval of Sir Jolo Barnard's bill is 1735, snd to considerable debate before the bill of 1737 becanue law. Lord Chesterfield's objection to the bill in the House of Lords was Dot unreasonable. "If the ployers,"
said he, "are to be punished, letit be by the lawe of their country, sad not by the will of an irresponsible despot." The discretion reposed by the Acts of 1737 and 1843 in the lord chanberlaia has been, according to the report of a select committee of the House of Commons in 1866, on the whole wisely exercised. On the other hand, there have been instancee where perhaps both he and his subordinate officer, the examiner of stage playe, have been somewhat nice in their objections. Thus, during the illness of George III., King Lear was inhibited. George Colman, when examiner, showed an extraordinsry antipathy to such words as "heavon" or "angel." The lord chamberlain's powers are still occasionally exerte. in the interests of public decency, less frequently for political ressons. Before 1866 the lord chamberlain appears to have taken into consideration the wants of the neighbourhood before granting a licence, but since thet year such a course bas beco abandoned.

I'he existing law of theatres is mainly statutory. It will be convenient to trest it as it regards the building, the performsnce, and the liccasing of the building and of the performance. A theatre may be defined with sufficient accuracy for the present parpose as a building in which a stage play is performed for hire. It will be seen from the following sketch of the law that there are a considerable number of different persons, corporate and unincorporate, with jurisdiction over theatres. A consolldation of the fsw eeems urgently required, and the placing of jurisdiction in the hands of a central eutherity for the United Kingdom. The committee of 1866 recommended the transfer to the lord chamber lain of the regulation of all plisces of amusement, snd ap appeal from him to the home secretary in certain cases, as also the exten. sion of his authority to preventive ceasorship in all public entertainments; but no legislation resulted. Several bills for the amendment of the law have been recently introduced, but hitherto without success in the face of more burning political questions.

Building.-A theatre (st any rate to make it such a building as can be liconsed) must be a permanent building, not a mere tent or bootb, unless when licensed by justicos st a lawful fair by $\S 23$ of the Act of 1843. It must, if in the metropolis, conform to the regulations ss to structure contained io the Metropolitan Building Acts and the Metropelis Msnagement Acts, espocislly the Act of 1878 (4I and 42 Vict. c. 32). This Act makes a certificate of structural fitness from the Board of Works necessary as a condition precedent for licence in the case of all theatres of a superficial sreas of not less than 500 square feet licensed after the passing of the Act, gives power to the bosrd in certain cases to call upon proprietore of existing theatres to remedy structural defects, and enables it to make regulations for protection from fire. Such regulations were issued by the board on May 2, 1879. As to theatres in provincial towns, the Towns Improvernent Act, 1847, and the Public Health Act, 1875, confer certain limited powers over the building on municipal cofporations and orban sanitary authorities. In nany towns, however, the structural qualifications of buildings used as theatre depend upon local Acts and the by laws made under the powers of such Acts. To a more limited extent the rules inade by junstices may enforce certain structural requirements.
Performance.-To constitute a building where a performance takes place a thestre, the performance must be (a) of a stage play, and (b) for hire. (a) By $\$ 23$ of the Act of 1843 the word "stageplay" includes tragedy, comedy, farce, opera, burletta, interlude, melodrama, pantomime, or other entertaioment of the stage, or any part thereof. The two tests of a stage play appear to be the excitement of emotion and the representation of action. The question whether a performance is a stage play or not seems to be one of degree, sad one rather of fact than of lav. A ballet d"action weuld usually be a stage play, but it weuld be otherwise with a ballet divertissement. \& 14 empowers the lord chamberlain to forbid the acting of any stage play in Great Eritain whenever he may be of opinion that it is fitting for the prescrration of good manners, decorum, or the public peace to do so. § I5 imposes a penalty of e50 on any one scting or presenting a play or part of a play after such inhibition, and ayoids the licence of tha thedtre where it appears. Regulations of po.ice respecting tho performance are contanised in 2 and 3 Viet. c. 47, and io many local Acts. A performance may also be proceeded against as a nuisance at common law, if, for instance, it be contra bonos mores or draw together a great concourse of vehicles, or if so much noise be heard in the neiglbburhood as to interfere with tho ordinary occupations of life. Vely curious instances of proccedings at common law are recorded. In 1700 the grand jury of Midulesex presentcl the tro playhouses and also the bear-girden on Bankside (the "Paris garden" of Henry VIII., 8"t v. sc. 3) as riotous and disorderly nuisances. In 1819 certain players Fere prosccuted and convicted before the court of great sessions of Wales for acting indecent open-air interludes at Berriew in Montgomeryshire. Performances on Sunday, Good Friday, and Cluristmas day are illegal (see Sunday). Regulations as to the salo of intozicating liquors during the performance are made Ly tha Licensing Acts and other public general Acts, as well as by local Acts and rulcs made by justices. It is frequently a con-
dition of the licence granted to provincial theatres that no excleeable liquors shall be zold or consumed on the premises. The Children's Dangerous Performances Act, 1879 ( 42 and 43 Vict. c. 34), foroids under a peaalty of $£ 10$ say public exhibition or par. formance whereby the life or limbs of a child under the age of fourtecn shall be endangered. It also makes the employer of any such child indictable for assault where an accident causing actual bodily harm has happened to the child, and enables the court of conviction of the employer to order him to pay the child conpensa. tion not excceling $£ 20$. (b) The perfermsnce must be for hire. § 16 of the Act of 1843 makes a building one in which scting for hire takes place, not only where money is taken directly or in. directly, but also where the purchsse of any article is a condition of admission, and where a play is performed in a place in which exciseahle lifuor is sold. In a recent case of Shelley v. Bethell (Law Reports, 12 Queen'e Beach Division, 11) it was held that the proprietor of a private theatre was lisble to penalties under the Act, though he lent the theatre gratuitously, becsuse tickete of admission were sold in aid of a charity.

Licensing of Building.-By $\$ 2$ of the Act of 1843 all theatres (other than patent theatres) must be licensed. By $\S 7$ no licence is to be granted except to tho actual and responsible manager, who is to be bound by himself sad two aureties for due observance of rules and for securing payment of any penalties incuried. The metropolitan theatres other than the patent theatres (es for at least as they are included in the boroughe named in the Act of 1843) are ricensed by the lord chamberlain. By $\$ 4$ his fee on grant of a license is not to exceed 10s. for each month for which the theatre is licensed. The lord chamberlain appears to have no power to make suitable rules for enforcing order and decency. Ho can, however, by $\S 8$, suspend a liceace or close a patent theatre where any riot or misbehsviour bas taken place.
Provincial theatres fall under three different licensing anthorities. The lord chamberlain licenses thestres in Windsor and Brighton, and theatres situated in the places where the queen occasionally resides, but only during the time of such occasional residence (§ 3). Theatres at Oxford and Cambridge, of within 14 miles thereof, are licensed by the justices having jurisdiction therein, but b-fcee any such licence can come into force the consent of the chancellor or vice-chancellor must be given. The rules made by the justices for the management of the thestre are subject to the spproval of the chancellor or vico chancellor, who may also impose such conditions upoa the licence ss he thinks fit. In case of any bresch of the rules or conditions, he may anuul the licence (§ 10). All other - proyincial theatres are licensed by four or more justices at a special session held within twanty-one days after application for a licence shall have been made to them (§5). The fee is not to exceed 5 s . for each month for which the theatre is licensed (§ 6). The justices, like the lord chamberlsin, sppear to have no discretion as to grant. ing a licenco. Their act is purely ministerial and confined to ascertaining that the applicant is the actual snd responsille manager, add that he and his sureties are of sufficient substance to provide the requisite bonds. § 9 gives the justices authority to make at the special session suitable rules for enforcing order and decency at the theatres licensed by them, and of rescinding or altering such rules at \& subsequcut special session. It also gives a secretary of state power to rescind or alter such rules, sud to make other rules. In case of riot or breach of the rules, the justices may order the theatre to be closed, and it thereupon becones an unlicensed house. Penalties are imposed by the Act for keeping or acting in an unlicensed theatre, and for producing or acting in ca unlicensed play.
Licensing Performance, - A stage play must be duly licensed before performance. § P2 of the Act of 1843 prescribes that a copy of every new play and of every addition to an old play, and of evers vaw prologue or epilogue or addition thereto (such cony to bi signed by the master or manager), shall be sent to the lord cham. berlaiu, and, if the lord chamberlain does not forbid it within seven. days, it may be represented. § 13 empowers the lord chamberlain to fix a scale of fees for examination; the fee is now two guinea. for a play of threc or more acts, one guinea for a play of less thar three acts. All plays represented previously to the Act are held to be licensed. A play once liceased is licensed once for all, unless the licence be revoked under § 14. Tha examination is the duty of a special officer of the lord chamberlsin's department, the examiner of stage plays.

Music Halls.-Music was at nu time the object of restrictione as severe as those imposed upon the drama. The present Music Hall Act ( 25 Geo. II. c. 36) was passed in 1752, probably in consequence of the publication in 1750 of Fielding's Inquiry into the Causes of the late Increase of Robbers. It is remarkalle that two works of the sams writer should from opposite causes have led to looth theatre anll music hall legislation of lasting importance. The Act was originally. passed for a term of three years, but was inade perpetual by 28 Geo. II. c. 19. It applies ouly to masic halls within 20 miles of London and Westminster. Every such music hall must be licensed at the Michaelmas quarter sessions, the licence to be signified undes the
hands and seals of four or more jnstices. The licence may be granted for music or dancing or both. Public notice of the licence is to be given by affizing over the door the inscription "Licensed pursuant to Act of Parliament if the twenty-fifth of King George the Second." The penalty for keeping an unlicensed music hall is f100. Music balls beyond the radius of 20 miles from London and Westmiuster aro usually governed by local legislation, which in most cases follows, mutatis mutandis, the lines of the Act of 1752. The music hall, like the theatre, must generally fulfil certain structural requirements. In one important respect the law is more lenient to the music hall than to the theatre?. A licence is necessary for a single performance of a stage play, but it is only babitual music or dancing that requires a misic hall licence.

Scolland. - In Scotland the theatre has always exercised a smaller amount of influence than in England, and there bas been little exclusively Scotch legislation on the subject. An Act of 1555 , c . 40, disconntenanced certain amusements of a semi-theatrical kind by enacting that no one was to be chosen Robert Hudo (sic), Little John, abbot of Unreason, or queen of May. A proclamation of James VI. in 1574, and an Act of 1579, c. 12, followed the lines of English legislation by making persons using nulawful plays, such as jugglery or fast and loose, punishable as vagabonds. In 1574 the General Assembly claimed to lieense plays, and forbade representations on Sunday. As in England, tho licensing power seems then to hare passed from the church to the crown, for in 1599 James VI. licensed a theatre at Edinburgh. The Act 1672, c. 21, exempted comedians while upon the stago from the sumptuary prorisions of the Act respecting apparel. The chamberlain of Scotland, while such an office existed, appears to have exercised a certain police jurisdiction over theatres. The Theatro Act of 1843 extends to Scotland, as did also the previous Act of 1737.

Ireland.-Theatrical legislation, as far as it went, was based upon English models. Thus ridicule of the liturgy was forbidden by 2 Eliz. c. 2 (lr.); common players of interludes and trandering minstrels were deemed vagabonds, 10 and 11 Car. I. c. 4 (lr.). In 1786 an Act was passed to enable the cromn to grant letters patent for one or more theatres in Dublin city and county, 26 Geo . III. c. 57 (1r.). The preamble alleges that the establishing of a well-regulated theatre at the seat of government will be productive of public advantage and tend to improve the morals of the people. Exceptions from the restrictions of the Act were made in favour of entertainments for the benefit of the Dublin lying-in hospital and exhibitions of horsemanship or puppet-shors.

United States.-Public entertainments, dramatic or otherwiso, are usually under the control of the minicipal authorities. In some States, such as Nen York and Massachnsetts, there is State legislation, requfring places of public entertainnuent to bo licensed by the proper authority. In many States it is a condition of the licence that intoxicating liquors shall not be sold in such places. Other conditions, more or less usual, are that there shall be no Sunday or dangerous performances, that acrobats shall be properly protected, and that female waiters shall not be employed. Structural qualifications are in some cases made necessary. Thus in 1885 the New York legislature passed an Act containing many minute provisions for ensuring the safety of theatres against fire. A characteristic piece of legislation is the New York Act of 1873 , c. 186 , enacting that no citizen is to be excluded from a theatre by reason of race, culour, or previous condition of servitude. This Act of course merely carries ont the important principle affirmed in art. xiv. of the amendments to the constitution of the United States. See Privileoe,
The most recent If not the only work on the law relating to theatres is Geary's Law of Theatres and Music Halls, 1885.
(J. W†.)

THEBES. See Egypt, rol. vii. p. 776 sq.
THEBES (anciently Ô̄ßah Thebæ; or in puetry sometimes $\Theta_{\eta} \beta a$, in modern Greek Phiva, or, according to the corrected pronunciation, Thivx), one of the most interesting towns in Greece, is situated on low hilly ground of gentle slope a little north of the range of Cithæron, which divides Boeotia from Attica, and on the edge of the Boootian plain, about 44 miles from Athens, whence it is now reached by two carriage-roads. It has about 3500 inhabitants, and is the seat of a bishop. The present town occupies the site of the ancient citadel, the Cadmea; two fragments of ancient wall are visible on the north, and another, belonging either to the citadel or the outer wall, on the south. Two streams, rising a little south of the town, and separated by an average distance of about half a mile, flow on the two sides, and are lost in the plain. These are the ancient Ismenus on the east and Dirce ( $\Delta^{\prime} \rho \times \eta$ ) on the west, which gave to the town its name S.rórauos. The Dirce, now Platziótissa, has several
spring. From the west side of the Cadmea another copious fountain (Paraporti) falls to the Dirce. In a suburb to the east is another (Fountain of St Theodore), and north-west are two more. The Cadmea itself is supplied with water brought from an unknown source to the south by works supposed of prehistoric antiquity. It now enters the town by an arueduct of twenty arches of Frankish construction. The "waters" of Thebes are celebrated both by Pindar ana by the Athenian poets, and the site is still, as described by Diczarchus (3d century
 pasha of Negroponte (Euboea) is said to have supplied his table, is still called "the spring of the cadi." Some of the marble basins, seats, \&c., remain, and, with the fragments of wall above mentioned, are the only relics of the classic time. The most curious of later briildings is the church of St Luke, south-east of the Cadmea, believed to contain the tomb of the evangelist. From the abundance of water the place is favourable to gardens, and the neighbouring plain is extremely fertile. But the population is scanty, and the town at present of no inportance.
In prehistoric times the Cadmea, with the enlarged city of Thebes into which it developed, was a power of the first rank, as is shown by its unrivalled legends. More particularly the mythical wars with Argos (see below) point to a time when the "Hellenes" of North Greece were still contending unequally against the "Achæans" of the Peloponnesus. In the legend as given by Eschylus these names are accurately preserved. At the beginning of continuous history (6th century. B.c.) Thebes had long been possessed by immigrants from Thessaly, who knew the previous inhabitants as Cadmeans ( $\kappa \mathbf{\alpha} \delta \mu \epsilon i \mathrm{o} t$ ).

The history of the town to the end of the 4th century is part of the general history of the nation (see Greece). It had an aristocratic constitution, and claimed a contested sovereignty over the other towns of Beotia. Down to 371 B.C. this status was not essentially changed. The battle of Coronea (394) showed the increasing military strength of the Thebans, and in 371 the genius of Epaminondas raised them by the victory of Leuctra for a brief period to the leading position in Hellas. Philip of Macedon spent part of his youth as a hostage at Thebes, and probably learnt there important lessons in mar. By him and his successor the state was destroyed. In 338 the Thebans shared with the Athenians the defeat of Chæronea, and received a Macedonian garrison; the lion-monument erected by them on the field of battle, and still existing there, though in fragments, is a more impressive memorial of their greatness than anything now visible at the town itself. In 335, after the death of Philip, they revolted, and were punished by Alexander with a fearful rengeance. It is said that 6000 Thebans were slain at the capture and 30,000 taken prisoners. The population was dispersed, and the town entirely razed (except, according to tradition, the house of the poet Pindar); and, though it was soon restored by the Macedonian Cassander (315), it never again played a leading part in history. In 86 b.c., having sided against the Romans in the Mithradatic war, it was plundered by Sulla, and fell into such decay that Strabo describes it as little better than a village. In the $2 d$ century the traveller Pausanias, who gives a full account of it (ix. 5 sq.), found only the citadel inhabited. In 395 A.d., however, it had some strength, for Alaric, on his way to the capture of Athens, did not think fit to attack it. In the later times of the Eastern empire (10th to 12 th century) it again became wealthy and important, being specially celebrated for the manufacture of silk and cloth. In 1143 it was plundered by the Normans of Sicily (who transferred thither the chief artisans of the silk trade). and, after the capture of Constantinople by
the crusaders (1204), became with Athens a fief of the feudal empire. In 1311 it was again plundered by the Catalan Gtrand Company, a body of Spanish mercenaries, and appears to have had no return of prosyerity.
of more lasting effect than the politics of Thebes have been ita legends. Beootia, or rather the Cadmeis (Thucyd., i. 12), was a land of poetry from extremely ancieut times, and the stories of Thebes are in Greek literaturn as inportant as those of Troy. The legends of the five chicf groups will be found under the names indicated in the fellowing division:-(1) the foundation of the Cadinea by Cadmus; (2) the foundation by Amphion, -to this belong originally the "seven-gated" wall, the name of intrduv入os Өispn, and the legends of Zethus, Antiope, and Dirco; (8) war of the "Seven" (under Adrastus of Argos); war of the Epigoni, or "descendants" of the Seven ; the story of Cdipus ; (1) legends of Bacchus,-at Thebes as elsewhere this religion was conpraratively late, but becanne characteristic of the town ; (5) legends of Heracles (commonly found with those of Bacclus; Theles was repnted the birthplace of both). Fron the eric poems, of which littlo but titles remain, these tales descended to the Attic tragediens ; upon them are fonnded the Scven agaiust Thcbes of Esclyylus, the CEtipus Tyrannus, Cdipus Coloncus, and Autigone of Sophocles, the Phanisse, Supplics, and Bacche of Euripidas, \&cc., with innumerable nlaye not extant. Apart fron direct imitation of theso works, the stories themselves, throngh Statius, Boccaccio, and others, have exercised a great influence on nodern literature. In historical times the Thebans were not conspicuous for intellectual accomplishments, but their reputation is sufficiently sustained by Finder, perhlps the most distinctively Hellenic of all the national poets.

The most famous monument of encient Thebes was the outer wall with its seven gates, which even as late as the 6th contrify B. © was probably the largest of $x$ Ertificial Greek fortresses. The names of the gates vary, but fur are constant, - the Preetides, Electre, Ncistaz or Noite, and Hemoloides; Paussnias gives the others as Ogygia, IIjpsiste, Crenax. There is evidence that the gato Electray was on the sonth, and near it was the tomb of the Thebans whe fell at the capture by Alexander. The gates shown to Parsanias as Niciste and Proetides led respectively north-west and north-east. Two of the springs have been identified with some jrobatility, 一that of St Theodore with the Edipncles, in which ©edirus is ssid to have purged himsolf from the pollu'tion of homicide, and the Parapntti with the dragen-guarded fountain of Ares (sce Cadmus). Dicmarchus, referring to tho town of Cassander, gives two measurements for the circuit, equal to about 9 miles an 151 miles, but even the smaller is impossible for the wall, and they probzbly $1 e$ fer to the terxitory proper of the town, or $\gamma \hat{n}$ enßals. Beyond this the topography is wholly uncertain. From the interest of the site in history and still more in literature, as the scene of so many dramas, the temptation to fix details has been specially strong. Conjectural plans or descriptions, diflering widely, are given by Leake, Forchhammer, Ulrichs, Bursian, and others (references below). All are based on the assumption that the description of Pausanias and the allusions of the Attic tragedians may be read together and combined, and that the result will give the plan as it existed in the 5 th and 4th centuries b.c. Bat to this two objections must be taken. (1) The account of Pausanias, even when clear in itself, is very nucertain eridence for anything earlier than tho destruction by Alexander. It is said indeed that the restored town occupied the amree area, but this is consistent with great disturbance of tradition ; and wo have further to allow for inaccurato transmission through 450 years of decadence, and finally for the quality of Pansanias's information, given apparently by casual guides to a travelier extremely uncritical. (2) It may be doubted whether the tragedians had accurate know. ledge of Theban tepography, and they had certainly no reason for introdncing it in their plays. Their ylota are laid in a remote pest ; and it is difficult to suppese them on the ono hand so careful as to fit their scenes to the actual Thebes, and on the other hand so careless as to presume tliat it had suffered no great changs between the times of Cadmus or of ©Edipus and their own days. . Indeed they did not make this mistake. The plays which contain most references to topograpby are the Scven against Yhcbes and the Phenissa. In the Seven the name of "Thebes" does not occur at all (the title is a misnomer, probably net given "by the author); the town is called by its ancient name "The Cadmea" (Kaঠцelá $\pi \delta \dot{\lambda}(5)$, and the whole play assumes that the "city of Cadmms" was much emaller than the Thebes contemporary with Æ.schylns can bave been. In the Phomissa the circnit of the walls is said to be so small that a porson within must neeesearily know all that had taken place in a general attack (v. 1356). None of the conjectural plans wonld ap proximately aatisfy this" nor can it have been true for the time of. Euripides. After this, it is not surprising so find that the attempt to use the plays as evidence is involved in nnanower:ad difficulties, \& few of which are given below.

In itsalf, however, and as relating to the rnins of the restorea town merely, tha description of Pausanius is carions und interestingThe princinsl buildings were at that tims (2d century) the temple of Apollo Ismenius, which must have stood somewhere ebont the present church of St Luke, tho theatre, neax the gate Proetides, the Heracleum, with a gymnasium and face-course, and the temples of Artemis Eucleia, of Ammon, and of Fortune (Túxŋ). Besides these Pousanias was shown all the gatos, all the legendary sites, the house of Pindar (north-west beyond the Dirce), statues, \&c., dedicated by him, several statnes of immeuse antiquity, others attributed to the greatest artists, aud in fact much more than it is easy to believe.

1. Apollo Ismenits and Apollo Spodius. - Sophocles (E. T., 21) mentions, as one of the Theban sanctuaries, "the oracular ashes of Ismenns," 'I $\sigma \mu \eta \nu 0 \bar{\vartheta} \mu \alpha \nu \tau \in\{\alpha, \sigma \pi \delta \delta o s$. Pausanias, who calls the river' not Ismenus but Ismenius, deseribes (1) a temple of lsmenius or Apollo Ismenius (ix. 10, 2), and (2) an altar of Apollo Spodins, made of ashes and used in a peculiar manner as an oracle (iz. 11, 7). Wo should suppose from Sophocles that hoth observations related to the same sanctuary; and Sophocles clearly identified the two. But in Pausanias they ara in different plsces and have uo connexion at all. Either therefore the topography and ritual of tho one peried differed from those of the ether, or, which is equally prohable, the poet used Theban names withont regard to accuracy.
2. The Fountain of Ares.- Euripides, in the Supplices (v. 650 sq.), describes an army adrancing on Thebes from the south as having its right at the Ismenian hill, its left at the fountain of Ares, and "the chariots below the momument of Amphien." Pausanias also places the Ismenian hill on the right of the southern gate. But the fountain of Ares he places on the samo side, a description quite inconsistent with this and other allusions. Ulrichs, While insisting ou the agreement about the hill, nerely observes on this that Pausanias is unintelligible, Of a still greater difficulty he saye nothing. The tomb of Amphion is placed by Eschylus north of the town, and there or in thet direction was show18 to Pausanias. The tnjegraphers accerdingly suppose that the "chariots" of Euripides were in the plain to the north. But there is no suggestion in the passage that any part of the advancing army was separated from thio rest, and the observer expressly says that he was at the prace where the chariots forght and had a particularty good vicw of this part of the battle (r. 681). Now be stood on the gate Electre, i.c., as far as possible from the tomb of Amphion, as placed by Rschylus and Pausanias. It is impossible to make a consistent account of this, and it seems plain that Euripides took up the name "tomb of Amphion" at hazard, an!! ignored or forgot that the real toun could not be brought into his picture.
3. The Altar of (Athena) Onca.-This was shewn to Pausanias (ix. 12, 1), who was teld that it marked the place where the lying down of a cow indicated to Cadmus the sito destined for his city
 acropolis there was formerly the house of Cadmus (Káspou oikio)." No other indication is given as to the place of the altar, and the natural inferonce is that it was shown in the Csdmea. But ISchylus (Septemb, 501) places it outside the walls. Accordingly it is suggested that the oracular sign only indicated the newich hourhood of the destined site, and that the altar shown to Pausanins wasnear that of Apello Spodius, which is mentioned lost before it, and may lhase been outside the mall. But this juxtaposition provee nothing about the place of Onca, for Pausanias himself shows that mention of Onca here is suggested by a reference to "oxen" irs connexion with the altar of Slodius. which breught to his mind the "cow" of the other legend.

The Tontb of Amphion and Zcthrss.-Apart from the confusion of Euripides already noticed, there is a difficulty abont the mention of this moumment in Pansanias and Eschylus. Parsanias, after describing several buildings near the gato Prcetides, concluding with somo in the inarket-place, mentions next (without further indication of flace) the tomb of Amphion and Zethus, and continucs thus, - " the way from Thebes to Chalcis (northeeast) is by this gate Proctiles, \&c.". Fschylus places the tomb of Amplhien outside the wall opposite the north gate (Scptem, 527), and the Preetides elsewhere. Ulrichs coueludes .llat Pausanias "evidently" went out by the north gate to view the monument and then returned to the Proetides. Of conrse this is possible, but it is useless to draw exact inferences from documents which require such an hypothesis. It is equally probable that Pausanias ideutified the tomb with a monnment called the Amphcion, which secms (Ulrichs, p. 17) to have been somewhere near the market-place. Indeed, there is no proof that they wers not identical, for the. only evidence that the tomb Was outside the wall (and therefore diferent from the Ampheion) is that of Eschylus and Euripides, whose imaginary cities were not much larger than the Cadmean hill, and must have excluded the Ampheion itself.

THECLA, ST, virgin, is commemorated by the Latin Church on September 23. The Breviary relates that sho was boru of illustrious pareatage at Iconium, and came under the personal teaching of the apostle Paul. In her eighteentli jear, having broken ber engagement with Thamyris, to whom she had been betrothed, she was accused by lher relations of being a Christian, and sentenced to be burned. Armed with the sign of the cross, she threw herself upon the prre, but, the flames thaving been extinguished by a sudden rain, slac came to Antioch, where she was exposed to the wild beasts, then fastened to bulls that she might be torn asunder, then thrown into a pit full of serpents, but from all these perils she mas delivered by the grace of Christ. Her ardent faith ead her boly life mere the means of converting many. Returning once more to her native place, she withdrew into a mountain solitude, and becaroo distinguished by many virtues and miracles, dying at the age of rincty. She was buried at Seleucia.
The substance of the foregoing narrative, with many other curions incidents, occurs in the sery ancient apocryphal book entited the $\pi$ epobsoc of Paul snd Thecla (Acta Pauli et Thecles). Tertullian tells us that this work wes written by a presbyter in Asia, "out of love to Paub," but that his condoct was not aprrored, and led to his deposition. What caused special offence was its recombition of the right of romen to preach and baptize. There is no doubt that the rresent differs rery considerably from the original form of the Acla, but even now its Gnostic origin is betrayed in several features wh:ch it atill retaius-for example, the rejection of marrisgc. For tho text, see the Acta Apos?', Apoor. of Tischendorf, who in the Prolegomeca gives a large body of exidence for its great antiquity a translation is given in the Ante-Nienc Christian Libram.
THEFI is, in modern legal systems, unirersuly treated as a crime, but the conception of theft as a crime is not no belonging to the earliest stage of lam. To its latest period Roman law regarded theit (jurtum) as a delict prima fucie pursued by a civil remedy,- the actio furte for a penalty, the vindicatio or condictio for tho stolen property itself or its value. In later times, wo doubt, a criminal remedy to mett tla graver crimes eradually grew up by the side oî the civil, and in the timo of Justinian the criminal renieds, where it existed, took precedence of the civil (Cod., iii. 8, 4). But to the last criminal proceedings could only bo taken in serious casce, c.g., against stealers of cattle (atigui) or the clothes of bathers (balncarii). The punishment was death, banishment, or labour in the mines or on public norls. In the main the Roman law of theft coincides with the English law. The definition as given in the Instizutes (iv. 1, 1) is "furtum est coatrectatio rei frandulosa, rel ipsius rei, vel etiam ejus usus possessionisve," to which the Digest ( $\mathbf{x} 1 \mathrm{vii} .2,1,3$ ) adds "lucri faciendi grotia." The earliest English definition, that of Bracton (150l), runs thus: "furtum est secundunt leges contrectatio rei aliens fraudulenta cum animo furandi inrito illo domino cujus res illa fuerit." Bracton omits the "lucri faciendi gratia " of the Roman defit tinn, becausu in English law the motive is immaterial, ${ }^{1}$ and the "usus ejus possessionisre," because the definition includes au intent to deprive the owner of his property permanently. The "animo furandi" and "invito domino" of Bracton's defnition are expansions for the sake of greater clearness. They scem to have been implied in Roman law. Furtum is 0:2 tho rhole a more comprebensive term than theft. This diffurence no daubt arises from the tendency to extend the bounds of a delict and to limit the bounds of a crime. Thus it was furtum (but it would not be theft at English coinmon law) to use a deposit of pledge contrary to the wishes of the owner, to retain goods found, or to steal a human being, such as a slave or filius familias (a special
