ever, ara but few in number: the large cats of South America are said to be able to tear them out of tha shell with their claws; and the ancient tale of Eschylus baving been killed by a tortoise carried aloft by an eagle and dropped on the head of the unfortunata poet seems to be founded on the fact that tortoises are a favourite prey of the Lämmergeyer (Gypactus), which has the habit of dropping them from a height on rocks in order to break the shell. On tha other band, among the carnivorous terrapins and freshwater turtles instances of protective resemblance are not scarce, and may even attain to a high degree of specialization, as in Chelys; their shells offer them less protection, and their enemies (crocodiles and alligators) ara more numerous; they also requiro this special provision to enabla them to approach or seize their prey with greater ease. The colours of land tortoises are generally plain or in simple patterns, whilst those of many terrapins are singularly varied, bright, and beautifnl.

Chelonians are diurnal animals; only a few are active during the night, labitually or on apecial occasions, as, for instance, during oviposition. Land tortoises are slow in all their novements, but all kinds living in water can exacute extremely rapid motions, either to seize their prey or to escape from danger. All Chelonians are stationary, residing throughout the year in the samelocality, with the exception of the marina turtles, which periodically migrate to their breeding stations. Species inhabiting temperate regions hibarnate.

Chelonians possess great tenacity of life, surviving injuries to which other Reptiles would succumb in a short time. The beart of a decapitated tortoise continues to beat for many hours after every drop of blood has been drained from the body, and the muscles of the trunk and head show signs of reflex action twenty-four hours after the eeverance of the spinal cord. The longevity of tortoises is likewise a well-known fact, to which reference will again be made.

Land tortoises, a few terrapins, and some of the marine turtles are berbivorous, the othera carnivorous, their prey consisting cliefly of fish, frogs, and other small aquatic animals.

All Cbelonians are oviparous, and the eggs are generally covered with a hard shell.

In the system ${ }^{3}$ proposed by Duméril and Bibron, and afterwards modified by Gray and Strauch, the Chelonians are arranged according to their mode of life, and divided into terrestrial, paludine, fluviatile, and marine forms. However natural such an arrangement may appear at first, a more carcful examination proves it to be (as all arrangements based solely upon the inode of life) at variance with the atructural affinities, whetber the recent forms alone be considered or the fossil as well. The division of the bulk of the order into Cryptodira and Plewrodira, as suggested by Agassiz, Cope, and Ruitimeyer, was a decided progress, as is also the elimination of the suborders Atheca and Trionychoidea recently proposed by Cope and Baur.

The order of Cbelonians may then be divided into the following suborders and families: ${ }^{2}$ -

Suborder I. ATHEC.E.
Vortebre and ribs free, sepsrated from a bony exoskeleton. Family ${ }^{-1}$. Sphargide
Limus paddle-shaped, clawless ; phalanges without condyles. Plastron reduced to an annular series of eight emall bones. Exookeleton consisting of numerocs small bony plates arrenged like mosaic. Pelagic.

Gemus: Dermalochelys (Sphargis).
Fossll genera: Paophophorus (Pllocene), Protosphargis (Crctaceous), Protostega (Cretaceous), Psephoderma? (THassle).
${ }^{1}$ The more important works on this order of Reptiles hnve been enumerated in the article Reptiles, vol. xx. p. 440.
${ }^{2}$ Only the more imporlant and best known of the extinct genera are admittel] Into this synopsis.

## Subonder II. TESTUDINATA.

Dorsal vertebre ancl ribs immovally united and expandel into boo" plates forming a carapace, which is bordered by a complete serie., of marginal bones. Epiplastra (clsvicles) in contact with hyoplastra; entoplastron (interclavicle), if present, ovsl, rhom boidsl, o: T-shaped. Sacral and caudal ribs articulating with the ceutrun and the neural arch! Digits with not more than three phalanges.

## Selies A. cryptodira.

Neck retractile by a sigmoid curvo in s verticsl plane. Pelvis not anchylosed to the carapace and plastron. Rarely ono or two epidermic scutes (intergular) in addition to the pormal six pairs.

Grour A. Digitata.
Digits slont or moderately elongate; rhalanges with condyles; claws four or five. Neck completely retractile.

## Family 1. Testedinide.

Plastral bones nine. Nuchal bone withont costiform processes. Carapaco with epidernic sentes. Candal vertebre procuelons. Tropical and temperate zones, with the exception of Anstralia.

- Recent Renera: Dermatemys;, Bntogur, Clemthys, Prangshura, Geoemyda, Cycle. mus. Envs, Cistruio, Manourlia, Testudo, Homopms. Cinyris, Pyris.
Fossil Eencta: Eurysternum: (Jurassic), Chitracephafus '(Cietaceous), Adocus (Cretrecolis), Palroochelys (Milocene), Pivchogaster (Miocene), Colossochetys (Plocene).

## Family 2. Platybtebnide.

Plastrsl bones nine $\approx$. Nuchal bone without costiform processos. Carapaco with epidormic scutes. ., Candal veriebre nostly opisthocelous. Indian region.

Gerus: Platysternum.,

## Family 3. Baenide.

Plastral boucs eleven, mesoplastra being present. Nuchal bone without costiform processes. Carapace with enidermic scutes. Candal vertebre opisthocrelous.
Fosoll genera: Platychelys (Jurassic); Buena (Eocene)

## Family 4. Cuelydride.

Plastral bones nine. Nuchal bone with long costifnem processes, oxtending below the marginsls. Carapace with epidermic scutes. Caudal vertebre mostly opisthocelous, Northeru and trapical Anerican regions.

Kecent genera: Chelydra, Macroclemimys
Fossil genus: Tietosternum (Crelaceous).
Family 5. Staunotypade (Eulenger).
Plastral bones nine. Nuchal bono with short costiform processes, exteneling below tho marginals. Carapaco with epilemmic scutes. Caudal vertebre procœlors. Central-Amcrican district. Genera: Staurotypus, Claudius.

## Family 6. Cinosternide

Plastral bones eiglit, the entoplastron being alsent. Nuchal bene with short costiform processes, extenling below the marginals. Carapace with epidarmic scutes. Caudal vertebra procelous. Northern and tropical Anerican regions.

Goners: Aromoclielys, Cinosteriuии.
Frmily 7. Psetdotrionychide (Boulenger).
Shell without epidermic scutes.
Fossll geucra : Pscuddrioniyx ond Anostira (Eocrne).

## Grout B. Pinnata.

Limbs paddle-shapel; phalanges withont condyles; claws ono or two. Neck imperfectly retractile; cervical vertebre_short. mostly articulated by amphiarthrosis.

## Family 8. Chelonide.

Plastral boncs nine. Nuchal without costiform processes. Carapace with epilermic sentes. Hyo-and hypo-plastra not meetsug mesially.". - Pelagic.
liceent menerd. Chelone, Caonmat, Carella.
Fossil genus: Puppigerus (Miocen' and Eocene)
SEhifs P. PLEURODIRA.
Neck not retractile, bending laterally. Pelvis ancliylosed to the carapree and phatron. When epidermic scutes are present, one or tivo intergulars in addition to the normal plastral scntes.

## Family 1. Chelydides

Plastral bones uine. Carspnce with enidermic scutes. Limbs with four or five claws. Australian and tropical Anerican regions.
Recent geners: Platenys, Chelymys, Elseya, Cheiodina, IIydraspis, Ifydromedusa, Chelys.
Fossij gunels: Plesiochelys (Jarassic), Craspedochelys (Junassic), Idiochelys (Jurassle), Volonorpha (Eiocene).

## Fanily 2. Pelomeduside

Plastral bones eleven, mesoplastra being present. Carapace with epidermic scutes. Limbs with four or five claws. African ond tropical American regions.
Recent gener's: Pelontedusa, Stemotharus, Dumerilta, Podocnenis, Pello. eephalus.
Fossil genera: Pleu"osternum (Cretaceons, Eocene), Bolhremys (Cretsccons), Taphrosphys (Cretaceous).

## Finily 3. Carettochelfotdos.

Plastral bones nioe. No enidermic sentes on the ohell. 2 Limby pacldla-shaped, with only two claws. New Guinea.
Genus: Carellochelys.
Family 4. Molaviide (Boulenger).
Candal vertebre opisthoccelous; tail long sud encased in a bony sheath. Australia.
Fossil genus : Miotania (Pletstocene).

## Sudohder III. TRIONYCHOIDEA.

Dorsal vertebre and ribs immovsbly united, forming a carapace; no 1 Ygal plata; marginal plates absent or forming an incomplete series. Plastron formed of nine bones, epiplastra separated-from the hyoplastra by the eutoplastron, which is $\Lambda$-shaped, without longitudinal process. Sacral and caulal ribs attached to trensverse processes of the neural arch. Fourth ligit with ${ }^{\text {four or five }}$ phalanges.

Family 1. Trionychide.
No epidernic sentes. Lionbs with three elaws. Indian, African, and American regions.
Genera : Chitra, lleptathyra, Trionyr, Cyctanostens, Emyda.
We add a few notes on such of the genera enumerated in this synopsis as have some special interest attached to them, either from a scientific or an ecunomic point of view,

The fanily Sphargide is represeuted in the recent fauna by a single species, Devmatochclys or Sphargis coriacca, the Leathery Turtle, the range of which extends over the tropicsl snd subtropical exas of both hemispheres, and which occasionally strays into tho northern parts of the Atlantic, its occurrence on the British coast having been recorded three or four times within the last century. It diflers from all other Chelonians by its rarapace being formed by ossifications of the skin only. Neither the vertebre nor tbe ribs enter intn its formation; the latter remain free, and are not particularly dilatecl. During the life of the amimal the carapace is Hexible like thick leather, tho Lony deposits being arranged liko mosaic, with several longitnelinal ridges of larger osseous tubercles. The limbs are, as in other marine turtles, padule-or fin-ehaped, the anterior much longer than the posterior, and all destitute of claws. This turtle is probably the laigest living Cbelonizn, exceeding 6 feet in length. The names Testudo lyna, Sphargis mercurialis, \&c., have referenco to the myth that the shell of this or some other turtle was used by Mercury in his construction of the lyre.
The fanily Tcstudinidre is composed of an unbroken series, from thoronghly aquatic freshwater tortoises like Dcrmatemys and Batagir to tho tortoises which live exclusively on land and are perfectly helpless in water. In the Central-American genus Dermatemys the digits are very broadly webbed, the epidermic scutes are thin, and the nose is much produced, -characters which, together with the strong depression of the shell, give these terrapins some. what the aspect of the freshwater turtles or Trionychides. Tbey feed exclusively unou leaves, grass, and especially fruit, and are eaten by the natives. Of the freshwater tortoisoc of the Old World the most thorongbly aquatic aro the Batagurs, which inhabit tho East Indies, and attaiu to a length of 2 feet. Like their American representative, Dcrmatemys, they aro essentially herbivorous, 3nd their flesh is eaten. The genus Clemmys is extremely abundant in species, most of which are of small size, and elegantly örnamented with symmetrical markings of bright colonr. The majority of the species occur in North Anicrica and Mexico, and are of amphibious lialits. Only one species, C. liprosa, inbabits southern Europe. A second European species Lelongs to tho genus Emys, E. orbicularis, which, towards the eud of the Quaternary period appears to have been distributed over a grest part of northern Europe, remains having been fonnd in peat in England, Belgium, Denmark, and Sweden. Its hisbitat is Low restricted to southern Europe, and sweden. Its bas survived in a few isolated northern stations, for instance, in the neighbourhool of Berlin and Konigsberg, aithough it is thero on the verge of extinction. The mobility of the lobes of the plastron, which distinguishes Emys from Clcmmys, is carried a degree further in the North-American genus Cistudo, the Box Tortoise; this terrapin possesses a hinge in the plastrou, rendering its anterior anel posterior portions movable, and converting theni into lids by which the openings of the shell cau be completely closed when the liead and limbs are retracted. A similar protective apparatus exists in the tortoises of the genus Cinusternum. In the African terrestrial genus Cinyxis it is the Iesterior portion of the carapace that is movable, and separated trom the anterior by a hinge. True land tortoises, Testuda, occur in Africa, southern Europe, southerm Asia, South America, and the southern parts of North Ancrica. Those best known in Europe are Tcstudo graca and the Moorish Tortoise, Tcstudo mauritunica, large numbers of which are imported into the United liingdom, chiefly from Morocco. But the most interesting are the gigantic tortoises which formerly inhabited in extreme abundance the Mascareno and Galapagos Islands, and are new on the verge of extinction, or have actually
becomo extinct. "At the time of their discovery those islands were $1870 \%$ anu, although known to havo beers more than eighty years uninlabited by man or any large mammal; tho tortoises, therefore, old, was still growing at the time of its death. There is no evidence to show that any of these tortoises were
 indigenous in the Scycliclles; the specimens kejst there in a semi-lomesticated stato liave been either directly imported fron Aldabra or are the descendants of imported individnals.

The family of Chclydridæ includes fresliwater tortoises, which are known under the names of Snapjers or Alligator Terrapins (fig. 3), ou account of their feroeity and long compressed crested tail. They aro now confined to North America east of the Rocky Mountains, Central America, and nortli. west South America, but remains of two species of Chelydra, closely related to their recent representative, have been found in the Oligocene and Mincene enjoyed perfect security; and this, as well as their extraordinary degree of longevity, accounts for their enormous size and their large numbers. They could lo captured in any quantity with the greatest ease within a few days, and proved to the shipg' companies who during their long voyages had to subsist mainly on salt provisions annst welcomo addition to their table. They could be carried in

110. 4 Loggerhead (Caouana carella)
thie hold of a ship, without food, for months, and wero slaugntered as occasion required, each tortoise yielding, according to size, from 80 to 300 pounds of excellent and wholesome meat. Under these circumstances the numbers of these helpless creatures decreased so rapilly that in the beginning of this century their extermination was accomplished in the Mascarencs, and now only a few remain in a wild state in Aldabra and in sone of the islands of the Galapagos group. Singularly, tho majority of these islands were inhabited each by one or more pecnliar forms, specifically distinct

Fig. 5 .-Gieen Iartle (Chelonia viradtsh
from those of the other islands. A large male specauen fron Aldabra, which was iuported into London somo years ago, weighed
of contral Enrope. A second genus, closely allied to Chelydra, Macroclemmys tomminckii, the shell of which attains to a length of 3 feet, and which is the largest known freshwater Chelonian, is restricted to the river-systems tributary to the Gulf of Mexico.
The family of Cinostemide contains a rather large number of small-sized species, distributed from the northern parts of the United Statcs to the northern parts of Brazil. They are of amphibious labits. The front and hind lobes of the plastron are movable, and in certain species of Cinostcrnum the animal can completely shut itself up in its shell.

The Chelonides, or marine turtles, contain but fer species, which are referred to three geuera,-Ccouana, Chclonc, and Carella, Their limbs are wholly modified into paddles, by means of which they can propel themselves with extraorlinary rapidity through the water, but which are entirely unfit for locomotion on land, where the progress of these aminals is as awkward ns tlat of a seal. The toes are euclosed in a common skin, out of which only one or two claws project. The carapace is broad and much depressed, so that when tho turtles are surprised on shore nnd turned

Fic. 6.-Hawksbill Turtte (Caretta mbricata).
over on tneir back, they cannot regain their natural posinon. Their capture forms a regular pursuit wherever they occur in any numbers. Comparatively few ate caught in the open sea, others in atake nets, but the majority nre intercepted at well.known periods and localities where they go ashore to deprosit their eggs. Theso are very numprnas, from 100 to 250 being producad by one female, and buried by her in tho sand; they are eagenly soarched for and caten. Some of the marine turtles are highly esteemed for the delicacy of their meat and of the gelatinous skinuy parts of their neck aud fins; others yield oil, and others again the tortoise. shell of commerce. Probably the largest of these marine turtles is the Loggerhead (Caozana), which lossessus fifteen vertebral and costal shields, and occurs in the Atlantic as well as in tho Indian

Ocean (fig. 4). It is carnirorous, feeding on fish, miolluses, and crustaccans, and not esteemed ss food, although it is caten by the pative fishermen. A great part of the turtle-oil which finds its

Fio. 7. - The Matamats (Chelys fimbricia), with sldo view of head, and separate view of plastron.
cop into the market is ohtained from the Atlantic species of this genus; also tortoiseshell of $8 n$ inferior quality is obtained from it. The (Green Turtle (fig. 5), whicl yields the msterials for the celobrated soup, beiongs to the genus Chelonia; it is distinguished from Caouana by having thirteen vertobsal snd costal shields only, which are not im.
are herbivorous, feeding
ou marine Algz only;
they occur in the Indo-
Facificand Atlantic; and, although several species bave hecn distinguished, they all may possibly be refersbie to one only. The turtle imported into Europe comes chicfly

Fio. 8.-Upper Vlew of the Turtlo of the Euphrates (Trionyx euphrafioc).
frem the West Indies. Instances are recorded of the flesh of this apecics hisving acquircd poisonous qualities. The Hzwksbill Turtle, Larcila (fig. 6), so named from its rather elongate und compressed
curved upper jaw, does not reacle the same size as the other turtles, and is readily recognized by the thirteen imbricate scutes of its carapsce. It seoms to be more abundsnt in the Indian than in the Atlantic Occan, hu't is plentiful only in certain locsiities. As, however, thesa turtles always resort to the locality where they were born, or where they have been wont to propagate their kind, and as their capture is very profitable, they become
scarcer and searcer at places where they are known to have beon abundant formarly. Í the plates of tortoiseshell are detached from the animsl when decom. position has set in, their colour becomes cloudel and milky, and hence

Fio. 9.-Lower Vlaw of Trionyx euphratica.
the cruel expedient is reserted to of suspending the turtle over firs till hest makes the shields start from the bony gart of the carapace, after which the cresture is permitted to escape to the wster. There is no doubt that turtles thas allowed to escape to the water after such an operation msy survive; but it is very improbshle that the epidernal shields are ever sufficiently regencrated to be fit for use. At Celebes, wheace the finest tortoiseshell is exportad to China, thonstives kill the turtle by blows on the head, and immarse the shell in boiling water to detach the plates; dry heat is only resorted to by the unskilful. The natives eat the flesh of this turtle, but it is unpratable to Europeans; the eggs, however, are regarded as equal to those of the other turtles.

Of the family Chclydids the most remarkahle type is the Matamata, Chelys fimbriala, a nstive of the Guisnas and northern Brazil (fig. 7). In its strongly depressed and ast head, long tubolike enont, weak jaws, minute oyes, skinny tentacles, it bears a striking sinilarity to the Surinsm toad, Pipa americana, which inhabits thasame countries. The neck is very broad and depressed, and fringed with foliated tentacles, lloating in the water like some vegatable growth, whilst the rough bossed carapace resembles a atoue, -an appearance which evidently is of as great usa to this creature in escaping the observation of its enemies as in alluring to it unsuspicious animals on which it feeds.
The family of Carctochelydidz con tains a single genus, Caretochciys, quite recently discovered in the Fly river, New Guioes, and exlibiting a remarksble combination of characters. Its linus sra formed very much like those of the marine turtlcs, whilst the shell lacks epidermic scntes, as in the Trionychids.

In the freshwater tnatles, or Trionychidse (figs. 8 and 8), the carapace is reduced to a flat disk, which is covered with soft ekin. The neck and limbs can be lodged under the brosd skinay horders of the carapace: also tho plastron is very imperfectly ossified, and sometimes dilated into larga flexible lobes which may cover tha limbs. The latter are much thattened and brasily webbed, and only the three inner toes armed with claws. The jaws are conccaled nnner brosd, feshy lips, the noso projecting like a enort proboscis. Theso turtles aro carnivorous, and very fcrecious; when they want to bita or seize their prey they project their neck and head with lightning rapidity. They are well known un the opper Nile, Euphrates, Ganges, Yangtse-kiang, and Mississippi, and, indeed, distributed over all the large fresh waters of tho geographical regioas to which
theso rivers belong. Some of the species excced a length of 3 feet. In the United States, where twospecies, Trionyx mulicus and Tionyx forox, occur, the flesh of the latter is said to be most delicate to eat, far surpassing in flavoinr that of the green turtle.
(A. C. G.)

TORTOISESHELL. The tortoiseshell of commerce consists of the epidermic plates of the hawksbill turtle, Caretta imbricata. The plates of the back or carapace, technically called the head, are 13 in number, 5 occupying the centre, flanked by 4 on each side. These overlap eachi other to the extent of one-third of their whole size, and Lence they attain a large size. reaching in the largest to 8 inches by 13 inches, and weighing as much as 9 ounces. The carapace has also 24 marginal pieces, called hoofs or claws, forming a serrated edge round it ; but these, with the plates of the plastron. or belly, are of inferior value. The plates of tortoiseshell consist of horny matter, but they are larder, more brittle, and less fibrous than ordinary horn. Their value depends on the rich mottled colours they display-a warm translucent yellow, dasled and spotted with rich brown tints-and on the high polish they take and retain. The finest tortoiseshell is obtained from the Eastern Archipelago, particnlarly from the east coast of Celebes to New Guinea; bnt the creature is found and tortoiseshell obtained from all tropical coasts. large supplies coming from the West Indian Islands and Brazil.

Tortoisesliell is worked preeisely as horn; but, owing to the high value of the material, care is taken to prevent any waste in ita working. The platea, as separated by heut from the bony skeleton, are keeled, curved, and irregnlar in form. They are first flattened by leat and pressure, and superficial inequalities are rasped away. Being harder and more brittle than horn, tortoiseahell requires careful treatment in monlding it into any form, and as high heat tends to darken and obaeure the material it is treated at as low a heat as practicable. For many purposes it is necessary to increase the thickness or to add to the superticial size of tortoiseshell, and this is readily done by careful cleoning aud rasping of the surfaces to be united, softening the plates in boiling water or sometimes by dry heat, and then pressing tiem tightly together by means of heated pincers or a vice. The heat softens and liquefies a superficial film of the homy material, and that with the pressure effects a perfect union of the surfaeea bronglit together. Heat and pressure are also emphoyed to mould the substance into boxes and the numerous artificial forms into which it is made up.

Tortoiseshell has been a prized ornamental material from very early times. It was one of the highly eateemed treasures of the far East brought to ancient Rome by way of Egypt, and it was eagerly sought by weaithy Romans as a vencer for their rich furniture. In modern timea it is most characteristically used in the elaborate inlaying of cabinet work known as buhl furniture. It is also employed as a veneer for small boxes and frames. It is cut into combs, monlded into snuffboxes and other sinall boxes, formed into knife-handles, and worked up into many other similar minor articles. The plates from certain other tortoises, koowa commercially as turtle-shell, possess a certain industrial value, but they are either opaque or soft and leathery, and cannot be mistaken for tortoiseshell. A close imitation of tortoisesliell can be made by staining translucent horu. See Comb, iol. vi. p. $17 \delta$.

## TORTOLA. See Virgin Islands.

TORTONA, a town of Italy, in the province of Alessandria, on the right bank of the Scrivia, at the northern foot of the Apennines, 13 niles to the east of Alessandria, was formerly a place of strength until its fortifications were destroyed by the French after Marengo (1799); the ramparts are now turned into shady pronenades. The cathedral, erected by Philip.II., is architecturally uninteresting; but contains a remarkably fine Roman sarcophagus. Silk-weaving, tanning, and hat-making are the chief industries; and there is some trade in wine and grain. The population in 1881 was 9023 (commune 14,442).

Deriona is spoken of by Strabo as one of the most important towua of Liguria, and is alluded to by Pliny as a Roman colony. In the Middle Ages it was zealously attached to the Guclphic cause, on which account it was twice laid waste by Frederick Barbarossa (in 1155 and 1163).
TORTOSA, a fortified city of Spain, in the province of Tarragona, and 40 miles by rail to the south-west of that town, is picturesquely situuted on the left bank of the

Ebro (here crossed hy a bridge of hoats), 22 miles abowe its mouth. It is for the most part an old walled town, with narrow, crooked, and ill-paved streets; the houses are lofty, and massively built of granite. The slope on which it stands is crowned with an old ruined castle, commanding a splendid view. The cathedral is a cor. picuous building near the river: it occupies tho site of a mosque built in 914 by eAbd al Ralmán; the present structure, which dates from 1347 , las its Gothic character disguised by a classical façade with Lonic pillars and much tasteless modernization. The stalls in the choir, carved by Cristobal de Salamanca in 1588-93, and the sculpture of the pulpits, as well as the ironwork of the choir-railing and some of the precious marbles with which the chapels are adorned, deserve notice. None of the other public luildings, which include an episcopal palace, a town-hall, and numerous churches, require special mention. The manufactures of Tortosa include paper, hats, leather, porcelain, majolica, soap, and spirits. There is an important fishery in the river, and an active trade is carried on through the harbour, which is accessible to vessels of 100 tons burden, corn, wine, oil, wool, silk, fruits, and liquorice (a specialty of the district) being among the learling articles of export. Near Tortosa are rich quarries of marble and alabaster, and the whole surrounding country is very fertile and beautiful. The population within the municipal boundaries in 1878 was $24,057$.
Tortosa, the Dertosc of Strabo and the Colonia Julia Augusta Dertosa of numerous coima, was a city of the Ilercaones in Hispania Tarraconensis. Under the Moors it became a place of great inportance as the key of the Ehro valley. It was taken by Louia the Pious in 811 (after an unsuccessful siege two ycars before), lunt was soon recaptured. Having become a haunt of pirates, sul exceel. iogly injurious to Italian commerce, it was made the object of a crusade proclaimed by Pope Eugenins III. in 1148, and nas accord. ingly captured by Raymond Berengar, assisted by 'Templars, Pisana, snd Genocas. Tortosa fell into the hauda of the dake of Orleans in 1708, and was again surrembered in the War of Independeuce in 1811 to the French under Suchet, who held it till 1814.

TORTURE. It is proposed to treat in this place not so much the inmunmerable modes of inflicting pain which have been from time to time devised by the perverted ingenuity of man as the subject of legal torture as it existed in the civilized nations of antiquity and of modern Europe, that is to say, torture inflicted with more or less appearance of legality by a responsible executive or jndicial authority. From this point of view torture was always inflicted for one of two jurposes-(l) as a means of eliciting evidence from a witness or from an accused person either before or after condemnation, (2) as a part of the punishment. Torture, as a part of the punishment, nay be regarded as including every kind of hodily or mental jain beyond what is necessary for the safe custody of the offender (with or without, enforced labour) or the destrnction of his life, - in the language of Bentliain, an affictive as opposed to a simple punishment. Thus tlie mmecessary sufferings endured in English prisons before the reforms. of Howard (see Howard and Prison Discipline) and the drawing and quartering in the old executions for treason fall without any straining of terms under the category of torture. The whole subject is now one of ouly historical interest as far as Europe is concerncd. It was, however, up to a comparatively recent date an integral part of the law of most countries (to which England, Aragon, and Sweden ${ }^{1}$ formed honourable exceptions), as much a commonplace of law as trial by jury in England. Ona reason for its long contiuuance was no doubt the view taken in an age of judicial perjury ${ }^{2}$ that truth was ouly to be attained by violent means, if not by torture then by ordeal or trial by battle. Speaking generally, torture may

[^188]be said to have succeeded the ordeal and trial by battle (compare Ordeal). Where these are found in full vigour, as in the capitularies of Charlenagne, there is no provision for torture. It was no doubt accepted reluctantly, bot tolerated in the absence of any better means of eliciting truth, especially in cases of great gravity, on the illogical assumption that extraordinary offences must be met by extraordinary remedies.

The opinions of the best authorities have been in theory almost unanimously agaiost the use of torture, even in a system where it was as completely established as it was in Roman law. "Tormenta," says Cicero, ${ }^{1}$ in words which it is almost impossible to translate satisfactorily, " gubernat dolor, regit quesitor, flectit libido, corrumpit spes, infirmat metus, ut in tot rerum angustiis nihil veritati loci relinquatur." Seneca says bitterly, "it forceseren the innocent to lie." St Augustine ${ }^{2}$ recognizes the fallacy of torture. "If," says he, "the accused be innocent, he will undergo for an uncertain crime a certain junishment, and that not for having committed a crime, but because it is unknown whether he committed it." At the same time he regards it as exclised by its necessity. The words of Ulpian, in the Digest of Justinian, ${ }^{9}$ are no less impressive. "The torture (questio) is not to be regarded as wholly deserving or wholly uudeserving of confidence ; indeed, it is untrustworthy, perilous, and deceptive. For most men, by patience or the severity of the torture, come so to despise the torture that the truth caunot be elicited from them; others are so impatient that they will lie in any direction rather than suffer the torture ; so it bappens that they depose to contradictions ind accuse not only themsclves but others." Montaigne's ${ }^{4}$ view of torture as a part of the punishment is a most just one :-"All that exceeds a simple death appears to mie absolutẹ cruelty; neither can our justice expect that he whom the fear of being executed by being beheaded or hanged will not restrain should be any more awed by the imagination of a languishing fire, burning piocers, or the wheel." Montesquien ${ }^{5}$ speaks of torture in a most guarded manner, condemning it, but without giving reasons, and eulogizing lingland for doing without it. The system was candemned by Bayle and Voltaire with less reserve. Among the Italians, Beccaria, ${ }^{6}$ Verri, ${ }^{7}$ and Man'zoni ${ }^{8}$ will be found to contain most that can be said on the subject. The influence of Becraria in rendering the use of torture obsolcte was undoubtedly greater than that of 'any other legal reformer. The great point that he makes is the unfair incidence of torture, as persons' minds and bodies differ in strength. Moreorer, it is, says he, to confound all relations to expect that a man should be both arcuser and accused, and that pain should be the test of truth; as though truth resided in the muscles and fibres of a wretch under torture. The result of the torture is 'simply a matter of calculation. Given the force of the inuscles and the sensibility of the nerves of an innocent person, it is required to find the degree of pain necessary to make him confess himself guilty of a given crime. Benthan's ${ }^{n}$ ohjection to torture is that the effect is exactly the reverse of the iotention. "Upon the face of it, and probably enough in the intention of the framers, the object of this institution was the protection of innocence; the protection of guilt and the aggravation of the pressure upon innocence was the real fruit of it." The apologists of torture, even anong jurists, are not numerous. In fact, theoretical objections to it are often urged by the authors of books of practice, as by Damhouder, Von Rosbach, Yon

Boden, and Voet. It is worthy of note, however, as illus trative of the feeling of the time, that even Bacon ${ }^{10}$ com. pares experiment in nature to torture in civil matters as the best means of eliciting truth. Myyart de Vouglaus 's derives the origin of torture from the law of God. Other apologists are Sinnancas, bishop of Badajos. ${ }^{12}$ Engel, ${ }^{13}$ and in England Sir R. Wisenaa. ${ }^{14}$

Greece.-The opinion of Aristotle was "in, favour of torture as a mode of proof. It is, he says," ${ }^{\text {a }}$ kind of evidence, and appears to carry with it absolute "credibility because a kind of constraint is applied. It is classed as one
 slaves, and probably at times resident aliens, were tortured, but it was never applied to free citizens, ${ }^{16}$ such application being forbidden by a psephism passed in the archonship; of Scamandrius. After the mutilation of the Hermæ in' 415 B.c. a proposition was made, but not carried, that it should be applied to two senators named by an informer! In this particular case Andocides gave up all his slaves to be tortured. 17 Torture was sometimes inflicted in. open court. The rack was used as a lunishment even for freo citizens. Antiphon was put to death by this means. ${ }^{18}$ The torture of Nicias by the Syracusans is alluded to by Thucydicles ${ }^{19}$ as an event likely to happen, and it was only in order to aroid the possibility of inconvenient disclosures that he was put to death without torture. Isocrates and Lysias refer to torture under the generic name of $\sigma \tau \rho$ é$\beta \lambda \omega \sigma \iota$. As might be expected, torture was frequently inflicted by the Greek despots, and both Zeno and Anax archus are said to have been put to it by such irresponsible authorities. At Sparta the despot Nabis was accustomed,? as we learn from Polybius, ${ }^{20}$ to put persons to death by an instrument of torture in the form of his wife Apega, a mode of torture no doubt resembling the Jungfernkuss once in use in Germany.

Rome.-The Roman system, was the basis of all subsequent European systems which recognized torture as a part of their procedure. The law of torture was said by Cicero to rest originally on custom (mores majorum). There are frequent allusions to it in the classical writers ${ }^{21}$ both of the republic and the empire. The law, as it existed under the later cmpire, is contained mainly in the titles $D e$ Qurstionibus ${ }^{22}$ of the Digest and the Code, ${ }^{23}$--the former consisting largely of opinions from the Sententix Receptix of Paulus, ${ }^{24}$ the latter being for the most part merely a repetition of constitutions contained in the Theodosian Code. ${ }^{25}$ Both substantive law and procedure were dealt with by these texts of Roman law, the latter, however, not as fully ${ }^{30}$ Nov. Org., bk. i. aph. 98. 1n the Advancement of Learning, bk. iv. cb. 4, Bacoa collects many instances of constancy under torture.

${ }^{15}$ See Dict. of Antiz., s.v. Báravos. In the Rana of Aristophanes, v. 617, there is a rist of kinds of torture, and the wheel is alluded to in Lysistrata, v. $846 . \quad 19$ vii. $86 . \quad 20$ xiii. 7.
${ }^{21}$ An interesting one, illustratiog the uselessness of torture in the face of courage and resolution, is the abortive result of the torture of a Spanish peasant in 25 A.D. On the charge of beiog the murderer ol Lucius Piso ('Tac., Ann., iv, 45). A somewhat similar case, occurring in Sicily, is given by Valerius Maximus, bk. iii. c. iii. The horrible torture of Epicharis, a freed woman, is described ly Tacitus, Ann., x.. 57. In Pliny's letter to Trajan (Epist., x. 97), he meations having put to the torture two Christiau deaconesses (ministre).

as in medieval codes, a large discretion being left to the judges. Torture was used both in civil and criminal trials, but in the former only upon slaves and freedmen or infanous persons-such as gladiators-and where the truth could not be otherwise elicited, as in cases affecting the inheritance (res hereditarix). Its place in the case of free citizens was taken by the refercnce to the oath of the party (see Oatп). During the republic torture appears to have been confined to slaves in all cases, but with the empire (accorrling to Dion Cassius under Tiberius) a free man became liable to it if accused of a crime, though not as a witness. If a Cliristian, of however bigh a condition, he was subject to torture during the period between tho erlict of Diocletian in 303 and the edict of tolcration of Galcrius in 311 . This short period excepted, the liability of a free man depended upon two conditions, the nature of tho accusation and the rank of the accused. On an accusation of treason every one, whatever his rank, was liable to torture, for in treason the condition of all was equal. ${ }^{1}$ Tho same was the case of those accused of sorcery (magi), who were regarded as humnti generis inimini. ${ }^{2}$ A wife might be tortured (but only after her slaves had been put to the torture) if accused of poisoning her husband. In accusations of crimes other than treason or sorcery, certain persons were protected by the dignity of their position or their tender ase. The main exemplions wero contained in a constitution of Diocletian and Maximian, and included soldiers, nobles of a particular rank, i.e., eminentissimi and perfectissimi, and their descendants to the third gencration, and resuriones and their children to a limited extent-that is to say, they were subject to the torture of the plumbats in certain cases, such as fraud on the revenue and cxtortion. In addition to these, priests (but not clergy of a lower rank), childrell under fourtcen, and pregnant women were exempt. A free man could bo tortured only where he had been inconsistent in his depositions. No one was to bo clained in prison before trial, nor could a prisoner be tortured while awaiting trial. The rules as to the torture of slaves were numerous and precise. It was a maxim of Roman law that torture of slares was the most efficacious means of obtaining truth. ${ }^{3}$ Ther could be tortured either as accused or as witnesses, but against their masters only in accusations of treason, adultery, frauds on the revenne, coining, and similar offences (which wero regarded as a species of treason), attempts by a husband or wife on the life of the other, and in cases where a master had bought a slave for the special reason that he should not give evidence against him. The privilege from accusations by the slave extended to the master's father, mether, wife, or tutor, and also to a former master. On the same principle a freedman could not be tortured against his patron. The privilege did not apply where the slave was joint property, and one of his masters had been murdered by the other, or where he was the property of a corporation, for in such a case be could be tortured in a charge against a member of the corporation. Slaves belonging to the inheritance could be tortured in actions concerning the inberitance. The adult slaves of a deceased person could be tortnred where the deceased had been inurdered. In a charge of adultery against a wife, her husband's, her own, and her father's slaves could be put to the torture. A slave manumitted for the express purpose of escaping torture was regarded as still liable to it. Before putting a slave to torture withont the consent of his master, security must be given to the master for his value. The master of a slave tortured on a false accusation could recover double his value from the accuser. The undergoing of torture had at one time a serious effect upon the after-life of the

[^190]slave, for in the time of Gaius a slave who had becus tortured could on mauumission obtain no higher civil rights than those of a dediticius. ${ }^{4}$ The rules of procedure were conceived in a spirit of as much fairness as such rules could be. Some of the nost important were these. The amount of torture was at the discretion of the judge, but it was to ho so applied as not to injure life or limb. The examination was not to begin by torture; other proofs must be exhausted first. The evidence ${ }^{5}$ must have ad vanced so far that nothing but the confession of the slave was wanting to complete it. Those of weakest frame and tenderest age were to bo tortured first. Except in treason, the unsupported testimony of a singlo witness was not a sufficient ground for torture. The voice and manner of the accused were to be carcfully observed. A spontaneous confession, or the evidence of a personal enemy, was to be received with caution. Repetition of the torturc could only be ordered in case of inconsistent depositions or denial in the face of strong evidence. There was no rule limiting the number of repetitions. Leading questions were not to be asked. $\Lambda$ judge was not liable to an action for anything done during the course of the examination. An appeal from an order to torture was competent to the accused, except in the case of slaves, when an appeal conld be made only by the master. ${ }^{6}$ The appellant was not to be tortured pending the appeal, but was to remain in prison. ${ }^{7}$ The principal forms of torture in use wero the equuleus, or rack (mentioned as far back as Cicero), the plimbate, or leaden balls, the ungulx, or barbed hooks, and the fidicatz, or cord compressing the arm. Other allusions in the Digest and Code, in addition to those already cited, may be shortly noticed. The testimony of a gladiator or infamous person (such as an accomplice) was not valid without torture. ${ }^{8}$ This was no doubt the origin of the mediæral maxims (which were, however, by no means universally recognized),- Vilitas personse pst jusin causa torquendi testem, and Tortura purgatur infamin. Torture could not be inflicted during the forty days. of Lent. ${ }^{9}$ Tobbers and pirates might be tortured even on Easter Day, the Divine pardon being hoped for where the safety of society was this assured. ${ }^{10}$ Capital punishment was not to be suffered until after conviction or confession under torture. ${ }^{11}$ Withdrawal from prosecution (abolitio) was not to be allowed as a rule after tho accused had undergone the torture. ${ }^{12}$ In charges of treason the accuser was liable to torture if he did not prove bis case. ${ }^{13}$ The infliction of torture, not judicial, but at the same time countenanced by law, was at one time allowed to creditors. They were allowed to keep, their debtors in private prisons, and most cruelly ill-use them, in order to extort payment, ${ }^{14}$ Under the empire prisate prisons were forbidden. ${ }^{15}$ in the time of Juvenal, if his sixth satire may be believed, the Foman ladics actually hired the public torturors to torture their domestic elaves. As a part of the punishmeat torture was ir frequent use. Crucifixion, mutilation, cxposure to wild beasts in the arena, and other cruel modes

[^191]of destroying life were common, espectally in the time of the persecution of the Christians under Nero. ${ }^{1}$ Crucifixion as a punishment was abolished by Cunstantine in 315 , in veneration of the memory of Him who was crucified for mankiud. The punishment of matilation was moderated by Justinian, who forbade amputation of both hands or feet or of any limb, and confined it in future to anputation of one hand. ${ }^{2}$ Scourging was inflicted only on slaves; free men were exempt by the Lex l'orcia and Lex Valcriu, except in a few cases, such as that of adultery, the penalty for which was scourging and cuttiog off the nose.s On the other hand, where the interests of the church were concerned, the tendency was in favour of greater scverity. Thus, by the Theodosian Code, a heretic was to be flogged with lead (contusus plumbo) before banishment, ${ }^{4}$ and Justinian made liable to torture and exile any one insulting a bishop or priest in a church.
The Church.-As far as it could the church adopted the Roman law, with the important aad characteristic difference (dating from the severe edicts of Theodosins the Great in 381) that heresy took the place of treason, it being regarded as a kind of treason against God ("crinien læsse majestatis divinæ") ${ }^{\circ}$. The doctrine of coufiscation for treason was so convenient and profitable that it was rapidly adopted by the church. ${ }^{7}$ As most instances in which torture was iuflicted by ecclesiastical tribunals would be accusations of heresy or Judaism-a specially revolting form of heresy to medixval Christians-this theory practically equalized all persons for the purpose of torture, in accordance with the doctrine that in treason all were equal. The chorch generaliy secured the almost eutire immunity of its clergy, at any rate of the higher ranks, from torture by civil tribunals. ${ }^{8}$ In many instances councils of the church prozounced against torture, e.g., in a synod at Rome in $384^{\circ}$. Torture even of heretics seems to bave been originally left to the ordinary tribunals. Thus a bull of Innocent IV., in 1252, directed the torture of beretics by the civil power, as being robbers and murderers of souls, and thieves of the sacraments of God. ${ }^{10}$ The church also enjoined tortore for usury." A characteristic division of torture, accepted by the church but not gencrally acknowledged by lay authorities, was into spiritual and corporal, the latter being simply the imposition of the oath of purgation, the only form originally in use in the ecclesiastical courts. The canon law contains little on the subject of torture, and that little of a comparatively humane nature. It laid down that it was no sin in the faitiful to inflict torture, ${ }^{12}$ but a pricst might not do so with his own hands, ${ }^{13}$ and charity was to be used in all punishments. ${ }^{14}$ No confession was to be extracted by torture. ${ }^{15}$ The principal ceclesiastical tribunal by which torture was inflicted in more recent times was of course the

## ${ }^{2}$ The well-known lines of Juvenal (Sat., i. 155 ),

Qus stantes ardent qui ixxo gutture tunaut,"
will serve as an example of such punishments.

Inquisition ( 1.0. ). The codo of instructions issuea by Torqueuada in Spain in 1484 . provided that au accused person might be put to the torture if semiplena probatio existed against the accused,-that is, so much cvidence as to raise a grave and not merely a light presumption of guilt, often used for the cvidence of one eyc or car witness of a fact. If the accused confessed during torture, and afterwards confirmed the confession, he was punished as convicted; if lie retracted, Le was turtured again, or subjected to extraordioary punishment. One or two inquisitors, or a commissioner of the Holy Office, were bomd to be present at every examination. Owing to the occurrence of certain cazes of abuse of torture, a decree of Mrily. 1I. was issued, in 1556, forbidding the adrainistration of torture without an order from the council. But this decree does not appear to have been fully observed. By the edict of the inquisitor-general Valdís, in 1561 , torture was to be left to the prudence and equity of the judges. They most consider mutives and circumstances before decreeing torture, and nust declare whether it is to be employed in cuput proprium, i.e., to extort a confessiou, or in caput alienum, i.c., to incrimiuate an accomplice. 'The accused was not to be informed of the grounds of torture. He was not to be questioaed on a particular fact, but was to bo allowed to say what he pleased. T'orture was not to be decreed until the termination of the process, and after defence heard, and the decree was subject to appeal, but ouly in doubtful cases, to the Council of the Supreme. It was also only in doubtful cases that the inquisitors were bound to consult the council; Where the law was clear (and of this they were the judges) there seed be no consultation, and no appeal was allowed. The judges, the registrar, and the executioners were the only yersons allowed to be present at the torture. They mere io be careful that the jailer suggested mothing to the accused furing the torture. On ratification twenty-four hours afterwards of a confession mado under torture, the accused migist bet reconciled, if the iuquisitors believed him to be sincerely repentant. If convicted of bad faith, he uight be relaxed, i.e., delivered to the secular power to be burned. The inquisitors had a discretion to allow the accused to make tho canonical purgation hy oath instead of undergoing corporal torture, but the rule which allows this to be done at the same time discountenances it as fallacious. It is remarkable that the rules do not allow much greater efficacy to torture. They speak of it almost in the terms of Roman law as dangerous and uncertain, and depending for its effects on physicai strength. ${ }^{16}$ Torture had ceased to be inflicted before the suppression of the Inquisition, and in 1816 a palal ball decreed that torture should cease, that proceedings should be public, and that the accuser should be confronted with the accused. ${ }^{17}$ It was still, however, customary for the fiscal, even in the latest times, to end the requisition by demanding torture as a matter of form. The rules in themsclves were not so cruel as the construction put upon them by the inquisitors. For instance, by Torquemada's instructions torture could not be repeated ualess in case of retractation. This led to the subtlety of calling a revewed torture a continuation, and not a repetition. ${ }^{1 s}$ The rules of Torquemada aud of Taldés are those of the greatest historical importance, the latter forning the code of the Holy Office uotil its suppression, not oaly
${ }^{10}$ The rules will be found in Llorente's Hist. of the Inruisition, cr. vi, xxii.
$\left.{ }^{17}\right]_{\mathrm{A}}$ case of actuat torture occurred in Spain in the case of Vam Halen, is 1817, in spite of the papal hull. In Soutl America, as late as 1809, power to torture was conferred on inquisitors by the dean and chapler of Sattiago. See Franciseo Moyen, or the Inquisitions in South America, by B. V. Mackenna 〈transl. by J. W. Duffy. 1869), p. 217.
${ }^{18}$ Prescott, Fordinand and Lsabeliu, vol ip 327.
in Spain, but in other countries where the Inquisition was established.' But several other codes of procedure existed before the final perfection of the system by Valdés. The earliest is perhaps the instructions for inquisitors (Directorium Inquisitorum) compiled a century earlier than Torquemada by Nicholas Eymerico, grand inquisitor of Aragon about 1368. ${ }^{1}$ Rules of practice were also framed two centuries later by Simancas, whose position as an apologist has been already stated. The text-book of procedure of the Italian Inquisition was the Sacro Arsenale. ${ }^{2}$ In the Netherlands, Francis Van der Helst was appointed inquisitor-general in 1521 , with authority to torture heretics without observing the ordinary forms of law, and without appeal. ${ }^{3}$. In 1545 and 1550 instructions for the guidance of inquisitors were issued by Charles V. ${ }^{4}$ The liability of a judge for excecding the law was not always recognized by the Inquisition to the same extent as by the lay tribunals. Llorente gives an instance of a warrant by an inquisitor to a licentiate ordering the torture of an accused person, and protesting that, in case of death or fracture of limbs, the fact is not to be imputed to the licentiate. ${ }^{5}$
Thus far of the law. In practice all the ingenuity of crnelty was exercised to find new modes of torment. ${ }^{6}$ These cruelties led at times to remonstrance from the civil power. One example is the edict of Philip II. just mentioned. Another and an earlier one is an ordonnance of Philip the Fair, in 1302, bidding the Inquisition confine itself within the limits of the law. ${ }^{7}$ At Venice the senate decreed that three senators should be present as inquisitors. Further details of the varieties of torture will be found, by those curious in such matters, in the works of Llorente, Herculano (History of the Inquisition-in Portugal), Motley, Garrido and Cayley, and Picart, to which may be added works giving accounts of the sufferings of individuals under the Inquisition, such as the narrative of the sufferings of William Lithgow at Malaga in 1622 and of Van Halen in 1817, and (in the Spanish and Portuguese colonies) the cases of Francisco Moyen in Chili, and of Dellon at Goa in $1673 .{ }^{8}$ Mental torture may be exemplified by Excommumication (.$\cdot v$. ), and by the secrecy and uncertainty of the proceedings of the inquisitors.

As the practice of torture, both by the civil and ecclesiastical power, became more systernatized, it grew to be the subject of casuistical inquiry by churchmen, to an extent far exceeding the scanty discussion of the question in the text of the canon law. It will be sufficient here to cite as an example the treatment of it by Liguori, who incorporates the opinions of many of the Spanish casuists. On the whole, his views appear to be more humane than the prevailing practice. The object of torture lie defines very neatly as being to tuin semiplena into plena probatio. For this proper indicic are necessary. He then proceeds to decide certain questions which had arisen, the most interesting of which deal with the nature of the $\sin$ of which the accused and the judge are guilty in particular instances. A jndge sins gravely if he does not attempt all

[^192]milder means of discovering truth before resorting to tor ture. He sins in a criminal cause, or in one of notabls infamy, if he binds the accused by oath to tell the truth before there is proof against him. It is the same if with. out oath he uses threats, terror, or exhibition of torment: to confound the witness. ${ }^{9}$ If any one, to avoid grave tormente, charges himself with a capital crime, he does not sin mortally. ${ }^{10}$ It was a doubtful question whether he sinned gravely in such a case.

England.-It is the boast of the common law of England that it never recognized torture as legal. One, perhaps the chief, reason for this position taken by the law is the difference of the nature of the procedure in criminal cases from that in general use in Continental countries. To use words more familiar in foreign jurisprudence, the English system is accusatorial as distinguished from inquisitorial. The common law of England has always shown itself averse to the inquisitorial system, and so (at least in theory) to the torture which may be regarded as an outcome of the system whose one end was to obtain a confession from the accused. The tendency of the small amount of statute law bearing on the subject is in the same direction. It was provided by Magna Clarta, § 29, "that no free man . . . . . should be destroyed in any way unless by legal judgment of his equals or by the law of the land." On this Sir E. Coke comments, "No man destroyed, \&c., that is, forejudged of life or limb, disinherited, or put to torture or death." 11 The Act of 27 Hen. VIII. c. 4 enacted that, owing to the frequent escape of pirates in trials by the civil law, "the nature whereof is that before any judgment of death can be given against the offenders they inust plainly confess their offence (which they will never do without torture or pains)," such persons should be tried by jury before commissioners under the Great Seal. Finally, the Bill of Rights provided that cruel and unusual punishments ought not to be inflicted. The opinions of the judges have been invariably against torture in theory, however much some of them may have been led to countenance it in practice. The strongest authority is the resolution of the judges in Felton's case (1628), "that he ought not by the law to be tortured by the rack, for no such punishment is known or allowed by our law." 12 In accordance with this are the opinions of Sir John Fortescue, ${ }^{13}$ Sir Thomas Smith, ${ }^{14}$ and Sir E. Coke. The latter says, -"As there is no law to warrant tortures in this land, nor can they be justified by any prescription, being so lately brought in." ${ }^{15}$ In spite of all this torture in criminal proceedings was inflicted in England with more or less frequency for some ceuturies, both as a means of obtaining evidence and as a part of the punishment. But it should be remarked that torture of the former kind was invariably ordered by the crown or council, or by some tribunal of extraordinary authority, such as the Star Chamber, not professing to be bound by the rules of the common law. In ouly two instances was a warrant to torture issued to a common law judge. ${ }^{16}$

A licence to torture is found as early as the Pipe Roll oi 34 Hen. II. ${ }^{17}$ The Templars (see Templars) were tortured in 1310 by royal warrant addressed to the mayor

[^193]and sheriffs of London. ${ }^{1}$ In this case it is recorded that torture was unknown in England, and that no torturer was to be found in the realm. ${ }^{2}$ A commission was issued concerning the tortures at Newgate in 1334. ${ }^{3}$ The rack in the Tower is said to have been introduced by the duke of Exeter in the reign of Henry VI., and to have been thence called "the duke of Exeter's daughter." ${ }^{4}$ In this reign torture seems to have taken its place as a part of what may Le called extraordinary criminal procedure, claimed, and it may be said tacitly recognized, as exercisable by virtue of the prerogative, and continued in use down to $1640 .{ }^{5}$ The infliction of torture gradually became more common under the Tudor monarchs. Under Henry VIII. it appears to have been in frequent use. Only two cases are recorded under Edward VI.,'and eight under Mary. ${ }^{6}$ The reign of Elizabeth was its culminating point. In the words of Hallam, "the rack seldom stood idie in the Tower for all the latter part of Elizabeth's reign." ${ }^{7}$ The varieties of torture used at this poriod are fully described by Dr Lingard, ${ }^{8}$ and consisted of the rack, the scavenger's daughter, ${ }^{9}$ the iron gauotlets or bilboes, and the cell called "Little Ease." The registers of the council during the Tudor and early Stuart reigns are full of entries as to the use of torture, both for state and for ordinary offences. ${ }^{10}$ Among notable prisoners put to the torture were Anne Ascue, the Jesuit Campion, Guy Fawkes, ${ }^{11}$ and Peacham (who was examined by Bacon "before torture, in torture, and after torture"). ${ }^{12}$ The prevalence of torture in Elizabeth's reign led to the well-known defence attributed to Lord Purghley, "A declaration of the favourable dealing of Her Majesty's commissioners appointed for the examination of certain traitors, and of tortures unjustly reported to be done upon them for matter of religion," $1583 .{ }^{13}$ The use of torture in England being always of an extraordinary and extra-judicial nature, it is comparatively certain that it could hardly lare been applied with that observation of forms which existed in countries where it was regulated by law. There were no rules and no responsibility beyond the will of the crown or council. This irresponsibility is urged by Selden ${ }^{14}$ as a stroug objection to the use of toriure.

So far of what may be.called torture proper, to wnich the common law professed itself a stranger. There were, howerer, cases fully recosnized by the common law which differed from torture only in name. The peine forte et dure was a notable example of this. If a prisoner stood mute of malice instead of pleading, he was condemned to ther peine, that is, to be stretched upon his back and to have iron laid upon him as much as he could bear, and more, and so to continue, fed upon bad bread and stagnant water through alternate days until be pleaded or died. ${ }^{15}$ It

[^194]was abolished by 12 Geo. III. c. 20, 7 and 8 Geo. IV. c. 28 enacted that a plea of "not guilty" should be entered for a prisoner so standing mute. A case of peine occurred as lately as 1726 . At times tying the thumbs with whipcord was used instead of the peine. This was.said to be a common practice at the Old Bailey up to the last century. ${ }^{16}$ In trials for witcheraft the legal proceedings often partook of the natnre of torture, as in the throwing of the reputed witch into a pond to see whether she would sink or swirs, in drawing her blood, ${ }^{17}$ and in thrusting pins into the body to try to find the insensible spot. Confessions, too, appear, to have been often extorted by actual torture, and torture of an unusual nature, as the devil was supposed to protect his votaries from the effects of ordinary torture.
Torture as a part of the puoishment existed in fact, if not in name, down to a very recent period. Matilation as a punishment appears in some of the pre-Conquest codes, such as those of Alfred, Athelstan, and Canute. Bracton, who does not notice torture as a means of obtain: ing evideuce, divides corporal punishment into that inflicted with and without torture. ${ }^{18}$ Later instances are the punishment of burning to death inflicted on beretics under the Six Articles (31 Hen. VIII. c. 14) and other Acts, aod on women for petit treason (abolished by $30 \mathrm{Gro}. \mathrm{III}. \mathrm{"c}. \mathrm{48)}$, the mutilation inflicted for violence in a royal palace by 33 Hen. VIII. c. 12, the puaisbment for high treason, which exister nominally mentil $1870^{\circ}$ (see Treason), the pillory (abolished by 7 Will. IV. and I Vict. c. 23), the stocks, and the buruing in the hand for felony (abolished by 19 Geo. III. c. 74). Corporal punishment now exists only in the case of juvenile offenders (see Summary Jurisdiction) and of robbery with violence (see Theft)! It was abolished in the arnyy by the Army Act, 1881. ${ }^{19}$
Scotland.-Torture was long a recognized part of Scottish crininal procedure, and was acknowledged as sucli by many Acts and warrants of the Scottish parliament, and warrants of the crowu and the privy council. Some of the more important instances are the following. In $15+2$ the forfeiture of John, Lord Glammis, was reduced by the parliament as having proceeded on a coufession extorted by threats of the "pynebankis." ln 1567 four persons were ordered by the Privy Council to be tortured for complicity iu Daruley's muriler. ${ }^{20}$ In 1591 a commission issued to torture cestain persons accused of witchctaft. ${ }^{21}$ James VI., in 1596, empowered the provost and bailies of Edinburgh to try rioters by torture. The torture was applied to Rhynd in 1600 , on a charse of being privy to the Gowrie House couspiracy. ${ }^{22}$. Two Acts in 1649 deate with torture: one took tho form of a warrant to examine witnesses against William Barton by any form of probation, ${ }^{23}$ the other of a warrant to-a committeo to inquire as to the use of torture against persons stispected of witchcraft. ${ }^{24}$ In 1650 the parliament ordained the committee appointed for the examination of prisoners to intimate to Colonel Sibbald that if his examination were not satisfactory the parliament would ordain him to be tortured. The judges, in 1689, were empowered by the estates to torture Chiesly of Dalrye, charged with the murder of the Lorl President. Lockhart, in order to discover accomplices. In the same ycar the use of torture without evidence or in ordinary cases was declared illegal in the Clain of Right. The careful vording of this will be noticed: it does not ohject to torture altogether, but reserves it for cases where a basis of evidence had already been laid, and for crimes of great gravity, thus admitting the dangerons principle, founded on Roman law, that the importance of the crime is a reason for departing from the ordinary rules of justice. However great the crime, it is no more certain than in the case of a crime of less gravity that the person accused vias the person who committed it. A warrant issued in the same year to put to the torture certain persons accusel of conspiring against the Government, and also certain dragoons suspected of corresponding with Lord Dundee. In 1690 an Act passed recit. ing the torture of William Carstares, a minister, in 1683, and re.

[^195]establishing his competency as a witness. ${ }^{1}$ The last warrant appears to be one in 1690 for torturing a manaccused of rape and murder. In 1728 torture in Scotland was finally abolished by 7 Anne c. 21 , § 5. Many details of the tortnres inflicted will be found in Pitcairn's Criminal Trials and the introduction to Maclaurin's Criminal Crases. Among other varieties-the nature of some of them can only be guessed-wero the rack, the pilniewinkis, the boot, "the caschie-lawe, the lang irnis, the narrow-bore, and, worat of all, the waking, or artificial prevention of sleep. ${ }^{8}$ The ingenuity of torture was exercised in a special degree on charges of witchcraft, uotably iu the reign of James V1., an expert hoth in witcheraft and io torture. The Act of 1649 already cited shoms that the priaciple survived him. Under the government of the dukes of Lavderdale and York torture as a practice in chargee of religious and political offences reached its height. "The privy council was gecustomed to extort coafessions by torture ; that grim diran of bishops, lawyers, and peers sucking in the groans of each undaunted onthusiast, in hope that some imperfect avomal migbt lead to the sacrifice of other victims, or at least marrant the execution of the present." " With such examples before them in the law, it is acarcely to be wondered at that persons in positions of authority; especially the nobility, sometimes exceeded the law and inficted torture at their own will and for their owa purposes. There are eeveral instances in the register of the privy council of suits against such persons, c.g., against the earl of Orkney, in 1605, for putting a son of Sir Patrick Bellenden in the boets.
Ireland seems to have enjoyed a comparative immnnity from torture. It was not recognized by the common or statute lam, and the cases of its infliction do not appear to be nunierous. In 1566 the president and council of Muoster, or any three of them, were empowered to inflict torture, "in cases necessary, upan veliement presumption of aoy great offence in ony party committed against the Queen's Majesty." ${ }^{5}$ In 1583 Hurley, an Irish pricst, was tortured in Dublin, by "toasting his feet against the fire with het boots." ${ }^{6}$ In the case of 3 yagh, in 1581 , the accused was brought over from Ireland by command of the lord deputy to he tartured in the Torer. ${ }^{7}$ In 1615 one O'Kennan was put to the rack in Dublin by virtue of the lard deputy's comrnission. ${ }^{8}$ In 1627 the lord deputy doubted whether he had autherity to put a priest named O'Culleasn to the rack. An auswer wes returned by Lorl Killultagh to the effect that "you ought to rack him if you ssw cause and hang him if you found reasour." ${ }^{\text {o }}$
British Colonics and Dcpendencies.-The iafiction of torture in any British colony or dependency has usually been regarded as contrary to law, and ardered only by arbitrary authority. It is true that in the trial of Sir Thomas Picton in 1806, for subjecting, while governor of Trinidad, a moman named Luisa Calderon to the torture of the picquet, ${ }^{10}$ one of the grounds of defence was that such tarture was authorized by the Spanish law of the islaud, but the accused was convicted in spite of this defeoce, and the final decision of the Court of King's Bench, in 1812, decrecing a respite of the defendant's recognizances till further order, was perhsps not so much an affirmation of the legality in the particular iustance as the practical expression of a wish to spare an eminent public servant. ${ }^{15}$ As to Iodia, the second charge agaiust Warren Hastings nas extortion from the begums of Oude by means of the torture of their servants. ${ }^{13}$ In the present Indian Penal Code and Evidence Act there are provisions intended, as Sir James Stephen says, ${ }^{33}$ to prevent the practice of torture by the police for the purpase of extracting confessions from persons in their custody. ${ }^{14}$ In Ceylon torture, which bad been allowed under the Dutch government, was expressly abolished by royal proclamation in 1799 .

United Slates.-One instance of the peine fortc et dure is known. It was ioficted in 1692 on Giles Cory of Salenı, who refused to nlead when arraigned for witcheraft. ${ }^{15}$ The constitution of the United States provides, in the wards of the Bill of Rights, that crucl and unusual punishments are not to be inflicted. ${ }^{16}$ This is repeated in the constitutions of most States. The infliction of crnel and unusual punishment by the master or officer of an American ressel on the high seas, or within the maritime jurisdiction of the Uaited States, is punishable with fine or imprisonment, or both. ${ }^{17}$

[^196]Continental States. -The principles of Roman law were generallf adopted. Want of spaco unfortuantely prevents a detailed examination of the law of other countries, but that of Italy may failly be taken as the type of a system which reached at its maturity a certain revalting eonpleteness of which it is difficult to speak with patience. The law as it existed in Italy is contaiaed in a long liue of authorities, chiefly supplied by the achool of Bologna, beginuing with the glossatores and coming down through tho yost-glossatores, ontil the system attained its perfection in the vast work of Farinaccius, written early in the 17 th century, where every possible question that could arise is treated with elaborate minuteness The writiags of jurists were supplemented by a large body of Iefislatipe enactmeots ia most of the Italian states, extending from the coastitutions of the emperor Frederick II. down to the last century. It is not until Bartolus (1314-1357) that the law begins to assums a definite and complete form. In his commentary on hook zlriii. of the Digest ho follows Roman law closely, but introduces some further refinements: e.g., though leading questions may not oe asked in the main iqquiry they are admissible as subsidiary. The:o is a beginning of classification of indicia. A very full discussion of the lar is contained in the work on practice of Hippolytus do Marsiliis, ${ }^{19}$ a jurist of Bolngna, notorious, on his own admission, as the inventor of the torture of keeping without sleep. He defines the question as inquisitio vertatis per tormenta et cordis dolorem, thus recognizing the mental as well as the physical elementa in torture. It was to be used only in capital cases and atrocious crimes. The works of Farinaccius and of Julius Clarus nearly a century later were of great authority frorn the high official positions filled by the writers. Farinaccius was procurator-general to Pope Paul V., and his discussion of torture is one of the most complete cf any. ${ }^{\text {ig }}$ It occupies 251 closoly printed folio pages with double columns. The length at which the subject is treated is one of the hest proofs of the science to which it hat been reduced. The chief feature of the work is the roinute and skilful analysis of indicia, fana, prasumptio, and other technical terms. Many defivitions of indicium are suggested, the best perhsps being conjectura ex probabilibus el ron necessariis orta, a quibus potest abesse veritas sed non צrrisimilitudo. For every infliction of tarture a distinct indicium is required. But this rule does not apply where it is iuHicted for discovering accomplices or for discovering a chiue other than that for which it wes originally inficted. Torture may be ordered in all criminal cases, except small offeuces, and in certain civil cases, such as deoisl of a depositum, bankruptcy, usury, treasure trove, and fiscal cases. It may be inflicted on all persone, unless specially exempted (clergy, miaors, \&e.), and even those exempted may bo tortured hy command of the sovereign. There are three kinds of torture, levis, gravis, and gravisima, the first and second corresponding to the ordinary torture of French mriters, the last to the cxtraordinary. Tbe extraordinary or gravissina was as much as could possibly be borne without destroying lifc. $A_{n}$ imunense varioty of tortures is mentioned, the mast nsual heing the tying of one hand only with the corl. The julge conld not begin with torture; it was only a subsidium. If inflictel mithout due course of law, it was veit as a pruaf. The judge ras liable to penalties if he tortured without proper indicia, if a privileged jerson, or if to the extent that death or permsnent illacss was the result. An immense variety of tortures is mentioued, and the list tculed to grov, for, as Farinaccius says, judgcs continually invented ncw modes of terture to please themselvcs. Numerous casuistical questions are treated at length. Could a priest reveal an acknowledgment of an intendel crime made to hinı in confession? What kinds of reports or how much hearsay ovidence constituted fame? How far was a confession allowed to be extorted by blandishmeats or false promises on the part of the julge? Were thele three or five grades in torture? Julius Clarns of Alessandria was a nember of the council of Philip II. ${ }^{20}$ To a great cxtent he follows Farinaccius. He puts the questions for the consideration of tho judge with great clearness. They aro-whether (1) a crine has been committed, (2) the charge is one in which tortore is admissible, (3) the fact can be proved otherwise, (4) the crime was secret or open, (5) the object of the torture is to elicit confession of crime or discovery of accomplices. IIe admits the tremendous power given to a judge of torturing a witness should he suspect that the latter knows whe truth and is concealing it. An accuser may not be racked with the accused in order to test his siucerity: The clergy can be tortured only in charges of tresson, poisoniag, and violation of tombs. On the great question whether there are tbree or five grades, he decides in favour of five, viz, threats, takiog to the place of torment, stripping aud binding, lifting on the rack, racking. Other Italian mriters of less emineace have been referred to for the purposes of this article. The burden of their writings is practically the same, but they have not attained the eystematic perfection of Farinaccias. Citations from many of them are made by Manzoni (see below). Among others are Guido de Suzara, Paris

[^197]fle Putco, Egidius Bossius of Milan, Casonus of Venice, Decianus, Follerius, and Tranquillus Ambrosianua, whose works cover tha period from the 13 th to tha end of the 17th century. " Tha law depended mainly on the writings of the jurists as interpretera of custom. At the asma tima in all or nearly all tha Italian atates the customary law was linited, supplemented, or ameaded by legislation. That a check by legislative authority was neceseary a ppears from the glimpsea aflurded by the writings of tha jurists that the letter of the law was by no neans alwaya followed. ${ }^{1}$ The earliest legislation after tha Roman law aecmas to be the constitutions of the emoeror Frederick 11. for Sicily promulgated in 1231.

Several instances of the torture of eminent persons occur in Italian history. The bistorical case of the greatest literary interest is that of the persons accused of bringing tha plagua into Milan in 1630 by smearing the walls of houses rith poison. Au analysis of the case nas undertaken by Verri ${ }^{2}$ and Manzont, ${ }^{3}$ anci puts in a clear light some of the abuses to which the systan led in times of popular panic. Convinciag argumeuts ara urged by Manzoni, after an exhaustive review of tha authorities, to prove the groundlessacss of the charga on which two iuroceut persons underrent tha torture of the canape, or hempen cord (the effect of which was partial or complate dislocation of the wrist), and afterwards auffered death by breaking on the wheel. Tha main argunents, shortly stated, ara these, all based upon the evidence as racorled. and tha law as laid dowa by jurists. (1) The unsupported evideuce of an accomplico was treated as an indicium in a casa not one of those exceptional ones in which such an indiciun was sufficiont. Tha avidence of two wituesses or a confession by tha accuscd wha necessary to establisli a remote indicium, such as lying. (2) IIearsay evideuce was received when primary eviclcuce was obtanable. (3) Tho confession made under torturo was not ratified afterwarda. (4) It was mada in consequedca of a promise of inupuity. (5) It was of an impossibla crime.
Moch general Information on the sablect will be found in the works of Mr Lea and Mr Lecky, to which reference has already been madio, in the Pemu" Cyclo. padiu, \&.y. "Torture," ta Zedler's Unicersal Lexicon E.r. "Tortar," and hu Bleytr'y Esp ut des Insibutions Juficiaures. ror England. Jerdine's work the the atandard authority. Thinty-six klods of torture are descrtied in Meycrs hon-ostraitions-Lezikon, s.v. "Mitur. Instmments of toitule art still preserved lo the $o w e r$ and Hague, and other places. Tho-e at the Tower are the troo collur, the ulbues, the shurobsrew, and the scavenger'i deughter. There is also a model of one of the
(J. Wt.) lordis of the rack.

## TORY. See Whig and Tory.

TOTEMISM. A totem is a class of material objects which a savage regards with superstitious respect. believing that there exists between him and every member of the class an intimate and altogether special relation. The name is derived from an Ojibway (Chippeway) word which was first introduced into literature, so far as appears, by J. Long, an Indian interpreter of last century, who spult it totam. ${ }^{4}$ The connexion between a man and his totell is mutually beneficent: the toteu protects the man, and the man shows his respect for the totem in various ways, by not killing it if it be an animal, and not cutting or gatbering it if it be a plant. As distinguished from a fetich, a totem is never an isolated individual, but always a class of objects, generally a species of animals or of plants, more rarely a class of inanimate natural objects, very rarely a class of artificial objects.

Considered in relation to men, totems are of at least three kinds:-(1) the clan totem, common to a whole clan, and passing by inheritance from generation to generation ; (2) the sex totem, common either to all the males or to all the females of a tribe, to the exclusion in either case of the orner sex: (3) the individual totem, belonging to a eingle individual aud not passing to his descendants. Other kinds of totems exist and will be noticed, but they may perbaps be regarded as varieties of the clau totem. The latter is by far the most important of all: and where we speak of totems or totemism without qualification the reference is always to the clan totem.

The Clan Zotem.-The clan toten: is reverenced by a body of men and women who call themselves by the name

[^198]of the totem, beliere themsclres to be of one blood. descendants of a common aucestor, and are bound tegether by common obligations to each other and by a common faith in the totem. Totemison is thus both a religions and a social system. In its religious aspect it consists of the relations of mutual respect and protection betweea a man and his totem; in its aocial aspect it consists of the relathons of the clansmen to each other and to mea of other clans. In the later history of totemisin these two sides, the religious and the social, tend to part company; the social system sometines survives the religions; and, on the other hand, religion sometimes bcars traces of totemism in countries where the social system based on totemism has disappeared. We begin mith the religious side.

Totemism as a Religron, or the Relation betroeen a Man and his Totern. -The members of a totem clan call themselves by tha namo of their totem, and commonly believe thenselves to be actually descendel from it.

Thus the Turtle clan of tha Iroqnoig ora descended from a fat Desceef turtle. which. burdeaed by tho welght of its sbell in walking, con-from trised by great areminos to throw it off, and tbereafter gradually totace. developed into a man. ${ }^{\text {B }}$ The Cray. Fish clan of tha Choctara were originally cray-fish and lived undergrouml, coming up occasionally throngh the mull to the surface. Once a party of Choctaws smoked them out, and, ticaling them kiluig, tanght them the Choctaw la: © $\quad$ 月ge, tougt then to walk on tho legs, mado :hem cut off their toe uaila and pluck the hair from their bodics, alter which they adopted them into the trike But the jest of their kindred, the cray-6sh, see still living uuderground. ${ }^{8}$ The Osages are desecuded from a male snail and a cenale bearcr. The suail burst his shell, sereloped arms, feet. and leas, and becanc a fina tail man; afterwards ho married the hemver maid.? Some of the clans of western Australia are descendal frum ducks, swans, and other waterfowl. ${ }^{5}$ In Sencgambia each fanily or clan is descended from au animal (hipropotnmus, scorpion, \&c.) with which it counts kindred."

Snaewhat different are tba mytha in which a homan ancestress is sail to hava given birth to an auimal of the toitn species. Thus the Suake clau among the Moquis of Arizona are descended from a women who gave birth to snakes ${ }^{10}$ The bakain\} in western equatorial Africa beliese that their wonou onca gava birth to the toten animals: one woman brought forth a calf, othars a crocudile, bippopotamus, monkey, hoa, and wild ligg. u

Believing himself to be descended from, and therefore Resped akia to, his totem, the savage uaturally treats it with respect. shown If it is an animal be will not, as a rule, kill nor cat it. In totera. the Mount Cambier tribe (South Australia) "a man does Lut kill or use as food any of the animals of the same subdivision with bimself, excepting when hunger compels; and then they express sorrow for having to eat their roingong (friends) or lumanuny (their flesb). When using the last word they touch then breasts, to indicate the close relationship, meaning almost a part of theinselres.

To illuatrate :-One day oue of the blacks killed a crow. Three or fonr davs alterwards a Buonws (crow) named Lary dicd. He bad heen ailing for souna days, but the killing of his rengong Lastened his death. ${ }^{\text {r }}$ The tribera about the Gulf of Carpentaia greatly revercuce their totema: if any one wore lo kill the totem animal in presence of the mun whose totem it was, tho latter would 6ay, "What for sou kill that fallow ? that my father !" or "That brutber belonging to ma youl have killal: why hud you do it !" 18 Sir George Grey says of the westera Austadinn thbes that a man will never kill an enimal of has kubug (tutem) spccica if he fod it asleep; "indeed, he always killa it reluctuntly. and neven without aflorling it a cliance to escape. This arises from the family belief tbai sonua oue individun of the sperica ia their neareat friead, to kill whom wnuld he a grat cmine, aud to be carcfully avoided." 14 Amougat the Inlians of British Columbua a man "il

fover kill his totem anlmal, If he seta asotfer do it, he will hide his face for shame, and afterwards demand compensation for the act. Whenever one of these Indians exhibita his totem badga (as by painting it on his forehead), all persons of the same totem ara bound to do honour to it hy casting property before it. ${ }^{1}$ The Damoras in South Africa are divided into totem clans, called "eandas"; and according to the clan to which they belong they refuse to partaka, e.g., of an ox marked with black, white, or red spots, or of a aheep without horas, or of draught oxcu.. Some of them will not aren touch vessels in which such food has been cooked, and avoid even the amoka of tha fire which has been used to cook it. ${ }^{2}$ The negrocs of Senegambia do not eat their totems. ${ }^{3}$ The Mundas (or Mundaris) and Oraons in Bengal, who ere divided into exognnous totem clans, will not kill or e日t the totern animala which giva their names to the clans.* A romarkable featuro of aome of these Oraon totema is that they are not whole animals, but parts of auimals, as the head of a tortoise, the stomach of a pig. In anch cases (wbich are not confined to Bencal) it is of course not the whole aoimal, but only the special part, that the clansmen are forbidden to eat. Such totems may be distinguished as splil cotcons. The Jagaunathi Kumlaar in Bengal abstain froos killing or injuring the totems of their respective clans, and they bow to their totems when they meet them.

When the totem is a plant the rules are sueh as these. A native of western Australia, whose totem is a vegetable, " may not gather it under certain circumstances and at a particular period of the jear." ${ }^{\circ}$ An Oraon clan, whose totem is the kujrar tree, will not eat the oil of that tree, nor sit in its shade. ${ }^{7}$ The Red Maize clan of the Omahas will not eat red maize. Those of the people. of Ambon and Uliase who are descended from trees may not use these trees for firewood.

The rules not to kill or eat the totem are not the only taboos; the clansmen are often forbidden to touch the totem or any part of it, sometimes even to look at it.

Thus the Elk clatı of the Omalhas neither cat tha flesh nor tonch any part of the male elk. ${ }^{\text {a }}$ Tha Decr-Head clen of the Omahas may not touch the skin of any auimal of the deer family, nor wear moccasins of deer skin, nor use tha fat of the deer for hair-oil; but they may eat Cize flesh of deer. ${ }^{\circ}$ Of the totem clans in Bengal it is said that they f'are prohibited from killing, eating, cutting, burning, carrying, nsing, \&c., "the totem. ${ }^{10}$ The Bechunanes in Sonth Africa, who have a welldoveloped totens systom, may not ent nor clothe themselres in tha 'akin of the toten animal. ${ }^{11}$ They even avoid, at least in some cases, to look et the totem. Thus to a man of the Bakuena (Bakwain) or "Crocodile claa, it is "hateful and unlucky" to meet or gaze on a crocodila; the sight is thought to canse inthammation of the eyea.

Sometimes the totern animal is fed or even kent aliva in captivity: Among the mountaineers of Formosa each clan or village keeps its totem (serpent, lenpard, \&c.) in a cage. ${ }^{12}$ A Samonn clan whose fotem was the eel used to present the first fruits of the faro plantations to the cela. ${ }^{13}$ Amongst the Narringeri in South Australie men of the Sanke clan aometines catch snakea, pull out their teeth or aew up their mouths, and keep them as pets. ${ }^{14}$ In a Pigeou clan of Samoa a pigeon was carefully kept and fed. ${ }^{15}$ Amonget the Kalang in Java, whose totem is the red dog, each family as a rula keeps one of these animala, which they will on no account allow to bo atruck or ill-nsed by any one. ${ }^{16}$

The dead totem is mouroed for and buried like a deard clansinan. In Sainoa, if a man of the Owl tatem found a dead owl by tho road side, he would ait down and weep over it and beat his forchead with stones till the blood flowed. Tho bird would theu be wrapped up and buried with es much ceremony as if it had beeu a human being. "This, bowaver, was not tha death of the god. He was supposed to ha yetalive, and incernata in all the owls in existenca." 17 Tho generalization hera implied is characteristic of totemism; it is not morely an individual but tho apecies that is reverenced. The Wanika in eostcra Africa look on the byeua as one of their

ancestora, and tho death of an hyxr.i is nourued ly the whofe peoplo; the mourning for a clice is said to be as nothing compared to the mourning for an hyona. ${ }^{18}$ A tribe of southern Arabia used to bury a slead gazalle wherever they fomd onc, aud tho whole tribo mourned for it ses en days. ${ }^{10}$ A Califormian tribo which roverenced the buzzard held an annual festival at whicle the chicf ceremony was the killing of a buzzard without lostng a drop of its blood. It was then skinned, the feathers were preservel to inske a sacred dresa for the medicine-man, and tha bolly was buried in holy ground anide the lamentations of the old women, who mourned as for the loss of a relatire or friend. ${ }^{20}$

As sonie totem clans evoid looking at their totem, so others aro careful not to speak of it by its proper name, but use descriptive epithets instead. The three totems of the Delawares-the wolf, turtle, and turker-were referred to respectively as "round foot." "craw-ler," and "not chewing," tho last referring to the birl"a habit of swallowing its food; aul the clans called thenselves, not Wolves, Turtles, oud Turkeys, but "Round Feet," "Crawlers," and "I'liose who do not chew. "'21 The Bear clan of the Ottawas called theia. selves not Beara but Big Feet. ${ }^{22}$ Tha object of these circemnlowitions is probably to give no offence to the worshipful animal.

The penalties supposed to be incurred by acting dirrespectfully to the totem are various. The Bakalai think that if a man were to ent bis totem the women of his clan would miscarry and give birth to animals of the totem kind, or die of an awful disease. ${ }^{23}$ The Elk clan anong the Omahas believe that if any clausman were to tonch any part of the male elk, or cat its flcsh or the flesh of the male deer, he wonld break out in boils and white spots in different parts of the body. ${ }^{24}$ The Ired Maize subclan of the Omalias believe that, if they were to eat of the red maize, they would bare running sores all round their mouth. ${ }^{25}$ And in general the Omalas believe that to eat of the totem, eren in-ignorance, would canse fickness, not only to the eater, but also to his wife and chilcren. ${ }^{2}$ s The worshippers of the Syrian godricss, whose creed was saturated with totemien, belicred that if they ate a sprat or an anchory their whole bodies wonld break out in ulcers, their legs would waste away, and their liver melt, or that their belly aud legs would swell up. ${ }^{27}$

The Samoans thought it death to mouse or eat their totems. The totem was supuped to take up his ahode in the sinner's body, and there to gender the very thing which he had eaten till it. caured his death. ${ }^{2{ }^{3}}$
Thus if a Turtle man ato of a turtle ho grow rery ill, and the Samon voice of tha turtle was heard in hia inside sinymg, "He ate mo; mode of I am killing him." 29 In ruch cascs, however, the famonns had a appeasi nuode of appensing the angry totcus. The offeuder limself or ono totem. of his clan was wripued iu leares and laid in an mbented oveu; as if be were aloout to be bsked. Thus if amoogst the Cuttle.Fish clan a visitor hod caught a cuttle-firln nud cooked it, or if a C'nttleFish man had heen present at the eating of a cuthic-fish, the Cuttle. Fish clau met and chose a nan or woman who weut tinungh the pretence of 1 cing haked. Otherwise a cuttle-fish would grow in the atomach of some of the clam and bu their death. ${ }^{30}$

In Australia, also, the punishment for eating the totem Aus appears to have been sickness or death. ${ }^{31}$ But it is not merely the totem which is taliooed to the Australians, they hare, luesides, a zery elaborate code of food jrohibitions, which vary chiefly witl age, lecing on the wholo strictest and most extensive at juberty, and gradually relaxing with advancing yeves Thus young meo arc for bidden to eat the emm; if they ate it, it is thought that they would be afflicterl with sores all over their bodics. 82

[^199]The relation between a man and his totem is one of mutual help and protection. If the man respects and cares for the totem, he expects that.the totern will do the same by bim. In Senegambia the totems, when they are dangerons animals, will not hart their clansmen; e.g., men of the Scorpion clan affirm that scorpions (of a very deadly kind) will run over their bodies without biting them. ${ }^{1}$ A Snake clan (Ophiogenes) in Asia Minor, believing that they were descended from snakes, and that snakes were thcir kinsmen, submitted to a practical test the claims of any man amongst then whom they suspected of being no true clansman. They made a snake bite him; if he survived, he was a true clansman; if he died, he was not. ${ }^{2}$ The Psyili, a Snake clan in Africa, had a similar test of kinship; they exposed their new-born children to snakes, and if the snakes left them unharmed or only bit without killing them, the children were legitimate; otherwise they were bastards. ${ }^{3}$ In Senegainbia, at the present day, a python is expected to visit every child of the Python clan within eight days after birth. ${ }^{4}$

Other totern clans regard a man who has been bitten by the totem, even though he survives, as disowned by the totem, and therefore they expel him from the clan. Among the Crocodile clan of the Bechuanas, if, a man has been bitten by a crocodile, or merely bad water splashed over him by a crocodile's tail, he is expelled the clan. ${ }^{5}$

But it is not enongla that the totem should merely abstain from injuring, he must positively benefit the men who put their faith in him. The Snake clan (Ophiogenes) of Asia Minor believed that if they were bitten by an adder they had only to 'put.a snake to the wound and their totein would suck out the poison and soothe away the inflammation and the pain. ${ }^{\text {® }}$ Hence Oraaha medicineenen, in curing the sick, imitate the action and voice of their (individual) totem. ${ }^{7}$ Menbers of the Serpent clan in Senegambia profess to heal by their touch persons who have been hitten by serpents. ${ }^{8}$ A similar profession was made in antiquity by Snake clans in Africa, Cyprus, and Italy. ${ }^{\text {a }}$

Again, the totem gives his clansmen important information by means of owens. In the Coast Murrins tribe of New Sonth Wales each man's totem warned him of coming danger; if his totem was a kangaroo, a kangaroo wonld warn him against his foes. ${ }^{10}$ The Samoan totems gave omens to their clansmen. Thus, if an owl flevr before the Owl clan, as they marched to war, it was a signal to go on: but if it flew across their path, or backwards, it was a sign to retreat. ${ }^{11}$ Some kept a tame owl on purpose to give omeus in war. ${ }^{12}$

When the conduct of the totem is uot all that his clansmea conld desire, they have various ways of putting pressure on him.
Thus, in barvest time, when the hirds eat the oorn, the Sunsll Bird clan of the Onullas take seme corn which they chew sad anit over tho field. This is thourlit to keep the bids frem the creps. ${ }^{13}$ If worms infest the corn the Reptile clan of the Omahas 'etch some of them and pound them up with some grains of orn which have been heated. They make a soulp of the mixture ald eat it, believing that the coro will not be iofestad agaill, at least for that year. ${ }^{14}$ During a log the men of the Turtla aubclan of the Onashas nsad to drew

[^200]the figure of a turtle on the grcum l with its face to the south On the head, tail, mildle of the hack, sud on each leg were placed amall pieces of a red breech-cloth with $\theta 0 \mathrm{me}$ tohscco. This was thought to make the fog disappear. ${ }^{10}$
In order, apparently, to put himself more fully under the protection of the totem, the clansman is in the habit of assimilating bimself to the totem by dressing in the skin or other part of the totem animal, arranging his hair and mutilating his body so as to resemble the totem, and repre senting it on his body by cicatrices, tattooing, or paint.

Among the Thlinkets on colemm occapione, auch es dances, menoriai festivals, and buials, iudiviluals oftea appear diaguised in the full fornt of thein totem animale; and, ss a rule, esch clans. man carries at least on evsily recogniagble part of his totom with him. ${ }^{16}$ Amongst the Omahas, the smaller boye of the Black Shoulder (Buffalo) clan wear two locks of hair in initatiou of horns. ${ }^{77}$ Thu Small Bird clan of the Omahas "Jeave a little hair in front, over the foreliead, for a bill, surl some st the back of the hesd, for the birl's tail, with milh over each ear for the wiuga." is The Turtle subclan of the Omahas "cut off all the hair from a hoy"e head, except six locks; two are left on each aide, one over the forehead, and one hanging lown the back iu imitation of the legs, head, and tail of a turtle." 19 The practice of knockiog out the upper frent tseth st puberty, which prevails in Anstrelia aud elsewhore, is, or was once, prolably an initation of the totell. The Batoks in Africa who edopt this practice say that they do so in order to be like oxell, while those who retaiu their teeth are like zebras, ${ }^{80}$

The Haidas of Queen Charlette Jslands are universally tattooed, Tatteas the design being in all cases the totem, executed in a conventional ing atyle. When several families of different totena live together in the sane large house, a Haids chief will have all their totems tattooell on his person. ${ }^{23}$ Tribea in South America sre especislly distinguished by their tattoo marks, hat whether these are totem marks is not said. ${ }^{22}$ T'lie Australians do not tattoo but raise cicatrices; in aome trihes these cicstrices are arrangod in patterns which aerve as the tribal badges, consisting of lines, dots, circles, semicircles, \&c. ${ }^{23}$ Accorrling to one authority, these Austraian tribsl badgea ere contetimes repreanatations of the totem. ${ }^{24}$

Again, the totem is unatimes painted on the person of the clensmau. This, as twe lisve seen (p. 408), is cometimes done by the Indians of British Colnmbia. Anong the Hurone (Wyandota) each clan has a distinctive mode of painting the face; and, at least in the case of the chiefs at installation, this painting represente the totem. ${ }^{25}$ Among the Mequis the representatives of the clans at foet-races, dances, \&c., have each a conventiousl representation of his totem blazoned ou breaet or back. ${ }^{28}$

The clansman also affixes his totem mark as a signature to treatiea and other documents, ${ }^{27}$ and paints or carves it on Lis weapons, lut, canoe, \&c.

The identification of a man with his totem appeare further to have been the object of various ceremonies olserved at birth, marriage, death, and on other occasions.

Birth Ceremonies.-On the fifth day after birth a child Birt of the Deer-Head clen of the Omahas is painted with red cere spots on its back, in imitation of a fawn, and red atripes mondes are painted on the child's arms and chest. All the Deer. Head men present at the ceremony nake red spots on their chests. ${ }^{28}$ When a South Slavonian women has givon birth to a child, an old woman runs ont of the house and calls out, "A ohe-wolf has littered a be-wolf," and the child is drawn through a wolfskin, as if to simulate actual birth from a wolf. Farther, a piece of the eye and heart of a

wolf are sewed into the child's shirt, or bung rouna its aeck; and, if several children of the family have died before, it is called Wolf. The reason assigned for some of these customs is that the witclies who devour childrea will not attack a wolf. ${ }^{1}$ In other words, the human child is disguised as a wolf to cheat its supernatural foes. The same desire for protection against supernatural danger may be the motive of similar totemic custorns, if not of totemism in general.

Marriaye Ceremonies.-Among the Kalang of Java, whose totem is the red dog, bride and bridegroom before marriage are rubbed with the ashes of a red•dog's bones. ${ }^{2}$ Among the Transylvanian Gipsies, bride and bridegroom are rubbed with a weasel skin. ${ }^{3}$ The sacred goatskin (xyis) which the priestess of Athene took to newly married women may have been used for this purpose. ${ }^{4}$ At liome bride and briderroom sat down on the skin of the sheop, which had been sacrificed on the occasion. ${ }^{5}$. An Italian bride smeared the doorposts of her new home with wolf's fat. ${ }^{0}$ It is difficult to separate from totemism the custom observed by totem clans in Eengal of marrying the bride and bridcgroom to trees before they are married to each other. The bride touches with red lead (a common marriage ceremony) a mahw tree, clasps it in her arms, and is tied to it. The bridegroom goes through a like ceremony with a mango tree.?

## Death

Death Ceremunies.-In death, too, the clansman seeks to become one with his totem. Amongst some totem clans it is an article of faith that, as the clan sprang from the toteni, so each clansman at death reassunes the totem form. Thus the Moquis, believing that the ancestors of the clans were respectively rattlesnakes, deer, bears, sand, water, tobacco, de., think that at death each man, according to his clan, is changed into a rattlesnake, a deer, \&c. ${ }^{8}$ Amongst the Black Shoulder (Buffalo) clan of the Omahas a dying clansman was wrapped in a buffalo robe with the hair out, his face was painted with, the clau nark, and his friends addressed him thus: "You are going to the animals (the buffaloes). You are going to rejoin your ancestors. You are going, or your four souls are going, to the four winds. Be strong." "9
Cere-
Ceremonies at Puberty.- The attainment of pmberty is aonies at celebrated by savares with ceremonies sonne of which seem suberty. to be directly connected with totemism. The Australian 'rites of initiation at puberty include the raising of these scars on the persons of the clansmen and clanswomen which serve as tribal badges or actually depict the totem. They also include those mutilations of the person by knocking out tectl, de., which we have scen reason to suppose are mea.at .to assimilate the man to his totem.

At one stage of thesc Australing rites a number of meu appear on the sceue liowlinur and ruming on all fon!s in imitation of the dingo or native Anstralian dog; at last tho leader jumps up, claspls hia hands, and shonts the totem mane "wild dog "to The Coast Murring tribe in New South Wales had an initiatory cere. mony at which the totem name "hrowu snake" was shonted, and a medicinc-man produced a live brown smake out of his mouth. ${ }^{11}$ As the fundamentul rules of toten societies are rules regnlating bocial intercourse, lerliapis these pantomimea were iutentod to bulpigy the youtlis with a symbolic language by means of which they uright communicate with persous speaking different languages,

[^201]aud thus iscertan whether they belonged to clans with which marriage was allowed. I'he totem clans of the Bechuanas have each its sjecial dance of pantomime, and whes they wish to ascertain a stranmer's clau they ask him, "What do you danoeq" 1a We finl elsewhere that dancing has Leen used as a mona of sexual selection.

But in sono cares these dances seem to be purely religious. At their initiatory rites the Yuin tribe in New South Wales mould figures of the totems in earth aud dance before them, and a medicine-mau brings up out of his inside the "magic" appropriate to the toten before which he stand.s: before the figure of the porcupine he brings up a stuff like chalk, before the kangaroo a stuff like glass, ic. ${ }^{13}$

Again, it is at initiation that the jouth is solemnly forbidden to eat of certain foods; but, as the list of foods prohibited to youths at puberty both in Australia and Anerica extends far beyond the simple totem, it would seem that we are here in coutact with those unknown general ideas of the savage, whereof totemism is only a special product.

Thus the Narrinyeri jouth at iuitiatiou are forbidden to eat twenty different kinds of game, besidea any food belonging to womeu. If they eat of these lorbidden foods it is thought they will grow ugly. ${ }^{24}$ In the Mycoolon tribe, near the Gulf of Carpentaria, the youth at initiation is forbiducn to eat of eaglelawk and its young, native companion and its young, some snakes, turtles, ant-eaters, and emul eggs. ${ }^{15}$ The Kurnai youth is not allowed to eat the fenale of any animal, nor the cmu, nor the porcupinc. He becomes free by laving the fat of the animal sineared on his face. ${ }^{15}$ On the other hand, it is said that."initiation confers many lיrivilegea on the youths, as they are now allowed to eat many articles of food which were previously forbidden to them." ${ }^{7}$ Thus in New South Wales before initiation a buy may eat only the females of tho animals which he catches; but after iuitiation (which, however, may not be complute for sovelal years) he may eat whatever lie finds. ${ }^{18}$ In North America the Creek youtha at puberty were forbidden for twelve montha to eat of young bucks, turkey-cncks, fowls, pease, aud salt. ${ }^{12}$

These ceremonies secm also to be meant to admit the youth into the life of the clan, and hence of the totem. The latter appears to be the meaning of a Carib ceremony, in which the father of the youth took a live bird of prey, of a particular species, and beat his son with it till the bird was dead and its head crushed, thus transferring the life and spirit of the martial bird to the future warrior. Further, he scarified his son all over, rubbed the juices of the Lird into the wounds, and gave hin the bird's heart to eat. ${ }^{20}$ Amongst some Australian tribes the jouth at initiation is smeared with blood drawu from the arms either of aged men or of all the men present, and he eveu receives. the blood to drink. Amongst some tribes on the Darling this tribal blood is his only food for two days. Among some tribes the youths at initiation sleep on the graves of their ancestors, in order to absorb their virtues. ${ }^{21}$ It is, however, a very notable fact that the initiation of an Australian youth is said to be conducted, not by men of the same totem, but by men of that portion of the tribe into which he may marry. ${ }^{22}$ In some of the Victorian tribes no person related to the youth by blood can interfere or assist in his initiation. ${ }^{23}$ Whether this is true of all tribes and of all the rites at initiation does not appear.

Connected with totemism is also the Australian cers? mony at initiation of pretending to recall a dead man to life by the utterance of his totem name. An old man lies

[^202]down in a grave and is covered up lightly with earth; but at the mention of his totem name he starts up to life. ${ }^{1}$ Sometimes it is believed that the youth himself is killed by a being called Thuremlui, who cuts him up, restores hins to life, and knocks out a tooth. ${ }^{2}$ Here the idea seems to be that of a second birth, or the beginning of a new life for the novice; hence he receives a new name at the time when he is circumcised, or the tooth knocked out, or the blood of the kin poured on him. ${ }^{3}$ Amongst the Indians of Virginia and the Quojas in Africa, the youths after initiation pretended to forget the whole of their former lives (parents, language, customs, \&c.), and had to learn everything over again like new-born babes. ${ }^{4}$ A Wolf clan in Texas used to dress up in wolf skins and rum about on all fours, howling and mimicking wolves; at last they scratched up a living clansman, who had been buried on pr rpose, and, jutting a bow and arrows in his hands, bade him de as the wolves domrob, kill, and murder. ${ }^{5}$ This may have been an initiatory ceremony, revealing to the nuvice in pantomime the double origin of the clan-from wulves and from the ground. For it is a commen belief with totem clans that they issued originally from the ground.
Connected with this mimic death and revival of a clansman appear to be the real death and supposed revival of the toten itself. We have seen that some Californian Indians killed the buzzard, and then buried and mourned over it like a clansman. Gut it was beliered that, as often as the bird was killed, it was made alive again. Much the same idea appears in a Zuni ceremony described by an eyewitness, Mr Cushing. He tells how a procession of fifty men set off for the spirit-land; or (as the Zunis call it) "the home of our others," and returned after four days, each man bearing a basket full of living, squirming turtles. One turtle was brought to the house where Mr Cushing was staying, and it was welcomed with divine honours. It was addressed as, "Ah! my poor dear lost child or parent, my sister or brother to have been! Who knows which? May bo my own great great grandfather or mother?" Nevertheless, next day it was killed and its flesh and bones deposited in the river, that it might "return once more to eternal life among its comrades in the dark waters of the lake of the dead." The idea that the turtle was dead was'repudiated with passionate sorrow; it had only, they said, "changed houses and gone to live for ever in the home of 'our lost others.' " $\theta$ The meaning of such ceremonies is not clear. Perhaps, as bas been suggested, ${ }^{\text {, }}$ they are piacular sacrifices, in which the god dies for his people. This is borne out by the curses with which the Egyptians loaded the head of the slain bull. ${ }^{8}$
Sex Totems.-In Australia (but, so far as is known at present, nowhere else) each of the sexes has, at least in some tribes, its special sacred animal, whose name each individual of the sex bears, regarding the animal as his or her brother or sister respectively, not killing it nor suffering the oprosite sex to kill it. These sacred animals therefore answer strictly to the definition of totems.

Thus amongst the Kurnai all the men were called Yeerung (Emn-Wren) and all the women Djeetgun (Superb Warbler). The birds called Yeerung wero the "brothers" of the mon, and the birls called Djeetgın were the women's "sistcrs." If the men killed an emu-wren they were attacked by the romen, if the women killed a superb warbler they were assailed by the men. Yeeruag and Djeetgun were the mythical ancestors of the Kurnai. ${ }^{9}$

[^203]The Kulin tribe in Victoria, in addition to sixteen clan totems, has two pairs of sex totems: olle pair (the emu-nreu and superb warbler) is identical with the Kurnai pair; the other pair is the bat (male totem) and tho small aight jar (femalo totem). The latter pair extends to the extreme north-western confines of Vice toria as the "man's brother" and the "woman's sister."10 The Ta-ta-thi gronp of tribes in New Sonth Wales, in addition to regular clan totems, has a pair of sex totems, the bat for men and $\mathfrak{a}$ small owl for women; men and women aldress each other as Owl and Bats; and there is a fight if a woman kills a bat or a man killd a small owl." Of some Victorian tribes it is said that "tho common bat belongs to the men, who protect it against injury, even to the half killing of their wives for its sake. The fern owl, or large goat. sucker, beloags to the women, and, althongh a bird of evll omen. creating terror at night by its cry, it is jealously protected by them. If a man kills one, they are as much enraged as if it was one of their children, and will strike him with their long poles."13
The sex totem seems to be still more sacred than the clan totem; for men who do not object to other people killing their clan totem will fiercely defend their sex totem against any attempt of the opposite sex to injute it. ${ }^{13}$
Individual Totems.-It is not only the clans and the Indi seses that have totems; iudividuals also have their own special totems, i.e., classes of objects (generally species of animals), which they regard as related to themselves by those ties of mutual respect and protection which are characteristic of totemism. This relationship, however, in the case of the individual totem, hegins and ends with the individual man, and is not, like the clan totem, transmitted by inheritance. The evidence for the existence of individual totems in Australia, though conclusive, is very scanty. In North America it is abundant.
In Australia we hear of a medicine-man whose clan totem through his mother was kangaroo, but whose "sectet" (i.e., individual) totem was the tiget-snake. Snakes of that species, therefore, would not hurt him. ${ }^{14}$ An Australian scems usually to get his individual totem by dreaming that he has been transformed into an animal of the species. This a man dreamed three times he was a kangaroo; hence ho became one of the kangaroo kindred, and might not cat any part of a kangaroo on which there was blooul; he might not even carry home one on which there was blood. He might eat cooked kangaroo; but, if ho were to eat the meat with the blood ou it, the spirits would no longer take him up aloft. ${ }^{15}$

In America the individual totem is usually the frst animal of which a youth dreams during the long and generally solitary fasts which American Indians observe at puberty. He kills the animal or bird of which ho dreams, and henceforward wears its skin or feathers, or some part of them, as an amulet, especially on the war-path and in hunting. ${ }^{16}$ A man may eren (thouglt this seems exceptional) acquire several totems in this way; thus an Ottawa medicineman had for his individual totems the tortaise, swan, woodrecker, and crow, because he had dreamed of them all in his fast at puberty. The respect paid to the individual totem varies in different tribes. Among the Slave, Hare, and Dogrib Indians a man may not eat, skia, nor if possible kill his individual totem, which in these tribes is said to be always a carnivorous animal. Each man carries with him a picture of his totem (bourght of a trader); when he is unsuccessfinl in the chase, he pulls out the picture, smokes to it, and makes it a speech. ${ }^{17}$

The Indians of Cnnarla changed their okki or manitoo (individual totem) if they had reason to be dissatisfied with it; their women had also their okkis or manitoos, but did not pay so much heed to. them as did the men. They tattooed theirindividual totems on their persons. ${ }^{18}$ Amougst the Indians of San Juan Capistraue, a figuro of the individual tatem, which was acquired as usual by fasting, was moulded in a paste made of crushed herbs on the right arm of the novice. Fire was then set to it, and thus the figure of, the totem was burned into the flesh. ${ }^{18}$ Sometimes the individua? totem is not acquired by the individual himself at puberty, but is

[^204]㐌xed for him iadependently of his will at birth. Thus among the tribes of the isthmus of Tehuantepec, when o woman was about to be confined, the relstions assembled in the hut and drew on the floer figures of different snimals, rubbiag each one out as soon as it was finished. This went on till the child was bern, and the figure that then remained aketched on the ground was the child's tona or totom. When he grew older the child procared his totem aninal and took care of it, beliaving that his life was bound up with the animal's, and that when it died he too must die. ${ }^{1}$ Similarly in Samea, at child-birth the help of several "geds" was invoked in succession, and the one who happened to be addressed at the moment of the birth was tlie infant's totem. These "gods" were dogs, eels, eharks, lizards, \&c. A Samosn had no objection to eat nnother man'e "god "; but to eat his own would have been death or injury to him. ${ }^{2}$ Sometimes the okkis or mauitoos acquired by dreams are not totems but fetiches, beiag not classes of objects but individual objects, such as a particular tree, rock, knife, pipe, \&c. ${ }^{3}$

Besides the clan totem, sex totem, and individual totem, there are (as has been indicated) some other kinds or varieties of totems; but the consideration of them had better be deferred till after the consideration of the social organization based on totemism.

Social Aspect of Totemism, or the relation of the men of Fa totem to each other and to men of other totems.-(1) Ail the members of a totem clan regard each other as kinsmen or brothers and sisters, and are bound to help and protect each other. The totem bond is stronger than the bond of blood or family in the modern sense. This is expressly stated of the clans of western Australia and of north-western America, ${ }^{4}$ and is probably true of all societies where totemism exists in full force. Hence in totem tribes every local group, being necessarily composed (owing to exogamy) of members of at least two totem clans, is liable to be dissolved at any moment into its totem elements by the outbreak of a blood feud, in which husband and wife must always (if the fend is between their clans) be arrayed on opposite sides, and in which the children will be arrayed against either their father or their mother, according as descent is traced through the mother or through the father. ${ }^{5}$ In blood feud the whole clan of the aggressor is responsible for his deed, and the whole clan of the aggrieved is entitled to satisfaction. ${ }^{6}$ Nowhere perlaps is this solidarity carried farther than among the Goajiros in Colombia, South America. The Goajiros are divided into some twenty to thirty totem clans, with descent in the female line; and amongst them, if a man bappens to cut himself with his own knife, to fall off his horse, or to injure himself in any way, his family on the mother's side immediately demand payment as blood-money from him. "Being of their blood, he is not allowed to spill it without paying for it." His father's family also demands compensation, but not so much. ${ }^{7}$
(2) Exogamy.-Persons of the same tatem may not marry or have sexual intercourse with each other. The Navajos believe that if they married within the clan "their bones would dry up and they would die." ${ }^{8}$ But the penalty for infringing this fundanental law is not merely natural; the clan steps in and punishes the offenders. In Australia, the regular penalty for sexual intercourse with a person of a forbidden clan is death.

It matters not whether the woman be of the same local group or has been captured in war from snother tribe; a man of the wrong

[^205]clan whe nses her ss his wife is hunted down and killed by his clansmen, and so is the womsn; though in some cases, if they succeed in eluding capture for a certain time, the offonce may be condoned. In the Ta-ta-thi tribe, New Sotuth Wales, in the rare cases which occur, the man is killed but tho woman is only boaten or apeared, or beth, till she is nearly dead; the reason given for not actually killing her being that she was prebably coerced. Even in casual smours tha clan prohibitions are strictly observed; auy violations of these prohibitions "are ragarded with the utmost abhorreace ond are purished by death."9 An inportant exception to these rules, if it is correctly reported, is that of the Port Linceln tribe, which is divided inte two clans, Mattiri and Karrarn, and it is said that though persons of the same clan never marry, yet "they do not seem to consider less virtuons connexions between partiee of the eame class [clan] incestuous." 10 Again, of the tribes on the lower Muray, lower Darling, \&c., it is said that though the slightest bloed rolationship is with them a bar to marrisge, yet in their sexual intercomrss they are perfectly free, and incest of every grade continually occurs. ${ }^{21}$

In America the Algonkins consider it highly criminal for a man to marry a woman of the same totem as himself, and they tell of cases where men, for breaking this rule, have been put to death by their nearest relations. ${ }^{12}$

In some tribes the marriage prohibition only extends to Pbratries a man's own totem clen; he may marry a woman of any totem but his own. This is the case with the Haidas of the Queen Charlotte Islands, ${ }^{13}$ and, so far as.appears, the Narrinyeri in South Anstralia, ${ }^{14}$ and the western Australian tribes described by Sir George Grcy. ${ }^{15}$ Oftener; however, the prohibition includes several clans, in none of which is a man allowed to marry: For such an exogamous group of clans within the tribe it is convenient to have a name ; we shall therefore call it a phratry (L. H. Morgan), defining it as an exogamous division intermediate between the tribe and the clan. The evidence goes to show that in many cases it was originally a totem clan which has undergone subdivision.

The Choctaws, for example, were divided into two phratrics, American cach of which included four claus; marriage was prohibitcd be-phratries, tween members of the sanne pliratry, but nombers of either phratry could marry into sny clan of the other. ${ }^{18}$ The Seneca tribe of the Iroquois was divided into two phratries, each includiug four clans, -the Bear, Wolf, Beaver, and Turtlo clans forming oue phratry, and the Deer, Snipe, Heron, and Hawk clans formiug the other. Origiaslly, as among the Chectaws, marriage was prohibited within the phratry but was permitted with any of the clane of the other phratry; the prohibition, however, has now broken down, and a Seneca may nuarry a worman of any clau but his own. Hence phratries, in our eense, no longer exist among the Senecas, though the organization survives for certain religions sud social purpeses. ${ }^{17}$

The phratries of the Thlizkets and the Mohegans deserve especial attention, becauso each phratry bears a name which ia also the name of one of the clans included in it. The Thlinkets aro divided as follows:-Raven phratry, with clans Raven, Frog, Goose, ScaLion, Owl, Salmon; Wolf plirstry, with claas Wolf, Bear, Eagle, Whale, Shark, Auk. Members of the Reven phratry must marry members of the Wolf phratry, and vice versa. ${ }^{\text {d }}$ Cousideriag the prominent parts played in Thlinket mytholegy by the ancestore of $t^{3}$, two phrstries, and considering that the names of the phratrics sre also names of clans, it seems probable that the Raven suld Wolf were the two origiunl clans of the Thlinkets, which afterwards by subdivision became phratries. This was the opinion of the Russian missionary Venisminoff, the best early authority on the tribe. ${ }^{19}$ Still more clearly do the Mohegan phratries appear to have been formed by subdivision fiom clans. They ere as follows : ${ }^{30}$ - Wolf phrstry, with clans Wolf, Bear, Dog, Opossum; Turtle

Thratry, with clans Littlo Turtle, Mul Tortle, Great Turtle, Yellow Eel; Turkey pliratry, with clans Turkey, Crane, Chickea. Hero we are almost forced to conclude that the Turtle phratry was origin. ally a Turtle clan which subdivided into a number of clans, each of which took the name of a particular kind of turtle, while the Fellow Eel clan may lave been a later subdivision. Thus we get a probable explanation of the origin of split totems; they seem to have arisen by the acgmentation of a single onginal clan, which had a whole animal for its totem, into a number of clans, each of which took the name either of a part of the original animal or of a sulspecies of it. We may conjecture that this was the origin of the Grey Wolf and Yellow Wolf and Great Turtle and Little Turtle clans of the Tuscarora-Iroquois; ${ }^{1}$ the Black Eagle and White Engle ant the Dectand Deer-Tail clans of the Liaws ; $^{2}$ and of the Ilighland Tuntle (striped), Mighland Turtle (black), Mud Turtle, and Smooth Large Turtle clana of the Wyandots (Hurons). ${ }^{3}$ Warren actually states that the puinerous Bear clan of the Ojibways was formerly subdivided into subelans, each of which took for its totem some ,art of the Bear's body (head, foot, ribs, \&c.), but that these have nov merged into two, the Common Bear and the Grizzly Bear. ${ }^{4}$ The subrivision of tho Turtle (Tortoise) clan, which on this hypothesis has taken place among the Tuscarora-Iroqpois, is nascent among tho Onoodaga.Jroquois, for among them "the name of this clan is Hahnowa, which is the general word for tortoise; but the clan is divided into two septa or subdivisions, the Hanyatengona, or Great Tortoise, and the Niknhoowaksa, or Little Tortoise, which together are held to constitute but one clan." "

On the other hand, fusion of elans is known to have taken place, as among the Haidas, where the Black Bear and Fin-Whale clans hare united; ${ }^{6}$ and the same thing has happened to some extent among the Omahas and Osages. ${ }^{7}$

In Australia the phratries are still more important than in America ilessrs Howitt and Fison, who have done so much to advance onr knowledge of the social system of the Australian aborigines, have given to these exogamous divisions the name of classes; but the term is objectionablo, because it fails to convey (1) that these divisions are kinship divisions, and (2) that they are intermediate divisions; whereas the Grcek term phratry eonveys both these meanings, and is therefore appropriate.

We lave seen examples of Australian tribes in which members of any clan are free to marry members of any clan but their own; but such tribes appear to be exceptional. Often an Australian tribe is divided into two (exogamous) phratries, each of which includes under it a nunber of totem clans; and oftener still there are subphratries interposed between the phratry and the clans, each phratry including two subphratries, and the subphratries including totem clans. We will take examples of the former and simpler organization first.
The Turra tribe in Yorke Peninsula, South Australia, is divided into. two phratrics, Wiltin (Eaglelawk) and Mñlta (Seal). The Eaglehawk phratry includes ten totem clans (Wombat, Wallaby, Kingaroo, Ignana, Wombat-Snake, Bandicoot, Black Bandicoot, Crow, Rock Wallaby, and Enuu); and the Seal Phratry includes six (Wild Goose, Butterfish, Mullet, Schnapper, Shark, aod Salmon). The phratrics are of course exogamous, but (as with the Choctaws, Mohegan, and, ao far as appears, all the American phratries) any clan of the one phratry may intermarry with any clan of the other phratry. ${ }^{\theta}$ But the typical Australian tribe is divided into two exogamous phratries; each of theso pliratries is subdivided into two subphratries; and these subphratrics ara subdivided into an iadefinite number of totem clans. The phratries being exogamons, it followa that their suldivisions (the subphratries and clang) cre so also. Tho well-kuown Kamilaroi tribo in New South Wales will serve as an cxample. lta subdivisions are as follows: ${ }^{9}$ -

[^206]In sach tribes the freedom of marriage is still more cartailed A subphratry is not freo to onarry into cither subphratry of the other phratry ; each suluphratry is restricted in its choice of partners to one suhphratry of the other phratry; Muri can only marry Kombo, and vicc versa; Kuhi can only marry Ipai, and vicc versa. Hence (aupposing the tribe to be equally distributed between the phratries aod subphratries), whereas under the two phratry and clan system a mao is free to chooso a wife from half tho women of the tribe, under the pliatry, subphratry, and clan system he ia restricted in his choice to one quarter of the women.

A remarkable featnre of the Australian social organization is that divisions of one tuibe have their recognized equivalents in other tribes, whose languages, including the names for the tribal divisions, are quite different. A native who travelled far and wide through Australia stated that "be was furnished with temporary wives by the rarious tribes with whom he sojourned io his travels; that his right to these women was recognized as a matter of course ; and that he conld always ascertain whether they belonged to the division into which he could legally marry, "though the places were 1000 miles apart, and the languages quite different." "12 Again, it is said that "in cases of distant tribes it can be shown that the class divisions correspond with each other, as for instance in the classes of the Flinders river and Mitchell river tribes; and these tribes are separated by 400 miles of country, and by many intervening tribes. But, for all that, class corresponds to class in fact and in meaning and in privileges, although the name may be quite different and the totems of each dissimilar." 12 Particular information, however, as to the equivalent divisions is very scanty. ${ }^{13}$ This systematic correspondence between the intermarrying divisions of distinct and distant tribes, with the rights which it conveys to the members of these divisions, points to sexual communism on a scale to which there is perhaps no parallel elsewhere, certainly not in North America, where marriage is alway: within the tribe, though outside the clan. ${ }^{14}$ Bit even in Australia a man is always bound to marry within a oertain kinship group; that group may extend across the whole of Australia, but nevertheless it is exactly limited and defined. If endogamy is used in the sense of prohibition to marry outside of a certun kinship group, whether that group be exclusive of, inchusive of, or identical with the man's own group, then marriage among the totem societies of Australia, America, and India is both exogamous and endogamous; a man is forbidden to marry either within his own clan or outside of a certain kinship group. ${ }^{25}$
(3) Rules of Descent.-In a large majority of the totem Rule: of tribes at present known to us in Australia and North descamen America descent is in the female line; i.e., the children belong to the totem clan of their mother, not to that of their father. In Australia the proportion of tribes with female to those with male descent is as four to one ; in America it is between three and two to one.

As to the totem tribes of Africa, descent allong the Damaras is in the female line, ${ }^{16}$ and thero are traces of fennale kin among tho Bechuanas. ${ }^{17}$ Among the Balalai property descends in the male line, but this is not a conclusive proof that descent is so reckoned; all the elans in the veighbourhood of the Bakalai have fomalo descent botli for blood and property. ${ }^{18}$ In Bewsal, where there is a considerable body of totem tribes, Mr Risley says that after careful search he and his coadjutors havo found $n 10$ tribe with fenale descent, and only a siurle trace of it in onc. ${ }^{19}$ Among tho totem

[^207]trilee of Bengal descent is male. ${ }^{1}$ In Aesam the exogamous totem cluns of the Xasias have female descent, ${ }^{2}$ as also have the exogamoue cluns of the Garos, but it does not appear whethar thoir clang are totem clane, though noine of their legeads point to totemism. ${ }^{\text {a }}$
In the Australian tribal organization of two phratries, four subphratries, and totem clans, there occurs a peculiar form of descont of which no plausible explanation has yet been offered. It seems that in all tribes thns organized the children are born into the rubphratry neither of their father nor of their mother, and that desceat in such cases is either female or male, according as the subphratry inte which the children are born is the companion subphratry of their mother's or of their father's subphratry. In the former case we have that may be called indirect female descent; in the latter, indirect male descent. But it is only in the subphratry that descent is thus indirect. In the totem clan it is always direct; the child belongs to the clan either of its mother or of its father. Thus, in the typical Australian organization, descent, whether female or male, is direct in the phratry, indirect in the subphratry, and direct in the clan.
 ab the phratries and subphratries are coocerned, in the Kamilaroi:-

This is an example of indirect female deacent, becsuse the children belong to the compaaion oubphratry of their nother, not to the companion oubphratry of their futher. But in the toteme the female descent is direct; e.g., if the father is Muri-Kangaroo and the mother is Kumbo-Emu, the children will be Inai-Engu; if the mother is Kumbo- Randicoot, the children will be Ipai. Bandicoot. ${ }^{4}$, ${ }^{\text {The }}$ following is the echeme of descent in the Kibar trihe The following is the echeme of descent in the Kiabara trihe: $0^{-}$-

| Phastries. | Nala. | Marriea | Childreu ara |
| :---: | :---: | :---: | :---: |
| $\left.\begin{array}{l}\text { Duebl. } \\ \text { Cubatina. }\end{array}\right\}$ | Barlog. Turawline. Bulcola. Bundah. | Bundah. Bulcola. Turawiae. Barling. | Turawine Baring. Bundah. Balcoln. |

This is en example of iudirect male descent, becanse the children belong to the companion aubphratry of their father, not to the companion oubphratry of their mother. We lave no information as to the totems, hut on the azalogy of indirect fermale descent we should expect them to be taken from the father. This at any rate is true of a large tribe or group of tribes to the south of the Gulf of Carpentaria; their rules of marriage and deecent, eo far as concerne (which at the lower like those of the Kiabara, and the totems (which at the lower Leichhardt river are the names of fish) are inhorited from father to oon. ${ }^{6}$
In some Aostralian tribes eone take their toteme from their father and daughters from their mother. Thus the Dieri in South Anstralia are divided into two phratries, each of whicb in Soluth undor it eixtean totem clans, (Caterpillar, Mullet, Dog, Ras, Kangaroo, Frog, Crow, \&c.) $7^{7}$ and if a Dog man marries a Rat woman, the soas of this marriage ere Dogs and the daughters are Anstralian Bight, has, with ceptain exceptions, the of the Great descent. ${ }^{9}$ Bight, has, with certain exceptions, the same rule of

Besides the tribes whose line of descent is definitely fixed in the female or male line, or, as with the Dieri and Ikula, half-way between the two, there are a number of :tribes among whom a child may be entered in either his 'miviher's or his father's clan. Among the Haidas, children regularly belong to the totem clan of their mether; but po very exceptional cases, when the clan of the father is reduced in numbers, the newly-horn child may be given

[^208]to the father's sister to suckle. It is then spoken of as belongiug to tlie paterual aunt, and is counted to its father's clan. ${ }^{10}$ Among the Delawares descent is regularly in the female line; but it is possible to transfer a child to its father's clan by giving it one of the names which are appropriated to the father's clan. ${ }^{11}$ In the Hervey Islands, South Pacific, the pareats settled beforehand whether the child should belong to the father's or mother's clan The father usually had the preference; but sometimes, when the father'e clan was one which was bonad to furnish human victims from its ranks, the mother had it adopted iute her clan by having the name of her totem pronounced over it. ${ }^{12}$ In Samoa at the birth of a child the father's totem was usually prayed to first; but if the birth was tedious, the mother's totem was invoked; and whichever happened to be in voked at the moment of birth was the child's totem for life. ${ }^{18}$
When a North American tribe is on the march, the members of each totem clan camp together, and the clans ara arrauged io ef fixed order is camp, the whole tribo being arranged in a great circle or in several concentric circles. ${ }^{14}$ When the tribe livea in eettled rillages or torus, each clan hae its өoparate ward. ${ }^{10}$ The clans of the Osages are divided into war clans and peace clong; when they are out ou the buffalo huat, they camp on opposite sides of the tribal circle; and the peace clans are not allowed to take animal life of any kiod; they mast therefore live on recgetables unless they can obtain neat in exchange for vegetables from the war clans, Mombers of the aame clan are huried together and apart from those of other clane; beace the remains of husband
and mife, beloaging as they do to separate clane, do not rest and mife, belonging as they do to separate clans, do not rest
together. 17
It ia remarkable that amoog the Thlinkets the body must alwaye be carried to the funeral prre and barued by mea of another totem, ${ }^{\text {² }}$ and the presenty distributed on these occasioue by the ropresentatives of the deceased must alnays be made to uned
of a differeat clan. 18

Here we must revert to the religious side of totemisn, Phratrity in order to consider some facts which have emerged from and anl the study of its social aspect. We bare seen that some phratries, both in America and Australia, bear the names of animals; ${ }^{20}$ and in the case of the Thlinkets and Mohegans we have seen reason to believe that the animals which give their names to the phratries were ouce clau totems. The same seems to held of the names of the Australian phratries, Eaglehawk, Crow, and Seal, or at least of Eaglehawk and Crow, for these are clan totems in other tribes, and are, besides, important figures in Australian mythology. Indeed, there appears to be direct evidence that both the phratries and subphratries actually retain, at least in Qeme tribes, their totems. Thus the Port Mackay tribe in Queensland is divided into two phratries, Iungaru and Wutaru, with subphratries Gurgela, Burbia, Wungo, and Kubera, and the Yungaru phratry has for its totem the alligator, and" Wutaru the kangaroo, ${ }^{21}$ while the oubphratries have for their totems the emu (or the carpot 6nake), ignana, opossum, and kangaroo (or scrub turkey). ${ }^{22}$

${ }_{2}^{21}$ Fison aud Howitt, 38 sg., 40.
${ }^{2}$ Fiaon and Howitt, p. 41. Tha toteme of the phratries and aub-, phratries are gives by differest authorities, who write the native sames of the subyhratrics difereatly. But they seem to be apeaking of the oqma tribe; at least Mr Fison onderstands them so

As the subphratries of this tribe are said to be equivaient to the subphratries of the Kamilaroi, it seems to follow that tue subphratries of the Kamilaroi (Muri, Kubi, Ipai, and Kumbo) have or once liad totems also. Hence it appears that in tribes organized in phratries, subphratries, and clans each man has three totems-his phratry totem, his subphratry totem, and his clan totem. If we add a sex totem and an individual totem, each man in the typical Australian tribe has five distiact kinds of totems. What degree of allegiance he owes to his subphratry totem and phratry totem respectively we are not told ; indeed, the very existence of such totems, as disticet from clan totens, appears to have been generally overlooked. But we inay suppose that the totem bond diminishes in strength in proportion to its extension; that therefore the clan totem is the primary tic, of which the subphratry and phratry totems are successively weakened repetitions.

In these totems superposed on totems may perbaps be discerned a rudimentary classification of natural objects under heads which bear a certain resemblance to genera, species, dc. This classification is by some Australian tribes extended so as to include the whole of nature. Thus the Port Mackay tribe in Queensland (see above) divides all nature between the phratries; the wind belongs to one phratry and the rain to another; the sun is Wutaru and the moon is Yungaru; the stars, trees, and plants are also divided between the phratries. ${ }^{1}$ As the totem of Wutaru is kangaroo and of Yungaru alligator, this is equivalent to making the sun a kangaroo and the moon an alligator.

The Mount Gambier triba in Sontb Australia is divided into two phratries (Kumi and Kroki), which ogain ara subdivided into totem clans. Everything in naturo belongs to a totem clan, thus: ${ }^{2}$ -

| Phratrles. | Totem Clans. | Including |
| :---: | :---: | :---: |
| Kuml. <br> SrokL | 1. JIala = F1sh1-Hawk. <br> 2. Parangal = Pellcan. <br> 3. $\bar{W} \bar{a}=$ Crow. <br> 1. Wus= Black Cockaloe. <br> 5. Karato =A hurmless Snaka. <br> 1. WëHe=Tea-Trea. <br> 2. Marna $=$ Aa cdibla Reot. <br> 8 Karáal = Black crestless Cock . atoo. | ```Smake, honeysuckle, trees, \&c. f Dogs, blackwond trees, fre, frost (rem.) Rain, thunder, ligitning, winter, hail. clouds, \&c. Stars, moon, de. fFisli, stingybark trees, seals, ecis, \&c. Ducks, wallables, owls, cray flsli, \&e \(\left\{\begin{array}{l}\text { Bustards, quatls, dolvich (a amall } \\ \text { kajgaroo). } \\ \text { Kangaroo, shc-oak trees, summer, } \\ \text { 日un, autumn (fem.) wind (fem.) }\end{array}\right.\)``` |

With reference to this classification Mr D. S. Stewart, the sutherity for it , says, "I have tried in vain to find some reason for she arrangement. 1 osked, "To what division does a bullock belong!' After a pause camo the answer, "It eats grass: it is Boortwerio.' I then said, 'A cray-fish does not eat grass; why is it Boortwerio ?' Then camo the etanding reason for all puzzling questions: "That is what our fathers said it was." "3 The natural pbjects thus classed under and sharing the regrect due to the totem may be conveniently called, as Mr Howitt proposes, ${ }^{4}$ subtotems. Araiu, the Wotjoballuk tribe in morth-western Victoria has a system of subtotems, thus: ${ }^{5}$ -

Of the subtotems in this tribe Mr Howitt says, "They appear to ane to ba totems in a state of dovelopment. Hot mind has at least Gve of them, white cockatoo has seventeen, and 60 on for the others. Able :hese surutotems are now in process of gaining a cort of inde. pedence may be shown by the following instance: a man who is Erokitch-Wartmut (hot wind) claimed to own all the five soltotems of bot wind (threa snakes and two birds), yet of these there was one which he enecially claimed as 'belonging' to him, namely, sfatwuk (carpet-soake). Thus his totem, hot wind, seens to havo geen in process of subdivision into minor totems, and this naan's

[^210]- Fison and Howitt, loc. cil. $8^{8}$ Fison and Howitt, 169.

- bid.
division might have become hot wind carpet-shike had not civilization iulcly stopred the process by slmost extiuguishing the tube."

Geographical Diffusion of Totemism.-In Australia totemisin is almost universal. ${ }^{6}$ In North America it may be roughly said to prevail, or have prevailed, among all the tribes cast of the Rocky Mountains, ${ }^{7}$ and among all ,the Indian (but not the Eskimo) tribes on the north-west coast as far south as the United States frontier. On the other hand, highly competent authorities have failed to find it among the tribes of western Washington, north-western Oregon, and California. ${ }^{3}$ [n Panama it exista apparently among the Guaymies . each tribe, family, and individual has a guardian animal, the most prevalent being a kind of parrot. ${ }^{9}$ In South America totemism is found among the Goajiros on the borders of Colombia and Venezuela, ${ }^{10}$ the Arawaks in Guiana, "1 the Bosch negroes also in Guiana, ${ }^{12}$ and the Patagonians. ${ }^{18}$ Finding it at such distant points of the continent, we should expect it to be widely prevalent; but, with our meagre knowledge of the South Americars Indians, this is merely conjecture. The aborigines of Peru and the Salivas on the Orinoco believed in the descent of their tribes from animals, plants, and natural objects, such as the sun and earth; ${ }^{14}$ but this, though a presumption, is not a proof of totemism.

In Africa totemism prevails in Senegambia, among the Bakalai on the equator, on the Gold Coast and in Ashantee, and among the Damaras and Bechuanas in southern Africa.'s There are traces of totemism elsewhere in Africa. In eastern Africa the Gallas are divided into two exogamous sections, and have certain forbidden foods. ${ }^{16}$ In Abyssinia certain districts or families will not eat of certain animals or parts of animals. ${ }^{17}$ The territory of the Hovas in Madagascar is divided and subdivided into districts, the names of the subdivisions referring "rather to clans and divisions of people than to place." One of these names is "the powerful bird," i.e., either the eagle or the vulture. The same clan is found accupying separate districts. ${ }^{13}$ One Madagascar tribe regard a species of lemur as "an embodiment of the spirit of their ancestors, and therefore they look with horror upon killing them." Other Malagasy tribes and families refrain from eating pigs and goats; others will not eat certain vegetables nor even allow them to be carried into their houses. ${ }^{19}$ The only accasion when the Sakalava tribe in Madagascar kill a bull is at the circumcision of a child, who is placed on the bull's back during the customary inrocation. ${ }^{20}$

In Bengal, as we have seen, there are numerous totem tribes among the non-Aryan races. In Siberia the Yakuts

[^211]are divided into totem clans; the clansmeu will not kill their totems (the swan, goose, raven, \&c.); ${ }^{1}$ and the clan's are exogamous. ${ }^{2}$ The Altaians, also in Siberia, are divided into twenty-four clans, which, though interfused with each other, retain strongly the clan feeling; the clans are exogamous; each has its own patron divinity and religious ceremonies; and the only two names of clans of these and kindred tribes of which the meanings are given are names of animals. ${ }^{3}$ Totemism exists among the monntaineers of Formosa, ${ }^{4}$ and there are traces of it in. China. ${ }^{6}$ In Polynesia it existed, as we have seen, in Samoa. In Melanesia it appears in Fiji, ${ }^{6}$ the New Hebrides, ${ }^{7}$ and the Solomon Islands. ${ }^{8}$ Amongst the Dyaks there are traces of totemism in the prohibition of the flesh of certain animals to certain tribes, respect for certain plants, dc. ${ }^{9}$ It exists in the islands of Ambon, Uliase, Leti, Moa, Lakor, Keisar (Makisar), Wetar, and the Aaru and Babar archipelagos. ${ }^{10}$ In the Philippine Islands there are traces of it in the reverence for certain animals, the belief that the souls of ancestors dwell in trees, \&cc. ${ }^{11}$
With regard to ancient nations, totemism may be regarded as certain for the Egyptians, and highly probable for the Semites, ${ }^{12}$ Greeks, and Latins. If proved for one Aryan people, it might be regarded as proved for all; since totemism could scarcely have been developed by any one Aryan branch after the dispersion, and there is no evidence or probability that it ever wss borrowed. Prof. Sayce finds totemism among the ancient Babylonians, but his eridence is not conclusive. ${ }^{13}$
No satisfactory explanation of the origin of totemism has yet been given. Mr Herbert Spencer finds the origin of totemism in a "misinterpretation of nicknames": savages first named themselves after natural objects, and then, confusing these objects with their ancestors of the same names, reverenced them as they already reverenced their ancestors. ${ }^{14}$ But this view attributes to verbal misunderstandings far more influence than, in spite of the so-called comparative mythology, they ever seem to have exercised.
Litcrature.- Apart from the original anthorities, the literature on totemiem is very scanty. The importance of totemism for the early bistory of society was first recognized by Mr J. F. M'Lennan in papers published in the Fortnightly Revicico (Oct. and Nor. 1869, Feb. 1870). The subject has since been treated of by E. B. Tylor, Early History of Mankind, p. 284 sq.; Sir John Lubbock, Origin of Civilization, 260 sq.; A. Lang, Custonn and $11 y$ th, P. 260 , se.; Id., Myith, Ritual, and Religion, i. p. bि sq., \&c.; E. Clodd, Myths and Dreams, p. 99 sq.; W. Robertson Smith, Einship and Marriagc in Early Arabia. See also Sacrifice, vol. xxi. p. 135. For fuller details, zee J. G. Frazer, Totemism (Edinburgh, 1887).

[^212]tóttenham, or Tottenham High Cross, a suburb of London, in the county of Middlesex, is situated on the old "Great Northern" road, about $4 \frac{1}{2}$ miles north from Shoreditch. The cross at Tottenham is not a market cross, and its origin is doubtful. Towards the close of the 16th century it consisted of a column of wood, capped with a square sheet of lead. The present cross of brick was erected by Dean Wood about 1600, and the ornamental work of stucco was added in 1809. In the time of Isaak Walton there stood over it a shady arbour of woodbine, sweetbriar, jessamine, and myrtle. Formerly Tottenham was noted for its "greens," in the centre of one of which stood the famous old elm trees called the "Seven Sisters"; these were removed in 1810, but the name is preserved in the Seven Sisters Road. Bruce Castle, occupying the site of the old mansion of the Bruces, but built probably by Sir William Compton in the beginning of the 16 th century, is now occupied as a private boarding school. The church of All Hallows, Tottenham, was given by David, king of Scotlaud, probably when he visited Henry in 1126, to the canons of the church of Holy Trinity, London. It has frequently been restored and altered. The older parts are the tower, nave, and south aisle of the Perpendicular period and the south porch of the 16 th century. There are a large number of monuments and brasses. Tottenham consists chiefly of an irregular line of houses for about two miles along the high road, with short side streets at intervals. There are a number of almshouses, including the Sanchez almshouses, founded in 1596 by Balthazar Sanchez, or Zanchero, confectioner to Philip of Spain; Reynardson's (1685); Pheasunt's, or "The Pound," for poor widows, originally founded by George Hynningham in 1536, and further endowed by Pheasunt and Saunders; and the sailmakers' almshouses, founded in 1869 by the Drapers' Company for forty-five inmates. The free grammar school was enlarged and endowed in 1686 by Sarah, dowager duchess of Somerset. The population of the urban sanitary district (area 4642 acres) in 1871 was 22,859 , and in 1881 it was 46,456 .

In the reign of the Confessor the manor of Tottenham was poseessed by Earl Waltbeof, who in 1070 married Judith, niece of the Conqueror, and was created in 1072 earl of Northumberland, Huntinglon, and Northampton, but joined the conspiracy against William, was betrayed by his wife, and was heheaded at Wiucliester. It was inherited by his daughter Mand, who was married first to Simon de St Liz and afterwards to David, sout of Malcolm 111., king of Scotland, who was crested by Henry 1. earl of Hunting. don, and received possession of all the lauds formerly held by Earl Waltheof. In 1184 the manor was granted by Willian the Lion, king of Scotland, to his brother David, earl of Augus and Gallo. way, the grant being confirmed in 1199 by ling Joln of Englaud; who created him earl of Huntingdon. He married Maud, liciress of Hugh, earl of Chester, and his sou John inherited both earldoms. The son married Helen, daughter of Llewelyn, prince of Wales, by whom he was poisoned in 1237, dying withont issue. She retained possession till 1254 , when the manor was divided between his coheirs Robert de Brus, John de Baliol, aud Henry de Hastings, each division forming \& distinct manor bearing the name of its owner. In 1429 they all camo into the possession of Alderman Gedeney. William Bedveell, the Arabic scholar, was vicar of Tottenham, aud published iu 1632 a Bricfe Description of the Towne of Totenhan, in which bo printed for the first time the burlesque poern, the "Turnament of 'Tottenhan."
See Robinsou's History of Tollenham, 1810.
TOUCAN, the Brazilian name of a bird, ${ }^{15}$ long since ${ }^{1}$ adopted into nearly all European languages, and apparently first given currency in England (though not then used as an English word) in $1668^{16}$ by Charleton (Onomasticon, $p$. 115) ; but the bird, with its enormous beak and feather:

[^213]like tongue, was described by Oviedo in his Sumario de la Natural Historia de las Indias, first published at Toledo in 1527 (chap. 42), ${ }^{1}$ and, to quote the translation of part of the passage in Willughby's Ornithology (p. 129), "there is no bird secures her young ones better from the Monkeys, which are very noisom to the young of most Birds. For when she perceires the approach of those Enemies, she so settles her self in her Nest as to put her Bill out at the hole, and gives-the Monkeys such a welcom therewith, that they presently pack away, and glad they scape so." Indeed, so remarkable a bird must have attracted the notice of the earliest European invaders of America, the more so since its gaudy plumage was used by the natives in the decoration of their persons and weapons. In 1555 Belon (Hist. Nat. Oyseaux, p. 184) gave a characteristic figure of its beak, and in 1558 Thevet (Singularitez de la France Antarctique, pp. 58-90) a somewhat long description, together with a woodcut (in some respects inaccurate, but quite unmistakable) of the whole bird, under the name of "Toucan," which he was the "first to publish. In 1560 Gesaer (Icones Avium, p. 130) gave a far better figure (though still somewhat incorrect) from a drawing received from Ferrerius, and suggested that from the size of its beak the bird should be called Burhynchus or Ramphestes. This fgure, with a copy of Thevet's and a detailed description, was repeated in the posthumous edition (1585) of his larger work (pp. 800, 801). By 1579 Armbroise Paré (Euvres, ed. Malgaigne, iii. p. 783) had dissected a Toucan that belonged to Charles IX. of France, and about the same time Léry (Voyage fait en la Terre du Bresil, chap. xi.), whose chief object seems to bave been to confute Thevet, confirmed that writer's account of this bird in most respects. In 1599 Aldrovandus (Ornithologia, i. pp. 801-803), always ready to profit by Gesner's information, and generally without acknowledgment, again described and repeated the former figures of the bird; but he corrupted his predecessor's Ramphestes (which was nearly right) into Ramphastos, and in this incorrect form the name, which should certainly be Rhamphestes or Rhamphastas, was subsequently adopted by Linneus and has since teen recognized by systematists. Into the rest of the early history of the Toucan's discovery it is needless to go. ${ }^{2}$ Additional particulars were supplied by many succeeding writers, until in 1834 Gould completed his Monograph of the family ${ }^{3}$ (with an anatomical appendix by Sir R. Oren), to which, in 1835, he added some supplementary plates; and in 1854 he finished a second and much improved edition. The latest systematic compendium on Toucans is Cassin's "Study of the Ramphastidæ," in the Proceedings of the Philadelphia Academy for 1867 (pp. 100-124).

By recent systematists 5 genera and from 50 to 60 species of the Family are recogaized; but the characters of the former have never been satisfactorily defiaed, much less these of numerous subdivisions which it has pleased some writere to iavent. There can be little doubt that the bird first figured and described by the earliest authors above named is the $R$. loco of nearly all ornithologists, and
1 The writer has oaly beea able to consult the reprint of this rare work cootaiaed is the Biblioleca de Autores Españoles (xxii. pp. 473515), published at Madrid io 1852.
${ }^{2}$ One point of come interest may, however, be noticed. In 1705 Plot (V. II. Oxfordshire, p. 182) rerorded a Toncaa found within two miles of Oxford in 1644, the body of which was given to the repositery in the medical school of that uoiversity, where, ho said, "it is still to bo seen." Already is 1700 Leigh in his Laneashire (i. p. 195, Birds, tab. 1, fig. 2) had figured another which had been found dead on the coast of that county about two years before. The bird is easily kept in captivity, and no doubt from carly times many were brought alive to Europe. Besidea the one dissected by Paré, as above mentioned, Joh. Faber, in bis additions to Hernandez'a work on the Natural History of Mexico (1651), figures (p. 697) 00e 6ceu and described by Puteus (Dal Pozzo) at Fontainebleau.
${ }^{3}$ Of this the brotherg Sturn in 1811 published at Nuremberg a German version.
as such is properly regarded as the type of the genus and therefore of the Family. It is one of the largest, measuring 2 feet in leugth, aod has a wide range throughout Guiana and a great part of Brazil. Tha huge beak, looking like the great claw of a lobster, more than 8 inches long aud 3 higb at the base, is of a deep orango colour, with a large black oval 6 pot near the tip. The eyc, with its double iris of green and yellow, has a broad blue orbit, and is surrounded by a bare space of deep orange skin. The plamage generally is black, but the throat is white, tinged with yellow and coinmonly edged bencath with red; the upper tail-coverts are white, and the lower scarlet. In other species of the genus, 14 to 17 in number, the bill is mostly particoloured-green, yellow, red, cbestnut, blue, and black varionsly combining so as oftea to form a ready diagnosis; but some of these tints are very fleoting and often leare little or no trace after death. Alteroations of the brighter colours are also displayed in the feathers of the throat, breast, and tail coverta, so as to be in like manner characteristic of the species, and in several the bare space round the eye is yellow, green, blue, or lilac. The sexes are almost alike in coloration, and externally differ chiefly in size, the males being largest. The tail is nearly square or moderately rounded. In the genus Pleroglossus, the "Aracaris" (pronounced Arassari), the sexes more or less differ in appearance, and the tail is graduated. The specics are smaller in size, and nearly all are banded on the beliy, which is generally yellow, witb black and scarlet, while except in two the throat of the males at least is black. One of the most remarkable and beautiful is $P$. beauharnaisi, by-some autbors placed in a distinct genus and called Beauharnaisius ulocomus. In this the feathers of the top of the head are very singular, looking like glossy curled shavings of black horn or whalebone, the effect being due to tho dilatation of the shaft and its coalescence with the consolidateck barbs. Some of the feathers of the straw-coloured throat and cheeks partake of the same structure, but in a less degree, while the snbterminal part of the lamince is of a lustrous pearly-white. ${ }^{4}$ The beak is richly coloured, being green and crimson above and lemon below. The upper plumage generally is clark green, but the mantle and rump are crimson, as are a broad abdominal belt, tho flanks, and many crescentic markings on the otherwise yellow lower narts. ${ }^{5}$ The group or genus Selenodera, ]roposed by Gould in 1837 (Icones Avium, pt. 1), contains some 6 or 7 species, having the beak, which is mostly transversely striped, and tail sborter than in Pteroglossus. Here the sexes also difer in coloration, the males laving the head and breast black, and the females the samo parts chestnut; but all have a yellow nuchal crescent (whence the namo of the group), The so-called Hill-Toucans have been separated as another genus, Andigcna, aud consist of some 5 or 6 species chiefly frequenting the slopes of the Andes and reaching an elevation of 10,000 feet, though one, often placed among then, but perhaps belongiug rather to Pteroglossiss, the A. bailloni, remark able for its yellow-orange bead, neck, and lower parts, inhabits the lowlands of sonthern Brazil. Another very singular form is $A$. laminirostris, which has affixed on either side of the maxilla, near the base, a quadrangu ar ivory-like plate, fornıing a featnre unique in this or almost in any Family of Birds. The gronp Aulaco. rhemphus, or "Groove-bills," with a considerable but rather un. certain number of species, contains the rest of the Toucans.
The moostrous serrated bill that so many Toucans possess was by Buffon, after his manner, accounted a grave dcfect of Nature, a ad it mist be confessed that no one has given what scems to be a satisfactory explaoation of its precise use, though on evolutionary principles noue will now doubt its fitucss to the bird's requirements. Solid as it looks, its woight is inconsiderable, and tho perfect hinge by which the maxilla is artionlated adds to its efficiency as an instrument of urehension. Swainson (Classif. Birds, ii. p. 138) imagined it merely "to contain an infiaity of nerves, disposed liko net-work, all of which lead immediately to the nostrils," and add to the olfactory faculty. This notion seems to be borrowed from Trail (Trans. Limu. Socicly, xi. p. 289), who adraittedly had it from Waterton, and stated that it was "an admirable contrivance of naturo to increase the delicacy of the organ of smell; " but Sir R. Owen's description shews this view to be groundless, and he attributes the extraordinary develop ment of tho 'loucan's beak to the need of compensating, by the additional power of masticatioa thus given, for the absence of any of the grinding structures that are so characteristic of the intestinal tract of vegetable-eating birds-its digestive organs possessing a general simplicity of formation. The question is ono worth deciding, and would not be difficult to decide by those who bave the opportunity. The nostrils are placed so as to be in most
${ }^{4}$ This curious peculiarity naturally atiracted the notice of the first discoverer of the species, Poeppig, who briefly described it in a letter published in Frorjep's Notizen (xxxii. p. 146) for December 1831.
${ }^{5}$ Readers of Mr Bates's Naturalist on the River Amazons will recollect the account (ii. p. 344) and illustration there given of lis eoconnter with a flock of this species of Toucan. His remisrks on the other mpecies with which be met are also excellent.

Forms invisible until songht, being obscured by the frontal feathers or the backward prolongation of the horny eheath of the beak. The wings ara somewhat feeble, and the legs have the toes placed in pairs, two before and two behind. The tail is capable of free vertical motion, and controlled by strong muscles, so that, at least in the true Toucans, when the bird is preparing to sleep, it is reverted and lies almost flat on the back, on which also the huge bill reposes, pointing in the opposite direction.

As may be inferred from the foregoing, the Toucans are a Neotropical form, and by far the greater number inhabit the northern part of South America, especially Guiana and the valley of the Amazons. Some three species occur in Mexico, and several in Central America. One, R. vitellinus, which has its headquarters on the mainland, is said to be coonmon in Trinidad, but none are found in the Antilles proper. The precise place of the Family in the heterogeneous group Picarix cannot yet be determined. Its nearest allies perhaps exist among the Capitonidx; but none of them are believed to have the long feather-like tongue which is so characteristic of the Toucans, and is, so far as known, possessed besides only by the Momotidx (cf. Motmot, vol. xvii. p. 3). But of these last there is no reason to deem the Toucans close relatives, and, according to Swainson (ut supra, p. 141), who had opportunities of observing both, the alleged resemblance in their habits has no existence. Those of the Toucans in confinement have been well described by Broderip and Vigors (Zool. Journal, i. p. 484 ; ii. p. 478), and indeed may be partially observed in many zoological gardens. Though feeding mainly on fruits, little seems amiss to them, and they swallow grubs, reptiles, and small birds with avidity. They are said to nest in hollow trees, and to lay white eggs.
TOUCH may be defined as a sense of pressure, referred usually to the surface of the body. It is often understood as a sensation of contact as distinguished from pressure, but it is evident that, however gentle be the contact, a certain amount of pressure always exists between the sensitive surface and the body touched. Mere contact in sach circumstances is gentle pressure; a greater amount of force causes a feeling of resistance or of pressure referred to the skin; a still greater amount causes a feeling of muscular resistance, as when a weight is supported on the palm of the hand; whilst, finally, the pressure may be so great as to cause a feeling of pain. The force may not be exerted vertically on the sensory surface, but in the opposite direction, as when a bair on a sensory surface is pulled or twisted. Touch is therefore the sense by which mechanical force is appreciated, and it presents a strong resemblance to hearing, in which the sensation is excited by intermittent pressures on the auditory organ. In addition to feelings of contact or pressure referred to the sensory surface, contact may give rise to a sensation of temperature, according as the thing touched feels hot or cold. These sensations of contact, pressure, or temperature are usually referred to the skin or integument covering the body, but they are experienced to a greater or less extent when any serous or mucous surface is touched. The skia being the chief sensory surface of touch, it is there that the sense is most highly developed, both as to delicacy in detecting minute pressures and as to the charpecter of the surface touched. Tactile impressions, properly so called, are absent from internal mucous surfaces, as has been proved in men having gastric, intestinal, and urinary fistulx. In these cases, touching the mucous surface caused pain, and not a sensation of tonch.
Organs of Touch.-Comparative Shetch.-Tha organs of touch present many varieties of form, from a simple filament of sensitive protoplasm to a highly complex end-organ connecied with the commoncement of a sensory nerve-fibre. The bodies of the lowest organisms ara formed of contractile protoplasm, and mechanical contact with any resisting substances causes a change of form. Hera is the eimplest kind of touch -a response on the part of any portion ef the surface of the body to a meclanical stimulus. The pseudopodia
of the Rhizopoda are also organs of tonch, and probably the clia, the flagellæ, and the short rod-like bodies eeen on many Mufusoria belong to the same class of sensory organs. Among the Ceeleatera (hydroid polyps, tubularians, Hydromedusæ, Medusæ, Anthozoa or sea-anemones) teatacles nra found, usually arranged in circles around the mouth or on portions of the body engaged in locomotion, as on the margins of the umbrella of Medusæ. These have a larga amount of sensibility, and serve as organs of touch. In some also thera are stiff hairs on the teutacles and around the mouth, more differentiated tactile organ:. The Vermes ghow organs of touch in the form of modified cells of the iutegament, connected with sensory nerves. These cells often assume the form of stiff rods projected from the surface (tactile setæ). Such are often found over the whola body of Turbellaria and Nemertina, on the tentaclas of Bryozoa, on the head segment of Lrmbricidæ, and on the tentacles and antaunæ of Chætopoda. In the latter group of animals tretile organs are also found in ring-like arrangements, called cirrhi, on the foot-stumps or parapodia. In sonse Hirudinca (leeches) complicated tactile rods are embedded in cup-shaped organs scattered over the body. Large prominences of the cuticle, called tactile papillæ, are also found in many of the Vernies near the oral and genital orifices. The Echinodernata have also special parts devoted to touch, and these slow their highest differentiation in the tentacles of the Holothuroida. Arthropoda show tactile organs iu the form usually of rod-like bodies projecting from the surface of the appendages and chiefly connecterl with nerves passing to ganglionic cells. In Crustacea such organs are found on the anteuur and other appendages, and on the antennæ in Aryriapoda and Insccta. In the latter they are also found on the tarsal joiuts of tha feet. The appearance of these rod-like bodies is seen in fig. 1.

Ciliated tentacular processes exist in the larva of Brachiopoda which are probably touch organs, but there are do definite organs of this kind in the adult form. The Mol lusca have the sense of tonch widely diffused. All the soft parts of the body are capable of feeling when touched, and in various situations there arefine hair-like prolongations from cells. These are supplied with werves, and are touch organs. Such are found on the edge of the mantle in Lamellibranchiata, where tliey
 ganglienic swelling; s, factlle rods
$c$, fine hairs of cuticle (Leydig). may be in rows; they also exist on the siphons, and "they serve to watch over the particles that get into the mantle cavity with the water " (Gegenbaur). Processes of a tactile kind are also found on the epipodium, the edge of the mantle, and the cephalic tentacles in many Gastcropoda, and on the dorsal tufts of the Nudibranchiata Here and thera also there ara enlargements of the integument covered with cilia and supplied by a nerve which have been regarded as touch organs, but are by some supposed to be connected with smell (see Sitell). The Tumicata bave cells with long filamentous processes in the integument, which are probably tactile in function.

In the great majority of fishes tonch is limited to the lips, to parts of the fins, and to special organs called barbels. In the Cyprinoids there is a fold of skin bordering the mouth which is highly tactile. The lip of the sturgcon is covered with pumerous papillæ; the sucking lip of the lamprey is papillose and bighly sensitive. The fins are in may fishes modified to serve as orgads of touch. Thus the gurnards (Triglidx) have three soft flexible rays detached from the fin, and "the filiform radial appendages of the Polynemidse, the prolonged ventral fins of Osphromenus, Trichogaster, aud ather Labyrinthibranchs, and of the Ophidirdx," are examples of this class of organs (Owen). Tho barbels are long slender processes of skin, either single or in pairs, found in tha Siluridx, loaches, barbels, cods, sturgeons, and in the parasitic Myxinide. The nerves for the barbels come from the fifth pair of cranial nerves. "A cod, bliud by absence or destruction of both eyeballs, has been captured in good condition, and it may be supposed to have found its food by exploring with the aymphysial barbule, as well as by the sense of smell" (Owen). Bodies somewhat similar to the Pacinian corpuseles (to be afterwards described) were discovered by Savi in 1844 in the torpedo; they aro arranged in linear series on the anterior part of the mouth and nostrils, snd over the fore part of the electrical organs. Each is composed of two capsules, oue counected with the other, and containing a granular aubstance in which the nerve end is embedded. Peculiar mucous glands are also found outside the electrical orgaus of the torpedo which are believed to mimister to touch. Similar organs exist in sharks, and John Huuter dissected the snout of the spotted dog.fish (Scyllium) "to show the manner of the nerves ramifying,
as also their apparenit termination in this part, each nltimste nerve appearing to terminste in the bottom of a tube or duct, the sides of which secrete and convey \& thick mucns to the skin." These "nerve-mucous" organs are fonnd in the sides and ander part of the head and on the fore part of the trunk.
The Amphibia snd Repitilia do not show any epecial organs of tonch. The lips of tadpoles have tactile papillæ. Some snakes heve s pair of tentacles on the sacut, but the tongue is probsbly tho chief organ of tonch in most serpents and liasrds. All reptiles possessing climbing powers have the sense of touch highly dereloped in the feet.

Rirds have epithelisl papilla on the soles of the toes thst are no donbt tactile. These are of grest length in the capercsilzic (Tetrax urogallus), "enabling it to grasp with more eeourity the frosted branches of the Narwegian pine trees" (Owen). It has been sug. gested that the delicate "pspillose" digits of the smaller birds assist them in mest-building by having the sense of touch highly developad. Around the root of the bill in many birds there ara special tactile organs, assisting the bird to nse it as a kind of sengitive probe for the detection in soft ground of the worms, grubs, and slugs that constitute its food. Special bodies of this kind have beon detected in the beak and tongue of the duck and goose. called the tactile corpnscles of Berkel, or the cerpuscles of Grandry (fig. 2). Similar bodies have been found in the epidermis of man and msmmals, in the outer root-sheath of tactile heirs or feelers. They corsist of small bodies comsposed of a cansn? e ecilosing two or
 more flattened aucleated

Fio. 2. - Tactua Corpuscles from dack a tongre. $n$, nerve.
cells, piled in a row. Esch corpnsele is separated from the others by a transparent protoplasmic disk. Nerve fibres terminsto oither in the cells (Merkel) or in the protoplasmic intercellular matter (Ranvier, Hesse, Izquierdo). Another form of ead-organ has been described by Herbst as existing in the mucous membranc of the duck's tengue. These corpuscles of Herbst are like sinall Pacinisu cerpuscles with thin and rery close lamellæ. Developments of in tegrument devoid of festhers, such as the "wattles" of the cock, the "carancles" of the vulture and turkey, are not tactile in their function.

In the great majority of Mammalia the general suriace of the skin shows sensitive-
 ness aod this is developed to a high degree on certain parts, such as the lips, the end of Fro.3.-Tactle Corpascle a teat, snd the generative organs. Where from the band. touch is highly dereloped, the akin, more especially the epidermis, is thin and deveid of hair. In the Monkeys tactile pspille are found in the skin of the fingers and palms, sad in the skin of the prohensile tails of rarious species (Aletes). Such rapillis also sbound in the oaked skin of the pose or enout, as in the shrew, mole, pig, tapir, and elephant. In the Ornithorhynchus the skin covering the mandibles is tactile (Oren). In many snimals certain hairs acquire great size, length, and stiffoess. These constitute the vibrisse, or whiskers. Each large hair grows from a firm capsulo sunk deep in the true skin, and the hair bulb is supplied with eensory perve filaments. In the walrus the espsule is cartilaginous in texture. The marine Carnivora have strong vibrisss which "act as a etaff, in a wayanslogous to that hold snd applied by the hand of a blind man " (Owen). Each species has hairs of this kind
 developed on the eyehrows, lips, or

Fro. 4.-Tactile Corpuscles from clitorls of rabblt. $n$, merve. cheeks, to suit a particular morie of existence, es, for examola, the long fine whiskers of the night-prowling felines, sad in the aye-aye, a monkey having nocturnal habits. In the Ungulata the hoofs need no delicacy of touch as regards the discriminstion of minute points. Such animals, however, hsve brosd, massive sensations of touch, ensbling them to spprecista the firmness of the soil on which they tread, snd under the hoof me find highly vaseular and sensitive lamellos or papilla, contributiog no doubt, not only to the growth of the hoof, but also to its sensitiveness. The Celaca havenumerons papillw in the skin, regarding which John Fnnter remarks: "These villi are soft and plisble; they float in water; and each is longer or shorter accorling to the size of the snimal. In the epermaceti
whale they are about a quarter of an inch long; in the grampos, bottlenose, mnch shorter; in sll they are extremely vascular; they sre shesthed in corresponding hellows of the epiderm." In some whales the skin is thrown into aumerons longitudinsl plaits on the nnder and fore part of the bedy (Balsnoptera). Prof. Owen remarks regarding these: "It is peculiar to the ewifter ewimming whales that pursue mackerel sud herring, and may serve to warn them of shoals, by apprecistion of au impulse of the water rebound. ing therefrom, and so conveying a seuse of the propinquity of eunken rocks or sand-baoks. Sensitiveness to the movements of the ambient ocesn is indicated by certain observed phenamena. The whale-fishers aver that when a straggler is sttscked its fellows will hesr dewa from some miles' distance, 86 if to its sssistance; and it may be that they are attracted by perception of the vibration of the wster caused by the struggies of the harpooned whale or cachslot" (Owen's Comparative Anatomy, vol. iii. p. 189). Bats have the sense of touch etrongly doveloped in the wings and external ears, and in some apecies in the flaps of akin found near the nose. These "nose-leaves" snd capanded ears frequently show vibratiio movements, like the antennse of insects, enabling the snimsl to detcet slight atmospheric impulses. In the vampires (Desmodi) and fruit-esting bats (Pteropi) the aurienlsr and nasal appendages are small; "such seasitiye tactile guides or sarners in flight are only peeded in the bats of active food, which must follow in owift evolutions, like the swallows, but in gloom, the volstile insects that people the summer air at dawn or dusk " (Owen). There is little doubt that many specisl forms of tactile organs will be found in animals using the nose or feet for burrowing. A peculiar eadorgan has bcen found in the nose of the mole, while there are "endcapsulee" in the tongue of the elephant and "nerre rings" in the ears of the mouse.

End-Organs of Touch in Man. - In man toree special forms of tactile end-organs have been described, and can be readily demonstrated.
(1) The End-Bulbs of Krause. -These are oval or rounded bodies, from $\frac{1}{860}$ to $\frac{1}{180}$ of an irch long. Each consists of a delicate capsule, composed of nucleated cone nectivé tissue eaclosing pumerous minute colls. On tracing the nerve fibre, it is found that the nerve sheath is continuous with the capsule, whilst the axis cylinder of the nerve divides into branches which lose themselves among the cells. Waldeyer and Longworth state that the nerve fibrils terminate in the cells, thus making these 3 bodies similar to the cells described by Merkel (ut supra). See fig. 5. These bodies are found in the deeper layers of the conjunctiva, margins of the lips, nasal mucous membrane, epiglottis, fungiform and circumvallate papille of the

Fio. $\delta$.-End-Bulb from haman conjunctive $a$, macleated capsale; $b$, cors ; $c$, enteriag nerve-fibra tarmlnating In th core at $\alpha$ tongue, glans penis and clitoris, mucous membrane of the rectum of man, and they have also been found on the under surface of the "toes of the guinea-pig, ear and body of the mouse, and in the wing of the bat" (Landois and Stirling). In the genital organs aggregations of end-bulbs occur, known as the "genital corpuscles of Krause" (fig. 4). In the synovial membrane of the joints of the fingers there are larger end-bulbs, each connected with three or four nerve-filaments.
(2) The Touch Corpuscles of Wagner and Meissner.-These are oval bodies, about $\frac{1}{300}$ of an inch long by $\frac{1}{500}$ of an inch in breadth. Each consists of a series of layers of connective tissue arranged transversely, and containing in the centre granular matter with nuclei
 (fig. 7). One, two, or three nerve fibres pass to the lower end of the corpuscle, wind transversely around it, lose the
white substance of Schmann, penetrate into the corpuscle, where the axis cylinders, dividing, end in some way unknown. The corpuscles do not conbain any soft core, but are apparently built up of irregular septæ of connective tissue, in clie meshes of which the nerve nbrils end in exmansions similar to Merkel's cells. Dr Thin describes imple and comnound corpuscles according to the number of nerve fibres entering Fio. 7.-Vertical Sectlon of the skin of the palm of the .hem. Thesebodies are found abundantly in the palm of the hand and

sympathetic, on the coccygeal gland, on the dorsum of the penis and clitoris, in the meso-colon, in the course of the intercostal and periosteal uerves, and in the capsules of lymphatic glands (Willianı Stirling).

Physiology of Touch in Man.-Such are the special endorgans of touch. It has also been ascertained that many sensory nerves end in a plexus of network, the ultimate fibrils being connected with the cells of the particular Itissue in which they are found. Thus they exist in the i cornea of the eye, and at the junctions of tendons with muscles. In the latter bituation "flattened end-flakes or plates" and "elongated oval end-bulbs" lave also beer found (Sachs, Rollett, Golgi). A consideration of these various types of structure show that they facilitate intermittent pressure being made on the nerve endings. They are all, as it were, elastic cushions into which the nerve endings penotrate, so that the slight variation of pressuro will be transmitted to the nerve. Probably also they serve to break the force of a sudden shock on the nerve endings.

Sensitiveness and Sense of Locality.-The degree of sensitiveness of the akin is determined by finding the smallest distauce at which the two points of a pair of compasses can be felt. This method, first where there may be as many as 21 to every square millimetre ( $1 \mathrm{~mm} .=\frac{1}{2} \frac{1}{5}$ inch). They are not so numerous on the lack of the hand or foot, mamma, lips, and tip of the tongue, and they are rare in the genital organs. "Kollmann describes three special tactile areas in the hand:-(1) the tips of the fingers, with 24 touch corpuscles in a length of 10 mus ; (2) the three eminences lying on the palm behind the slits between the fingers, with $5 \cdot 4-2.7$ touch-corpuscles in the same length; and (3) the ball of the thumb and little froger, with $3 \cdot 1-3 \cdot 5$ touch corpuscles. The first two areas also contain many of the corpuscles of Vater or Pacini, whilst in the latter these corpuscles are fewer and scattered. In the other parts of the hand the nervous endorgans are much less developed" (Landois and Stirling).
(3) The Corpuscles of Vater or Pacini.-These, first described by Vater sa long ago as 1741, are small oval bodies, quite visible to the naked eye, from $\frac{1}{18}$ to $\frac{1}{10}$ of an inch long and $\frac{1}{25}$ to $\frac{1}{2 \sigma}$ of an inch in breadth, attached to the nerves of the hands and feet. They can be readily demnostrated in the mesentery of the cat (fig. 8). Each corpuscle consists of 40 to 50 lamellæ or coats, like the folds of an onion, thinner and closer together on approaching the centre. Each lamella is formed of an elastic material mixed with delicate connective tissue fibres, and the inner surface of each is lined by a single continuous layer of endothelial cells. A double-contoured nerve fibre passes to each. The white substance of Schwana becomes continuous with the lamellæ, whilst the axis cylinder passes into the body, and ends in a small knob or in a plexus. Sometimes a bloodvessel also penetrates the Pacinian body, with the nerve. Such bodies are found in the subcutaneous tissue on the nerves of the fingers and toes, near joints, attached to the nerves of the abdominal plexuses of the

These investigations show not only that the skin is sensitive, but that one is able with great precision to distinguish the part toucbed. This latter power is usually called the sense of locality, and it is influenced by various conditions. The grester the number of sensory nerves in a given area of skin the greater is thes degree of accuracy in distinguishing different points. Contrast in this way the tip of the finger and the back of the hand. Scnsitiveness increases from the joints towards the extremities, and, as pointed out by Viepordt, sensitiveness is erreat in parts of the body that are actively moved. The 3ensihility of abo linibs is finer in
the transverse axis thau in tho loag axis of the limb, to the extent of $\frac{1}{1}$ on the flexor surfaca of the upper limb and $\frac{7}{7}$ on the extensor surface (Landois). It is doubtul if exerciso improves sensitivenesa, as Francis Galton found that the performances of blind boys were not superior to those of otber boys, and he says that "the guidance of the blind denends mainly on tha multituds of collateral indications, to which they give much heed, and not their superiority to any one of them." When the skin is mai.tened with indifferent fluids sensibility is increased. Suslowa made the curious discovery that, if the area between two points distinctly felt be tickled or be stimulated by a weak electric current, tha inupressions are fused. Stretching the skin, and baths in water containing carbonic acid or common salt, increase tha power of localizing tactile impressions. In experimenting with the com. passes, it will be found that a smaller distance can bedistinguished if one proceeds from greater to smaller distances than in the reverse direction. A smallier distauce can also be detected whed the points of the conpasses are placed one after the other on the ekin than when they are placed simultanoously. If the points of the comprases are unequally heated, the sensation of two contacts becomes coafused. Anauæmic condition, or a state of venous congestion, or the application of cald, or violeat stretching of the skin, or tho uso of such substances as atropine, daturin, morphia, strychnine, alcohol, bromida of potassium, canuabin, and hydrate of chloral blunt sensibility. The only active substance said to increase it is caffein.
Absolute sensitiveness, as indicated by a sense of pressure, has been determined by various methods." Two different weights are placed on the part, and the smallest difference in weight that can bo perceived is noted. Weber placed sluall weights directly on the skin; Aubert and Kammler loaded small plates; Doliru made use of a balance, hnving a blunt point at one sud of the beam, resting on the skin, whilst weights were placed on the sther ead of the bean to equalize the pressure; Eulenberg invented an instrument like a spiral spring paper-clip or balance (the barasthesioneter), having an index showing the pressure in grammes; Goltz employad an india-rubber tube filled with water, and this, "to ensure a constant surface of contact, bent at one spot over a priece of cork, is touched at that spot by the cutauesus part to bo examined, and, by rhythmically exerted pressure, waves analogons to those of the artariai pulse are producel ia the tube" (Hermann); and Landsis invented a mercurial balance, enabling him to make rapid variations in the weight without giving rise to agy slock (figureul in Landois and Stirieng's Physiology. p. 1155). These nethods hare given the following gemerel results. (1) Tha greatest acuteuss is on tha forehead, termples, and lack of the hand and forearm, which detect a pressure of 002 gramine; fingers detect 005 to 015 gramme; the ckiz, abcomon, and nose '04 to "05 gramme. (2) Goltz's method gives the sanie general rasults as Weber's experiment with the compasses, with the exception that the tip of the tongue has its sersation of pressure much lawer in the scale than its sensation of toacb. (3) Eulenberg found the following grailations in tha fineness of the pressure sense:- the forehead, lips, back of the cheeks, and temples apprecinte differences of $\frac{1}{40}$ to ${ }^{3}$ ( $200: 205$ to 300: 310 grammes!. The back of the last phalanx of the fingers, the forearm, hand, 1st and 2 d phalanges, the palnar surface of the hand, forearm, and upper armi dstimguish differences of is to $\frac{1}{20}$ (200: 220 to 200: 210 gramincs). The front of the leg and thigh is similar to the forearm. Then follow the back of the foot and toes, the scle of the foot, aud the back of the leg and thigh. Dohrn placed a woight of granme on the skin, and then determined the least additional weight that could be detected, with this result:Sd phalanx of finger, 499 gramme; back of the foot, 5 gramma; 2d.phalanx, 771 granue; 1 st phalans, 82 gramme; leg, 1 gramase; back of hand, $1-156$ grammes; poltn, $1 \cdot 108$ grammes; patella, 1.5 grammes; forearm, 1.90 gramines; umbilicus, 3.5 gramines; and back, 3.8 grammes (Landois and Stirling). 14) In passing from light to heavier weirlits, the ocuteness increases at once, a maximum is reached, an? then with heary weights the pawer of distinguishing the differencea diminishes (Hering, Biedermann). (5) A senaation of pressure after tha weights have been removed may bo noticed (ufler-pressure sensution), eapecisily if the weight be considerable. (6) Volentine noticed that. if the Gnger were held against a blunt-toothed wheel, and the whel were rotated with a certain rapidity, he felt a soooth margin. This was experieaced when the iatervals of time between the contacts of suc. cessive teeth were less than from tove to oto of a second. The same expariment can be readily mado by holdiog the fuger over the holes in one of the outermost circles of a large syren rotating quickly: the sensations of individual holes bccome fused, so as to give rise to a feeling of touching a elit. (7) Vibrations of atrings ara detacted aven when the aumber is about 1500 per eecond ; abova this the eensation of vibration ceases. By attaching bristles to tha prongs of tuning forks, and bringing these into contact with the lip or tongue, sensations of a very acute character are exivericmed, which are most intense when the forks vibrate fron. 600 to 1500 per second.

Information from Tactile Impressions, -These euable us to come to the following conclusions. (1) We note the existence of something touching the somsory surface. (2) From tho iuteusity of the sensation we deternine the weight, teneion, ur intensity of tha preesure. This sensation is in the first instance referred to the skin, but after the pressure bas reached a certain amonnt muscular sensa. tions ary alsu experienced-the so-called muscular cense. (3) The locality of the part touched is at onca determined, and from this the probable position of the tonching body. Like the visual feld, to which all retinal impressions are referred, point for point, there is a tactile tield, to which all points on the skin aurface may be referred. (4) By touching a body at various poiats, from tha difference of prossure and from a comparison of the positious of various points in the tactile field we judge of the coafiguration of the body. A number of "tactile picturey" aro obtained by passing the skin over the touched body, and the shape of the body is further determined by a kuowledge of the inuscular movements Decessary to briug the cutaneous surface into contact with different portions of it. If there is abnormal displavement of position, a false conception may arise as to the shape of the body. Thus, if a small marble or a pea be placed between the index and middle finger so as to touch (with the palm downwalds) the outer side of the index finger and tha iuner side of the middle finger, a sensation of touching one roumd body is experienced; but if the fongers be crossed, so that the marble touches the inner side of the index fiuger and the outcr side of the middle finger, there will be a feeling of two round bodies, because in these circumstances there is added to the feclings of contact a feeling of distortiou for of muscular action) like what would take place if the fingers, for purposes of touch, were placed in that abnormal position. Again; as showing thst our knowledge of the tactile field is precise, there is the well-known fact that when a piece of skin is transplanted from the forchead to the nose, in the operation for removing a deformity of the nose arising frem lupus or other nlcerative disease, the patient feels the new nasal part as if it were his forehead, and he may have the curious seusation of a nasal instead of a frontal headache. (5) Froun the number of points touched we judge as to the smoothness or roughness of a bolly. A body having a uniformly level surface, like a billjard ball, is sinooth; a body baving points irregular in eize ond number in a given área is rough; and if the points are very close together it gives rise to a sensation, like that of the pile of velvet, almost intolerable to somo indivi. duals. Again, if the pressure is ao uniforan as not to be felt, as wheu the body is immersed in water (paradoxical as tlis mazy seem, it is the case that the seasation of contact is felt only at the limit of the fluid), we experience the sensation of being in contact with a fuid. (6) Lastly, it weuld appear that touch is always the restilt of raria. tion of pressure. No portion of the body when touching anything can be regardea as absolutely motionless, and the slight oscillations of the sensory surface, and in many cases of the body touched, produce those variations of pressure on which touch depends.

Theories as to Touch.-To explain the phenomenou of the tactile field, and more especially the remarkable rariations of tactile sensibility above describerl, various theories have been advanced. (1) The one most generally known is that of E. H. Weber, as modified or restatad by Lotze, Meissner, Czermak, and others. It assumes that, whilst ve refer every tactile eensation to a certain position in the tactile field, we do not refer it merely to a poiut, but to a circular or oral arra ou the skiu, called a circle of sensibility. Furcher, it is nssmmed that if $t$ wo such circles touch or overlap they cannot be individually perceived, and that they can only be so individually perceived when one or more circles of sensibility intervene, or, is ether words, when there is a "non-irri
tated sensery eletated sensery els-
ment" betwern the tro peiats tonched (figs. 10 and 11).
Each circle of sensibility may ba supposed to be inuervated by a distioct fibre: Tbus, suppose the eensitive surface of tho skia to be diagranmatically represented as in figs. 10 and 11, e9ch squara would be a "circle of aeneibility." In more sensitive regions the squares woulrl be smaller and the number of nerve terninations greater than in leas sensitive rogions. In fig. 10 the area contains nine "circles" and bas nine nerve terminations, whilst in fig. 11 , although tho total area is the came, thera are thirty-six "circles" and thirty-six nerve filaments. If the points of the compasses be placed at $a$ and $c$ in fig. 10 tbe sensation will ba that of one point ; there would alsc be a scnsation of one point if they were placed at $c$
nd $d$; but if the points touch $c$ and e there will be a double sensa. ion, hecause the "circle" $d$ intervenes. Again, in fig. 11 , where the "circles" are much smaller and more numerous, the minimum distance at which two sensations are experienced is much less than In fg .10 , for this would happen when the compasses touch $a$ and $d$. [t will also be observed that the same distance $d e$ in fig. 10 would give a single seasation, whilst it would give a double senaation in fig. 11. But $c e$ in fig. 10 gives a double aensation, and jet the aame distance wonld give a single sensation if the points of the compasses toucbed adjoiaing "circles." A "circle of sensibility," however, caonot be regarded as an anatomical magnitude or "cutaneous sensory unit," or, in other words, the area of distribution of a single nerve-fibre. Tbe extent of any such hypothetical circle can be altered by practice and attention, and we may therefore assume that the circles overlap, and that even the sama ares of skin receives aumerous nerve fila. meats, and that consequently, when a body is touched, it excites at once many filaments. This is illustrated by fig. 12.

It will be seen that each ares receives a certain number of nerve fibres and each nerve fibre supplies filurils that cross the fibrils of ad. joining nerves. If the point of the compass touch at $a$, it will irritate all the fibres from 1 to 7 , hut these will not be excited with equal intensity ; the excitation will be at a maximum at 4 , more feeble for 3 and 5 , and still more feeble for 2 and 6; so foble for 2 and 0 ; so "circlea of senslbulity" (Erom Beaunis.) that the intensity of the excitation may be represented by the curve above a. In this case the sensation will be that of one point, because all the fibrils have been excited. If the other point of the compass be placed at $b$, there will ba an intermediary region not excited, aod two points will be felt. Suppose now the second point of the compasses is moved to $c$, all the fibrils between the two points $a$ and $c$ are excited, and there is Jikely a sensation of siogle contact; but the excitation of the fibrils 7 and 8 is very feeble, and it is possilile, by attention aud practice, to leave these out, and then there will be a sensation of two contacts (Benumis). This mechanicel theory has no anatomical basis, except it be tbe staternent made by Krause that the distance of the two points of the compesses at which two points are felt includes in the mean 12 tactile corpuscles. Whilst attention has been roainly directed to the skin as the locality where an anatomical explanation is to be sought for, it must not be forgotten that processes may be in operatioo in the nerve centres. It is well known that irradiation of nervous inpulses occur in the nerve centres (see Physiolooy, vol. xix. p. 29), and it is not unlikely that, when a nervous impression reaches the brain from a particular area of skin, this may bo diffused to neighbouring nerve-cells, exciting these, and that then the effect on these cells, in accordance with the law that sensations in nerve centres are referred to the origins in-the periphery of the seasory nerve fibres reaching them, will be referred to adjoining areas of skip, or. in other words, to adjoining points in tbe tactile field.

Wundt has propouuded a psycho-physiological theory that every part of the akin with tactile sansibility slways conveys an impreseion of the locality of the sensation. Each area of skio has a "local colour," and this diminishes from srea to area. The gradstion is suddeu where the sense of locality is acute and gradual where it is obtuse. - A circle of sensation is an area where the local colour changes so little that two separate impressions fuse io to one" (Landois). Practice eoables one to notice the changes of local colour, and thus more and mora accurately to discriminate points closer and closer together. This theory does not appear to explain anything; it simply restates the phenomena for which an explanation is desired.

Sensations of Temperature. - The okin is not merely the geat of tactile impressions, but also of impressions of temperature. This depends on thermic irritation of the terminal organs, as proved by the following experiment of E . H. Weber:- "If the ellow be dipped into a very cold flnid, the cold is only felt at the immersed part of the body (where the fibres terminate); pain, however, is felt in the terminal organs of the ulnar nerve, namely, in the finger points; this pain, at the same time, deadens the local ensation of cold." If the sensation of cold were due to the irritation of a specific-nerve fibre, the sensation of cold would be referred to the tips of the fingers. When any part of the skin is above its normal mean temperature, warmth ia felt; in the opposite case, cold. The normal mean temperature of a giveo area varies according to the distribution of hot blood in it and to the activity of nutritive changes occurring iu it. When the skin
is hrought into contact with a good conductor of hest there is a eensation of cold. A sensation of heat is axperienced when heat is carried to the ekin in any way. The following are.the chief facts that have been ascertained regarding the temperature sense. (1) E. H. Weber found that, with a skin temperature of from $15^{\circ} \cdot 5 \mathrm{C}$. to $35^{\circ} \mathrm{C}$., the tips of the fingers can distinguish a difference of $-25^{\circ} \mathrm{C}$. to ${ }^{\prime} 2^{\circ} \mathrm{C}$. Temperatures just below that of the blood $\left(33^{\circ} \mathrm{C}\right.$.$\left.27^{\circ} \mathrm{C}.\right)$ are distinguished by the most $\begin{aligned} & \text { ensitive parts, even ta }\end{aligned}{ }^{\circ} 05^{\circ}$ C. (2) The thermal sense varies in different regions as follows:tip of tongne, eyelids, cheeks, lips, neck, belly. The "perceptible minimum " was found to be, in degrees C. :-breast, $4^{\circ}$; back,.$^{\circ}$; back of hand, $3^{\circ}$; palm,.$^{\circ}$; arm,.$^{\circ}$; back of foot, $\cdot 4^{\circ}$; thigh, $\cdot 5^{\circ}$; leg, $6^{\circ}$ to $2^{\circ}$; cheek, $4^{\circ}$; temple, $3^{\circ}$. (3) If two different temperatures are appliad side by aide and simultaneously, the impressions often fuse, especially if the areas are close together. (4) Practice is said to improve the thermal sense. (5) Sensations of heat and cold may curiously alternate; thus "when the skin is dipped first into water at $10^{\circ} \mathrm{C}$. we feel cold, and if, it be then dipped into water at $16^{\circ} \mathrm{C}$. we liave at first a feeling of warmth, but soon agaiu of cold " (Landois). (6) The some temperature applied to a large area is not apprecisted in the same way as when applied to a emall one; thus "the whole hand when placed in water at $29^{\circ} \cdot 5 \mathrm{C}$. feels warmer thān wheus finger is dipped intc water at $32^{\circ} \mathrm{C}$.

There is every reason to hold that there are different nerve fibres and different central organs for the tactile and thermal sensations, but nothing definito is koowa. The one sensation andoubtedly affects the other. Thus the minimum distance at which two com. paes points are felt is diminished when ove point is wermer than the otber. Again, a colder weight is felt as heavier, "so that tho apparent difference of pressure becomes greater when the heaviel weight is at the same time colder, and lesa when the lighter weight is colder, and differeace of preasure is felt with equal weights of unequal temperatura" (E. H. Weber). Great sensibility to differences of temperature is noticed after removal, alteration by vesicants, or deatruction of the epidarmis, and in the skin affection called herpes zoster. The same occurs in some cases of locomotor ataxy. Removal of the epidermis, as a rnle, increeses tactile sensibility and the sense of locality. Increased tactile sensibility is termed hyperpselaphesia, and is a rare phenomenon in nervous diseases. Paralysis of the tactile sense is called hypopselaphesia, whilst its entire loss is apsclaphesix. Brewn-Séquard mentions 8 case in which contact of two points gave rise to a sense of a third point of contact. Certpin conditions of the nerve centres affect the seases both of touch and temperature. Under the influence of morphia the person may feel abnormally enlarged or diminished io size. As a rule the senses are affected simultaneously, but cases occur wbere one may be affected moro than the other. Herzen states that "limbs which are sleeping" feel heat and not cold (Landois).
Pain.-In addition to seusations of touch and of temperature referred to the skin, there is still a third kind of geosation nulike either, amaly, paip. This sensation cannot be supposed to be excited by irritations of the end-organs of touch, or of epecifio thermal end-organs (if there be such), but rather to irritation of ordiuary sensory nerves, and there is every reasoo to believe that painful impressions make their way to the brain along spinal tracks in tho apinal cord. If we consider our mentel condition as regards sensation at any moment, we notice numerous sensations more or less definite, not referred directly to the surface, nor to external ohjects, such as a feeling of general comfort, free or impeded breathing, hunger, thirst, malaise, horror, fatigue, and pain. These are all caused by the irritation of ordinary sensory nerves in different localities, sad if the irritation of such nerves, by chemical, thermal, mechanical, or nutritional stimuli, passes beyond a certaiu maximum point of intensity the result is pain. Irritation of a nerve, in accordance with the law of "peripheral reference of sensation," will cause pain. Sometimes the irritation applied to the trunk of a sebsory nerve may be so jotense as to destroy its normal function, and loss of sedsation or anæsthesia results. If then the stimulus be increased further, pain is excited which is referred to the end of the nerve, with the result of produciog what has been called anæsthesia dolorosa. Pains frequently cannot be distinctly located, probably owing to the fact of irradiation in tho nerve centres and subsequent reference to areas of the body which are not really the seat of irritations. The intensity of pain depends on the degree of excitability of tha sensory nerves, whilst its massiveness depends on the number of nerve fibres affected. The quality of the pain is probably produced by the kind of irritation of the nerve, as affected by the structure of the part and the greater or less continuance of severe pressure. Thus there are piercing, cuttiog, boring, bnrning, throbbiog, pressing, gnawing, dull, and acute varieties of pain. Sometimes the excitability of the cutaneons nerves is so great that a breath of air or a delicate touch may give rise to suffering. This hyperalgia is found in inflammatory affections of the skin. In neuralgia the pain is cbaracterized by its character of shooting along the course of the nerve and by
serere exacerbations. In many nervous diseases there are dis. ordered sensations referred to the skin, such as alternatious of heat and cold, burning, creeping, itching, and a feeling as if insecta were crawling on the surface (formication). This condition is tormed paralgia. The term hypalgia is applied to a dimination and anulgia to paralysis of pain, as is produced by auæsthetica.

Muscular Sense. -The sensory impressions consicured in this article are closely related to the so-called muscular sense, or that aense or feeling by which we are aware of the state of the muscles of a limb as regards contraction or relaxation. Some have held that the muscular sense is really dus to greater or less siretching of the skin and therefore to irritation of the nerves of that organ. That this is not the case is evident from the fact that disordered movements indicating perversion or loss of this sense are not affected by remnval of the skin (Claude Bernard). Further, cases io the humau being have been noticed where there was an entire loss of cotaneous sensibility whilst the muscular sense was unimpaired. It is also known that inuscles pnssess sensory nerves, giving rise, in certain circumstances, to fatiguc, and, when strongly irritated, to the pain of cramp. Duscular sensations are really excited by irritation of sensory nerves passing from the mnscles themselves. We are thus made conscious of whether or not the muscles aro contracted, and of the amount of contraction necessary to overcome resistance, and this knowledge enables us to judge of the amonnt of voluntary intpulse. Loss or diminution of the muscular sense is seen in cheren and especially in locomotor ataxy. Increase of it is rare, but it is seen in the curious affection called anxietas tihiarum, "a painful condition of unrest, which leads to a continual change in the position of the limbs" (Landois). See also Physiologr.
(J. G. Dt.)

TOUL, a town of France, chef-lieu of an arrondissement in the department of Meurthe-et-Mose!le, on the left bank of the Moselle, 199 miles east of Paris by the railway to Nancy, at the point where the Marne Canal joins those of the Rhine and the East. The isolated hills of St Michel and Barine respectively rise 548 feet and 574 feet above the town, which is a stronghold of the first order, the centre of an entrenched camp protected by numerous forts and redoubts, and a link in the chain of fortifications which extends from Verdun to Belfort. The light and elegant church of St Etieane (formerly the cathedral) has a fine choir and transept, dating from the 13 th century; the nave and aisles are of the $14 t h$, and the beautiful recently restored façade and the towers ( 246 feet) of the 15 th The interior ( 118 feet in height, 289 in length, and 89 in width) lias fine glass, a remarkable organ-loft, and some interesting monuments. The bas-reliefs of the charming Gothic cloister (13th and 14th centuries) were much damaged during the Revolution. The choir and transept of St Gengoult, a fine church of the 13 th century with a façade of the 15 th, contain some interesting 13 thcentury glass ; and the light groups of supporting columns, and the sculptures in the cloisters (first half of the 16 th century), should also be mentioued. The old episcopal palace (18th century) is now used as the town-hall ; it contains the museun and library, in which is preserved the golden bull by which the emperor Charles IV. in 1367 contirmed the liberties of the city. The population, 9632 in 1881, was 9981 in 1886 (commune 10,459 ).

Toul (Tullum) is one of tho oldest tovens of Frauce; originally capital of the Ineuci, in tho Belgic coufederation, it acquired great importance under the Romans. It was evangelized by St Mansuy in the latter half of the 4 th century, and became one of the leading sees of north-east Gaul. After being sacked successively by Goths, Burgundians, Vandals, and Huns, Toul was conquered by the Franks in 450. Under the Merovingians it was governed by counts, assisted by elective officers. The bishopa, who had become increasingly powerfu], were invested with sovcreign rights in the 10th century, holding only of the emperor, and for a period of 300 years ( 13 th to 16 th centuries) the citizens maintained a long atrugerle against them. The town was ferced to yield for a time to the Count.of Vaudemont in the 12th centory, and twice to the duke of Lortaine in the 15 th, and was thrice devastated by the plague in the 16 th. Charles V. roado a solems entry into the town in 1544 , but in the following year, at the iastance of the Cardinal de Lorraine, it placed itself under the perpetual pratection of the kings of France. Henry II. took possession in 1552, but the town with its territory was not officially incorporated witl France till 1648. Henry JV. was received in state ill 1603, and in 1637 the parlement of Metz was transferred to Toul. Iu 1700 Viaubad recou.
structed the fortications of the town, and in 1790 the bishopric was suppressed and the diocese united to that of Nancy. Toul capitulated in 1870, after a bombardment of twelve anys from heights now included in the new fortifications.

TOULON, a French fortress of the first class, chef-lieu of an arrondissement in the department of Var, of the 5th naval arrondissement, and of a military subdivision, is situated on the Mediterranean, 42 miles east-south-cast of Marseilles by the railway to Nice. The bay, which opens to the east, has two divisions, the "grand rade" and the "petite rade"; it is sheltered on the north and west by high hills, closed on the south by the peninsula of Capes Sicis and Cépet, and protested on the casts by a litgo

Environs of Toulon.
breakwater, - the entrance, 1300 feet wide, being defensible by torpedoes. A ship coming from the open sea must first pass the forts of St Marguerite, of Cape Brun, of La Malgue, and of St Louis to the north, and the battery of the signal station to the south; before reaching the petite rade it must further pass under the guns of the battery of Le Salut to the east, and of the forts of Balaguier and L'Éguillette to the west. The Bay of La Seyne lies west. of the petite rade, and is defended by the forts of Les Six-Fours, Napoleon (formerly Fort Cairo), and Malbousquet, and the batteries of Les Arénes and Les Gaus. To the north of Toulon rise the defensive works of Mont Faron and Fort Rouge, to the east the forts of Artigues and St Catherine, to the north-east the formidable new fort of Le Coudon, and to the south-east that of La Colle Noire, respectively dominating the highway into Italy and the valley of Hyères with the Bay of Carqueyranne. The port of Toulon consists of the old duck, "of which one-third is reserved for the national navy, a new dock, wholly so devoted, a harbour capable of receiving trading vessels drawing from 16 to 18 feet, but only used for cargoes of wood and wine, and the Castigneau dock. The naval arsenal (including the arsenal of Castigneau, which is contiguous with it, in the direction of La Seyne) extends over 4 miles, has an area of 667 acres, and employs from 12,000 to 13,000 men. It contains the offices connected with the administration of the port, the ottice of naval construction, a well-stored naval museum, and a greab variety of workshops. These last include a rope-work $1050 \times 66$ feet, covered building yards, careening basins, iorges, armourers' and joiners' shops, general magazines, reconstructed on a fireproof principle since the conflagra-
tion of 1793 , in which are stored al! materials required in the arsenal and oin board ship, a park of artillery, a splendid collection of arms, and separate storohouses for various classes of rigging. The Castigneau arsenal contains the nary bakery of twenty orens, capable of cooking 600,000 rations daily, the foundry and boiler-making works, engineers' workshops, forges, three large careening basins, a washing house, a slaughter house, stores of prorisions, coals, anchors and machinery, and the like. The Mourillon arsenal, to the south-east of the town, has stores of wood, building yards, and appliances for naval construction in wocd and iren. The town, enlarged to the north under the second empire, has on that side a fine new quarter ; but in the old town the streets are for the nost part narrow, crooked, and dirty, and to their insanitary state the cholera epidemic of $188 t$ has been attributel. The cbief buildings are the old cathedral of St Marie Majeure, the church of St Louis, the town-hall, the theatro (seating 2000 persons), the museum, the library ( 18,000 volumes), the naval and military hospital, with a natural history collection and an anatomical museum attached, a naval school of medicine, a school of hydrography, and large barracks. The imports are wine $\{2,470,000$ gallons in 1581), corn, wood, coal, bemp, iron, sugar, coffee, and fresh fish; the exports are salt, copper ore, harks for tanning, and oils. In 1882 the movement of the port was represented by 280 vessels ( 41,000 tons). The interesting buildings and gardens of the bospital of St Mandrier stand on the peninsula of Cape Cépet, and near them is the lazaretto. In 1881 the population of Toulon was 48,832 , and in 1886 it was 53,941 , exclusive of 12,487 soldiers, sailors, \&c. (commune 70,122).
The Roman Telo Martius is supposed to have stood near the lazaretto. The town was successi: ely sacked by Goths, Burguadians, Franks, and Saracens. During the early Midlle Ages, and till conquered by Charles of Anjou in 1259, it was noder lords of its own, and entered into alliance with the repuldics of Marseilles and Arles. St Lonis, Louis XII., and Francis 1 strengthened its fortifications. It was seized by the enperor Charles $V$. in 1524 and 1536. Henry IV. founded a naval arsenal at Toulon, which was further strengthened by Richelieu, and Vauban made the nert dock, a new enceinte, and several forts and batteries In $170^{7}$ the town was unsuccessfully besiegerl by the duke of Savoy, Prince Eugene, and an English fleet. In 3721 there was an outbreak of the plague. In 1792, after great and sanguinary disorder, the royalists of the town sought the support of the Engiisla and Spanish fleets cruising in the neiglbbourhood. The convention having replied by putting the towis "bors la loi," the inlabitants opened their harbour to the English. The ammy of the repiblic now laid siege to the tomn, and it was on this occasion that Napoleon Bonaparte first made his name as a soldier. The forts commanding the town having been taken, the English ships retirel after setting fire to the arsenal. The conflagration was extinguished by the prisoners, but not before 39 out of a total of 56 vessels had been destroyed. Under the Directory Toulon became the most important French military fort on the Mediterranean; it was heve that Napoleon organized the Egyptian campaign, and the expedition against Algiers set out from Toulon in 1830. The fortifications have been strengthened by Napoleon 1., Louis Philippe, Napoleon 111., and since 1870.

TOULOUSE, chef-lieu of the French department of Haute-Garonne, 478 miles south from Paris and 160 southeast from Bordeaux, stands on the right bank of the Garonce, which here describes a bold outward curve to the east. On the left bank is the Faubourg St Cyprien. The river is spanned by three bridges, -that of St Pierre to the north, that of St Michel towards the south, and the Pont Neuf in the centre; the last-named, a fine construction of seven arches, was begun in 1543 . The city is peculiarly subject to great floods, such as that of 1855 , which destroyed the suspension bridge of St Pierre, or the still more disastrous one of June 1875, which, besides carrying away that of St Michel, laid the Faubourg St Cyprien under water, destroyed 7000 houses, and drowned 300 people. East and north of the city runs the great Canal du Midi (from the Mediterranean), which here joins the Garonne.

Betwen this canal an l the city proper extends the long line of bor:!evards (Boulevards Lacrosses. d’Arcole, du 22 Seutembre. de.) leading by the Allee St Etienne to the Boulidgrin, whence a series of allées shoot out in all directions. Soutl-west the Allee St Michel leads towards the Garonne, and south the Grande Allie towards the Faubourg St Miche!. Theso boulevards take the place of the old city wails. Between them and the canal lie the more modern faubourgs of St Pierre, Arnaud-Bernard, Matabiau, \&c.

Plan of Tonlouse
The more ancient part of the city consists of narrow irregular pebble-paved streets. Most of the houses are of brick, and none of any great architectural pretensions, except. those which date back at least to the 17 th century. In 1868 the municipal authorities determined to construct two entirely new streets, broad and straight, intended to cut one another at right angles near the centre of the city. Of these the first, the Rue de Metz, starts eastward from the Pont Neuf, and will ultimately intersect the Rue d'Alsa!eLorraine running from north to sonth. These alterations, however, go on very slowly. The Place du Capitole may the regarded as the centre, whence streets branch out in eveiy direction. Eastward and nortb-east the Rue La Fayetto leads across the boulevards towards the Allée La Fayetie, beyond which, across the Canal du Midi, are the Eccle Veterinaire and the railway station, and still farther uff the obelisk erected to commemorate the battle of Toulouse (April 10, 1814), and the observatory. From the northwest of the Place du Capitole the Rue du Taur runs due north past the ancient Eglise du Taur to the great Eglise St Sernin, the largest and most famous church of southern France. From the north-west corner of the same Place the Rue des Lois conducts towards the École de Droit and the arsenal. In a more westerly direction the Rue Pargaminière stretches towards the venerable church and the bridge of St Peter From the south-west corner the Rue des Balances extends towards the Rue de Metz and the Pont Neuf. From the south the Rue St Rome, Rue des Changes, and Rue des Filatiers lead to the Place des, Carmes or de la Republique; while from the south east corner the Rue de la Pomme and the Rue' Boulbonne' lead 'across the Rue d'Alsace-Lorraine to the cathedral of St Stephen. In the
south of the city lies the palais de justice, near which are the ancient church of the Inquisition and several of the finest houses in Toulouse. Going northwards, the traveller passes the E.glise de la Dalbade on his way towards the Pont Neuf. immediately to the north of which is the Eglise de la Daurade. North of this churel, but somewhat farther from the river, is the military hospital, to the immediate east of which lio the lycee, the church of the Jacobins, and the public library. South-east from this, about halfway towards the cathedral, is the museum. North of the military hospital and beyond the Rue Pargaminiere lie the arsenal and the Faubourg St Pierre. Slightly to the northvest of the Pont St Pierre the Canal de Brienne (finished 1778) cuts across the angle formed by the Garonue and §anal du Nidi. Between the Canal de Brienne and the faronne is the cliief manufacturing part of the city, where the great Bazacle flour-mill stands. Along the right bank of the river run the various quays of $\mathrm{St}^{\prime}$ Pierre, dcc . In - the Faubourg St Cyprien, just north of the Pont Neuf, is the Hôtel Dieu St Jacques, said to have been founded before the 12 th century, with its large gardens. Close to the Foat St Piére is the hospital of St Joseph de la Grave, which makes up 1432 beds, and affords shelter to foundlings and the aged. South of the Allee St Michel is the Jardin des Plantes, founded by the ill-fated La Pérouse.

The most interesting building is the churcle of St Sernin or Saturainns, whom legend represents as the iirst preacher of the gospel in Toulousc, where he was perhaps inartyred towards the middle of the 3 d century. The oldest part of the present building was consecrated by Urban II. in 1096. This church is now the largest edifice of sonthern France, beiríg 375 feet from east to west and 217 feet in its utmost breadth. Thie pave ( 12 th and 13 th centuries) is remarkable for having donble aisles, Four pillars, supporting the central tower, are sitrounded by heavy masonry, which somewhat eproils the general larmony of the interior. In the southern transept is the "rortail des comtes," so named becauso near it lie the tonlbs of William Taillefer, l'ons, and other early counts of Toulonsc. The little chapel in which these tombs (as. cribed to the 11 th century) are found was restored by the capitols of Toulouse in 1648. A nother chapel contains a Byzantine Christ of late 11 th-century workinansliip. The choir (11th and 12th centurics) ends in an apsc, or rather clevet, surrounded by a range of colunns, marking off an aisle which in its turn opens into five elapels. The stalls are of 16 th-century work and very grotesquely carved. Agaiust the uorthern wall is an ancient table d daztel, which an 11 th-century inscription declares to have belongell to St Sernin. In the crypts are many relics, whiol, however, were robled of their golld and silver slirines during the Revolution. Tho finest gato is on the sontlh, and is surmounted by a fine representation of the. Ascension in Byzantine style. The capitals of the St Scruin pillars are somectimes ornamented with leavcs and sonetimes with grotesque animals, \&ce. The belfry consists of five stories, of which the two higclest are of later date, but harmenize very well with the thiree lower ones. The cathedrul, dedicated to St Stephen, dates from three different erochs. The nive, commensed by Rayniond VI. towards the beginning of the 13th century, still displays the sculptured arms of its founder, and a few yeals ago prescrved the pulpit in which St Bernard and St Dominic are sail to have preached. The elooir, commencel by Bertrand de Lillo (ce 1272), was burned in 1609, but restored in the sane egntury. It is surtounded by seveuteen clapels, which were finishled by the Cardinal d'On'sns, nophey of Loutis XI, towards the beginning of the 16 th onntury. These chapels are adorned with glass dating from the 15 th to the 17 th century. The great westera gate was constructed by Peter dn Moulin, areh bishop of Toulouse, fronn 1439 to 1451. It has been greatly battered, and presents but a poor approximation to its ancient Leanty. Over this grand gate, whicle was once orluameated with the statues of St ournn, St Exuperius, and the twelve apostlcs, as well as those of the two brother archbishops of Toulouse, Denis (1423-1439) and Peter du Moulin, there is a beautiful 13th-century rose-window, whose centre, however, is not in a perpeodicmlar line with the point of the Gothic arch below. . In the same way the choir and the wave have not the same exis.

- Among other remarkable clurches nay be noticell those of St fierre des Cnisines (12th century), with its beautifully sculptured apitals; of Notre Datme de la Daurade, near the Pont Neuf, built on the site of a 9 th-century Bcucdictine abbey, but reconstructed in 1764; and of Notre Dame do la Dalbade, perbans existing in she. 111 hi century but in its present form datiug from the 15 th. The Eglise des Jacolins, held by Viollet le Due to be "one of the wost beaut ful brick churches constructed in the Middle Ages."
was built towards the end of the 13 th century, and originally consisted of but one structure divided iato two aisles by a range of columns. It has a beautiful octaronal belfry. Before the Revolution it contained the mansolenm of Thomas Aquinas. On the left of the Garonne stands the cnurch of St Nicholas, also with an octagonal belfry and a spire doting from the I5til century. There are many other churches of co:ssiderable aatiquity.

Of secular buildings the most note vorthy are the capitole, the museum, and the lycee. The capitule (16th-17th centurics) bas a long Ionic façade constructed by Cammas (1750-60). The theatre is situated in the left wing. Ruuning along alinost the whalo length of the first floer is the "salle des illustres" edorned with the busts of forty-four great natives of Toulouse; the word "native" has, however, been construcd very liberalls. In the capitole tbo Académie des Jeux Floraux holds its annual meetings. The nuseum (opened 1795) occupics the chureh and other buildings of the Angustinian convent ( 14 th-15th cent.). It contains a splendid collection of antiquities arranged in two cloisters, and a collection of pictures The uatural history muscum is at the Jardin des Plantes. The lycée occupies the group of buildings known as "Les Jacobins," the Hotel Bernui (16th century), sc. Here is the public library (65,000 volumes).

Toulouse is singularly rich in mansions of the 16 th and 17th centuries. Several of these are richly adorned by Bachelier, Michel angelo's pupil. The Hobtels d'Assezat, de St Jean, Las Bordes, Felzios, Duranti, aad Maison de Pierre may be specially mentioned. A few houses are said to date from the 14 th century or even earlier. Near the Allée St Michel is the palais de justicc, the old meeting house of the parlenent oi Ioulousc. Close by was the old Château Narbonnais.
Besides its university, which ranks next to those of Paris ond Lyons, and has faculties of law, science, letters, and medicine, Toulouse possesses many educational and learned societies, arnong which may bo mentioned the Ecole des Peaux Arts et des Sciences Iodustrielles, the Ecolo Normale, the Ecole de Musique, the Académies des Jeux Floraux, des Sciencce et des Belles Lettres et Arts, aod de Législation, the Société d'Agriculture, and the archrological Société du Midi.

The geographical position of Tonlouse, on the plain of Languedoc, has made it the chief entrepot of the district for wine, corn, and almost all the industries of the ncirhbourhood. Besides the grinding of flour, its leading industries are cabinetmaking, hat-naking, calico priating, the manufacture of pots and pans, macaroni, aud starch, leather-naking (moroceo), cloth and paper making, glass. blowing, saddery, and pottery. The tobaceo factory occupies 1250 hands, and manufactures 1000 tons of snulf, a correspowdiug quantity of tobacco, and 250 tons of cigars amually.
The peprulation of the city, 127,196 in 1881, numbered 133,775 in 1886, that of the commune being 147,617 .
Tolosa (To入 $\omega \sigma \sigma a$ ), chief town of the Volcæ Tectosages, does not seem to have been a place of great importance during the early centuries of the Roman rule in Gaul, thoukl one incident in its early history gave rise to the famous latin proverb "habet aurum Tolosanum" (Aul. Gell., iii. c. 12). It was possessed of a circus and an amphitheatre, but its most remarkable vemains are to be found on the licights of Old Tonlouse (vetus Tolosa) some 6 or 7 miles to the east, where huge accumulations of broken pottery and fragmeats of an old carthen wall mark the site of an ancient settlement. The numerons coins that have been discovercd ou the samo spot do not date back farther than the $2 d$ century B.C., and seem to indicate the position of a Roman manufacturing centre then beginning to occupy tise Gallic hill-fortress that, in earlier days, had in times of peril been tho stronghold of the native tribes dwelling on the river bank. Tolosa docs not scem to lave been a Koman colony; but its importance must have increased greatly towards the middle of the 4 th century. It is to be found eutered in more than one itinerary dating from about this time; and Ausonius, in his Ordo Nobilium Urbium, alludes to it in terms implying that it then had a large population, In 419 it was taken by Wallia, king of the Visigotlis, under whom or whose successors it became the seat of the great Teutonic kinglom of the West-Goths, -a kingdom that within fifty years had extended itself from the Loire to Gibraltar aul from the lihone to the Atlantic. On the defeat of Alaric II. (507) Toulouse fell into the haads of Clovis, who carried away the royal treasurcs to Angonleme. Under the Mlcrovingian kings it seems to have remained the greatest city of southern Gaul, and is said to have been governed by dukes or counts dependent on one or other of the rival kincs descended from the great founder of the Frankish monarchy. It figures promimently in the pages of Gregory of Tours and Sidonins Apollinaris. About 625 Dargobert erected South Aquitainc into a kingdow for his brother Charibert, who close Toulouso as his capital. For the next eimlety ycars its history is obscure, till we reach the days of Charles Martel, when it was besieged by Seina, the leader of the Saraceas from Spain ( $c$. 715-20), but delivered by Endo, "princeps Aquitanix," 10 whom later writers discovered the ancestor of all the later counts of Toul. ous..- Modern_criticism however has discredited this genealogy;
and the real history of Tomouse recommences in 780 or 781, when Charlemagne appointed lis little son Lonis king of Aquitais?, with Toulouse for his chief city.

During the minority of the young king his tutor Chorson ruled at Toulouse with the title of duka or count. Being cleposed at the council of Worms (790), he was succeeded by William Courtnez, tha traditional hero of southero France, who in 806 retired to his nawly fouoded monastery at Gellone, whers ha died in 812. In the unhappy days of Louis the Pious and his children Toulouse sulfered in comanon with the rest of western Europe. It was besieged by Charles the Bald in 844 , and taken four years later by the Normans, who in 843 had sailed up the Garonna as far as its walls. About 852 Raymond I., count of Querci, sueceeded bis brother Fridolo as count of Rouergue and Toulouse; it is from this noble that all the later counts of Tonlouse trace their deseent. Raymond I.'s grandchildren divided their parent's estates; of these Raymond II., ti:e elder (d. 924), becamo count of Toulouse, and Ermengaud, the younger, count of Rouergue, while the hereditaty titles of Gothia, Querci, and Albi were shared between them. Raymond II.'s grandson, William Taillefer (d. c. 1037), married Emma of Provence, and hamled down part of that lordship to his younger sod Bertrand. ${ }^{1}$ William's elder son Pons left two children, of whom William IV. succeerled his father in Toulouse, Albi, Querci, \&c.; while the younger, Raymond IV. of St Gilles (c. 1066), made himself master of the vast possessions of the counts of Rouergue, married his cousin the heiress of Provance, and about 1085 began to rule the imnense estates of his elder brother, who was still living.

From this time the counts of Toulouse were the greatest lords in southern France. Raymord JV., the hero of the first crusade, assumed the formal titles of marquis of Provenca, duke of Narbonne, and count of Toulouse. While Raymond was sway in the Holy Laud, Toulouse was seized by William 1X., duke of Aquitaine, who claimed the city in right of his wifa Philippa, tha daughter of William IV., but was unable to hold it long (1008-1100). Raymond's son and successor Bertrand followed his father's example aud set out for the Holy Land in 1109, leaving lis great estates at his death to his brother Alplonse-Jourdain. The rule of this prince was disturbed by the ambition of William IX. and his grand. daughter Eleanor, who urged her lusband Louis VII. to aupport her clams to Toulonse by war. On her divorce from Louis and her marriage with Henry II., Eleanor's claims passed on to this monarch, who at last forced Raymond V. to do him homage for 'foulouse in 1173. Raymond V., tha patron of tlia troubadours, died in 1194, and was succeeded by his son Raymond VI., under whose rule Languedoc was desolated by the remorseless crusaders of Si.noo de Montfort. Raymond VII., the son of Raymond VI. and Princess Joan of England, succeeded his father iu 12\%2, and died in 1249, leaving an only danghter Joan, married to Alfonso tha brother of Louis IX. On the death of Alfonso and Joan in 1271 the vast inheritance of the counts of Toulousa lspsed to the crown. ${ }^{2}$

From the middla years of tha 12 th century the peopla of Toulonse seen to have begun ts frea themselves from the most oppressive feudal dues. An act of Alphonse-Jourdain (1141) exempts them from the tax on salt aud wina; and in 1152 we have traces of a "commune consiliun Tolosæ" making police ordinances in its own name" with the advice of Lord Raymond, count of Toulouse, duks of Narbonne, and marquis of Provence." This act is witnessed by six "capitularii," four duly appointed judges (judices constituti). and two adrocates. Twanty-three years later there are twelva capitularii or consuls, six fue tha city and six for its auburba, all of them elected and sworn to do justice in whatever municinal matters were bronght before them. In 1222 their numbar was increased to twenty'four; but they wers forbidden to touch the city property, which was to remain in the charge of certain "communarii" chosen by themselves. Early in the 14th century the consuls took tha name of "domini de capitulo" or, a little later, that of "capitulum nobilium." From the 13th century the coasuls met in their own house, tha "palatium communitatis Tolose" or bôteldeville. In the 16th century a false derivatiou changed the ancient consuls (domini de capilulo) into the modern "capitouls" (domini capitolii Tolosani), a barbarous etymology which in its turn has, in tha present century, transformed the old assembly housa of Toulouse into the capitole.

The parlement of Toulousa was established as a permanent court in 1443. Louis XI. transferred it to Montpellier in 1467, but restored it to Toulonse before the close of the next jear. This

[^214]parlement was for Languedoc and southern Frauce what the parle ment of Paris was for the north. Towards the end of the 16 th century, during the wars of tho Lesgue, it was split up into three different sections, sitting respectively at Carcassonne or Béziers, at Castel Sarrasin, and at 'foulouse. The threa were reunited in 1596. Ubder Francis 1. it hegan to persecuta heretics, a nd in 1618 renderad itself notorious by burning tha philosopher Vaniai. Tha univer. sity of Toulouse owes its origin to the action of Gregory IX., who in 1229 bound Raymond V11, to maintain four masters to teach theology and eight others for canon law, grammar, and the liberal urts. Civil law and medicine were taught only a few yeara later. The famous "Floral Games" of Toulonse, in which the poets of Languedoc contended (May 1-3) for the prize of the golden violet and other gold or silver flowers, given at the expense of the city, were instituted in 1323-24.

(TA A. A.)
TOUNG-NGU, a district in the extreme north of the Tenasserim division of Burmah, with an area of 6354 square miles, and lying between $17^{\circ} 37^{\prime}$ and $19^{\circ} 28^{\prime} \mathrm{N}$. lat., and between $95^{\circ} 53^{\prime}$ and $96^{\circ} 53^{\prime}$ E. long. It is bounded on the N. by Upper Burmab, on the E. by a high mountain range known as the "Great Watershed," on the S. by Shwe-gyeng district, and on the W. by the Pegu Yomas. Three mountain ranges traverse the district-the Pegu Yomas, the Poung-loung, and the Nat-toung or "Great Watershed,"-all of which have a north and south direction, and are covered for the most part with dense forest. The Pegu Yomas have a general elevation of from 800 to 1200 feet, while the central range averages from 2000 to 3000 feet. The rest of Toung-ngú forms the upper portion of the valley of the Tsit-toung (Sittang) river, the only large river in the district, the chief tribntaries of which are the Tsliwa, Khaboung, Hpyu, Thouk-re-gat, and Rouk-thwa-wa, all heing navigable for a great portion of their course Limestone appears in various places, and in the north-east a light grey marble is quarried for lime. The rivers form the chief means of communication during the rainy season. Of late years some good roads have been constructed, and the Burmah State Railway, when completed, will intersect the district from south to north.
In 1881 the population numbered 128,848 (males 68,484, females 60,364), of whom 93.997 were Budclisists, 17,448 Christians, 2086 Hindus, 1982 Molamnedans, and 12,612 aborigines. The only town in the district is Toung-ngli, on the Tsit-toung river in $18^{\circ} 55^{\prime} 24^{\prime \prime}$ N. lat. and $96^{\circ} 31^{\prime} 4^{\prime \prime}$ E. long., with a population of 17,199 in 1881. Of the total area ouly 59 square miles are actually under cultivation, owing mainly to the hilly nature of the country. Rica is tha chief product; other crops inclule oil-seeds, augar. cane, cotton, fruit, and vegetables. The principal inanufactures are silk, saltpetre, and gunpowder. In 1885-86 the gross value of the district was $£ 15,098$, of which the land produced $£ 5880$.

TGUR, Márice Quentin de la (1704-1788), the rcuowned pastellist, was born at St Quentin on the 5th September 1704. On leaving Picardy for Paris he entered the studio of an artist named Du Pouche, and then that of Spoede, -an upright man, but a poor inaster, rector of the Academy of St Luke, who still continued, in the teeth of the Royal Academy, the traditions of the old guild of the master-painters of Paris. This possibly contributed to the adoption by De la Tour of a line of work foreign to that imposed by an academical training; for pastels, though occasionally used, were not a principal and distinct branch of work until 1720, when Rosalba Carriera brought them into fashion with the Parisian world. In 1737 De la Tour exbibited the first of that splendid series of a hundred and fifty portraits which formed the glory of the Salon for the succeeding thirty-seven years. In $1740^{\circ}$ he was received by the Academy; and in 1751, the following year to that in which be received the title of painter to the king, he was promoted by that body to the grade of councillor. His work had the rare merit to satisfy at once hoth the taste of his fashionable models and the judgment of his brother artists. His art, consummate of its kind, achieved

He task of flattering bis sitters, wailst hiding that flattery behind the just and striking likeness which, says Mariette, hir hardly ever missed. His portraits of Rousseau. of Voltaire, of Louis $X V$., of bis qucen, of the dauphin and daıphiness, are at once documents and masterpieces unsurpassed except by bis life-size portrait of Madame de Ponipadour, which, cxlibited at the Salon of 1755 . is still the chief ornament of the cabinet of pastels in the Louvre. It is and will probably always be the most perfect model of this class of work as long as time and damp spare the fragile dust to which it owes its beauty. The museum of St Quentin, howerer, also possesses a magnificent collection of works which at his death were in his own hands. De la Tour retired to St Quentin at the age of 80 , and there he died on 17 th February 1788. The riches amassed during his long life were freely bestowed by him in great part before his death; he founded prizes at the achool of fine arts in Paris and for the town of Amiens, and endowed St Quentin with a great number of useful and charitable institutions. He never married, but lived on terms of warm affection with his brother (who survived him, and left to the town the drawings now in the museum); and his relations to Mdlle. Fel, the celebrated singer, were distinguished by a strength and depth of feeling not common to the loves of the 18 th century.

See, in alluition to the general works on French art, Desmaze, three works, of which the most important is Le Reliquaire de la Tour; Guiffrey and Tourneux, Correspondance Inedite de M. Q. de la Tour; Champfleurs, De la Tour, and Peintres de Laon ei de Sl Quentin; and Dréollo do Nodon, Ėloge Biographique de Mr. Q. de la Tour.

TOURACO, the name, evidently already in use, under which in 1743 Edwards figured a pretty African bird, ${ }^{\text {J }}$ and presumably that applied to it in Guinea, whence it had been brought alive. It is the Cuculus persa of Lin-

White-Created Touraco (Turraous albicristatus). After Schlegel.
nreus, and Turacus or Corythiair persa of later authors, who prreeived that it required generic separation. Cuvier, in 1799 or 1800 , Latinized its native name (adopted in the meanwhile by hoth French and German writers) as above, for which barbarous term Illiger, in 1811, substituted a

[^215]more classical word. In 1788 Isert described and figured (Bcobacht. Geselloch. naturf. /'reunde, iii. pp. 16-20, jl. 1) a bird. also from Guinea, wuich he called M/vsnz/hay violacea. Its affinity to the original Touraco was soon recognized, and both forms have been joined by modern systematists in the Family Jhusophayidre, commonly Englisheu Plantain-eaters or Touracos, sometimes spelt Tourakoos.

To take first the Plaatnin-eaters projwr, or the genus Musophaga, of which only two speces aro known. Ons about the size of a Crow 18 comparatively common iu museums, and is readily recor. nued by haviug tho horny liase of ita fine yellow bill proionged backwards over tho forehead in a kiud of abield. The top of tho head, and the primaries, except their oater edga and iip; are deep crimson; a white atreak extends behind the eye; and the rest ol the plumage is of a rich glossy purple. The second species, $A f$. rosse, which is rare, chiefly differs by wanting the white eye-streak. Then of the Touracos-the sureies oriminally describel is about the size of a Jay, and has the head, crest (which is vertically com. pressed and tipled with red), neck, and breast of a fine glass-grcen, varied by two conspicuous white atreaks-one, from the grape to the upper part of tho crimson orbit, separated ly a black patcli from the other, which runs bencath and behind the cyc. The wingo coverts, lower part of tha back, and tail ace of a liright steel-purple, the primaries deep crimson, edged and tipled with bluish-lilack Over a dozen other congeneric apecies, mose or luss resembling this, havo now been described, and all inhahit somodstrict of Africa; but thero is only room here to mentiou that found in the Cape Colony and Natal, whers it is known as the "Lary" ( $c f$. vol. xv. p. 7, note 1), and, though figured by Daubunton aad others, first differentiated in 1841 by Stricklanil (Aun. Níl. Hislury, vii p. 33) as Turacus albicristatus-its crest having a conspicuous white border, while the ateel-purple of T. persa is replaced by a rich and glossy bluisb-green of no loss beauty. In nearly all the species of this genus the nostrils are almost completely lidden by the frontal feathers; but there aro two others in which, though closely allicd, this is not tha case, and soune aystrmatists woukl place them in a separate geaus Gallircx; while another species, the giant of the Family, bas beez moved into a third genus as Corythæola cristatu. This differs from any of the foregoing lyy the absence of the criason coloration of the primaries, and seenus to lead to amother group, Schizorrhis, in whicla the plumage is of a still plainer type, and, morcover, the nostrils bere are not only exposed hut in the form of a rlit, instead of being oval as in all the rest. This geuus contains about half a dozen specics, ono of which, $S$. concolor, is the Grey Touraco of the colonists in Natal, and is of an almost uaiform slatybrown. A good deal has been written about these hirds, which form the aubject of one of the most beautiful monorraples ever published - De Toerako's afgebeld en beschreven,-by Schleprel and Westerman. brought out at Amsterdan in 1860; while the latest collected information is contained in an elaborate essay by Herr Schalow (Jour. f. Ornithologic, 1886, 1p. 1-77). Still, much remains to bo mada known as to their distribution throurgnut Africa, and their habits. They aeem to be all fruit-caters, and to frequent the biginest trees, aaldom coming to the rround. Very littlo can be conficutly asserted as to their nidification, but at l'ast one species of Schizorrhis is aaid to make a rough nest and therein lay three efgs of a pale blue colour. An extraordinary peculiarity attends the crimson coloration which adorns thic primaries of so many of the Afusophagids. So long aro as 1818, Jules Verreaux observed (Proc. Zool. Society, 1871, 1. 40) that in the case of T. abbicristalus this beautiful hue vanishes on cxposure to heavy rain and reappears only after coma interval of time and when the feathers are dry. ${ }^{2}$

The Afusophagide form a very distinct Family of Prof. Huxley's Coccygomorphw, baving perhaps the Coliidx and Cuculide as theirnearest allies. Eyton pointed out (Ann. Nal. IIistory, ser. 3, ii. p. 458) a feature possessed in common by the latter and the Musophagadx, in the "process attached to the anterior edge of the ischium," which he likened to the so-called "marsupial" bones of Didelphian Mammals. J. T. Reinhardt bas also noticed (I'idensk. Meddels. Naturlist. Forening, 1871, pp. 326-341) another Cuculine character offered by the os uncinatum affixed

[^216]to the lower side of the ethmoid in the Plantain-eaters and Touracos; but too much dependence must not be placed on that, since a similar structure is presented by the Frigate-bird (vol. ix. p. 786) and the Petrels (vol.玉viii. p. 711). A corrésponding process seems also to be found in Trogon (q.v.). The bill of nearly all the species of Musophagidx is curiously serrated or denticulated along the margin, and the feet have the outer toe reversible. No member of the Family is found outside of the continental portion of the Etbiopian Region.
(A. x.)

TOURCOING, a manufacturing town of France in the department of Nord, 7 miles north-east of Lille on the railway to Ghent, is rapidly becoming one with the peighbouring towa of Roobaix (q.v.). Wool, cotton, linen, and silk are spun in more than 65 mills ( 40,000 spindles); there are upwards of 25 combing establishments (by machine and hand), 50 to 55 manufactories of velvet-pile carpets, furniture stuffs, and all kinds of woven goods, besides dye-works, soap-works, a sugar refinery, and machine workshops. The total industrial production of Tourcoing may be set down at about $£ 6,800,000$ per aonum. Tourcoing possesses a chamber of commerce, a conseil de prudhommes, a consultative chamber of arts and manufactures, a wool "conditioning" bureau, schools of drawing, painting, music, and architecture, and a horticultural society. In 1866 a pyramid was erected to commemorate a battle gained by Jourdan and Morean in the neighbourhood in 1794. The population, $34, \pm 15$ in 1881 , was 41,570 iu 1886 (commune 58,008).

Famed since the 14th ceatury for its woollen manufactures, Tourcoing was fortified by the Flemings when Lonis XI. of France disputed the inheritance of Charlesthe Bold with Mary oi Burgundy. The town suffered much frons the Frencli is 1477, from the Huguenots in- 1556, and by fire in 1607 and 1711. The inhabitants, 18,000 in 1789, were reduced by the French Revolution to 10,000, but a nen cra prosperits began in 1832. In 1801 the population of the commune was 23,493 , and in 1871 it was 43,322 .

TOURGUENIEFF, Ivan (1818-1883), the descendant of an old Russian family, was born at Orel, in the government of the same name, in 1818 . His father, the colonel of a cavalry regiment, died when our author was sisteen years of age, leaving two sons, Nicholas and Ivan, who were brought up under the care of their mother, the heiress of the Litvinoffs, a lady who owned large estates and many serfs. Ivan studied for a year at the university of Moscow, then at St Petersburg, and was fually sent in 1843 to Berlin. His education at howe had been conducted by German and Freuch tutors, and was altogether.foreign, his mother only speaking Russian to her servants, as became a great lady of the old school. For his first acquaintance with the literature of his country the future novelist was indebted to a serf of the family, who used to read to him verses from the Rossiad of Kiheraskoff, a once-celebrated poet of last century. Tourguenieff's early attempts in literature,-consisting of poems and trifing sketches, nay be passed over here; they were not without indications of genius, and were farourably spoken of by Bielinski, then the leading Russian critic, for whom Tourguenieff ever cherished a warm regard. Our author first made a name by his striking sketches "The Papers of a Sportsman " (Zapishi Ohhotuika), in which the miserable coodition of the peasants was described with startling realism. The work appeared in a collected form in 1852 . It was read by all classes, including the enperor bimself, end it undoubtedly hurried on the great work of emaneipation! Tourguenieff had always sympathized with the muzhiks; he had often been witness of the cruelties of his mother, a narrow-minded and vilidictive woman. In somo interesting papers recently contributed to the "European Messenger" (Tiestnik Evropî) by a lady blought up in the hóusehold of Mme Tourghenieff, sad
details are given illustrative of her character. Thus the dumb porter of gigantic stature, drawn with such power in Mumu, one of our author's later sketches, was a real person. We are, moreover, told of his mother that she could never understand lonw it was that her son became an author, and thought tliat he had degraded himself. How could a Tourguenieff submit himself to be criticized if

The next production of the novelist was "A Nest of Nobles" (Dicuriansioe Gnie:do), a singularly pathetic story, which greatly increased his reputation. This appeared in 1859 , and was followed the next year by "On the Eve" (Nakanue), -a tale which contains one of his most beautiful female characters, Helen. In 1862 was published "Fathers and Children" (Otzi i Dieti), in which the author admirably described the nihilistic doctrines then beginning to spread in Russia, he himself inventing the word nililism, which seems likely to become permanent. In 1867 appeared "Sinoke" (Dîn), and in 1877 bis last work of any length, "Yirgin Soil" (Nov). Besides his longer stories, many shorter ones were produced, some of great beauty and full of subtile psychological analysis, such as Rudin, "The Diary of a Useless Man" (Dnernik Lishnago Choloviekil, and Qthers. These were afterwards collected into three volumes. "The last works of the great novelist were "Poetry in Prose" and "Clara Milich," which appeared in the pages of the "European Messenger."

Tourguenieff, during the latter part of his life, did not reside much in Russia; he lived either at Baden Baden or Paris, and chiefly with the family of the colehrated singer Viardot Garcia, to the members of which he was much attached. He occasionally visited England, and in 1879 the degree of D.C.L. was conferred upon him by the university of Oxford. He died at Bougival, near Paris, on September 4, 1883 ; according to his wish, his remains were taken to St Petersburg, and buried in the Volkoff cemetery, near, those of the critic Bielinski.
Unquestionably Tourgnenieft may be considered one of the greatest novelists of our own or any other times, and worthy to be ranked with Thackeray, Dickens, and George Eliot: with the genius of the last of these he has many affinities. His studies of human gature are profound, and he has the wide sympathies which are essential to genius of the highest order. A melancholy, almost pessimist, fceling pervades his writings, but perhaps this is always found in those who have truly listened to the "still, sad music of humanity." This morbid self-analysis seems natural to tho Slavonic mind, and Tourguenieff has given abundant proof of possessing it. The closing clapter of "A Nest of Nobles" is one of the saddest and at the same time truest pages in the whole range of existing novels.
The writings of Tourguenieff have been made familiar to persons unacquainted with Russian by Frencl translations. There are some versions in English, but the only two worthy of notice are tho trasslation of the "Nest of Nobles" under the name of "Lisa," by Mr Ralston, and "Virgin Soil," by the late Mr Ashton Dilke.

TOURMAL jNE. See Electricity, vol. viii. p. 99; Geology, vol. x. p. 228 ; and Mineralogy, vol. xvi. p. 409.

TOURNAI (Flem. Doornik), a town of Belgium, capital of an arrondissement in the province of Hainault, 53 miles by rail west-south-west from Brussels, is divided into two parts by the Scheldt, which is here spanned by seven bridges and lined with spacious tree-shaded quays. The older, which is also the busier and more important portion of the town, stands on the left bank; the new town is distinguished by its neat regular streets and modern architecture. The cathedral, which is a fine example of the Romanesque style, is' a cruciform basilica, with a series of chapels and five towers. The nave was probably corsecrated in 1171 : the transepts date from the 13th century; and the (Gotbic) choir was completed in 1338. at which time also the Romanesque façade was altered, and a poreb in the Pointed style added. The sculntules in the porch range in date from the 13 th to ths.

17th century, and deserve special notice, particularly those of later date by native artists. The general effect of the interior is harmonious and impressive. The capitals of the pillars are rich and varied ; the passage round the choir contains several pictures of the Flemish school ; the richly sculptured Renaissance roodloft dates from 1566 ; and most of the stained glass in the transept dates from about 1456. The adjacent belfry, dating originally from 118T, and partly rebuilt in 1391, was restored in 1852. In the Grande Place, not far from the cathedral, is the church of St Quentin, sometimes suoken of as "la petite cathédrale," in the Transition style, and nearly of the same date as the cathedral. The church of St Jacques dates from the 13th and 14th centuries, and that of St Brice from the 12th. The bnildings of the old monastery of St Martin, on the sonth-west side of the town, are now used as an hotel de ville, in connexion with which there is a small picture gallery containing same examples of Rembrandt, Rubens, and Van Dyck. The town contains courts of law, an athenæum, a theatre, a school of arts and manufactures, an eppiscopal palace and seminary, a natural history museum, leesides other public buildings. The fortifications of Vauban, extended after the second treaty of Paris, are now demolislied, and their place taken by boulevards. The leading objects of manufacture are stockings and "Brussels" carpets ; the other industries include paper-making, threadmaking, and the spinning of wool and flax. The trade of the place is very considerable, as vessels of 150 tons burden can ascend the river to this point, and its railway communications are good. The population in 1876 was 32,145.
Tournay, supposed to be the Civilas Necriorum of Cassar, and afterwards known as Tournacus, was ove of the firsi places conquored by the Franks, and Cloris made it for a time lisis capital. In modern timea, stauding as it does on the frontier between Belgium and France, it bas been frequently, besieged and taken. History records specially the siegs by Alexander of Parma in 1581, when it was bravely but unsuccessfully defended by the $V_{\text {rincess }}$ D'Epinoy, whose statue now stands in the Grande Place. Perkin Warbeck was a native of Tournai.

TOURNAMENTS. Tournaments and jousts were the chief military exercises and displays of the age of chivalry. Besides being the apprepriate sports and pastimes of a warlike era and caste, they were intended to test the skill and exhibit the provess of the knights and squires who took part in them. Considered under their more serious aspect, apart from their association with pomp and festirity, they were, practically speaking, the equivalents of the reviews and slam-fights of later times, and were designed as a preparation for the actual manourres and real conflicts of the battlefield. Tournaments and jousts differed from one another principally in the circumstance that in the first several combatants on each side were engaged at once, and in the second the contention was between two combatants only. The former consisted of the mutual charges of equal troops of cavalry, while the latter consisted of a duel on horseback. Du Cange says that the French tournoi, English "tournament," "was a general expression which comprehended all sorts of combats that were pelformed by way of exercise. But it more properly meant such as were performed by companies, where many were in confict against the same number, representing the form of a battle. When those general combats were ended, then single ones commenced ; for all who were desirous of displaying their address, and attracting public notice for their valour, offered single combat with sword or lance against all who should present themselves"; and he adds that these combats were called by the old Frensh writers "joustes," which is the same word as the English "jousts." But jousts were held far more frequently than, and quite independently of, regular
tournaments throughout the period in which the customs of chivalry were observed, and, according to some authorities, the lance alone was used in them, while in the others all weapons except firearms were employed. In both cases such weapons were usnally although not invariably rendered innocuous, and it was only rarely that the combatants were killed or injured by wounds, as distinguished from fails and bruises. But in one way or another tournaments and jonsts were always extremely dangerous, and a long list of eminent persons met their death in them, from Raoul, Comte de Guines, to Henry II. of France. It may be assunied that jousts in some shape existed at all periods, in which men fought in armour and on horseback, and were in the habit of practising themselves in time of peace for the exigencies of warfare. But it is very doubtful when and where tournaments, in the proper sense of the term, were originally institnted. The older writers on the sulject saught to connect them with the "Troja" or "ludus Troje" among the Romans. But this is a piece of archrology of the same sort as that which identified the knighthood of the Middle Ages with the ancient "ordo equestris," and will not, of course, bear examination. Much reliance again has bcen placed by some of then on the account of a sham-fight which was held at the celebrated interview between the emperor Louis and Charles the Bald in 841, which in certain respects bore a close resemblance to a tournament, and was no doult the kind of exhibition out of which the tournament of a later age was developed. Others attribute the institutio:: of tonrnaments to the emperor Henry the Fowler, who died in 936 , or to Geoffrey de Prenilly, the ancestor of the counts of Tours, who died in 1066. However this may be, it is certain that they were in vogue on the Continent at the end of the 11th century, and that in the early part of the 12th century they were introduccd into England. In the 13th and 14th centuries they were comonon all over Christendom, including the Eastern as well as the Western empire and the states comprised in or adjacent to it. It was not until the end of the 16th century that tilts and hastiludes passed out of fashiou in Britain, and even in the earlier years of the 17 th century they wore occasionally celebrated under the patronage of Henry, prince of Wales, son of King James 1.
The older anthorities on tournaments and jousts aro exceediugly numerous. But all tbat is material in what they lave written will be found in Ste Palaye's Mennoires sulv. C'Ancienne Chcevalcric and Mills's History of Chizulry. The "Dissertations" of Du Cange at the end of Joinville's Memoirs and the Chronicles of Froissant and Monstrelet may also be consulted. Ste Palaye nud Mills were both industrious compilers, and the sccond is much indleltrad to the first.
TOURNEBOUT, a wind instrument of wood, in which a cylindrical column of air is set in vibration by a reed. The lower extremity is turned up in a half circle, and from this peculiarity it las gained the French names tourrebout and cromorne, - the latter a corruption of the Cerman name Kinummhork. There appears to be no English equivalent. The reed of the tournebout, like that of the bassoon, is formed by two tongues of cane, adapted to the small end of a conical lirass tube, the large end being inserted in the body of the instrument. It presents, however, this difference, that it is not, like that of the bassoon, in contact with the player's month, but is covered again by a cap pierced with a hole in the upper part, through which opening the air is introduced which sets the reed in vibration, the reed being therefore subject to no pressure of the lips. The compass of the instrument is naturally limited to the simple fundamental sounds which the successive opening of the lateral holes gives rise to. The tournebouts have not much length for the deep sounds they produce, which arises from these instruments sounding, like all tubes of cylindrical bore provided with reeds, the same as the stopped pipes of au organ. That is to say, theoretically,

VXIII. - 69
they require only half the lengths necessary for the open pipes of an organ, or for conical tubes provided with reeds, to produce notes of the same pitch. Moreover, when, to obtain a larmonic, the column of air is divided, the tournebout will not give the octave like the oboe and bassoon, but the twelfth, corresponding in this peculiarity with the clarinet and all stopped pipes or bourdons. With the ordinary boring of eight lateral holes, the tournebout possesses a limited scale embracing a ninth. Sometimes, however, the deeper sounds are completed by the addition of one or more keys. By its structure the touraebout is one of the oldest wind instruments; it is evidently derived from the Greek aulos and the Roman titia, which cousisted equally of a simple cylindrical pipe of which the column of air was set in vibration by a double reed.

Notwithstanding the successive imprevements that were introduced in the manufactrre of wind instruments, the tournebout scarcely ever varied in the details of its construction. Such as we see it represented in the treatise by Virdung ${ }^{1}$ we find it again about the epoch of its disappearance, in $L$ 'Art du Faiseur d'Instruments de l'Encyclopédie de Diderot et d'Alembert (Paris. 1751-80).

The tournebeuts existed as a complete family from the 15 th century. According to Virdung, it was formed of four individual instrumenta; Pretorius ${ }^{2}$ cites five, -the deep bass, the bass, the tenor or alto, the cantus or soprane, and the higb soprano, with compass respectively of

A band, or, to use the expression of Preetorius, enf "accort," of tournebouts compre. hended-1 deep bass, 2 bass, 3 alto-tener, 2 cantus (soprane), 1 high soprano $=9$.
Tho tournebouts were not always an orchestra by themselves; they allied themselves also to otber instruments, and notably to fintes and oboes. It was thus that the little groups of musicians iu the service of princes, or those engaged by some large town on the occasion of a festival or public ceremony, were composed of several tournebout players combined with some flautista and oboo playerg. In 1685 the orchestia of the Neve liirche at Strasburg comprised two tournebonts, and until the mildle of the last century these instruments formed part of the music called "la grande écurie" in the survice of the French kings. Tournebouts have in our days become of extreme raity, and scarcely exist in collections. The masenm of the Conservatoiro Royal do Musique at Brussels has the good fortune to possess a complete family, which is regarded as having helonged to the duko of Ferrara, Alphonso II. d'Este, a prince who reigned from 1559 to 1597. The soprano (cantus or discant) has the same compass as above, white the alto, tho teuor (furnished with a koy), and bass bave an extent respectively of

aul 9

Tho bass (see accompanying figure), besides having two keys, is distinguished from the others by a kind of small bolt, two of which slide in grooves and close the two holes that form the lowest notes of the instrument. It is very curious to observe that the employ. ment of these bolts, placed at the extremity of the tournobout and out of reach of the fingers of the instrumentalist, forces him to require the assistauce of a person whose sole mission is to attend to these bolto during the performance.
The "Platerspil" of which Virdung gives a drawing is only a tind of tournebout. It presents esprecially the peculiarity that,

[^217]instead of having a cap to cover orer the reed, there is a spliericai receiver surrounding the reed, to which the tube for insufflation is adapted. This receiver was of wood worked round, ur perhaps consisted of a simple gourd.
(V. M.)

TOURNEFORT, Joseph Pitton de (1656-1708), a botanist of considerable reputation, was born at Aix, in Provence, in 1656. He studied in the convent of the Jesuits at Aix, aud was destined for the church, but the death of his father left him free to follow his botanical inclinations. After a couple of years collecting, he studied medicine at Montpellier, but soon returned to his favourite pursuit, and was appointed professor of botany at the Jardin des Plantes in 1683. By the kiag's order he. travelled through western Europe, where he made very extensive collections, and subsequently spent three years in Greece and Asia Minor (1700-1702). Of this journey a description in a series of letters was posthumously published in 3 vols. (Relation t'un Voyage du Levant, Lyons, 1717). His principal work is eatitled Institutiones Rea Ilerbarix ( 3 vols., Paris, 1700), and upon this rests chiefly his claims to remembrance as one of the most eminent of the systematic botanists who prepared the way for Linnæus. His exact position among these bas been discussed at length by Sachs (Geschichte d. Botanik, Munich. 1875). He died December 28, 1708.

TOURNEUR, CYRIL, a tragic poet of the first order, has left no record of his existence beyond the respectire dates of his first and last extant works (1600-1613). An allegorical poem, worthless as art and incomprehensible as allegory, is the earliest of these; an elegy on the death of Prince Henry, son of James I., is the latest. The two plays on which his fame rests, and on which it will rest for ever, were published respectively in 1607 and 1611, but all students have agreed to accept the internal evidence which assures us that the later in date of publication must be the earlier in date of composition. His oniy other known work is an epicede on Sir Francis Vere, of no great merit as poetry, but of some value as conveying in a straightforward and masculine style the poet's ideal conception of a perfect knight or "happy warrior," comparable by those who may think fit to compare it with the more nobly realized ideals of Chaucer and of Wordsworth. But if Tourneur had left on record no more memorable evidence of his jowers than might be supplied by the survival of his elegies, he could certainly have claimed no liigher place among English writers than is now occupied by the Rev. Charles Fitzgeoffrey, whose voluminous and fervent elegy on Sir Francis Drake is indeed of more actual value, historic or poetic, than either or than both of Tourneur's elcgiac rhapsodies. The singular power, the singular originality, and the singular limitation of his genius are all equally obvious in The Atheist's Tragedy; a dramatic poem no less crude and puerile and violent in action and evolution than simple and noble and natural in expression and in style. The executive faculty of the author is in the metrical parts of his first play so imperfect as to suggest either incompetence or perversity in the workman; in The Revenger's Tragedy it is so magnificent, so simple, impeccable, and sublime, that the finest passages of this play can be compared only with the noblest examples of tragic dialogue or monologue now extant in English or in Greek. There is no trace of imitation or derivation from an alien source in the genius of this poet. The first editor of Webster has observed how often he imitates Shakespeare ; and, in fact, essentially and radically independent as is Webster's genius also, the sovereign influence of his master may be traced not only in the general tone of his style, the general scheme of his composition, but now and then in a direct and never an unwortly or imperfect echo of Shakespeare's very phrase and accent.' But the resemblance between the tragic verse oi Tourneur.
and the tragic verse of Shakespeare is simply such as proves the natural affinity betwecn two great dramatic poets, whose inspiration partakes now and then of the quality more proper to epic or to lyric poetry. The fiery impulse, the rolling music, the vivid illustration of thought by jets of insuppressible passion, the perpetual sustenance of passion by the implacable persistency of thought, which we recognize as the dominant and distinctive qualities of such poetry as finds vent in the utterances of Hanilet or of Timon, we recognize also in the scarcely less magnificent poetry, the scarcely less fiery sarcasm, with which Tourneur bas informed the part of Vindice-a harder-headed Hamlet, a. saner and more practically savage and serious Timon. ITe was a satirist as passionate as Juvenal or Swift, but with a finer faith in goodness, a purer hope in its ultimate Eecurity of triumph. This fervent constancy of spirit ${ }_{10}$ lieves the lurid gloom and widens the limited range of a tragic imagination which otherwise might be felt as (יppressive rather than inspiriting. His grim and trenchant humour is as peculiar in its sardonic passion as his elo!uence is original in the strenuous music of its cadences, in the roll of its rhythmic thunder. As a playwright, his method was almost crude and rude in the headlong "siraightforwardness of its energetic simplicity; as an artist in character, his interest was intense but narrow, bis power magnificent but confined; as a dramatic poet, the force of his genius is great enough to ensure him an enduring place ainong the foremost of the followers of Shakespeare.
(A. c. s.)

TOURS, a towr. of France, formerly the capital of Tonraine, now chef-lieu of the department of Indre-etLoire, the see of an arch hishop, and the headquarters of the 9 th coups d'armée, lies 145 miles (by rail) south-west of Paris, on the left bank of the Loire, a little above the

Plan of Tours.
junction of the Loire and Cher. Many foreigners, especially English, live at Tours, attracted by the town itself, its mild climate, its beautiful situation in "the garden of France," and the historic chateaus of the neighbourhood. The Loire is crossed by two suspension bridges, by a railway bridge, and by a fine stone bridge, but its waters too often either expose large stretches of sand, or come down in devastating flood. Many of the inhabitants belong to the leisured class, and the town possesses societies of science, art, and literature, of agriculture, of horticulture, of archæology, of medicine, and a library ( 50,000 volumes, and 1200 MSS., including a gospel of the 8th century, on which the kings of France took oath as honorary canons of the church of St Martin). The industrial establishments
include four large silk mills, the printing and publishing works of Mame ( 1200 workmen), manufactories of cloth, carpets, files, white lead, stained glass, boots and shoes, and pottery. A considerable trade is carried on in wine, brandy, ana dried fruits, and the sausages and confectionery of the town are well known The population, 52,209 in 1881, was 59, 185 in 1886.
Tours, under the Gauls the capital of the Turones or Turons, originally stood on the right bank of the Loire, a little above the present village of St Symphorien. At first called Allionos, the town was aiterwards officially known as Casarodunum. The Romans removed the own from the liill whero it originally stood to the plain on the left bank of the river. Behind the present cathe. dral. remaing of the amphitheatre ( 443 feet in length by 394 if breadth) built towards the end of the 2 d century might till lately be seen. Tours became Christian about 250 through the preaching of Gaticn, who founded the bishoprric. The first cathedral was buill a hundred years later by St Litorius. The bishopric became an archbishopric when Gratian made Tours the capital of Lugdunensis Tertia, and abont the same time the official name of Cessarodunum was clianged for that of Civitas Turonorum. St Martin, the great apostle of the Gauls, was bishop of Tours in the 4th century, and he was buried in a suburb which soon became as important as the town itself from the number of pilgrims who flocked to his tomb. Towards the end of the 4 th century, apprehensive of barbarian invasion, the inhabitants pulled down some of their earlier buildings in order to raise a fortified wall, the course of which can still be traced in places. Their advanced fort of Larcay still overlooks the valley of the Cher. Affliated to the Armorican confederation in 435, the town did not fall to the Visigoths till 473 , and the new masters were always hated. It became part of the Frankish dominions under Clovis, who, in consideration of the help afforded by St Martin, presented the church with rich gifts out of thc spoils taken from Alaric, confirmed and extended its right of sanctuary, and accepted for himself and his suceessors the title of canon of StMartin. The basilica, built under Bishop St Perpetuus from 472 to 477, was the largest and finest church of Frauce, and one of the most important built in the Wes. daring the decline of the Roman empire ; it is said by St Gregory of Tours to have been 160 feet long, 60 wide, and 45 high It seems to have been one of the first which had an ambulatory round the choir. Toury grew rapidly in prosperity under the Merovingians, but abuse of the right of sanctuary led to freat disorder, and the church itself became a hothed of crine. Charle.magne re-cstablished discipline in the disorganized monastery and set over it the learned Alcuiio, who established at Tours one of the oldest public schools of Christian philosophy and theology. The abbey was made into a collegiate church in the 11th century, and was for a time amliated to Cluny, but soon cane under the direct rule of Rome, and for long had bishops of its own. The suburb in which the monastery was situated became as important as Tours itself under the name of Jartinopolis. The Normans, attracted by its riches, pilla ged it in 853 and 903 . Strong, walls were erected from 906 to 910 , and in the 12 th century the name was changed to that of Chateaunueuf. Philip Augustus abolished the disorderly commnne in 1212, but the insumerable offerings of princes, lords and pilgrims maintained the prosperity of the town all through the Diddle Ages. A 13 th -century writer speaks with euthusiasm of the wealth and luxnry of the inhahitants, of the beauty and chastity of the women, and of the rich slrine of the saint. A third church, replaciag one which had been built after the burning of that of St Perpetuus in 997, was begun in 1175, and finished in the 13 th century. It was 374 feet long and 85 feet high, and had five towers, of which only two remain. The rest of the church, sold to epeculators after the Revolution, disappeared under the frst empire. of the monastic buildings, only a beautiful inclosed gallery, built by Bastien Frangois, nephew of Xichel Colomb, in the tirae of the Renaissance, remains, but the streets which formerly belonged to Châteauneuf show nany in teresting relica of ecclesiastieal and civil architecture. About 1130 Arclibishop Hilderert built a cathedral iu the old Roman town itself, on the ruins of those successively erected by Litorins and Grecory of Tours. This was burnt in 1166 during the quarrel between Louis V1I. of France and Henry II. of Encland, the latter being lord of Tours and count of Anjou. The work was resumed in 1175, but not finished till 1547. Part of the towers helong to the 12th century; the choir to the 13 th; the transept and Grat bays of the Dave to the 14 th; the remaining bays, the cloister on the north, and the fine fagade to the 15th: and the two Renaissance towers (217 feet and 223 fect) to the 16 th. The building is nevertheless remarkable for the harnong and regulerity of its construction; specially uotemorthy details are the rriple westcra portal, the upper staircase of the north tower, a Reuaissance staircase in the cloister, the old woodwork in chestnut-wood. and tho splendid-glass of the 13th, 14 th, and 15th centurics. A pretty little mavsoleum, built in 1506 by Jean Juste, is the burial-place of three young sone of Charles
VIII. The archbislop's palaco is to the right of the cathedral, with an interesting chapel of the 12 th century, and an outside pulpit of tha 16 th. During the 10th century the Benedictine abley of St Julien was re-established by Archbishop Théotolon, and a Romanesque churcls built, of which the great square tower still remains. St Julien has a fino nave and double aisles; the straight terminal wall has two 16 th-century apses attached. There arc somo paintings of the 12th century under the tower.

The magnificence of Tours declined in the 14th century; it was then united to Châteauoenf by a common wall, of which an elegant round tower (the Tour de Guise) remains near the quay, and both towns were put under the same government. The numerous and long-continued visits of Charles VII., Louis XI., and Charles VIII. in Tonraine during the 15 th ceutury favonred the commerce and industry of the town, then peopled by 75,000 inlabitants. To the flourishing school of art which existed at the Renaissance are due several privata houses, a fountain, and the church of Notre Dame Lis licha, with splendil windows by Pinaigrier. An unimportant buildiag, part of a modern chateau, is all that remains of the royal residence and magnificent gardens of Plessis-les.'T'ours, where Louis XI. shut himself up and died, the states in 1506 proclaimed Louis XII. the father of his people, and Henry III. and Henry of Navarre united in 1589 against the League. From that ycar Tours was sleserted by the kings of France. A fine bridge of fifteen arches was built across the Loire from 1765 to 1777 by Bayeux. The chief modern buildings ara the theatre, the church of St Joseph, the railway station, and a museum with collections of antiquities, pictures, pottery, and mineralogy. There are also antiquities in the museum of the archeological society of Indre-et-Loire. Tho gardens and a remarkable portal of the archbishop's palace, a marnificent iron gate of the 18 th century in the-prefecture, once the cenvent of the Visitation, and the general hospital (1200 beds) should also be mentioned. In 1870 Tours was the seat of the government of the national defeuce. Tours "is tbe birtbplace of the heretic Berengarius, the two marshals Boucicant, the novelist Honore de Balzac, the poet Destouches, the painters Fouquet and Clouet, and Madame de la Valliére.
tousSaint louverture, Pierre-Dominique (1746-1803), one of the liberators of Hayti, claimed to be descended from an African chief, his father, a slave in Hayti, being the chief's second son. He was born 20th May 1746 at Breda, and was at first suruamed Breda, which was changed to Louverture in token of the results of his valour in causing a gap in the ranks of the enemy. From childhood he manifested unusual abilities, and succeeded, by making the utmost use of every opportunity, in obtaining a remarkably good education. He obtained the special conlidence of his master, and was made superintendent of the other negroes on the plantation. After the insurrection of 1791 he joined the insurgents, and, having acquired some knowledge of surgery and medicine, acted as physician to the forces. His rapid rise in infuence aroused, however, the jealousy of Jean François, who caused his arrest on the ground of his partiality to the whites. He was liberated by the rival insurgent chief Baisson, and a partisan war ensued, but after the death of Eaisson he placed himself under the orders of Jean François. Subsequently he joined the Spaniards, but, when the Freach Government ratified the Act declaring the freedom of the slaves, he came to the aid of the French. In 1796 he was named commander-in-chief of the armies of St Domingo, but, having raised and disciplined a powerful army of blacks, he made himself master of the whole country, renounced the authority of France, and announced himself" "the Buonaparte of St Domingo." For further details of his career see Hayti (vol. xi. p. 545). He was taken prisoner by treachery on the part of France, and died in the prison of Joux, near Besançon, 27th April 1803.

TOWNSHEND, Charles Townseend, Second Viscount (1674-1738), a statesman of unsullied integrity, was the eldest son of Horatio. the first viscount, and was
born in 1674. He succeeded to the peerage in December 1687, and was educated at Iton and King's College, Cambridge. When he took his seat in the House of Lords his sympathies leant to Toryism, but this predilection soon faded away, and in February 1701-2 it was rumoured among the conrtiers that he would hold the office of privy seal in the Whig ministry which William III. had in view. For some years after the accession of Queen Anne he remainod without office, hut on 29th September 1707 he was created captain of the yeomen of the guard, and in the same year he was summoned to the privy council, a distinction renewed by the queen's two successors on the throne The command of the yeomen remained in his kands until 13th June 1711, but its responsibilities did not prevent him from acting as joint plenipotentiary with the duke of Marlborough in the peace negotiations with France which were carried on at Gertruydenberg, near Breda, or from serving as ambassador extraordinary at The Hague congress (2d May 1709-26th March 1711). Townshend was high in favour with George I., and on that king's arrival at The Hague in September 1714 he published the appointment of Townshend as secretary of state for the southern department, and entrusted to his new minister the privilege of nominating. his own colleague. Horace Walpole, bis brother-in-law and private secretary, recommended Stanhope for the vacant post, and Stanhope was duly appointed. - Townshend did not neglect to avail himself of the advantages afforded by his attendance. on the king, and before the arrival of George I. in England he had obtained complete ascendency both over his mind and the dispositions of the advisers by whom his line of conduct was generally determined. The policy of the new ministers at home and abroad lay in the promotion of peace. With this object they endeavoured to limit the charges against their predecessor Harley, Lord Oxford, to high crimes and misdemeanours. To gain this end they brought about, in 1716, an alliance between those ancient rivals in arms, France and England. In spite of their success, their influence was gradually undermined by the intrigues of Lord Sunderland and by the discontent of the Hanoverian favourites, who deemed the places and the pensions which they had gained an insufficient reward for their exertions. In October 1716 Stanhope accompanied the king on his journey to Hanover, and during this visit was seduced from his allegiance to his colleagues by the wily Sunderland, who had ingratiated himself into the royal favour. George I. was induced to believe that Townshend and Walpole were caballing with the prince of Wales, and were forming designs against the royal authority. Townshend was dismissed in December 1716 from hls place of secretary of state, and was offered in lieu thereof the splendid banishment of lord-lieutenant of Ireland, a gilded sinecure which he at first contemptuously declined and only condescended ultimately to accept on the condition that he was not required to set foot on Irish soil. His latent spirit of hostility to this arrangement quickly developed into open antagonism, and in March 1717 Townshend was dismissed from his position. At the close of May 1720 a partial reconciliation took place between the opposing Whig sections of Stanhope and Townshend. The latter was readmitted into the ministry as lord president of the council (11th June 1720), and his devoted relation and colleague sir Robert Walpole became paymaster-general. When the South Sea Bubble burst, the fortunes of the principal members of the ministry shared in the misfortune of the scheme which they had promoted Stanhope, in a paroxysm of passion during a heated debate, broke a bloodvessel, and Sunderland, though acquitted of the cbarge of personal corruption, was forced to retire into private life. The withdrawal of these statesmen assigned to their rivals
the chief prizes in the state: Townshend became (10th February 1721) secretary of state, and Walpole gained the position of first lord of the treasury and chancellor of the exchequer. The death of George 1. threatened a change of advisers, but the dismay of the new king's favourite, Spencer Compton, at being cailed upon to draw up the rojal speech, led to the old ministers of the crown being retained in their places. What the attacks of the opposition could not effect, the internal strife of the administration accomplished. Townshend was of a proud, impetuous disposition, born with a nature more accustomed to rule than to obey. His fanily had for several generations stood higher in the social life of Norfolk than Walpole's progenitors, and when he himself attained to distinction in politics his position as a member of the Upper House was greater than that enjoyed by his friend in the Commons. As the power of the Lower House increased, and as Walpole became more and more the object of the attacks of the Tories, the pre-eminence of Townshend passed from him. So long, to use the witty remark of Sir Kobert Walpole, as the firm was Townshend and Walpole, things went well with them, but when the positions were reversed jealousies arose between the partners. The growing alienation was bastened by the death, in 1726 , of the secretary's wife, the sister of Walpole. At the close of 1729 Townshend endearoured to obtain the appointment of his old and attached friend, Lord Chesterfield, as his fellow secretary of state, and the failure of the attempt brought about a fierce scene between Walpole and himself. They broke out into passionate words, eeized one another by their coat-collars, and would hare come to blows had they not been prevented by their friends who were preseat. After this outbreak of passion further co-operation was impossible, and Townshend, haring the good sense to recognize the position, retired into private life on 15 th May 1730. The chief domestic erents of his ministry were the impeachment of Bishop Atterbury, the partial restoration of Lord Bolingbroke, and the troubles in Ireland sver the granting to a man called Wood of a patent for coining peace. Its concluding act was the signing of the treaty of Scville (9th Norember 1729). Townshend died ¢!. apoplexy 21st June 1738 .

Townshend was slow in forming, but risolute in adhering to, his opinion, and, like most other men of that stanp, was impationt of contradiction. His mnaners lave been styled "coarse, rustic, and eccmingly brutal," but these defects were not visiblo in his donestic life. Never clid minister leave office with cleaner hands; he dirl not add one acre to his estate nor leave large fortunes to his younger cbildren.

TOWNSHEND, Charles (1725-1767), a politician ever to be remembered as the embodinent of wit and indiscretion, was the second son of Charles, third Viscount Townslend, who married Audrey, the daughter and beiress of Edward Harrison of Ball's Park, near Hertford, a lady who rivalled ber son in brilliancy of wit and frankness of expression. Charles was born 29 th August 1725, and was sent for his education to Leyden and Oxford. At the Dutch university, where he matriculated 27 th October 1745, be associated with a small koot of English youths, afterwards well known in varions circles of life, among whom were Askew, the book-collector, Dowdeswell, his subsequent rival in politics, Wilkes, the witty and unprimipled reformer, and Alexander Carlyle, the genial Scotchman, who devotes some of the pages of his Autobiography to chronicling their sayings and their doings. He represented Great Yarmonth in parliament from 1747 to 1761, when he found a seat in the treasury borough of Harwich. Public attention was first drawn to his abilities in 1753 , when be delivered a lively attack, as a younger son who might hope to promote his advancement by allying himself in marriage to a wealthy heiress, against Lord

Hardwicke's marriage bill. Although this measure passed into law, he attained this object in August of the following year by marrying Caroline, the eldest daughter of the second duko of Argylo and the widow of Francis, Lord Dalkeith, the eldest son of the second duke of Buccleugh. In April 1754 Towashend was transferred from the position of a member of the Doard of Trade, which he had held from 1749 , to that of a lord of the admiralty, but at the close of 1755 bis passionate attack against the policy of the ministry, an attack which shared in popular estination with the scathing denunciations of Pitt, the supreme success of Single-Speech Hamilton, and the hopeless failure of Lord Chesterfield's illegitimate son, caused his instant dismissal. In the administration which was formed in December 1756, and which was ruled by Pitt, the lucrative office of treasurer of the chamber was given to Townshend, and in the following spring he was summoned to the privy council. With the accession of the new monarch in 1760 this volatile politician traosferred his attentions from Pitt to the young king's favourite, Bute, and when, at the latter's instance, several changes were made in the ministry, Townshend was promoted to the post of secretary of war. In this place le remained after the great commoner had withdrawn from the cabinet, but in December 1762 he threw it up. Bute, alarmed at the growth in numbers and in influence of lis enemies, tried to buy back Townshend's co-operation by sundry tempting promises, and at last secured his object in March 1763 with the presidency of the Board of Tracle. Whea Bute retired and George Greaville accepted the cares of official life, the bigher post of first lord of the adiniralty fell to Townshead's lot, but with his usual impetuosity he presumed to designate one of his satelliter to a place under bim at the board, and the refusal to accept the nomination led to his exclusion from the new administration. While in opposition his mind was swaycd to and fro with conficting emotions of dislike to the head of the ministry and of desire to share in the spoils of office. The latter feeling ultimately triumphed; he condescended to accept in the dying days of Grenville's cabinet, and to retain through the "lutestring " administration of Lord Rockinghann,"pretty summer wear," as Townshend styled it, "but it will never stand the winter,"-the higbly-paid position of paymaster-general, refusing to identify himself more closely with its fortunes as chancellor of the exchequer. The position which he refused from the hands of Lord Rockingham le was forced to accept from the imperious litt (August 1766), and a few weeks later his urgeat appeals to the great minister for increased power were favourably answered, and he was admitted to the inner circle of the cabinet. Dowdeswell, his predecessor at the exchequer, resented his removal for his brilliant rival. The new chancellor proposed the continuance of the laod tax at four shillings in the pound, while be beld out hopes that it might be reduced neyt year to three shillings, whereupon his predecessor, by the aid of the landed gentlemen, carried a motion that the reduction sbould take effect at once. This defeat proved a great mortification to Lord Chatham, and in his irritation against Townshead for this blow, as well as for some acts of insubordination, he meditated the removal of his showy colleague. Before this could be accomplisbed Chatham's mind became impaired by some mysterious malady, and Townshend, who was the most determined and infuential of his colleagues, §wayed the ministry as he liked. His wife was creatcd (August 1767) Baroness Greenwich, and his brother was made lord-lientenant of Ireland. He hinself delivered in the House of Commons many speeches unrivalled in parliamentary bistory for wit and recklessness; and one ...f them still lives in history as the "champagne speeciu".

His last act was to pass through parliament resolutions which even his colleagues deprecated in the cabinet, for taxing several articles, such as glass, paper, and tea, on their importation into America, which he estimated would produce the insignificant sum of $£ 40,000$ for the English treasury, and which shrewder observers prophesied would lead to the loss of the American colonies. Shortly after this event he retired to his wife's country seat in Oxfordshire, where he died on 4th September 1767, from a fever which he had neglected.
Tho universal tribute of Townshend'a colleagues allows hint tis possession of boundless wit and ready cloqueoce, set off by perect melody of intouation, but marsell by an unexampled lack of judg. ment and discretion. Ha slifted his ground in politics with every new noon, and the world fastencd on him the nickuame, which ha himself sdopted in his "clampagne" speech, of the Weathercock. His official knowledge was considerable; and it would be unjust to his memory to igoore the praises of his contemporaries or his profound koowledge of his country's commercial interests. The House of Commons recognized iu him its spoilt child, and Burke happily said that "he never thought, did, or aaid anything" without judging its effect on his fellow-members. Charles Townshend is the subject of a memoir by Mr Percy Fitzgerald.

## TOXICOLOGY. See Poisons.

TRACHIS, a city of ancient Greece, at the foot of Mount CEta, a little to the north-west of Thermopyla. As commanding the approach to Thermopylæ from Thessaly, it was a place of great military importance. According to Homer, it was one of the places subject to Achilles, and was famed in legend as the scene of Hercules's deathan event which forms the subject of Sophocles's play The Trachinian Women. In historical times it first attained importance on the foundation of Heraclea by the Spartans in 426 b.c. The Thessalians, jealous of the establishment of a Spartan outpost on their borders, attacked Heraclea, and in 420 the Heracleots were defeated by them with heavy loss. In the winter of 409-8 Heraclea sustained another disastrous defeat. In 395 the Thebans expelled the Spartans, and restored the city to the old Trachinian and Etiean inhabitants. In later times Heraclea was one of the mainstays of the Etolian power in northern Greece. In 191' в.c., after the defeat of Antiochus at Thermopylæ, Heraclea was besieged and taken from the Ætolians by the Romans under the consul Acilius Glabrio. From Liry's account of the siege (xxxvi. 24), it appears that the citadel was outside the town, which lay on the low ground between the rivers Karvunaria (Asopus) and Mavra-Neria (Melas). There are still traces of the citadel on a lofty rock above.

TRACT SOCIETIES are associations for publishing or circulating religions treatises or books. The circulation of short treatises for the promotion of Christian knowledge is older than the invention of printing. Wickliffe, for instance, was a great writer and circulator of tracts, employing his Oxford friends and pupils to multiply copies. So was Luther in his day, with the help by that time of printer and bookseller. In later times John Wesley was a busy worker in this way; and Hannah More, from her own pen, produced what were known as the "Cheap Repository Tracts," highly lauded by Bishop Porteus, and widely nsed towards the close of the 18th century. Before this time there had been efforts of associated labour for the same object, a "book society for promoting religious knowledge among the poor" having been established in 1750. A similar society was formed at Edinburgh in 1793. But it was at the close of the century, in 1799, that there was founded in London the Religious Tract Society, an institution unparalleled in the extent and variety of its operations, and the parent of numerous societies in different parts of the empire as well as in the Unitcd States and on the continent of Lurope. There are other associations with kindred objects, but in connexion
with particular ecclesiastical systems. Thus the tract department of the Christian Knowledge Society is specially connected with the Church of England; and the Wesleyans, Baptists, and other denominations have their own tract societies. The Church of Rome also has now similar associations. The Religions Tract Society is alone in being confined to the diffusion of religious trath common to all Protestant Christians, to the exclusion of topics touched by ecclesiastical divisions. This catholicity is secured by; the fundamental rules of the society, and by its managing committee being composed half of Churchmen and half of Nonconformists of all denominations.
A brief atatement of the proceedings of the Religious Tract Society, as presented in its latest annual Rcport, will best serve to show the general objecta and operations of all such organizations,any special or varied action elsewhere adopted being noted as we proceed. The main object of the aociety is the preparation and publication of religious literature. At first this consisted mostly of tracts and small treatisea. After a time larger booka were published, including serics of reprinted works of the early Reformers and English Protestant theologians and Biblical expositors, and also books on conmon subjects treated in a religious spirit. The socisty also issues magazines for all classes. Four of these period. icale, the Leisure Hour, the Sunday at Hone, the Boys' Own Paper, and the Girls' Own Papcr, have a united circulation, including monthly parts anil jearly volumes, of nearly 600,000 numbers weokly, or above 30 millions in the year. The total annual issuc, iocluding books, tracts, \&c., at bome and abroad, is nearly 86 millions.
The distribution of this is chiefly through the ordinary channels of trade, with the exception of the tracts, which are circulated by bome and foreign missionary aocieties, and various agencies public and private. Almost every missionary agency is indebted to the Religious Tract Socicty for the work carried on through the press. Grants aro made, either fres or as nearly as possible at cost price; and, when it is advisable to produce publications at foreign stations, grants of paper and other material, as well as money paymeats, are voted. The publications are in almost every tongue, the lisz containing works in 174 langunges and dialects.
The funds for this large and varied work come partly from dontions, subscriptions, a od legacies, but chicfly from the profits of the sales of the society's publicatioas. The total missionary and evangelistic expenditure in the year ending March 31, 1886, amounted to $£ 47,722$, of which $£ 19,019$ wae supplicd from the trade funds, which have also borne the cotire cost of management, both of the business and missionary departments. The iotal amount received from sales, subscriptions, and all other sources was $£ 212,731,11 \mathrm{~s} .8 \mathrm{~d}$.
The American Tract Socicty and some of the Continental societies undertake the distribution as well as the production of tracts and hooks, by means of paid colportenrs aod other agents. The Continental societies produce most of their own booke ard tracts, aided largely by granta of money and paper from the Religious Tract Society.

TRACTION, Electric The driving of vehicles by electricity was made commercially practicable by the invention of the dynamo-electric machine, which gave a ready means of producing electrical energy by the expenditure of mechanical work, and by the further discovery that the function of the dynano could be reversed,-that it was capable of acting efficiently as a motor to do mechanical work when supplied with energy in the electrical form. Experiment has shown that when a dynamo is used to produce an electric current, which, in its tuen, drives another dynamo serving as a motor, the double conversion of energy may be performed with no very seripus loss. In favourable cases, when the dynamo and motor are close together, the motor will yield more than 80 per cent. of the work which is spent in driving the dynamo. When they are far apart there is an additional loss, due to the resistance of the conductor which connects them, and a further loss due to its imperfect insulation. The use of high electromotive force, which reduces the first of these, tends to increase the second; it is, however, practicable to keep both within reasonable limits. Early attempts to apply electricity to traction were made by Robei1 Davidson, who placed an clectromagnetic locomotive on the Edinburgh and Glasgow Railway in $\mathbf{1 8 3 7}$, and by Jacobi
of St Peitrsburg, who propelied a boat on the Neva in 1839 by an electromagnetic engine driven by a battery of Grove's cells. The ine揺ciency and bulkiness of early electromotors, and the cost of producing electric energy when a galvanic battery was the source, made it impossible for electricity under such conditions as these to compete with other methods of traction. A good battery using zinc as the active metal consumes from 1 to 2 tb of zinc per hour per horse-power developed; a good steam-engine consumes from 2 to 3 lb of coal in doing the same amount of work, and the cost of zioc is about fifty times that of coal. Heace, notwithstanding modern improvements in electromotors, the cost of producing mechanical power by means of electricity, when a zinc-consuming battery is the source, is still prohibitive.

The earliest practical electric railway was constructed at the Berlin exhibition of 1879 by Dr Weruer Siemens. At one station was a dynamo driven by a steamengine. The current was conducted to the moving car through a special rail placed between the ordinary rails and insulated from the ground by blocks of wood. From this rail it passed through a motor-dynamo on the car, and the ordinary rails completed the circuit. Electrical contact with the ordinary rails was made by the wheels, and with the central rail by a pair of brushes made of copper wire which rubbed against its sides. Spur-wheels were used to connect the motor shaft with the wheels and to effect a suitable reduction of speed. The line was balf a mile long and of 2 -feet gauge. The motor developed about $3 \frac{1}{2}$ horse-power, and was carried by a separate truck, forming a locomotive which drew a car with 20 passengers at a speed of from 4 to 7 miles an hour.

The success of the Berlin experiment was complete, and Messrs Siemens followed it up in 1881 by the construction of a permanent electric tramway, $1 \frac{1}{2}$ miles in length, at Lichterfelde, which has now (1887) been in continuous operation for six years. At Lichterfelde the ordinary rails, insulated by wooden sleepers, are the only conductors. Where roads cross the line the rails are cut out of circuit, and the current is carried past the gap by underground cables, but switches are provided by winch the current can be sent into the insulated sections if required. Each car takes 24 passengers, and runs at a speed of 12 miles an hour. There is no separate locomotive, the motor-dynamo being on the car itself. 1n 1882 Messrs Siemens constructed an electric tramway in the mines of Zankerode, in Saxony, and built for it a locomotive able to draw 8 tons at a speed of $7 \frac{1}{8}$ miles an hour. Overhead conductors were enployed, consisting of a pair of insulated 1 -shaped rails fixed to the roof of the workings; the current was conveyed to and from the locomotive by means of a pair of contacl carriages sliding on these conductors, and connected with the car by short flexible cables. A similar line was opened in 1883 at the Hohenzollern colliery in Upper Silesia.
The same year witoessed the completion of another pioneer undertaking of the first importance, an electric tramway 6 miles long connecting Portrush and Bushmills, in the north of Ireland. Here the insulated conductor is a special rail, carried alongside of the line on wooden posts at a height of $1 \frac{1}{2}$ feet above the ground. Contact is made by springs shaped like carriage-springs, which project from one side of the car at both ends, so that the length of the car. enables contiouous contact to be maintained at crossroads, where there are gaps in the conductiug rail, past which the current is taken by underground cables. The ordinary rails serve as return conductors. The dynamos are driven by turbines at a station nearly a mile distant from the line; they supply a current of 100 amperes with an electromotive force of 250 volts. The motors are
placed ou passenger cars; their speed is regulated by means of resistance coils, which the driver of the car switches into the circuit. A similar tramway, 3 miles long, connecting Bessbrook and Newry; was opened in 1885 ; there also water-power is made use of to drive the generating dynamos. On these lincs the train usually consists of a motor car with passengers, followed by two or three goods waggons, and the whole working cxpenses are from 3 d , to 4 d . per train-mile. The speed is 10 miles an hour.

Amongst early electrical railways Mr Volk's short line on the beach at Brighton deserves mention. There the rails themselves act as conductors, and are insulated only by wooden sleepers lying on the shingle. The line has been in operation since 1883 , with a working expense of only 2d. per car-mile.

Other English and Continental lines wall be referred to later; it is, however, in America that electrical traction has hitherto found its widest development. In 1880 Mr Edison ran an electric locomotive on an experimental track near his laboratory at Menlo Park. Soon after the Chicago exhibition of 1883 , at which an electric railway was shown in action, a large number of permanent lines were established. There are now more than twenty electrical tramways at work in the United States, under the patents of Edison, Field, Daft, Van Depoele, Sprague, and others. Many more lines are projected, and experiments are in progress on the application of electrical traction on a large scale to the elevated railways of New York.

In all the instances which have been referred to above, electricity Electrié is employed as a means of transmitting power as it is wanted from traction a generating station to the cars, througb a conductor extending by storage along the track. Another method of effecting electric traction is batteries. to carry a store of energy on the car or on a special loconotive, by usigg secondary batteries which are charged from time to time at the generating station. This system, which was introduced in England by Mr Rackevzaun and on the Contipent by M. Julien. has been successfully employed on several lines.
The system of stcrage, by means of sccondary batterics, has the great advantare over the system of trausmission through a conductor that it makes each car independent and that it is applicable to ordinary tramway lines. As regards econony of power, we lave in the stolage system a more complex series of transformation of energy, and therefore a larger number of items of loss. In both systems alike we have a certain loss of eoergy at the dynamo and at the motor. A secondary battery yields in the electrical form only about 70 per cent. of the cocrgy given to it. In comparing the two methods, the loss which this involves has to be set off against that which occurs in the transmission system in the process of conduction, an iten which may be very small in favourable cases, but which becomes large when there are many cars to be driven, when the liue is long, and when, owing to the use of an exposed conduclor, the electromotive force lias to be kept low. Under average conditious it is probable that the conductor system has a slight adratage over the other in this respect, but the difference is not material, especially as the cost of power is a comparatively small part of the whole working expense of a linc. The differcace is slightly affected by the fact that in the storage system there is an extra weight to be carried-namely, the batteries-amountiag to about $\frac{1}{4}$ or $\frac{7}{6}$ of the whole weight, and the tractive force required to overcome friction is increased in a corresponding degree. A serious objection to the storage system is the probable cost of renewing batteries. In respect, however, both of durability and of power (in relation t.) weight) secondary batteries have of late undergono a marked i , provement: and it is likely that the storage system will prove the most applicable to tramways in city strects, where conductors on the level of the road are impracticable aod overhead conductors would not be perimitted.
The existing methods of electrical traction as applied to tramways may be classitied as follows:-
I. Motor driven by storage batteries, the batteries and motor being carried either ( $\alpha$ ) in the car itself or (b) on a separate truck forming a locomotive. Reckenzaun's and Iulien's cars, in which the batteries are under the seats, are examples of the first plan, which is in operation ou lines at Antwerp, Hamburg, Brussels, and New York. Mr Elieson's tramway loconotive working in London on the North Metropolitan tramways is an example of the second plan. It is obviously preferable, when space can be found on the car itself for the motor and batteries, to place thens there rather than on a separate truck. When a separate locomotive is used it
sust bo heavy enough to grip the rails, and the whole weight to be drawn is then cousiderably greater. ${ }^{1}$
II. Conductor systems, which may be classified thus:-
(a) Those using the ordinary rails as tha only conductors. The lines at Lichterfelde and Brightoh, already mentioned, are examples of this plan, which is quite inspplicable where the rails are laid fush with the roadway as in city atreets.
(b) Thuse using a third (insulated) rail, above ground. To this class belong the lortrush, the Besshrook, and several Arucrican lines. This plan, like the last, is not spplicable to city streets.
(c) Those osing onc (or in some cases two) overhead conductors. A line of this type has been successfully worked between JIodling and Hinterbriihl, near Vienna, and another between Frankfort and OIfenbach, both sioce 1884, at a cost of about $3 \frac{1}{2}$ d. per car-mile. The conductors consist of slotterl tubes 1 inch ia bore supported on ninsts 18 feet high and stayed by wires at internediate points to Fiep them from sagging. The contact carriages are pistons sliding in the tubes. ${ }^{3}$ The Daft lines at Baltimore am other places in America, and the Tan Depoela lines, of which some 30 miles are in operation, are mostly worked by means of overhead coaductors.
(d) Those using undergronad conductors in a slotted chanael or conduit. This system, which lias the obvious advantage that the conductor is placed entirely out of the way of street traffe, has been introduced at Blackpool by Mr Holroyd Smith, ausl, in America, at Cleveland by Messrs Bentley and Knight aurl at Plailadelphia by Mr. Schlesinger. In the Blackpool liue the conductor is split into two parts which run parallel to each other withiu the conduit on its two sides, and are tonched by a contact am which reaches down through a narrow ceitral slot at the lovel of the street; an electromotive force of 200 volts is cmployed. The conduit is placed midway between the rails, hut it may be queationed whether, in view of the conditions of ordinary street trafic, a better place for it weuld not be at one side. Afr Ficid lus proposed a trammay with two conduits, oue heside each rail, containing two conductors, one to be charger posititely and the other negatively, so that a comparatively high resultala diflerence of potential is available for the motor althongh the polertial of ncilher conductor differs to a dangerous degree from lhat of the calll.
(c) Ona system remains to he described, which was proposed in 1881 by Hesars Ayrton and Yerry as specially applicable to electric railways of considerible length, in which an exposed conductor would give rise to much loss though leakage. Their plan is to nse a well-insulated conducior in a closed channel underground. The line is divided into short sections; each of these has an exposed conductor, which may be one of the rails, and this is placed in temporary conlact with the insulated conductor as the train passes, by the pressure of the wheels on a flexible rail or stad, or by means of autumatic electronagnetic suitches. Leakage is thus restricterl to the continuous and well-insulated conductor, logether with that section of the surface conductor which is in contact with the former at any one lime; and the system lias the further adrantage that it gi: ies the meang of providing an automatic block by which snccessive trains are kepl from overtaking one another.
The form and disposition of the motor-dynamo and the mode by which it is connected with the driving-axle of the car are matters in which much variety of practice exists. The question of gearing is complicated by the fact that the frame of the car oscillates vertically with respect to the axles. Spur-wheels, worm-gear, frictiongear, belts, multiple-band gear, and chain-gear are or have been used. Mr Reckenzaun'a car is carried by two bogie trucks, one uoder each end, and each bogie carries a motor whose axle, placed longitadinally, drives a central spur-wheel on one axle of the hogie by means of a worm. An advantage possessed by two motors is that, by coupling them in series or parallel, or by using one only, the driver is able to command different grades of power without the ree of resistance coils. In cars driven by storsge batteries the same slject may be secured by varions groupings of the cells.

Telpherage. In all the methods of electrical traction to which reference has luen marle the road on which the cars rum is essentially a railway or tramway of the kint used in borse traction and stean traction. In 1881 the late l'rof. Fleming Jenkin devised a system of electric locomotion in which the vehicles are buny upon what resembles an exaggeratell telegraph line. To this he gave the name of telpheruge. As developed hy the inventor, in conjunction vith Messrs, Ayrton and Perry, the system is especially adapted to the transport of goods at a slow spepil, in localities where the trattic would he insufficient to support an ordinary railway.

The telpher line is a stepl rod or eable, suspended from brackets on posts about 70 fect apart: it serves at once as carrier of weights and conductor of electricity. The line may le made rigid, and in that case a bich speed of trinsit may lee attained; but in general the line is flexib]o and tho trains travel slowly in what may be, if the 2 For a comparison of the welghts to be drawn and tha tractive force required

2 For details of the construction and working expenses of these and other Mnes, see the valnibla peper by Mr Reckenzaun, Jour. Soc. of Arts. April $20,1887$. Statistles of American lines will be fund in a poper by T. C. Martin, read before
voluwa of traftic requires it, a mearly contimons strean. Dack train consists of a serics of buckets or skeps which hang each fron a single runuing wheel or pair of wheela, and are spaced by woodec connecting bars. A small electric motor, which hangs below the line and is geared by spur and chain gearing to a pair of driving wheels, formus the locomotive. In general, the line is electrically divided into equal sectioas, which have the same length is a single train, so that the front carriage is always on the section in advance of the rear carriage. The train is furnished with a contimunus couductor from end to end, through which it malies electric contact between the section in front and the section behind, and the motor is included in the circuit of this conductor. Two systems of workiog are used, which enable trains to bo run either in electricsl series or "prallel." In the series system the successire sections of the line are electrically conaected, so long as no traiu is on then, by means of switches at the joints between the sections, so tliat the whole forms one continuous conductor. When a train comes on any ono section it breaks contact at the joint betwcen that section and the one behind it; the circuit, however, remsing closed through the conductor on the train itsclf, and in this way the motor leceives the current which is passing thronigh the line. Other trains at other places in the line reccire the same current, each by breaking for the time the ordinary contact between the two sections it touches, and substituting a coulact throumh its own conductor and motor. When a train leares a section it replaces the switch that makes contact with the section behind. If, how. ever, there sre more than one train on the liue, ao automatic block system is sdded to prevest ono frow ovcrtakirg another by letting the section which a traim leaves stand insnlated for a time. Ne control is exercised from the vehicles thenselves; in fact, the trains run without attendants. In the simplest pural!el system of telpherago a continuous coarluctri distinct from the ine is stretchad alongside of it; the trains suake contacl ketween the two. The figure shows auother plat, f howr as the csoss-over parallel system,

Which is autable whore a dnuble line of trains is desired. There $A_{1}, B_{2}, A_{3} \ldots$ form succecsive scctions of one line, and $B_{1}, A_{2}, B_{3}^{\prime}$ of another. $\Lambda_{1}, \lambda_{2}, \lambda_{0} \ldots$ arg electrically continnous, and
comected to one pole of the dy namo. $B_{1}, B_{1}, B_{3} \ldots$ are also continuons, and are comected to the other pole. Thas the sections of each line are altemately pusinive and negative. Any trsin, such as $P$ or $Q$, bridges the gap hetircen two sechions and receives a cmrent which sullers reversal as the rrain passes from, one section to the next. It is to be regretted chat space does not adnuit of any descrigtion of the details of tclpherage, mauy of which present tho ulonost ingennity. The system was shown to be practicable by experiments on an experimental line at Weston. The first telpher line on a commercial losis was cructed in 3885 al Glynde, in Sussex, and has been maintained in operation notwithstanding manv dim. culties isseparable from so completely novel an uadertaking.

The electrical propulsion of boals, by means of storage batteries, Pron bsa been the subjcet of several successful experiments, but has not pulaion found systemstic application. In this connexion reference should of boaton be matle to a schense proposed by Ayrton and Perry for the haulage of boata on canals or of waggons upon roads. Their proposal was to have a conductor rangel along the towing path, or along the side of the road. A motor running on this was to pull itself along ani drag the baat or waggon ofter it.

In aerial mavigstion, storage batteries working an electric motor Aerial have been used to drive the propeller of a "dirigible" balloon. navigatios
Space does not admit of more than the briefest reference to the Theorg theory of electric motors. A motor may be regarded as a dynamo of acting to produce an electromotive force $e$ which is opposite in motowa direction to the externally impressed electromotiva force L . The resultant electronotive force is $\mathrm{E}-c$, and on this, together with the resistance of the circuit, the strength of the current $C$ depends. The electrical power supplied is CE, and of this the motor utilizes Cc. The efticiency is $\epsilon / E$. It is easily seen, as was first shown by Jacobi, that the power developed by the motor (Ce) is a maxinum when $c=\frac{1}{2} \mathrm{E}$. But this condition of maximum power involves that half the energy supplied is wasted; to secure higher efficiency, notors are in practice run at much less than their maximum power, so that e may approach more nearly to equality with E. 1 The field ragnets of motors, like those of dynamos, may be wound with coils in series with the armature coil, or with coils forming a sbunt to the armature, or with a combination of botb. A very important part of the theory deals with the automatic regulation of speed by the use of componnd winding. In a paper of fundamental importance with regard to this part of the subject, Messrs Ayrton and Perry ${ }^{3}$ have shown that a motor may be made to rux

[^218]at constant speed under varying losds when the exteraal electronotire force is coastant, provided that a differential combination of direct ehunt and reverse gerics winding be employed, - the shunt coil serving to energize tho magnets and the serics coil to reduca their msgnetism to a certain extent when the current in the anma luro 15 mereased. The propertion of series to shunt wiuding Jecessary for this result depends on the relation of tho resistance of the srms:ure to that of the shuat coil, and it is an easy deduction from tha theory that, whea the resistance of the armature is afgligibly small, the specd of a simple shant-wound motor driven by mesns of a coostant external electromotive force is seasibly constant, a result which bas been experimentally demonstrated by Mr Mordey (Phil. Mag., Jan. 1886). It is shown in the sanne paper that a similar means of governing may be used when the curreat passing through the inotor is kent constant, instead of the external electromotive forcc. The principle of differential contpound windieg to secure automatic regulation of speed has beeu applied in several American motors, Dolably by Mr Spraroue.
Detalls of most of the electrical tramways and raflways meationed in the text will be lound lin the Journels Electrica! Recieve, Etectrician, and Electrical World (New York) of the dates referred to. See also The Electric Notor ond its Applications, by T. C. Martin and J. Wetzler (New iork, 1887). The Portrush une la described by E. Hopkloson and A. Slemens in o paper reat before the Society of Arts, April 1883. For telpherage, in aditituo to articles in the foumats named, sco Fireming Jenkin "On Telpherage," Jour. Soc. tracy, Antorne Louis Cladde Destutt, Comte de (1754-1836), was born in Bourbonnais on July 20, 1754. The noble family to which be belonged was of Scottish descent, tracing its origin to Walter Stutt, a gentleman who in 1420 accompanied the earls of Buchan and Douglas to the court of France, and whose family afterwards rose to be counts of Tracy. The father of Destutt de Tracy (as he is usually called) was a soldier, and died a field-marshal. Destutt de Tracy began his studies under the superintendence of his mother, and afterwards prosecuted them at the university of Strasburg. During his student days, however, he was chiefly noted for his skill in every kind of manly exercise. On leaving the university he embraced a military career, in which his advance was rapid. When the Revolution broke, Tracy, who was then thirty-five years of age, took an active part in the provincial assembly of Bourbonnais. He was elected a deputy of the nobility to the states-general, where he sat alongside of his friend La Fayette. In the spring of 1792 be received the rank of field-marshal, along with the sole command of the cavalry in the army of the Norib; but, as the conduct of affairs fell more and more into the hands of the extremists, he took an indefinite leave of absence, and settled with his family at Autfuil. Here, in the society of Condorcet and Cabanis, ho devoted himself to scientific studies. Under the Reign of Terror he was arrested and imprisoned for nearly a year. It was his solitary meditations at this pariod, we are told, which discovered to him his true bent. Under the influence of Locke and Condillac he abandoned the natural sciences for the study of mind. On the motion of Cabanis he was named associate of the Institute in the class of the moral and political sciences. He soon began to attract attention by the mémoires which he read before his colleagues-papers which formed the first draft of his comprehensive work on ideology. The society of "ideologists" at Auteuil embraced, besides Cabanis and Tracy, who have been called respectively the physiologist and the metaphysician of the school, Volney, who has been called its moralist, and Garat, its professor in the National Institute. Under the empire he was a member of the scnate, but took little part in its deliberations. Under the Restoration he became a peer of France, but protested against the reactionary spirit of the Guvernment, and remaired in opposition. $\ln 1808$ he was elected a member of the French Academy in room of Cabanis, and in 1832 lie was also named a member of the Academy of Moral siciences on its reorganization. He appeared, however, coly once at its confercnces. He was old and nearly bind. and filled with saduejs, it is said, by the loss of his friends and the discredit into which his nost firmly
cherished opinions had falleu. "His on!y distraction was to have Voltaire read aloud to him." He died at Paris on the 9 th of March 1836.

Dcstutt de Tracy was the last emineat representative of the scnsualistic scheal which Condillac fouaded in France upon a onesided interpretation of the doctrines of Locko. He pushed the scasualistic priaciples of Condillac to their last consequences, being ia full agicemant with the materialistic viows of his friend Cabanis, theugh the attention of the latter was devoted more to the plysiological, that of Tracy to the nsjeliological or "ideological "side of man. His ideology, he frankly atated, formed "a lart of zonlogy," or, as we should say, of biology. To think is to fcel. The iour faculties into which lie divides the consciuus life-percejrion, memory, judgment, will-are alt varicties of seusation. Perception is sensation cansed by a present affection of the external extreunities of the nerres; menory is sensation caused, in the absence of preseat excitation, by dispositious of the aerves which are the result of past experieuces; judgment is the perception of relatious between sensations, and is itself a opccies of sensation, because if we are sware of the censations we must slse be aware of the relations between them; will he identities with the feeling of desirc, aud therefore includes it as a rariety of sensation. It is easy to see that such concinsions ignore important distinctions, and are, iudeed, to a large extent an aluse of language. As a psycholngist. Destutt do Tracy leserves credit for his distiwction between active snd passive touch, which has developed in to the nodern theory of the mnscular sense. His account of the notion of external existence, as derirel, not from puro sensation, but from the experience of action on the oae linnd and resistance on the olher, may be compared with the account of Baiu and later psychologists. Tracy worked up his sefrarate monographs extending aver a number of years into the Eléments d'Idtologic (1817-18 and 1824-5), which presents his complete doctrine. He slso wrote in 1806 a Commentaive sur l'Esprit des Lois de Montesquicu, in which he argues ably iu support of a free constitution on grounds which hardly sdunt of theing harmonized with his general philosophical principles. The book was trasslated in America by lis friend President Jefferson, who recommended it for use in the colleges. The first French edition sppeared in 1817, aod it was several times reprinted.

TRADE, Board of. The greater part of such supervision of commerce and industry as exists in the United Kingdom is exercised by the "Committee of Privy Council for Trade" (see Privy Councin), or, as it is usually called, the Board of Trade. As early as the 14 th century councils and commissions had been formed from time to time to advise parliament in matters of trade, but it was not till the middle of the 17 th century, under the Commonwealth, that any department of a peruanent character was attempted. Cromwell's policy in this respect was continued under the Restoration, and in 1660 a committee of the privy council was appointed for the purpose of obtaining information as to the imports and exports of the country, and improving trade. A few years later another committee of the council was appointed to act as intermediaries between the crown and the colonies, or foreign plantations, as they were then called. This joint commission of trade and plantations was abolished in 1675, and it was not until twenty years later that the Board of Trade was revived under William III. Among the chief objects set before this board were the inquiry into trade obstacles and tho employment of the poor; the state of the silver currency was also a subjent on which Jobn Locke, its secretary, lost no time in making representations to the Government. Locke's retiremert in 1700 remored any chance of the Board of Trade adrocating more enlightemed opinions on commercial suojects than those generally held at that time. It had only a small share in making the constitutions of the coloni $s$, as all the American ones except Georgia and Nova f were formed before the reign of Charles II. ; and in 1.co a secretary of state for the colonics was appointed, to whom the control drifted away. In 1780 Burkc made bis celebrated attack on the public offices, which resulted in the abolition of the board. In 1786 , howerer, another permanent committee of the privy council was formed by order in council, and with one or tr:o small exceptions the, legal constitution of the Board of Trade is still regulated by that order. Under it all the principal officers of state,
including the first lords of the treasury and admiralty, the secretaries of state, and certain members of the privy council, among whom was the archbishop of Canterbury, outained scats at the board ex officio; and ten unofficial members, including several eminent statesmen, were also placed on the committee. The duties of the revived board were made the same as they were in the beginning of the century, hut, in addition, the regulation of the food supply of the country, by restricting or relaxing the export and import of corn, was brought into prominence owing to a larger population requiring to be fed. New duties were thrown on the hoard by the growth of joint-stock cnmpanies, the development of railways, and the increase in shipping, and it was necessary to break it up into departments charged with the administration of the various Acts of Parliament. The Eoard of Trade thus became a mere name, the president bcing practically the secretary of state for trade, and the vicc-president became, in 1867, a parliamentary secretary, with similar duties to those of a parliannentary under-secretary of state. At present, besides the president, who has usually a seat in the cabinet, the parliamentary secretary, and a permanent secretary, there are six assistint secretaries, each in charge of a department.

1. The Conmercial Dcpartment is the real remains of the origiual Board of Trade, as it combines the charge of the trade statistics with the general consnltative dnties with whiel King Charles 1I.'s boand was originally eutrusted. The statistical work includes comprling the abstracts relating to the United Kingdon, the col. onies, and foreizn conotries, the supervision of the trade accounts, and the preparation of slipping, railway, emigration, and fishery statistics. A recerd of the prices of com has been obtained from actual sales in the chief market towns for about a hundred years, the originai object being the sliding scale of coru duties, but these are now continued to govern the tithe pryments, and forman unbroken series of prices bascd on actual transactions, and not mere market quetations, Foreign and colonial customs tariffs and regulations are also matters on which infornation is published, and labeur statistics are for the future to have special attention. In 1872 ane of the most inportant functions of the commercial departmont, viz., the negotiation of ccommercial treaties, was transferred to the Foreign Office, but the Buard of Trade is still consulted on these matters by the Foreign Office, as well as by the Colonial Office on colonial commercial matters, and by the other puhlie departments. The Bankruptey Act of 1883 added a new branch of work, but for this there is now a seprate establishoent onder an in-pectur-general. The last new woik undertaken by the department is the [mblication (begun August 1886) of a Monthly Journel of commercial information, chielly from official sources.
2. The lailway Department was originally constituted in 1840 , and performs multifarious dutica muler varions Railway Acts ineloding the inspection of railways before they are open, inquiries into accidents, reports oa jroposed railways, approval of bye-laws, appoint rent of arbitrators in disputes, as well as many duties under pivate Ralway Acls. The inspection of tramways, their bye-laws and "provistonal orders," are all dealt with here, as are similar orders relating to gas and water schemes and to electric lighting. Patents, designs, and trade marks are now dealt with by the Patent Office, which is subordinate to the railway department, and copy right, art unions, and industrial exhibitious are also amoag the matters dealt with by the departinent.
3. The Marine Department was created a separate branch of the Board of Trade in 1850, about which time many new and impertant marine questions came under the Board of Trade, such, for example, as the survey of passenger steamers, the compulsory examination of masters and mates, the establishment of shipring offices for the engagoment and discharge of scamen. Further work fell to the marine department by the Act of 1853, which gave it the control of lighthouse fonds, and to a certain extent of pilotage. The consolidating Merchant Shipping Act of 1854 and subsequent legislation so much increased the department that in 1866 it was divided inte three, viz., the present marine department, which deals with ships and seamen, the liarbour department, and the mance department.
4. The Harbour Department was, as stated above, \& branch of the marine department until 1866, so far as it is connected with the physical adjuncts of navigation, but various other matters have smine beea added, c.g., the charge of the foreshores belonging to the crown, formerly managed by the commissioncra of wooda and forests, and the protection of navigablo harbonrs and channels, long under the contrel of the Admiralty. Lighthouse funds, provisional orders for owser and susefl fisheries, the macamement of

Helyhead and Ramsgate harbours and of Dover pier, wreck, and quarantine are all anong tite matters dealt with by this department, whicl also has charge of the standards department los weights and measures.
5. The Finance Department was, like the haroour department, acparated in 1866 from the marine departncut. The accounts of all the branches of the Board of Trade are in its charge, including the subordinate offices. It also deals with the accounta of harboura, lighthouses, and mercantile marine offices, and of the murchant seamen'a fund, and with the consuls' accounts for disabled scamem sbroad. Savings banks and seamen's noney orders are also amone the accounts and payments with which it is charged, and ontsids these marime matters it lus to prepare fer parliament the life in. surance companies' acceunts and to take charge of the bankruntcy estate accounts
6. The Fishcries Department.-By a recent Act the powers of the Home Office over salmon and other fisherics have been transferred to the Board of 'rrade, and a small department has consequently beeu created charged with the care of these industries.

TRADE-MARLS. There seems no reason to dorbt that the practice of employing a mark to denote the goods of a particular trader (not necessarily the manufacturer) grew out of the use of signs, which, first affixed to the dealer's shop, were afterwards represented on his tokens. and eventually placed on the goods themselves. Trade marks proper appear to have been in use in England in: the reign of Elizabeth. The first reported case was in 1783, when Lord Mansfield decided that the sale by the defendants of a certain medicine under the name or marsi of the plaintiff was a fraud. By other decisions it was affirmed that the use of another's trade-mark was actionable, even without the intent to defraud. The law, however, remained in an unsatisfactory condition till, by the Merchandise Marks Act in 1862, it was made a misdemean our to forge or counterfeit a trade-mark, while penalties were inflicted for the sale of articles bearing a forged mark.

In 1875 the Trade Marks Registration Act estahlished for the first time a registry of trade-marks in Britain, greatly facilitating the proof of title. A more precise definition of a trade-mark was also provided. In 1883 the Act was rcpealed by the Patents, Designs, and Tradค Marks Act, in which its principal provisions were incorporated. All proceedings for the registration of trade-marks are now regulated by the Patents Act. A trade-mark may he a name printed or otherwise delineated in some particular os distinctive manner, or a signature, or a device, mark, hrand, \&c. Registration is compulsory, at least in the sense that the owner cannot prevent infringement or sue for damages for infringement unless he las registered, though it would appear that this disability exists only in the case of a mark capable of being registered under the Act. There are certain indicia which cannot be registered because they do not fall within the definition of a trade-mark, but which may yet be protected at equity. Registration is deemed equivalent to public use of the mark, and, after the expiration of five years, is conclusive evidence of right to exclusive use. Applications for regristration have to be addressed to the comptroller of patents ; should he refuse to register, there is an appeal to the Board of Trade. If there is opposition, the matter goes to the High Court of Justice. Registration holds good for fourteen years, at the end of which time it has to be renewed. Special provision is made in the Act for the retention of certain of the ancient privileges of the Cutlers Company of Sheffield. The total number of marks now upon the register is nearly 50,000 .

The Customs Consolidation Act, 1876, forbids the importation of articles of foreign maoufacture bearing any mark purporting to be the mark of manufacturers resident in tbe Uaited Kingdom, or atating or implying that auch articles were mannfactured in the United Kingdom. The Merchandise Marks Act, 1887, consolidated and amended the law of offences relating to trade-marks and trade oescriptions. It $r \in$ pealed the Act of 1862 and replaced it by fuller provisions. It is now an offence to forge a trade-mark, to falsely apply to gooda any trade-mark or any mark so nearly resembling a thadc-mark as to deceive, to make any die, \&c., for the purpose of
forging or for being used for forging a Trade-mark, to apply any false trade doscription to goods, to dispose of or bave in possession any die, \&c., for the parpose of forging a trade-mark, or to cause any of the above-mentioned things to be done. There are apecial sections in the Act dealing with its application to watches and watch-cases. Where a wstch-case is of foreiga manufacture it must, if stamped at an assay office in the United Kingdom, bear a mark differing from the mark placed upon watches manufactured in the United Kingdon. A warratty is implied in the sale of goods bearing a trade-mark or trade description. See Warranty.
In most foreign countries provisions have long exiated for tho registration of trade-marks ; and the $j_{j}$ slso form one of the classes of "industrial property" for the protection of which an international convention was formed in 1883. This convention now includes sixteeu states, -the mor important being Belgium, France, Great Britain, Italy, Netherlands, Norway. Portugal, Snain, Sweden, Switzerland, and the United States. The subjects of all the contracting states enjoy in each state the saine rights and privileges, as that state grants to its own subjects for the protection of trade-marks. Registration also in one of the states conferg certain rights of priority in the others.

United States.-The legislation of the differeut Ststes and Territiories varies considerabls, seme providiag for the registration of trade-marks either with or without protection for onregistered trade-marks, while othcrs provide only for protection without reristration. On March 3, 1851, Cougress passed an Act "tn authorizo the registration of trade-marks and to protect the same," which provides that owners of trade-marks usedi ia comoerce with foreign nations or with the Indian tribes, providel auch owners be domiciled in the Uaited Statee or located in aty foreign conutry or tribo which affords similar mivileges to citizens of the United States, may obtain registration of trade-onarks under the Act. Registration is not compulsory; failure to registrp a trade-mark, or to renew registration, does nut de jrive the owner of suy remedy he might have at law or in equity; and the conrts will, generally spenking, protect the unregistered equally with the registered.

For iuller informatlon keo L. B. Sebastien'm Lavo of Trarte Marks, or R. W. Willace's edttlou of the Patents, Delp ns, and Trude Murks Act: and in Antrici Rowland Cox's American Trade-Mark Came. Cox's Jfamal of Trade-Mark Cases,
and Willam Llenry Brown's Trealise oz the Law of Trado Marks

TRADE UNIONS are combinations for regulating the relations between workmen and masters, workmen and workmen, or inasters and masters, or for imposing restrictive coaditions on the conduct of any industry or business. By the common law all such combinations were, with certain rare and unimportant exceptions, regarded as illegal. They were considered to be contrary to public policy, and were treated as conspiracies in restraint of trade. Those who were engaged or concerned in them were liable to be criminally prosecuted by indictment or information, and to be punished on coaviction by fine and imprisonment. The offence was precisely the same whether it was committed by masters or by workmen. But, although the provisions of the common lav applied mulatis anutandis to both of them alike, it was, practically sueaking, in refereace rather so the latter than to the former that their effects were developed and ascertained. While it was held to be perfectly lawiul for workmen, as individuals, to consent or to refuse to labour for any remuneration or for any time they pleased, when two or more of them joined together, and agreed to labour only on certain stipulated terms with respect either to the payment or the duration of their labour, they were guilty jso facto of a misdemeanour. It was immaterial whether the end they had in view was to determine wages or to limit rork; or whether the means they adopted for promoting its attaiament was a simultaneous withdrawal from employment, an endeavour to prevent other workmen from resuming or taking employment, or an attempt to control the masters in the management of their trude, the engagement of journeymen or apprentices, or tho use of machinery or industrial processes ; or whether in secking to enforce their demands they relied merely on advice and solicitation. or resorted to reproach and menace, or proceeded to actual violence. In any erent their combination in itself constituted a crimioal conspiracy, and reudered them amenable to prosecution and puoishment. From the reign of Edward I. to the reign of George IV. the operation of the comnon law whs enforced and
enlarged by between thirty and forty Aots of Parliament, all of which were more or less distinctly and explicitly desigued to prohibit and prevent what wo bave learned to describe and recognize as the "organization of labour." But the rise of the manufactaring system towards the end of tho last century, and the revolution which accompanied it in the industrial arrangements of the country, were attended by a vast and unexpected extension of the movement which the legislature bad for so long and with so much assiduity essayed to suppress. Among the moltitudes of workmen who then began to be employed in single factories or in neighbouring factories in the same towns, trade unions in the form of secret societies speedily becane numerous and active, and to meet the norel requrements of the situatiou a more summary method of procedure than that which had hitherto been a vailable was provided by the 40 th Geo. III. cap. 106. By this statute, passed in 1800, it was enacted that all persons combining with others to adrance their wages or decrease the quantity of their work, or in any way to affect or control those who carried on any manufacture or trade in the conduct and management thereof, might be convicted before one justice of the peace, and might be committed to the common jail for any time not exceeding three calendar months, or be kept to hard labour in the house of correction for a term of two calendar months. The discontent and disorder of fhich, in conjunction with a state of comnercial depres. sion and national distress, the introduction of steam and improved appliences generally into Eritish manufactures was productive in the first quarter of the current century led to the nomination of a select committee by the House of Commons, to inquire into the whole question of what were popularly and comprehensively designated the "combination lars," in the session of 1824 . After taking evidence, the colomittee reported to the House that "those laws had not only not been efficient to prevent combinations either of masters or workmen, but on the contrary had, in the opinion of many of both parties, had a tendency to produce mutual irritation and distrust, and to give a violent cbaracter to the combinations, and to render them highly dangerous to the peace of the community." They further rejorted that in their judgment "masters and workmen should be freed from such restrictions as regards the rate of wages and the hours of working, and be left at perfect liberty to make such agreements as they mutually think proper." They therefore recommended that "the statute laws which interfered in these particulars between masters and workmen should be repealed," and also that "the common law under which a peaceable meeting of masters or workmen might be prosecuted should be altered." la pursuance of their report, the 4 th Geo. N. cap. 95 was at once drafted, brought in, and passed. But the immediate results of the change which it effected were rectarded as so inconvenient. formidable, and alarming that in the session of 1825 the House of Commons appointed another select committee to re-examine the various problems, and review and recossider the evidence which had been submitted to their predecessors in the previous year. They reported without delay in favour of the total repeal of the 4th Geo. IV. cap. 95, and the restoration of those provision: of the combination laws, whether statutory or customary. which it had been more particularly intended to abrogate. The consequence was the enactment of the 6th Geo. IV cap. 129, of which the preamble ueclares that the 4 th Geo. IV. cap. 95 had not been found effectnal, and that combinations such as it had legalized were "injurious to trade aud commerce. dangerous to the tranquillity of the country, and especially prejudicial to the interests of all who were concerned in them." The effect of the Gth Geo. IV. cap. 129 was to leave the commor law of conspiracy
in full force against all combinations in restraint of trade, except such as it expressly exempted from its operation as it had been before the 4 th Geo. IV. cap. 95 was passed. It comprised, however, within itself the whole of the statute law relating to the subject, and under it no persons were liable to punishment for meeting together for the sole purpose of consulting upon and determining the rate of wages or prices which they, being present, would require for their work or pay to their workmen, or the hours for which they would work or require work in any trade or business, or for entering into any agreement, verbal or written, for the purpose of fixing the rate of wages or prices which the parties to it should so receive or pay. But all persons were subjected to a maximum punishment of three months' imprisonment with hard labour who should by violence, threats or intimidation, molestation, or obstruction do, or endeavour to do, or aid, abet, or assist in doing or endeavouring to do, any of a series of things inconsistent with freedoin of contract which the Act enumerated and defined. Afterwards, in order to remove certain doubts which had arisen as to the true import and meaning oif the words "molestation" and "obstruction," it was provided by the $22 d$ Vict. cap. 34 that " no person, by reason merely of his endeavouring peaceably and in a reasonable manner, and without threat or intimidation direct or indirect, to persuade others to cease or abstain from work, in order to obtain the rate of wages or the altered hours of labour agreed to by him and others, should be deemed to have been guilty of 'molestation' or "obstruction." In spite of the partial recognition which trade unions had thus received, they continued to be unlawful, although not necessarily criminal, associations. In certain cases, they were by statute exempted from penal consequences, and their members were empowered to combine for specified purposes, and to collect funds by voluntary contributions for carrying them into effect. But in the estimation of the common law the special privileges which had been accorded to them under particular circumstances did not confer any general character of legality upon them, and where their rules were beld to be in restraint of trade, as in the prohibition of piece-work or the limitation of the number of apprentices, they were still regarded as conspiracies. Hence they were practically excluded from the advantages in regard to the security of their property and the settlement of their disputes which, under the Friendly Societies Act, 18 th and 19th Vict. cap. 63, had been granted to all assaciations established for any purposes which were not illegal. In this condition the law was when what became notorious as the "Sheffield and Manchester outrages" suggested the appointment of the royal cemmission on trade unions, which investigated the subject from 1867 to 1869 . The outcome was, first, a temporary measure for the more effectual protection of the funds of trade unions, passed in 1869, and, secondly, the two measures which, as amended and amending, are cited together as the "Trade Union Acts 1871 and 1876 "the 34 th and 35 th Vict. cap. 22 and the 39th and 40 th Vict. cap. 31.

By these statutcs, construed with ine Censpiracy an Protection of Property Act, 1875 , the 33 and 39 Vict. cap. 86 , the law relating to combinations, whether of workmen or of masters, assumed the shape in which it exists at the present time. In cenvexion with trade disputes no person can now be prosecuted fer conspiracy to commit an set whicn would nat be criminal if cemmitted by him singly, and consequently empleyers and employed alike may lawfully do in combination all that they would be entitled to do as individuals. The purnoses of a trade union are not to be deemed illegal merely because they are in restraint of trade, and the circumstance that they are in restraint of trade is not to render any member of it liable to prosecution, nor is it to avoid or make void. able any agreement or trust 'relating to it. No court, hewever, can entertain legal proceedings with the object of directly enforcing or reccvering damages for the breach of an agreement between the
members of a trarle unien as such, concerning the cunditiens on. which the mombers for the time being shall or shall not sell their goods, transact their business, employ or be employed, or the payment by any person of any subscription or penalty to a trade union, or for the application of the funds of a trade union to provide benefits or to furnish contributions to any emplojer or workman not a member of such trade union in censideration of such empleyer or workman acting in confernity with the rules or resulutions of such trade union, or to discharge any tine imposed upon any person by any court of justice or any agreement made between one trale voien and another, or any bend to secure such agreenients. But such incapacity to sue on such agreements is not to be taken as constituting any of them illegal. Every person, howeyer, commits a misdemeanour, and on conviction is liable to a maximum fine of $£ 20$, or to a maximum imprisonment of three menths with baril labour, who wilfully and malicieusly breaks a contract of Eervice or hiring, knowing, or having reasonable cause tn believe, that the probable consequence of his so deing, either alune or in combination with others, will be to endanger human life or cause serious bodily injury, or to expose valuahle property, whether real or personal, to destruction or serions injury; or who, being employed by a municipal autherity or by any company or contractor on whon is imposed by Act of Parliament, or who have otherwise assumed, the duty of smplying any place with gas or water, wilfully and maliciously breaks a contract of service or hiring, knowing, or having reasonable cause to believe, that the probable consequenoe of his so doing, alone or in combination with others, will be to deprive the inhabitants of that place, wholly or- in part, of their supply of gas or water; or who, with a view to compel any other person to de or to abstain from doing any act which such other person has a right to abstain from deing or to do, wrongfully and without legal authority uses vielence to or intimidates such other person or his wife or children, or injures his property; or who persistently follows such person about frem place to place; or who hides any tools, clotbes, or other property owned or used by such other person, or deprives him of or hinders him in the use thercof; or who watches or besets the house or other place where such person resides or works or carries on business or happens to be, or the approach to snch house or place; or who follews such other person with two or more other persons in a disorderly manner in or threugh any street or road. But attending at or ncar the house or gllace where a person resides or works or carries on business in order 'merely to ebtain or comniunicate information is net watching or besetting within the statiate. In regard to registration, trade unions are placed on a similar footing with friendly and provident and industrial societies, and they enjoy all the privileges, advantages, and facilities which those associations possess and command. On their side, bowever, they have to comply with the same conditions, ari subject to the same liabilities, and are compelled to make the same periodical returns.

Although there are several large and influential secieties among the employers of labour which come within the legal definition of trade unions, what are commenly as well as more accurately mesnt by trade unions are societies exclusively composed of the employed, -the suppliers of labour whether skilled or anskilled. Of trado unions in this sonse, -thnse of which the members are all artisans or labourers, -the organization is cverywhere pretty much the same, although the tules and regulations of various asseciations differ in detail more or less distinctly and widely from one another. Their ordinary constitution is that of a society divided into districts, and again into smaller lncal bodies. The seat of the governing anthority -the general or executive council-is usually fixed at some large centre of industry or commerce, as Lendon, Manchester, or Birmingham, and it is often changed at stated intervala by a vote of the society at large. It is the policy of the trade unions, by this method of organization, to extend the area of their influence, and so to increase their power in dealing with the masters or in con. trolling their own mernbers in any emergency. Eanh of the branches has a separate government for special purpnses. But for general purposes all the branches are under the command of the exccutive conncil or central committee, which is constituted of members or officers who are elected by the whole society. The terins on which members are admitted are different in different associations. But in all of them there are certain limita as to age and the number of years during which the candidate has been apprenticed to or has worked in the trade. The revenue and reserve of all the societies are derived from admission fees and weekly or monthly subscriptions, together with the amount of thp fines which are imposed for neglect of duty and breaches of the rules and regulations. These sources of incorne are sufficient for ordinary purposes; and extraordinary charges, such as are entailed by a "strike" or a "lock-out," are nearly always, if not invariably, met by means of "levies" made on the members by order of the executive council or central committee. The following account of the Amalgamated Society of Engincers may be accepted as furnishing a typlcal example of the organization and management of a large and flourishing trade union.

According to the thirty-third annual Report of that oociety, it appesrs that in 1883 the union consisted of 424 branches, chiefly in towns in the British Isles, but with a fair sprinkling in Canada, the United States, Australia, India, and other parts of tho globe. The number of members was 50,418 . A branch must consist of not fewer than ee rea members or more than three hundred. The coustitution is pre-eminently democratic. Each branch is itself a completely organized body. It selects and elects its own officers; it collects, holds, sud spends its own funds; and it manages the whole of the business which affects itself alone. The officers of the branch are elacted at ganeral meetiogs at which every member must be present under the penalty of a fine. Members who refuse to ba nominated for office, or who refuse to serve if elected, are also subject to fiues, and officers who neglect their business either by coming lats to meetiogs or absenting themselves altogether are similarly punished. A meeting of the members of each brauch is held avery fortnight for the transaction of ordinary business, such as receiving subseriptions and deciding upon propositions for new membars. These meetiags begin at hall-past 7 in the evening. and close at half-past 9 or 10 o'clock, but the hours are altered when it is convenient to alter them. The duties of the secretary are onetous, and bis responsibility is great. No one therefore is eligible who has not been in the society two jears succcasively, and "no member shall be elected as secretary who keeps a public or beer house." He has charga of the accounts of his lranch, and conducts its correspondence. He has to see to the payment of members who are entitled to trarelling relief dunation, sick, superannuation, or funeral benefit. He has to summon meetings, keep minntes, report to the general oecretary as to the state of trade in the district, the number of men out of work, or on the other hand he has to state what men are wanted, end he has also "to transact any other business that belongs to his office." The president, vicepresident, and assistant secretary of a branch are elected quarterly, while the secretary and referes are elected annually. Members are exempt if they are fifty years of age, or if they reside mere than 3 milas from the club house; and they are disqualified if they are 10月. in arraar with their contributions. There are also bookkeepers, money stewards, doorkeepers, treasurers, and ouditors, the naturs of whose work is evident from their titleg. There ara also sick stewards, whose duties are to visit the sick twice a week, to report their visits to the neetings of the branch, and to carry the invalid his sick benefit. Nons of the offices are honorary. In branches numbering fewer than fifty members every officer is allowed 4d., and in branches numbering fifty and upwards 6d., for his attendance on branch meeting nigl is. The eecretary is paid annually and according to the size of the branch. The lowest amount is $£ 1,58$. for a branch of ten members, the highest $£ 10$, 4s. for a branch of thres hundred. The auditors are paid at a lower rate, which raries from 9d. to 4s. 8d., while the treasurer is paid 10 per cent. on the sunn set apart for use. Each branch has also a cumnoittee, which has power to determine anything whereon the sociaty's rules are silent. The books of the branch are open to their inspection; they can eummon meetings, and they have various other duties. Each member of this committee receives 6d. for each meeting be attends, and is fined 6d. for each meeting from which he is absent. In any district in which there are more branches than one, a local district committee must be formed, consisting of saven members, each branch as nearly as practicahle selectivg an equal number. Where there are seven branches, each one sends a representative. The duties of this committee are to "watch over the interests of the trade, and transact such husiness as affects the district generally." it inust not. however, interfere with the business of any particular hranch of the society. The central authority is vested in a general or executive council, conaisting of thirty-seven members, of whom eleven represent metropolitan branches, the others being from the provinces, including Scotland and Ireland. As the country councillors cannot conreniently attend frequent meetings in London, tho ordanary mauagement is entrusted to the eleven London menters, who sre calleu the local council, and the council is also further broken up into various committees for managing the details of the society. This council hears a ppeals from braochcs, advises, forbids, initiates, and terminates strikes. The general secretary receives a Ealary of $£ 4$ a week and lives rent free. He also receives ls. 6d. each time he attends a council meeting, and is paid for any special journeys undertaken or extra work done. His assistants receive $£ 2,10$ s. a week eaeh, and have to give the whole of their time to the association. They have to compile and issue a monthly report as well as quarterly and yearly reports. The last-named is quite a rormidablo volume, consisting of nearly 400 pazes of large post octavo, and those of other societies are similar. Tbe general sccretary's hours of business are fixed from 9 A. M. to 6 P. M. He has power to authorize members who sre on donation to be removed from ons branch to another where there is a probability of employment, and hs has to keep a register of sll the members of tho soeiety, stating When and where admitted, age, married or single, aod whether a oember has reeeived any part of the financial money. In the

Amalgamated Society of Engineers the contribution of cach member is generally 1s. a week, and if a man be in arrears he is suspended from tha benefits of the society, unless indecd he is ont of work or in distressed circumstances. At the end of 1883 the union had a balance in hand of $£ 178,128$, or upwards of $£ 3,10$ s. a mın.

In some trade unions--for example, those of the compositorsthere is a special hody (" lathers of chapels") whose business it is to see that the rules and regulations of the societies they belong to are faithfully observed in the establishments where they sie employed. In others sgain-for instance, in the National Agricultural Labourers Union, as distinguished from the Federai Union of Agricultural Labourers-the system of management is completely centralized, the secretary or the executive committes havitg entire control of the funds and business of the whole association. In all large towns there are trade councils formed of delegates from the different trade unions within their area, whose functiou it is to discuss and aupervise the general interests of the unionists in the several trades of which they ara representative. Moseover, an annual trade unions congress is held in some great centre of industry and population in one of the three kingdoms, at which delegates frum almost all the trade unions throughout tha realm are present and take part in debating questions, whether social or political, which are of special interest to tha working classes. At these assemblies, which hsva now been held for twenty consecutive years, a parlismentary committes, which remains in existence for the ensuing twelvemonth, is chosen, to whom the whole body of trade unionists looks for counsel and assistance with respect to legislation intended or desired on their behalf. To the action of the trade unions congress and their parliamentary committee mach of tho legislation which has been recently effected on questions affecting the welfare of the order of the community to which they belong is to be attributed, - notably the Emplogers' Liability Act and the ameoded Factory and Mines Acts. (See Trade Unions, \&c., by William Trant.)

The ohjects of trade nnions are twofolu, - first, those of a friendly or benefit society, and, secondly, those of a trade saciety or guild. In the former capacity they afford relief to their members when they are out of work from auy cause, including sickness or accident; they occasionally provide them with supcrannuation allowances, and they almost always make hurial allowances ou account of deceased members and their wives. In tha latter eanacity it is their special business to promoto what they conceive to be the interests of the trade with which they are conneeted by placing the workmen, so far as combination will fulfil that parpose, on a footing approaching to equality with the capitalists by whon they ara employed in the disposal of their labour. Of canrse this is the great object for which the unions really exist. But, as the commissioners on trade unions have pointed out, it is Cound desirable to conjoin the ohjects of a friendly or benefit society with it, because by that means additional members and funds are obtained, and the authority which the undon as a trade society has over its members is thus augmented. The leading aims of all trade unionism are to increase wages and to diminish the labour by which it is needful to eara them, and further to secure a more equal distribution of work among the workmen in aoy given trade than would be the casa under a reginsa of unrestricted competition. Hence their rules prescribe a minimum amount of wages to be accepted and a maximum amount of work to be dons by their nuenbers, and pruhibit piece wark or working overtime. The methods by which the unioniste endeavour to accomplisli their end, which is in a sense the monepoly of the labour market, aro either direct or intirest. The direct method is a "strike," ur simultaueous cessation of labour on the part of the workmen. It is the ultimate sanction as between the employel and their employers of the dernands made by the union. But, where the unioniste are strong, the mere threat of a strike is often suffient to fulfil the intended purpose, and arbitration is still more frequently fouod effectual for bringing about a settlement or compromise. The indirect methods to which the trade unionists resort for reachiog their aims are by liniting the number of workmen to be euployed in any trade and by repressing or discountenancing competition among those who are actually employed in it. Most of them forbid the admission of more than a stipulated proportion of apprentices, aud some of them prohibit the engagenent of women to do work which can be done by men. Nearly all of them resist the common ernployment of mionists and pon-unionists, and do their best to exclude non-urinnists from employment altogether. But the amount expended by wade unione in the conduct of trade disputes is very much less thao is gencrally imagined. Mr George Howell, for instance, showed conclusively in the Contemporary Revievo that auch was the case three or four years ago, and Mr Murchie, tho chairman of the parliamentary committee, stated the trade unions coogress at Stockport in the autuma of 1885
Mr Howell's contentions had been signally confirmed by mor recent experience. Taking the seveu largest trade unions, thus whose statistics had leee relied on by Mr Howell-name: M , the Amalgamated Engineers, the Ironfounders, the Boilcr Makers
and Iron Shipbuilders, the Steam-Eogioe Makers, Ironmoulders of Scotland, Amalgamated Tailors, and Amalganated Carpenters and Joiners-be affirmed that, while in the nioc years preceding $18 S 4$ their receipts were $£ 2,818,548$, their expenditure was $£ 2,963,186$, of which amount' $£ 1,207,180$ was spent in unemployed beuefit, $£ 592,273$ in sick beoefit, $£ 975,052$ in compensation for loss of tools, superanouations, accidents, fuaerals, minor grants a ad benefits, and cxpense of managemeat, only $£ 188,680$ bad been spent in connexion with "trade movements," or about 6 $\frac{1}{2}$ per cont. of the whole sum expended.

There are no really trustworthy means of arriving at anything a pproaching to an accurate estimate of the actual numerical atrength of the trade unions in the United Kingdom. According to the last Report of the registrar general of friendly societies, there were in the year 1883 registered in his office 195 trade unious with 253,088 members aad $£ \ddagger 31,495$ funds, of which 12 returned over $£ 10,000$ fuads, 9 over 10,000 members, and 6 over $£ 10,000$ income. But this of coarse conveys a very inadequate notion of the dimensions to which trade unionism has attained, since many of the largest ond most influential societies are still unregistercd.

Tbe followiag tahle shows the aumber of delegates and the aggeegate membership of the societies represented by them at the trade unions congresses in the years from 1880 to 1886 , both iaclusive:-

|  | $\begin{gathered} \text { Number } \\ \text { of } \\ \text { Delegates. } \end{gathered}$ | Number of Bodies represented. | Trade Councils represented. | Trads Unlons represented directly. | Total Number of Persons represented. | Number represented by Trade Connclls. | Unlonists represented directly (8pproximate). |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1880 | 122 | 105 | 37 | 88 | 474,218 | 92,511 | 381,702 |
| 1881 | 154 | 122 | 18 | 101 | 460,797 | 86,376 | 374,421 |
| 1882 | 153 | 126 | 23 | 103 | 608,337 | 102,972 | 405,365 |
| 1888 | 173 | 135 | 21 | 114 | 561,091 | 94,166 | 466,925 |
| 1884 | 142 | 116 | 21 | 95 | 597,636 | 109,984 | 487,652 |
| $18 \$ 5$ | 162 | 136 | 27 | 109 | 631,606 | 131,368 | 500,238 |
| 1886 | 143 | 121 | 24 | 97 | 635,380 | 122,207 | 513,173 |

Weshall not be far wrong, perhaps, if we set down the number of trade unionists in all the three kingdoms at about 800,000 .
(F.DR.)

## TRAGEDY. See Drama.

TRAJAN (c. 53-117 a.d.). Marcus Ulpius Teaianus, the fourteenth Roman emperor, was a native of Italica, in Spain. The family to which he belonged was probably Italian and not Iberian by blood. His father began life as a common legionary soldier, and fought his way up to the consulship and the governorship of Asia. He was one of the bardest fighters in Judæa under Vespasian and Titus; he served too against the Parthians, and won the highest military distinction open to a subject, the grant of the triumphal insignia. Thus he acquired a promicent place among the brand new patricians created by the Flavians as substitutes for the nobles of old descent who had succumbed to the cruelty and rapacity of the emperors from Tiberius to Nero. The younger Trajan was rigorously trained by his father, and deeply imbued with the same principles and tastes. He was a soldier born and bred. No better representative of the true old hardy Roman type, little softened either by luxury or education, had come to the head of affairs since the days of Marius. The date of his birth was probably 53 A.D. His training was almost exclusively military, but his ex. perience as an officer gave him an acquaintance with almost every important province of the empire which was of priceless value to him when he came to the throne. For ten years he held a commission as military tribune, which took him to many lands far asunder; then he filled important posts in Syria and Spain. How much actual warfare Trajan saw in those days we can hardly tell; he certainly went through some severe service under his father's command against the Parthians. By the year 89 he had achieved a considerable reputation. At that time L. Antonius Saturninus headed a rebellion in Germany, which threatened seriously to bring Domitian's rule to an end. Trajan was ordered in hat haste from Further Spain to the Rhine. Althongh he carried his troops over that long and arduons march with almost unexampled rapidity, he unly arrived after the insarrection had been fat down.

But his promptitude raised him higher in the favour of Domitian, and he was advancel to the consulship in 91 Of the next five years of his life we know nothing posi tively. It is not unlikely that they were spent at Rom or in Italy in the fulfilment of some official duties. Whes the revolution of 96 came, and Nerva replaced the murdered Domitian, Trajan had conferred upon him one of the most important posts in the empire, that of consulay legate of Upper Germany. An officer whose nature, ai the event showed, was interpenetrated with the spirit on legality was a fitting servant of a revolution whose aim it was to substitute legality for personal caprice as the dominant principle of affairs. The short reign of Nerva really did start the empire oa a new carcer, which lasted more than three quarters of a century. But it also demonstrated how impossible it was for any one to govern at all who had no claim, either personal or inherited, to the respect of the legions. Nerva saw that if he could not find an Augustus to control the army, the army would find another Domitian to trample the senate under foot. In his difficulties he took counsel with L. Licinius Sura, a lifelong friend of Trajan, and in October 97 ho ascended the Capitol, and with all due solemnity proclaimed that he adopted Trajan as his son. The senate confirmed the choice, and acknowledged the emperor's adopted son as his successor. In a letter which Nerva sent at once. to Trajan he quoted most significantly a line from the beginning of the Iliad, where Chryses, insulted by Achilles, prays to Apollo: "May thy shafts afford me vengeance on the Greeks for my tears." After a little hesitation Trajan accepted the position, which was marked by the titles of imperator, Cæsar, and Germanicus, and by the tribunician authority. He immediately proceeded to Lower Germany, to assure himself of the fidelity of the troops in that province, and while at Colugne be reccived news of Nerva's death (January 98). The authority of the new emperor was recognized at once all the empire over. The novel fact that a master of the Romans should have been born on Spanish soil seems to have passed with little remark, and this very absence of notice is significant. Trajan's first care as emperor was to write to the senate an assurance like that which had been given by Nerva, that he would neither kill nor degrade any senator. He ordered the establishment of a temple and cult in honour of his adoptive father, but he did not present himself at Rome for nearly two years after his accession. Possibly he had taken measures before Nerva's death to secure the revenge which Nerva craved, but probably did not live to see. In his dealings with the mutinous pretorians the strength of the new emperor's hand was shown at once. He ordered a portion of the force to Germacy. They did not venture to disobey, and were distributed among the legions there. Those who remained at Rome were easily overawed and reformed. It is still more surprising that the soldiers should have quietly submitted to a reduction in the amount of the donative or gift which it was customary for them to receive from a new emperor, though the civil population of the capital were paid their largess (congiarium) in full. By politic management Trajan was able to represent the diminution as a sort of discount for immediate payment, while the civilians had to wait a considerable time before their full due was handed to them.

The secret of Traján's power lay in his close personal relations with the officers and men of the army and in the soldierly qualities which commanded their esteem. He possessed courage, justice, and frankness to a high degree. Having a good title to military distinction himself, he could afford, as the unwarlike emperors could not, to be generous to his officers. The common soldiers, on the other hand, were fascinated by his personal prowess and
his somewhat ostentatious camaraderie. His features were firm and clearly cut; his figure was tall and soldierly, and exhibited the sinewy hard health of a veteran campaigner_ His hair was already grey before he came to the throne, though he was not more than forty-four years old. The stoutness of the emperor's arm had been proved in the face of his men in many a hard fight. When on service he used the mean fare of the common private, dining on salt pork, cheese, and sour wine. Nothing pleased him better than to take part with the centurion or the soldier in fencing or other military exercise, and he would appland any shrewd blow which fell upon his own helmet. Ho loved to display his acquaintance with the career of distinguished veterans, and to talk with them of their battles and their wounds. Probably he lost nothing of his popularity with the army by occasional free indulgence in sensual pleasures with which, as Bacon remarks, the soldier is apt to pay himself for the perils he encounters. Yet every man felt and knew that no detail of military duty, however minute, escaped the emperor's eye, and that any relazation of discipline would be rigidly punished, yet with unwavering justice. Trajan emphasized at once his personal control and the constitutionality of his sway by bearing on his campaigns the actual title of "proconsul," which no other emperor had done. All things considered, it is not surprising that be wes able, without serious opposition from the army, to remodel the whole military institutions of the empire, and to bring them into a shape from which there was comparatively little departure so loag as the army lasted. In disciplinary matters no emperor since Augustus had been able to keep so strong a control over the troops. Pliny rightly praises Trajan as the lawgiver and the founder of discipline, and Vegetius classes Augustus, Trajan, and Hadrian together as restorers of the morale of the army. The confidence which existed between Trajan and his army finds expression in some of the coins of his reign.
For nearly two years after his election Trajan did not appear in Rome. He had decided already what the great task of his reign should be-the establishment of security upon the dangerous north-eastern frontier. Before visiting the capital he determined to put affairs in train for the attainment of this great object. He made a thorough inspection of the great lines of defence between the Danube and the Rhine, and framed and partly carried out a vast schẹme for strengthening and securing them. The policy of opposing uncivilized tribes by the construction of the limes, a raised embankment of earth or other material, intersected here and there by fortifcations, was not his invention, but it owed in great measure its development to him. It is probable that the northernmost part of the great limes Germanix, from the Rhine at Rheinbrohl, nearly midway between Coblenz and Boun, to a point on the Main east of Frankfort, where that river suddenly changes its course from north to west, was begun by Domitian. The extension of this great barrier southwards was undertaken by Trajan, though wo cannot say how far he carried the work, which was not entirely completed till long after his time. The limes leaves the Main at Miltenberg, a point at which the north and south course of the :iver is broken by a great angle, and then follows a line generally parallel to the stream of the Neckar, till it reaches Lorch, a place between Stuttgart and Aalen. Here it meets the so-called limes Rxtixe, which trends eastward till it cuts the Danube at Keltsim, a place some distance short of Ratisbon, the ancien - Castra Regina. This grand work, which would have oxitited the envy of Avgustus, is traceable in its main 6 stent at the present day. We may without hesitation follow the opinion of Mommsen, whe maintains that the limes wss not intended, like Hadrian's wall
between the Tyne and the Solway, and like the great wall of China, to oppose an absolute barrier against incursions from the outside. It was useful as marking definitely the boundary of the Roman sway, and as assuring the Romans that or inroad could be made without intelligence being had of it beforeland, while the limes itself and the systen of roads behind it enabled troops to be directed rapidly to any threatened point, and the fortified positions could be held against large numbers till reinforcements arrived. Great importance was no doubt attached to the perfection of the lines of communication bearing on the limes. Among a people of roadmakers, Trajan was one of the greatest, and we have definite evidence from inscriptions that some of the military roads in this region were constructed by him. The more secure control which the Romans now maintained over the territory within the limes tended to its rapid civilization, and the Roman influence, if not the Roman arms, soon began to affect powerfully the regions beyond.

After his careful survey of the Rhine end of the great defensive barrier, Trajan proceeded to consider it and plan it from the Danube. From the age of Tiberius onwards the Romans possessed the whole southera bank of the river from its source to the Enxine. But the precarious tenure of their possession had been deeply impressed on them by the disasters and bumiliations they had undergone in these districts during the reign of Domitian. A prince had arisen among the Dacians, Decebalus by namse, worthy to be placed at the head of all the great barbarian antagonists of Rome. Like Maroboduus, he was able to combine the forces of tribes commonly hostile to each other, and his military ability almost went the length of genius. After he had swept the province of Mcesia bare, he was defeated by one of Domitian's lieutenants, but the position of affairs on the Danubio-Rhenish border was still 80 threatening that the emperer was glad to conclude a treaty which conferred extraordinary advantages on his foe. Not only did the Romans stipulate to pay to Decebalus an annual subsidy, which he must have regarded as a tribute, but they agreed to supply him with engineers and craftsmen skilled in all kinds of construction, but particuiarly in the erection of fortifications and defensive works. During the nine or ten years which had elapsed since the conclusion of this remarkable treaty, the Dacian prince had immensely strengthened the approaches to his kingdom from the Roman side. He had also equipped and drilled his formidable army after the Roman fashion. It was impossible for a soldier like Trajan to endure the conditions laid down by Domitian ; but the conquest of Dacia had become one of the most formidable tasks that had ever confronted the empire. Trajan no doubt planned a war before he left the Danube for Rome late in 99.

The arrival of the emperor had been amaited in the capital with an impatience which is expressed by Plipy and by Martial. ${ }^{1}$ All that had happened since Trajan's elevation to the throne had raised high ad Rome the hope of a prosperous and glorious reign. As he entered the city and went on foot to the Capitol, the plaudits of the people were unmistakably genuine. During his stay in' the city he riveted more firmly still the affections, bnth of the senate and of the people. The reconciliation of the empiro with liberty, inaugurated, as Tacitus says, by Nerva, seemed now to be securely achieved. Trajan was absolutely open and simple, and lived with men at Rome as he had lived with his soldiers while on service. He

1 It has been conjectured, not improbably, that the Germania of Tacitus, written at tha period, had for one of ita aime the enlighten. ment of the Romans concerning the formidable charaoter of the Germans, so that they might at once bear more readily with the emperor'a prolonged absence and be prepared for the necessity of decisive action on the frontier.
realized tho senate's ideal of the citizen ruler. The assurance that no senator should suffer was renewed by oath. All the old republican formalities were most punctiliously observed-even those attendant on the emperor's election to the consulate, so far as they did not involve a restoration of the old order of voting at the comitia. The reneration for republican tradition is curiously attested by the reproduction of many republican types of coin struck by senatorial officers. Trajan seized every opportunity for emphasizing his view that the princeps was merely the greatest of the magistrates, 'and so was not above but under the laws. He was determined, he said, to be to his subjects such a ruler as be had desired for himself when a subject. There is a pretty story to the effect that he handed the commander of the prætorians his sword, and said, "Use it for me if I do well, but against me if I do ill." Martial, who had called Domitian his lord and his god, now cried, "In him we have no lord, but an imperator!" Real power and influence were accorded to the senate, which had now, by the incorporation of members whose origin was provincial, become in a manner representative of the whole empire. Trajan associated with the senators on equal terms, and enjoyed in their company every kind of recreation. All pomp was distasteful to him, and discarded by him. There was practically no court, and no intrigues of any kind were possible. The approach to his house was free, and he loved to vass through the city unattended, and to pay unexpected visits to his friends. He thirsted for no senator's bluod, and used severity against the delatores alone. There was but one insignificant conspiracy against him during his whole reign. Though not literary himself, Trajan conciliated the literary men, who at all times had close relations with the senate. His intimate, M. Licinius, played an excellent Mæcenas to his Augustus. In his efforts to win the affections of Roman society, Trajan was excellently aided by his wife Plotina, who was as simple as her husband, benevolent, pure in character, and entirely unambitious. The hold which Trajan acquired over the people was no less firm than that which he maintaioed upon the army and the senate. His largesses, his distributions of food, his public wcrks, and his spectacles were all on a generous scale. The exhibitions in the arena were perhaps at their zenith during his tenure of power. Though, for some unexplained 'reason, he abolished the raimes, so beloved of the populace, at the outset of his reign, be availed bimself of the occasion of his first triumph to restore them again. The people were delighted by the removal of the imperial exedra in the circus, whereby five thousand additional places were provided. Taxation was in many directions reduced, and the financial exactions of the imperial officers controlled by the erection of a special court. Elaborate precautions were taken to save Italy from famine; it is said that corn for seven years' consumption at the capital was retained in the granaries. Special encouragement was given to merchants to import articles of food. The corporation of bakers was organized, and made more effective for the service of the public. The internal trade of Italy was powerfully stimulated by the careful maintenance and extension of the different lines of road. Bnt the most striking evidence of Trajan's solicitude for his people's welfare is found in his institution of the alimenta, whereby means were provided for the rearing of poor and orphan children in Italy. The method had been sketched out by Nerva, but its great development was due to Trajan. The moneys allotted by the smperor were in many cases supplemented by private benevolence. As a soldier, I'rajan realized the need of men for the maintenance of the empirc against the outer karbarians, and he preferred that $t^{\text {he }}$ ese men should be of Italian birth. He was only
carrying a step farther the policy of Augustus, who by a system of rewards and penalties had tried to encourage marriage and the nurture of children. The actual effect of Trajan's regulations is hard to measure ; they were probably more effectual for their object than those of Augustus. The foundations were confiscated by Pertinax, after they had existed less than a century.

During the year 100, when Trajan was consul for the third time, Pliny, who had been designated consul for a part of it, was appointed to deliver the "Panegyric" which has come down to us, and which forms the most important source of our knowledge concerning this emperor. Pliny's eulogy of Trajan and his denunciation of Domitian are alike couched in extravagant phrases, but the former perhaps rests more uniformly on a basis of truth and justice than the latter. The tone of the "Panegyric" certainly lends itself to the supposition of some historians that Trajan was inordinately vain. That the emperor had an bonest and soldierly satisfaction in his own weil-doing is clear; but, if he had had anything like the vanity of a Domitian, the scnate, ever eager to outrun a ruler's taste for flattery, would never have kept within such moderate bounds.

Towards the end of 100 , or early in 101, Trajan left Rome for the Danube. Pretexts for a Dacian war were not difficult to find. Although there was no lack of hard fighting, victory in this war depended largely on the work of the engincer. The great military road connecting the posts in Upper Germany with those on the Danube, which had been begun by Tiberius, was now extended along the right bank of the river as far as the modern Orsova. The year 101 was spent mainly in road-making and fortification. In the following campaign, after desperate fighting to the north of the Danube in the mountainous region of Transylvania, such as Cæsar never encountered in all his Gaulish wars, the capital of Decebalus was taken, and he was forced to terms. He agreed to raze all fortresscs, to surrender all weapons, prisoners, and homan deserters, and to become a dependent prince under the suzerainty of Rome. Trajan came back to Italy with Dacian envoys Who in ancient style begged the senate to confirm the conditions granted by the commander in the field. The emperor now enjoged his first Dacian triumph, and assumed the title of Dacicus. At the same time he royally enter tained the people, and no less royaily rewarded his brave officers. But the Dacian chief could not school his high spirit to endure the conditions of the treaty, and Trajan soon found it necessary to prepare for another war. A massive stone bridge was built across the Danube, near the modera Turn Severin, by Apollodorus, the gifted architect who afterwards designed the forum of Trajan. In 105 began the new struggle, which on the side of Decebalus could now only lead to victory or to destruction. The Dacians fought their ground inch by inch, and their army as a whole may be said to have bled to death. The prince put an end to his own life. His kingdom became an imperial province; in it many colonies were founded, and peopled by settlers drawn from different parts of the empire. The work done by Trajan in the Danabian regions left a lasting mark upon their history. The emperor returned to the capital in 106 , laden with captured treasure. His triumpla outdid in splendour all those that went before it. Games are said to have been held continuously for four months. Ten thousand gladiators contended in the arena, and eleven thousand beasts were killed in the contests. Congratulatory embassies came from all lands, even from ludia. The grand and enduring monument of the Dacian wars is the noble pillar which still stands on the site of Trajan's forum at Rome.

The end of the Dacian wars was followed by seven years of peace. During part of that time Pliny was imperial
legate in the proriuces of Bithynia and Pontus, and in constant communication with Trajan. The correspondence is extant, and gives us the means of observing the principles and tendencies of the emperor as a civil governor.
The provinces (hitherto हenatorial) were in considerable disorder, Which Pliny was sent to cure. It is clear from the emperor's letters that in regard to nine ont of ten of rie matters which his anxious ind deferential legate reforred to him for his decision he would have been better pleased if the legate had decided thern for himself. Trajan'a notions of civil government were, like those of the duke of Wellington, strongly tinged with militery prepessessions. He regarded the provmcial ruler as a kind of officer in command, who ought to be able to discipline his province for himself, and only to a preal to the commander-in-chief in a dificult case. In advising P'iny about the different free commanities in the provinces, Trajan showed the same regard for traditional rights end privileges which be had exhibited in face of the senate at Rame. At the same time, these letters bring home to us his conviction that, particularly in financial effairs, it was necessary that local self-goverament should le carrical on under the vigilaut eupervisiou of imperial officers. The control which he began in this way to exercise, both in Itaiy and in the provinces, over the "municipia" nad "hberace civitates," by means of agents entitled (then or later) "correctores civitatium liberarum," was carried continually farther and farther by his successors, and at last onded in the complete centralization of the gavernment. On this account the reign of Trajan constitules a turning point in civil as in military history. In other directions, though we fud many salutary civil measures, yet there were no far-reaching achemes of reform. Many details in the administration of the law, and particularly of the criminal law, were improved. To cure corruption in the senate the ballot was introduced at elections to magistracies. The finances of the state were economically managed, and taxpayers were most carefully guarded from oppression. Trajan nevor lacked money to expend on great works of public utility; as a builder, he may fairly be compared with Augustus. His fornm and its numerous eppendages were constructed on a mognificent scale. Many regions of Italy and the provinces besides the city itself benefited by the care and munificence which tho emperor bestowed on such public improvementa. Hisattitude towarda religion was, like that of Augustus, moderate and conservative. The famous letter to Pliny about the Christians is, according to Roman ideas, merciful and considerate. It was impossible, however, for a Roman niagistrate of the tinie to rid himEelf of the idea that all forms of religion must do homage to the civil power. Hence the conflict which made Trajan appear in the eves of Christians like Tertullian the mast infamons of monsters. On the whole, Trajan's civil administration was sound, careful, and sensible, rather than brilliant or epoch-making.

In 113 or 114 Trajan left Italy to make war in the East. The never-ending Parthian problem confronted him, and with it were more or less connected a number of minor difficulties. Already by 106 the position of Rome in the East had been materially improved by the peaceful annexation of districts bordering on the province of Syria. The district of Damascus, hitherto a dependency, and the last remaining fragment of the Jewish kingdom, were incorporated with Syria; Bostra and Petra were permanently occupied, and a great portion of the Nabathrean kingdom was constituted the Roman province of Arabia. Rome thus obtained mastery of the most important positions lying on the great trade routes from East to West. These changes could not but affect the relations of the Roman with the Parthian empire, and the affairs of Armenia became in 114 the occasion of a war which has been described under Persia, vol. xviii. p. 603. Trajan's campaigns in the East ended in complete though brilliant failure. In the retreat from Ctesiphon (117) the old emperor tasted for almost the first time the bitterness of defeat in the field. He attacked the desert city of Hatra, westward of the Tigris, whose importance is still attested by grand ruins. The want of water made it impossible to maintain a large force near the city, and the brave Arabs routed the Roman cavalry. Trajan, who narrowly escaped being killed, was furced to withdraw. A more alarming difficulty lay before him. Taking adrantage of the absence of the emperor in the far East, and possibly by an understanding with the leadors of the rising in Armenia and the annexed portions of

Parthia, the Jews all over the East had taken up arms at the same moment, and at a given signal. The massacres they committed were portentous. In Cyprus 240,000 men are said to have been put to deatb, and at Cyrene 220,000 . At Alexandria, on the other hand, many Jews were killed. The Romans punished massacre by massacre, and the complete suppression of the insurrection was long delayed, but the Jews made no great stand against disciplmed troops. Trajan still thought of returning to Mesopotamia, and of a arenging his defeat at Hatra, but he was stricken with sickness and compelled to take ship for Italy. His illness increasing, he landed mn Cilicia, and died at Selinus in that country about the end of July 117. Trajan, who had no children, had continually delayed to settle the succession to the throne, though Pliny in the "Panegyric" had pointedly drawn his attention to the matter, and it must have caused the senate muck anxiety. Whether Hadrian, the cousin of Trajan, was actually adopted by him or not is impossible to determine ; certainly Hadrian had not been advanced to any great honours by Trajan. Even his military service bad not been distinguished. Plotina asserted the adoption, and it was readily and most fortunately accepted, if not believed, as a fact.
The senate had decreed to Trajan as many triumphs as be chose to celebrate. For the first time a dead general triumphed. When Trajan was deified, he appropriately retained, alone among the emperors, a title he had won for himself in the field, tbat of "Parthicus." He was a patient organizer of victory rather than a strategic genius. He laboriously perfected the military machine, which when once set in motion went on to victory. Much of the work he did was great and enduring, but the last year of his life forbade the Romans to attribute to him that felicitas which they regarded as an inborn quality of the highest generals. Each succeeding emperor was saluted with the wish that he might be "better than Trajan and more fortunate than Augustus:" Yet the breach made in Trajan's felicitas by the failure in the East was no greater than that made in the felicitas of Augustus by his retirement from the right bank of the Rhine. The question whether Trajan's Oriental policy was wise is answered emphatically by Mommsen in the affrmative. It was certainly wise if the means existed which were necessary to carry it out and sustain it. But succeeding history proved that those means did not exist. The assertion of Mommsen that the Tigris was a more defensible frontier than the desert line which separated the Parthian from the Roman empire can bardly be accepted. The change would certainly have created a demand for more legions, which the resources of the Romans were not sufficient to meet without danger to their possessions on other frontiers.

The recards of Trajan's reign are miserably deficient. Our best authority is the 68th book of Dio Cassius; then comes the "Panegyric" of Pliny, with his correspondence. The facts to be gathered from other ancient writers are scattered and scanty. Fortunately the inscriptions of the time are abundant and iaportant. Of modern histories which comprise the reign of Trajan the best in English is tbat of Merivale; but that in German by H. Schiller (Gcschichle der römischen Kaiserzeit, Gotba, 1883) is more on a level with recent inquiries. There are special works on Trajan by H. Francka (Giistrow, 1837), De la Berge (Paris, 1877), and Dieraner (in M. Büdinger's U'ntersuchungen zur rönischen Kaisergeschichte, Leipsic, 1868). A paper by Mommsen in Hermes, iii. pp. 30 sq., entitled "Zur Lebensgeschichte des jüngeren Pliuius," is iuportant for the chronology of Trajan's reign.
(J. S. R.)

TRALEE, a market-town and seaport, and the chief town of Kerry, Ireland, is situated on the Ballymullen or Leigh river, about a mile from where it discharges itself into Tralee Bay, and on the Great Southero and Western Railmay, 21 miles north-west of Killarney and 18 south west of Listowel. It is a neat, well-built, and compara tively prosperous town. The principal public buildings are
the crurt-house, the town-hall, the corn exchange, the chamber of commerce, the worlshouse, the infantry barracks, the county hospital, and the fever hospital. A ship canal, permitting the passage of ships of 200 tons burden, and constructed at an expense of $£ 30,000$, connects it with Tralee Bay. Coal, iron, and timber are imported, and there is a considerable export of grain. There is a large trade in butter. The population of the town in 1871 was 9506 and in 1881 it was 9396.
Tralee, anciently Traleigh, the "strand of the Leigh," owes its origin to the foundstiou of a Dominican monsstery iu 1213 by John Fitz.Thomas, of the Gersldine family. During the reign of Elizabeth it was in the possession of Earl Desmond, on whose forfeiture it came into possession of the Dennys. At the time of the rebellion in 1641 the English families in the neighbourhood saked to be placed in the castle under the charge of Sir Edward Denny, but during his absence a surrender was made。 The town was incorporated by a charter in the 10th of James I., and hed the privilege of sending two members to the Irish parliament. Though disfranchised at the Union, it obtained the privilege of returning one member in 1832, but in 1885 it was merged in the county.

TRAMWAY. Originally a tramway signified a wheel crack laid ${ }^{0}$ with timbers, and afterwards with iron plates, having a flange on the inner edge by which wheels of the ordinary sort were kept in the track (see Railuay). The introduction of the flanged wheel and edge rail-caused tramways to be superseded by railways, but not until many miles of tramroads had been laid and successfully worked in various parts of the United Kingdom. Although the name is sometimes given to a light railway, by a tramway is now generally understood a street railway, constructed so as to interfere but little with the ordinary traffic, on which vehicles baving flanged wheèls are propelled by animal or mechanical power. Tramways in this sense originated in the United States.

A street railway for passengers was laid in Now York in 1832, but it was soon removed on account of the accidents caused by it. In 1852 a French engineer, Loubat, revived tramways in New York, and they were soon afterwards laid in other American cities. A short line was also laid in Paris in 1853 . The rails used were of wrought-iron, 5 inches wide, having a groove for the flanged wheels of the cars $1 \frac{3}{4}$ to $2 \frac{1}{4}$ inches wide and 1 to $1 \frac{1}{2}$ inches deep (fig. 1). To lessen the inconvenience to ordinary traffic occasioned by this rail, the "step rail" (fig. 2) was introduced, consisting of a fiat surface 3 to 5 inches wide, which can be used by ordinary wheels, and a raised tread on the outer side 1 inch higher and $1 \frac{3}{4}$ inch wide, on which the flanged wheels of the cars run.

Fig. 1.

Fig. 2. This form of rail is still very general in America, and is a good one for the tramways, though not for the general public. In 1858-9 Train, an American, endeavoured to obtain an Act of Parliament authorizing tramways in London; failing in that, he laid tramways, by consent of the road authority, first in 1860 at Birkenhead, and soon afterwards in London. The rail laid at Birkenhead had a step of $\frac{3}{4}$ inch between flat surfaces 3 inches and $1 \frac{1}{2}$ inches wide. That laid in London was narrower, with a step of half an inch, but the slippery flat surface and the step of the rail caused serious inconvenience and numerous accidents to carriages, and the tramways were removed in a few months, after one of them had been successfully indicted as a nuisance In Birkenhead, in spite of complaints of the inconvenience caused to the general traffic, the original rails remained until 1864, when, after a short length had been laid as an experiment with a rail of the grooved section now in general use (fig. 3), the whole of the tramway, several miles in length, was relaid with it The
tramway was subsequently indicted as a nuisance, but ${ }^{2}$ he trial resulted in a verdict in favour of the grooved rail In 1868 an Act of Parliament authorizing the construction of about 63 miles of tramways in Liverpool was obtained ; and in 1869-71 Acts for 61 miles of tramways in London were passed, and were soon followed by other Acts for tramways in Glasgow, Dublin, Edinburgh, and other provincial towns.

In .1870 the Tramways Act was passed, enabling the Board of Trade to make provisional orders euthorizing the construction of tramways in Great Britain, with the conseat of the local authorities, and giving considerahle powers for regulating their construction and working. By the Act the gauge, unless otherwise prescribed by special Act, is to be such as will admit* of the use of carriages constructed for use on railways of a gauge of 4 feet $8 \frac{1}{2}$ inches.' Tramways for which Acts had been previously obtained were of 4 feet $8 \frac{1}{2}$ inches gauge, to comply with a standing order intended for railways, and not to make them a vailable for railway rolling stock, which the narrow groove of an ordinary trammay rail will not admit. There is reason to think that a narrower gauge, such as 3 feet 6 inches, is often sufficient and preferable to the 4 feet $8 \frac{1}{2}$ inches gauge.

Tramways in towns, authorized by provisional order, are to be constructed in the middle of the road, and are not to be so laid that for 30 feet and upwards a less space than 9 fect 6 inches shall be left between the outside of the footpath and the rail, if one-third of the owners or occupiers of premises abutting upon that part of the road object. Vehicles are thus enabled to stop at the road side without hindrance from the tramcars. To leave 9 feet 6 inches on each side of a single line of tramway of 4 feet $8 \frac{1}{2}$ inches gauge a street must be upwards of 24 feat wide. No carriage used on a tramway must extend more than 11 inches beyond the outer edge of the wheels, and there must be a space of at least 15 inches between the sides of the widest carriages or engines to be used, when passing one another. A width of not less than 3 feet 2 inches between double lines and at passing places is thus necessary, and a double line of tramway, leaving 9 feet 6 inches space on each side, requires a street at least 32 feet 6 inches wide between the footways. In narrow roads there is a convenience in having the tramway at the side, and it is sometimes provided for in special Acts. The space between the rails, and for 18 inches bejond them, is repairable as part of the tramway. Power is given to local authorities to purchase tramways at the expiration of twenty-one years, and they may be removed under certain circumstance3.

It appears from a parliamentary return that in 1886 there were 779 miles of street tramways open for traffic in Great Britain, on which a capital of $£ 11,503,438$ had been expended, the net receipts for the year being $£ 563,735$, and the working expenses 79 per cent. of the gross receipts.

The groored rail first laid in England was $4 \frac{1}{3}$ inches wide er sn inch thick, having a tread or rolling surface for the wheel 13 inches wide, and a groore $\frac{8}{4}$ inch deep, $\frac{3}{4}$ inch wide at the bottom, and $1 \frac{4}{4}$ inches wide at the top (fig. 3). The rail was spiked through to a longitudinsl timber lisid on crosa sleepers, and secured to them by angle brackets and spikes. This rail snd method of laying were generally sdopted, but it was found
 that the heads of the spikes wore off, snd the rails required respiking, sud split and worked loose at the joints. A rail knomy as the box-rail was introduced, having flanens hrlow on each side, through holes in which clips are driven to fasten the rail to the trie
ber．This constitutes a good fastening，and the flanges give atiffoess to the rail，bue the clips canso gaps between the rail and the paving stones，wlich lead to the formation of ruts alongside the rails．The longitudinal timbers，instead of being laid on cross sleepers，on which the paring does not bed well，are citen fixed in cast－iron chairs con－ nected by trausverse tie－bars．A bed of concrete is alwaya laid under the longitudinal timbers，and should extend to the whole width of the paviog．The rails first laid weighed 40 tb per yard，bat it was soon found desirable to increase the weight to 60 to per yard．It is， however，impossible to fish the joints of rails like the above，and it was found that the working of the joints under the passage of the cars loosened the ends of the rails，dislocated the paring，and damaged both the tramway cars and ordinary vehicles．Tramways proved hardly able to withetand beavy atreet trafic；and to provide for steam traction a stronger form of rail and a better aystem of perma－ nent way became necessary．Many forms of iron bearings have been derised，the rail being either supported continuously or on chairs at intervale．In the best of these the tram rail can be replaced when worn without disturbing the foundation．In the syatem used in Liverpool cast－iron longitudinal sleepers weighing 80 and 90 lb a yard carry ateel rails of a $T$ section（fig．4）woighing 40 Ib a yard， both sleepers and rails being held down by bolts to jawe anchored in the concrete foundation．The rails can be renewed and the sleepers can be taken up with very little distarbance of the naving．

Fig． 4.

Fig． 5

Steel rails of a flatfooted or a bridge section，and of such a depth as to constitute both rail and sleeper，are also used．In some of the latest and hest examples the rail is of a flatfooted section（fig．5）， 6 or 7 inches deep，and 6 or 7 inches wide at the base，weighing 65 to 93 tb per yard．Tho head has a groove either planed out or rolled in it，giving the usual proile to the upper surface．The joints are fished in the ordinary way，and are as etrong as the rail itself．Cross ties are sometimes used，but when the sail is slightly bedded in the concrete foundation they are dispensed with．The paring is aet in cement close against the rail，and is bedded directly or in sand on the base of the rail，upon which there is a bearing of 1⿱十口⿱⿰㇒一乂凵，or 2 inches．Such a tramway will stand ateam traction and the heariest street traffic，bat the rail，which is of an expensive section，requires entire renewal when the head is worn out．Iron or steel continuous bearings are less elastic，and therefore more jarring and noisy than timber slecpers．

The profile of the upper surface of tram rails has been little altered since the first grooved rail was devised for Birkenhead in 1863， though slight modifications have been made in the form of the groove with the ohject of lessening tractive resistauce．For the sake of the ordinary traffic the groove should not exceed 1 inch in Fidth，and a rounded section with sides splaying outwards facili－ astes the forcing out of the mud and dirt．A nearly npright side aest the tread or rolling surface with a pplay on the inner side throws the mud aray from the wheel．The upper corners of the rail should be angular，to mako as thin a joint as possible betreen the rail and the paving．There has been a tendency to diminish the width，and a rail as narrow as 3 inches has leen laid．A deviation from the usual profile has been adopted in Liverpool， where the groove is in the middle of a rail $3 f$ inches wide．

A tramway rust not only afford a good rolling surface capable of bearing the weights running on it，hut it must also be able to resist the shocks of heavy vehicles crossing the rails in all directions． The space between the raile，and for 18 inches beyond them，which is repairable with the tramway，is slways paved，eometimes in pro－ rincial towns and in the suburbs of London with wood，but generally rith stone sets in the best manner on a corrcrete foundation．The sots alongside the rail should be carefully dressed and fitted to make a thin joint．There is much extra wear，and a tendency to form a rut alongside the rail，arising from ordingry wheels using the tram rail，and unless the aurface of the paring is kept to the level of the rail the wheels of carriages are caught by the rail，and damago and accidents are caused．To resist the wear near the rails，chilled cast－ iron blocks have boon nsed where the traffic is great．On a mac－ adamized road there is the same tendency to form a rot along the poter edge of the tramwey paring，which is to some extent prevented by giving a eerrated edge to the paving．There is alwaya great diffi－ culty in keeping the road surface to the level of the paring，and it is better to pave the entire width of a etreet in which a tremway is laid．

Although cars can be drawn round very sharp curves，the latter should be as casy as possible．A radius of 150 to 200 fect is the least that should be used when there is any choice，hat necessit？ may compel the use of curves of 50 or even 30 feet radius．On such curves，however，the cars are liable to be strained，aid the resistance to traction is greatly increased．

A single line of tramway must have passing places for the cars， consisting of pieces of double line of length sufticient to hold two cars at least，with connecting curves and the necessary points and crossings．Where steam or other mechanical power is to be used the passing loops should be at least 200 feet in length．There is inevitable delay and interference with the street traffic at passing places，and where cars are to be run at frequent intervals it is better to lay down a douhle line if the atreet is wide enough．It is a great advantage to the ordinary traffic to have the cars moving always in the same direction on the same line of rails．

For horse traction fixed points of chilled cast－irou or steel ar eufficient，as the driver can turn his horses and direct the car on to either line of rails．When mechanical power is used，drop puin－ or movable points are required．In the former the groove leadino into the road to be taken is of the full depth，and the other groove shallow，so that the engine and cars naturally take the former． On coming out of the shallower groove to the deeper there is，how－ ever，a drop onconntered which is damaging to the rolling stock， and especially to the engines．Movable points require setting by hand，or they are actuated by a spring or balance weight．In one form of epring point one groove is filled up by a tomgue which is pressed down by wheels passing out of a loop，but which forms the side of the groove for wheels running the opposicu direction．A epring point of eteel，which is forced aside by the flange of the wheel passing ont，and shuts close again by its own elasticity，is also successfully used．A movable point on one side of the way is sufficient．Crossings are eithcr built up from rails cut to the required angle，or they are cast solid in steel or chilled iron．Fill． ing pieces of the same material，roughened on the surface for foot－ hold，are inserted between the rails at the angles of points and crossings．Both points and crossings wear rapidly，and are trouble－ some to maintain in good condition，and when not so maintained are dangerous to ordinary traffic．

The rramcars generally in use in the United Kingdom are con－ structed to carry 22 persons inside and 24 outside．They are 16 feet long in the body，or 24 feet including the platforms at each end，and weigh $2 \frac{1}{3}$ to $2 \frac{3}{4}$ tons when empty and about $5 \frac{1}{3}$ tons when fully loaded Smaller cars to carry 20 or 14 persons inside，drann by one horse，ere useful to run at short intervals when the traffic is not great，a frequent service of care being a great element of success．The car wheels are usually of steel or chilled iron，with a flange half an inch deep，and are fitted with powerful brakes． The axles are about 6 feet apart，giving a short wheel－base to enahle the cars to pass sharp curves，but with the disadvantage of overhanging ends．Cars to be drann by mechanical power，espe－ cially if outside passengers are to be carried，should hare a flesible wheel－base，either by means of bogie frames or radiating axles． In Hamburg and Copenhegen tramcars have wheels witbout flanges， and a emall guiding wheel running in the groove，which can be raised to allow the car to leave the track．

The tractive force required on a straight and level tramway is foand to vary from Ibo to to of the load，according to the con－ dition of the rails．On a tramway in average condition it is about $\frac{1}{1}$ ．The resistance is thus at the best nearly double that on a railway，and sometimes as much as on a good pavement． This is due to the friction of the flange of the wheel in the grooved rail，and to the circumstance that the latter is always more or less clogged with dirt．The clearance between the flange and the groove is necessarily small，as the former must have sufficient strength，and the latter must be narrow．The least inaccuracy of gauge，therefore，cauaes extra friction，which is greatly increased on curves．By removing the flanges from two of the four wheels of a tramway car Tresca found that the resistance was reduced from $\frac{1}{10}$ to $\frac{1}{18}$ of the load．The resistance due to gravity is of course not lessened on a tramway；and，if $\frac{1}{100}$ of the load be the tractive force required on the level，twice as much，or $\frac{1}{60}$ of the load， will be required on a gradient of 1 in 100 and three times as much on a gradient of 1 in 50 ．To start a tramcar，four or five times as great a pull is required as will beep it in motion afterwards，and the constant starting after stoppages，especially on inclines，is very destructive to horses．Horses employed on tramwaye are worked only a few honrs a day，a day＇s work being a journey of 10 or 12 miles，or much less on steep gradients．In London a tram car horse bought at the age of five years has to be aold at a low price alter about fonr years work．On the Edinburgh tramways，in conscquence of the steep gradients，the horses last a lese time，and they have to be constantly shifted from ateep to easier gradients． The cost of traction by horses is generally $6 d$ ．or 7 d ．per milo for two horses，and more when the gradients are stecp．

The application of steam as a motive power on strect tramweys 15 attended with epecial diffeulties，arwing from the conditions
ander which the eogines have to work. A tramway engine must be able to draw its load up steep gradients, demending perhaps seven or eight times the power required on a level, and it must have tire necessary adhesion without being too heavy for the permanent way. It must be capable of traversing sharp curves, of going backwards or forwards with safety, and of stopping and starting quickly. Por the safety and convenience of the public the Board of Trade require that tramway engines shall have brakes to each wheel, to be applied by haud and by steam, a governor eo arranged as to shut off the steam and apply the brakes when the engine -xceeds the speed of 10 miles an hour or other stated speed, an indicator to show the speed, a whistle or bell to be sounded as a waraing, and a fender to push aside obstructions; the engine must be free from noise produced by blast, and from clatter of machinery suoh a to constitute a reasonable ground of complaint; and the machinery and fire must be concealed from view; no smoke or steam must be emitted so se to constitute any reasonable sround of complaint to passengers or the public.

The first attempt to use steam on a modern tramway was with Grantham's combined engiue and car. It was about 25 feet long, having a vertical boiler in a central compartment, with the steam cylinders below, driving one pair of wheels 2 feet 6 inches in diameter. It carried 20 passengers inside and 24 outside, weighing $6 \frac{1}{2}$ tons empty and 12 tons when fully loaded. In a later car the boilor and machinery were at one end, and the body of the car was carried on a bogie frame. In a combined engine and car the weight of the car and passengers is utilized for adhesion of the driving wheels, and this is conveniently effected in Rowan's car, in which there are two four-wheel bogies, the leading one csrrying the engine and boiler, and half the bady of the car and passengers. The engine can be detached from the car for repair and another engine can be substituted in a few minutes. Economy of rolling atock, and the advantage of being abla to use cars intended for horses, are in favour of independent engines. They are usually in general construction similar to locomotives, but are enclosed so as to resemble in outward appearance a short tramcar. The cylinders are 6 to 9 inches in dismeter, with a stroke of 10 to 12 inches. The wheels are coupled, 2 to 3 feet in diameter, and the engines weigh 4 to 6 tons mith fuel and water. The governor to shut of steam and apply the brakes when any determined speed is attaine is actuated either by the engine wheels or by an independent wheel to prevent the possibility of the brakes being put on when the driving-wheels slip. An effectual way of rendering the exhaust steam invisihle is to condense it by passing it throngh water in a tank, or through a shower of water let off at each blast, but when the water gets hot it must be changed, and in streets it is difficult to get rid of the hot water. Several methods of superheating by passing the exhanst steam through the fire have been adopted, but they are all attended with an increased consumption of fuel, which in cold damp weather is considerable. It is now preferred to pass the stean into tubes exposed to the air on the top of the engine car, from which the condensed water is returned to the feed-tank, to be again pumped into the hoiler at a high temperature. Any stesm remaining uncondensed passes into the smoke-box. Compound cylinders have been applied to tramway engines, giving a greater range of power, economizing fuel, and rendering the exhaust steam easier to deal with. The extra complication of. a compound engine is, however, e drawback.

The cost of steam traction with engines of ordinary size is generally 3 d . to 4 d . per mile run by the ongine, snd more on lines with stcep gradients: 'To this must be added for depreciation 10 per cent., or, according to some authorities, 15 per cent. on the original cost of the engines, making altogether 4 d . to 6 d . per mile run on a tramway with average gradients.

Fireless engines were first tried io New Orleans, and have been in successful use on tramways in France for some years. The motive power is obtained from water heated under pressure to a very high tomperature in atationary hoilere and carried in a reservoir, where it gives off sieam as th 7 pressure and temperature are reduced. Two tons cf water heated io give a steam-pressure of 250 tb to the squars inch serves for a run of 8 or 10 miles, leaving more thain $\frac{0}{20}$ of the water and a pressure of 20 to 25 Ib above the atmosphere on returning wo the hoiler. Large boiler-power is required to reheat the engine reservoirs quickly, and this cannot be afforded for only a few engines, but, when worked on a sufficient scale, the fireless engines are claimed to be economical, the economy resulting from the generation of the steam in large stationary boilers.

Compressed air as a motive power offers the advantage of haviug noither steam nor the products of combustion to be got rid of. In Scott Moncrieffe engine, which was tried on the Vale of Clyde tramways in 1876, air was compressed to 310 方 on the square inch, and expanded in the cylinders from a uniform working pressure to that of the atmosphere. There is a considerable loss of beat during the expansion of the air which is attended with a serious lass oi pre ....o, and in Mékarski's system, which has been in use tor the pr...s.on of tramcars at Nates for eeven yeare, the lose of pres-
sure is considerably lessened by heating the air during expansion. The air, at a pressure of 426 to per square inch, is stored in cylindrical reservoirs beneath the car, and before use is passed through a ressel three quarters full of water heated to $300^{\circ}$ F., by which it is heated and mixed with steam. The heat of the latter is absorbed by the air during its expansion, first to a working pressure which cen bo regulated by the driver, and then to atmospheric pressure in the cyliuders. At Nantes the average cost for three years for fropelling a car holding 34 persons was about 6 d . per mile.
ln San Francisco a main charged with air at a pressure of about 120 ib per equare inch has been laid along the tram route, from which reservoirs on the cars are charged. by means of standpipes and flexible connexions at convenient points, the operation taking a very short time. The inventor claims to utilize 30 per cent. of the power applicd to the compressor.

Strcet tramways-worked by mesns. of a wire ropo have been in successful operation in San Francisco since 1873. There are now upwards of 24 miles of double line in San Francisco, and 10 miles in Chicago, and the system is being adopted in other American and colonial cities. It has also been in operation in Englaud at Highgate Hill for aeveral years, and is about to he adopted in other localities. The motive power is transmitted from a stationary engine by a rope of steel wire running always in one direction up one track and down the other, in a tube midway between the rails, on pulleys which are arranged so as to suit curves and changes of gradient as well as straight and level lines. Over tho rone is a slot $\frac{3}{4}$ inch wide, in which travels a flat arm of ateel connecting the dummy car with the gripper which grasps the cable. 'l'he flat arm is in three pieces, the two outer ones constituting a frame which carries the lower jow of thegripper, with grooved rollers at each end of it, over which the cable runs when the gripper is not in action. The upper jaw is carried by the middle piece, which slides within the outer frame, and can be do. pressed by a lever or screw, pressing the
cable firston the rollers, and then on the lower jaw until it is frmly held. The speed of the cable, which is genorally 6 to 8 miles an hour, is thus imparted to the car gradually and without jerk. The arrangements for passing the pulleys, for

Fís. 6.-Gripper. changing the dummy and cars from one line to the other at the end of the road, for keeping the cable uniformly taut, and for crossinge ond junctions with other lines are of considerable ingenuity. When the cars are cast off from the cable they must be stopped by hand brake., which on stcep gradients especially must be of great power.

The systerm has advantages on double lines with few and easy curvee when the gradients are long and oteep, and it can bo employed on gradients too steep for steam traction. On level lines it is doubtful if it could compete in economy with steam, or
 en with borse traction, unless with a very frequent service of cars, though then it presents the advantages of being comparatively quiet, and freo from snmoke and steam, aud of admitting a frequen service of cars with little extra cost. On the cable roads of San Franciaco it has been found that, of the average daily power employed, 68 per cent. is expended in moving the cables, \&ic., 28 per cent. for the cars, and 4 per cent. for passengers. It is considered that it is practicable to utilize in moving cars and passengers as much as 50 per cent. of the power, providod the cars are fully loaded and run at short intervals.

Electricity has been applied as a motive power on a tramway about 2 miles long at Blackpool. The current is conveyed by two copper conductors in a central channel beneath the roadway, and is communicated to the motors in the car by a collector runniug
apon the conductors and fissiog through a narrow slit in the channel. The return current passes through tho rails. The cars carry as many as 56 passengers on a level line. Traniways have also been worked by accumulators at Antwerp and Brussels, but the weight of them appears to be at present prohibitory to this method of applyiog electricity, oxcept for short trips. See Traction.

TRANCE. See Sleep; also Magnetism (Animal).
TRANI, a seaport of Italy, on the Adriatic, in the province of Bari, and 26 miles by rail west-north-west of that town, still retains its old walls and bastions, with the citadel, now used as a prison. Some of the streets remain much as they were in the medieval period, and many of the houses display more or less of Norman decoration. The cathedral, on a raised open site near the sea, dating from about the year 1100, is a basilica with three apses, a large crypt, and a lofty tower. The arches of the Romanesque portal are beautifully ornamented, in a manner suggestive of Arab influence ; the bronze doors, executed by Barisanus of Trani in 1175, rank among the best of their period in southern Italy. The capitals of the pillars in the crypt are fine examples of the Romanesque. The interior of the cathedral has been barbarously modernized. The vicinity of Trani produces an excellent wine (Moscado di Traai); and its figs, oil, almonds, and corn are also profitable articles of trade. The harbour was once deep and good, but latterly has got silted up. The population of the town in 1881 was 25,173 (commune 25,647 ).
Trani is the Turenum of the itiDeraries. It first became a Pourishing place under the Normans and during the crusades, but attaiued the acme of its prosperity as a eeat of trade with the East ander tho Aagevine princes. Several synagogues continue to afford an indication of its former commercial prosperity.

TRANQUEBAR, a seaport town in the Tanjore district of Madras presidency, India, in $11^{\circ} 1^{\prime} 37^{\prime \prime}$ N. lat. and $79^{\circ} 55^{\circ}$ E. long. In the 17 th centnry it belonged to the Danes; it mas taken by the Eritish with other Danish settlements in 1807, but restored in 1814, and finally purchased in 1845 for a sum of $£ 20,000$. In Danish times Tranquebar was a busy port, but its prosperity has fluctuated considerably of late years, and is now at a very low ebb. It was the first settlement of Protestant missionaries in India, founded by Ziegenbalg and Plutschau (Lutherans) in 1706 ; and as a mission station it still retains its importance.

TRANSBAIKALIA (Zabaikalskaya Oblast), a province of Eastern Siberia, to the east of Lake Baikal, has Irkutsk on the west, Yakutsk on the north, the province of Amur on the east, and Mongolia on the south. Its area ( 240,780 square miles) is about as great as that of AustriaHungary, but its population is under half a million. With regions of a purcly Siberian character on the one hand, and including on the other the outer borders of the Mongolian steppes and the upper basin of the Amur, Transbaikalia, forms an intermediate link between Siberia, Mongelia, and the northern Pacific littoral. The inountains of the Yablonovoi Khrebet, which run in a north-easterly direction from the sources of the Kerulen to the bend of the Olekma in $56^{\circ} \mathrm{N}$. lat., divide the province into two quite distinct parts: to the west the upper terrace of the high East Asian plateau continucd from the upper Selenga and Yenisei (from 4000 to 5000 feet high) towards the plateau of the Vitim ( 3500 to 4000 fest) ; and to the east the lower terrace of the same plateau (about 2800 feet high), which appears as a continuation of the eastern Gobi. The continuity of the high plateau extending from the upper Selenga to the upper Vitim was for a long time overlooked in consequence of a broad and deep valley by which it is intersected. Beginning at Lako Baikal, it pierces the huge north-western border-ridge of the plateau,
aud runs eastrard up the Uda, with an imperceptible gradient, like a gigantic railway cutting enclosed between two steep slopes, zending another brahch south towards Kiakhta. After having served, through a succession of geolugical periods, as an outiet for the water and ice which accumulated on the plateau, it is now utilized for the two highways which lead from Lake Baikal over the plateau ( $3500-4000$ feet) to the Amur in the east and the Chinese depression in the south. Elsewhere, the high and massive border-ridge on the north-western edge of the plateau can be crossed only by difficult footpaths. The border-ridge just mentioned, pierced by the wide operning of the Selenga, runs from south-west to north-east under different names, being known as Khamar-daban to the south of Lake Baikal (the Khamar-daban peak raising its bald summit to a height of 6900 feet above the sea), and as"the Barguzia Mountains ( 7000 to 8000 feet) along the eastern bank of the Barguzin river, while farther to the north-east it has been described by the present writer under the names of the South Muya and Tchara Mountains ( 6000 to 7000 feet). Resting its south-east base on the plateau, it descends steeply on the north-west to the lake, or to the broad picturesque salleys of the Barguzin, the Muya, and the Tchara. Larch, fir, and cedar forests thickly clothe the ridge, whose dome-shaped rounded summits (goltsy) rise above the limits of tree vegetation, but do not reach the snow-line (here above 10,000 feet). The high plateau itself has the aspect of an undulating table-land, intersected by low ranges, which rise some 1500 or 2000 feet above its surface, and are separated by broad, flat, and marshy valleys, which the rivers languidly traverse till they find their way across the border-ridges. Those of the valleys which are better drained have fine meadow lands, but as a whole the plateau has the appearance, especially in the north, of a wet or marshy prairie in the hollows, while the hills are thickly clothed with forests (almost exclusively of larch and birch). Numberless lakes and ponds occur along the river courses. Tungus hunters find a livelihood in the forests and on the meadows, but permanent agricultural settlements are impossible, corn seldom ripening on account of the early frosts. The lower parts of the broad and flat valley of the Djida have, however, a few Cossack settlements, and on the upper Selenga and Yenisei Mongolian shepherds (Uryankhes and Darkhates) inhabit the high grassy valleys abont Lake Kossogol ( 5560 feet above tha sea). Quite different is the lower terrace of th ...au, occupied by the eastern Gobi and the Ne. wansk region of Transbaikalia, and separated from the above by the Yablonovoi ridge. This last is the south-eastern border ridge of the higher terrace. It rises to 8250 feet in the Sokhondo peak, but elsewhere its dome-shaped summits do not exceed 5000 or 6000 feet. When crossing it from the north-west, about Tchita, the traveller hardly perceires that he is approaching the great water-parting between the Arctic and the Pacific oceans. Numberless lakes, with liat undefined borders, feed streams which flow lazily amidst marshes, some of them to join the great northward rivers, others to find their way to the Amur and the Pacific. Low hills rise gently abore the edge of the plateau, but an abrupt slope descends towards the south-east, where the hill-foots of the Tablonovol are nearly 1500 and 2000 fept lower than on the north-west. Climate, flora, and fauna suddenly change as soon as the Yablonovoi has becil crossed; the steppes of Dauria (continuations of those rif the Gobi), covered with a bright luxuriant regetation, meet the view of the spectator. The Siberian flora give way to the mucb richer Daurian flora, which in turn is exchanged for the Pacific littoral fiora as 8000 as th, traveller descends from the lower terrace of the platea, towards the Manchurian plains and lowlands.

The lower terrace, occupied in Transbaikalia by the Nertchinsk district, has the character of a steppe, hut is also intersected by a number of ranges, all ruuning southwest to north-east, and all being plications of Silurian and Devonian rocks, containing silver, lead, and copper, and also auriferous sands. Agriculture can be easily carried ou in the broad prairies, the only drawbacks beng droughts, and also frosts in the settlements in the higher close valleys of the Nertchinsk or Gazinur Mountanns. The lower terrace is in its turn fringed by a border-ridge-the Great Khingan -which has, with reference to the lower terrace, the same characters as the Yablenovoi in relation to the upper, and separates Siberia from northern Manchuria. This inportant ridge, as shown elsewhere (vol. xxii. pp. 3, 4), does not run from south to north, as represented on the old maps, but from south-west to north-east ; it is pierced by the Anur near Albaziu, and joins the Othotsk ridge, which in its turn does not join the Yablonovoi Mountains. The inountains drawn west and east on older maps to connect the Yablonovoi with the Okhotsk ridge bave no actual existence.
The rivers bclong to three different systems, -the affuents of Lake Baikal, of the Lena, and of the Amur. Of the first tho Selenga ( 800 niles long) rises io the Hanghai Mountains of uorthwestern Mongolia, oue of its great tributaries (the Ehin-gol) being an emissary of Lake Kossogol. It flows past Selenghinsk and enters Lake Baikal from the south east, forminga wide delta. The Tchikoi, the Khitok, and the Ulla are its chief tributaries in Transbaikalin. ${ }^{2}$ The Pargnzin and the Upper Angara are two large tributaries of Lake Baikal from the north-east. Of the tributarius of the Lenn, the Vitim with its afluents (Karenga, Tsipa, Minya, Kitar, Katakan) flows on the ligh platean through nninhakited regions, as also does the Olckma. The tributaries of the Amur, which is formed by the junction of the Shilka and the Arguü, are much more inportant. The Arguni, which at a quite recent enoch received the waters of the Dalai-1uor, and thus had the Keruleîi for its source, is no longer iu communication with the rapidly drying Mongolian lake, anill las its sources in the Gañ, which flows from thic Great Khinyan. It is not navigable, but reeeives the Gazinur and scveral other streans which water the Nertehinsk mining district. The Shilka is formed by the union of the Onou and the Tchita rivers, and is uavigable from the town of Tchita, thus leing an important clamael of transit to the Amur.
Lake Baiknl, with an area of 12,430 sqquare miles (nearly equal to that of Switzerland), exteuds in a hulf cresceut from sonth-west to north-east ; it has a length of over 400 miles aud a wilth of fro:n 20 to .53 miles. Its lecrel is 1561 fect above the sea. ${ }^{3}$ About the middle it is tliviled into two parts, the Great Lake and the Little Lake, by tho island Olkhon and the peniusula of Svyatoi Nos, which closely approach one another. Between the two thero is a subunerged ridpe, which must be considered as a continnation of the Rarguzin $A$ pps. The wide delta of the Sclenga nariows the Great lake in its middle part, and renders it more shallow in the east than in the west-the gyteatest depth ( 4186 feet) having been reachecl by $D_{\mathrm{r}}$ Godlerski in the sonth-west. The depth of the Little Like does not exceed 210 feet. According to Tcherskv, the trongh yov occuried by the base had its origin int three separate synclinal valleys, which dato from the Azoic epocl, and wero gilfs of the ocean during the Silurian or Huroman preziod. They coalesced at a much later epoch. ${ }^{3}$ Of other lakes, the Gusinoye and Lako launt on tho Vitim plateau, aull Oron at its lasc, aro worthy of notice. Many lakes yield common salt or sulphato of patron.
The high $r^{\text {latean }}$ consists of granites, gneisses, and syenites, Covered with Laurentian schists. Silurian aud Devouian marine denosits occur only on the lower terrace. Siace that timic the region has not been under the sea, aud only freshwater Jurassic deposits and coal-beds are met with in the depressions. During the Glacial period most of the high terrace of the platean andl its looriler ridges were nndouhtedly covered with yast glaciers. Volcanic rocks of more recent origin (Mesozoic ?) are nict with in the north-western border ridge and on its slopes, as well as on the Vitim platcau. During the Glacial period the fanna of the lowest parts of Transbaikalia was decidedly aretic; while during tho Lacustrine or Post-Glacial period it was covered with uumberless lakes, the

[^219]shores of which were inhabited by Neolithic man. Only few traces of these have remained, and they are rapidly drying up. Easthquakes are very frequent on the shores of Lake Baiksl, especially at the mouth of the Selenga, exteoding as far as Irkutsk, Barguzin, and Sclenglunsk; in 1862 an extensive area was submerged by the lake. Numerous iniveral spings, some of thens of ligh repute, ate spread all over Transbaikalia. The chicf of them are the hot alkaline springs ( $130^{\circ} \mathrm{F}$.) at Turka, at the month of the Barguzin, whither hundreds of patients resort annally, those of Pogromna on the Ula (very similar to the Scltzer springs), those of Motokova near Tchita, and those of Darasm in the Nertchiusk aistrict (very rich iu carbone acid and phosphate of iron).

The flora and fama of Transbaikalia, owing to their intermediate character between a purely Siberian flora and fanna and those characteristic of the Mongolian and Manchurian regions, bave bects the subject of many careful investigations siace the time of Pallas down to those of TUrezaninoff, Middendorff, Schrenck, Radide, and Polyakoff. Their various characters in different parts of this extunsive territory could not be described withou eotering too largely into details. The realer may consult the works of the authors jnst nameil (seo vol. xxii. p. 12).
The clinate is, as a whole, exceedingly dry and exticme. The winter is cold and dry; snow is so trifling that the horses of the Buriats fiad their food thronghout the winter on the steppes, and in the rety middle of the winter wheelod vehicles are used all over the west. To the east of the Yablonovoi ridge the Nertchinsk district feels the influcnce of the North Pacific monsoon region, and snow falls more thickly, especially in the valleys, but thic summer continnes to be hot nud dry. On the high platean, even the summer is cold, owing to the altitude and the hunidity arising from the marshes, and the soil is frozen to a great depth. In the vicinity of Lake Baikal the moderating influcnce of the grat water basin is felt to some extent, and there is a cooler summer : in winter exccedingly deep snow covers tho goltsys and valleys of the mountains around the lakc.*
The population ( 497,760 in 1882) is exceedingly sparse, unless the immense minhalitable spaces of the plateans lee left ont of accomnt. Even on the lower terrace nearly the whole of the region on the leff bauk of the Sliilka is unsnited for agriculture, as also are the Gazimur Mountains, whert only a few settlers gain a livelihoud in some of the valleys, suruggliug amainst an unliealthy climate and the ilhnence of goite. The Russian pupulatinn there gathers arount the crown mines of the Nertehinsk district, while the steppes aro occupien by liuriats. A succession of villages, supported partly by agriculture and partly by huntidg and traile with Mongolia, are settled along the Shilka between Tehita amel Sryetensk, while farther lown the river Jlows in such a will mountain region that ouly a fow fanilies are settled, at distances some 20 mits apmet, to inaintain communication. The same is true with regard to the lower Arguñ. The valleys of the Ula, the lower Sulenga, and especially tha Tchikoi and the Khitok layo becu occuphel since the beginning of the century by Raskoluiks, who have receivel tho rane of Sencistiye on account of their large (compurnd) fanilics, and there one fiuds, in a condition of prosperity snch as is unknown in Russia proper, somo of tho tinest repeschtatives of the Russian race. The remoinder of the stepre of the Uda is occupied by Buriats, while the forests and marslicy of the platenu are the hunting grounts of the nonad Tungnses. Only the valley of the Djida ia the south of the Khamar-daban is settled in its lower parts.
The Eussiaus of Transbaikalia present a great varicty of cthnological types. Moinly owng to the difficulties of communication, maly Great Russian Rinskolnks and Little Fussian settlers liave prescrved their ethnographical features pure from any admixture; while there are, on the other ham, villages in the Nertelinsk district, chiclly composed of the earliest liussian settlers, where a great almixture of Tungrisian or Mougoliun L!ood is observable. On the upper Argun the Cossacks are in features, character, language, and mancrs largely Mongolian. The Russians along the Chimese Prontier ennstinte a separato voisko of the Transbaikalinn Cossacks. Thore is great uncertainty as to the numbers of the Buriats ; they are estimated at about 150,000 . The Tunguses munber ouly a very few thousands.

Agriculture is carried ou to a limited extent ly tho Burints and in all Russian settlements; but it prospers only in the valleys of west Transhaikalia, and partly in the Nertchinsk region, while in the steppes of the Argnin and Onon even the Russians resort chiclly to cattle-lycerling and tralc, or to hunting. On the wholc, com has to bo imported; summer wheat and summer rye, oats, and barley are the chief crops in the east, winter rye not being sown in consequence of tho waut of suow. Cattlc-rearing is extensively carrict on, especialiy by the Buriats, but thoir herds and flocks, which wander freely over the stepnes throughout the winter, are often destroyel in creat numbers by the snow-storms of spring. Hunting is an important occupation, even with the Russians, many of

[^220]whom leave their homes in October to spend six weeks in the taiga (forest-region). The fisheries of Lake Baikal and the lower parts of its aftuents are important. Enormous quantities of Salmo omul are taken every year; and, although the curing is most primitive, the annual yield is valued at $£ 20,000$. The Salmo thymalus, S. oxyrhynchus, and S. fluviatilis aro also taken laruely.

The possibilitics of discoverica of gold are absorbing all the iodustrial forces of Transbaikalia. Gold-diggings occur chiefly in the basins of the Shilka and the upper Yitim, also on the Tchikoi and the Khilak. No less than $25,400 \mathrm{tb}$ is extracted anuually by private cnterprise, and about 3200 Hb by the crown, at the Kare goll-digning\%, where nearly 1400 convicts are employed. The silver miming fornierly carricd on at several crown works is now on the decrease (see Nertchinsk); the quantity extracted in 1884 was only 211 th. Erery hind of manufactured ware has to be importer fron Rusoia ; and even petty trades are almost unknown in the villages.

The trade of the prorince is chiefly represented by that of Kiaklita Jhn Cossacks on the frontier carry on some trade in brick rea, eatlle, and bides with Mongolia. The export of furs is of considerahie value.
The communications of Transbaikalia are linited to the great Amur highway, which fringea the sonth coast of Lake Baikal and passes through Verkhneudinsk, Tchita, and Nertchiusk to Sryetensk, WL rr ee steamers ply down to the mouth of the Amur; in winter, further :ommunication with the Amor heyond Sryctensk is maintained on sledges on the ice of the Shilka, but in the autumn and apriog a horseback journey as far as Kumara is the only possible rethod of reaching the middle Amur. Steamer communication is also maintained for six or seven months across-Lake Baikal, from Posolskoye, at the month of the Selenga, to Listrenichnaya, 40 miles from Irkutsk. A highway connects Verkhneudinsk with Selenghinsk and kiakhta, and communication on the steppes of the Arguñ and the Onon as well as np the Barguzin is easy. The rest of Transbaikalia can be risited only on horseback.

Transbaikalis is divided into five districts, the chief towns of which (with popu'ations in 1880) are Tchita, capital of the province (12,600 inhabitants), Barguzin (800), Nertchinsk (4070), Selenglimsk (1150), and Verkhneudinsk (4150). Kiakhta has 4290 inlabitants, and Sryetensk, being at the head of the navigation, is © rising town.
(P. A. K.)

TRANSCASPLAN REGION (Zakaspiyskaya Oblast), an extensive territory to the east of the Caspian, annexed by Ruвsia within the last fifteen years, is bounded on the S. by the highlands of Khorasan and Afghanistan, on the N. by Uralsk (from whicb it is divided by a line drawn from the Mortryi Kuftuk Bay of the Caspian to the south extremity of Lake Aral), on the N.E. by Kihiva and Eokhara, and on the S.E. (where it penetrates towards Herat on the slopes of the Paropamisus, and includes the Eadhyz plateau) by Afghan Turkestan. So defined, it has an area of 220,000 square miles.

Although nine-tenths of this territory consists of uninhabitable desert, an interest attaches to it on account of the great physical changes it has undergone during the Post-Glacial period. Since Pallas visited its borders, and still more since Humboldt discussed its history, it has never ceased to attract the attention of geographers. In fact, some of the mast intercsting problems of geography, such as those relating to the changes in the cuurse of the Jaxartes and the Osus, the bifurcatiou and the oscillation of a great river, and the supposed periodical disappearanco of Lake Aral, are connected with the Transcaspian deserts; and it is here that we must• 100 k for a clue to the great physical changes which transformed the Mediterranean of Western Asia - the Aral-Caspian and Pontic basin-into a serics of separate seas, and desiccated them, powerfnily influencing the distribution of floras and faunas, and compelling the inhabitants of Western and Central Asia to enter upon their great migrations. But down to a very recent date the dry and barren deserts, peopled only by wandering Turcoman bands, remained almost a terra incog. nila, and only now are we beginning to make the very first steps towards their really scientific exploration.

A mountain chain, in length comparable to the Alps, spparates the deserts of the Transcaspian from the highlands of Khorasan. It runa from north-west to south-east, and appears as a contiuuation of the Caucasus. It begiss io the Krasnodovak peninsula of
the Caspian, under the names of Kuryanin-kara and Great Balkana, whose masses of granite and ather crystalline rock reach a beight of more than 5000 feet. Farther to the south-east these are cantinned in the muclı lower Little Balkans and Kynren-dagh (2000 feet), the Kopepet-dagh, Kesty-dagh, Asilma, and Zarya-kul, -the name of Kopepet-dagh or Kopet-dagh heing often now used to designate the whole chain which rises stecp aud wild above the flat deserts from the Caspian to the river Murghab,-a stretch of 600 miles. In structure it is homologous with the Caucasus chain; it appeers as an outer wall of the Khorasan plateau, and is scparated from it by a broad valley, which, like the Rion and lyura valley, of Transcaucasia, is watered by two rivers flowing in opposite directions,--the Atrek, which flows north-west into the Caspian, and the keshefrud, which flows to the sonth-east, and is a tributary of the Murghab. On the other side of this valley the Allahdagh and the Binalund border.ridges ( 9000 to 11,000 feet) fringe the edge of the Khorasau plateau. At its south-eastern extremity this onter wall loses its regularity where it meets with the spurs of the Hindu-kush. Descending towards the steppe with steep stony slopes, it rises to heights of 6000 and 9000 feet to the east of Kizil-arvat, while the passes which lead from the Turcoman deserts to the valleys of Khorasan are seldom as low as 3500 , usually rising to 5000,6000 , and even 8500 foet, and in most cases being very difficult. This wall is pierced by but one wide openiug, that between the Great and Little Balkans, throngh which the sea which once covered the steple maintained connexion with the Caspian.

While the Allah-dagla and Binalund border-ridges aro chiefly composed of crrstalline rocks and metamorphic slates covered with Devonian deposits, a series of more recent formations-Upper and Lower Cretaceous, aud Miocene-are shown in the otter wall of the Kopet-dath. Here astain wo find that the mountains of Asia which stretch towards the north-west continued to be uplifted at a geologically recent cpoch. Quaternary deposita have an extensive derelopment on its slopes, and its hillfoots are bordered by a girdle of loess.
The loess terrace, called "Atok" ("mountain hase"), is but narrow, ranging in width from 10 to 20 miles; still its chain of settlements have rendered it possitlo to lay down a railway which now connects the Caspian with Sarakhs. It is very fertile, but could produce nothing without irrigation, and the streams flowing from the Kopet-dagh are few and meagre. The winds which reach the northern slope of the mountains have been deprived of all their moisture in crossing the Kara-kum-the Black Sands of the Turcoman desert; and even such rain as falls on the Kopet-dagh ( $10 \frac{1}{3}$ inches at Kizil-arvat) too often reaches the soil iu the shap of showers which do not saturate it, so that the average relative humidity is but 56 and the average nebulosity only $3 \cdot 9$, as against 62 and $4 \cdot 1$ at even so dry a place as Krasnovodsk. Still, at thos places where the mountain streams are closer to one another, as at Geok-tepe, Askabad, Lntfabad, and Kahka, the villages are more populous, and the bouses are surrounded by gardens, every square yard and every tree of which is fed by irrigation.
Beyond thia narrove strip of irrigated land begins the desert, the Kara-kum, -which exteods from the mountaina of Khorasan to Lake Aral and the Ust.Urt, and from the Caspian to the Annu, interrupted only by the oases of Merv and Tejcin." It appears, how. erer, that the terrible shifting sanils blown into barkhans, or elongated hills, sometimes 50 and 60 feet in height, are groupe chiefly in the west, where the country has more recently emerged from the sca. Farther to the east tho barkhans are more stable, their slopea being covered with bushes (for the most part leafless): the caravans sometimes follow their crests, and the ahifting sands occupy restricted spaces. Large areas amidst the sands are occupied by lakyrs, or flat surfaces covered with clay which is hard as a rule, but becomes almost impassable after heavy rains. In these tazyrs the Turcomans dig ditches, draining into a kind of cistern-the hak-where the water of the spring rains kecps for a few months. Wells are sunk also along the routes of the cararaus, and water is found in them at deptha of 10 to 50 or occasionally 100 feet and more. All is not desert in the strict sense; in spring there is for the most part a covering of grass, which allows of journeys across the desert. There are sootpaths in several directions, especially from the irrigated and cultivated Atok towarda Khiva.
The vegetation of the Kari-kum cannot bo described as poor ; the typical representative of the sand deserts of Asia, the saksanl (Anabesis Ammodendron), las been almost destroyed within the last hundred years, and never appears in forests, but the borders of the spaces covered with saltcd clay are briglatened by forests of tamarisk, which are inlabited by great numbers of the desert warbler (Atraphornis aralensis) - a typical inhabitant of the sands,-sparrows, and ground-choughs (Podoces); the Houbara macquentii, Gray, though not frequent, is characteristic of the region. Hares and foxes, jackals and wolves, marmots, moles, helgehogs, and one species of marten live in the steppe, especially in spring. As a whole, the fauna is richer than night be supposed, While in the Atok it contains representatives of all the
species known in Turkestan, mixed with Persian and Himalaynu species. ${ }^{1}$

The Uzboi.-A feature distinctive of the Turcomon desert is seen in the very numerous shors, or elongated depressions, the lower 1 ortinns of which are occupied mostly with: sand impregnated with buackis? water. They are obvionsly the remains of brackish lakes, and, like the lakes of the Kirghiz steppes, they often follow one another in close succession, thus closely resembling river-beds. As the dinection of these shors is generally from the higher terraces watered by the Amu-Daria towards the lowlands of the Caspian, they were nsually regarled as old beds of the Amu-Daria, and were helil to support the idea of its once having flowed across the Turcoman desert towards what is now the Caspian Sea. A few years ago it seemed almost settled, not only that that river (sce Oxus) Howed into the Caspian during listorical times, but that, aftel having ceased fo do so in the 7 th century, its waters were again diverted to the Caspian about 1221. A succession of elongated depressions, having a faint resemblance to old river-beds, was traced from Urgenj to the gap between the Great and the Little Balkans, marked on the maps as the Uzboi, or old bed of the Oxns. ${ }^{2}$ The idea of again diverting the Amu into the Caspian was thus set afloat, and expeditions were sent out for explorations with this view. The result of these investigations by Russian engineers, especially Hedroitz, Konslin, Mushketeff, Lessar, and Svintsoff, ${ }^{3}$ was, however, to show that the Uzboi is no river-bed at all, and that no river has ever discharged its waters in that direction. The existence of an extensive lacustrine depression, where the small Sary-kamysh lakes are now the only remains of a wide basin, was proved, and it became evident that this depression, haviug a length of more than 130 miles, a width of 70 miles, and a depth of $2 S 0$ feet below the present level of Lake Aral, would have to be filled by the Amu, before its waters could adrance farther to the south-west. The sill of this basin being only 28 feet below the mesent level of Lake Aral, this latter could not be made to disappear, nor even be notably reduced iu size by the Anum flowing from Urgenj to the sonth-west. A more careful exploration of the Uzboi has shown moreover that, while the deposits in the Sary kamyslr depression, and the Aral shells they contain, bear unmis. takable testimony as to the fact of the basin having once been fed by the Amn-Daria, no such traces are found along the Uzboi below the Sary-kamysh depression; ${ }^{4}$ on the contrary, shells of molluscs still inliabiting the Caspian are found in mumbers all along it, and the smpposed ald bed has all the characters of a series of lakes which continned to subsist at the hillfoots of the Ust. Urt plateau, while the Caspian was slowly receding westwards during the Post-Pliocene period. On rare accasions only did the waters of the Sary-kamysh, when raised by inundations above the sill just mentioued, send their surplus into the Uzboi. It appears most probable that in the 16 th century the Sary-karoyblh was confounded with a gulf of the Caspiant ${ }^{3}$ and this gives nutheh plausibility to Koushin's supposition that the changes in the lower course of the Amu (which no geolarist would venture to ascribe to man, if they were to mean the alternative discharge of the Amm into the Caspian and Lake Aral) merely meant that by means of appropriate dams the Amu was made to fow, in the 13th, 14th, $15 t h$, and 16 th centuries, alternately into Lake Aral and into the Sary-kamysh.

As for the ancient texts with regard to the Jaxartes and Oxns, it becomes more and more probable that their interpretation, if pessible at ail, is ouly so when it is admitted that, since the epoch to which these relate, the outlines of the Cavpian Sea and Lake Aral have undcrgone notable changes, commensurate with those wbich are supposed to have occurred in the courses of the Central Asian rivers. The desiccation of the Aral-Caspian basin proceeded with such rapidity that the shores of the Caspian conld not possibly maintain for some twenty centuries the outlines which they have at present. When studied in detail, the general configutation of the Transcaspian region leaves no doubt that both the Jaxartes and the Oxus, with its former tributaries, the Murghab and the Tejeñ, once flowed torards the west; but the Caspian of that time

[^221]Was mot tho sea of ar layo; its galfs penetrated the Turcoman step ${ }^{10}$, and washed the luse of the I'st-Urt platean, as is shown by the depesits of it; sleells des rihed by the Russian engineers.

Kelif-Uzboi. -There is also no doubt that, instead of flowing north-westward of Kelif. the Amu once flowed to join the Murghab and Tejeñ; the suecession of depressions described by the Russian engineers as the Kelif-Uzhoi ${ }^{6}$ supports this hypothesis, which a geugrapler cannot avoid making when studying a map of tho Transcaspian region; but the date at which the Oxus followed such a course, and the extension which the Caspian basin then lad towarls the east, remain unsettled. Nuch, however, has still to be ilone before we can Iully reconstnuct the geological history of that region since the Plioces.0 epoch, or show how far the data of Piny, Straho, and Ptolemy were descriptions of entual facts. ${ }^{7}$

Popultelion. - With the exception of some 35,000 Kirghiz encamped with their herds on the Ust-Urt platean (a swelling sonne 600 to 1000 feet in leight and nearly 92,000 square miles in extent, which, owing to its dryness and cold winter, can be inhabited only by nomal cattle-breeders) and a fow Persians in the Lutfabad and Shilghyan villages of the Atok, the whole of the pormation of the Transcaspian region consists of Tuicomans. Until a very recent date their chief occupation was cattle-rearing and robbery. Even these Turcomais whe had settled abodes on the oases of the Atok, Tejeâ, and Metv were in the lhabit of encamping during spring in the steppes, and these practising robbery. Robber bands were easily formed, and on their powerful horses they extended their excursions to distances of 200 and 300 miles from their abodes. They infested the Astrabad province; and the villages of the klianates of Afghan Turkestan, from Balkh to Meshhed, were periodically devastated by them. The aspect of the steppe has, however, greatly changed since the Russian advance, the fall of the Turcoman stronghold of Geok-tepe, and the massacres which eusued; the Persians are already begiuning to avenge themselves oll the iolnabitants of the Atok by disputing with them the surplies of water coming from the Kopet-dagh.

The chief oasis of the Turcoman desert is the Atok, which extends along the base of the Kopet-dagh, and is now traversad by the Transeaspian railway. The Akhal and the Arakadj oases, collectivcly called Atok, now have a popnlation of about 42,000 Tekke-Turcomans, who hare recently settled there, and live for the most part in miserable clay huts or in felt tents (kibitkas). They raise wheat, barley, and lucerne ; and the Persians have excellent gardens. Some cotton is also grown, and the culture of the silk. worm is beginning to spread. The chief settlements are Askabad, Kizil-arvat, and Geok-tepe.
The oasis of Merv (g.v.) is inhabited by Akbal-tekkes (about 160,000), mostly yoor. In Jannary 1887 they submitted to Russia.
The oasis of Tejeñ has recently sprnng up where the river Tejeñ (Heri-rul) terminates in the desert. Formerly it was only temporarily visited by the Tekkes who came to cultivate the ficlds in summer. In 1883 it was estimated to have 7500 inhabitants.

South. II cst I'urcomania. -The region between the Heri-rud and the Murghab, as they issue fron the highlands, described in English maps under the name of Badhyz, and by the Russians as Sonth- West Turcomania, has of late attracted a good deal of attention since the Rnssian occupation of Sarakhs on the Tejeñ (see AFGhanistan and Persia) and Penjdeli on the Murghab. It has the characters of a platean reaching about 2000 feet above the sea, with hills 500 and 600 feet high covered with sand, the spaces between being filied with loess. The Borkhut Mountains which conuect the Eopet-dagh with the Sefid-kuh, reach 3000 to 4000 feet, and are crossed in a gorge by the Heri-rud. Thickets of poplar and willow follow the courses of both the Mnrghab and Heri-rud, and the treesreach a considerablo size. Pistachio and mmberry trces grow in isolated gronps on the hills; but there are few places avaibable for culture, and the Saryks (some 60,000 in number) congregate in only two oases at Yot-otan and Penjcleh. Cattle-breeding is their chiefoccnpation, and enables them to live in a certain degree of affuence. Brigandage, formerly a notable source of income, is now being suppressed. The Sarakhe oasis is now occupied by the Salors, hereditary enemies of the Tekkes, who number about 3000 tents at Old Sarakhs, and 1700 more on the Murghab, at 'Tchardjui, at Maimene, and close to Herat. - Great modifications in the life of the stenue have of course been brought about by the Russian conquest, which was followed with

[^222]great rapidity by the cunstruction of a rsilmaj from Mikbsilorsk on the Caspian to Kizi-arvat and Sarakhs, and thence to Merv and now being continued scross Bokhars tomards Samarksad. Attempts at growing cotton and tes are beiug made, snd land has been rented at Merv for cotton plantations. Cotton is to be pressed hy stesma at Bokhara and Tchardjui, to be sent to Russia by the Transcaspian railway. ${ }^{1}$
Caspiar Littoral.-The Caspisn littoral is divided into two districts, Krasnovodsk and Msnghishtsk. The fnemer has about 15,500 settled inhabitants and 3056 Turcoman krbitkss (partly shifted in summer to Persisn territory). The chief settlements of the district sre Krasnovodsk on the Krasnovodsk Gulf. Mikhsilovek, the termiaus of the Trsascaspian railmay, in regular communicstion by steamer with Baku; and Tchikishlyar, close to the mouth of the Atrek. The Manghishtak distriet, which includes the Ust-Urt plateau, has \& popnlation of abunt $34,500 \mathrm{Kirghiz}$. Its chief settlement is Alexandrovek.
The total population of the Trenscaspian region was estimated in 1883 -that is, before the annexations in South-West Turcomsnia -st from 214,000 to 260,000 inhabitants
(P. A. K.)

TRANSCAUCASIA, the name given to that portion of the Russian empire (in Caucasus, Armenia, and Asia Minor) which lies to the south of the main Caucasus ridge. It comprises the goveroments of Kutais (inclusive of the province of Batum), Tiflis, Elisabethpol, Erivañ, and Kars, with parts of Daghestan and most of Baku, and the separate military districts of Tchernomorsk and Zakataty. Sometimes Transcaucasia is identified with Southern Caucasus, and then it is intended to include the whole of Daghestan. So defined, it would have an area of 95,930 equare miles, and a population of $4,173,380$.

Threo regions must be distinguished:-(1) the narrow strip of land between the main Caucasus ridge and the Black Sea (Tchernomorsk district, q.v.) ; (2) the broad valley, watered by the Rion in the west and the Kura in the east, which scparates the main Caucasus ridge from the region next to be mentioned; (3) the highlands, mountains, and plateaus of Lazistan, Kars, and Armenia.

The valley referred to, which crosses the isthmus from the Black Sea to the C8spian, consists of two widely different sections, - the drainage-area of the Rion, which is Mediterranean in its physical characteristics, and the valley of the Kura and Araxes, which slopes to the Caspian, and in its lower parts becomes purely cis-Caspian. The Mesques or Meshik Mountains ( $3000-5000$ feet), a ridge running south-west to north-east, and probably a continuation of the Black Sea coast ridge (Tchorokh Mountains), separate the two. The drainage area of the Rion, which corresponds approximately to the government of Kutais, inclodes the former provinces of Imeritia, Mingrelia, Guria, and Swanetia on the upper Ingur and Tshenistshali. With the exception of the valley of the Rion (some 25 miles broad), and the sandy and marshy littoral, it is wholly occupied by spurs of the main Caucasus ridge, the Meshik, and the Wakhan Moontains; the last-named rise to 10,000 and II, 000 feet above the sea in their highest summits, and are intersected by deep and fertile valleys. The region is characterized by a heavy rainfall and a moist maritime climate. The vegetation, which is luxuriant, is of a circom-Mediterranean character : fine forests of decidnous trees clothe the menntain slopes, and the highland villages nestle amid thickets of azalea, almond, and rhododendron. Maize, the mulberry, the vine, and a great variety of fruit trees are cultirated. Mingrelia and Imeritia are the real gardens of Caucasus ; but the high valleys tributary to the Ingur, inhabited by Swanians, are wild and difficult of access ; in some of them, which are narrow and marshy, fevers and scurvy prevail. The Rion is not navigable, and of its tributaries only the Tshenis-

[^223]tshali and the Kvirila are worthy of mention. Several lakes (such as the Paleostom, surrounded by marshes at tho month of the Rion) occur in the coast region. The population consists of Imeritians, Mingrelians, Gurians, and Swanians, all belonging to the Kartvelian branch of Caucasians (see vol. x. p. 433), with a few Ossetians, Jews, Armenians, and Tartars. Russians are not numerous.

The pass of Suram, by which the Transcsucasisn railway now crosses the Mesques Mountaine, lesds from the valley of the Riom to that of the Kura. Spurs from the Csucasus and the Anticancasus fill up the hroad longitudinal depression between these, eo that above Tiflis the bottom of the valley is but a narrow etrip. But below that city it suddenly wideus, and otretchee for nearly 350 ruiles eastward towards the Caspian with a oteadily increasing bresdth, until it becomes mearly 100 miles wide in the steppe of Mngañ on the Caspian littoral. The snow-clad peake of the main Caucasus, descending by short steep slopes, fringe the valley on the nortb-east; while a buge wall, nuch lower, and having the characters of a border-ridge of the Armenian plsteau, bounds tho valley on the sonth-west. ${ }^{2}$ The floor of the valley gently slopes from 1200 feet at Tiflis to 500 feet in its middle, and to 85 feet below the level of the ocean on the Caspian shore; but a plateau ranging from 2000 to 3000 feet in height, very fertile along the Alszañ, a left-hand tributary of the Kura, stretchee along the southern hillfoots of the main ridge. In its lower course the Kura is joined by the Araxes, a river nearly as large as itself, which brings to it the waters of the Armenian platesu.
The bighest mountains of the Caucasas enclose the upper parts of the valley (now the government of Tiflis). An unbroken series of peaks, from 10,000 to 12,600 feet in height, mostly 6 now-clad and separated by hut slight depressions, is seen in profile as one looks from some height of the Anticaucssus towerds the main chain and the broad valley of the Kurs. Deep ehort gorges and valleys indent the steep slopes which are inhshited by Ossetians, Tubbes, Pshavs, and Ehersurs in the west, and by the various tribes of the Lesghisns in the eact. Every available pstch is osed in these high and stony valleys for the culture of barley, even at heights of 7000 and 8000 feet sbove the sea; bat csttle-breeding is the chief resource of the mountsineere, whose little communities are separated from one annther by passes in few cases lower than 10,000 feet The steppes which corer the bottom of the valley are for the most part too dry to be cultivated without irrigation. It is only nearar the hillfoots in Kshetia, where multitudinous streame supply the fields and the gardens of the platesu of the Atazan, that wheat, millet, and msize are grown, and orchards, vineysrds, and mulberrytree plantations are possible. Lower down the valley csttle-rearing becomes the chief source of wealth, while in the small towns and villages of the former Georgisn kingdom (fee Georoia) various petty trsdes, testifying to s bigh development of srtistic taste and technical skill, are widely diffused. Further down the Kura, in the government of Elizsbethpol, and especislly ou the right hsnk of the river, a population of Russisu a sriculturists-chiefly Nonconformists on the Gsidja. besutiful forests, The slopes of the Anticaucasus are covered with brosd and wide sternes rine is grown at tatir hase, warse, sud sheop The lower part of the Kura valley, which belongs mainly to the province of Baku, assumes the character of a dry steppe where the rainfall hardly reaches 13.7 inches at Bsku, and is etill less in the Mugañ eteppe (in most striking contrast with the moistness of the Lenkoran region close by). The steep slopes of the Great Caucasus are still covered with thriving forests; but forests and meadows dissppear in the eteppe, whose scanty vegetation has a Ceutral-Asian character. Only hegais, or thickots of poplar, dwsrf oak, tamarisk, and so ou, follow the sctusl course of the Kura, whose delia is covered with impenetrable grow the of rushes. The Mursin stoppe, however, does not deserve its sncient evil reputstion; the serpente with which it was said to abound are entirely fshulous, and in the winter it is full of life; herds of antelones roam over it, and its southern irrigsted parts promise to become the granary of Csucasus, ${ }^{3}$ although its unirrigated parts will probably never recover their former richaess, the Kurs liaving excavated its bed to a much greater depth. The Apsheron peninsuls, in which the Grest Caucasus terminates at Baku, to be continued farther bouth-east by a oubmarine plsteru of the Casplan, is the best of those remarkable andhtha springs which have recently given rise to an importaut while the and now supply most of the Tolga steamers with fuel, or Lenkorañ district on the elopes of the Armenian the Tatysh, account of their rich verctation of the Armenian plateau-an one of the most beautiful possessions of Ruesia in Asia.

[^224]The population includes only a few Russians (about 16,000 ); the majority are Tartar alepherds, next to whom come the Iranian Tates and Talyshes (the latter prolably aborigines of baku), whe constitute $23 \cdot 1$ jer cent. of the propulation; some 27,000 Armenians, chiefly about Shemakha, and 35,000. Kurins, or Lezghiaus, on the slope of the Great Caucasus, must be added, as also some Jews and Arabs.
A mining iudustry. of some importance has bcen growiug up of lato in this part of Trauseaucasia. The copper works of Kedabek in Elizabethpol yield from 10,000 to $15,000 \mathrm{cw}$ ts. of copper annually; nearly 300,000 cwts. of manganese are extracteif in Kutais, and 30,000 cwts. of sulphur in Daghestan and Baku; the coal-mioes of Kutais, the alum ores of Elizabethpol, and the fire-clay and cemont of Tchernomorsk, are but recently opened up.

The highlands of Transcaucasia, which extend from nortlu-west to soutleeast for nearly 375 miles, with in average width of 160 miles, must in their turn he surb. divided into two sections-the Armenian plateau, including the provinces of Erivain and Kars and parts of Baku, and the Black Sea coast-region, including the former province of Batum (now the Batum and Artvin districts of Kutais).

The former of those is an immense plateau separated by iae valley of the Araxes from the highlands of Adherbaijan and of Turkish Armenia, which belong to the drainage-areas of the Euphrates or those of Lakes Van and Urmia. All over Kars and Erivañ is a series of plateaus ranging in altitude from 5000 to 6500 feet, sometimes quite flat, sometimes broadly undulating, covered with rich meadows, and for the most part available for agricnlture. Dome-shaped mountains, isolated, or grouped into relatively low ridges, rise from these plateaus to heights which range from 8000 to 9500 feet, and occasionally reach 10,000 or 11,000 above sea-level. Several summits in the east exceed that height, and the Alaghöz reaches 13,436 feet.

This platear region is hounded on the south by the valley of the Araxes, the river which forms the frontier with Turkey, except where it is crossed by Russia-int the south of Kars and west of Erivañ. Thero the river flows in a broad valloy 4500 feet above ezs-level, aud the Kara plateau falla towards it by a steep slope, while on the other side a steep, rocky ridge of exceedingly wild aspect rises as the northern border-ridge of the South Armenian (Alaskzert) platean and the water-parting between the Caspian Sea and the Indian Ocean. This ridge, which inchedea the Allah-dagh and Kösa-dàgh ( 10,720 and 11,260 feet respectively), as also the Great and Little Ararats ( 17,100 and 12,990 feet), has no general name, but is described under the names of Shah-ioly, or Agri-dogh. ${ }^{1}$

A umber of lakes occur on the plateau, especially along its northern border-rifge, the chief being that of Goktcha, an extensive aipine basin ( 500 square miles 6310 feet above sea-level) surroutded by wild mountains. Most of the depressions of tlee Hateau bear traces of having been under water during the Lacustrine (Post-Glacial) peried. Granites and other uustratified rocks constitute the unclous of the Armenian and Kars plateaus. These are covered with Azoic slates, and partly with Devonian and Carboriferous deposits; Jurassic and Cretaceous are wanting, but the Tertiary (Eoceue and Miocene) are widely apreal both in the valley of the Rion and Kura and in the depressions of the plateau. Rocks of volcanic origin are widely diffused all over Erivañ: the Alexandropol plateau, surrounled by extinet volcanoes, is all covered with voleanic products, which overlie the Tertiarv deposits and in turn are covered with Glacial boukereclay.

The Alaghöz, the Ararats, aud the peaks around Lake Goktcha are. huge trachitic masses surrounced by voleanic rocks. "lrou and copper. ores are widely spread; alum and rock-salt are obtained; the latter at liulpi and Naklichevañ. Mineral springs are numerous. The region is watered by the upper Araxes-too rapid and rocky to lue navigated-and its tributaries, most of which How at the bottoms of deep gorges. The upper Kura waters western Kars. The climate presents all the varieties which might bo expected in a region of so varied altitudes. While cotton growa in the dry and bot climate of the valley of the lower Araxes, the winter is severe on the plateau, and Alexaudropol ( 5010 feet) bas an average temperature of only $41^{\circ} \cdot 5$ (Jan. $12^{\circ} \cdot 8$; July, $73^{\circ} \cdot 6$ ). The differeuce between summer and winter is still more striking at Erivay (3210 feet, which has in January an average of only $5^{\circ}$ while that of August reaches $77^{\circ} \cdot 7$. On the Kars plateau the winter is still more severe. - Kaghyzman ( 4620 feet) and Sary-kamysh ( 7800 fect) havo the winter temperature of Finland, and the latter place, with an annual mean the same as that of Hammerfest $\left(36^{\circ} \mathrm{F}\right.$ ), has frosts of
W. Massalsky, "Government of Kars," in Izvestia of Russ. Geotr. Soe., vol, xxiii.. 1887.
$27^{\circ}$ and heats of $99^{\circ}$. The regetation of the Kars plateau reflects these extremes of elimate, and, lesides the alpine vegetation of the high yailas (alpine meadows), we find there the Anatolian, Armenian, and Pontic floras meeting. The population of Erivan cousists of Armenians ( 54 per cent.), 'Tartars ( 40 per cent.), some $28,000 \mathrm{Kurds}$, and some 4400 Russians, together with a few Greeks and Jews. In localities under 4000 feet cotton and rice are the chief crops, oil-yjelding plants, the vioe, the mulberry, and fruit trees being also cultivated. Higher up wheat and barley are growu, while at altitudes above 6000 and 7000 feet the Tartara aurd Kurds support themselves by rearing cattle. .Many petty trades are developed in the towas among the Ammenians, and the trade of Erivañ with Persia and Turkey amounta to about $10,000,000$ ronbles.
The popnlation of the province of Kars $(167 ; 610$ in 1883) is very mixed. In a remote antiquity it was inlabited by Armenians, whose capital Ani, Mren with its beautiful ruius of a grand eathedral, and several other towus now in ruing testify to the former wealth and populousness of the country: After the fall of the Armenian empire the Turks occupied the regiou; Kurds from Kurdistan and Diarbekr invaded tho alpiue pasturages of the valley of the Araxes; later ou, Kabards, Circassians, Osses, and Karapapakhs fund refuge there; and-finally, after the last war the Mohammedans emigrated to Asia Minor (82,760 in 1878-81), while Christian Armeuians, Greeks, Russion Raskoluiks, and some Yezids took their place. The population consists now of Turks, Armeniaus, Turcomans, Greeks, Kurds, Adherbaijan Tartars, Gipsies, and Russiaos. The Kara sanjak, which was one of the grauaries of Turkey, las lost this reputatiou; but the crops (chiefly wheat and bailey) are now again increasing where the early frosts do not interfere with agriculture. Cotton is raisod in the Olty regiou; and in the valley of the Araxes gardening and the culture of the silkworm are widely diffused; while cattle-rearing is the chief source of iucome in the highlands, especially with the Kurds, who move their felt tents on the yailas to higher levels as the suminer sun buras up tlie regetation.

The western part of the Trauscaucasinn highlands comprises the Batmm and Artvin districts, which now belong to Kutais. The whole of the region is occupied by alpine ridges-the Pontic ridge in the mest, and those of Arjar and Arsian in the east, whose highest yeaks rise to 10,000 and 11,000 feet, without, howerer, reaching the limits of perpetual snow. The Tchorokh and its tributaries, mountain streams enclosed in deep valleys, water the region; the Tchorokh is navigable by small boats for 60 miles.

The coast region enjoys an excellent climate; the average yearly temperature at Batum is $65^{\circ} \mathrm{F}$., that of the coldest month (February) being $41^{\circ} 5$, and that of $\mathrm{July} 76^{\circ} \cdot 5$. During the last four years the thernometer never fell lower than $39^{\circ} \cdot 5$ at Batum. The rainfall is excessive ( 93.4 inclues), nod days are recorded on which the amount of rain exceeded 10 inches. The region has accordingly a very luxuriant and bubtropical vegetation, and even higher up the hills the villages are literally luried amidst gardens. The higher hills have luxuriant meadows. Rice is cultivated in the coast.region, and millet, barley, tobacco, and a variety of fruittrees on higber altitudes. The inlabitauts (about 90,000 in 1884) are chiefly Georgians, approaching the Gurians most nearly. The Lazes number about 2000 and the Kurds about 1000. A Sew Thernshilli, or Mobammedan Arnenians, bave found refuge in the gorge of Makrial.

Towns.-The chief towns of Traascaucasia are more important than those of northern Caucasus. Tiflis ( $q . v$.$) , with 104,024 in-$ halitants in 1883, is the capital of Caucasia. Kutais (q.v.) (13,000), to which traditiou assigus an age of 4000 or 5000 years, has grown rapidly of late, owing to its situation at the head of the alluvial plain of the Riou and the proximity of the Tlevibula coal deposits ond the Kyirila manganeso mioes. Kioni ( 4000 ) and Orpiri aro nere aduinistrative centres of Kutais. Redut-kale (620) bas lost its importaoce as a seaport, and Poti (3110), at the mouth of the Rion, has not yet become au important poit, notwithstanding efforts to improve its roadstead aud its railway connexion with Tiflis and Baku. The chief Black Sea pert of Transcaucasia is Batum ( $q: v$. ), Which has been diligently fortified of late, and has now a popula. tion of 12,000. Artvin (5860) aod Ardjari are the two otber chief towas of the Batum region. The chief tawns of the goverument ff Tiflis besides its capital are Gori, capital of Georgia (population4800), Mltzhet (770) at the junction of the Vladikavkaz higbway with the Transcaucasian railway, Telav (702u), Dushety (3600), Zakataly (1050), chief town of a separato military district, aad Signakh ( 10,340 ), whinh are built in the spurs of the main chain; while Akhattaikh (18,270), on the upper Kura and on the Kars plateau, is a lusy centre for petty trades. The old city of Ahatkataki (3200) on the same platcau is now a Russian cort. Flizabetrrol, NukHa, and Shosha (qq.v.) are tha principal towns in the province of
Elizabethpol. Baku (q.v.), the terminus of the Transcaucasian
railway, and in regular steamcr communication with Mikbailorsk ln the Transcaspian region, derives its importance from the naphtha wells which surround it. Siemakha (q.iv) ( 23,810 ), and Saligny ( 10,170 ), at the head of the delta of the Kura, and notable for its fisheries, are the only places of importance in the proviuce of Baku. Erivas (q.v.) (12,450), capital of the province of Erivañ, and the chief city of the Armenian platcan, 15 onc of the oldest cities of the country, and, owing to its position, would be inuch more important than it is, but for its climate. Etchmadzin, or Vagarshanad (2910), is the real capital (the Rome) of Armena, for its antiquities, monastery, library, and printing offices. Nakhitcherañ (5390)-the Naxuana of Ptolemy-is another centre of Armenia. The most populous town of the region, however, is Alexandropol ( 23,010 ) or Gumri (q.v.), the chief Russian fortress of Transcatcasia,-the othe: towas of Erivañ being Ani, or Oni, Norobayazet at Lsko Goktcha, and Orduhad (3600) The long-disputed Kars (q.v.), which has now 7340 inhabitants, is the chief town of the new Rassian proviace of the same name, annexed in 1878 . Kaghyzman ( 3700 ), on the upper Arazes, is but a collection of clay houses surrounded by rich gardens; Ardahan (1270), on the upper Kura, and Olty (530) are the only other towns of Kars worthy of notice as administrative centres.
(P. A. К.)

TBANSIT CIRCLE, or Meridian Ctrcle, an instrument for observing the time of a star's passing the meridian, at the same time measuring its angular distance from the zeaith. The idea of haring an instrument (quadrant) fixed in the plane of the meridian occurred even to the ancient astronomers, and is mentioned by I'toleniy, but it was not carried into prectice until Tycho lirahe constructed a large meridian quadrant: This instruinent enabled the obserfer to cetermine simultaneously righte ascension and declination, but it does not appear to have been much used for right ascension during the 17 th century, the method of equal altitudes by portable quadrants or distance measures with a sestant being preferred (seo Obsertatory and Time). These methods were, however, very inconrenient, which induced Roemer (q.v.) to invent the transit instrument about 1690 . It consists of a horizontal axis in the direction east and west resting on firmly fixed supports, and having a telescope fixed at right angles to it, revolving freely in the plane of the meridian. At the same tine Roemer invented the altitude and azimuth instrument for measuring vertical and horizontal angles, ard in $170 t$ he combined a vertical circle with his transit instrument, so as to determine both coordinates, at the same time. This latter idea was, however, not adopted elserfere, although the transit instrument soon came into unirersal use (the first one at Greenwich was mounted in 1721), and the mural quadrant continued till the end of the century to be employed for determining declinations. The adrantage of using a whole circle, as less liable to change its figure, and not requiring reversal in order to obserre stars north of the zenith, was then again recognized by Ramsden (q.v.), who also improved the nethod of reading off angles by means of a micrometer microscope as desuribed below. The making of circles was shortly afterwards taken up bj Troughton (2. \%), who in 1806 constructed the first modern transit circle for Mr Groombridge's observatory at Dlackheath, but he afterwards abandoned the idea, and designed the mural circle to take the place of the mural quadrant. In the United Ningdom the transit instrument and mural circle continued till the middle of the present century to bo the principal instruments in obserratories, the first transit circle constructed there being that at Greenwich (mounted in 1850), but on the Continent the transit circle superseded then from the jears $1818-19$, when two circles by Repsold (q.v.) and by Reichenbach (q.v.) mere mounted at Göttingen, and one by Reichenbach at Konigsberg. ${ }^{1}$ The firm of Repsold was for a number of years eclipsed by that of Pistor and Martins in Berlin, who furnished the obserratories of

[^225]Copenhagen, Albany, Leyden, Leipsic, Berlin, Washington, and Dublin with first class instruments, but since the death of Martins the Repsolds have again taken the lead, and have of lste years made transit circles for Strasburg, Bonn, Wilhelmshafen, Williamstown (Massachusetts), Madison (Wisconsin), \&c. The observatories of Harvard College (United States), Cambridge, and Duri Echt have large circles by Troughton and Simms, who also made the Greenwich circle from the design of Airy. ${ }^{2}$

Wo shall describe the principal features of a transit circle, referring for smaller transit instruments and altazimuths to the article Survering (vol. xxii. p. 719).
In the. earliest transit instrument the telescope was not placed in the middle of the axis, but much nearer to one end, in order to provent the axis from bending under the weight of the telescops. It is now always placed in the centre of the axis. The lattor consists of one piece of brass or gun-metal with carefully turned cylindrical pivots at each eud. The centre of the axis is shaped like a cube, the sides of which form the basis of tro cones which end in cylindrical parts. The pirots rest on $Y$-shaped bearings, either let into the massive stone or brick piers which support the instrument or attached to metal framerworks bolted on the tops of the piars. In order to religve the pivots from the weight of tha instrument, which would soon destroy their figure, the cylindrical part of each end of the axis is supported by a book supplied with friction rollers, and suspended from a lever supported by the pier and comuterbalanced so as to leave only about 10 pounds pressure on each bearing. Near each end of the axis is attached a circle or wheel (generally of 3 or $3 \frac{1}{2}$ feet diameter) finely divided to $2^{\prime}$ or $5^{\prime}$ on a slin, of silver let into the face of the circle near the circumference. The graduation is read off by means of microscopes, generally four for each circle at $90^{\circ}$ from each other, as hy taking the mean of the four readings the eccentricity and to a great extent the accidental errors of graduation are eliminated. ${ }^{3}$ In the earlier instruments by Pistor and Martins the microscopes were fixed. in holes drilled through the pier, but alter-
 wards they let the piers te made narrower, so that the microscopes could be at the sides of them, attached to

radial arms starting from near the bearings of the axis. This is preferable, as it allows of the temporary attachment of auxiliary microscopes for the purpose of investigating the errors of graduation of the circle, but the plan of the Repsolds and ol Simms, to make the piers short and to let the microscopes and supports of the axis be carried by an iron framework, is better still. as no part of the circle is explosed to radiation from the pier, Which may cause strain and thereby change the angular distance between various parts of the circle. Each microscope is furnished with a micrometer screm, which moves a frame carrying a cross, c।
${ }^{2}$ This instrument differs in many particulkrs from others: the important principla of symmetry in all the parts (scrupulously followed in all others) is quite discarded ; thera is only ona circle and the instrument cannot ba reversed. Thero is a similar instrumeri at the Cape observatory.
${ }^{3}$ On I.eichenlach's circles there wera verniers instead of micro. scopes, and they Tyere attac' ed to an alidade circle, the immovability of which was tested by a lè al.
better two clese parallel threads of spider's web, with which the distance of a division line from the centre of tha field can be measured, the drum of the screw being divided to single secands of arc ( $0^{\prime \prime} .1$ being estimated) while the numher of revalutions are counted by a kind of comb in the field of siew. The periodic errors of the scresv must be investigated and taken into account, and care must be taken that the microscopes are placed and kept at such a distance from the circle that one revolntion will correapood to $1^{\prime}$, the excess or defect (error of run) being determined from time to time by measuring standard intervals of $2^{\prime}$ or $5^{\prime}$ on tbe circle.

The telescope consiste of two slightly conical tubes screwed to the central cube of the axis. It is of great importance that tiris connexion ahould be as firm and the tube as stiff as possible, ${ }^{1}$ as the flexure of the tube will affect the declinations deduced from the observations. The flexure in the horizontal position of the tube may be determined by means of two collimators or telescopes placed horizontally in the meridian, north and south of the trassit circle, wath their object glasses towards it. If these are poonted on pae another (through boles in the central cube of the talescope), so that the wire-crosses in their foci coincide, then the telescope, if pointed first to one and then to the other, will hare described exactly $180^{\circ}$, and by reading off the circle each time the amount of flexure will be found. M. Loewy has constructed a very ingenious apparatus ${ }^{2}$ for determining the flexure in any zenith distance, but fencrally the ohserver of standard stars endeavaurs to eliminate the effect of flexure in one of the following waya:-either the tube is so arranged that eye-piece and object-glass can bo interchangel, whereby the mean of two observations of the same star in the two positions of the object-glass will oo free from the efficct of ficxure, or a star is not only obserred directly (in zenith distance $Z$ ), but also by refexion from a mercury trough (in zeoith distance $180^{\circ}-Z$, as the mean result of the Z . D. of the direct and reflexion observas. tions, before and after reversing the instrument east and wcst, will only contain the terms of the flexure depeading on $\sin 2 Z$, $\sin 4 Z$, , $\&$ c. In order to raise the instrumput a reversing carriage is provided which runs on rails betreen the piers, and on which the axis with circles and telescope can be raised by a kind of screw-jack, wheeled out from between the piers, turned exactly $180^{\circ}$, wbecled back, and gently lowered on its bearings.
The eye end of the telescope has in a plane through the focus a number of vertical and one ar two horizontal riires (spider lines). The former are used for observing the transits of the stars, cach wire furnishing a separate result for the time of transit over the middle wire by adding or subtracting the known interval betiveen the latter and the wire in question. The intervals are determined by observing the time taken by a star of known declination to pass from one wire to the other, the pola star being best on account of its slow mation. ${ }^{3}$ The instrument is provided with a clamping apparatus, by which the obsarver, after having beforehand set to the approximate declination of a star, can clamp the axis so that the telescope cannot be moved except very slowly by a handle pushing the end of a fino acrew against the clamp arm, which at the other side is pressed by a strong spring. By this slow motion the star is made to rum along one of the borizontal wires (or if there are two close onss, in the middle betwean them), after which the microscopes are read off. The field or the wires can be illuminated at tbe obserrer's pleasure; the lamps are placed at some distance from the piers in order not to heat the instrument, and the light passes through holes in the piers and through the hollow axis to the cube, whence it is directed to the eye-end by a systcm of The
The time of the atar's transit over the middle wire is never exactly equal to the actual time of its meridian passage, es the
plane in which the telescope turns never absolutely caincides with the meridian. Let the production of the west end of the axis meet the celestial sphere in a point of which the altitude above the berizon is $b$ (the error of inclination), and of which the azimuth is $90^{\circ}-a$ (the azimuth being counted from south through west), while the optical axis of the telescope makes the angle $90^{\circ}+c$ rith the west end of the axis of the instrument, then the correction to the observed time of transit will be $a \frac{\sin (\phi-\delta)}{\cos \delta}+b \frac{\cos (\phi-\delta)}{\cos \delta}+c \sec \delta$, Where $\phi$ is the latitude of the station and ô the declination of the star (see Geodesy, vol. x. p. 166). This is called Tobias Mayer's forinula, and is very convenient if only a fen ohservations bave
to be reduced. Putting $b \sin \phi-a$ cos $\phi=n$ 1 Reichenbach supplicd his tobes with counterpolsing levers like those on the

3 The tiansity are elther obselve by " of the olock and comparing the distance of the atar from the wire at secood beate before the transit over the wire with the distunce at the wire at the last beat translt, th this way estmating the time of transtt to ours ; or the observer employs a "chronograph," and by pressing an electrle key causes a mark to be made ou a paper seretched over a uniformly revolving drum, on which the clock beats are at the same thme also marked electricaily:
The Idea of Illaminatlag throagh the it is is doe to Ussher. piotessor of
strcoomy it Dubla (d. 1790).
mula, which gives the correction $-b \sec \phi+n(\tan \delta--\tan \phi)+c \sec \delta$, which is nore convenient for a grcater number of obsorvations, The daily aberration is always deducted from $c$, as it is alsc multiplied by sec $\delta$ (being $0^{*} .31 \cos \phi \sec \delta$ ) The above corrections are for upper culnination; below the pole $180^{\circ}-\delta$ has to be substituted for $\delta$. The constant $c$ is determined liy pointing the instrument on one of the collimators, measuring the distance of its wire-cross from the centre wire of the transit circle by a vertical wire movable by a micrometcr screw, reversiog the instrument and repeating the operation, or (without reversing) by pointing tine two cultunators on one another and measuring the distance of first one and the山 the other wire cross from the centre wire. The inclination $b$ is nuessuren directly by a level which can be suspended on the pivats. Having thus found $b$ and $c$, the obsarvation of two stara of known right asceu:-n will furnish two equa:zons from which tbe clock error and the asimuth can be found. For finding tho azimuth it is most advantagenus to use two stars differing as nearly $90^{\circ}$ in declination as possible, such as a star near the pole and one near the equator, or better still (if the weather permita it) two successive meridian transits of a close circumpolar star (one above and one below the pole), as in this case errors in the assumed right asrension will not influence the result.
The interval of time between the culminations or meridian transits of two stare is their difference of right ascension, 24 hours corresponding to $360^{\circ}$ or 1 hour to $15^{\circ}$. If once the absolute right ascensions of a number of standard stars are known, it is very simple by means of these to determine the R.A. of any number of stars. The absolute R.A. of a star is found by observing the interral of tima between its culnination and that of the suo. If the inclination of the scliptic ( $\epsilon$ ) is known, and the declination of the sun ( $\delta$ ) is observed at the time of transit, we hare sin a tan $e$ $=$ tan 8 , which gives the R.A. of the sun, from which together with the observed interval of time corrected for the rate of the clock, we get the R.A. of the star Differentiation of the formula shows that observations near the equinoxes are noost advantageous, and that errors in the assumed $\epsilon$ and the abserved $\delta$ will have no influence if the $\Delta a$ is observed at two epochs when the suo's $R$. $A$. is $A$ and $180-A$ or as near thereto as possible. A great nombea of observations of this kind will furnish materials for a standard catalocue; but the right ascensions of many important cataloguc have been found by making use of the K. A.'a of a previons cata logue to detcrmino the clock error and tla is to improve the individnal adopted R. A.'s of the former cstalogue.
ln order to determine absolnte dechations or polar distances, it 28 first necessary to determine the co-latitude (or distance of the polr from the zenith) by observing the upper and lower culminatio of a number of circumpolar stars. The difference betwecn th. circle reading after observing a star and the reading correspondir: to the zenith is the zenith distance of the star, and this plus th. co-latitude is the north polar distance or $90^{\circ}-\delta$. In order te determine the zenith point of the carcle, the telescope is directed fertically dombwards and a basin of mercury is placed under it forming an absolutely horizontal ouirror. Losking through the telescope the obsorver sces the horizontal wire and a reflected image of the same, and if the telescope is moved so as to mal:e these colncile, its aptical axis will be parpendicular to the plane of the horizon, and the circla reading will be $150^{\circ}+z$ zenith point. I! observations of stars refraction has to be taken into account as well as the errors of graduation and flexure, and, if the bisection of tho star on the horizontal wire was not made in the centre of the field, allowacce most be made for curvature (or the deviation of the star's $[$ ath from a great circle) and for the inclination of the borizontal wire to the horizon. The amount of this ioclination is found by taking repeated obscrvations of the zenith distance of a star during the one transit, the pole star being most suitable oring to its slow motior.

Liferature. - The methods of investlgatiog the errors of a transit circle and Chaovenet's manuals (see Time). For detailed description In Brinnow's and chacienet's manuals (see Time). For detailed descriptions of modern transit Obsercasfons for 1s65, and the Publications of the Weyden (vol. b.), the Trashington The Grecawich circle is described in an appeatire Washburn observatory (val ii.). for 1852 .

## TRANSMIGRATION. See Metemfsychosis. TRANisportation. See Prison Discipline. TRANSUBSTANTLATION. See Eecharist.

TRANSVAAL, or South African Republic, a country in South Africa, northeramost of the European states, lying between $22^{\circ} \mathrm{I} 5^{\prime}$ and $28^{\circ} \mathrm{S}$. lat., and $25^{\circ}$ and $32^{\circ} 10^{\circ}$ E. long., is bounded N. and N.. W. by the Limpopo, separating it from the NaLalaka and Bamangwato conntries: W. partly by the Marico and the Hart, partly by an irregular line between these streams, separating it from the naw British protectorate of Bechuanaland; S. by the Vaal and the Buffalo, separatiug it from the Orange Free State and

Natal; E. by the Libomba Mountains, separating it from Zaluland and the Portuguese East African possessions. ${ }^{2}$ Transvaal thus forms a compact inland territory nearly as broad as long, not more than 45 or 50 miles from the Indian Ocean at Delagoa Bay, but otherwise lying completely within the outer rim of the vast South African tableland. A line drawn from the south-west extremity, where it touches Griqualand West, north-eastwards to the Limpopo-Shasha confluence, gives an extreme length of 500 miles, the distance from the same confluence southwards to the Natal frontier being 425, and the greatest length east and west between the Zulu and Bechuana frontiers about 400 miles. In the absence of accurate surveys, the total area las been variously estimated at from 110,000 to 120,00 ) square miles, with a population (including aborigines) roughly calculated at from 750,000 to 800,000 .

Physical Features.-Physioaily Transvaal forms a wellmarked section of the great South African plateau, an elevated shallow basin with a mean altitude of over 3000 feet, whose conformation has been compared to that of a saucer. On the south and east this basin is separated from the coast by a lofty inner and 'ess elevated outer rim, the former from 6000 to 10,000 , the latter about 2000 feet high, sweeping round in curves concentric with that of the seaboard; from Cape Colony through Natal and the east side of Transraal northwards to the equatorial regions. The inner rim, whose various sections in the extreme south are known as the Roggeveld, Nieuweveld, and Quathlamba ranges, takes in Natal and Transvaal the general name of tbe Drakenberg Mountains. From the Natal frontier to the Lipalule (Olifant) tributary of the Limpopo, the Drakenberg maintains the aspect of a more or less continuous range 5000 to 7000 feet high, culminating in the Mauchberg (8725), the highest point in Transvaal: A little to the east is the Spitskop (5637), and further south the Klipstad (6020) and Holnek. (5600). This section, whose several ridges are known as the Verzamelberg, Randberg, Slangapiesberg, and Komatiberg, falls everywhere precipitously eastwards towards the Libomba range, or outer rim of the plateau, which maintains a mean elevation of 2006 feet along the eastern border of Transval. Beyond the Lipalule, the Drakenberg loses the character of a well-defined mountain system, broadening out into uplands moderately elevated above the surrounding plateau, and breaking into ridges, such as the Murchison and Zoutpansberg ranges, which ruu east and west between the Lipalule and Limpopo. The whole system slopes gently westwards to the central tableland, which is itself intersected by several broken ranges, such as the Maquassieberg, Gat Rand, Witwater Rand, and Magaliesborg in the south; the Dwarsberg, Marikele, Hanglip, Watcrberg, and Blauberg in the north, all mostly trending in the direction from east to west. But few of these ridges rise much above 4000 feet, and, as the plateau has a mean altitude of considerably over 3000 feet, they detract little from the aspect of a vast level or slightly rolling upland plain, almost everywhere presented by "ransvaal west of the Drakenberg orographic system.

The numerous fossil remains of aquatic life, together with extensive sandy tracts and the presence in several places of water-worn shingle, give to the central tableland the appearance of an upheaved lacustrine basin, whose waters escaped at one time through the Limpopo to the Indian Ocean, at another through the Vaal to the Orange river, and thence to the Atlantic. The Vaal and Limpopo are still the two great fissures in the plateau, which carry off most of the surface waters to the surrounding marine

[^226]basins. The water-parting between these two river systems lies, not in the Drakenberg, itself pierced by the Lipalule and several of its affluents, but in the Witwater Rand towards the scuth-west of the state. From this point the Limpopo, or Crocodile, sweeps round first to the west, then to the noth-east, describing a semicircle of about 1000 miles to the Limvuba (Pafuri) confluence, where it leaves Transvaal, flowing thence for nearly 340 miles through Portuguese territory south-east to the Indian Ocean. Captain G. A. Chaddock has shown (1884) that it is navigable for steamers to this confluence, above which it is obstructed by the Tolo Azime and other rapids. Throughout its whole course it receives nunerous affluents on both sides, such as the Shasha and Nuanetsi from the north, the Marico, Nyl, Limvuba, Lipalule, and othere from Transvaal, of which region it drains fully 95,000 square miles. With the exception of a few tracts watered by the headstreams of the Buffalo (Tugela), Mvolozi, Usutu, and Umcomati (King George), flowing in independent channels eastwards to the Indiau Ocean, all the rest of Transvaal is drained by the Vaal westwards to the Orange and Atlantic. The Vaal has its easternmost sources in the Wakkerstroom district on the west slope of the Draken berg, whence it flows for about 450 miles, partly within, but mainly along, the southern frontier of Transvaal, of which, with the Hart and other tributaries on its right bank, it drains about 20,000 square miles altogether. Besides these perennial streams, there are numerous shallow lagoons or saltpans scattered over the western and northern districts, as well as thermal and mineral waters, such as the Warmbad in the Nyl valley. But the only lake properly so called is Lake Chrissie, a sheet of water nearly 40 miles round, and in parts very deep, which lies on the west side of the Drakenberg, 5755 feet above sea-level.

Climate.-Although lying on the border of and partly with!n the trepics, Transvaal, thanks to its great elevation above the sea, aud to the absence of extensive rarshy tracts, enjoys on the whole a bealthy invigorating climate, well suited to the European constitution. Owing to the dryness of the air, due to the proximity of the Kalahari desert, the western and central districts are specially favourable to persons suffering from consumption and other chest complaints. But some of the low-lying moist tracts along the Limpopo and other river valleys, close to or within the torrid zone, are extremely insalubrions, fever of the general African tyje being here endemic, aod its prevalence usually marked by the presence of the destruetive tsetse fly. The route from Delagea Bay to the interior also traverses a fever-stricken const district between the sea and the Libomba esearpment, dangerous especially in tho rainy summer season. The rains generally begin about Octaber, sametimes a little before or after, and last ir termittently till A pril. But the rainfall is very unequally distributed, most of the moisture-bearing clouds from the Indian Ocean being arrested by the great larrier of the Drakenberg, or countcracted by the dry west winds from the Kalahari descrt. Thus, while there is abundauce of rain in tho east, the comutry gradually becomes dricr as it approaches Bechuana land. During the dry winter season (April to September) keen frosty winds blow from the south, sweeping freely over the contral plains and carrying the moisture to be precipitated as snow along tho eastern highlands. Novertheless, according to the careful meteerological observations made by Mr Lys at Pretoria between 1877 and 1880 , the mean annual temperature is consiterahly over $68^{\circ} \mathrm{F}$., falling to about $40^{\circ}$ in June and rising to $90^{\circ}$ and occasion ally even $95^{\circ}$ in January. The rainfall in the same central district seldom reaches 30 inches, which is probably a fair average for the whole of Transvaal, falling to 12 towarls the western and risiog to 60 on the eastera frentier.

Mineral Resources. - Transvaal yields to no other African regron in the abundance of its mincral resources, while it is altogether unsivalled in their extraordinary varicty. These include, hesiles the precious metals and diamonds. iron, copper, lead, cobalt, sulphar, saltretre, and coal, this last with gold, coppcr, and iron bcing probably the most abundant and widlly distributed. Gold, largely diffused throughout the Drakenberg and in the northern Zoutpans berg and Waterberg districts and in the Rastenburg and Marica districts in the extreme west, as well as in the highlands between 'fransvaal and the Zambesi, has hitherto been workec chierly in the rich anriferous region of Lydeuburg about Mount Manchberf and Mount Spitskop in the rentral parts of the Drakenkerg rango. and farther somh in the dihannesbury, and Lower Kaals (Shelia)
district, Mideelburg. The Lydenbarg deposits, discorered in 1873, lie st an eleration of 4500 to 5000 feet 40 miles south of the Lipalnle river and 125 north-west of Lorenza Marques on Delagoa Bay, the chicf diggiugs being at Pilgrim's Rest and Mac Mac elose to the Spitskop. In the Middelburg diatrict the chief centres of mining operations are the recently founded towns of Barberton and Johannesburg. In some years the Lydenburg, Darabastad, aod other diggings hare jointly yielded over $£ 300,000$, nbtained by washing and without any quartz-crushing. Iron ores are also widely distributed, and the Izerberg ("Iron Mountain") near Marabastad ( $24^{\circ}$ S., $30^{\circ}$ E.) consists of an enormons mass of rich iron ore, which the natives have worked for ages. Diamonds are chielly confinced to the Bloemhoff district on the Vaal above the breat diamautiferous region of Kitaberley in Griqualand Weat. Coal abounds in the sonth-eastern districts (Wakkerstrona, Utrecht), and also farther north in. Middelburg (Nazareth) and Lydenburg. In some places seams 7 or 8 feet thick lie so near the surface that they aro quarried and the coal carted away by the natives. The provailing formations where this great miueral wealth is embelded are quartz, porphyry, granites, clay slates, greenstone, Lower Deronian strata, conclomerates, and lımestones.
Flora. - In Transpaal, as in most of the continent, an herbaceous flora prevaila largely oper forest growths, which are here confined chiefy to the deep kloofs (gorges) of the mountain ranges, and to the courses of the larger streans. Bush, including mimosas, thorn thickets, and ereepers, covers extensive tracto on the northern and southera plaina, and the Wakkeratroom and Utrecht districts towards Natal are well monded. But elsewhere the characteristic features are grasslands, downa, bill slopes, flots, aud even maniy parts of the higher uplends being covered with savaunahe generally affording good pasturage and fodder for cartle. In the woodlands the prevailing species are three varietice of yellow wood (Podocarpus), often graving to an enormous size, the Cape beech (Myrsine), aeveral varieties of the wild pear (Olinia) and of stinkwood (Oreodaphene), ironwond, and eboby. The Boers and other settlers have hitherto oceupied themselves ehiefly with stock-lreeding (sheep, cattlo, and horses), but there can be no doubt that much of the country is eminently suited for the cultivation of cereala, yielding two annual crops and producing some of the finest wheat in the world. Tobaceo, the vine, and most European fruits and vegetables also thrive well, while semi-tropical produrets, such es cotton, sugar, and coffee, might be raised in the warmer northern districts.
Founa.-By the early settlers Transraal was deseribed as the paradise of hunters," ${ }^{1}$ abounding in the characteristic large animals, ouch as the lion, lenpard, rhinoceros, elephant, giraffe, zebra, quagga, sevcral varietiea of antelope, and the ostrich, which roam over the continent from Soudad to the Cape. All theso animals still exist, but in greatly reduced numbers, being now largely replaced by the domestic animals-cattle, sheep, and horses -introduced by tho white settlers. All the large rivers are inhabited by the hippopotamus and crocodile, the latter giving an alteraative name to the Lirmpopo; the bullalo, gnu, eland, springbok, wildbeeste, baboon, and sereral other members of the ape family are also frequently met with. The country is occasionally awept by destructive fights of locusts; but the greatest enemy of the stock-breeder is the tsetse fly, which infests the coastlands and many of the riverine tracts, lut shors a tendeney to disappear with the large gamo, retreating with the advanco of the plough. A tsetse belt 40 miles wide along the whole course of the Limpopo still bare the spread of European settlements beyond Transraal in the direction of the Zambesi.

Inhabitants.-Of the population not more than 50,000 ate whites, mostly Eoers (descendants of the early Dutch, French, and Germar immigrants to the Cape), with a large and increasing percentage of British settlers, attraeted in recent years especially to the Lydenburg and other mining districts All the reat are natives, belonging mainly to the Baanto and Bechuana brancles of the Bantu family, and consequently allied in speech and to a large extent in physique to their Zulu-Kaffre neighbours: A conaiderable nuriber of these natires have abandoned the tribal state ard taken service, cither freely or by compulsion, with the whites as furm labourers in the rural districts, and as domestic sertanta in the towas, and are now also largely employed in mining operations The great bulk of the rest, who retain their national usages and recognize the authority of more or less independent tribal chiefs, are concentrated in the northern and eastern provinces of Zoutpansherg $(304,000)$, Waterberg ( 174,000 ), and Lydenburg ( 123,000 ). There aro also about 40,000 in Bloemhoff (extreme south-west), and the same number in the western provinces of Ruatenburg and Marico, but only a few scattered groups in all the rest of the country. These western and sonth-western trilies (Barolongs, Batlapins, Bakwenas, Takhatlas, \&e.) are all Bechnanas; the others mainly Makatis, as the Basutos are here collectively called. It may be stated in a general way that the whole country south of the Lipalule is now free of native claims and open to European colonization, while

On tha route between the Orange and Vaal ( $1333-37$ ) the - voor-trekkerg re sald to have gilled as many as 200 llons.
the northern region between that river and the Limpopo is atill to a large extent occupted by unreduced or unbroken Basuto cormmunties.

Natural and Political Divisions.-Transvaal has been divided inta three more or less distinct uatural regions, determinel chiefly by the relief of the land, and its climatic and economic conditions. Thase are - (1) the Hooge veld, or uplands, comprising the aouther11 districts drained by the leal and the Drakenberg highlands as far north as the Lipalule, about 35,000 square miles altogether, with an altitude rangiog from 4000 to 7000 feet; (2) the Banken weld, or terrace lands, comprising the low eastern zone between the Drakenberg and Libomba ranges, falling in mavy places down to a level of 2000 feet, with an area of 15,000 to 20,000 square niles : (3) the Bosch weld, or bush country, comprising all the rest of the land, with an altitude of 3000 to 4000 feel and an area of 60,000 square miles. For administrative purnoses the country is again divided in to thirteen provinees:-Zoutpansberg and Waterherg in the north; Lydenburg, Middellurg (formerly Nazarctly), Pretoria, Rustuburg, and Marico in the centre; Utrecht, Loudiua, Wak kerstroam, Heidelberg, Potebefstroom, and Bloemhotf in the south. In the sonthera part of Lydenburg lies the somewhat detached district of Ner Scotland, comprising some 500,000 acres seleeted by the late Mr M'Corkindale as a Scotch pastoral and agricultural settlement. It is a bealthy prosperoas country, lying on the slopes of the Drakenberg, within 310 milos of Durban, Natal. But the most thickly settled province is Potchefstroonk, a fertile tract, 3500 to 5000 feet high, abundantly watered by the Mooi, Schoen. and other streams flowing to the Vaal, and well suited for tillage onl pasturage. Its capital of like asme (derived from elements in those of Potgieter, Suberf, and Stockeustroom, three popular Loen leaders during the early migrations) is the most setticd and one of the largest towus in Transvaal. The only other phaces deserving the name of town are Pretoria, eapital ol the province of like uarae and of the state, occupying a somewhat central position 100 miles north-esst of Potehefstroom, 980 from Cape Town, 820 from Pon Elizabeth, and 400 from Durban ; Barberton, in the Lomer Kaap mining district, 150 miles by road from Delagoa Bay, only three years old, but already by far the largest place in the state, with a population (1887) of 15,000 ; and Johannesburg. centre of the goldfiells of the same nanie, 30 milea sorth-east of Protoria, and 72 east of Potchefstroom, founded in 1886, but already larger thau Pretoria, with a population of over 4000 .
Administration and Statistics.-Transpaal enjoys representative institutions, with a volkgrad or pasiatirent of torty-four members elected for four years, one-hall returing every two years, the executive being entrusted to a president elected for tive years by the whole body of electora, assisted by a council of four, the ex. officio vice-president and the stato secretary, with two others appointed by the volksrasd. The revenue, derived chiefly from laud sales, quit rents, stamps, hnt-tax, and custonis, balanced the expenditure in $1 \$ 85$, and exceeded it by $£ 15,000$ in 1886 , the re. spectire sums being $£ 260,000$ and $£ 245,000$. In 1884 the public debt was $£ 396,000$, the exports (gold, ivory, corn, wool, hides, cattle, ostrich feathers, \&c.) about $£ 600,000$, and the imports probab!y over $\mathfrak{L l}, 000,000$. The long-projected railnay, intended to aford an outlet to the coast at Delagoa Bay, was completed in $188 \%$ from Lorenzo Marques, the seaward terminus, to the Transraal frontier, a distance of 50 miles. Transraal is in telegraphic communication with the Cape and the rest of the world through the Orange Free State.
History. - The historic life of Transvaal begins wath the "Great Trek," or general exodus of the Cape Colony Boers, who, being disaatistied, especially with the liveral policy of the British Government towards the natives, removed northwards in large numbers between the gears 1833 and 1837. By 1836 some thousands had already crossed the Vaal, that is, had reached the "Trans-Vaal" country, which at that time mas mostly under the sway of tha powerful refugee Zulu chief Moselekatze, whose prineipal kraal was at Mosega in the present Marico district on the west frontier. Ta avenge the massacri of some cmigrant bands, the Boers unde: Marizz and Potgieter attacked and utterly lefeated Moselekatze at this place in 1837. Next year the Zuln chief withdew beyoud the Limpopo, where be founded the present Matelele state between that rirer aud the Zambesi, thus leaving the region between tha Vaal and Limpope rirtually in the hauds of the Trekkere. But their positiou was reudered inseeure on the east side by the militar: despotism of the fierce Zulu ebief Dingasn, who, after the murdeit of his brother Cbaka, had asserted his authority over the wholo of Zululand and most of the present Natal. The situation was rendered almost desperate by the conplete rout aná wholesale massacre (1838) of the right division of the emigrant lloers, who had ventured to crass the Buffala under Pieter Retief, anil who were defeated by Dingaan, first at Umkongloof ("Aceldama"), then at Weenen ("Weeping "'), and again sonn after ander Uya, Jicritz, and Potgieter, when as many as 800 fell beiore the irrecistibla onslaught of the disciplined Zulu warrion. At ${ }^{2}$ thin eitical iuncture the Trekkers were saved from sitier externination "

Andries Pretorius of Grasf Reinet, hy whom Dingaan met with a first check before the close of 1838, followed in January 1840 by a still more crushing defeat. Dingaan having beeu soon aftel murdered, the friendly Panda was set up in his place, and Natal proclaimed a Roer rejulblec. But the British occupation of that territory in 1843 intheed tho Locrs to retiro in two banda across the Drakenherg, the southeru division settliug in the preseat Orauge Free State, the northeru again passing into Transvaal. Rut, owing to internal dissensions, and the perpetual bickeriugs of the two most promineat personalitics, Pretorius and Petgieter, all attempts at establishing an organized system of goverument throughr out Transvaal ended in failure, till Pretorius iuduced the British Government to sign the Sand River conventiou (Jausary 17, 1852), which virtually established tho political indenendence of that region The eleath both of Pretorius and Potgieter in 1853 prepared the way for a period of intercal peace under Pretorius's eldest son Marthinus Wessels Pretorius, first president of the "Dutelh African Republic," whoso title was afterwards altered (1858) to that of the "South Africau Republic." But a fatal element of weakuess lay in the persistent refusal of the Boers to treat tho natives on a footing of equality, or cven with commen justice. The murder of Hermann Potgicter and family (1854), avenged by Pretorius at Makapan's Cave, was followed (1856) hy the "Apprentice Law," establishing a system of disguised slavery, which was further strengthence by the sanction (1858) of the Grond wet, or "Fundamental Law," declaring that the "people will admit of no equality of persons of colour with the white inhabitants either in state or church." Owing to this policy opposition was constautly shown both to the English traders, disposed to deal fairly with all, and to tho missiodaries, preachers of universal equality, as illustrated by the plunder of Livingstone's house by the commando sent against the native chief Secheli in 1852. A brief chronicle must here suffice of subsequent events down to the present time:-
1857. Invasion of the Orange Free State by Prctorius; dispute settled without bloodshed by the ireaty of June 1.
1859. Pretorius elected president of the Free State; fails to effect the union of the two states.
1863. Return of Pretorius, during whose absence affairs had fallen into confusion ; contipued troubles with the natives; quarrels with the Batlapios, Barolongs, and Griquas in the west; in the east with Ketchywayo, king of Zululand, about the Boers' right to the Wakkerstroom and Utrecht districts
1867. Discovery of diamonds, and Mauch's snyouncement of goldfields in the interior.
1868. Pretorius's proclamation extending the houndaries of the state west to Lake Ngami, east to Delagoa Bay, whence dispuntes and negotiations with Eagland and Portugal, Delagoa Bay being ultimately awarded (July 1875) to Portugal by the French president, Marshal MacMshon, to whose decision the matter had been referred.
1871. Boundary disputes tawards the south-west settled by the award of Lieutcmant Goveroor Keate of Natal, leading to the resignation of Pretorius and appointment of Presideat Burgers.
1875. The Fundamental Law forces Burgers to measures leadiag to the war with Sikokuni, chief of the Bapedi, south of the Olifant river, who claimed large part of Lydenburg and even of Pretoria: Burgers's visit to Europe in connexion with the Delagoe Kailway scheme; on lis return he finds everything in the greatest confinsion; Boers dispirited by reneated reverses in the Sikokuni war; an empty treasury; broken credit; the state practically bankrupt and exposed to imminent danger of invasion by Bapedis and Znlus. Hence
1876-77. Intervedtion of England, and Sir Theophilua Shepstone's proclanation (April 12, 1877) annexiog Transvaal, followed by the appointment of Sir W. Owen Lanyou as British sdinimistrator.
1880-81. Revolt of the discontentod Boers, who, being successful in a few contests with Rritish troops, induced the british Geverument to restore the republic nader the "suzersinty" of the queen, by the treaty of peace of March 21, 1881, a British resident being appointed, with the functions of a consul-general.
1883. S. J. Faul Krüger eiected presideat.
1884. Convention of Lonaon (February 27, ratified by the volksraxd, August 8) recognizing the state as tho South African Republic, and considerably restricting the British suzerainty.
1835. Proclamation (March 23) of the British protecterate over Bechnanaland, thereby arresting the westward adyance of the Doers into the Bamangwato, Bakwens, Bangwaketsi, and Baroloner territories, and keeping open the great trade route from Cape Colony through Hopetown and Shoshoog to the Zambesi.
1 536 . Fresh discoreries of rich suriferous deposits espenially in the Midilelburg province, followed by a great influx of Englist speaking. populations, thrcatening to swamp the Botr element.
1886. Projected South African confederation, opposed by Krüger, but supported by the Orange State, Cape Colony, aud a najority of the Transvas Boers. Connected with this scheme is the proposal of a uniform tariff and the immediate construction of a through railway from Cape Town to Delagon Bay.
(A. H. K.)

TRANSVERSE FlUte, Tee, -or German Flute, as it was formerly designated in Great Britain,-may be described as a musical instrument in which a column of air is set in vibration by regular pulsations derived from a current of air directed by the lips of the executant against the side of an orifice serving as an embouchure, picrced laterally in the substance of the pipe and towards its upper extremity. This mode of blowing appears to be of very ancient origin: the Hindus, Chinese, and Japanese claim to have used it from time immemorial ; in Europe the high antiquity of a latéral embouchure is generally admitted, although it does not rcally rest, so far as our present knowledge goes, on any conclusive cvidence. ${ }^{1}$

The sblique flute of the Greeks was of Egyptian origin, and it is therefore safest to suppose it to have been like the instrument frequently figured on the monuments of ancient Egypt, which, held obliquely, was blown through the orifice itself of the pipe at its upper extremity. The same instrument (called "nay") is still used in Mohammedan countries. The flute is often mentioned in mediæval poetry, but no details of its construction are given. It was the custom, moreorer, to designate various instruments by this name. The oldest representation we know of the transverse flute is found in the 11 th-century frescos of the cathedral of St Sophia at Kieff. Eustache Descharops, a Freach poet of the 14th century, in one of his ballads, makes mention of the "flute traversaine," and we are justified in supposing that he refers to the transverse flute. It had certainly acquired some vogue in the 15 th century, being figured in an engraving in Sebastian Virdung's celebrated work, ${ }^{2}$ where it is called "Zwerchpfeiff," and, with the drums, it already constituted the principal element of the military mnsic. : Agricola ${ }^{3}$ alludes to it as the "Querchpfeiff" or "Schweizerpfeiff," the latter designation dating, it is said, from the battle of Marigoan (1515), when tlae Swiss troops used it for the first time in war.

From Agricola on wards transverse flutes formed a complete family, ssid to comprise the discant, the alto end tener, end tho bass, -
 o ments must in fact have produced
sounds an octave higher than those noted. Pretorins, ${ }^{4}$. who in a special note warns his readers against inaceuracies of this kind which were then frequent, designates the transverse flate as "traversa Querpfeiff" and "Querfiot," and notifies the bass in 0 , ane fenor - in in O in in time included two discants, four altos or tepors, zad two basses. The same author distinguishes between the "Traverss" and the "Schweizerpfeif" (which he also ealls "Feldpfeiff," i.e., military fute), elthough the construction was the same. There were two kinds of ? "Feldpfeif,"
 plojed exclusively with the military drum. ${ }^{5}$
${ }^{1}$ The Louvre has two sacient statues (from the Vills Borghese) represeating satyrs playigg upon transverse flutes. Uafortunately these marblea have been restored, especially in the details affectiag our present subject, and are therefore examplea of no value to us. Another statue represeating \& flute-player occurs in the British Musenm. The instrument has beeo supposed to be a transverse flute, but erroaeously, for the iosufliation of the laterat tube against which the instrumentalist presses his lips, cuuld not, without the iaterveution of a reed, excite the vibratory movement of the column of air.
${ }^{2}$ Musica getulscht und auszgenogen, Basel, 1511.
${ }^{8}$ Musica Insirumentalis, Witwenberg, 1529
${ }^{3}$ Organagraphia, Wolfeahüttel, 1618.

- It is from the word Pfeiff that the French Fifre and the English Fife, still applies to the military flutes in preseat nse, are ovidently derived.

Mersenne's account of the transverse flute, then designsted "flute d"sllemsind" or "flute sllemande" in France, is obscure bough; but the tabletures and an "Air de Cour" for four flutes in his work lead us to believe that there were then in tise in France the sopra. - the tenor foll sud the bass
 The Múseum of the Conservatoire o Royal of Brussels possesses specimens of ell varieties hitherto mentioned except the last. All of them are laterally pierced with six fioger holes; ${ }^{2}$ they have a cylindrical bore, and are fashioned out of a single piece of wood. Their compass consists of two octaves and a fifth. The successive opening of the lateral holes gives rise to a series of fundamental notes forming the first octave. By a stronger pressure of the breath these motes sre reproduced in the noxt octave higher, and the extent of compass of the instrument is completed in the higher region by the production of other harmonics. ${ }^{8}$

The largest bass flute in the Brussels museum is in D:-bo at the Freach normal pitch A 435 double vibrations per second. It measures. 0.95 m . from the centre of the blow orifice to the lower extremity of the tube. The disposition of the lateral holes is such that it is impossible to cover them with the fingers if the flute is held in the ordinary way. The instrument must be placed against the mouth in an almost vertical direction, inclining the extremity of the tube either to the right or the left. This inconvenieut position makes it necessary that the instrument should be divided into two parts, ensbling the player to turn the head joint that the embouchure may be most commodiously approsched by the lips, which is oot at all easy. The first and fourth of the six lateral holes are double, but those holes are stopped up with wax which have become useless. through the player's habit of using the fingers of the right or loft band to cover the higher three holes. The bass flute shown in fig. 1 is the facsimile of an instrument in the Museo Civico of Verena. The originsl, nnfortunately no longer fit for, use, is nevertheless sufficiently well preserved to allow of all its proportionate measurements being given. The lowest note, $E$, is obtained with a remarkable amplitude of sound, thus apsetting a very prevalent opinion that it is impossible to produce by lateral insunflation souuds which go s little Fig. 1. Fir. 2. lower than the ordinary limit downwards of the modern orchestral flate. ${ }^{4}$

The buss flute cited by Merscnne ahould not differ much from that of the Museo Civico at Verona. We suppose it to have beeo in and that it was furnished with an open key like that Which was applied to the recorders (fates douces) of the sajo epoch, the function of the key being to aggment by another note the compass of the instrument in the lower part. Following Quantz, ${ }^{5}$ it was in France and about the middle of the 17th contury that the first modifications were intreduced in the manufacture of the flute. The improvements at this period con. sisted of the sbandonment of the cylindrical bore in favour of a conical one, with the wide part in the head of the instrument. At the same time the flute was made of three separate pieces called head, body, and foot, which were ultimately further subdivided. The body or middle joiat was divided into tiro pieces, so that the instrument could be tuoed to the different pitches then in use by a replacement with longer or shorter pieces. It was probsbly about 1677, when Lully iatroduced the German flute into the operz, that recourse was had for the "first time to keys, and that the key of D was applied to the lower part of the instrument. ${ }^{6}$ The en. graving of B. Picart, dated 1707, which ornaments the work of the French flautist Hotteterre-le-Romain,? represents the flute as having reached the atage of improvement of which we have just spoken, but the body was still formed of one plece only. In 1726 Quantz, ${ }^{9}$ finding himself in Paris, had a second key applied to

5 Versuch einer Anveisumg die Fiote traversiè zu spielen, Berin, 1752.

- Unlus where the contrary is stated, we have always in view, in describing the enccessive improvements of the fate, the treble finte in $D$, which is considered to be typical of the famlly. 8 "Herrn Johaon Joechlm Qusntzias Lebenslanf, von thm selbst entworfed," Sn the Historisch-Kritsche Betraige zur Aufnakme der Musik, by Murporg,
the fiute, placed nearly st the same height as the firat, that of the intended to differentiste the D shd the Eb. This jnnoration was generally well recêived in Germany, but does not appear to have met with corresponding success in other countries. In France and England manufacturers adopted it but rarely; in Italy it was declared useless. ${ }^{\circ}$ About the samie time flutes were constructed with the lower extremity lengthened and furnished with tro supplementary keys to produce the $C=$ and C. This innovation, spoken of hy Quantz, did not meet with a very favourable recoption, and was shortly afterwards abandoned. Passing mention may be made of the drawing of a flute with a $\mathbf{C}$ key in the Music-Saal of J. F. B. Mayers, Nuremberg, 1741.
The tuniag of the instrument to different pitches was effected, as already explained, by changes in the length, and notably by substituting a loager or shorter upper piece ic the middle joint. So wide were the differences in the pitches then in use that seven such pieces for the upper portion of it were deemed necessary The relative proportions between the different parts of the instrument being altered by these modifications in the leogth, it was conceived that the just relation could be re.established by dividing the foot into two pieces, below the key. These two pieces were adjusted by means of a tenon, and it was asserted that, in this way, the foot could be leagthened proportionately to the length of the middle jeiat. Flutes thus inproved took the name of "flutes à registre." The register system was, about 1752, applied by Qunatz to the head joint, and, the embouchare section being thus capable of elongation, it was allowable to the performer, according to the opinion of this professor, to lower the pitch of the fute a sernitone, without having recourse to other lengthening pieces, and without disturbing the sccuracy of iatonation.

The upper extremity of tho flute, beyond the embouchure orifice, is cloged hy means of a cork stopper. On the position of this cork depends, in a great measure, the accurate tuaing of the flute. It e is in its right place when the accompraying octaves are true. Quantz, in speaking of this accessory, mentions the use of a ant-screw to give the required position to the cork. He does not name the inventor of this sp-
pliance, but, according to Tromlitz, ${ }^{10}$ the improvement was due to Quantz himself. The invention gees back to 1726.

When the Method of Quantz appeared there were still in ase, besides the orchestral flute in $D$, the little fourth flute in $G$, the low fourth lute in- A, and the flute d'amour a note higher; is Frsece they had, moreover, the littleoctave flute in D (octave). A bass finto in D had also been sttempted (see fig. 2). When Ribos published his Bemerkungen aber die Flote ${ }^{11}$ the flute had already the five keys here shown. This auther does not cite the inveater of these now keys, but eome claim them for Kusder, a musical -instru. ment maker in London, others for Johann
 George Tromlitz of Leipsic, snd Ribocq declares he has seen no flutes so constructed other than by these two makers. But Tromlitz lays no claim for himself to the credit of this improvement. He only saye that "he had occupied himself for several years in applying these keys so as not to augment the difficulty of playing, but, on the contrary, to render the handling of them as easy as possible." 12 We may therefore regard the London maker as the author of the first finte with five keys, with, however, \& reservation as to the G , key, which, from 1727, had been applied by Hoffmann of Rastenberg ${ }^{2 s}$ to the transverse flute and the oboe. The higher key of CH, adepted froas 1786 by Tromlitz, we believe to have been first recommended by Ribocq (1782).

In 1785 Richard Potter, of London, improved Qnantz's slide aprlied to the head joint as well as to the register of the foot by a couble system of tubes forming double sliding air-tight joints. In the document ${ }^{24}$ describing this improvement Potter patented the ides of clothing the holes which were covered by keys formed by motal cooical valyes. The keys mentioned in the patent were
 finte dowawards was taken up again about the same time by two players of the flute in London named Tacet and Florio. They devised a new disposition of the keyo $C$ and $C$, sad confided the execu. tion of their invention to Potter. In Dr Arnold's Ncw Instruictions for the German Flute occars a tablature, the engraving of which goes bsck to the end of the 18th century, and bears the following title, "A Compiete Drawing snd Concise Scale and Description of Tacet and Florio'e new invented German Flute, with sll the sddi tional keys explained." It explains the use of six keyo, - C, C
 ment of so many keyo was at once sdmitted. Tromlitz himself, who, however, made flutes with nine keys, - Eiding Eb, another F, snd Ch, declared that he was not in favour of so great a complication, sind that he preferred the flute with only two keys, Dt and Cb,

[^227]With a recister toot joint and a cork nut-screw at the head joint. This iustrument met all requirements. He was even against the use of the keys for C and $\mathrm{C}=$, because they altered the recognized quality of tone of the instrument. When Tromlitz published his methorl, the family of flutes had become modified. It comprehended only the typical flute in D , the finte d'amnur a minor third lower, a "third" 且ute a miuor third hifler, and, finally, the little octave fute.
While Tromlitz was struggling ill Germany with the idea of anginenting the compuss of the thite downwards hy cmploying open keys for C and $\mathrm{C}=$, an Italian, Giovanui Batista Orazi, ${ }^{1}$ mereased the scale of the instrument downwards by the application of five now keys, viz., $B, B b, A, A$, and $G$. At the same time that he produced this invention? he conceived the plugging of the lateral holes by tho valve keys then recently invented by Potter. But it, was hardly possible to obtain a perfect plugging of seven lateral holes with the aid of as many keys, for the control of which there were only the two little fingers, and therefore this invention of Orazi proved a failure.
In 1808 Frellerick Nolan, ${ }^{8}$ of Stratford, near London, conceived an open key, the lever of which, terminating by a ring, permitted the closing of a lateral hole at the same time the key was being acted upon. The combination in this double action is the embryo of the mechenism that a little later was to transform the system of the flute. Two years later Macgregor, ${ }^{4}$ a musical-instrument maker in London, constructed a bass flute an octave lower than the ordinary flute. The idea was not new, as is proved by the existence of the hass flute meationed nbove. The differeace betwcen the two instruments lies in the mechanism of the keys. That employed by Macgregor consistell of a double lever, a contrivance dating from before the mildle of the 18 th century, of which the application is seen in an oboe of large dimensious preserved in the National Museum at Munich. ${ }^{5}$
About 1830 the celebrated French flautist Tulou added two more keys, those of $F \neq$ and $C_{\#}^{\#}$, and a key, called "de caderce," to facilitate the accompanying shakes.
To increase the number of keys, to improve their system of plugging, and to extend the scale of the instrument in the lower region, -these had hitherto been the principal problems dealt with in the improvement of the flute. Nn maker, no inventor whose labours we have called attentioo to, had as yet devoted his attention to the rational division of the column of air by means of the lateral holes. In 1831 Theobald Bochm, a Bavarian, happeniog to be in London, was struck with the power of toue the celebrated Kinglish performer Charles Nicholson drew from his instrument. Boehm leuracd, and not without astooishment, that his English colleague obtained this result by giving the lateral holes a much greater diameter than was then usually admitted. About the aame time Boehm made the acquaintance of an amateur player named Gordon, who had effected certain improrements; ho bad bored the lateral hole for the lower E, and had covered it with a key, while he had replaced the key for $F$ with a ring. These innovations set Boehm about attempting a complete reform of the instrument. ${ }^{\circ}$ He went resolutely to work, and during the year 1832 ho produced the new flute which bears his name. This instrument is distinguished by a new mechanism of keys, as well as by larger boles disposed along the tube ia geometrical progression.
Boehm's system had preserved the key of G open ; Coche, ${ }^{7}$ a professor in the Paris Conservatoire, assisted by Auguste Buffet the younger, a musical-instrument maker in that city, modified Boehm's flute bv closiag the Gf with a key, wishing thus to render the new fingering more contormable to the old. He thus added a key, facilitating the shake upon $\mathrm{C}_{\tilde{f}}$ with $\mathrm{D}_{\text {f. }}$. and brought about aome other changes in the instrument of less importance.

Boehm had not, however, altered the bore of the flute, which had been conical from the end of the 17 th centingy. In 1846, however, he made further experiments, and the results oltained were put in practice by the construction of a new instrument, of which the body was bored cylindrical, but the head was modified at the embouchure. The inventor thus obtained a remarkable equality in the tones of the lower octave, a greater sinorousness, and a perfect accuracy of intonation, by establishing the more exact proportions which a column of air of cylindrical form permitted.

The priority of Boelna's invention was long contested, his detrantors maintaining that the honour of having reconstructed the flute was due to Gordon. But an impartial investigation

[^228] 5 Apother specinen, almost the same, constricied about 1775 , and called Basse da stusette, may be scen in the Musenra of the Paris Conservatoire.
Stee Ueber den F'lölenbau und die nevesten Verbescerungen desselben, Malnz, 1847; and W. S. Breadwood, Ar Essoy on the Construction of Fiutes originally wrilten by Theobald Boehm, published with the addition of Correspondence and other Documente, I.oninn. 1882.

E'zamen crilinue de la Finito Ordinaire comparée à la Flute Boehm, Parls, 1228
vindicates the claim of the forner to the iovention of the lavge lateral holes. ${ }^{\text {a }}$ His greatest title to fame is the invention of the mechaoism which allows the production of the eleven chromatic semitoaes intermediate between the fuadamental note and its first harmonic by means of eleven holes so disposed that in opening them successively they shorten the column of air in exact proportional quantities. ${ }^{9}$ Boehas ${ }^{10}$ has published a diagran or scheme to be adopted in determiniog the position of the note-holes of wind instruments for every given pitch. This diagram gives the positiou of the intermediate holes which he had been enabled to establish by a rule of proportion based on the law of the lengths of strings.

The Boehin flute, notwithstanding the high degree of peifection it bas reached, has not sechred unanimous favour; even now there are players who prefer the ordinary thute. The change of fingering required for sone notes, the great delicacy and liability to derangement of the mechanism, have something to do with this. In Eagland especially, the ordinary flute retains many partisans, thanks to the improvements introduced by a clever player, Abel Siccania, in 1845. ${ }^{11^{2}}$ He bored the lateral holes of E and A lower, and covered them with open keys. He added some keys, and inade a better disposition of the other lateral holes, of which he increased the diameter, prnducing thus a sonorousness alinost equal to that of the Boehm flute, while yet preserving the old fingering for the notes of the first two octaves. But in spite of these improvements the old flute will not bear an impartial comparison with that of Boehm.
(V. M.)

TRANSYIJVANIA (Germ. Siebenbürgen), a mountainous principality (Gross-Fürstenthum) forming the extrene eastern portion of Austria-Hungary, is bounded on the W. and N. by Hungary proper, on the E. by Bukowina and Moldavia, and on the S. by Walachia. The German name is usually derived from the seven principal fortified towns or "burgs" founded by the Gerinan colonists, though some authorities prefer to connect it with the Zibin Mountains on the south frontier. The Latin name appears first after the lyth century, and signifies "beyond the woods," i.e., from Hungary ; the Magyar and Roumanian names (Erdély and Ardcalu) both mean "forest-laud." For all political and administrative ends, and in the official statistics and returns, Transylvania is now wholly incorporated with Hungary (q.v.), and to all intents and purposes is a part of that kingdom. The principality has the form of an irregular circle, with an area of about 21,000 square miles, and is on all sides surrounded by mountain chains, while the interior is barred and striped with lower ranges. On the west or Hungarian side there are various wide and comparatively easy passes into the interior, but on the east and south frontiers the lofty bounding mountains present steep and rugged faces outwards, giving to Transylvania the general aspect of a huge natural fortress. These mountains are a continuation of the Hungarian and Galician Carpathians; in fact, the mountains of Transylvania may be regarded together as forming the southeastern main group of the Carpathian system. The loftiest and most rugged peaks are on the north and south boundaries. On the north the highest summit is the Pietross ( 7534 feet), one of the Rodna Alps; on the south are the Butshetsh ( 8262 feet), the Königstein ( 7357 feet), and the Negoi ( 8340 feet). The east is bounded by several parallel chains, the highest peak in which is the Pietrossul ( 6910 feet); and on the west border the greatest height is attained towards the south, where several peaks reach 7200 feet. On the west are the Transylvacian Ore Móuntains (Erzgebirge), with the curious Detunata ("thunder-smit "), and the Bihar group, with its numerons caverns. There are numerous valleys, ravines, and canoss in the network of mountains covering the interior of the country, but it is only along the courses of the principal rivers that plains of any size are found. The chief rivers are the Aluta or Alt, which flows south, pierces the southern boundary mountains at the Rother Thurm Pass,

[^229]and joins the Danube, and the Maros, to the west, and the Szamos, to the north, both tributaries of the Theiss, which also falls into the Danube. All these are navigable, and are fed by various tributaries. The largest lake is the Hodoser or Eseger See, 13 miles long. Transylvania abounds in mineral springs of all kinds, especially saline and chalybeate. The climate is tolerably severe: hot summers alternate with very cold winters; but the rainfall is not great.
The mineral wealth of Transylvania is very cousiderabie. Gold is found in certain quantity in mines, snd it is also "washed" in some of the streams, chiefly by Gipsies. The gold is often found in conjunction with tellurium (first discovered in Transylvania in 1782, and until the present century not found anywhere else, see Teliunical. Silwer, copper, Iead, and iron are also worked to some proft. Coal occurs in considerable abuudance, and it is mined in the Schilthal, but the superabundance of timber has retarded its exploitation. Hills larg: y formed of pure salt are met with here and there, and there are also very rich subterranean deposits of salt, sometimes cropping up on the surface. Some of the saline springs also yith salt enough to render their evaporation profitable. The vegetation of Transylvania is luxuriant, except of course in the bigher monntain zones. Fruits sbound, as apples, pears, peaches, a pricats, plums, cherries, chestnuts, and almonds; mulbervies are also cultivated. The vine flourishes bost in the valley of the Maros. Agriculture is one of the nost important industries, though the available good land is by no means fnlly taken up. The chief crop is maize ; but wheat, ryo, and other grains, potatoes, saffron, hemp, flax, and tobacco are also grown. Extensive forests clothe much of the country, but are ia a some. what ueglested condition. On the boundary mountains the trees are mainly coniferous ; in the interior oaks. elms. beechea. aud ashes are conspicuous.
The forests afford covor for many wild animals. Bears, wolves, foxes, boars, and various varisties of game are found, and on some of the mountains the chamois. There is abundant pasturage on which excellent cattle are reared; and in some diatricts bulfaloes are bred for draught purposes. Nore important is the breeding of a sturdy race of horses, thousands of which are annually exported. The mountains maintain very large flocks of sheep, of which two kinds are distingnished-with a fine ehort-stapled and a coarse long-stapled wool respectively. Silkworms are bred, and some silk is apun; and the export of honey and wax, from both wild and domestic bees, is not inconsiderable. Ne ther the means of commnaication with the external world nor the manufacturing indastry in Transylvania is developed to any important extent; the latter, indeed, has to a sertain extent gone beck. The most industrious "Saxons"; and trade, the great bylk of the popalation are the "Saxons"; and trade, the great bulk of which is with Roumania, is mainly in the hands of Armeaians and Greeks. The chief commercial centres and principal towns are Hermannstadt, Kronstadt, Bistritz, and Szamos-Ujvar.
Perhaps the most interesting point in connexion with TransylVania is the variety of its population, which in 1880 numbered 2,084,043 in all. Unti! 1845 the chief inluence and privileges, as well as the only political rights, were divided among the three "privileged nations" of the H:agarians, SzekIers, and Saxors The first are the descendants of the Magyar conquerors. The Szeklers, i.ee, "guardians," chiefly on the east borders, settled in eastern Transylvania to act as guardians of the frontiers. The Saxons are the posterity of the German immigrants brought by King Geisa II. (1141-1161) from Flanders and the lower Rhine to eultivate and repeople his desolated territories, At first these were known as Teutones, Teutonici Hospites, and Flandreases, hat since the beginning of tho 13th centnry the genersI name of "Saxons," as tantamount to "Germans," has prevailed (ff. Saxony, vol. xxi. P. 351). The Hungarians and Szeklers tugether namber 609, 208, and the Saxnes 204,713, but by far the most numerons element, though loag excluded from power and political equality, is formed by the Walachians or Rommanians, $1,146,611$ in number, a mixed race, not entitled to the descent which they claim from the early Koman colonists of Dacia The Gipsies of Transylvania, who are heard of under a voivode or prince of their own in 1417, are estimated at 46.460; many of them have abandoned a nomadic Ife anil havo taken to agriculture or gold-washing. Jewa, Armenians, Bulgarians, Rutheuians, and Greeks are also represented in the medley of peoples. About 70,000 (chiefly children) are returned, "noclassed, as "not able to speak." The Magyars are mostiy Roman Catholics or Unitarians, the Germsns Protestants, aud the Roumanians adherents of the Greek Church.
Transylrania formed part of the Roman province of Dacia. After the withdrawal of the Romans the conntry becasae for centuries the prey of the various peoples who swept across it in their restless migrations. At the beginning of the 11 th century 'tonat Strohm I af Hungarv made hinself master of the lani', which was chencerorward governea as an fungarian province by a
voivode. In 1538 the voivode, Johu Zapolya, succeoded in rendering himself independent, and he and his successors, who were generally elected by the people, were snpported by the Turks against the honse of Austria, while the difficult nature of their country preserved them on the other hand from becoming too dependent on their powerful allies. After the defeat of the Turks at Vienna in 1683, their influence in Transylvania waned, and in 1699, by the pesce of Carlowitz, the Porte acknowledged the suzerainty of Leopold I. of Austria over Trazsylvania. By the Leopoldine diploms of 1691 Leopold had guaranteed the ancient rights and laws of the land, and united it formally with the Hungarian crown. In 1765 Maria Theresa made it a grand principality (Gross. Fürstenthun). The efforts of the Romanian iuhabitants to secure recognition as a fourth "uation," and the opposition of the noll-Magyar population to a closer union with Hungary, led to troubles and disagreement early in the 19th ceritury, culminating iu bloody interoecine struggles in 1848. Ia 1849 Transylvania rans divided from Hungary by an imperial decree, and became an Austrian crown-land; but in 1860 the old order was renewed, and the complete incorporation with Hungary was pelfected in 1868. Since that time the policy of the Hnugarian jarty has on the whole prevailed, and the Magysrization of the principality is steadily being carried through, in spite of the bitter protests aud discontent of both the Saxons and Roumanians. An Hungarian university was founded at KIsuseuburg in 1872; and Hungarian is recognized as the officiai langunge.
(F. MU.)

TRAPANI, a seaport of Italy, capital of the province of Trapani, and an episcopal see, lies on the extreme north-west coast of Sicily, 19 miles to the north-north-east of Marsala and 4 miles to the west-soath-west of Monte St Giuliano. It lies on a sandy peninsula resembling a sickle (whence the name, from $\delta$ рє́тavor), projecting westward and concare towards the north. It is a place of considerable enterprise; the streets are, comparatively speaking, regularly built and well kept; and the population are above the average iu industry and intelligence. The town is still surrounded by a wall with bastions. Some of the mediæral houses are interesting architecturally, but none of the public buildings require special notice. Among the institutions of Trapani may be mentioned the lyceum (with natural history collection and picture gallery), the gymnasium, the technical and navigation ochools, and the library. Some of the churches contain choice piorks of art. The industries of the place include linen manufacture and rorks in coral, wood, iron, marble, alabașter, mother-of-pearl ; there are also extensive salt lagoons in the immediate neighbourhood, and there is considerable traffic in salt, soda, sulphur, and grain. The harbour, on the south-west side of the sickle, is sheltered by a mole and protected by a fort in the islet of Columbara; it has a lighthouse at the entrance, and is accessible to vessels of about 400 tons. The population in 1881 was 32,020 .
Trapani, the ancient Drepanuzn or Drepana, was the seaport of Eryx (see Eryx and Monte San Gidliano), and is represented by Yirgil as the scene of the death of Anchises, and of the funeral games celebrated in his hononr. Towards the beginaing of the First Punie War (c. 260 e.c.) it was made a fortress by Hamilcar Barca, who removed hither the greater number of the inhabitants of Eryx, the remainder being transferred in 249. It fell into the hands of the Roniansat the end of the war, and does not figure again in ancient history. It appears, however, to have continued to flourish as a commercial town, being mentioned both by Cicero and by Pliny. In the Middle Ages it became a royal residence.
TRAPPISTS. The abbey of Notre Dame de la MaisnaDieu de la Trappe was founded in 1140 by Rotrou, connt of Perche, at Soliguy-la-Trappe, a village of Haut-Perche, now in the arrondissement of Mortagne, department of the Orne, so named from the narrow gorge which forms its entrauce, comparable to a trap-door. It was at first attached to the congregation of Savigny, a minor offshoot of the order of Fonterrault, but that congregation was uuited in 1148 to the Cistercian order, and, by the special intervention of $S t$.Bernard, was affliated, with ali its dependencies, to his own abbey of Clairvaux No medieval monastic order fell more rapidly and signaliy from the spirit of its original iustitute than the

Cistercian, and La Trappo formed no exception to the general decay. Indeed, its geographical position in a district fiercely contested during the long war between France and England hastened its declension, for it was several times taken and pillaged, while the members of the community, at last compclled to break up and disperse, returned at the close of tlee war with their traditions interrupted, their discipline relaxed, and their moral tone deteriorated. Nor was this the worst. The introduction of the "commendam" system into the French Church, whereby secular ecclesiastics were cappowered to hold monastic beaefices without residence or conformity to the rule of the society in which they ranked as heads, wrought yet further mischief ; and, thougl the Trappists at first endeavoured to resist Jean du Belloy; the celebrated bishop of Paris (afterwards cardinal-bishop of Ostia), whom Francis I. nominated in $15 \underline{-6}$ as abbot commendatory, and were upheld by the pope in continuing to elect their own abbots, yet their cfforts were fruitless, and Du Bellay was succecded by a series of titular abbots, unde. whose nominal rule the estates of the abbey were impor. erished, the buildings suffered to fall into nearly total ruin, and the conduct of the monks became a public scandal. In fact, the community was broken up, the dismantled inonastic buildings were abandoned to afew domestics and their familics, and the scattered Trappists scldom reassembled save for hunting partics and similar amusenuents. Such was the condition of things when a reformer arose in the jerson of one of those rery abbots commendatory whe har been the ruin of the institute.

Armand Jcan Bouthillier de Rancé, second son of Denis Bouthillier de Rancé and Charlotte Joly his wife, was born in Paris on January 9, 1626. Ey his father's side he was sprung from a patrician family of Preton origin long scttled in Normandy; by his mother's he was connected with powerful members of the offieial hierarchy: His near kindred wore wealthy, titled, and highly placed in the magistracy, the army, and the dignities of the chureh; while the fact that Cardinal Tichelieu was one of his sponsors and gave him his own fore-names sufficiently attests the political infuence just then at their disposal. The child showed carly tokens of considerable abilities, and was intrusted by his father to accomplished tutors, under whom he made rapid progress. Ife was originally" intended to enter the order of tho Knights of Malta, but the desth of his cider brother in 1637, after a long illness, changed his father's plans, and the child (who had been tonsured in 1635 by way of precaution against such a contingency) was at once put in possession of the various bencfices which had been secured for his elder; so that, while still under eleven years of age, he was cenon of Notre Dame de Paris, abbot of La Trappe, of Notre Dame du Val, and of St Symphorian of Beatrvais, and prior of Boulogne, near Chambord, and of St Clementin, in Poitou. In 1642 he was sent to the College d'Harcourt, where he hegan the usual course of philosophy; but addicted himself almust at once to the then popular study of judicial astrolocy, which he soon forsook for the cognate delusion of alchemy. Nevertheless, be distinguished himself in the more accredited studies of the college, and graduated as M.A. in 1044. It was then usual for Parisian students in theology to attend the course of lectures delivered at the Sorbonne, but De Rancé preferred to return homo and pursuc his theological studies under prirate instruction He was ordained deacon in 1648, and, being in the heje day of youth, with high spirits and popular manners, fell readily into the dissipations of the time, leading a very i:regular life, yet not so as to forfeit the goodwill of even lis stricter acquaintance. IIe was ordained pricst in 1651, lut made ne alteration in his habits, and yet so far kopt
up his studies that, wnen examined in 1652 for his licence as bachelor in theology, he came out at the head of the candidates, whilo the famous Bossuet ranked only as third. In 1653 he lost his father, who bequeathed property to him which doubled his already large income, and in 1654 he graduated as doctor of divinity, when his uncle, the archbishop of Tlours, made him one of his archdeacons, linting that this preferment wonld be merely the prelim. inary of a mitre. He never so much as pretended to discharge the dutics of his ners office, but spent his time amusing himself at his chateau of Verctz; in despite of which his uncle nominated him as deputy from the diocese of Tours to the gencral assembly of the Freneh elergy convoked by the king in 1655 to discuss the Jansenist controversy. The chief matter of interest in this conncxion is that he was one of the minority of 65 doctors of the Sorbonne who refused to vote, with the majority of 127 , a censure upon the Jansenist leader Arnauld, though he took part later against that school. The sudden death of the duchess of Rolan- Montbazon, with whom he was intimate, and whose relations with him were the subject of much hostile comment, is said to have been the first great slook which began the process of cbange in his views of life and duty. A story, which was first given currency in an anonymous account of his conversion published at Cologne in 1668, much heightens this by alleging that De Rance arrived at the duchess's houso unaware of her death, and went direct to her apartiment without being warned by the servants, only to find her head lying apart from her decapitated body, laving been cut off because the coffin was too short and there was no time to procure another. The truth of this story (itself containing several improbable incidents) was promptly denied by Maupeou, the carliest of De Rance's biogra. phers, and has beon rejected by Bayle and St Simon, though accepted by La Harpe and Voltaire. What is certain is that the alteration in his habits nearly synchronizes with the death of Madame de Montbazon, and that the years $1657^{\circ}, 1658$, and 1659 were mainly spent in solitary studies or in visits to the monasteries of which he was titular head, varied by conferences with eminent ecclesiastics whose advice he sought, while in 1660 the death of the duke of Orlcans, whose chicf almoner he was, appears to have given the final direction to his thoughts, though it was not for some years that he carried out his now plans to the full. Hlis first resolution was to sell his patrimony and resign his benefices, and in 1662 he actually sold his chatean of Véretz, nade over two mansions in Paris to the hôtel-dieu, and obtained permission to transfer all his abbeys except Boulogne and La Trappe to resident heads chosen by himself. His canonry of Notre Dame had been resigned so far back as 1653 because of some difficulty about residence. After making provision for family claims, and retaining a comparatively small sum for the repair of Boulogne and La Trappe, he distributed the remainder of his property to the poor. In 1662 he visited La Trappe, which he fornd in a deplorable enndi tion, and the few resident monks so indisposed to listen to his projects of reform that they threntened to murder him and throw his body into the abbey ponds. In his turn he threatened then with the king's direct interforence, and such was the terror of Louis XIV.'s name that they at once submitted, and consented to retire upon the payment of a moderate pension; whereupon De Fancé filled their places in 1603 with monks of the strict Cistcrcian observance, and carefully repaired the monastic buildings there and at Loulognc. In that same year he finally decided to enter the monastic life, and began bis noviciate at the Cistereian abbey of Perseigne in llaine, assuming, on lus frofession in 1664 . the actual headship
of the abbey of La Trappe, whose nominal abbot he had been for nearly thirty years. Associating himself with other personages who desired to revive the Cistercian discipline, he made two journeys to Rome to obtain papal sanction for their plans, and after considerable delay a brief was procured from Alexander VII. authorizing the abbot of Citeaux, as general of the Cistercians, to hold a grand chapter of the order to discuss the proposed reforms, which actually did meet in 1667. But De Rance's ideas went much beyond the mere re-establishment of the strict observance; and, though he judged some details of the original rule unsuited to his own day, and blended with it some particulars borrowed from the Benedictine rule, yet he was so far from diminishing its general austerity that he added to the protracted fasts, the total abstinence from flesh-meat, fish, eggs, and wine, the laborious manual occupations, the hard beds, and the severe asceticism, even in the church services, which made part of the original rule, also the obligation of perpetual silence, save at prayers (to which eleven hours daily are devoted), and save also the "Memento mori" with which the Trappists greet each other on first meeting, which is the distinguishing feature of La Trappe, a rule from which none are dispensed save the abbot and the guest-master, as obliged to bold some degree of intercourse with outsiders; and he further ordained that each monk should spend some time each evening digging his own grave, and should sleep on straw in his coffin for a bed. These austerities, though chearfully embraced by the morks of La Trappe, and attracting enthusiasts from without, were far from being approved generally, even in the Cistercian order itself, and, when a decree was issued by the council of stato in 1675 giving the abbot of Citeaux absolute authority over all Cistercians of the strict observance, De Rancé took alarm, and, thinking it possible that an attempt might be made to mitigate the severities he had introduced (particularly as the mortality amongst the members of his society had been very large, and was currently attributed to insufficient nutriment), induced them to renew their vows and to pledge themselves against the admission of any relaxations. Nor was he content with opposing this kind of resistance to the bishops, abbots, and others who remonstrated with him upon the subject, but he also tock up his pen in defence of his views, and published in 1683 his treatise De la Sainteté et des Devoirs de la Vie. Monastique, which involved him in much controversy, notably with the learned Benedictine Mabillon, who replied to bim in his well-known work Traité des Études Monastiques, puoblished in 1691. Advancing years and curemitting asceticism told even on the strong constitution of De Rance, and he found bimself unable to take his share of the manual labours of the bouse, or even to be present in chapter, so that in 1695 he felt obliged to resign the abbacy, and procured the nomination of the prior Zosimus to succeed him, but he died before the arrival of the bulls for his installation, and Dom Francis-Armand was substituted in his room, and inducted into offce in 1696. He proved a failure as a ruler, and La Trappe broke up into two factions during his headship, some holding to him and others to De Rancé, till the new abbot resigned in a fit of disgust of which he soon repented, but could not succeed In recalling his abdication. Dom Jacques de la Tour, a man in sympathy with De Rancé, was then nominated by the crown, and while he was still abbot De Rancé died, on October 20, 1700, in the seventy-fifth year of his age.
De Rancé was a tolerably copious author, though most of his writings were little more than occasional pamphlets suggested by the controversies in which he was engaged, short devotional treatises, and notices of deceased members of his community, but his reputation for ability and scholar-
ship was never contested. He was a successful admini strator, and, though the exireme severity of his institute resulted in the failure of fully six-sevenths of the postulants who presented themselves, he gathered rouad bim during bis government of the abbey no fewer than three hundred ascetics, French, Belgians, Germaus, Italians, and Irishmen, one-third of whom were drawn from less austere communities or from the ranks of the parochial clergy and candidates for the priesthood. Of lay outsiders who joined him, the largest proportion consisted of rural artisans and labourers, and of soldiers, from officer to private (a class for which La Trappe has always continued to have attractions), with a small sprinkling of the legal profession; while two plysicians and a single tradesman complete the tale of those who persevered out of the two thousand or so who presented themselves. No daughter houses were founded from La Trappe during De Rancés life, for, though he was ready enough to send some of his monks for a time or even permanently to revive the Cistercian discipline in other monasterics, he was opposed on principle to every scheme which tended to drain the resources of La Trappe itself, and it was not till 1705 that the first offshoot of the Trappists was planted at Buon-Solazzo, near Florence, at the solicitation of Cosmo III., grand-duke of Tuscany.
No remarkable events oesurred in connexion with La Trappe till the French Revolution, when the order was included in the geueral suppression of monastic societies by the Constituent Assembly in 1790. Even then the bigh character borne by La Trappe, and honourably distinguishing it from too many monasteries at that time, seemed likely to exempt it from the common fate, and great efforts wers made to obtain its exclusion from the operation of the decree. A petition addressed by the Trappists to the National Assembly was referred to the council-general of the department of the Orne at Alencon, which reported against it to the ecclesiastical committee of the assembly, though admitting that all the local municipalities which they had consulted were in favour of sparing the abbey. Dom Augustin (Louis Henri L'Estrange), at that time master of the novices, foreseeing the result of the inquiry, went to Switzerland to provide a refuge for the brethren, and obtained permission from the authorities of canton Freiburg to take possession of Val-Sainte, an unoccupied Cistercian monastery, and to bring no more than twentyfive persons thither. This necessitated leaving more than a hundred at La Trappe to await the coming storm, which burst upon Trinity Sunday, June 3, 1792, when commissioners seized all the movable goods scleduled in their inventory, and compelled the inmates to disperse. Some betook themselves to Soleure; a few retired singly into private dwellings; but various groups set out together to found colonies in Spain, Germany, England, and Canada; while the earlier Swiss and Tyrolese houses were compelled to break up and seek refuge elsewhere from the Frencil invaders. But amidst all difficulties and discouragements the order not merely maintained itself, but grew and strengthened, and in 1808 ventured to plant anew two houses in France itself. This same year, however, saw the division of the order into two congregations, because the Trappists of Darfeld, under their prior Eugene de Prade, resisted what they considered to be the excessive demands made upon them by the abbot, of the order, that very L'Estrange who had led out the colony of Val-Sainte (and who had been constituted its head, and that of the whole society, by a brief of Pius VI. in 1794), and the dispute was appealed to Rome, with the result that in June 1808 judgment was given against L'Estrange, and Darfeld was erected into an independent abbey under De Prade as abbot, and subjected to the jurisdiction of the bishop of Münster. Nearly every Trappist house at this date was
within Napoleon's dominions, and, as the order sided with the pope against the emperor, the latter expelled its monks from all monasterics in the einpire, and imprisoned not a fon of them. With his fall they revived again, and obtaincl permission to return to France, whither between 1814 and 1825 they drifted lack from most of their places of exile, though 1450 were expelled anew in 1880 under the operation of the Ferry laws. La Trappe itself was repurchased by L'Estrange, and became once more the mother honse, while there are lifteen other French monasteries of the order, four Belgian, two English (Mount St licrnard, Leicestershire, and Stape Hill. Dorset), two in lreland, one cach in Germany, Savoy, and Algiers, $t$ wo in Italy, two (Gcthsemane in Kentucky and New Melleray in lowa) in the Ünited States, and one originally settled in I'ennsylvania, but now at Tracadie in Nova Scotia. An order of Trappistine nuns was founded by Dom Augustin in 1827, and has nine Frencl houses and one English. The total numbers are computed at 3000 members of both sexes.

The bibliograplyy relating to De Rance and the Trappists is copious, and the following list is not exhaustivc. Savary (Bishop of Sécz), Imago I. P. Dom. Arn. Joan. lo Bouthillier de Rance, Ablutis de Trappa, 1701 ; Manpeou, Vie ce M. l' Abé nic la Trappe, l'aris, 1702; Marsollier, Vie de $l$ Alle Beulhillicr ric Jiance, Paris, 1702; Le Nain (brother of Tillemont), lic ic Le Deuthillicr de limuce, Able el Reformateur de la Trappe, Rouen, 1715; Inguimbert, Genainus Character D. Arm. Joannis Bultilicri Sancei, Kome, 1718; Charles Butler, "Life of De Rancé," Misceclanies, vol. iii., London, 1817; Dubois, Histoirc de $l$ Abbe De Mance el de sa Reffonne, 2 vols., Paris, 1866; Félibien, Description de la Traphe, Paris, 10,72; Helyot and Badiche, Histoire rics Ordrcs Rcligieux, art. (R. F. L.)

TRAS-OS-MONTES (i.e., "Behind the Monntains") is the north-east frontier province of Portugal, situated on the other side of the Serra de Marão from Oporto. On the W. it is bounded by Entre Minho e Douro, and on the S. by Leira. The area is 4260 square miles, and the population increased from 393,279 in 1878 to 396,076 in 1881. Physically the province is a mountainous plateau, the most elevated in Portugal, and characterized by the picturesqueness and wildness of its scenery. Monte Zinho reaches a leight of 7445 feet. Vast tracts are covered with heath; but in certain parts the soil is fertile, and the rich winegrowing district on the upper Douro (Alto Douro) is the native country of port. Silk-growing is also carried on; and wheat, rye, hemp, and fax appear among the exports. The province is divided into the tro administrative districts of Villa Real and Draganza. Besides the two towns thus named, two only, Chaves and Miranda do Douro, are of any considerable size.

TRAVANCORE, a native state in Madras presidency, India, between $8^{\circ} 4^{\prime}$ and $10^{\circ} 22^{\prime} \mathrm{N}$. lat. and between $76^{\circ}$ $12^{\prime}$ and $77^{\circ} 38^{\prime}$ F. long., with an area of 6730 square miles. It is bouncled on the N. by the native state of Cochin, on the E. by the Lritish districts of Madura and Tinnevelli, and on the S . and W. by the Indian Ocean. This state is described as one of the most picturesque portions of southern India. Its most marked physical feature is furnished by the TVestern Ghats, which rise to an elevation of 8000 feet and are clothed with magnificent primeval forest; they throw out spurs towards the coast, along which there is a belt of flat country of about 10 miles in width, covered with an almost unbroken mass of cocoanut ard areca palms, which to a great extent constitute the wealth of the country. The whole surface is undulating, and presents a series of bills and valleys traversed from east to west by many rivers, the floods of which, arrested by the peculiar action of the Arabian Sea on the const, spread theniselves out into lagoons or hackwaters, connected here and there by artificial canals, and forming an inland line of smooth-water communication for nearly
the whole length of the coast. The chief river is the Pe iyar, which is narigable for 60 miles; other important rivers are the Pambai and its tributary the Achinkoil, the Kallada, and the Western Támbraparni. Iron is abundant. Elephants are numerous, and tigers, leopards, bears, bison, elk, and various kinds of deer abound in the forests. The state possesses some good roads, and, on the whole, internal communication is tolerably complete. Travancore bas an abundant rainfall, with every variety of climate and temperature.

In 1881 the population of Travaneore was found to number $2,401,158$ (males 1,197,134, females $\}, 204,024$ ), of whom 1,755,610 were Hindas, 146,909 Mohamnedans, and 498,542 Christians. The clief towns are Trivasdivm (q.v.), tho capital, Alephi, tho commercial centre and chief seaport of the state, and Quiton, another seaport and military headquarters. Among the principal articles which the state pruluces are rice, cocoz-1ut paim, peplocr, areeanut, cardamoms, tamarind, coffee, timher, \&e. The manufactures comprise cocoa-nut, gingelly, lemon-grass, and laurl oils, jagaery and molasses, salt, nrrack, cotton cloths aud yans, lottery, and coir yarn, rope, and mattiag. Its revenae in $1884-85$ was ustimated at $\{640,548$. Tra rancore stato is in suhsidiary alliance with the British Governmeut, to which it pays a tribute of $£ 80,000$ a year. It is one of the fer states which lave never turned against the British. Under the enlightened rule of the late maharajilh tho country made great progress, and it now stands very high anong native states. It is free from debt, and has a shrplus of revenue over expenditure. The sovereignty as well as the inheritance of property passes in the female linc.

## TRAWLING. See Fisheries.

TREASON. The law which punishes treason is a necessary consequence of the idea of a state, and is essential to the existence of the state. Most, if not all, nations have accordingly, at an early period of their history; made provision by legislation or otherwise for the punishment of those offences against public order which consist in more or less direct attacks upon the safety of the state or its chief. The principle is universal; it is the application of the principle which leads to differences of opinion. What would have been a capital crime at Rome under Tiberius may be no offence at all in England. It is to tho adrantage of both the state and the citizen that what is treason and what is not should be clearly defined, so that as little as possible discretionary power, apt to be strained in times of popular excitement, should be left to the judicial or executive authorities. The importance of this was seen by Montesquieu. Vagueness in the crime of treason, say's he, is sufficient to make the government degenerate into despotism. ${ }^{1}$ At the-same time, "it may be observed that despotic Governments have not always left the crime undefined. The object of Henry VIII., for instance, was rather to define it as closely as possible by making certain acts treason which would not have been so without such definition. In both ancient and modern history treason has generally been a crime prosecuted by exceptional procedure, and visited with affictive as distinguisbed from simple punishments (to use the terminology of Bentham).

In Roman law the offences originally falling under the head of treason were almost exclusively those committed in military service, such as in England would be dealt with under the Army Act. The very name perducllio, the name of the crine in the older Roman law, is a proof of this. Perluelles were, strictly, 1,ublic enemies who bore arms against the state; and traitors were regarded as haring no more rights than public enenies. The Twelve Tables made it puaishable with death to communicate with the enemy or to betray a citizer to the enemy. Other kinds of perduellio were punished by interdiction of fire and water. The crime was tricd before a special tribunal, the duumviri perducllionts, perhaps the earliest permanent criminal court existing at Romc. At a later period the

[^230]name of perduellio gave place to that of lasa majestas, deminuta or minuta majestus, or simply majestas. The lex Julia majestatis, to which the date of 48 B.c. has been conjecturally assigned, continued to be the basis of the Roman law of treason until the latest period of the empire. The original text of the law appears to have still dealt with what were chiefly military offences, such as seading letters or messages to the enemy, giving up a standard or fortress, and desertion. With the empire the law of majestas received an enormous development, mainly in the reign of Tiberins, and led to the rise of a class of professional informers, called delatores. ${ }^{1}$ The conception of the emperor as divine ${ }^{2}$ had much to do with this. It became a maxim that treason was next to sacrilege ${ }^{3}$ in gravity. The law as it existed in the time of Justinian is contained chiefly in the titles of the Digest ${ }^{4}$ and Code ${ }^{5}$ "Ad legem Juliam majestatis." The definition given in the Digest (taken from Ulpian) is this: ":najestatis crimen illud est quod adversus populum Romanun vel adversus securitatem ejus committitur." Of treasons other than military offences, some of the more noticeable were the raising of an army or levying war without the command of the emperor, the questioning of the emperor's choice of a sue(essor, the murder of (or conspiracy to murder) hostages or certain inagistrates of high rank, the occupation of public places, the meeting within the city of persons hostile to the state with weapons or stones, incitement to sedition or administration of unlawful naths, release of prisoners justly confined, falsification of public documents, and failure of a provincial goveroor to ozithis prevince at the expiration of his office or to deliver his army to his successor. The intention (voluntas) was punishable as much as an overt act (effectus). ${ }^{8}$ The reported opinions as to what was not treason show the lengths to which the theory of treason must have been carried by at least some person in authority. It was not treason to repair a statue of the emperor which had decayed from age, to hit such a statue with a stone thrown by chance, to melt down such a statue if unconsecrated, to use mere verbal insults against the emperor, to fail in keeping an oath sworn by the emperor, or to decide a case contrary to an imperial constitution. Treason was one of the "publica judicia," i.e., one of those crimes in which any citizen was entitled to prosecute. The law went further than this, and deprived the accused in a charge of treason of his ordinary remedy for malicious prosecution. It also took from bim the privilege (which those accused of other crimes generally possessed) from accusation by women or infamous persons, from liability to be put to the torture, and from having his slaves tortured against him (see Tortore). The punishment from the time of Tiberius was death (usually by beheading ${ }^{7}$ and confiscation of property, coupled with completa civil disability. A traitor could not make a will or a gift or emancipate a slave. Even the death of the accused, if guilty of treason of the gravest kind. such as levying war against the state, did not extinguish the charge, bui the memory of the deceased became infamous, and his property was forfeited as though he had been convicted in his lifetime.

[^231]The law of England corresponds to a consideradir extent with Roman law; in fact, treason is made by Blackstene the equivalent of the crimen lass majestatis. The history of the crime in the tro systems agrees in this that in both the law was settled by legislation at a comparatively early periocs and subsequently developed by judicial construction. In both, too, there were exceptional features distinguishing this crime from other offences. ${ }^{8}$ For instance, at commen law treason was not bailable (except by the Queen's Bench) or clergyable, could not be cleared by sanctuary, and did not admit of accessories, for all were principals, nor could a married woman plead coercion by her husband. To stand mute and refuse to plead did not save the lands of the accused, as it did in felony, so tbat the "peine forte et dure" (see Torture) was unnecessary in treason. These severities were due to the conception of treason as a breach of the oath of allegiance Other differences introduced by statute will be meritioned later. In some cases a statute simply affirmed the common: law, as did the Statute of Treasons to a great extent, and as did 26 Hen. VIII. c. 13 , depriving those accused of treason of the benefit of sanctuary. How far the Romal: law was consciously imitated in England it is impossible to determine. It was certainly not adopted to its full extent, for many acts were majestas which were never treason, even in the most despotic periods. Treason was the subject of legislation in many of the pre-Conquest codes. The laws of Alfred ${ }^{9}$ and Athelred ${ }^{10}$ punished with death any one plotting against the life of the king. Soor: after the Conquest the Leges IIenrici Primi ${ }^{11}$ put any one slaying the king's messenger in the king's mercy. The crime was shortly defined by Glanvill ${ }^{12}$ and at greater length by Braston, ${ }^{13}$ who fellows Roman law closely. He includes under treason sedition and coining. Treason seems to have rested chiefly, if not wholly, upon common law until the year 1352, whien the famous Statute of Treasons (25 Edw. III. st. 5, c. 2) was passed. The statute appears to have arisen from a petition of the Commons in 1348, praying for a definition of the offence of accroaching royal power, a charge on which several persons-notably Gaveston and the Despencurs-had suffered. The offences made treason by the statute are these:-(1) to compass or imagine ${ }^{14}$ the death of the king, ${ }^{15}$ the queen, or their eldest son and heir ; (2) to violate the king's courpanion, or lis eldest duughter unmarried, or the wife of his eldest son and heir; (3) to levy war against the king in his realm, or be adherent tn the king's enemies in his realm, giving them aid and comfort in the realm or elsewhere; (4) to counterfeit the king's great or privy seal or his money ; (5) to bring false money into the realm, counterfeit to the money of England, as the money called Lushburgh, ${ }^{16}$ knowing the money to be false ; (6) to slay the chancellor, treasurer, or the king's justices of the one bench or the other, justices in eyre, or justices of assize, and all other justices assigned to hear and deternine, being in their, places doing their offices. The statute further defined petty treason to be the slaving of a master by his servant;'; a husband by his wife, or a prelate by a man secular or religious owing him allegiance. In all cases of treason not specified in the statute the justices before whom the case came were to tarry without going to judgment until the cause had been

[^232]showed and declared before the king and his parliament whether it ought to be judged treason or felony. The statute, so far as it defines the offence, is still law, except the clauses as to counterfeiting the seal, coining, and petit treason, repealed respectively, after a considerable amount of intermediate modification by statnte, by 11 Geo. IV. and 1 Will. IV. c. 6G, 2 and 3 Will. IV. e. 34,30 Geo. Ill. c. 48, and 9 Geo. IV. c. '31. Petit treason is now treated as murder, 24 and 25 Vict. c. 100.1 From the time of the passing of the Statute of Treasons the limits of treason wero coutinually being extended for a time, and again reduced to the bounds fixcd by the statute It protected only the king's life, and its insufficiency was supplemented in periods of danger by legislation, often of a temporary vature. Under Richard II, and Henry VIII. many new offences were mado treason, ${ }^{2}$ but the Acts creating these new treasons were repealed at the earliest opportunity by the parliaments of their successors, and the Statute of Treasons was made the final standard Ly 1 Mary, sess. 1, c. 1. The reign most prolific in statatory additions to the law of treason was undoubtedly that of Henry VIII. Legislation in this reign was little more than a register of the fluctuating opinions of the monarch. Thus, by 25 IIen. VIII. e. 22 it was treason not to believe Mary illegitimate and Elizabeth legitimato; by 28 Len. VIII. c. 7 it was treason to believe either legitimate; by 35 Hen. VIII. c. 1 it was treason not to be'ieve both legitimate. An interesting act of this reign, 37 Hen . VIII. c. 10 , shows that a class of men like the Poman delatores mast have been called into existence by all th:a new legislation. The Act constituted it felony to make anonymons charges of treason without daring to appeair in support of them before the king or council. Out of the mass of Henry VIII.'s Acts, only two are still !aw,-28 IIen. VIII. c. 15 and 35 Hen. VIII. c. 2, giving power to try treasons committed within the jurisdiction of the admiralty and out of the realn Many other instances of offences of a tomporary kind made treason at different times occur among the statutes, especially in those levelied at the papal jurisdiction by the parliaments of Elizabeth. A few of the more interesting of other kinds may be brielly noticed. It was treason by 21 Ric. II. c. 4 to attempt to appeal or annul jndgments made by parlianeat against certain traitors; by 2 Hen. V. st. 1, c. 6, and 29 Hen. VI. c. 2 to break a truce or safeconduct; by 5 and 6 Edward VI. c. 11 to hold castles, fortresses, or munitions of war against the king; by 17. Car. II. c. 5 to adhere to the United Provinces; by 9 Will. III. c. 1 to return without licence if an adherent of the Pretender; by 12 and 13 Will. JII. c. 3 to correspond with the Pretender; and ly 57 (ieo. III. c. 6 to compass or imagine the death of the prince regent. In addition to these, many Acts of attainder were passed at differcut times One of the most severe was that against Catherine Lloward, 33 Hen. VIII. c. 21 , which went as far as to make it treasomablo for any queen to conceal her antenuptial incontineuce. Other Acts were thaso against Archbishop Scrope, Owen Glendower, Jack Cade, I.ord Seymour; Sir Joln Fenwick, James Stuart, and Bishop Atterbary. In one case, that of Cromwell, Ireton, and Bradslaw, an Act of attainder was passed after the death of those guilty of the treason, 12 Car. II c. 30 . At times

[^233]Acts of indemnity were passed to relieve those who hed taken part in the suppression of rebellion from any possible liability for illegal proceedings. Three such Acts we.e passed in the reign of Willian III.
The Statute of Treasons, as interpreted by the judges, is still the standard by which an act is deternined to be trenson or oot. The judicial interpretation has been sometimes strained to meet cases scarcely within the contemplation of the framera of the statute. c.g., it becane estallished doctrine that a couspiracy to levy war against the king's person or to imprison or depose him might bo given in evilence as an overt act of compassing his death, aod that shokin words, though tleey could not in themselves onombt to treason, night constitute au overt act, and so be evidence. Besides decisions on particular cases, the jwiges at dufferent times came tc general resolutions which had an apprecinble effect oo the law. The principal resolutions were thoso of 1397 (confirmed b/ 21 Ric. In. c. 12), of 1557 , and those argreed to in tho ease of the regiciles at the lestoration and neportel by Sir John keljng. A remarkable resolution in furorem ree monong the latter was that a prisoner onght not to be ironed during trinl. The result of judicial decisions on the Stature of Treasots was smmmed up in s.cta passed in 1786. made permanent in 1817 and in 1848 (57 Geo. T1T. c. 6 and 11 Vict c. 12, the latter often called the 'Tueason Felony Act). The elfect of this legislation, necming to Mr Justice Stepheo, is that such of the judicial constructions as extend tho imagining of the kng's death to inagining his death, dustruction, or any bodily harm tending to death or destruction, main or wounding, imprisomment or restraint, bave been alontel, while sutb of the constructions as mako the insagining of his deposition conspiring to levy war against him, and instigating foreigners to invade :he reahn, have not been abo!ished, but ure lett to rest on the guthor ty of deciled enses. The pexent stato of the law has been incorpurated by skilled lawyers in the draft criminal code, which will no doubt becomo on Act $u$ teu parlianent has leisure to devoto to matters of this linal. The collo draws a distmotion between treason and treasonabie crimes, the former including such acts (omitting those that are obvions? $y$ obsolete) ass by the Statute of Trensons and subseqnent legislation are regarded as theasoa proper, the latter inchuling the crimes contained $m$ the Act of 1848. In the words of th:e code (\$76) "treason is (a) tho act of killing Her Majesty, or doing her any bodily harm tending to death or destruction, maim or wounding, and the ant of imprisoning or restraining her; or (b) tho forming aud manifesting by an ovelt act an intention to kill Her Majesty, or to du licr any bodily harn temding to death or destruction, maine or womding, or to imprison or to restrain her ; or (c) the ast of killing tho eldest son and hois-apparent of Her Majesty; or the quenconsort of any king of the United Kingdom of Great Britain and 1roland: or (d) the forming aad manifesting by an overt act an intention to kill the eldest son and heir-apparent of Her Majesty, or the qucen consort of any king of the United Kinglom of Creat Britain and Ireland; or (e, conspiring with any person to kill Her Majesty, or to do licr any bodily harm tending to death or destruction, maim or wouuding, or consjiring with any person to imprison or restrain her ; or ( $f$ ) lerying war against Her Blajesty either with mtent to depose Her Majesty from the style, hanour, and royal name of the imprexial cromn of the Uoited Kingdom of Great Prituin and Ireland or of any other of Her Majesty's dominions or countries; or in order by force or constraint to compel Her Majesty to change her measubes or conosels, or in order to intimidate or overave both Houses or cither Honse of Parliament ; or (g) consphing to levy war anainst Her Majesty with any such intent or for any such purpose as aforesaid; or ( $h$ ) Hethating any forcigner with fore to invalle this realm or any other of the doniniobs of !ler Majesty; or (i) assisting aay public onemy at war with Her Majesty in such war by any nam whatsoever; or (b) viulating, whether with her consent of nut, a queen consort, or the "ife of the checst son and hein-tipurent for the time being of tho king or queen regnimt." There are a few oulher Acts shll in force besides those of 1817 mud 1848 which have dealt will snbstantivo law. By 1111 mery VII. c. 1 obedicnce to the de facto sovereigo for the timo bene of is nut treason. Byy 1 Anoe st. 2, c. 21, it is treason to endeavour to hinder the next successor to the crown from succeeding, and by 6 Anne $c$. 41 it is treason to malicious!y, advisedly, and directly by writing or printing maintain and aftim that any person has a nght to the crown otherwise than aecording to the Acts of Settlement and L゙nion, or that the crown and parliament canner pass statutes for the limitation of the succiession to the crown.
The Acts dealing with proceduro and punshment are more nonerous, and are characterized by a slowly increasing favour showi to the accused, -in fact, considerably greater than in felony, for connsel were not allowed to prisouers in charges of folony putil 1836, and such prisoners are still not entitled to a copy of the indictment or the names of the witnesses or jury. With respect to the mode of trial, the cffect of common law and legislation is that there are unw four varieties, -Lmbeachmexir (q.e.), trial of a pue

By the peors, court rartiai, sod trial by a judge of the High Court of Justice and a jury. The offence cannot be tried at quarter sessions. Trial by battle in cases of treason ceased in the 14th century, as far as regards appeals in the common law courts or in parliament, by the effect of several statutes passed between 1332 and 1399. Appeals of treason were finally abolished in 1819 (see Appeal). In the court of the lord high constable an award of battle occurred as lately as 1631 in the case of Lord Rea. ${ }^{1}$ Traitors in the reign of Edward IV., and perhaps later, were at times tried by martial law. The issue of commissions of martial law in time of peace was declared illegal by the Petition of Right in 1628. The prerogative of the crowa to try traitors by martial law in time of open rebellion still exists, and is recognized by statute. In two Acts, for instance, dealing with Ireland, 43 Geo . 11 I . c. 117 and 3 and 4 Will. IV. c. 4 , it was provided that nothing in the Acts was to takeaway the undoubted prerogative of the crown for the public safoty to resort to the exercise of martial law against open enemies and traitore. A peer is tried before the House of Lords, or the court $\mathrm{c}^{5}$ the lord high steward if the trial be during the recess of parliament. Procedure in such trials is regulated by 7 and 8 Will. III. c. 3, and other Acts. The last trial of a peer for treason was that of Lard Lavat in 1746-47. Persons subject to naval or military law are triable by court martial in certain cases under tha nowers given by the Naval Discipline Act, 1866, and the Army Act, 1881. The trial of treason committed out of the realn is regulated by 35 Heu . VIII. c. 2, 5 and 6 Edw. VI. c. 11, and 7 Anne c. 21. Lord Macguire was tried by jury in England under 35 Hen. VIII. c. 2 for treason conmitted in Ireland. ${ }^{2}$ Pracedure before and at the trial depends upon a larga uumber of Acts, of which the most important is one passed in $1695 .(7$ and 8 Will. III. c. 3). It enacted that persons indicted for treasou are to have a copy of the indictment delivered to them five daye before trial. The court is empowered to assign connsel for the prisoner (a power extended to impeachments by 20 Geo. II. c. 30). The oath of two witnesses, or confession in opien court, or refusal to plead, or peremptory challenge of more than thirty-five jurors is necessary for conviction. The witnesses must be both to the same overt act or one to one and tho other to another overt act of the same treason. If two or more treasons of divers kinds are alleged in one indictmrent, one witness to prave one treason and another to prove another are not sufficient. No person is to be indicted unless within three years after the offence, except on a charge of attempted assassination of the king. The accused is to have copies of the panel of the jury ${ }^{3}$ twa days before trial. He is entitled to the samo process to compel his witnesses to apper as is usually granted to compel the witnesses for the prosecution. No evidence is to be given of any overt act mot expressly laid in the indictment. The Act expressly denied the prisoner the uames of the witnesses against him. The law on this puint was altered by 7 Anne c. 21 , which enacted that a list of such witnesses was to be delivered to lim ten days before trial. Such witnesses had previously been nnade examinabla unon oath by 1 Annest. 2, c. 9. By 5 and 6 Vict. c. 51 (extending the provisious of an Act of 1800) the advantages given by the Act of William III. aro not to exteud to a prisoner charged with treason in compassing or imagining any bodily harm tending to the death or destruction, naiming or rounding of the queen, where the overt act is an attemut to iujure the person of the queen. In such a case the trial is to proceel in every respect and out the like evidence as if it were for murder. By 11 Vict. co 12 no prosecution for a felony under the Act, in so far as it is expressed by open and alvised speaking only, is to be instituted nuless information be given to a justice or sherif' withiu six days and a warrant issued within ten days of the information, and no person is to be convicted of such an offence except on confossion iu open court or proof by two witnesses. The prisoner is not to be aequitted if the facts amount to treason. There may be accessories to felonies under this Act, which, as has been already stated, there cannot be to treason. The prosecutor and witnesses are not entitled to costs. By a later Act of the same year (11 and 12 Vict. c. 42,823 ) a person charged with treason is nut to be edinitted to buil except by order of a secretary of state or by the Cueen's Bench Division or a judge thereof in vacation.
The punishuent of treason at conmon law was barbarous in the extreme. ${ }^{4}$ The sentence was that the oftender, if a man, be drawn na hurdle to the place of execntion, that there he be langed by the neck till he be deal, that his baal be severed from lis body. und that his body be clivided into four quarters, the head and yuarters to be at the disposal of the crown. A woman was drawn to the nlace of execution, and there bnrned alive. Tha Acts of 30 Geo. III. c. 45 aud 54 Geo. III. c. 146 changed the sentenco to

[^234]hanging in the case of women, and in the case of men ematled the cromn, by warrant ander the sign manual countersigned by a secretary of state, to change the sentence to beheading or remit it altogether. By the Felony Act, 1870, the punishment is langing only, but 54 Geo. III. c. 146 appears to be still so far in forco that beheadiog may be substituted by warrant of the crown where the criminal is a man. Attainder and forfeiture are abolished by the Felony Act, 1870, except where the offender has been outlawed. ${ }^{3}$ The maximuni peualty for a fclony under the Act of 1848 is penal servitude for life. In every pardon of treason the offence is to be particularly specified therein (seo Pardon).

Trials for treason in Great Britain and Ireland have been very numerous, and occupy a large part of the numerous volumes of the State Trials. Some of tha more interesting may be mentioned. Before the Statute of Treasons were those of Gaveston snd the Despensers in the reign of Elward II. ou clarges of accroaching the royal power. After the Statute were those (some before the peers.by trial or impreachment, most beforo the ordinary criminal courts) of Enipson sud Dudley, Fisher, More, the eatl of Surrey, the duka of Somerset, Anne Boleyn, Lady Jane Grey, Sir Thomas Wyatt, Crammer, the queen of Scats, Sir Walter Ralcigh, Strafford, Laud, Sir Hemy Vane and other rericides, Willian, Lord Kussell, Algernon Sidney, the duke of Monnonth, aud those implicated in the Pilgrimage of Grace, the Gunpowder, Popish, Rye Honse, and other plots. Cases where tha proceeding was by bill of attaiuder bave been already mentioned. Oecasiovally the result of a trial was confrmed by statute. In some of these trials, as is well known, tha law was considerably strained in order to insure a conviction. Since the Revolution there have been the cases of those who took part in the risings of 1715 and 1745, Lord George Gordon in 1780, Hardy and Horne 'looke in 1794, the Cato Sireet conspirators in 1820, Frost in 1840, add the Feniaus in 186.7. It should be noticed that many cases of proceedings for treason against foreigoers occur. Ileason committed by them withiu the realm is a breach of what has been called local allegiauce, due to the sovereign of the country in which they reside. Such are the cases of Lestie, bishop of Rous, amibassador to Elizabeth from the queen of Scots, the Marquis de Guiscard in Queen Anne'e reign, and Gylleuborg, the ambassalor from.Sweden to George II. I'roceedings against ambassadors for treason have uever gone beyoud imprisonment, more for safe custedy than as a punishment. No amount of residence abroad will suffice to exempr a native-born subject from the pelualty of treason if he bear arms against the country of his birth. ${ }^{6}$

Misprision (from the old French mespris) of treason, in the words of Blackstoue, " consists in the bare knowledge and coucealment of treason, without auy degree of assent thereto, for auy assent inakes the party a pincipal traitor." At common law even the concealment was treason, but 5 and 6 Edw. VI. c. 11 and 1 aud 2 Ph . and M. c. 10 made concealuent a misprision only. The effence was dealt with by many Acts, under same of which rather renarkable crinues were made misprision; e.g:, 14 Eliz. ${ }^{\circ}$ c. 3 constituted the counterfeiting of foreigu coinage a misprision. The procedure in trials for misprision is in general the same as that followed in trials for treasom, most of the Acts regulating procedure including both crimes. The punishment is loss of the profit of the lauds of the offender during life, and imprisonment for life.

Cognate Offences.-Under this head may he conveniently grouped certain affences against public order which, though not technically treason or treasonable offcuces (to use the language of the draft ciminal cole), are so मearly allied to them as to make it convenient to treat them under the head of treason. The most interesting of these for listorical reasous is premmenire. The word is derived from premunire or pramoneri facias, the introductory words of the writ of summons to the defendant to answer the charge. From this the word came to be used to denote the offences prosecuted by means of such a writ, usually of an ecclesiastical kind. Tha Statute of Premunire, specially se called, is 16 Ric. 11. c. 5, ellacting that the procuring at Rome or elsewhere of any translations, bulls, \&c, against the king pute the persons offending out of the King's protection, subjects their goods to forfeiture and thensclves to attachment or process of premunire facias. The Act introduced no new principle, but simply continued the anti-napal policy visible in the Statutes of Provisors, the earliest of which dated from 1307. At different times many other Acts were passed, extendiug the penalities of premunire to other crimes, usually those conuected with the slupremacy of the pope ( 2 Hen. IV. c. 4, mentinned under Tithes, is an example), but sometimes of a more distinctly political as distingnished from religious nature. Tbus it is premunire by 13 Car. I. c. 1 to affrrn the power of parliament to legislate with. out the crown, by the Habeas Corpus Act to scnd a prisouer beyond seas, and to terbally assert the right of a person to the crown cons l'oceedings afser the death of an allesed faitor might at one tizne have
been taken, but ony to a very linited exiunt as compared with what was gllowed in Roman and Scots law. Sir E. Cobe ( 4 Rep., 5i) siates that there might have been forfeit:are of the land ni guods of one slatn * 4 ebellion on view of the body by tite lord chicf justice of England as supreare carocer

- See Eneas Macdonald's case, 18 Sate Trials, 857.
tregy to tho Acts of Settloment and Union is premunire by 6 Anne Ta do so by writing or printing is, as has been aaid, treason. Tho letest Act constituting o præmunire is the Royal Mrarriage Act, 12 Geo. 1II. c. 11, which subjects to the penalties of premunire any one guilty of a breach of the provisions of the Act. A peer charged with præmunire is not entitled to trial by his peers, but is to bo tried by a jury. The most famous historical instance of a prosectition on the Statuto of Premunire was that of Wolsey in 1520. Other offences cognate to treason are publishing scandslous stories sbont the king (the leasing-making of Scotch Iaw), malsdministration aud aale of public offices, coining, offences against the Foreign Enlistment Act, and the crimes specially provided angainst by 33 Hen. Vlll. c. 12 and 5 and 6 Vict. c. 51. The former Act punished malicions striking in the kiag's palace by perpetual imprisonment, fine, and loss of the right hand. The minute provisions for the matilation of the offender are very curious, but not of immediate interest, as that part of the Act which inflicted mutilation was repealed by 9 Geo. IV. c. 31. By 5 nad 6 Vict.c. 51 it is a inigh misdemesnour, puaishahle by ponal setvitule for geven years, to wilfully discharge, point, aim, or present st the person of the cileen suy gun or other arms, loaded or not, or to strike at or attempt to throw snything upon the queea'a person, or to produce any firearms or other arms, or any explosive or dangerons matter, near her person, with intent to injure or alarm her or to commit a breach of the peace. For other offences which are more or less nearly connected with tresson reference may be made to the articles Libel, Oaths, Petition, Riot, and Senjtion. ${ }^{1}$
Scolland. - Treason included tresson proper, or crinies agaiust the crown or the state, auch as rebellion, snd crimes which, though not tochnically treasouable. were by legislation punisherl as treason. Examples of the latter were the remaining in Englsud sgainat the king's will, 1430, c. 19 ; wilful fre-raising, 1526, c. 10; kidnapping, 1567 , c. 27 ; theft, reset, and stouthrief by banded men, 1537 , c. 34. There were glso many acts dealing with offences in the nature of resistance to suthority, such as unlswful convocations, and with creasous of a inerely transitory nature, such as attempting to restore the Ruthvens ( 1600 ), taking or owning the Covenauts (1085), or corresponding with James V1I. (1638). Acts of forfeiture were sometimes directed egainst individuals, as 1645, c. 23 , against the marquis of Huntly. Scottish preccdure wiss ss a rule less favourable to the accused than English. In one mstter, however, the opposite was the case. Advocates nompellable to act on belislf of the accused were allowed hin by $1!37$, c. 57 , more than a century before the concession of a similar indulgence in England. At one time trial in absence and even after death mas allowed, as in Roman law. In tho case of Robert Leslie, in 1540, a summons after death was held by the estates to be conapetent, and the hones of the deceased were exhuned and preseuted at the bar of the court. ${ }^{3}$ The Act 1542 , c. 13 , confiued this revolting procedure to certaiu trensons of the more beinous kind. By 7 Anne c. 21 trial in absence-the last instance of which had occurred in 1698-was sbolished. The aame Act assimilated the law and practice of treason to that of England in other respects by enacting that no crine should be treason or misprision in Scotland but such as was treason or misprision in England. The Act further provided that the trial was tc be by a jury of twelve, not fifteen as in other crimes, before the court of justiciary, or a commission of oyer and terminer containing at least three lords of justiciary. To slay a lord of jnsticiary or lord of session, or to counterfeit the great seal, was made treason. The Act also containod provisions as to forfeiture, ${ }^{3}$ qualification of jurors, and procedure. Ontlawry for treason was regulated by 22 Geo. II c. 48. The punishment still remains the aamo as it was in Eogland before the Felonj Act, 1870, snd attainder and iorfeiture are atill the effects of condemuation for treason, the Act of 1870 not extending to Scotlauk. One or two other atatutory provisions msy be briefly noticed. The trial of a peer of Great Britain for treasou committed in Scotlaud is to be by a commision from the crown, on indictment found by a jury of twelve ( 6 Anae c. 23, 6 Geo. IV. c. 66). Bail in treason-jelony is only to he allowed bs consent of the public prosecutor or warraut of the high or circuit court (11 Vict. c. 12). The term lese-majesty was sometines used for what was treason proper, e.g. in $1524, \mathrm{c} .4$, making it lese-majesty to transport the king nut of the realin, sumetimes as a aynonym of leasing-nıthing. This crime (also called

Verbal aedition) consisted in the engendering discord between king and people by clander of the king. ${ }^{4}$ The earliest Act against leasing-making ea nomine was in 1524. The reign of James VI. was ure-eminently prolific in legislation against this crime. It is now of no practical interest, ss prosecutions for leasing-making have long fallen into desuetude. At one time, howerer, the powers of the various Acts were put into force with grcat severity, espacially in the trial of the earl of Argyll in 1681. The punishment for leasing-making, once capital, is now, by 6 Geo. IV. c. 47, fine or imprisonment, or both. The offence of promunire was introduced into Scotland at a comparatively late period. By 6 Anne c. 23 it is premunire for the peers of Scotlaud sssembled to elect represen. tativos to treat of any other mstter. ${ }^{5}$

Irbland. - Numerous Acts, beginning with 18 Hew. VI. c. 2, were passed by the Irish parlianent-in many cases mere echoes of previous English legislation. As in England and Scotland, there was a teudency to include under treason crimes of quite another character. Murler was made treason by 10 Hen. Vil. c. 21 , and arson by 13 Hen. VIII. c. 1. Apparently the law must sometimes lave hesn atrained against accused persons, for 3 and 4 Ph . and MI. c. II enacted that trials for treason were to be according to tho common law. Treasons of a temporary nature were often the sulject of legislation. Au example is 11 Eliz. c. 6, making it treason to assume the name and authority of $O^{\prime}$ Neill. The provisions of the English Act of William III. as to witnesses, \&c., were not extended to Ireland until 1821 by 1 and 2 Geo. IV. c. 24 Many Acts of indemnity were passed both by the parliaments of Ireland and of tho United Kingdom. Among the more important were an Irish Act of 1799 ( 39 Geo. Ill. c. 3), indemnifying those who had been active in suppressing the treasonable rising of the previous year, and one of the parliament of the United Kingdom ( 41 Geo. IlI. c. 104), indemnifying those who had taken part in the suppression of rebellion subsequent to 1799 . The law is now practically the aanne as that of England, unless where exceptional political circumstances have led to exceptional legislation. Thus a series of enactments called the "Whiteboy Acts" (passed by the Irish and the United Kingdom parliaments betwren 1775 and 1830) was intended to give adc tional facilities to the executive for the suppression of tumultuons risings. Many Irish Acts dealt with unlicensed posses: sion and manufacture of arms. A similar policy was continned after the Union, and sppears in the Peace Preservation Act, 1881, contipued in 1887 for five yesrs. Some Acts, such as 3 and 4 Will. IV. c. 4, went as far as to make offenders in a proclaimed district triable by court-martial. By the Preventiou of Crime Act, 1882, now expired, the lord-lientensnt was empowered to issue special commissions for the trisl without jury of treason and treason-felony. The nower was never exercised. The Criminal Law and Procedure (Ireland) Act, 1887, desls with resistance to authority and offences of a tressonsble nature, especially "dangerous associatious," though treason is not mentioned by name.

British Colonies and Dependencies. -The law in the msin agrees with that of the mother country, but it is quite competent for a colony to deal with treasou by its own legislation which need not necessarily be in accordance with English law, and is sometimes expressed in more definite terms. Thus the Indian penal code makes it punishable with transportatiou for life to wage war sgainst the Government of any Asiatic power in alliance or at peace with tho queen, or to attempt to excite feelings of disaffection to the Government. Numerous temporary Acts were passed about the time of the mutiny, oue of the most characteristic being an Act of 1858 making rebellious villages liable to confiscation. By the Cape of Good Hope statutes it is treason to deliver arms or gunpowder to the queen's enemies. Many colonics adopt the Euglish legislation as to procedure, and some, as Now South Wales, \&c., enact the Treason Felony Act. A atriking feature of colonial legislation on this subject is the great number of Acts of indemnity passed after different rebellions. Instances of auch Acts occur in the legislation of Canada, Ceylon, the Cape of Good Hope, New Zealand, St Viucont, and Jamaica. The most important in the history of law is the Jamaica Act of 1866 , indemnifying Mr Eyre for any scts colnmitted during the suppression of the rising in the previous year. It was finally held by the Exchequer Chamber in 1870 that this Act protected Mr Eyre from being sued successfully in England on a cause of action arising out of his acts during the outbreak ("Phillips v. Eyre," Lavo Reports, 6 Queen's Bench, 1).

United States. -The law is based upon thei of England. By Art. 3 я. 3 of the constitution "treason against the United States ahall consist only in lerying war against them, or in adhering to their enemies, giving them aid and cornfort. No person shall be convicted of treason unless on the testimony of two wituesses to the same overt act, or on confession in open court. The Congress shall have power to declare the punishment of treason; but no sttainder of treason shall work corruptiou of blood or forfoiture, except during the life of the person attainted." By Art. 2 в.

[^235]impeachruent for and conviction of treason is a ground fol moving the prosident, vice-presidcnt, and other civil officers. The panlahment by an Act of 1790 was declared to be death by hanging. But daring the Civil War a new Act (17 July 1862) was passed, pronding that the ponishment should bc death, or, at the discretiou of the court, imprisonment at hard labour for uot less than five years, and a fine of not less than 10.000 dollars to be levied on the real and personal property of the offender, in addition to disability to hold any office under the United States. The Act of 1862 aud other Acts also deal with the crimes of inciting or engagug in rebellion or inaurrection, criminal correspondeuce with foreign Governments in relation to any disputes or controversies with the United States, or to defeat the measures of the Government of the United States, acditions, conspiracy, recruiting ooldiers or sailors and enlistment to aerve against the United States. Tho Act of 1790 further provides for the delivery to the prisoner of a copy of the indictment and a list of the jurors, for defence by counsel, and for the finding of the indictment within three years after the commission of the treasov. Misprision of treason is defined to be the crime committed by a person owing allegiance to the United States, and having knowledge of the conmission of any crime against them, who conceals and does not as aoon as may be diaclose and make known the same to the presudent or to some judge of the United States, or to the governor or to some judge or justice of a particular State. The punishment is imprisonment for not more than aeven years aud a five of not more than 1000 dollare (see Revised Statutes, §§ 1033, 1034, 1043, 5331-5338; Story, Constitution of the United Statcs, §§ 1290-1301, 1796-1802). Treason against the United States cannot be inquired into by any State court, but the States may, aod some of them have, their own constitutiona aud legislation as to treasons committed against themselves, generally following the linea of the coustitution and legislation of tho United States. Iu come cases there are differences which aro worth notice. Thus the constitution of Massachusetts, § 25 , declares that no subject ought iu any case or in any time to be declared guilty of treason by the legislature. The same provision is contained in the constitutions of Vermont, Connecticut, Pennsylvania, Alabaurs, and otliers. In some States the crime of treason cannot be pardoned; in otleers, as in New York, it may be pardoned by the fegislature, and the governor may auspend the sentence until the end of the aession of the legislature next following conviction. In some States a pereon convicted of treason is disqualified for exercising the franchise. Iu New York conviction carries with it forfciture of rcal eatate for the life of the convict and of his goods and chattels.
(J. WT.)

TREASURE-TROVE is defined by Blackstone to be modey or coin, gold, silver, plate, or bullion found hidden in the earth or other private place, the owner thereof being nuknown. This definition is simply an extension of the Roman law definition of thesaurus inventus as an ancient deposit of money (vetus deposilio pecunix) found by accident and without actual search. The right to treasuretrove was not, however, the same in Rounan and English law. The former at its latest stage divided it between the finder and the orner of the land on which it was found, except where it was found on public or imperial property, when one-half went to the fisc. If a man found treasure on his own land, he had a right to the whole. The rights of the crown, modified by those of the feudal lord, gradually became more extensive in the feudal law of Europe, so much so as to become, in the words of Grotius, "jus commune et quasi gentlum." In more receut times there has been a return, at any rate in the case of France, to the division made by the Roman law. In England the common law, which at one time apparently conferred treasuretrove, wherever found, npon the finder, now gives it all to the king, in accordance with the maxim "quod uullius est fit domini regis." This is always provided that the owner cannot be known or discovered. If he can be he and not the king is entitled to it.

A right to treasure-trove may be granted by the British crown as a Francaise ( $q . v$.). It is the duty of one finding treasure to make it known to the coroner. By the statute De Officio Coronatoris ( $\ddagger \mathrm{Edw}$. I. 日t. 2), the coroner is to inquire of treasure that ia found, Who were the finders and likewise who is anspected thereof, and that may be well perceived where one liveth riotously, haunting taverns, and hath done so of long time. Concealment of treasuretrovs is a misdemeanour at common law. There can be no larceny of it uutil it has been found by the coroner to be the property of the crown. The Home Office has recently issued a notification
modifying the existing regulations ao far as to pernut the finders of coins an $\{$ autiquities coming under the description of treasare trove to retain articles not actually required fer mational institu tions, and the oum received from euch iastitutions as the antiquarian value of any articles retained, aubject to a deduction of 20 per cent. from the antiquarian value of the objects retained and 10 per cent. from the valie of other objects. In the United States treasuretrove is usually vested in the State as bona vacantia. Louisiane follows the French Code Civil, and gives half to the finder and half to the landowner. The importance of treasure-trove in India led to the passing of tho Indian Treasure-Trove Act (Act vi. of 1878). It provides that treasure is to be delivered to tho fiuder if no owner appears. If the owner cau be found, three-fourths go to the finder snd one-fourth to the owner, power being reserved to the Government to acquire it by payment of a aum equal to one-fifth more thau the value of the material.

TREATIES. 1. A treaty is a contract between two or more states. The term "tractatus," and its derivatives, though of occasional accurrence in this sense from the 13 th century onwards, only began to be commonly so employed, in lieu of the older technical terms "conventio pablica," or "fœdus," from the end of the 17 th century. In the lauguage of modern diplomacy the term "treaty" is restricted to tho more important international agreements, especially to those which are the work of a congress, while agreements dealing with subordinate questions are described by the more general term "convention." The present article will disregard this distinction.
2. The making and the observance of treaties is neces sarily a very early phenomenon in the history of civilization, and the theory of treatics was one of the first departments of interuational law to attract attention. Treatics are recorded on the monuments of Egypt and Assyria; they occur in the Old Testament Scriptures; and questions arising under ouvөŋ̂кaь and "fœedera" occupy much space in the Greek and Roman historians. ${ }^{1}$
3. Treaties have been classified on many principles, of which it will suffice to mention the more important.' A "personal treaty," having reference to dynastic interests, is contrasted with a "real treaty," which binds the uation irrespectively of constitutional changes; treaties creating outstanding obligations are opposed to "transitory conventions," e.g., for cession of territory, recognition of independence, and the like, which operate irrevocably once for all, leaving nothing more to be done by the contracting partics; and treaties in the nature of a definite trausaction (Rechtsgescheift) are opposed to those which aim at establishing a general rule of conduct (Rechlssatz). With reference to their objects, treaties may perhaps be conveniently classified as (I) political, including treaties of peace, of alliance, of cession, of boundary, for creation of international servitudes, of neutralization, of guarantec, of submission to arbitration; (2) commercial, including consular and fishery conventions, and slave trade and navigation treaties; (3) confederations for special social objects, such as the Zollverein, the Latin monetary union, and the still wider unions with reference to posts, telegraphs, submarine cables, and weights and measures ; (4) relating to criminal justice, e.g., to extradition and arrest of fugitive seamen; (5) relating to civil justice, e.g., to the protection of trade-mark and copyright, to the execution of foreign judgments, to the reception of evidence, and to actions by and against foreigners ; (6) providing general rules for the conduct of warfare, e.g., the declaration of Paris and the convention of Geneva. It must be remarked that it is not always possible to assign a treaty wholly to one or other of the above classes, siuce many treaties contain in combiuation clauses referable to several of them.
${ }^{1}$ For the celebrated treaty of 509 в.c. between Rome and Carthage, see Polybins iii. 22; sud, on the aubject generally, Barbeyrac's foll but very uncritical Mistoire des Anciens Traíés, 1739; MullerJoclsmas, Geschichle des Völherrechts in Alterthum, 1848; E. Egger, Eludes Historiques sur les Traites Publice cher les Grecs et chez ice Romains, new ed.. 1866.
4. The analogy between treaty-making and legislation is striking when a congress agrees upon general principles which are afterwards accepted by a large number of states, as, for instance, in the case of the Geneva convention for improving the treatment of the wounded. Many political treaties containing "transitory" conventions, with reference to recognition, boundary, or cession, become, as it were, the title-deeds of the nations to which they relate. ${ }^{1}$ But the closest analogy of a treaty is to a contract in private law, as will appear from the immediately following paragraphs.
5. The making of a valid treaty implies several requisites. (1) It must be made between competent parties, i.e., scvereign states. A "concordat," to which the pope, as a spiritual authority, is one of the parties, is therefore not a treaty, nor is a convention between a state and an individual, nor a convention between the rulers of two states with reference to their private affairs. Semisovereign states, such as San Marino or Egypt, may make conventions upon topics within their limited competence. It was formerly alleged that an infidel state could not bo a party to a treaty. The question where the treatymaking power resides in a given state is answered by the municipal law of that state. It usually resides in the executive, though sometimes, as in the United States, it is shared by the legislature, or by a branch of it. (2) There must be an expression of agreement. This is not (as in private law) rendered voidable by duress; e.g., the cession of a province, though extorted by overwhelming force, is nevcrtheless unimpeachable. Duress to the individual negotiator would, however, vitiate the effect of his signature. (3) From the nature of the case, the agreement of states, other than those the government of which is autocratic, must be signified by means of ugents, wbose authority is either express, as in the case of "plenipotentiarics, or implied, as in the case of, e.g., military and naval commanders for matters, sucb as truces, capitulations, and cartels, which are necessarily confided to their discretion. When an agent acts in excess of his implied authority ho is said to make no treaty, but a mere "sponsion," which, unless adopted by bis Government, does not bind it, e.g., the affair of the Caudine Forks (Livy, ix. 5) and the convention of Closter Seven in 1757. (4) Unlike a contract in private law, a treaty, even though made in pursuance of a full power, is, according to modern views, of no effect till it is ratified. (5) No special form is mecessary for a treaty, which in theory may be made without writing. It need not eren appear on the face of it to be a contract between the parties, but may take the form of a joint declaration, or of an exchange of notes. Latin was at one time the language usually employed in treatics; and continued to be so employed to a late date by the emperor and the pope. Treaties to which several European powers of different nationalities are parties are now usually drawn up in French (the use of which became general in the time of Louis XIV.), but the final act of the congress of Kienna contains a protest against the use of this language being considered obligatory. A great European treaty usually commences "In the name of the Most Holy and Indivisible Trinity," or, if the Porte is a party, "In the name of Almighty God." (6) It is sometimes said that a treaty must bave a lawful object, but the danger 'of accepting such a statement is apparent from the uso. which has been made of it by writers who deny the validity of any cession of national territory, or even go so far as to lay down, with Fiore, that "all should be regarded as void which are in any way opposed to the development of the free activity of a nation, or which binder the exercise of its natural rights." (7) The making of a treaty is some-

[^236]times accompanied by acts intended to secure its better performance. The taking of oaths, the assigning of "conservatores pacis," and the giving of bostages are now obsolete, but revenue is mortgaged, territory is pledged, and treaties of guarantee are entered into for this purpose.
6. A " transitory coavention "operates at once, leaving no duties to be subsequently performed, but with reference to conventions of other kinds questions arise as to the duration of the obligation created by them, in other words, as to the moment at which those obligations come to an end. This may occur by the dissolution of one of the contracting states, by the object-matter of the agreement ceasing to exist, by full performance, by performance bocoming impossible, by lapse of the time for which the agreement was made, by contrarius consensus or mutual. release, by "denunciation" by one party under a power reserved in the treaty. By a breach on eitber side the treaty usually becomes, not void, but voidable. A further cause of the termination of treaty obligations is a total change of circumstances, since a clảuse "rebus sic stantibus" is said to be a tacit condition in every treaty. ${ }^{2}$ Such a contention can only be very cautiously admitted. It bas been put forward by Russia in justification of ber repudiation of the clauses of the treaty of Paris neutralizing the Black Sea, and of her engagements as to Batoum contained in the treaty of Berlin. The London protocol of I871, with of view to provent such abuses, lays down, perhaps a little too broadly, "that it is an essential priaciple of the law of nations that no power can liberate itself from the engagements of a treaty, nor modify the stipulations thereof, unless with the consent of the contracting powers, by means of an amicablo arrangement." Treaties are in most cases suspended, if not terminated, by the outbreak of a war between the contracting parties, and are therefore usnally revived in express terms in the treaty of peace.
7. The rules for the interpretation of treaties are not so different from those applicable to contracts in private law as to need bero a separate discussion.
8. Collections of treaties are either (i.) general or (ii.) national.
(i) The frst to publish a general collection of treaties was Leibuitz, whase Codex Juris Gcxtium, containing documents trom 1097 to 1497, "ea qua sola inter liberos populos legam sunt loco," appeared in 1693 , and was followed in 1700 by the Mantissa. The Corps Universel Diplomatique du Droit des Gens of Dument, con. tinued by Barbeyrac and Rousset in thirtcen folio volumes, containing treaties from 315 A.D. to 1730 , was published in 1726-39. Wenck' Corpus Juris Gentium Recentissimi, 3 vols. 8vo, 1781-95, contains treaties from 1735 to 1772. The 8 ro Recucil of G. F. de Martens, centinued by C. de Martens, Sa\&lfeld, Murhard, Samver; Hepf, and Stoerk, commenced in 1791 with treaties of 1761 , and is still in progress. The series in 1887 extended to sixty-four volumes. See also the following periodical publicatiens:-Das Statsarchiv, Sammluag der officiellen Actensticke zur Geschichte der Gegcnwart, Leipsic, comrueacing in 1861; Archives Diplomatiques, Stutigart, eince 1821; Archives Diplomatiques, Recuril Mensucl de Diplomatic et d'Histoire, Paris, since 1861; and Hertslet's British and Forcign State Papers, from the Lermination of the War of 1814 to the latcst pcriod, compiled at the Foreign Office by the Librarian and Kecpor of the Papers. London, since 1819, and atill in progress.
(ii.) The more important collections of national treaties are those of M. Neumanu and MI. de Plassan for Austria, 1855-84; Beutner for the German empire, 1883; Calvo for "1'Amérique Latine," 1862-69: De Clercq for Franco, 1864-86; De Garcia de la Vega for Belgium, 1850-83; Lagemans for the Netherlands, 1858-82; Soutzo for Greece, 1858 ; Count Selar de la Marguerite for Sardinia, 1836-61; Do Castro for Portugal, 1858-78; Rydberg for Sweden, 1877; Kaiser (1861) and Eichmann (1885) for Switzerland; Baron de Testa (1864-82) and Aristarchi Bey (1873-74) for Turkey ; F. de Martens for Russia, 1874-85; Mayers for China, 1877. The official publication fer Italy begins in 1864, for Spain in 1843, for Denmark in 1874. The treaties of Japan were pub. lisbed by autherity in 1884. Those of the United States are contained in the Stalutes at Large of the United States, and in the

[^237]collections of J. Elliott (1834) and H. Minot (1844-50) ; see also Mrr Bancroft Davis's Notes upan the Treaties of the United States vith other Powers, preceded by a List of the Treaties and Conventions with Foreign Powers, chronologically arranged, and followed by an Analytical Index and a Synoptical Index of the Treatics, 1573. In England no traties wero published before tha 1 th century, such masters being thought "not fit to he made vulgar." Tha treaty of 1604 with Spain was, however, published by authority, as were many of the treaties of tha Stuart kings. Rymer's Fadera was published, under the orders of the Government, in twenty volumes, from 1704 to 1732 . Treaties are officially published at the prosent day in the London Gazette, and are also presented to parliament, but for methodical collections of treaties made by Groat Britain we are indebted to private enterprise, which pro duced threo volumes in $1710-13$, republished with a fourth volume in 1732. Other thres volumes appeared in 1772-81, the collection commonly known as that of C. Jenkinson ( 3 vols.) in 1785 , and that of Chalmers ( 2 vols.) in 1795. J. Macgregor published (1341-44) eightvolumes of commorcial treaties, but the great collection of the commercial treaties of Great Britain is that of L. Hertslet, librarian of tha Foreign Office, continued by his son and successor in office, Sir Edward Hertslet, entitled A Completc Collection. 0 the Trcaties and Conventions and Reciprocal Regulations at prescnt subsisting between Great Britain and Foreign Poucrs, and of the Laws and Orders in Council concerning the same, so far as they relate to Commerce and Navigation, the Slave Trade, Post Ofice, dec., and to the Privileges and Interests of the Subjcets of the Contracting Parties,1820-86,16 vols. Sir Edward Hertslet also commenced in 1875 a series of volumes containing Treaties and Tariffs regulating the Trade bctwocn Britain and Foreign Nalions, and Extracts of. Treaties bctwcen Forcign Powers, containing the Most Favaured Nation Clauses applicable to Great Dritain. The treaties affecting British India are officially set out, with historical notes, in A Collection of Treatics, Engagements, and Sannuds relating to India and Neighbouring Countries, by C. W. Aicheson. This work, with the index, extends to eight volumes, which appeared at Calcutta in 1862-68.
9. It may be worth while to add a list of some of the more important treaties, now wholly or partially in force, especially those to which Great Britain is a party, classified accordiag to their objects, in the order suggested in paragraph 3.
(i.) The principal treaties affecting the distribution of territory betmeen the various states of Central Europe are those of Westphalia (Osnabrück and Münster), 1648 Utrecht, 1713 ; Paris and Hubertsburg, 1763 ; for the parti tion of Poland, 1772, 1793; Vienna, 1815; London, for the separation of Belgium from the Netherlands, 1831, 1839 Zurich, for the cession of a portion of Lombardy to Sardinia, 1859; Vienna, as to Schleswig-Holstein, 1864; Prague, whereby the German Confederation was dissolved, Austria recognizing the new North German Confederation, transferring to Prussia her rights over Schleswig-Holstein, and ceding the remainder of Lombardy to Italy, 1866 ; Frank fort, between France and the new German empire, 1871. The disintegration of the Ottoman empire has been regulated by the great powers, or some of them, in the treaties of London, 1832, 1863, 1864, and of Constantinople, 1881, with reference to Greece ; and by the treaties of Paris, 1856 ; London, 1871 ; Berlia, 1878 ; London, 1883 , with reference to Montenegro, Roumania, Servia, Bulgaria, and the navigation of the Panube. The encroachments of Russia upon Turkey, previous to the Crimean War, are registered in a series of treaties beginning with that of Kutchuk-Kainardji, 1754, and ending with that of Adrianople in I829. The independence of the United States of America was acknowledged by Great Britain iu the treaty of peace signed at Paris in 1783 . The boundary between the United States and the British possessions is regulated in details by the treaties of Washington of 1842,1846 , 1871. Switzerland, Belgium, Corfu and Paxo, and Luxemburg are respectively neutralized by the treaties of Vienna, 1815, and of London, 1839, 1864, 1867. A list of treaties of guaranteo to which Great Britain is a party, and which are supposed to ${ }^{\circ}$ be still in force, beginning with a treaty made with Portugal in 1373 , was presented to parliament in 1859.
(ii.) For the innumerable conventions to which Great Eritain is a party as to commerce, consular jurisdiction, fisheries, and the slave trade, it must suffice to refer to the exbaustive and skilfully devised index to Hertslet's Commercial Treaties, forming volume xvi., 1885.
(iii.) The social intercourse of the world is facilitated by conventions, such as those establishing the Latin monetary union, 1865 ; the international telegraphic union, 1865 ; the universal postal union, 1874 ; the international burean of weights and measures, 1875 ; and providing for the protection of submarine cables in time of peace, 1884. Such treaties are somewhat misleadingly spoken of by recent writers (L. von Stein and F. de Martens) as constituting a "droit administratif international."
(iv.) The following are the n -w operative treaties of extradition to which Great Britain is a party:-with the United States, 1845 ; Brazil and Germany, 1872; Austria, Denmark, Italy, Norway and Sweden, 1873 ; Hayti and Netherlands, 1874 ; Belgium and France, 1876 Spain, Portugal (as to India only), 1878 ; Tonga, 1879, Luxemburg, Equador, and Switzerland, 1880; Salrador, 1881; Uruguay, 1884; Guatemala, 1885 ; Russia, 1886. It will be obserped that all these, excent the treaty with tho United States, are subsequent to and governed by the provisions of 33 and 34 Vict. c. 52 , "The Extradition Act, 1870." Before the passing of this general Act, it bad been necessary to pass a special Act for giviag effect to each treaty of extradition. The most complete collec tion of treaties of extradition is that of F. J. Kirchner. L'Extradition, Recucil, dc., London, 1883.
(v.) General conventions, to which most of the European states are parties, were signed in 1883 at Paris for the protection of industrial, and in 1886 at Bern for the protection of literary and artistic, property.
(vi.) Certain bodies of rules intended to mitigate the horrors of war have received the adhesion of most civilized states. Thus the declaration of Paris, 1856 (to which, howerer, the United States, Spain, Mexico, Venezuela, Columbia, Bolivia, and Uruguay have decliued to accede), probibits the use of privateers and protects the commerce of neutrals; the Geneva convention, 1864, gives a neutral character to surgeons and hospitals; and the St Peters burg declaration, 1868 , prohibits the employment of explosive bullets weighing less than 400 grammes.

It were greatly to be wished that the official publication of treaties could be rendered wore speedy and more methodical than it now is. The labours of the publicist would also be much lightened were it possible to consolidate the various general collections of diplomatic acts into a new Corps Diplomatique Universel, well furnished with cross references, and with brief annotations showing how far each treaty is supposed to be still in force.
10. In addition to the works already cited in the course of this article the following are for various reasons important:-Joh. Lupus, De Confederatione Principum, Strasburg, 1511 (the first pnblished monogtaph upon the aubject); Bodinns, Dissertatio de Contractibus Summarum Potestatum, Halle, 1698: Neyron, De Vi Faederum inter Gentes, Gött., 1778; Neyron, Essai Historique et Poluiquo sur les Gararties, \&c., Gott., 1797; Waichter, De Modis Tollendi Pacta inter Gentes, Stuttg., 1780; Dresch, Ueber die Dauer der Völkervertrage, Landshut, 1808; C. Bergbohm, Staalsverträg4 und Gestre als Quellen des Volkerrechts, Dorpat, 1877; Jellinek, Die rechtliche Natur der Statenverträgen, Vienna, 1880; Holzen. dorff, Handbuch des Volkerrechis, vol. iii, 1887. On the history of the great European treaties generally, seo the Histoire Abregee des Traits de Paix cntre les Puissances de 1 Europe, by Koeb, as recast and contlnued by Schöll, in 1817 and 1818, and again by Count de Garden in 1848-59; as also the Recueil Manuel of De Martens and Cussy, now continued by Geffcken. For the peaco of West phalia Puitter's Geist des westphulischen Friedens, 1795, ia useful; for the congress of Vienna, Klüber's Acten des Wiener Congressss, 1816-19, and Le Congress de Vienne et les Trailes de 1815, precede des Conferences de Dresde, de Prague, at de Chatillon, suivi des Congres d'A ix-la-Chapelle, Troppau, Laybach, et VErone. by Count
'Angeberg. The last-mentioned witer has alao publiahed collections of treaties relating to Poland, 1762-1862; to the Italian question, 1859 ; to the congress of -Paris, 1856 , and the revision of its work by the conference of London, 1871; and to the FrancoGerman War of 1870-71. For the treaties regulating the Eastern question, see The European Concert in the Eastern Question, by T. E. Holland, 1885, and La Turquie et le Tanzimat, by E. Engelhardt, 1882-84.
(T. Е. H.)

TRERIZOND, in Greek Tralezua, a city of Asia Minor, situated on the Black Sea, near its south-eastern angle, from the time of its foundation as a Greek colony to the present day has always been a considerable emporium of commerce, and at one time was for two centuries and a half the capital of an empire. Its importance is due to its geographical position, because it commands the point where the chief and most direct trade route from Persia and Central Asia to Europe: over the tableland of Armenia by Bayazid and Erzeroum, descends to the sea. Its safety also was secured by the barrier of rugged mountains which separates its district, from the rest of Asia Minor, rising to the height of 7000 or 8000 feet above the sea-level. Sc complete is the watershed that no streams pass through these ranges, and there is hardly any communication in this direction between the interior of Asia Minor and the coast. For the same reason, together with its northern aspect, the climate is humid and temperate, and favourable to the growth of vegetation, unlike that of the inland regions, which are exposed to great extremes of heat in summer and cold in winter. The position which was occupied by the Hellenic and medixval city is a sloping table of ground (whence the original name of the place, Trapezus, or the "Tableland"), which falls in steep rocky precipices on the two sides, where two deep valleys, descending from the interior, run parallel at no great distance from one another down to the sea. The whols is still inclosed by the Byzantine walls, which follow the line of the cliffs, and are carried along the sea-face; and the upper part of the level, which is separated from the lower by an inner cross wall, forms the castle; while at the highest point, where a sort of neck is formed between the two valleys, is the keep which crowns the whole. The forsifications and their surroundings are singularly picturesque, for the towers, some round, some augular, which project from them are in many cases covered with creepers, and the gardens that occupy the valleys below teem with luxuriant regetation. On each side, about half-way between the keep and the sea, these ravines are crossed by massive bridges, and on the further side of the westernmost of these, away from the city, a large tower and other fortifications remain, which must heve served to defend the approach from that quarter. The area of the ancient city is now called the Kalch, and is inhabited by the Turks ; eastward of this is the extensive Christian quarter, and beyond this again a low promontory juts northward into the sea, partly covered with the houses of a well-built suburb, which is the principal centre of commerce. The barbonr lies oa the eastern side of this promontory, but it is an unsafe roadstead, being unprotected towards the north-east, and having been much silted up, so that vessels cannot approach within a considerable distance of the siore. The neighbourhood of this is the liveliest portion of the city, as it is from here that the caravans start for Persia, and at certain periods of the year long trains of camels may be ecen, and Persian merchants conspicuous by their high black zaps and long robes. The total population of the place is estimated at 32,000 , of whom 2000 are Armenians, 7000 or 8000 Greeks, and the rest Turks.

The city of Trapezua was a colony of Sinope, bat it first comes into notice at the time of the Retreat of the Ten Thousand, who found repose there. Notwithstanding its commercial inıportance, the renoteness of its position prevented it from being much known to fame eitner is the Mellenic or the early medireval nerion :
its greatneas dates from the time of the fourth crussde (1204), when the Byzantine empire was dismombered and its capital occupied by the Latins. During the confusion that followed that event a acion of the inporisl family of the Comneni, called Alexius, escaped into Asia, and, having collected an army of Iberian mercenariea, entered Trebizond, where he was acknowledged as the legitimate sovereign, and assumed the title of Grand Comnenus. Though only twenty-two yeara of age, Alexius was a man of ability and resolute will, capable of establishing order in a time of anarchy; and thus be succeeded without difficulty in making himself master of the greater part of the southern coast of the Black Sea. The empire that was thus founded continued to exist until 1461, when the city was taken by Mohammed Il., eight yeara after he had captured Constantinople. The cause of this long duration, and at the same time the secret of its listory, is to be found in the isolated position of Trebizond aud its district, between the mountaina and the sea, which has already beeu described. By this means it was able to defy both the Seljuks and the Ottnmans, and to maintain its independence agsainst the emperors of Nicsa and Constantinople. But for the seme reason its policy was alwaya narrow, go that it never exercised any beneficial infuenco ou the world at large. It was chiefly in the way of matrimonial alliancea that it wsa brought into contact with other states. Tho imperial family were renowned for their beauty, and tho princesses of this race were sought as brides by Byzsntive emperora of the dynasty of tho Palæologi, by Western noblea, and by Mobammedan princea; and the convexions thua formed originated a variety of diplomatic relations and friendly or offensive alliances. The palace of Trebizond was famed for its magnificence, the court for its luxury and elaborate ceremonial, while at the same time it was frequeutly a hotbed of intriguo and imnorality. The Grand Comneni were also patrons of art and learning, and is consequence of this Trebi2ond was resorted to by many cminent men, by whose agency the library of the palace was provided with valusble manuscripta and the city was sdorned with splendid buildings. The writers of the time spesk with enthusiasm of its lofty towera, of the churchea and monaateries in tho suburbs, and especially of the gardens, orchsris, and olive grovea. It excited the admiration of Gonzales Clarijo, the Spanish envoy, when be passed through it on his way to visit the court of Timur at Samarkand (Clavijo, Historia del Gran Tantorlan, p. 84) ; and Cardinal Bessarion, who was a nativo of the place, in the latter part of his life, when the city had passed into the hands of the Mohammedans, and he was bimself a dignitary of the Roman Church, so little forgot the impreasion it had made upon him that ho wrote a work entitled "The
 mannacript at Venice. Little was known of the history of the empire of Trebizond until the subject was taken in hand by Prof. Fallmersyer of Mnnich, who discovered the chronicle of Dichael Panaretus among the books of Cardinal Bessarion, and from that work, and other sources of information which were clicfly unkuown up to that time, compiled his Geschichte dis Kaiscrithuns won Trapezunt (Munich, 1827). Finlay's account of tho period, in the fourth volume of his History of Grecec, is based ou this. From time to time the emperora of Trebizond paid tribute to the Seljúk sultana of Iconium, to the grand khana of the Mongola, to Timur the Tartar, to the Turcoman chieftains, and to the Ottomena; but by means of skilful negotiations thoy were ensbled practically to secure their independence. We find then also at war with many of these powers, and with the Genoese, who endearoured, to monopolize the commerce of the Black Sea. The city was aeveral times besieged, tho most formidable attack being that which ocetirred in the reign of Andronicus I., the secoud emperor, when the Seljuks, uuder the command of DIelik, tho son of the great sultan Ala-ed-din, first assaulted the northern wall in tho direction of the sea, and afterwarda endeavoured to storm tha ulleer citadel by night. They failed, bowever, in both attempts; and in the latter, owing to the darkness, and to the occurrence of a violent storm which suddenly swelled tho torrents in the raviues, their force was threwn into inextricable confusion, and they were compelled to abondon their esmp and make the best of their escape from the country. So great was tlee strength of tlao fortificationa that, when Mohannmed 11. turncd his thoughta towards the sulyjugation of this state, le might Lave experienced much difficulty in reducing it, and might have been disposed to oflcr favouralılo terms, had it not buen for the pusillauimoua couduct of lavid, the last emperor, who surrendered the place almost ariconditionally.

Several interesting monuments of this period remain at Trelizoml in the form of chorches in the Byzantine stylo of architcctule. Ode of these is within the ares of tho old city, viz., tho church of the Panaghia Chrysokephalos, or Virgin of the Goldcn Ilcad, \& large and massivo but excessively plain building, which is now the Orta-hisaar mosque. On the further side of the eastern ravine standa a smaller but very well proportioned structure, the chlurch of St Eugenius, the patrou saint of 'l'rcbizond, now tho Yeni Djuna djami, or New Friday mosque. Still more important is the churela of Ieghia Sophia, which occupies a conspicunus posilion overlook-

Ing the sea, about two miles to the west of the city. The porches of this are handsomely ornamented, and about a hundred fect from it rises a tall companile, the inner walls of which have been covered in parts with frescos of religious subjects, theugh these are now much defacod. But the most remarkable memorial of the Middle Ages that exista in all this district is the monastery of Sumelas, which is situated among the mountains, about 25 miles from Trebizond, at the aide of a rocky glen, at a height of 4000 feet above the oea. Its position is most extraordinary, for it occupies a cavern in the middle of the face of a perpendicular cliff a thonsand feet high, where the white buildings offer a marked contrast to the brown rock which forms their setting. It is a pproached by a zigzag path at the side of the cliff, from which a flight of stone atcps and a wooden ataircase give acceas to the monastery. The valley below is filled with the richest vegetation, the undergrowth being largely composed of azaleas and rhododendrons. An antiquity of 1500 years is claimed for the foundation of the monastery, but it is certain that the first persen who raised it to importance was the emperor Alexius Comnenus III. of Trebizond; he rebuilt it in 1360, and richly eadower it. The golden bull of that emperor, which became theaceforth the charter of its foundation, is atill preserved ; it is one of the finest specimens of auch documents, and contains portraits of Alexius bimself and his queen. The monastery also possesses the firman of Mohemmed II. by which he accorded bis protection to the monks when he became master of the country.
(H. F. T.)

TREDEGAR, a town of Monmouthshire, England, is situated on the Sirhowy river, and on the London and North Western Railway system, 7 miles east-north-east of Merthyr Tydvil and 249 west of London. The town owes its existence to the establishment in the beginning of the century of the works of the Tredegar Iron and Coal Company, who lease the soil and minerals from Lord Tredegar. The iron-works, chiefy for the smelting of iron and the manufacture of iron and steel rails, are of enormous extent, and employ npwards of 4000 men . The town is also surrounded by iron and coal mines, the property of the company. It consists chiefly of workmen's houses, but is built with regularity and neatness, the principal streets diverging from as open space called the Circle, in the centre of the town, where there are a number a? good ehops. The church of St George is a tasteful modern building in the Norman style. The temperance hall, union workhouse, and literary institute and library deserve notice. The population of the urban sanitary district (area 7029 acres), a emall portion of which is in Erceknockshire, in 1871 was 16,989 and in 1881 it was 18,771
TREE-CREEPER, one of the smallest of British birds, and, regard being had to its requirements, one very generally distributed. It is the Certhia familiaris of ornithology, and remarkable for the stiffened shafts of its long and pointed tail-feathers, aided by which, and by its comparatively large feet, it climbs nimbly, in a succession of jerks, the trunks or branches of trees, invariably proceeding upwards or outwards and generally in a spical direction, 2 s it eeeks the small insects that are hidden in the bark and form its chief food. When in the course of its ecarch it nears the end of a branch or the top of a trunk, it flits to another, always alighting lower down than the place it has left, and so continues its work.

Inconspicuous in colour, for its upper plumage is mostly of variousshades of brown mottled with white, buff, and taray, and beneath it is of a ailvery white, the Tree-Creeper is far more common than the incurious euppese; but, atteation once drawn to it, it can be frequently seen and at times heard, for though a shy singer its song is loud and awcer. The nest is neat, generally placed in a chink formed by a half-detached piece of bark, which secures it from observation, and a considerable mass of material is commonly used to partly stnff up the opening and give a sure foundation for the tiny cup, in which are laid from six to nine eggs oif a translucent White, apottcd or blotched with rust-colour. The Tree-Cleeper inhabits almost the whole of Europe as well as Algerie, and has beon traced across Asis to Jrnan. It is naw recognized as an inhabitant of the greater part of North America, though for a time oxamples from that part of the world, which differed slightly In the tinge of the plumage, were accounted a distinst epecies (7. americana), and even those from Mexico and Guatemala (C).
mexicana) have lately been referred to the same. It therefore occupies an area not exceeded in extent by that of many Passerine birds, and is one of toe atrongest witnesses to the close alliance of the so-called Ncarctic and Palæarctic Regions.

Allied to the Tree-Creeper, but wanting its leagthened and stiff tail-feathers, is the genus Tichodroma, the single member of which is the Wall-Creeper ( $T$. muraria) of the Alps and some other mountainous parts of Europe and Asia, and occasionally seen by the fortunate visitor to Switzerland fluttering like a big butterfy arainst the face of a rock, conspicuous from the scarlet-crimson of its wing-coverts and its white spotted primaries. Its bright hue ia hardly visible when the bird is at rest, and it then presents a dingr appearance of grey and black. It is a species of wide range, extonding from Spain to China; and, thongh but seldom leaving its cliffe, it has wandered even so far as England. Merrett (Pinax, p. 177) in 1667 included it as a British bird, and the corrcspondence between Marsham and Gilbert White (Proc. Norf. and Norw. Nat. Socicty, ii. p. 180) proves that an example was shot in Norfelk, 30th October 1792 ; while another is reported (Zoologist, ser, 2, p. 4839) to have been killed in Lancashire, 8th May 1872

The genus Certhic as founded by Linnæus contained 25 species, all of which, except the two above mentioned, have now been shewn to belong elsewhere ; and for a long while so many others were referred to it that it became a most heterogeneous company. At present, eo few are the forms left in the Family Certhiida that systematists are not wanting to unite it with the Sittide (cf. Nutgatch), for the two groups, however much their extreme members may differ, are linked by so many forms which still exist that little violence is done to the imagination by drawing upon the past for others to complete the series of descendants from a common and not very remote ancestor, one that was possibly the ancestor of the Wrens (q.v.) as well. One thing, however, has especially to be noticed here. The Certhiidax have not the least affinity to the Picidx (cf. Woodpecker, infra), but are strictly Passerine, though the Australien genus Climacteris may possibly not belong to them.
(A. ‥)

TREEFERN. In old and well-grown specimens of some of the familiar ferns of our temperate climates the wide-spreading crown of fronds may be observed to rise at a distance often of a good raany inches above the surface of the ground, and from a stem of considerable thickness. The common male fern Nephrodium (Lastræa) furnishes the commonest instance of this; higher and thicker trunks are, however, occasionally presented by the royal fern (Osnunda regalis), in which a height of 2 feet may be attained, and this with very considerable apparent thickness, due, however, to the origin and descent of a new series of adventitious roots from the bases of each annual set of fronds. Some tropical members and allies of these genera become more distinctly tree-like, e.g., Todea; Pteris also has some sub-arboreal forms. Oleandra is branched and shrub-like, while Argiopteris aud Marattic (Marattitces) may also rise to 2 feet or more. But the tree ferns proper are practically included within the family Cyatheacex. This includes five genera (Cyathea, Alsophila, Hemitelia, Dicksonia, Balantium) and nearly 200 species, of which a few are herbaceous, but the majority arboreal and palm-like, reaching frequently a height of 50 feet or more, Alsophita excelsa of Norfolk Island baving sometimes measured 60 to 80 feet. The fronds are rarely simple or sinuply pinnate, but usually tripinnate or decom. pound, and may attain a length of 20 feet, thus forming a splendid crown of foliage. The stem may occasionally branch into many crowns. The genera are of wide geographical range, mostly of course within the tropics of the Old and New World ; but South Australia, New Zealand, and the Southern Pacific islands all possess their tree-ferns. In Tasmania Alsophila australis bas been found up to the snow-level, and in the humid and mountainous regions of the tropics tree-ferns are also found to range up to a considerable altitude. The fronds may either contribute to the apparent thickness of the stem by leaving mure or lese
of their bases, which become hardened and persistent, or they may be articnlated to the stem and fall off, leaving characteristic scars in spiral series upon the stem. The stem is frequently much increased in apparent thickness by the downgrowth of aerial roots, forming a black coating several inches or even a foot in thickness, but its essential structure differs little in principle from that familiar in the rhizome of the common bracken (Pteris). To the ring or rather netted cylinder of fibro-vascular bundles characteristic of all fern stems scattered internal as well as external bundles arising from these are superadded ; and in a treefern these are of course in greater nambers. The outer bundles give off branches to the descending roots from the region where they pass into the leaves.

Tree-ferns are of course cultivated for their beanty alone; a fem, however, are of some economic applications, chiefly as sonrces of starch. Thas the beautiful Alsophitla excelsa of Norfolk Island is said to be threatened with extinction for the sake of its sago-like pith, mhich is greedily eaten by hegs; Cyathea medullaris also furnishcs a kind of aago to the ustives of New Zealand, QueensIand, aud the Pacific islands. A Javaness apeciea of Dicksonin (D. chrysotricha) furnishea silky hairs, which have been imported as a styptic, sud the leng silky or rather woolly hairs, ao a aundant on the atem and frond-leaves in the various species of Cibotiun, have not only been put to a similar use, but in the Sandwich Islands furnish wool for stuffing mattresses and cnshions, which was formerly an article of export. The "Tartarian lamb," or Agnus scylhicas of old travellers' tales in Chins and Tartary, is simply the woolly stcek of C. Barometz, which, when dried and inverted and all save four of lits frond-stalks cut away, has a droll resemblance to a toy sheep.

tregelles, Samuel Prideaux (1813-1875), Now Testament scholar, was born at Wodehouse Place, uear Falmouth, on January 30, 1813. His parents were Qnakers, and he himself for many years was in communion with the (Darbyite) Plymouth Brethren, but latterly he became a member of the Church of England. He was educated at Falmouth grammar school, and afterwards, without having attended any university, held various modest educational appointments, but finally devoted himself entirely to a laborious student life, until he was incapacitated for literary work by paralysis in 1870. He died at Plymouth on April 24, 1875.
Most of his numerous publications had reference to his great critical edition of the New Testament (see Blble, vol. iii. p. 648 ). They include an Account of the Printed Text of the Greel New Teslament (1854), a dew edition of Horue's-Initroduction (1860), and Canon Mruratorianus: Earliest Catalogue of Books, of the Newo Testament (1868). As early as 1844 he published an edition of the Apocalypse, with the Greek text ao revised as to rest almost ontirely uporis ancient evidence. Tregelles wrote Heads of Hebrew Grammar (1852), translated Gesenius's Hebrevo Lexicon, and was the anthor of a little work on the Jansenists (1851) and of various works in expesition of his special eschatological views (Reniarlis on the Prophetic Visions of Danicl, 1852, new cd. 1864).

TREMATODA, popularly known as "flleses," form one of the three main divisions of the flatworms or Platyhelminthes. They have been defined thus (Jackson, 1):1-
"Unisegméntal Vermes, with a flattish, leaf-like, more or less eylindrical body provided with organs of adhesion in the shape of suckers and sometimes of chitinoid hooks. The cuticle, so called, appears to be a metamorphosed layer of cells. There is a well-developed nervous system, the ganglia of which are entirely supra-pharyngeal, i.e., dorsal. There is a mouth, and an alimentary canal which is usually forked, but no anus. The excretory system has the form of more or less branching tubes commencing with flamecells, and either ending in a contractile vesicle or opening by two independent orifices. Hermaphrodite self-impregnation occurs, as well as reciprocal impregnation. The embryo either develops direct into the sexual form (monogenetic Trematodn) or gives origin to a series of inter-

[^238]mediate non-sexual dimorphic forms (digenetic Trematoda). Parasitic."

Historical Sketch.-Some of the more salient points in the history of our knowledge of these animals have already been alluded to in the article Parasitism (q.v.) ; a few additional facts must, however, be mentioned here. The Irenatoda were first formed into a group by Rudolphi (2), who included in it the following genera:-Monostoma, Amphistoma, Distoma, Tristoma, Pentastoma, and Polystoma; the name had reference to the suckers, which Rudolphi regarded as being for the most part openings into the body (Gr. $\tau \rho \eta \hat{\mu} \mu$, an aperture). . Some of these forms were soon perceived to liave but small connexion with the others; and Cuvier (3) reduced the whole to one genus, for which he adopted the name Fusciola, Linn. The Pentastomes have since been transferred to the Arachmids (q.v.).

Our scientific acquaintance with the group may be said to date from 1831, when Meblis noticed that the eggs of certain Distomes hatched into a minute ciliated body with an eye-speck resembling an Infusorian, an observation which gave the key to the life-history of these forms. Von Siehold in 1835 (4) supplemented this discovery by the observation that the ciliated embryo of Monostomum mutabile contained, as a "necessary parasite," as it was termed, an organism identical with the "kingsyellow worm " (Redia), found by Bojanus in pond-snails, and Von Baer had previously shown (5) that these gave rise to free-swimming organisms not unlike tailed Trematodes. The materials were thus ready to hand for a co-ordination of the whole life-history, and Steenstrup recognized it as in instance of the so-called "alternation of generations" (6). " 1 hese researches received important additions at the hands of Pagenstecher (7) and others, who showed experimentally that encysted Distomes grow mature directly after their transference from one host to another, and thus that a migration is necessary to the attainment of their mat urity. Diesing's great work (8) appeared in 1850, and has formed the groundwork of all subsequent treatises on the systematic arrangement of parasitic worms, althengh it included forms which really belong to quite different groups. In 1861 Van Beneden gained a prize offered by the French Academy by his elaborate memoir on the intestinal worms (9), in which be not only described many new and interesting forms, but gavo anatomical details regarding others previously known, and entered into detailed comparisons between the Cestodes and Trematodes, both in their adult and immature states. Of recent years the chief additions to our knowledge have been more in the direction of further details regarding the structure and life-history of special forms than the elaboration of new general principles.

Anatomy. - In endeavouring to give a very brief account of the mere salient points in the anatomy of the Trematoda it has been thought expedient to select some well-known form as a type, and afterwards to indicate the characters in which other species differ from it; for this purpose tho common liver-finke, Fasciola (Distomum) hepatica has been clooseu, as it is not mofrequently found in the bile-ducts of sheep and other domestic animals, and censtitutes a scourge much dreaded by farmers. The account here given is in the main sbstracted frem Sommer (10).
External Appearance. -The animal has a flatteued eval shapa, with a sub-triangular process on the broader end, which represents the head. The total length raries from 20 to 35 mm ., the breadth from 6 to 12 mm . On superficial examination two narrower latcral areas may generally be distioguished from a broader median ono; the former are occasionally of a coarsely granular appearanco and reddish-brown or orange in colour, and increase in breadth towards the pesterior end of the body, where they commonly unite. The median area is commoniy greyish-yellow in colour, sometimes spotted with black; its anterior portion corresponds to the uterus, the posterior to the testes. Two suckers (fig. $1, A, 0, s$ ) are in the middle line of the bedy; one is at the anterior extremity, and is directed forwards and somewhat downwards; it is known as the
anterior or oral sncker, being perforated by the cesophagus. The postericr or ventral ancker is aituated, is its name impliea, on the inferior aurface of the body, just bahind the head-papilla. The

auckers measure on an average about 1 inm , in diameter, the venwith the outcr rorld by four a pertures:-(1) the mouth $(0)$ situated with the outcr rorld by four apertures:-(1) the mouth ( 0 ), aituated at the anterior pale of the body and perforating the oral sucker;
(2) the excretory pore ( $x$ ), placed at the opposite extremity, and giving exit to the effete products; (3) the prorus genitalis (fig. 1, B, p), leading into a ainus into which the ducts of both sots of genital organs open, -it is to be found ont the under surface of the headpapilla at or near its centre; (4) the opening of the Laurer-Stieda canal, aituated on the dorsal eurface of the animal, near the junction of the two portions of the median area, -it is excessirely minute and difficult of datection. and leada by a narron caual into tha duct of the yolk-gland.
Interanl Structure.-All Tremnioda have ben conmonly regarded, like other flat-worms, as devoid of a lody-caritr (ccelorii), and as consisting of paranchymatous tissue, in which tha rarious organs were embeldct. Recent researches of Fraipont (15) appear to ahow, however, that the intercellular spaces in this tissue are to be regarded as the homologus of a coelom. The body is suclosed by a complex sheath (cortex), which may be resolved into several layerg, which nill be discussed in order, proneeding from without inwards. (1) The cutiele, which oucloses the wholo body, is a thin, pellucid, atructureless membrans; at the margin of the coouth it is reflected so as to form a lining for the cesophagus, and similarly at the opening of the genital sinus it passes invarda to form a lining to the vagina. The same phenomenon is observed at the excretory aperture. By the application of ammonia the cuticle may be separated from the auljacent tissucs and its peculiaritios deuonstratad; although apparently emooth to the naked sye, it presents under the microscops numcroua sherp backwardly directed processes, each of which cncloses a hard atylat-sheped body. These prominences ara closely set orer the whole body except iramediately
around the auckers, extcnding even into the iuterior of the cinns genitalis, The cuticle is furthermore perforated by innumerablo fine pores, directed outrwards and somewhat backwards. With regard to the homology of the cuticle of Trematodes the eame nncertainty prevails as in the caso of Cestodes (eee Tare-Worms)y the geueral opinion is that it is not comparable with the chitinoua cuticle of $A$ rthropoda, but is either a apecially developed base-ment-mambrane (Kerbert, 11) or a layer of modified cells (Ziegler, 12, and Schmarze, 13). (2) The outer cellular layer is the matrix of the cuticle. (3) The minscular coat consists of three different layers:-(i.) a thin layer of circular fibres; (ii.) the longitudinal muscles, which form a series of aeparate bundles; (iii.) the oblique muscles, confined to the anterior half or third of the body, and crossing so as to form a rhomboidal lattice-mork,-they are especially atrong on the anterier ventral asnect of the animal. (4) The inner cellular layer cousists of elements which closely resemble those of the outer, but are 60 me what larger; they have been mistaken by various observers for cuticular glands. The suckers may be conaidered as parts of the cortical layer; apeaking generally, each has the form of the segment of a ephere, although the anterior one ie. 6 hallower at the lover than at the upper margin, and is ponstrated by the cosophagus. Each ronsists of three cets of muscles, $-a$ thin outer equatorial layer, a eecond horidional, and a mass of radially disposed fihres forming the greater part of the substance. It wonld appear that the function of the first two of these groups is to flatten out the sucker, whilst the radinl ones reatore its cavity and thus produce a sucterial action. To the ventral sucker are attached a number of muscular fibres helooging to tho dorso ventral system, and in particular a atrong bundle. Which passes from behind downwards and forwards.
The digestive ayatem (fig. $1, \mathrm{~A}$ ), the presence of which furnishes one of the most characteristic differences between Trematodes and Cestodes, extends throughout the body ou a plane between the peripheral nervous and reproductive ayctems. It has only ons aporture, as above nientioned, in the ccutre of the anterior eucker. The anterior portion or pharynx, althougli very short, messuring not much more than 1 mm . in length, is again divisible into two sections. The hinder of thesa is the larger, and is sometimes apheroidal but more commonly fusiform in shaps; it has strong muscular walls, which, in conjunction with protractor and retractor muscles, bring about a kind of pumping action whereby nutritive fluids are taken iuto the stomach, which name may be applisd to the larger posterior section of the alimentary tract, since in it the digestire procesees are carried on. The canal, which leads from the posterior end of the pharyns, divides almost immediately into two branches, Which diverge at first rapidly and then run almost parallel, as far as the hinder end of the body. Each of these gives off from its outer aspect 60 me 16 or 17 lateral branches (c), which divide and sabdivide till their ramifications fill nearly the whiole area of the body. The digestive tract is lined by a layer of simple cells, resembling a cylinder epithelium. These bebave towards the blood corpuscles and other contonts of the intestine exactly as rould a number of A noebse, putting out processes or pseudopodia, which ingest them, so that, in common with many of the lower Invertehratea, the liverfluke lives by "intracellular digestion" (see Metschnikoff, 14).

The canala of the excretory system ( $m$ ) may be divided in to thres groups. (1) The collecting network conaists of very fine tubnles Which anastomose freely with each other: they are aituated on the boundary botween the cortical and middle layers, and are therefore visible from either side of the body. (2) Conducting vessels ( $0, d)$ receive the contents of this network. Each of these fs formed by the union of a larger or smaller number of the delicate canals just described, and after a longer or shorter course opens into the niedian excretory canal ( $m$ ) On the may, howiever, it communicates with the neighbouring vessels, ao that a second network is formed, which is distinguished from that of the collecting tubules by the greater siza of its meshes and by the fact that it is apecially visiblo from the dorsal surface of the animal. In the head four of these conducting vessels arise, which are disposed in two pairs, ons situatod dorsally and one ventrally. As they rass backwards they receive many branches, the doreal unites with the rentral of its own side, aud the two tulues thus formed unite to constitute the last division of the excretory syatem. (3) The median vessel ( m ) passes along the body for the posterior two-thirda of its length, immodiately heneath the doreal cortical layer. It is widest near the commancomant, whacre it measures shout 0.5 mm . in diameter, aud finally opens at the posterior extremity of the body. The wall of tho excretory apparatua is constitutcd overywhers hy an exceedingly delicato olastic membrane, which exhibits naither a cellular lining nor cilia; furthermore, neither valves nor musciea hava be日n demonstrated in connexion with it It contains a thin colourless fluid, in which rery small highly refractive drops are anspended.
The detaila of the termination of the excretory system seem to have been first clearly made out by Fraipont (15), who worked apon apecies in which they are more distinct than in the form now ander coneideration: The apaces betrecn the round connectivetissue cells of the body are atar-shaped in form, and into these the

Ginest excretory tubules, above mentioned, open by funnels (fig. 1, D), into eacl of which projects a vibratile cilium, thus constituting the so-called "flama-cells." These researches have given rise to numerous differences of opinion, as regards questions both of fact (16) and of priority (17).

The liver-Huke contains a complete cet of male aud female organs, which form the most conspicuous part of its anatomy, and both of which open into the genital sinus which has been described above. A. The Male Organs. (i.) The testes (fg. 1, B, t) are two in number, situated one behind the other in the hinder division of the median area. They rest upon the ventral cortical layer in the parenchyma of the body, and immediately above them are the ramifications of the digeative tract. Each consists of a large number of ramifying tubes, oftel with slightly dilated extremities. These unite into thrse or four, aud eventinally into two, main excretory ducts ( $v a$, vp), which terminate at the base of the cirrus-pouch. Within the testicular tubules may be found spermatozoa in all stages of development; the first stage appears to conaist of small roundish membraneless colls with a single nucleus; the nucleus then divides and the cells become polygonal from mutual pressure. These large cells lie in the middle rather than at the sides of the tube, and among them are a number which, while they possess on one side a smooth egenly ronnded contour, are on the other very irregularly and deeply serrated. These serrations elongate until they become the delicate filaments of spermatozoa, the small abining heads of which are still embedded in the protoplasm of the cell. (ii.) The vasa deferentia ( $v a, v p$ ) are a pair of slender elougated canals, which lio on the two sides of the middle line, and unite at the inner extremity of the cirrus-patch, which they penetrate ia common. Their walls consist of a very delicate homageneous but resistaut membrane, upon which contractile fibres are disposed, close together and parallel to the exis. (iii.) The cirrus-pouch (cs) is a muscular eggshaped organ ; tho upper pc?e, which receives the united vasa deferentia, is situated abore the ventral sncker and separated by only a very slight interval from the dorsal cortical layer, whilst the position of the lower pole is indicated by the porus genitalis (p). The muscles are disposed in two layers, of which the inuer is thin and composed of circular fibres; the outer longitudinal layer is much thicker, and its fibres ore disposed in bundles; furthermore its aper receives a large number of dorso-ventral fibres. Within the cirrus-pouch the two terminal sections of the male conducting apparatusare situated. (iv.) The first of these is the vesicula seminalis (fig. $1, \mathrm{~B}$, es; $\mathbf{C}, g$ ), a large, epinclle-shaped dilatation of the canal usually more or less curved upon itself. Its wall is somewhat more complex than that of the vasa deferedtia, consisting of a layer of tiasue with many nnclei but no distinct cell-boundarics, succeeded by a delicate layer of circular muscular fibres, which is again followed by a layer of lougitudinal oues. (v.) The ductus ejaculatonius (fig. 1, C, $h$ ), which immediately succeeds the vesicula seminalis, is a long slender tube, disposen in coils, and usually projecting like a papilla into the base of the sinus genitalis. Its walls are furnished with a number of unicellular glands. E. The Female Organs. The fenale reproductive apparatus may be roughly divided into two portions, that which produces the eggs and that which conveys them to the outside of the body; in the former of these processes three organs take part-ono prodicing the germ, another the secondary or food-yolk, anl a third the egg-shell. (i.) The germarium or ovary (fig. 1, B, o) is situated between the anterior testis aud the ventral sucker, in obout three cases out of four on the right hand side of the body. It has tho form of a braocling tubular gland, the ramification heing dichotomous throughout; in most cases the branches are about ns large as the stems which give rise to then. The oviduct passes towards the shell-gland, marrowing as it a pproaches this, and finally unites with the excretory duct of the yolk-glands. (ii.) The yolk-glands ( $y$ ) of the liver-lluke are paired orgalis of considerable size; they extend over both lateral aress, to which thoy impart the opaque appearauce and reddish colour above alluded to. They are composed of innumerable small acini, spheroidal in sliape and situated in groups on minute ductules, which unite to forma longitudiual canal on either side of the body. These canals ore ou the whols parallel to the margins of the animal and distant from it ahout one-fifth of its greatest breadth. At the anterior margin of the tcsticular area each longitudinal canal gives off a transverso branch, which unites with its fellow of the opposite side in the middla line to form a pear-shaped reservoir, situated just behind the posterior margin of the shell-gland. From this reservoir the coramon yolk-duct passes forwards in the subatance of the shellgland and there unites with the oviduct. Previously to this, howaver, it gives off a minute canal, which after an upward course opens on tho dorsal surface of the animal; it is known as the Laurer. Stiela canal, and its function bas been the subject of much discussion. It has been anpposed (1) "to serve for copulatory purposes," as has beed aecn by Zeller (18) in Polystomum, and as is supported by its structure in Axine and Microcotyle, and (2) "to act as a safety tube for the escape of over-aboadant or altered vitelline products and spermatozon," the wain argument in support of which is that its calibre is too nerrow to admit of copulation taking place by
its means ; compare Sommer (10), Kerbert (11), Poirier (19), Looss (20), and Lorenz (21). (iii.) The uterus or female condacting apparatus ( $u$ ) originates at the union of the ducts of the germarium and yolk-gland. Its first portion, which lice within the ehell-gland, is a delicate narrow canal, cxcept when it is distended either by eggs or by eemen. The median section of the organ is by far the largest bath ia length and breadth; it oocupies almost the whole of the anterior part of the medion area of the animal, between the ventral oncker aud the shell-gland, and forms four or five large coils lying alternately right and left, which as a rule aro filled with completely formed eggs. The third section of this organ includes the coils which lie above and anterior to the ventral sucker; it is sometimes called the vagina. Then it contains eggs these are generally iu a siugle file, and thus giveit a moniliform appearance; it lies entirely ou the left side of the body, gradually approaching the middle line as it passes forward, until it ends below the cirrus-poucb at the left and posterior a日pect of the genital pore (Eg. 1, C, e). (iv.) The sbell-gland (fig. 1, B, s), which (as its name implies) furnishes the external coating of the eggs, has been already several times mentioned. In the Trematodea, as in the tape-worms, it forms a kind of central point of the femele geuerative system; it is a spheroidal mass of unicellular glands, each of which apens by its own special duct in to the commencement of the uteriss. The secretion of the shell-gland is liberated in the form of small pellucid droplets, which unite to form drops; afterwards it becomes thick and riscid and of a mabogany brown colour, In this condition the drops are dispersed through the uterms mired with the secretions of the other genital glauds, and they apply themselves to the recently formed eggs, producing a delicate membrane around them. This process is carried on in those coils of the uterus which lie immediately outside the shell-gland, corresponding to the "ootype" described by Van Beneden in other Trematodes.

The eggs undergo a gradual development as they pass along the uterus. The ripe primitive ovum, on enteriog the female conducting apparatus, becomes conted with a larger or smaller number of spherules of sccondary yolk, and then nndergoes the process of segmentation which leads to the formation of a morula. At this point it receives the secretion of the shell-giand. The completely tormed egg (fig. 1, E) has a length of 0.13 mra . and is ovoid in shape, witli a small lid or operculum at tho broader end; its contents consist of a number of roundly polygonal cells, with only a small quantity of secondary yolk remaining among them. All of these but oue have a thick granular protoplasm, the exceptional cell having bomogeneous aud strongly refracting contonts. It usually lies immediately under the operctlum, and is partly embedded in the other cells. They are of ten present in the bile-ducts in such quantities as to form a stiff brownish mass resembling wet sand, and the number produced by a single fluke has been estimated at half a million.

The mode of fortilization of the liver-fluke hes-given rise to much discussion. According to Sommer, the organ which bas usually been described as a cirrus or penis is merely the genital sirus avaginsted by abnormal pressure (fig. 1, C, d); it is furthermore but ill-adapted to enter either of the canals which could possibly serve as a vagina. He is therefore of opioion that self-impregnation occurs, the external sperture bcing closed by the oblique muscles, and the semeu passing directly from the vas deferens through the genital simus into the uterus. The whole question of the fertilization of the Trematodes is a matter ou which very varied opinions have been expressed, even by authors who have examined the same forms. The assertion of Von Siebold that a direct internal communication exists between the male and female organs has been denied by Stieda (22) and by many subsequent writers, but has been restated by Lorenz (21) and by Zeller in the case of Polystomum integerrimum (18); however this may be, there can ba no donbt that eelf-impregoation does occur in certain cases. The stucture of the organs renders it more than probable in some species (see Poirier, 19, p. 582) ; Zaddach has observed it actually taking place in Distomum cirrigevoum encysted in Astacus (23), and a single Polystomum integorrimum has been found in a frog's bladder with sperm in the female passages. Reciprocal fcrtilization, in which tro individuals act both os male and female simultaneously, has been recorded by Zeller in Polystomv:m intcgerrimum, by Looss (20) in Distomum clavigerum, and by Cobbold in Distomum campula.
The uervous system consists of a commissure passing round the œsophagus very obliquely, and swelling out into ganglia at three points. Trislomum molx possesses ejes of en extremely simple type, the retina being merely a ganglion cell (Lang, 24).
Life-History and Development. -The life-history of Fascrohe hepatica was worked ont independently by Thomas (25) and Leuckart (26); regarding the question of priority see Jackson (27).

The development of the embryo can only take place outside the body of the host and at a lower temperature, the most favourable being from $23^{\circ}$ to $26^{\circ} \mathrm{C}$, at which the process occupies twa or three wecks. The free embryo (fig. 2, A) is conical in shape, with a rounded apex, ite avarage langth being 0.13 mm . At the broader anterior and is a retractile head-papilla, with the exception of which the body
en cilisted all over. The interier of the bedy as cempesed of granular nuclested cella, and it contains a deuble eye-spot, composed of two crescentic masses of pigment. There are also two ciliated funnels forming the rudiments of the excretory system and a graaular mass behind the head-papilla, probably representing the digestive tract. The embrye swims actively about, but.if it does not succecd in meeting the appropriate host for its next atage of development (Limnæus sruncatulus, a small pond snail) its peried of vitality seems to be linited to about eight hours. If it should meet with one of these

snails it applies the head-papilla to come part of its anrface sud beging to bore, twisting round and ronnd on its axis by means of ats cilia, the head-papilla bocoming pointed and elongated to four or five times its original langth. Eventually the tissues of the tnail are aeparatad as if by a wedge, and a gap is formed through which the ombryo forces an entrance into its body. Here it undergoes a metamerphesis, losing its ergans of locemotion and becoming what is tarmed a "sporocyst" (fig. 2, B). This is on elliptical sac, which commonly attains a length of 0.7 mm Its wall consists of a structurcless cuticle, beneath which are exteraal, circular, and internal longitudinal muscle-fibes. These are succeeded by an ejithelium, the elements of which vary greatly in size. Theac sporocysts may be produced by a process of transverse fission. Within tho sporocyst rounded masses of colls are formed (mornla), which undergo a process of invagination, producing a gastrule, which again devalops by the formation of a digestive tract into what ts known as a "redia" (fig 2, C, D). This forces its way throngh the wall of the sperecyst, which heals up immediately, and then waudera throngh the tissue of the snail, most commonly finding its way to tha livar. If many reciio are present the snail usually perishes. Tho adult redia may sttain a length of 1.6 mm . It has an elongated cylindrical form, and near its posterior extremity are two processes directed backwards, which probably servo as aids to locemetion. At the anterier extramity is the mouth, leadiag into a muscular pharynx, folloved by a saccalar digestivo tract. A ring: shapel thickoning is soen a little way behind the menth, and Immadintely posterior to this a spocial aperture for the exit of the germs formed withiu the redia. About a scoro of thase are usually to bo found in all stages of development, the carliest being a pounded mass of cells (morula), whicls elongates, ono cnr at the
same time becoming more attenusted than the other, ad gradually forming an elongated tail, while the body becames oval and dopressed (fig. 2, E). Two suckers and the rudiment of the future digestive tract make their appearancc. As soon as the "cercaria," this being the name givcn to the present organiam, has attained this atage of developmeat it emerges from the redia, and by the aid of its suckera and tail wriggles its way out of tho host, swimming freely about in the water. Like other cercarix developed in redio this one has no head-spine, but in mature examples the anterior of the body oftea exhibits a number of very minute apines. An interesting feature in the animal is the presence of the "cystegenous cells," two lobate masses arranged one on each side of the body. These cells contain small rod-like bodies, whence they have beon termed "cellules à batonnets," and similar bodies have been found in the protective cyst which they excrete; Sonsine (28) has sliggested that they may assist in imparting stiffness to this atructure, and has noticed that they are mere abondant in these forms which encyst in the open air. When the cercaris has swum about for a short time it finds its way to the water-plants, and encysts itself on their stoms and leaves. During this process the tail is swung vigerously about, until finally a more vielent motion detaches it; at the same time the cells just mentioned threw out a gummy secretion, which rapilly hardons and encloses the cercaria in a kind of case. It is in this condition that the larve are awallower by the grazing sheep to form sexually maiure flukes in their livers.
The life-history of a typical digeuetic Trematole may be summed up as follows:-(1) the egg, produced saxually ; (8) the cilialca embryo; (3) the sporocyst; (4) the redia, produced asexually; (5) the ccrcaria, prorluced asexually; (6) the adult Trematode. Hence it would appear that the digenetic forms have at least one, usually many, esexual generations before the sexual one appears. The embryo may form oither a sporocyst or a redia, these two forms being distinguished by the presence of a digestive tract and of a special birth-opening in the latter. Within these parent forme the germs may arise from two sources, - the cells which occupy tho central region of the young sporocyst or redia, or the epithelium liaing the body-walls. "The germs to which a sporecyst gives origin may develop in some instances into sporecysta, in others inte redie or inte cercarie. And it dees not seem certain that there is any limit to the possible number of successive generations of redie. Both cercarix and redim may occur side by side in the same nurse. The last term in the series is, however, invariably a cercaria."

Pagenstecher, Ercelani (29), and others hare stated that the tail of a cerearia may become a sperecyst and produce germs, bnt this has not mot with general acceptance, and the supposition io not supperted by tha structure of the tail, which consiata of a "contractile substance, occupying the axis and periphery, with large vesicular cells between" (Schwarze, 13). Ercolani (29) has also published striking statements to the effect that the structure of these ontozoa is se profoundly modified by their habitat that what have beeu hitherte deacribed as distinct species may be only "local varieties"; thus he finds that Cercaria armata develons in Tropr. donotus iato Distonnem signatum, wbilst in Mus musculus and $M$. decumanus it becomes a distinct divarfed form, $D$. muris.

Pathological and Economic Relations.-Although the number of Tromatedes which have been recorled from the human body is about equal to that of the Cestodes, the nredical aignificance of the former is much less than that of the latfer, becanse as a rule they occur in smaller numbers and are lesa apt to invale ergans of vital imporrance. For tha general princinlcs which gavern tho pathological effects of Trematodes in common with other entozoa, referenca may bo made to the article Taps-Worms; only a few aperial casea need ba alluded to here The occurrence of most of the forms in the above list has only been recerded very few times, and in many cases the efferts produced were very inadequately atudied, so that we can hardly be said to possess a knowledgo of their individual pathology. In a case of fistomum lanccolatum whicln occurred in Bohemia, the liver was enormonaly enlarged and the contracted gall-bladder contaiued ejrglit calculi and forty-soven fukes; the eymptoms during life were emaciation, pain over the liver, aud distention of the abdomen.

Tha ellects produced by Bilharzit hæmatobia are very well defined and exceelingly disastrous. The mature worms in couplee

Tababit the veins, especially those of the urinery bladder and mesentery ; extravasations of blood and villous growthe or ulcerations of the mucous menlbraue of tle bladder present themselves, and thus the eggs of the parasite find their way lato the urine, in which they are evacuated, and can le detected by raicroscopic examination. With the charecteristir presence of the eggs are associated colic, anæmia, and great prostration of the vital powers, more particularly in the later stages; the discaso when once fairly eetablished is almost always fatal ; see Cobbold (1).
From a practical point of view by far the most important Trema tode is Fasciola (Distomum) hevatica, which gives rise to the discase known as "liver rot" in sheep. It is always more or less abund. ant in certain districts, and it is estimated that in the United Kingdom the annual loss of sheep due to it is not less than $1,000,000$. The symptoms are said to bur emsciation, tenderness in the loins, harshness and dryness of the wool, and a scaly condition of the skin. On post-mortem examination fluid is found in the peritoneal cavity and the viscera have a blanched appearance the liver is dark chooolate or sometimes pale in colour, nodular and uneven, the ducts are thickencd and Distomes are found wiihin them. Dead flukes have been known to furnish the nucle of gall-stoncs in the gall-bladder. Briefly stated, the priucipal preventive measures secm to be as follows :-(1) destruction of the cges, and especially abstention from putting manure of rotten sheep on damp ground; (2) slaughter of sheep which are badly Guked ; (3) adequate drainage of pastures; (4) an allowance of salt and a little dry food to the shcep; and (5) dressinga of lime or salt on the ground to destroy the embryos (Thomas, 25). A series of wet seasons increases the prevalence of the malady, and animals which have been allowed to graze in low-lyirg ill-drained lands are apecially liable to infection-facto which are readily explicable on a consideration of the life-history given above.
Systematic Arrangement.-The Trematoda may bo classified as Iollows :-

MONOGENEA; Van Beoeden; development dreet, that is, withoot the media tiou of aurbe ferms.
(i.) Tristomanz, Lewckart; body roundlah or elongato; posterior estromity dever specialy cuvelopod. Two acoñal anckers often preseat: a large veatral sucker often armed with chitisold structures. Sexoal apertares 00 the left side or admediag. Laures-Stleda canal singls or double. Tra with a filamedt at one pele only.
4. Tristomidar, Van Beacdea.-1. Trislomum, Cuvler; about a dozen genera of previous witers are here inciuded; over 14 apecies are known, nll parasitic on tishes; Tascheaberg (30).
7. Mooocotylldae, Taschenberg.-1. Calicotyle, Diesiog; only opecicá C. kroyer' (31). 2. Pseudocoryte, Tascheaberg. 3. Honocolyte, Tascherb berg; only one rpeciea, 1. myliobatis, on the gills of the eagle-ray (Myliohatis aguila).
. Udooellidx, Juhnst en.- 1. Udonella, Jhost; flve specics, the typa belng O. carigorum, parasitic en a crustacean (Caligus), which in fts turn in. fests the holbbit (IIippoglossus ruhgaris).
(U.) Polfstomest, Lenckart; body elongate, pointed and narrow anteriorly bioad behind and gencrally provided with special organs of adhesion in the shape of auckers or chitineid jonlss of suckers or claspers with chtinold struciares. Two adoral suckerg In come instances. Sexual apertures median. Laurer-Stieda canal siggle or doublc. Male scxan
aperturo often armed with chitinuid hooks. Ova frequently provided aperturo aften armed with
with two long appendaces.
*. Octebothrijtla, Tasclsenberg.-1. Octobothrium, Nordmasa; abont a dozen genera of various authors are here Included by Tascheoberg (30), containing fourteen specles, parusitic on fahes, and almost Invariably on the mills. "2. Aithocotyle, Hesse sod Van Beneden; ode spectes (A, merlucia), found in the hsike. 3. Phyllocolyle, Hesse and Van Bencden ; ono species, fron the kumard. 4. Platycolyle, Hesse and Van Beneden; one species, from the gurnard. B. Pleurocolyte, Gervais and Vag Beneden ( $=$ Gruben cochlear; Dies.); ooe specles, from the gille of the inackerel. 6. Diplozvon, Nordinano (see below). 7. Hexacotyle, Blalowilla: one kpeciew, from Thynnus brachyplerus. 8. Pleclanocotyle, Dies.; from the gills of Labrax mucronalus.
4. Polystenidx, Van Beneden,-1. Polystomum, Zeo̊er; two apecles, best known P. integerrmum (sco bejnw); Hexathyridinm is prebnbly e synony'm. 2. Onchocotyle, Dies.; tive ypecjes, [rom the gills of oharks and rays. 3. Erpocotyle, Jlesse and Van Beneden; ono apecles, from tha gills.nf Mustelus levis. 4. Diplubothrium, F. S. Leuckart; ooe specles, from the gills of a sturgeon.

- Mtrocotylide, Taschenberg.-1. Arine, Abildganerd; two bpectes. 2. Mierocolyle, Var Beneden; about half a dozen apectes, ull parasitic o. the gits of fishes (see below). 3. Gastrocotyle, Flesse and Van Beneden; ons specles, from tho gills of Caranx brochurus. 4. Aspidogoster, Von bacr (see below). 3. Colylaspis, Leidy; ona species, occuring in Anodonta. 6. Aspidocotyle, Dles.

4. Gyrodactylhx, Van Beneden.-1. Oyrodaclylus, Nordmann (sea below), 2. Dactylogyrus, Dics; about tweaty speclcs, all parasitic on fishes, mostly on the gills. 3. Tetraonchus, Dies.; threa apeclos, on the ghts of freshwater fishes. 4. Dipiectrum, Dies. . D. Calceostomum, Fan Beneden; ona species, on the sills of Sciena aquila. 6. Sphyranura, Wrlght $(34,45)$; on species, Irom the modth of Jenobranchus lateralis.
5. DIGENEA, Van Benciea; one or more das-sexnal forms foterrede between two successive 日exnal forms.
(.) Monostomids, Van Beneden; elnngate, oval, or rounded Ia shape; one oral sucker.-1. Monostomum, 7.eder; fifty to sixty species in mammala, birda, and ilshes; type, $N_{\text {. }}$ nunlabile, Feder, found in the bedy-cavity and eyo of water-birds. 2. Yolocatyle, Dies, ; $N$. 'riseriate, Dies.
bistomu vism Distonida, in beneden; bedy fiattlsh, wore or less leafilke or Disfornum Ketzius (see below) sub-median or posterior sucker.-1. koown. F. hepatica is descitbed sbove $F$ giganca inhable the llver af the graffe 3 , (see belew). 4. Echinostomum, Dujardin; E. gadorum, Vin Beneden, (n the ratestine of Godus carbonarius (the coal-ish), and twenty-ive
atber species la the almentary canal of mammmis, birds, and fishes. 5. Amphistomum, Rodolphi; about twenty apecies io different Vartsbrates; A. subclanatum (Goze) Io the rectom of the frog. 6. Gastrodis cus (?), Lenckart (see aiso 87). 7. Homalogasier, Poirier (38). 8. Qas. trothylax, Polfler. 9. Eurycolium, Brock (44), has the oscretory vessels dilated into wide chambers ( 3 ccelom).
Gasterostomios, Von Slebold; oral sacker sub-medjan and ventr d; alse an anterior ancker.-1. Gasierosiomum, Ven Siebold; elglit specles, adl in fishes; farval form Bucephalus (see below).
(1.) Holostoxid.s. Claus (43); bedy fiattened, nad dividad Into as saterior and postevior part, tha former bearlng an anterior and veatral spcker; wo adozal lubes with glands in connexion, or a cireumoral fold with lobes.-1. Holustomum, Nltzsche; twenty-three speclea, most io waterblids: In. variabile, is varions rsptorial birdo; larval forms Tetracotyla wild-cat two in blys. 2. Hemistomum, Dies; three specles, oDe in tho

Fro. 3.-A, Dfolozoon parodorum; two unlted specimens. B, Polystomum inta. gerrimun; $x$ about 100 (after Zeller). $C$, Hicrocolyle mornayri; $\times 7$. $D, E$,
$t w e$ views of the chitinous Iramework of a sucker of Axine belones; liglily magnlied (after Loreoz). F, Aspidoguster conchicola; $x$ about 25 (after Aubert). G, Gyroduclylus elegons; $\times$ abuut 80 (after Wagener).
008 extremity. The embryo is elongated oval in shape, and ciliated allover; oa its Lack are two eyes, coasistiog of a cup-shaped inass of pigment, with a spheroida lenticular bedy. It preseats alse the mouth with two pecaliar suckers, the cesophagus and latestlne, nod the two claspers of the Diporpa. The ambjyo $5 w 1 \mathrm{~ms}$ yigorously, about until it finds its way te the gill of a minnow, failing which it dies In about six hours. Attached to its host it may livo lsolated for a consiferablo tlme, facrea:ing in size; ugaully, however, it unites with another Individual in s kInd of reciprecal copulation (Ag. 3, A). Oac individusl by means of its ventra bucker selzes tha durssi papma of another, and thentho tho twist across each other 80 that the sucker of the second seizes the papilla of the flast. After this a complete fusion of thu individuals takes place, the papllar and suckers growing tegether so firmly as to be anatomlcally inscparable. Both iadivicuals contiouo to grow and ocvelop s second, thit, and sometimes a fourth pair of claspers.
io Polystomum integerrimpm (18), which insabits the bladder of tho 110 g , the esgs are developed doring the winter and are laid in the spring, when the frog resort to the water. It appears probable that the worm protiudes its body from the frog and thus deposits the egs directly in the water. Tho yound worm, as it escapea from tho egz, which takes place after a lapso of siz or eight weeks measures abont 0.3 mm . in length, a.d swims vlgorausly about by 2 ha ald of a coating of cilia. At Its posterlor extremity is a rounded dsk (\$g. 3, B, jonad the margin if which slateen delicute hnoks are placed nt equal intervals, Above the feur hindmost of thess are two others gtill smaller and more delicate. Upon tha back aro aitaated four eyes dlaposed la palrs. The month is wide and leads into a pharymx and thls into the infestine; two excretory vessels are present, but thero is no trace of ceocrallve orpang. The hindermost pair of suckers is the firy to be derepoped and they enclose these two hooks which lio at the outer aldc of the very fulicate ones mentloned above, which eventually become the stroos termioal books of the adit The other two palrs of suckers aro formed in a similar manner the derclopment of all mece being usnally completed daring the month of July, The youns polyscomyon att acks not the full-crown froc but the tadpale enteing the cill-cavity and subsequently proceediog to the bladder tiks the frog it requirty four or flve years to uttain sexual maiurity, In certaio case the polystomum does not mipiete; it then becomes prematuruly gexosl an dies when the taipele indercees metamorphosls. under these circumatances th
 sexal coll and lis ted anterior porton.

Microcolve mormuri, Lorenz (21) (fig. 3, C), has no penfa, the semen Issulng by a opeolag posterior to the 6 piked birth-opeoing; tha ragina apeas medially, not
marginally. Tho posterlor extremily la polnted. Axine befones, Ablldg., resemblee it, but is broad and obliquely truncaied behind, this margin bearing a row of fifty to seventy peculiar attachisg organs, wblch are of the form of a hand-astchel (fg. 3, D, E), the metsi clasp belng represented by a complicated chitnous framework. There are four groups of hooks and one riog of the same round the genital opening. The mouth has a sucker at elther side, and sbove It an be ovaginated like the preboscis of a Dendrocele Plaiserlan.

Aspidogaster conchicola (32) Is found in the pericardal cavity of the ireshwater mussel; it is conical anteriorly with a terminal oral sucker; the ventral sucker fs vory largs and disided into rectangular arcas; the excretory pore is at the posferlor extremity of the budy, and the genital organs open on the left alde of tbe fore-part of the anlmal (fly. $3, F$ ).
Gyrodactylus elegans ( 83 ) Is found on the fins and surface of the bedy of the plke, aticklebsck, and other frcshwster fishes, and measures about 0.5 mm . in feagith ; it is flattened in iorm and tapers towards elther end (fig. 3, G). At the anterlor extrembty are two lappets, while the posterlor is furnished with a subtrlangular plate, which bears the organs of attachment in the shape of two large cnived hooks in Its centre and sixteen smaller ones on its clrcumfereace. The most Interesting peculiulty, howerer, of this form is to be found in the fact thet each crobryo bciore it is extruded (the onlmal is viviparous) contains another embrye, sud this in its turn another, oc that three embryoulc.generationsare prosent simultaneously.
present 6 multaneously. the present time over 300 हpecles, which eccur almost exclusively in Vertebratee; the presen the most important are perhaps D. ianceorain, when frog, ond D. miritare, Van tloas as Fasciola hepatica, D. clavigerum, from ne frog, anio D. miniore, an Bencdea, from the intestine of the duck, priorliy over Discomun (Diatoma) of Retzlus, whicls, however, has obtained extenslve currency. The name Fasciola may eppropriately bs used in a restricted scnse for forms which have a branched digestove trect, $\mathrm{R}_{\mathrm{c}}$ hepatica above deseribed being taken as the type. This Eeparation has not met Welntand hns proposed nition, alhough supported hy Blanchard and Cobuiduln, for Distomum, retainfng to substituto the term Dicroccelium, used hy Dujurain, for pistomum, retaining Fasciola for the type-species, but this proposal has not met with ncceptance. The Distomes vary in size from forms almost microscopic to those which, like $D$. ingens, Monlez ( 35 ), messure 8 cm . long in alcoliel, or even 12.5 cm . In the fresh condition (D. gigas, Nardo). Distomum halosaur, Bell (36), is parasltic upen a deep-sea, fish taken in 1090 fathoms. Distomum macrostomum (tig. 4, B) of the woodpecker (Apternus twdactylus) hes a remarkiable larval form known as beucechlorioium paradozum, wblch io parasitic on succined puris, and consists of a
number of bronchlng thronds, from which are developed one or two contractile number of brenching threads, from which are developed one or two contractio

Fio. 4.-A, Bilharzia hæmatobia, the thin female in the gynæcophoric canal of the stouter male; $\times 15$ (after Leackart). B, Distomum macrostomum, sbowing the digestive and the grcoter part of the genltal npparatus with tbe cirrus protruded: $\times 30$. C, Snall (Succiaea), the tentacles deformed by leucochloridium ; natural slze. D, Leucochloricitum removed from the feotacle; natural elze (after Zuller). E, Bucephalus polymorphus; highly mognifled (after Ziegler). F, Portlon of a sporacjest contalning Bucephali in process of development; $\times$ about 50 (after Lacaze-Duthiers).
hangs outwards. The threads wlthin the Succinea contain only gisnular cells, whilst the contractile sac is occupled by an orgnnism ovold in form, with a thlek clesr border, the judimeats of two suckers, \& digestlve tract, and excretary systern. Bilharaia himatoivia, Cobbold ( 1 ), is one of the most dengerons hnman psrasites, and occurs in tho blood of the portal vein and In the velus of the mesentery and bladder. The scxes aro distinct, the femalo lieing from 16 to 20 mm . In length, bladder. The scxes aro distinct, the femalo heng from 16 to 20 . The male is anly fram 10 to 14 mm . in length, but nuch theker. The surface of the femule is only from 10 to 14 mm . In length, but nuch thicker. The surface of the female is covered with fine epiaes most distinct owards the tall; at the antelior pointed extremity is thio oral sucker, flom which a nsrrow opeming leads inte n wide wain uniting posterlarly to the generative organs. Tho ventral sucker ls placed
only 0.2 mm . behind the oral me, and it is fmmediately acceeded by a long narrow groove, which extends down the ventra
The stages io the life-history of Gasterostomum are on remarkabla thet a short account of them must be given. From the egg there escapes (1) a club-shaped embryo, which in a manner hitherto unobserved entera tbe freshwater mossel Anodonia or Unio, whers it forms (2) the sporocyst (fig. 4, F); thie is several ccoti metres long and provided with lateral braaches; It occurs chlefly in the llrer and ovary, and it is best developed near the ekin. The wall of the sperocyet cooalsts of cells, muscles, and perliaps a cuticle; the extremities are poloted and flled with cells, and it is here that growth takes place. Within monlliform dilatations of these ramlfled tubes are formed balls af cells, esch of which develops lato (8) a "bucepbalus." This organism (fig. 4, E) consists of a amall eval body abou 0.25 mm . In length with a double tall. At one extremity is a mass of glands with an invagination of the integament, which has been mistaken by many observers for the almcotary chnal. This, however, opens about the midde of the body, and consists of a muscular pharynx, a formardy-directed cesophegus, and a simple sacculsr intestime. The excretory aystera terminetes lo a0 S-shaped vesicle, which opens postariorly in such a way that its coatrachon diver the fiuld into the tsil, whence it probsbly finds its exlt by osmosis. Tracer of geaital organs are found in the form of an elongated plug of cells in the hinder fouth of the body, and twe rounded masses of undifferentisted ceils bituated dorsally. The tall is dorble, and from about 0.5 to 2.5 mm . long sccording to its atate of contraction. Each half consists of a spberoldal basal portion, and en elengatel tapering flament. These caudal sppendsges contain many nucleated connectivetissue cells with fine protoplasmic processes. The lsI'va 6 wim freely in the water but sink and pertsh after aboot twelve hours, ualeos they enter the moath of cettain Ashes (e.g., Leuciscus erythrophthalmus), when (4) they leae their talls and become encapsuled under the skin. The reaeratlve organs now become further developed; cutlcnior spines and the unterior bucker are formed. If the fleh thas Infected be swallowed by a plke or perch the cyst is dissolved, and the woims (5) become adult, cmintine to live in the Intestine, and produce eggs. For further detalls, aee Ziegler (12)

Phylogenctic Relations. - The detailed eomparisons of Van Beneden (9) and the subsequent researches of othors leave no doubt that the Trematoda are closely related to the Cestoda. A consideration of their peculiarities leads moreover to the opinion that the former are more primitive than the latter; that is to say, the common ancestors of the two groups resembled Trematodes rather than Cestodes. Tho ancestry of the Trematoda is probably to be sought in types such as the Planarians rather than the Leeches; characters uniting them with the former are the possession of a commonly branched alimentary canal without an anus, but with a powerful pharynx; the genorative system is hermaphrodite, and similar arrangensents obtain in the exeretory vessels, nerves, and muscles, while histological agreements also are not wanting. Furthermore, certain forms are known whieh help to fill up the gap between the two groups: Monocelis caudatus has a discoid posterior organ of attachment, and $M$. protractilis a true sucker. Such forms as these could scarcely be distinguished from ectoparasitic Trematodes except for their. ciliated epithelium (Leuckart, 1). In this connexion, however, it is worth while to call attention to the researches of Fewkes (40) on a marine cercaria, which had a tail distinctly annelid in coaracter, with bundles of bristles disposed at intervals alongit. Compare also Schauinsland (41).

TrenCH, Richard Chenevix (1807-1886), arch bishop of Dublin, poet, scholar, and divine, was born at Dublin, September 9, 1807, and graduated at Trinity College, Cambridge, in 1829. While incumbent of Curd ridge Chapel, near Bishop Waltham in Hampshire, be published (1835) The Story of Justin Martyr and other Poems, wbich, having been very favourably received, was followed in 1838 by Sabbation, Honor Neale, and other Poems, and in 1842 by Poems from Eastern Sources. These volumes revealed the author as decidedly the most gifted
of the immediate disciples of Wordswerth, with a warmer colouring aud more pronounced ecclesiastical sympathics than the master, and strong affinities to Tennyson, Keble, and Milues. In 1841 he resigned his living to become curate to Samuel Wilberforce, then rector of Alverstoke, and upon Wilberforce's promotion to the deanery of Westminster, in 1845, he was presented to the rectory of Itchenstoke. In 1845 and 1846 he preached the Hulsean lecture, and in the former year was made examining claplain to Wilberforce, now bishop of Oxford. He was shortly afterwards appointed theological professor and examiner at King's College, London, In 1851 he established his fame as a philologist by his charming little work on The Study of Words, originally delivered as lectures to the pupils of the Diocesan Training School, Winchester. llis purpose, as stated by himself, was to show that in words, even taken singly, "there are boundless stores of moral and historic trutlf, and no less of passion and imagination laid up" -a truth enforced by a number of most apposite illustrations. The book may bo regarded as a comment on the saying that "language is fossil poetry." It was followed by two equally delightful little volumes of similar character-English Past and Present (1855), and A Select Glossary of Enylish Words (1859). All have gone through numerous editions, and they have probably contributed more than all the labours of severer but less cultured and tasteful philologists to promote the historical study of the English tongue. Yeit Treuch did little more than indicate the existence of a vast region of research extending over all literary languages. Another great scrvice to English philology was rendered by his paper, read before the Philological Society, "On some Deficiencies in our English Dictionaries" (1857), which gave the first impulse to the great enterprise now proceeding under the auspices of Dr Murray. His adrocacy of a revised translation of tho New Testament (1858) powerfully aided to promote another great national undertaking. In 1856 he published a valuable essay on Calderon, with a translation of a portion of Life is a Dream in the origiaal metre. He had not, meanwhilo: been forgetful of professional claims apon his pea. In 1841 he had published his Notes on the Parables, and in 1846 his Notes on the Miracles, works which, containing much to gratify every school of thought, and little to offend any, obtained the most extensive popularity, and hare been resorted to by English theologians of all persuasions, who have turned the anthor to the same account as he has turned his patristic, Romanist, and Lutherau predecessors. There is, in fact, very little originality in these volumes, but they are treasuries of erudite and acute illustration, selected from various quarters with admirable judgment, and displayed with consummate taste.
In 1856 Trench was ransed to the deanery of Westuninster, probably the position in the whole church which suited him best. In January 1864 he was advanced to the more dignified but less congenial post of archbishop of Dublin. Stanley had been named, but rejected by the Irish Church, and, according to Bishop Wilberforce's correspondence Trench's appointment was favoured neither by the prime minister nor the lord lieutenant. It was, moreover, unpopilar in Ireland, and a blow to English literature; yet the course of events soon proved it to have been most fortunate. Trench, indeed, could do nothing to prevent the disestablishment of the Irish Church, though be resisted with dignity, and repelled the insidious proposal that she shonld do execution upon herself. But, when the disestablished communion had to be reconstituted under the greatest difficulties, it was found of the highest importance that the occupant of his position should be a man of a liberal and geniad spirit, able to ward off the
narrowness which would have alienated the sympathies of English ${ }^{\text {ech }}$ churchmen, and sown the seeds of schism in a body beyend all others in need of amity and nuity. This was the work of the remainder of Trench's hife; and, if less personally agreeable and of less general utility than the literary performances which might have been expected from him if be had remained at Westminster, it was much more weighty and important. It exposed him at times to considerable misconstruction and obloquy, but be came to be appreciated, and, when in November 1884 he resigned his archbishopric from infirmity, clergy and laity unanimously recorded their sense of his "wisdom, learning, diligence, and munificence." He had found time for Lectures on Mediæval Church History (1878); his poetical works were rearraaged and collected in two volumes (last edition 1885). He died in London, after a lingering illness, on March 28, 1886.

As a man Trench was universally heloved and eateemed. He was romarkable for a high apirit, munificence, and ganeral olevation of sentiment. As a prose anthor he ranksamong the most useful ard agrecable of his generation, and may almost be said to gain in both reapects by bis deficiency in originality. Both as Biblical commentator and philologist, he has done far more by popularizing the researchea of more exact acholars and more profound thimiers than he could have done by striving to make discoveries of his awn. For durable fame as a poet originality is indispensable, and here Trench fails. Tbe style of his poems is frequently admirable, but avan when not obviously derived from some other writer it wants the stamp of atrong individuality. He has written littla beyond the reach of any man uniting exquisite culture to the accomplishment of verse: the pieces where poctry scems a natural language with him are chiefly to bo found among his elegiac poems, which express real peraonel experienca, and appeal movingly to the heart.
(R. G.)

TRENCK, the name of two barons of old Gerinan extraction, who, endowed with exceptional physical powers, and each blending to a singular if not to an insane degree the hero and the Bobadil, have left startling records of not wholly dissimilar adventures and misfortunes.

1. Franz, Baron von der Trenck (1711-1749), was born at Reggio, Calabria, where his father was lieutenantcolonel in the Austrian service. After bis rough early training in the camp, he made himself so unendurable at the college of Vienna that he was speedily removed, and entered in 1727 as ensign in the Palfy regiment, from which, however, after a brief but riotous course of duelling, gambling, and love-making, be received a nêw dismissal. He returned to his father, and, on the outbreak of war between the Russians ánd Turks, raised a corps of 300 men at his own expense and joined the liussian army on the Hungarian frontier. His brilliant exploits won him the favour of his commander, but a breach of orders, followed by an assault on bis colonel, brought him under sentence of death, from which a daring feat of arms alone saved him. A sentence of exile to Siberia, incurred soon after by a second affray with a.superior afficer, was commuted to imprisonment at Kieff and expulsion from the country. His term of imprisonment having expired, he retired to his estate, where he armed and drillcd his vassals, and in a series of encounters compelled the Slavonian brigands to seek refuge in Turkish territory. From these marauders he recruited in 1740 the formidable body of pandours with which he joined the levies in aid of Maria Theresa. Repulsing the French near Linz, be penetrated into Bavaria, took Deckendorf and Reichenhall, and destroyed Cham,-the conduct of his troops leing marked not less by atrocity than by desperate courage. Recalled to Vienna to render account for the cruelties practised, he pfused to defend himself, and, being set at liberty, rejoined his men, opened in 1743 a passage across the Khine for the army, and became as much the terror of Alsace as he had been of Bavaria. On the retreat of the army to Bohemia ite covered the rear and took sereral tomns, but had his right
foot crushed by a cannon-ball. Maria Theresa sent him a surgeon, and, having made a species of triumphal entry into Vienna, he resumed his command. But in September 1745, after having boldly penetrated with his pandours to the tent of Frederick II., he suffered the king to escape him while his followers were stopping to plunder, and he was thereupon accused of laving been bribed by that monarch to release him. He was condemned on inquiry to pay an indemnity for peremptory dismissal to the officers accusing him, but he refused to acknowledge the sentence, and, raising new troops, added to the list of his expleits. His conduct leading to a renewal of the inquiry, he laid hands on the president of the court-martial and was thrown into prison, but was enabled to escape by the baroness Lestock, with whom he fled to Holland. He was brought back to Vienna, and condemned to perpetual imprisonment in the Spielberg, where, finding escape impossible, he poisoned himself, October 1749, at the age of 38.
See Lis autobiography-Merkuviirdiges Leberv und Thaten des Friciherrn Franz vond der Trenck, Yienna, 1770; also, Franz con der Tsenck, by E. F. Hïbnet, with preface by Schubart, 3 vols., 1788.
2. Friedrich, Freiherr von der Trenck (1726-1794), cousin of the preceding, born at Königsberg, 16 th February 1726. His precocions abilities won him the favour of Frederick the Great, in whose guards he was encolled at an early age as cadet, and by whom he was made cornet in 1743 and aide-de-camp for his gallantry in 1744. An intrigue with the princess Amelia, sister of the king, led to his temporary confinement until the campaign of 1745 recalled him to the army. He was again thrown into prison, however, on the discovery of a correspondence between him and his cousin, then fighting with his pandours in the service of Maria Theresa, but in December 1746, after many failures, he succeeded in escaping from the fortress of Glatz. He went to Vienna, was involved in several duels by his cousin, who was too closely confined to give expression to his animosities except by prozy, and finally accepted a company in the service of the czar. On the declaration of peace the empress Elizabeth bestowed on Lim a diamond-hilted sword, and a Russian princess left him a fortune, which was still further increased by the death of his cousin, who, on condition of his entering none but the Austrian service, made him his heir. The latter inheritance being heavily burdened, he spent the next three years in a series of lawsuits, and then, after a journey to Italy, became a captaii in an Austrian regiment of cuirassiers. At the death of his mother he revisited Germany, but was promptly seized by the unforgetful king and closely imprisoned in the fortress of Magdeburg, his efforts to escape securing him the honour of a specially constructed cell; a heavy burden of chains, and the additional pnnishment of being roused every quarter of an bour by the sentries. Still unsubdued, he found means to remove his chains in the brief intervals afforded him, and occupied himself with French and German composition. In the meantime the princess Amelia had not ceased to move in favour of his release, and Trenck, Laving been set free in 1763, returned to Vienna only to be reconfined there as a lunatic. He was speedily released by the intervention of the king, and raised to the rank of major by way of compensation; but, being by this time satiated with royal patronage and prisons, he retired to Aix-la-Chapelle, commenced business as a wine merchant, and devoted his leisure to literature and politics, publishing, among other works, a gazette entitled the F'riend of Man and an attack on Frederick II. as the "Macedonian hero." His commercial experieaces, however, were not encouraging, and, after spending three years (1774-1777) in England, he returned to Vienna, became the secret agent of Maria Theresa, and at her death withdrew to his castle of Zwer-
bach, where he gave himself to agriculture and wrote his famous autobiography. Not until 1787 was he permitted to return to his own country, where he is said to have had an affecting interview with the princess Amelia a few days before her death. The publication of his memoirs (Lebenggeschichte) in 1786, translated into French by bimself in 1789, gave him imuediate and wide notoriety, and wax effigies of the illustrious prisoner in his chains were exhibited on the Parisian boulevards à deux sous en sortant. Despite the grounds which the memoirs undoubtedly furnish for Carlyle's terse characterization of him as an "extensively fabulous blockhead," they took a strong hold of the popular imagination, and obliterated for a time the fame of his more darkly passionate pandour cousin. . The tragic elements in the story were, however, to be emphasized by a still more tragic close. His ready advocacy of the French Revolution involved bim in disgrace with the Austrian authorities, and, after defrivation of his pension and further imprisonment, he set out towards the close of 1791 for Paris. In place of an enthusiastic reception, he was arrested by order of the Committee of Public Safety as a secret emissary of the king of Prussia, and, after confinement in the St Lazarus prison, was literally dragged to the guillotine on 25th July 1794. His Sümmelliche Gedichte und Schriften were published at Leipsic in 1786.
TRENDELENBURG, Friedrich Adolf (1802-1872), one of the chief revivers of Aristotelian study in the present century, was born on November 30, 1802, at Eutin, near Lübeck. He received his education at the gymnasium of his native town and at the universities of Kiel, Leipsic, and Berlin, displaying from his earliest years an extraordinary industry and thirst for knowledge. He was introduced to philosophy by König, the rector of the gymnasium a Kantian ; and at Kiel be came under the influence of Reinhold and Von Berger, to the latter of whom, a follower of Schelling, some of his own most characteristic views may be traced. At Berlin he beard Hegel and Sckleiermacher ; but his university studies lay chiefly in the direction of classics and classical philology under Wachsmuth, Hermann, and Boeckh. The combination of the philosopher and the philologist, together with a definitely historical turn of mind, is what is most distinctive of all Trendelenburg's work. He became more and more attracted to the study of Plato and Aristotle, and his doctor's dissertation, published in 1826, was an attempt to reach through Aristotle's criticisms a more accurate knowledge of the Platonic philosophy (Platonis de Idcis et Numeris Doctivina ex Aristoctcle Illustrata). Recognizing the sphere in which his best life-work could be done, be declined the offer of a classical chair at Kiel, and accepted instead a post as tutor to the son of Herr von Nagler, postmaster-general, and an intimate friend of Altenstein, the enlightened minister of education in Prussia. He held this position for seven years (1826-33), occupying his leisure time with the preparation of a critical edition of Aristotle's De Anima, and conscientiously extending his knowledge in all directions. His acquaintance with Karl Ferdinand Becker, the philologist and scientific gram. marian, was of importance for his own views on the origin of the logical categories and the relation of thought to language. In 1833 Trendelenburg wås appointed extraordinary professor in Berlin, and four years later be was advanced to an ordinary professorship. During nearly forty years he proved himself markedly successful as an academical teacher, treating in turn all the usual philosophical disciplines, besides holding more select classes for the study of Aristotle with advanced students. . During the greater part of that time he had also to examine in philosophy and pedagogies all candidates for the scholastic profession in Prussia. He died ou the 24th of January 1872.

It was with a view to the philosophical preparation in the gymnasia that he published (1836) his Elementu Logices Aristotelicss. This useful little book contains a selection of passages from the Organon, giving in a conneoted form the substance of Aristotle's logical doctrine. The Greek text is furnished with a Latin transle. tion and notes, sud at a later date Trendelenburg supplemented this book with further explanations for the use of teachers (Erläuterungen zu den Elementen der aristotelischen Logik, 1342). The Elementa has passed througb eight editions, and the Erläuler engen through three. In 1840 appeared the first of his important works, which, under the modest title of Logische Untersuchungen, develops a coherent philosophical theory, besides acutely criticizIng other standpoints, and in particular the then dominant Hegelian Bystem. The Logische Unlersuchungen were, iudeed, an important factor in the reaction against Hegel which set in about thet time in Germeny. Two articles written by Trendelenburg in the controversy which ensued were republished separately, ander the title Die logische Frage in Hegel's System (1813). A eecoud and enlarged edition of the Logische Untersuchangenz appeared in 1862, and s third in 1870 . In 1846 be published the first volume of his "Historical Contributions to Philosophy" (Historische Beiträge zur Philosophie), containing a history of the doctrine of the categories, which forms a pendant to his own elaboration of the same anbject in the Logische Untersuchungen. A second volume of the "Historical Contributions" sppeared in 1855, and a thirl in 1867, consisting of detached essays on points of iuterest in the history of philosophy. A number of these are papers originally read before the Prussian Academy of the Sciences, of which Trendelenburg was made a member in 1846." Hewas secretary of the philoscphicohistorical section from 1847 till 1871, snd devoted much of his valuable time to the duties devolving unon him. A number of his papers dealing with non-philosophical-mainly with national and educational-subjects have been collected in his Kleine Schriflen (2 vols., 1871). In 1800 the second of his larger works appeared, N゙aturrceht auf dem Grunde. der Ethiti (second enlarged edition, 1868). In 1865 Trendelenburg became involved in a controversy with Eano Fischer on the interpretation of Kant's doctrive of epace, which was carried on with no little acrimony for a number of years. The war of 1870 drew from him a short treatise on the defects of internationel law,-Lücten im' Volkerrecht. He had always had a deeply patriotic interest in the political development of Prussia, and throngh Prussia of Germany, snd in the stormy times after 1848 had even acted for a stort period as deputy to the Prussian chamber.
Trendeleaburg's philosophizing is cond tioned throughout by his loring stndy of Plato and Aristotle, whom he regards not as opponents but as building jointly on the broad basis of idealism. His own standpoint may slmost be called a modern version of Aristotle thus interpreted. While denjing the possibility of an absolute method and an absolute philosophy, as contended for by Hegel and others, Trendelenburg was emphatically an idealist in the ancient or Platonic sense; his whole work was devoted to the demoostration of the ideal in the real. But he maintained that the procedure of philosophy must be analytic, rising from the particular facts to the universal in which we find them explained. We divino the system of the whole from the part we know, just as from a torso we may reconstruct \& work of art; but the process of reconstruction must, in the case of philosophy, remain approximative. Onr position forbids the possibility of a final system. Instead, therefore, of constantly beginning afresh in opeculation, it ahould be our duty to attach ourseives to what may be considered the permanent resnlts of historic developinent. The classical expression of these results Trendeleaburg finds mainly in the Platonico-Aristotelian system. The philosophical question is stated thus-How are thought and being united in knowledge? how does thought get at loing? and how does being enter into thought? Proceeding on the principle that like can only be known by like, Trendelenburg next reaches a doctrive peculiar to himself (though based upon Aristotle) which plays a central part in his speculations. Motion is the fundamental fact common to being and thought; the actual motion of the exteral world has its counterpart in the constrnctivo motion which is iovolred in every instance of perception or thonght. From motion he proceeds to deduce time, space, and the catcgories of mechanics and natural science. These, being thus derived, are at once subjective sad objective in their scope. It is true matter can nerer be completely resolved into motion, but the irreducible remainder may be treated like the $\bar{\sigma} \rho \omega \dot{T} \eta \eta$ ü $\lambda \eta$ of Aristotle as an alstraction which we asymptotically approach hut never reach. The facts of existence, however, are not adoquately explained by the mechanical categories. The ultimate interpretation of the universe can oaly be found in the higher category of Eud or final canse. Here Trendelenburg finds the dividing line between philosophical systems. On the one side stand those which acknowledge nove but efficient causes, -which make force prior to thought, and explain the universe, es it were, a tergo. This may be called, typically, Democritism. On the other side stands the "organic" or teleological view of the world, which interprets the
parts throngh the illea of the whole, and sees in the efficient causes only the vehicle of ideal ends. This may be called in a wide sense Platonism. Systems like Spinozism, which seem to form a third class, neither sacrificing force to thought nor thought to force, yet by their deniel of final canses inevitably fall back into the Demo critic or esscutially materialistic stand foint, leaving us with the great antagonism of the mechanical and the organic systems of philosophy. The latter view, which receives its first support in the facts of life, or organic nature as such, finds its culenination and nltimate verification in the ethical world, which essentially consiste in the realizstion of ends. Trendelenburg's Naturrechs may; therefore, be taken as in a manner the completion of his system, his working out of the idcal as present in the real. Tho ethicel end is taken to be the idea of Lumanity, not in the abstract as formulated by Fant, but in the context of the state and of history. Law is treated throughont as the velicle of ethical requirements. In Trendelenburg's trestment of the state, as the ethical organism in which the individual (the potential man) may be said first to emerge into actuality, we may trace his nurture on the best ideas of Hellenic antiquity.
(A. SE.)

TRENT (Tridentum; Ital. Trento; Germ. Trient), a city of the Austrian empire, capital of Italian or "Welsch" Tyrol, stands on the left bank of the Adige, where it is joined by the Fersina, on the Brenner Railway, 35 miles below Botzen and 60 miles above Verona. It has a very picturesque appearance, especially when approached from the north, with its embattled walls and towers filling the whole breadth of the valley, a conspicuous feature being the rocky citadel of Dos Trento (the Roman Verruca) on the right bank of the river. Of the old walls some massive remains are attributed by local tradition to Theodoric the Goth. Notwithstanding many symptoms of decay, Trent, with its numerous palaces, substantial houses, broad streets, and spacious squares, still retains the aspect of a flourishing Cisalpine town. In appearance it is quite ltalian, and the inhabitants speak Italian only. The cathedral, on the south side of the spacious Piazzaldel Duomo, was begun in its present form in 1212, and finished about the beginning of the 15 th century. It preserves, however, some Lombardic features of ornamentation in the portals and elsewhere which possibly date from the 7th or 8th century. The church of St Maria Maggiore, a simple but good example of the Italian sityle of the 15 th century, was the meeting-place of the famous council (see below), and possesses a picture containing portraits of the nuembers. Trent is the seat of a prince-archbishop, and has all the public offices according with its administrative rank. It has a museum and library, a gymnasium, a "lyceum," a seminary, and a deaf and dumb institute. The chief industries are silk-spinning and weaving, tanning, sugarrefining, and glass-blowing; and there is considerable trade in wine, grain, and fruit, as- also in marble from the extensive quarries in the neighbourhood. The population in 1880 was $19,585$.

Tridentnm is mentioned by the geographers as capital of the Tridentini, and seems uitimately to have been made a Roman colony. It suffered much during the period of berbaric invasion, but was resuscitated by Theodoric, becoming the seat successively of Gothic and Lombard dnkes and Frankish counts. In 1027 it passed under the rule of its bishops, with whom it had frequent disputes, in which it sought the favour and alliance of the lords of Tyrol. The Venetians made repeated efforts to set up the lion of St Mark within the walls of Trent, but were decisively and finelly repulsed in 1487.

TRENT, The Council or, which may be described as the watershed of Roman Catholicism and Protestantism, is the most important occurrence in post-mediæval church history. It is the culminating event in a long series of similar assemblies, convoked to remedy the evils occasioned during and by the great schism of the papacy, and by the dissolution of lay and clerical morals to which the pagan temper of the Renaissance had largely contributed. But the councils if Pisa, Constance, Basel, Ferrara-Florence, and the Lateran had met and parted without attempting to deal effectually with any of. the practical scandals and abuses in the church whicb were sapping the loyalty and
affection it had formerly enjoyed; and these repeated failures, by destroying all hope of redress at the hands of the constituted authorities, precipitated the crash of the Reformation, which was in its inception scarcely concerned with doctrina! íssues directly, but aimed mainly at faults of administration and morals.

Consequently a largely new problem presented itself for solution, and necessitated a fundamental change in the attitude of those concerned. Hitherto, whatever may have been the fierceness and bitterness of the disputes which the 15 th-century councils had attempted to allay, they were, so to speak, family quarrels between members of the same great household, accustomed to the same mode of looking at religious questions, acknowledging the same hierarchy, and accepting the same standards, and thus with a vast body of agreement to go upon as a basis of reconciliation, leaving only comparatively minor details to be adjusted. But the German and Swiss Reformation had gencrated new communions, novel alike in their polity and much of their theology, and in active revolt, not merely against this or that detail or abuse, but against the Roman Catholic Church in its entirety, hierarchical, ductrinal, and political. The movement had not bcen confined long to its earlier limits, but had spread over all western Europe, had virtually conquered Holland and Scandinavia, was making great strides in France and England, and was beginning to threaten even Italy and Spain. Thns, the task was no longer the coroparatively simple one of satisfying the demands of friendly remonstrants, but of winning back alienated pations, and, if that were too much to hope for, at least of saving the remnant of the Roman obedience from further disintegration. And for this purnose it was no. longer sufficient, as it would have been a few years earlier, to discuss administrative details alone, but a review of the whole theological fabric of Latin Christianity, no part of which had been left wholly unimpeached, became a necessary factor in any possible scheme of reconciliation. True, a precedent had been set in the theological discussions at the council of Ferrara-Florence, with its abortive effort to reunite Oriental and Latin Christendom, but the area and number of differences to be reconciled upon that occasion were incomparably smaller than those which had subsequently arisen, and the situation was thus one of extreme difficulty and delicacy, since there was alrays the danger of alienating many who had continued loyal so far, if very large concessions were made to the revolted Protestants, not a few of whom, besides, had already passed beyond the possibility of reconciliation. But, on the other hand, Luther had himself appealed to a general council from the bull "Exsurge Domine" launched at him by Leo $X$. in 1520, and his demand was taken up by the emperor and the princes of Germany, whether Catholics or Protestants, as the only conceivable means of terminating a crisis whoss religious and political results might prove far more serious than even the least hopefu! rentured to forecast. There was thus steady pressure from one side put upon the Roman curia to obtain the conrocation of such a council, while scarcely less resistance to the proposal was offered by two very unlike parties in the Roman Church itself. For not only did those oppose it who were interested in the maintenance of the principal abuses complained of, and who feared that sweeping measures might be taken for their abolition, but some of the ablesi champions of internal reforns, such as Cardinals Sadolet, Contarini, and Reginald Pole, were equally hostile to it, for the very different reason that they believed any such council likely to contain a majority determined on making it as abortive as those great synods had beeu which were fresh in the memory of all. Accordingly, this section gave its voice for the alternative scheme of pro-
ceeding by way of less formal conferences, at which mutual explanations and concessions might be made by Catholics and Protestants, whereby a modus virevdi could be established, with less chance of the whole effort being wrecked by the intrigues of those who desired nothing less than practical reforms. A fresh difficulty was presented by the oplosition of the German princes to the assemblage of the council at Rome or abywhere outside Germany, as they distrusted the probable action of the Italian element, certain to preponderate in that event; and, as the curia was equally bent on holding it within the sphere of direct papal influence, this dispute made it impracticable to agree even on the prelininaries during the pontificates of Hadrian VI. and Clement VII. The diet of Spires in 1529 renewed the demand for a general council, to be held in some large German city; and the diet of Augsbarg in 1530 summoned the Lutherans to return into Catholic communion at once and unconditiosally, leaving their doctrines (formulated in the Confession of Augsburg that very year) to be jndged of in a fnture council, which the emperor Charles V. pledged himself to obtain mithin a briof space. Clement VII., then pope, was displeased at this initiative on the emperor's part, bnt offered to convoke a council in some Italian city, such as Mantna or Milan, belonging to the empire, and outside the States of the Church, - expressing his wish that Charles V. should personally attend it. But he hampered this proposal with conditious which made it valueless for the main object of such an assembly, by declaring that no theological questions upon which the church had spoken could be reopened, and that, if Protestants were to be admitted to the council at all, it must be, not as disputants, but as on their trial, and pledged beforehand to submit to the decisions of the council. No result, consequently, followed upon this step, nor was an embassy which Clement sent in 1533 to the German princes and to the kings of France and England with rery similar provisions more successful, for it merely drew ont a peremptory rejection of the scheme from the Protestants assembled at Schmalkald, by the emperor's desire, for the purpose of discussing it. So the matter rested till the accession of Alexander Farnese to the papal throne as Pau! III. in 1534. A much abler nan than his predecessor, he was also more alive to the imperative need of at least appearing to approve some measure of reform, if the church was to be saved from intpending dangers (indeed, a report on this subject, drawn up at his desire by a committee of cardinals in 1536, is one of the most important documents of the era), and he was thought to be farourable to the project of a council, whereas there is little doubt that Clement VII. had weighted his acceptance of the plan with impossible conditions, in order to a roid its realization, yet so as to let the responsibility of refusal rest with others than himself Paul III. sent Vergerio as envoy into Germany, to confer with the emperor and the princes, offering to convoke a conncil at Mantua, and urging the danger of attempting to hold it in Germany, by reason of the violent lengths to which the Anabaptists were then proceeding. But, while the Catholic princes were content with this offer, it was refused by the Protestants, aud the ambassadors of France and England supported them in their attitude. Vergerio, who had also a fruitless interview with Lnther, returned to Rome early in 1536, but Paul III. was not discouraged by his failure, and proposed, in a cousistory on April 8, to ronroke a council at Mantua. This plan was in turn upset, not only by the continued resistance of the Protestants, but by the refusal of the duke of Mantua to permit the use of his city for such a purpose, unless upon conditions which the pope was uawilling to accept. Notice was accordingly given of a conucil to be opened.
at Vicenza on May 1, 1538, and legates were despatched thither to make the preliminary arrangements, and to preside 80 soon as the members shculd assemble. But when the appointed time was only five days off not one bishop had arrived, and the pope was forced to prorogue the council again and again. Meanwhile. the method which Contarini and Sadolet had recommended, that of conferences between the Catholics and Protestants, was being acted on in Germany, and meetings of this nature were convened successively at Haguensu, Worms, and Ratisbon, at the last of which, in 1541, Contarini was present as legate of the pope, and showed so much tact, moderation, and sympathy that he succeeded in securing a large measure of agreement upon the controversies in dispute, notably on the vexed questicn of Justification. But, as his concessions and explanations were promptly repudiated at Rome, no practical result followed. In 1542 Paul III. sent Murone as his envey to the diet of Spires to offer Trent as his final concession of the place of assembly, on the ground that its position in Tyrol, and its being part of the dominions of the king of the Romans, ought to meet all the reasonable requirements of the German princes. Ferdinand, king of the Romans, who presided at the diet, was content with this offer, as were the catholic princes generally, but the Protestants cont:nued to object, and refused any council which should not be completely free from papal influence and authority. However, the pope issuecl on May 22, 1542, a bull appointing the meeting of the council for November 1 followiug. He sent three legites to Trent to make prepara-tions,-Morone, Parisio, and Reginald Pole ; but they did not reach the city till three weeks later than the appointed date for opening the council, and so few bishops arrived during seven months froun that time that it was necessary to prorogue the assembly: In fact, the idea of the conncil was distasteful to a Dery large proportion of the Latin clergy, especially such $a$ a apprehended danger to their private interests from the retorning plans of the pope, and also such as were alariued lest serious religrous innovations might be made in order to conciliate the Protestants. While this delay contiuned, another dict at Spires in 1544 resulted in great advantages to the Lutherans, who availed themsalves of the political atraits of Charles V. to extort several important concessions from him. The obnoxious edicts passed against them at Worms and Augsburg were rescinded; they were permitted to retain such ecclesiastical property as they had seized; they were made eligible for such civil and ecclesiastical ofices as had been previously barred against them ; and general toleration for the time being waz established. This policy was extremely distasteful to the pope, who addressed a brief to the emperor, strongly remonstrating against it, and renewing his offer of a council. Charles Y., who had not been a free agent in the matter, was much of the pope's mind, and proceeded to relieve himself of one difficulty in the way of reversing bis action, by concluding peace with Francis I. of France on September 8, 1544. Hereupon Paul III. directed public thanksgivings to be offered throughout the whole Latin Church, and issued a buil removing the suspension of the council, and summoning it to meet at Trent on March 15, 1545 . Unable from age and illness to be present himself, as he had wished, he named Giammaria del Monte, bishop of Palestrina (afterwards Pope Julius IIL.), Marcello Cervini (afterwards Pope Marcellus II.), and Reginald Pole as his legates. The oxperience of former abortive openings was repeated, for they found but one bishop awaiting them, and so few continued to arrive that a fresh prorogation was forced upon the legates, and the pope, in the bull authorizing this action, added a proviso that no proxies should be received,
but that all bishops summoned should attend in person, under severe penalties for contumacy. On November 7, 1545 , the legates received final instructions to open the council upon December 13, and did so with solemn coremonial, but only as a formal initiative of the proceedings, for the first session was postponed till Jonuary 7, 1546. When that time arrived, no more than aome fipe and twenty archbishops and bishops, five generals of religious orders, and the ambassadors of King Ferdinand had assembled, and none of the conciliar officers had yet been nominated, nor any programme of procedure aketched out. The most important question arising under this last head was whether the voting.should be taken by nations, as at the council of Constance, or by individuals, and the matter was referred to the pope, who gave his decision for the latter, as at once the more ancient (since Constance and Basel were the only precedents for the national vote) and the more convenient. Moreover, this ruling secured from the outset a working majority of Italizn bishops in the assembly, at once by reason of the small size of the average Italian diocese, and of the greater ease with which Trent could be reached from Italy than from any other country which sent representatives thither, besides enabling the pope to swell the majority (as in the Vatican council three centuries later) with bishops in partibus, having no dioceses or jurisdiction, thus amply justifying the objection taken all along by the German Protestants to the assemblage of the council anywhere outside Germany.
Some prcliminaries had to be settled before the second session, and the plan of holding privste "general congregations," where theologians of non-episcopal rank could ait and share in the discussion and preparstion of the decrees to be pronosed snd voted on in public session, was at once adopted and observed thenceforward. And first, the question was raised whether sny persons except bishops should be sllowed to vote upon matters of doctrine. The decision twa that the rote should bc allowed to the genersls of religious orders also, and that the right of the proxies of absent bishops to vote should be referred to the pope. The title to be given to the council at the head of the decrees in esch session was then discussed, snd a propossl to add the words "representing the church universal " (as st Basel and Constance) to the usual formula "genersl and cecumenical" was rejected at the instance of the legates, as indirectly menacing to papal autocracy. The legates also privately informed the pope that the majority of the members desired to take up the question of practical reforms before that of doctrize, and that it might he necessary to yield the point to svoid scandal or the imputation of eympathy with abuses, but thst they would insist, in that case, on msking the measures of reform apply all round, to princes and laymen as well as to ecclesiastics, which would probably damp the ardour of its edvocates.
The actuel busiuess of the second session (Jsnuary 7, 1546) was coufined to the promulgation of a decree touching the discipline to be observed by the members of the council durlog its progress, as well in the mstters of their private devotion and their food as in the conduct of the debates. The congregations which preceded the third session were mainly occupied with debating the thorny question of the order in which the discussion of fsith end of discipline was to come, and it was at last agreed to take them eimultaneously.
So few additionsl bishops had arrived up to this time that it was judged inexpedient to promulgste sny decrees in the third session (Februsry 4, 1548), and little was done except the public recitation of the Niceno-Constantinopolitan creed as the authoritative confession of the Roman Church, and, as the council worded it, "thet firm end only foundation against which tho gates of hell ehall not prevail." A fortnight after this third eession Mfstin Luther died (Februsry 18, 1546), Just as the eitustion in Germasny was becoming more strained, sud the emperor, alsrmed at the rapid sdrance of Reformed opinione snd practices (notably in the Palstinste, where the elector had made large concessions), was taking measures fot suppressing the religious revolt by force of srms. The canon of Scripture was proposed in the congregations before the fourth gession as the subject for discussion, and the three following questions were raised:-(1) Were all the books of both Testements to be approved and received! (2) Was there to be a fresh inquiry into their canonical clasracter before giving such spproval f (3) Should there be any distinction drawn between the books, as being some of them read merely for moral instraction, and others for proving the doctrines of Christian belief? The first of these questions was decided affimatively. The second led to much de-
XXIII. - 69
bate; tho conclusion arived at was that a secret examiuatiou of public actso should be made, but not suffered to appear in the tively. These congregations were the first whercin thed negaexperts and canonist, not being members of the council, were admitted to a share in the discussions. The nature and function the pope that there was a strons this time, and the legates informed the pope that there was a strong tendency in the council to set it Another burniug quastion debatell was the sole standard of a ppeal. tion and lay study of Scripture. The resnlt in the folar transla(April 8, 1546), was the promulgation of two decrees, the firet of which enacts, under anathcma, that Scripture and tradition ere to he received and venerated equally, and that the dcutero-canonical wooks are part of the canou of Scripture. The second decree de clared the Volgate to be the oole authentic and etandard Latin version, and gave it euch authority as to supersede the original texts; forbade the interpretation of Scripture contrary to the eense reccived by the chnrch, "or even contrary to the unanimous consent of the fathers"; imposed various restrictions upon printers and vendors of Bibles; made liccnces to read aoy Biblical ananu. script or publication compulsory; and prohibited the application of Scripture language to prolane and euperstitious purposes. The reformation takon up were the doctrine of original ein and the reformation of abuses coocerned with nreachers aud lecturers, which Were made the matter of two decrees in the fifth session (June 17, clause, whereby the tereate point in the former is the saving Blessed Virgin the tonet of the Immaculate Conception of the enjoins the ercetion of a collegiate churches, and monasteripo of Scripturo in all cathedrals, upon all bishops and persons with e, imposcs the duty of preaching rules as to preaching licences, and forl souls, laysdorn stringent is, the collectors of alms commissioned by the mendicant ardere to preach anywhere. There was a treaty coucluded betwcen the pope and the emperor a fow days after this session, to make war against the German Protestants on the express ground of their relusal to submit to the conncil, and from this may he dated the end of any scrious effort in the council itself to donl with the question of reconciliation, although tho original motive for its Roman cpisconate io the so little interest was felt even by the ccessions cominr to trocecdings at Trent that, instesd of fresh defections took place, recruit the small munbers present, constant any bishop to quit Trent withont formal stop this by forbidding The doctrino of Justification mat formal permission was carried. mioence given to it in Lutheran thicolory, was nuest take the prothis being, $\theta$ to spent, a ners controversy with taken up, and, to guide the council, the discussion traversy, with fersp precedents It is noteworthy that Luther's views found some supporters, and the resignation of the legateship at this tine by keginald Pole, his dissatisfaction from the council, nevor to return, is attributed to in its decree. that of the obligation of rasy question discussed at this time was and dcerees upon both thesesudence, especiully as regards bisbops; session (Jantary 13, 1547), - that on Justification bed in the sixth dogmatic treatise in sixteen chat on Justification bcing a formal on residence reviving former canons, and imporite canons; that but avoiding the solution of a question hotlr debated in the council, whether the residence of bisliops was obligatory jure divino or nerely by ecelesiastical precept. Meaorbile, Charles V. Was victorions in his war with the Protestants, and had all Germany in his power, but, instead of nsing the opportunity, as the thay expected, to put down the Reformers, be alleged that the recent war had not been one of religion, and assumed an attitude of toleration. Hereupoa Paul III., in order to break up this truce, sent instructions to the legates to press on decrees displeasiog to the rotestants, judging that the emperor's well-known interest in the conncil would causa hinn to be accounted responsible for its measures, and thus lose all credit for lis recent forbearance. In the eeventh defining the sacraments as scren in numere promulgated, -one channels of grace, also nulding sen in number, aad as being all and confirmation ; the other dealing with concerning baptism benefices, repair of churches, and fith pluralities, unions of great stringency. A more important mared matters, but with no session was the open declaration of a part of the business of this the legates had been privately po a measure which the pope and ferance of the council from Trentaning for some time, the transpapal control; for, while Trent suffena oity more directly under Protestants, yet it was found that a virtur headquartere as against Spanash, French, and Gernun hish virtual coalition batwoen the fered with the intentions of thshops to resist the Italians interellectively broken un by a change papal court, and could be most logly taken from an outbreak of digcise accasion was accord at Trent to issue a bull transferring the council to be infectious,
was read in the seventh session, while the promulgation of a decree in accordance with it formen the whole business of the eighth sessiou (March 11, 1547). When it had been passed, the legates produced a briel which thcy had obtained more than two yeare before, empoweriug them to transfer tho council as they pleased. But, while they themgelves quitted Trent the next doy, and were followed by the majority of the bishops, those of the emperor'e party continued in session at Trent, and refused to leavo it without the permission of their sovereigu, though they abstained from all conciliar ection, in order to avoid the charge of schism. Charles $V$., incensed at the pope日 action, e日nt a mandato approving aud conirming their cominct. The nioth session, held at Bologng (April 21, 1547), and the tenth also (June 2, 1547), were merely formal, nothing being lone ave to prorogue the council. Tà practical result of this epllit in the council was to reliere the Protestants from irmminent peril; for, while the emperor's auccesses enabled him to put sovere pressure upon them to submit to its decrees, it was itself inctuacitated for valid action, as neither the bishops at Bologes nor those ąt Trent cond claim to be the whole council, nor demand acceptance of their acts as binding. Hence Charles V. Was argent for the roturn of the entire body to 'Trent, and thrcatoned, in case of refusal, to go to Rome, and hold the council there himself. And he took an even more peremptory step hy constituting himself arbitcr of the whole con troversy, appointing Julius Pflug, bishop of Naumburg, a prelate kuown to be friendly to the Lutherans, Michael Ilolding, called Sidouius, afterwards bighop of Mersoburg, and John Agricola, a Latheran writer of some hark, to dralt an eircnicon upon the points in digpute, which was published undor the title of the "Interim," ly the emperor't anthority, at the diet of Angsburg, May 15, 1548. It proved however, inefficacious, and was formally repudiated and enswered by the Catholic princes and atates of the empire, and yet more reremptocily by the Protestants, its only result being tho "Io. terinistic controversy." It was succeeded by auother formulary concening rcformation, acceptel by the diet. While the cmperor Was endeavouring to force the "Interin" "pon his lominions, the pope, on his part, strove to remove the dead-lock of the divided thanch, and conrokel a committee to consist of members of both astical rcforms. But lizuentine eections to confor upon ecclesiwith the empero the hishops at Tront, having conmonicated fused to leangr, legatos at Bologna to ilismiss the bishops assunbled there end to anuounco the ouspension of the council, which was accordiogly done upou Soptember 17, 1549. Panl 1II. died on Norenber 10, 1549, and was succeeded on February 7, 1550, by Cardinal del III The chicf legate at the council, who took the titic of Julius these The break in the continuity of the council occasioned by was hell ass lasted til May 1, 1551, when the eleventh aceeion solo legato iu tity under the presidency of Cardinal Crescenzio, solo legato iu tite, but with two nuncios, Pighini and Lippomani, welfth scssion, on Sops. It was merely formal, 6 , was also the 11., king of France, baving quarrelle 1551. Just at this time Henry of Parma, sent an anig quarrelled with the pupe about the duchy styling it a "convention," denying its occumenical character declaxing that it was not accessible to himself or to the Frenct bishops, and notifying a protest against the validity of itg proceedings, which he desired inight he registered, and a copy of the register returned to him. No reply was mado to this demand; so Henry dismissed the papal noncio from his court, and published a manilesto to justify himsolf, at the same time thet, in order to repel any charge of eympathy with the Protestants, he prominlgated a severe edict agaiost them. But the absence of French biehops, and the comparatirely ecanty atteıdance froni Germany, threw appeared fre than ever into the hands of the Italian majorits, as (October 11, 1551), aud in promulgated in the thirteenth session logateg just before it. For the obstinate refusal of the Protestants way, and the impecognize the council mas on the point of giving way, and the imperial ambassadors demanded a eale-cooduct for such as might present themselves, with eome warranty that it decision on the afo. They also desired the postponement of any the communion of the laity in Eucharist, and espccially as regards himsolf willion of the laity in the chalice. The pope expressed was paid to to grant botu theso denuads, but no real attention Protestants, the lett of Ase. As respects the atteadence of the in Spain to Che lettors of Francis Vargas, fiscal (attordey-general) that the doing everything to preventended to desire it, avd were $\begin{gathered}\text { eccretly }\end{gathered}$ delay had been preprevent it, while the very points as to which delay had been promised were made the subject of the decrees in specially directed session. Luthe decres ou the Eucharist was recently broached, and was Lutheran and Zwinglian opinions then canons appended. It reasserted the doctrine of Transubstantiation, already defined by the fourth Lateran council in 1216, while, by
the third of the canons, which declares that the wnole gacrament is entire in each kiud, it indirectly, though effectively, ruled against the grant of the chalice to the laity; and in fact tho Reformed thesia that they were entitled to it by divine right, and could not bo debarred from it without sin, was noauimously condemned in the previons congregation. Some unimportant decrees affecting the criminal jurisdiction of bishons, and for referring the trials of bishops theinselves to the pope, were eaacted at the eame time; but more noleworthy was a decree for postponing the decision upon lay and infant comnunion, and for granting a safe-conduct to the Protestants, which was the last business transacted apon this occasion. But the safe-conduct was worded so as to excite general and reasonable suspicion ou the part of those to whom it was offered, and Vargas, who was no friend to their opinions, comments freely upon its deceptive ambiguity. In the lourteenth eession (November 25, 1551) decress upon penance and extreme unction, prepared in the congregatiom"; and embodied in twelve chapters upon the iormer and three on the latter topic, followed severally by fifteen and four canons, were promulgated. Some disciplinary enactments affectiog the clergy, and corrective of minor abusee, were enacted at the same time, the most important provisions being the sholition of the papal dispensations exempting their holders from the jurlediction of the ordinary, snd the restriction of the antion of titular bishops. But the reforming party in the council was much discuntented with the inadequacy of these measures, which added little to the rery small progress unade eo far in the revival of discipline. Although no Protestant theolegians had yet presented themselves at Trent, representatives of the duke of Wirtemberg arrived at this time, who were instructed to lay the Wurtemberg Confession before the council, and to say that Protestant divines who could give explanations of it were waiting some forty miles from 'rent, and were prepared to attend the council so soon as a safe-conduct exactly conformable with that granted to the Bohemians by the council of Basel was issued, and on the further conditions that the discussions actually going on should Le suspended and all the matters so far decided bo reopened, that the pope should cease to preside by legates or othervise, but declare his own submission to the decrees of the council, and absolve the bishops from their oath of allegiance to himself in order to secure their liberty of action. The eavoys refused to treat with the legatos at all, and conducted their negotiations through the imperial ambassadors. Crescenio was very angry, and refused all concession, eren going so far as to abstract the conciliar sal, lest the safe-conduct might be granted; but pressure was put upon him by the imperial annbasadors, and he was forced to consent to the admission of the Protestant enroys at a private congregation to be held in his own house, though he resisted the demand for introdacing then to a public session. And, when the safe-conduct was recast, it was found to differ seriously from that proposed as its model, especially by failing to give the Protestants the rights of session and suffrage, of observing their own religion in their houses, and of heing guaranteed against insults to their creed. To the rcmonstrances made in consequenco the legnte returned a peremptory reply, refusiog to make any further change, and only the instances of the emperor, then at Indsbruck, but tbree days ${ }^{2}$ journey from Trent, induced the Protestant envoya to remuin a littlolouger, to find if any better terms could be obtained. Some more Protestant envoys from Strasburg and other cities, and from Maurice of Saxon5, arrived early in 1552 , and were admitted to a congregation held on Janusry 24, where they renewed the demands already mentioned, and required also that the decrees of Constanco and Basol, declaring the pope inferior and subject to a general council, should he reaffirned. They were promised an answer in due time, and the fifteenth session was held the next day (Jannary 25, 1552), wherein the council was prorogued, and a asfe-conduct more in accordance with the Protestant demands was drawì up and pub. lished. It is remarkable, however, for one omisaion, and for ooe simbificant clause. The omission is that of toleration for the private exercise of their religion; the insertion is a proviso pledging the council not to avail itself, "for this one occesion," of any lavs or canons whatever, "especially those of Constance and Siena," as egainat the Protestants. The reference is to the canon of Constance by means of which John Huss was tried sod burnty declaring a safe-conduct no protection against trial for heresy, even if the accused has come io reliance on the gafe-condect, and would not have come without it, which canon was reaffirned at the cooncil of Siena in 1423. While the negotiations occasioned by these proceedings were in course, war broke out onew in Germady, and Maurice of Saxony obtained cousiderable euccesses oper the emperor, took Augshurg, and was marching dowu upon Tgrol, so that Charles V.fled in haste from Inushruck, and the legate convened the gixteenth session (April 28, 1552) of the council, Wherein a decree was promulgated auspending it for two yeara in consequence of the perils of war. Tbere was a general stampede from Trent at once, and the legate Crescenzio, then very ill, had just stredgth to reach Verona, where he died three days after his arnival.

So ended what is styled by some historians, and correctly, the first council of Trent, for, although thie asnal computation recognizes only one such council, yet an interruption of ten years, a widely changed personality, and a marked alteration in tone make the resumed synod virtually another assembly, and one by no means entitled to the degree of rcspect which the ability and learning of many members of that first convoked won for it. When the council dispersed, Julius III. at once in consistory repeated the policy of Paul IIL, and nominated a committee to prepare a scheme of reform, but it never took action of any kind; and at the close of the two years' suspension of the council the question was put in consistory as to the resumption of the sessions, and decided, with the pope's approval, in the negatice. Julius III. died on March 23, 1555, and was succeeded on April II, 1555, by Cardinal Marcello Cervini, one of the former legates at the council, a man of high reputation for personal devoutness and freedom from that sympathy with abuses which marked too many of the dignitaries of the time. He took the title of Marcellus II., and bis first public utterance was to intimate his purpose of reassembling the council, and of carrying out a plan of thorough reform in discipline, particularly directed to abating the pomp and luxury of the prelacy. But he was in feeble health when elected, and the fatigues of his new position brought on an attack of apoplexy which carried him off three weeks after bis accession. In his room was chosen, on May 23, 1555, Cardinal Giovanni Pietro Caraffa, who took the title of Paul IV. He was known to profess great austerity of life, to have actually founded the Theatines, an ascetic community, and to be a stern and implacable advocate for several measurcs of repression against innovators in matters of religion or impugners of papal prerogative, as he quickly showed by setting up the Inquisition in Rome, and taking care that it should not be idle. His election consequeutly caused much alarm, and was especially displeasing to the emperor; and the earlier acts of his pontificate seemed to justify tho estimate formed of his character and the fears of those who apprehended that he would proceed to reform discipline in a swifter and more crastic fashion than had bitherto been essayed. For in fact he pledged himself to this effect in the first bull published after his accession, following it up with a show of activity by at once setting some minor reforms on foot.

During these three years important eveuts had taken place in Germany. By the peace of Passau in 1552, the Protestants of the Augsburg Confession were secured from all molestation, and in the free exercise of their religion and of their civil rights, and this was followed up by a decree of the diet of Augsburg, on September 25, 1555 , that, failing a national council to settle the religious disputes, the empcror, the king of the Romans, and the other Catholic princes should not interfere in any way with the religious liberties of the Lutherans holding to the Confession of Augsburg, provided they in their turn would exhibit equal tolerance towards Catholics; that no penalty, sare the loss of benefices, should be imposed on any Catholic ecclesiastics joining the Lutheran body; and that such benefices as the Protestants bad already annexed for the support of their sclools and ministers should remain in their possession. Paul IV. was much incensed at these proceedings, and used all efforts to procure their repeal, on the failure, of which he openly broke with the emperor, formed an alliance with the French king against him, and imprisoned the cardinals and other personages of the imperial party on whom be could lay hands, confiscating the property of such as aaved themselves by fight. He continued for a time in the measures of reform with which
he began his reign, striking against jobbery, pluralities, dispensations, and laxity of clerical manners; but all this short-lived zeal was speedily neutralized by his nepotism, surpassing that of any of his predecessors, and throwing the government of the States of the Church into the hands of his dissolute nephews, upon whom he rained all the wealth, honours, and authority in his power to bestow. And, as was to be expected, he set bimself steadily to oppose every one of the class of reforms which touched doctrinal questions, just those for which the Protestants were urgent, encouraging only such as promoted the unity and discipline of the Roman Church itself, and made it more capable of effective resistance to the Reformation. He was not favourable to the reassembling of the council, not merely because of his experience of its languid action, nor even his dislike of the struggles of the non-Italian minority to assert some measure of independence against the coercive tutelage exerted by the several papal legates from the very first, but because he regarded himself as the sole and proper person to consider such matters at all, and a bull of his own promulgation a better mode of procedure, at once in fulness of authority and swiftness of formulation, than any conciliar decree. Consequently, no step for the resumption of the council was taken during his reigo, which ended on August 18, 1559. After a longer interregnum than usual, Giovanni Angelo de' Medici (not a inember of the great Florentine house, but of humble Milanese extraction) was elected on December 26, 1559, as Pius IV. Markedly unlike his predecessor in almost every personal quality, he was much his superior in practical shrewdness and tact, and had none of that dislike to a council which Paul IV. had shown. So great, too, had been the strides made by the Reformation during his predecessor's reign that he might well think Paul IV.'s policy undesirable, and he had this special motive for reversing it, that a movement was going on in France for the convocation of a national council there to consider the whole religious situation, which might very conceivahly result in a revolt like that of England from the Roman obedience. Accordingly, Pius IV. determined ou the resumption of the council of Trent, and issued a bull on November 29, 1560, convoking it anew.

But the whole face of Western Christendom, the whole religious situation, had materially changed since the original assemblage of the synod in 1545. First, the imposing personality of Charles V. was removed from the scene, and Ferdinand I., his successor, enjoyed neither his per. sonal ascendency nor his political power, and cou'd not be accounted as a possible competitor with the pope for the first place in the Catholic world, nor even as an ally with means for crushing the Reformation. Next, the Reformation itself was by this time an accomplished fact, a consummated revolt from mediæval Christianity. It had taken definite shape in various conntries; it had its 'own theological systems and traditions; besides that a whole generation had now grown up under its influence, never having had any personal associations with Latin Christianity. And, on the other hand, the very lengths to which some of the Reformers had gone in their revolt generated a corresponding reaction in the Roman Church, so that many influential persons who had been in favour of moderate reforms and of explaining disputed points of theology were convinced that no limits could be logically or practically set to concessions in this direction, and therefore that it was necessary to make a stand against any concessions at all. And, what is more, one noticeable effect of the wave of controversy which lad swept over western Europe was to accentuate points of difference, to close questions previously open, to make the current beliefs more incisive and, so to speak, legal in. form, to diminish
seriously the neutral area betreen the competing religious systems, and thus to bring them face to face as irreconcilable foes. One factor more, of greater importance at the time than any other, contributed to the revolution which is marked by the second council of Trent. As Spain took the political lead in the earlier half of the 16 th century, so it took also the lead in theology. The Spanish divines were abler and more learned than all save the very foremost in any other country, and their influence was throughout the greatest at the council of Trent on purely theological issues. Now, the political and the theological geaius of Spain had hoth just found their highest exponent in one person and the organization which he devised, Ignatius Loyola and the Company of the Jesuits. Two of his immediate disciples and recruits, Salmeron and Laynez, were chosen to be the pope's theologians at the council of Trent, and exercised a greater influence than any other divines there in the formulation of its dogmatic decrees. But the Jesuits were to do more than this. The militant spirit of their founder had nothing in common with the alarm and vacillation which had for the most part marked the action of the Roman Church in deaiing with the Lutheran and Calvinist revoit; and, instead of being content with devising schemes for stnading on the defensive, and saving the remnant yet left to the Roman obedience, he conceived the bolder and safer plan of vigorous aggres: sion, to reconquer all that had been lost, and to add fresh acquisitions thereto. The Counter-Reformation whish he initiated was in full operation when the second council of Trent assembled, and it was by this spirit that it was guided in its deliberations and decrees. 'The very thcught of compromise was abandoned in fact, if not in open expression, and the only reforms thenceforward taken into consideration were such as would remove causes of weakness and scandal in the Latin Church, enabling it, without sacrificing one of its claims, to overcome by superior mass and discipline, by closer unity and more organized enthusiasm, the heterogeneons, disordered, and already dissociated forces of Protestantism. The most obvious effect of these principles upon the second council of Trent was that the diminution, the all but disappearance, of variety of opinion amongst its members, and the resolution to crush Protestantism rather than to parley with it in any scheme of mutual concession or accommodation, tended to shorten the preliminary discussions in a marked degree, so that little is to be noted of the long and animated debates of the earlier period, and the last few sessions exhibit even tokens of actual hurry to end the matter anyhow.
There was no intention on the pope's part to proclaim the Counter-Reformation as the policy of the council, even is it may be safely assumed that he could predict its action, and he sent nuncios to the Protestant sovereigns as well as to the Catholics to signify the approaching resumption of its sittings. Francis II. of France bad died between the promulgation of the bull and its notification in France, but the young kireg Charles IX., by the advice of the parlement of Paris, directed all the bishops of the kingdom to be in readiness for journeying to Trent. Three nuncios were despatched to Germany, but the princes assembled in diet at Naumburg received thera unfavourably, asserting anew their determination to recognize no council which did not avow Scripture as its standard of appeal and give right of free discussion to Protestants, denying the right of any one save the emperor to convene a general council at all, and inveighing strongly against the papacy. The king of Denmark declined to admit the nuncio on any terms, declaring that neither be nor his father had ever had any dealings with the pope; and Martinenghi, the nuncio commissioned to Elizabeth of England, was stopped by a messenger while still on the

Continental side of the Channel, and informed that he would not be permitted to land on the English coast. The free cities of the empire also refused the summons, as did five of the Swiss cantons; and even a large number of Roman Catholic prelates, while professing unqualified obedience to the pope's commands, showed much unwillingness to act upon them, and pleaded age, illness, or diocesan business as excuses for absenting themselves from the council. In this unpromising posture of affairs the preparations for the council were pressed on, and Cardinals Ercole Gonzaga, bishop of Mantua, Seripando, Hosius, Simoneta, and (later on) Altemps, the pope's nephew, were named as legates, being directed to open the session of the council upon Easter Day, April 6, 1561. But they did not even arrive in Trent until April 16, and found no more than nine bishops awaiting them. Several causes conduced to this disappointment: the king of Spain had not yet accepted the bull convoking the council; the Frencl bishops were more than fully occupied with the rapid advances of the Reformation in their midst; and the Germans bad no great inclination for the repetition of their experience ten years before. It was thus necessary to postpone the assemblage till January 1 and then to January 18, 1562. That there might be a sufficient number of Italian bishops present to outvote any possible combination of others, the pope collected a large number of prelates, appointed thom salaries for maintenance, and sent them off to Trent. Two questions of the highest practical importance came up for discussion in the preliminary congregation, wherein ninety-two bishops were present:-(1) Was the council to be styled a "continua tion" of the previous one, or to be reckoned as a new synod ! (2) Should the unprecedented clause in the papal decree for opening the council (bat not found in the bull of convocation), "proponentibus legatis ac presidentibus," be accepted and acted on, or rescinded ? To declare the council a "continuation" of its precursor was to accept and ratify all which had been done therein; to treat it as a dew one was to make every decree or tne carlier sessions merely provisional and alterable. To adopt the novel clause cmbodied in the papal decree was to gag the council from the outset and deprive it of freedom by concentrating the initiative in the kands of the legates; and Guerrero, archbishop of Granada, pressed this objection with much urgency. On the other band, this same prelate, acting on the orders of Pbilip II., demanded that the council should bo plainly declared a continuation of its precursor, for Philip had already introduced some of the regulations of that synod into his dominions, and would lose credit if they were rescinded, or even treated as lacking full sanction. Contrariwise, the bishops of other nations present held that there was no prospect of inducing the Germans, English, and other partly alienated nationalities to send representatives, anless the proceedings so far should be regarded as capable of reconsideration and alteration at the hands of the actual assembly. The authorities ait Rome were not unprepared for some difficulty on this head, and had endeavoured to evade it by using the indeterminate word "celebrated," which might be taken either way, and the Spanish remonstrants'were privately told that it was understood that business should be taken up just where it had left off under Julius III., thus raaking the synod a continuation of the former one, but that any express statement to that effect had been carefully avoided, lest the Protestants should take offence, and thus one aim of the council might be defeated. The Spaniards were partly contented with this reply, but urged that nothing which could be interpreted as the convocation of a new council shqula be suffered to appear in the wording of the decree about to be publicly read, which was conceded.

The sereateenth session was beld (Jsnuary 18, 1562) in the presence of the legates,-106 bishops, 4 alubots, 4 generals of orders, and the dnke of Mantus, nephew of the chief legate, being present. Four Spanish bishops lodged a protest against the proposing clause -two of them unreservedly, two in a more qualified manner-and they particularly objected to the novelty of the clause, and to the manner in which it had been sprung npon the conncil, the archbishop of Granada sad the bishop of Orense pointing out that it wse not in the originsl bull, with which the subsequent decree ought to be in complete agreement, and the former adding that it was not ever in the copy of the decree chown to him. But the Italian majority was too strong, and the protest was overruled, the prorogation of the council to February 26, 1562, beiog the only further business transacted. But a very important question was laid before the congregations which followed this session, that of providing some remedy for the injury done to the Roman Catholic Church by the circulation of more or less hostile books, a difficulty made incomparably greater from the middle of the 15 th century onwards than at any previous time in history, by rcason of the inveation of priating. The council of Lateran in 1515 had made a liceace from the ecclesiastical authorities requisite before sny book could be printed, under pain of excommuaication, but this peaalty did not affect Protestant printers, and the issue of a catalogue of books forbidden to Catholics became a necessary sddition. Such a catalogue was issued by Paul IV. in 1559, but some machinery for supplementing it as fresh books poured from the press could alone meet the permsneut danger. Another matter debated in these congregations was the invitation of Protestsnts to attend, and in what character. In the eighteenth session (February 26,1562 ) two decrees on these subjects were promulgated, -one sppointing a committee to report to the council on the whole question of beretical books; the other publishing a safe-conduct to the German Protestants, extended by a rider to those of other nstions. The congregations beld after this oession were busied chiefly with the questions of residence and the abuse of indulgences, besides several less important details of reform. A warm debate arose as to the nature of the obligation to reside, -the Spaniarde holding it to be of divine right, the Italians to be of no more than ecclesiastical precept. So powerful a body in the council took the Spanish view that the legates were alarmed, especially as ominous speeches were made to the effect that the Roman curia must be reformed on the basis of the report of cardinals to Paul III. before anything of moment could be done in the way of resl improvement. $\mid$ Accordiagly, they eent a messenger to the pope, bringing with him a scbedule of the proposed reforms, and asking for advice in the crisis. The pope desired them to counteract the opposition bishops, to postpone the question of resideace, if they could not suppress it altogether, and despstched Visconti, bishop of Ventimiglion as extra nuncio to the council, to report accurately to him everything said or done there, and with him sent also all the bishops who conld be collected st Rome to swell the Italian vote, sud thas defeat the opposition indirectly. There was much debate slso on the scope of the safe-conduct, as the Spaniards were anxious that it should not protect those against whom the Inquisition had taken action, while others desired to see its terms endarged sufficieatly to meet the requiremeats of the Protestants, who objected to its suspicious silence on several weighty particulars. As the French ambasssdors were expected, nothing was done in the nineteeath session (May 14, 1562) save to prorogue the council. On May 26, 1652, Do Laussac (who had been lately French envoy at Rome), Du Ferrier, and De Pibrac, eqvoys from Charles 1X., were admitted to audience, and demanded, amongst other matters, that the council should be formally declared a new one, wherein the imperial ambasssdors supported them, while Philip II. of Spain, contrarimise, insisted that it should be ojeclared a contiouation of tho former synod. The legates strove to satisfy both parties, and received contradictory directions from Rome, at first ordering them to announce the continuation of the former council, and sfterwarde leeving the matter to their discretion. So little agreement could be arived at that the twentieth session (Juae 4, 1562) was held merely to prorogue the council. The question of communion in both kinds was the next to come up for consideration. It was such a capital one, if aay hope of winaing back the Protestanta was to be entertained, that the imperisl and French ambassadors had special injuactions to forward by all means in their power an affimative decision. The Freachmen saw little prospect of carrying this matter in the temper of the Italian majority, and were for opposing the discussion which the legates had announced, bnt the imperial ambassadors were more horeful, and persuaded them to give way. While the question was being dehated in the congregations, the Venetian and Bavarian ambassadors arrired, the latter armed with a formidable schedule of complaints against prevalent abuses, sad of demands for correspondiagly drastic reforme, beginning with the pope and the curia, and making havoc amonest cardinals. dispeasations, exemptions, plaralities, office-books, exclusively Latin services, and other like inatters, thus threateniog all manoer of rested interests and long-rooted customs. The
legrates put them off, alleging the pressure of other business, notably the question of communion in both kinds, which was, in fact, beiog discussed and decided in accordance with the views of the Italians and Spauiards, and against those of the French and Germans. In the twenty-first session (July 16, 1562) a decree conched in four dogmatic chapters and four canons was promulgated apon it, to the following purport:-laymen, and priests other than the actual celebrant, are not bound hy divioe right to com. monicate in both kinds; the church has full power to make what chsoges it pleases in the mode of administering sacrameats; the whole sacrament of the Eucharist is received entire under either kind siogly; aod little children are not hound to communicate. The canons pronounce anathemas against maintainers of the contrary propositions. At the same time a decree upon reformation was enacted, most of the clauses dealing with the duties of bishops in the matters of ordination, patronage, division, and anion of beuefices, discipline of ineffective parish priests, aod visitation of monasteries, but a more permaneot interest attaches to the nioth aod concluding chepter of the decree, whereby the name and office of the "questors of alms," that is to say, the vendors of indulg. ences, are abolished on the ground of the impossibility of other. wise putting a stop to the abuses and depravity of their proceedings. All privileges and customs to the coutrery, even if of time immemorial, are rescinded; the publication of indulgences is confined thenceforth to the ordinaries of esch place, assisted by two members of the chapter; and these same officers are directed to collcct the alms and charitable donations of the people, but forbidden to receive any commission or payment for so doing. This decree is a virtual confession of the justice of the egitation against Tetzel and his fellows which served as the signal for beginaing the great religious strifo of the 16 th century; and it is noticeabla that it was the pope's own voice against the system which decided the action of the council, whercin a powerful minority was found to defend it. Several weighty matters then camn bsiore the congregations, that of residence again being pressed by the Spaniards, while the imperial and Bavarian ambassadors ronewed their requisition for perinissive communion in both kinds for the decree on that subject had gooe no further than to declare it unnecessary, and bad not explicitly forbidden it), aod the French ambassador not only supported them in their demand, but added on his own part that in France they desired vernacnlar services, the abolition of imageworship, and permission for the clergy to marry. The nuncio Visconti wrote to the pope in great alarm, expressing apprehensions at the very free language employed by the fathers of the conncil on these matters, the probability of their coaceding the emperor's demands, and of similar ones beiog advanced therenpon, all making in the same direction. An intrigue to compel the resignation of Cardinal Gonzaga, who was not thought sufficiently epposed to these measures, and who was far less percmptory in his presideacy of the council and use of the closure than Crescenzio liad been, was set on foot, and defeated only by tho sirong representations made at Rome by the archbishop of Lanciano, who said that there was already so much division in the council that it could but just hold togetlier, and would almost certainly be broken up by any step of the kind. The oext subject which rins brought on for consideration was the sacrifice of the Mass, 2.0 d the debates thereon were very animated, disclosing considerabla variety of opinion amongst the theologians,--no fewer than five clearly distiact riews of the tenet, apart from mere verbal or minor differeuces, being adduced and argued for. As sixty French bishops, to be accompanied by twelve theologians, and headed by Charles de Guise, cardioal of Lorraine, mere under orders to repair to Trent, the French ambassador pressed the legates to postpone the next sessiou till their arrival, as De l'Isle, ambassador at Fome, did the pope; but each replied evasively, referring th.s applicant to the other. The question of communion in both kinds was also very warmly discussed, and the council was warned that a negative decision would lead to the secession of multitudes who had not Jet broken with the Roman Church; but the Jesuit Laynez, who was the chief advocate for refusal, replied that to diminish the church would not destroy it, and that anythiog was better than concession io the matter. The numbers in the division taken on the question were as follows:-29 were in favour of granting communion in both kiuds; 31 agreed thereto, but desired the execution of the decreo to be left to the pope's discretion; 38 were for total refusal; 24 strove to evade responsibility by referriog the matter to the pops entirely; 19 were willing to make the concession to the Bohemians and Hungarians, but would refuse it to all others; 14 asked for a postponement; and 11 remained neutral, declining to rote any way - being a total of 166 suffrages, so split un as to make it impracticable to frame a decree. In this difficulty, the legate seized the opportunity of persuading the council to refer the matter to the pope's decision, thereby at ouce checkmating the reforming section, and indirectly ruling the vexed point of the relative auperiority of pope and council in favour of the former, and 80 virtually reversing those decrees of Constance and Basel which had long been thorns in the side of the Roman curia. In point of
fact, the pope had written some time hefore to the legates, rccommending them to yield to the eaperor's demand of the chalice for the laity, but they had replied that it fould be impolitic to make it a conciliar act, and that it would be more expedient to frame a mere general declaration that it might lie proper to make the concession in certain cases, but that the pope should be the sole judge of them. In the twenty-second session (September 17, 1562) the decree on the sacrifice of the Mass was promulgated in nine chapters aod as many canons, directed for the most part against current Protestant objections to the doctrine and ceremonial of the Missal. Rules to secure greater order and reverence io the celebration of Mass, and for the suppression of sundry superstitious observances coonected therewith, were also enacted,-besides some minor reforms of little note, and a decree referring to the pope the whole question of the coacession of the chalice. The meagreness and insignificance of the reforms eaacted thus far camsed much displcasure in France, and the kiog directed his amhassador to press once more for delay till the arrival of the French, German, and Polish bishops who were expected at Treat, as the emperor elso instructed his enroy. But the pope was busy in recruitiog the Italiao majority, and was unfavourable to this request, lest the Italiaos should be outvoted by the new-comers; yet so contentious were the debates on the sacrament of orders, and on the nature andex. tent of the rights of bishops-notably whether they were inherently above priests, aod whether they were necessarily subject to the pope, deriving their jurisdiction and other powers solely through delegation from him, or if they were not of Divine iostitution, and his colleagues rather than his deputics (which latter thesis ras steadily maintained by the Spaniards)- that it proved impossible to frame the decrees and hold the session before the arripal of the cardinal of Lorrainc, who reached Trent on November 13, 1562, accompanicd by fourteen bishops, three abbots, and eighteeu theologians.

The discussions, furtber complicated with the question of residence, wore reaewed hereupon, and long before any signs of a creemert were visible the French ambassadors laid before the legatcs a sohecule of reform in thirty-four articles, requiriog, net only the removal of various abuses in patronage, and the punishment of megligence on the part of the parochial and monastic clergy, butalso that vernacular services should be permitted, and communion ia both kinds enjoined, while all abuses and superstitions coonected with image-worship, indulgences, pilgrimsges, and relics should bo summarily aoolished. Lorraine, on being asked how far he agreed with thess demands, said that he disapproved of some of them, but that if he had not consented to take charge of them in their actual forn, they would have been made still more drastic. No definite action Was taken upon them cither at Treat or at Rome, and the proceediogs dragged on ineffectively for some months longer. On Lisrch 2, 1563, Cardioal Gonzaga, first legate, died, and *คs speedily followed by Cardinal Seripando. The imperial and . rencin ambassadors endeavoured to get the cardinal of Lorraine named as first legate and president, but he was not acceptable at Rome, and the post was given to Cardioal Morone, with whom Caraiual Navagero was associated, to fill the place of Scripaodo. All theso eyents delayed the treaty-third session motil Jnly 15, 1563 , nearly ten months later than the preceding one. A decree on the sacrament of orders, in four chapters and eight canoos, Jaid cown that there is a sacrificial priesthood of the New Testameat, instituted by Christ; that there have been seren orders in the Christian ministry from the earliest times; that holy order is a sacrament; thiat orders are indelible; that bishops are superior to priests; that a call from the laity, or from any secular authority, is unnecessary as a titlo to ordination, and that a merely lay call is invalid, while bishops appointed solcly by the pope, Without tie intervention of any other persons, are validly created. A decree of cighteen chapters on reformation, enacting, amongst much else, penalties for non-residence on the part of beoeficiaries, and providing for the erection of those theological seminaries which have ever since been the nurseries of the Latin clergy, was also promulgated in this session. The congregations which followed it were occupied chiefly with the question of matrimony, which had been mooted earlier, but with no definite result, and with framing a scheme to repress the encroachments of the civil nower upon the church in most countries, one clause of which proposed to exempt all ecclesiastics from civil jurisdiction in all cases whatever, and from the payment of taxes, with peoalty of excommunication upoo such civil authorities as contraveoed this ruling. This was never pushed to the stage of promulgation, but it was successful as a manifestation against the reforming party in the council, and actually drove the French ambassadors away, since they judged their further prosenco useless io such a temper of the assembly. Yet it was itself by oo means agreed or harmonions. The old disputes about the claim of the council to represent tho church universal, about the proposing clause, limiting the initiative to the legates, and about the need of reform in the Roman curis itself were renewed, and that with much acrimony, but with no practical result. In the tweuty-fourth session (November 11, 1563) a decree on matrimony, conched in ten chapters and eleven canons,

Was promulgated, the most noticeable points of which are the assertion that the church can constitute other impediments to matrimony besides the forbidden degrees of tha Levitical code, and can dispense with such impediments; that clerks in holy orders and regulars vowed to celibacy cancot contract valid marriage; and that celibacy is superior to matrimony. The sinultaneous decree on reformation lays down rules for the creation of bishops and cardinals, 80 as to avoid unfit promotions; directa that diocesan oynoda shall be held yearly, and provincial synods triennially, laya down rules for episcopal visitatious, and for the qualifications to be exacted of persons promoted to cathedral dignities nad canonriea; aploints the provincial synod the judga of minor causes against bishops, referring graver causcs to the pope'a decision; and enacts various other technical regulations. By this time all concerned wera thoroughly weary of the council, and tha remaining matters for discussion Fere hurriedly discussed, resulting, in the twenty-fifth and last aession (Decenber 3 and 4, 1563), in a decree, very cantiously worded, upon purgatory, the cultus of saints, and that of relica and images. In this same session was also enacted a decree in twenty-two chapters, regulating several matters affecting the discipline of convents of monks and nuns; and another decrea on reformation, in twenty-one chapters, the most important of which eujoin all cardinala and bishops to keep modest households, and not to enrich their kindred with church property; that all rirelates shall recaive and publish the decrecs of the council ; that duelling sloll be prohibited under severe penalties; and that the authorlty of the Holy Sce both is, an ia to be understood to be, untonched by any decrees of the council toucl. ing the reform of morals and discipline. On the last day of the session was passed a somewhat indefinite decree upon indulgences, forbidding all evil gains connected therewith, and directing that, Wherever abuses or superstitions are prevalent concerning them, the bishops shell collect the facta, lay them before the provincial -jnod, and after discussion there refer then to the nops for ultimata decision. Tha distinction of meats, and the due observance of festivals and fasts, were also enjoined; and a formal statement was mada that the committees which had been engaged upon the index of prohibited books, on the draft of a catechism, and on tha revision of the Missal and Breviary, thinking that the synod could not deal with them conveniently, had determined to lay their reports before the pona to ratify and publish at his pleasure. Formal acclamations, and an apathema against all heretics, closed the session; and the legates, after forbidding any bishop, under main of excommunication, to leava Treat till he had either signed his assent to the decrees, or left documentary proof of such assent, gave the blessing and dissolved the assembly.

Two hundred and fifty-five signatures were attached to the decrees, and also those of the ambassadors still remaining at 'rreat. The bull of confirmation was issued at Rome on January 26, 1564, and followed by another fixing May 1,1564 , as the date from which the decrees should be beld binding. The bull of confirmation forbade all persons whatsoever, whether ecclesiastics or laymen, to gloss or interpret the decrees upon any pretext whatever, without papal authority for the purpose. The republic of Venice was the first power to signify its reception of the decrees, followed speedily by the other Italian states (except Naples) and by Portugal ; but the king of Spain, though receiving the decrees, issued them at first in his own name, and not in that of the pope; the emperor and the king of Bohemia demanded the lay use of the chalice and the marriage of priests 29 the terms on which they would accept the council, and obtained a partial conccssion of the former demand, but were refused the latter ; and in France, while the dogmatic decrees were accepted, the disciplinary ones were not, and have never, in spite of efforts many times Ienewed, made part of French ecclesiastical law. The proFision referring the explanation of the conncil to the pope was given slape by Sixtus V., who erected in 1588 a Congregation of the Council of Trent to sit permanently at Rome, where it has ever siuce continued to be included amongst those standing committees which divide among them the administration of the pontifical government.

Two questions remain to be considered in relation to this great synod:-how far was it free, and representative of the mind of Latin Christianity at that time? and what have been its effects upon dogma and discipline? Ample materials exist for anstrering the first question, in the form of contemnorary lotters, either separately published, as
those of Vargas, or included in the great collection of documents made by Le Plat, and in the official acts of the council itself, drawn up by the secretaries Paleotto and Massarelli. From these it is perfectly clear that the council was never free for a moment, but was hampered and fettered, not merely by the permanent fact of a large Italian majority, subsidized by the pope, ${ }^{1}$ but by the method of procedure in the congregations, since by a skilful distribution of the members into groups or classes, so as to prevent combined action, and by careful packing of the sub-committees to which the preparation of business for debate was entrusted, little could be done save when and how the majority pleased ; and, above all, the vigilant supervision exercised by the legates, their constant reference to Rome of every point of any importance before they would permit it to come on for regular discussion (so that Lanssac, one of the French envoys, somewhat profanely said that the Holy Spirit was brought to the council in a carpet-bag from Rome), and their uncompromising use of their presidential authority to interrupt or silence unacceptable speakers (as frequently appears in the Acts) effectually bound the counci! hand and foot; and thus its decisions, as a whole, represent little more than the Italian and, to somy extent, Spanish opinions of the time, and not those of German, French, or Hungarian Catholics. The demeanour of the legates differed much, and there is a wide interval between the open browbeating employed by Crescenzio and the high-bred dignity of Gonzaga or the diplomatic subtlety of Morone; but the policy was alike in all cases, and its results the same. As to the dogmatic effect of the council, it went much further than merely restating the current Catholic theology of the preReformation era; for it raarks a new departure, closing many questions previously left open (nathing is more noteworthy in the debates than the manner in which several divines of unquestioned ability and loyalty delivered themselves of opinions closely allied to those advocatnd by leading Reformers, and then still tenalle within the Roman obedience), re-wording old propositions, or framing new ones, in an incisive fashion. It recovered for papal authority all it had lost, or was likely to lose, through tine action of Basel and Constance; and, above all, it unified Roman teaching for the first time, and crystallized it into rigid compactness. Thus it made concessions and explanations for the reconciliation of the revolted Protestants, although the primary cause of the council, practically impossible thenceforward, since the Romay Catholic system, thus bastily consolidated out of a fcrmer condition of partial flux, became like a "Prince Rupert's drop," from which, if the smallest fragment be broken, the mass is at once resolred into disintegrated powder. In the matter of disciplinary reform the council enacted but little of an effective nature, except in the abolition of the traffic in indulgences, and the establishment of theological seminaries, waich has proved the most effectual agency for creating that doctrinal uniformity which now prevails throughout the Roman obedience ; and the real bonours of the CounterReformation rest with the Jesuits, to whose unremitting diligence, powerful organization, and ceaseless precept and example must be attributed by far the larger part of the abatement of ecclesiastical abuses and scandals which marks the succeeding era. Doubtless, the Tridentine decrees, in strong and resolute hands, proved most useful subsidiary weapons to compel lecal reforms; but decrees of little less stringency had been enacted by presious

[^239]synods, and had rusted unused, because there was no one able and willing to put them in operation against the passive resistance of powerful vested interests.
The blbllography of the councll of Trent is very extensive, bat a comparatively small aumber of rinmes really suffices the atuleot. The frot work of lmportance is $F_{0}$. Paolo Sarpl'a Isloria d:l Conculio Tradenino, orlglnally pobllshed in Lundoa (1619) by Antonlo de Dominis, archblshop of Spalato, under the pseudonym of Pietro Soave Polano (an imperfect anegram of Paolo Sarpl Veneto), but of Pietro Soave Polano (an impelifect anegram of Paga sarpi eneto), but better studled in tha French verdon by Palavilno Istoria del Concilio dis notes (sea Sarpl). Tha rival work of Sforza Palavielno, 1 storia del Concilio de Trento (1656-57), whitten to order as a refutation of Sarpi s work, is also indispensable. Tra had free access to many officlal documents which Sarpi could not consult, and often corrects lim upon points of detail, but a careful reader will ind that ha confirms him far oftener than he rafutes him. It is not enoagh, as Ronke polnts out, to conpare those two, and take the mean atatement as a guide, for they are sometlmes ta blank coatradletion, and other wlinesses must he called in to decide the matter. The Acts of the councli, so far as they were drafted by Paleotto, were first pablished by Mendham in 1842 ; the complete Acts by both Paleotto and Masssrelli, Wers not accessible till published as Acta Genuina Ecumenici Concilii Tridentini by Theiner in 1874 . The vast complintion of Jodocus La Plat, Monumentorum ad Historiam Concilii Tridentini Amplissuma Collecio (7 7019. 4to, 1781-87), is full of valuabio and interesting matter. The speeches of the Jesult laynez, which had auch a powerful effect upon the councll, have been recently published under the title of Lainez, Disputationes Tridentine, 2 vols., 1886. Vurgas, Lettre: et Mémoires concernant le Conctie de Trent (1700, partiy translated in Geddes, The Council of Trent no Free Assemibly, 1714), is of much valuc. The canona and decrees of tha councll have been many times published, and are readily accessible; the best edition is that by Richter and Schulta ( 1853 ). There is a convenlent abiddgment of Palaviclno's history prefixed to tha Rev. James Woterworth"e English vorsion of the Decyees and Canons of Trent (1843), but it is $n$ it trustwortly, for tha translator has anppressed many atatements of tho orgit al which tellin various ways agalnst the freedom of the action of the councll. To thesa may be added Sickel, Aktenstucle zur Geschuchte des Konzils ${ }_{2!}$ TVient, 1872; Calenzto, Documenti Ineditie Juovi Lavori Letterarii sul Concilto di Trento, 1874: Döllinger, Sammiung von Urkunden zur Qeschichte des Concils von Trient, 1876; and the artlcle on tha couchll in Wetzer and Weltes ${ }^{\text {a }}$ Kirchenlexicon.
(R. F. L.)

TRENTON, a city of the United States, county seat of Mercer county, Now Jersey, and capital of the State, is situated in $40^{\circ} 14^{\prime} \mathrm{N}$. lat. and $74^{\circ} 45^{\circ} \mathrm{W}$. long., 33 miles nerth-east of Philadelphia and 57 seuth-west of New York. It lies very near sea-level (under 45 feet), apon the left (easteru) bank of the Delaware river, at the head of navigation. The city is irregularly built, the streets of different sections running in various directions, without any appearance of system; this is doubtless due to the fact that different portions of the city were originally settled as independent villages. Till recently Trenton was rather backward in the matter of monicipal improvements, but an extensive system of paving and sewage has now been entered on. The water supply is obtained by pumping into a reservoir. Street cars run upon one or two of the principal streets; and the city is traversed on the main line of the New York division of the PennsyIvania Railroad. Manufactures are the leading industry, the capital invested in 1880 having been $\$ 6,966,830$ and the production $\$ 12,712,762$. In iron and steel manufactures over $\$ 2,000,000$ were invested, the industry next in importance being the manufacture of stone and earthen ware, for which this city has a national reputation. Rubber goods, watches, and woollen cloths are also made. The population, 22,874 in 1870 , was 29,910 in 1880 .

Trenton was formed by a consolidation uoder one charter of several independent villages, known as Falls of the Delaware (settled in 1680), Kingsborough, Bloomsburg, and Lamberton. The name Trenton was given to the aettlements about 1720 . Its early growth was slow. In 1790 it was selected as the Stata capital, and two years later it received a city charter. Its growth since that time has been steady, and during the past thirty years has beca very rapid.

TREPANG. See Béche-de-Mer.
TRESPASS, in law, is any transgression of the law less than treason, felony, or misprision of either. The term includes a great variety of torts committed to land, goods, or person, distinguished generally by names drawn from the writs once used as appropriate to the particular transgression, such as vi et armis, quare clausum fregit, de bonis asportats, ae uxare abducta cum bonis viri, quare filium et heredem rapuit, \&c. Up to 1694 the trespasser was regarded, nominally at any rate, as a criminal, and was liable to a fine for the breach of the peace, commuted for a small sum of money, for which 5 W . and M. c. 12 substituted a fee of 6 s . Sd. recoverable as costs agaicst the defendant. Trespass is not now crimins! except by special
statutory enactment, e.g., the old statutes against forcible entry, the Game Acts, and the private Acts of many railway companies. When, howover, trespass is carried sufficiently far it may become criminal, and be prosecuted as assault if to the person, as nuisance if to the land. At one time an important distinction was drawn between trespass general and trespass special or trespass on the case, for which see Tort. The difference between trespass and case was sometimes a very narrow one ; the general rule was that where the injury was directly caused by the act of the defendant the proper remedy was trespass, where indirectly, case. The difference is illustrated by the action for falso imprisonment : "if the defendant himsell imprisoned the plaintiff the action was trespass; if a third person did so on the information of the defendant it was case. A close parallel is found in Roman law in the actio directa under the lex Aquilia for injury caused directly, the actio utilis for that caused indirectly. One of the reasons for the rapid exteasion of the action on the case, especially that form of it called assumpsit, was no doubt the fact that in the action on the case the defendant was not allowed to wage his law (see Wager).

In its more restricted sense, trespass is generally used for entry on land without lawful authority by either a man, his servants, or his cattle. To maintain an action for such trespass the plaintiff must have possession of the premiscs. The quantum of pessession necessary to enable him to bring the action is often a question difficult to decide. In most instances the tenant can bring trespass, the reversioner only case. By the Judicature Act, 1873, a mortgagor in possession can sue for trespass in his own name. Remedies for trespass are either judicial or extra. judicial. The most minute invasion of private right is trespass, though the damages may be nominal if the injury was trivial. On the other hand, they may be exemplary if circumstances of aggravation were present. Pleading in the old action of trespass was of a very technical nature, but the old-fashioned terms alia enormia, replication de injuria, new assignment, \&c., once of such frequent occurrence in the reports, are of merely historical interest since the introduction of a simpler system of pleading, unless in thoso American States where the old pleadiog has not been reformed. The Vevee (q.v.) in trespass was formerly local, in case transitory. In addition to damages for trespass, aa injunction may be granted by the court. The power to grant injunctions against threateaed or apprehended trespass has been considerably enlarged by tho Judicature Act, 1873. The principal instances of extra-judicial remedies are distress damage feasant of cattle trespassing, and remoral of a trespasser without unnecessary violence, expressed in the terms of Latin pleading by molliter manus imposuit.
Trespass may be justificd by exercise of a legal right, as to servo the process of the law, or by invitation or licence of the owner, or may be excused by accident or inevitable nccessity, as deviation from a highway out of repair. Whera a man abuses an authority given by the law, his wrongful act relates back to his entry, and he becomes a trespasser ab initio, that is, liable to be treated as a trespasser for the whole time of his bcing on the land. More breach of contract, such as refusal to pay for wine in a tavern which a person has lawfully entered, does not constitute bim a trespasser $a b$ initio. A trespass of a permanent nature is called a continuing trespass; such rould be the permitting of one's cattle to feed on another's land without authority:
la Scots law trespass is used only for torts to dand. By the Trespass (Scotland) Act, 1865, trespassers ara liablo on summary conviction to fine and imprisomment for encamping, lighting fires, \&c., on land withont the consent and permission of the awner.

TREVES (Freach, Trèves; Germau, Trier), formerly the capital of an archbishopric and spiritual electorate of the empire, and now the seat of a Roman Catholic bishop and the chief torn of a.governmental district in the Prussian mrovince of the Fhine, is situated on the right
bsak of the Moselle, pleasantly surrounded by low vineclad hills, 60 miles south-west of Coblentz and 86 miles sonth of Cologne. It lies in the midst of a carefully cultivated and fertile plain, the rich vegetation of which forms a pleasing setting to its red sandstone walls and venerable towers. Most of the old streets of the town are quaint and irregulas ; but minch of the space enclosed within the circuits of the walls is now occupied by orchards and gardens. The population of Treves in 1885 was 26,125 , five-sixths of whom were Roman Catholics. Their chief occupations are fruit-growing and vine-dressing ; the industries of the place, including the manufacture of cotton and linen, dyeing, and tanni.g, are not very extensive. A specialty of Treves is the preparation of stones for Gothic churches, which are sent off ready to be at once placed in position. A river traffic is carried on in wine, cattle, and wood.

Treves claims to be tho oldeat town in Germany, atd It containe more important Romau remains than any other place in northern isurope. The most remarkable of these is the Porta Nigra, a huge fortified gateway, 115 lect long, 70 to 95 feet high, and 30 feet deep. It is formed of ancemented blocks of sandstone, held logether by clamps of Iron, and now blackened with time; the detaila are very rude. Opinions vary videly as to the date of its erection, but recent anthorities refer it to the lat century of tho Christian era During the Middlo Ages the strncture woa converted into two churches, one above the other; all additious have, however, now bcen remored, except the ajse of the east end. The basilica, long used as the drchiepiacopal palace and now consecrated as a Proteatant charch, probably detes from the reign of Constantine. The so-called Roman baths are in all probability the relica of en extensive imperial palace. Just outside the town are the remains of an amphitheatre, capable of accominolating 30,000 spectators, where Constantine caused eevcrel thousand Franks and Bracteri to le butchered for the public amusement. Perheps the oldest Romen remaina in Treves are some of the piers of the bridge over the Mosellc, dating from about 28 b.c. This bridgc, which is at one corner of modern Treves, lay ncar the mildle of the much more extenaive Roman city. There are alao namerous Roman antiquities iu the neighbourhood of Treves, the inost fmportant of which are the lael column, a sepulchral monnmout of the 2 d century, and tho mosasc pavements at Nennig and Flicssens.

Another group of intereating buildings belongs to the accond period of prosprity enjoyed by Treves under the rule of its medieval prelates. The cathedral, described by Lübke as tho most important example of pre-Carlovingian building in Germany, Hirrore the entire history of the town. Its kernel consists of part of a Romen basilica of the 4 th century, which seems to have Lcen converted into a Chriation church at a very early periorl. It pas restored by Bishop Nicetius about 550, and in the 11th and 12th centuries it was again restored and greatly extended by Archbishop Poppo and his anccessors. Fho adcled an apse at each end and left it substantially in its present form. The cathedral is connected by besutiful cloiaters of the 13th century with the circuler Liebfranenkirche, one of the moss interesting early Gothio churches in Germany ( $1227-43$ ), catching up the architectural thread at the point dropped by the catheriral. Among the treasurea of the latter" is the "holy cost of Treves," belioved by the devout to bo thie ecamleus garment worn by our Saviour et the cracifixion, and said to hare been presented to the town by the empress Helena, the central figure in Treveran Christian legend. Its exhibition in 1844 attracted a million and a half of pilgrims to Treves According to recent anthorities, the earliest churches in Treves wore those of Sts Eucharius, Meximin. Matthew, and Panl, all without the walls, now rebailt or converted to secular purposes Of the modern buildings none call for special remark. The tow dilrary contains abont 100.000 volumes, including several valueble specimens of early printing. Its greatest treasure is the C'odex Aureus, a onnascript of the Gospels preseated to the ebbey of St Maximin by Ada, sister of Cherlemagne. The same building also contains an interesting collection of Roman and medirval antiquitios

A medieval legend, preserved in an inscription on the old Rothes IIans inn, places the foundation of Treves 1300 ycars before that of Rome, and ascribes it to Thelbetas, son of Ninus, king of Assyria But, fable epart, we must atill allow thet Treves has goor cleim to cell itself the oldest town in Germeny. It is a little doubtful whether the Trepiri were of Tentonic or Celtio stock. St Jerome records that the language of the Treviri of the 4 th conturs resembled that of the Ganls of Asia; but, even $1 f$ we ednuit this evidence as uunclusive of their Celtio origin, we most recognize the fact thet thoy were Celts who were lang nndel Tentonic influence. Their sutlientic history begins with the etory of their sobjection by Jnlus

Cæsaı ( 56 в. C. ), who deacriles them as a nerlike race, with the beer cavalry in Gaul. The Romar town, Colonia Augusia Trevirornm (or Treveroraun), was probably founded by the emperor Claudius, and rapidly obtained a wealth and insportance which justified the poes Ausonins (4th century) in describing it as the second motropolis of the enpire, or "Rome beyond the Alps." It became the capital of Belgica Prima, aud during the 4th centnry was a farourita residence of Conetantine and other Roman emperors. Most of tho paleces and publio buildings, of which the remains are atill extant, were built ot this period, while the eurrounding hilla wers covered with villas. Trever was loid in ruins by Attila in 451 , and sbout 465 was permauently taken possession of by the Franka It Fas included in the kingdom of Anstrasia, and became a German city in 870. Like its prototype Rome, it attained a second era of prospority and importance as an ceclesiastical capital (ses below), and in the Middle Ages the "Sancta Civites Trevirorum" swarmed with "religions" of all kinds and graries Unlike most of the German episcopal citles, however, it did not oncceed in shaking off the ecclesiastical yoke, nor did it attain, except transitorily, the position of a frue imperial city. Wars and sieges occasionally checked but did not stop its growth. Art and science were eedulously fostered in the monastic achools, and a nuiversity, founded in 1473 , existed dowa to 1798. The importance of Treves departed with the overthrow of the ccclesiestical principality. In 1786 the last elector shiftod his residence to Coblentz, and from 1794 to 1814 Treves was capital of the French department of the Sarre. Since the latteı date it has belonged to Prussia.

The archbishorric and acclesiastical electorate of Treves, bounded by Nassau, Cologno, Luxemburg, Lorraine, the Rhenish Palatinate, Hesse-Rheinfels, and Katzenelnbogen, had an area of about 3200 square miles and a population of 250,000 to 300,000 . Its suffragan bishops were those of Metz, Toul, and Verdun, and after 1777 also those of Nancy and St Dié. As elector of the German empire the arch bishop took the eecond place, and bore th.e atyleof arch-chencellor of Gaul or Burgundy. Legend places the foundetion of the bashopric of Treves in the 1st century of the Cliristian era, hat the first bishop known to history is Agricins, who flourished abort 314. The eee appears as an archbiehopric in the 9th century, and in the Middle Ages the archbishops attained considerable temporal pover. Among the most prominent were Baldwin of Luxemburg (13971354), brother of the emperor Henry VII., who mpy be iegarted as the founder of the teriitorial greatness of the see and Richard ron Greiffenklen (1511-1531), who distinguished himself by his anccessinl opposition to the Reformation. The last archlishop way Clemens Wenccslans (1768-1802) of Saxony. The part of the erchbishopric on the left bank of the Rhine was taken by France in 1801, and the rest was secularized in favou of the prinee of JJassan Weillurg in 1803. After the fall of Napoleon the archlishuprif was incorporatcd with Prussia. A new bishopric of Treves waj instituted in 1821, the boundaries of which are almost conterminow witil those of the old archbiehopric; the bishop ia a euffragar to the archbishon of Cologne.
See "Augasta Treverorum," ar artlele by E. A. Freeman in the Ertus Quarterty Review Ior July $1877^{\circ}$.
treviranus, Gottfried Reinhold (1776-1837), German naturalist, was born at Bremen, February 4, 1776, studied medicine at Güttingen, in 1797 became professor of mathematics in the Bremen lyceum, and died at Bremen. February 16, 1837.
He made numerons inportant contribntions to comparative anatomy, eapecially in regard to birds and apiders Thongh noted for his lcarning and acnte observation, his stadies in geographical distribution cannot le said to heve led to any very definite results. It is rather on account of his contributions to ætiology thet he doserves to be remembered, though his work in this department hes licen to a great extent overlooked. In the first of his larger works, Biologie oder Philosophio der lebenden Natur, which sppeared from 1802-1805, he geve clear expression to the theory of "deacent with modification." He believel that simple forms (Protists), which he termed "zoophytes," were "the primitive types from which all the organisms of the higher classes hed arisen by grednal development." "Every living creature has a potentiality of endless modification of adapting its atructure to the changes in the external Forld." $\mathrm{H}_{\mathrm{c}}$ also maintained that each epecies has its dey or period at the end of which it does not become extinct, hut has simply ceased to be, becanse it has become something else. That he atated the theory of descent with mach clearncss, and with a anfficient background of actual koowledge of forms, must be ackoowledged by all; the onls difficulty relates to the question of priority. The first volume of his biology was published in 1802, but he otates that this baul been written abont 1796. Now it was not till 1801 thet Lamarck first began to free himself from the traditional dogma of the lmmnta bility of speeies, and to publish his views of evolution. Neither Goothe nor Oken can be said to have done much more than follove up the ironical insingations of Buffon (1753-76) and the ingenious up the ironics insinuations of Erasinas Darwin, whose Zrenomiz was trauslatad

Into German between 1795 and 1797, while both Treviranus and Lamarek tackled the preblem not merely of the theory of descent but of the mechanism of evolution. On this point the merits of Lamarck certainly outweigh those of his contemporary. Treviranus laid down as a fundamental proposition "that all living forms arc the results of physical influences which are still in operation, and vary only in degree and direction." Like many after him, he directed attention to the influence of the male elements in fertiliza tion as a source of variation, but laid emphasis only on the intra. organismal power of adaptation to aurroundings. Whatever opinion he entertained in regard to the priority and the importance of the contribution made by Treviranus to the theory of evolution, it is at least certain that he was a leamed maturalist and au acute thinker. His most important later work of a synthetic nature was entitled Erscheinunger und Gcsctze des organischen Lebens (1831).

See Evolution ; E. Haeckel's SchöDfungsgesthiches, pp. 83-5; Carua, Geschichte der Zoologie, p. 610.
TREVISO, a town of Italy, in the province of the same nàme, lies in the ruidst of a district of great fertility, at the confluence of the Piavesella with the Sile, which is here navigable for large boats and communicates by canals with the lagoons of Venice ( 17 miles distant). It is an old town, with narrow irregular colonnaded streets and some good squares. The cathedral of San Pietro, dating from 1141 and restored and enlarged in the 15 th century by Pietro Lombardo, but still unfinished, contains a fine Annunciation by Titian (1519), an Adoration of the Shepherds, the nasterpiece of Paris Bordone (born at Treviso in 1500), and frescos by Pordenone. There are numerous statues and reliefs by Pietro, Tullio, and Martino Lombardo, and by Sansovioo. The Gothic church of San Niccolo (1310-52) contains a fine tamb by Tullio Lombarde, frescos by Ciovanni Bellini, and a large altar-piece by Fra Marco Pensabene and others; in the adjoining chapter-house are forty portraits of celebrated Dominicans by Tommaso da Modena (1352). The Monte di Pietà contains an Entom'~ment by Pordenone (according to others by Giorgione). The churches of S. Leonardo, S. Andrea, S. Maria Maggiore, and S. Maria Maddalena also contain precious art treasures, and the town is enriched besides by various open-air frescos. The town-ball and theatre are also conspicuous buildings. Silk and cotton goods, cutlery, majolica, and paper are the chief manufactures of the place, and an active trade is also carried on in corn, fruit, and cattle. The population in 1881 was 31,249 .
Treviso, the ancient Tarvisium, is not mentioned by any of the ancient geegraphers, though Pliny speaks of the Silis as floming "ex montibus Tarvisanis." In the 6th century it appears as an important place. From 1318 it was for a short time the seat of a university (see Universitues). In 1339 it came under the Venetian sway. In the 15 th century its walls and ramparts were renewed under the direction of Fra Giocondo, two of the gates being built by the Lombardi. Treviso was taken in 1797 by the French under Morties (duke of Treviso). In March 1848 the Austrian garrison was driven from the town by the revolutionary party, but iu the following June the town was bombarded and compelled to capitulate.

TREVITHICK, Richard (1771-1833), inventor of the locomotive, was descended from a family of great antiquity in the county of Cornwall, and was born 13th April 1771, in the parish of $11 l o g a n$. Shortly afterwards the family removed to Penponds, near Camborne, where the boy attended his first and only school, his attainments beiag limited to reading, writing, and arithmetic. Though slow and obstinate as a scholar, he spent much time drawing lines and figures on his slate, and possessed such instinctive skill in mechanics that while still a youth be was able to solve a difficulty in the correction of underground levels which had puzzled some of the mine agents. He inherited more than the average strength for which his family were famous, standing 6 feet 2 inches in height, while his frame was the very model of an athlete. His feats in wrestling and lifting and throwing weights were unexampled in the district. At the age of eighteen he began to assist his father as mine manager, and, manifesting great fertilitv of mecbas:ical in-
vention, was soon recognized as the great rival of Watt in improvemeats on the steam-engine (see vol. xxii. p. 476). On the death of his father in 1797, he succeeded him as leading engineer in Cornish mining. He married the same year. His earliest invention of importance was his improved plunger pole pump (1797), which has superseded all others for deep mining. In 1798 he applied the principle of the plunger pole pump to the construction of the waterpressure engine, which he subsequently improved in various ways. About this time he also perfected a high-pressure non-conducting steam-engine, which became a successful rival of the low-pressure steam-vacuum engine of Watt. At an early period he had begun experiments in the construction of locomotives, and a model constructed by him before 1800 is now in the South Kensington Museum. On Christmas eve 1801 his common road locomotive carried the first load of passengers ever conveyed by steam, and on 24th March 1802 he and Andrew Vivian applied for a patent for steam-engines in propelling carriages. In 1803 his locomotive was run in the streets of London, from Leather Lane by Gray's Inn Lane and along Oxford Street to Paddington, the return journey being made by Islington. The cost was, however, found too great, and his thoughts were now directed to the construction of a steam locomotive for tramways, with such success that in February 1804 he worked a tramroad locomotive in Wales, ruming with facility up aod down inclines of 1 in 50 . In 1808 ho constructed a circular railway in London near Euston Square, on which the public were carried at the rate of twelve or fifteen miles an hour round curves of 50 or 100 feet radius. The ideas of Trevithick were successfully developed by Stephenson so as to revolutionize the system of modern travelling, but Trevithick had made considerable progress towards this before Stephenson had begun his cxperiments. Trevithick applied his high-pressure engine with great success to rock boring and breaking, as well as to dredging. In 1806 he entered into a twentyone years' engagement with the board of Trinity House, London, to lift ballast from the bottom of the Thames, at the rate of 500,000 tons a year, for a payment of 6 d . a ton. The following year be was appointed along with Vazie to execute the Thames driftway, but the work was abandoned owing to disputes about payment when unexpected difficulties had occurred. He then set up workshops at 72 Fore Street, Limehouse, for the construction of iron tanks and buoys and model iroo ships. He was the first to recognize the importance of iron in the construction of large ships, and in various ways his ideas have also influenced the construction of steamboats. In the application of steam to agriculture the name of Trevithick occupies one of the chief places. A high-pressure steam threshing engine was erected by him in 1812 at Trewithen, the property of Sir Cbarles Harrkins, while, in the same year, in a letter to the Board of Agriculture, he stated his belief that every part of agriculture might be performed by steam, and that such a use of the stean-engine would "double the population of the kingdom and make onr markets the chcapest in the world." In 1814 he entered on an agreement for the construction of engines for the Peruvian mines, and to superintend their working removed to Peru in 1816. Thence he went in 1822 to Costa Rica. He returned to England in 1827, and in 1828 petitioned parliament for a reward for his inventions, but withont success. He was equally unsuccessful in his endeavours to induce the lords commissioners of the Admiralty to afford him facilities for demonstrating the value of certain improvements he claimed to have made in steam navigatior. He died 22 April 1833.

See Life of Rickard Trevithick, with an Account of his Inventions, by Francis Trevithick, C. E., 2 vols., 1572.

TRIAL, in law, is the examination of, a cause before a conrt of justice. It is the stage in the cause next after Pleading (q.v.). Advance in legal development is generally marked by difference in the mode of trial. This was especiully the case in the history of Roman law, and it has been the same in England (see Action). Many forms of trial, notably those by Ordeal ( $q . v$. ), by wager of battle or of law (see Wager), and by grand assize, have become obsolete, and new forns have been created by legislation in order to meet altered circumstances of eociety Up to a very recent date the tendency of the Roman and English systems was in opposite directions. In the former and in systems fernded on it, such as the Scotch, trial by the judge became the rule, in the latter trial by judge and jury. But the Judicature and Surmary Jurisdiction Acts have recently made considerable innovations upon the old common-law right to trial by JURY (q.v.) or per pais, as it was also called. The modes of trial in England are very numerous, as to a certain extent each Court (q.v.) has its own procedure. Certoin broad rules of justice are observed by all courts, such as that both sides are to be heard, or to have an opportunity of being heard, before decision, and that (unless in very oxceptional cases) the trial is to be in public.
For purroses of conveuience rather tlian as a scientific divisiou trials may be divided into civil and criminal. An ordinary trial in a civil case may ho sither in a court of appellate jurisdiction (in which case it is perhaps more properly called a hearing), in the High Court of Justica before a judge or referee, or in an inferior court. Where the trial is in a court of first instance, it may be either with or without a jury. In Chancery and Admiralty proceedings a jury is not used, and the right to a jury in tho Queen'a Bench Division has been considerably restricted by the Rules of the Supreme Court, 1883, Order xxsyi. Before these rule either party had an absolute right to have issues of fact in an action in that division tried by jury. Now, unless in certain actions, mainly of tort, in which a jury is as of right, a jury can only be obtained by application of a party to the action, subject to the power of the court to direct trial withont a jury of any issue requiring prolonged examination of documents or accounts or ecientific or local investigation: The question of Vevee (q.v.) in civil actions has ceased to Se of importance sinco tho Judicature Acts. Most courts are entitled in proper cases to the assistance of assessors. Trial with assessors is in frequent use in the Admizalty Division. A trial whether by jury or not may be by affidavit or on viva vocce evidence. The lattor is the rule where the trial is by jury. In a county conrt a jury of five is allowed in certain cascs on application. In other inferior courts of local jurisdiction a jury is aometimes tha rule, as in tho (London) Lord Mayor's Court, sometimes not, as in the Chancellor's Court at Oxford or Cambridge. In criminal casea the trial ie by jury, axcept whare a court of Sumpary Jurisdictien (a.v.) is ampowered to try offonces of a comparatively unimportant nature. The right to trial by due process of law before condemiation is secured to the subject by sec. 29 of Magna Charta. A new trial masy be ordered in civil actions and in misdemeanours (in the Latter case only after conviction of tho defendant) on various grounds, the most usual of which are misdirection by the judge, improper adinission or rejection of evidence, and the finding of a veruict agaiust the weight of evidence. In actions in the High Court nery trials are less liberally granted than was the caso beforo the Judicature Acts, Order $x x x i x$. considerably restricting the right. An application for a naw trial of an action is no Songer made by exparte motion in the first instance, as was the course before 1883, lut upon notice of motion. Besidee the ordinary modes of trial, there ara othera of an exceptional nature or of rars occurreuce. In a tial by arbitration, the tribunel is chosen by the parties themselves, and they are nat entitled to object to the trial as conducted by the arbitrator ss long as it conforms to rules of ordinary justice. Peers are tried for treason or felony before the House of Lords, or the court of the Lord High Steward if the trial takes place during the recess of parliament. A trial at bar-a survival of the universal mode of trial before the writ of $\mathbb{N I S I I}^{\text {PrIve }}(q . v$.$) was given by tha$ Statute of Westminster tha Second-takes place before three or four judges of the Queen'e Bench Division, and is in use as of right where the crown is interastad in the litigation, or at the discretion of the court in other cases where questions of unuaual importance or difficulty are raisod. The trial of a petition of right (see Pertition, voL xviii. . P 705) is now assimilated to that in civil sctions. Trialg by record, by cartificate, snd by iuspection, though not expreasly abolished, appear to have become obsolete. Impeachment' (q.v.) is etill a right of tha House of Coinmons, but has not recently bceu
exercised. Court-Martial (q.v.) is the mode of trial for offences committed by persons in the naval or military aervice of the crown.

In Scotland and the United States trials are elther with or without a jury. The most usual trials in Scotland are those before a judge of the Court of Session or the High Court of Justiciary or in a sheriff court. In the United States trials are either in a United States or a State court; in the latter case thay aro regulated by State legislation.

TRIBONIAN, the famous jurist and minister of Justinian, was bern in Pamphylia in the latter part of the 5 th century. Adopting the profession of an advocate, he came to Constantinople and practised in the prefectural courts thcre, reaching such eininence as to attract the notice of the emperor Justinian, who appointed him in 528 one of the ten commissioners directed to prepare the first Codex of imperial constitutions. In the edict creating this commission (known as Hæc Qux) Tribonian is named sixth, and is called "virum magnifcum, magisteria dignitate inter agentes decoratum" (see Hæc Quæ and Summa Reipublicx, prefixed to the Codex). When the commission of sixteen eminent lawyers was created in 530 for the far more laberious and dificult duty of compiling a collection of extracts from the writings of the great jurists of the earlier empire, Tribonian was made president and no doubt general director of this board. He had already been raised to the office of quæstor, which at that time was a sort of ministry of law and justice, its holder being the assessor of the emperor and his organ for judicial purposes, something like the English lord chancellor of the later Middle Ages. The instructions given to these sizteen commissioners may be found in the constitation Deo Auctore (Cod., i. 17, 1), and the method in which the work was dealt with in the constitution Tanta (Cod., i. 17, 2), great praise being awarded to Tribonian, who is therein called ex-qurestor and ex-consul, and also as magister officiorum. This last constitution was issued in December 533, when the Digest was promulgated as a law-book. During the progress of the work, in January 532, there broze ont in Constantinople a disturbance in the hippodrome, which speedily turned to a terrible insurrection, that which goes in history by the name of Nika, the watchword of the insurgents. Tribonian was accused of having prostituted his office for the purpeses of gain, and the mob searched for him to put him to death (Procop., Pers., i 24-26). Justiuian, yielding for the moment, removed him from office, and appointed a certain Basilides in his place. After the suppression of the insurrection the work of codification was resumed. A little earlier than the publication of the Digest, or Pandects, there had been published another but much smaller law-book, the Institutes, prepared under Justinian's orders by Tribonian, with Theophilus and Dorotheus, professors of law (see Preface to Institutes). About the same time the emperor placed Tribonian at the bead of a fourth commission, consisting of himself as chief and four others,-Dorotheus, profcssor at Beyrut, and three practising advocates, whe were directed to revise and re-edit the first Codex of imperial constitntions. The new Codex was published in November 534 (see constitution Cordi Nobis prefixed to the Codex). With it Tribonian's work of codification was completed. But he remained Justinian's chief legal minister. He was reinstated as questor some time after 534 (Procop., Pers., i. 25 ; Anecd., 20), and seems to have held the office as long as he lived. He was evidently the prime maver in the various changes effected in the law by the novels of Justinian (Novellee Constitutiones), which became much less frequent and less important after death had removed the great jurist. The date of his death has been variously assigned to 545,546, and 547. Procopius says (Arecd.4 20) that, although he left a son and many grandchildiren, Justinian confiscated part of the inheritance.

The above facts, which are all that we know about Tribonian, rest on the authority of his contemperary Procopius and of the varions imperial constitutions already cited. There are, however, two articleg in the Lexicon of Suidas under the name "Tribonianos." They appear to be different articles, purporting to refer to different persons, and have been generally so received by the editors of Suidas and by modera legal historians Some authorities, however, ae for instance Gibbon, have supposed them to refer to the same person. The first article is unquestionably meant for the jurist. It is based on Procopius, whose very words are to some extent copied, and indeed it adds nething to what the latter tells us, except the statement that Tribonian was the son of $\$ 1$ acedonianus, was $\alpha \pi \delta \delta \delta \leqslant \eta \gamma \delta \rho \omega \nu$ т $̂ v \nu \dot{v} \pi d \rho \chi \omega v$, and was a heathen and atheist, wholly averse to the Christian faith. The second article says that the Tribonian to whom it refers was of Side (in Pamphylia), was also $\alpha \pi \delta \delta \iota \kappa \pi \gamma \delta \rho \omega \nu \tau \hat{\omega} \nu \nu \dot{\nu} \pi \dot{p} p \chi \omega \nu$, was a man of learning, and wrote parious books, among which are mentioned certain astronomical treatises, a dialogue On Happincss, and two addresses to Justinian. None of these books relate to law; and the better opinion seems to be that there were two Tribonians, apparently contemporarics, though possibly some of the attributes of the jurist have been, by a mistake of the compilers or transcribers of the Lexicon of Suidas, extended to the man of letters of the same name.
The character which Procopius gives to the jurist, even if touched by personal apite, is entitled to some credence, because it is contained in the Histories and not in the scandalous and secret Anecdota. It is as follows:-"Tribonian was a man of great natural powers, and had attained as high a culture as any one of his time; but he was greedy of money, capable of selling justice for gain, and every day ho repcaled or enacted some law at the instance of people who purchased this from him according to their several needs. . He was pleasant in manner and generally agreeable, and able by the abundance of his accomplishments to cast into the shade his faults of avarice " (Pers., i. 24; 25). In the Anecdota Procopius adds as an illustration of Juatinian's vanity the story that he took in good faith an observation made to him by Tribonian while sitting as assessor, that he (Tribonian) greatly feared that the emperor might some day, on account of bis piety, be suddenly carried up into heaven. This agrees with the character for flattery which the minister seems to lave enjoyed. The charge of heathenism we find in Suidas is probahle enough; that is to say, Tribonian may well have beeu a crypto-pagan, like many other eminent coarticrs and litterateurs of the time (including Procopius himself), a person who, while professing Christianity, was at least iadifferent to its dogmas and rites, cheriahing a seutimental recollection of the older and more glorions days of the empire.

In modern times Tribonian has been, as the master workman of Justinian'o codification and legislation, charged with three offences, -bad Latinity, a defective arrangement of the legal matter in the Code and Digest, and a too free handling of the extracts from the older jurists included in the latter compilation. The first of these charges cannot be denied; but it is hard to see why a lawyer of the 6 th century, himself born in a Greek-speaking part of the cmpire, should be expected to write Latin as pure as that of the age of Cicero, or even of the age of Gaius and the Antonines. To the second charge also a plea of guilty must be entered. The Code and Digest are badly arranged according to our notions of scientific arrangement. These, however, are modern notions. The ancienta generally cared but little for what we call a philosophic distribution of topics, and Tribouian seems to have merely followed the order of the Perpetual Edict which custom had already establiahed, and from which custom would perhaps have refused to permit him to depart. He may more fairly be blamed for not having arranged the extracts in each title of the Digest according to some rational principle; for this would have been casy, and would bave spared much trouble to students and practitioners ever since. As to the third complaint, that the compilers of the Digest altered the extracts they collected, cutting out and inserting words and sentences at their own pleasure, this was a procesa absolutely necessary according to the instructions giveu them, which were to prepare a compilation representing the existing law, and to be used for the actual administration of justice in the tribunals. The so-called Emblemata (insertiona) of Tribonian were therefore indispensable, though, of course, we cannot say whether they were always made in the best way. Upon the whole subject of the codification and legislation in which Tribonian bore a part, gee Justinian.

Tribonian, from the little we know of him, would seem to have been a rcmarkable man, and in the front rank of the great oneg of his time. There is nothing to chow that he was a profound and philosophical jurist, like Papinian or Ulpian. But he was an energetic clear-headed man, of great practical force and skill, cultivated, accomplished, agreeable, flexible, possibly unscrupulous, just the gort of person whom a restless despot like Justinian finds useful. His interest in legal learning is proved by the fact that he had collected a vast legal library, which the compilers of the Digest found valuable (seo const. Tanta).
The usual criticisms on Tribonlan mav be found in the Antr.Tribontanns
(1567) of Francis Hotman, the aim of which is ohown by its alternative title, Sive discursus in quo jurisprudentiee Tribonianeas sterilitas et legum palriarurn excellentia exhibetur; and au answer to them in J. P. von Ludewig, Vita Justiniani et Theodorse, nec non Tribonianio
(J. BRe)

TRIBUNE (tribunus) was a name assgged to officers of several different descriptions in the constitution of ancient Rome. The connexion of the word with tribus, "tribe," is obvious. The original tribunes were no donbt the commanders of the several contingents of cavalry and infantry which were supplied to the Roman army by the early gentilician tribes,-the Ramnes, the Tities, and the Luceres. In the historical period the infantry in each legion were commanded by six tribunes, and the number six is probably to be traced to the doubling of the three tribes by the incorporation of the new elements which received the names of Ramnes secundi, Tities secundi, Inceres secundi. The tribuni celerum or commanders of the cavalry no longer existed in the later times of the repiublic, having died out with the decay of the genuine Roman cavalry. ${ }^{1}$ So long as the monarchy lasted these tribunes were deubtless nominated by the commander-inchief, the king; and the nomination passed over on the establishment of the republic to his successors, the consuls. But, as the arny increased, the popular assembly insisted on laving a voice in the appointments, and from 362 s.e. six tribunes were annually nominated by popular vote, while in 311 the number was raised to sixteen, and in 207 to tweuty-four, at which figure it remained. The tribunes thus elected ranked as magistrates of the Ioman people, and were designated tribuni militum a populo, while those who owed their office to the consuls bore the curions title of tribuni rufuli. The rights of the assembly passed oa to the emperors, and "the military tribunes of Augustns" were still contrasted with those nominater in the camp by the actual commanders. The obscure designation tribunus ararius, "tribune of the treasury," had also, in all probability, a connexion with the early orgazization of the army. The officer thus designated was at any rate the paymaster of the troops, and the soldier who was defranded of his pay was allowed to exact it from this tribune by a very summary process. There was still another and important class of tribunes who owed their existence toythe army. In the long struggle between the patrician and plebeian sections of the population, the first distinctions in the public service to which the plebeians forced their way were military, and the contest for admission to the consulate was in large part a contest for admission to the supreme command of the national forces. In 445 в.c., the year in which mixed marriages of patricians and plebeians were for the first time permitted, power was given to the senate (then wholly patrician) of determining from year to year whether consuls or military tribunes with consular authority (tribuni militares consulari potestate or imperio) should be appointed. But, even when the senate decided in favour of electing tribunes, no election was valid without the express sanction of the senate superadded to the vote of the centuriate assembiy. If it happened to be too invidious for the senate openly to cancel the election, it was possible for the patricians to obtain a decision from the sacred authorities to the effect that some religious practice had not been duly observed, and that in consequence the appointment was invalid. According to tradition, reconrse was had to this device at the first election, a plebeian having been successful. Forty-five years elapsed after the creation of the office before any plebeian was permitted to fill it, and it was held by very few clown to the time at which it was abolished ( 367 в.c.) and the plebeians were fully admitted to the consulate. The number of consular

[^240]triounes elccted on each occasion varied from three to six ; there was no jear without a patrician, and to the patrician members were probably confined the most highly esteemed daties, those relating to the administration of the law and to religion.

But by far the most important tribunes who ever existed in the Roman community were the tribunes of the commons (tribuni plebis). These, as has been explained in Rome (vol. xx. p. 736 sq .), were the most characteristic outcome of the long struggle between the two orders, the patrician and the plebeian. When in 494 b.c. the plebeian legionaries met on the Sacred Mount and bound themselves to stand by each other to the end, it was determined that the plebeians should by themselves annually appoint executive officers to stand over against the patrician officers, -two tribunes (the very name commemorated the military nature of the revolt) to confront the two consuls, and two helpers called ædiles to balance the two patrician helpers, the quastors. The came ædile is obviously connected with sedes, "a tcmple," and is an indication of the fact that there was a religious core to the insurrection, just as there was a religious core to the patrician opposition. The temple of Diana and Ceres on the Arentine Hill became for a time to the plebeians what the temple of Saturn was to the patricians, -their official centre and their record office. The insurgent leaders also pressed religion into their service in another may. The masses assembled on the Sacred Mount bound themselves by a solemn oath to regard the persons of their tribunes and ædiles as inviolable, and to treat as forfeited to Diana and Ceres the lives and property of those who offered them insult. That this purely plebeian oath was the real ultimate basis of the sanctity which attached to the tribunate during the whole time of its existence can bardly be believed, though this view has had powerful support both in ancient and in recent times. The revolution must have ended in something which was deemed by bottr the contending bodies to be a binding compact, although the lapse of time has blotted out its terms. The historian Dionysius may have been ouly technically wrong in supposing that peace was concluded between the two parties by the fetial priests, with the forms adopted by Rome in making treaties mith a foreign state. If this were fact, the "sacrosanctity" of the tribunes would be adequately explained, because all such formal fodera were "sacrosanct." But, notwithstanding that the plebeians may safely be assumed to have been conscious of baving to a large extent sprung from another race than the patricians and their retainers, it is not likely that the feeling was sufficiently strong to permit of the compact taking the form of a treaty between alien powers. Yet there must have been a formal acceptance by the patricians of the plebeian conditions; and most probably the oath which was first sworn by the insurgents was afterwards taken by the whole community, and the "sacrosanctity" of the plebeian officials became a part of the constitution. There must also have been some constitutional definition of the powers of the tribunes. These rested at first on an extr nsion of the power of veto which the republic bad introduced. Just as one consul could annul an act or order of his colleague, so a tribune could annul an act or order of a consul, or of any officer inferior to him. There was no doubt a vague understanding that only acts or orders which sinned against the just and established practice of the constitution should be annulled, and then only in cases affecting definite individuals. The tribune was to give his help against illegality in concrete instances. The cases which arose most commonly concerned the administration of justice and the levying of troops.

Although the revolution of 494 gave the tribunes a footbold in the constitution, it left them with no very definit.
resources against breaches of compact by the patricians. The traditional history of the tribunate from 494 to 451 B.c. is obscure, and, so far as details are concerned, nearly worthless; but there is a thread running through it which may well be truth. We hear of attacks by patricians on the newly won privileges, even of the assassination of a tribune, and of attempts on the part of the plebeians to bring patrician offenders to justice. The assembled plebeians attempt to set up a criminal jurisdiction for their own assembly parallel to that practised by the older centuriate assembly, in which the nobles possess a preponderating influence. Nay, more, the plebs attempts something like legislation; it passes resolutions which it hopes to force the patrician body to accept as ralid. As to details, only a few are worth notice. In the first place, the number of tribunes is raised to ten, how we do not know; but appareatly some constitutional recognition of the increase is obtained. Then an alteration is made in the mode of election. As to the original mode, the ancient authorities are hopelessly at rariance. Some of them gravely assert that the appointment lay with the assembly. of the curix-the most ancient and certainly the most patrician in Rome, even if we allow the view, which, in spite of great names, is more than doubtful - that the plebeians were members of it at any time when it still possesscd political importance. The opinion of Mommsen about the method of election is more plausible than the others. It was in accordance with the Roman spirit of order that the tribunes, in summoning their assemblies, should not ask the plebeians to come $\epsilon n$ masse as individuals, and vote by heads, but should organize their supporters in bands. The curia was certainly a territorial district, and the tribunes may have originally used it as the basis of their organization. If tribunes were elected by plebeians massed curiatim, such a meeting would easily be mistaken in later times for the comitia curviata. At any rate, a change was introduced in 471 by the Publilian Law of Volero, which directed that the tribunes should be chosen in an assembly organized on the basis of the Servian or local tribe, instead of the curia. This assembly was the germ of the comitia tributa. The question by what authority the Law of Volero was sanctioned is difficult to answer. Possibly the law was a mere resolution of the plebeians with which the patricians did not interfere, because they did not consider that the mode of election was any concern of theirs. In the first period of the tribunate the tribunes almost certainly agitated to obtain for their supporters a slare in the benefits of the state domain. Aud, whatever riew may be taken of the movement which led to the decemvirate, an important element in it was of a certainty the agitation carried on by the tribunes for the reduction of the law of Rome to a written code. Until they obtained this, it was impossible for them effectually to protect those who appealed against harsh treatment by the consuls in their capacity of judges.
During the decemvirate the tribnnate was in abeyance. It was called into life again by the revolution of 449 , which gave the tribunes a considersbly stronger position. Their personal privileges and those of the ædiles were renewed, while sacrosanctity was attached to a body of men called judices decemviri, who secm to have been the legal assistants of the tribunes. The road was opened up to valid legislation by the tribunes throngh the assemhly of the tribes, but in this respect they were submitted to the control of the senate. The growth of the infucace of the tribe assembly over legislation belongs rather to the history of tho Comitia (q.v.) than to that of the tribunate. After the Hortensian Law of 287 g.c. down to the end of the repnblic nearly all the legislation of Rome was in the hands of the tribunes, The details of the history of the tribunate in itstsecond period, from 449 to 367 b.C., are hardly less obscure than those which belong to the earlier time. There was, however, on the whole, undoubtedly an advance in dignity and importance. Gradually a right was acquired of watching and interfering with the proceedings of the senate, and even with legislation.

Whether the absolnte right of veto had been achieved before 967 may well ba doubted. But the original auxitiun, or right of protecting ildividuals, was, during this period, undergoing a very remarkable expansion. From forbidding a single act of a magistrate in relation to a single person, the tribunes advanced to forbidding by anticipation all acts of a certain class, whoever the persons effected by them might prove to be. It therefore became aseless for the senate or the comitis to pass ordinances if a tribnoo was reary to torbid the magistrates to carry then out. Ultimately the mere announcement of euch au inteution by a tribune was sufficient to cause the obnoxious project to drop: that is to say, the tribunes acquired a right to stop all business both in the delibcrative assembly, tha aenate, and in the legislative assemblies, the comitia. The technical name for this right of veto is intercessio. To what extent the tribunes during the time from 449 to 367 took part in criminal prosecutions is matter of doubt. The XII. Tables had aettled that offenders could only be punished in person by the centuries, but tradition speaks of prosecutions by tribunes before the tribes where the penalty sought was pecuniery. The two main objects of the tribunes, however, at the time of which we are speaking were the opening of the consulate to plebeians and the regulqtion of the state domain in the interests of the whole community. Both were attained by tha Licinio-Sextiau Lawe of 367.
Then a coosidcrable change came over the tribunata. From being an opposition weapon it became an important wheel in the regular machine of etate. The senate became more and more plebeian, and a new body of nobility was evolved which comprised both orders in the state. Tha tribunes at first belonged to the same notable plebeian families which attained to the consulate. The old friction between senate and tribunes disappeared. It ras foond that the tribunate served to fill aome gaps in the constitution, and its power was placed by common consent on a solid constitutional besis. From 357 to 134 b.c. (when Tiberius Gracchus became tribune) the tribunate was for the most part a mere organ of eenatorial government. As the change made by the Grecchi was rether in the practice than in the theory of the tribunate, it will be convenient at this point to give a definite skotch of the couditions and privileges attaching to tho office.
Even after the difference between patrician and plebeian birth had ceased to bo of much practical consequence in other directions, the plebeian charactar was e necessity for the tribune. When the patricians P. Sulpicius Rufus and, later, P. Clodius (the antagonist of Cicero) desired to enter on a demagogic course, they were compelled to divest themselves of their patrician quality by a peculiar legal process. Even the patricians who became eo by mere fiat of the ermperors were axcluded from the tribunate. The other nccessary qualifications were for the most part such as attached to the other Roman magistracies, -complete citizenship, absence of ccrtain conditions regarded as disgracoful, fulfilment of military duties. The minimum age required for the office wes, as in the case of the quæstorship, twenty-seven. The tribunate stood outsida the round of magistracies the conditions of which were regulated by the Villian Lavy of 180 B.c. The election took place in a puraly plebeian assembly, ranged by tribes, under tha presidency of a tribune selected by lot. The tribune was bound by law to sce a complete aet of ten tribunes appointed. Tcchnically, tho tribunes wero reckoned, not as magistrates of tho Roman people, but as magistrates of tho Roman plebs; they therefore bad no special robe of office, no lictors, but only messengers (viatorcs), no official chair, like the curule seat, but only benches (subsellia). Their right to sommou the plebs together, whether for the purpose of listening to a speech (in which case the meetiog was a contio) or for passing ordinances (comitia tribuia.), was rendered absolute by the "laws under sacred sanction" (leges sacratas), which bat been incorporated with the constitution on tho abolition of the decemvirate. The right to summon the senato and to lay business before it was acquired eoon after 367, but was seldom exercised, as the tribunes bad abundant mcans of securiug what they wanted by pressure applied to the ordinary presidents, - the consuls or the urben pretor. When an interregnum came about and there were no "magistrates of the Romen poople," the plebeian tribunes became the proper presidents of the senate and couductors of ordinary state business. At the end of the republic there were interregna of several months' duration, when the tribunes beld a position of more than usual importance. A tenure of the tribunate did not, until a comparatively late period (probebly abont the time of the Second Punic War), confer a claim to a permanent seat in the senate. The condidates for the office were mainly young men of gocd family who were at the beginning of their political career, but the office was often filled by older men of ambition who were etruggling upwards with few advantages. The plebeian ædiles very soon after 367 becsme dissociated from the tribunes and associated with the curule ædiles, so that in the political hierarchy they really ranked higher than those who were originally their superior officers.

The real kernel of the tribnne's power consisted in bis inter. sessio or sight of annulling ordinances, whether framed by the senate
or proposed by a mogistrate to the comitic, or issued by a magistrate in pursuance of his office. From 367 B.C. down to the time of the Gracchi the power of veto in public matters was on the whole nsed in the interesta of tha aristocratic governing families to check opposition arising in their own ranks. A recalcitrant consul was most readily brought to obedience by an exercise of tribunician power. But, although modern readers of the aucient bistorians are apt to carry away the idea that the tribunate was au intensely political office, it is safe to say that the occasions on which tribnnes found it possible to play a prominent part in politics were extremely few, even in the late republic. On the other hand, the tribunes found a field for constant activity in watching the administration of justice and in rendering assistance to those who had received harsh treatment from the magistrates. The tribunes were in fact primarily legal functionaries, and constituted in a way the only court of appeal in republican Rome. It was to this end that they were forbidden to pass a whole night away from the city, except during the Latiu festival on the Alban Mount, and that they mere expected to keep their doors open to suppliants by night as well as by day. They held court by day in the Forum close by the Porcian basilica, and frequently made elaborate legal inquiries into cases where their holp was sought. Naturally this ordinary humdrum work of the tribunes has left little mark on the pages of the historians, but we hear of it not unfrequently in Cicero'e epeeches and in other writings which daal with legal mattere. According to the general priaciple of the constitution, magistrates could forbid the acts of magistrates equal to or inferior to themselves. For this purpese the tribunes were deemed ouperior to ell other officers. If a tribune exercised his veto no other tribune conld annul it, for the veto could not be itself vetoed, but it was possible for another tribuna to protect a definite individual from the consequences of disobelience. The number of the tribunes (ten) made it always posaible that one might baulk the action of another, except at times when popular feeling was strongly rouaed. In any case it was of little use for a tribune to move in any important matter unlesa ha had secured the co-operation or at least the neutrality of all his colleagues. The vetc was not, however, absolute in all directions. In come it was limited by statute: thus the law passed by Gaius Gracchus about the consular provinces did not permit a tribune to veto the annual decree of the scuate concerning them. When there Fas a dictator at the head of the state, the veto was of no avail against bim. One of the important political functions of the tribunes was to condnct prosecutions of state offenders, particularly ex-magistrates. These prosecutions began with a sentence pronounced by the tribuno upon the culprit, whereupon, exercising the right given him by the XII. Tables, the culprit appealed. If the tribune sought to inflict punishment on the culprit's person, the appeal was to the essembly of the centuries; if he wished for a large fine, the appeal was to the assembly of the tribes. As the tribune had no right to summon the centuries, ho bad to obtain the necessary meetings through the urban protor. In the other event he himself called together the tribute assembly and proposed a bill for fining the culprit. But the forms of trial gone through were very similar iu both cases.

It is commouly stated that a great change passed over the tribunate at the time of the Gracchi, and that from their day to the end of the republic it was used as an instrument for setting on foot political agitation and for inducing revolutionary changes. This view is an inversion of the facts. The tribunate did not create the agitation and the revolutions, but these found vent through the tribunate, which geve to the democratic leaders the hope that acknowledged evils might be cured by constitutional means, and in the desperate otruggle to realize it the best democratic tribunes strained the theoratic powers of their office to their muin. Far the bad tribunes did not hesitate to use for bad ends the powers which had been strained in the attempt to eecure what was good. But herein the tribunate only fared like all other parts of the republican constitution in its last period. The consuls and the senate mere at least as guilty as the tribunes. After a serere restriction of its powers hy Sulla and a restoration by Pompey, which gave a twenty years' lespite, the tribunate was merged into the imperial constitution, of which indeed it becam. the chief corner-stone. The emperors did not become tribunes, bu took ap into their privileges the essence of the office, the "tribunicien authority." This dis. tinction between the cssential principle of the office and the actual tenure of the office was a creation of the late republic. Pompey, for example, when be went to the East, was not made procousul of all the Eastern provincee, but he exercised in them a "pro. consular autbority" which was superior to that of the actual proconsuls, -an authority which was the prototype of the imperial authority on its military sile. Siznilarly tho emperor, as civil governor, without being tribune, exercised powers of like quality with the powers of the tribune, though of euperior force. By virtue of his tribunician authority he acquired a, veto on legislation; he hecame the supreme court of appeal for the empire, and to his pere son was attacked the aocient sacrosanctity. Augustus showed the highest atatesmanship in founding his power upoa \& metamorphosed
tribunate, rather than upon a metamorphosed dictatorship, non traditions which wera democratic rather than upon traditions which were patrician and optimate. The tribunes continued to exist till a late period, with gradually vanishing dignity and rights; but it is not zecessary here to trace their decay in detail.

The name "tribune" was once again illuminated by a passing glory when assumed by Cola di Rienzi. The movement which he headed was in many respects extremely like the early movements of the plebcians against the patricians, and his scheme for nniting Italy in one free republic was strangely parallel with the greatest dream of the Gracchi. See Rome, vol. xx. p. 800 sq.
The history of the trihunate is interwoven with that of Rome, and must, to a lerge extent, be sought for in the same sonrces. The principles attaching to the ofice are profoundly analysed by Mommsen in his staatsrecht, and are clearly set forth by E. Herzog in his Geschichte u. Systcm der römischen Staalsverfassung (Leipsic, 1884).
(J. S. R.)

TRICHINA, TRICHINOSIS. See Nematoidea, and Pafasitism, vol. xviii. p. 270.

TRICHINOPOLI, a district of British India, in the Madras presidency, lying between $10^{\circ} 37^{\prime}$ and $11^{\circ} 30^{\prime} \mathrm{N}$. lat. and $78^{\circ} 12^{\prime}$ and $79^{\circ} 30^{\prime} \mathrm{E}$. long. Its area is 3561 square miles. It is bounded on the north and north-west by Salem, on the north and north-east by South Arcot, on the east and sonth-east by Tanjore, on the south by Pudukottai state and Madura, and on the west by Coimbatore. The surface is generally flat, though diversified by masses of crystalline rock, of which the Trichinopoli rock in the fort is a well-known example. The district is well wooded, though nothing worthy of the name of forest is to be found in it. The only mountains are the Pachaimalais, which rise to 2500 feet and extend into Salem district. The Kaverr (q.v.) and its branch the Calerun are the only rivers of any importance. Trichinopoli has numerous roads, and the South Indian Railway traverses it from east to west. The climate is very hot, and not liable to great, variations; the annual average rainfall is about 38 inches.
In 1881 the population of the district was 1,215,033 (males 586,434, females 628,599), of whom Hindns numbered 1,119,434, Mohammedans 34,104, and Christians 58,809. The only town with a population exceeding 10,000 is Trichinopoli, the capital, with 84,449 inhabitants. This city is chiefly noticeable for its strong fort, perched on a granite peak 500 feet high, and the group of temples and temple bvildings situated on and around it. The town next in importance is Srirasgam (q.v.). The chief crops of the district are rice, cotton, tobacco, indigo, sugar-cane, cocoa-nut, plantain, areca-nut, and chillies; and the most important local industries are weaving and the manufacture of cigars. The principal exports are grain of all kinds, especially rice; the imports, tobacco and salt. In 1885-86 the gross revenue of the district was $£ 225,896$, the land-tax yielding $£ 185,889$. Trichinopoli district, along with the rest of the Carnatic, of which it formed part, passed to the British by treaty in 1801.

TRIC TRAC. See Bacrgammon, vol. iii. p. 199.
TRICYCLE. Though velocipedes were made and used more than one bundred years ago, none were practically successful until the brothers Starley constructed in 1876 the Coventry tricycle. One of the earliest descriptions of a cycle occurs in the Journal de Paris of 17 th July 1779. Somewhat later M. Richard invented a machine driven by mechanism almost identical with that of the modern omnicycle, but without the expanding segments. Early in the 19th century the cranked axle worked by treadles and levers came into fashion; then the heavy four-wheelers were preferred. All these machines, however, laboured under three fatal defects: it was almost impossible to drive them up-hill, to check them in going down-hill, and to prevent their overturning in rounding a corner.

It was the success of the early bicycle (see Bicycle) which suggested the belief that a serviceable tricycle could be made. One of these bicycles was specially constructed for ladies, the hind wheel being placed well on one side; but, though it could be ridden, it was not a commercial success. The brothers Starley, by putting a second small wheel in front of the large driving wheel and on the same side as the small hind wheel, gave stability to the machine;
it was steered by turning the small wheels opposite ways, and driven by the large wheel by means of cranks and connecting rods. The same machine with chain driving -the Coventry rotary-is still very largely used. In 1877 James Starley, it is believed without any knowledge of the gear used by Fowler for traction engines, re-invented the same differential gear for tricycles. By this the same force is, under all circumstances, applied to each of two equal driving wheels, and the evil effects of driving a single wheel are done away with. This gear was psed in the original Salvo tricycle, which is the type of ti, 2 e surest machine at the present day. In the early days; of the modern tricycle other designs were carried out, which have now become practically obsolete. In one form the hind wheel of a bicycle was replaced by a pair of equal wheels, one on each side, but the instability of such a construction was fatal. In another, the Challenge, the two wheels were placed in front of the large driver and turned together to steer the machine; stability was obtained by putting the rider in front of the large wheel and lower down, the power being communicated by cranks and connecting rods. But the weight of this machine and the small proportion of the load on the driving wheel were serious defects.

Single-driving rear-steerers were at this time very common, and, though highly objectionable, are still to be seen. Rear-steerers were improved by making both front wheels drivers and allowing for the overrunning of one or the other by clutch, as in the Cheylesmore, or by ratchet driving; but steering by the hind wheel is essentially wrong, and these machines are avoided by experienced riders. Rear-steerers have, however, lately been made with a through axle and differential gear (Rover), the rider being placed further back so as to increase the load on the steering wheel ; but the evil of rear-steering is, only reduced, not removed. The clutch is also employed on some front-steerers; and, though in certain respects it has an advantage over the differential gear, for general use it is not so suitable. The differential gear is an essential feature of the modern tricycle.

In 1878 Messrs Doubleday and Humber patented the Humber machine, which is both driven and steered by the two front wheels, the rider being seated on a trailing backbone and hind wheel as in the bicycle. This machine requires skill to manage: the steering is at first difficult to control and a spill over the handles is quite possible; under a skilful rider, however, the Humber is generally recognized as one of the fastest machines. It is steered by. a cross handle, like the bicycle, and this method of steering, in spite of the fact that it boxes the rider into the machine, is becoming very general in front steerers in place of the rack and pinion steering hitherto in use. The Cripper is a very popular example. The brake is an innportant feature in roadster tricycles. It is always made to act on the box of the differential gear where that is used; but in clutch or single-driven machines one or two independent band-brakes or spoon-brakes are used.

In early days the steering wheel was made small to save weight; the drivers were often 50 inches or more in diameter; and the machine was as short as possible. Owing to the discomfort attending a small wheel and a short base the tendency at present is to increase the size of the steering wheel and the length of the base, and to diminish the diameter of the drivers, two notable examples being the Quadrant and the Crescent. It is usual, especially when small driving wheels are used, to gear the machine up, just as in the old days they were commonly geared down; that is, the chain wheel on the crank axle has more or fewer teeth than that on the wheel axde, and thus the wheels turn faster or slower than the
cranks, or are equivalent to larger or smaller wheels. Twospeed gears are becoming general, among which may be especially mentioned the Cryptodynamic. By means of these it is possible to change the gear of the machine so as to have a high gear under favourable conditions and a low gear when mud, mind, or an ascent make travelling difficult. Although chain gearing is used in nearly every machine made, connecting rods, wheels, or bands are fitted instead to some machines. The necessity for such mechanism has been avoided by making the wheel axle also the treadle axle; but great instahility is the result.
Machines in which the arms instcad of the legs supply the power are made, and are of inmense service to those who lave lost the nse of their legs.
Owing to the inconvenience caused hy doorways being often too narrow to allow a tricycle to pass through, many machines are made to fold up into a narrower space or to shut up like a telescope.
It is important that the rider should be so placed that he can, without leaning forward, put most of his weight on tho treadles, and this is more than ever needed as the steepness of an ascent increases, trecause the slope of the machine has a contrary effect. Sliding seats were arranged for this purpose; but Mr Warner Jones has made use of a swinging frame which the rider can lock in any position he pleases. It is this samo swinging frame which gives such cosfort to the rider of the Otto bicycle, placing him at all times in the position most suitable for the occasion.

Carifer tricycles, in which duo provision is made for the proper distribution of the load, are largely used by the post-office and by tradesmen in their business. Tho "Coventry chair" is a kind of bath chair driven as a tricycle hy a rider beltind. When invalids have overcome a certain projudice as to the danger of this kind of vehicle, it will no doubt be more generally used.

In machines for two riders the riders sit side hy side (sociables) or one is placed before the other (tandens). Sociable machines are both front-steering and rear-stecring. Fear-steerers with each rider driving the wheel on his side only are nearly as objectionable as the single-driving rear-steerer. Front-steering sociables with dif ferential gear are safe and comfortable: but all sociables are slow machines. For nearly every nake of singlo tricycle there is a corresponding tandem. The Coventry rotary in the tandem form suffers more from the single-side driving than in the single form, the rear-steering maclines not so much, owing to the greater weight which the steering wheel has to bear. Tlie Humber is less sensitive in the steering, owing to the greater moment of inertia of the frame and the front rider. The front-steerer cannot be made safer, but an excellent tandem is formed by placing the rear-rider on a trailing tail as in the Humber. Tanclems have an advantage orer sociables and perhaps over single tricycles in the matter of speed; they are, however, not quite so safe, and their appearance alone prevents many from riding them. Many sociables and tandems are convertible into single machines with but little trouble.
The following tables of quickest times which have been accomplished up to the end of 1886 (certified by the National Cyclists' Union) will slow the comparative value of the bicycle and tricyele as racing mnchines.

On a prepared racing path.

| Distance. | Time, tricyclc. | Time, bicycle. |
| :---: | :---: | :---: |
| 1 mile | 2 min .45 .8 sec . | 2 min .32 .4 sec . |
| 5 miles. | $14.27^{\circ} 6$ | 14 , 18 |

TRIESTE (Germ. Triest, Slav. Trst, Lat. Tergeste), the principal seaport of the Austrian-Hungarian empire, is picturesquely situated at the north-east angle of the Adriatic Sea, in the Gulf of Trieste and at the foot of the barren Karst Hills. The old town, nestling round the hill on which the castle stands, consists of nariow, steep, and irregular streets. It is connected by the broad and handsome Corso with the well-built new town, which lies on the flat expanse adjoining the crescent-shaped bay, partly on ground that has been reclaimed from the sea. . The prevailing air of the town is Italian rather than German. The scastle, built in 1680 , is ${ }^{4}$ believed to occupy the site of

[^241]the Roman capitol (see below). Near it is the cathedral of S . Giusto, an unimposing but interesting building, mainly of the 14 th century, and incorporating fragments of a Roman temple and early Christian churches. Don Carlos of Spain (d. 1855) is interred in the south aisle, and Fouché, Napoleon's minister of police, in front of the church, while the churchyard contains the grave and monument of Winckelmann, the archæologist, who was murdcred at Trieste in 1768. The Arco di liccardo, also in the old town, derives its name from a popnlar delusion that it was connected with Richard Cœur-de-Lion, but is probably an arch of a Roman aqueduct. A collection of Roman antiquities found in or near the town has been formed near the castle. The most prominent building in the new town is the Tergesteo, a huge edifice containing the exchange and numerous shops and offices. The new municipal buildings, with the haudsome hall of the provincial diet, the Palazzo Revoltella, the offices of the Austriau Lloyd's and the handsome old exchange are also noteworthy. The church of S. Maria Maggiore is

Plan of Trieste.
a characteristic specimen of Jesuit architecture, and the new Greck church is one of the handsomest Byzantine structures in the empire. The city hospital has accommodation for 2000 patients. The huge Politeama is the largest theatre. In front of the Palazzo Revoltella is a monument to the emperor Maximilian of Mexico, who had becn an admiral in the Austrian service. His sumptuous chatteau of Miramar is one of the lions of the neighbourhood. The capacious harbour, consisting of two parts, the old and the new, is protected by extensive moles and breakwaters, and has been greatly improved within the last ten or fifteen years. From the harbour the Canal Grande extends into the town, allowing large vessels to unload at the warehouses. At the end of the Molo Sta Teresa is a lighthouse upwards of 100 feet high. The population of the town (6424 in 1758) and district of Trieste in 1880 was 144,844 , of whom 74,544 belonged to the town proper and 133,019 to the town and suburbs. The town population is very heterogeneons, but the Italian element far exceeds all the rest. There are about 5000

Germans and also numerous Greeks, English, and French. The population includes 26,000 Slavs, most of whom live in the country districts and are engaged in agriculture

Tricste bee been a free inserial port since 1719. It may be said Eo nearly mouopolizo the trade of the Adriatic, and bas loug cclipsell its ancient rival Venice. The aumual value of its exports ond inforts is about 30 millions sterling. Among the cbief imports are coffec, wine, fruit, grain, tabacco, petrolemn, cotton, coals, and manufactured goods of rarions kinds; the exports iuclude apirits, ligueurs, sugar, meal, timber, glass, and machinery. Large quantilies of fish are sent to rienna. In 1885 the port was entered by c9it vessels with an aggregate burden of $1,267,946$ tons. The trading fleet of Trieste numbers about 500 ships of 100,000 tons burder. The chicf shipping company is the Austrian Lloyd'a, fonuled in 1836, the steamers of which ply to the Mediterranean ports, Alexandria, Constantinople, the Black Sea, \&c. The extenaive wharfs and dockyards of the company lie to the sauth of the town. The chief branches of industry practised at Trieste are shipbnilding, soap, boiling, zaachine-making (especially merine engines), taning, brewing, rope-making, and the manulacture of liqueurs (rosoglio). Trieste is the seat of government for the so-
called Kuistenlond or Coast district, ami is the seat of naval and military commanders and other ofticials. The town council, presided over by the poolesti, is also the diet of the crownland of Treste (35 square miles). "Thieste is the seat of the bishop of Capo d'Istria.
History.-At the time of the foundation of Aquileia by the Romans, the district which how includes Trieste was occupied by Celtic aud Illyriau tribes; 8ud the Roman colony of Tergeste does not seem to bave been established till the reign of Vespasian. Afte: the break-11p of the Roman dominion Trieste shared the geueral fo: tunes of Istira and passed through various hands. From the en; feror Lothaire it received an independent existence under its coun:bishops, and it maintained this position down to its capture by Venice in 1203. For the next 180 years its history cousists chiefy of a series of conflicts with this city, which were finally put ai end to by Trieste placing itself in 1382 under the protection of Leopold III. of Austria. The overlordship thus established in sensibly developerl into actual possession; and except in th; Napoleonic period (1797-1805 and 1809-1813) Trieste has aine: remained an integral part of the Anstrian dominious.

TRIGGER-FISH. See File-Fish.

## TRIGONOMETRY

TIRIGONOMETRY is primarily the science whirh is concerncd with the measurement of plane and spherical triangles, that is, with the determination of three of the parts of such triangles when the numerical values of the other three parts are given. Since any plane triangle can be divided into right-angled triangles, the solution of all plane triangles can be reduced to that of rightangled triangles; moreover, according to the theory of similar triangles, the ratios between pairs of sides of a right-angled triangle depend ouly upon the magnitude of the acute angles of the triangle, and may therefore be regarded as functions of either of these angles. The primary object of trigonometry, therefore, requires a classifeation and numerical tabulation of these functions of an angular magnitude; the science is, however, now understood to include the complete investigation not only of such of the properties of these functions as are necessary for the theoretical and practical solution of triangles but also of all their analytical properties. It appears that the solution of spherical triangles is effected by mans of the same functions as are required in the case of plane triangles. The trigonometrical functions are employed in many branches of mathematical and physical science not directly concerned with the measurement of angles, and lience ariscs the importance of analytical trigonometry. The solution of triangles of which the sides are geodesic lines on a spheroidal surface requires the introduction of other functions than those required for the solution of triangles on a plarre or spherical surface, and therefore gives rise to a new branch of science, which is from analogy frequently called spheroidal trigonometry. Every new class of surfaces which may be considered would have in this extended sense a trigonometry of its own, which would consist in an investigation of the nature and properties of the functions necessary for the measurement of the sides and ancles of triangles bounded by geodesics drawn on such surfaces.

## History.

An account of Greek trigonometry is given under Ptolemy (g.v.).

The Indians, who were much more apt calculators than the Greeks, availed themselves of the Greek geometry which came from Alexandria, and made it the basis of trigonometrical calculations. The principal improvernent which they introduced consists in the formation of tables of half-chords or sines instead of chords. Like the Greeks, they divided the circumference of the circle into 360 degrees or 21,600 minutes, and they fonnd the length in minutes of the arc which can be straightened out into
the radus to be 3438 The value of the ratio of the circumference of the circle to the diameter used to make this determination is $62832: 20000$, or $\pi=3 \cdot 1416$, which value was given by the astronomer Aryabhata (476-550; see Sanskrit, vol. xxi. p. 294) in a work called Âyathatiya, written in verse, which was republished ${ }^{1}$ in Sanskrit by Dr Kern at Leyden in 1874. The relations between the sines and cosines of the same and of complementary arcs were known, and the formula $\sin \frac{1}{2} a=\sqrt{ } 1719(\overline{3} \overline{43} \overline{8}-\cos a)$ was applied to the determination of the sine of a balf angle when the sine and cosine of the whole angle were known. In the Sitrya-Sidillhonta, an astronomical treatisc which has been translated by Ebenezer Bourgess in vol. vi. of the Journal of the American Oriental Society (New Haven, 1860), the sines of angles at an interval of $3^{\circ} 45^{\circ}$ np to $90^{\circ}$ are given; these were probably obtained from the sines of $60^{\circ}$ and $45^{\circ}$ by continual application of the dimidiary formnla given above and by the use of the complementary angle. The values $\sin 15^{\circ}=890^{\circ}$, $\sin 7^{\circ} 30^{\prime}=449^{\prime}$, $\sin 3^{\circ} 45^{\prime}=225^{\prime}$, were thus obtaincd. Now the angle $3^{\circ} 45^{\prime}$ is itself 225' ; thus the arc and the sine of $\frac{1}{8}$ th of the circumference were found to be the same, and consequently special importance was attached to this arc, which was called the right sine. From the tables of sines of angles at intervals of $3^{\circ} 45^{\prime}$ the law expressed by the equation
$\sin (\sqrt{n+1} .225)-\sin \left(n .225^{\prime}\right)=\sin \left(n .225^{\prime}\right)-\sin \left(n-1.225^{\prime}\right)$

$$
-\sin \frac{\left(n .225^{\prime}\right)}{225}
$$

was discovered empirically, and used for the purpose of recalculation. Bhâskara (. 1.1150 ) used the method, to which we have now returned, of expressing sines and cosines as fractions of the radius; he obtained the more correct values $\sin 3^{\circ} 45^{\prime}=100 / 1529, \cos 3^{\circ} 45^{\prime}=466 / 467$, and showed how to form a table, according to degrees, from tho ralues in $1^{\circ}=10 / 573, \cos 1^{\circ}=6568 / 6569$, which are much more accurate than Ptolemy's values. The Indians did not apply their trigonometrical knowledge to the solution of triangles; for astronomical purposcs they solved rightangled plane and spherical triangles by geometry.

The Arabs were acquainted with Ptolemy's Almagest, and they probably learned from the Indians the use of the sine. The celebrated astronomer of Batnæ, Abú 'Abdallahı Mohammed b. Jābir al-Battánı (Bategnius), who died in 929930 A.D., and whose Tables were translated in the 12 th century by Plato of Tiroli into Latin, under the title De scientia stellarum, employed the sine regularly, and was fully conscious of the advantage of the sine over the chord; indeed, he remarks that the continual doubling is sared

[^242]by the use of the former. He was the first to calculate sin $\phi$ from the cquation $\sin \phi / \cos \phi=h$, and he also made a table of the lengths of shadows of a vertical object of height 12 for altitades $1^{\circ}, 2^{\circ}, \ldots$ of the sun; this is a sort of cotangent table. He was acquainted, not ouly with the triangle formule in the Almayest, but also with the formula $\cos a=\cos b \cos c+\sin b \sin c \cos A$ for a spherical triangle $A B C$. Abú 'l-Wafá of Baghdad (b. 940) was the first to introduce the tangent as an independent function: his "umbra" is the half of the tangent of the double arc, and the secant he defines as the "diameter umbre." He cinployed the umbra to find the angle from it table and not merely as an abbreviation for sin/cos; this improvement was, however, afterwards forgotten, and the tangent was re-inrented in the 15 th century. Ibn Yinos of Cairo, who died in 1008, showed even more skill than Al-Battíni in the solution of problems in spherical trigonometry and gave inproved approximate iormulæ for the calcnlation of sines. Among the West Arabs, Abú Mohammed Jabir b. Aflah, known as Geber b. Aflah, who lived at Seville in the 11 th century, wrote an astronomy in nine books, whech was translated into Latin in the 12th century by Gerard of Cremona and was published in 1534. The first book contains a trigonometry which is a considerable improvement on that in the Almagest. He gave proofs of the formule for right-angled spherical triangles, depending on a rule of four quantities, instead of Ptolemy's rule of six quantities. The formule $\cos B=\cos b \sin A, \cos c=\cot A \cot B$, in a triangle of which $C$ is a right angle bad cscaped the notice of Ptolemy and were given for the first time by Geber. Strangely enough, he made no progress in plane trigonometry. Arrachel, a Spanish Arab who lived in the 12 th century, wrote a work of which we have an aualysis by Purbach, in which, like the Indians, he made the sine and the are for the value $3^{\circ} 45^{\prime}$ coincide.
Purbach(1423-1461), professor of mathematics at Vienna, wrote a work entitled Tractatus super propositiones Ptolemxi de sinubus et chordis (Nuremberg, 1541). This treatise consists of a development of Arrachel's method of interpolation for the calculation of tables of sincs, and was published by Regiomontanns at the end of one of his works. Johannes Müller (1436-1476), known as Regionoxtants (q.v.), was a pupil of Purbach and taught astronomy at Yadua; he wrote an exposition of the Almagest aud a more important work, De triangulis planis et sphericis cum tabulis sinuum, which was published in 1533 , a later edition appearing in 1561 . He re-invented the tangent and calculated a table of tangents for each degree, but did not make any practical applications of this table, and did not use formulw involving the tangent. His work was the first complete European treatise on trigonometry, and contains a number of interesting problems; but his methods were in some respects behind those of the Arabs. Copernicus (1473-1543) gave the first simple demonstration of the fundamental formula of spherical trigonometry; the Trigohometria Copernici was published by Rheticus in 1542. George Joachim (1514-1576), known as Rhetices (q.v.), wrote Opus Pulatinum de triangudis (see Tables, p. 9 above), which contains tables of sines, tangents, and secants of arcs at intervals of $10^{\circ}$ from $0^{\circ}$ to $90^{\circ}$. His method of calculation depends upon the formulx which give sin na and $\cos n a$ in terms of the siues and cosines of $(n-1) a$ and $(n-2) a$; thus these formulæ may be regarded as dne to him. Rheticus found the formula for the sines of the Lalf and third of an angle in terms of the sine of the whole angle. In 1599 there appeared an important work by Pitiscus (1561-1613), entitled Trigonometrix sez de dimensione triangulorun; this contained several important theorems on the trigonouretrical functions of two angles, some of which had been given before hy Finck, Landsberg,
and Adriaan van Roomen. François Viète or Vieta (q.v.) (1540-1603) employ cd the equation $\left(2 \cos \frac{1}{2} \phi\right)^{3}-3\left(2 \cos \frac{1}{2} \phi\right)$ $=2 \cos \phi$ to solve the cubic $x^{3}-3 a^{2} x=a^{2} b\left(a>\frac{1}{2} b\right)$; he obtained, however, only one root of the cubic. In 1593 Tan Roomen proposed, as a problem for all mathematicians, to solve the equation
$$
45 y-3795 y^{3}+95634 y^{5}-\ldots+945 y^{43}-45 y^{43}+y^{45}=C
$$

Viete gave $y=2 \sin \frac{1}{45} \phi$, where $C=2 \sin \phi$, as a solution, and also trenty-two of the other solutions, but he failed to obtain the negative roots. In his work Ad angulares sectiones Viète gave formulæ for the chords of multiples of a given arc in terins of the chord of the simple arc.

A new stage in the development of the science was commenced after Napier's invention of logarithms in 1614. Napier also simplificd the solution of spherical triangles by his woll-known analogics and by his rules for the solution of right-angled triangles. The first tables of logarithmic sines and tangents were constructed by Edmund Gunter (1581-1626), professor of astronomy at Gresham College, London; he tras also the first to cmploy the expressions cosine, cotangent, and cosecant for the sine, tangent, and secant of the complement of an arc. A treatise by Albert Girard (1590-1634), published at The Haguc in 1626, contains the theorms which give areas of spherical triangles and polygons, and applications of the propertics of the supplementary triangles to the reduction of the number of different cases in the solntion of spherical triangles. He used the notation $\sin$, tan, sec for the siae, tangent, and secant of an arc. In the second half of the 17th century the theory of infinite series was developed by Wallis, Gregory, Mercator, and afterwards by Newton and Leibnitz. In the Analysis per xquationes numero terminorum infinitas, which was written before 1669 , Nerston gare the series for the arc in powers of its sine; from this he obtained the series for the sine and cosine in powers of the arc ; but these series were given in such a form that the law of the formation of the coefficients was hidden. James Gregory discovered in 1670 the series for the arc in powers of the tangent and for the tangent and secant in powers of the arc. The first of these scries was also discovered independently by Leibnitz in 1673, and published without proof in the Acta eruditorum for 1682. The series for the sine in powers of the arc he published in 1693; this he obtained by differentiation of a series with undetermined cocflicients.

In the 1 Sth century the sciecce began to take a more analytical form; evidence of this is given in the works of Kresa in 1720 and Mayer in 1727. Oppel's Analysis triangulorum (1746) was the first complete work on analytical trigonometry. None of these mathematicians used the notation $\sin$, cos, tan, which is the more surprising in the case of Oppel, since Euler had in 1744 employed it in a memoir in the Acta eruditorum. John Bernoulli was the first to obtain real results by the use of the symbol $\sqrt{-1}$; he published in 1712 the general formula for $\tan n \phi$ in terms of $\tan \phi$, which he obtained by means of trans fornatiou of the are into imaginary logarithms. The greatest advance was, however, made by Euler, who brought the science in all essential respects into the state in which it is at present. He introduced the present nota tion into general use, whereas until his time the trigono metrical functions had been, except by Girard, indicateo by special letters, and had been regarded as certain straigh? lines the absolute lengths of which depended on the radirs of the circle in which they were drawn. Euler's great im. provement consisted in his regarding the sine, cosine, $\cdot d c .$. as functions of the angle only, thereby giving to equations connecting these functions a purely analytical interpreta. tion, instead of a geometrical one as heretofore. Tho
exponential values of the sine and cosine, Do Moirre's theorem, and a great number of otber analytical properties of the trigonometrical functions are due to Euler, most of rhose writings are to be found in the Memoirs of the St Petersburg Academy.
The preceding sketch has bcen mainly drawn from the following sonrces:-Cantor, Gesch. d. Math.; Hankel, Oesch. d. Math.; Marie, Hist. des sc, math. ; Suter, Cesch. d. Math.; Elügel, Math. Wörterbuch.

## Plane Trigonometry.

Imorine a straight line terminated at a fixed point $O$, and initially coincident with a fired straight lino $O A$, to -solve round $O$, and finally to take up any positiou $O B$. We shall suppose that, whea this $r^{-}$ volving straight line is turning in one direction, say that opposite to that in which the hands of a clock turn, it is describing a positive sugle, and when it is turning is the other direction it Is describing a negative angle. Before Ginally taking up the position $O B$ the traight line may have passed any number of times through the position $O B$, naking sny number of completo revolutions round $O$ in cither direction.
 Each time that the straight line makes a complate revolution round $O$ we consider it to have described four right angles, taken with the positive or negative sign according to the direction in which it has revolved; thus, when it stops in the position $O B$, it may have reyolved through any one of an infinite sumber of positive or negative angles any two of which differ from one another by a positive or negative multiple of four right angles, and all of which have the same bounding lines $O A$ and $O B$. If $O B^{\prime}$ is the final position of the revolving line, the smallest positive angle which can have been described is that described by the revolving line making more than one-half and lcss than the whole of a complete rovolution, so that in this case we have a positive angle greater than two and less than four right angles. We have thus shown how we may conceive an ancle not restricted to less than two right angles, but of any positive or negative magnitude, to be generated.

Two syetems of numerical measuremant of angular magnitades are in ordinary use. For practical measurements the sexagesimal system is the one employed : the ninetieth part of a right angle is taken as the unit and is called a degree ; the degree is divided into sixty equal parts called minutes ; and the minute into sirty equal parts called seconds; angles amaller than a second are usually messured as decimals of a second, the "thirds," "fourths," \&c., not being in ordinary use. In the common notation an angle, for example, of 120 degrees, 17 minutes, and 14.36 seconds is mritten $120^{\circ}$ $17^{\prime} 14^{\prime \prime} 36$. The decimal systom measnrement of angles has never come into ordinary use In analytical trigonomatry the circular measure of an engle is employed. In this eystem the unit angle is the angle subtended at the centre of a circle bs an arc equal in length to the radins. The constancy of this angle follows from the geonetrical propositions-(1) the circumferences of different circles vary as their radii ; (2) in the same circle angles at the centre are proportional to the arcs which subteod them. It thas follows that the unit mentioned above is an anglo independent of the particular circle nsed in defining it. The constant ratio of the circumference of a circle to its diameter is a quantity incommensurable with unity, nsually denoted by $\pi$. We shall indicate later on (p. 571 sq.) aome of the methods which bare been emploged to approximate to the valne of this quantity. Its value to 20 places is $3 \cdot 14159255358979323846$; its reciprocal to the same number of places is 31830985618379067153 . In circular messnre every angle is measured by the ratio which it bears to the unit angle. Two right angles are measured by the quantity $\pi$, and, since the same angle is $180^{\circ}$, we see that the number of degrees in an sugle of circular messure $\theta$ is obtained from the formula $180 \times \theta / \pi$. The ralue of the anit of circular measure bas been found to 41 places of decimals by Glaisher (Proc. London Mfath. Soc., vol. iv.); the ralue of $\frac{1}{\pi}$, from which the unit can be casily calculated, is given to 140 places of decimals in Orunert's Archio, vol. i., 1841. To 10 decimal places the value of the unit anglo is $67^{\circ} 17^{\prime} 44^{\prime \prime} 8062470964$. The unit of circular measure is too large to be convenient for practical purposes, but its ase introduces a simplification into the series in analytical trigonometry, owing to the fact that the sine of an angle and the angle itseif in this measure, when the magnitude of the angle is indefinitely diminished, are ultimstely in a ratio of equality.
If a polot moves from a position $A$ to snother position $B$ on a straight line, it has described a length $A B$ of the straight line. It is convenient to have a simple mode of indicating in which direction on the straight line the length $A B$ has been described; this may
be done by supposing that a poi:.t moving in one specified direction is describing a positive length, and when moring in the opposits direction a negative length. Thus, if a point moving from $A$ to $B$ is moving in the positive direction, we consider the length $A B$ as positive; add, sixce a point moving from $B$ to $A$ is moring in the aegative direction, we consider the length $B A$ as negative. Heñco any portion of aa infiuite atraiglt line is considered to be positive or negative according to the direction in which we suppose this portion to be described by a moving point; which direction is tha positive one isy of coarse, a matter of convention.
If perpendiculars $A L, B M$ he drawn from two points $A, B$ on any straight line, not necessarily in the same plane with $A B$, the length $L M$, taken with the positive or negative sign according to the convention as stated above, is called the projection of $A B$ on the given straight line; the projection of $B A$ being $M I L$ has the opposite sign to the projection of $A B$. If tro points $A, B$ be joined by a number of lines in any manser, the algebraical sunt of the projections of all these lines is $L J f_{\text {, - that }}$ is, the same as the projection of $A B$. Hence the sum of the projections of all the sides of any closed polygon, not necessarily plane, on any straight line, is zero. This principle of projections we skall apply below to obtain some of the most important propositions in trigonometry.
Let ns now return to the conception of the gencration of an angle as in fig. 1. Draw $E O B^{\prime}$ at right angles to and equal to $A^{\prime}$.

Fig. 2 We shall auppose that the direction from $A^{\prime}$ to $d$ is the positive one for the atraight line $A O A^{\prime}$, and that from $B^{\prime \prime}$ to $B$ for $B O B^{\prime}$. Suppose $O_{2}^{P}$ of fixed length, equal to $0 A$, sud let $P M, P N$ be drawn perpendicular to $A^{\prime} A, E^{\prime} B$ respectively; then $O M$ and $O N$, taken with their proper signs, are the projections of $O P$ on $A^{\prime} A$ and $B^{\prime} B$. The ratio of the projection of $O P$ on $\overline{B^{\prime} B}$ to the absolnte leugth of $O P$ is dependent only on the magnitude of the angle $P O A$, and is called the sine of that angle; the ratio of the projection of $O P$ on $\mathcal{A}^{\prime} A$ to the length. $O P$ is called the cosine of the angle POA. The ratio of the sine of an angle to its cosine is called the tangent of the anglc, and that of the cosine to the sine the cotangent of the angle ; the reciprocal of the cosine is called the eecsat, and that of the sine the cosecant of the angle. These functions of an angle of maguitude a are denoted by $\sin \alpha, \cos a$, $\tan \alpha, \cot a, \sec \alpha, \operatorname{cosec} \alpha$ respectively. If any straight line $R S$ be drawn parallel to $O P$, the projection of $I S$ on either of the straight lines $\mathcal{A}^{\prime} \mathcal{A}, B^{\prime} B$ can be easily secn to bear to $R S$ the same ratios which the corresponding projections of $O P$ bear to $O P$ : thus, if a be the angle which $R S$ makes with $A^{\prime} A$, the projections of $R S$ on $A^{\prime} A, B^{\prime} B$ are $R S$ cos a and $R S$ ain a respectively, where $R S$ denotes the absolute length $R S$. It nust be observed that the line $S R$ is to be considered as parallel not to $O P$ bnt to $O P^{\prime \prime}$, and therefore makes an angle $\pi+\alpha$ with $A^{\prime} A$; this is consistent with the fact that the projections of $S R$ are of opposite sign to those of RS. By observing the signs of the projections of OP for the positions $P, P^{\prime}, P^{\prime \prime}, P^{\prime \prime \prime}$ of $P$ we see that the sine and cosine of the angle $P O A$ are both positive ; the sine of the angle $P^{\prime} O A$ is positive and its cosine is negative ; both the aine snd the cosine of the angle $P^{\prime \prime} O A$ are negative; and the sine of the angle $P^{p \prime \prime} O A$ is negative and its cosine positive. If a be the numerical value of the amallest angle of which $O P$ and $O A$ are bonndaries, we see that, since these straight lines also bound all the angles $2 n \pi+o_{0}$ where $n$ is any positive or negative integer, the aines aud cosines of all these angles are the eame as the sine and cosine of $\alpha$. Hence the sine of any angle $2 n \pi+a$ is positive if $a$ is between 0 and $\pi$ and negative if $a$ is between $\pi$ and $2 \pi$, and the cosine of the same angle is positive if $a$ is between 0 end $\frac{1}{3} \pi$ or $\frac{1}{2} \pi$ and $2 \pi$ and negative if $\alpha$ is between $\frac{z_{3} \pi}{} \pi$ and $\frac{3}{8} \pi$.
In fig. 2 if the angle $P Q A$ is $a$, tho angle $P^{\prime \prime \prime} O A$ is $-\alpha, P^{\prime} O A$ in $\pi-\alpha, P^{\prime \prime} O A$ is $\pi+\alpha, P O B$ is $\frac{\pi}{2}-\alpha$. By obscrring the signs of the projections me see that

$$
\begin{aligned}
& \sin (-a)=-\sin a, \sin (\pi-a)=\sin \alpha, \sin (\pi+a)=-\sin \alpha_{f} \\
& \cos (-\alpha)=\cos \alpha, \cos (\pi-a)=-\cos \alpha, \cos (\pi+\alpha)=-\cos \sigma_{5} \\
& \sin \left(\frac{1}{2} \pi-\alpha\right)=\cos \alpha, \cos \left(\frac{1}{2} \pi-\alpha\right)=\sin \alpha .
\end{aligned}
$$

Also $\sin \left(\frac{3}{3} \pi+a\right)=\sin \left(\pi-\frac{1}{2} \pi-a\right)=\sin \left(\frac{1}{2} \pi-a\right)=\cos c$ $\cos \left(\frac{1}{3} \pi+a\right)=\cos \left(\pi-\frac{\pi}{3} \pi-\alpha\right)=-\cos \left(\frac{1}{2} \pi-a\right)=-\sin \alpha_{0}$
From these equations we hara $\tan (-a)=-\tan a_{1} \tan (\pi-a)=-\tan a_{2}$ $\tan (\pi+a)=-\tan a, \tan \left(\frac{1}{3} \pi-a\right)=\cot \alpha, \tan \left(\frac{1}{2} \pi+a\right)=-\cot \alpha$, with corresponding equstions for the cotangent.
The only angles for which the projection of $O P$ on $B^{\prime} B$ is the amme as for the giver angle POA $(=a)$ are the two sets of anglea bounded by $O P, \circ O A$ and $O P, O A$; these angles aro $2 n \pi+\alpha$ an 1 $2 n \pi+\pi-a$, and are all included in the formula $r \pi+(-1)^{\prime} \alpha_{2}$, where $r$ is any integer; this therefore is the formola for all angles laaring the ame sine as $\alpha$. The only angles which hare the same cosir, as $a$ are those bonnded by $O A, O P$ and $O A, O P^{\prime \prime \prime}$, and thes? sro all included in the formula $2 n \pi \pm$. Similarly it can la showa
that $\pi \pi+\alpha$ includes all the angles which have the same tangent as a.

From the Pythagorean theorem, the sum of the squares of the projections of any straight line upon two straight lines at rifht angles to one another is equal to the square on the projected line, we get $\sin ^{2} \alpha+\cos ^{2} \alpha=1$, and from this by the help of the definitions of the other functions we deduce the relations $1+\tan ^{2} \alpha=\sec ^{2} \alpha$, $I+\cot ^{2} \alpha=\operatorname{cosec}^{2} \alpha$. We have now six relations between the six functions; these enable us to express any five of these functions in terms of the sixth. The following table shows the values of the trigonometrical functions of the angles $9, \frac{1}{3} \pi, \pi, \frac{3}{3} \pi, 2 \pi$, and the signs of the functions of angles between these values; $I$ denotes numerical increase and $D$ numerical decrease.

| Angle | 0 | 0... $\frac{1}{2} 75$ | $\frac{1}{2} \pi$ | $\frac{1}{2} 7 . . .7$ | 7 | W... ${ }^{\text {d }}$ | . 37 | ? $\pi$. . $2 \pi$ | $2 \pi$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\sin \theta$ | 0 | $+I$ | 1 | $+D$ | 0 | -I | -1 | $-1$ | 0 |
| Cosine | 1 | $+D$ | 0 | -1 | -1 | -D | 0 | $+1$ | 1 |
| Tangent | 0 | $+I$ | $\pm \infty$ | - D | 0 | $+I$ | $\pm \infty$ | - D | 0 |
| Cotangent | $\pm \infty$ | $+D$ | 0 | -I | $\pm \infty$ | $+D$ | 0 | -I | $\pm \infty$ |
| Secant |  | $+I$ | $\pm \infty$ | $-D$ | -1 | -I | $\pm \infty$ | $+D$ | : |
| Cosecant | $\pm \infty$ | $+D$ | 1 | $+I$ | $\pm \infty$ | $-D$ | -1 | -I | $\pm \infty$ |

The correctness of the table may be verified from the figure by considering the magnitudes of the projections of $O P$ for different positions.

The following table shows the sine and cosine of some angles for which the valnes of the functions may be obtained geometrically:-

| $\frac{\pi}{12}$ | $15^{\circ}$ | $\frac{\sqrt{6}-\sqrt{2}}{4}$ | $\frac{\operatorname{cosine}}{4}+\sqrt{2}$ | $75^{\circ}$ | $\frac{5}{12} \pi$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\frac{\pi}{10}$ | $75^{\circ}$ | $\frac{\sqrt{5}-1}{4}$ | $\frac{\sqrt{10+2 \sqrt{5}}}{4}$ | $72^{\circ}$ | $\frac{2}{5} \pi$ |
| $\frac{\pi}{6}$ | $30^{\circ}$ | $\frac{1}{2}$ | $\frac{\sqrt{3}}{2}$ | $60^{\circ}$ | $\frac{1}{3} \pi$ |
| $\frac{\pi}{5}$ | $36^{\circ}$ | $\frac{\sqrt{10-2 \sqrt{5}}}{4}$ | $\frac{\sqrt{5}+1}{4}$ | 54 | $\frac{3}{10} \pi$ |
| $\frac{\pi}{4}$ | $45^{\circ}$ | $\frac{1}{\sqrt{2}}$ | $\frac{1}{\sqrt{2}}$ | $45^{\circ}$ | $\frac{1}{4} \pi$ |

These are obtained as follows. (1) $\frac{\pi}{4}$. The sine and cosiue of this angle are equal to one another, $\operatorname{since} \sin \frac{\pi}{4}=\cos \left(\frac{\pi}{2}-\frac{\pi}{4}\right)$; and since the sum of the squares of the sine and cosine is unity each is $\frac{1}{\sqrt{2}}$. (2) $\frac{\pi}{6}$. and $\frac{\pi}{3}$. Consider an equilateral triangle; the projection of one side on another is obviously half a side; hence the cosine of an angle of the triangle is $\frac{1}{2}$ or $\cos \frac{\pi}{3}=\frac{1}{2}$, and from this the sine is found. (3) $\frac{\pi}{10}, \frac{\pi}{5}, \frac{2 \pi}{5}, \frac{3 \pi}{10}$. In the triangle constrmeted in Enc. iv. 10 each angle at the base is $\frac{2 \pi}{5}$, and the vertical angle is $\frac{\pi}{5}$. If $a$ be a side and $b$ the base, we have by the construction $a(a-b)=b^{2}$; hence $2 b=a(\sqrt{5}-1)$; the sine of $\frac{\pi}{10}$ is $\frac{b}{2 a}$ or $\frac{\sqrt{5}-1}{4}$, and $\cos \frac{\pi}{5}$ is $\frac{a}{2 b}=\frac{\sqrt{5}+1}{4}$. (4) $\frac{\pi}{12}, \frac{5 \pi}{12}$. Consider a right-angled triangle, baving an angle $\frac{1}{8} \pi$. Bisect this, angle, then the opposite side is cut by the bisector in the ratio of $\sqrt{3}$ to 2 ; hence the length of the imaller segment is to that of the mhole in the ratio of $\sqrt{3}$ to $\sqrt{3}+2$, therefore $\tan 5^{2} \frac{2}{2} \pi=\frac{\sqrt{3}}{\sqrt{3}+2} \tan \frac{1}{8} \pi$ or $\tan \frac{1}{12} \pi=2-\sqrt{3}$, and from this we can obtain $\sin \frac{1}{12} \pi$ and $\cos \frac{1}{12} \pi$.

Draw a straight line $O D$ making any angle $A$ with a fixed straight
line $O A$, and draw $O F$ making an angle $B$ with o $O D$, this angle being measured positively in the same direction as $A$; draw $F E$ a perpendicular on $D O$ (producel if necessary). The projection of $O F$ on $O A$ is the sum of the projections of $Q E$ and $E F$ on $O A$. Now $O E$ is the projection of $O F$ on $D O$, and is therefore equal to $O F \cos B$,
 and $E F$ is the projection of $O F$ on a straight line making an angle $+\frac{1}{2} \pi$ with $O D$, and is therefore equal to $O F \sin B$; hence
$O F \cos (A+B)=O E \cos A+E F \cos \left(\frac{1}{2} \pi+A\right)$
$=O F(\cos A \cos B-\sin A \sin B)$,
or $\quad \cos (A+B)=\cos A \cos B-\sin A \sin B$.
The angles $A, B$ are absolutely unrestricted in magnitude, and thus this formula is perfectly general. We may change the sign of $B$, thus $\cos (A-B)=\cos A \cos (-B)-\sin A \sin (-B)$,
or $\quad \cos (A-B)=\cos A \cos B+\sin A \sin B$.
If tre projected the sides of the triangle $O E F$ on a straight line raking an angle $+\frac{1}{2} \pi$ with $O A$ we should obtain the formnla
$\sin (A \pm B)=\sin A \cos B \pm \cos A \sin B$,
which are really contained in the cosine formula, since we may put $\frac{1}{2} \pi-B$ for $B$. The formulæ
$\tan (A \pm B)=\frac{\tan A \pm \tan B}{1 \mp \tan A \tan B},-\cot (A \pm B)=\frac{\cot A \cot B \mp 1}{\cot B \pm \cot A}$
sre immediately deducible from the above formulx. The equations $\sin C+\sin D=2 \sin \frac{1}{2}(C+D) \cos \frac{1}{2}(C-D)$,
$\sin C-\sin D=2 \sin \frac{1}{2}(C-D) \cos \frac{\frac{1}{2}}{2}(C+D)$,
$\cos D+\cos C=2 \cos \frac{1}{2}(C+D) \cos \frac{1}{2}(C-D)$,
$\cos D-\cos C=2 \sin \frac{1}{2}(C+D) \sin \frac{1}{2}(C-D)$,
may be obtained directly by the method of projections. Take two equal straight lines $O C, O D$, making angles $C, D$ with $O A$, and draw $O E$ perpendicular to $C D$. The angle which $O E$ makes with $O A$ is $\frac{1}{2}(C+D)$ and that which $D C$ makes is $\frac{1}{2}(\pi+C+D)$; the angle $C O E$ is $\frac{2}{2}(C-D)$. The sum of the projections of $O D$ and $D E$ on $O A$ is equal to that of $O E$, and the sum of the projections of $O D$ and $D E$ is equal to that of $O C$; hence tbe sum of the projections of $O C$ and $O D$ is twice that of $O E$, or $\cos C$ $+\cos D=2 \cos \frac{1}{2}(C+D) \cos \frac{1}{2}(C-D)$. The
 difference of the projections of $O D$ and $O C$ Fis. on $O A$ is equal to that of $E D$, hence we have the formula $\cos D-$ $\cos C=2 \sin \frac{1}{2}(C+D) \sin \frac{1}{2}(C-D)$. The other two formule will bt obtained by projecting on a straight line inclined at an angle $+\frac{1}{2}$ ? to $0 A$.
As another example of the use of projections, we will find the sum Sum of of the series $\cos \alpha+\cos (\alpha+\beta)+\cos (\alpha+2 \beta)+\ldots+\cos (\alpha+n-1 \beta)$. series of Suppose an unclosed polygon each sagle of whicl is $\pi-\beta$ to be in- cosines scribed in a circle, and let $A_{1}, A_{2}, A_{3}, \ldots, A_{n}$ be $n+1$ consecutive in arith angular points ; let $D$ be the diameter of the circle ; and suppose a metical straight line drawn making an angle $\alpha$ with $A A_{1}$, then $\alpha+\beta$, progrea $\alpha+2 \beta, \ldots$ are the angles it makes with $A_{1} A_{2}, A_{2} A_{3}, \ldots$; we have by sion. projections
$A A_{n} \cos \left(\alpha+\frac{\overline{n-1} \beta}{2}\right)=A A_{1}(\cos \alpha+\cos \alpha+\beta+\ldots+\cos \alpha+\overline{n-1} 8)$
also

$$
A A_{1}=D \sin \frac{\beta}{2} \quad A A_{n}=D \sin \frac{n \beta}{2}
$$

nence the sum of the series of $\operatorname{cosines}$ is $\cos \left(\alpha+\frac{\overline{n-1} \beta}{2}\right) \sin \frac{n \beta}{2} \operatorname{cosec} \frac{\beta}{2}$
By a double application or the addition formule we may obtain the Formad formulæ

$$
\begin{aligned}
\sin \left(A_{1}+A_{2}+A_{3}\right)= & \sin A_{1} \cos A_{2} \cos A_{3}+\cos A_{1} \sin A_{2} \cos A_{1} \\
& +\cos A_{1} \cos A_{2} \sin A_{3}-\sin A_{1} \sin A_{2} \sin A_{3} ; \\
\cos \left(A_{2}\right. & \left.+A_{2}+A_{3}\right)=\cos A_{1} \cos A_{2} \cos A_{3}-\cos A_{1} \sin A_{2} \sin A_{3}
\end{aligned}
$$ $-\sin A_{1} \cos A_{2} \sin A_{3}-\sin A_{2} \sin A_{2} \cos A_{3} \quad$,

We can by induction oxtend these formula to the case of $n$ angles
Assume $\sin \left(A_{1}+A_{2}+\ldots+A_{n}\right)=S_{1}-S_{3}+S_{5}-\ldots$ $\cos \left(A_{1}+A_{2}^{2}+\ldots+A_{n}\right)=S_{0}^{-}-S_{2}+S_{4}-\ldots$
Where $S_{r}$ denotes the sum of the products of the sines of $r$ of the angles and the cosines of the remsining $n-r$ angles; then we have

$$
\begin{aligned}
\sin \left(A_{1}+A_{2}+\ldots+A_{n}+A_{n+1}\right) & =\cos A_{n+1}\left(S_{1}-S_{3}+S_{5}-\ldots\right) \\
& +\sin A_{n+1}\left(S_{n}-S_{2}+S_{4}-\ldots\right)
\end{aligned}
$$

The right-hand side of this equation may be written
$\left(S_{1} \cos A_{n+1}+S_{0} \sin A_{n+1}\right)-\left(S_{3} \cos A_{n+1}+S_{2} \sin A_{n+1}\right)+\ldots \cdot$
or

$$
S_{1}-S_{3}^{\prime}+\ldots
$$

where $S_{r}$ denotes the quantity which corresponds for $n+1$ sugle to $S_{r}$ for $n$ angles; similarly we may procecd with the cosime for mula. The theorems are true for $n=2$ and $n=3$; thos they are $\tan \pi A$
true generally. The formnla
$\cos 2 A=\cos ^{2} A-\sin ^{2} A=2 \cos ^{2} A-1=1-2 \sin ^{2} A$,
$\sin 2 A=2 \sin A \cos A, \quad \tan 2 A=\frac{2 \tan A}{1-\tan ^{2} A}$,
$\sin 3 A=3 \sin A-4 \sin ^{9} A, \quad \cos 3 A=4 \cos ^{3} A-3 \cos A$,
$\sin n A=n \cos ^{n-1} 4 \sin A-\frac{n(n-1)(n-2)}{\mid 3} \cos ^{n-3} A \sin ^{3} A+\cdots$

$$
\begin{gathered}
\pm(-1)^{r n(n-1) \ldots(n-2 r)} \\
\cos n A \equiv \cos n A-\frac{n(n-1)}{\frac{12}{2 r+1}} \cos ^{n-2 r-1} A \sin ^{2 r+1} A \\
+\left(-1 \sin ^{2} A+\ldots\right. \\
\frac{n(n-1) \ldots(n-2 r+1)}{\mid 2 r} \\
\cos ^{n-2 r} A \sin ^{2 r} A+\cdots
\end{gathered}
$$

may all be deduced from the addition formulx by making कise angles all equal. From the last two formula we obtain by division
$n \tan A-\frac{n(n-1)(n-2)}{18} \tan ^{5} A+\ldots+(-1)^{r} \frac{n(n-1) \ldots(n-2 \cdot)}{12 r+1} \tan ^{2 r+1} A^{\prime}+$.
$=\frac{\left.1-\frac{n(n-1)}{12} \tan ^{2} A+\ldots+(-1)^{r^{n}(n-1) \ldots(n-2 r}+1\right)}{\tan ^{2} r i t \ldots}$
In the particular case of $n=3$ we have $\tan 3 A=\frac{3 \tan A-\tan ^{3} A}{1-3 \tan ^{2} A}$

The ralues of $\sin \frac{1}{2} A, \cos \frac{1}{2} A, \tan \frac{1}{2} A$ are given in terms of $\cos A$ by the formulx

$$
\begin{aligned}
& \sin \frac{1}{2} A=\left(-1^{\prime n}\left(\frac{1-\cos A}{2}\right)^{\frac{1}{2}}, \cos \frac{1}{2} A=(-1)^{9}\left(\frac{1+\cos A}{2}\right)^{\frac{3}{2}},\right. \\
& \tan \frac{1}{2} A=(-1)^{r}\left(\frac{1-\cos A}{1+\cos A}\right)^{\frac{1}{2}},
\end{aligned}
$$

where $p$ is the integrat part of $\frac{A}{2 \pi}, q$ the integral part of $\frac{A}{2 \pi}+\frac{1}{2}$, and $\cdot$ the integral pert of $\frac{A}{\pi}$.
$\sin \frac{3}{2} A, \cos \frac{1}{2} A$ are given int terms of sinl $\alpha$ by the formuleo $2 \sin \frac{1}{2} A=(-1)^{p^{\prime}}(1+\sin A)^{\frac{3}{2}}+(-1)^{q^{\prime}}(1-\sin A)^{\frac{1}{2}}$,
$2 \cos \frac{1}{2} A=(-1)^{P^{\prime}} \cdot(1+\sin A)^{\frac{1}{2}}-(-1)^{Q^{\prime}}(1-\sin A)^{\frac{1}{2}}$,
where $p^{\prime}$ is the integral part of $\frac{A}{2 \pi}+\frac{1}{4}$ and $q^{\prime}$ the integral part of $\frac{A}{2 \pi}-\frac{1}{4}$
In any plnue triangle $A B C$ wo will denote tho lengths of the sides $B C, C A, A B$ by $a, b, c$ respectively, and the angles $B A C$, $A B C, A C B$ by $A . B, C$ respectively. The fact that the projections of $b$ and $c$ ou a straight line perpendicular to the side $a$ are equel to one anotleer is expressed by the equation $b \sin C=c \sin B$; this equation and tlie one obtained by projecting $c$ and $a$ on a straight line perpendicular to a may be writton $\frac{a}{\sin A}=\frac{b}{\sin B}=\frac{c}{\sin C}$. The equation $a=b \cos C^{\prime}+c \cos B$ expresses the fact that the side $a$ is equel to the aum of the projections of the sides $o$ and $c$ on itself; thue we obtain the equations

$$
\left.\begin{array}{l}
a=b \cos C+c \cos B \\
b=c \cos A+a \cos C \\
c=a \cos B+b \cos A
\end{array}\right\} .
$$

If we multiply the first of these equations by $-a$, the second by b. and the third by c, aud add the resulting equetinus, we ohtain the formola $b^{2}+c^{2}-a^{2}=2 b c \cos A$ or $\cos A=\frac{b^{2}+c^{2}-a^{2}}{2 b c}$, which gives the cosine of an angle in terms of the sides. Fro:n this oxpression for cos $A$ the formule $\sin \frac{7}{2} A=\left\{\frac{(s-b)(s-c)}{b c}\right\}^{\frac{1}{2}}, \cos \frac{1}{2} A=\left\{\frac{s^{i}(s-a)}{b c}\right\}^{\frac{2}{2}}$, $\left.\tan \frac{1}{2} A=\left\{\frac{(s-b)(s-c)}{s(s-a j}\right\}^{\frac{3}{3}}, \sin A=\frac{2}{b c}\{s(s-a)(s-b): s-c)\right\}$, whero s dedotes $\frac{1}{2}(a+b+c)$, can lie deduced hy means of the dimidiary formnla.
From any general relation between the sides and angles of a triengle other relations may he leduced by verions methods of transformation, of which we give two examplea.
(a) Io ody general relation between tho sines and cosines of the engles $A, B, C$ of a triangle we may onbatitute $p A+q B+r C$, $r A+p B+q C, q A+r B+p C$ for $A, B, C$ respectively, where $p, q, s$ are any quantities ench that $p+q+r+1$ is a poaitive or uegs. tive multiple of 6 , provided that we change the aigns of all the sides. Suppose $p+q+r+1=6 \pi$, then the sum of the thrse angles $2 n \pi-(p A+q B+r C), 2 n \pi-(r A+p B+q C), 2 n \pi-(q A+r B+p C)$ is $r$; and, since the given relatiou followe from the condition $A+B$ $+C=\pi$, wo may sulustitnto for $A, \mathcal{D}, C$ respectively any angles of which the sum is $\pi$; thate the trausformation is admissible.
( $\beta$ ) It may easily he ghown that the sides end angles of the triangle formed by joining the feet of the perpendicnlars from tha angular points $A, B, C$ on the opposite sides of the triangle $A B C$ are respectively $a \cos A, b \cos B, c \cos \mathrm{C}, \pi-2 A, \pi-2 B, \pi-2 C$; we may therefore sulustitute these expressions for $a, b, c, A, B, C$ respectively in any general formula By drawing the perpendiculars of this second triangle and joining their feet as hefore, we olstair a triengle of which tie sides are $-a \cos A \cos 2 A,-b \cos B \cos 2 B$, $-c \cos C \cos 2 C$ and the angles are $4-\pi, 4 B-\pi, 4 O-\pi$; we may therefore substitute these oxpressiona for tha sides and angles of the original triangle; for example, we ohtain thus the formula

$$
\cos 4 A=\frac{a^{2} \cos ^{3} A \cos ^{2} 2 . A-b^{2} \cos ^{2} B \cos ^{2} 2 B-c^{2} \cos ^{2} C \cos ^{2} 2 C}{2 b c \cos B \cos C \cos 2 B \cos 2 C}
$$

This transformation ohrionsly admits of further extension.
(1) Tho three sides of e triangle $A B C$ being given, the angles can be letermined by the formula
$I_{s} \tan \frac{A}{2}=10+\frac{1}{2} \log (s-b)+\frac{1}{2} \log (s-c)-\frac{1}{2} \log s-\frac{1}{2} \log \left(s-a_{1}\right.$ and two corresponding fonnulæ for the other angles.
(2) The tro sides $a, b$ and the iacladed angla $C$ being given, the engles $A, B$ can ba determiaed from the formules

$$
\begin{aligned}
A+B & =\pi-C, \\
L \tan \frac{1}{2}(A-B) & =\log (a-b)-\log (a+b)+L \cot \frac{3}{2} C,
\end{aligned}
$$

and the side $c$ is then obtaioed from tha formula
$\log \mathrm{c}=\log a+L \sin C-L \sin A$.
(3) The two sides $a, b$ and the angle $A$ being given, the value of sin $B$ mav be found by means of the formula

$$
L \sin B=L \sin A+\log b-\log a
$$

this gives two supplementary values of the anglo $B$, if $b \sin A<a$. If $b \sin A>a$ there is no solution, and if $b \sin A=a$ there is one solution. In the case $b \sin A<a$, both values of $B$ give eolutions provided $b>a$, but the acnte value onl $y$ of $B$ is edmissible if $b<a$.

The other side $c$ can the be determined as in case (2).
(1) If two engles $A, B$ end a sids a are given, the engle $C$ is de. termined from the formule $C=\pi-A-B$ and the sido $b$ from the formula $\log b=\log a+L \sin B-L \sin A$.
Tie area of a triaggle is half the product of a side into the perpendicular from vhe opposite angle on that sida; thna we ohtain the expressions $\frac{3}{2} b \sin A,\{s(s-a)(s-b)(s-c)\}^{\frac{2}{2}}$ for the ares of a tringle. A large collection of formule for the area of a triangle are given in the Anvals of Mathematics for 1885 by M. Baker.
Let $a, b, c, d$ denote the leagths of the sides $A B, B C, C D, D A$ respectively of any plane quedrilateral and $A+C=2 \alpha$; we may obtain an expression for the area $S$ of tho quadrilateral in terme of the sides and the erigle $a$.
W9 havo $\quad 2 S=a d$ in $A+b \dot{e} \sin (2 a-A)$ and $\quad \frac{1}{2}\left(a^{2}+d^{2}-b^{2}-c^{2}\right)=a d \cos A-b c \cos (2 a-A)$; bence $\quad 4 S^{2}+1\left(a^{2}+d^{2}-b^{2}-c^{2}\right)^{2}=a^{2} d^{2}+b^{2} c^{2}-2 a b c d \cos 2 a$. If $2 s=a+b+b+d$, the valne of $S$ may be rritten in the form $\left.S=\{s \cdot s-a)(s-b)(s-c)(s-d)-a b c d \cos ^{2} a\right\}^{\frac{1}{2}}$.
Let $R$ denote the radius of the ciscumscribed circle, $r$ of tho io. Radii of ecribed, and $r_{2}, r_{2 r},{ }^{\prime}$, of the escribed circles of a triaggle $A B C$; the circamvalues of these radii are given by the following formnlæ. scribed,

$$
\begin{aligned}
& R=\frac{a b c}{4 S^{\prime}}=\frac{a}{2 \sin A^{\prime}} \\
& r=\frac{S}{3}=(s-a) \tan \frac{1}{3} A=4 R \sin \frac{1}{2} A \sin \frac{1}{2} B \sin \frac{1}{2} C, \\
& r_{2}=\frac{S}{s-a}=3 \tan \frac{1}{2} A=4 R \sin \frac{1}{3} A \cos \frac{\pi}{3} B \cos \frac{1}{2} C
\end{aligned}
$$

## Sulurical Trigonometry

We shall thecughout assume each eiementary propositione in 8pherical geometry as are required for the parbose of the investiga tion of forafulm given below.

A epherical triangls is tha portion of the sarface of a sphere Defin:bounded by three ares of great circles of the sphess. If $B C, C A$, tion of $A B$ denote these arcs, the circular messare of ths erglas suhtended apherice by thesa arce respectively at the centre of tho sphere are the sides triengle $a, b, c$ of the spherical triangls $A B C$; and, if sha portione of plases passing throngh thesa arcs and the centee of the ephere be drann, the angles hetreen tha portinos of planes intersecting at $A, B, C$ respectively ere the anglos $A, B, C$ of the spherical triangle. It is not necessary to consider trianglos in whici a side is greater than $\boldsymbol{v}_{\text {, }}$ since we may replace snch a side by the remairing arc of the great circle to which it belongs Since two great circles interaect eerh other in two points, there are cight trianglea of which the sides are arce of the eaine three great circles. If we consider one of these triangles $A B C$ as the fundemental one, then one of the othert is equal in all respects to $A B C$, and the remaining six lave each one side equal to, or common mith, a side of tis triangle $A B C$, the opposite anglo equal to the correspoding angle of $A B C$, and tho other sides and angles supplementary to the corresponding sides end angles of $A B C$. These triangles may he called the sssociated triangles of the fundamental one $-\{B C$. It follows that from any general formula containing the sides and angles of a spheical triangle we may obtain othar formula by replacing two eides and the two engles opposite to them by their supplements, the remaining side and the remaining engle being unaltered, for such formulm are ohtained by applying the given formnle to the associated triangles.

If $A^{\prime}, B^{\prime}, C^{\prime}$ are those poles of the arce $B C, C A, A B$ respectively which lic npon the same sides of them as the opposite angles $A, B, C$, then the triangle $A^{\prime \prime} D^{\prime} C^{\prime}$ is called the polar triangla of the trianglo $A B C$. The sides of the polar triangla ara $\pi-A, \pi-B, \pi-C$, and the angles $\pi-a, z-b, \pi-c$. Hence from any general formula connecting the sides and angles of a spherical triangle we mas obtain another formula by changing each sida in to the supplement of the opposite angle a ad each angle into the supplement of the op. posite side.

Let $O$ be the centre of the sphere on which is the epherical triangle $A B C$. Draw $A L$ perpendicular to $O C$ a ad $A B$ perpaodicular to
the plene $O B C$. Then the projection of $O A$ on $O B$ is the sum of the projections of $O \Sigma$, $L M, M A$ on the samestraight line. Since $A M$

$\mathrm{F}_{16} 5$.
has mo projection on any straight line in the piane OBC, this gives O. A cos $c=O L \cos a+L I I \sin a$.

Nav $O L=O A \cos b, L A=A L \cos C=O A \sin b \cos C$;
therefore $\quad \cos c=\cos a \cos b+\sin a \sin b \cos C$.
We may obtan similar formula by interclanging the letters $a, b, a$
thus
$\cos a=\cos b \cos c+\sin b \sin c \cos A$ $\cos \delta=\cos c \cos a+\sin c \sin a \cos B$ $\qquad$
$\cos c=\cos a \cos b+\sin a \sin b \cos C$ )

These formulæ (1) may be regarded as the fundamental equations connecting the sides and angles of a spherical triangle; all the other relations which we shall give below nuny be deduced analytically from them; we shsll, however, in most cases give independent proofs. By using the polar triangle transformation we have the formule $\cos A=-\cos B \cos C+\sin B \sin C \cos \alpha)$ $\cos B=-\cos C \cos A+\sin C \sin A \cos b$ $\cos C=-\cos A \cos B+\sin A \sin B \cos c)$
In the figure we have $A M=A L \sin C=r \sin b \sin C$, where $r$ denotes the radins of the sphere. By drawing a perpendicnlar from $A$ on $O B$, we may in a similar manner show that $A M=r \sin c \sin B$, therefore $\quad \sin B \sin c=\sin C \sin b$.
By interchanging the sides wo have the equation

$$
\frac{\sin A}{\sin a}=\frac{\sin B}{\sin b}=\frac{\sin C}{\sin c}=k
$$

we shall find below a symmetrical form for $k$.
If we climinate $\cos b$ hetween the first two formale of (1) we have $\cos c \sin ^{2} \varepsilon=\sin b \sin c \cos A+\sin c \cos c \operatorname{sia} a \cos B ;$
therefore $\cot a \sin c=\frac{\sin b}{\sin a} \cos A+\cos c \cos B$

$$
=\sin B \cot A+\cos c \cos B
$$

We thas have the six equstions
$\cot a \sin b=\cot A \sin C+\cos b \cos C$
$\cot b \sin a=\cot B \sin C+\cos a \cos C$ $\cot b \sin c=\cot B \sin A+\cos c \cos A$ $\cot c \sin b=\cot C \sin A+\cos b \cos A$
$\cot c \sin a=\cot C \sin B+\cos a \cos B$
$\cot a \sin c=\cot A \sin B+\cos c \cos B$ )
When $C=\frac{\pi}{2}$ formula (1) gives $\cos c=\cos a \cos b$.
and (3) givcs $\quad \sin b=\sin B \sin c$ ( $\beta$ ) ;
from (3) we gat $\quad \tan a=\tan A \sin b=\tan c \cos B$
The formnlæ
$\tan b=\tan B \sin a=\tan c \cos A$ and $\cos c=\cot A \cot B$ $\cos B=\cos b \sin A$
follow at once from $(a),(\beta),(\gamma)$. These are the formulae which are ased for the solntion of right-angled triangles. Napier gave mnemonical rules for remembering them.

The following proposition follows easily from the theorem in equation (3):-lf $A D, B E, C F$ are three arcs drawn throngh $A, B, C$ to meet the opposite sides in $D, E, F$ respectively, and if these arcs pass through a poiut, the segments of the sides satisiy the relation $\sin B D \sin C E \sin A F=\sin C D \sin A E \sin B F$; and conversely if this relation is satisfied the sres pass through a point. From this theorem it follows that the three perpendiculare from the angles on the opposite sides, the three bisectors of the angles, aud the three arcs from the angles to the middle points of the oppesite sides, each pass through a paint.
Pormnles If $D$ be the point of intersection of the three or sine bisectors of the angles $A, B, C$, and if $D E$ be und co- ilrawn perpendicular to $B C$, it may be shown tue $\cap \mathrm{f}$ that $B E=\frac{1}{2}(a+c-b)$ and $C E=\frac{1}{3}(a+b-c)$,

Fig. 8. salf sud that the angles $B D E, A D C$ are supplementary. We have encles:

Hence the quantity $k$ in ( 3 ) is
$\frac{1}{\sin a \sin b \sin c}\left\{1-\cos ^{3} a-\cos ^{2} b-\cos ^{2} c+2 \cos a \cos b \cos c\right\}^{\frac{1}{2}}(8)$.
Apply the poler triangle transformstion to the formule (5), (6), of he (7), (8) snd we obtain

$$
\begin{align*}
& \cos _{\frac{a}{2}}^{a}=\left\{\frac{\left.\left.\cos \frac{A+C-B}{2} \cos \frac{A+B-C}{2}\right)^{\frac{1}{2} B \sin C}\right\}^{\prime} \cdots}{} \begin{array}{l}
\sin \frac{a}{2}=\left\{\frac{-\cos \frac{B+C-A}{2} \cos \frac{A+B+C}{2}}{\sin B \sin C}\right\}^{\frac{1}{2}} . \\
\operatorname{tsn} \frac{a}{2}=\left\{\frac{-\cos B+C-A}{2} \cos \frac{A+B+C}{2}\right. \\
\cos \frac{A+C-B}{2} \cos \frac{A+B-C}{2}
\end{array}\right\} . \tag{9}
\end{align*}
$$

If $k^{\prime}=\frac{1}{\sin A \sin B \sin C^{1}}\left\{\cos ^{2} A-\cos ^{2} B-\cos ^{2} C-2 \cos A \cos B \cos C\right\}^{\frac{1}{2}}$, we have $k k^{\prime}=1$
Let $E$ be the middle point of $A B$; drav $E D$ at right angles to De$A B$ to meet $A C$ in $D$; then $D E$ bisects the angle $A D B$. Let $C F$ bisect the angle $D C B$ and draw $F^{\prime} G$ perpendiculer to $B C$, thea

$$
\begin{gathered}
C G=\frac{a-b}{2}, \angle F B E=\frac{A+B}{2}, \\
\angle F C G=90^{\circ}-\frac{C}{2}
\end{gathered}
$$

From the triangle CFO we hare cos $C F G$ $=\cos C \alpha \sin F C C O$, and from the triangle $F E B \cos E F B=\cos E B \sin F B E$. Now

the angles $C F G, E F B$ sre each supplementary to the angle $D F B$, therefore

$$
\cos \frac{a-b}{2} \cos \frac{C}{2}=\sin \frac{A+B}{2} \cos \frac{c}{2}
$$

## Also $\sin C G=\sin C F \sin C F O$ and $\sin E B=\sin B F \sin E F B$;

therefore

$$
\sin \frac{a-b}{2} \cos \frac{C}{2}=\sin \frac{A-B}{2} \sin \frac{c}{2} .
$$

Apply the formulw (13), (14) to the assaciated triangle of which $a, \pi-b, \pi-c, A, \pi-B, \pi-C$ are the sides and sngles, we then have

$$
\begin{align*}
& \sin \frac{a+b}{2} \sin \frac{C}{2}=\cos \frac{A-B}{2} \sin \frac{c}{2} .  \tag{15}\\
& \cos \frac{a+b}{2} \sin \frac{C}{2}=\cos \frac{A+B}{2} \cos \frac{c}{2} . \tag{16}
\end{align*}
$$

The four formule (13), (14), (15), (16) were first given by Delsmbre in the Connaissance des Temps for 1808. Formulx equivalent to these were given by Mollweide in Zaclı's Monalliche Correspondens for November 1808. They were slso given by Gauss (Thcoria notus, 1809), and are usually called after him.

From the ame figure we hare

$$
\tan F G=\tan F C G \sin C G=\tan F D G \sin P G ;
$$

Napier
therefore

$$
\begin{align*}
\cot \frac{C}{2} \sin \frac{a-b}{2} & =\tan \frac{A-B}{2} \sin \frac{a+b}{2}, \\
\tan \frac{A-B}{2} & =\frac{\sin \frac{a-b}{2}}{\sin \frac{a+b}{2}} \cot \frac{C}{2} \ldots \ldots
\end{align*}
$$

Apply this formula to the associated triangle ( $\pi-a, b, \pi-c, \pi-A$, $B, \pi-C$, and we have

$$
\begin{align*}
& \cot \frac{A+B}{2}=\frac{\cos \frac{a+b}{2}}{\cos \frac{a-b}{2}} \tan \frac{C}{2}, \\
& \tan \frac{A+B}{2}=\frac{\cos \frac{a-b}{2}}{\cos \frac{a-b}{2}} \cot \frac{C}{2} . \tag{18}
\end{align*}
$$

or
If we spply these formuln (17), (18) to the polar triangle, we hsvi

$$
\begin{align*}
& \tan \frac{a-b}{2}=\frac{\sin \frac{A-B}{2}}{\sin \frac{A+B}{2}} \tan \frac{c}{2}  \tag{19}\\
& \tan \frac{a+b}{2}=\frac{\cos \frac{A-B}{2}}{\cos \frac{A+B}{2}} \tan \frac{c}{2} \tag{20}
\end{align*}
$$

The farmulæ (17), (18), (19), (20) are called Napier's "Analogies" they were given in the Mirif. logar. canonis descriptio.

If tre use the ralues of $\sin \frac{a}{2}, \sin \frac{b}{2}, \sin \frac{c}{2}, \cos \frac{a}{2}, \cos \frac{b}{2}, \cos \frac{c}{2}$ giren by (9), (10) and the saslogons formulre obtsined by interchanging the letters, we obtaiu by multiplicstion

$$
\left.\begin{array}{l}
\sin \frac{\pi}{2} \cos \frac{b}{2} \sin C=\sin \frac{c}{2} \cos \frac{B+C-A}{2} \\
\cos _{2}^{a} \cos _{2}^{b} \sin C=\cos { }_{2}^{c} \cos ^{A+B-C} \\
\sin _{2}^{a} \sin \frac{b}{2} \sin C=\cos \frac{c}{2} \cos \frac{A+B+C}{2}
\end{array}\right\}
$$

These formulæ were giveu by Schnteisser in Crelle's Joumı., vol. х.
The relstion $\sin b \sin c+\cos b \cos c \cos A=\sin B \sin C-\cos B \cos C \cos a$ was given by Cagnoli in his Trigonometry (1786), and was redis. covered by Csyley (Plil. Mag., 1859). It follows from (1), (2), sad (3) thus: the right-hsod side of the equation equals siu $B$ sin $C$ $+\cos a(\cos -A-\sin B \sin C \cos a)=\sin B \sin C \sin ^{2} a+\cos a \cos A, 8$ nd this is equsi to $\sin b \sin c+\cos A(\cos a-\sin b \sin c \cos A)$ or $\sin b \sin c+$ $\operatorname{cus} b \cos c \cos A$.
The formulæ we have giren are sufficient to determine three parts of a triangle when the other three parts are given: moreover such formulem msy always be chosen as are sdapted to logarithmic calculation. The solutions will be unique except in the two csses (1) where two sides and the sigle opposite one of them sre the giveu parts, and (2) where two sagles and the eide opposite one of them sre giveu.

Surpose $a, b, A$ are the giren parts. We determine $B$ from the formuls $\sin B=\frac{\sin h}{\sin \pi} \sin A$; this gires two supplementary values of $B$, one acnte and the other obtuse. Then $C$ and care determined from tho equations $\tan \frac{C}{2}=\frac{\sin \frac{a-b}{2}}{\sin \frac{a+b}{2}} \cot \frac{A-B}{2}, \tan \frac{c}{2}=\frac{\sin \frac{A+B}{2}}{\sin \frac{A-B}{2}} \tan \frac{a-b}{2}$.
Now $\tan \frac{C}{2}, \tan \frac{c}{2}$ must both be positire; heace $A-B$ and $a-b$ must have the same sign. We shsll distinguish three cases. First, supjose $\sin b<\sin a$; then we hive $\sin B<\sin A$. Hence $A$ lies botween the two values of $B$, and therefore only one of these values is admissible, the acuto or the obtuse value according as $a$ is greater or less than $b$; there is therefore in this case always one solution. Secondly, if sin $b>\sin \pi$, there is no solution wheu $\sin b \sin A>\sin a$; but if $\sin b \sin A<\sin a$ there are two ralues of $B$ both grester or both Jess thau $A$. If $a$ is acute, $a-b$, sud therefore $A-B$, is negative; hence theresre two solutions if $A$ is acute and none if $A$ is obtuse. These two solutions fall together if $\sin b \sin A=\sin a$. If $a$ is obtuse there is no solution unless $A$ is obtuse, sod in that case there are two, which coincide ss before if $\sin b \sin A=\sin a$. Hence in this case there are two solutions if $\sin b \sin A \leqq \sin a$ and the two jarts $A, a$ sre both acute or both obtuse, these being coincilent in case $\sin b \sin A \equiv \sin a ;$ and there is no solution if one of the two $A, a$ is acuto sind the other obtuse, or if $\sin b \sin A>\sin a$. Thirdly, if $\sin b=\sin a$ thed $B=A$ or $\pi-A$. If $a$ is scute, $a-b$ is zero or negatire, bence $A-B$ is zero or negative; thns there is no solution unless $A$ is scate, snd then there is one. Similarly, if $a$ is obtuse, $A$ must be so too in order that there may be a solution. If $a=b=\frac{\pi}{2}$, theie is no solution unless $A=\frac{\pi}{2}$, and theu there are an infinite number of solutions. bince the ralues of $C$ and $a$ become indeterminste.
The other case of s mbiguity mey be discussed in a similar manner, or the different cases nswode deduced from the sbove by the use of the polar triangle transformation. The method of classification sccording to the three cases sin $l=\sin a$ wes given by Professor Lloyd Tinner (Messenger of Math., Vol. xiv.).

If $r$ is the angular radius of the emall circle inscribed iu the triangle ${ }^{* *} A B C$, we heve at ouce $\tan r=\tan \frac{A}{2} \sin (s-a)$, where $2 s=a+b+c$; from this we can derive the formales $\tan r=n \operatorname{cosec} s=\frac{N}{2} \sec \frac{A}{2} \sec \frac{B}{2} \sec \frac{C}{2}=\sin a \sin \frac{B}{2} \sin \frac{C}{2} \sec \frac{A}{8}(21)$, where $n, N$ denote the expressions

$$
\left.\left.\{\sin s \sin (s-a) \sin (s-b) \sin (s-c)\}^{\frac{1}{3}}, C\right)\right\}
$$

The escribed circles are the smsll circles inscribed in three of the associsted trisagles; thus, spplying the above formula to the triangle $(a, \pi-b, \pi-c, A, \pi-B, \pi-C)$, we hare for $r_{1}$, the radius of the escribed circle opposite to the sagla $A$, the following formule
$\tan r_{1}=\tan \frac{A}{2} \sin s=n \operatorname{cosec}(s-\alpha)=\frac{1}{2} \sec \frac{A}{2} \operatorname{cosec} \frac{B}{2} \operatorname{cosec} \frac{C}{2}$

$$
\begin{equation*}
=\sin a \cos \frac{F}{2} \cos \frac{C}{2} \sec { }_{2}^{A} \tag{22}
\end{equation*}
$$

The pole of the circle circumsnribing a triangle ls that of tha circle inscribed in the polar triangle, sud the radii of the twi circles sre complementary; beace, if $I$ be the radius of the circum. scribed circle of the trisngle, snd $R_{1}, l_{2} R_{3}$ tle vadii of the circla circumscribing the associsted trisagles, we bare by writiug $\frac{\pi}{2}$,
for $r, \frac{\pi}{2}-R_{\downarrow}$ for $r_{2}, \pi-a$ for $A$, \&c., in the sbore formulm
$\cot I=\cot \frac{a}{2} \cos (S-A)={ }_{2}^{n} \operatorname{cosec} \frac{a}{2} \operatorname{cosec}{ }_{2}^{b} \operatorname{cosec}{ }_{2}^{c}=-N \sec S$

$$
=\sin A \cos _{2}^{b} \cos _{2}^{c} \operatorname{coscc} \frac{a}{2} \cdots \cdots \quad \text { (2S) }
$$

$$
\begin{equation*}
=\sin A \sin _{2}^{b} \sin _{2}^{c} \operatorname{cosec} \frac{a}{2} . \tag{21}
\end{equation*}
$$

The following relstions follow from the formula just given:$2 \tan R=\cot r_{1}+\cot r_{2}+\cot r_{3}-\cot r_{1}$,
$2 \tan n_{1}=\cot r+\cot r_{2}+\cot r_{3}-\cot r_{1}$,
taur tan $r_{1}$ taur $r_{2}$ tan $r_{3}=n^{2}, \sin ^{2} s=\cot r \tan r_{3}$ tan $r_{2}$ tau $r_{3}$ $\sin ^{2}(s-a)=\tan r \cot r_{2} \tan r_{2} \tan r_{3}$.
If $E=A+B+C-\pi$, it may be shown that $E$ multiplied by the Eorm wip square of the rsulius is the ares of the triangle. Wre give some of for the inore important expressions for the quantity $\mathcal{E}$, which is called spher the eplierics excess.
We lizve $\frac{\cos \frac{A+B}{2}}{\sin \frac{6}{2}}=\frac{\cos \frac{a+b}{2}}{\cos \frac{6}{2}}$ and $\frac{\sin \frac{A-B}{2}}{\cos \frac{6}{2}}=\frac{\cos \frac{a-b}{2}}{\cos \frac{c}{2}}$,
or

$$
\frac{\sin \left(\frac{C}{2}-\frac{E}{2}\right)}{\sin \frac{6}{2}}=\frac{\cos \frac{a+b}{2}}{\cos \frac{2}{c}} \text { and } \frac{\cos \left(\frac{C}{2}-\frac{B}{2}\right)}{\cos \frac{C}{2}}=\frac{\cos \frac{a-b}{2}}{\cos ^{c} 2}
$$

heare
therefore

$$
\frac{\sin \frac{C}{2}-\sin \left(\frac{C-E}{2}\right)}{\sin \frac{C}{2}+\sin \left(\frac{C-E}{2}\right)}=\frac{\cos \frac{C}{2}-\cos \frac{a+b}{2}}{\cos \frac{c}{2}+\cos \frac{a+b}{2}}
$$

$$
\frac{\tan \frac{E}{4}}{\tan ^{2} \frac{C-E}{4}}=\tan 2_{2}^{s} \tan \frac{s-c}{2}
$$

Similarly

$$
\begin{equation*}
\tan \frac{E}{2} \tan \frac{C^{2}-E}{4}=\tan \frac{s-\theta}{2}-\tan \frac{s-b}{2} \tag{25}
\end{equation*}
$$

therefore $\tan \frac{E}{i}=\left\{\tan _{2}^{s} \tan \frac{s-a}{2} \tan \frac{s-b}{2} \tan \frac{s-c}{2}\right\}^{\frac{1}{2}}$.
This formula was given by L'Euillier.
Also

$$
\begin{aligned}
& \sin \frac{C}{2} \cos \frac{E}{2}-\cos \frac{C}{2} \sin \frac{E}{2}=\frac{\cos \frac{\prime+b}{2}}{\cos \frac{6}{2}} \sin \frac{C}{2} ; \\
& \cos \frac{C}{2} \cos \frac{E}{2}+\sin C_{2}^{\prime} \sin \frac{E}{2}=\frac{\cos \frac{a-b}{2}}{\cos \frac{6}{2}} \cos \frac{C}{2} ;
\end{aligned}
$$

whence, solving for $\cos \frac{E}{2}$, we get

$$
\begin{equation*}
\cos \frac{E}{2}=\frac{1+\cos a+\cos b+\cos c}{4 \cos \frac{a}{2} \cos \frac{b}{2} \cos \frac{c}{2}} \tag{26}
\end{equation*}
$$

This formula was given by Euler (Nova actir, vol. x.). If we find $\sin \frac{E}{2}$ from this formuls, wo obtain after reductiou

$$
\sin \frac{E}{2}=\frac{n}{2 \cos \frac{a}{2} \cos \frac{b}{2} \cos \frac{2}{2}} \text {, }
$$

a formule given by Lescell (Acte Petrop., 1782).
Froin the cquations (21), (22), (23), (24) we oblain the following formula for the sphericsl excess:-
$\sin ^{2} \frac{E}{2}=\tan R \cot R_{1} \cot R_{8} \cot R_{3}$

$$
=\frac{4\left(\cot r_{1}+\cot r_{8}+\cot r_{8}\right)}{\left(\cot r-\cot r_{1}+\cot r_{2}+\cot r_{3}\right)\left(\cot r+\cot r_{1}-\cot r_{2}+\cot r_{3}\right)}\left(\begin{array}{l}
\left(\cot r+\cot r_{1}+\cot r_{2}-\cot r_{3}\right)
\end{array}\right.
$$

The formula (26) msy be expressed geometrically Let $3 r_{3} N$ be the middle points of the sides $A B_{\mathrm{s}} A C$. Then we find $\cos \mu N$ $=\frac{1+\cos a+\cos b+\cos ^{\circ} c}{4 \cos \frac{b}{2} \cos \frac{c}{2}} ;$ heoce $\cos \frac{H^{\prime}}{2}=\cos M N \operatorname{sce}_{2}^{a}$

A geometrical construction lias been given for $E$ by Gudermann̄n (in Crelle's Journ., vi. and viii.). : It las been shomn by Cormeliv Keogh that the rolume of the perallelepiped of which the radii d
the sphere passing through the middle points of the sides of the triangle arc edges is $\sin \frac{E}{2}$

Let $A B C D$ be a spherical quadrilateral inscribed in a small circle; let $a, b, c$, $d$ denote the sides $A B, B C, C D, D A$ respectively, and $x, y$ the diagonals $A C, B D$. It can easily be shown by joining the angular points of the quadrilateral to the pole of the circle that $A+C=\bar{B}+D$. If we use the last expression in (23) for the radii of the circles circumscribing the triangles $B A D, B C D$, we have

$$
\sin A \cos \frac{\alpha}{2} \cos \frac{d}{2} \operatorname{cosec} \frac{y}{2}=\sin C \cos \frac{b}{2} \cos \frac{C}{2} \operatorname{cosec} \frac{y}{2} ;
$$

Thence

$$
\frac{\sin A}{\cos \frac{b}{2} \cos \frac{c}{2},}=-\frac{\sin C^{c}}{\cos \frac{a}{2} \cos \frac{d}{2}}
$$

This is the proposition corresponding to the relation $A+C=\pi$ for a plane quadrilateral. Also we obtain in a similar manuer the theorem

$$
\frac{\sin \frac{x}{2}}{\sin B \cos \frac{b}{2}}-\frac{\sin \frac{y}{2}}{\sin A \cos \frac{d}{2}},
$$

analogous to the theorem for a plane quadrilateral, that the diagonals are proportional to the sines of the angles opposite to then. Also the chords $A B, B C, C D, D A$ are equal to $2 \sin \frac{a}{2}, 2 \sin \frac{b}{2}, 2 \sin \frac{c}{2}, 2 \sin \frac{d}{2}$ respectively, and the plane quadrilateral formed by these chords is inscribed in the same circle as the spherical quadrilateral ; hence by Ptolemy's theorem for a plaze quadrilateral we obtain the analogous theorem for a spherical one

$$
\sin \frac{x}{2} \sin \frac{y}{2}=\sin \frac{a}{2} \sin \frac{c}{2}+\sin \frac{b}{2} \sin \frac{d}{2}
$$

It has been shown by Remy (iu Crelle's Journ., vol. iii.) that for any quadrilateral, if $z$ be the spherical distance between the middle points of the diagonals,

$$
\cos a+\cos b+\cos c+\cos d=4 \cos \frac{1}{2} x \cos \frac{1}{2} y \cos \frac{1}{2} z .
$$

This theorem is analogous to the theorem for any plane quadrilateral, that the eum of the squares of the sides is equal to the sum of the squares of the diagonals, together with twice the square on the straight line joining the middle points of the diagonals.

A theorem for a right-angled spherical triangle, analogous to the Pythagorean theorem, has been given by Gudermann (in Crelle's Journ., vol. zlii.)

## Analytical Trigonome:ry.

Penodi- Analytical trigonometry is that branch of mathematical analysis sity of in which the analytical properties of the trigonometrical functions sunctions. are investigated. These functions derive their importance in ana* lysis from the fact that they are the simplest singly periodic functions, and are therefore adapted to the representation of undulating magnitude. The sine, cosine, secant, and cosecant have the single real period $2 \pi$; i.e., each is unaltered in value by the addition of $2 \pi$ to the variahle. The tangent and cotangent have the period $\pi$. The sine, tangent, cosecant, and cotangent belong to the class of odd functions; that is, they change sign when the sign of the variable is changed. The cosine and secant are even functions, since they remain nnaltered when the sign of the variable is reversed.
The theory of the trigonometrical functions is intimately connected with that of complex quantities,-that is, of quantities of the form $x+\varepsilon y(b=\sqrt{-1})$. Suppose we multiply together, by the rules of ordinary algebra, two such quantities, we have

$$
\left(x_{1}+c y_{1}\right)\left(x_{3}+i y_{2}\right)=\left(x_{1} x_{2}-y_{1} y_{2}\right)+\iota\left(x_{1} y_{3}+x_{2} y_{1}\right) .
$$

We observe that the real part and the real factor of the imaginary part of the expression on the right-hand side of this equation are similar in form to the expressions which occur in the addition formule for the cosine and sine of the sum of two angles; in fact, if we put $x_{1}=r_{1} \cos \theta_{1}, y_{1}=r_{1} \sin \theta_{1}, x_{2}=r_{2} \cos \theta_{3} y_{2}=r_{2} \sin \theta_{3}$ the above equation becomes
$r_{1}\left(\cos \theta_{1}+\iota \sin \theta_{1}\right) \times r_{2}\left(\cos \theta_{2}+\iota \sin \theta_{2}\right)=r_{1} r_{2}\left(\cos \overline{\theta_{1}+\theta_{2}}+\iota \sin \overline{\theta_{1}+\theta_{2}}\right)$.
We may now, in accordance with the nsual node of representing complex quantities, give a geometrical interpretation of the meaning of this equation. Let $P_{1}$ be the point whose coordinates referred to rectangularaxes $O x, O y$ are $x_{1}, y_{1}$; then the point $P_{1}$ is employed to represent the quantity $x_{1}+\iota y_{1}$. In this mode of representation real quantities are meesured along the axis of $x$ and imaginary ones along the axis of $y$, additions being performed according to the parallelogram law. The points $A, A_{1}$ represent the magnitudes $\pm 1$, the points $a, a_{1}$ the magnitudes $\pm_{6}$ Let $P_{2}$ represent the expression $x_{2}+i y_{2}$ and $P$ the expression $\left(x_{1}+i y_{1}\right)\left(x_{2}+i y_{2}\right)$. The quantities $r_{2} \theta_{1}, r_{21} \theta_{2}$ are the golar coordinates of $P_{1}$ and $P_{2}$ respectively referred
to $O$ as origin and $O x$ as initial line; the above equation shows that $r_{1} r_{2}$ and $\theta_{1}+\theta_{3}$ are the polar coordinates of $P$; hence $O A$ $: O P_{1}$ :: $O P_{2}: O P$ and the angle $P O P_{2}$ is equal to the augle $P_{1} 0$ A. Thus we have the following geometrical construction for the determination of the point $P$. On $O P_{a}$ diaw a triangle similar to the triangle $O_{A} P_{1}$ so that the sides
$O P_{2}, O P$ are homologous to the sides $O A, O P$, and so that the angle $P O P_{2}$ is positive; then the vertex $P$ represents the proluct of the expressions represented by $P_{1}, P_{z}$ If $x_{2}+\iota y_{2}$ were to be divided ${ }^{3}$. by. $x_{1}+\iota y_{1}$, the triangle $O P^{\prime} P_{2}$ would be drawn on the uegative side of $P_{2}$, similar to the triangle $O A P_{1}$ and having the sides $O P^{\prime}, O P_{2}$ homologous to $O A, O P$, and $P^{\prime}$ would represent the quotient.

If we extend the abore to $n$ comples quantities by continual repeti-
tion of a similar operation, we
have-

$$
\left(\cos \theta_{1}+t \sin \theta_{1}\right)\left(\cos \theta_{2}+6 \sin \theta_{2}\right) \ldots
$$

$=\cos \left(\theta_{1}+\theta_{2}+\cdots+\theta_{n}\right)+\iota \sin \left(\theta_{1}+\theta_{2}+\ldots\right.$
$+\theta_{n}$ ).
Fig. 8.
If $\theta_{1}=\theta_{2}=\ldots=\theta_{n}=\theta_{1,}$, this equation becomes $(\cos \theta+\iota \sin \theta)$ $\cos n \theta+i$ sin $n \theta$; this shows that $\cos \theta+\iota \sin \theta$ is a value of $(\cos n \theta+$ $\iota \sin n \theta) \frac{1}{n}$. If now we change $\theta$ into $\frac{\theta}{n}$, we see that $\cos \frac{\theta}{n}+\iota \sin \frac{\theta}{n}$ is a value of $(\cos \theta+\iota \sin \theta)^{\frac{1}{n}}$; raising each of these quantitics to auy positive integral power $u, \cos \frac{m \theta}{n}+\iota \sin \frac{m \theta}{n}$ is oue value of ( $\cos \theta$ $+6 \sin \theta)^{\frac{m}{n}}$. Also

$$
\cos \left(-\frac{m}{n}\right) \theta+t \sin \left(-\frac{m}{n} \theta\right)=\frac{1}{\cos \frac{m}{n} \theta+\iota \sin \frac{m}{n} \theta} ;
$$

heuce the exprcssion of the left-land-side is one ralue of $\frac{1}{(\cos \theta+\imath \sin \theta)^{m / n}}$ or of $(\cos \theta+\iota \sin \theta)^{-\frac{m}{n}}$. We lave thus De Mairie' ${ }^{\text {B }}$ theorera that $\cos k \theta+\iota \sin k \theta$ is always one value of $(\cos \theta+\iota \sin \theta)^{k}$. where $k$ is any real quantity.
The principal object of De Moivre's theorem is to enable us to The . find all the values of an cxpression of the form $(a+c b)^{\frac{m}{n}}$, where m compter and $n$ are positive integers prine to each other. If $a=r \cos 0$, $b=r \sin \theta$, we require the values of $r^{\frac{m}{n}}(\cos \theta+\iota \sin \theta)^{\frac{m}{n}}$. One value is immediately furnished by the theorem; but we obscrve that, since the expression $\cos \theta+t \sin \theta$ is unaltered by adding any multiple of $2 \pi$ to $\theta$, the $\frac{n}{m}$ tll power of $r^{\frac{m}{n}}\left(\cos \frac{m \cdot \theta+2 s \pi}{n}+i \sin \frac{m \cdot \theta+2 s \pi}{\imath}\right)$ is $a+t b$, if $s$ is any iuteger; bence this expression is on of the values required. Suppose that for two values $s_{1}$ and $s_{2}$ of $s$ the values of this, expression are the same ; then we must have $\frac{\mu . \bar{\theta}+2 s_{1} \pi}{n}-\frac{m . \theta+2 s_{2} \pi \text {; }}{n}$ a multiple of $2 \pi$ or $s_{1}-s_{2}$ must be a multiple of $\kappa$. Therefore, if we give $s$ the values $0,1,2, \ldots n-1$ successively, we shall get $n$ different values of $(a+b b)^{\frac{m}{n}}$, and these will be repeated if we give $s$ other values: heuce all the ralues of $(a+i b)^{\frac{m}{n}}$ are obtained by giving ? the values $0,1,2, \ldots n-1$ in the expression $r^{\frac{m}{n}}\left(\cos \frac{m \cdot \theta+2 \Delta \pi}{n}\right.$ $+\left(\sin \frac{m \cdot \theta \overline{+2 s \pi}}{n}\right)$, where $r=\left(a^{2}+b^{2}\right) \frac{2}{4}$ and $\theta=\arctan \frac{b}{a}$.
We now return to the geometrical representation of the complex quantities. If the points $B_{1}, B_{2}, B_{3}, \ldots B_{n}$ represent the expression $x+t y,(x+t y)^{3},(x+i y)^{3}, \ldots(x+t y)^{n}$ respectively, the triangles $O A B_{1}, O B_{1} B_{2}, \ldots O B_{n-1} B_{n}$ are all similar. Let $(x+c y)^{n}=a+\iota b$, then the converse problem of finding the 2 th root of $a+a b$ is equivalent to the geometrical problem of describing such a series of triangles that $O A$ is the first side of the first triangle and $O B_{n}$ the second side of the $n$ th. Now it is obrious that this geometrical problem has more solutions than one, since any number of complete revolutions round $O$ may be madel in travelling from $B_{1}$ to $B_{n}$. The first solution is that in which the vertical angle of each triangle
 is $\frac{1}{n} B_{n} O A$; the second is that in which each is $\frac{1}{n}\left(B_{n} O_{X} A+2 \pi\right)$, in this case one comnlcte revolution being made round 0 ; the third
has $\frac{1}{n}\left(B_{n} O A+4 \pi\right)$ for the vertical angle of each triangle；and so on．There are $n$ sets of triangles which satisfy the required condi－ tions．For simplicity we will take the caso of the determination of the values of $(\cos \theta+t \sin \theta)^{\frac{2}{2}}$ ．Suppase $B$ to re－ present the expression $\cos \theta+九 \sin \theta$ ． If the angle $A O P_{1}$ is $\frac{3}{3} \theta_{2} P_{1}$ represents the root $\cos \frac{\theta}{3}+\iota \sin \frac{\theta}{3}$ ；the angle $A O B$ is filled up by the angles of the three similar triangles $A O P_{1}, P_{1} O p_{1}, p_{1} O B$ ． Also，if $P_{3} P_{5}$ be such that the angles $P_{1} O P_{2} P_{2} O P_{3}$ are $\frac{2 \pi}{3}, \frac{4 \pi}{3}$ respectively，
 the troo sets of triangles $A O P_{r,} P_{2} O p_{3}$ ， $p_{3} O B$ and $A O P_{32}, P_{3} O p_{23} p_{2} O B$ satisfy the conditions of simi－ larity and of having $O A, O B$ for the bounding sides；thus $P_{2}$ ， $P_{3}$ represent the roots $\cos \frac{\theta+2 \pi}{3}+九 \sin \frac{\theta+2 \pi}{3}, \cos \frac{\theta+4 \pi}{3}+九 \sin \frac{\theta+4 \pi}{3}$ respectively．If $B$ coincides with $A$ ，the problem is reduced to that of finding the three cube roots of unity．Oze will be repre－ sented by $A$ and the others by the two angular pointa of an equi－ lateral triangle，with $A$ as one angular point，inscribed in the circle．
The problem of determining the values of the $n$th roots of nnity is equivalent to the geometrical problem of inscribing a regular polygou of $n$ sides in a circle．Gauss has shown in his Disquisi－ tiones arithnetice that this can always be done by the compass sud ruler only when $n$ is a prime of the form $2^{p}+1$ ．The determins－ tion of the nth root of any complex quantity requires in addition， for its geometrical solution，the division of an angle into $n$ equal parts．

We are now in a position to factorize an expression of the form $2^{n}-(a+b)$ ．Using the values which we have obtained above for $(a+i b)^{\frac{1}{n}}$, Te have

$$
\begin{equation*}
x^{n}-(a+b)=\stackrel{s=n-1}{P}\left[x-r^{\frac{1}{n}}\left(\cos \frac{\theta+2 s \pi}{n}+c \sin \frac{\theta+2 s \pi}{n}\right)\right] \tag{1}
\end{equation*}
$$

If $b=0, a=1$ ，this becomea

$$
\begin{align*}
x^{n}-1 & =P_{s=0}^{s=n-1}\left[x-\cos \frac{2 s \pi}{n}-\iota \sin \frac{2 s \pi}{n}\right] \\
& =(x-1)(x+1) P_{s=1}^{s=\frac{n}{2}-1}\left(x-\cos \frac{2 s \pi}{n} \pm \iota \sin \frac{2 s \pi}{n}\right) \\
& =(x-1)(x+1) P_{s=1}^{s=\frac{n}{2}-1}\left(x^{2}-2 x \cos \frac{2 s \pi}{n}+1\right)(n \text { even })(2) . \\
x^{n}-1 & =(x-1) P_{s=1}^{s=\frac{n-1}{2}}\left(x^{2}-2 x \cos \frac{2 s \pi}{n}+1\right) \quad(r \text { odd }) \quad \ldots(3) . \tag{3}
\end{align*}
$$

If in（1）we put $a=-1, b=0$ ，and therefore $\theta=\pi$ ，te have

$$
\begin{align*}
x^{n}+1 & =P=P_{s=0}^{s=n-1}\left[x-\cos \frac{\overline{2 s+1} \pi}{\pi}-\iota \sin \frac{\overline{2 s+1} \pi}{n}\right] \\
& =P_{s=0}^{s=\frac{n-2}{2}}\left[x^{2}-2 x \cos \frac{\overline{2 s+1} \pi}{n}+1\right] \text { ( } n \text { even). } \tag{4}
\end{align*}
$$

$$
x^{n}+1=(x+1) \sum_{s=0}^{s=\frac{n-3}{2}}\left[x^{3}-2 x \cos \frac{\overline{2 s+1} \pi}{n}+1\right] \quad(n \text { odd })(5)
$$

also $x^{2 n}-2 x^{n} y^{n} \cos n \theta+y^{2 n}$

$$
\begin{align*}
& =\left(x^{n}-y^{n} \cos n \theta+6 \sin n \theta\right)\left(x^{n}-y^{n} \cos n \theta-t \sin n \theta\right) \\
& =P_{s=0}^{s=n-1}\left(x-y \cos \frac{\theta+2 s \pi}{n} \pm \imath \sin \frac{\theta+2 s \pi}{n}\right) \\
& =P_{s=0}^{s=n-1}\left[x^{s}-2 x y \cos \overline{\theta+\frac{2 s \pi}{n}}+y^{2}\right] \tag{6}
\end{align*}
$$

Airy and Adams have given proofs of this theorem which do not invalve the use of the symbol t（see Camb．Phil．Trans．，vol．xi．）．

A large number of interesting theorems may bo derived from Do Mlairro＇s theorem and the factorizations which we have deduced from it；we shall notice one of them．

In equation（6）put $y=\frac{1}{x}$ ，take logarithms，and then differentisto each side with respect to $x$ ，and we get

$$
\frac{2 n\left(x^{2 n-1}-x^{-2 n-1}\right)}{x^{-n}-2 \cos n \theta+x^{-2 n}}=\sum_{s=0}^{s=n-1} \frac{2\left(x-x^{-9}\right)}{x^{2}-2 \cos \theta+\frac{2 s \pi}{n}+x^{-2}}
$$

Put $x^{2}=\frac{a}{b}$ ，then we have the expression

$$
\left(a^{2}-b^{2}\right)\left(a^{2 n}-2\left(a^{2 n}-b^{n}-b^{n}\right)\right.
$$

for the sum of the series

$$
\sum_{s=0}^{s=n-1} \frac{1}{a^{2}-2 a b \cos \theta+\frac{2 s \pi}{n}+b^{2}}
$$

We ohall now consider what meaning can bo assigned to the aymbol $e^{x+t y}$ ．The quantity $e$ io defined as the limit of $\left(1+\frac{1}{n}\right)^{2}$ ， where $n$ is a positive quantity，and is increased indefinitely；then， for a real value of $x, z^{z}$ is the limit of $\left(1+\frac{1}{n}\right)^{n x}$ or of $\left(1+\frac{x}{m}\right)^{m}$ ， where $m=n x$ ，when $m$ is increased indefinitely．We may define $e^{x+t y}$ as the limit of $\left(1+\frac{x+t y}{m}\right)^{m}$ when $2 n$ is iucreased indefinitely． To determine the ralue of this limit put $1+\frac{x}{m}=r \cos \theta \frac{y}{m}=r \sin \theta$ ； then $e^{x+t y}$ is the limit of $r^{m}(\cos m \theta+\imath \sin m \theta)$ ，and $r^{m}$ is equal to $\left\{1+\frac{2 x}{m}+\frac{x^{2}+y^{2}}{m^{2}}\right\}^{\frac{m}{2}}$ or ultimately to $\left(1+\frac{2 x}{x}\right)^{\frac{m}{2}}$ ，which has $\epsilon^{x}$ for its limiting value．Also $\theta$ is arctan $\frac{y}{x+m}$ or $\frac{y}{x+m}$ in the limit； hence $m \theta$ is ultimately equal to $y$ ，and thus the equation $\boldsymbol{e}^{z+\iota y}=e^{x}(\cos y+\iota \sin y)$ follows from our definition．It may be shown at once that $e^{x+t y} \times e^{x_{1}+t y_{1}}=e^{x+x_{1}+\iota\left(y+y_{1}\right)}$ ，and，if we suppose that $a^{x+t y}$ denotes $d^{(x+t y) \log a}$ ，we may ohow that complex expon． ents defined thus obey the 68 me lsws as real ones．
When the exponent is entirely imsginary we have，in accordance Expor， with the above definition， ential
$c^{y}=\cos y+6 \sin y$ and $e^{-4 y}=\cos (-y)+6 \sin (-y)=\cos y-6 \sin y$ ；valnee of we thus obtain the exponential values of the sine and cosine－

$$
\sin y=\frac{1}{2 l}\left(e^{y y}-e^{-y}\right), \cos y=\frac{1}{2}\left(e^{y y}+e^{-y}\right)
$$

If we give imaginary or complex values to the variables in alge－Expan： braical expansions we obtain anałogous trigonometrical theorems；sious of it is，however，necessary to consider the convergency of the series sines 80 obtained in order to determine within what limits the values of and the variables must lie．If me expand $e^{y y}$ and $e^{-s y}$ by putting oy cosines and $-t y$ in the series $1+y+\frac{y^{2}}{1 \cdot 2}+\frac{y^{3}}{1 \cdot 2 \cdot 3}+\ldots$ ， we obtain the series $\sin y=y-\frac{y^{3}}{[3}+\frac{y^{5}}{15}-\frac{y^{7}}{17}+\ldots$ ；

$$
\cos y=1-\frac{y^{2}}{\frac{2}{2}}+\frac{y^{4}}{4}-\frac{y^{6}}{6} \not \ldots \ldots
$$

These series are convergent for sll finite values of $y$ ．They miry also be got from the expressions which we have obtained for the cosine snd sine of a multiple of an angle in terms of the cosine and sine of the sagle，and would thus be mudo to rest upon a hasis independent of the oymhol $t$ ．

Consider the binomial theorem

$$
\begin{aligned}
& (a+b)^{n}=a^{n}+n a^{n-1} b+\frac{n(n-1)}{12} a^{n-2 b^{2}}+\ldots \\
& +\frac{n(n-1) \ldots(n-r+1)}{\underline{r}} a^{n \rightarrow b^{r}}+\ldots+b^{n}
\end{aligned}
$$

Putting $a=e^{\iota \theta}, b=e^{-\epsilon \theta}$, Te obtain
$(2 \cos \theta)^{n}=2 \cos n \theta+n 2 \cos \overline{n-2 \theta}+\frac{n(n-1)}{\frac{\mid 2}{2}} 2 \cos \overline{n-4 \theta}+\ldots$

$$
+\frac{n(n-1) \ldots(n-r+1)}{\frac{r}{r}} \cos (n-2 r) \theta+\ldots
$$ and co． sines in series of ：ines anf cosines of multiple Eirs

When $n$ is odd the last term is $2 \frac{n(n-1) \ldots \frac{b}{3}(n+3)}{\left\lvert\, \frac{1}{2}(n-1)\right.} \cos \theta_{0}$
and when $n$ is even it is $\frac{n(n-1) \ldots\left(\frac{1}{3} n+1\right)}{1 \frac{3}{2} n}$ ．
If we put $a=c^{\iota \theta}, b=-c^{-\iota \theta}$ ，we ohtain the formula
$(-1)^{\frac{n}{2}}(2 \sin \theta)^{n}=2 \cos n \theta-2 n \cos (n-2) \theta+\frac{n(n-1)}{1 \cdot 2} 2 \cos (n-4) \theta-$

$$
\begin{aligned}
& \quad+(-1)^{n-r} \frac{n(n-1) \ldots(n-r+1)}{\mid r} 2 \cos (n-2 r) \theta_{\ldots}+(-1)^{\frac{n}{2} n(n-1) \ldots \frac{1}{3} n+1} \frac{1}{n} \\
& \text { when } n \text { is even, and }
\end{aligned}
$$

$\begin{aligned}(-1)^{\frac{n-1}{2}}(2 \sin \theta)^{n} & =2 \sin n \theta-n \cdot 2 \sin (n-2) \theta+\frac{n(n-1)}{1.2} \\ & +(-1)^{\frac{n-1}{2} \frac{n(n-1) \ldots \frac{1}{2}(n+3)}{1 \frac{1}{2}(n-1)}} \sin \theta\end{aligned}$
When $n$ is odd．These formule enable us to express anv nosition integral power of the sine or casine in terms of sines or cosines e multiples of the argument．Where are corresponding formille whe $n$ is not a positive integer．

Coneicer tha: 1 entity $\log (1-p x)+\log (1-q x)=\log \left(1-p+q x+p q x^{2}\right)$. Expand lotin sides of this equation in powers of $x$, and equate the cuedicients of $x^{n}$, we then get

$$
\begin{aligned}
& p^{n}+q^{n}=(p+q)^{n}-n(p+q)^{n-2} p q+\frac{n(n-3)}{\frac{12}{2}}(p+q)^{n-1} p^{2} q^{2}+\ldots \\
& +(=1)^{r n(n-r-i)(n-r-2) \ldots(n-2 r+1)}(p+q)^{n-2 r} p r q+\ldots
\end{aligned}
$$

If we write this series in the reverse order, we have

$$
\begin{aligned}
v^{n}+q^{n}= & 2(-1)^{\frac{n}{2}}\left[(p q)^{\frac{n}{2}} \frac{n^{2}}{\mid 2}(p q)^{\frac{n}{2}-1}\left(\frac{p+q}{2}\right)^{2}+\frac{n^{2}\left(n^{3}-2^{2}\right)}{\mid 4}(p q)^{\frac{n}{2}-2}\left(\frac{p+q}{2}\right)^{4}\right. \\
& \left.\frac{n^{2}\left(n^{2}-2^{3}\right)\left(n^{2}-4^{2}\right)}{\mid 6}(p q)^{\frac{n}{2}-3}\left(\frac{p+q}{2}\right)^{0}+\ldots+(-1)^{\frac{n}{2}} \frac{1}{2}(p+q)^{n}\right]
\end{aligned}
$$

Rhen $n$ is even, snd

$$
\begin{aligned}
n^{n}+q^{n} & =2(-1)^{\frac{n-1}{2}}\left[n(p q)^{\frac{n-1}{2}}\left(\frac{p+q}{2}\right)-\frac{n\left(n^{2}-1^{2}\right)}{\mid 3}(p q)^{\frac{n-3}{2}}\left(\frac{p+q}{2}\right)^{0}\right. \\
& \left.+\frac{n\left(n^{2}-1^{2}\right)\left(n^{2}-3^{2}\right)}{\mid 5}(p q)^{\frac{n-5}{2}}\left(\frac{p+2}{2}\right)^{6}+\ldots+(-1)^{\frac{n-1}{2}} \frac{1}{2}(p+q)^{n}\right]
\end{aligned}
$$

Then $n$ is odd. If in these three formulæ we put $p=e^{t \theta}, q=e^{-t \theta}$, We obtain the following series for $\cos n \theta$ :-
$2 \cos n \theta=(2 \cos \theta)^{n}-n(2 \cos \theta)^{n-2}+\frac{n(n-3)}{\frac{12}{2}}(2 \cos \theta)^{n-4} \ldots$

$$
+(-1)^{r} \frac{n(n-r-1)(n-r-2) \ldots(n-2 r+1)}{\underline{r}}(2 \cos \theta)^{n-2 r}+\ldots \text { (7) }
$$

When $n$ is any positive integer;
$(-1)^{\frac{n}{2}} \cos n \theta=1-\frac{n^{2}}{12} \cos ^{2} \theta+\frac{n^{2}\left(n^{2}-2^{2}\right)}{14} \cos ^{4} \theta-\frac{n^{2}\left(n^{2}-2^{2}\right)\left(n^{3}-4^{2}\right)}{16} \cos ^{6} \theta$

$$
\begin{equation*}
+\ldots+(-1)^{\overline{2}} 2^{n-1} \cos n \theta . \tag{8}
\end{equation*}
$$

when $n$ is on even positive integer ;

$$
\begin{gather*}
(-1)^{\frac{n-1}{2}} \cos n \theta=n \cos n \theta-\frac{n\left(n^{2}-1^{2}\right)}{\frac{13}{\frac{n-1}{2}} \cos ^{9} \theta+\frac{n\left(n^{2}-1^{2}\right)\left(n^{2}-3^{2}\right)}{\frac{15}{}} \cos ^{6} \theta-} \\
\ldots+(-1)^{\frac{2}{2}} 2^{n-1} \cos ^{n} \theta \ldots \ldots \ldots \ldots \ldots . . \tag{9}
\end{gather*}
$$

Fhen $n$ is odd. If in the same three formula we put $p=e^{l \theta}, q=$ 18 ${ }^{-1 \theta}$, we obtain the following four formulæ:-
$(-1)^{\frac{n}{2}} 2 \cos n \theta=(2 \sin \theta)^{n}-n(2 \sin \theta)^{n-2}+\frac{n(n-3)}{\underline{12}}(2 \sin \theta)^{n-4}-\ldots$
$+(-1)^{r} \frac{n(n-r-1) \ldots(n-2 r-1)}{\underline{\mid r}}(2 \sin \theta)^{n-2 r}+\ldots(n$ even $)(10) ;$

$$
\begin{equation*}
(-1)^{\frac{n-1}{2}} 2 \sin n \theta=\text { the same series }(n \text { odd) } \tag{11}
\end{equation*}
$$

$\begin{aligned} \cos n \theta=1-\frac{n^{2}}{12} \sin ^{2} \theta & +\frac{n^{2}\left(n^{2}-2^{2}\right)}{\frac{14}{4}} \sin ^{4} \theta-\frac{n^{2}\left(n^{2}-2^{2}\right)\left(n^{2}-4^{2}\right)}{\mid 6} \sin ^{6} \theta \\ & +\ldots \frac{2^{n-1}}{} \sin ^{n} \theta \text { (xeven) }\end{aligned}$

$$
\begin{equation*}
\left.+\ldots 2^{n-1} \sin ^{n} \theta \text { ( } \kappa \text { even }\right) \ldots \tag{12}
\end{equation*}
$$

$+(-1)^{\frac{n-1}{2}} 2^{n-1} \sin ^{n} \theta(n$ odd $)$.
Next consider the identity $\frac{p}{1-p x}-\frac{q}{1-q x}=\frac{p-q}{1-(p+q) x+p q x^{2}}$. Expand both sides of this equation in powers of $x$, and equate the coefficients of $x^{n-1}$, then we ohtain the equation
$\frac{p^{n^{2}} q^{n}}{p-q}=(p+q)^{n-1}-(n-2)(p+q)^{n-8} p q+\frac{(n-3)(n-4)}{\frac{12}{2}}(p+q)^{n-8} p^{2} q^{2}-$.

$$
+(-1)^{r(n-r-1)(n-r-2) \ldots(n-2 r)} \frac{1 r}{}(p+q)^{n-2 r-1} p^{r} q^{r}+\ldots
$$

If, as before, we write this in the reverse order, we have the series

$$
\begin{aligned}
&(-1)^{\frac{n}{2}-1}\left[n\left(\frac{p+q}{2}\right)(p q)^{\frac{n}{2}-1}-\frac{n\left(n^{2}-2^{2}\right)}{\frac{\mid 3}{n}}\left(\frac{p+q}{2}\right)^{8}(p q)^{\frac{n}{2}-3}\right. \\
&\left.+\frac{n\left(n^{2}-2^{2}\right)\left(n^{2}-4^{2}\right)}{15}\left(\frac{p+q}{2}\right)^{5}(p q)^{\frac{n}{2}-5}+\ldots+(-1)^{\frac{n}{2}-1}(p+q)^{n-1}\right]
\end{aligned}
$$

When $n$ is even, and
$(-1)^{\frac{n-1}{2}}\left[(p q)^{\frac{n-1}{2}}-\frac{n^{2}-1^{2}}{12}\left(\frac{p+q}{2}\right)^{2}(p q)^{\frac{n-3}{2}}\right.$

$$
\left.+\frac{\left(n^{2}-1^{2}\right)\left(n^{2}-3^{2}\right)}{14}\left(\frac{n+q}{2}\right)^{4}(p q)^{\frac{n-5}{2}}+\ldots+(-1)^{\frac{n-1}{2}}(p+q)^{n-1}\right]
$$

Then $n$ is odd.
[f we put $p=c^{\iota \theta}, q=e^{-t \theta}$, we obtain the formola
$\sin n \theta=\sin \theta\left\{(2 \cos \theta)^{n-1}-(n-2)(2 \cos \theta)^{n-3}+\frac{(n-3)(n-4)}{\underline{2}}(2 \cos \theta)^{n-1}\right.$

$$
\left.+(-1)^{r} \frac{(n-r-1)(n-r-2) \ldots(n-2 r)}{\mid r}(2 \cos \theta)^{n-9 r-1}+\ldots\right)(14)
$$

where $n$ is any positive integer ;
$(-1)^{\frac{n}{2}-1} \sin n \theta=\sin \theta\left\{n \cos \theta-\frac{n\left(n^{2}-2^{2}\right)}{\frac{13}{15} \cos ^{9} \theta+\frac{n\left(n^{2}-2^{2}\right)\left(n^{2}-4^{2}\right)}{15} \cos ^{5} \theta \ldots n}\right.$

$$
\left.+(-1)^{\frac{n}{2}-1}(2 \cos \theta)^{n-1}\right\}(n \text { even }) \ldots \ldots \ldots \ldots(15)
$$

$(-1)^{\frac{n-1}{2}} \sin n \theta=\sin \theta\left\{1-\frac{n^{2}-1^{2}}{\underline{\underline{2}} \cos ^{2} \theta+\frac{\left(n^{2}-1^{2}\right)\left(n^{2}-3^{2}\right)}{\underline{4}} \cos ^{3} \theta-\ldots . . . . . . . ~}\right.$

$$
\begin{equation*}
\left.+(-1)^{\frac{n}{2}-1}(2 \cos \theta)^{n-1}\right\}(n \text { odd }) . \tag{16}
\end{equation*}
$$

If we put in the same three formula $p=e^{\iota \theta}, q=-e^{-\iota \theta}$. we obtain the series
$(-1)^{\frac{n-2}{2}} \sin n \theta=\cos \theta\left[\sin ^{n-1} \theta-(n-2) \sin ^{n-5} \theta+\frac{(n-3)(n-4)}{2} \sin ^{n-8} \theta-\ldots\right.$

$$
\left.+(-1)^{r} \frac{(n-r-1)(n-r-2) \ldots(n-2 r)}{\mid r} \sin ^{n-2 r-1} \theta+\ldots\right](n \text { even })(17) ;
$$

$$
\frac{n-1}{2}
$$

$(-1)^{2} \cos n \theta=$ the same series ( $n$ odd) $\ldots . .$. (18);
$\sin n \theta=\cos \theta\left\{n \sin \theta-\frac{n\left(n^{2}-2^{2}\right)}{13} \sin ^{9} \theta+\frac{n\left(n^{2}-2^{2}\right)\left(n^{2}-4^{2}\right)}{14} \sin ^{5} \theta+\right.$

$$
\begin{equation*}
\left.\ldots+(-1)^{\frac{n}{2}-1}(2 \sin \theta)^{n-1}\right\}(n \text { even }) \ldots \tag{19}
\end{equation*}
$$

$\cos n \theta=\cos \theta\left\{1-\frac{n^{2}-1^{2}}{12} \sin ^{2} \theta+\frac{\left.i n^{2}-1^{2}\right)\left(n^{2}-3^{2}\right)}{14} \sin ^{4} \theta-\ldots\right.$

$$
\left.+(2 \sin \theta)^{n-1}\right\}(n \text { odd })
$$

We have thus obtained formulæ for $\cos n \theta$ and $\sin n \theta$ both in ascending and in descending powers of $\cos \theta$ and $\sin \theta$. Viète obtained formulm for chords of maltiple arcs in powers of chords of the simple or complementary arcs equivalent to the formulx (13) and (19) sbove. These are contained in his work Theorenzata ad angulares,sectiones. James Bernoulli found formule equiralent to (12) and (13) (Mem. de l'Acadénie des Sciences, 1702), and transformed these series into a form equivalent to (10) and (11). John Bernoulli published in the Acta eruditorum for 1701, among other formule already found by Viète, one equivalent to (17). These formula have been extended to cases in which $n$ is fractional, negative, or irrational; seo a paper by D. F. Gregory in Camb. Math. Journ., vol, iv., in which the series for $\cos n \theta, \sin n \theta$ in ascending powers of $\cos \theta$ and $\sin \theta$ are extended to the case of a fractiona value of $n$. These series havo been considered by Euler in a memoir in the Nova acta, vol. ix., by Lagrange in his Calcul des fonctions (1806), and by Poinsot in Recherches sur l'analyse des sec. tions angulaires (1825).

The general definition of Napierian logarithms is that, if $e^{x+t y}$ Theory $=a+b b$, then $x+t y=\log (a+\imath b)$. Now we know that $e^{x+t y}=e^{x} \cos y$ of loga $+e^{x} \sin y$; hence $e^{x} \cos y=a, e^{x} \sin y=b$, or $e^{x}=\left(a^{2}+b^{2}\right)^{\frac{1}{2}}, y=$ rithmes $\arctan \frac{b}{a} \pm m \pi$, where $m$ is an integer. If $b=0$, then $m$ must be eveu or odd according as $a$ is positive or negative; hence

$$
\log _{\theta}(a+b)=\log _{0}\left(a^{2}+b^{2}\right)^{\frac{3}{2}}+c\left(\operatorname{arotan} \frac{b}{a} \pm 2 n \pi\right)
$$

or $\quad \log _{e}(a+b)=\log _{e}\left(a^{2}+b^{2}\right)^{\frac{3}{2}}+\iota\left(\arctan \frac{b}{a} \pm \overline{2 n+\pi}\right)$,
according as $a$ is positive or negative. Thus the logarithm of any complex or real quantity is a multiple-valued function, the differ. ence between successive values being $2 \pi t$; in particular, the most general form of the logarithm of a real positive quantity is obtained by adding positive or negative multiples of $2 \pi t$ to the srithmetical logarithm. On this subject, see De Morgan's Trigonometry and Double Algebra, chap. iv., and a naper by Prof. Cayley in vol. ii. of Proc. London Math. Soe.
We may euppose the exponeutial values of the sine and çosine extended to the case of complex arguments; thus we accept $\frac{e^{\imath(x+\iota y)}+e^{-\iota(x+\iota y)}}{2}$ and $\frac{e^{\iota(x+\imath y)}-e^{-\iota(x+\imath y)}}{2 t}$ functions $\cos (x+t y), \sin (x+t y)$ respectively. If $x=0$, we have $\cos t y=\frac{c^{y}+e^{-y}}{2}$ and $\sin t y=\frac{1}{2}\left(e^{y}-e^{-y}\right)$. The quantities $\frac{e^{y}+e^{-y}}{2}$ $\frac{e^{y}-e^{-y}}{2}$ are called the hyperbolic cosine and eine of $y$ and are written $\cosh y, \sinh y$; thus $\cosh y=\cos \imath y, \sinh y=-\iota \sin t y$. The functions $\cosh y$, sinh $y$ arc connected with the rectangular hyperbola in a menner analogous to that in which the cosine snd sine are
connected with the circle. We may easily show from the definitions that

$$
\cos ^{2}(x+y)+\sin ^{2}(x+(y)=1
$$

$$
\begin{aligned}
\cosh ^{2} y-\sinh ^{2} y & =1 \\
\cos (x+y y) & =\cos
\end{aligned}
$$

$\cos (x+c y)=\cos x \cosh y-\iota \sin x \sin l_{1} y$,
$\sin (x+t y)=\sin x \cosh y+6 \cos x \sinh y$,
$\cosh (\alpha+\beta)=\cosh \alpha \cosh \beta+\sinh \alpha \sinh \beta$,
$\sinh (\alpha+\beta)=\sinh \alpha \cosh \beta-\cosh \alpha \sinh \beta$.
These formulæ are the basis of a complete hyperbolic trigonometry. The conmexion of these functions with the hyperbola was first pointed out by Lamihert.
If wa equate the coeftirients of $n$ ou looth sides of equation (13), 4we get

$$
\begin{equation*}
\theta=\sin \theta+\frac{1}{2} \sin ^{3} \theta+\frac{1.3}{2.4} \sin ^{8} \theta+\frac{1.3 .5}{2.4 \cdot 6} \frac{\sin ^{5} \theta}{7}+\ldots \ldots \tag{21}
\end{equation*}
$$

$\theta$ must lie letween the values $\pm \frac{\pi}{2}$. This equation nay also be written in the form

$$
\begin{aligned}
& \text { the form } \\
& \arcsin x=x+\frac{1}{2} \frac{x^{3}}{3}+1.3 x^{5} \\
& 2.4 \frac{1}{5}+\frac{3.5 a^{7}}{2.4 .6} 7^{+\ldots}
\end{aligned}
$$

when $x$ lies between $\pm 1$.
By cquating the coefficiente of $x^{2}$ on hoth sirles of equation (12) we get

$$
\begin{equation*}
\theta^{2}=\sin ^{2} \theta+\frac{2}{3} \frac{\sin ^{4} \theta}{2}+\frac{2.4}{3.5} \sin ^{6} \theta+\frac{2.4 .6}{3.5 .7} \frac{\sin ^{8} \theta}{4}+ \tag{22}
\end{equation*}
$$

whiclı may also be writtea in the form

$$
\left(\arcsin \boldsymbol{A}^{6}\right)^{2}=2^{2}+\frac{2}{3} \frac{x^{4}}{2}+\frac{2.4}{3.5} \frac{2}{3}+\frac{2.4 \cdot 6}{3.5 \cdot 7 \frac{x^{8}}{4}}+\ldots
$$

when $x$ is lectween $\pm 1$. Differentiating this cquation with regard to $x$, we get

$$
\frac{\arcsin x}{x^{1}-x^{2}}=x+\frac{2}{3} x^{3}+\frac{2 \cdot 4}{3 \cdot 5} x^{5}+\frac{2 \cdot 4 \cdot 6}{3 \cdot 5 \cdot x^{7}+\ldots ;}
$$

if we put aresin $x=\arctan y$, this equation becomes

$$
\text { arc tan } y^{\prime}=\begin{gather*}
y  \tag{23}\\
1+y^{2}
\end{gather*}\left\{1+\frac{2}{3} \frac{y^{2}}{1+y^{2}}+\frac{2 \cdot 4}{3 \cdot 5}\binom{y^{2}}{1+y^{2}}^{2}+\ldots\right\}
$$

This equation was riven with two proofs by Euler in the Nova acta for 1793.

We have

$$
\frac{1}{2} \log _{1-x}^{1+x}=x+\frac{\rho^{3}}{3}+\frac{\partial^{3}}{5}+\frac{x^{7}}{i}+\ldots
$$

 or $\begin{aligned} & \text { arc tan } y \\ & \text { 土al }\end{aligned}$;
hence arctan $y \pm n \pi=y-\frac{y^{3}}{3}+\frac{y^{5}}{5}-\frac{y^{7}}{7}+\ldots$
The sorics is convergent if $y$ lies hetween $\pm 1$; if we suppose arc tan $y$ restricterl to values between $\pm \frac{\pi}{4}$, we lave

$$
\begin{equation*}
\underset{\text { arcten } y=y-\frac{y^{3}}{3}+\frac{y^{8}}{5}-\ldots .}{\text { series. }} \tag{24}
\end{equation*}
$$

Which is Cregory'a series.
Various series derived from (24) have been employed to colenlate the value of $\pi$. At the end of the 17th century $\pi$ was calculated to 72 places of decimals by Abraham Sharp, by means of the meries olitained by putting arctan $y=\frac{\pi}{6}, y=\frac{1}{\sqrt{3}}$ in (2t). The calculation is to lic found in Sherwin's Mallomatical Tables (1742). About the ssme time Machin employed the serics obtained from the equation 4 arc $\tan \frac{1}{5}-\arctan \frac{1}{239}=\frac{\pi}{4}$ to calculate $\pi$ to 100 decimal places. Long ofterwards Euler employed the serics obtoined from $\frac{\pi}{4}=\arctan \frac{1}{2}+\arctan \frac{1}{3}$, which, however, gives loss rapidly converging series (Intrad., Anal. infin., vol. i.). Lagny employed tha formula arctan $\frac{1}{\sqrt{ }} 3=\frac{\pi}{6}$ to calculate $\pi$ to 127 places; the result was communicated to the Paris Acalemy in 1719. Tega calculated $\pi$ to 140 decimal places by means of the sories obtained from the aquation $\frac{\pi}{4}=5 \arctan \frac{1}{7}+2 \arctan \frac{3}{10}$. The formula $\frac{\pi}{4}=\arctan \frac{1}{2}+$ arctan $\frac{1}{5}+\arctan \frac{1}{8}$ was used by Dasa to calculate $\pi$ to 200 derimal places. Rutherford used the eçustion $\pi=4 \arctan \frac{1}{5}-\arctan \frac{1}{70}+$ $\arctan { }^{1} 99^{\circ}$

If in ( $39^{\circ}$ we put $y=\frac{1}{3}$ and $\frac{1}{7}$, we hare

$$
\begin{aligned}
& \pi=9 \arctan \frac{1}{3}+4 \arctan \frac{1}{7}=2 \cdot 4\left\{1+\frac{2}{3} \cdot \frac{1}{10}+\frac{2.4}{3.5} \frac{1}{10^{2}}+\ldots\right\} \\
&+56\left\{1+\frac{2}{3} \cdot 2+\frac{2}{3.4}\binom{2}{100}^{2}+\ldots\right\}
\end{aligned}
$$

a rapidly convergent series for $\pi$ which was first given by IIutton in Phil. Trans. for 1776, and afterwards by Enler in Nova acta for 1793. Euler gives an equation deduced in the same manner from the identity $\pi=20 \arctan \frac{1}{7}+8 \arctan \frac{3}{79}$. The calculation of $\pi$ has been carried out to 707 pleces of decimals; see Pror. Roy. Soc., xxi. ahd xxii. ; also Squ゙ariNo the Crrcle (vol. axii. j. 435 sq .).

We shall now obtain expressions for ain $\%$ and $\cos x$ es infinite products of rational factors. We havo
$\sin x=2 \sin \frac{x}{2} \sin \frac{5+\pi}{2}=2^{5} \sin \frac{x}{4}$ ain $\frac{x+\pi}{4} \operatorname{ain} \begin{gathered}x+2 \pi \\ 4\end{gathered}$ sin $\frac{x+3 \pi}{4} ;$ procecding continually in this way with each factor, we obtain

$$
\sin x=2^{n-1} \sin \frac{x}{x} \sin \frac{x+\pi}{x} \sin \frac{x+2 \pi}{n} \ldots \text { ain } \frac{x+\overline{n-1} \pi}{n}
$$

where $n$ is any positive integral $2 \times$ rer of 2 . Now

$$
\sin \frac{\gamma+r \pi}{n} \sin \frac{r+n-r \pi}{n}=\sin \frac{r+r \pi}{n} \sin \frac{r \pi-x}{n}=\sin ^{2} \frac{1 \pi}{n}-\operatorname{ain}^{2} \frac{x}{x}
$$

and

$$
\sin \frac{x+\frac{1}{2} \pi \pi}{n}=\cos \frac{r}{n}
$$

Henca the alore mey he written

$$
\begin{gathered}
\sin \varepsilon=2^{n-1} \sin ^{x}\left(\sin ^{2} \frac{\pi}{n}-\sin ^{2} \frac{x}{n}\right)\left(\sin ^{2} \frac{2 \pi}{n}-\sin ^{2} \frac{2}{n}\right) \ldots \\
\\
\left(\sin ^{2} \frac{\pi \pi}{n}-\sin ^{2} \frac{x}{n}\right) \cos ^{x},
\end{gathered}
$$

Where $k=\frac{1}{2} n-1$. Lat $x$ be indefinitely small, then we have

$$
1=\frac{2^{n-1}}{n} \sin ^{2} \frac{\pi}{n} \sin ^{2} \frac{2 \pi}{n} \ldots \sin ^{2} \frac{k \pi}{n}
$$

hence
$\sin 2:=n \sin \frac{x}{n} \cos \frac{x}{n}\left(1-\frac{\sin ^{2} x / n}{\sin ^{2} \pi / n}\right)\left(1-\frac{\sin ^{2} x / n}{\sin ^{2} 2 \pi / n}\right) \ldots\left(1-\frac{\sin ^{2} x / n}{\sin ^{2} k \pi / n}\right)$. We may write this

$$
\operatorname{ain} x=u \sin \frac{x}{n} \cos \frac{x}{n}\left(1-\frac{\sin ^{2} x / n}{\sin ^{2} \pi / n}\right) \ldots\left(1-\frac{\sin ^{2} x / n}{\sin ^{2} m \pi / n}\right) n_{1}
$$

where $R$ denotes the product

$$
\left(1-\frac{\sin ^{2} \frac{x}{n}}{\sin ^{2} \overline{m+1} \frac{1}{n}}\right)\left(1-\frac{\sin ^{2} \frac{x}{n}}{\sin ^{2} \frac{m+2 \pi}{n}}\right) \cdots\left(1-\frac{\sin ^{2} \frac{x}{n}}{\sin ^{2} \frac{k \pi}{n}}\right)
$$

and $m$ is any fixed integer independent of $n$. It is necessary, when we make $n$ infinite, to determine the limiting value of the quentity $n$; then, aince the limit of $\frac{\sin x}{n \sin \frac{x}{n} \cos \frac{x}{n}}$ is $\frac{\sin x}{x}$, and that of $\frac{\sin n l \pi / n}{m \pi / n}$ is unity, we hare

$$
\frac{\sin x}{x}=\left(1-\frac{x^{2}}{\pi^{2}}\right)\left(1-\frac{x^{2}}{2 \pi^{2}}\right) \ldots\left(1-\frac{x^{2}}{n^{2} \pi^{2}}\right) R
$$

Now $R$ is less than unity, since $\sin \frac{x}{\pi}$ is less than $\sin \frac{m+1}{9} \pi$, sin $\frac{n+2}{n} \ldots$; also by an elementary algebraical proposition $R$ is grater than $1-\sin ^{2} \frac{2}{n}\left(\operatorname{cosec}^{3} \frac{\overline{n+1} \pi}{n}+\ldots+\operatorname{cosec}^{2} \frac{k \pi}{n}\right)$ and $\operatorname{cosec} \theta<\frac{\pi}{2 \theta}$, if $\theta<\frac{\pi}{2} ; R$ is therefore greater then

$$
1-\frac{x^{2}}{4}\left(\frac{1}{m+11^{2}}+\frac{1}{m+21^{2}}+\ldots+\frac{1}{h^{2}}\right)
$$

or than $1-\frac{x^{2}}{4}\left\{\frac{1}{m}-\frac{1}{m+1}+\frac{1}{m+1}-\frac{1}{m+2}+\ldots+\frac{1}{k-1}-\frac{1}{k}\right\}$,
or than $1-\frac{x^{2}}{4 m}$. Henca $R=1-\frac{\theta x^{2}}{4 m}$, where $\theta$ is some proper fraction; whence

$$
\sin x=x\left(1-\frac{x^{2}}{\pi^{2}}\right)\left(1-\frac{x^{2}}{2^{2} \pi^{2}}\right) \ldots\left(1-\frac{x^{2}}{m^{2} \pi^{2}}\right)\left(1-\frac{\theta x^{2}}{4 m}\right)
$$

When $m$ is indefinitely increased this becomes

$$
\sin x=2\left(1-\frac{x^{2}}{\pi^{2}}\right)\left(1-\frac{x^{2}}{2^{2} \pi^{2}}\right) \ldots=x_{n=-\infty}^{n=+\infty}\left(1+\frac{x}{n \pi}\right) \quad \text { (25). }
$$

The expression for $\cos x$ in factors may be found in a similar inanger by means of the equation $\cos x=2 \sin \frac{\pi-2 x}{4} \cos 3 \pi-2 x$, or may be deduced thus

$$
\begin{array}{r}
\cos x=\frac{\sin 2 x}{2 \sin x}=\frac{P\left(1-\frac{4 x^{2}}{n^{2} \pi^{2}}\right)}{P\left(1-\frac{x^{2}}{n^{2} \pi^{2}}\right)}=\left(1-\frac{4 x^{2}}{\pi^{2}}\right)\left(1-\frac{4 x^{2}}{3^{2} \pi^{2}}\right)\left(1-\frac{4 x^{2}}{5^{2} \pi^{2}}\right) \ldots \\
=P=+\infty  \tag{26}\\
n=-\infty
\end{array}\left(1+\frac{2 x}{2 n+1 \pi}\right) \ldots \ldots \ldots \ldots \ldots(26) .
$$

If we change $x$ into $b x$, wo hava the formulæ for ainh $x, \cosh x$ as infinite products-

$$
\operatorname{ainh} x=\underset{n=0}{n=\infty}\left(1+\frac{x^{2}}{n n^{2} \pi^{2}}\right), \cosh x=P_{n=0}^{n=\infty}\left(1+\frac{4 x^{2}}{2 n+11^{2} \pi^{2}}\right) .
$$

In the formula for $\sin x$ as an infinite product put $x=\frac{\pi}{2}$, wo then get $1=\frac{\pi}{2} \cdot \frac{1 \cdot 3 \cdot 3 \cdot 5 \cdot 5 \ldots}{2 \cdot 2 \cdot 4 \cdot 4 \cdot 6 \ldots}$; in we stop after $2 n$ factors in tha numerator and denominator, we obtain the approximate equation

$$
1=\frac{\pi}{2} 1^{2} \cdot 3^{2} \cdot 5^{2} \cdot 4^{2} \cdot 6^{2} \cdots(2 n-1)^{2} \cdot(2 n+1)
$$

or $\frac{2 \cdot 4.6 \ldots 2 n}{1.3 .5 \ldots 2 n-1}=\sqrt{n \pi}$, where $n$ is a large integer. This ex. pression was obtained in a quite different manner by Wallis (Arith. metica infinitorum. vol. i. of $O p p$.).
We have

$$
\frac{\sin (x+y)}{\sin x}=\frac{(x+y) P\left(1+\frac{x+y}{\pi \pi}\right)}{x P\left(1+\frac{x}{n \pi}\right)}
$$

or $\cos y+\sin y \cos x$

$$
=\left(1+\frac{y}{x}\right)\left(1+\frac{y}{x+\pi}\right)\left(1+\frac{y}{x-\pi}\right)\left(1+\frac{y}{x+2 \pi}\right)\left(1+\frac{y}{x-2 \pi}\right) \ldots
$$

Equating the coefficients of the first power of $y$ on both sides we obtain the series

$$
\cot x=\frac{1}{x}+\frac{1}{x+\pi}+\frac{1}{x-\pi}+\frac{1}{x+2 \pi}+\frac{1}{x-2 \pi}+\cdots \quad \ldots \ldots \text { (27). }
$$

From this we may dednce a corresponding eeries for $\operatorname{cosec} x$. for, since $\operatorname{cosec} x=\cot \frac{x}{2}-\cot x$, we obtain
$\operatorname{cosec} x=\frac{1}{x}-\frac{1}{x+\pi}-\frac{1}{x-\pi}+\frac{1}{x+2 \pi}+\frac{1}{x-2 \pi}-\frac{1}{x+3 \pi}-\frac{1}{x-3 \pi}+\ldots$
By reselving $\frac{\cos (x+y)}{\cos x}$ into factors we should obtain in a similar manner the sericg
$\tan x=\frac{2}{\pi-2 x}-\frac{2}{\pi+2 x}+\frac{2}{3 \pi-2 x}-\frac{2}{3 \pi+2 x}+\frac{2}{5 \pi-2 x}-\frac{2}{5 \pi+2 x}+\cdots$.(29), and thence

$$
\sec x=\tan \left(\frac{\pi}{4}+\frac{x}{2}\right)-\tan x=\frac{2}{\pi-2 x}+\frac{2}{\pi+2 x}-\frac{2}{3 \pi-2 x}
$$

$$
-\frac{2}{3 \pi+2 x}+\cdots
$$

These four formulay may also be derived from the product formulme for $\sin x$ and $\cos x$ by taking logarithms and then differentiating. Glaisher has proved them by resolving the expressions for $\frac{\cos x}{\sin x}$ and ${ }_{\sin x^{3} \ldots \text { as prodncts into partial fractions (see Quart. Journ. }}$ Mall., vol. xrii.). The series for cot $x$ may also be obtained by a continued use of the equation $\cot x=\frac{1}{2}\left(\cot \frac{x}{2}+\cot \frac{x+\pi}{2}\right)$ (see a paper by Dr Schröter in Schlomilch's Zeitschrift, vol. xiii.).
Series for Various scries for $\pi$ may be derived from the series (27), (28), (29), $\sigma$ derived (30), and from the series obtained by differentiating them one or more from times. For example, in the formula (27) and (28), by putting series for $x=\frac{\pi}{\pi}$ we get
cosec.

$$
\begin{aligned}
& \pi=n \tan \frac{\pi}{n}\left\{1-\frac{1}{n-1}+\frac{1}{n+1}-\frac{1}{2 n-1}+\frac{1}{2 n+1} \cdots\right\} \\
& \pi=n \sin \frac{\pi}{n}\left\{1+\frac{1}{n-1}-\frac{1}{n+1}-\frac{1}{2 n-1}+\frac{1}{2 n+1} \cdots\right\} ;
\end{aligned}
$$

If we put $n=3$, theso become

$$
\begin{aligned}
& \pi=3 \sqrt{3}\left(1-\frac{1}{2}+\frac{1}{4}-\frac{1}{5}+\frac{1}{7}-\frac{1}{8}+\ldots\right), \\
& \pi=\frac{3 \sqrt{3}}{2}\left(1+\frac{1}{2}-\frac{1}{4}-\frac{1}{5}+\frac{1}{7}+\frac{1}{8} \ldots\right) .
\end{aligned}
$$

By differentiating (27) we get

$$
\operatorname{cosec}^{2} x=\frac{1}{x^{2}}+\frac{1}{(x+\pi)^{3}}+\frac{1}{(x-\pi)^{2}}+\frac{1}{(x+2 \pi)^{2}}+\frac{1}{(x-2 \pi)^{2}}+\ldots,
$$

fut $x=\frac{\pi}{6}$, and we get $\pi^{2}=9\left\{1+\frac{1}{5^{2}}+\frac{1}{5^{2}}+\frac{1}{11^{2}}+\ldots\right\}$.
These series, among otlers, were given by Glaisher (Quart. Journ. Mrath., vol. xii.).

We have $\sinh \pi x=\pi x P\left(1+\frac{x^{2}}{n^{2}}\right)$, $\cosh \pi x=P\left(1+\frac{x^{3}}{2 n+11^{2}}\right)$; if we differentiate these formulæ after taking logarithms, we obtain the series

$$
\begin{aligned}
& \frac{\pi}{2 x} \operatorname{coth} \pi x-\frac{1}{2 x^{2}}=\frac{1}{1^{2}+x^{3}}+\frac{1}{2^{2}+x^{2}}+\frac{1}{3^{3}+x^{2}}+\cdots \\
& \frac{\pi}{2 x} \tanh \pi x=\frac{1}{1^{2}+x^{4}}+\frac{1}{3^{3}+x^{3}}+\frac{1}{5^{2}+x^{2}}+\cdots
\end{aligned}
$$

These series were given by Kummer (in Crcllc's Journ. vol. xvii.). The sum of the more general series $\frac{1}{1^{2 n}+x^{2 n}}+\frac{1}{2^{2 n}+x^{2 n}}+\frac{1}{3^{2 n}+x^{3 n}}$ +..., has been found by Glaisher (Proc. Lord. Mruth. Soc., vol. vii.).
If in the series (12) and (13) we put $n=2 x, \theta=\frac{\pi}{6}$, we get

$$
\begin{aligned}
& \cos \frac{\pi x}{3}=1--\frac{x^{2}}{\frac{12}{2}}+\frac{x^{2}\left(x^{2}-1^{2}\right)}{\frac{14}{2}}-\frac{x^{2}\left(x^{3}-1^{2}\right)\left(x^{2}-2^{2}\right)}{\frac{16}{6}}+\ldots \\
& \sin \frac{\pi x}{3}=\sqrt{3}\left\{x-\frac{x\left(x^{2}-1\right)}{\frac{13}{13}}+\frac{x\left(x^{3}-1^{2}\right)\left(x^{3}-2^{2}\right)}{\frac{5}{2}} \ldots\right\}
\end{aligned}
$$

These series were given by Schcllbach (in Crelle's Journ.. vol. zlviii ; If in the same series (12), (13) we put $\theta=\frac{\pi}{2}, n=\frac{2 x}{\pi}$, we get $\cos x=1-\frac{4 x^{3}}{1.2 \pi^{2}}+\frac{4 x^{2}\left(4 x^{2}-2^{2} \pi^{2}\right)}{1.2 .3 .4 \pi^{4}}-\frac{4 x^{2}\left(4 x^{2}-2^{2} \pi^{2}\right)\left(4 x^{2}-4^{2} \pi^{2}\right)}{1.2 .3 .4 .5 .6 \pi^{6}}+\ldots$ $\sin x=\frac{2 x}{\pi}-2 x\left(4 \cdot \bar{x}-\frac{\left.\pi^{2}\right)}{2 \cdot}+\frac{2 x\left(4 x^{2}-\pi^{2}\right)\left(4 x^{2}-3^{2} \pi^{2}\right)}{1.2 .3 .4 \cdot 5 \pi^{5}}-\ldots\right.$
Wo have of course assuraed the legitimacy of the substitutious made. These last scries have been discussed by M. David (Bull. Soc. Jrath. de France, vol. xi.) and Glaisher (Mess. of Math., vol. vii.)
If $U_{m}$ denotes the sum of the series $\frac{1}{1^{m}}+\frac{1}{2^{m}}+\frac{1}{8^{m}}+\ldots, V_{m}$ that of the series $\frac{1}{1^{m}}+\frac{1}{3^{m}}+\frac{1}{5^{m}}+\ldots$ and $W_{m}$ that of the series $\frac{1}{1^{m}}-\frac{1}{3^{m}}$ $+\frac{1}{5^{m}}-\frac{1}{7^{m}}+\ldots$, we obtain by taking logarithms in the formalm (25) and (26)
$\log (x \operatorname{cosec} x)=U_{2}\left(\frac{x}{\pi}\right)^{2}+\frac{1}{2} U_{4}\left(\frac{x}{\pi}\right)^{4}+\frac{1}{3} U_{0}\left(\frac{x}{\pi}\right)^{6}+\ldots$,

$$
\log (\sec x)=V_{2}\left(\frac{2 x}{\pi}\right)^{2}+\frac{1}{2} V_{s}\left(\frac{2 x}{\pi}\right)^{4}+\frac{1}{3} V_{6}\left(\frac{2 x}{\pi}\right)^{6}+\ldots
$$

and differentiating these seriee we get

$$
\begin{align*}
& \frac{1}{2} \cot x=\frac{1}{2 x}-\frac{U_{9}}{\pi^{2}} x-\frac{U_{4}}{\pi^{4}} x^{3}-\frac{U_{6}}{\pi^{6}} x^{5}-\ldots \ldots \ldots \ldots . .  \tag{31}\\
& \frac{1}{2} \tan x=\frac{V_{3}}{\pi^{3}} 2^{2} x+\frac{V_{4}}{\pi^{4}} 2^{4} x^{3}+\frac{V_{0}}{\pi^{6}} 2^{6} x^{5}+\ldots \ldots \ldots \ldots \tag{32}
\end{align*}
$$

In (31) $x$ must lie between $\pm \pi$ and in (32) between $\pm \frac{1}{2} \pi \quad$ Writ. equation (30) in the form

$$
\sec x=\Sigma(-1)^{n} \frac{(2 n+1) \pi}{\left(\frac{2 n+1}{} \frac{\pi}{2}\right)^{2}-x^{3}}
$$

and expand each term of this series in powers of $x^{3}$, then we get

$$
\begin{equation*}
\sec x=\frac{2^{2} W_{1}}{\pi}+\frac{2^{4} W_{3} x^{3}}{\pi^{3}}+\frac{2^{6} I V_{5} x^{4}}{\pi^{5}}+\ldots \tag{33}
\end{equation*}
$$

where $x$ must lie between $\pm \frac{1}{2} \pi$. By comparing the series (31), (32), (33) with the expansions of $\cot x, \tan x, \sec x$ obtained otherwise, we can calculate the values of $U_{2}, U_{4} \ldots V_{2}, V_{4} \ldots$ and $W_{1}, W_{3} \ldots$ When $U_{n}$ has been found, $V_{n}$ nay be obtained from the formula $2^{n} V_{n}=\left(2^{n}-1\right) U_{n}$.

For Lord Brounker's series of $\pi$, see Squarino the Circle (rol. Conxxii. p. 435). It can be got at once by putting $a=1, \bar{b}=3$, tinued $c=5 \ldots$ in Euler's theorem $=\frac{1}{a}-\frac{1}{b}+\frac{1}{c}-\ldots . .=\frac{1}{a+} \frac{a^{2}}{b-a+} \frac{b^{2}}{c-\bar{b}}+\cdots$ farton for

Sylvester gave (Pril. Mag., 1869) the continued fraction

$$
\frac{\pi}{2}=1+\frac{1}{1+} \frac{1.2}{1+} \frac{2.3}{1+} \frac{3.4}{1+} \cdots
$$

which is equivalent to Wallis's formula for $\pi$. This fraction was originally given by Euler (Comm. Acad. Petropol., rol. xi.); it is also given by Stern (in Crelle's Journ., vol. x.).

It may be shown by means of a transformation of the series for Con. $\cos x$ and $\frac{\sin x}{x}$ that $\tan x=\frac{x}{1-} \frac{x^{3}}{3-} \frac{x^{2}}{5} \frac{x^{3}}{7-} \ldots$ This may be ulso tinued easily shown as follows. Let $y=\cos \sqrt{x}$, and let $y^{\prime}, y^{\prime \prime} \ldots$ denote for trigo the differential coefficients of $y$ with regard to $x$, then by forming nometrithese we can show that $4 x y^{\prime \prime}+2 y^{\prime}+y=0$, and thence by Leibnitz's tions. theorem we have

$$
4 x y^{(n+2)}+(4 \pi+2) y^{(n+1)}+y^{(n)}=0 .
$$

Therefore $\frac{y}{y^{\prime}}=-2-\frac{4 x}{y^{\prime} / y^{\prime \prime \prime}} \frac{y^{(n)}}{y^{(n+1)}}=-2(2 n+1)-\frac{4 x}{y^{(n+1) / y^{(n+2)}}}$;
hence $\quad-2 \sqrt{x} \cot \sqrt{x}=-2-\frac{4 x}{-6-} \frac{4 x}{-10-} \frac{4 x}{-14-} \ldots$
Replacing $\sqrt{x}$ by $x$ we have $\tan x=\frac{x}{1-} \frac{x^{2}}{3-} \frac{x^{2}}{5-} \ldots$
Eeler gave the continued fraction
$\tan \pi x=\frac{n \tan x}{1-} \frac{\left(x^{2}-1\right) \tan ^{2} x}{3-} \frac{\left(n^{2}-4\right) \tan ^{2} x}{5-} \frac{\left(n^{2}-9\right) \tan ^{2} x}{7-} \ldots$,
this was published in Mérn. de $T_{\text {' } A c a d \text {. de St Petersb., vol. vi. }}^{\text {Nis }}$ Glaisher has remarked (Mess. of Math., vol.v iv') that this may be derived by forming the differential equation

$$
\left(1-x^{0}\right) y^{(m+2)}-(2 m+1) x y^{(m+1)}+\left(n^{3}-m^{2}\right) y^{(m)}=0
$$

Where $y=\cos (n \operatorname{arc} \cos x)$, then replacing $x$ by $\cos x$, and proceeding as in the former caso. If we put $n=0$, this becomes

$$
x=\frac{\tan x}{1+} \frac{\tan ^{2} x}{3+} \frac{4 \tan ^{2} x}{5+} \frac{9 \tan ^{2} x}{7+} \ldots
$$

Whence we have

$$
\arctan x=\frac{x}{1+} \frac{x^{2}}{3+} \frac{4 x^{2}}{5+} \frac{9 x^{3}}{7+} \ldots+\frac{n^{2} x^{3}}{2 \pi+1+} \ldots
$$

It is possible to make the investigation of the properties of the simple circular functions rest on a purely analytica basis. The sind
of $x$ would be defined as a function such that, if $x=\int_{0}^{y} \frac{d y}{\sqrt{1-y}}$, then $y=\sin x$; the quantity $\frac{\pi}{2}$ would be defined to be the complete integral $\int_{0}^{1} \frac{d y}{\sqrt{1-y^{2}}}$. We chould then have $\frac{\pi}{2}-x=\int_{0}^{1} \frac{d y}{\sqrt{1-y^{2}}}$. Now change the pariable in the integral to $z$, where $y^{2}+z^{2}=1$, we then have $\frac{\pi}{2}-x=\int_{0}^{x} \frac{d z}{\sqrt{1-z^{2}}}$, and $z$ must be defined as the cosine of $x$, and is thus equal to $\sin \left(\frac{\pi}{2}-x\right)$, satisfying the equation $\sin ^{2} x+\cos ^{2} x=1$. Next consider the differential equation

$$
\frac{d y}{\sqrt{1-y^{2}}}+\frac{d r}{\sqrt{1-z^{2}}}=0
$$

This is equivalent to

$$
d\left(y \sqrt{1-\frac{z^{3}}{2}}+z \sqrt{1-y^{2}}\right)=0
$$

hence the integral is

$$
y \sqrt{1-z^{2}}+z \sqrt{1-y^{2}}=\text { a constant. }
$$

The constant wiu he equal to the value $u$ of $y$ when $z=0$;
whence
$y \sqrt{1-z^{2}}+z \sqrt{1-y^{2}}=u$.

The integral may also be obtained in the form
Let $\quad \alpha=\int_{0}^{y} \frac{y z-\sqrt{1-y^{2}} \sqrt{1-z^{n}}=\sqrt{1-u^{2}}}{\sqrt{1-y^{2}}}, \quad \beta=\int_{0}^{2} \frac{d r}{\sqrt{1-z^{2}}}, \quad \gamma=\int_{0}^{u} \frac{d u}{\sqrt{1-u^{2}}} ;$
we have $\alpha+\beta=\gamma$, and $\sin \gamma=\sin \alpha \cos \beta+\cos \alpha \sin \beta$,
$\cos \gamma=\cos \alpha \cos \beta-\sin \alpha \sin \beta$,
the addition theorams. By mesns of the addition theorems and the values $\sin \frac{\pi}{2}=1, \cos \frac{\pi}{2}=0$ we cen prove that $\sin \left(\frac{\pi}{2}+x\right)=\cos x_{1}$ $\cos \left(\frac{\pi}{2}+x\right)=-\sin x ;$ and thence by another use of the addition theorems that ain $(\pi+2)=-\sin x \cos (\pi+x)=-\cos x$, from whick the periodicity of the functions $\sin x, \cos x$ follows.
We have also $\int \frac{d y}{\sqrt{1-y^{2}}}=-t \log _{z}\left(\sqrt{1-y^{3}}+t y\right)$;
whence $\log _{e}\left(\sqrt{1-y^{3}}+t y\right)+\log _{e}\left(\sqrt{1-z^{2}}+t z\right)=$ a constant.
Therefore $\quad\left(\sqrt{1-y^{2}}+(y)\left(\sqrt{1-z^{2}}+t z\right)=\sqrt{1-u^{2}}+t u\right.$,
eince $u=y$ when $z=0$; whence we have the equation
$(\cos \alpha+\iota \sin \alpha)(\cos \beta+\iota \sin \beta)=\cos (\alpha+\beta)+\iota \operatorname{in}(\alpha+\beta)$,
from which De Moirre'e theorem followe.
(E. W. H.)

TRILOBITES. See Crustacea, pol. vi. p. 659 sq.
TRLNCOMALEE, a town and naval station in the island of Ceylon, is situated on the north-east coastwhich is bold, rocky, and picturesquely wooded-by road 113 miles north-north-east of Kandy, in $8^{\circ} 33^{\prime \prime} 30^{\prime \prime}$ N. lat. and $81^{\circ} 13^{\prime} 10^{\prime \prime} \mathrm{E}$. long. It, is built on the north side of the Bay of Trincomalee, on the neck of a bold peninsula separating the inner from the outer harbour. There is a lighthouse on the extremity of Foul Point at the southern side of the bay, and another on the summit of Round Island. The inner harbour is landlocked, with a safe anchorage and deep water close to the principal wharyes; the outer harbour has an area of about 4 square miles, with a depth of about $\tau 0$ fathoms. There is an admiralty dockyard, and the town is the principal naval station in the Indian seas. The breadth of the streets and esplan. ades samewhat atones for the mean appearance of the houses, but the town generally bas a gloomy and impoverished aspect. Pearl oysters are found in the lagoon of Tambalagam to the mest of the bay. The Government buildings include the barracks, the public offices and residences of the civil and naval authorities, and the official house of the officer commanding-in-chief in the Indian seas. There is an hospital and outdoor dispensary, and aiso a friend-in-need society. The population of Trincomalee in 1881 was $10,180$.
The town was one of the earliest settlements of the Malabar race in Ceylon, who at a very early period erected on a height at the extremity of the peninsula, now crowned by Fort Frederick, a temple dedicated to Konatha, or Konasir, named the "temple of a thousand columns."r The building was desecrated and destroyed in 1622, when the town wes taken hy the Portnguese, who made nse of the materials for the erectiou of the fort. The town was successively held by the Dutch (1639), the French (1673), the Dutch (167t), the French (1782), and the Dutch (1783). After a siege of three weeks it aurrendered to the British fleet in 1745, and with other Dutch possessions in Ceylon was formally ceded to Great Britain by the treaty of Amiens in 1801. Its fortificatiuns have lately been strengthened.

TRLNLDAD, a West Indian isiand, lying nortb-east of Fenezuela, between $10^{\circ} 3^{\prime}$ and $10^{\circ} 50^{\prime} \mathrm{N}$. lat. and $61^{\circ} 39^{\prime}$ and $62^{\circ} \mathrm{W}$. long., being the most southern of the chain of islands separating the Atlantic from the Caribbean Sea. Its area is 1754 square miles, or nearly $1,123,000$ acres. In shape the island is almost rectangular, but from its north-west and south-west corners project two long horns towards Venezuela, eaclosing the Gulf of Paria. The north-west horn terminates in several islands, in one of the channels between which (the Boca Grande) lies the small British island of Patos. The general aspect of Trinidad is lerel. But three parallel ranges, varying from 600 to 3100 feet in height and clothed with forests, rud from
east to mest. The plains are matered by numerous streams, and the mountains are deeply furrowed by innumerable ravines. The rivers falling into the gulf are somewhat obstructed by shallows, especially the Caroni and the Coura. Geologically, as well as botanically acd zoologically, Trinidad differs little from the adjacent mainland, with which at one time it probably was connected. .The soil, which is

Map of Trinided.
fertile, consists of clay, loam, and alluvial deposits. The Moriche palm and mountain cabbage, as well as the cedar and the balata, are prominent objects. Poisonous and meaicinal plants grow everywhere, and the woods contain an inexhaustible supply of timber: There are two mineral springs. The most curious natural feature of the island is the pitch lake ${ }^{1}$ in La Brea, 90 acres in extent, which furnishes an important export. The climate is healthy, the mean temperature belng in January $76^{\circ}$ Fahr, and in Soptember $79^{\circ}$; it occasionally reaches $90^{\circ}$.

The population, which numbered 109,638 in 1871 , was retarned in 1881 at 153,128 ( 83,716 males and 69,412 females), and in 188 d at 171,914. Of these about 100,000 aro matives of the island, prind cipally of African race, 50,000 are coolies introduced from lndid (an industrious and prosperous element of the population), whild the remainder includes the English and other European settlers. About 2000 coolies are introduced annually. Many French families from other parts of the West Indics settled in Trinidad many years ago, and traces of this and of the Spanish occupation are obvions in laws, municipal arrangements, language, and population. The two priacipal towns aro Port of Spain and San Fernando. The former ( 34,000 inhabitants), the capital of the island, is built on a gently inclined plain near the north-east angle of the Gulf of Paria,
${ }^{1}$ This is vividly described by Charles Kiogsley in At Lass..
and is a fine and eafo port. In the town there are two cathedrale (the Roman Catholic and the Anglican), and eutside it a botanical garden. San Fernando, ebout 30 milea southward, with a population of 7000 , is sn important shipping place.
Of the total area about 300,000 acres are cultivated. The principal productions of the island are sugar and cocoa; coffee is also becoming inportant. Trinidad has suffered much from the effect of foreign etate bonntiee, especially the export premiuns of Germany and France. The eugar production in 1871 was E3,000 tons, in 188144,000 toдs, and in 188564,000 tons. The principal exporta in 1885 were-sugar, 64,000 tons (valne £684,675); rum, 72,525 galla. (£7878) ; molasses, 2,416,761 galla. (£45,835); cocoa, $14,904,840 \mathrm{lbs}$. ( $£ 421,974$ ) ; coffee, $20,270 \mathrm{lba}$; asphalt, 28,505 tona raw "and 6731 tons boiled; cocoa-nuts, $9,645,700$; bitters (Angostura and othora) end liquors, 32,240 galla. ; the total value was $£ 2,246,664$, including $£ 707,421$ вpecio and bullion. The imports in 1885 (including bullion and specie) were $£ 2,241,478$. Among the principal itoms are cottons, linens, woollens, and textiles generally (largely from the United Kingdom), £235, 895 ; fiah, flour, and provisions (principally from the United States), $£ 270,000$; lumber (from Canada), $£ 43,075$; rice (half from India), £113,940: hardware and machinery (principally from the United Kingdome, £116,894; gold (principally from Venezuels in tranait), £651,398. The sailing reasela entering Trinidad ports in 1885 had a burden of 150,219 tons, the stesmers a burden of 385,950 tons. The total public revenue in 1885 was $£ 429,307$, of which $£ 240,444$ was for customa and excise. The tetal expenditure was $£ 443,920$. There are 145 public schoola, of which 61 are Government and 61 assistad, with a total attendance of 13,282 scholara. The priacipal towna are connected by railway lines.

Trinidad was discovered by Columbus on 31et Jnly 1496. It remained in Spanish possession (although its principal town, San José de Oruüa, was burnt by Sir Walter Raleigh in 1595) nntil 1797, when a Britiah expedition from Martinique caused its canitu: lation, and it was fimally, ceded to Great Britain in 1802 by the treaty of Amiens. Ita real starting-point as a productive country was in 1781, when the Madrid Govermment hegan to attract forcigu immigrants Trinidsd is otill strictly a crown colony of Great Britain. The legislative council includes the governor as president, and six official and eight unofficial memberb, all appointed by the crown. During the labour crisis caused by omancipation and the aubsequent equalization of the British duties on free and slavesrown augar, the colony was greatly assisted by the ekilful administration of Lord Harris, governor from 1846 to 1851.
See De Verteuil, Trintdad; Colontal ofice List; Guppy, Trindiad Almanao; and Government Genlogical Survey.
TRINITARIANS (Ordo Sancto Trinitatis et Captorum), a religious order instituted about the year 1197 by Innocont III., at the instance of John de Matha (1160-1213) and Felix de Valois (ob. 1212), for the ransom of captives among the Moors and Saracens. The rule was the Augustinian, the dress white with a red and blue cross. De Matha was the first general and De Valois the first abbot of the mother house at Cerffroid near Meaux, where the idea of the institution had originated in a miraculous apparition. By 1200 as many as 200 Christians had been redeemed out of slavery in Morocco by the order, which accordingly spread rapidly not only in France but also in Italy and Spain. Further favoured by Honorius III. and Clement IV., the Trinitarians epread into Portugal, the United Kingdom, Bohemia, Saxony, Poland, and Hungary, and even into America. In the 18 th century they had in all about 300 houses; but the order is now almost extinct. . About the middle of the 17 th century it was stated that in France the "redemptions" up to that time had numbered 246 , the number of prisoners bought off being 30,720 ; for Castile and Leon the corresponding figures were 362 and 11,809. The order is sometimes spoken of as the "ordo asinorum" from the circumstance that originally its members were not permitted to use any other beast of burden. - In France they were known as Mathurins from the chapel of St Mathurin or Mathelin in Paris, which belonged to them.
TRINITY hoUSE, Corporatien of. An association of Euglish mariners, which originally had its head-quarters at Deptford in Kent. In its first charter, received from Henry VIII. in 1514, it was described as the "guiid or fraternity of the most glorious and undividable Trinity of Sit Clement," the court being made to consist of master,
wardens, and assistants, numbering thirteen in all and elected annually by the brethren. Deptford having been made a royal dockyard by Henry VIII., and being the station where outgoing ships were supplied with pilots, the corporation rapidly developed its influence and usefulness. By Henry VIII. it was entrusted with the direction of the new naval dockyard. From Elizabeth, who conferred on it à grant of arms in 1573, it received authority to erect beacons and other marks for the guidance of navigators along the coasts of England. It was also recognized as the authority in the construction of vessels for the royal nary. In 1604 a select class was constituted called elder brethren, the other members being called, younger brethren. By the charter of 1609 the sole management of aftairs was conferred on the elder brethren, the younger brethren, however, having a vote in the election of master and wardens. The practical duties of the fraternity are discharged by the acting elder brethren, who have all had experience in naval affairs; but hs a nark of honour persons of rank and eminence are admitted as elder brethren and now form a large proportion of the members. In 1647 the corporation was dissolved by parliament, but it was reconstructed in 16.60, and the charter was renewed by James II. in 1685. A new hall and almshouses were erected at Deptford in 1765; but for some time the offices of the corporation had been transferred to London, and in 1798 their headquarters were removed to Trinity House, Tower Hill, built from the designs of Wyatt. By an Act of 1836 they received powers to purchase from tho crown, as well as from private proprietors, all interests in coast lights. For the maintenance of lights, buoys, \&c., they had power to raise money by tolls, the ourplus being devoted to the relief of old and indigent mariners or their near relatives. In 1853 the control of the furds collected by the corporation was transferred to the Board of Trade, and the money over which the brethren were allowed independent control was ultimately reduced to the private income derived from funded and trust property. Their practical duties in the erection of lighthouses, buoys, and beacons remain as important as ever, the number of persons employed in their service being over 800 . They also examine navigating lieutenants in the royal navy, and act as nautical advisere in the High Court of Admiralty.
TRINITY SUNDAY, which immediately follows Whitsunday, was in the older liturgies regarded merely as the "Octave" of Pentecost. The habit of keeping it as a distinct festival seems to bave sprung up about the 11th century. According to Gervaso of Canterbury, it was Thomas Becket whe introduced it into England in 1162. The universal enservance of it was established by Pope John XXII. in 1334.

TRIPOLI, a North African state, bounded by the Mediterranean on the north, by the desert of Barca (or Libyan Desert), which separates it from Egypt, on the east, by the Sahara and Fezzan on the south-east, south, and south. west, and by Tunis on the north-west. The country is made up of a strip of fertile soil adjacent to the sea, with vast sąndy plains and parallel chains of rocky mountains, which finally join the Atlas range near Kairwán in Tunis. It is naturally divided into five parts, viz.,-Tripoli proper, to the north-east of which is the plateau of Barca and Jebel al-Akhdar, to the south the oasis of Fezzan, to the south-east that of Aujala, and to the south-west that of Ghadames. ${ }^{1}$ It is very badly watered: the rivers are

[^243]small and the desert wells and watering places are often dry. As regards the coast, it is extremely difficult to fix the exact border between Egypt and Tripoli. The seaboard of the Libyan Desert is so little known to Europeans that the spacious harbours of Tebruk (Tabraca and Tabarka) and Bomba (Bombæa) have almost escaped notice. The land bordering the sea to the west of Cape Rás al-Tín does not partake of the sterile character of the wastes of Barca. The district of Jebel al-Akhdar ("the Green Mountain"), which intervenes between Rás al-Tín and Bengházi, abounds in wood, water, and other resources; but its ports are scarcely worthy of the name, except Derna (Darnis), where vessels from Alexandria call to embark honey, wool, and wax. From Mersí Suza (Apollonia, later Sozusa), now a mere boat cove, but once a powerful city of Cyrenaica, to Bengházi the coast abounds in extensive ruins. Benghazi itself, on the Bay of Sidra (Syrtis Major), is an insignificant fortified town trading in cattle and other produce. The principal products of the country are corn, barley, olives, saffron, figs, and dates, -these last being perhaps the finest in the whole of North Africa. Fruitalso is abundant in certain parts, and so are many kinds of vegetables. The horses and mules, though small, are capable of much hard work. The native tissues and pottery are almost as good as those of Tunis. Great quantities of castor oil come from Tadjura. In consequence of recent events in Tunis, Tripoli has become the last surviving centre of the caravan trade to Northern Africa. It is at least 250 miles nearer the great marts of the interior than either Tumis or Algiers. A large proportion of the commerce of Tripoli is in the hands of British merchants or dealers in British goods, who send cloth, cutlery, and cotton fabrics southwards and receive in return esparto grass, ivory, and ostrich feathers. The sirocco blows with great force at times during the autumn, and the heat is as a rule much greater than in Tunis. The climate is very variabie; cold nights often succeed warm days; storms are of frequent occurrence; and rain is at times wanting for many months. In addition to the capital Tripola (see below), called Tarábulus al-Gharb to distinguish it from the town of the same name in Syria, the only important places are Murzuk and Ghadámes in the interior and Bengházi (Beremice) on the coast. The population of the country consists of Moors, Arabs, Kabyles, Kuluglis (descendants of Turkish fathers and Moorish mothers), Turks, Jews, Europeans, and Negroes. Nothing like a census has ever been attempted, and the number of inhabitants is purely a matter of conjecture. In the interior the population is very scattered, and it is not probable that the total exceeds from 800,000 to a million. The Europeans ( 2500 or 3000 ) on the coast are nearly all Maltese. There is a Jewish colony of about 4000 in the capital, and the trade is almost entirely in their hands and in those of the Maltese. ${ }^{1}$
Since 1835 Tripoli has lost the semi-independent character of a regency which it formerly enjoyed in common with Tunis, and has become a vilayet or outlying province of the Turkish empira. For 1 dministrative purposes it is divided into fiva districts, which are again subdivided into twenty-five cantons, the former being governed by motasarrifs and the latter by csimscams. Esch village has its sheikh, who is assisted by a sort of municipal council. Since tha invssion of Tunis by the French, the Turkish garrison of Tripoli has been considerably reinforced, snd many now fortifcations are partially erected on the coast. The chief judga or cadi is nominated by the Porte; the muft is are subject to his authority. There sre also a criminal court, and a commercial sribunsl. The taxes are collected by a recciver-general, also nominated from Constantinople, and thay presa very heavily on all classes of the
${ }^{1}$ The best known English work on Tripoli is F. W. and H. W. Beechey's Proceedings of the Expedition to Expiore the Northepn Coast of Africa from Tripoli Eastucards, London, 1828: Admirsl W. H. Smyth's Mediterranean, London, 1854, contains a description of the coast. See slso Rie, Country of the Moors, London, 1877, snd Broad. ley, Tunis Past and Present, London and Edinburgh, 1882.
inhabitants. The principal sources of revenue are the ususl Mohammeden taxes. The constant succession of Turkish governors, each of whom invariably follows a different policy from that of his predecessor, has been fatal to the mstcrial progress of the conntry. There sre few elementary schools in the capital, and instruction in the interior is entirely limited to the Korsn.

Mistory.-After falling-successively iuto tha hsnds of the Phoenicians, Romans (a foursided trimplial arch, erected in honour of Aurelius Antoninus and Aurelims Yius, still stands near the Marina gate), Vandals, snd Greeks, Tripoli was finally conquered by tha Araba twelva centurica ago, aud hss remained a Moslem state ever since. lu 1510 Ferdiuand the Catholic of Spain took it, and thirteen years later it was given to the Knights of St John, who were expelled in 1553 by the I'urkish corsairs Dragut and Sinan. Dragut, who afterwards fell in Malta, lies buried in a much venerated fiubba close to one of the mosques. After his decease the conmaxion between Tripoli and Constantinople seema to have been considerably weakened. But the Tripolitsn pirates soon becam 3 the terror and scourge of the Mediterrancan; half the states of Europe seem at soma time or other to hsve sent their fleets to bombard tha capital. In 1714, when Hosain ibn "Ali founded the present line of the beya of Tunis, ${ }^{2}$ Ahmed Pasha Caramanli achieved independence, and his descendanta governed Tripoli until 1835. In that year the Turks took advantage of a civil war to reassert their authority, snd since that date Tripoli has been governed by representatives of the sultau.

The khouan (ikhwan) or semı-religious semi-political fraternities which exercise such considerable influence in Tunis, Algeria, and Morocco are perhaps still more powerful in Tripoli. The most ramarkable is that of the Senuisiya, the centra of whose authority is Jaghbub or Jerabuh, north-west of the oasis of Siws. The sectaries of Senuisiga are found in all parts of North Africa, but exist in unusual force in Tripoli, and particularly iu Ghadsmes and Murzuk. A. certain halo of romance surrounds the history of this powerful sect; but its chief has, up to the present time (1887), not played any conspicuous part in tha"affairs of the Soudsn. or in those of the North African littorsl. Mohemmed el-Senuei came originally in 1830 from Mostaghánem in Algeria. He acquired a high reputation for sanctity at Fez in Morocco. After a visit to Mecca and the holy places he started a záwiya or convent-college at Alexandria, but, being excommunicated hy tha sheikh al-Islam at Csiro, he fled across the Libyan Desert to the Jebel al-Akhdar near Bengházi. He afterwards removed to Jaghbub, which has never been visited by any European trsveller. Here he estsblished his záwiys in the midst of palm-groves and soon gathered nesrly a thousand followera. His sustere doctrines are received with enthusiasm in tha Moslem statea of Northern and Centrsl Africa. He established some one hundred sanctuaries in every considerable place between Morocco and Mecca, snd appointed muksddemin or fieutenants in naarly every part of Islam. Senusi the elder died in 1860 and wss succeeded by his son, who bore the title of AlMshdi. Under bis rule the prosperity of the záwiya st Jersbub is said to have grestly increased. Pilgrims to Mecca from North Africa, as well as those coming from Bornou and the Salisran provinces, flock there to seek his blessing. He not only receives caravans of ivory snd ostrich feathers from tha different sultans of the interior, but cargoes of arma and ammunition often srrive for him at the almost unknown harbours of the coast. Rohlts, Dachtigal, and Duveyrier found their passage barred by Senusian agents. It was confidently expected Senusif would make eome demonstration at the beginning of the 14 th century of the Hijrs (November 1882). His followers were, however, doomed to disappointment. Most of the Tripolitan sheikhs are affliated to the Sentisiya confrateruity.

From an archæological point of view Tripoli possessea an interest equal to, if not greater than, that which attaches to Tunis. On this subject the fullest information is afforded by the book of the Beecheys, and in a less degree by that of Mr Rae. Tha former is illustrated by numerous plans and engravings and still affords the safest guide to the antiquities of Tripoli.

TRIPOLI, the capital of the above country, is situated in $32^{\circ} 53^{\prime} 40^{\prime \prime} \mathrm{N}$. lat. and $13^{\circ} 11^{\prime} 32^{\prime \prime} \mathrm{E}$. long., on a promontory stretching out into the Mrediterranean and forming a small bay. Its crenellated enceinte wall has the form of an irregular pentagon. A line of small half-ruined forts is supposed to protect one side of the harbour, and the castle of the governor the other. The desert almost touches the western side of the city, while on the east is the verdant oasis of Meshiga, where are still to be seen the tombs of the Caramanlian sultanas and the twelvc-domed marabout of Sy Hamod da. In the town itself there are seven
${ }^{2}$ The Letters (London, 1819) of Richard Tully, who was consal at Tripoli from 1783 to 1793 , throw s strange and vivid light on Tripolitan life during the 18 th cantury.

## TRI-TRI

principal mosques, six of them possessing lofty minarets in the Turkish style. The atreets are narrow, dirty, and unpaved; there is no European quarter properly so called : Tripoli is still a typical Moorish city. Its population numbers about 20,000.

TRIPOLI (Tarabulus), a town of Syria, capital of Liwā, on the river Kadisha or Abu ' Al , in $34^{\circ} 26^{\prime} \mathrm{N}$. lat. and $35^{\circ} 50^{\prime}$ E. long., is situated in a fertile maritime plain covered with orchards and dominated by a castle over: hanging a gorge of the river, some parts of which are, perhaps, the work of the crusaclers. The port (Al-Miná) is about two miles distant, on a small peninsula. The population is estimated at 17,000 , with the port at 24,000 or a little more. Nearly half of these are Christians, the Maronites preponderating. There is a considerable export of silk cocoons and a native silk manufacture; the sponge fishery is a large industry; tobacco is exported; and soap is made from the olive oil of the district. There are eighteen churches, and several monasteries, nunneries, and large kháns.

The ancient Phœenician city which we know only by its Greck name of Tripolis was the seat in Persian times of the federal council of Sidon, Tyre, and Aradus, each of which cities had its separate quarter in the "triple town" (see vol. xviii. p. 809). In the second and first centuries B.o. it struck coins, on which it is designated a "holy and autonomons" city. These are succeeded by imperial coins ranging from 32 B.c. to 221 A.D. About 450, and again in 550, it was destroyed by earthquake. The Arabs took it in 638 after a prolonged siege, the inhabitants withdrawing by sea. It appears from Beladhori (p. 127) tbat at this time the city still consisted of three fortified places. Mo'áwiya recruited the population by a colony of Jews and gave it fortifications and a garrison sgainst the nsval attacks of the Greeks, who, notwith. otanding, retook it for a brief space in the time of Abdalualik (Beladh., ut sup.). It was again taken by the Greeks in the war of $966-69$ and was besieged by Basil II. in 995, after which date it was held by a garrison in the pay of the Fatimite caliphs of Egypt, who treated the city with favour and maintained in it a trading fleet. At this time, according to the description of Násiri Khosazau (ed. Schefer, p. 40 sqq.), who visited it in 1017, it lay on the peninsula of Al-Mina, bathed on three sides by the sea, and had about 20,000 inhahitants and important industries of sugar and paper-makiug. Of the great sea-walls and towers thero are atill imposing remains. From this date till it was taken by the crusaders, after a fire years' siege, in 1109, the ruling family was that of 'Ammã", who founded a library of over 100,000 volumes. Under the crusaders Tripoli continued to flourish, exported glass to Venice, and had 4000 looms (Quatremère, IIist. des Sultans Mamlouks, ii. 103). In 1289 it was taken and destroyed by the sultan Kalaún of Egypt, and a new city was begun on the present site, which rapidly row to importance (Ibn Batúta, i. 137). Its medixval prosperity has obliterated most relics of remoter antiquity. See Renan, Mission de Phenicie, p. 129 sqq.
TRIPOLITZA, officially Tripolis, a town of Greece, capital of the nomarchy of Arcadia, is situated in a plain 3000 feet above sea-level, 22 miles' south-west of Argos. The name has reference to the three ancient cities of Mantinea, Pallantinm, and Tegea, of which Tripolitza is the modern representative. Before the war of independence it was the capital of the Morea and the seat of a pasha, with about 20,000 inhabitants; but in 1821 it was taken and sacked by the insurgents, and in 1825 its ruin was completed by Ibrahim Pasha. The town has since been rebuilt, and now (1887) contains about 10,000 inhabitants.

TRISMegistus. See Hermes Trismegistus.
TRISTAN. Sce Romance, vol. xx. p. 644 sq.
TRISTAN DA CUNHA, a group of three small volcanic islands, situated in the South Atlantic nearly midway between the Cape of Good Hope and the coast of South America, the summit of the largest being in $37^{\circ} 5^{\prime} 50^{\prime \prime} \mathrm{S}$. lat. and $12^{\circ} 16^{\prime} 40^{\prime \prime} \mathrm{W}$. long. They rise from the low submarine elevation which runs down the centre of the Atlantic and on which are likewise situated Ascension, St. Paul's Rocks, and the Azores; the average depth on this ridge is from 1600 to 1700 fathoms, while depths of 3000 fathoms are found on each side of it. The depth between
the islands is in some places over 1000 fathoms. Tristan, the largest and northernmost island, is nearly circular in form, about 7 miles in diametcr, with a volcanic cone in the centre ( 7640 feet). Precipitous clifis, 1000 to 2000 feet in height, rise directly from the ocean on all sides, except on the north-west, where there is an irregular plain, 100 fect above the sea, and $2 \frac{1}{2}$ miles in length and $\frac{1}{2}$ mile in breadth. The crater of the central cors is said to be filled with a freshwater lake which never freezes. Inaccessible Island, the westernmost of the group, is about 20 miles from Tristan. It is quadrilateral in form, the sides being about 2 miles long. The highest point ( 1840 feet) is on the west side; all round there are perpendicular cliffs 1000 feet in height. At the base of these are in some places narrow fringes of beach a few feet above the sear level. Nightingale Island, the smallest and most southern of the group, is 10 miles from Inaccessible Island. Its coasts, unlike those of the other two islands, are surrounded by low cliffs, from which there is a gentle slope up to two peaks, the one 1100 feet, the other 960 feet high. There are two small islets-Stoltenkoff (325 feet) and Middle ( 150 feet)-and several rocks adjacent to the coast. The rocks are feldspathic basalt, dolerite, augite-andesite, sideromelane, and palagonite; some specimens of the basalt have porphyritic augite. The caves in Nightingale Island indicate that it has been elevated several feet. On almost all sides the islands are surcounded by a broad belt of kelp, the gigantic southern sea-weed (Macrocystis pyrifcra), through which a boat may approach the rocky shores even in stormy weather. There is no good or safe anchorage. The beaches and lower lands are covered with a dense growth of tussock grass (Spartina arundinacea), 8 to 10 feet in height, which shelters millions of penguins (Eudyptes chrysocoma), which there form their rookeries. There is one small tree (Phylica nitida), which grows in detached patches on the lower grounds. Independently of introduced plants, fifiy-five species have been collected in the group, twenty-nine being flowering plants and twenty-six ferns and lycopods. A majority of the species are characteristic of the present general flora of the south temperate zone rather than any particular part of it: botanically the group is generally classed with the islands of the. Southern Ocean. A finch (Nesospiza acunhx), a thrush (Nesocichla eremita), and a water hen (Gallinula nesiotis) are the only land birds-the first two being peculiar to the islands. In addition to the penguins numerous other sea birds nest on the islands, as petrels, albatrosses, terns, skuas, and prions. One or two land shells, a few spiders, several Coleoptera, a small lepidopter, and a few other insects are recorded, but no Orthoptera or Hymenoptera. The prevailing winds are westerly. December to March is the fine season. The climate is mild and on the whole healthy, the temperature averaging $68^{\circ}$ Fahr. in summer, $55^{\circ}$ in winter, - sometimes falling to $40^{\circ}$. Rain is frequent; hail and snow fall occasionally on the lower grounds. The sky is usually cloudy. The islands have a cold and barren appearance The tide rises and falls about four feet.

The islands were discovered and named by the Portugnese in 1506. The Dutch described them in 1643. D'Etcheverri landed on them in the year 1767, when he gave Nightingale and In. accessible Islands their names. Their exact geographical position was determined by Captain Denham in 1852, and the "Challenger" completed the exploration of the group in 1873. When first discovered the islands were uninhabited. Towards the end of the 18th and in the beginning of tho 19th century several sealers resided on them for longer or shorter periods. In 1816 the islands were taken possession of by Great Britaid. In 1817 the garrison was withdrawn, but Corporal William Glass, his wife and family, and two men were sllowed to remain. This small colony received additions from time to time from shipwrecks, from whalers, snd from the Cape of Good Hope. In 1826 there were 7 men and 2 women

besides children. In 1873 there were 84 inhabitants, in 188697. They possess cattle, shecp, and gecse. There are usually good potato crops. Tho settlement has always been on the flat stretch of land on the north-west of Tristan, and is called Edinburgh. Two Germans lived for several years on Inaccessible Island, but with this exception there have been no settlements either on this or on Nightingale Island.
TRITON. The genus Triton was constituted by Laurenti, in his Synopsis Reptilium, and the uame was adopted by nearly all writers on Amphibia. In Brit. Ifus. Cat.: Batraehia Gradientia, by G. A. Bonlenger, the genus is expanded and called by the name Afolge, which was used by Merrem in his Tentamen Syst. Amphibia, 1820. The genus belongs to the division Mecodonta of the family Salamandrida in Strauch's classification (see Amphibia, vol. i. p. 771). The definition of Molge given by Boulenger, which closely agrees with that of Triton adopted by Strauch, is as follows. Tongue free along the sides, adhcrent or somewhat free posteriorly. Palatine teeth in two straight or slightly curved series. Fronto-squamosal arch prescnt (except in M. cristatus), ligamentous or bony. Toes five. Tail compressed. In Bell's British Reptiles, 2d ed., 1849, four species were described as occurring in Britain. According to Boulenger, there are cnly three British species, Molge cristata, Boul. (Laurenti), Mf. vulgaris, Boul. (Linn.), and M. palmata, Boul. (Schncider). We give a short account of these under the names Triton eristatus, T. eulgaris, and T. palmatus respectively.
The name Triton cristatus for the first spccies has been resed by a graat number of authoritativo writers on Annphibia, including Laurenti, Tschudi, Bonaparte, Duméril and Bibron, and Strauch, and also by Bell and Fleming among stulents of British fauna. ${ }^{1}$ The diagnosis of $T$. cristatus is as follows:-The males have a dorssl crest which is toothed ; the fron to-squamosal arch is absent ; the colour of the ventrsi surface is orange with black spots. This species is commonly known as the great water-newt. The avcrage length of the adult is 6 inches. The colours are mest brilliant in the male, and more dercloped in the breeding season-spring and summer-than in winter. The back is blackish or yellowish brown, with round black spots; the sides of the tail are white. The dorsal crest of the malo is separated entircly from the tail crest, and both disappear in winter. The skin is covered with warty tubercles. There are no parotids; hut glandular pores are present over the eyes and in a longitudinal series along each sidc. The spectes is pretty common in ponds and ditches in most parts of Britain, but more abundant in the south than in the north; in the neighbourhood of London it is found in great numbers. Its food consists of aquatic insecta and other small animals; in the spring it devours tho young tadpoles of the frog with avidity, and occasionally it feeds on the smaller species, T. vulgaris. In winter it hibernates, either quitting the water nnd hiding under stones or remaining torpid at the bottom of the water. It brecds chiefly in May and June. As in all Salamandrida, a true copulation takes place and the fertilization of the ova is internal. The fermale deposits each egg separately in the fold of a leaf, which she bends by means of her hird fect; the adhesive slime surrounding the vitellus keens the leaf folded. The tadpole when first hatched is much more fish-like in form than that of the frog, the body diminishing in thickness gradually to the end of the tail. A continuous median fin runs along the back from the head, round the end of the tail, along the ventral median line, to the region of the gills, thns extcnding, as in many fish larvæ, in front of the anus, The larva possesses three pairs of branched external gills, and in front of these a pair of processes by which it can adhere to fixed objects in the water. T. crislatus is abundant throughont Europe, ranging from Sweden and Russia southwards to Greece, and from Britain to the Caucasus.

The diagnosis of $T$. vilgaris, the Lissotriton punctatus of Bell, is :-Males with a dorsal crest continnons with the caudal, and festooned; belly not brillianily coloured; back spotted. This species, often called the common or small newt, has a smooth skin, no glandular pores on the sides, but two patches on the head. It is as abundant in Britain as the former, or more so, but differs somerwinat in habits, in autumn and winter being almost entirely terrestrial, and only living in water during tho breeding season. Like the former species it is carnivorous. It is found in most parts of Britain, and throughont Europe, except in the south of France, Spain, and Portugal; it also extends into temperate Asia.
T. palmatus Tschndi (Schneider), the Lissotriton yalmipes of Bell, is thus distinguished :-Nalo with dorsal crest, which is low

[^244]with an even margin and continuous with the caudal fronto. squamosal arch long; toes in male webbed. Other less distinctive features are that the back is flattened, with a raised line on each side, and the tail in the male truncate, terminating in a short slender filament. This species is not so common in Britain as the other two; it is widely distributed throughout Europe. It was first discovered in Eritain in 1843."

Boulenger recognizes nincteen species of Molge, of which nine besides those found in Britain are European. Only two species occur in America. Strauch gives twenty species.
TRIUMPH, an honour awarded to generais in ancient Rome for decisive victories over foreign enemies; for victories in civil war or over rebels a triumph was not allowed. The power of granting a triumph rested with the senate; and it was a condition of granting it that the victorious general, on his return from the war, should not have entered the city until le entered it in triumph. Lucullus on his return from Asia waited outside of Rome three years for his triumph. The triumph consisted of a solemn procession, which, starting from the Campus Martius outside the city walls, passed through the city to the Capitol. Rome was en fëte, the streets gay with garlands, the temples open. The procession was headed by the magistrates and senate, who were followed by trumpeters and then by the spoils, which included not only arms, standards, statues, \&cc., but also representations of battles, and of the towns, rivers, and mountains of the conquered country, models of fortresses, \&c. Next came the victims destined for sacrifice, especially white oxen with gilded horns. They were followed by the prisoners who had not been sold as slaves but kept to grace the triumph; they were put to dcath when the procession reached the Capitol. The chariot which carried the victorious general (triumphator) was crowned with laurel and drawn by four horses. The general was attired like the Capitoline Jupiter in robes of purple and gold borroved from the treasury of the god; in his right haud he held a laurel branch, in his left an ivory sceptre with an eagle at the point. Above his head the golden crown of Jupiter was held by a slave who reminded him in the midst of his glory that he was a mortal man. Last came the soldiers shouting Io triumphe and singing songs both of a laudatory and scurrilous kind. On reaching the temple of Jupiter on the Capitol, the general placed the laurel branch (in later times a palm branch) on the lap of the image of the god, and then offered the thank-offerings. A feast of the magistrates and senate, and sometimes of the soldiers and people, concluded the ceremony, which in earlier times lasted one day but in later times occupied several. A naval or maritime triumph was sometimes celebrated for victories at sea. Generale who were not allowed a regular triumph by the senate had a right to triumph at the temple of Jupiter Latiaris on the Alban Mount.
TRIVANDRUM, a town of India, capital of the native state of Travancore (q.v.), is situated in $8^{\circ} 29^{\prime} 3^{\prime \prime}$ N. lat. and $76^{\circ} 59^{\prime} 9^{\prime \prime}$ E long., near the coast, not far from Cape Comorin. It is the residence of the maharajah, and contains an observatory and a museum, besides several other fine buildings. Commercially it is inferior in importance to Aleppi, the trade centre of the state. In 7.881 it had a population of 37,652 .

TROAD and TROY. The Troad ( $\eta$ T Tpuás), or land of Irrey, is the north-western promontory of Asia Minor. The uame "Troad" is never used by Homer,-who calls the land, like the city, Tpoin,--but is already known to Herodotus. The Troad is bounded on the nortb by the Hellespont and the westernmost part of the Propontis, on the west by the Ægean Sea, and on the south by the Gulf of Adramyttium. The eastern limit was variously defined by ancient writers. In the widest acceptation, the Troad was identified with the whole of western and southwestern Mysia, from the Esepus, which flows into the

Propontis a little west of Cyzicns, to the Caicus, which Hows into the Ægean south of Atarueus. But the true eastern boundary is undoubtedly the range of Ida, which, starting from near the south-east angle of the Adramyttian Gulf, sends its north-wcstern spurs nearly to the coast of the "Propontis, in the region west of the Nsepus and east of the Granicus. Taking Ida for the eastern limit, we have the definition which, as Strabo says, best corresponds with the actual usage of the name Troad. Ida is the key to the physical geograply of the whole region; and it is the peculiar character which this monntain-system inuparts to the land west of it that constitutes the real distinctness of the Troad from the rest of Mysia. Nature has here provided Asia Minor with an outwork against invaders from the north-west; and as in the dawn of Greek legend the Troad is the scene of the struggle between Aganemnon and Priam, so it was in the Troad that Alexander won the battle which opened a path for his further adrance.

The length of the Troad from north to south-taking a straight line from the north-west point, Cape Sigeum (Yeni Shehr), to the sonth-west point, Cape Lectum (Babà-Calessi) -may be roughly given as forty miles. The breadih, from the middle point of the west coast to the nain range of Ida, is not much greater. The whole central portion of this area is drained by the Mendere (the ancient Scamander), which rises in Ida and is by far the most important river of the Troad. The basin of the Mendere is divided by hills into two distinct parts, a southern and a northern plain. The southern-anciently called the Samonian plain -is the great central plain of the Troad, and takes its modern name from Bairamitch, the chief Turkish town, which is situated in the eastern part of it near Ida. It is of an elongated form, the extent from north to south being large in proportion to the average width, and is enclosed by hills which, especially towards the south, are low and undulating. From-the north end of the plain of Bairamitch the Mendere winds in large curves through deep gorges in metamorphic rocks, and issues into the northern plain, stretching to the Hellespont. This is the plain of Troy, which has an average length of seven or eight miles from north to south, with a breadth of some two or three from east to west. The hills which enclose it on the south and east are quite low, and towards the east the acclivities are in places so gentle as to leave the limits of the plain somewhat indefinite. Next to the basin of the Mendere, with its two plains, the best marked feature in the riversystem of the Troad is the valley of the Touzla, the ancient Satniois. The Touzla rises in the western part of Moant Ida, south of the plain of Bairamitch, from which its valley is divided by hills; and, after flowing for many miles almost parallel with the sonth coast of the Troad, from which, at Assus, it is less than a mile distant, it enters the Ægean about ten miles north of Cape Lectun. Three alluvial plains are comprised in its course. The easternmost of these, into which the river issnes from bugged mountains of considerable beight, is long and narrow. The next is the broad plain, which is overlooked by the lofty site of Assus, and whicly was a ferite source of supply to that city. The third is the plain at the embonchure of the river on the west coast. This was anciently called the Halesian ('A $\lambda \dot{\eta} \sigma \circ \circ$ ) plain, partly from the maritime salt-works at Tragase, near the town of Harnaxitus, partly also from the bot salt-springs which exist at some distance from the sea, on the north side of the river, where large formations of rock-salt are also found. Maritime salt-works are still in operation at the mouth of the river, and its modern name (Touzla $=$ salt) preserves the ancient association. A striking feature of the southern Troad is the high and narrow plateau which
runs parallel with the Adramyttian Gulf from east to west, forming a southern barrier to the valley of the Touzla, and walling it off from a thin strip of seaboard. This plateau seems to have been formed by a volcanic upheaval which came late in the Tertiary period, and covered the limestone of the south coast with two successive flows of trachyte. The lofty crag of Assus, washed by the sea, is like a tower standing detached from this line of mountainwall. The western coast is of a different character. North of the Touzla extends an undulating plain, narrow at first, but gradually widening. Much of it is covered with the valonia oak (Quercus Rgilops), one of the most valuable products of the Troad. Towards the middle of the west coast the adjacent ground becomes higher, with steep acclivities, which sometimes rise into peaks; and north of these, again, the seaboard subsides towards Cape Sigeum into rounded hills, mostly low.
The timber of the Troad is supplied chiefly by the pine- Natura: forests on the slopes of Mount Ida. But nearly all the prodicit plains and hills are more or less well wooded. Besides the valonia oak, the eln, willow, cypress, ind tamarisk shrub abound. Lotus, galingale, and reeds are still plentiful, as in Homeric days, about the streams in the Trojan plain. The vine, too, is cultivated, the Turks making from it a kind of syrup and a preserve. In summer and antumn water-melons are among the abundant frnits. Cotton, wheat, and Indian corn are also grown. The Troad is, indeed, a country highly favoured by nature-with its fertile plains and valleys, abundantly and continually irrigated from Ida, its numerous streams, its fine west seaboard, and the beauty of its scenery. Under a good government, it could not fail to be exceedingly prosperous. Under Turkish rule, the natural advantages of the land suffice to mitigate the poverty of the soarse population, but have scarcely any positive result.
In the Homeric legend, with which the story of the Early Troad begins, the people called the Troes are ruled by a history king Priam, whose realm includes all that is bounded by "Lesbos, Phrygia, and the Hellespont" (It., xxiv. 544), i.e., the whole "Troad," with some extension of it, beyond Ida, on the north-west. According to Homer, the Achæans under Agamemnon utterly and finally destroyed Troy, the capital of Priam, and overthrew his dynasty. But there is an Homeric prophecy that the rule over the Troes shall be continued by Æneas and his descendants. From the "Homeric" Hymn to Apkrodite, as well as from a passage in the 20th book of the Iliad (75-353)-a passage undoubtedly later than the bulk of the book-it is certain that in the seventh or sisth century b.c. a dynasty claimirg descent from Æneas reigned in the Troad, though the extent of their sway is unknown. The Homeric tale of Troy is a poetic creation, for which the poet is the sole witness. The analogy of the French legends of Charlenagne warrants the supposition that an Achæan prince once held a position like that of Agamemnon. We may suppose that some memorable capture of a town in the Troad had been made by Greek warriors. But we cannot regard the Iliad in any closer or more exact sense as the historical document of a war. The geographical compactness of the Troad is itself an argument for the truth of the Homeric statement that it was once united under a strong king. How that kingdom was finally broken up is unknown. Thracian hordes, including the Treres, swept into Asia Minor from the north-west about the beginning of the seventh century b.c., ard it is probable that, like the Gauls and Goths of later days, these fierce invaders made bavoc in the Troad. The Ionian poet Callinus has recorded the terror whick they caused furthel south.
A new period in the history of the Troad bcgins with the foundation of the Greek settlements. The earliest
and most important of these were Eolic. Lesbos and Cyme in Eolis seem to have been the chief points from which the first Eolic colonists worked their way into the Troad. Commanding positions on the coast, such as Assus and Sigeum, wonld naturaliy be those first occupied; and some of them may lave been in the hands of Eolians as early as the 10 th century b.c. It appears from Herodotus (v. 95) that abont 620 b.c. Athenians occupied Sigeum, and were resisted by Kolic colonists from Mytilene in Lesb.os, who had already cstablished themselves in that neighhourhood. Struggles of this kind may help to account for the fact noticed by Strabo, that the earlier colonies had often migrated from one site in the "Troad to another. Such changes of seat have been, he observes, frequent causes of confusion in the topography; and the fact has an inportant bearing on attempted identifications of the more obscure ancient sites.

Among the Greek towns in the Troad, three stand out with especial prominence-Ilium in the north, Assus in the south, and Alezandria Troas in the west. The site of the Greek Ilium is marked by the low mound of Hissarlik ("place of fortresses") in the Trojan plain, about three miles frem the Hellespont. The early Greek settlers in the Troad naturally lored to take Homeric names for their towns. The fact that Homer places the town of Dardania far inland, on the slopes of Ida, did not hinder the founders of the Eolic Dardanus from giving that name to their town on the shores of the Hellespont. The site of the historical Thymbra, again, cannot be :cconcilcd with that of the Honeric Thymbra. Similarly, the choice of the name Ilion in no way justifies the assumption that the Greek settlers found that spot identified by tradition with the sits of the town which Homer calls Hlios. It does not even warrant the hypothesis that they found a shrine of Athene Hias existing there. For them, it would be enough that the sounding name could be safely appropriated, - the true site of Homeric Ilias being forgotten or disputed, -and that their town was at least in the neighbourhood of the Homeric battlefields. Tbe Greek Ilium may have been founded abont 700 b.c. It is noticeable that no ancient writer suggests a later date than the time of Cresus (c. 550 b.c.); and Strabo says that the establishment of the colory at Hissarlik-after previous occupution of a different site-took place "in the time of the Ljdiaus" ( $\left.\epsilon_{\pi}^{*} \pi i \Lambda v \delta \omega \nu\right)$. It would be reasonable to infer that the Greek Ilium preserved some well-marked traces of Lydian influence, perhaps in architecture or art, perbaps in manners or traditions. The traces of Lydian workmanship found in the exeavations at Hissarlik are thus easily explained, without recourse to the shadowy hypotbesis of a distinet Lydian settlement on the spot. When Xerxes visited the Trojan plain, he "went up to the Pergamon of Priam," and atterwards sacrificed to the Ilian Athene (Herod., vii. 42). It is doubtful whether the "Pergamon" meant was at the Greek. Ilium, or at another site (to be mentioned presently), Bunárbashi ; strong reasons in favour of the latter have lately been adduced by Mr George Nikolaides, in his 'Idıáóos ETpat $\eta \gamma \iota \kappa \grave{y}$ $\Delta u \sigma \kappa \epsilon \mathrm{~m}_{1}$. In the 4th century Ilion is mentioned among tho towns of the Troad which yielded to Dereyllidas (399 в.c.), and as captured by Cbarideraus ( 359 в.c.). It possessed walls, but was a petty place, of little strength. In 344 b.c. Alexander, on landing in the Troad, visited Ilium. In their temple of Athene the Ilians showed him arms which had served in the Trojan war, including the whicld of Achilles. Either then, or after the battle of Granicus, Alexander directed that the town should be enlarged, and should have the rank of "city," with political independence, and exemption from tribute. The battle of 1 psus ( 301 b.c.) added north-western Asia Mingr to the
dominions of Lysimachas, who executed the intentions of Alexander. He gave Ilinan a wall a miles in circum: ference, incorporating with it some decayed towns of the neighbourhood, and built a bardsome temple of Athene. In the 3d century b.c. Ilium was the head of a federal league (kotróv) of free Greek towns, which probably in clnded the district from Lampsacus on the Hellespont to Gargara on the Adramyttian Gulf. Twice in that century Ilium was visited by Gauls. On the first oceasion ( 278 B.c.) the Gauls, under Lutarius, sought to establish a stronghold at Ilium, but speedily abandoned it as being too weak for their purpose. Forty years later (218 в.c.) Gauls were brought over by Attalus I. to help him in hiss war against Acheus. After deserting his stardard they proceeded to pillage the towns on the Fellespont, and finally bes:eged Ilium, from which, however, they were driven off by the troops of Alexandria Troas. At the heginning of the 2 d centiny b.c. llimm was in a state of decay. As Demetrius of Seepsis tells us, the houses "had not even roofs of tiles," but merely of thatch. Such a loss of prosperity is sufficiently explainerl by the ineursious of the Ganls and the insecure state of the Tread during the latter part of the 3 d century. The temple of the Ilian Athene, however, retained its prestige. In 192 b.c. Antiochus the Great visited it befors salling to the aid of the Etolians. In 190 B.c., sloortly before the battle of Magnesia, the Romans came into the Troad. At the moment when a Roman arny was entering Asia, it was politic to recall the legend of Roman deseent from Eneas. Luelus Scipio and the llians were alike eager to do so. He offered sacrifice to the Ilian Athene; and after the peace with Antiochus (189 b.c.) the Romans annexed Rhoeteum and Gergis to Ilium, "not so much in reward of recent services, as in memory of the source from which their nation sprang." The later history of Ilium is little more than that of Roman benefits. A disaster befell the place in 85 e.c., when Fimbria took it, and left it in ruins; but Sulla presently caused it to be rebuilt. Augustus, while confirming its ancient privileres, gave it new territory. Caracalla (211-217 A.D.) visited Hinum, and like Alexander paid bonours to the tomb of Achilles. The latest coins found on the site are those of Constantius II. (337-361). In the 4 th eentury, as some rhetorical "Letters" of that age show, the llians still did a profitable trade in attracting tourists by their pseudo-Trojan memorials. After the 4th century the place is lost to view. But we find from Constantine Porphyrogenitus (911-959) that in his day it was one of the places in the Troad which gave names to bishoprics
While the Greek Ilium at Hissarlik owed its importanceasens to a sham pretension, which amused sight-seers and oceasionally served politicians, Assus, on the south coast, has an interest of a more genuino kind, and is, indeed, a better type of ancient town-life in the Troad. Its situation is one of the most magnificent in all the Greek lands. The seaward faces of the isolated und sea-washed rock on which Assus stood are carved to soath and south-west into terraces. The natural cleavarge of the trachyte into joint planes had already searped out shelves which it was comparatively easy for human- labour to shape; and sc, bigh up ry this cone of trachyte, the Greek town of Assus was buil with its colonnades, batbs, theatre, its public walks and its monuments of the dead, mounting tier above tier, till the summit of the crag was crowned with a Doric temple of Athene. Tho view frons the summit is not only very beautiful but also of great historical interest. In front is Lesbos, one of whose towns, Methymna, is said to have sent forth the founders of Assus, as early, perhaps, as 1000 or 900 b.c. The whole south coast-line of the Troad is seen, and in the south-east tho ancient territory
of Pergamum, from whose masters the possession of Assus passed to Rome by the bequest of Attalus III. (133 B.c.). The great heights of Ida rise in the east. Northward the Touzla is seen minding through its rich valley from a rocky defile in the east to the oak-forests in the western hills. This valley was traversed by the road which St Paul must have followed when he came overland from Alexandria Troas to Assus, leaving his fellow-travcllers to proceed by sea. The north-mest gateway of Assus, to which this road led, is still flanked by two massive towers, of Hellenic work, and of an age which leaves no doubt that they are the same between which St Paul entered the town. On the shore below, the ancient mole at which he embarked for Mytilene with his companions can still be traced by large blocks under the clear water. Assus affords the only harbour on the 50 miles of coast bet ween Cape Lectum and the east ond of the Adramyttian Gulf ; hence it must always have been tho chief shipping-place for the exports of the southern Troad. Too much off the highrays to become a centre of import trade, it was thus destined to be a commercial town, content with a modest provincial prosperity. The great natural strength of the site protected it against petty assailants; but, like other towns in that region, it has known many masters, Lydians, Persians, the kings of Pergamum, Romans, and Ottoman Turks. From the Persian wars to about 350 b.c. Assus enjoyed at least partial independence. It was about 348-3:5 b.c. that Aristotle spent three years at Assus with Hermeas, an ex-slave who had succeeded his former master Eubulus as despot of Assus and Atarneus. Aristotle has left some verses from an invocation to Arete (Virtue), commomorating the worth of Hermeas, who had been seized by Persian treachery and put to death. Under its Turkish name of Beibram, Assus ${ }^{1}$ is still the commercial port of the southern Troad, being the place to which loads of valonia (acorn-cups for tanning) are conveyed by camels from all parts of the country. The recent excarations at Assus, conducted by explorers representing the Archroological Institute of America, have yielded results far more valuable for the history of Greek art and architecture than any excavations yet undertaken in the Troad. The sculptares form one of the most important links yet discovered between Oriental and early Greek art, especially in respect of the types of animals. The later Hellenic tomn-walls of Assus also well repay the uew study which they have received. With their ramparts, towers, and posterns they form the finest and most instructive evtant specimen of Greek military engineering. The director of the exploration, Mr J. T. Clarke, publisked in 1882 an exceilent report on the work lso far as it had then becn carried.

Alexandria Troas stood on the west coast at nearly its middle point, is little south of Tenedos. It was luilt by Artigonus, perlhaps about 310 b.c., and was called by him Antigonia Troas. Early in the next century the name was changed by Lysimachus to Alexandria Troas, in honour of Alexander's memory. As the chief port of north-west Asia Minor, the place prospered greatly in Roman times, and the existing remains sufficiently attest its former importance. The site is now covered with valonia oaks; but the circuit of the old walls can be traced, and in several places they are fairly well preservt i. They had a circumference of about 6 English miles, and were

[^245]fortificd with towers at regular intervals. Remains of some ancient buildings, including a bath and gymnasium, cau be traced within this area. The karbour had two large basins, now almost choked with sand. A Roman colony was sent to the place, as Strabo mentions, in the reign of Augustus. The abridged name "Troas" (Acts xvi. 8) was probably the current one in later Roman times. The site is now called Eski Stambul.

Many classical sites of less note in the Troad have been identified with moro or less certainty. Neandria seems to be rightly fixed by Mr F. Calvert at Mount Chigri, a hill not far from Alexandria Troas, remarkable for the fine view of the whole Troad which it commands. Cebrene has been conjecturally placed in the eastern part of the plain of Bairamitch, Palescepsis being further cast on the slopes of Ida, while the new Scepsis was near the site of Bairamitch itself. The evidence for this, however, is ambiguous. At the village of Kulaklee, a little south of the mouth of the Touzla, some Corinthian columns and other fragments mark the temple of Apollo Smintheus and (approximately) the site of the Homeric Chryse. Colonæ was also on the west coast, opposita Tenedus. Scamandria occupied the site of Enel, in the middle of tho plain of Bairamitch, and Cenchrex was probably some distance north of it. The shrine of Palamedes, mentioned by ancient writers as existing at a town cailed Polymedium. has been discorered by Mr J. T. Clarke on a site hitherto unvisited by any modern traveller, between Assus and Cape Lectum. It proves to have been a sacred enclosure (temenos) on the acropolis of the toms; the statue of Palamedes stood on a rock at the middle of its southern edge. Another interesting discovery has been made by Mr Clarke,-viz, the existence of very ancient town walls os Gargarus, the highest peak of Ida.

The modern discussion as to the site of Homoric Troy Site c: may be considered as dating from Lechevalier'e visits io il cmern the Troad in 1785-86. Homer describes Troy as "a great Proy town," "with broad streets," and with a high acropolis, or "Pergamus," rising above it, from which precipitous rocks descend abruptly to the plain beneath. These are the precipices over which the Trojans proposed to hurl the wooden horse, "when they had dragged it to the summit." Homer marks the character of the acropolis by the epithets " lofty," "windy," and more forcibly still by " beetling." One site in the Trojan plain, and one only, satisfies this most essential condition. It is the hill at its southern edge called the Bali Dagh, above the village of Bunárbashi. It has a height of about 400 feet, with sheer precipices descending on the south and south-west to the ralley of the Scamander (Mendere). Remains found apon it-though it has never yet been thoroughly exploredshow it to have been the site of an ancient city. Homer describes two natural springs as rising a little to the north-west of Homeric Troy. A little to the north-west of Bunárbashi these springs still exist. "This pair of rivulets are the immutable mark of nature by which the height towering above is recognized as the citadel of Hium" (E. Curtius).

The low mound of Hissarlik-the site of the Greek Ilium-stands only 112 feet above the level of the open plain in which it is situated. To call it "beotling" (íфpróeroa) would have been a travesty of poetical licence on which no poet could have ventured, and to describe it as "lofty" or "windy" would have been not less strange. There are no natural springs near it, such as Homer mentions. The Elolic settlers, having called the place Ilion, naturally persisted in maintaining its identity with Troy. Polemon, a native of the Greek Ilium, who lived about 200 B.c., declared that his fellow. townsmen could shaw the very stone on which-Palamedes
ad given lessons in the game of draughts. The onls other ancient writer who is known to have admitied the Hlian claim is Hellanicus of Lesbos (c. 452 -397 B.c.), who, as Strabo remarks, wished "to gratify the Ilians, as is bis wont." Like the Ilians, Hellanicus was of Eolian origin; and in compiling the local legends of rarious places be is knewn to have been wholly uncritical, merely repeating what was told to him as le lad heard it. On the other hand, the claim of the Greek Ilium to stand on the site of Troy was decisively rejected by the general consent of those ancient writers who had any claim to critical authority. The orator Lycurgus (c. 332 B.o.) speaks of the site of Troy as deso!ate, and this at a moment when the recent visit of Alexarder the Great to the Greek Ilium ( $33 \pm$ b.c.) had drawn attention to the claim made by its inhabitants. Demetrius, a native of Scepsis in the Troad, who flourished about 160 B.c., wrote a book entitled「Гршїко̀s $\Delta$ са́коб $\mu$ оs ("The Marshalling of the Trojans"), an exhaustive commentary on the catalogue of the Trojan forces in the secoud book of the Iliad. Demetrius knew the topography of the Troad as thoroughly as ke knew the text of Homer. The extant notices of his work, which had a great reputation in antiquity, warrant the belief that he was not only learned but acute. In the Diacosmus, which was the chief work of his life, he muse have bestowed much thought on the question as to the site of Homeric Troy, -the central point of his subject. He pronounced decidedly, as we know from Strabo, against the claim of the Greek tlium. It has been suggested that Demetrins rcjected the Tlian claim beeause, as a natire of Scepsis, he was jealous of Ilium, -a suggestion which is not only absurd in itself, since it assumes that such a motive would have induced Demetrius to mar his bife's work, bit also betrays ignorance of Strabo's text. Scepsis was not a possiblo claimant of the coutested honour, siuce it was not in the plain of Troy but in the plain of Bairanitch; and further, Demetrius had already provided in another manner for the Homeric dignity of Scensis by makiug it the royal seat of Eneas on the strength of its position relatively to Lyrnessus. The verdict of Demetrius against the Ilian claim was aiso the general verdict of the other ancient writers consulted by Strain, as the latter's language shows. From the passage in which Strabo notices the various defnitions of the Troad (xiii. § 4) it appears that among such writers were the foilowing historiars and geograplers :-Charon of Lampsacus (fior 500 e.c.), Damastes of Sigeum ( 400 b.c.), Scylax of Caryanda ( 350 b.c.), Ephorus of Cyme ( 340 в.c.), Eudoxus of Cyzieus ( 130 в.c.). It is to such writers as these that Strabo refers when he indicates the general consent of his authorities. In favour of the claim of the Greek Ilium, on the other land, there are only two literary witnesses, and these, as we have secn, are alike worthless. Equally valueless from a critical point of siew is the fact that the Ilian claim was sometimes allowed by soldiers or statesmen who wished to utilize Trojan memories. They required an official Troy, and they cared not where they found it. Nothing could more curiously illustrate the extreme poverty of the case for the Greek Ilium than the fact that some of its adrocates have been reduced to arguing as if Alexander and Lucius Scipio, when they led their armies through the Troad, had boen conducting archicological excursions, and as if their acquiescence in a convenient local myth had the weight of independent eritical testimonies.

In negativing the Ilian clain the conclusion of ancient criticism has been confirned by a great preponderance of modern opinion. Since Lechevalier visited the Troad in 1785-86 an overwhelming majority of competent judges have favoured his belief that the Bali Dagh above Bunár-
bashi was the Pergamus of the Homeric yoet's conceptiou. Before Leake's visit this opinion had been expressed by Cheiseul-Gouffier, Morritt, Hawkius, Geil, and Hami'ton. Leake spoke with a decision which derives adzitional weight from the habitual sobriety of his acute jarigment, and from the care with which, in this case, bo bad examined the alleged objections to the riew rhich lio finaïy adopted. He remarks that no one accustomed to observe the sites of ancient Greek towns could fail to fix on Bundrbashi "for the site of the chief place of the surrounding country." So Mr Tozer, in Lis Highlands of Turkey, says: "A person accustomed to observe the situation of Hellenic cities would at once fix on this as far more like', to bave recommended itself to the old inhabitants of the country than any other in the neighbourhood." Count von Mloltke has expressed the same opinion, that "he knew do other site in the Trojan plaia for a chief town of ancient time." Another supporter of Buuárbashi is Forchhanmer. Auother is Kiepert. The opinion of Ernst Curtius has been already cited. But space precludes more names; it is enough to say that the correspondence of the Bali Dagh with the Homeric Pergamus - a correspoudence absolutely unique in the Trojan plain-has been recogrized with virtual unanimity by modern travellers who have patieutly inspected the scenery of the Iliadl, having competent knowledge, and being free from bias in favour of a theory formed before their visit. Partial excavatious on the summit of the Bali Dagh lasve beer more than once undertaken, with the result of discovering ancient walls. Pottery, too, Ehas been found there, part of which is allowed on all lands to be probably as old, at least, as 900 b.c. But the Eali Dagh kas never yet been explored with any approach to thoroughness.

The result of the excaratious conducted by Dr Schli: mann on the mound of Hissarlik has been to lay bare the remains of the Greek Ilium, and also, below these, some prehistoric remains of a rude and poor kind ir. Troy, his fret book on the sulject, the explorer beld that the remains of the Greek Ilium ceased at a depth of 6 feet below the surface, and that all the other remains, dumn to $52 \frac{1}{2}$ feet, were prehistoric He distinguished the latter into five groups, represeatiug five prelistoric "cities" which had succeeded each other on the site; and in his second work, Illoo, he adided to these a sixth prelistoris city, on the streagth of some scanty restiges of supposed Lydian worknanship, found at a depth of $6 \frac{1}{2}$ feet. In both books, Homeric Tiroy was ideutificd with the third prehistoric city from the bottom, which was supposed to have been destroyed, though not tetally, by fire. Professor Jebb was the first to show (1) that the lines of demarcation between the alleged prekistoric strata, as drawn in Ilios could not be accurate, and (2) that, if any part of the prehistoric remains could be supposed to represent Homeric Troy, it must be that part which Dr Schliemanu had called the second city from the bottom, and the destruction of which by fire appeared to have been total. In 1889 the architects employed by Dr Schliemann proved that the stratification given in llios bad in fact been incorrect. The errors, too, affected precisely that region of the deposit which was most important to the Trojan hypothesis, viz., the lower strata. In Dr Schliemann's third volume. Troja, these errers were admittcd; and Troy was now ideutified, no longer with the third city, but with the second, of uhich the supposed area was now enlarged. Another fact to which the English critic had drawn attention was that the reraains of the Greek Ilium must extend to a considerably greater depth than 6 feet below the surface. Further examination confirmed this view also. It showed that the remains on the mound at Hissarlik belong to the folluwing periods or groups. (1) At the top, the remains of the Greek Ilium as it existed iu the Roman age, i.e., as rebuilt
after its destruction by Fimbria in 85 b.c. (2) A city which, like the former, extended beyond the mound of Hissarlik (its acropolis) over the adjacent plain. This corresponds with the Greek Ilium of the Macedonian age, as embellished and enlarged by Lysimachus, c. 300 в.c. (3) A smaller city, probably confined to the mound. Here we may recognize the Greek Ilium as it existed before the Macedonian age. It was a small and poor place, as appears from the known incidents of its history in the 5 th and 4 th centuries b.c., owing its chief importance to the shrine of Athene Ilias. (4) A petty town or village, confined to the mound, and poorly built. The cvidence of architecture fails to decide whether it was Hellenic or not; if Hellenic, it might represent the primitive settlement of the 不olic colonists, perhaps c. 700 b.c. It was a small honse in this village that Dr Schliemann at first identified with Priam's palace. The ground-plan shows four rooms, of which the largest measured 24 feet 4 inches by 12 feet. (5) A large town, to which the mound was only acropolis, and which extended to some distance south and south-east over the plain. These remains are unquestıonably prehistoric. (6) A few remains of a small settlement which, if indeed distinct from No. 5, preceded it. The reason for distinguishing 6 from 5 is that some of the acropolis buildings of 5 are above those of 6 , and seem to lave been built on carefuliy levelled ground. Apart from architectural evidence, objects found in the excavations prove that the remains of the historical age extend much below 6 feet. One of these was a terra-cotta disk, stamped with the head of a warrior, in an advanced style of workmanship, found at 26 feet 3 inches below the surface (Troy, p. 294). Another is a terracotta ball, found at 26 feet, which cannot be older than $c$. 360 b.c. Then, at 20 feet, was found another terra-cotta, marked with the Greek letter I. A piece of ivory, lelonging to a seven-stringed lyre, and therefore not older than c. 660 b.c., was found at 26 feet. Thus we have at Hissarlik the remains of the Greek Ilium in three successive phases,-Roman, Macedonian, and Elic, and below these the remains of at least one prehistoric settlement, the age and origin of which are unknown.
Their re- We can no longer either prove or disprove that theso ation to prehistoric remains are those of a town which was once - ${ }^{2}$ mer. prehistoric remains are those of a town which was once legend of Troy. But most certainly it is not the "lofty" Troy of which the Homeric poet was thinking when he embodied the legend in the Iliad. The conception of Troy which dominates the Iliad is based on the site at Bunarbashi, and suits no other. The sole phrase in the epic which favours Hissarlik occurs in book xx. (216 sq.), where Dardania is said to lave been built on the spurs of Ida, when Ilios "had not yet been built in the plain"; and this phrase occurs in a passage which, as the best recent critics agree, is one of the latest interpolations in the Iliad, having been compnsed after the Grcek Ilium had actually arisen "in the plain." Its purpose was the same as that which appears in the Hymn to Aphrodite, viz., to glorify reputed descendants of Æneas, and it probably belongs to the same age, the 7 th century b.c. The tactical data of the Miad-those derived from the incidents of the war-cannot be treated with such rigour as if the poem were a military history. But Nikolaides has shown that they can at least be brought into general agreement with the site rat Bunarbashi, while they are hopelessly incompatible with Hissarlik. The Iliad makes it clear that the general description of the Trojan plain was founded on accurate knowledge. At this day all the essential Homeric features can be recognized. And it is probable that the poet who created the Troy of the Iliad knew, personally or by description, a strong town on the Bali Dagh above Eunar. bashi. The legend of the siege may or mav not have
arisen from an older town at Hissarlik, which had then disappeared. The poet might naturally place his Troy in a position like that of the existing strong city on the Bali Dagh, giving it a "beetling" acropolis and handsome buildings, while he also reproduced the general course of the rivers and that striking feature,-an indelible mark of the locality, - the natural springs at the foot of the hill, just beyond the city gates on the north-west. But, while be thus imagined his Troy in the general likeness of the town on the Bali Dagh, he would retain the privilege of a poet who was adorning an ancient legend, and whose theme was a city that had long ago vanished. Instead of feeling bound to observe a rigorous accuracy of locail detail, he would rather foel impelled to avoid it; he would use his liberty to introduce some traits borrowed from other scenco known to him, or even from imagination. To this extent, and in this sense, his topography would be celectic. Such a consideration might suffice to explain the fact, well known to those who have studied this question on the spot, that neither Punarbashi nor any other one site can be harmonized with every detail of the poem. The recommendations of Bunárhashi are, first, that it satisfies the capital and essential conditions, while no other site does so, and secondly, that the particular difficulties which it leaves unsolved are relatively slight and few. This character of Homeric topography becomes still easier to understand, if, as most critics would now concede, our Iliad contains twork of various hands and ages. Few questions, perhaps, of equal literary interest have been so much confused by inattention to the first conditions of the problem The tale of Troy, as the Iliad gives it, is essentially a poetical creation; and we have no evidence other than the Iliad. That is, our sole data are (1) of the mythical class, (2) of inadequate precision, and (3) af uncertain origin. But they show a general knowledge of the ground ; and the question is how far particular features of the ground can bo recognized in the poem. It may be doubted whether the case admits of any solution more definite than that which has been indicated above.

Bibliograpky.-1. Works dealing with the Troad generally,Strabo, bk. xiii. ch. 1, is the principal source for the ancient Troad. Of booka by modern travellers in Asia Minor the following may be mentioned:-Philıp Barker Webh, in the Italian Biblioteca Accrbi, June and July, 1821, whose studies are better known through the French edition, Topographie de lu Troade, 1844; W. M. Leake, Journal of a Tour in Asia Minor, London, 1824; P. de Tchihatchef, Asie Mineure, \&c., Paris, 1853-69; R. Virchow, "Beitrage zur Landeskande der Troaa " in Trans. of Berli» Arad., 1879 ; H. F. Tozer, The Highlands of Turkcy, 1869; H. Schliemann, Rcise dev Troas in Mai, 1881 ; Joseph T. Clarke, Neport on the Investigations at Assos, Boston, U.S.A., and London, 1882, including "Notes on the Geology and Topography of the Troad "by J. S. Diller, and on "Bunarbashi," \&c., by W. C. Lawton and C. H. Waiker. J. T. Clarke's "Notes on Greek Shores," in the Report of the Archæo. logical Institute of America for 1850, are also valuable.

## I.Egend of Troy.

According to Greek legend, the oldest town in the Troad was that fourded by Teucer, who was a son of the river Scamander and the nymph Idrea. Tzetzes says
that the Scamander in question was the Scanander in Crete, and that Teucer was told by an oracle to settle wherever the "earth-born ones" attacked him. So when he and his company were attacked in the Troad by mice, which gnawed their bow-strings and the handles of their shields, he eettled on the spot, thinking that the oracle was fulfilled. He called the town Sminthium and built a temple to Apollo Sminthius, the Cretan word for a mouse being sminthius. In his reign Dardanus, son of Zeus and the nymph Electra, daughter of Atlas, in consequence of a deluge, drifted from the island of Samothrace on a raft or a skin bag to the coast of the Troad, where, having received a portion of land from Tencer and married his daughter Batea, he founded the city of Dardania or Dardanus on high ground at the foot of Mount Ida. On the death of Teucer, Dardanus succeeded to the kingdom and called the whole land Dardania after himself. He begat Erichthonius, who begat a son Tros by Astyoche, daughter of Simois. On succeeding to the throne, Tros called the country Troy and the people Trojans. By' Callirrhoe, daughter of Scamander, he had three sons,-Ilus, Assaracus, and Ganymede. From Ilus and Assaracus sprang two separate lines of the royal house, - the one being Ilus, Laomedon, Priam, Hector; the othe: Assaracus, Capys, Anchises, Eneas. Ilus went to Phrygia, where, being victorious in wrestling, he received as a prize from the king of Phrygia e spotted cow, with an injunction to follow her and found a city wherever she lay down. The cow lay down on the hill of the Phrygian Ate ; and here accordingly llus founded the city of Ilios. It is stated that Dardania, Troy, and Ilios became one city. Desiring a sign at the foundation of Ilios, Ilus prayed to Zcus and as an answer he found lying before his tent the Palladium, a wooden statue of Pallas, three cubits high, with her feet joined, a spear in her right hand, and a distaff and spiudle in her left. Ilus built a temple for the image and worshipped it. By Eurydice, daughter of Adrastus, he had a son Laomedon. Laomedon married Strymo, daughter of Scamander, or Placia, daughter of Atreus or of Leucippus. It was in his reign that Poseidon and Apollo, or Poseidon alone, built the walls of Troy. In his reign also Hercules besieged and took the city, slaying Laomedon and his children, except one daughter Hesione and one son Podarces. The life of Podarces was granted at the request of Hesione ; but Hercules stipulated that Podarces must first be a slave and then be redeemed by Hesione ; she gave her veil for him ; hence his name of Priam (from priasthai to buy). Priam married first Arisbe and afterwards Hecuba and had fifty sons and twelre daughters. Among the sons were Hector and Paris, and among the daughters Polyxena and Cassandra. To recover Helen, whom Paris carried off from Sparta, the Greeks under Agamemnon besieged Troy for ten years. (Sea A chilles, agameynon, Ajax, Hector, Helen, Paris.) At last they contrived a wooden horse, in whoso hollow belly many of the Greek heroes hid themselves. Their army and fleet then withdrew to Tenedos, feigning to have raised the siege. The Trojans conveyed the rooden horse into Troy; in the night the Greeks stole out, opened the gates to their returning friends, and Troy ras taken.
See Homer, $\Pi .$, vii 452 s7., xx. 215 sq., xxi 446 sq. ; Apollodorus, ii 6, 4, iii. 12; Diodorus, iv. i5, v. 48 ; Tzetzes, Schol. on Lycophron, $29,72,1302$; Conon, Xarral., 21; D́ionysus Halicarn, Anciq. Rom., i. 68 sq. The liad deals witb a period of fifty-ous daya in the tenth year of the war. For the wooden horse, see Hnmer, Od., iv. 271 sq.; Virgil, ERi., ii. 13 sq.
TROGLODYTES ( $\tau \rho \omega \gamma \lambda 0 \delta \dot{c} \tau a \iota$ ), a Greek word meaning "cave-dwellers." Caves have been widely used as human babitations both in prehistoric and in historic times (sce Cave), and ancient writers speak of Troylodytes in various parts of the world, as in Mresia near the lower

Danube (Strabo, vii. $5, \mathfrak{i} .318$ ), in the Caucasus (Id., xi. 5, 1. 506), but especially in various parts of Africa from Libya (Id., xvii. 3, p. 828) to the Red Sea. Herodotus (iv. 183) tells of a race of Troglodyte Ethiopians in ioner Africa, very swift of foot, living on lizards and creeping things, and with a speech like the screech of an cwl. Tho Garamantes honted them for slaves. It has been supposerl that these Troglodytes may be Tibbus, who still in part are cave-dwellers. Aristotle also (Hist. An., vii. 12) speaks of a dwarfish race of Troglodytes on the upper course of the Nile, who possessed horscs and were in his opinion the Pygmies of fable. But the best known of these African caved wellers were the inhabitants of the "Troglodyte country" on the coast of the Red Sea, who reached as far north as the Greek port of Berenice, and of whose strange and savage customs an interesting account has been preserved by Diodorus and Photins from Agatharchides. ${ }^{1}$ They were a pastoral people, living entirely on the flesh of their herds, or, in the season of fresh pasture, on mingled milk and blood. But they killed only old or sick cattle (as indeed they killed old men who could no longer follow the flock), and the butchers were called "unclean"; nay, they gave the name of parent to no maa, but only to the cattle of which they had their subsistence. This last point seem= to be a confused indication of totemisn. They went almost naked; the women wore necklaces of shells as amulets. Marriage was unknown, except among the chicfs, -a fact which agrees with the prevalence of female kinship in these regions in much later times. They practised circumcision or a mutilation of a more serious kind. The whole account, much of which must be here passed by, is one of the most curious pictures of savage life in ancient literature.
The Biblical Horim, who iuhabited Mrount Seir beforo the Edom.' ites, bore a name which means cave-divellès, and may prohably have been a kindred people to the Troglodytes on the other side of the Red Sea. Jerome, on Obadiah 5, glpeaks of this region as containing many cave-dwellings, and such habitationa aro still sometimes used ont the bordera of the Syro-Arabian desert.
TROGON, a word apparently first used as English ${ }^{2}$ by Shaw (Mus. Leverianunt, p. 1iT) in 1792, and now for many years accepted as the general name of certain birds forming the Family Trogonidx of modern ornitholory, tho species Trogon curracui of Linnæus being its type. But, since doults exist as to whether this is that which was subsequently called by Vieillot T. collaris or the T. melenurus of Swainson, though evidence is in favour of the former (cf. Cabanis, Mus. IIeineanum, iv. p. 177, and Finsch, Proc. Zool. Society, 1870, p. 559), several recent writers have dropped the Linnwan specific terın.
The Trogons are birls of moderate aize: the smaliest is harily bigger then a Thrush and the largest less bulky than a Crow. In most of then the bill is very wide at the gape, which is invariably beset bp recurved bristles. They seize most co the:r food, whether caterp:llars or fruits, on the wing, thongh their alar power is not exceptionaily great, their flight being described as short, rapid, and epasmodic. Their feet are weak and of a unique structure, the second toe, which in most lirds is the inner anterior one, beling icverted, and thus the Trogons stand alone, since in all other birds that have two toes before and two belind it is the outer toe that is turned backward. The plumage is very remarkable and characteristic. There is not a species which has not beauty beyond most birda, and the glory of the group culminates in the QuEzaL ( $q . v$. ). But in othera golden green and stecly hluo, rich crimson ${ }^{3}$ and tender
${ }^{1}$ See also Artemidorus io Strabo, xvi. 17, p. 785 sq.
${ }^{2}$ Trogonen! (the oblique case) occurs in Pliny ( $H . N ., x, x, 16$ ) as the uanje of a bird of which he knew nothiog, sare that it was mentioned by Hylas, ad augur, whose work is lost ; but seme would read Trygonent (Turtle-Dore). In 1752 Mohriog (Av, Feneru, p. 85) applied the name to the "Curicui" (prooounced "Siruquí" fide Bates, Nat. Amazons, i. p. 254) of Marcgrave (IIst. N'at. Brasilie, p. 211), who described and figured it in 1648 reeognizably. Io 1760 Brisson (Ornithologic, io. p. 164) adopted Trogon as a geveric Leron, and, lid. neus hariug followed bis example, it bas since been univessally accepted.

3 iI. . Inatola Bogdenoff determined the red pignent of the fenthers
pink, yellow varying from primrose to amber, via with ona another in vivid coloration, or contrasted, as happens in many apecies, with . warm tawny or a sombre slaty gray-to say nothing of the delicato freckling of black and white, as minnte as the markings of a moth'a wing-the whole set off by bands of white, producing an effect bardly equalled in any group. It is impossibla within brief apaca to describa its glowing tints; but tha plumaga is further remarkabls for the larga size of its contour-feathers, which ara extremely ooft and so loosaly seated as to come off in scores at a touch, and there is no doma. Tha tail is generally a rery characteristic feature, the rectrices, thongh in soma cąses pointed, being often curiously squared at the tip, and when this is tha casa thay are usmally barred ladderlika with whits and black ${ }^{1}$ According to Gould, they ara larger and mora pointed in tha young than in the old, and grow aquarer and hava the white bands narrower at each ancceeding moult. Ho also asserts that in tha species which hava the wing-coverts freckled, the freckling becomes finer mith age. So far as tas been observed, the nidification of thesa birds is in holes of trees, wherein are laid without any bedding two roundish eggs, generally whita, but certainly in ons species (Quezal) tinted with bluish grean.

Tha Trogons form a very well-marked Family, belonging to tha multifarious group treated in the presant aeries of articlea as Picaris; but, instead of being (so far as is known) like all the rest of them and, as Prof. Huxley Believod, "desmognathous," they have been shown by W. A. Forbes (Proc. Zool. Society, 1881, p. 836) to be "achizognsthous"-thus demonstrating, in the worda of tha latter, "that the etructure of the palata has not that aniqne and pecnliar signifcance that hes been claimed for it in the classification of birds." Perbaps the explanation of this anomaly may lie in the fact that tha Trogons ara a very old form. Tha remains of one, T. gallicus, have been recognized by Prof. A. Milna-Edwards (Ois. foss. de la France, ii. p. 395, pl. 177, figs. 18-22) from the Miocena of the Allier, and it may not be too much to aupposa that the echizognathons structure was more ancient than tha desmognathous. Again too this fortnnate discovery of that eminent palæontologist scems to account for the remarkable distribution of the Trogona at the present day. Whila they chiefly abound, and hare developed their climaz of magnificanca, in the tropical parts of the Naw World, they yet occur in tha tropical parts of the Old. The apecies now inhabiting Africa, forming tha group Hapaloderma, can hardly be apparated generically from thosa of tho Neotropical Trogon, and tha differenca between the Asiatic forms, if aomewhat greater, is still comparatively alight. It is plain then that the Trogone ara an exceptionally persistent typa; indaed in the whole Class few aimilar instances occur and perhaps none that can bo called parallcl. Tha extremo development of tha type in tha Naw World just noticed also furnishes another hint. While in aoms of the American Trogons (Pharomacrus, for instance) the plumaga of the famales is not very much less beautiful than that of the males, there are others in which the hen birds retain what may be fairly deomed a mora ancient livery, whils the cocks flaunt in brilliant attire. Now tha plumaga of both eexes in all but ons ${ }^{2}$ of the Aaiatic Trogons, Harpactes, resembles rather that of tha yonng and of those females of the American species which ara modestly clothed. Tha inferenca from this fact would aaem to ba that tha general coloration of tha Trogona prior to the establishment, by gaographical estrangament, of tha two types was a russet similar to that now worn by the adults of both aexes in the Indian region, and by a portion only of the iemales in the Neotropical. Tha Ethiopian type, as already said, very closely agrees with the American, and therefora would ba likaly to have been longer is connexion therewith. Again, whila the sdults of most of the American Trogons (Pharomacrus and Euptilotis excepted) have the edges of tha bill aerrated, their young hava them smooth or only with a single notch on either eide near thatip, and this is ohservabla in tha Asiatic Trogons at all ages. fit the sama time the most distinctiva features of tha whole group, which ara assily taken in at a glance, but are diffeult to express brielly in words, ara equally possessad by both branches of the Family, showing that they were in all likelihood-for the possibility that the peculiaritios may have baen avolved apart is not to be over-lookad-reached before tha geographical sundaring of these branches (whareby they aro now placed on opposite sides of the globa) was effected.
It remains to say that about sixty species of Trogons are recognized, which Gould in the second edition of his ITonograph of the Family (1875) divides into seven genera; but their characters are hardly laid down. Pharomacrus, Euptiotis, and Trogon inhabit the mainland of tropical

[^246]America, no species passing to the northward of the Rio Grande nor southrard of the forest district of Brazil, while none occur on the west coast of Peru or Chili. Prionotelus and Tmetotrogon, each with one species, are peculiar respectively to Cuba and Hispaniola. The African form Hapaloderma has tro species, one found only on the west coast, the other of more general range. The Asiatic Trogons, Harpactes (with eleren species according to the same authority), occur from Nepal to Malacca, in Ceylon, and in Sumatra, Jara, and Borneo, while one species is peculiar to some of the Philippine Islands.
(A. N.)

TROGUS, Cn. Poxperids, a Roman historian, nearly contemporary with Livy. Although the cpitome of his historical writings by Justin, and a fow fragments, are all that hare come down to us, there is abundant reason to believe that he deserves a place in the history of Roman literature by the side of Sallust, Livy, and Tacitus. Oi his life little is known He was almost certainly of Greek descent. His grandfa'her served with Pompey in the war against Sertorius, and received through the influeuce of that general the Roman citizenship; hence the name Pompeius, which was adopted as a token of gratitude to the benefactor. The father of Trogus was an officer of Cæsar. Trogus himself seems to have been a man of encyclopædic knowledge. He wrote, after Aristotle and Theophrastus, books on the natural history of aninals and plants, used by the elder Pliny, who calls Trogus "one of the most precise among authorities" (auctor ipse e severissimis). But the principal work of Trogus consisted of forty-four Libri Historiarum Philippicarum. This was a great history of the world, or rather of those portions of it which came under the sway of Alexander and his successors. The tale began with Ninus, the founder of Nineveh, and censed at aboat the same point as Liry's great work, viz., 9 A.D. The last event recorded by the epitomator Justin (q.v.) is the recovery of the Roman standards captured by the Parthians ( 20 в.c.). The history of Rome was treated as merely subsidiary to that of Greece and the East. The work was based upon the writings of Greek historians, such as Theopompus, Ephorus, Timæus, Polybius. It has been contended that Trogus did not gather together the information from the leading Greek historians for himself, but that it was already combined into a single book by some Greek, whom Trogus followed closely with some superficial errors. But the assumption appears improbable in itself, merely on a review of the remains of the historical writings, and is moreorer inconsistent with what we know of the works in natural history, for which Trogus certainly went back to what were re garded in his time as frst-hand authorities. It is generally admitted that Trogus had genuine qualifications for writing history, though he could not rid himself entirely of the faults of his authorities. His idea of history was more severe and less rhetorical than that followed by Sallust and Livy, whom hc blamed for putting elaborate specches in the mouths of the characters of whom they wrote. Yet his own Latin style had a vivid force which is still to be rccognized in the extracts made by Justin. For the ancient history of the East, Trogus, even in the present mutiated state of his historical work, often prores to.be an authority of great importance.

The chief modern editions are those of Gronorius (Leyden, 1719 and 1760 ); Frotscher (Leipsic, 1827-30); and Jeep (Leipsic, 1859 and 1862). In Engelmann's Bibliotheca Scriptorum Classicomem, ii, under Jnstin and Trogus, will be found a large nomber of references to scattered modern articlea. Perhaps the most important is that of A. F. Gntschmid on the sources of the history of Trogns, in tha second supplemontary vol of the Jahrbb. f. class. Philol. (Leipsic, 1857).

TROITST, a district town of Russia, in the goverament of Oreaburg, sifuated in \& fertile stcppo 392 miles to the
north-east of Orenburg, on the Siberian highmay, is one of those towns which have grown rapidly of late in the south-east of Russia. The Troitskiy fort, erected in 1743, became a centre for the exchange trade with the Kirghiz steppe and Turkestan, and in that trade Troitsk is now second only to Orenburg. Cotton, silk, and especially horses and cattle are imported, while leather, cotton, and woollen and metal wares are exported. An active trade in corn for the Ural gold-mines is carried on. The population in 1884 was 13,000 .
TROLLOPE, Anthony (1815-1882), English novelist, was born in Keppel Street, Russell Square, London, according to most authorities, on 24 th April 1815 ; in his own sutobiography he merely gives the year. His father, a barrister, who bad been fellow of Nex College, Oxford, brought limself and his family into the sorest straits by unbusincss-like habits, by quarrelling with his profession, or at least with the attorneys, and by injudicious speculations, espccially in farming. Trollope's mother, Frances Milton, according to her sun, was nearly thirty when she married in 1809. By ner husband's wish she made a strange journey to Arnerica in 1827, for the purpose of setting up a kind of fancy shop in Cincinnati, which failed utterly. Her visit, however, furnished her with the means of writing The Domestic Manners of the Americans. This at once brought her in a considerable sum, and thenceforward she continued to be the meinstay of her family. Her husband being obliged at last actually to fly the country from his creditors, his wife maintained him by ber pen, at Bruges, till his death there in 1835 . For some time Mrs Trollope wrote chiefly travels; but she soon became known as a novelist, and was very industrious. Her novels, the best of which are probably The licar of Wrexhill and The Tidoro Barnaby, are now rarely read, and indeed were never at their best above good circulating library level : they are written with cleverness indeed, and \& certain amount of observation, but with many faults of taste, and with an almost total want of artistic completeness and form. Her late beginning, her industrious career (for she wrote steadily for more than thirty years, till her death in October 1863, at Florence), and the entire absence in her of any blue-stocking or feninue-savante weakness would have made ber remarkable, eren ii she had not transmitted, as she undoubtedly did transmit, her talent, much 1 ncreased, to her children.
Anthony Trollope was the thard son. By his own account fer English men of lcters have had an unhappier childhood and youth. He puts down his own misfortunes, at Harrow, at Wirchester, at Harrow again, and elsewhere, to his father's pecuniary circumstances, which made his own appearance dirty and shabby, ard subjected hin to various lumiliations. But it is permissible to suspect that this was not quite the trath, and that soine peculiarities of temper, of which in after life he had many, contributed to his unlopularity. At any rate be seems to lave reached the verge of manhood as ignorant as if he had had no education at all. While living abroad he tried ushership; but at the age of nineteen he was pitchforked by favour (for he could not pass even the ridiculous examination then usual) into the post-office. Even then his troubles were not over. He got into debt; he got into ridiculous entanglements of love affairs, which he has very candidly avowed; he was in constant hot water with the authoricies, and he seems to lave kept some very queer company, which long afterwards stood him in stead as models for some of his novel 1 ictures. At last in August 1841 he obtained the appointinent of clerk to one of the post-office surveyors in a remote part of Ireland, with a very small nominal salary. This balary, however, was practically quadrupled by allowances; living was cheap; and the life
suited Trollope exactly, being not office work, which he always hated, buta kind of travelling inspectorship. And here he not only began that habit of hunting which (after a mànner hardly possible in the stricter conditions of official work nowadays) he kept up for many years even in England, but within three years of his appointment engaged himself to Miss Rose Heseltine, whom he had met in Ireland but who was of English birth. They were married in June 1844. His headquarters had previouslv beer at Banagher ; he was now transferred to Clonmel.

Trollope had always dreamt of novel-writing, and his Irish experiences seemed to supply him with promising subjects. With some assistance from his mother he got his first two books, The Macdermols of Ballycloran and The Kiellys and the O'Kellys, published, the one in 1847, the other the next year. But neither was in the least a success, though the second perlaps deserved to be; and a third, La Vendée, which followed in 1850, besides heing a much worse book than either, was an. equal failure. Trollope made various other literary attempts, Lut for a time ill fortune attended all of them. Meanwhile he was set on a new kind of post-office work, which suited him even better than his former employment-a sort of roving commission to inspect rural post deliveries and devise their extension, first in Ireland. then throughout the west of England and South Wales. That he did good work is undeniable ; but his curious conception of official duty (on his discharge of which he prided himself immenseiy) is exhibited by his confessions that be "got his hunting out of it," and that he felt "the necessity of traveliing miles enough [he was paid by mileage] to keep his horses." It was during this work that he struck the vein which gave him fortune and fame-which might perhaps have given him more iame and not much less forture if he had not worked it so hard-by conceiving The IVarden. This was published in 1855. It brought him little inmediate profit, nor was even Barchester Towers, which followed, very profitable, though it contains his freshest, his most original, and, with the exception of The Last 'Chronicle of Barset, his best work. The two made him a reputation, however, and in 1858 he was able for the first time to sell a novel, The Three Clerks, for a substantial sum, £250. A journey on post-offce business to the West Indies gave him material for a book of travel, The Thest Indics and the Spanish Main, which he frankly and quite truly acknowledges to be much better than some subsequent work of his in the same kind. From this time his production (mainly of novels) was incessant, and the sums which he received were very large, amounting in one case to as much as $£ 3525$ for a single book, and to nearly $£$ i 0,000 in the twenty jears between 1859 and 1879. All these particulars are given with great minuteress by himself, and are characteristic. The full high tide of his fortunes began when the Cornkill Magaine waz established in the autumn of 1859. He was asked at short notice to write a novel, and wrote Framley Parsonage, which was extremely pupular ; two novels immediately preceding it, The Bertrams and Casile Richmond, had been much less successiul.

As it will be possible to notice few of his subsequent works in detail, the list of them, a sufficiently astonishing one, may be given here:-Tales af All Cmuntries (3 series, 1351-1870); Orles, Farm, Varth Ancrica (1862) ; Rachacl Ray (1863); The Small If nuse as Allingtan, Can You Furgive Her ? (1864) ; Miss Mackenzie (1865); Tho Claverings, Nina Balatka, The Last Chranicle of Barset (1867); Linda Trcssel (1868); Phincas Finn, He Krew He IF as Right (1862); Brawn, Jones, and Robinsan, The Vicar of Bullhwmplan, An Editars Talcs, Casar (1870) ; Sir Harry Hatspuer of Liumbletincaile, Ralph the Ileir (1871); The Galden Lian of Granpere (1872) ; The Eustace Diamands, Australia and Ncw Zealand(1873); Phineas Redux, Harry Heathcatc of Gangoil, Lady Anna (1874); The Way We Live Navo (1875) ; The Prime Minister (1876); The American Senalor (1877); Is Ho Popenjoy'S South Africa (1878); John Caldigate, An Eye fur
in Eyc, Cousin Henry, Thackeray (1879); The Duke's Children, Cicero (1880); Ayala's Angel, Dr Worlle's School (1881); Frau Frohmann, Lord Palmersion, The Fixed Period, Kept in the Dark, Marian Fay (1882); Mr Scarborough's Family, The Land Leagucrs (1883) ; and An Old Man's Love (1884).

How this enormous total was achieved in spite of official work (of which, lightly as he took it, he did a good deal, and which he did not give up for many years), of hunting three times a week in the season, of whist-playing, of not a little going inte general society, he has explained with his usnal curious minuteness. He reduced novel-writing to the conditions of regular mechanical work-so much so that latter!y he turned out so many words in a quarter of an hour, and wrote at this rate so many hours a day. He divided every book beforehand into so many days' work and checked off the tallies as he wrote.

A life thus spent could not be very eventful, and its events may be summed up rapidly. In 1858 he went to Egypt also on post-office business, and at the end of 1859 he got himself transferred from Ireland to the eastern district of Englancl. Here be took a house at Waltham. He took an active part in the establishment of The Fortrightly Reviern in 1865; he was editor of St Paul's for some time after 1867; and at the end of that year be resigued his position in the post-office. He stood for Beverley and was defeated; he received from nis old department special missions to America and elsewhere (he had already gone to America in the midst of the Civil War). He went to Australia in 1871, and before going broke up his household at Waltham. When he returned he established himself in Iondon, and lived there till 1880, when he removed to Harting on the confines of Susses and Hampshire. He had visited South Africa in $18 i 5$ and travelled elsewhere. On 3rd November 1882 he was seized with paralysis, and died on 6th December.

Of Trollope's personal character it is not necessary to say much. Strange ds his conception of official duty may seem, it was evidently quito honest and aincere, and, though he is eaid to hare been as an officis! popular neither with auperiore nor inferiors, ha no doubt did much good work Privatoly he was much liked and much disliked, -a great deal of real kindness being accompanied by a blastering and overbearing manner, and an egotism, not perhaps moro deep than other men"s, but more vociferous. His literary work needs more notice. Nothing of it but the novels is remarkable for merit. His Casar and the Cicero are curions examples of a man'e undertaking work for which he was not in the least fitted. Thackeray exhibits (though Trollopa appears to have both adnired Thackeray as an artist and liked hiro as a man) grave faulto of taste and judgment and a complete lack of real criticism. The booke of travel are not good, and of a kind not good. Nina Balatka and Linda Tressel, published anonymously and as experiments in the romantic style, have been better thought of by the author and by soine competent judges than by the public or the publishers. Brown, Jones, and Robinson was still more disliked, and is certainly very bad as a whole, but bas touches of curious originality in parts. The rest of the novels have been judged very differently by different peraons. Thare is mo doubt that their enormous volume prejudiced readers against them even long before the author let the public into the secret of their manufactura, which has made the prejudice deeper. There is also no doubt that Trollope seldom or never creates a character of the first marit (Mr Crawley in the Last Chronicle of Barset is the one possible exception), and that not oue of his books can bo called a work of genius. At the same time no one probably has produced anything lika such a volume of anything like such merit. He claims for himself that his characters are always more or less alive, and they are. After his first failures lie never produced anything that was not a faithful and sometimes a very amusing transcript of the sayings and doings of possible men and woutn. His charactera are never marionettes, much less sticka. Ho has some irritating mannerisms, notably a trick of repetition of the same form of words. He is sometimes absolutely vulgar. that is to say, he does not deal with low life, but shoms, thongh always robust and pure in morality, a certain coarseness of taste. Ho is constantly rather trivial, and perhaps nowhere out of the Barset series (which, howaver, is of itself no inconsiderable work) las he produced books that will live. The very faithfulness of his representation of a certain phase of thought, of cultivation, of sociaty, uninformed as it is by any higher spirit, in the long run dameged, as it had frat helpod, the popularity of his work. But.
allowing for all this, it may and must still bo said that he held up his mirror steadily to nature, and that the mirror itself was fashioned with so inconsiderable art.
(G. SA.)

TROMBONE, a musical instrument of brass. It has a cupped mouthpiece, and is formed of two principal parts -the bell, the bore of which gradually widens, and the slide, which is composed of two cylindrical tubes parallel to each other, upon which two other tubes, communicating at their lower extremities by a pipe curved in a half-circle. glide without loss of air. The mouthpiece is adapted to one of the upper ends of the slide and the bell to the other end. When the slide, which is mored by the right hand, is closed, the instrument is at its highest pitch ; the note is lowered in proportion as the column of air is lengthened by drawing out the slide.

Formerly the trombone was known as the sackbut; its modern designation-great trumpet-comes from the Italian. The Germans call it posaune. It is diffcult to say where or at, what epoch the instrument was invented In a manuscript of the 9 th century, preserved at Boulogne, there is a drawing of an instrument which bears a great resemblance to a trombone deprived of its bell. Virdung ${ }^{1}$ says little about the trombone, but he gives an engraved representation of it, under the nanse of busaun, which shows that early in the 16 th century it was almost the same as that employed in our day. By that time the trombone had come into rogne in England: the baud of musicians in the service of Henry VIII. included ten sack. but players, and under Elizabeth, in 1587, there were six English instrumentalists then enjoyed a certain reputation and were sought for by foreign courts; thus in 1604 Charles III. of Lorraine songht to recruit his sackbut players from English bands. Pratorius ${ }^{2}$ classes the trom. bones in a complete family, the relative tonalities of which were thus composed:-1 alt-posaun, 4 geneine rechle posa unen, 2 quart-posaunen, 1 octav-posaun,- 8 in all. The alt. posaun was in D With the slide closed it gave the first of the accompanying harmonics: The gemeine rechte posaunen, or ordinary trombones, were in
A. Without using the slide they gate the subjoined sounds:
 The quart-posaun was made either in E , the fourth below the gemeine rechte posaun, or in D , the lower fifth. In the latter case it was exactly an octare below the alt-posaun. The octav-posaun was in A. It was constructed in two different fashions: either it had a length double that of the ordinary trombone, or the slide was shortened, the length of the column of air being still maintained by the adaptation of a crook. The first system, which was invented by Hans Schreiber four years before the work of Pratorius appeared, gave the instrumentalist a slide by which he could procure in the lower ortare all the sounds of the ordinary trombone. The second system, which Prætorius had known for years, was distinguished from the first, not only by modifications affecting the form, but also by a larger bore. Mersenne ${ }^{3}$ calls the trombone trompette harmonique, but he does not appcar to have made himsel! acquainted with its construction, for we can scarcely find an allusion in the confused text of his work to the tonality of the trombone then in vogue. He established this fach however, that it was customary in France to lower the instrument a foufth below the pitch of the ordinary trombone by means of a torili, a kind of crook with a donlle turn that was fitted between the bcil and the slide, "in order," he said, "to make the bass to hautbois conccrts." The compass of the trombone is not limited to the nere harme

[^247]now obtained by fearicg the nnstrument at its shortest lengththat is, with the slide close np; it in fact comprises seven positions, which are obtaned by shifting the slide es many lengths and in such a way that each of these produces a series of harmonics a semitone lover than the length which has preceded. This system, so simple and rational, might have been expected always to scrve for the hasis of the technique of tha instrument; but from the middle of the 18 th century the art of playing the trombone became the object of purely empiric teaching. Only four positions were made use of. ${ }^{1}$ By the first-that is, with the slide close up-there was obtained from the ordinary trombone, thien called the tenor trom. bone, the first series of the suhjoined harmonics (the aumerals indicating the order):
the fundamental or first note boing difficult to obtain ; the second position produced

and the forth In thus lowering by semitones, the gave the tenor trombone a diatonic scale from This scale was formed with notes that could be perfectly just, but the result rouid have
been less satisfactory to the ear if the player had atrictly observed the rules laid down by the teaching of that period for the production of the chromatic intervale. Thus to pass from a note furnished by one of the four positione to another a semitone lower it was uecessary to lengthen the slide by two fingers; if the semitone higher was required the slide had to be shortened to the eame extent. ${ }^{3}$ A consideration of the laws affecting lengths of pipes will show the viciousness of that rule.

Of all wind instruments the trombone has perhaps been least modified in form; changes have occasionally been attempted, but for the most part with only trifling auccess. The innovation which has had the most vogue dates from the end of the 18th century; it consisted in bending the tube of the hell in a half circle above the head of the executant, which prodnced a very bizarro effect. It also gave rise to very serious inconveniences: by destroying the regularity of the proportions of the bell it prejudicially affected the quality of toue and intonation of the instrument. For a long time the curved bell with its serpent's mask was maintained in military music, and it is only about twenty years ago that it was completely given up. By giving a balf turn more to the bell tube its opening was directed to the back of the executant; but this form, in fashion for a little while ahout 1830, was not long adhered to, and the trombone reassumed its primitive form, which is atill maintained. As appears from a patent derosited by Stölzel and Blimel at Berlin on 12th April 1818, the application of ventils or pistons was then made for the first time. ${ }^{3}$ The ventils, at first two in number, effected a decided lengthening of the instrument. The first augmented the length of the tube by a tons, lowering by as much the natural harmonics. The second produced a similar effect for a semitone, and the simultanecus em. ployment of the two pistons resulted in the depression of a tone and a bali. The principle, therefore, of the employment of ventils or pistons is the same as that.which governs the use of slides. For instance, a trombone is provided with three pistons, and without their help it produces the first of the following sets of harmonics (the numbers indicating the order). Thea by pressing dowa the serond piston we obtain a lengthetuag of the column of air that lowers tho in. strument by a semitone and makes it produce the second set of harmonics here shown ; with the aid of the first piston we relengthen the column, so as to get a whole tone lower, producing the third set of sounds; the third piston, in the same way, lowers the iustrument a tone and a half, as in

(4) ; by the simultaneous employment of the second and third pistons we arrive at two tones, as in (5); (5)
( $)$ ene the combination of the frst and
two tones and s half, as shown in (6);

[^248] finalyy, uniting the three pistans lowers the trombone three tones and a balf, as shown in (7). Notwithatanding the increased facility obtained by the use of pistone, they are very far from having gained the
suffrages of all players: many prefer the alide, beliering that it gives a facility of emission that they cannot ohtain with a piston trombone. For this illustratiou of the use of pistons, we have taken a tenor trombone in Bb ; the flat tonalities having been preferred for military music aince the commencement of the 19th century, the pitch of each variety of trombones has heen raised a eemitoue. At present six trom: bones are more or less in use, viz., the slto trombone in $F$, the alto in Eb (formerly in D ), the tonor in Bb (formerly in A ), the bass in G, the bass in F (formerly in E), the base in Eb (formerly in D). This transposition has no reference to the number of vibrations that may be officially or tacitly adopted as the standard pitch of any country or locality. A trombone an octave lower than the tenor has recently been reintroduced into the orchestra, principelly by Wagner. The different varieties just cited are con. etructed with pistons or elides, as the case may be.
(V. M.)

## TROMP, the name of two famous Dutch admirals.

I. Martin Harpertzoon Tromp (1597-1653) was born at Brielle, South Holland, in 1597. At the age of eight he made a voyage to the East Indies in a merchantman, but was made prisoner and spent several jears on board an English cruiser. On making his escape to Holland he entered the navy in 1624 , and in 1637 was made lieutenantadmiral. In February 1639 he surprised, off the Flemish coast near Gravelines, a large Spanish fleet, which he completely destroyed, and in the following September he defeated the combined fleets of Spain and Portugal off the English coast-achievements which placed him in the first rank of Dutck nasal commanders. On the outbreak of war with England Tromp appeared in the Downs in command of a large fleet and anchored off Dover. On the approach of Blake he weighed anchor and stood over towards France, but suddenly altered his course and bore down on the English feet, which was much inferior to his in numbers. In the engagement which followed (19th May 1652) he had rather the worst of it and drew off with the loss of two ships. In November he again appeared in command of eighty ships of war, and a convoy of 300 merchantmen, which he had undertaken to guard past the English coast. Blake resolved to attack bim , and, the two fleets coming to close quarters near Dungeness on the 30th November, the English, after severe losses, drew off in the darkness and anchored off Dover, retiring next day to the Downs, while Tromp anchored off Boulogne till the Dutch merchantmen had all passed beyond danger. The statement that he sailed up the Channel with a broom at his masthead in token of his ability to sweep the seas is probably mythical. In the following February (1653), while in charge of a large convoy of merchantmen, he maintained a running fight with the combined English fleets under Blake, Penn, and Monk off Portland to the sands of Calais, and, though baflling to some extent the purposes of the English, had the worst of the encounter, losing nine ships of war and thirty or forty merchantmen. On 3d June he fonght an indecisive battlë with the English fleet under Dean in the Channel, bu: the arrival of reinforcements under Blake on the following day enabled the English to turn the scale against him and he retired to the Texel with the loss of seventeen ships. Greatly discouraged by the results of the battle, the Dutch sent commissioners to Cromwell to treat for peace, but the proposal was so coldly received that war was immediately renewed, Tromp again appearing in the Channel towards the end of July 1653. In the hotly-contested conflict which followed with the English under Monk on the 29 th Tromp was shot by a musket bullet through the heart. He was buried with great pomp at Deift, where there is a monument to his memory in the old church
II. Cornelits Trosp (1629-1691), the second son of the preceding, was born at Rotterdam on 9 th September 1629. Ai the age of nineteen he commanded a small squadron charged to pursue the Algerian pirates. In 1652 and 1653 he served in Van Galen's fleet in the Mediterrapean, and after the action with the English fleet off Leghorn, 13th March 1653, in which Van Galen was killed, Tromp was promoted to be rear-admiral. On 13th July 1665 his equadron was by a hard stroke of ill fortune defeated by the English under the duke of York. In the following year Tromp served under De Ruyter, and on account of De Puyter's complaints of his negligence in the action of 5 th August he was deprived of his command. He was, however, reinstated in 1673 by the stadtholder William, afterwards king of England, and in the actions of 7th and 14th June, against the allied fleets of England and France, manifested a skill and bravery which completely justified his reappointment. In 1675 he visited England, when Charles II. created bim a baron. In the following year he was named lieutenant-admiral of the United Provinces. He died at Amsterdam, 29th May 1691, ehortly after he had been appointed to the command of a fleet ggainst France. Like his father he was buried at Delft.
See H. de Jager, Het Ceslacht Tromp, 1883.
TROMSÖ, a town of Norway, capital of the amt of the same name and an episcopal see, stands on the eastern shore of a low fertile islet of the same name between Hraloe and the mainland, in $69^{\circ} 38^{\prime} \mathrm{N}$. lat. and $18^{\circ} 55^{\prime} \mathrm{E}$. long. It consists principally of one wide street of wooden houses ; the chief public buildings are the town-hall, the national shurch, the Roman Catholic church, and the museum, which contains a good zoological collection. The town has a high school and a normal seminary. The main specialty of the place is bears' skins and other kinds of fur. The herring fishery of Tromsö is very productive, and the activity of the town is further increased by the circumstance that it is the port of cell for ships making for the seal fishing and walrus bunting on Spitzbergen and Nova Zembla. Tromsö was founded in 1794. The population, which in 1816 did not exceed 300 , was 5409 in 1882.
TRONDHJEM. Ses Throndijem.
TROPIC-BIRD, 80 called of sailors from early times, ${ }^{1}$ because, as Dampier (Toyages, i. p. 53) among many others testifies, it is "never seen far without either Tropick," and hence, indulging a pretty fancy, Linnæus bestowed on it the generic term, continued by modern writers, of Phaethon, in allusion to its attempt to follow tie path of the sun. ${ }^{2}$ There are certainly three wellmarked species of this genus, but their respective geographical ranges have not yet been definitely laid down. All of them can be easily known by their totipalmate condition, in which the four toes of each foot are united ty a web, and by the great length of the two middle tail-quills, which project beyond the rest, 80 as to have gained for the birds the names of "Rabijunco," "Paille-en-queue," and "Pijlstaart" among mariners of different nations. These birds fly to a great distance from land and seem to be aitracted by ships, frequently hovering round or even settling on the mast-head.
The Yellow-billed Tropic- bird, $P$. favirostris or candidus, appeare to have hahitually the most northerly, as well, perhaps, 89 the
${ }^{1}$ More recently aailors have taken to call it "Dostamain-bird"a name probably belonging to a very different kind (cf. SkJa).
${ }^{2}$ Occasionally, perhaps throngh violent etorms, Tropic-hirds wander very far from their proper haunte. In 1700 Leigh, in his $N$. H. Lancashire (i. pp. 164, 195, Birds, pl. i., fig. 3), described and figured a "Tropick Bird" found dead iu that county. Another is said by Mr Lees (Zoologist, eer. 2, p. 2666) to have bean found dead at Cradley near Malpern-apparently before 1850 (J. H. Gurney, jun., op. cit., p. 4786)-Which, like the laet, would eeem (V. H. Heston, op. cit., p. 5086) to have been of the epecies known as $P$. aethereus. Naumanu was told (Rhea, i. p. 25) of its supposed occurrence at
widest range, visiting. Bermuda yearly to breed there, but also occurring numerously in the southern Atlantic, the Indian, and a great part of the Pacific Ocean. In some islends of all these three it breeds, sometimes on trees, which the other apecies are not known to do. However, like the rest of its congenere, it lays but a single egg, and this is of a pinkish white, mottled, opotted, and omeared with brownish purple, often oo closely as to conceal the ground colonr. This is the emallest of the group, and hardly exceeds in size a large Pigeon; but the epread of its wings snd its long tail meke it appear more bulky than it really is. Except some blsck markings on the face (common to all the species known), a large black patch partly covering the scapulars and wing-coverts, sud the black shafts of its elongated rectrices, its ground colour is white, glossy as astin, and often tinged with roseate. Its jellow bill readily distinguishes it from its larger congener $P$. acthercus, but that has nearly sll the upper surface of the body and winge closely barred with black, while the shafts of its elongated rectrices are white. This opecies has a range almost equally wide as the last ; but it doee not seem to occur in the western part of the Indian Ocesn. The third and largest species, the Red-tsiled Tropic-bird, P. rubricauda or phenicurus, not only has a red bill, but the elongated and very attenuated rectrices are of a bright criman sed, and when adult the whole bocy ghowe a deep roseate tinge. The yonng aro beautifully barred above with blsck arrow headed markings. This opecies has not been known to occur in the Atlantic, but is perhaps the most numerous in the Indian and Pacific Oceans, in which last great value used to be attached to its tail-festhere to be worked into ornaments. ${ }^{3}$
That the Tropic-birds form a distinct family, Phaethontides, of the Steganopodes (the Dysporomorphes of Prof. Huxley), was originally maintained by Brandt, and is now generally admitted, yet it cannot be denied that they differ $\&$ good deal from the other members of the group ${ }^{4}$; indeed Prof. Mivart in the Zoological Transactions (x. p. 364) will hardly allow Fregata and Phaethon to be steg. anopodous at all; and one curious difference is shown by the eggs of the latter, which are in eppearance so wholly unlike those of the rest. The osteology of two species has been well described and illustrated by Prof. Alph. Milne-Edwards in M. Grandidier's fine Oiseaux de Mada. gascar (pp. 701-704, pls. 279-281a).
(A. N.).

TROPPAU (Slavonic Opava), the chief town of Austrian Silesia, is a busy commercial place on the right bank of the Oppa, close to the Prussian border. A welli-built town with extensive suburbs, it has two market-places and contains six charche's, an old town-house recently restored ir the Gothic style, and numerous educational, benevolent, and commercial institutions. The site of the former fortifications is laid out in pleasant promenades. Troppau manufactures large quantities of cloth, especially for the army; and its industrial establishments include a large sugarrefinery and manufactories of machines and stoves. In 1880 the population was 20,562 . German is spoken in the town proper, but a dialect of Polish prevails in the suburbs.

Troppau was founded in tho 13 th century; but almost its ouly claim to historical menticn is the fact that in 1820 the monarche of Austria, Rassia, and Prussia met bere to deliberate on the tendencies of the Neapolitan revolution. This congress of Troppau, however, left nearly the whole matter to be considered and decided o.t Laibach. The former principality of Troppau is now divided between Austria and Prussia, the latter holding the lion's share.

TROTZENDORFF, or TROCEDORFIDS, VALENTIN Friedland (1490-1556), called Trotzendorff from his birthpiace, near Görlitz, in Prussian Silesia, was born on 14 th February 1490, of parents 80 poor that they could not keep him at school. Tho boy taught himself to read and write while lerding cattle; he made paper from birch bark, and ink from soot. When difficulties were orercome and he was sent for education to Görlitz, his mother's last

Heligoland, and Col. Legge (13. Ceylon, p. 1174) mentions one taken in India 170 miles from the cea. The case cited by MM. Degland and Gerbe (Ornith. Europeenne, ii. p. 363) seems to be that of an Albatros.

A fourth species, $P$. indicus, has been described from the Gulf of Omnu, lut doubt is expressed as to its validity (cf. Legge, ut supra, pp. 1173, 1174).

- Sulidg (Gannet), Pelecaniug (Prlican), Plotide (Snafe-birn), Phalucrocoraida (Cormorant), and Fregatide (Frioate-bird).
words were "stick to the school, dear son." The words determined his career : he refused all ecclesiastical promotion, and lived and died a schoolmaster. He became a distinguished student, learned Ciceronian Latin from Peter Mosellanus and Greek from Richard Croke, and after graduation was appointed assistant master in the school at Görlitz. There he also taught the rector and other teachers. When Luther began his attack on indulgences, Trotzendorff resigned his position and went to study under Luther and Melanchthon, supporting limself by private tuition. Thence be was called to be a master in the school at Goldberg in Silesia, and in 1524 became rector. There he remained three years, when he was sent to Liegnitz. He returned to Goldberg in 1531 and began that career which has made him the typical German schoolmaster of the Reformation period. His system of education and discipline spcedily attracted attention. He made his best elder scholars the teachers of the younger classes, and insisted that the way to learn was to teach. He organized the school in such a way that the whole ordinary discipline was in the hands of the boys themselves. Every month a "consul," twelve "senators," and two "censors" were chosen from the pupils, and over all Trotzendorff ruled as "dictator perpetuus." One hour a day was spent in going over the lessons of the previous day. The lessons were repeatedly recalled by examinations, which were conducted on the plan of academical disputations. Every week each pupil had to write two "exercitia styli," one ia prose and the other in verse, and Trotzendorff took pains to see that the subject of each exercise was something interesting. The fame of the Goldberg school extended over all Protestant Germany, and a large number of the more famous men of the following generation were taught by Trotzendorff. He died on 20th April 1556.
See Herrmann, Merkcoürdige Lebensogeschichte eincs beriühmtes Schulmans, V. F. Trotzendorfs, 1727; Frosch, V. F. Trotzendorff, Ieftor $\approx u$ Goldberg, 1818 ; Pinzger, V. F. Trotzendorff (with tbe Goldarerg portrait, and a complete list of his writings), 1825 ; Kochler, V. F. Trotzendorff, ein biographischer Versuch, 1848 . These biographies appear to take all their facts from a funeral or memorial oration dolivered by Balthasar. Rhau in the university of Wittenberg on 15 th August 1564, and published in an edition of Trotzendorff's Rosarium, 1565.
troubadours. See Provençal Literature, vol. xx. p. 873, and France, vol. ix. p. 646.

TROUGHTON, EDWARD ( $1753-1835$ ), instrument maker, was born in the parish of Corney in Cumberland in October 1753. He joined his elder brother John in carrying on the business of mathematical instrument makers in Fleet Street, London, and continued it alone after his brother's death, until he in 1826 took W. Simms as a partner. He died in London on 12th June 1835.
Trougbton was very successful in improving the mechanical part of most nautical, geodetic, and astrononical instruments. He was completely colour-blind, which prevented hin from attempting ex. periments in optics. The first modern transit circle (see RoEmer) was constructed by him in 1806 for Groombridge; but Troughton was dissatistied with this form of instrument, which a few years sfterwards was brought to great perfection by Reicherbach aud Repsold (qq.v.), and designed the mural circle in its place. The first instrument of this kind was erected at Green wich in 1812, and ten or twelve others were subsequently constructed for other observatories; but they were ultimately superseded by Troughton's earlier design, the transit circle, by which the two coordinates of an object can be determined eimultaneously. He also made transit instruments, equatorials, \&c.; but his failure to construct an equatorial mounting of large dimensious, and the consequent lawsuit with Sir James South, embittered the last years of his lifo.

Trout. See Salmonide; also Avgling, vol. ii. p. 41.
TROUVILLE, a fashionable seaside town of France, chef-lieu of the department of Calvados, and a port of the English Channel, is situated at the mouth of the river Touques, on the right bank, 136 miles west-north-west of Paris and 34 north-east of Caen by rail. The climate is raild, and the neighbourhood well wooded; there are villas
in all styles of architecture, a casino, and vast stretches of sand where the visitors ( 15,000 in 1881) bathe and walk. With Havre, which lies on the other side of the estuary of the Seine, 8 or 10 miles off, there is continual steamer communication. In 1886 the population was 5750 (commune 6300). Deauville, on the left bank of the Touques, opposite Trouville, is remarkable for its casino, terrace, and fine mansions, but, except during the race-week in August, is comparatively deserted. In 1886 its population was 2100 (commune 2220). In 1866 a dock, 985 feet in length by 262 in breadth, with 24 feet of depth at high water, was constructed between Trouville and Deauville; in 1882292 vessels ( 54,391 tons) entered and 283 ( 53,510 tons) cleared.
TROVER, or trover and conversion, the name of a form of action in English law no longer in use, corresponding to the modern action of conversion. It was brought for damages for the detention of a chattei, and differed from detinue in that the latter was brought for the return of the chattel itself. The name trover is due to the action having been based on the fictitious averment in the plaintiffs declaration that he had lost the goods and that the defendant had found them. The necessity for this fictitious averment was taken away by the Common Law Procedure Act, 1852. An action of trover lay (as an action of conversion still lies) in every case where the defendant was in possession of a chattel of the plaintiff and refused to deliver it up on request, such refusal being prima facie evidence of conversion. The damages recoverable are usually the value of the chattel converted. In an action for detention of a chattel (the representative of the old action of detinue), the plaintiff may have-judgment and execution by writ of delivery for the chattel itself or for its value at his option. An action for conversion or detention must be brought within six years. The corresponding action in Scotch law is the action of spuilzie. It must be brought within three years in order to entitle the pursuer to violent profits, otherwise it prescribes in forty years.

TROWBRIDGE, an ancient town of Wilts, England, is situated on the river Mere or Biss, a feeder of the Avon, and on a branch of the Great Western Railway, 33 miles north-west of Salisbury and $97 \frac{1}{2}$ west of London. The parish-church of St James is an ancient stone structure in the Gothic style, with a west square tower, surmounted by a spire 159 fect in beight, and a baptistery (1885). The site of the ancient castle was at the mound called Courthin, but all traces of it have long disappeared, it having been demolished before the reign of Henry VIII. Among the charitable institutions are the Edward and Yerbury almshouses (1698), the old men's almshouses, and the cottage hospital (1886). There are a market house and a town hall. Public gardens 4 acres in extent were opened in 1884. A water company (incorporated in 1873) supplies the town with water from the chalk hills in the neighbourhood of Biss. The principal industry is the manufacture of kerseymere and of broad and other woollen cloths, established as early as the reign of Henry VIII. The town is governed by a local board of health of twentyone members. The population of the urban sanitary district (area 2080 acres) in 1871 was 11,508, and in 1881 it was 11,040 .
The town was defended in bebalf of Matilda against Stephen by Humphrey de Bohun. By Lelsnd it is called Throughbridge or Thoroughbridge. Anciently it was a royal manor forming part of the duchy of Lancaster, having been grauted by the crown to John of Gaunt. Afterwards it reverted to the cruwn and was given by Henry VIII. in the 28th year of his reign to Sir Edward Seymour. It again lapsed to the crovn under Elizabeth, and in tho 24th year of her reign was assigned to Edward, earl of Hertford. By marriage it passed to the Rutland family, who, however, crentually sold $i$ t. It formerly gave the title of baron to the Seymour family. The poet Crabbe was rector of the parisll from 1814 to 1832.

TROY. See Troad.
TROY, a city of the United States, county seat of Rensselaer county, New York, is situated in $42^{\circ} 44^{\prime} \mathrm{N}$. lat. and $73^{\circ} 41^{\circ}$ W. long., upon the east bank of the Hudson river, at the head of tide water. It is nearly north of New York City (147 miles) and somewhat north of west from Boston ( 136 miles). The city, which has a length of about 4 milles, with an average breadth of 1 mile, is built mainly upon a level terraco slightly elevated above the river, but of late years the residence portion has extended up the hills (rising to 400 feet) which limit this plain on the east. It is in the main regularly laid out, and is traversed by street railways. Troy is situated at what is practically the terminus of the Erie Canal, connecting the Hudson river (here navigable for vessels of 8 to 10 fect draught) with Lake Erie, and of the Champlain Canal. It has three railroads, by which it is connected with New York on the south, Buffalo on the west, and also with the east and north. The principal industries, which in 1880 gave employment to 22,434 persons, are metalworking, especially in iron and steel, and tho making of stoves and liuen goods. The value of the products was $\$ 26,497,163$. The city is the seat of the Rensselaer Polytechnic Institute, which was for many years the leading engineering school of the United States, and still maintains a high reputation. The population, which in $1810^{\circ}$ was only 3895 , had in 1830 risen to 11,556 , and by 1880 to 56,747 ( 27,154 males and 29,593 females, the excess of the latter being explained by the large number of women employed as factory operatives). The proportion of foreign born $(16,938)$ was large.

The city was founded in 1787 by the Dutch, under the name of Vanderheyden, and two years later the present name was adopted. In 1794 it was incorporated as a village, and in 1816 it recoived a city charter. The opening of the Erie and the Champlain Canals in 1823 insured its prosperity and rapid growth.

TROY, Jeaf Françols de (1679-1752), a French painter, highly endowed by nature, was born at Paris in 1679. He received his first lessons from his father, himself a skilful portrait-painter, who afterwards sent his son to Italy. There his amusements occupied him fully as much as his studies; but his ability was such that on his return he was at once mado an official of the Acadeny and obtained a large number of orders for the decoration of public and private buildings, executing at the same time a quantity of easel pictures of very unequal merit. Amongst the most considerable of his morks are thirtysix compositions painted for the hotel of De Live (1729), and a series of the story of Esther, designed for the Gobelins whilst De Troy was director of the school of France at Rome (1738-51), -a post which he resigned in a fit of irritation at court neglect. He did not expect to be taken at his word, but found himself forced to return to France, and was making ready to leave when he died suddenly (24th January 1752) of an attack on the lungs.
His desire to make a figure in the world led him to neglect his more serious duties and injured his professional reputation. The life-size painting (Louvre) of the First Chapter of the Order of the Holy Ghost held by Fenry IV., in the church of the Grands Augustins, is one of his most complete performances, and his dramatic composition, the Plague at Marseilles, is widely known chrough the excelleat engraving of Thomassin. The Cochins, father and son, Fessard, Galimard, Bauvarlet, Herisset, and the painters Boacher and Parrocel Lave engraved and etched the works of De Troy.

## TROY, West. See West Troy.

TROYES, a town of France, formerly the capital of Champagne, and now chef-lieu of the department of Aube, and an episcopal see, is 104 miles south-east of Paris by the railway to Belfort, at the junction of the line from Orleans to Challons. Several arms of the Seine and also
the Haute-Seine Canal run through the town. The cathedral of St Peter and St Paul, the building of which lasted from 1206 till the 16 th century, still wants the south tower. Ths choir, the end chapels, and the sacristry were restored in 1849-1866. The 16th-century façade, witl mutilated bas-reliefs and statues, is surmounted by the tower of St Peter (230 feet). The choir, one of the most beautiful in France, belongs to the 13 th century, as does also its remarkable glass. The treasury contains gospels of the 11 th and 12th centuries, precious stones brought from the East at the time of the crusades, and ancient and beautiful lace. The unfinished church of Sit Urban, begun in 1262 at the expense of Urban IV., is a charming specimen of the best period of Gothic architecture, the side portals being remarkably light and delicate. The church of St Madeleine, built at the beginning of the 12 th century, enlarged in the 16 th, and recently restored, contains a rich rood-screen by Jean de Gualde (1508). In 1420 the treaty of Troyes was signed in the church of St John, where Henry V. of England and Catherine of France were subsequently married. The church of St Remy, with a Romanesque tower, the churches of St Nizier and St Nicholas, both of the 16 th century, and that of St Pantaléon, of the 16 th and 17 th, should also be noticed. There are some curious fireplaces in the town hall ( 17 th century), and the municipal archives contain the correspondence of the dukes of Lorraine and Guise. The old abbey of St Loup is occupied by the library ( 80,000 volumes and 2720 manuscripts) and a museum containing numerous collections; that relating to natural history is rich in ornithology and entomology, and has many aerolites. Blost of the old honses of Troyes are of wood, but some of stone of the 16 th century are remarkable for their beautiful and original architecture. The chief industry of Troyes and the surrounding district is the manufacture of cotton and woollen hosiery, which is woven almost entirely by hand, and is exported to America and Switzerland. One-fourth of the population live by subsidiary industries. There are 14 cotton mills with 10,000 spindles, bleaching, dressing, and dye works, workshops for making looms, needle factories, iron and copper foundries, 8 flour mills, and nursery and market gardens. A trade is carried on in pork and cheese. A few miles from the town stands the curious church of St Andrew (16th century), with a remarkable portal. The population in 1886 was 46,972 ( 46,067 in 1881).
At the beginning of the Roman period Troyes (Augustobona) $\pi$ Tas the principal settlement of the Tricassi. It was christianized in the 3rd century, and its bishop St Loup (426-479) founded renowned schools, and averted the fury of Attila. In 484 Troyes passed into the hands of Clovis, and belonged sometimes to Neustria, sometimes to Austrasia, till all Gaul was united under Charles Martel. In 878 Pope John VIII. presided at a council in Troyes. The town was fired and sacked by the Saracens in 720, and by the Normans in 889 and 903 . In 1229 Theobald IV., besieged in his capital, ras delivered by king Lauis IX., and in 1230 he granted the inhabitants a municipal eharter. From this time the fairs of Troyes became celebrated. During the captivity of King John in England, Troyes resisted all attacks, and after Agincourt took the part of the Burgundians. In 1417 the sule of Queen Isabeau of Bavaria was establisheú in Troyes, where in 1118 the parlement of Paris met ; and on 21st May 1420 Henry V. of England, Charles VI. of France, Isabeau, and Philip of Burgundy signed the famous treaty of Troyes. On 9th July 1429 the town capitulated to Joan of Arc. In the 16th century Protestantism made rapid progress, but in 1562 the Hinguenots were forced to retire to Bar-sur-Seine; after the massacre of Si Bartholomew in Paris, the Calvinists in the prisons of Troyes met the same fate. In 1577 the inhahitants joined the Lcague, and only opened their gates to Henry IV. in 1594. In 1787 the parlement of Paris again met here. In 1814 both the allied and the imperial armies occupied Troyes; and iu 1870 the town was occupied by the Germans.

TROYES, Chrestien de. See Chrestien de Trozes, and Romance, vol. xx. p. 645.

TRUCE OF GOD. The orderly administration of justice and the unirersal peace, which the Roman empire
established from the Euphrates to the Atlantic, did not long survive the inroads of the Teutonic tribes who in western Europe divided the inheritance of the Latin world. All the early Teutonic codes, being based, howerer remotely, on the right of private war and private vengeance, might discourage, but were powerless to abolish, the instinct which impels the merabers of half-civilized communities to avenge their own wrongs. Hence the pax Romana died with the empire ; nor could the splendid organization of Charlemagne do more than effect a very partial resuscitation of it. Throughout the 9 th and loth centuries, as the life-benefices of the later Carolingian kings became gradually transformed into hereditary fiefs, the insecurity of life and property grew greater; for there was no central power to curb the injustice of the petty dukes and counts who warred and pillaged at their will. At this moment, when western Europe threatened to sink back into the chaos from which it had been won by Rome, the church came forward to arrest the process of its dissolution. Speaking at frst in her own interest and in that of the poor, whose great protector she claimed to be, she decreed a special peace for the unarmed clerk and the industrious husbandman. The council of Charroux in Poitou led the way in 989 . With the opening of the next century the movement spread over Aquitaine and the rest of France. Everywhere the bishops set themselves to exact from the whole diocese, noble and simple alike, a novel oath to abstain from violence and to respect the sanctity of churches. William V. of Aquitaine, the most powerful lord of southern France, lent his inîuence to the cause at the councils of Limoges (994) and Poitiers (999). The latter council prescribed the methods by which all who violated their solemn engagement should be punished. The times, however, were bardly ripe for the inauguration of an era of peace. Gerard of Soissons, perhaps, was not the only bishop who eyed this dream of universal harmony askance, as tending to encroach on the king's prerogative (see Bouquet, x. 201); and, on the whole, it may be said that the "Peace of God"was at best but a somewhat ineffectual protection to churches, priests, and labourers. If there was any hope of restraining the mutual feuds of the barons it must be by other means. And here the church again, reeognizing the impossibility of absolutely stopping all feudal warfare, endeavoured to limit it. This limitation of the right of perpetual warfare, reduced to writing, sanctioned by an oath, and confirmed by the decrees of councils, assumed the name of the "Truce of God" (treva or treuga Der). The truce of God seems to have been first established at the synod of Tuluges, near Perpignan in Roussillon, on 16th May 1027. In accordance with its decrees all warfare was to be suspended from noon on Saturday till prime on Monday; and the peace of God was permanently extended to all monks, clerks, bishops, and churches. Like the pax ecclesix, this laudable example was soon followed elsewhere. About 1041 it extended itself over Aquitaine and all France; in 1012 the council of Caen, under the sanction of Duke William, established it in Normandy-a country in which, according to a contemporary writer (Rodolph Glaber, $\mathrm{\nabla}$. 1), it was not at first accepted. By this time its terms had been much enlarged; and we may perhaps tale the provisions of a sccond synod at Tuluges (1041) as representing its normal form. According to this synod the treuga Dei was to last from the Wednesday evening to the Monday morning in every week, from the beginning of Advent to the octare of the Epiphany, from the beginning of Lent till the octave of Pentecost, for the feasts of the Holy Cross, the three great feasts of the Virgin, and those of the twelve apostles and a fewt other saints. More usually the interral between tle Epiphany netave and Lent and that from Easter to

Rogations recte left subject to tho weekly truce only. Thus from being a mere local institution it spread rapidly over all France, and seems to have crossed into Germany, Italy, Spain, and England. It had also its special courts and methods of procedure. Excommunication and banishment for seven or thirty years were its penalties. Defors long both the pax ecclesix and the treuga $D \in i$ were sanctioned by the holy see. Special clauses were added to protect pilgrims, women, merchants, monks, and clerks; while the cattle and agricultural implements of the peasant -his ox, horse, plough, and even his olive-trees-were covered by the ægis of the church. The first clause of the council of Clermont (1095), at which Urban II. preached the first crusade, proclaimed the weekly truce for all Christendom, and perhaps enjoined it in its most extended form, adding also a clanse by which the oath was to be rencwed every three years by all men above the age of twelve, whether noble, burgess, villain, or serf. ${ }^{1}$ The same council seems to have accorded safety to all who took refuge at a wayside cross (cap. 29) or at the plough (homines ad carrucas fugientes). The truce of God was most powerful in the 12th century, during which period it was sanctioned hoth by local and papal councils, such as that held at Rheims by Calixtus Il. in 1119 , anci the Lateran councils of 1139 and 1179 . With the 13 th century its influence began to decline, as the power of the king gradually led to the substitution of the king's peace for that of the church.
For an exhaustive account of the whole question, see M. Semichon's book, to ribich the above article is largely indebted.

TRUCK SHS'FEM. See LABour, vol. siv. p. 172, and Wages.

TRUFFLE, the name of several different species of subterranean fungi which are used as food. The species sold in ${ }^{\circ}$ English markets is Tuber æstivum; the commonest speciez of French markets is T. melanosporum, and of Italian the garlic-scented ${ }^{T}$. magnatum. Of the three, the English species is the least excellent, and the French is possibly the best. The truffo used for Perigord pie (paté de foie gras) is T. melanosporum. When, however, the stock of T. melanosporum happens to be deficient, some manufacturers use inferior species of Tuber, such as the worthless or dangerous Choromyces meandriformis. Even the rank and offensive Scleroderma vulgare (one of the puffball series of fungi) is sometimes used for stuffing turkeys, sausages, \&r. Indeed, good truffes, and then only T. astivum, are seldom seen in English markets. The taste of $T$. melanosporum can be detected in Perigord pie of good quality. True and false truffes can easily be distinguished under the microscope.

Tubor æstivum, the English truffe, is roundish in shape, covered with coarse polygonal warts, black in colour outside and brownish and veined with white within; its average size is about that of a amall apple. It grows from July till autumn or winter, and prefers beech, oak, and birch woods on argillaceous or calcareous soil, and bas sometimes been observed in pine woods. It grows gregariously, often in company with T: brumale and (in France and ltaly) T. melanosporum, and sometimes appears in French markets with these two species, as well as with $T$. nicsentericum. The odour of T. æstivum is very strong and penetrating ; it is generally esteemed powerfully fragrant, and its taste is considered agreeable. Its price in England is two or three shillings a pound. The common French trufle, T. melanosporum, is a winter species. The tubers are globose, bright brown or black in colour, and rough with polygonal warts; the mature flesh is blsckish grey, marbled within with white veins. It is gatbered in autumn and winter in beech and oak moods, and is frequently seen in Italian markets, wlicre it is sometimes sold for $12 s$ : 6 d . a pound. The odour of T. melanosporum is very pleasant, especially when the tubers are young, then somewhat resembling that of the strawberry; with age the smell gets very potent, but is never considered really unpleasant. The come mon Italian trufle, T. magnutum, is pallid ochreous or brownish buff in colour, smooth or minutely papillose, irregularly globosc. and lobed; the interior is a very pale brownish liver colour reined
${ }^{1}$ Labba'a Concilia; $x x .816$; with which of. Semichon, Lx Paix ot la Tréve de Dieu, Paris, 1869, p. 125.
with white. It grows towards the end of autumn in plantations of willows, poplars, and oaks, on clayey soil. Sotnetimes it occurs in open cultivated felds. The odour of the mature fungus is very potent, and is like strong garlic, onion, or decaying cheese. I'. brumale, referted to above, grows in Britain. It is a winter truffle, and is found chiefly under oaks and abele trees from October to Decomber. It is black in colour, globose, more or less regular in shape, and is covered with sharp polygonal warts; the mature flesh is blackish grey marbled with whito veios. The odour is very strong and lasts a long time; the taste is generally esteemed agreeable. Chevomyces meandriformis, which occurs in Britain, is sometimes sold for T. magnatum, the colour of the flesh of both species being somewhat similar. Scleroderma vulgare, the "false trufle," is extremely coramon on the surface of the ground in woods, and is gathered by Italians and Frenchmen in Epping Forest for tha inferior dining-rooms of London where Continental dishes are served. It is a worthless, offensive, and possibly dangerons fungus. A true summer truHfe, T. mesentericum, fonnd in oak and birch woods on calcareous clay soil, is frequently eaten on the Continent. It is esteemed equal to T. æstivum. It probably grows in Britain. Another edible species, T. macrosporum, also grows in Britain, in clayey places nuder young beeches and oaks, on the borders of streams and roads, and sometimes in fields; more rarely it grows in plantations of willow and poplar. It has a strong scent of onions or garlic. Terfezia leonis, a famous truffle of Italy, Algeria, Sardinia, \&c., resembles externally a potato. It grows in March, April, and May. Som persons eat it in a raw state, sliced, and clipped in oil or egg. It is not scented, and its taste is generally considered iosipid or soapy. Sometimes an ally of the puff.balls, and therefore (like Scleroderma) not a true truffe, Melanogaster vuriegatus, is eateu in England and France. It has been, and possibly still is, occasionally sold in England under the name of "red truffe." It is a small ochreous brown species with a strong aromatic and pleasant odour of bitter almonds. When the plant is eatom raw the tasto is sweet and sugary, but when cooked it is hardly agreeable. The odour belonging to many truffes is so notent that their places of growth can be readily detected by the odour exhaled from the ground. Squirrels, hogs, and other animals commonly dig up trumes and devour them, and pigs and dogs have long been trained to point out the places where they grow. Pigs will alrays eat truffles and dogs will do so occasionally; it is therefore usual to gire the trained pig or dog a small piece of cheese or some little reward each time it is auccessful. Truffes are reproduced by apores, bodies which serve the same purpose as seeds in flowering plants; in true truffles the spores are borne in transparent asci or sacs, from four to eight spores in each ascus. The asci are

Spores of the chief European truffes. Eularged 500 dianetere. 1 , Tuber estivum; 2, T. brumale; 3, T. melanosporum; 4, T. mesentericum; 5, T. magnatum; 6, Charomyces meandrivormis, 7. Scleroderma vulgare; 8, Melanagas. ter variegatus.
embedded in vast numbers in the flesh of the truffle. In false trutiles the spores are free and are borne on minnte spicules or supports. The spores of the chief European truffles, true and false, enlarged five hundred diameters, are shown in the accompanying illustration. Many references to truffes occur in classical authors. The truffe Elaphomyces variegatus was till quite recent times used, under the name of Hart's nut or Lycoperdon uut, on account of its supposed aphrodisiac qualities.

TRUMBULL, the surname of more than one individual of note in the literature, art, and politics of America.

1. Benjamin Trombull was born at Hebron, Connecticut, on 19th December 1735, and died at North Haven, Connecticut, on 2d February 1820. He graduated at Yale in 1759, and entered the ministry. His literary work was considerable, the most important being the standard $H$ istory of Connecticut to 1764.
2. Joan Trumbull was born at Waterbury, Connecticut, on 24th April 1750, and died at Deiroit, Mlichigan, on 12th May 1831. He graduated at Yale in 1767, and became a lawyer and anthor of high reputation. His best
work is Mc Fingal, a Hndibrastic poem, intendel to strve the Whig side in the Anerican Revolution.
3. John Trumbull, son of the following, was born at Lebanon, Connecticut, on 6 th June 1756, and died at New York City, on 10th November 1843. He graduated at Harvard in 1773 , studied painting with Benjamin West in London, and left at his death a number of historical works. The earlier of these are the better; the later and larger were painted for the capitol at Washington.
4. Jonathan Trombole was born at Lelanon, Connecticut, on 10th June 1710, and died at the same place on 17 th August 1785. He graduated at Harvard in 1727, and became a lawyer and coionial politician. His place in American bistory was gained as governor of Connecticut from 1769 until 1783, through the whole period of the American Revolution. He was a trusted supporter and confidential adviser of Washington, who was accustomed to speak of him as "brother Jonathan," and the term has since passed into popular use as equivalent to the people of the United States.
5. Jonathan Trumbull, son of the preceding, was born at Lebanon, Connecticut, on 26th March 1740, and died at the same place on 7th August 1809. He graduated at Harvard in 1759, and served as member of congress, 1789-95 (being speaker of the house of representatives during the last two years of his term), as United States senator, 1795-96, and as governor of Connecticut, 1798-1809.

TRUSIPET, a musical instrument, consisting of a long, narrow brass tube, cylindrical for the greater part of its length: the fusiform development which terminates in the bell or opening of the lower end only begins at a point that varies from a third to a fourth of the total length from that extremity. The air inside is set in vibration by the lips (which act as true reeds) applied to the edges of a basin-like mouthpiece fitted to the upper part of the instrument. The material has nothing to do with the production of that brilliant quality of tone by which the trumpet is so easily distinguished from every other mouthpiece instrument: the difference is partly due to the distinct form given to the basin of the mouthpiece, but principally to the proportions of the column of air determined by the conical or cylindrical form of its envelope.

The possibility of producing sonorous disturbance of a mass of air throngh a mouthpiece, or more simply through the orifice of the tube, has been known from a very early period, - a shell bored at its extremity, or a horn with the point removed, being without doubt the most ancient instrument for producing sound. Nearly all the nations of antiquity had mouthpiece instruments; but the greater number of these, though grouped under the general designation of trumpets, have only a very distant relationship to the modern instrument The Romans had four such instruments, - the tuba, buccina, cornu, and lituus. The tuba, represented in the bas-reliefs of the triumphal arch of Titus, was a kind of straight bronze clarion, with a conical column of air. It is ordinarily designated the Roman trumpet, and was about 39 inches long; its compass șhould not go beyond the first six proper notes of the harmonic scale. The Roman tuba and the Greek salpinx are supposed to be one and the same instrument. The buccina was also of bronze, with a tube measuring fully 11 feet in length. The tube is only slightly conical, and the quality of tone bears a striking resemblance to that of the bass trombone in $G$; the proper tones for harmonics were those subjoined. ${ }^{1}$ The cornu was
 often made of a bullock's horn, but bronze wass also employed,

[^249]ss in a specimen in the British Museum. This instrument measured 4 feet 6 inches in length, and the scale was that herewith shown. The Roman cornu was probably like the Greek keras. The three preceding instruments were used in giving signals to the infantry. The caralry calla were given with the lituus, a specimen of which exists in the muscum of the Vatican, found in 1827 in a tomb at Cerveteri (Cære). The tube is cylindrical for the greater part of its length, its conical development beginning only at the lower end, where the instrument begins to curve. The lituus easily produces the accompanying $=$ proper notes; its quality of tone is like that of a trumpet
in G. In Ireland and Denmark numerous mouthpiece instruments in bronze have been found, sixteen different specimens being preserved in the museum of the Rojal Irish Academy at Dublin, and six (of which facsimiles exist in South Kensington Nuseum) in the museum at Copenkagen. But none of these hare the proportions of a trumpet; all, by the conical development of the tube as well as by the eurved form, recall their first model, the hern, successive transformations of which have given rise to the clarion and the numerous family of bugles.

We have no precise information as to the form which the lituus, the ancestor of the modern trumpet, assumed during the Middle Ages. A miniature in the Bible ${ }^{1}$ presented in 850 to Charles the Bald places the lituus in tho hands of one of the comprnions of King David, but we are not-warranted in concluding from this that the Etruscan instrument was in use in the 9th century. The carliest representation of the trumpet with its present proportions of tube and form of beil seems to belong to the 15th century. Fra Angelico (d. 1 155) has painted angels with trumpets having either straight or zigzag tubes, the shortest being about 5 feet long. The perfect representation of the details, the exactness of the proportions, the natural pose of the angel players, suggest that the artist painted the instruments from real models.

The credit of having bent the tube of the trumpet in three paraliei leanches, thus creating its modern form, has usually been claimed for a Frenchman named Maurin (1498-1515). But the transformation was really made in Italy about the middle of the 15 th century, as is prored by the bas-reliefs of Luca della Robbia intended to ornament the organ chamber of the cathedral of Florence (see rol. xx. p. 588) ; there a trumpet having the tube bent lack as just described is very distinctly figured. From the beginning of the 16th century we kave numerous sources of information. Virdung ${ }^{2}$ cites three kinds of nouthpiece instruments-the felterunet, the clareta, and the thurner horn; unfortunately be does not mention their distinctive characters, and it is impossible to make them out by examination of his engravings. Probably the felttrumet and tho clareta closely resembled cach other ; but the compass of the former, destined for military signals, hardly went beyond the 8th proper tone, while the latter, reserved for high parts, was like the clarino (see belom7. The thuruer horn was probably a kind of जarino or clarion used by watcimen on the towers. The wuminet and the jüger trommet are the only two mouthicee instruments of the trumpet kind cited by Preterius. ${ }^{3}$ ce frst was tuned in D at the ciamber pitch or "kamI orton," but with the help of a shan's it could be put i) C, the equivalent of the " ahorton" $D$, the two differ$\because g$ about a tone. Sometimes the trummet mas lowered

[^250]to B and eren By. The jäger trommet, or "trompette de chasse," was composed of a tube bent several times in circles, like the posthorn, to make use of a comparison employed by Prætorius himself. His drawing does not make it clear whether the column of air was like that of the trumpet; there is therefore some doubt as to the true character of the instrument. The same author further cites a wooden trumpet (hözern trommet), which is no other than the Swiss alpen-horn or Norwegian luur. Mersenne's ${ }^{4}$ information is not sery instructive; but he gives a description of the sourdine, a kind of mute or damper introduced into the bell, already employed in his time, and still made use of to weaken the sound. The shape of the trumpet, es seen in the bas-reliefs of Luca del.a Robbia, was retained for more than three hundred years: the first alterations destined to revolutionize the whole technique of the instrument were made about the middle of the 18 th century. Notwithstanding the imperfections of the trumpet during this long period, the performers upon it acquired an astonishing dexterity.
The usual scale of the typical trumpet, thest in D, is

Pretorins exceeds the limits of this compass in the higher range, for he says a good trumpeter could produce the subjained notes. (f) en en
in a trumpet solo which ends the
cantata "Der Himmel lacht," wrote up to the twentieth of these sounds. So considerable a compass could not be reached by one instrumentalist : the trampet part bad therefore to be dividcd, and each division was designated by a special name. ${ }^{\text {. The fundamental or first }}$ proper note was called flattergrob, the second grobstimme, the third faulstimme, the fourth mittelstimme. The part that was called principal went from the fifth to the tenth of these tones. The higher region, which 1 ad received the name of "clarino," was sgain divided into two parta: the first began at the eighth proper tone and mounted up towari the extreme high limit of the compass, according to the skill of "he executant; the second, beginning at the sixtl proper tone, rarely went beyond the twelfth. Each of these parts was confided to a special trumpeter, who ezecuted it by using a larger or a smaller mouthpiece.

Playing the clarino differed essentially 1 rom playing the militar trumpet, which corresponded in compass to that called principal. Compelled to employ rery small moutbpieces to facilitate the emis. sion of rery high eounds, clarino players could not fail to slter the tone of the instrument, and instead of getting the brilliant and energetic quality of tone of the mean register they were only able to produce more or less donbtful notes without power and eplendour. Apart from this inconvenience, the clarino presented nnmerous deviations from just intonation. Hence the players of that time failed to obviate tho bad effects incritably resulting from the natursl imperfection of the harmonic scale of the trumpet in that extreme part of its compass; in the execution, for instance, of the works of Rach, where the trumpet ehould give sometimes -2 0 , and $\Rightarrow-20$, the instrumentalist could only com-解 Further, the thirtecath proper tone, for which is really too flat, and it is absolutely im- possible to remedy this defect, since it entirely depends
 upon the laws of resonance affecting columns of air.
Sirice the abandonment of the clarino (about the middle of the 18th cenlury) onr orchestras have been enriched with trumpets that purmit the execution of the old clarino parts, no* ouly with perfect justuess of intonation, but with a quality of tome that is not defieicnt in character when comparcd with the mean register of the old principal instrument. The introdaction of the clarinet or little clarino is one of the causes which led to tlio abandonment of the older instrument and may explain the prcference given by the composers of that epoch to tho mean register of tho trumpet. The clarino laving disappeared befors Mozart' 8 day, he hed to change the trumpet parts of Hardel and Bach to allow of their execation by the performacrs of his own time. It was now that irooks began to be frequently nsed. Trumpets were made in F instead of in $D$, furnished with a scrics of shanks of increasing length for the tonalities of $E, E\rangle, D, D_{D}^{\prime}, C, B, D h$, and sometimes even A.

[^251]The first attempts to extend the limited resourees of the instrument in its new employment srobe out of Hempel'g ides of lowering the harmonic sounds by introducing the hand into the bell. But, instead of fixing the shanks between the mouthpiece snd the upper extremity, they were adapted to the body of the instrument itsolf by a double slide, upon the two branches of which tubes were inserted bent in the form of a circle and graduslly lengthened as required. This modifed instrument became known ss tho "invention horn." This system was applied to the trumpet by aichel Woegel (born at Rastait in 1748), whose "invention trumpet" bad a great success, notwithstanding the unaveidable imperfection of a too great disparity in quality of tone between the open and the closed sounds. The idea of applying the trombone slide to the trumpet is obvious. The slide trumpet is mentioned by T. E. Altenburgs ${ }^{1}$ who compares it, snd with reasen, to the alto trombone: and thero are grounds for identifying it with the "tromba da tirarsi" employed by J. S. Each in some of his compositions. The slide trumpet is still used in England in a somewhat modified form. About 1760, Kolbel, a Kussian musician, applied a key to the horn, and soon afterwards the trumpet received a similar sddition. By opcning this key, which is placed near the bell, the instrument was raised a distonic semitone, and by corrocting errors of intenation by the pressure of the lips in the mouthpiece the following diatonic succession was obtained. in 1801 by Weidinger, trumpeter to the imperial court at Vienna, whe increased the number of keys and thus mede the trumpet chromatic thoughout its scale. The instrument shown in the accompanying figure is in $G$; the keys are five in number, and ss they open one after another or in combination it is pessible to connect the second proper tone with the third by chromatic steps, and thus produce the following succession. The number者产 gaps between the oxtreme sounds of the interval of a fifth; and a like result was arrived st more easily for the intervals of the fourth, the major third, \&c., furnished by the proper tones of 3,4 , 5 , \&c. But, though the koyed trumpet was a notable improvement on the invention trumpet, the sounds sbtained by means of the latoral openings of the tube did not pessess the qualities which distinguish sounds cansed by the resenance of the air-column vibrating in its entirety. But iu 1815 Stölzel made a genuine chromatio trumpet by the invention of the ventile or piston; for this ingenious mechanism, see Tronsone The siluple trumpet is now no longer employed except in cavalry regiments. It is usually in Eb. The bass trumpot in Eb, which is an actere lower, is sometimes, but rarely, nsed. Trumpets with pistons are generally constructed in F , with crooks in E aud Ej . In Germany trumpets in the high $B$ b with a crook in $A$ are very often used in the orchestra. They are easier for cornet à piston players than the trumpet in F. The present writer has recently constructed for the concerts of the Conservatoire at Brussels trumpets in the high D, an octave above the old trumpet in the same Key. They permit the execution of the high trumpet parts of Handel and J. S. Bach. The bass trumpet with pistons used for Wagaer's tetralogy is in Eb, in unison with the ordinary trumpet with crooks of $D$ and C; but, when constructed so as to allow of the productien of the second proper toue as written by this master, this instrument belongs rather to the trombones than to the trumpets. (V. M.)

TRUMPET, Speaking and Hearing. The speaking trumpet, though some instrument of the kind appears to have been in earlier use in more than one part of the world, is connected in its modern form with the name of Athanasius Kircher and that of Sir Samuel Morland, who in 1670 proposed to the Royal Society of London the question of the best form for a speaking trumpet. Lambert, in the Berlin Memoirs for 1763 , seems to have been the first to give a theory of the action of this instrument, based on an altogether imaginary analogy with the behaviour of light. In this theory, which is still commonly put forward, it is assurned that sound, like light, can be propagated in rays. This, however, is possible only when the aperture through

[^252]which the wave-disturbance passes into free air is large compared with the wave-length. If the fusiform mouth of the speaking trumpet were half a mile or so in radius, Lambert's theory might give an approximation to the truth. But with trumpets whose aperture $\mathrm{j}_{3}$ only a foot in diameter at most the problem is oue of diffraction; and it has not yet been seriously studied from this point of view.

In the case of the hearing trumpet, the disturbance is propagated along the converging tube much in the same way as the tide-wave is propagated up the estuary of a tidal river.

Until the theory has been rigorously worked out the only safe course to adopt in manufacturiug either class of instruments is to be guided by the results of varied trials.

The theoretical foundations of the subject will be found in Lord Rayleigh's Sound and in Sir G. Airy's Tides and Waves, respectively. In speaking and hearing trumpets alike all reverberation of the instrument should be avoided by making it thick and of the least elastic materials, and by covering it externally with cloth.

TRUMPETER, or Trumpet-Bird, the literal rendering in 1747, by the anonymous English translator of De la Condamine's travels in South America, (p. 87), of that writer's "Oiseau trompette" (Mém. de l'Acad. des Scicnces, 1745 , p. 473), which he says was called "Trompetero" by the Spaniards of Maynas on the upper Amazons, from the peculiar sound it utters. He added that it vas the "Agami " of the inhabitants of Yara and Cayenne, ${ }^{2}$ wherein be was not wholly accurate, since those birds are specifically distinct, though, as they are generically united, the statement may pass. But he was also wrong, as had been Barrere (France Equinoxiale, p. 132) in 1741, in identifying the "Agami" with the "Macucagua" of Marcgrave

White-winged trumpcter (Psophia leucopiera), After Mitchell
for that is a Tinamou (q.v.) ; and both still more wrongly accounted for the origin of the peculiar sound just mentioned, whereby Barrere was soon after led (Ornith. Spec. Novum, pp. 62, 63) to apply to the bird the generic and rulgar names of Psophia and "Petteuse," the former of which, being unfortunately adopted by Linnæus, has ever since been used, though in 1766 and 1767 Pallas (Miscellanea, p. 67, and Spicilegia, iv. p. 6), and in 1768 Vosmær (Descr. du Trompette Américain, p. 5), showed that the

[^253]notion it conveys is erroneous. Among English writers the name "Trumpeter" was carried on by Latham and others so as to be generally accepted, though an author may occasiona!!y be found willing to resort to the native "Agami," which is that almost always used by the French.
Messrs Sclater and Salvin in their Nomenclator (p. 141) admit 6 species of Trumpet-Birds-(1) the original Psophia crepitans of Guana; (2) P. napensis of eastern Ecuador (which is very likely the original "Oiseau trompette" of De la Condamine) ; (3) $P$. ochroptera from the right bank of the Rio Negre ; (4) P. leucoptcra from the right bank of the upper Amazons; ( 5 ) P. viridis from the right hank of the Madeira ; and (6) P. obscura from the right hank of the lower $\Delta$ mazons near Para. And they have remarked in the Zoological Proceedings ( 1867, p. 592) on tha curieus fact that the range of the aeveral species appeara to be separated hy rivera, a atatement coafirmed by Mr Wallaca (Geogr. Distr. Animals, ii. p. 358); and in connexion therewith it may be observed that these birds have abort wings and aeldom fly, hut run, though with a peculiar gait, very quickly. A saventh species, P. cantatrix, from Bolivia, has aince been indicated ly Prof. W. Blasius (Journ. f. Ornith., 1884, pp. 203-210), whe has given a monegraphic summary of the whole gronp very worthy of attention. The chief distinctions between the species lie in colour and aize, and it will be here enough to describe briefly the best known of them, $P$. crepilans. This is about the aize of a large barndoor Fowl ; hut its neck and lega are longer, so that it is a taller bird. The head and neek are clothed with ahort velvety feathers; the whole plumage is black, except that on the lower front of the neck the featbers are tipped with golden green, changing according to the light into violet, and that a patch of dull rusty bromn'extends across the middle of the back and ming-coverts, pessing into ash-colour lower down, where they lisng over and conceal the tail. The lega are bright pea-green. The hisbits of this hird are very wonderful, and it is much to he wished that fuller accounts of them had appeared. The curious sound it utters, noticed by the earliest observers. has heen alreädy mentioned, and by them also was its singularly aocial disposition towards man described; but the information aupplied to Buffon (Oiscaux, Iv. pp. 496.501) by Manoncour and De la Borde, which lias been repeated in many works, is still the best we have of the carious way in which it becomes aemi-domesticated by the Indians -nd colonists and shows strong affection for its owners as well as for their living property-poultry or sheep-though in this reclaimed condition it seema never to breed. 1 Indeed nothing can be positively asserted as to ats mode of nidificatton; hut its eggs, according to Mr E. Bartlett, are of a creamy white, rsther round, and about the size of Bantams'. Waterton in his W'anderings (Second Journey, chap. iii.) speaks of falling in with flecks of 200 or 300 "TWaracahas," as he called them, in Demerara, but added nothing to our knowledge of the species; while the contributions
 (Mue. Nol. History, ser. 2, ii. pp. 490-492) as regards its habits only touch upon them in captivity.

To the Trumpeters must undoubtedly be accorded the rank of a distinct Family, Psophiida; but like so many other South-American birds thev seem to be the less specialized descendants of an ancient generalized group -perhaps the common ancestors of the Rallidx and Gruedx-and they are therefore rightly placed in Prof. Huxley's Geranomorphes. ${ }^{2}$ The structure of the syrinx is stated by Trail (ut supra) to be quite unique; but his description of it is unsatisfactory, and he clearly had not an adult male to dissect or he would have hardly failed to notice the curious arrangement of the trachea in that ser made known by Hancock (ut supra). This, though different from that described in any Crane (q.v.), suggests an early form of the structure which in some of the Gruidx is so marvellously developed, for in Psophia the windpipe runs down the breast and belly immediately under the skin to within about an inch of the anus, whence it returns in a similar way to the front of the sternum, and then enters the thorax. Analogous instances of this formation occur in several other groups of birds not at all

[^254]allied to the Psophiidx. The skeleton and some of tire detached bones are figured in Ejton's Osteol. Avium (pls. xxix. and 5 k ).
(A. N.)

TRURO, a city, municipal borough, and port of Cornwall, England, is situated on a kind of peninsula formed by the river Allen and Kenwyn, which below the town unite with a branch of Falmouth harbour called Truro creek or river. Truro is 300 miles south-west of London by the Great Western Railway, and 11 north of Falmouth to which there is a branch line. The town is regularly built, chiefly of granite, with spacious streets, through.the principal of which there flows a stream of water. The new cathedral of St Mary by Mr Pearson, R.A., one of the mosi important modern ecclesiastical buildings in Englana, is a fine example of Early English at its best period. The olv south aisle of the church previously existing is ingeniously incorporated in the new edifice. The secular buildings include the town-hall and market-house in the Italian style (1846), the corn exchange, the theatre, the public rooms, the music-hall, and the county library (1792). There is also a theological library, presented by Bishop Phillpotts in 1856 and largely augmented by a bequest of books in 1883. Among the educational and benevolent institutions are the grammar-school (founded by a member of the Borlase family, and haring two exhibitions at Exeter College, Oxford), the cathedral divinity schools, the Wesleyan middle schools, the litemry institution, the royal Cornwall infirmary, the dispensary, and a hospital for ten widows. There is sufficient depth of water in the channel of Truro creek to permit vessels of 70 tons burden to come up to the town quay. The principal imports are coal from Wales and timber from Norway, and the exports consist of tin, iron ores, lead, and zinc, from the mines in the neighbour hood. The population of the municipal borough (area 1171 acres) in 1871 was 11,049 , and 10,619 in 1881.
Truro is ono of the oldest towns in England. It is the seat of the stannary and other courts connected with the dachy of Cornwall (see Cornwall, vel. vi. p. 427). It was one of the ancient privileged tin coinage tomas. Anciently it was called Tueura, Treurs, and Truruburgh. It was a horough by prescription, but w3s incorporated by Reginald, earl of Cornwall. In the 12th contury it belonged to Richard de Lucy. In a charter of Henry VII. it is called the "rille de Tcuro." The gevernment was yested in a mayor and burgesses by Elizaheth, who gave the corporation juris. diction over the port of Fslmouth, the port dues of that torru heing collected by them until its incorporation by Charles II. Norden, writing of Trure in 15\%4, says, "there is not a towne in the west part of the shire more commendable for neatness of buyldinges, nor mere discommendahle for the pride of the people." In 1642 Sir Ralph Hepton levied here a large body of men for the king. By the Municipal Act Truro Tas divided into two wards, and is governed by a major, six aldermen, and eighteen councillers. The corpor, stion act as the urben sanitary anthority. Truro sent two representatives to parliament from the 23d year of Edward I., but ceased to be separately represented in 1885. By Act 39 and 40 Vict c. 54 it was constituted the head of a new diocese comprising th archdeaconry of Cornwall.

TRUST. In Roman and English law alike that leg relation between two or more persons implied in the mord trust was of comparatively late growth. The trust of English law is probably based upon a combination of the Roman conceptions of usus and fideicommissum. To usus is perhaps due the name as well as the idea of that right over property, coordinate with the right of the nominal owner, possessed by the person haring the use. To fideicommissum appears to be due the name as well as the idea of that confidence reposed in another which is the essence of the modern trust. Usus was in Roman law a personal servitude, or right of one person over the land of another, confined to his personal wants and without the right to the produce and profits which ususfructus carried. It' has little in common with the use of English law but the name and the conception of a dual orrership. The fideicommissum is more important; see Rousan Law, pul. xx. p

Dy the legislation of Justiman the law of Iegata was practically assinilated to that of indeicommissm. The only thing that distinguished the one from the other was the mode in thich the gift was made: if by words of direct bequest, it was a legatum, if by precatory words, a fideicommissum. It may be noticed, as an illustration of the course afterwards taken by the law in England, that fideirommissa in favour of the church were so far favoured over others that if paid over by mistale they could not be recorered. In addition to usus and fideiconmissum, the Roman division of ownership into quiritary and bonitary (to use words invented at a later time) may perhaps to some eztent have suggested the English division into lepal and equitable estate. The two kinds of ownership were analgamated by Justinian. Legal and equitable estate are still distinct in England, though attempts have been marle in the direction of amalgamation. The gradual naunter iu which the beneficiary became subject to the burdens attaching to the property of which he enjoyed the benefit was a feature common to both the Roman and the English system.
U'ses in Eurly English Lrvo. - The uso or trust ${ }^{2}$ is said to have Leen the invention of ceelesiasties well acquainted with Roman lav, the object being to eseape the provisions of the laws against Nurtmais ( $q$ qu.) by obtaining the convegance of an estate to a frieud on the understanding that they should retain the use, the actual profit and enjoyinont of the estate. Uses were soon extended to other purposes. They were found raluable for the defeat of creditors, the aroiling of attainder, and the charging of portions. A use had also the advantage of being freo from the incidents of feudal tenure: it could be aliensted inter rizos by seeret convesance, and could be devised by will. In many cases the feoffee ${ }^{2}$ to uses, as he was called, or the person seised to the uso of another. seems to have been specially cliosen on account of his rank and station, which would enable hinn to defy the common law and protect the tstate of his cestrici quc use, or the person entitled to the beneficial enjeywout. Tho Aet of 1 Ric. II. c. 9 was directed agaiost the choice of such persons. This alienation of land in nse was looked upon with great disfavour by the common law courts, in whose ejes the cestui que use was only a tenant at will. Pessibly the cround of their refusal to reeognize uses was that the assizes of tl:s Ling's court could only be grauted to persons who stood it a fendas eclation to the king. The denial of the right followed the denis! of the remody. The use was on the other hand supported by the Conirt of Chancery, and execution of the confidence reposed in the fcofies to uses was enfored by the court in virtue of the general furisdiction which as a sourt of conscience it ciaimed to exercisr iper breach of faith. Jurisdiction was no doubt the more readily assumed hy eeclesiastical judges in favour of a system by which the enureh was generally the gainer. A double ownership of land thus graluaily arose, the nowinal and ostensible owuershi p, 一the ouly ene acknowledged in the courts of common lave, -and the beneficial cwnership protected by the Ceurt of Chansery. The reign of Henry $\searrow$. to a great exteut corresponds with that "f Aapurel us at Roine, as the point of time at which legal recognition was giveal to rinst had previously been binding only in honour. The weans of briaging the feoffee to uses before the court was the writ of subpene, said to have been invented by John de Wattham, bshhop of Salisbury and taster of the rells in the reigu of lichard II. Dy meane of this writ the feoffiee to uses could be compelied to auswer on oath the claina of his cestui que use. The doctrine of the Court of Chancery es to the executiou of a uso varied according as thero was transmntation of possession or not. In the former case it was Lrnecessary to prove consideration ; in the latter, generally a case of bargain and sale, tho court would not cmforce the use unless it was executed in law, that is, unless there was a valuable consideration, even of the smallest anmount. Where wo consideratiou crull be proved or implied, the use resulted to the feofor. This theery Led to the insertion up to a recent date in deods (especially in the lease of the lease and release peried of conveynacing) ot a nemmal consideration, generally five shiillings. Lands eitber in possession, reversion, or remainder could be granted in use. Most persens could be feeffees to uses. The king and coriorations aggregate

[^255]worc, however, exceptions, and were entitied to hold the lands discharged of the use. Ou tho accession of Lichard III., who from his position of authority had heen a favourite feoliee, it was necessary to pass a special Act ( 1 Ric. I1I. c. 5), vesting the lands of which ho had been feoffee either in his co-feolfecs or, io the albence of sofeoflees, in the cestui que use. The practical convenicuce of uses was so obvious that it is said that by the reign of Heary VII. most of the land in the kingdem was held in use. The freedom of uses from liabilicy to forfenture for treason must have led to their general adopition during the Wars of the Roses. ${ }^{3}$ The secrecy with which a use could be trausferred, coatiary aa it was to the publieity required for livery of Seisin ( $q . v_{0}$ ) at common law, led to the interforence of the legislature on several ocrasions hetween the reigns of RichardII. and Hemry VIIf, the general tendeney of the legislation being to make the cestui yue use more and more suoject to the burdeus incident to the ownership of land. One of the most important statutes was the Statute of Mortmain (15 Ric. II. c. 5), forbidding evasion of the Statute De Religiosis of Edward I. oy means of leotiments to uses. Other Acta enabled the cestui que use to transfor the use witheut the eoncurrence of the feaflee to uses ( 1 Ric. III. c. 1), made a writ of formedon maintainatle against him ( 1 Hen. VII. c. 1) rendered bis heir liable to wardship and relief ( 4 Hen . TII. $\mathrm{c}_{\text {. }}$ 17), and his lands liable to execution (19 HeL VII. c. 15). At length in 1535 the famous Statute of Uses ( 27 Hen. ViII. c. 10) was passed. ${ }^{4}$ Tho prearulle of the statute enumerates the mischiefs which it was cousidered that the universal prevalence of uses had occasioned, among others that by fraud ulent fooffaents, fines, recoverirs, and other like assurances to uses, confictences, sud trusts lords lost their feudal aids, men their tenancies by the curtesy, momen thrir dower, manifest periuries in trials were committed, tho king linst the profits of the ?ands of persons attuin ted or enfeoffed to the use cf alrens, and the kiog and lords their rights of year, day, and waste, and of eacbeats of ielons' lands. To remedy this state of things it was enacted, zoner alia, that, where any person was seised of any bereditaments to the use, confidence, or trust of any other furson by ary uneans, the person having such use, confidence, or trusi should be seised, deetned, and adjulged in lawful seisir, estate, and possession of such hereditarmenta. Fuil legal ronedies were given to the ceatui que use by the statute. Ile was crabled to distrain for a rent charge, to have action, entry, cendition, \&c. The effect of this edretment was to make the cestui que use the owaer at law as well as in equity (as had been cono onee before under the oxceptional circuastances which led to 1 Ric. III. O. 5), provided that the use was one which before the statute would lave been enforead by the Cou't of Chancery. For some timo alter the passing of the statute an equitable as distinet from a legal estate did not pist lunt the somewhat narrow construction of the statute by the common law courts in 'Tyrrel's ease (1557) enabled estates coguizable ouly in equity to be again created. In that case it was lield that a use upon a use could not be exceuted; therefore in a feoffment to $A$ and his heirs to the use of $B$ and his heirs to the use of $C$ and his heiry only the first use was executed by the statute. The use of $B$ lieing executed in him, that of C was not nekuowleelged by the common daw judges; but equity regarded C as beneficially entitled, ano his mote:cst as an equitable estate lield for him in trust, corvesponding to that whirh 13 would have had liffoco ibe statute. The position taken by lue Cou't ct Chancery i: trusts maj be conpared with that taken in Montgace (q.v.). Ithe Julicature Act, 1873, while oot going as far as the Statute of Uses anl combunure the legal and equitable cstales, makes eyuitalla rights cognizallo in atl nomrts From the decision in 'lyrrel's Hole anolern iaw of uses and trusts. lu modern legal lar.नunege nse is restricted to the creation of legal estate under

Statuli. of l"ses, trust is confineut to the equitable estate of the cestui yure turst or bunediciary.
Ust since 1535. - The statuto of Uses is still the hasis of conveyancug. A grant in a deed is stial, a fer the alterations in the law mado by tho Conreyancing Act, 1881 , made to and to the uso of A." The statute does sot, however, apply iudiscriminately to ail eases, ga nuly ceriain uses are executed by it. It doos not apply to leas holeis or cojyholus, or to cases where tho graratee to uses is anythine more than a mere passive instrumat, e $\because$ g., where thero is any direction to him to sell the property. Tho seisin, too, to be excoute 1 by the statute, must be in another thant him who has tho nse, for where $A$ is seised to the use of $A$ it is a common law grant. The dill rence is important as far as regards the doctrine of Possession (q.v.). Constructive possession is ghven ly a deod operating mader the statute even before entry, Lut not by a common law grant (at any rate sufficient to entitle the grantee to be registered as a voter), until actual recejpt of ront by the

3 The use, as in later times the trust, was, however, forfeited to the crown on attainder of the feofiee or trustee for treasen.

4 it was adopted in lreland exactly a century iater by 10 gon: 1. c. 1 (lr.). The law of usea and trusta io Ireland is practieally tbo as nur as tlat, in England, the main differeners heing in procellure rather Hiay iv substantive law.

- Dyer's Reports, 155 n.
gannlep. The operatiou of the Statute of Uees was supplemented by the itarute of Inrc!ments and that of Wills. (See WILL.) The Statute of Lusolments ( 27 Hen. VIII. c. 16) enacted that D ? bargain aul sale should pass a freehold unless by deed indented and involed within six months after its date in one of the courts at Westininster or with tho custos rolulorum of the county. As tho statute referred only to freeholds, a bargain and sale of a leasehold interest passed without inrolment. Conveyancers took advantage of this omission (whether intentional or not) in the Act, and tho practical effect of it was to introduce a modo of secret alienation of real property, tho lcaso and release, which was the general form of conveyanco up to 1845 . (See Real Estate, Saleo) Thus the pubiicity of transfer, which it was the special object of the statiute of Uses to effect, was alnost at oace defeated. In addition to the grant to uses there were other modes of conveyance under the statute which are now obsolcte in practice, viz., the covenant to stand seised and the bargain and salc. Wider the statute, as before it, the use bas been found a raluab? means of limiting a remainder to the person creating the use and of making an estato take effect in derogation of a former estato by means of a slifting or epringiug use. At common law a frechold could not bo nuade to commence in futuro; but this end moy bo attained by a shifring ase, such as a grant (commoa in marriago settlements) to $A$ to the ase of $E$ in fee sinple until a marriage, and after the celebration of the marrisge to other uses. Au example of a springing use would he a grant to $A$ to such uses as $B$ shouid appoint and in default "I and until appointment to C in fee simple. The difficulty of leciding where the scisin was during the suspension of the uso led to the inveution of the old theory of scintilla juris, or continued possibility of seisin iu the grantee to uses. This theory was holished by 23 and 21 Vict. c. 38 , which enacted that all uses should take effect by force of the estate and seisin originally vested in the person seised to tloe uses. The most frequent instances of a springing nse are powers of appointment, usual in wills and settlements. There liss been inucb legislation on the subject of powers, tho main efect of which has been to gire greater facilities for tlicir exccution, relcase, or abandomment, to aid their defective exccution, and to abolish tize old doctrine of illusory appointments.

Trusts.-A trust in Englisb law is defingd by Mr Lewin, adopting Coke's definition of a use, as "a contideuce reposed in some other, not issuingout of the lard, but as a thiug collateral, annexed in privity to the estate of the land, and to the person touching tbe land, for which cestui guee trust bas no remedy but by subpoena in Chancery." The termi er isist or trust csiate is also used to denote the beueficial interest of the cestui que trust. The term truster is not nsed, as it is in Scotland, to denote tho creator of the trust. A trust lias some features in common with Costract (q.e.); but the great clifference between them is that a contract can only be enforced by a party or one in the position of a party to $i t$, while a trust can he, and generally is, enforced by one not a party to its creation. It has more resemblance to fideicommissum. But the latter could unly we created by a testamentary instruneut, while a trust can be created either by will or inter viros; nor was there any trace in Ronau law of that permanent legal relation which is suggested bj the position of trustec and cestui que trust. The heir, too, in Roman law was entitled, from 50 A.d. to the reign of Justinian, to one-fourth of a hereditas fulcicommissaric as agaiust the benelieiary, while the very essence of the trust is its gratuitous character. Trusts may be divided in more than oue way, according to the ground taken as the basis of division. One division, and perLajis the oldest, as it rests on the authosity of Bacon, is into simple aod specint, the first being where the trust is simply vested in a trustee \&ill the asture of the trust left to construction of law, the sewind where there is an act to be performed by the trustee. Ansther divisiou is intc. lavoful and unlauful, and corresponds to Bacons division into i.ntents or confideuces and frauds, covins, or collusions. A third division is into public and private, tho former beiug synonymous rith charitable trusts. A division often adopted in wuderu text-books, snd recognized by parliament in the Trustce Act, 1850 , is into express, iinplich, and construclive. An express trust is determined by the person creatiug it. It may be either exerated or cxecutory, the furmer where tha limitations of tho equitali, interest are completra and final, the latter whero such limita. tinus are intended to setvo merely as minutes for perfecting the settiement at some futuro period, as in the caso of marriage articles drawn op, na a basis of a marriage settlement to be in conformity with thelu. An implien? trust is forunded upon the intention of the jerson creating it ; examples of it are a resultiag trust, a precatory trust, aud the trust beld by the vendor on behalf of tho purchaser of an estate after contract and beforo oonveyance. In this case the vendor is sometimes calle da trusteo sub modo and tho purchaser a costui yue trust sub muilo. A constructive trust is judicially created frolu a considerati un of a persou's conduct in order to satisfy. the demanils of ulstice, without reference to intertion. The distinction herween an im" very ronsistently mesmetainel. Thus ths josition of a vendor towarls a purchisp:r after contract is sometinies called a construc-
tive trust. The pressnt lary goreming trusts rests upon the doctrines of equity as altered by legislation. Its great importance bas led to its beceming one of the most bighly develeped derrartments of equity. Tho devolution of successive interests in wills and settleinonto is almaat wholly attained by means of trusts.

Who may be a Trustee or Cesiui que Trust. - The mocorn Trust is considerably more exteusive in its operation than the ancient nse. Thus the crown and corporations aggтegato can bo trustees, and personalty can bo beld in trust. Provision is made lyy tho Manicipal Corporations Act, 1859, for tho administration of charitabls and special trusts by municipal corporations. The cromi does not appear to be a trustes to as complote a desres as a subject may be. Unsuccessful attempts luave recently beea made to impress the cromn, or a secretary of state as agent of the crown, mith trusts of funds voted by parliament for the public service, of booty of war granted by rcyal marrant, and of money paid over by a forsign state in pursuance of a treaty. There ars cortain persons who for obvious reasons, even if not legally disqualifed, ought not to be eppointed t.ustees. Such are infants, lueatics, persons domiciled abroad, felons, bankrupts, and cestuis quetrusicnt. The appointment of any sucb persow, or the falling of any existing trustee into eucb a position, is gencrally gronnd for application to the court for appointment of a new trustee in his place. Any cne may ba a'cestui que trust except a corporation aggregate, which cánnot bo a cestui que trust of rcai estate without a licenco from the cromb.

Creation and Extinction of the Trust. - A trust may be created either by act of a party or by operation of law. Where a trust is created by act of a party, the creation at common law yeed not be in writing. Tho Statute of Frauds (sce Fraud) altered the commou law by enacting that all declarations or. creations of trusts or confidences of auy lauds, tonements, or bereditaments shall be manifested and proved by some rriting, signed by the party who is by law cnabled to declare such trust, or by his last will in briting, or elso they slall be ntterly void and of none effect. Trusts arising or resulting by inıplication or construction of law are excepted, and -it has beet beld that tho statute applies ouly to real estate and cbattels real, so that a trust of personal chattels may still be declared by parol. The declaration of a trust by the crown must be by letters patent. Trusts created by will must conform to the requiremeats of the Wills Act (see Will). Except in the case of charitable trusts, the cestui que trust must be a definite persou. A trust, for instance, merely for keepiag op family tombs is void. Aiteration of tho trust estate by alpointmeut of a new trusteo conld up to 1360 ouly bo male whero tho instrument creatng the trust, gare a power to so appoint, or oy order of tho Court of Chancery. Eut now by tho Conveyancing Act, 1881 (superseding Lord St Leonards"s Act of 1860 ), the surviving or continuiug trustee or trustees, or the personal representatire of the last surviving or continuing trustee, may nominate iu writing a netw trustee or new trustees. On such appointment the number of trustees may be increased. Existing trustees may by deed consent to the discharge of a trusteo wishing to retire. Trust property may be vested in wew or continuing trustees by a sinple declaration to that effect. By the Conveyancing Act, 1882, a seprarate set of trmstees may be appoisted for any part of the property beld on distinct trusts. Trusts created by operathon of law are either those which are tho etfect of the appication of rules of equity or those which liare been constituted by a judicial authority. Tley include resulting and constructive tiosts. A resulting trust is a species of implied trust, and consists of so much of the equitable interest as is murlisposed of by tle instrument creating the trust, which is sail to result to the creator and his representatives. An example is the purchase of an estate in the namo of the parcliascr aud others, or of otbers only. Tiere the bene氏cial interest is the purcliaser"s. An cxauple of a construetive trust is a resewal of a lease by a trustee in lis own namse, where tho trustee is held to be constructively a trusteo for those intercsted in the benefcial term. An instance of a constnative trust unon rhich the courts have ofter beeu calied mpon to lecide is the fiduciary relation between the promoter of a lreposed joint-stock company and the members of tho company when forment. The other trusts falliug uor?er tlae head of trusts by operation of law wonld be those imposed upoar a trustee by order of a court, even th:ougb they are imposed in pursuanco of provisions contained in a trust created by a party. Such would be the trusts which bare como within the cognizance of tho court by virtue of tho Trustee Act, 1850, or in any other way. The powers of tlee court orer trusts have been much exteniled by legislation. Tho Act of 1850 ( 13 and 14 Tict. c. 60) enabled the Court of Chavcery to alppiut new trustees whero expectient, and to make vesting orders in many coses whero such orders could not pueviously care beca made, as where a trustee was a lunatic, or an infant, or refused to convey. Fhis Act was extended by tho Trustee Extension Act, 1852 ( 15 and 16 Vict. c. 5... By the Conveyancing Act, 1881, a trusteo ar. pointed by the Chancery Division is to liave the samo powers as if ho had hean originally appointed a trustce by the iustruannt creating the trust. The Bankuptcy Act, 1883 , eaables tho court to appoint a new tustes in the place of a baukrupt trustee. Bo-
sides being daly created, it is necessary for tho validity of the trust that it should be a lawful one. An unlawful trust is one which contravenes the policy of the law in any respect. Examples of such trusts aro trusts for a corporation without licence, for a perpetuity, and for purposes subversive of morality, such as trusts for !legitimate children to be hereafter born. Superstitious uses (see Foman Catholio Church, vol. xx. p. 632) also fall under this head. There are also certain trusts which are avoided by statute mader $j$ articular circumstances, sueh as settlements in fraud of alitor (see Bankruptcy, Settlement). The law cannot be
aded ly attempting to constitute a secret trust for an unlawful purpose. If an estate be devised by words prima facie carrying the beneficial interest, with an understanding that the derisee will toid the estate in trust fer sueh a purpose, he may be compelled t. answer as to the secret trust, and on acknowledgment or proof of it there will be a resulting trust to the heir-at-law. In the case of' an adrowson suspected to be held for the benefit of a Roman Catholic patron, there is a special enactment to the same effect (see Quare Impedit). Tho rules of equity in charitable trusts (which include all those mentioned in the preamble to 43 Eliz. c. 4) ${ }^{1}$ are less striet than those adopted in private trusts. Charitable trusts must be lawful, e.g., they must not contravene the Statutes of Mortmain ; but a wider latitudo of construction is allowed in order to carry out the intentions of the founder, and they will not be allowed to fail for want or uncertainty of objects to be benefited. The court, applying the doctrine of cy pres, will, on failure of the original ground of the charity, apply the funds as nearly as possible in the same manner. On this prineiple gifts originally made for purely charitable purposes have been extended to educational purposes. Further, trustees of a charity may act by a majority, but ordinary trustees cannot by the act of a majority (unless specially empowered so to do) bind a dissenting miuority or the trust property. A trust estate is subject as far as possible to the rules of law applicable to a legal estate of a corresponding nature, in pursuance of the maxim, "Equity follows the law." Thus trust property is assets for payment of debts, may be taken in execution passes to creditors in bankruptcy, and is subject to dower and curtesy, to the rules against perpetuities, and to the Statutes of Limitation. This assimilatiou of the legal and equitable estates has been produced partly by judicial decisions, partiy by legisla tion. A trust is extinguished, as it is created, either by act of a party or-by operation of law. An example of the former mode of extinction is a release by deed, the general means of discharge of a trustee when the purposes of the trust have been accomplished. Extinetion by operation of law takes place when there is a failure of the objects of the trust: $\varepsilon_{0} g_{\text {. }}$, if the cestui que trust die intestate without heirs or next of kin, the trustee jetains the property discharged of the trust if it be real estate, if it be persoualty it falls to the crown. Equitable interests in real estate abroad are as a rule subject to the lex loci rei sitz, and an English court has no jurisdiction to enforce a trust or settle a scheme for the administra tion of a cbarity in a foreign country. An English court has, however, jurisdietion to administer the trusts of a will as to tho whole real and personal estate of a testator, cven though ouly a very small part of the estate, and that wholly persoual, is in England. This was decided by the House of Lords in a well-known case in $1883 .{ }^{2}$

Rights and Duties of the Trustce.-The principal general properties of the office of trustec, as given by Mr Lewin, are these:-(1) A trustee having once accopted the trust cannot afterwards renounce. (2) He cannot delegate it. (3) Iu the case of co-trustees the offico must be exercised by all the trustees jointly. (4) On the death of one trustee there is survivorship : that is, the trust will pass to the survivors or survivor. (5) One trustee shall not be liable for the acts of his co-trustee. (6) A trustce shall derive no personal benefit from the trusteeship. The office cannot be renounced or delegated, because it is one of personal confidence. It can, however, be resigned, and recent legislation, as lias been already stated, has given a retiring trusteo large powers of appointing a successor. Iu the case of the death of a single or last surviving trustee of real estate, the trust estate by the Conveyancing Aet, 1831, now derolves unon his personal representative instead of upon his heir or devisee. The liability of one trustee for the acts or defanlts of another often raises rery difficult questions. A difference is made between trustees and oxecutors. An executor is liable for joining in a reccipt pro forma, as it is not necessary for him to do so, one executor baring authority to act without his co-executor; a trusteo can show that he only joined for conformity, ad that another received the money. A trustee's receipt in writing is, under tho Conveyancing Act, 1881 (superseding Lord St Leonards's Act of 1860), $\approx$ sufficient discharge, and exonerates the person paying from seeing that the money paid is duly applied according to the trist. If one trustee be cognizant of a breach of trust committed by another, and conceal it or do not take active measures to protect the cestui que trust's interests, he will be liable for the breach of trust. An inderonity

1 See Charities, where the preamble of the statute is set out in full.
2 Ewing v. Orr-Ewing, Law Reports, 9 Appeal Cases, 34.
clause is now implied by statute in every trust deed, but this does not protect a trustee against liability which would attach at law. A trustec, if he commit a breach of trust at the request of his cestui que trust, may secure himself by an indemnity, provided that the cestui que trust has been fully informed of the faets of the ease, and is not under any disability to consent, such as infancy. The rulo that a trustee is not to benefit by his office is subject to some exeeptions. He may do so if the instrument creating him trustee specially allows him remuneration, as is usually the case where a solicitor is appointed. Where the trust entirely fails, as has beeu said above, the trustee is indireetly remunerated by his right to retain the trust estate. The main duties of trustees are to place the trust property in a proper state of security, to keep it (if personalty) in safe custody, and to properly iavest and distribute it. A trustee mast bo carcful not to place himself in a position where his interest micht elash with his duty. As a rule he cannot safely purchase from his cestui que trust while the fiduciary relation exista between them. In all purchases with trust money he is bound to olitain the best price, unless where an Act of Parliasnent, like the Housing of the Working Classes Aet, 1885, specially authorizes sale at an under value. Investments by trustees demand special notice. The general rulo is that a trustee must take as much care of the trust property as of his own. He is, therefore, justified in following the usual conrse of business adopted by prodent men in making investments, e.g., by employing a stock-broker in the ordinary way. At tho same time he has not an uncontrolled power of investment, for (unless authorized by the instrument creating the trust) he cannot lend trust money on personal security or invest in shares of a private company. A trustee of shares may be liable as a beneficial owner, even thongh his name appears on the register of the conipany as a irustee. By recent legislation trust. ees, where not expressly forbidden by the instrument ereating the trust, have either an absolute or qualified right to invest in certain securities. They have an absolute right to invest in real securities in the United Kinglon (but not on a second mortgage), in charges or mortgages under the Improvement of Land Aet, 1864, in consols, exchequer bills. or any security the interest whereon is guaranteed by parliament, in Bank of England, Bank of lreland, East India, and Metropelitan Board of Works stock. They have a qualifed power of investment (that is, an extension of poners already given in the instrument) in debentures or debenture stock of railway and other compauies, and of corporations and local authorities under the Local Loans Act, 1875, in mortgage deben. tures uhder the Mortgage Debenture Acts of 1865 and 1870 , and in securities of the Isle of Man Government. Trustees under the Settled Land Act, 1882, have somewhat larger powers as to railway stock. lo many cases there are restrictions on investment in stock certificates payable to bearer, although in authorized securities. A power of varying investments is generally implied, though not erpressly giren by statute, as in Scotland. The duties of trustees in the distribution of trust funds have been made less onerons by the Trustee Relief Acts of 1845 and 1849, whicl enabled trustees or a majority of them to pay iuto the Baak of England to the account of the rarticular trust any moneys belonging to the trust, thus bringing the property within the jurisdiction of the court, from which it can only he obtained on petition. Similar powers were conferred upon trustees of charities by 18 and 19 Vict. c. 124. By more recent Acts (22 and 23 Vict. c. 35,23 and 24 Viet. c. 38 ) application for advice may be made by a trustee to a judge of the Chancery Division on a petition or summons. The liability of a trustee to his cestui que trust on any elaim for property held on an express trust or in respect of breach of such trust is not barred by any statute of limitations, 36 and 37 Vict. c. 66 , s. 26 (2). The powers of trustees have lately been considerably extended by the Conveyancing Act, 1881, and the Settled Land Act, 1882, in other matters besides those that have been already noticed. One of the mast important of the new yowers is that of compounding, compromising, or abandoning claims relating to the trust. For the trustee in bankruptcy, see Bankrdptcy. The trustee to preserve contingent renainders, at one time common in conveyancing, has ceased to be necessary (see Remainder, Term). A bare trustee is one to whose office no duties were criginally attached, or who, though such duties were attached, would on the requisition of the cestui que trust be compellable to convey the estate to him or by his direction. The term is used in some Acts of Parliament, for instance the Vendor and Purchaser Act, 1874. ${ }^{3}$

Rights and Duties of the Cestui que Trust.-These may be to a great extent deduced from what has been already said as to the correlative dutics and rights of the trustee. The cestui que trust has a general right to the due management of the trust property, to proper accounts, and to enjoyment of the profits. He can as a rule only act with the concurrence of the trustee, unless he seeks a remedy against the trustee himself. Thus the trustee must be a party to an action brought in respect of the trust estate, and must join in presenting a petition in bankruptcy on account of a debt
3 The phrase "hare trust" oceurs as long ago as 1086 , Nevil v. Saunders,
1 Vernnn"s Ren. 415 .

Sue to the estate, but the cestui que trust on giving indemnity can tequire the trustee to lend his name as a party. He may also require the trustee to execute conveyances of the legal estate according to his directions. Trust property, if parted with by the trustee in fraud of the trust may be followed by the cestui que trust, even into the hands of a purchaser for value with notice of the trust. The cestui que trust may lose his rights by fraud, by laches, and by concurrence or acquiescence in a breach of trust. Though no lapse of time bars his remedy against the trustee personally, he cannot, by the terms of the Real Property Limitation Act, 1874, recover land or reut vested in a trustee upon an express trust sfter twelve years from the time when the right accrued or six years after the cesser of any dissbility. The equitable right of the cestui que trust has sometimes been recognized by statute in cases There it mould be manifestly unjust that be ahould suffer disability by virtue of his having merely an equitable interest. The cestui que trust has the right of voting for members of parliament, and is qualified to serve as a juror. On bankruptcy of the trustee the trust estate is not affected. Nor was it affected even before the Felony Act, 1870 , by the conviction and attainder of the trustee for felony. Attainder of the trustee for treason involved, however, forfeiture of a trust estato of inheritance. (See Treason.) The recognition of the cestui que trust as owner is otill not complete. Thus no notice of a trust is recognized in certain public documents, as the books of the Bank of Engiand and the registers kept under the Merchant Shipping Act, 1854, the Companies Act, 1862, the Land Transfer Act, 1875, sind the Colonisl Stock Act, 1877.
Procedure. - This $1 s$ regulated almost entirely by legislation. Proceedings relating to a trust may be brought in different courts of first.instance, -(1) the Chancery Division of the High Court of Jastice or the Chancery Court of the County Palatine of Lancaster, (2) a court of bankruptcy, (3) a county court, (4) a criminal conrt. (1) By the Judicature Act, 1873, § 34, the execntion of trusts, charitable or private, is assigned to the Chancery Division. The rules of the Sapreme Court, 1883, provide for epecial indorse. ment in an action on a trust, for the parties to the action, for interrogatories and pleading, and for proceeding by originating summons. (See Sumarss.) Forms of pleading are given in the appendix to the rules. An injunction rather than an action may eometimes be the proper remedy, as in the case of threatened breach of trust. The Trustee Relief Acts, the Trustee Act, and Lord St Leonards's Act of 1855 provide for proceeding by petition or summons. Applications nuder the Conveyancing Act must be in chambers in the first instance, and so must applications under the Trustee Relief Acts rhere the money or securities in conrt do not exceed $£ 1000$ or $£ 1000$ nominal value. The procedure in charitable trusts differs to some extent from that in use in private trusts. The most nsnal course of proceeding is by information in the name of the attorney-gencral. Another mode is by petition under Sir Samnel Romilly's Act, 52 Geo. IlT. c. 101 , supereeding the cumbrous procedure by commission which had been previously in use under 43 Eliz. c. 4. A third mode is under the potiers of the Charitable Trusts Acts, the first of mbich was passed in 1853 . No proceeding under these Acts can be taken without the suthority of the charity commissioners. (2) The equitable dett due from the trustee to the cestui qne trust will support a petition in bankruptcy, and is a debt provable in bankruptcy. An order of discharge in bankruptcy does not release the bankrupt from any debt or liability inourred by means of fraudulent breach of trust, nor does it release a co-trustee of the bankrupt. (3) The County Courts Equitable Jurisdiction Act, 1865, confers on county colurts the authority of the High Court in the execution of trusts and proceedings under the Trustee Acts where the trust estrate dees not exceed £500 in smount or value. By the County Ccurts Act, 1867, applications may be made at chambers for transfer to a county court of an action pending iu the High Court where the property does not exceed $£ 500$ in amount or value. The same Act allows trust funds not exceeding that limit to be paid into the post office savings bank in a county court town in the name of the registrar. A county court has jurisdiction in charitable trusts where the income of a charity does not exceed $£ 50$. The county conrt rnles, 1886, contain orders regulating the practice with respect to both privace and charitsble trusts. Powers similar to those given to connty courts in England have been conferred upon the civil bill courts in Ireland. (4) At common lav trustees committing a fraudulent breach of trust could not be punished criminally. This was altered by the Fraudulent Trustees Act of 1857, now euperseded by the Larceny Act, 1861, under which a trustee on en express trust, wiother public or private, created by deed, sill, or instrument in writing, who with intent to defraud converts to his own nse or benefit or the nae or benefit of any other person than the cestui que trust, or for any purpose other than the public or charitable purpose, or otherwise disposes of or destroys such property or 3ny part thereof, is guilty of misdemeanour and punishable with penal servitude for a term not exceeding seven years. No prosecution is to be commenced without the sanction of the attorney.
general or-where civil procecdings have been already taken against the trustee-without the sanction of the civil court. The offence cannet be prosecuted at quarter sessions. ${ }^{1}$
Scolland.-The history of the lew differs considerably from that of England, though perhaps the position of the Scotch trustee is now not very different from that of the trustee in England. The Statute of Uses did not apply to Scotland, since neither fhat nor any similar legislation was necessary in a syotem in which law and equity were administered by the same tribunals. Trusts seem to have existed from time immemorial, and have been frequently regulated by statute. The policy of the English Statute of Frauds was no doubt intentionally imitated in the Act $1696, \mathrm{c} 25$, enacting that no action of declarator of trust should bo sustained as to any deed of trust made for thereafter, except upon a declaration or back bond of trust lawfully subscribed by the person alleged to be trustee and against whom or his heirs or assiguees the declarator should be intended, or unless the same were referred to the eath of the party simpliciter. The Act daes not apply to all cases, hut only to those in which by the act of parties documents of title are in the name of a trustoe, but the beneficial interest. in snother. The person creating the trust is called the trustcr, a term unknown in England. On the other hand the term cestui que trust is unknown in Scotland. The office of trustee is prima facie gratuitous, as in England, it being considered to fall under the contract of mandate. Some of the main differences between English and Scotch law are these. There is no presumption in Scotland of a resulting trust in favour of a purchaser. A trust which lapses by the failure of a beneficiary goes to the crown as ultimus heres, not to the trustee. The office of trustee is not a joint office, therefore there is no right of eurvivorship, and on the death of a trustee the survivors are incompetent to act, unless a certain number be declared or presumed to be a quorum, or the office be conferred on trustees and the accedors and survivors of them. Sometimes the concurrence of one trustee is rendered absolutely necessary by his being named sine quo non. The Court of Session may appoint new trustees, but generally appoints a judicial factor. There has been a considerable amount of recent legislation, chiefly in the direction of extending the powers of trustees and of the court, in trust matters. By 24 and 25 Vict. c. 34 (amended by 26 and 27 Fict. c. 115) an appointment of gratuitous trustees by deed or local act was to be held to include certain provisions usually included in deeds of sppointment, i.e., powers of resignation and of assumption of new trustees, and provisions that the majority of crustees accepting and surviving should be a quorum, and that each tustee ehould only be liable for his own acts and intromissions and should not be liablo for omissions. The Trusts Act, 1867 (30 and 31 Fict. c. 97), sdded to the common law powers of trustees by giving them authority to appoint factors and law agents, to discharge trustees who lave resigned, to grant leases for a limited period, to uplift, discharge, or assign debts, to compromise claims, to grant all necessary deeds, and to pay debts due by the truster or the trust estate. It also gave the Court of Session power (exercisable by the lord ordinary in the first instance) beyond what it possessed by its nobile officiun, in cases of expediency, of selling the trust estate, of granting feus or long leases, and of borrowing and excambion. Power was given to trustees to appoint additional trustees by dced of assumption, and where such assumption could not he made the court might appoint. Anthority was conferred upon the beneficiary of a lapsed trust to complete title on petition. The powers of investment given to trustees have since been largely increased by the Trusts Amendment Act, 1884. They are now much the same as those allowed in England. The principal differences are that in Scotland there is a statutory porer to vary securities, and that statutory investment by a Scotch trustee is not allowed in Bank of Ireland stock or on real security in Ireland. The Titles to Land Consolidation Act, 1868 (31 and 32 Vict. c. 101), contained provisions as to the mode of completing title by a judicial factor on a trust estate and by trustees in seqnestration and as to the vesting in trustees of heritable property conveyed for religious or educationsi phrposes. The Conveyancing Act, 1874 (37 and 35 Vict. c. 94), dea?t with compositions payable by trustees on the death of a vassal, and with completion of title by the heir of a sole or last surviriar trustee, by a successor of an ex officio trustee, and by trustees where words of conveyance are not expressed to be in favour of euch trustees. Forms of documents relating to trust property will bs found in Juridical Styles and in the schedules to the Acts of 1867, 1868, and 1874. A conveyance in trust may be either absolute with a back-bond or in form a conveyance in trust. A trustes is responsible for the due execution of the trust, snbject to the limitations contained in 24 and 25 Vict. c. 84. The provision $=6$ tbe Companies Act, 1862 , that no trust is to be entered on the

1 The principal authority is Lewin's Law of Trusts (Sth ed., 1885). The powers of trustees under the Converancingand Settled Land Acts will be fourd anmmarized in the treatises on these acts by Wolstenholme ond Tarner. Tho principal authorities on charitatle trusts are Shelford and Todor (1802). For the history may be conaulted Bacon, Law Tracts; Reading, On the Statute of Uses; Gilbert, On Uscs; Sanders, On C Ses and Trusts; Spence, Equitable vir
diction, vol. 1. p. 435 ; Digby, Hist of the Law of Real Pronerty, chapa vi. vi.
register, does not apjly to Siotland. A trustee, a member of a pint-stock company, though entered on the register as a trust disponee, may incur pursonal liability as a partuer, unlesa the cou. trary be cxpressed. Liability under such circumstances was established ide the litigation which followed the ouspension of the City of Glasgow Bank in 1878. ${ }^{1}$ A sheriff court las jurisdiction over actions of declarator, relating to queations of leritable right or title, where the value of the subject in disputa loes not exceed $£ 50$ by the year or $£ 1000$ in value ( 40 and 41 Vict. c. 50 ). A judicial factor may be appoiuted by the sheriff court where the yearly value of the estate does not exceed $£ 100$ ( 43 and 44 Vict. c. 4). Fraululent trustees aro criminally liable at common law, not liy statutory eunctment, as in England. Adjudieation on a trust bond is a mode of obtaiuing the decision of tlie Court of Session ou a bond by a fictitious creditor, for the purpose of giving title to the heir, hy preventing hia liability to possible passive representatiou. It is regulated by 1695, c. $24 .{ }^{2}$

United Slates. - In New York and some other States uses and trusts have been abolished (with certain exceptious), and every oitate, subject to thooo exceptions, is deemed a legal right cogniz. able in courts of law. The exceptiona are in New York implied tuusts and express truste to sell land for the bosetit of creuitors, to sell, inortgage, or lease laıds for the benefit of legatees, or for the parpose of satisfying any charge thercon, to recqive the rents and profits of lands and apply them to the use of any person duriug the life of such persou or any shorter term, or to receive such sents and profts, and accumulate the aanno within the linits allowed by the law. Trusts of porsoualty for public purposes aro wery generally allowed in States where mivate trusts do not exist. I'rovisions simalar to those of the English Statute of Frands have been generally adopted by the Statea which recognize private trasts. Some States go further thau the statute and allew the creation of trusts (other than those arising by implication or operation of lar) euly by means of will or deed. Where the trust is of real estate, the deed must gencrally be registered (sce Registratron). Forma of deeds of trust are given in the Statutes of Virginia and other States. The English doctrine of cy pres ceems to have been edopted ouly in Ponusylvauia. Conveyences in trust for the settlor are geuerally void against creditors by the policy of the Acts of Elizabeth. By tho legislation of some States a freehold may commence in feturo without the operation of the Statute of Uses. Societies of professional trustees, receiving a percentage of the incoms of the property as paymeut for their tromble and liability, are frequently recoguized by law. Such societics are geuerally moder an obligation to make periodical returns of their receipto and expenditure. A pubicic trustee as a corpuration sole exists in soine Stateg. Trustee process in the New England States is what is gemerally known as garnishee procesa in Eugland, that is, a means of reaching property and credita of a debtor in the liands of third persous for the wenefit of an attaching creditor. ${ }^{8}$
(J. W W.)

TSARITSYN, a district town of the government of Saratoff, Russia, situated on the right bank of tho lower Volga where it suddenly turns towards the south-east, only 40 miles distant from the Don. It is the terminus of a railway line which begins at Riga ard, running southtastrards, crosses all the main lines which radiate from Moscow to the south. It is also connected by rail with Katatch on the Don, where merclandise ifrom the Sea of Azoff is disembarked and transported by rail to Tsaritsyn, to be sent thence by rail or steamer to different parts of Russia. Corn from Middle Russia for Astrakhan is trausferred from the railway to boats at Tsaritsyn; timber and wooden wares from the upper Volga are unloaded hero and sent by rail to Katatch; and fish, salt, and fruits sent from Astrakhan by boat up the Volga are here unloaded and despatched ly rail to the interior of Jussia. The town has grown rapidly since the completion of the railway system, an d has a large trade in maplitha from Baku, which is shi pped up the Volga to Tsaritsyn and sent thence by rail to the interion of liussia. The railway betweeu the Basknncliak salt lakes of Astrakhan and the Volga Las mado Tsaritsyn also a àputt for tho salt trade. In $188210,000,000$ ewts. of merchandise, valued at one million sterling, were landed at 'Tsaritsyn, and since then the

[^256]figures have notally increased. In addition Tharitsyn is the contre of thie trade connected with the mustard plantations of Sarepta, Duborka, and the neighbourhood; 170,000 cwts. of mustard seed are eitber ground or converted into oil annually, the exports being 70,000 cwts. of mustard and half the corresponding quantity of oil (valued at $£ 250,000$ ). The fisheries of the place arc also important. The population (6750 in 1861) numbered 31,220 in 1882. It is still larger in summer, Tsaritsyn having becoune the gathering-place of poor people in search of work, and the misery and filth in its poorer quarters are very great. The luildings of the town do not improve proportionatcly with the increase of wealth. They include a (wooden) theatre, a public library, and two gymnasia for loys and girls. The old church of St John (end of 16 th century) is a fine specimen of the architec 'ure of its period.

Tsaritsyn was founded in the 16 th century, when a fort was orected to prevent the incursions of the fuce Cossacks and runaway serfs who gathered on the lower Volga, as also those of the Kalmucks and Circassians. In 1606 Tsaritsyn took part in the rising in favour of the false Demetrins, and Raziu toak the town in 1670. The Kaluucks and Circassiaus of the Kubañ attacked it repcatedly in the 17 th century, so that it had to be fortified by a strong earthen and palisaded wall, traces of which are still visible.

TSARSKOYE SELO, a district tewn of Russia, in the government of St Tetersburg, and an imperial residence, 18 miles to the south of the capital, is situated on the Duderbof Hills and consists of the town proper, surrounded by several villages and a German colony, which are summer resorts for the inhabitants of St Petersburg, and the imperial parks and palaces. The tomn is built according to a regular plan, and its houses, a great number of which have been erected by the crown, are nearly all surrounded by gardens. The cathedral of St Sophia is a miniature copy of that at Coustantinople. The town has two gymnasia for boys and girls. The imperia! parks and gardens cover 1680 acres; the chief of them is the "old" garden containing the "old palace," built by Rastrelli, the gallery of Cameron adorned with fine statues, and numerous pavilions and kiosks. The population numbered 15,000 in 1885.

Wheu l'eter I. took possesaion of the mouth of the Nera a Finnish village, Saari-mois, stood ou the sito now occupied by the torn, aud its Russified name Sarskaya was changed into Tsarskoye when Peter I. presented it to his wife Catheriue. It was especially em. bellished by Elizaheth. Under Catherine II., a town, Sophia, was built close by, but its inhabitants were transforred to Tsarskoyo Selo under Alexander I. The railway counecting the town with St Petersbarg (1833) was the first to Le constructed in Russia.

TSCHUDI, or SceUDY, the name of one of the oldest and most distinguished families of the land of Glarus, Switzerland. From 1029 to 1253 a member of the clan leld the office of stemard of the abbess of Sïckingen on the Phine, the lady of the manor ; and after Glarus joined the Swiss Confederation in 1352 various members of the family held high political offices at home, and were distinguished abroad as soldiers and in other ways. In literature, its most eminent nember was Giles or AGIDIUs Tscnudi (1505-1572), who, after baving served his native land in various offices, in 1553 became the chief magistrata or "landammann." Originally inclined to moderation, be became later in life moro and more devoted to the causo of the counter-lieformation. It is, however, as the historian of the Swiss Confederation that he is best known; by incessant wanderiugs and unwearied researches amongst original documents he collected material for three great works, which therefore can never wholly lose their value, though his researches have been largely supplemented and corrected by those of more recent students. In 1538 his book on Rlıetia, written in 1528, was published in Latin and in German-De prisca ac vera Alpina Rhxtia, or. Die uralt vouhrhaffig Alpisch Rhȧtia.

His oither works were not published until long after lins death.

The Beschrcibung Gallix Comate appeared under Gallati＇s editorslip in 1758 ，and is mainly devoted to a toporraphical，historical，and antionarian deacription of ancient Helvetia and Rhatia，the latter part beiug his early work on Rhætia revised and greatly enlarged． This book was designed practically as an introduction to his mag－ numplomes，the Chronicon Helveticum，part of which（from 1100 to 1470）was published by J．R．Iselin in two stately folios（1734－36）； the rest（to 1564）consists only of rough materials．The value of the work rests very largely on the constant use of original docu－ ments，no fewer than 750 being printed in Iselin＇s edition，though the transcripts do not always in point of accuracy come up to the standard demanded by the modern critical historian．Many ballads are incorporesed and also many oral traditions，both being employed to give life and picturesqueness to his story，though often at the expense of historical truth，the stock instance of which is the manner in which he completed and elaborated the Tell legend（see Tell）． In many ways his boek，save in its flowing aud quaint German， is rather like the work of a 14th－century chronicler thas a critical history；but it las been tle source from which all later Swiss writers have drawn their information，and in many cases preserves the evi－ dence of original documents which have since disappeared．It is in short a history rather resembling that of Livy than that of Hallam or Stubbs．
Suhjoined is a list of other prominent members of the family． Dominic（1506－1654）was a Benedictine monk at Muri and wrote a painstaking work，Origo et gencalogia gloriosissimorum comitum de Habsburg（1651）．JOSEPH，a Benedictine mouk at Einsiedcln， wrote a nseful history of his abbey（1823）．The family，which be－ came divided in religious matters at the Reformation，also includes several Protestant miuisters，－JOHN HENRT（1670－1729），who wrote Beschreibung des Lands Glarus（1714）；Jons Twosas（1714－1788）， who left behind him several elaborate MSS．on the local history of Glarus ；and John James（1722－1781），who compiled an elaborate fanily history from 900 to 1500 ，and an account of other Glarus families．JOHN Louis（d．1784），who settled in Metz and contri－ butcd to the Encyclopedic，and Frienricy（1820－1886），the author of Das Thicrlcben der Alpenwolt，rere distinguished naturalists． Among the soldiers may be mentioned CHRISTOPHER（1571－1629），a knight of Malta and an excellent linguist，who served in the French and Spanish armier；while the brothers Louis Leonard（1700－ 1779）and Josegh Anthony（1703－1770）were in the Neapclitan service．Valentine（1499－1555），the cousin of Giles，was，like the latter，a pupil of Zwingli，whom he afterwards suceeeded as pastor of Gla．us，and by his moderation gained so much influence that during the thirty jears of his ministry his services where attended alike by Catholics and Protestants．
TSE－NAN FOO，the capital city of the province of Shan－ tung in China，stauds in $36^{\circ} 40^{\prime} \mathrm{N}$ ．lat．and $117^{\circ} 1^{\prime} \mathrm{E}$ ． long．It is situated in one of the earliest settled districts of the empire，and figures repeatedly in the records of the wars which troubled the country during the six centuries that preceded the Christian era．On the establishment of the Han dynasty（b．c．206）it had the name which it now bears；but during the next 200 years it was known at different periods as P＇ing－yuen，Ts＇ien－sh＇ing，and Po－hai． In the 4th ceutury its name was changed to Tse；and by the founder of the T＇ang dynasty（618－907）it was christened Lin－tsze，by which name it was known until the overthrow of the Mongol dynasty in the l4th century， when the name of Tse－nan was restored to it．The city， which lies in the valley of the present clanuel of the Yellow river（Hoang－Ho），and at a short distance from its banks，is surrounded by a triple line of defence．First is the city wall，strongly built and careiully guarded，outside this a granite wall，and beyond this again a mud rampart． The streets are full of good shops，among which book， picture，and flower shops are conspicuous．There are two une examination halls，one for bachelors of arts and the other for doctors of law，several handsome temples，and a metropolitan＂drum＂tower．The most noticeable feature about the city is three springs outside the west gate，which throw up as many streams of tepid water to a height of about 2 feet．This water，which is pleasant to the taste，and is highly prized for its bealing qualities， flews in such abundant quantities that it fils the moat and forms a fine lake in the northern quarter of the city． With the taste which Chinamen always show in such ruatters，the lake is divided into a rumber of water avenues by＿trating banker．on whicb flowers and trees are skilfully
arranged，and is further adorned with several picturesque summer houses，which form points of attraction to picnic parties and pleasure－seckers during the warmer months． Its waters abound with many species of edible fish．The population of the town is reckoned at about 100,000 ， among whom are 2000 Moharmmedan families．The city is the centre of a Roman Catholic see，and has opened its gates to several Protestant missionary bodies．

See Williamson，Jormeys in North China，Lendon， 1870.
TSETSE FLY（Glossina morsitans）．The tsetse fly，so much dreaded by the traveller in South Africa，belongs to the sub－family Muscinx and is closely allied to Stomoxys． It is searcely larger than the common house fly，which it resembles in its general shape．It can，however，be easily distinguished by its colour and the position of its wings These are longer than the abdomen，and when at rest they project hehind it，overlapping one another at their tips． This gives the ify $a$ longer and narrower ontline than that of the house fly．The colour is somewhat like that of the honey bee：the thorax is chestnut brown with four longltudinal black stripes，the abdomen light yellow with transverse bars of dark brown on its doisal surface． The proboscis，with which the fly inflicts its sting，is grooved and contains two long styles；and it is guarded by a pair of setose palps．At the base of the proboscis is a dilated horny bulb， and in this swelling it is supposed that the poison is secreted．The bite of the tsetse is innocuous to man and is not
 more painful than that of a gnat．Large game，goats， and apparently all animals whilst suckling，are also un－ affected by it．But to the horse，ox，and dog it is fatal． The poison may take cffect after a few days，or the animal may remain apparently unaffected for some months；but eventually symptoms of poisoning appear． These symptoms seem to be rather variable；as a rule swellings arise under the jaws and around the navel，the eyes and nose begin to run，and，although the animal con－ timues to graze，it becomes more and more emaciated， suffers violently from purging，aud at length succumbs to extreme exhaustion．Post－mcrtem examination chows that the muscles，and especially the heart，are in a ver， soft and flabby condition．The lungs and liver are affected， the gall bladder distended with bile．The fat is of a greenish yellow colour and oily consistency，the blood small in quantity and very thin，with hardly any power of staining．At present no cure is known for the bite，nor does inoculation seem to afford any protection．The fly is said to avoid animal excreta，and in some parts a paste composed of milk and manure is smeared on cattle which are about to pass through the＂fly－belts．＂Thiş affords a certaiu amount of protectios．Lion＇s fat is used in the same way，and is said to be efficacious．
The fly is found as a rule in tlio neighbourhood of water，and its h．bitat is usually sharply defined．Often it occurs on one side of a stream but not on the other．The limits of the＂fly－belts＂are well known to the natives，and travellers can ensure comparative saicty to their cattle by passing through these districts after sun－ down．The northern limits of the area inhabited by the tsetse are not known．It is found throughout the vailey of the Limpopo river，but docs not come much south of this，except in the eastern borders of the Transraal．Here it extends far south of Delagoa Bay，and iufests the Lobombe Mountains and the Amatonga country，reaching to the confines of Santa Lucia Bay．It appears to be gradually retreating northwards，following the big game．
The Ay is figured in Proc．Zool．Soc，1850，and by Frank Oates，Matabele Land and the tictoria Falls， 1881 ．
TUABI，a market town and episcopal city of Galway Ireland，is the terminus of the Athenry and Tuam Railway and lies 20 miles north－east of Galway and 129 west of Dublin．An abbey was founded here towards the end of ths

5 th century, and in the beginnung of the 6th an episcopal see by St Jarlath. The new Protestant cathedral of St Mary occupies the site of the original cathedral, built in 1130 , and includes the chancel.arch of the ancient building, now forming the great doorway,-a very fine specimen of the old Romanesque. The Roman Catholic cathedral in the later Early English style is one of the finest modern Catholic churches in Ireland. Adjoining it is the Roman Catholic college of St Jarlath, usually called the "New College," founded in 1814 for the education of candidates for the priesthood. To the west are the archbishop's palace and a convent of Presentation nuns. The other public buildings are the workhouse, the dispensary, and the market-house. The town has a considerable retail trade, and is a centre for the disposal of agricultural produce. From 4223 in 18 :l the population decreased to 3567 in 1881
The see of Tuan was raised to an archbishopric about 1152. Under the Church Temperalities Act of 1839 it was reduced to a bishopric, but is still the e日at of a Roman Cathelic archbishop. It receired its first charter in the 11th year of James I. It formerly returned two members to parliament, but was disfranchised at the Union.
TUAMOTU ARCHIPELAGO, ${ }^{1}$ a broad belt of seventy coral islands lying between $14^{\circ} 5^{\prime}$ and $23^{\circ} 22^{\prime} \mathrm{S}$. lat. and $134^{\circ} 25^{\circ}$ and $148^{\circ} 40^{\prime} \mathrm{W}$. long., and now under the protection of France. They trend in irregular lines in a northwest and south-east direction, and cover 1500 miles of the Pacific, the easternmost Tuamotus being 3600 miles from Peru. ${ }^{2}$ With the exception of a few insignificant islands the archipelago consists of atolls (see Corals and Pacific Ocean), mostly chains of low islets that crown the reefs and sometimes also obstruct the deep lagoons which they uncircle. The largest island, Nairsa (Dean's Island), with a lagoon 45 miles long by 15 wide, is made up of twenty islets. Fakarava, the next in size, consists of fifteen islets, and its oblong lagoon affords the best anchorage in the group. Hao has fifty islets, and its lagoon is dangerously studded with coral. The symmetrically placed eleven islets of Anao suggested to Captain Cook the name of Chain Island. Matahiva, Niau, and Mururoa aro good specimens of the horse-shoe-shaped atoll. Nengonengone, Fangataufa, and Marutea, true lagoon islands, form unbroken rings round their lake-like lagoons. In a few of the smaller atolls the lagoons have been completely silted up. To the south-east lie the Gambier Islands, a eluster of four larger and many smaller rolcanic islets, enclosed in one wide reef. The wooded crags of Mangareva, the largest islet, 5 miles in length, rise to a height of 1300 feet and are covered with a rich regetation, quite Tahitian in character; but, as in the other Tuamotus, there is a dearth of animal life. This group was discovered by Captain Wilson of the Lo.ldon Missionary Society in 1797. Tahitian teachers were sent thither in 1834 ; hut Catholic missionaries followed in 1836, and converted the entire population. The natives, once very numerous, now number less than a thousand, and are still decreasing. Cannibalism was formerly prevalent. In physique, language, religion, and custom the Gambier Islanders closely resemble the Rarotongans. Beechey surveyed the group in 1826, and D'Urville in 1838. Pitcairn Island and a fer uninhabited rocks lie still farther to the south-east. The Tuamotus are healthy and as a rule have a lower mean

[^257]temperature tnan Tahiti. The easterly trade winds prevall. Rain and fogs occur even during the dry season. The stormy season lasts from November to March, when devastating hurricanes are not uncommon and a southwesterly swell renders the western shores dangerous. Plants and animals are very meagrely represented, eveu more so than in the atolls of Micronesia. Cocoa-palms and the pandanus thrive on many of the islets, and the bread-fruit, banana, pine-apple, and arum have been introduced from Tahiti into the western islands. Mammals are represented by a rat; among land-birds a parakeet, a thrush, and a dove are noticeable; and of reptiles there is only one lizard. Insects are scarce. But the sea and lagoons teem with turtle, fish, mollusks, crustaceans, and zoophytes. Coral grows luxuriantly everywhere. From the abundance of pearl-oysters the archipelago gets its name of Pearl Islands; pearl-fishing indeed is the only remunerative indnstry. Under French control the newest appliances for obtaining shells have now mostly superseded the laborious diving of the natives. The Tuamotus are very thinly inhabited by a fine strong Polynesian race, more muscular and mostly darker-skinned than that inhabiting Tahiti. In the west considerable intermixture with other races has taken place. Of the habits of the people little is known, and many of the islands are still marked "hostile inhabitants" on the English Admiralty" charts. In the eastern islands cannibalism existed Tattooing is not universal. Clothing and ornaments areivery scanty. The huts aro mean square buildings, often mere shelters of leaves. Good outrigger and single and donble canoes are built, the larger ingeniously stitched together of small pieces of drift mood. Fishing with net and hook is much practised. Food besides fish consists almost exclusively of cocoa-nuts and pandanus fruit. Water is scarce.
Marellan's first discovery of laud after reaching the Yacitic in 1520 was one of the Turmetus. Varieus pertiens of the archipelago were in tura crossed by Queiros (1605), Lemaire and Schouten (1616), Roggereen (1722), Byron (1765), Wallis (1767), Bougainville (1768), Cook (1769), the "Duff" (1797), Krusenstern (1803), Lotzebue (1816), Fitzroy (1835), D'Urville (1838), and Belcher (1840). The first systematic sliryey was instituted in 1818 by Bellinghauseu, and was continued in 1823 by Duperry, in 1826 by Beechey, and in 1839 by Wilkes. Thanks to these many explorers, the islauds hare been clisistened and rechristened with a chaos of Spanish, Dutch, English, French, German, and Russian nsmes.
See the narratives of the varions explorers cited above, and Meinicke, Inseln des stillen oceans (Leipsic, 18:6); for general statistics and an sccount of the pearl-fisheries, see Notices Coloniales, Paris, 1856.
TUBERCLE. See Pathology, vol. xviiı. p 405, and Pathisis.
TUBEROSE. The cultivated tuberose (Polianthes tuberos $\alpha$ ) is allied to the Mexican agares and is a native of the same country. The tuberous root-stock sends up a stem 3 feet in height, with numerous lanceolate leaves and terminal racemes of white furnel-shaped, very fragrant flowers. Each flower is about $1 \frac{1}{2}$ inches long, with a long tube and a six-parted limb. The stamens are six in number, emerging from the upper part of the tube, and bear linear anthers. The ovary is three-celled; but the mature fruit and seed are not botanically known. The plant is largely grown in the United States and at the Cape of Good Hope for export to England, as it is found that imported bulbs succeed better than those grown in the United Kingdom. The cultivated plants have double flowers and require a rich soil, considerable heat, and, at first, abundance of water.

TUUBINGEN, the university zown of Würtemberg, is picturesquely situated on the lilly and well-wooded banks of the Neckar, at the junction of the Ammer and Steinlach, 18 miles south of Stuttgart, and on the S.E. border of the Black Forest. The older town is irregularly built and unattractive, but the newer suburbs, the chief of rhich is the Wilhelmsstrasse, are Lendsome. The mor*
conspicuous building is the old ducal castle of Hohentubingen, built in 1507-1540 on a hill overlooking the town, and now containing the university library, observatory, chemica! laboratory, \&c. Among the other chief buildings are the quaint old Stiftskirche (1469-83), and the new aula and numerous institutes of the university, all of which are modern. A monument was erected in 1873 to the poet Uhland (1787-1862), who was born and is buried here. Tübingen's chief claim to attention lies in its famous university, founded in $14 i T$ by Duke Eberhard. The university adopted the Reformed faith in 1534, and in 1536 a Protestant theological seminary - the so-called Stift-was incorporated with it. In 1817 a Roman Catholic theological faculty (the "Convict") and a faculty of politics and economics were added, and in 1863 a faculty of science. The leading faculty has long been that of theology, and an advanced school of theological criticism, the founder and chief light of which was F. C. Batr (q.v.), is known as the Tübingen school. Melanchthon was lecturer at Tübingen before he was summoned to Wittenberg. The university is attended by about 1400 students, a considerable proportion of whom are foreigners, and has a teaching staff of 53 professors, 17 extraordinary professors, and 10 lecturers. The commercial and manufacturing industries of the town are slight. Printing, book-selling, the manufacture of surgical and philosophical instruments, and the cultivation of hops, fruit, and" vines are among the leading occupations of the inhabitants. The population in 1885 was 12,660 ( 11,708 in 1880). The country in the neighbourhood of Tübingen is very attractive; one of the most interesting points is the former Cistercian monastery of Behenliausen, founded in 1185, and now a royal hunting-chateau.
Tübiugen is montioned as a strons fortress in 1078. In 1342 it was purchased by the count of Wirtemberg, whose descendanta afterwards acquired the title of duke. The treaty of Tiuhingen is tho name given in German history to an arrangement made in 1514 between Duke Ulrich and his subjects, wy which the latter acquired rarious rights and prixileges on condition of relieving the Cormer of his debts. The town was captured by the Swabian League no 1519, hy Turenue in 1647, and again in 1688 by the French, who destroyed the fortifications. Tübingen was male a garrison town in 1875.

TÜCKER, Abraham ( $1705-17$ T4), holds a place of his own among the English moralists of the 18th century. He was born in Loudon, of a Somerset family, on 2d September 1705 . His father, a wealthy city merchant, died in his son's infancy, leaving hiu to the guardianship of his uncle, Sir Isaac Tillard, a man of a rare integrity of character, to whom Tucker never failed to acknowledge deep debt of gratitude. In 1721 Tucker entered Merton College, Oxford, as a gentleman commoner. Here he devoted himself chiefly to philosophical and mathematical studies, झut also found leisure to master French and Italian, and to acquire considerable proficiency in music. He afterwards studied law at the Inner Temple, but as his fortune made him independent of a profession he was never called to the bar. In 1727 he bought Betch worth Castle, near Dorking, where he passed the remainder of his life, occupied, in addition to his favourite studies, with the usual pursuits of a well-to-do country'gentleman. He took no part in politics, however, and even wrote a panphlet, The Country Gentleman's Advice to his Son on the Suljeet of Party Clubs (1755), cautioning young men against the dangers of rashly pledging themsel res to political principles and measures of which their riper judgruent may disapprove. In 1736 Tucker married Dorothy Barker, the daughter of a neighbouring landed proprietor. His wife, to whom he was fondly attached, died in 1754, leaving him with two daughters. "As soon as the first excess of his grief was somewhat mitigated," we are told, "he occupred himself in collecting together ull the letters that bul passed hetween
them at periods when they were acculentally separated from each other, wiich he transcribel twice over, under the title of 'The Picture of Artless Love.' One coply he gave to Mr Barker, his father-in-law, and the other he kept, aul frequently read over to his daughters." He tock an active part in the education of his daughters, and from this time ouward began to occupy himself with the composition of the work by which he is known-The Light of Nature Pursued. He made sereral sketches of the plan of his work, one of which-in dialogne-he went the length of printing before finally decidmg on the method he should pursue. He also solyght to «tralify himself for anthorship by the study of the unt felegant Greek and Latin classics and by translating the most adluired passages of Cicero, Demosthenes, and Pliny several times over. MLoreover, after his work was written, he twice transcribed it with his own hand. In 1763 he published a specimen under the title of "Free Will." The strictures of a critic in the Monthly Review of July 1763 drew from him a lamphlet called Mur in Quest of Himself, by Cuthbert Comment. This, as its sub-title states, is "a defence of the indipiduality of the human mind or self"; it has been repriuted in Parr's Metaphysical Tracts (1837). In 1765 the first four volumes of his work were published under the pseudonym of Edward Search. The remaining three volnmes did not appear tull after his death. His eyesight failed him completely in 1771, but his cheerfulness did not leave him. He contrived an ingenious apparatus which evabled him to write so legibly that the result could easily be transcribed by his daughter. In this way he completed the later volumes, which were ready for publication when he was seized by his last illness. He died on 20th November 1774.

A second edition of The Light of Nature spypeared in 1805, with a short life of the author by liis grandson, Sir H. 1'. St Johu Mildmay, which forms the sole biegraphical sentre. The work has since been repeatedly re-publislied in two large closely printed volumes. A nseful abridgment was published (anonymeusly) lyy Hzzilitt in 1807; for, as he truly says, it is "sswelled out with endless renetitious of itself. The author was a private gentleman, who wrote at his ease, and for his own amusement. When a eubject presented itself to him, he exhausted all he had to say upou it, and then dismissed it for anether. If the same subject recurred again in a different connexion, he turned it over in hiis thoughrs efresh ; as his ideas arose in his mind, he committed them to paper ; he repeated the same things over again or inserted any new observation or example that suggested itself to him in confirmation of his argument; and thas by the help of a new title, and by giving a different application to the whole, a new chapter was completed. By this means, as he himself remarks, his writings are rather a tissue of loose essays than a regular work." In opite of Tucker's elaborate care in composition, there is no doubt that this fairly characterizes the rambling prelixity of his book; but it may be questioned whether an epitome can convey the real merits of such a style and treatment-qualitica which have earned for Tucker frow Sir James Mackintosh the designation of a "metaphysical Montaigue." These are his sound bearty conimon sense, the originality of a mon who looks at everything for himelf completely untrammelled by system, a remarkable aptness in illustration, and occasional gleams of a mill humour. Thongh the The Light of Nature embraces in its scope many psychological and more strictly metaphysical discussions, it is chiefly in connection with ethes that Tucker'e speculations are remembered. This is the subject which the author puts into the foreground himself; from his earliest youth, he tells us, his thoughts took a tur'n "toward searching into the foundations and measures of right and wrong." In some important points Tucker anticipates the utilitarianium shortly afterwards systematizel hy Paley, and Paley, it may be noted, expresses in the amplest terms his ohligations to his prenlecessor. "Every•mau's own satisfaction" Tucker holds to he the ultimate end of action ; and satisfaction or pleasure is one and the same in kind, however much it may vary in dcgree. This mirersal motire is further conncted, as by Paley, througl the will of God, with the " general good, the root where out all our rules of cenduct and sentiments of honour are to brauch." Tucker adopts from Hartley the principle of association, or, as he calls it, "translation," to explain the formation of the moral sentiments and the phenomena of disnnterested action generally. In his genemal analysis of the mind he professes to follow Locke, though with greal latitude in letsils, and eren in much that is not matter of detail.

TUCKER, Jos1ä ( $1711-1799$ ), dean of Gloucester from 1758, a sagacious and candid writer on politics and political economy. See Polrtical Economy (vol. xix. p. 365).

TUCSON, a city in Pima county, Arizona Tenitory, United States, is situated in $32^{\circ} 13^{\prime} \mathrm{N}$. lat. and $110^{\circ} 53^{\prime}$ W. long. at an elevation of 2403 feet above the sea, upon the Santa Cruz river and on the Southern Pacific Railroad, about 70 miles from the Mexican frontier. The surrounding country is arid and barren, except where it has been fertilized by irrigation. The climate is exceedingly hot and dry. The principal industries of Tucson, besides stockrcaring, are connected with mining, as it is a supply point for mining districts in the ncighbouring mountains and has several smelting works. The population, which in 1860 was 915 , in 18703224 , had grown by 1880 to 7007, and in 1887 was estimated to number nearly 10,000 . About one-half are of \{oreign birth, a large proportion being Mexicans. Tucson is one of the oldest settlements in the United States, laring been founded as a Jesuit mission by the Spaniards in the 17 th century.
tucuman, or, more fully, San Miguel de Tucuman, capital of the province of Tucuman, in the Argentine Republic, is a straggling town, on the right bank of the Tala (a subtributary of the Rio Salado), at the eastern base of the Sierra de Aconquija, in $26^{\circ} 50^{\prime}$ S. lat. and $64^{\circ} 35^{\prime} \mathrm{W}$. long. It is connected by rail with Cordova and Rosario. The surrounding district is fertile, and also produces excellent timber. Leather and sugar are the principal objects of industry. The population was recently estimated at 17,000.

TUDELA, a city of Spain, in the province of Navarre, is situated on the right bank of the Ebro where it is joined by the Queyles, and on the railway from Zaragoza to Pamplona, about 50 miles to the north-west of the former city. The Ebro is here crossed by a fine old bridge, 400 yards in length, consisting of seventeen arches. The only building within the town of any interest is the fine church of Santa Maria, founded in 1135 and consecrated in 1188, the doorways and cloisters being specially rich in sculptural ornamentation. The manufactures of the place (cloth, silk, pettery) are unimportant. There is some trade in wine and oil. The population within the municipal bouncararies in 1877 was 10,086 .
Tudela, anciently Tutela, was the hirthplace of the celebrated medieval travcller Bentanix ( $q . v$. ) of Tudela. It was made an -piscopal see in 1783 , which was supprcssed in 1851.
tudor, House of. See Henry Vii. and Lancaster, Hodse of, vol. xiv. p. 257.

TUKE, SANUEL (178.4-1857), English philanthropist, son of Henry Tuke, born at York in 1784 , greaily advanced the cause of the amelioration of the condition of the insane, and devoted himseli largely to the York Retreat, the methods of treatment pursued in which he made more widely known by his Description of the Retreat near. York, ifc. (York, 1813). His writings on the construction of asylums and on other subjects connected with the insane are well known. He died in 1857.

TUKE, Wmliant (1732-1822), English philanthropist, was born at York in 1732. He devoted himeelf to many philantliropic objects, but his name is more especially known in connexicn with the humane treatment of the insane, for whose care he projected in 1792 the Retreat at York, which became famous both abroad and in Great Britain as an institution in which a bold attempt was made to manage lunatics without the excessive restraints then regarded as essential. Not less remarkaole was the departure from the beaten track of treatment in regard to copions bleedings and the frequent administration of emetics and depressing remedies. The asylum was entirely under the management of the Socity of Friends, and
remains so at the present time, but there are a large number of inmates not connected in any way with this body. Tho original character of the methods pursued at the Retreat attracted much attention, and its marked success led to comparisons being made between it and other establishments, the abuses in some of which became so notorious as to be brought ander the notice of parliament, and led to more stringent legislation in the interests of the insane. The condition of this unfortunate class became greatly improved in consequence. William Tube did not live to see tho most dimportant of the Acts passed, but When he died, in 1822, the superiority of the traatment adopted at the Retrcat was fully acknowledged.

See Report of the Select Corn mittec of the House of Commons, 1815. 1816; Dr Conolly, Treatmert of the Insane without Mechanical Restraints, 1856 ; Dr Hack Tuke, Criapters in the LYistory of the Insare in the British Isles, 1882.
Hexry Tuke (1756-1814), son of the preeeding and father of Samuel Take, co-operated with his father in the reforn at the York letreat. He was the author of sereral moral and theological treatises, which have been trinslated into German and French.

TULA, a government of central Russia, bounded by Moscow on the N., Ryazaĩ on the E., Tamboff and Orel on the S., and Kaluga on the W., has an area of 11,950 square miles. It is intersected from south-west to northeast by a gently undulating plateau, frora 950 to 1020 feet in height, which separates the drainage area of the Oka from that of the Don. The average elevation of Tula is about $S 00$ feet, and its surface is an undulating plain; but the rivers flow in ralleys so deeply cut and so scored with ravines that in their neighbourhond the country assumes the aspect of a hilly region. Devonian limestones, dolomites, and sandstones appear chiefly in the south-west; Lower and Middle Carboniferous limestones and clays occupy the remainder of the area. The former contain deposits of coal, which are now worked (chiefly at Malevka and Noroselsk) to the extent of nearly one and a half million ewts. annually. Jurassic clays are found in patches here and there. Glacial boulder clay covers most of the region, while Lacnstrine deposits are widely spread in the valleys and depressions. Iron-ore is found all over the government; limestone, fire-clay, and pottery clay are also obtained. The soil is black earth in the sonth and east and clay or sandy clay in the north-west. Tula is watered chiefly by the Oka and its tributaries (Upa, Zusha, Osetr, and Pronya). The Don rises in Lake Iran-Ozero (which feeds also a tributary of the Ola), and has a course of 35 miles within Tula. It is not navigable, and Peter I.'s attempt to counect it with the Oka by means of a canal was never carried out. Lakes and inarshes (chiefly in the north-west) are fow. Forests ( 8 per cent. of the area) are rapidly disappearing. The climate is less rigorous than that of Moscow, the arerage yearly temperature being $40^{\circ} .2$ Fahr. (January, $13^{\circ} .8$; July, $67^{\circ} 5$ ).
The flora of Tula degcrees some attention as marking the trans. ition from that of the south-east steppes to that of north-west Russia. A line drawn on the northern slope of the water-parting already mentioncd (a few miles to the south of the city of Tula, divides the province into two parts, of which the southern is a black earth region and the ather is chiefly covered with bouleles clay. The boundary is marked hy a scries of crown forestsformerly a means of defence against the nomad tribes, whence their name Zasycka-which at the same time constitute a line that in not passed by several species characteristic of the steppe region, such as the Lilia of the steppes, Lilium Martagon, Linum flurzm, Lathyrus pisifarmis, Geranium sanguineum, Pyrethrum corym. bosum, and Serratula helcrophyila. On the other hand, screral northern species, which are quite common in the narshes of Moscorr, do not penetrate into Tula, and several athers, such as Linnaa borealis, Viola palustris, Cirsium palusire, Pcdicularis palustris, do not cross the Zasyeha. The same forests shelter several northern species which do not appear either in northern or southern Tula, as also sereral southern herbaceuns plants which are now only occasionally met with in the black earth steppes of sonth Russia Scveral West-Euronean plants (Sanicula europæa, Carex romota,

Ceprialantrere ensifolia, Allium ursinum) find their eastern limits In Tula Another interesting feature is the extension down the valley of the Oka, not ouly of pine forests, which are not found elsewhere within the province, but also of many herbaceous plants originally from the snuth or south-weet. The steppe flora of Tula is being rapidly impoverished in consequence of the epread of agriculture: many steppe plants are now found only in their last retreats on the dry nucultivated limestone crags.
The population of the goverament ( 750,000 in 1777) in 1883 was 1,360,000, of whom 1 15,570 were urban. They are all Great Russians, and either Orthoroz Grcelss or Raskolniks. Their chief occupation is agriculture, i) por cent. of tho area being arable. Nearly one-half of the soil be-ongs to landiords and merchants, and the other half to the peasant conmmunties ( $5 \$$ per cent. of the area, and 58 per cent. of the land un.ler culture). The crops for 1883-85 averaged $7,574,200$ quarters of grain and $10,172,000$ bushels of potatoes, largely used for distilleriss. Beet-root culture is increasing ( 8520 acres in 1885, yielding 59,850 cwts of sugar). The growth of tobacco is also epreading ( $10,006 \mathrm{cwts}$. in 1885). There wero in 1883 380,620 horses, 203,500 cattie, and 786,000 sheep. Maunfactures aro rapidly developing; their eggregate production was valued at $£ 1,649,720$ in 1883 (distileries $£ 293,956$, sugar-works $£ 601,827$, tanneries $£ 148,356$, iron wurks, brass works, \&c., about $£ 150,000$ ). Petty trades, especinlly the manufacture of tea-nrns, small brass ware, and harmonicms, and a/so weaving, are extensively carried on and support a lively export trade ; timber, raw metals, and various mańufactured weres are imported. The government is traversed by the Moscow and Sebastopol and the Ryazhsk and Vyazemsk Railways, as well as by the Oka. The government is divided into twelve districts, the chief towns of which, with their population in 1882, are Tola (see pelow), Alexin ( 4960 ), Bogoreditsk (8030), Byeleff (9300), Epifan (3820), Efremoff (7Ti0), Kashira (4610), Krapivna (1560), Norosil (4600), Odoeff (5140), and Tcherã (2675). Byeleff, Alexin, and Kashira are important loading places ou the Oka. The rillages Malevka (cual-mlaes) and Nikitino have more than 5000 inhabitants each.
History.-Before the Slaronic immigration, the territory of Tula was inhabited by the Mordres on the north and the Mestchers in the sonth. The Slavs who occupied the Oka belongcd to the branch of. the Vyetichis, who were soon compelled to pay a tribute to the Khazars. Sulsequently the territory on the Oka belonged is the principality of Tchernigoff, thus maintaining its connexion with south.west Russia Io the luth century pait of it fell onde the rule of Ryazañ and Moscow, while the remainder was under Lithnanian dominion till tha 15 th century. Several of the towns of Tula were founded in the 12th century, but the colonization of this fertile region went on slowly on account of the raids of the Tatars.

TULA, capital of the above government, is situated on the Upa, 120 miles by rail to the south of Moscow. Other railway lines connect it with Ryazañ and Orel. It is built in the broad but low, marshy, and unhealthy ralley of the Upa and is divided into three parts,-the Posad on the left bank, the Zaryetskaya or Oruzheinaya on the right bank, and Tchulkora between the Upa and the Tulitsa. It is an old tomn of Old Russia, but its growth began only towards the end of the 18 th century after the manufacture of arms had commenced, and now (1887) its population has reached 65,100 ( 63,500 in 1882). They are employed chiefly either at the imperial gun factory or at numerous private factories (about 130 , with 4350 men) and small workshops. The main branch of the industry is the making of rifles (from 20,000 to 30,000 annually). Next in importance comes the manufacture of samovars (tea-urns), in which more than 5000 persons are engaged. All sorts of cutlery and ironmongery are manufactured in the small workshops of Tula, which have a high repute in Russia. No ferer thau 240,000 harmoniums are turned out annually; nearly 150,000 cwts. of steel, iron, and brass are imported every year for this industry alone.
The town of Tula is first mentioned in 1147 ; but ita former site seems to have been higher up the Tulitsa. Its wooden fort was replaced in 1514-1521 by a stone "kreml," which still exista. Boris Godunoff founded a gun factory at Tula in 1595 , and in 1632 a Dutchman, Winius, established an iron fonadry. Michael Alexis and Peter I., especially the last-mamed, took great intercst io the gun factories, and large establishments wcre built in 1705 and 1714 , which soon turned out 15,000 rifes in a ycar. Catherine II. and Paul I. further improved the manufactures, which during the wars with France supplied more than haif a million siffes.

TUL1P (Tulipa), a genus of bulbous herbs belonging to the Liliaces. The species are found wild along the
northern shores of the Ifediterranean, in the Levant, Armenia, Caucasus, Persia, Cential Asla, and Afghanistan. The cup-shaped flowers have six regular segments in two rows, as many free stamens, and a three-celled ovary with a sessile stigma, which ripens into a leathery many-seeded capsule. The species are numerous, and are distinguished one from another by the scales of the bulb being woolly or smooth on the inner surface, by the character of the flowerstalks, by the filamerts being hairy or otherwise, and by other characters. Owing to the great beauty of the flowers they have been favourites in European gardens for two or three centuries, and have been crossed and recrossed till it has become almost impossible to refer the plants to their original types. The early flowering "Yan Thol" tulips, the segments of which are mostly scarlet with jellow edges, are derived from T. suaveolcns, a native of the Caspian region. T. Gesneriana, a nativo of Armenia and central Russia, is the origin of some of the later flowering varieties. T. pubescens, thought by Mr Baker to be a hybrid between the two species just named, is the source of some of the early flowering kinds known as "pottebakker," dc. T. oculus solis and $T$. Clusiana are lovely species, natives of southern France, and T. silvestris, with elegant yellow pendulous flowers, is a doubtful natire of England. During the last fow years, owing to the exertions of Russian naturalists, a large number of new species have been discovered in Turkestan, and introduced into Europe. Some of these aro very beautiful, and render it probable that by intercrossing with the older species still further difficulties will be presented in the way of identification. These difficulties are further enhanced by the fact that, quite apart from any cross-breeding, the plants, when subjected to cultivatiou, vary so greatly in the course of two or three years from the original species from which they are directly descended that their parentage is scarcely recognizable. This innate power of variation has enabled the florist to obtain, and ultimately to "fix," so many remarkable varieties. At the present day tulips are less fashionable than they once were, and consequently the enormous prices given for new or improved varieties no longer obtain, though, even now, two and three guineas are asked for special bulbs. It must, however, be remembered that the "tnlipomania" of the 17 th century was really a form of gambling, in which admiration of the flower and interest in its culture were very secondary matters. Tulips were introduced into the Low Countries in the 16 th century from Constantinople and the Levant by way of Vienna and Vence. There is a legend that au Antwerp merchant, to Whom bulbs were sent, cooked them for onions; and to this day the natives of some parts of Persia and Afghanistan use the bulbs of Tulipa chrysantha for food. The mode of growth of a tulip bulb is worthy of attention. In spring, at tho flowering period, each bulh is a composite structure. It consists, first, of the bulb of the Jear, which produces the flowers and the leaves. From the axil of one (or more) of the scales of the flowering bulb emerges a secondary bulb, destined to form leaves and flowers for the next season's growth. In like manner from the side of the second generation are prontuced tertiary bulbs, which flower in the third year after their formation. Each bulb, therefore, has an existence of three years, flowering in the third year, and dying aftermards, so that the bulb planted in the autumn is not the same ono that Howered in the spring, but a second generatiou. For tho cultivaticer cf tulips, see Horriculiure, vol. xii. p. 259.

TULLE, a tuwn of France, chef-lich of tho departmerat of Corrèze and a bishop's see, is 61 miles east-north-east of Périgneux by tho railway from Bordeaux to Clermond Ferrand. The tows rises picturesquely on loth banks o: the Corrèze, a sub-tributary of the Dordogne. The Correze,
crossed by four bridges, flows between enbankments, and the narrow streets on the steep left bank are connected by stairs. Of the 12 th-century cathedral only the porch and the nave of six bays remain, the choir and transept having been destroyed in 1793 ; but there is a 14 th-century tower, with a fine stone steeple. The neighbouring cloister (13th century) is being restored. 'The abbot's house ( 15 th century) has a carved doorway and well-preserved windows; and somo curious houses of the 12 th, 13 th, and 14 th centuries still exist. Tulle possesses normal schools for male and female teachers, and is the headquarters of the Historical Society of Lower Limousin. The principal industry is the manufacture of fircarms. The Government establishments employ from 1500 to 3000 workmen, and can turn out 70,000 guns annually. Manufactories for the variety of lace called "tulle" were first estahlished here. There is a collection of the firearms of all nations. The population in 1886 was 10,635 (commune 16,275).

Tulle (Tutcla Lemovicum) owed its importance in the Middle Ages to an abbey founded by St Martin, or, according to another authority, in the 7th century, which was raised to a bishopric in 1317. Mascaron was bisbop in the 17 th century. The town was taken by the English in 1346, and was subsequently ravaged by the Black Death. It was again conquered by the English in 1369; but, when the inhabitants succeeded in freeing themselves, they were exompted from all imposts by Charles V. The viscount of Turenne, leader of the Protestants, tried in vain to seize 'fulle iu 1577, but was successful in 1585.
TULLE, a term restricted in England to a fine bobbinnet of silk, used for veils, scarves, millinery purposes, and trimmings of ladies' dresses, \&c. The French used the word to mean all machine-made lace the basis of which is tho intertwisted net-work made on the bobbin-net machine. The word is derived from the town of Tulle in France (see above).

TULLOCH, JoHn (1823-1886), Scottish theologian, was born at Bridge of Earn, Perthshire, in 1823, went to school at Perth, and received his university education at St Andrews and Edinburgh. In 1845 he became minister of St Paul's, Dundee, and in 1849 of Kettins, in Strathmore, where he remained for six years. His literary gifts, shown in his contributions to various reviews, as well as his taleut for society drew attention to him, and in 1854 he was appointed to the principalship of St Mary's College, St Andrews. Tho appoinṭment was imnediately followed by the appearance of his Burnet prize essay on Theism. At St Audrews, where he held along with the principalship the post of professor of systematic theology and apologetics, his work as a teacher was distinguished by several features which at that time were new. He lectured on comparative theology and treated doctrine historically, as being not a fixed product but a growth. From the first he secured the attachment and admiration of his students. In 1862 he was appointed one of the clerks of the General Assembly, and from that time forward be took a leading part in the councils of the Church of Scotland. In 1878 he was chosen moderator of the Assembly. No one, except perhaps Dr Robert Lee, has done more during the last generation to widen the national church. Two nositions on which he repeatealy insisted in the Assembly have taken a firm hold of the mind of that church, -first, that it is of the essence of a church to be comprehensive of various views and tendencies, and that a national church especially should seek to represent all the elements of the life of the nation; secondly, that subscription to a creed can bind no one to all its details, but only to the sum and substance, or the spirit, of the symbol. For three years before his death he was convener of the church interests committee of the Church of Scotland, which had to deal with a great agitation for disestablishment. He was also deeply interested in the reorganization of education in Scotland, both in school and university, and acted as one
of the temporary board which settled the primary school system under the Education Act of 1872. His death took place at.Torqnay on 13th Fehruary 1886.

Tulloch's best known works are collections of biographical sketches of the leaders of great movements in church history, such as the Reformation and Puritanism. His most important book, Rational Theology and Christian Philosophy (1872), is one in which the Cambridge Platonists and othertleaders oi lispassionate thought in the 17 th century ore similarly treated. He delivered the second series of the Croall lectures, ou the Doctrine of Sin, which were afterwards published. He also published a small work, The Chrisb of the Gospels and the Christ of History, in which the riews of Renan on the gospel history were dealt with ; a monograph on Paseal for Blackwood's Foreign Classics series; and a little work, Beginning Life, addressed to young men, written at an earlier period. A Life of Tulloch by Mrs Oliphant is in preparation.

TULLUS HOSTILIUS, third legendary king of Rome, is represented as having reigned for ihirty-two years (670-638 b.c.). His successful wars with Alba, Fidenæ, and Veii shadow forth the earlier conquests of Latian territory and the first extension of the Roman domain beyond the walls of Rome. See Rome, vol. xx. p. 733.

TUMKUR, or Toomeoor, a district of India, in the west of the Nandidrúg division of Mysore, situated between $12^{\circ}$ $43^{\prime}$ and $14^{\circ} 10^{\prime} \mathrm{N}$. lat. and $76^{\circ} 10^{\prime}$ and $77^{\circ} 30^{\prime} \mathrm{E}$. long., with an area of 3420 square miles. It is bounded on the north by the Bellary district, on the east by Kolar and Bangalore, on the south by Mysore, and on the west by Chitaldrúgr and Hassan. Tumkar consists chiefly of elevated land intersected by river valleys. A range of hills rising to nearly 4000 feet crosses it from north to south, and forms the water-parting between the systems of the Krishna and the Kaveri. The principals streams are the Jayamangala and the Shimsha. The mineral wealth of Tumkur is considerable: iron is obtained in large quantities from the hill sides; and excellent building. stone is quarried. The slopes of the Devaráy-durga Hills, a tract of 18 square miles, are clothed with forests, in which large game are numerous, including tigers, leopards, bears, and wild hogs. The climate of Tumkur is generally considered as equable and healthy; the average annual rainfall amounts to nearly 33 inches. The Mysore State Railway enters the district at the south-east corner and traverses it to the west.

In 1881 the population of Tunkur numbered 413,183 (males 203,253, females 209,930), embracing 395,443 Hindus, 17,130 Mohanmedans, and 603 Cbristians. Tumkur town, situated at the base of the Devaráy-durga Hills; 43 miles north-west of Bangalore, with a population of 9909 , is the administrative headquarters. The cultivated products consist chiefly of rigi, millet, wheat, sugarcane, varions, pulses, and oil seeds. Of the total area 745 square miles are cultivated and 1544 cultivable. The chief industries are the making of coarse cotton cloths, woolleu blankets, and ropes The ezports compriso rigi, unlusked rice, cocoa-nuts, areca-nuts, earth silt, pulses, and vegetables; the imports include European picee grods, rice, spices, cotton, \&c.

Tho history of Tumkur is common to the rest of Mysore. After the assumption of the administration of Myscre by the Briţish in 1832 the district received its present name ond limits.

TUMOUR. See Pathology, vol. xviii. D. 367, and Surgery, rol. xxii. p. 687.

TUMULUS. See Architecture, vol. ii. v. 38t, and Barrows, vol. iii. 397.

TUNBRIDGE, or Tonbridge, a town of Kent, England, is situated on rising ground above the Medray, and on the South-Eastern Railway, 41 miles (by rail) south-east of London and 33 north-west of Hastings. The Medway is crossed by a stone bridge, erected in 1775. The town consists chiefly of one long main street and a large number of suburban villas. The church of St Peter and St Paul, chiefly Decorated and Perpendicular with some portions oi an carlier date, has lately beeu restored. The grammar school, founded by Sir Andrew Judd, an alderman of London, in the 1st year of Edward VI., was rebuilt in 1865 , remodelled in 1880, and extended in 1887. Amorig other public buildings are the town hall and market louse, the
public hall, and the free library. Some traffic is carried on by the Medway, which has been made navigable for barges. Tumbridge ware, chiefly sold at Tunbridge Wells, is largely manufactured. There aro gunpowder mills on the banks of the Medway; and wool-stapling, brewing, and tanning are carried on. The population of the urban sanitary district (area-1200 acres) in 1871 was 8209 and in 1881 it was 9317.
Tunbridge owed its early importance to the castle built by Richard, earl of Clare, in the reign of Henry I. The castle was besieged by William Rufus, was taken by John in the wars with the barous, and again ly Prince Edward, son of Henry III. Subsequently it became the property of the Staffords, and on the attainder of the duke of Buckingham in the reign of Henry VIII. was taken possession of by the srowu. It was dismantled during the Ciril War. The remains now consist chiefly of a finely preserved gateway flanked by two round towers. Formerly it was defeuded by three moats, oue of them formed by the Medway. The lords of the castle had the right of attending the archbishops of Canterbary on etate occasions as chief butlers.

TUNBRIDGE WELLS, an iuland watering-place of England, chiefly in Kent but partly in Sussex, is situated in the midst of charming and picturesque scenery, on the South-Eastern Railway and at the terminus of a branch line of the London, Brighton, and South Coast Railway, 46 miles (by rail) south-east of London and 5 soutb of Tunbridge. It owes its popularity to its chalybeate spring and its romantic situation The wells are situated near the Parade (or Pantiles), a walk associated with fashion since the time of their discovery. The houses and shops in the Parade somerthat resemble the Rows at Chester. It was pared with pantiles in the reign of Queen Anne. The town is built in a picturesquely irregular manner, and a large part of it consists of districts called "parks," occupied by villas and mansions. On Rustball common, about a mile from the town, is the curiously shaped Toad Rock, and about a mile south-west the striking group called High liocks. The principal public buildings are the pump-room, the town-hall, the corn exchange, the public hall, the mechanics' institute, the friendly society's hall, the dispensary and infirmary, and the prorident dispensary. The Tunbridge Wells sanatorium is situated in grounds sixty acres in extent, and is capable of receiving 150 visiters. There is a large trade in Tunbridge ware, which is made chiefly at Tunbridge, and includes work tables, boxes, toys, \&c., made of hard roods, such as beech, sycamore, holly, and cherry, and inlaid with mosaic. The town is governed by a local board of twenty-four members. The population of the urban sanitary district (area 3351 acres) in 1871 was 19,410 and in 188124,308 .

The town owes its rise to the discovery of the medicinal springs by Dudley, Lord North, in 1606. Henrietta Maria, wife of Charles I., retired to drink the waters at Tunbridge after the birth of her eldest son Charles. Soon after the Restoration it was visited by Charles II. and Catherine of Braganza. It was a favourite residence of Agne previous to her accession, and from that time became one of the special resorts of London fashion. It reached the beight of its comparative popularity in the latter half of the 18 th century, and is speciplly associated with Colley Cibber, Samuel Johnson, Cumberland the dramatist, Garrick, Richardson, Reynolds, Eeau Nash, Miss Chadleigh, and Mrs Thrale. The Tunbridge of that period is sketched with uucb graphic humour in Thackeray's Vir. ginians. Though it still attracts an increasing number of visiters, its importance in reference to London society has considerably declined.

T"UNG-CHOW, a sub-prefectural city in Chih-li, the meiropolitan province of China, is sitnated on the banks of the Peiho in $39^{\circ} 54^{\prime}$ N. lat. and $116^{\circ} 41^{\prime} \mathrm{E}$. long., about 12 miles south-east of Peking. Like most Chinese cities, T'ung-Chow has appeared in history under various names. By the founder of the Han dynasty ( 206 b.c.) it was called Lu -Hien; with the rise of the T'ang dynasty ( 618 A.D.) its name was changed to Heuen-Cbow ; and at the beginning of the 12 th century, with the adv-nt of the Kin dynasty to power, Heuen-Chow became T'ung-Chow. The
city marks the highest point at which the Peiho is navigable, and here reerchandise for the capital is transferred to a canal, by which it reaches Peking. The city, which is faced on its eastern side by the river, and on its other three sides is surrounded by populous suburbs, is upwards of 3 miles in circumference. The walls are about 45 feet in height and about 24 feet wide at the top. They are being allowed to fall into decay. Two main thoroughfares run through the city, one connecting the north and south gates; and the other the east and west gates. The place derives its importance from the fact that it is the port of Peking. Its population was estimated at about 50,000 in 1887.

It was at T'ung-Chow that Sir Harry Parkes, Sir Henry Loch, and their escort were treacherously taken prisoners by the Chinese when they were sent forward by Lord Elgin to negotiate terms of peace after the troubles of 1860 .

TUNGSTEN (Germ. wolfram, or, antiquated, scheel), one of the metallic elements of chemistry. The suineral tungsten (meaning in Swedish "heary stone") used to be taken for a tin ore until this mas disproved by Cronsted. Scheele showed in 1781 that it is a compound of lime with a peculiar acid, the metallic nature of which was recognized in the same year by Bergmann. It ocrcurs only as a component of a number of relatively rare minerals, the most important of which are wolfram or wolframite, ( $\mathrm{Fe}, \mathrm{Ma}$ ) $\mathrm{O} . \mathrm{WO}_{3}$, and scheelite (tungsten), $\mathrm{CaOWO} \mathrm{O}_{3}$ (see Mineralogr). The metal is prepared from the pure oxide $\mathrm{WO}_{3}$ by reduction with hydrogen in a platinum tube at a high むemperature. It forms resplendent tin-white or grey plates, or a dull black powder similar to hydrogen-reduced iron. Sp. gr. $=19 \cdot 129$, water of $4^{\circ} \mathrm{C} .=1$ (Roscoe). It is more difficult to fuse than even Manganese (q.v.). It is unalterable in ordinary air ; oxygen and even chlorine act upon it only at a high temperature. Hydrochloric and sulphuric acid do not attack it. Nitric acid attacks it slowly, aqua regia readily, with formation of the triozide $\mathrm{WO}_{3}$. Impure tungsten is now being prepared industrially for the production of a peculiar kind of steel (see Iron, vol. xiii. p. 352).

Chlorides.-Tungsten forms four chlorides, $-\mathrm{WCl}_{2}, \mathrm{WCl}_{4}, \mathrm{WCl}_{5}$, WClso. The highest, WCle, is obtained by heating the pure pordery metal in a carrent of absolutely pure chlorine. In the presence of moisture or air oxy-chlorides are produced. It sublimes off as a dark red liquid, freezing into crystals. Thes9 fuse at $275^{\circ} \mathrm{C}$. 3nd resolidify at $270^{\circ}$; the liquid loils at $346^{\circ} \cdot 7$. The sp. gr. of the vapour is in accordance with the formula at $350^{\circ}$; at higher tempera. tures it dissociates into $\mathrm{WCl}_{5}$ and $\mathrm{free}^{\mathrm{Cl}} \mathrm{Cl}_{2}$ (Roscoe). When the vapour of $\mathrm{WCl}_{\mathrm{f}}$ is passed over heated trioxide, the two bodies unite, $\mathrm{TO}_{3}$ with $2 \mathrm{WCl}_{\text {g }}$ into $3 \mathrm{WOCl}_{4}$, forming magnificent red needles, which fuse at $210^{\circ} .4$ and boil at $227^{\circ} \cdot 5 \mathrm{C}$. (Wöhler). Both compounds, $\mathrm{WCl}_{6}$ and $\mathrm{WOCl}_{4}$, are decomposed by water, the oxy-chloride more readily, with formation of hydrochloric acid and trioxide. For other chlorides and oxy-chlorides, see the ordinary hand-books of chemistry.
Oxides, WO $O_{2}$ and WO $_{3}$, and Compounds of These with Each Other. - The trioxide, popularly known as tungstic acid, is the more - important. Impure trioxide is producible by treating sch helito ( $\mathrm{WO}_{3} \mathrm{COO}$ ) with hot hydrochloric scid. Wolframite is not so readily decomposed; but when fused with twice its weight of chloride of calcinm it passes into lime salt, obtainable as an insoluble residue by lixiviation of the fuso with water. The oxide obtained forms a yellow powder insoluble in water and in hydrochloric acid. To purify it, it is washed, dissolved in aqueous ammonia, and the filtered solution eraporated, when an acid tungstate of ammonia separates out in scales of great purity. These, when heated in air, leare belind them a pseudo-morphose of pure yellow oxide. Trioxide of tungsten combines with basic sxides into tungstates; but the proportion in which it unites with 3 given base is subject to great variation: for instance, the quantity $\mathrm{T} \varepsilon_{2} \mathrm{O}$ of soda unites into so many definite tungstates with $1,1,2,2 \frac{1}{2}, 2 \frac{2}{2}, 2 \frac{1}{2}, 4$ times $\mathrm{WO}_{3}$ and in each case more or less of water. To each of these soda salts corresponds theoretically a certain tungstic acid,- - to the salt $\mathrm{Na}_{2} \mathrm{OW}_{2} \mathrm{O}_{8}$ for instance, the acid $\mathrm{H}_{2} \mathrm{OW}_{3} \mathrm{O}_{8}$ or $\mathrm{H}_{2} \mathrm{~W}_{3} \mathrm{O}_{7}$. But few of theso hydrates sctually exist, and they are not individual acids in the sense in which the three phosphoric acids are, except perheps that remarkable substance known as motatungetic acid,
$\mathrm{H}_{2} \mathrm{~W}_{4} \mathrm{O}_{13}+7 \mathrm{H}_{2} \mathrm{O}$. This acid forms crystals of the stated composition; it dissolves in water and the solutiou unites with bases into meeta-tungstates. Most meta-tungstates are soluble in water; of the tungstates proper only the alkali salts are so solubla. The soda tungstate, $5 \mathrm{Na}_{2} \mathrm{O} .12 \mathrm{WO}_{3}+x \mathrm{H}_{2} \mathrm{O}$, known as para-tungstate of soda, is 1oada industrially by fusiug wolframite with carbonate of soda and lixiviating the fuse with water. The insoluhle oxides of iron and mangaoese are filtered off ; the filt rate, while still hot, is nearly neutralized with hydrochloric acid and allowed to crystallize. It forins large crystals contaning tweuty-ouc, twenty-five, or twentyeight times $\mathrm{H}_{2} \mathrm{O}$ according to the temperature at which they ere formed. The salt has been recomrmended as a mordant in dyeing and calico-printing, but has not taken root in these industries. Oppenheim and Versmann recommended it before 1862 as the best aneana for rendering textile fabrics uninflamaabla. If a colution of the para-tungstate is boiled with hydrated tuagstic acid (as obtained by precipitating any ordinary alkaline tuogstata solution with hydrochloric acill in the heat), or is simply mixed with excess of acetic acid, the meta-tungstate is formed; in the latter case it separates out as a heavy oil. Meta-tungstate of soda forms octahedral crystals of the composition $\mathrm{Na}_{2} \mathrm{O} .4 \mathrm{WO}_{3}+10 \mathrm{H}_{2} \mathrm{O}$. If concentrated warm solutions of this salt and the equivalent quantity of chloride of bariun are mixed and allowed to cool after addition of a litule hydrochloric acid, meta-tungstate of barium crystallizes out as $\mathrm{BaO} .4 \mathrm{WO}_{3}+9 \mathrm{II}_{2} \mathrm{O}$, in large quadratic pyramids which are very easily eoluble in water. From this salt the free acid is easily produced by addition of the exact quantity of sulphuric acid required to precipitate the baryta, and from it any other metatungstate is easily produced. Meta-tungstic acid solution is a sensitive and characteristic precipitant for almost all alkaloids (strychnine, quinine, \&c.). The alkaloid, whatever its name, goes down as a flocculent insoluble meta-tungstate. Tungstic acid combinss with phosphoric acid and with silicic acids into highly complex phospho-tungstic acids and silico-tungstic acids. Of the former there is quite a series, cach consisting of one $\mathrm{P}_{2} \mathrm{O}_{5}$ united with respectively fourtecn, sixteen, cighteen, twenty, twenty-two, twentyfour times $\mathrm{WO}_{3}$ and eix $\mathrm{H}_{2} \mathrm{O}$ of basic water. Of silico-tungstic acids three are known, amely, one $4 \mathrm{H}_{2} \mathrm{O} . \mathrm{SiO}_{2}, 10 \mathrm{WO}_{3}+3 \mathrm{Aq}$ and two $\mathrm{SiO}_{3} .12 \mathrm{WO}_{3} \mathrm{xH}_{2} \mathrm{O}$. All these complex acids (both kinds) are easily eoluble in water. The phospho-acids are delicate precipitauts for all alkaloids.
The binoxide, $\mathrm{WO}_{2}$, is obtained when the trioxide is reduced by hydrogen at a dull red heat. This oxide is very prone to pase into trioxide or tungstate. An interesting and beautiful class of componnds of $\mathrm{WO}_{3}$, $\mathrm{WO}_{2}$, a a d hases are known as tungsten bronzes. The first of these was discovered by Woller. Normal tungstate of soda, $\mathrm{Na}_{2} \mathrm{OWO} \mathrm{O}_{3}$, is fused, and trioxide added to it as long as it dissolves. The product is then heated in hydrogen os long as water gocs a way, and the substauce thus reduced is exlisusted successively with water, hydrochloric acid, caustic potash ley, and again with water. A residue of the ccapposition $\mathrm{Na}_{2} \mathrm{O}$. $\mathrm{W}_{2} \mathrm{O}_{6}+\mathrm{WO}_{2}$ remains in the ehape of magnificent goldelike lustrous cubes, of specific gravity 6.617 , which conduct electricity liko a metal. Only hydrofluoric acid dissolvee this soda-tuogsten bronze. There are a number of other tungsten bror zes, all distinguished by metalic lustre and magnihicent purple, red, yellow, or blue coluurs.
Analysis. - Oxides of tungsten dissolve in fused microcosmic ealt, $\mathrm{Na}_{2} \mathrm{OP}_{2} \mathrm{O}_{5}$; the bead becomes blue in the reducing flane, in the presence of iron blood-red, and in the oxidizing flame colourless. When heated on charcoal with (not too much) carbonate of soda or cyanide of potassium in the reducing llame, they yield a grey heavy powder of metal, ohtainable by elutriation. The process fails in the presence of too much alkali. Insoluble tungstates (e.g., the ordiuary tuigsten minerala) are disintegrabio by fusion with alkaline carbouta ; the fuse, when treated with water, rields a solution of alkaline tungstate. This solution, when nixed with excess of hydrochloric acid, gives a whito precipitata of hydrated trioxide, which on boiling becomes yellow by partial dehydration. The yellow unignited precipitate is soluble in aqueous ammonia. If tuogstate of alkali solutions are mixed with hydrochloric acid and then treated with metallic zinc, they become blue through the formation of a compound of $\mathrm{WO}_{3}$ and $\mathrm{WO}_{3}$ or rather the respective chloride; this reaction gains in defioitencss through the preseuce of phosphoric acid.
(W. D.)

TUNGUSES, a wide-spread Asiatic people, forming a main branch of the Mongol division of the Mongol-Tatar family. They are the Tung-lu of the Chinese, probably a corrupt form of tonki or donki, that is, "men" or."people.". The Russian form Tungus, wrongly supposed to mean "lake people," appears to occur first in the Dutch writer Massa (1612); but the race has been known to the Russians ever since they reached the Yenisei. The Tungus domain, covering many lundred thonsand square miles in central and east Siberia and in the Anur basin, stretches from
the Yenisei eastwards to the Pacific, where it occnpies most of the seaboard between Corea and Kamchatka. It also reaches the Arctic Ocean at two points, in the Nisovaya tundra, west of the Khatanga river, and in a comparatively small enclosure in the Yana basin over against the Liakhoff (New Siberia) Archipelago. But the Tunguses proper are chiefly centred in the region watered by the three large eastern tributaries of the lenisei, which from them take their names of the Upper, Middle or Stony, and Lower Tunguska. Here the Tunguses are known to the Samoyedes by the name of Aiya or "younger brothers," implying a comparatively recent immigration (confirmed by other indications) from the Amur basin, which appears to bo the original home both of the Tunguses and of the closelyallied Manchus. The Amur is still mainly a Tungus river almost from its source to its mouth: the Oroches (Orochus), Daurians, Birars, Golds, Manegrs, Sanagirs, Ngatkons, Nigidals, and some other aboriginal tribes scattered along the main stream and its affuents, -the Shilka, Sungari, and Usuri, -are all of Tungus stock and speech. On the Paciee the chief subdivisions of the race are the Lamuts, or "sea pcople," grouped in small isolated hunting communities round the west coast of the Sea of Okhotsk, and further south the Yu-pi-ta-tze ("fish clad"), the Tazi of the Russians, between the Amur delta and Corea. The whole race, exclusive of Manchus, numbers probably about 80,000, of whom 15,000 are in the Amur basin, the rest in Siberia.

The Tuugus type is essentially Mongolic, being characterized by broad flat leatures, small nose, wide mouth, thin lips, small hack and somewhat oblique eyes, black lank hair, dark olive or bronze complexion, low stature, averaging not more than five feet four inches; they are distinguished from otber Mongolic peoples hy the square shape of the skull and the slina, wiry, well-proportioned figure. This deseription applies more especially" to the Tunguska tribes, who may bo regarded as typical Tunguses, 'and who, unlike most ather Mongols, betray no tendcacy to obesity. They are classed by the Russians, according to their various pursnits, as Reindecr, Horse, Cattle, Dog, Steppe, and Forest Tunguses. A few have become settled agriculturists; but the great bulk of the race are still essentially forest hunters, using the reindecr both as mounta and as pack animals. Nearly all lead nomad lives, in pursuit of fur-bearing animals, whose skins they supply to I mssian and Yakut traders, in exchange for provisions, clothing, and other necessaries of life. The picturesque and even clegant national costume shows in its ornamentatiou and general style decided Japanese influence, due no doubt to long-continued intercoursa with that nation at some period previous to the spread of the race from tha Amur valley to Siberia. Many of the Tungus tribes have been baptized, and are, therefore, reckoned as "Greek Christians"; but Russian orthodoxy has not penetrated far below tha surface, and most of them are etill at heart Shamanists and natuse-worshippers, secretly keeping the teeth and claws of wild animals as idols or amulets, and observing Christian rites only under compulsion. But, whether Cluristians or pagans, all alike are distioguished above other Asiatics, perhaps above all other peoples, for their truly noblo moral qualities. All observers describe them as "cheerful under the most depressing circumstances, persevering, open-hearted, trustworthy, modest yet self.reliant, a fearless race of hunters, born amidst the gloom of their dense pine-forests, exposed from the cradle to every danger from wild beasts, coll, and hunger. Want aud hardships of evory kind they endure with surprising fortitude, and notbing can induca them to take service under the Russians or quit their solitary woodlauds' (Keana's Asia, p. 470). Their numbers are steadily decreasioy oming to the ravages of small-pox, scarlet fever, and especially famine, their most dreaded enamy. Their domain is also being contiuually encroached upon by the aggressive Yakuts fron the uorth and cast, and fron the south by the Slavs, now settled in compact bodies in the province of Irkutsk about the upper course of the Yenisei. It is remarkable that, while the Russiaus often show a tendeucy to become essimilated to the Yakuts, the most vigorous and expansive of all the Siberian peoples, the Tunguses everywhere yield beforo the advance of their more civilized neighbeurs or become ahsorbed in tha surrounding Slar communities. In the Amur valley the aame fate is overtaking the kindred tribes, who are disappearing before the great waves or ©hinese migration from the south and Russiad encroachments both from the east end west. In 1880 the Orocles were already reduced to about 260, and tho Tazi to a little over 200. For the philplogical relations of the Tunguses, see vol. xviii. p. 770.

## TUNICATA

THIS group of animals was formerly r agarded as constituting along with the Polyzoa and the Brachiopoda the invertebrate class Molluscoidea. It is now known to be a degenerate branch of the Chordata, and to be more nearly related to the Tertedrata than to any group of the Inveríberata

## History. ${ }^{1}$

More than two thousand years ago Aristotle gave a short account of a Simple Ascidian under the name of Tethyum. He described the appearance and some of the more important points in the anatomy of the animal. From that time onwards to little more than a century ago, although tarious forms of Ascidians had been briefly described by writers on marine zoology, comparatively little advance was made upon the knowledge of Aristotle. Schlosser and Ellis, in a paper containing a description of Botryllus, published in the Philosophical Transactions of the Royal Society for 1756, first brought the Compound Ascidians into notice; but it was not until the commencement of the 19th century, as a result of the careful anatomical investigations of Cuvier (I) upon the Simple Ascidians and of Savigny (z) upon the Compound, that the close relationship between these two groups of the Tunicata was conclusively demonstrated. Up to 1816, the date of publication of Savigny's great work (2), the few Compound Ascidians then known had been generally regarded as Alcyonaria or as Sponges; and, although many new Simple Ascidians had been described hy O. F. Müller ( $f$ ) and others, their internal structure had not i,amarck been investigated. Lamarck (3) in 1816, chiefly as the result of the anatomical discoreries of Savigny and Cuvier, instituted the class Tunicata, which he placed between the Radiata and the Jermes iu his system of classification. The Tuncata included at that time, besides the Simple and the Compound Ascidians, the pelagic forms Pyrosoma, which had been first made known by Péron in 180t, and Salpa, described by Forskal in 1775.

Milce-
Edwar:

Chamisso in 1820 made the important discovery that Salpa in its life-history passes through the series of changes which were afterwards more fully described by Steenstrup in 1842 as "alternation of gcremtions"; and a few years later Kuhl and Van Hasseltemwetigations upon the samé animal resulted in the discorery of the altermation in the directions in which the ware ot contraction passes along the heart and in which the blood cinalates through the body. It has since been formd that his obsuration holds good for all groups of the T'unisutu. In 1826 II. MilneEdwards and Audouin made a series of observations on living Compound Ascidians, and amongst other discoveries they found the free-swirmming tailed larva, and traced its lerelopment into the young Ascidian. Milne-Edwards (5) also founded the group of "Social" Ascidians, now known as the Clavelinidx, and gave a classification of the Compound Ascidians which was unitersally accepted for many years. From the ycar 1826 onwards a number of new and remarkable forms were discovered, as, for instance, some of the Bolteninr (Macleay), Chelyosoma (Brodcrip and Sowerby, and afterwards Eschricht), Oikopleura (Mertens), Perophora (Lister), Pelonaia (Forbesand Goodsir), Chondrastachys and Diplosoma (Denis Macdonald), Diazona (Forbes and Goodsir), and Rhodosoma (Ebrenberg, and aiterwards Lacaze-Duthiers).

In 1845 Carl Schmidt ( 6 ) first announced the presence

[^258]in the test of some Ascidians of "tunicine," a substance rery similar to cellulose, and in the following year Lüwig and Kölliker (7) confirmed the discovery and made some additional observations upon this substance and upon the structure of the test in general. Huxley (8), in an irn. portant series of papers published in the Transactions of the Royal and Linnean Societies of London from 1851 onwards, discussed the structure, embryology, and affinities. of the pelagic Tunicates Pyrosoma, Salpa, Doliolum, and Appendicularia. These important forms were also in vestigated about the same time by Gegenbaur, Vogt, H. Müller, Krohn, and Leuckart. The most important epoch in the history of the Tunicata is the date of the publication of Kowalevsky's celebrated memoir uson the derelopment of a Simple Ascidian ( 0 ). The tailed larva had heen previously discovered and investigated by several naturalists-notably H. Milne-Edwards (5), J. P. van Beneden (10), and Krohn (II) ; but its minute structure had not been sufficiently examined, and the meaning of what ras known of it had not been understood. It was reserved for Kowalevsky in Relation1866 to demonstrate the striking similarity in structure stip to and in development between the larval Ascidian and the Verte. rertebrate embryo. He showed that the relations between brates. the nervous system, the notochord, and the alimentary canal are much the same in the two forms, and have been brought about by a rery similar course of embryonic development. This discovery clearly indicated that the Tunicata are closely allied to Amphioxus and the Vertebrata, and that the tailed larva represents the primitive or ancestral form from which the adult Ascidian has been evolved by degeneration, and this led naturally to the view usually accepted at the present day, that the group is a degenerate side-branch from the lower end of the phylum Chordata, which includes the Tunicata (Urochorda), Amphi. oxus (Cephalochorda), and the Vertebrata. Kowalevsky's great discotery has since been confirmed and extended to all other groups of the Tunicata by liupffer (12), Giard Kupfer, (13 and 15), and others. Important observations upon Gara, se the process of gemmatiou and the formation of colonics in Gerama various forms of Compound Ascidians have been made by tion.
Krohn, Metschnikoff, Kowalevsky, Ganin, Giard, Della Yalle, and others, and have gradually led to the establishment of the general principle, that all the more importan' layers of the bud are derived more or less directly from the corresponding regions in the body of the parent.

In 1872 Fol ( $144^{4}$ ) added largely to the knowledge of the Fol, sc Appendiculariidx, and Ciard (15) to that of the Compound Ascidians. The latter author described a number of new forms and remodelled the classification of the group. Fhe most important additions which have been made to the Compound Ascidians since Giard's work have been those described by Von Drasche (16) from the Adriatic and those discovered by the "Challenger" expedition (57). The structure and the systematic arrangement of tho Simple Ascidians have been mainly discussed of receut years by Alder and Hancock (18), Heller (19), Lacaze-Duthiers (20), Transtedt (21), and Herdman ( 57,22 ). In 18is Ussoff (23) investigated the minute structure of the nervou: system and of the underlying gland, which was first dis covered by Hancock, and showed that the gland bas a duct which communicates with the front of the brarchial sac or pharynx by an aperture in the dorsal (or "olioctory") tubercic. In an important paper published in 1880 Julis (24) drew attention to the similarity in structure and rels. tions between this gland and the hypophysis cerebri of the vertebrate brain, and insistcd upon their homology. Ho suggests that they perform a renal function. The Thaliacew
have of late years been the subject of severa, very important memoirs. The researches of Todaro, Brooks (25), Salensky (26); and others have elucidated the embryology, the gemmation, and the life-history of the Salpidx; and Grobben, Barrois (27), and more especially Uljanin (28) have elaborately worked out the structure and the details of the complicated life-history of the Doliolidx. Finally, in an important work published in 1886 on the morphology of the Tunicata, E. van Beneden and Julin (30) have, mainly as the result of a close comparison of the embryology of Ascidians with that of Amphioxus and other Chordata, added considerably to our knowledge of the position and affinities of the Tunicata, and of the exact relations of their organs to the corresponding parts of the body in the Vertebrata.

## Anatony.

As a type of the Tunicata, Ascidia mentald, one of the larger species of the Simple Ascidians, may be taken. This species is found in most of the European seas, generally in shailiow water on a muddy bottom. It has an irregularly ovate form, and is of a dull grey colour. It is attached to some foreign object by one end (fig. 1). The opposite end of the body is usually narrow, and it has a terminal opening surrounded by eight rounded lobes. This is the mouth orbranchial aperture, and it always indicates the anterior end ${ }^{1}$ of the mimal. About half-way back from the anterior end, and on a rounded projection, is the atrial or cloacal aperturean opening surrounded by six lobes-which is always placed upon the dorsal region. When the dscidian is living and undisturbed, water is being constantly drawn in through the branchial aperture and passed out through the atrial. If coloured particles be placed in the water near the apertures, they are seen to be sucked into the body through the branchial aperture, and after a short time some of them are ejected with considerable force through the atrial aperture. The current of water passing in is for re- Fra. 1. - Ascid.a mentetata from the rishe spiratory purposes, and it apertue; ; $t$ testre (Criginal.) also convers food into the animal. The atrial current is mainly the water which has been used in respiration, but it also contains all excretions from the body, and at times the ova and spermatozoa or the embryos.

The outer grey part of the body, which is attached at cr near its posterior end and penetrated by the two apertures, is the "test." This is a firm gelatinous cuticular secretion from the outer surface of the ectoderm, which is a layer of flat cells lining its inner surface. Although at first produced as a cuticle, the test soon becomes organized by the migration into it of cells derived from the ectoderm (see fig. 2).. These test cells may remain as rounded or fusiform or stellate cells imbedded in the gelatinous matrix, to which they are constantly adding by secretions on their

[^259]surfaces; or they may develop vacuoles in their proto plasm, which become larger and fuse to form a hinge ovate clear cavity (a "bladder cell "), surrounded by a delicate film of protoplasm and having the mucleus still visible at one point ; or they mayform pigment granales in theprotoplasm; or, lastly, they may deposit carbonate of lime, so that one or several

Fig 2.- Diagrammatic section of part of mantle and lest of an Ascidian, ahowing the formatiou of a vessel and the structure of the test m, mantle ; $e_{3}$ ectoderrs ; ic test cell; $t m$, matrix; blc, bladder cell; $s, s$, blood ainns in mantle being drawn out into test; me, mantle cells $y$, septum of vessel. (From Herdman, Chailenger Report.
of them together produce a calcareous spicule in the test Only the unmodified test cells and the bladder cells are found in Ascidia mentula. Calcareous spicules are found chiefly in the Didennidx, amongst Compound Ascidians; but pigmented cells may occar in the test of almost all groups of Tunicata. The matrix in which these structures are imbedded is usually clear and apparently homogeneous; but in some cases it becomes fizely fibrillated, especially in the family Cynthiid dx. It is this matrix which contains tunicine. At one point on the left side near the posterior end a tube enters the test, and then splits up into a number of branches, which extend in all directions and finally terminate in rounded enlargements or bulbs, situated chiefly in the outer sayer of the test. These tubes are known as the "vessels" of the test, and they contain blood. Each vessel is bounded by a layer of ectoderm cells lined by connective tissuue (fig. 3, $B$ ), and is divided into two tubes by a septum of con-

nective tissue. The septum does not extend into the terminal bulb, and consequently the two tubes com-

Fic. 3. -4 , a vessel from the test. $B$, dla grammatic transverse section of a ves. sel $c$, ectoderm; $c \alpha$, connective tissse $s, s$, the tivo tubes; $\psi$, septum ; $l k$, ter minal bulu. (originil.)
municate at their ends (fig. 3, $A$ ). The vessels are formed by an outgrowth of a blood sinus (derived originally from the blastoccele of the embryo) from the body wall (mantle) into the test, the wall of the sinus being formed by connective tissue and pushing out a covering of ectoderm in front of it (fig. 2, s'). The test is turned inwards at the branchial and atrial apertures to line two funnel-like tubes, -the branchial siphon leading to the branchial sac and the atrial siphon leading to the atrial or peribranchial cavity.
The body wall, inside the test and the ectoderm, is formed of a layer (the somatic layer of mesoderm) of connective tissue, inclosing muscle fibres, blood sinuses, and nerves. This layer (the mantle) has very much the shape of the test ontride it, but at the two apertures it is drawn out to form the branchial and atrial siphons (fig. 4). In the walls of these siphons the muscle fibres form powerful circular bands, the sphincter muscles. Throughout the rest of the mantle the bands of muscle fibres form a rude irregular network. They are numerous on the right side of the body, and almost totally absent ou the left. The museles are all formed of very long fusiform non-striped fibres. The connective tissue of the mantle is chiefiy a clear gelatinous
matris, containing cells of various shapes; it is frequently pigmented and is penetrated by numerous lacunæ, in which the blood flows. In. side the mantle, in all parts of the body, except along the ventral edge, there is a cavity,-the atrial or peribranchial cavity, -which opens to the exterior by the atrial aperture. This cavity is lined by a layer of cells derived originally frem the ectoderm $^{1}$ and directly continuons with that layer through the atrial aperture (fig. 5) ; consequently the mantleis covered both externally and internally by ectodermal cells.

The branchial aperture (mouth) leads into the branchial siphon (buccal cavity or stomodæum), and this opens into the anterior end of a very large cavity (the branchial sac) which extends nearly to the

posterior end of the body (see figs. 4 and 5). This branchial sac is an enlarged and mouiticea pharyma, ata is therefore properly a part of the alimentary canal. The œesophagus opens from it far back on the dorsal edge (see below, p. 612). The wall of the branchial sac is pierced by a large number of vertiral slits, -the sfigmata, -placed in numerous transverse rows. These slit3 place the branchial sac in communication with the

perihranchial or atrial cavity, which lies outside it (fig. 5 , B) Between the stigmata the wall of the branchial sac is traversed by blood-vessels, which are arranged in three regular series (fig. 6),-(1) the transverse vessels, which run horizontally round the wall and open at their dorsal and ventral ends into large longitudinal ressels, the dorsal and ventral sinnses ; (2) the fine longitudinal vessels, which run vertically between adjacent transverse vessels and open into them, and which bound the stigmata; and (3) the internal longitndinal bars, which run vertically in a plane

[^260]internal to that of the transverse and fine longitudinal vessels. These bars communicate with the transverse vessels by short side branches where they cross, and at these points are prolonged into the lumen of the sac in the form of hollow papille. The edges of the stigmata are richly set with cilia, which drive the water from the branchial sac into th3

A peribranchial cavity, and so cause the currents that flow in throngh the branchial aperture and out through the atrial.

A and $B$ are drawn to diferent ucales. (From Herdman, CLallenger Report.) sac is continuous externally with the mantlo (fg. $5, B$ ), white internally it is thickened to form two parallel longitndinal folds bounding a groove, the "endostyle," hypobranchial groore, Endor ventral furrow (igs. 4, 5, end). The endodern cells etyls which line the eiuostyle are greatly enlarged at the bottom and on parts of the sides of the furrow so as to form projecting pads, which bear very long cilia it is generally supposed that this organ is a gland for the prodnction of the mucous secretion which is spread round the edges of the branchial sac and catches the food particles in the passing current of water; but it has recently been pointed out that there are comparatively few gland cells in the epithelium of the endostyle, and that it is more probable that this furrow is merely a ciliated path along whech the mucous secretion (rroduced possibly by the subneural gland) is conveyed posteriorly along the ventral edge of the branchial sac. At its anterior end the edges of the Pen endostyle become continuous with the right and left halves pharyo of the posterior of two circular ciliated ridges,-the peri- Eand pharyngeal bands,-winch run parallel to one another round the front of the branchial sac. The dorsal ends of the posterior peripharyngeal band bend p steriorly (en- Darma: closing the epibranchial groove), and then join to form lamine the anterior end of a fold which rnns along the dorsal edge of the branchial sac as far as the esophageal aperture. This fold is the dorsal lamina (figs. 4, 5, $d l$ ). It probably' serves to direct the stream of food particles entangled in a string of mucus from the anterior part of the dorsal lamina to the œesophagus. In many Ascidians this organ, instead of being a continuous membranous fold as in $A$. mentula, is represented by a scries of elongated triangular processes-the dorsal languets,-one attached in the dorsal median line opposite to each transverse vessel of the kranchial sac. The anterior peripharyngeal band is a complete circular ridge, having no connexion with either the endostyle or the dorsal lamina. In front of it lies the prebranchial zone, which separates tho branchial sac belind from the branchial siphon in front. The prebranchial 7one is bounded anteriorly by a muscular band-the posterior edge of the sphincter muscle,-whica bears a circle of long deiicate processes, the tentacles (figs. 4, 7, 8, tn). Thess Froject inwarda at rigbt angles so as to form a network across the entrance to the branchial sac. Each tentacle consists of connective tissue covered with epithe-
linm (endoderm), and contains two or more cavites which are continuous with blood sinuses in the mantle. In the dorsal median lino near the anterior end of the body, and imbedded in the mantle on the ventral surface of the nerve ganglion, there lies a small glandular mass-the subneural gland-which, as Julin has shown (24), there is reason to regard as the homologue of the hypoplysis cerebri of the vertebrate brain. Julin and E. van Beneden have suggested that the function of this organ may possibly be renal. ${ }^{2}$ The subncural gland, which was first noticed by Hancock, communicates anteriorly, as Ussoff (23) pointed out, by means of a narrow duct with the front of the branchial sac (pharynx). The opening of the duct is enlarged to form a funncl-shaped cavity, which may be folded upon itself, convoluted, or even broken up into a number of
Dorsal tulercles a complicated projection, called the dorsal tubcrele, situated in the dorsal part of the prebranchial zone (fig. i). The dorsal tubercle in $A$. mentula is somewhat horse-shoe-shaped (fig. 8); it varies' in form in most Ascidians according to the genus and species, and in some cases in the individual also. Possibly, besides being the opening of the duct from the subneural gland, it may be a sense-organ for testing the quality of the water entering the branchial sac.
Nervous The single elongated ganglion in
syotem. the median dorsal line of the mantle between the branchial and atrial siphons is the only nerve-centre in $A$. mentuld and most other Tunicata. It is the degenerate remains of the anterior

part of the cerebro-spinal nervous system of the tailed larval Ascidian (see helow, p. 614). The posterior or spinal part has entirely disappeared in most Tunicata. It persisis, however, in the Appendiculariides, and traces of it are found in some Ascidians (e.g., Clavelina; see Julin). The ganglion gives off distributory nerves at both ends,

[^261]which run through the mantle to the neighbourhood of the apertures, where they divide and subdivide. The only sense-organs are the pignuent spots between the branchial and atrial lobes, the tentacles at the base of the branchial siphon, and possibly the dorsal tubercle and the languets or dorsal lamina. These are all in a lowly developed condition. The larval Ascidians on the other hand have welldeveloped intra-cerebral optic and auditery sense-organs; and in some of the pelagic T'unicate otocysts and pigment spots are found in connexion with the ganglion.

The mouth and the pharynx (branchial sac) hare already been described. The remainder of the alimentary canal is a bent tube which in A. mentule and most other Ascidians lies imbedded in the mantle on the left side of the body, and projects into the peribranchial cavity. The œesoplagus leaves the branchial sac in the dorsal middle line near the posterior end of the dorsal lamina (see fig. 4, $\propto a$ ). It is a short curved tube which leads ventrally to the large fusiform: thick-walled stomach. The intestine emerges from the ventral end of the stomach, and soon turns anteriorly, then dorsally, and then posteriorly so as to form a curve-the intestinal loop-open posteriorly. The intestine now curves anteriorly again, and from this point-runs nearly straight forward as the rectum, thus completing a second curve-the rectal loop-open anteriorly (see fig. 4). The wall of the intestine is thickened intelnally, to form the typhlosole, a pad which runs along its entire length. The anus opens into the dorsal part of the peribranchial cavity near to the atrial aperture. The walls of the stomach are glandklar; and a system of delicate tubules with dilated ends, which ramifies over the outer wall of the intestine and communicates with the cavity of the stomach by means of a duct, is probably a digestive gland.
A mass of large clear vesicles which occupies the rectal Excreloop, and may extend over the adjacent walls of the in-tory testine, is a renal organ without a duct. Each vesicle is organs the modified remains of a part of the primitive coelom or body-cavity, and is formed of cells which eliminate nitrogenous waste matters from the blood circulating in the neighbouring blood-lacuna and deposit them in the cavity of the vesicle, where they form a concentrically laminated concretion of a yellowish or browu colour. These concretions contain uric acid, and in a large Ascidian are very numerous. The nitrogenous waste products are thus deposited and stored up in the renal vesicles in place of being excreted from the body. In other Ascidians the renal organ may differ from the above in its position and structure; but in no case has it an excretory duct, unless the subneural gland is to be regarded as a renal organ.
The heart is an elongated fusiform tube placed on the Blood. ventral and posterior edge of the stomach, in a space (the vasculas pericardium) which is part of the original coelom or body- system cavity, the rest of which exists merely in the form of lacune celore and of the cavities of the reproductive organs and renal vesicles in the adult Ascidian. The wall of the heart is formed of a layer of epithelio-muscrilar cells, the inner ends of which are cross-striated; and waves of contraction pass along it from end to end, first for a certain number of beats in one direction and then in the other, so as to reverse the course of circulation periodically. At each end the heart is continued into a vessel (see fig. 9), a large sinus or lacuna, lined with a delicate endothelial layer. The sinus leaving the ventral end of the heart is called the branchio-cardiac vessel, ${ }^{2}$ and the heart itself is merely the dufferentiated posterior part of this sinus and is therefore a ventral vessel. The branchio-cardiac vessel, after giving off a branch which, along with a corresponding branch from the cardio-visceral vessel, goes to the test, runs along the

[^262]ventral edge of the branchial sac externally to the endostyle, and communicates laterally with the veniral ends of all the transverse vessels of the branchial sac. The sinus leaving the dorsal end of the beart is called the cardio-visceral vessel, and this, after giving off to the test the branch above mentioned, breaks up into a number of sinuses, which ramify over the alimentary canal and the other viscera. These visceral lacunæ finally conmunicate with a third grsat simus, the viscero-branchial vessel, which runs forward along the dorsal edge of the branchial sac externally to the dorsal lamina and joins the dorsal ends of all the transverze vessels of the branchial sac. Besides these three chief systems there are rumerous lacunæ in all parts of the body, by means of thich anastomoses are established betweon the different currents of blood. All these blood spaces and lacunæ are to be regarded as derived from the blastoccele of the embryo, and not, as has been usually supposed, from tho coelom (30). When the heart contracts ventro-dorsally, the course of the circulation is as follows : the blood which is flowing through the vessels of the branchial sac is collected in an oxygenated condition in the branchio-cardiac vessel, and, after receiving a stream of blood from the test, enters the heart. It is then propelled from
 the dorsal end of the Fio. 0. - Tiagram nf circulution in Astrin. Lettering as be
 the cardio et, vessels sto test. (Original.)
viseeral ressels, and so reaches the test and digestive and other organs ; then, after circulating in the visceral lacunæ, it passes into the viscero-branchial vessel in an impure coudition, and is distributed to the branchial vessels to be purified again. When the heart on the other hand contracts dorso-ventrally, this course of circulation is reversed. As the test receives a branch from each end of the beart, it follows that it has afferent and efferent vessels whichever way the blood is flowing. In some Ascidians the vessels in the test become very numerous and their end branches terminate in swollen bulbs close under the outer surface of the test. In this way an accessory respiratory organ ${ }^{2}$ is probably formed in the supericial layer of the test. The blood corpuscles are chiefly colourless and anoeboid ; but in most if not all Ascidians there aro also some pigmented corpuscles in the blood. These are generally of an orange or reddish. brown tint, but may be opaque white, dark indiga blue, or of intermediăte colours. Precisely similarly pigmented cells are found throughout the connective tissue of the mantle and other parts of the body.
A. mentula is hermaplrodite, and tho reproductive organs lie, with tiee alimentary canal, on the left side of the body. The ovary is a ramified gland which occupies the greater part of the intrastinal loop (see fig. 4). It contains a cavity which, along with the cavities of the testis, is derived from a part of the crigizal ceelom, and the ora are formed from its walls and fill when mature into the cavity. The oviduct is coniinusus with the cavity of the ovary and leads forwards alougsint the rectum, finally opening near the anus into the peribranchial cavity. The testis is compozed of a great numior of delicate branched tubules, which ramify over the ovary and the adjacent parts of the intestinal wall. Thoso tubules terminato in ovate swellings. Near the commencement of the rectum the larger tubules unite to form the vas deferel \} a tube of considerable size, which runs forwards alongside the rectum, and, like the oviduct, terminates by opening into the peri-

[^263]branchial cavity closo to the anus. The lumen of the tubules of the testis, like the cavity of the ovary, is a part of the original ceelom, and the spermatozoa are formed from the cells lining the wall. In some Ascidians reproductive organs aro present on both sides of the body, and in others (Polycarpa) there are many complete sets of both male and female systems, attached to the inner surface of the mantle on both sides of the body and projecting into the peribranchial cavity. ${ }^{2}$

## Embryolooy ${ }^{3}$ and Life History.

In most Ascidians the cgga are fertilized in the peribranchial cavity, and nudergo most of their develomment before leaving the parent; in como cases, however, the eggs aro laid, and fertilization takea place in the surronnding water. Tho scrmentation is complete and regular (fig. $10, A$ ) and results in tio formation of a apherical blastula, which then undergoes invagination (fig. 10, B). The embryo elongates, and the blastopore or invagination opening comes to be placed on the dorsal edge near the posterior end (fig. $10, \mathrm{C})$. The hypoblast cells lining the archonteron are columbar in form, while the epiblast cells are mora cubical (fig. 10, B, C, D). The dorsa! surface of the embryo now becomes flattened and then depressed to form a lougitudinal groove, cxtending forwarda from tho blastopore to near the front of the body. This "medullary groove" מow becomes converted into a closed canal by its aide Walls growing up, arching over, and coalescing in the median dorsal

line (fig. 10, D). This union of the lamine dorsales to form the neural canal commences at the posterior end bchind the blastopore and gradually extanos forwards. Consequently the blastopore comes to open into tho posterior end of the neural canal (fig. 10, D), while the anterior cnd of that cavity remains open to tha exterior. In this ray tho archenterou communicates indirectly with the exterior. The short canal leading from the neural cansl to tha archenteron is known as the neurenteric canal (fig. 10,
${ }^{2}$ For structure of other forms, see p. $61 \pm$ sa. below.
3 For reproduction by gemmation, see under "Classification,"
$6148 \%$ below.

D, nec). Previous to this stage some of the hypoblast cells at the front edge of the blastopore and forming part of the dorsal wall of the archenteron (fig. 10, C, ch) have become separated off, and then arranged to form an elongated band, two cells wide, underlying the posterior half of the ncural canal (fig. $10, \mathrm{D}, \mathrm{E}, \mathrm{ch}$.). This is the origin of the notechord. Outgrowths from the sides of the archenteron give rise to latcrally placed massea of colls, which are the origin of the mesoblast. These masses show no trace of metameric segmentation. The cavities (reproductive and renal reaicles) which are formed later in the mesoblast represent the colom. Consequently the body-cspity of the Tunicata is a modified form of enterocole. The anterior part of the embrye, in front of the notochord, now becomes enlarged to form the trunk, while the posterior part elengates to form the tail (fig. 10, E). In the trunk the antcrior part of the srchenteron dilates to form the mesenteron, the greater part of which becomes the branchial sac; st the aame time the anterior part of the neural canal enlarges to form the cerobral vesicle, and the opening to the exterior at the front end of the canal now closes. In the tail part of the cmbryo the neurs] canal remsins as a narrow tube, while the remsins of the wall of the archenteron-the dorsal part of which becomes the notechord-are converted into lateral 10 uscle bands (fig. 10, G) and a ventrsl cord of cells, which eventually hreaks up to form blood corpuscles. As the tail grows longer, it becomes bent round the trunk of the embryo inside the egg-membrane. About this period the cpiblast cells begin to form tbe test as a cnticular deposit upon their outer aurface. The test is at first deveid of cells and forms a delicaie gelatinous investment, but it alhortly afterwards becomes cellular by the migration into it of test cellis formed bv oreliferation from the epiblast. ${ }^{3}$

The embryo 18 hatched about two or three days after fertilization, in the form of a tadpole-like larva, which swims sctively througli the aea by vibrating its long tail. The anterier end of the hody is provided with thres adhering papilla (fig. 10, F, adp) in the form of epiblastic thickeings. In the free-swimming tailed larva the nervous system, formed from the walls of the neural canal, becomes considersbly differentisted. The anterior part of the cerebral vesicle remains thin-walled (fig. $10, \mathrm{~F}$ ), and two unpaired sense organs develop from its wall and project inte the cavity. These are a dorsally and posteriorly placed optic organ, provided with retina, pigment layer, lens, and cornes, and a ventrally placed suditory organ, consisting of a large spherical partially pigniented otolith, attached by delicate hair-like processes to the summit of a hollow crista acoustica (fig. 10, F, au). The posterior part of the cerebral vesicle thickens to form \& oolid ganglionic mass traversed by a narrow central canal. The wall of the neural canal behind the cerebral vesicle becomes differentiated into an anterior thicker region, placed in the poaterior part of the trunk and having a auperficial layer of nerve fibres, and a pesterior narrower part which traverses the tail, lying on the dorsal surface of the notochord, and gives off aeveral pairs of nerves to the muscles of the tail. Just in front of the anterior end of tha nervons system a dorsal involution of the epiblast breaks through into the upturned anterior end of the mesenteron and thus forms the mouth opening. Along the ventral edge of the mesenteron, which becomes the branchial sac, the endostyle is formed as a narrow groove with thickencd side walls. It probably corresponds to the median portion of the thyroid bedy of Vertebrata. A curved ontgrowth from the pesterior end of the mesenteron forms the alimentary canal (œesophagua, atomach, and intestine), which at first ends blindly. An anus is formed later by the intestine opening into the left of two lateral epiblastic involutions (the atria), which rapidly become larger and fuse dorsally to form the peribranchial cavity. Ontgrowths from the wall of the branchial asc meet these eniblastic involutions and fuse with them to give rise to the first formed pair of stigmata, which thus come to open into the peribranchial cavity ; snd these slone correspond to the gill clefts of Amphioxus and the Vertebrata.

After a ahort free-swimming existence the fully developed tailed larva fixes itself by its anterior adhering papillas to some foreign object, sud then undergees a remarkable series of retrogressive changes, which convert it into the adult Ascidian. The tail atro. phies, until nothing is left hut aome fatty cells in the posterior part of the trunk. The sdhering papillæ disappear and are replaced The nervous system with its sense organe neighbouring oljects. duced to the single small its sense organs atrophies until it is repharynx, and a slight nerve cord running for dorsal cdge of the teriorly (Van Beneden and Julin). of tha egg follicle.
manner $8 s$ they are in Amphioxus and other Chordata. (2) The free-awimming tailed larva possesses the essential characters of the Chordata, inasmuch as it hes a longitudinal skeletal axis (the notochord) separatlng a dorsally placed nervons systcm (the neural canal) from a ventral alimentary canal (the archenteron); and therefore during this period of its life-history the animal belongs to the Chordata. (3) The Chordate larva is more highly organized than the adnlt Ascidian, and therefore the changes by which the latter is produced from the former may be regarded as a process of degeneration (31). The important conclusion drawn from all this the primitive Chordata (see below p. 618).

## Classification and Characters of Grours.

## Order I. -LARVACEA.

Free-swimming pelagic forms provided with a lorge locomotory appendsge (the tail), in which there is a skeletal sxis (the urochord). A relatively large test (the "Haus") is formed with great rapidity as a sccretion from the ectoderm; it is morely a temporary structure, which is cast off and replaced by snother. The branchial aac is aimply an enlarged pharnyx with two ventral ciliated openings (stigmata) leading to the exterior. There is no scparate peribranchial cavity. The nervous system consists of a large dorsally placed ganglion and a long nerve cord, which stretches backwarda over the alimentary canal to reach the tail, along which it runs on the left side of the urochord. The anus opens rentrally on the eurface of the body in front of the stig. mata. No reproduction by gemmation or metamorplosio is known in the life-history.
This is one of the most in. teresting groups of the Tunicata, ss it shows more completely than any of the rest the characters of the original ancestral forms. It has undergane little or no degen. eration, and consequently corresponds more nearly to the tailed-larval condition than to the sdult forms of the other groups. The order Fio. I1.-Oikopleura cophocerea in "Hans" includes a singlo family, the (after Fol), seen from right side, magnified APPENDICULARIIDE, all the
six times. The arrows indicate the course men of the water; $x$, lateral ndiciculated course members of which are minute "Haus." ter; $x$, lateral reticulated parts of and free-avimming. They
"Haus. occur on the surfece of the sea in most parts of the world. They possess the power to form Strucwith great rapidity au enormonsly large investing gelatinous layer ture of (fig. 11), which corresponds to the test of other groups. This was Appen-

Fio. 12.-Serai-diagrammatic view of $A$ ppendicularia from the right. $a$, anus. al, one of the atras apertures; opp, tail; br, branchial aperture; brs, branchial sac ; dt, dorsal tubercle; end, endostyle; $h$, heart; $i$, intestine; $m$, muscle band of tail ; $n$, serve cord in body ; $n$, derva cord in the tail; $a$, , cesophagus; ot, otocyst; ov, ovary; pp, peripharyngeal band; $n g$, cerehral ganglion ; $n g^{\prime}$, csudal ganglion; Mo', enlargenient of merve cord in tail; so, sense organ (tactile) on lower lip; sg, ciliated apertura in pharynu; st, atomach ; tes, testis ; $u$, urochord; $u^{\prime}$, its cut end. (Original.)
first described by Von Mertens and by him named "Haws." It is only loosely attached to the body and is frequently thrown of eoon after its formation. The tail in the Appendicularider is at. tached to the ventral surface of the body (fig. 12), and usually
points more or less anteriorly. It shows distinct traces of meta. meric segmentation, having its muscle bands broken up into myotomes, while the nerve cord presents a series of enlargements from which distributary nerves are given off (ig. 12, $n g^{\prime \prime}$ ). Near the baso of the tail there is a disinct elongated ganglion (fig' 12, inf'). The anterior (cerebral) ganglion has connected with it an otocyst, a pigment spot, and a tubular process opening into the branchial sac and representing the dorsal tubercle and associsted parts of an ordinary Ascidian. The branchial sperture or mouth leads into the branchial sac or pharynx. There are no tentacles. The endestyle is short. There is no dorsal lamina, and the peripharyngeal bands run dorsally and posteriorly. Tho wall of the branchial sac hss only two ciliated apertures. They are homologous with tho primary stigmsta of the typical Ascidians and the gill clefts of Vertebrstes. They aro placed far back on the ven-
tral surface, one on each side of the middle line, and lead into short funnel-shaped tubes which open on the surface of the body hehind the anus (fig. 12, at). These tuhes correopond to the right and left atrial involutions which, in sn ordinary Ascidian, fuse to form the peribranchial cavity. Tho heart, sccording to Lankester, is formed of two cells, which are placed st the opposite ends and connected by delicats contractile protoplasmic fibrils. The large ovary and testis are placed at the posterior end of the body. The remainder of tha structural details can be msde out from fig. 12.

The family Appendiculariids comprises the genera, - Oikoplcura (Mertens), and Appendicularia (Cham.), in both which ths body is short and compact and the tail relatively long, while the cndostyle is"atraight ; Fritillaria (Q. and G.), in which the body is long and composed of anterior and posterior regions, the tail relatively short, the endostyle recurved, sud an ectodermal hood is formed over the front of the body; and Kowalevskia (Fol), s remarkable form described by Fol ( 54 ), in which the heart, endostyle, sud intestino re said to be absent, while the branchial sac is provided with four Cors ef ciliated tooth-like processes.

## Order II.-THALIACEA.

Free-swimming pelagic forms which msy be either simple or compound, and the sdult of which is never provided with a tail or a notochord. The test is permanent and may be either well developed or very slight. The musculature of the mantle is in the form of more or less complete circular bands, by the contraction of which locomotion is effected. The branchial sac has either two large or many small spertures, leading to a single peribranchial cavity, into ' which the arus opens. Altcrnstion of generations occurs in the lifehistory; and may be complicated by polymerphism. The Thaliacea comprises two eroups, Cyclomyaria and Hemimyaria.

## Sub-order 1.-Cyclomyaria.

Freo-swimming pelagic forme which exhibit alternation of geucra. tions in their life-history but never form permanent colonies. The body is cask-shaped, with the branchial snd strial apertures at the opposite ends. The test is more or less well developed. The mantle has ita musculature in the form of circular bands surrounding the body. The branchial sac is fairly large, occupying the anterior half or more of the body. Stigmata are usually present in its posterior part only. The peribranchial cavity is meinly posterior to the branchial sac. The slimentary canal is placed veutrally close to the posterior end of the branchial sac. Hermaphrodite reproductive organs are placed ventrally near the intestine.

This group forms one family, the Dolioliden, including two genera, Doliolum (Quoy and Gaimard) and Anchinia (C. Vogt).

Doliolum, of which several species are known from varions seas, hss a cask-shaped body, usually from 1 to 2 cro. in length. The terminal branchial and atrial apertures (fig. 13) are lobed, and the lobes are provided with sease organs. The test is very slightly developed and contains no cells. The mantle has eight or nine circular muscle bands surrounding the body. The most anterior and posterior of these form the branchial and atrial sphincters. The wide branchial and strial apertures lead iute large branchial and peribranchial cavities, separated by tho posterior wall of the branchial sac, which is pierced by stigmata; conscquently there is a free passage for the water through the body along ita long exis, and the animal swims by contracting its ringlike muscle-bands, so as to force out the contained water posteriorly. Stigmata may also be found on the lateral walls of the branchial sac, and in that case there are corresponding anteriorly directed diverticula of the peribranchial cavity. There is a distinct endostyle on the rentral edge of the branchial sac and a peripharyngeal band surrounding its anterior end, but there is no representative of the dorsal lainina on its dorwal edge. Thee cesophagus commences rather on the ventral cdge of the posterior end of the Lranchial sac, and runs bavkwrds to open into the stomach, which is followed by a curved intestive opening into the peribranciial cavity. The alimentary canal ss a whole is to the right of the middle line. The Lermaphrodite reproductive orgars are to the Wit of the middle line alongside tle alimentary cana:. They open
into the peribranchial cavity. Tho ovary is nearly spherical, while the testis is clongated, and may be continued anteriorly for a long distance. The heart is placed in the middle line ventrally, bs-

Fic. 13.-Doliolum denticulatum, sexusl geveration, from the left slde. Letter ing 89 for $f$. $12 ; m^{1}-m 8$, muscle hands; ng, nerve ganglion; ${ }^{80}$, stigmata ; sgl, subneural gland ; pbr, peribranchial cavity; atl, strial lobe9: so. sease organa; brl, branchial lobes. (Original.)
tween the posterior end of the endostyle and the cesopnageal aperture. The nerve ganglion lies about the middle of the dorsal edge of the body, and gives of many nerves. Under it is placed the subucural gland, the duct of which runs forward ond opens into the anterior cnd of the branchial sac by a simple aperture, surrounded by the spirally twisted dorsal eud of the peripharyngeal band ( $\mathrm{fig} .13, d t$ ).
The ova of the sexual generation produce tailed larva; these Developr develop into forms known as "nurses" (blastozooids), which are ment of asexual, and are characterized by the possession of nine muscle Doliobands, an auditory sac on the left side of the body, a ventrally-lum placed stolon near the hcart, upon which buds are produced, and a dorsal outgrowth near the posterior end of the body. The buds give rise eventually to the sexual generation, which is polymerphous, having three distinct forms, in two of which the reproductive organs remain undeveloped. Tho buds rhile still very young migrate from their place of origin on the stolon, divide by fission, and become sttached to the dorsal outgrowth of the body of the nurse, where they develop. The three forms produced are as follows. (1) Nutritive forms (trophozooids), which remain permanently attached to the nurse and serve to provile it with food; they have the body elongated dorso-ventrally, and the musculature is very slightly developed. (2) Foster forms (phorozooids), which, like the preceding, do not bccome sexually mature, but, unlike them, are set free as cask-shaped bodies with cight muscle bands and a ventral outgrowth, which is formed of the stalk ty which the body was formerly united to the nurse. On this outgrowth the (3) forms (gonozooids) which become sexually mature are attached while still young bads, and after the foster forms are set free these reproductive forms gradually attain their complete development, and are eventually set free and lose all trace of their conuexion with the foster forms. They resemble the foster forms in having a cask-shaped body with eight muscle bands, but differ in baving ne outcrowth or process, and in having the reproductive organs fully developed. ${ }^{\text {d }}$

Anchinia, of wbich only one species is known, A. rubra, srom Anchinior
the Mediterranean, has the sexual forms permaneutly attached te pertions of the dorsal ourgrowth from the body of the unknomn nurse. The body is elongated dorso-ventrally. The test is well developed and contains branched cells. The musculature is not se well developed as in Doliolum. There are tiro circular bands at the anterior end and two at the posterior, and two on the middle of the body. The stigmata aro confined to tho obliquely placed posterior end of the branchial sac. The alimentary canal forms a U-shaped curre. The reproductive organs are placed on tho right side of the body. The life-histery is still imperfectly known. As in the case of Doliolum the sexual generation iz polymorphous, and has three forms, two of which remain in a rudimentary condition so far 85 the reproductive organs are concerned. In Anchinia, however, the three forms do not occur together on one stolon or outrrewth, but are produced successiveiy, the reproductive forms of the sexial generation being independent of the "foster forms" (see Ba-rois, 27).

Sub-order 2.-Hemimyaria.
Free-wimming pelagic forms which exhitil slternation of generitions in their life-history and in the sexual condition form colonies. The body is more or less fusiform, with the long axis antero-posterior, and the branchial and atrial apertures nearly terminal. The test is well developed. The musculature of the mantle is in the fore of a series of transversely-running bands, which do not forme cem. plete independent riugs as in the Cyclomyaria. The branchial and

1 For further details see U\Jania (25).
peribranchial cavities form a continuous space in the interior of the body, opening externally by the branchial and a trial apertures, and traversed obliquely fromi the dorsal and anterior ond to the ventral and posterior by a long narrow vascular band, which represents the dorsal lamina, the dorsal blooci-vessel, and the neighbouring part of the dorsal elge of the branchial sac of an ordinary Ascidian. The alimentary eanal is placed ventrally. It may cither bo stretched out so as to extend for some distance anteriorly, or-as is more usual-be concentrated to form along with tho jeproductive organs a rounded opaquo mass near the posterior end of the body, known as the visceral mass or "nucleus." The embryonic develonment is direct, no tailed Jarva being formed.
This sub-order contains two very distinet families, the SalpIDE, wich aro the typical nembere, and the Octacnemider, including a single very remarkable f.rm (Octacnconus bythius), which in some respects docs not conform whth tho characters given above.
The Salpidez includes tho single genus Salpa (Forskål), which, however, may bedivided in to two well-marked groups of spocies,-(I) those, such is.S. pinnata, in which tho alimentary canal is stretched
out along the veatral surface of the body, and (2) those, such as
 S. fusiformis (fig. 14, A), in which the alimentary canal frms a compact globular mass, the About fifteen specres altorcther of the body. About fifteen species altogether are linown; they are all pelege forms and ore found in forms-the solitary asex. forms-the solitary asex. the argrregated sexual (proles gragaria)-vhiel are usually quito unlike one another. The solitary form (fig. $14, \mathrm{~B}$ ) gives rise by internal gemmation to a complex tubular etolon, which contains processes from all the more important organs of tho parent body and which becomes seg. mented into a series of Fto. 14- -Salpa rumonnfa fusi/ormis. ## Order III.-ASCIDIACEA.

Fised or free-swimming Simple or Compound Ascidians which in Ascid. tho adult are never provided with a tail and lase no trace of a iacca. Asochord. The free-swimming forms are colonies, the Simple Ascicians being always fixed. The test is permanent and well dereloped; as a rule it increases with the age of the individual. The branchial sac is large and well developed. Its walls are perforated by mumerous slits (stigmata) opening into the perihranchial cavity, which conmunicates with the exterior by the a trial aperture. Mlany of the forms reproduce by gemmation, and in most of them the sexually-proluced embryo develops into a tailed larya.
the Compound Ascidians, and the free-swimming celonial Ascidians,

## Sul.order 1.-Aecidia Simplices.

Fixed Ascidians which are solitary and very ravely meproduce by gemmation: if colonies are formed, the nembers are not buried in a common investing mass, but each has a distinct test of its own. No strict line of demarcation can be drawn betivecn the Simple and
the Compound Ascidians, and one of the the Compound Ascidian's, and one of the families of tho former gromp the typical Simple forms, which Ascercr reproduce fy a transition to the Compound forms, which always do (seo produce by gemmation, Asciatie Simplices nay be diviled into the following families : The
Family Y.-Clavelinides, Simplo Aseidians which repioduce by gemmation io form small colonies in which each ascidiozooid has a distiznt test, but all are counected by a commnn ulood-gystem,

Buds formed on stelons which are vascular outgrowths from the pos. terior end of the body, containing prolongations from the cctoderim, mesoderm, and endoderm of the asciliozooid. Branchial sac not folded; internal lengitudinal bara usually sbsent; stigmata straight; tentacles simple. This family contains three genera: Ecteinascidia (llerdman), with internal longitudinal bars in braochial sac; Clavelina (Savigny), with intestine extending behind branchial saa; and Perophora (Wiegmann), with intestine alongside branchial sac. Family II.-Ascidninc. Solitary fixed Ascidians with gelativous test ; branchial aperture usually eight-lobed, atrial aperturo usually six-lobed. Branchial sac not folded; internal longitudinal bars usually present; stigmsta straight or curved; tentacles simple. This family is divided into three sections:-
Sub-family I.-Hypobythisiz. Branchial ace with no internal longitudinal bars. One genus, Hypobythius (Moseley).
Sub-family 2.-Ascinine. Stigmata straight. Many genera, of which the followiog are the more importsot:-Ciona (Fleming), dorsal languets present; Ascidia (Linoæus, =Phallusia, Savign:j), dorsal lamiaa present (see figs. 1 to 10) ; Rhodosoma (Ebrenberg), anterior part of test modified to form operculum ; Abzssascidia (Herdman), iateatine oo right side of branchial sac.
Sub-fsmily 3.-Corellines Stigmata curved. Threegenera:Corella (Alder and Hancocki, test gelatincus, body sessile; Corynascidia (Herdman), test gelatineus, body pedunculated; Chelyosoma (Brod. and Son:), test madified into horny plates.

Family III.-CyNTIIMDE Solitary fixed Aacidians, usualiy with leathery test; branchidl and atrial apertures osually both four-lobed. Branchial sac loogitudinally folded; stigmata straight; tentacles simple or compound This family is divided into three sections:-Sub-family l.-Strelinse, not more than four folds on each side of branchial sac; tontacles simple. The more important genera are -Styela (Mscleay), stigmata normal, and Bathyoncus (Herdmsn), stigmata absent or ruodified.

Sub-f.mily 2. -Cynthine, more than eight folds in branchial sac; t atacles compound; bedy sessile The chief
genus is Cinthia (Ss. genus is Cynthia (Ss.
vigay), with a large number oi species.
Sub.fanily 3. - Boz. TENINE, more than eight folds in bracchial sac; teatacles compound ; body pedunculsted (fig. 18, A). The chief geoera sre-Bolienia (Savigny), branchial aperture fourlabed, stigmata normal; and Culcolus (Herd. Fio. 18. - Culeolus willemast. A. Entle body, man), branchial aper- matural size. B. Part of braschial aac mag. ture with less than four lobes, stigmata absectro modified (fig. 18, B). This last is a deep-sea
 genus discovered by the "Challenger" expedition (see 17 ).

Family IV.-Molaulides. Solitary Ascidians, sometimes not fixed; branchisl aperture six-lobed, atrial four-lobed. Teat usually iacrusted with sand. Branchial sac longitudinally folded; stigmata more or less curved, usually arraaged in spirals; teataclea compound. The chief geoera sre-Molgula (Forbes), with distinct folda in the branchial sac, and Eugyra (Ald. and Hanc.), with no distinct folds, but mercly broad internal longitudinal bars in the branchial sac. la some of the MFolgulidx (geaus Ancrella, Lacaze-Duthiers, 20 ) the eubrye does not become coaverted iata a tailed larva, the development being direct, without metamorphosis. The embryo when hatched assumes gradually the adult structure, and neper shows the features characteristic of larval Ascidiana, such as tbo urociord and the median sense-organs.

## Sub-order 2.-Ascidiz Compooitis.

Fixed Ascidians which reproduce by geromation, so as to forru colonies in which the ascidiozooids are buried in a common investiog mass and have no separate tests. This is probahly a somervhat artificial assemblage formed of two or threo groups of Ascidians which produce colonics iu which the ascidiozooids are so intimately united that they possess a common test or inresting mass. This is the only character which distinguishes them from the Clavelinidæ, but the property of reproducing by gemmation separates then fion the rest of tho Ascidiz Simplices. The Ascidias Compositis may be divided into the following families:-

Family I.-Distomide. Ascidiozooids divided into two regions, thorax sind abdomen; testes numerous; vas deferens not spirslly ceilcd. The chief genera are-Distoma (Gaertner) ; Distaplia (Della Valle) ; Colclla (Herdman), forming a pedunculated colooy (see fig. 19, A) in which the ascidiozoonds devclop incubatory pouches, connected with the perabranchial cavity, iu which the embryea anderge their development ( 57 ) ; and Chondrostachys (Macuonald).

Family II.-Cglocormider Colony not tixed, having a large axial cavity with a terminal aperture. Branchial epertures five-lobed. This includes one species, Colocormus huxlcyi (IIcrdnan), which is a transition form between tho ordinary Cowpound Aacidians (c.g., Distomidx) and the Ascidix Salpiformes (Fyrosoma).

Farnily III.-DiDemide Colony usually thinsna incrustang Test containing stellate calcarcous syicules. Testis singlc, large; vas defercns spirally coiled. The chicfgenera are-Didcmuum (Savigny), in which the colony is thick aod fleshy and there aro only three rows of atig. mata meach side of the braochial sae; and Leptoclinum
 (Milne-Edwards), in which tbe colony is thin and iocrusting (fig. 19, B) snd there are four rows of stignata on eaca sida of the branchial sac.

Fa:nily IV.-Diplosomidz. Test reduced in amount, rarcly containines spiculcs. Vas deferens not spirally coilcd. Iu Diplosoma (Macdonald), the most important genus, the larva is gemmiparous.
Family V.-Polyclinide. Ascidiozooids divided into three regions, -thorax, abdomen, and post-abdomen. Testes numerous; vas defereńs not apirally coiled. The chief geners sre-Pharyngodietyou (Herdman), with stigmsta absent or modifed, containing one species, Ph. mirabilc (fig. 19, C), the only Compound Ascidian known from a depth of 1000 fathoms ; Polyclinum (Savigay), with a smooth-malled stomach; Aplidium (Savigny), with the stomach wall longitudinally folded; sod Amaroucium (Milne.Edwards), in which the ascidiozooid has a long post-abdomen and a large atrial languet.

Family VI.-Botryllide. Asciarezooids having the intestine and reproductive organs alongside the braocbial sac. Dorsal lamina present ; ioternal longitudiasl bars present in branchisl sac. The chief genera are-Botryllus (Gaertn. and Psll.), with simple stellate ayatems (fig. 19, D), aod Botrylloides (Milne-Edwards), with elongated or ramified systems.

Family VII. - Polystyelide. Ascrarozooids not groupea in syatems. Branchial and atrial spertures four-lobed. Branchial sac may be folded; internal longitudinsl bars present. The chief generit are-Thylacium (Carus), with escidiozooids projecting sbovo general surface of colony; Goodsiria (Cunniogham), with sscidiozooids completely imbedded in investing mass; and chorizo. cormus (IIerdnan), with ascidiozooids united in little groaps which are connected by stolons The last gemus contains one species, Ch. reticulatus, a transition form between the other Polystyelides and the Styelinse amongst Simple Ascidians.
The metboda of reproductiou by gemma. tion differ in their detaila in the various groups of Compound Ascidians; but in all cases the process is easentially a giviag off from the parent body of groups of cells reresentiog the ectoderm, the mesoderm, and the endoderm, which develop into the correspendiag layers of the bud. The first ascidiozooid of the colony produced by the tailed larva docs not form sexnal reproductive organs, but raproduces by gemma. tion so as to make a colong. Thus there is altornation of generations in the lifehistory. In the most completely formed colooies (e.g., Botryillus) the ascidiozooida are srranged in groups (systems or cœoobii), and in each system are placed with their atrial aperturcs torzards one another, and all communicating with a common cioscal cavity which opens to the exterior in the centre of the system (fig. 19 D ).

Sub-order 3.-Ascidiz Salpiformes.
Free-swimming pelarric colonies haring the form of a hollow cylinder clescd atooe end. The ascidiozooids forming the colony are imbedded in the common test in sucha on the outer surface sad the strisl apertures on the inner surfaco next to the central cavity of the colony. The sacidiezooids are produccd by gemmation from a rudimentary larva (the cyathozooid) developed sexually.

## Repro-

 duction by gem

Fro. Ro.- Pyrosoma e?gans, patural size. A. Side view
of entire colony. B. End of extire colony. B. End vien of op=n extremity. vievt of op
(Original.)

This suh-order includes a aingle family, the l'rrosomide, containing ona well-marked genus, Pyrosoma (Péron), with several species. They are found awimming near the aurface of the sea, chiefly in tropical latitudes, and are brilliantly phosphorescent. A fully developed Pyrosoma coleny may be from an inch or two to upwards of four feet in length. The shape of the colony is seen in fig. 20. It tapers sligbtly towards the clesed end, which is reunded. The opening at the opposite end is reduced in size by the presence of a membranous prolengation of the common test (fig. 20, B). Tha branchial apartures of the ascidiozoeids are placed upon short papille projectins from the general aurface, and mest of the ascidiozooida have long conical processes of tha teat projecting outwards beyond their branchial apertures (figa. 20, 21, and 22). There is only a single layer of ascidiezoeids in the Pyrosoma colony, as all the fully developed ascidiozooida are placed with their anteropostarior exes at right angles to the surfaca and communicate by their atrial apertures with the central cavity of the colony (fig. 21).

F10. 21.-Part of a longltudibal aection through wall of Pyrasoma, showing arrangament of ascidiozooida, magnifled (partly after Sarigny). af, atrial spertures; br, branchial apertures ; asc, young ascidiozooid of a fature colony produced by budding from cy, cyathozooid; em, embryos in various stage日; $t$, teat ; tp, proceasea of teat ; brs, brsnchial ssc; yas, young ascidiozooid.
Their dersal eurfaces are turned towards the open end of the celeny. Tha more impertant pointa in the atructure of the ascidiozooid of Pyrosoma are shown in fig. 22. A circle of tentacles, of which one, placed ventrally (fig. 22, $t n$ ), is largor than the rest, is found juat inside tha branchial aperture. From this print a wide cavity, with a faw circularly-placed muscle banda running round its walla, leads back to tha large branchial eac, which accupies tha greater part of tha body. The stigmata are elongated tranaversaly and crossed by internal langitudinal bars. The dersal lamina is repre. sented by a series of eight langueta ( $l$ ). The nerve ganglion (on which is placed a small pigmented sensa organ), the subneural glaud, the dorsal tubercle, tha peripharyngeal bands, and the endostyle aro placed in tha usual pesitions. On each side of the anterior end of the branchial aac, close to the paripharyngeal bands, is mass of rounded gla cence. The alimgand cella which are the source of the phosphoresary canal is placed posteriorly to the branchial sac, and tha anus opens into a larga peribranchial (or atrial) cavity, of which only tha median pesterier part is ahown ( $p b r$ ) in fig. 22 . The repreductive organs ara developed in a diverticulum of the peri-
hranchial cavity, and consist of a lebed testis and a single orum at a time. The developmant takes place in a part of the peribranchial cavity (fig. 21, cm ). The segmeutation is meroblastic, and an elengated embryo is formed on the surface of a mass of yelk. The embryo, after the formation of an alimentary cavity, a tubular nerrous system, and a pair of laterally placed atrial tubes, dividea inte an anterior and a posterior part. Tha anterior part then aegments into four pieces, which afterwards develop into the first ascidiezooids of the coleny, While the pasterior part remains in a rudimentary condition, and was called by Huxley the "cyathezooid" ; it aventually atrophies. As tha four ascidiozoeida increasa in size, they grow round the cyathozooid and soon encircle it (fig. 21, ase and cy). Tha cyathozooid absorba the nourishing yolk upen Which it liea, and distributes it to the ascidiezooida by means of a heart and system of vessels which have heen manwhile formed. When the cyathozooid atrophies and is absorbed, its original atrial apertura remains and deepens to become the central cavity of the young colony, which now consists of four ascidiozooids placed in a ring, around where the cyathezoeid was, and enveloped in a comroon test. The colony gradually increases by the formation of buds from these four original ascidiozooids.

## Peilogent.

The accompanying diagram ebers graphically the probable origin and coursa of evolution of the varieus groups of Tunicata, and therefore exhibits their relations to one another much more correctly than any system of linear classification can do. The ancestral Proto-Tunicata are hera regarded ${ }^{1}$ as an offshoat from the Prolo-Chordata-the common ancestors of the Tunicata (Urochorda), Amphioxus (Cephalochorda), and the Vertsbrata The ancestral Tunicata were probably frao swimming forns, not very unlika tha existing Appendiculary ide, and are represented in the lifc history
of nearly all aections of the Tunicata by the tailed larval atage. Tha Larvacea are? the first offshoot from the ancestral forms which
 5
 gave two linea of descendanta, the Prolo-Thaliacea and the ProtoAscidiacea. The Proto-Thaliacea then split into the ancestera of the existing Cyclomyaria and Femimyaria. The Proto-Ascidiacca gave up their pelagio mode of lifa and became fixed. This ancestral process is rapeated at the present day when tha free-swimming larva of the Simple and Compeund Ascidians becomes attached. The Proto-Ascidlacea, after tha change, are probably most nearly repre. sented by the existing genus Clavelina. They hava given rise directly or indirectly to the various groups of Simple aud Com. pound Ascidians and the Pyrosomide. These groupa form two lines, which appear to have diverged close to the pesition of the family Clavelinidse. The one line leads to the mors typical Compound Ascidians, and includes tha Polyclinidx, Distomides, Didcmnide, Diplosomide, Colocormidæ, and finally the Ascidiæ Salpiformes. The second line gave risa to the Simple Ascidians, and to the Botryllids and Polystyclidx, which are, therefore, nol closely allied to the other Compeund Ascidiana. The later ProtoAscidiacea were probably colonial forms, and gemmation was ratained by the Clavelinidæ and bs the typical Compound Ascidians (Distomids, \&c.) derived from them. The power of forming colonies by budding was lost, hewever, by the primitiva Simple Ascidians, and must, therefore, hava been regained independently by tha ancestral forms of the Botryllidre and the Folystyelida. If this is a correct interpretation of the coursa of evolution of the Tunicata, we arrive at the following important conclusions. (1) The Tunicata, as a whele, form a degenerate branch of the ProtoChordata; (2) the Ascidies Salpiformes (Pyrosoma) ara much more closely related to the typical Compound Ascidians than to the other pelagio Tunicata, viz., the Larvacea and the Thaliacea; and (3) the Ascidir Composita form a polyphyletic group, the sectiong of which have arisen at eeveral distinct points from the encestral Simpla Ascidians.

TUNING FORK, a small bar of cast tool stcel with tolerably defined edges, bent into a fork with two prongs. A handle of the same metal extending from the bend of the fork serves as a sound-post to transmit the vibrations of the fork to any resonance board or body convenient for reinforcing the sound. The fork is set in vibration by striking one of the prongs against any hard substance, by pressing the prongs together if the fork is a light one, or, if it is large, by drawing a double bass bow across one of the prongs. The larger forks are sometimes made with a worm upon the handle in order that they may be screwed into a resonance box, the dimensions of which should agree with the pitch of the fork. The ordinary use of a tuning fork is to serre as a pitch carrier or standard, for which it is particularly suited owing to the permanence mith which it maiutains the pitch to which it may be tuned. It is flattened by heat and sharpened by cold about 1 vibration in 20,000 for every degree Fahr., so that the exact pitch always depends npor the temperature. A tuning fork is tuned by fling the ends of the prongs or between them near the ends to make it sharper, or by filing between them near or at the bend to make it flatter. Less filing is required to flatten than to sharpen. It should bo allowed to rest after tuning, on account of the disturbance of the molecular structure by the filing, and after a few days should be compared again with the pitch required, and corrected. The tuning fork is also of value in certain physical investigations, from the constancy of its rate of ribration. In England it is generally tuned to C in the treble clef, because organ-builders start their tuning from that ncte; in France it is tuned to $A$ in the treble clef, which is the note of the third open string of the violin. The French diapason normal is tuned to A at $15^{\circ} \mathrm{C} .\left(=59^{\circ}\right.$ Fahr.) and is fixed at 435 double vibrations in a second. The inventor of the tuning fork was John Shore, rojal trumpeter in 1711, sergeant trumpeter at the entry of GeorgeI. in 1714, and lutanist to the chapel royal in 1715.

According to Chladni, whose analysis of the tuning fork has been gezerally accepted, it has two nodes or points of least vibration at the bead, with a veatral or vibrating loop between, by which its ribrations are trensmitted to the handle. That this is not the case has been shown by Mr W. F. Stanley. ${ }^{1}$. The fundamental note appears to be on octave below the note which the ear recognizes as the pitch of the fork. -Helmholtz, Tyndall, and others accept the latter as the fundamental, and Helmholtz expressly says that each prong may be regarded as an elastic rod fixed at one end ${ }^{3}$ The fork is really a bent elastic rod vibrating at both ends, with a node at the bend, throngh which, and in the same way as with the bridge of any etringed instrument, the vibrations are conducted. As well es the efcond partial, the third and fourth are in large forke frequently distincuishable, bot sucb partials above the octave are very weak. In addition to the lower harmonic partials it is generally easy to produce with a blow a very high inharmonic tinkle or ringing metallic note, that will continue to sonnd for some time withont biending rith the trae note of the fork. The precise interval varies, but is nscally tro octaves and between 6 fat fifth and a major exth above the recognized pitch of the fork With ordinary tuining forks this tinkling note is so bo found amongst the highest treble notes of lo pianoforte. Theorists give other sharmonic proper tones in dre ascending order; they are derived from calculation on the assumption that they proceed as the squares of the odd nambers, but are bejond practical verification oring to

[^265]their extreme position in the scale of masical sounds and the rariation of power in different ears to distinguish them.

The tuning fork was ased by Schcibler (1777-1837) as the easiest mesns for correctly determining the pitch numbets of ribrations To make a Scheibler tonometer, take a fork in which the octare can be easily heard and intercalate 83 many forks $6 s$, giving conntable beata with each other, will fill up the octave. The addition of the whole number of beats and their fractions in the octare will be the ribrating number, in double vibrations per secoud, of the lower fork. In order to measuro the fractions of vibrations accu. rately forks ehould be chosan that are audible for 40 , or st least 20 scconds. For instance, 60 beata conated in 20 seconds rould he 3 a sccond, and 65 in the same time 325 . The forks shonld remain for toree montha after filing before their differences are finally determined, and the whole examination ehould be conducted in a known, aniform temperature. Scheibler considered four beats a second between two forks a good number for counting; but Mr A. J. Ellis, who has used Scheibler's in reation as a basis for an exhaustive historical statement of musical pitch ${ }^{3}$ and as the novel and exact means for determining the non-harmonic musical scales of various nations, especially Lastern nations,4 considers three beats a second the best counting number. This mould increase the number of intermediate forks.

Attempts have becn made to nas tuning forks instead of strings for key-board instrumenta, the object being to obtain permanence of tuning with the soft, unexciting quality of tone furnished by the fork. The inventions of Clagget, London, 1788, of Rifflsen (the melodikon), Copenhagen, 1803, and of Schuster (the adiapbonou), Vienna, 1819, were of this uature. The latest adaptation of a key. board to tuning forks bas been effected by Mr Machell of Glasgow; it mas shomn at tho Iaventions Exhibition, South Kensington, Loudon, 1885.

TUNIS, Regency of, formerly one of the Barbary states Pate $\mathcal{F}_{0}$ of north Africa, but since 1881 a dependency of France, whose resident-general excrcises all real authority in the nominal dominions of the bey. Is bounded on the west by Algeria, on the north by the western basin of the Mediterranean, on the east from Cape Bon to the Gulf of Gabes (Kabis) by the eastern basin of the same sea, and on the south-east by the province of Tripoli. On the south the boundary is the Sahara and the frontier line is indefinite. The greatest breadth from east to west is about 150 miles, the length from north to south about 300 miles. The population does not exceed a million and a half.

Physical Foatures.-Tunis is formed by the prolongation towards the east of the two great mountain chains of Algerla ( $q . v$. ), and closely resembles that country in its physical features, products, and climate; see Arrica, rol. i. p. 265. The northern Algerian chain (the Little Atlas) is prolonged through Tunis to Ras Sidi 'Ali al-Makky, the highest summits never attaining an altitude of 4000 fect. It forms a picturesque, fertile, and well-watered region, with extensive cork woods in its western parts, and separated from the southern mountains by the valley (the ancicnt Zeugitana) of the Mejerda (the ancient Bagradas), the most important river of north Africa, which after a tortuous course of nearly 300 miles falls into the Gulf of Tunis at Porto Farina. Tho basin of the Mejerca, winch is now tra versed by the railway from Algiers to Tunis, is very fertile, and many important ruins testify to its prosperity in Roman times. The rich lacustrine deposits in the Dakhila, or plain of Bulla Regia, show that it was only in relatively recent times that its upper waters found a passage to the sea by

[^266] Narch 8nd 21 April 1880 ; see also 7th January 1881.
"Oo Mrusical Scales," ibil., 27th March and 30tk October 1885.
cutting a deep gorge through the cretaceous barrier that shnts in this upland plain upon the east. The southern wall of the Mejerda valley and of the Guif of Tunis is formod bry a branch of the southern Algerian chain, connected with Jebel Aurás (Mount Aurès) by the plateau of Tebessa (Theveste) and running north-east to Cape Bon. Its highest summits (Zilk and Zaghwán) rise above 5000 foot. Another branch of tho southern chain runs frem the Sehara side of Mount Aures south-east towards the head of the Lesser Syrtis or Gulf of Gakes. Between these two branches lies a mountainous plateau, whose waters descend eastward but do not reach the sca. Arrested by a line of hills running parallel to the coast, they form a chain of lakes and marshes, which for tiae most part dry up in summer. It is to this recion of inland drainage (the ancient Byzacene) that the plain of Kairwan belongs. Its southern part from Sbeitla (Sobaitala) to the Syrtis is relatively sterile, and even in antiquity appears to have formed an exception to the general fertility of the country, which was one of the granaries of Rome. The upland district from Tebessa southward sinks into the desert by step-like series of great plateaus, separated by rugged walls of variegated marls, sands, and alluvium, torn into fantastic shapes, and scored with deep ravines by streams which at some remote period of copious rainfall poured down into the Sahara. Farther east the plateans disappear and the mountains rise like a rampart from the Sibâkh (sing. Sebkha), or Saharian marshes and salt-flats. The depression to which the Sibakh belong terminatea to tho east in the Shott (Shatt) al-Jerid, which is separatel from the Lesser Syrtis only by a narrow isthmus; see Sabara, vol. exi. p. 151. Even the Sahara of Tunis abounds in fertilo oases.

Climate. -The mean annnal temperature at Susa is $75^{\circ} \mathrm{Fahr}$.; the mean of the winter or rainy scason $60^{\circ}$ and of the hot season 97. At Tunis the temperature rarely exceeds $90^{\circ}$, except with a wind from the Sahara. The provailing winds from May to Beptember are east and north-east and during the rest of the year northwest and eact. A rainy peason of about two months usually beging in January; the spring season of verdure is over in May; eumnoer ands in October with the first rains. Violent winds are common st both equinoxes.

Flora and Fauna.-Both are geverally tho same 23 thoso of alaeria (q.v.). The lion and panther are almost extinct, but the sportsman finds in abundance the wild boar, partridge, Carthage fowl, quail, and snipe. The African mouffon still exists in the oonthern mountains. Herds of bufaloes are found in the distriot of Mater. The stag occurs in the eastern districts. The camel, now $\theta$ important, was hardly known here before the Roman soveroigaty. Red mnllet, tunny, and other fish abound around the coast ; and fishing stations are numerous. The town of Bizerta and the Kerkenna Islands are mainly depencent on their fisheries. The coral and sponge fisheries, of which Sfax and the island of Jerba (Djerba) are centree, are also considerable. Of noxious creatures may be named the scorpion, much more formidable than that of Algiers, a venomous tree enake (Ech is carinata), in the eandy lande botween Kafsa and Sfax, and a species of python called taguerga, which infests some parts of ths southern mountains.

Cork and "zen" trees cover about 360,000 acres towards the Algerian frontier, and the pine and deciduous oak almost as large au ares outh of tho Mejerda; but the country is mouch less wooded than in antiquity. The richness of the grain crops ls etill remarkable, in spite of imperfect cultivation. Olives aud many excellent fruits are largely produced, and vineyards have been much extended since the French occupation. Esparte grass abounds in the uplands. The oases of the Jerid are deveted to the date palm and produce the hest dates known in the European market.

Minerals. - The mineral wealth of Tunis, like that of Algeria, is considerable, but it has been imperfectly explored. The iron mioes of the northern mountains and the argentifercus lead mines of Al-Resás near Tunis were worked in antiquity, as were aiso the marble quarrics of Simittui (Chcinton), on the upper Mcjerda, which are now in the hands of a Belgian company. The thermal eprings of Hammam al-Anf on the Bay of Tunis are siapposed to hars hesling virtues; they are now connected with the capital by rail.

Inhabilants. - The industrious Berbers (Kabyles), the oldest siock in the country, are less sharply marked off from the Arabs than in Algeria, but are distingushable by their lighter complexion and often fair hair. They form a large part of the population in the
northern and easterr mountains, and in the island of Jeroa (Jirba). They are orgauized in tribcs with purely demerratis selfgovermment, and laws of their own, which ale not those of the Koran. The pastoral Arab nomads are descended from the second Arab invasion, which began in the 11th century (see below). They have little agriculture and are still as indolent and unruly as their ancestors. The Arahs of the towns are nsually known às Mcors; among them the Spanish Moors, descendants of the Andalusian refugees, form an exclosive and aristoctatic class. The pure Turks and the Kuluglis (sons of Turkish fathers by Moorish women or alave girls) are no longer numerous. Of Europeans there are some 10,000 Italians, 8000 Naltese, and 4000 French (exclusire of the army). The Jews number some 50,000 , of whom perhaps half are in the capital. The trade of the conntry is largely iu their hands.

Towns.-For the capital Tunis, see below. Of tha coast towns SFAX and Susa have separato notices; Bizerta (Lenzert), the ancient Hippo Zarytus, is the chief place on the north coast, with 5000 inhabitauts. It stends on a canal connecting the sea witi a lake which might easily be converted into a magnifirent land-locked harbour. On the east coast are Hammamet (Hamimat), with 9700 inhabitants ; Monastir, with 5600 inlabitants and a texde in cereale and oils; Mahdiys (Mehedia), with 6300 inhalitants, the fallen city of the Fátimites, which eince the French occupation tas bemun to riso arrain, and has a new harbour ; and Gabea (Kibis) on the Syrtis, a group of small villages, with an aggregate population of 14,000 , the port of the shott country and a depot of the esparto trade. Of the inland towns the holy city of Karrwan (q.v.) is the most remarkable. Its fine mosques are now open to visiters. Sbeitla (Lat. Sufetula), in the wountains bouth-west of Kairwan, is remarkable for its maguificent Roman renains, the triumphal arch of Constantine, and the three temples which form the hieron. The principal towns of the Mejerda basin are Bedja (BÁja), the anciont Vaga, an important corn market, and higher up, near the border, the fortress of Kéf (Sicca Vezeria), with 4000 inhabitants, boldly perched on the steep slope of a voicanic mountain.

Commerce. -The total importa of the regency in 1885 wero valued ot $£ 1,098,047$, of which abont 27 per cent were British goods, chiefly cotton fabrics. In 1884 the imports were valued at $£ 1,157,182$ Tho most important export is clive cil, and after it como wheat, esparto grasa, barley, sponges. The value of the tatal exporto in 1884 was $£ 745,554$, end is $1885 £ 852,946$. In 18851,035 ve9sels ( 71,133 tons) entered tbe port of Goletta, and the entries at other ports were 3033 ( 55,650 tons).

History. - The history of Tunis hegins for us with the establish. ment of the Phonigian colonieg; see vol. xviii. p. S06, Pbexncia and Carthage. The Punic settlars Semitized the coast, but left the Berbers of the interior almost untouched. The Romans entered into the heritare of the Carthaginians and of the vassal kings of Numidia, and Punle epeech and civilization gave way to Latin, a change which from the tirae of Cossar was bc!ped on by Italian colonization. Rich in corn, in herds, and in later times also in oil, and posscssing valuable fisheries, mincs, and quarties, the province of Africa, of which Tuis was the most impertant part, attained undor the empire a prosperity to which Roman remsins in all parts of the country still bear vitness. Carthage was the second city of the Latin part of the empire, "after Rome the busicst and nerhaps the most corrupt city of the West, and the chief centro of Latin culture and letters." In the early history of Latin Christianity Africa bolds a more important place than Italy. It was here that Christian Latin literature took its rise, and to this province belong the names of Tertullian and Cyprian, of Arnobius and Lactantius, above ell of Allgustine. Lost to Rome by the intasion of the Vandals, who took Carthage in 439, the province was recovered by Belisarius a century later (533-4), and semained Roman till the Arab invasion, for which see vol. xvi. p. 567. The con. queror 'Okha founded the city of Kairwan (c. 670), which was the residence of the governozs of Africa under the Omayjads and thereafter the chpital of the Aghlabite princes, the eonguerors of Sicily, who ruled in merely nominal dependence on tho 'Abbásids (see vol. xvi. p. 579).

The Latin element in Africa and the Christian 「aith disappeared in a single generation; the Berbers of the mountains, who had never been Latinized and never really Úhristianized, accented Islam without difficulty, but ahowed their subbborn nationality, net onsy in the character of their Mohammedanism, which has alrays been mized up with the worship of living as well as dead saints (marabouts) and other peculiarities, but also in political movements The empire of the Fatimites (see vol xvi. p. 587) rested on Berber support, and from that time forth till the advent of the Turks the dynas ${ }^{t \cdot 3}$ of north Africa were realiy native, even when they claimed desccat fion some illustrious Arab etock. When the seat of the Fátimice empire was remeved to Egypt, the Zírites, a house of the Sanlaja Berbers, ruled as their lieutenants at Mahdíya, and about 1059 Mo'izz the Ziritc, is connexion with a religions movement against the Shi'ites, transferred his very nominal allegiance to the Abbasid caiiphs. The Fátimites in revenge let loose upon Africa a vast horde of Bedouins from. Upper Egypt (B. Hilal and Solairo
the ancestors of the modern nomads of Barbary. All Africa mes ravaged by the invaders, who, though unable to fonnd an cmpire or overthrow the settled goveroment in tho towna, forced the agricul. tural Berbers iato the mountaios, and, retaining from generation to generation their lamless and predatory habits, have evor sinco made order and prosperity almost impossible in the open parts of the country. The Zírite dynasty was finally extinguished by Roger 1. of Sicily, who took Mahdija in 1148 and established bis authority over all the Tuaisian cozit. Even Moalem historians speak favourably of the Norman rule in Africa; but it was brought to so early end by the Almohade caliph ' $\AA$ bd al-Mu'min, who took Mahdiya ia 1160. The Almohade $\in$ mpire soan began to decay, and in 1336 Ahủ Zakariy's, prince of Tuais, was able to proclaim himself indionandeat aud found a dywasty, which subsisted till the advent cf the Turks. The Hafsites (so called from Abú Hafs, the ancestor of Ahú Zakarýá, a Berber chieftain who had been ciee of the intimato cisciples of the Almohade mahdi) assumed the title of Pribee of the Faithiul, a dignity which was ackuowledsed even at Mecca, when in the days of Mostansir, the second Hafsite, the fall of Baghdad left lsham without a titular head. In its best days the empire of the Hafsices extended from Tlencen に Tripoli and they received homaga from tho Merinids of Fcz; they beld their own against repeated Frankish iavasions, of which tha moat notabla wero that which cost St Louis of France lis l:fo (12:0) and that of the duke of Bourbon (1390), whea English troops took part in the unsuccessful siege of Mahdiya. They adorned Twisis with noosques, schools, and other institutions, favoured letters, and in gencral appear to have risen above the nsual level of Hostews sovereigns. But their rula was troubled by continual rara aod insurrections; the support of the Bedouin Arahs was imperfectly secured by pensions, which formed a heary burden on the livances of the state; ${ }^{1}$ and in later times the dynasiy was weakened by faurily dissensions. Leo Africanus, mriting early in the 16th century, gives a favourable picture of the "greait city" of Tunis, waich bed a Courishing manufacture of fine cloth, a prosperons colony of Christian traders, sud, including the suburbs, niae or ten thonsand hearths; bat he speaks also of the decay of once Rourishing provizsial tomes, and especially of agriculture, the greater part of the open country lying waste for fear of the Arab marauders. Taxation was heavy, and the revenue very considerable: Don John of Austrie in a report to Philip II. states that the land revenue alono under the last Hafsite mas 375,935 ducats, but of this a great part wert in pensions to the Arabs.

Th:3 conquest of Algicrs by the Turks gavo a dangeroua meiginhour to Tenis, and after tho death of Mohammed the Hafite in 1525 a disputed succession supplied Khair al-Din Barbarossa with a pretext for occupying the city in the name of the sultan of Constantinonle, Al-Hasan, the son of Mohammed, seught hel? from the emperor, snd was restored in 1535 as a Spanish vassil. hy a force whiç Charles V. commanded in person, while Andrea Loria was admiral of the fleet. But tbo conquest was far from complete, and was uever consolidated. The Speniards remained at Coletta and made it a strong fortress ; but the interior was a frey to anarchy and civil war, until in 1570 "Ali Pasha of Algiers utterly defeated Hamid, the sou and successor of Hasmn, and occupied Tmis. In is 153 the Turks again retreated on tho appreach of Don John, tro kad dreans of making himself king of Tumis; but this auccess was not followed up, end in the next year Sultan Sclim II. eent a strong expedition, which drove the Spaniards irom Tunis and Coletia, and reduced the country to a Turkish province. The civil admioistration was now placed under a pasha; but in a few years a military revolution transferred the supreme power to a dey elected by the janissarics, whe forned the army of occupation. Tho goverument of tho deys lasted till 1705, but mas sooo narromed cr crershadowed by the authority of the beys, whose proper functiou was to manage the tribes and collect tribute. Frors 1631 to 1702 the affice of bey was hereditary in tie aescentants of Moríd, a Corsican racgegade, and their rivalry mith the deys and internai dissensions kept the country in coustant diserder. Ibrahim, the last of the deys (1702.1505), destroyed the houss of Murid and absorbul the lieyship in his onsn office: lut, when lo fell is lattlo with th: Algeriang, Mosain h. 'Ali, the son of a Creek renegade, tras proclaimed sovereigo by the troops under the title of "bey," amil, heing a prince of encegy and ability, was able to establisi the letc livary envereignty, which has lasted witlout change of dynasty to the preseat time.
Frequent ware with Algiers, which need not detain us, form the chiof incidents in the internal history of Tunis under the beya Under deys and beys alile Tunis was esseatially a pirate state. Occasional acts of chastiscment, of wbich the bombardment of Porto Farina by Blake in 1655 was the most notahle, and repeated treaties, extorted by Europcan powers, checiked from time to time, bet never put an end to, the labitnal piracies, on which iodeed the public revenue of Tunis was rainly dependent.' The powers were

[^267]gencrally less concerned for the captives than for the acquisition of trading privileges, and the beys took advantage of the commercial rivalry of Englaod and France to playy off the one pomer agaiust the other. The release of all Christian slaves was not effected till after the bombardment of Algiers; and tho defnite abandonment of piracy may bo dated from the presentation to the hey in 1819 of a collectivo note of the powers assemhled at Aix-las Chapelle. The Government had not elasticity enough to adapl itself to so profourd a change in its ancient traditions; the finances became more and more hojelessly embarrassed, in spite of ruinoue taxation; and altempts at European ionovations in the court ane army made matters only worse, so long as no attern twas made to improve the interaal condition of tho couniry. In the thirs quarter of the 19th century not moro thau a tenth 1 art of ti: fertile land was under cultivation, and the jearly charge on to. public deht exceeded the whole anoual rorenue. Jo these circum. etances only the rivalry of tho European percrs that hed interezts in Tunis protracted from year to year the incvitable revolution. The French kad long regarded the dominioue of the bey as their natural inheritance, aud in 1881, havidg got a gricrance against the bey in a commercial transaction of tho Frencl African Societrs with tho exceution of which he had interfeed (the afficir of the Enfida estate), a Freach force crossed the Algerian frontier under pretezt of clastising the independeat Froumir or Ehomair tribes in the yorti-east of the rcgency, and, quickly dropping the nask, adraoced on the capital and compelled the bey to accept the French protectorate. The actual conquest of the country was not efiected without a 8 erious struggle with Moslem fanaticism; but all Tunis was brought completcly upder Freuch juristicticy and aiministra. tion, supported by military posts at every imporiant yinat. Tbs power of the hey is uull and his dignity morcily nominal, -a fact acknomledged by Great Eritain by the surscader in 1883 of Her Majesty'a consular jurisenction in the regency.
Lilcroatro--Of Arabic sources accessiblo in +onslations the peogranhical

 to the 10th, 11 th, sad 12th centuries respectively; the history of lla Khald ung (II ist. des Rerkeres, by De Slane, 4 vols., Algiers, 1552 -56) inclutía the earlict Hafsites, that of Al-Kairawanf (Uist. de l'Afripuc, by Pellissier and Remuast Parle, 1845, in Exph, scient. do l'Aljerie, Tol viin; Arabic text, Tunis, 1230 A.n.) deals especially with Tunis, and goes down to 1cs1. The geography of Tunis is treawd by E. Pellissier (Explor, Scicnl. do 7 Alditic, vol. xivi, Paris, $1 \in 3$ ),
 Eicndhook, by Sir li. Plasfair (1887), who has also published Travels in the $F$ jol steps of Bruce in Al], and Tunis London, 1887). A French survey is in progr tys, and eome of the mas are published. For the modern listor, see Ioussian Annales Tunistenates (Algiers, 1804), snd Brosdiey, Tunis Past and Present (Ediaburgh, 1889); for the archæology, Davis, Carthage and her Renains (Lon. don, 1860), Gueria, Vosage Archéologigue (1862), sud D'Herisson, MI ission Arcréol. en Tunisie (Parie, 1881). Tio excellent description of Africa by Leo Africanus is in Ramusio and Purchas. Sbaw'e Travels (1738) pay still be consulted. Of other books of travela fítitzan's feise (Leipsic, 18:0) deserves mention

TUNIS, capital of the regeacy of the same name, in $36^{\circ} 50^{\circ} \mathrm{N}$. lat, and $10^{\circ} 12^{\prime} \mathrm{E}$. long., is situated ou au istbmus betweeu tro salt lakcs, a marily scbkha to the south-west and the shallow Eolucira to the north-east. The latter is twelre miles in circumference, and on the side opposite Tunis is connected with the Bay of Tunis at the port of Goletta (Hals al-Wād) by a short canal. The old town, of whic - the walls have in great part disappeared, lies between tro suburbs, the Ribat al-Soweika or the north and the Ribát Lab al-Jezira on the south. These suburbs were surrounded by a wall in the begrinaing of the 19th century. Between the old town and the Marine Gate on the Boheira a European quarter, containing the palece of the resident, public offices, the 1 ,rorisional cathodral, and huge blocks of new houses in the Fheuch style, has sprung $u_{1}$. At the cxtreme west-of the old town is the citadel, now used as barracks, whose lofty circuit includes the mosque built by Abri Zakarifé the Hafsite in 1232. To the same century belongs the great mosque of the Olive Tree (Jami al-Zcituna) in the centre of the town, with its many domes and spacious cloister, which possesses a library and serves as a college for somo 450 students of Muslem learning. Tp the north near the walls of the old town rises the dome of the mosque named after Sidj Mahrez, a renowned saint of the 5th century of the. Flight, whose tomb gives it a right of sanctuary for debtors. There are many other mosques and chapels, but all are closed against Curistians. TLe palace of the bey, between the citadel and the mosque of the Olive Tree, is partly in bad French taste. but contains sozne rooms of tho 18 th ceutury with dulun:
able Moorish decoration in the delicate stucco arabesque work for which Tunis was formerly famous. The chief attraction of the old town lies in its bazaars, which retain their Oriental character unimpaired. Water is supplied to numerous fountains by an ancient aqueduct from Jebel Zaghwan, repaired at a cost of half a million sterling by the late Bey Molummed al-Sádik. The principal educational establishments besides that of the great mosque are the Sadikiya college, founded in 1875 for gratuitous instruction in Arabic and European subjects, the college of St Charles, conducted by priests and open to Christians and Moslems alike, and the normal school, founded in 1884 by the bey to train teachers in the French language and European ideas. The population of Tunis is about 125,000 , of whom onefifth are Jews and one-fifth Europeans, chiefly Maltese and Italians.
The envitons of Tunis are admirable from the beautiful viens they present; the finest prospects are from the hill on the southeast, which is crowned by a French fort, and from the Belveder on the north of the town (Jebel al-Tíba), on which stande a very ancient fortress. Half-en-hour's drive west of the town is the decaying palace called the Bardo, a little town in itself, remarkable for the " lion court " and some apartments in the Moorish style. The port of Goletia, with 4000 inhabitants, is connected with Tunis by a railway 10 miles long. The older or sonthern part of the town next the canal has a fortress, now used as barracks, built by the Turks on the site of the Spanish fortress destroyed in 1574. The ruins of Carthage lie a few miles north of Goletta. The chief manufactures of Tunis are still textiles, as in the time of Ler Africanus. The manufacture of silk dates from the settlement of Moorish refngees from Spain abont 1600. Tbere are also tanneries, a tobacco factory, and some minor industries. The annual exports of grain, oil, stuffs, hides, and essences are valued at $£ 720,000$, and the imports, chiefy of cotton goods, at $£ 560,000$. There are two French steamers weekly between Marseilles and Goletta, and the coast tomis are served and connected with Malta both by Froach and Italiau packets.
History.-Tunis was a Carthaginian city and is repeateclly mentioned in the history of the Punic wars. Strabo speaks of its hot baths and quarries. Under tle: Arabs it rose to importance, hecame the usual port for those going from Koirwau to Spain, and was one of the resideuces of the Aghlabites. In the 10th ceutury it suffered severely, and was repeatedly pillaged in the wars of the Fátimites with Ahi Yazid and the Zenáta Berbers. For its later fortunes see above in the history of the country, of which siuce the accession of the Hafsites it has been the capital.
TUNNELLING. The process of making a more or less horizontal underground passage, or tunnel, without removing the top soil is known as tunnelling. In former times any long tube-like passage, however constructed, was called a tunnel. At the present day the word is sometimes popularly applied to an underground passage constructed by trenching down from the surface to build the arching and-then refilling with the top soil ; but a passage so constructed, although indistinguishable from a tunnel when completed, is morə correctly termed a "covered way," and the operations "cutting and covering," instead of tunnelling. Making a small tunnel, afterwards to be converted into a larger one, is called "driving a beading" and in mining operations small tunnels are termed "galleries," "driftways," and "adits." If the underground passage is vertical it is a shaft; if the shaft is commenced at the surface the operations are known as "sinking," and it is called a "rising" if worked upwards from a previously constructed heading or gallery.

Tunnelling has been effected by natural forces to a far greater extent than by man. In limestone districts innumerable swallow-holes, or shafts, have been sunk by the rain water following joints and dissolving the rock, and from the bottom of these shafts tunnels have been excavated :o the sides of hills in a manner strictly analogous to the ordinary method of executing a tunnel by sinking shafts at intervals and driving headings therefrom. Many rivers find thus a course underground. In Asia Miner one of the rivers on the route of the Mersina Railway extension pierces
a hill by means of a natural tunnel, whilst a little south at Seleucia another river flows through a tunnel, 20 feet wide and 23 feet high, cut 1600 years ago through rock so hard that the chisel marks are still discernible. The Mammoth cave of Kentucky aad the Peak caves of Derbyshire are cxamples of natural tunnelling. Mineral springs bring up vast quantities of matter in solution. It has been estimated that the Old Well Spring at Bath has discharged since the commencement of the 19th century solids equivalent to the excavation of a 6 feet by 3 feet heading 7 miles long; and yet the water is perfectly clear and the daily flow is only the 150th part of that pumped out of the great railway tunnel under the Severn. Tunnelling is also carried on to an enormous extent by the action of the sea. Where the Atlantic rollers break on the west coast of Ireland, on the seaboard of the western Highlands of Scotland, and elsewhere, numberless caves and tunnels have been formed in the cliffs, beside which artificial tunnelling operations appear insignificant. The most gigantic subaqueous demolition hitherto carried out by man was the blowing up in 1885 of Flood Rock, a mass about 9 acres in extent, near Long Island Sound, New York. To effect this gigantic work by a single instantaneons blast a shaft was sunk 64 feet below sea level, from the bottom of which four miles of tunnels or galleries were driven so as to completely honeyconb the rock. The roof rock ranged from 10 feet to 24 feet in thickness, and was supported by 467 pillars 15 feet square; 13,236 holes, averaging 9 feet in length and 3 inches in diameter, were drilled in the pillars and rcof. About 80,000 cubic yards. of rock were excarated in the gaileries and 275,000 remained to be blasted away. The holes were charged with 110 tons of "rackarock," a more powerful explosive than gunpowder, which was fired by electricity, when the sea was lifted 100 feet over the whole area of the rock. Where natural forces effect analogous results, the holes are bored and the headings driven by the chemical and mechanical action of the rain and sea, and the explosive force is obtained by the expansive action of air locked up in the fissures of the rock and compressed to many tons per square foot by impact from the waves. Artificial breakwaters have often been thus tunnelled into by the sea, the compressed air blowing out the blocks and the waves carrying away the debris.

With so many examples of natural caves and tunnels in existence it is not to be wondered at that tunnelling was one of the earliest works undertaken by man, first for dwellings and tombs, then for quarrying and mining, and finally for water supply, drainage, and other requirements of civilization. A Theban king on ascending the throne began at once to drive the tunnel which was to form his fiual resting place, and persevered with the work until death. The tomb of Menptah at Thebes was driven at a slope for a distance of 350 feet into the hill, when a shaft was sunk and the tuncel projected a further length of about 300 feet, and enlarged into a chamber for the sarcophagus. Tunnelling on a large scale was also carried on at the rock temples of Nubia and of India, and the architectural features of the entrances to some of these temples might be studied with advantage by the designers of modern tunnel fronts. Petrie has traced the method of underground quarrying followed by the Egyptians opposite the Pyramids. Parallel galleries about 20 feet square were driven into the rock and cross galleries cut, so that a hall 300 to 400 feet wide was formed, with a roof supported by rows of pillars 20 feet square and 20 feet apart. Blocks of stone were removed by the workmen cutting grooves all round them, and, where the stone vas not required for use, but merely had to be removed to form a gallery, the grooves were wide enolgh for - man to stand up in.

Where granite, diorite, and other hard stone had to be cut, the work was done by tube drills and by suws supplied with corundum, or other hard gritty material, and water, -the drills leaving a core of rock exactly like that of the modern diamond drill As instances of ancient tunnels through soft ground and requiring masonry arching, reference may be made to the vaulted drain under the southeast palace of Nimrúd and to the brick arched tunnel, 12 feet ligh and 15 feet wide, under the Euphrates. In Algeria, Switzerland, and wherever the Romans went, remains of tunnels for roads, drains, and water-supply are found. Pliny refers to the tunnel constructed for the drainage of Lake Fucino as the greatest public work of the time. It was by far the longest tunnel in the world, being more than $3 \frac{1}{2}$ miles in length, and was driven under Monte Salviano, which necessitated shafts no less than 400 feet in depth. Forty shafts and a number of "cuniculi" or inclined galleries were sunk, and the excavated material was drawn up in copper pails, of about ten gallons capacity, by windlasses. The tunnel was designed to be 10 feet high by 6 feet wide, but its actual cross section varied. It is stated that 30,000 labourers were occupied eleven years in its construction. With modern appliances such a tunnel could be driven from the two ends without intermediate shafts in eleven months.

No practical advance was made on the tunnelling methods of the Romans until gunpowder came into use. Old engravings of mining operations early in the 17th century show that excavation was still accomplished by pickases or hammer and chisel, and that wood fres were lighted at the ends of the headings to split and soften the rock in advance (see fig. I). Crude methods of ventilation by

Fle. 1.- Method of mining, 1621. (From De Re Betallica, Basel, 1621 .) shaking cloths in the headings and by placing inclined boards at the top of the shafts are also on record. In 1766 a tunnel 9 feet wide, 12 feet high, and 2880 yards long was commericed on the Grand Trunk Canal, England, and completed eleven years later; and this was followed by many others. On the introduction of railways tunnelling became one of the ordinary incidents of a contractor's work; probably upwards of 4000 railway tunnels have been executed.
Subaqueous Trunneliing. - In 1825 Branel commenced and in 1843 completed the Thamies tunnel, which was driven ot llointa throngh liquid mud by the sid of a "shield " at a cost of about £1300 per lineal yard. It is now used by the East London Railway. In 1872 Chesborongl began tunnelling under the Detroit river, hetween Canada and Slichigan, U.S., but the work was abandoned nuring to continued irrnptions of water after some 600 yards of
hieadings had beea drivea.

The most umportant subaqueous work yet accomplished-the Severn tunnel, $4 \frac{4}{3}$ miles in length-was commenced in 1873 and finished in 1886, Messrs Hawkshaw, Son, Hayter, and Richardson being the engineers and Mr T. A. Walker the contractor. The bed of the Severn is formed principally of marls, sandstones, and conglomerates in nearly horizontal strata, overlying highly inclined coal measures, shales, and sandstones, which are also exposed in the bed of the river. The tunnel is made almost wholly in the Trias and Coal Measure formations, but for a short distance at its eastern end it passes through gravel. The lowest part of the line is below the "Shoots," where the depth is 60 feet at low water and 100 feet at high water, and ths thickness of Pennant sandstone over the brickwork of the tunnel is 45 feet. Under the Salmou Pool, a depression in the bed of the river on the English side, there is a cover of only 30 feet of Trias marl. Much water was niet with through. out. In 1879 the works were flooded for some months by a large land spring on the Welsh aide of the river. The water which eupplied the spring came from fissures in the carboniferous limestone, which was met with only at this place , and it is now conveyed by a side heading parallel to the tunnel to a shaft 29 feet in diameter, in which are fixed punpps of adequate power. On another occasion the works were flooded by water which burat through a hole in the river bed at the Salmon Pool. This hole, which was in the Trias marl and had an area of 16 feet by 10 feet, was sulssequently filled with clay and the works were completed beneath it. The tunnel is for a double line of rail way and is lined throughout with vitrified bricks set in Fortland cement mortar. A heading was first driven entirely across the river to teat the ground and subsequently another heading at a lower level. "Breakups" were made at intervals of two to five chains and the arching was carried on at each of these points. All parts of the excaration were timbered, and the greatest amount excavated in any one week was 6000 cubic yards. Owing to the inrush of water it was frequently necessary to completely roof tbe timbering with felt or corrugated iron before the bricklayers could commence the arching. The total amount of water raised at all the pumping stations is abont $27,000,000$ gallons in twenty-fonr hoira ; but the total pumping power provided is equal to $66,000,000$ gallons in twenty-four hiours. The ventilation is effected by a fan of the Guibsl pattern, 40 feet in diameter and 12 feet wide, making forty-three revolutions and drawing 447,000 cubic feet of air per minute from the tunnel through an 18.-feet shaft at Sudbrooke (Mionmouth).
Aiother example of subaqueous tunneling, second only in importance to the foregoing, is the Mersey tunnel, the length of which between the purnping shafts on each side of the river is 1 mile. From each ghatt a drainage heading was driven through the red sandstone with a rising gradient towards the centre of the river. This heading was partly bored out by a Beaunount machine to a diameter of 7 feet 4 inches, and at a rate attaining occasionally 65 lineal yards per week. All of the tunnel excavation, amounting to 320,000 cubic yards, was got out by hand labour, since heavy blasting would have shaken the rock. The minimnm cover between the top of the arch and the bed of the river is 30 feet. Pumping machinery is provided for $27,000,000$ gallons per day, which is more than donble the usual quantity of water ; and ample ventilation is secured by two 30 - feet diameter and two 40 . fcet diamoter Guibal fans. Messrs Brunlees and Fox were the engineers, and Messrs Waddell the contractors for the works, which were opened in 1886, about 6 years after the commencement of operations.
Proposals for the construction of a tunnel about 30 miles in length to connect England and France have been brought forward periodically from the commencement of the 19 th century, but nothing was done until 1881, when preliminary works of some inportance were commenced by Sir Eaward Watkin and the SouthEastern Railvay Company. At the proposed point of crossing the deepest part of the channel is 210 feet, and, as the beds on the English side and those on the Frenclh side, so far as relates to the grey chalk and chalk marl, are each 225 feet thick, it is assumed that those strata are continnous and that the tunnel सuald be driven through a water-tight material. Shafta have been sunk ncar Folkestone, and experimental headings have becu driven 2000 yards under the sea, on the line of the tnnnel. The heading, 7 fcot in diameter, was cut by a Beaumont boring machine, having two arms with steel teeth, and driven by compressed air ; the nsnal rate ot progress was 15 lineal yards per day.
A partially constructed snbaqneous tunnel now ries urownea under the Hudson river at New York. An sttempt was made to drire a double tunnel througll the mud and silt forming the river bed. In 1880, when about a hundred sarda had been completed, the water burst in, and twenty men were drowned. Work was subsequently resnned on the following plan (see fig. 2): A pilot tunnal, consisting of an iron tube of 6 feet 6 inches in diameter, was advanced from 30 to 40 feet ahead of the main tunnel, to forna a frm support for the iron plates of the latter by means of radial screws. Compressed oir, pumped into the tunnel at a pressure of about 20 th per square inch, prevented the weigit of silt and water from crushing the plating and flowing into the tuunel. 'fle cxcavated
ailt was mixed with water and ejected by compressed air. Between the shafts the length of the proposed tunnel is 1 mile, and about

Fia. 2.-Hudson river tumbel-method of work.
3ne-cighth of the distance had been accomplished when the worka were stopped for financial reasons.

Small subaqueous tunnels havo heen driven through ciay vithout difficulty under Lakes Michigan and Eric, and elsewhere in Amerca. In England a heading मras driven uearly across the Thames in 1807, and eighty years later two 10 feet 6 inch iron-lined tunnels were constructed under the river close to the foundation of Londun Eridge by Mr Greathead, with the aid of a simple annular shield aivanced by six hydraulic presses. Where open gravel or water has to be tumnelled tbrough a diaphragm must be fitted to the s?iseld. Mallet proposed in 1858 to carry in this way a tubular tunnel across the English Channel. Varioue plans have beeu sugrested for the remural of the soil in advance of the shield. Mr Greathead would effect it by the circulation of a closed eurrent of water, carrying the atuff through the shichl from front to back; and an American plan provides for forcing it bodily out of the way by a pluugh-shaped shicld, aided by jets of water at a rery high pressure.

Tunnelling through Alountains. - Where a great thickness of rock orerlies a tunuel, it is vecessary to do the nork wholly from the two enda, withont iuternediate shafts. The problem resolves itself into devising the most expeditions way of excavating and romoving the rock, and thero are none of the nncertaintieg and difficulties which make subaqueons tunnelling of so ligh an interest. Experience has led to great edrances in speed and economy, as will bo seen from the following particulars of the three tumels through the Alps, the longest yet conatriacted.

| Tunnel. | Length. | Progress per Daj. | Cost. |
| :---: | :---: | :---: | :---: |
|  | Miles. | Innea? Yards. | Per Lineal Jard. |
| Mont Cenis............... | $7{ }^{7}$ | 2.57 | £206 |
|  | 9f | 6.01 | 1.13 |
| Arlberg | 06 | $9.0{ }^{\circ}$ | 105 |

In 1857 the first blast was firel in connexion with the Mont Cenis works; in 1861 machine drilling was introduced; and in 1871 the tunnel was opened for traflic. With the exception ol about 300 yerds the tunnel is lined throughout with brick or stone. Iittle interest now attaches to the ineihod of tunnclling adopted at Mont Cenis, as it is in ocveral respects obsolete. During the first four years of liand labour the average progress fias not more than 9 inches per day on each sille of the Alps; but with compressed. air rock-drills tho rate towarls the eud was five tinoes grcater.

In 1872 the St Gettharil tunnel was commenced and in 1881 the first locomotive ran through it. Mechanical drills wero used from the commencenent, Tunnelling was carrier on by driving in advance a top leading about 8 feet square, then ellarging this sideways, and finally sinking the excavation to invert luvel (see Sgs. 3 and 4). Air for norking the rock-drills was compressed to seven atmospheres by turhines of about 2000 horse-jower. Six to to eight Ferroux drills, making about 180 blows a minute, were mounted on a carriage and pushed up to the point of attack. From thirteen to eighteen boles were drilled by the machine and its sixteen attendants to dep,tha of from $2^{\prime} 7^{\prime \prime}$ to $4^{\prime} 3^{\prime \prime}$ in three to five hours, and the work of charghg with dynamite, firing, and clearing away was then done by twenty -two men in three to fonr hours, The charge per 'iole averaged is to, aud after firing a strong current
of compressed air was directerl over the face of the excavation. Four aots of bolea wero minder farourable rircumstances drilled in

twenty-four bours, which rendered a progress of 13 feet yer day in such roek as gneiss attainable in each hearling.

The driving of the Arlberg tunnel was colvmenced in 1880 and the work was completed in litele more than three ycars. The main heading was driven aloug the hottom of the tunnel and shafts were opened up 25 to 70 yards apart, from which emaller headings were driven right and loft. The tunnel mas enlarged to its full section at different points simultaneonsly in lengths of 8 yarla, the excava. tion of each occupying about twenty days, and the masonry 14 days. Ferronx percussion air drills and Braudt rotary hydraulic drills were uspd, and the performance of the latter was especially satisfactory. After each blast a fine spray of pater wes injected, which assisted the ventilation materially. In the St Gothard tunnel the discharge of the air drills was relied on for ventilation. In the Arlberg timinel over 8000 cubic fect of eir per minute wore thrown in by ventilators. In a long tunnel the quick transport of materials is of equal importance with lapid dilling ond blasting. In the Arlberg, to keep pace With the misers, 900 tons of excavated material liad to be removed, and 350 tons of masonry to be is:troduced, daily at each end of the tumel, which neecssitated the transit of 450 wagons. This traffic was carrice on as er a length of $3 \frac{1}{3}$ miles on a singio track of 27 -inch gauge $u$ ith two didings. When the locomotives ran into the tunnel the fires were damped down, and, as the pressure in tho boiler was fifteen atmosphares, the stored. up heat in the water furnished the necessary power. The cost per lineal yard varied according to the thickness of mase nry lining and the distanco from tho mouth of the tunnel. For the first 1000 yards from the entrance the prices per linsal yard were $£ 11,8 \mathrm{~s}$. for the lower heading; $£ 7,12 \mathrm{~s}$. for the upper one ; £30, 10 s , fo: the unlined tunnel: $£ 45$ for the tunnel with a thin lining of masonry; and f124, 反s. with a lining 3 feet thick at the arch, 4 feet et the sides, and 2 feet 8 inches at the invert.

Long Tunnels--Tho new Croton aqueduct tuanel from Crnion dam to the reservoir in New lork is worthy of note both for its great lengh and the rapid progress made with it. The distance is $33 \frac{1}{d}$ miles and practically the whole is tunnelled through rock. Shafts were ounk about $1 \frac{1}{2}$ miles apart and headings driven cach way. Ingersoll drills were clitefly used, and the rato of advance with the heallings was in 1856 it males per month. "The old Croton aqueduct was 7 feet 8 inclius wille ly 8 feet 5 iuches high; the new one is 13 feet 7 incios in width anel height.

Tennelling in Toons, - Where tumels have to be carried through aoft soil and in proximity to valuable buldings special precaution,

Mias. © and 6.-Grent Northeru Ral!way tusae!. Method of tunnel. ling inder the Motropolitan cattle matket, London.
have to be taken to avoid ocitlement. The important Metropolitan tunnels constructed by Sis John F'owler Lave already been de. scribed under Railway (vol. xx. p. 235;. Ancther successful ex-
ample of auch work is the tunnel driven in 1886 by $\operatorname{Mr}$ Jolinson, the Great Northern Company'a engincer, under the Metropolitan cattle market. Where clear of buildings the tunnel was executed in 12 feet lengths measured from the finished brickwork, the excavation extending another 5 feet. The face of the excavation was carried out in four sections, the first between the head trees and the first sill was formed with a rake of 1 in $4 \frac{1}{2}$, the aecond and third with a rake of 1 in 6 , and the fourtl was vertical, the whole face being close boarded (see figs. 5 and 6 ). The areh and side walls were eight rings and the invert six rings thick. A 12 -fect length was completed in 12 to 14 days, and the oubsidence in the ground was about $3 \frac{1}{2}$ inches. Under buildings and roads the tuanel was executed in 6 -feet lengths. The crown bars, 15 inches in diameter, alternating six and seven in number, were built in with solid brickwork in cement and bard wood wedging. The skeleton centies for the arching were supporterl by props notched into the ribs and provided with wedges for tigbtening up. A 6 -feet length was built in six days, and the surface subsidence, consequent upon tbe inpossibility of exactly fitting the poling boards to the clay, was only from 1 incli to $1 \frac{3}{4}$ inches. Several heavy buildings were tunnelled under without any structural damage arising.

Where open ballast and running sand heavily charged with water are met with a tun. nol cannot be driven on the ordinary system without seriously endangering adjoining buildings. To nieet such cases, and also to provide a safe means of tunnelling under dock basins, canals, and rivers, the pneumatic shield (see fig. 7) was designed by Mr Benjamin Baker. The shicld is supported against external pressure by vertical girders about 6 feet apart. Horizontal shelves of steel plates with cutting edges are spaced about 4 feet apart, and the face of the shield is clesed by vertical plates and slides; the arrangement is

Fio. 7.-Mr B. Baker's pneumatic abield. snch that any slide can be opened to admit of the ballast or sand being excavated, whilst the compressed air filling the tunnel prerents the influx of water during the process. Where hard watertight clay is encountered, sections of the shield plates are unbolted to admit miners. When sufficient material bas been excarated the sbicld is advanced by bydraulic pressure and the brick arching built.
See Aquedect and Rallwar; also Drinker's Tunnelling, New York, 1878 (a most important work); and Proa Inst. Civ. Eng., art. "Tunnels." (B. B.)

TUNNY (Thynnus thynnus), one of the largest fishes of the family of Mackerels, belongs to the genus of which the Bonito (Th. pelamys) and the Albacores (Th. albacora, Th. alalonga, \&c.) are equally well-known members. From the latter the tunny is distinguished by its much shorter pectoral fins, which reach backwards only to, or nearly to, the end of the first dorsal fin. It possesses nine short finlets behind the dorsal, and eight behind the anal fin. Its colour is dark bluish above, and greyish, tinged and spotted with silvery, below. The tunny is a pelagic fish but periodically approaches the shore, wandering in large shoals, at least in the Mediterranean, within well-ascerfained areas along the coast. The causes by which its wanderings are regulated in the Atlantic Ocean are much less understood; it not unfrequently appears in small companies or singly in the English Channel and in the German Ocean, probably in pursuit of the shoals of pilchards and herrings on which it feeds. The regularity of its appearance on certain parts of the coasts of the Mediterranean has led to the establishment of a systematic fishery, which has been carried on from the time of the Phonicians to the present day. Immense numbers of tunnies were caught
on the Spanish coast and in the Sea of Marmora, where, however, this industry has much declined. The Sardinian tunnics were considered to be of superior excellence. The

Tunny (Thynnus thynnus.
greatest number is now caught on the north coast of Sicily, the fisheries of this island supplying most of the preserved tunny which is exported to other parts of the world. In ancient times the fish were preserved in salt, and that coming from Sardinia, which was specially esteemed by the Romans, was known as Salsamentum sardicum. At present preference is given to tunny preserved in oil. Many of the fishes, especially the smaller ones, are consumed fresh. The tunny occurs also in the South Pacific; but several other species seem to take its place in the IndoPacific Ocean. It is one of the largest fishes, attaining to a length of ten feet and to a weight of more than a thousand pounds.

On the tunny fisheries of ancient and modern times, see Cavier and Valenciennes, Hist. Nat. des Poissoms (vol. viii. pp. 71-92).

TUNSTALL, a market tow is situated on a branch line of the London and NorthWestern Railway and on the Trent and Mersey Canal, 4 miles north-west of Stoke and 168 north-west of London. Among the public buildings are the market ( $18^{\circ} \mathrm{5} 8$ ), town hall (1884), old court-house (now used as a free library and reading room), and board schools (1880). The chief manufactures are those peculiar to the Potteries district; there are also large iron-works (coal and iron being obtained in the neighbourhood), and brick and tile works. The town is chiefly the growth of the 19th century, and in 1811 numbered only 1677 inhabitants. In 1885 it was included for parliamentary purposes in the borough of Newcastle-under-Lyme. It is governed by a local board of twenty-four members. The population of the urban sanitary district (area 690 acres) was 13,540 in 1871, and 14,244 in 1881.

TURANIAN. This word means etymologically no more than "not Iranian," and in this sense the word Turan was used by Sasanian monarchs to cover those parts of their realm that did not belong to Iran. The application of the word to denote the Ural-Altaic family of languages is extremely unfortunate and seems to be falling out of use. See Philology, vol. xviii. p. 779.

TURB1NE. See Hxdromechanics, vol. xii. p. 524.
TURBOT, ${ }^{1}$ the largest and best known of a genus of fat fishes, Rhombus, which bears the appropriate systematic name of Rh. maximus. The turbot has great width of body, and is scaleless, but is covereu with conical bony tubercles. The eyes are on the left side of the body, the lower being slightly in advance of the upper; the mouth is large and armed with teeth of uniformly minute size. The turbot is found all round the coasts of Europe (except in the extreme north), preferring a flat sandy bottom with from 10 to 50 fathoms of water. The broad banks off the Dutch coast are a favourite resort. It is a voracious fish, and feeds on other fish, crustaceans, and mollusks. It

[^268]seems to constantly change its abode, wandering north ward during the summer, and going into deeper water in the cold season. Some thirty years ago it was estimated that the Dutch supplied turbet to the London market to the palue of $£ 80,000$ a year. At present (1887) the value of turbot annually sold in London cannot be ascertained; but it must be several times that amount, and is principally earned by English line-fishermen and trawlers. Although the turbot abounds off the west coast of Ireland, the fishing is not carried on with the same energy and success as in the English Channel and German Ocean. The turbot is also common, though not abundant, in the Mediterranean, and is replaced in the Black Sea by an allied species with much larger bony tubercles ( $R h$. mæoticus). Both species grow to a large size, being usually sold at from 5 to 10 fb ; but the common turbot is stated to attain to a weight of 30 D. Both from its size and the excellent flavour of its flesh it ranks next after the codfish among British sea-fishes.
turenne, Henri de la Tour d' Auvergne, Vicomite de (1611-1675), a famous French general of the 17 th century, was the second son of Henri, Duc de Bouillon, by Elizabeth, danghter of William I, prince of Orange, and was bern at Sedan on 11th September 1611. He was carefully educated in the strictest doctrines of the Reformed religion, and at the age of thirteen was sent to learn war from his uncles Manrice and Henry of Nassau in the campaigns of these princes against the Spaniards. In 1626 he received a commission as captain of infantry in the service of Holland, and by 1630 had shown such military capacity that Richelieu invited him back to France and appointed him colonel of a regiment. He was present at the relief of Casale, and on 21st June 1635 was made a maréchal de camp for his services at the siege of La Motte in Lorraine under De la Force. In that jear he took command of a division in the army under Cardinal La Valette in the defence of Mainz, and, wheu the cardinal's army had to fall back on Metz from want of provisions, Turenne commanded the rear-guard, covering the retreat with admirable skill. In 1636 he was present under La Valette at the siege of Saverne, where he was wounded, and in the campaign in Franche Comté; in 1637 he served under the same commander in Flanders, took Landrecies, and drove back the cardinal infant from Maubeuge. In 1638 he served under Bernhard of Saxe-Weimar at the siege of Breisach, and in the following year was transferred to the army of D'Harcourt in Italy. It was at this epech that the established his fame as a general. In November 1639 he covered the retreat of the army, and fought a famous engagement, known as the battle of the "route de Quiers"; in 1640 he saved Casale, and insisted upon net abandoning the siege of Turia, which town surrendered on 24th September; in 1641 he took Coni, Ceva, and Mondevi; and on 11th March 1642 he was prometed to the rank of lieutenant-general. After he had served for a short time in Roussillon, he was appointed by Richelieu in 1643 to the command of the army in Italy, under Thomas of Savoy, although his brother, the Duc de Bouillon, had just before been arrested as an accomplice in ihe conspiracy of Cinq Mars. Mazarin did not exbibit euite so much confidence in Turenne, and in December 1643 removed him from Italy, sending him to collect the remains of Bernhard of Saxe-Weimar's army and form them once more into an organized force; but he softened the transference by creating Turenne a marshal of France on 16 th May 1644.

Tu:enne's four campaigns in Germany, which largely contributed to the peace of Westphalia, have always been regarded as models in the art of war. In June 1644 he crossed the Rhine at Breisach, and was marching against the Comte do Mercy, the Imperialist general, who was at Freiburg, when he was superseded by the Duc d'Enghien,
better known by his later title of the Prince de Conde D'Enghien, after fighting the three days' battle of Freiburg, left the army again to Turenne, who took Philippsburg and Mainz, and then went into winter quarters. In May 1645 Turenne was surprised by Mercy at Marienthal and defeated; but he skilfully cencentrated the remains of his army and retreated into Hesse, where he was soon joined by D'Enghien. The two marshals, having reorganized their army, marched against Mercy and totally defeated him at Nördlingen on 3d August 1645, when Mercy was killed. D'Enghien again left the army to Turenne, whe in conjunction with the Swedish army under Wrangel overran Franconia and Swabia, taking all the fortresses there in 1646. In 1647 he conducted a still more masterly campaign, and after beating the Bavarians and Imperialists in two engagements he and the Swedes occupied Bararia, and drove the old duke out of his deminions.

When the troubles of the Fronde (see France, vol. ix. p. 572, and Mazariv) broke out, Turenne, whe was in command of the reteran troeps of Bernhard of Saxe-Teimar in Alsace, hesitated which side to take, till the Duchesse de Longuehlee ( $q . v$. ), with whom he fell violently in leve, persuaded him to side with the parlement. But his troops refused to follow him, and he had to fly with her to Flanders. He there took a command in the Spanish army under Don Estevan Gomar, and, when trying to raise the siege of Réthel, was utterly defeated by Du Plessis-Praslin. But in 1652 he defeated Coudé at Gien, and nearly annihilated his army in the battle of the Faubourg St. Antoine. When the troubles of the Fronde were over, Turenne marched upon the frontier, and in several campaigns defeated the Spaniards over and over again, by these victories paving the way for the peace of the Pyrenees (1659), the natural complement of the peace of Westphalia. In these campaigns he had once more to fight against Condé, general-in-chief of the armies of Spain, and in 1654 he showed his superiority by raising the siege of Arras and driving the Spaniards from their lines. In 1656 Condé, assisted by Don John of Austria, won an exactly similar victory and relieved Valenciennes, which Turenne was besieging. The prolonged contest between the two was decided in 1658 by Turenne's victory of the Dunes, in which Cromwell's contingent of 6000 soldiers took part.

Louis XIV. now began to rule in reality, and one of his first acts was to create Turenne in 1660 marshal-general of the armies of France. Seven years later Turenne occupied French Flanders and took all the fortresses in that province, though the king was nominally in command of the army,-an exploit equalled in the following year by Condés rapid occupation of Franche Comté. It was in 1668 that Turenne made his noterious change of faith. Born of Calvinist parents and educated a Protestant, he had in compliance with the tenets of his religion refused to marry one of Richelieu's nieces in 1639, and had eventually married a daughter of the Protestant Marshal de la Force. But it can hardly be believed that he was converted at the age of fifty-seven from religious convictions. In 1672 the second great European war broke out, brought about by the ambition of Louis XIV. Turenne once mere took command of the army, which the king accompanied, and speedily occupied the greater part of Holland, which, hewever, they were forced to evacuate owing to the Dutch cutting their dykes. In the following year Turenne marched into Westphalia to oppose the imperialist forces, and, though his army was swall compared to that of M.ontecuculi, the imperialist general, he managed to make head against both him and the elcetor of Brandenburg. In 1673 he was compelled to act on.tho defensive; but in 1674 in spite of his inferiority of numbers
he boldly resumed the aggressive. Crossing the Rhine at Philippsburg in June, and marching rapidly to Sinsheim, he defeated the imperialist general Caprara and the duke of Lorraine. He then retired for a time, but in December of the saine year he nade a sudden rush into the enemy's winter quarters and utterly routed the elector of Brandenburg, who was then general of the imperialists, at Colmar. Between the battle of Sinsheim and the dash at Colmar, Turenne, undes orders from Louvois, committed the acts which are the greatest blot upon his fame by devastating the Palatinate. After the rout of Colmar, and the dcfeat of Türkheim which followed it, he laid waste the greater part of Alsace, as a defensive measure against another advance of the imperialists. He then advanced into the heart of Germany, and again met Montecucnli, who had succeeded the elector of Brandenburg as general-in-cbief. The two generals manceuvred for four months in much the same way as Wellington and Marmont marched and counter-marched before the battle of Salamanca; at last, on 27 th July 1675 , their field of battle was chosen, and, as Turenne was directing the position of a battery, he was struck by a cannon ball and killed on the spot. The news of his death was received with universal sorrow; Fléchier, Mascaron, Saint-Évremond, and Lamoignon wrote cloges of him; and Madame de Sevigné describes the consternation caused by his sudden loss. His body was taken to St-Dénis, and buried with the kings of France. Even the extreme revolutionists of 1793 respected it , and, when the bones of the sorereigns were thrown to the winds, the remains of Turenne were preserved at the museam of natural bistory until 23 rd September 1800, When they were removed by order of Bonaparte to the church of the Invalides at Paris, where they still rest.
Turenue's fastae rests on his military achievements; as a man he was not more distinguished for his virtues than the duke of Marllorongh, whom in many respects ho resembled. He had indeed tbe calmness of all philosophic, cold-minded temperaments, but ferv other praiserorthy qualities. As a politician he hoids no high place.
(H. M. S.)

TURGAI, a Russian province in Central Asia, formerly a part of the Kirghiz steppe, and norv embodicd in the governor-generalship of the Steppes, is bounded by Uralsk and Orenburg on the W. and N., by Akmolinsk on the E., and by Syr-Daria and the Sea of Aral on the S. This extensive and irregularly-shaped territory, which has an area ( 176,800 square miles) as large as that of Caucasia and Transcaucasia taken together, belongs to the AralCaspian depression. It has, however, the Mugojar Hills on its western border and includes a part of the southern Urals; and from Akmolinsk it is separated by a range of hills which runs between the two chief rivers of the Kirghiz steppe-the Turgai and the Sary-su. In the north it includes the low belt of undulating land which stretches from the Mugojar Hills towards the north-east and separates the rivers belonging to the Aral basin from those which flow towards the Arctic Ocean, and beyond this range it embraces the upper Tobot. The remainder is steppe land, sloping gently towards the Sea of Aral. The Mugojar Hills consist of an undulating plateau nearly 1000 feet in beight, built up of Permian and Cretaceous deposits, and deeply grooved by rivers. They are not the independent chain which our maps make them out to be ${ }^{1}$ : they merely continue the Urals towards the south, and are connceted with the Ust Urt plateau by a range of hills which was formerly an island of the Aral-Caspian Sea. Their northern extremity joins the undulating plateau (400 to 600 feet), built up of sandstones and marls, which scparates the tributaries of the Tobot from those of the Ural, and falls by a range of steep crags-probably an old

[^269]shore-line of the Aral basin-towards the steppes. The steppe land of Turgai is only some 300 feet above the sea-level, and is dotted with lakes, of which the Tchotgardenghiz, which receives the Turgai and its tributary the Irghiz, is the largest. The Turgai was, at a recent epoch, a large river flowing into the Sea of Aral and receiving an extensive system of tributaries, which are now lost in the sands before joining it. Remains of aquatic plants buried in the soil of the steppe, and shells of Irytilus and Cardium, both still found in the Sea of Aral, show that during the Glacial period this region was covered by the waters of the Aral-Caspian Sea.

The climate of Turgai is exceedingly dry and continental. Orsk, a town of Orenburg, on its north-western horder, has a January as cold as that of the west cosst of Nova Zembla ( $-4^{\circ}$ Fahr.) while in July it is as hot as July in Morocco ( $73^{\circ}$ ); the corresponding fgures for Irghiz, in the centre of the province, are $7^{\circ}$ and $77^{\circ}$. At Irghiz and Orsk the anuual rainfall is somewhat under 10 and 12 inches respectively ( 3 inches in summer). The west winds are desiccated before they reach the Turgai steppes, and the northeast winds, which in winter briug cold, dry snows from Siberia, raise in summer formifable clouds of sand. A climate so dry is of course incompatible with a vigorous forest growth. There is some timber on the southern Urals, the Mugojar Hills, and tho waterparting of the Tobot ; elsewhere trces are rare,-only shrubs, snch as the wild cherry (Cerasus Champcerasus) and the dwarf almond (Amygdalus nana) growing on the hilly slopes, while the rich blackearth soil of the steppe is chiefly covered with feather grass (Stipa peuzata), the well-known oruanent of the south Russian steqpes. In spring the grass regetation is luxuriant, and geese and cranes are attracted in vast numbers by the fields of the Kirghiz from the depth of the steppe. The jerboa (Dipus jaculus) and the marnot (Spermophilus rufescens) are characteristic of the fauna of the region; another species of "18rmat (Aretomys bobac) and the Canis corsac are common; and the saiga autelope of Central Asia is occa. sionally met with. Further suuth the black carth disappears and with it the feather grass, its place being taken by its congener, Slipa capillata. Trees disappear, ani among the bushes along the banks of the rivers willows and the pseudo-acacia or Siberiaus pea tree (Caragana microphyla) are most prevalent. In the middle parts of the province the clayey soil is completcly clothed with wormwood (Artcmisia fragrans and A. monogyna), with a few grassy plants on the banks of the rivers and lakes (Lasiagrostis splendens, Alhagi camelorum and A. Kirghizorum, Obione portulacoides, Halimodendrum argenteum); while large areas consist of shifting sands, salt clays clothed with a rich carpc: of various Salsolacex, and dried beds of oid lakes. Such lakes as still exist, notwithstanding the rapid desiccation now going on, are surrounded by rush thickets, -the retreat of wild boars. Turgai is thus the borderland between the flora of Europe and thast of Central Asia.

In 1882 the population of Turgai was estimated at 323,110, all nomad Kirghiz, with the exception of some 3600, who are settled in four villages officially described as towns. Agriculture is in its earliest stage of development ; but some 100,000 quarters of corn are raised in the scuth-west by the Kirghiz, who sell some of it in Orenburg. Cattle-breeding is tho chief occupation, and within the province there aro some 800,000 horses, 335,000 cattle, about 200,000 camels, and more than two million shecp. But the want of fodder in spring occasious violent murrains, wbich sometimes restlt in actual famine among the Kirghiz. Endeavours have recently been made to induce the people to make communal stores of hay, but the $300,000 \mathrm{crts}$. yearly collected in this way are insufficient. The Kirghiz of the southern parts go in winter to the better shelterel parts of Syr-Daria, while in the summer some 30,000 kibitkas (felt tents) of nomads como from tho neighbouring provinces to graze their cattle on tho grassy steppes of Turgai. Some 30,000 cwts. of salt are annuslly got from the lakes. The four settlements of the province are Turgai, chief town and seat of the provincial administration, with less than 400 inhabitants, and the "district towns" of Irghiz (920), Ak-tube (400), and Karabutak (300), the last two being more or less fortified. Several merchants in these carry on trade with the Kirghiz, exchanging manufactured goods for wool and skins, which are sent to the fronticr settlemente of Orenburg. Thero is a brisk caravan traffic through Turgai.
turgot. Anne Robert Jacques Turgot, Marquis de l'A line (1727-1781), French statesman and economist, was born at Paris, 10th May 172\%. He was the third sou of Michel Etienne Turgot and of Madeleine Françoise Martineau. His family, which was ancient and noble, is said to have been originally Scottish, but had long been settled in Normandy. His ancestors parly abandoned the
sword for the robe. Both his father and grandfather had been in the civil service of the state: his father was "prévôt des marchands" at Paris, and won a high reputation as a magistrate and administrator. Turgot in his childhood was timid, and showed in company an absent and combarrassed air, from which he never afterwards entirely freed himself, and which in later life was sometimes unjustly attributed to hauteur. His mother, through excessive or injudicions efforts to correct these fault, appears to have aggravated them. He obtained his early education at the College Louis-le-Grand, and was afterwards a student of the Collége du Plessis. He then entered the seminary of St Sulpice, and thence passed to the Sorbonne with the view of taking his licence in theology. But he decided finally in 1751 not to fellow the ecclesiastical profession. His opinions were inconsistent with that calling, and he said "he could not consent to wear a mask all his life." He showed at this time an enthusiastic love of literature and powers of memery which are described as "prodigious," as well as a penetrating intellect and a sound judgment. We have the testimony of the Abbe Morellet, who was then his intimate acquaintance and constant companion, to the singular purity, the simplicity, modesty, and frank gaiety which characterized him.
As prior of the Sorbonne (an honorary office conferred annually on some distinguished student) he wrote and delivered publicly in 1750 two remarkable pieces,-one On the Benefits which the Christian Religion has conferred on Mankind, the other On the Historical Progress of the Human Mind. Having chosen the law as his profession, he was appointed in 1752 "conseiller substitut du procureur général," and afterwards "conseiller au parlement." The controversy arising from the refusal of the sacraments to the Jansenists by the archbishop of Paris being then agitated between the parlement and the clergy, Turgot wrote (1753) Letters to a Vicar-General on Toleration and a pamphlet entitled Le Conciliateur, in favour of religious liberty and against the interference of the temporal power in theological disputes. In 1753 he became "maitre des requêtes." He discharged his professional duties with scrupulous purity and conscientious industry. He continued at the same time his studies in ancient and modern literature (including English and German), mathematics, astronomy, chemistry, and natural history, and frequented the salons of Madame de Graffigny (authoress of Les Lettres Péruviennes), Madame Geơfrin, and Madame du Deffand. Whilst he enjoyed the acquaintance and society of D'Alembert, Baron d'Holbach, Raynal, Marmontel, Morellet, Galiani, Helvétius, and other notabilities of the time, he maintained his intellectual independence and refused to connect himself with any party or political group. About this time he also entered into relations with Quesnay and Gournay-the principal members of the physiocrats. He was attracted to them by the similarity of their sentiments on social questions and their opinions on economic policy to those which he himself entertained. Turgot accompanied Gournay in 1755 and 1756 in his official tours of inspection as intendant of commerce, and on Gournay's death in 1759 he wrote his Eloge. He then made a short visit to eastern France and a part of Switzerland. When he arrived at Genera he went to see Voltaire at Les Délices, and formed with him what proved to be a lasting friendship. He contributed about this period several articles to the Encyclopédie. In 1761 the controller-general Bertin appointed him intendant of the généralité of Limoges. In that district the mass of the people were sunk in poverty and barbarism ; the corvees for the construction of roads snd the transport of military equipages were oppressive; the country was depopulated by the requisitions for the militia - the taxation was excessive and unfairly distri-
buted; the state of the roads was wretched; ana the general condition of agriculture was deplorable. Turgot's administration of the district lasted for thirteen years, and was marked by a steady pursuit of the public grod, and a firm resistance to inertia, prejudice, and corruption. In particular he strongly maintained the cause of the industrious poor, and insisted on a more equitable assessment of the public charges which pressed undnly upon them. With nobly disinterested spirit be refused to be transferred to other généralités in which the salary was higher and the administration easier. Rising above the common prejudices of the philosophes, he sought the cooperation of the clergy, both to inform him of everything relating to the circumstances of the people which it was desirable for him to know, and to explain to their flocks the nature and objects of the measures he proposed to jut in operation; and he acknowledges that he found in them earnest and active auxiliaries. But he was not seconded as he ought to have been by the central Government, and had often to remonstrate with the Abbe Terray, minister of fanance. During the scarcity of 1770 and 1771, which was particularly severe in Limousin, he devoted himself with untiring assiduity to the relief of the distressed, and, when he had exhausted such public funds as were available, incurred for the same object a personal debt of more than 20,000 lirres. Shortly after the accession of Louis XVI. Turgot was airininted by Maurepas (19th July 1774) minster of marine, and in that capacity began at once to initiate important reforms and to conceive far-reaching projects. But he filled the post only for five weeks, being then (21st August) promoted to the ministry of finance. In his new office he addressed to the young king a declaration of the principles by which he intended to be guided: "No bankruptcy, no increase of taxation, and no borrowing." Economy and wise management were to be his only resources. Fearing the opposition he must encounter, he appealed to Louis to support him. By a decree of the 13 th September 1774, he re-estallished free trade in grain within the kingdom, which had been suspended by Terray, and authorized the importation of supplies from abroad; the traffic in other alimentary substances was also relieved of many impediments, and various monopolies and exelusive privileges were abolished; the octroi taxation was reformed, public works promoted, and improvernents in agriculture encouraged. Some of these measures were made the pretext for disturbances, known as la guerre des farines, which Turgot always suspected the Prince de Conti of having fomented. The riots had to be suppressed by armed force, and the energetic action of the minister against them was made a ground of attack by his enemies The parlement had been weakly recalled by Louis from the exile to which in the preceding reign Maupeou had condemned it. It now constituted itself the organ of the resistance of menaced interests to the measures of Turgot, who would gladly have abolished it, providing in its place better political securities and courts of justice on a new plan. In January 1776 he presented to the king a memoir proposing, amongst other things, the abolition of the corvée, to be replaced by a territorial tax, from which the privileged classes were not to be exempt, and the suppression of the jurandes (exclusive trade corporations). The edicts for these purposes were submitted to Miromesnil, keeper of the seals, a secret enemy of Turgot, who, spurred on ly Maurepas, wrote a memoir against them, and opposed them in the king's council. The courtiers, the nobility, the clergy, and the leading members of the industrial corporations now combined against the minister, and were joined by a large part of the common people, who did not understand his policy. The Count de Provence, afterwards Louis XVIII., wrote a pamphlet, entitled The Dream of M. de

Maurepas, against Turgot. The parlement refused to register the decreer; but the king held a lit de justice, which Voltaire proposed to call a lit de bienfaisance, and conpelled the registration. This forced submission only aggravated the rancour of Turgot's enemies, and the king had not the firmness to sustain his minister against the coalitiou. A vile conspiracy laving poisoned Louis's mind against hinn, he addressed to the king an eloquent letter in which he pointed out the grave perils inpending over the throne and the state, and warned Lonis that princes who are tempted to give themselves up to the direction of courtiers should remember the fate of Charles I. The minister received his dismissal on the 12th of May 1776 . He had been in office only twenty months, of which he had lost six in repressing sedition, and for seven nore had been confined to his bed by the gout; lut he had done during his tenure an extraorlinary amount of work. Voltaire. howevir. nobly avenged Turgot on his enemies in his Epittre $\dot{a}_{1}$, Homone. The fallen minister deroted his rewaining yurn to his favourite stndies, especially to lhysical science and tue ancient poets; lie enjoyed the society of Lavoisier, D'Liembert, Condorcet, Bossut, Rochon. and Ronelle. and attcurled the meetings of the Acadenny of Inscriptions, of whicth he was elected vice-director in 17i7. He also corresponded with Price and Frauklin, ancl, if we may believe Coudorcet, with Adam Sinith, whose acquaintaince be lard mado at Paris in $1766 .{ }^{1}$ Turgot lied at Paris on 18th March 1781.
Turgot's official career is for ever menorable in the history of su' al politics. Ncver diel a public man give hinnself to the service of ,he cominunity with niore earnest and nnselfish devotion. He maile it his ohject to conrince before commanding, in orrler that hi: qius might the better understood and bis directions nore aurely olcyeel; and, in issung any instruction, making any decision, or airisising any legislative act, he stated fully, by way of preamble. the groonds on which he proceeded. In the documents which he prepared on these occasions ne hare a borly of raluahle materials on admiuistrative and economic questions ; sonme of them coutain the sabstunce of chayters in the Merthth of Aations. When he became minister, the finances wero in what seemed a deaperate condition, and the general stato of affars justifed the prediction of Lonis XY. -" apres noi le deluge." Turgot franed a vast plan of reform, at once administrative and econonic, as the only hope for the salvation of the state. He fyeaks of his system of measures as intended for "the regulatiun of the kingrooro", thus showing that he contempinted nothing less than a pacific rerolution. But the first condition of success in such an efforl was wanting, nautely, the entire confidence and unfaltering support of the king, and the energetic exercise of the royal porter in caits ing out a policy of thorough reform aysoinst all allver.e iulluences ${ }^{2}$ Thrgot's struggle, though it failed from causes indlevendent of himself, canmot he regarided without profound sinnpathy aud adniration. Non was it without a large neasure of Bummediate success Whilst Fe sermpuloosly observed ail the pecuniary olli yoations of the state, he greatly diminished the crushing deficit wlich he found on his accession to office, and re-established the public credit in such a degree that the Dutch hankers offered hini a loan of sixty millione of livres at less than 5 per cent. His fiuancial and otler plans, of course, fell with him, and his most important toeasures nere annulled; but liis policy and lis writings exercised s lasting iufluence, and nany of his projects were realized ly the Rerolutivo. Turgot is altogether one of the most massive and imposing figures of the 18th century. His whole character and public action are marked ly an air of austere grandeur. Single-mindectness and veracity were of the very essence of his nature. Absolutely nonliased ls selfish cods, he lived only for France. for truth, and for his duty. Believiog intensely in a definite system of aocial and economic principles, whichl he layd carly formed by independent study and reflexion, he was prepared to carry theni out with dauntless determinatiou,

[^270]and with a lofts contempt for the interested or prejudiced opposition they were sure to eucounter. He has heen accused of a doctrinaire rigidity, and it is possible that, as a practical man, he wanted flexibility; yet he was often willing, not indeed to disguise his convictione, but to postpone the realization of his plans. In his public acts be alwass showed a lively. concern for the poor and the suffering ; in private life le was humane and benevolent; in his relations with his frieuds, amiable and affectionste. Malesherbes, the only other minister of his time who was worthy to be his colleague. said of him that "he had the head of Bacon and the heart of L'Hôpital." and, on the moral sile at least, this was no exaggerated estimate.

Possessed of a many-sinerl culture, Turgot wrote on a great variety of subjects-philosophic, scientitic, and literary-though political economy is the brancls of koowledge with which his nane must always he most closely associated. Already in 2749, whilst a sturent at St Sulpice, he addressed to his friend, Abbé de Cicé, alterwards bishol, of Auxerre, a Lelter on Paper Money, in which he asserter, in opposition to the viewe of Law and his followers, doctrines similar to those now accepted by all competent authorities. In oue of his discourses at the Sorbonne in 1750 , moving into the higher regions of the phiiosoplyy of society, he makes a remarkable attennt to work out the pregnant conception, already enunciated by Pascal, of the continnity of the intellectual movenient of our race, thus prelaring the way for C'nndorcet's Esquisse, and ultimately for the sociology of Comte. In 1753 he translated under the title of Questions Importantes sur le Commerce, a tract of Dr Josiah Tucker on the expedieucy of uaturalizing foreigners. He contributed to the Encycloperlie the articles Etymologie, Existence, Exparsibilite, Foudations, and Foircs et Marches. The first of thess contains much that is just as well as interesting, though in the lime of Turgot the subject could not yet be treatesl on genuinely scientific bases. In the second he undertakes a refutation of the Derkeleian theory. The third contains some ingenious suggestions iu practical pbysics. The article on foundations maintains the right of the Govermment to dispose of them for the public good, suppressing them if hurtinl, and directing the funds to more useful objects; the policy edrocated in it was afterwards carried into effect by the constituent assembly. In the paper on fairs and markets he argues that these are institutions arlapted only for an inmature state of cominercial relations, and that more good would Le done by liberating trade from the legiolative fetters which everyWhere iupeder it than by bestowing apecial privileges or other cncouragements on particular localities as ceutres of exchange. In the Eiloge of Gournay he combines with his tribute to the memory of his friend a vindication of the principle of industrial freedom, which that friend had condensed in the oft-repeated maxim, "Laissez faire; laissez passer." To the period of 7"urgot's intendance belong his unfinished Valeurs et Mfonnaies, intedded to form an article in the Dictionnaire de Commerce of Morellet ${ }^{-}$; his Lelters (to the Ahle Terray) on the Frecdom of the Conr-Trade; his menoir Sur lcs Prêts đ'Argent, in which he insists on the necessity of leaving free the iuterest on loans; and that on the principles which should direct legislation respecting mines and quarries, as well as the work on which his reputation as a systematic economist mainly rests, namely, his Reflexious sur la Formation el la Distribution dcs Richesses. This treatise was written for two Chinese youths who had been sent orer by the Jesuit missionaries to study in France. T山e nork was first published in 1766 in the Ephénérides du Citoyen. edited by Dupont de Nemours, and speedily passed through four editious. It gires in brief compass a Inminous statement of same of the nost important principles relatiug to the economic constitution of societies-the division of labour, the origin and use of mones, the nature of capital and the different modes of its enployment, the necessary rise of capitalist chiefs of industry, the legitimacy of interest on loans, and the impossibility of arbitrarily fixing the rate of that interest. It unfortunately contains, along with many tritiss, the erroneons doctrines of the physiocrats on the exclusive productireness of agriculture and on the consequent propriety of imposing taxes only on the land of a country. This book was erroneously represented by Condorcet as "the germ of the Wealth of Nations," and has becn spaken of by others as "anticipating some of the leading principles" of Smith. The truth is, most of what it contains had either been fully set forth by the earlier economista or was familiar to Quesnay and his group. It is, in fact, not a work of research but of exposition, aud, recgarded in this light, has real originality and may justly be pronounced a masterpiece.
Fuller informstion on the life, administrative lsbours, and writings of Turgot will be fonnd in the following works:-Dupont de Nemours. Notes et Nemoires sur la V'ie, $l$ Administration, et les Ouvrages de Turgot, 1rs2, sud enlarged in his edition of Turgot'a works mentioned below; Condorcet, 'ie de Turgot, $1: 86$ A. Batbie, Turgot, Ph ilosophe, Economiste, Admiristraterr, 1361 ; J. Tissot. Turgo, sa Vie, son Administrafion. ses Ourrages (s memoire couran re, 1862 ; A. Neymarck,

writings was published for the frst time by Dupont in 9 vols. (Paris 1808.11); this most complete and in every respect best edition is that contained in the Collection des Principanax Economistes of Coquelia and Guillaumin, 2 vols., 1844, with g.biographical notice by Eugene Daire. An English translation of The Formation and Distribution of Weclith was published in London in 1793, and was reprinted in 1859 in Lord Overstone's Select Collection of Scarce and Valuable Economical Tracts, edited by J. R. JI'Culloch.
(J. K, 1.)

TURIN, a city of northern Italy, formerly the capital of Piedmont and the Sardinian states and now the chief town of a province in the compartimento of Piedmont, is situated in $45^{\circ} 4^{\prime} 8^{\prime \prime} \mathrm{N}$. lat. and $7^{\circ} 48^{\prime} 22^{\prime \prime}$ E. long. in the alluvial valley of the Po, just above the confluence of the Dora Riparia. By rail it is 54 miles from the Mount Cenis tunnel. The communal palace stands 788 feet above the sea. The Monte dei Cappuccini in the neighbourhood reaches 922 and La Superga 2405 feet. As viewed from the east the city stands out holdly against the Alps. Taken as a whole Turin may be described as a very modern city, with broad and regular streets, and large squares and public gardens. The cathedral of St John the Baptist is a cruciform Renaissance building dating from the close of the 15th century. The site was first occupied by a church erected, it is said, by the Lombard duke Agilulf (7th century). Behind the high altar of the cathedral (from which it is separated by a glass screen) is the chapel of the Sudario or Sidone, built (1557-1694) by Guarini as a royal burialplace. The "sudario" from which it takes its name is asserted to be the shroud in which Joseph of Arimathea wrapped the body of Jesus. La Beata Vergine della Consolata, another of Guarini's works, has a tower which originally belonged to the church of St Andrew, founded by the monk Bruning in 1014, and attracts attention by Vin-

cenzo Vela's beautiful kueeling statues of Queeu Maria Teresa and Queen Maria Adelaide, as well as by the image of the Madoma, which has the credit of having warded off the cholera in 1835. Other churches of some note are San Felippo Neri (1672-1772), the dome of which fell in jnst as it was approaching completion under the hands of Guarini, and La Gran Madre de Dio, erected to commemorate the return of the royal family in 1814. Of the secular buildings the more interesting are the Madama palace, first erected by William of Montferrat in the close of the 13th century, and the extensive royal palace begun in the 17 th century The university, founded in 1400 by Lodovico di Acaja, has faculties of jurisprudence, medicine and surgery, literature and philosophy, and the mathematical. vhysical,
and naiural sciences. The number of students enrolled was 2132 in 1886. About 1876 the old university buildings erected in 1713 by the Genoese architect Ricca began to prove too small for their purpose; and at the present time (1887) new buildings, fitted more especially for the medical and scientific departments, are being erected. The area of the botanical gardens has also been extended and the observatory enlarged. The medical school derives advantage from the number of important hospitals in the city. The royal lunatic asylum can accommodate 980 patients. Turin has a prison on the cell system ( 672 cells) and a female penitentiary for 300 , besides two houses of correction. The academy of sciences was founded in 1757. It occupies a building erected in 1687 by Guarni as a Jesuit college. The museum of antiquities and the picture gallery, of which it has the custody, are both of high in-terest-the former for the local antiquities of Piedmont and Sardinia (notably from Industria) and for the Egyptian treasures collected by Donati and Drovetti, and the latter for its Van Dycks. There is a museum of zoology and mineralogy in the royal palace (another of Guarini's buildings), and the Castello palace contains the royal armoury (a collection made by Charles Albert in 1833) and the royal library with its rich manuscript collection and its 20,000 drawings, among which are sketches by Raphael, Michelangelo, and Da Vinci. The civic museum has a great varicty of artistic and literary curiosities, among them a remarkable collection of autographs and the Lombard missal (1490). The Jewish synagogue, a striking and conspicuous building, erected in 1863 by Alessandro Antonelli, was purchased by the municipality in 1879 for a Renaissance museum. Other public institutions are the Alhertine academy of the fine arts, the geographical society, and the Alpine club.
The industries of Turin and its suburbs give empleyment to 17,936 persons ( 13,305 men, 4631 women). Spinning-mills, weav-ing-factories, "vesta" factories (De Medici), breweries, and ironworks are among the more extensive establishments. The com. mercisl relations of the city are very extensive. It is the seat of the central offices of the North Italian Railway, and the central station is one of the most imposing huildings of its class in the country. The mean annual temperature at Turin (1866-84) is $53^{\circ}$ Fabr. (Jan. $36^{\circ}$, July $74^{\circ}$ ), with a maximum of $96^{\circ}$ and a minimum of $4^{\circ} \%$. Mista are frequeat in the wioter mornings, and to a less degree in autumn. Snow seldom falls in any great quantity, and on an average only on 7 days per anmum. The rainfall, distributed over 100 days, reaches 32 inclies-December being 1.6 and April 4.3. Water of good quality is brougbt to the city from a distance of 15 miles. The population of Turin was only about 4200 in 1377 and 9000 in 1580 ; but by 1702 it was returacd вs 43,866 . In 1848 it had risen to 136,849 , and in 1861 to 204,715 . In spite of the changes caused by the remeval of the capital, first to Florence and then to Rome, the census of 1881 slowed 233,124 inhabitants (cominuze 252,832).
Turin, Augusta Taurinorum, took its name from the Taurini or Taurisei, an ancient Ligurian pcople. The town is first alluded to (but not distinctly by name) in the year 218 b.o., when it was captured by Hannilal after a three days' siege, being at that tione a place of great strength. A colony of Reman veterans was introdueed into the city, possibly after the battle of Philippi, or at any rate after the battle of Actium. It was assigned to the Stellatino tribe. Of Roman architecture scarcely any trace remains even in the oldest parts of Turin, but the arrangement of the streets of tho old town recalls the aligoments of the Roman military settlement. The Palazzo delle due Torri, often designated the Porta Palatina, is probally part of a building of the 8 th century. Turin centinued to be a place of importance and military strength under mumerous vicissitudes, till at length it was made the chief town of Piedmont by Amadeus, first duke of Savoy. Under Emmanuel Philibert it became the usual resideuee of the ducal family, and iu 1515 the bishopric was raised to metropolitan rank by Leo X. Between 1536 and 1562 Turin was occupied by the French, and in 1630 it lost 8000 of its citizens by the plague. The French were masters once more from 1640 to 1706 , and again from 1798 till 1814, when the Sardinian states were restored to the house of Savoy. Between 1859 and 1865 Turin was the capital of united Italy. Ameng the many met of mark born in Turin it is enough to mention Lagrange, Gioberti, Cesare Balbo, Cavour, Marochetti the sculptor, D'Azeglio, and Sommellier.

## TURKESTAN

TVFE terms "Thirkestan" and "Central Asia" are often used indiscriminately to describe the whole of the immense territory t, the east of the Caspian, comprised between Siberia on the north and Khorasan (Persia), Afghanistan, and "Tibet on the south, or to designate eeparate, sometimes arbitrarily determined, parts of the same region. In the beginning of the 19 th century the whole of the territory just named, with its great variety of altitudes, climate, inhabitants-these last differing as much in their history as in their present characteristicswas comprised under the rague denomination of High Tartary, or High or Interior Asia. After the appearance of Humboldt's first draft of Asic Centrale in 1831, the term "Central Asia "came into favour. But Humboldt's limits of Central Asia were too mathernatical (from $39 \frac{1}{2}^{\circ}$ to $49 \frac{1}{2}^{\circ}$ N. lat.), and were further unsatisfactory because ínfluenced by his erroncous conception of the mountains of Central Asia, which he supposed to run either along parallels or along meridians. Richthofen made an attempt to limit the sense of the term, proposing to apply it only to that region-embracing the Tarim drainage area and the Gobi -which has no outlet either towards the ocean or to the Sea of Aral and Lake Balkash (Balkhash), and which constitutes the Hang-hai of the Chinese and the supposed bed of the Tertiary Asiatic Mediterranean. But this terminology, besides the drawback of including within Central Asia the steppes of the Gobi as far east as Transbaikalia and the Great Khingan, notwithstanding the broad differences by which they are distinguished from the drainage area of the Tarim, was open to another objection, which has been pointed out in M. Mushketoff's Turkestan. It excluded from Central Asia Turkestan proper, which nevertheless bas had the same recent geological history as the Tarim region, and therefore has so many features in common with it as regards soil, climate, flora, fauna, population, aad even civil history. On the other hand, if Central or Interior Asia were to include West Turkestan, and its limits to be determined by those of the drainage-areas which have no outlet to the ocean, the basins of the Volga and Ural, -that is, territories purely European in character, -would have to be comprised under the same denomination. The fact is that in Asia, as so often elsewhere, hydrographical considerations alone furnish no sound basis for geographical delimitations, and that these last must result from a complicated variety of considerations, chiefly orographical, inasmuch as orographical are indicative of other physical characters, such as geology, climate, flora, fauna, and so on. Such were the views of Ritter and Humboldt, and we are now brought back to their conceptions, but corrected into accordance with improved knowledge of the Asiatic continent. The name Central Asia can still be used with great advantage to designate that immense portion of the continent to the east of the Caspian and the Ust-Urt plateau which is limited on the north by the important climatic and geo-botanic boundary of the Irtish and Aral water-parting and the Great or Ektagh Altai, on the east by the eastera Gobi, and on the south by the northern border of the Khor plateau (Attyn-Tagh and Kuen-Lua), the Hindu-Kush, and the Kopet-Dagh. Extensive as it is, this territory has its own climatic and geobotanic features; it forms a distinct part of the coatinent, when the orography of Asia is broadly vicwed; and its inhabitants have a number of common characteristics resulting directly from the physical features of the territory. But this immense area must be subdivided; and its subdivisions become apparent as soon as the orographical features are grasped.

Two great plateans constitute the two backbones, as it were, of the orographical structure of Asia,-that of eastern Asia, an immense triangle stretching north-eastwards, having the Himalayas for its base and the peninsula of the Tchuktchis for its apex; and that of western Asia, which extends at right angles to the above from the lower Indus to the Black Sea. The Hindu-Kush connects these two massive swellings, both contineats of the oldest formation in Asia. Both are fringed on their northern edges by lofty chains of mountains. The Tian-Shan, the Altai, the Sayan, and the Vitim Mountains rise in a long succession on the borders of the former, while a serics of chains, which might be described under the general name of Kopet-Dagh, continued into the Transcaucasian chains, rise on the north-eastern edge of the western plateau.

Aa immense trapezoidal depression occupies the angle west on the west where the great plateaus meet, and this de- Turk pression is West Turkestan. Its south-eastern limits are ${ }^{\text {estap }}$ the Hindu-Kush and the Tian-Shan; on its south-western edge it has the Iranian plateau; and its north-west and north-east boundaries correspond with the edge of the UstUrt and the Irtish and Aral water-parting, which separates it from Siberia. The trapezium is 1100 miles long from south-west to north-east, and. 900 miles wide from southeast to north-west. It thus includes, not only the depression at the junction of the two plateaus, but also the girdle of alpine tracts which fringes them, and in whose deep and sheltered ralleys the Turkish and partly Iranian population of Turkestan find a fertile soil and plenty of water for their fields, while their herds graze on the rich alpine meadows in the very heart of the Tian-Shan. Not orographically only but also in respect of its recent geological past, its climate, flora, fauna, and inhabitants, this regiou forms a geographical domain by itself, quite distinct from the steppes of south-eastern Russia, the prairies of Siberia, and the two great plateaus by which it is inclosed; and, although it is easily subdivided into two parts-the dry lowlands of the Transcaspian depressiou and the plains and highlands of Turkestan proper-it presents one geographical whole when contrasted with the surrounding regions. Some doubt may arise as to the propriety of including in it the plateau of Pamir ; but its flora and fauna are so closely connected with those of the Tian-Shan that, although better treated as a separate sub-region, like the Transcaspian Turcoman steppes, it cannot be separated from the abore. For the orographer, the "Roof of the World " is merely a succession of the wide syrts or alpine plateaus that are characteristic of the Tian-Shan. Most of this territory has within recent years been annexed to the Russian empire. Bokhara, with its rassal khanates in the gorges of the Pamir slopes, and Khiva, although they are still described as independent, are in reality rapidly becoming dependencies of Russia, and the railway from the Caspian, which is about to connect Merv with Samarkand, will complete the annexation of Bokhara. West Turkestan, therefore, is often called Russian Turkestan, as distinguished from Chinese or East Turkestan.

This second great region of Central Asia also has well. defined limits. A glance at any receat map shows that there is in the great eastern plateau a depression bordered by the deep slopes of the Pamir (Humboldt's Bolor) on the W., the border-ridges of Tibet (Kuen-Lun and AltynTagh) on the S., the eastern Tian-Shan on the N., and the western Gobi on the E. ${ }^{1}$ Although we call it a depression,

[^271]because it is much lower than the surrounding plateaus, it is itself a plateau, ranging from 3000 to 4000 feet above sea-level. This depression-the Hang-hai of the Chinese, which, during the later Tertiary and earlier Quaternary period, was covered by a sea, of which a very small survival still exists in Lob-Nor-is now drained by the Tarim. Its deserts, in which human settlements are now very rare, though formerly the population was much denser, have been described under a variety of names (Littlo Bokhara, Alty-shar or Jity-shar, Kashgaria, and so on); but the name of East Turkestan has prevailed, and there is no reason for abandoning it, provided it is not confounded with Dzongaria (q.v.) in the north and the great Desert of Gobi in the east. Dzungaria is a deep trench leading from the lowlands to the central plateau, and has special physical
features and a history of its own. The Mongolian Cobi, on the other hand, owing to its position on the lower terrace of the plateau of castern Asia, must be regarded as a separate unity. In fact, it appears to be more closely connected with the plateau of the Selenga on the north and that of Ordos on the south than with East Turkestan; and it, too, has its own physical features, its own inhabitants, and its own history.

The expression Central Asia thus includes the following countries. (A) West Turkestan, compnsing the Tian-Shan highlands, the Balkash plains, and the Aral-Caspian lowlands, politically divided into Russian Turkestan (the general-governorship of Turkestan and the Aral-Caspian slope of Turgai and Akmolinsk), the Chinese oasis of Kulja (Kuldja), the Transcaspian region, Khiva, Bokhara and

Map of East and West Turkestan. ${ }^{1}$
its vassal khanates, and parts of Afghan Turkestan. (B) In height second only to that of Tibet; the immense comEast Turkestan, comprising the Tarim region as far east as Lob-Nor, (C) Dzungaria, limited on the north-east by the Tarbagatai, Altai-Nauru, Irdyn-ula, and Artsa-bogdo Mountains.

## West Turkestan.

As comprised within the above limits, West Turkestan has an aret of nearly $1,080,000$ square miles, and a population of nearly $8,500,000 .^{2}$ It presents a very great variety of aspects, including the lonely plateau of Pamir,

[^272]plex of alpine tracts described under the general name of Tian-Shan (three times as long as the Alps of Europc), which lift their snow-clad peaks four and nearly five miles above the sea, and feed huge glaciers, while their deep valleys and gorges partake of almost every variety of climate and vegetation; rich prairies and still wider lowlands descending bclow the level of the occan; and deserts where the winds, burning hot or icy, but always dry, hare free scope to modify the surface, which is bare of vegctation.

Nevertheless West Turkestan is sharply divided into two Highlum parts,-the highlands in the south-east and the plains and region. 's deserts in the north-west. The former cover an area nearly 1000 miles long by 270 broad, of which the northern parts are described under the general name of Tian-Shan (properly, Than-Shañ). Their distinctive feature is that, like the highlands of Siberia they constitute a high border-
ridge, running W.S.W. to E.N.E. on the edge of the great plateau of eastern Asia. This plateau is fringed on its onter side by a complex of shorter ranges, which mostly run parallel to the border-ridges and send off a series of isolated chains, due to a later system of upheaval, through the plains and steppes in a north-western direction. Down to the middle of the 19th century these highlands were almost absolutely unknown, and the orography of Central Asia as shown on our maps was quite hypothetical. Numerous surveys by Russian and British explorers have, however, recently disclosed the real structure of those regions; and it has now become possible to discriminate the leading features of the orographical conformation of the country. The Hindu-Kush, with its snow-clad summits of 18,000 and 20,000 feet, limits the highlands of Turkestan to the south-east. It appears now to be settled that this ridge runs from north-east to south-west, as far at least as the latitude of Cabul, and possibly still farther south; and the last Russian surveys of the Pamir show that it extends north-east as far as Tash-Kurgan ( $37^{\circ} 45^{\prime} \mathrm{N}$. lat., $75^{\circ} \mathrm{E}$. long.). At the foot of its north-western slope it has the plateau of Pamir-the "Roof of the World,"-with an area of about 37,000 square miles. A series of chains, gently sloping and dome-shaped, rising 4000 or 5000 feet above the level of the plateau, traverse it from south-west to north-east, with a remarkable parallelism, dividing it into a series of broad parallel flat-bottomed grooves or valleys, which do not sink below 10,000 , and sometimes 14,000 , feet above sea-level. Thus the features of the lower plateaus of north-eastern Asia reappear here on a greater scale, having the same characters and the same direction in the plaitings of the earth's crust.

Nearly 150 miles to the north-west of the Hindu-Kush lies the north-western border of the Pamir, fringed by the lofty Trans-Atai Mountains. Their crest, covered with onow, rises nearly 4 miles above the sea (Kaufmann Peak 23,000 feet); but the traveller appreaching them from the south would hardly guess their height, because their southern slope towards the wildernesses of the plateau, themselves 13,000 feet high, is very gentle. The great elevation of the border-chain is only realized when it is seen from the Atai valley on the north, where its steep and deeply furrowed sides tower up like a dark wall, from 11,000 to 14,000 feet high, above the high and broad valley of the Kizil-su. The geological structure of the Atai valley must not be inferred from its orographical features, otherwise we should describe it as longitudinal. It is watered by the Kizil-su, which flows towards the west-eouth-west and joins the Amu-Daria under the name of Vaksh (or Wakhsh). On the north it has the lofty AtaiTagh range, also partially snow-clad. On our best maps the Trans-Atai Mountains are figured as an isolated range, some 120 miles in length; and it cannot yet be affirmed with certainty which chains of the Tian-Shan, possessing the same border-ridge characters, ought to be considered as its continuations. Further research is needed to determine whether it is continued south-west by the Darvaz, or Lahor, Mountains, where the group of lofty Sel-tau peaks feed the extensive Fedtchenko glacier, or by the Hoja-Mahomet chain on the left bank of the Amu-Daria. ${ }^{1}$ Thus the real north-western limits of the Pamir are still unsettled. As for the northeastern continuations of the Trans-Atai, the present writer is inclined to trace-them, not in the Kokshat-tau, but in the Terskei Ala-tau and the high mountains of Sary-yassy, whete the Khan-Tengri lifts its snow-clad granitic cap 24,000 feet above the sea, and is surrounded by numerous vast glaciers (Semenoff's and Mushketoff's Muz-art). It would thus separate, broadly apeaking, the drainage area of the Tarim from those of See G. Grum-Grimailo, in Izvestia of Russ, Geog. Soc., vol. xxii., 1886.

Lake Balkash and the Sea of Aral. Thus the border-ridge of the Central Asian plateau would have a length of more than 1000 miles from the Amu to Kulja, and the valleys of the upper Naryn and Tekkes would therefore be homologous with that of the Ałai.
A girdle of alpine tracts, from 150 to 180 miles in width, which fringes the outer edge of the Pamir plateau, consists of shorter chains running parallel to the border ridge and ranging from 11,000 to 17,000 and 20,000 feet in altitude. They are separated by deep valleys, mostly with three separate foldings of Azoic rocks. Some of these ranges are covered with perennial snow and feed great glaciers, among which Schurovsky and Fedtchenko glaciers around the lofty Kok-su group are especially worthy of mention. These subsidiary chains all belong to the oldest system of upheavals, which have had a north-east direction, and which at four different places are modified by more modern ones having a north-western direction. In lat. $47^{\circ}$ N . the orographical structure becomes more complicated, the alpine region being pierced by the broad Dzungarian trench, which leads from the lowlands of the Irtish to the heights of the Central Asian platean. A high ridge-the Tarbagatai-continued in the Tchinghiz (Jinghiz) and Karkaralinsk Mountains, branches off north-westwards, separating iurkestan from Siberia. Further east the TianShan is continued on our maps in an eastern direction; but our knowledge of it still remains very imperfect. ${ }^{2}$

A series of deep depressions,-Balkh, Ferghana, Issyk- Lacaso kul, and Kulja,-sinking to low levels amidst the Tian-Shan trine highlands follow one another in a north-east direction. That hasins of of Issyj-kul is occupied by the lake of the same name Tian( 5000 feet above the sea), while the second and fourth, now desiccated, are lacustrine basins. A great number of smaller lacustrine basins, mostly filled with Tertiary conglomerates, occur higher up in the mountains. For the orographer and the geologist they are homologous with those of the Altai and east Siberia (Bukhtarma, Us, Irkut, Barguzin, and others). The rivers that issued from the high alps had to pierce many parallel ridges in order to reach the plains, and they frequently expanded into wide lakes before cleaving through the chains of mountains the narrow and deep transverse gorges by yhhich they descended to the lower terraces.

Like the highlands of Siberia, those of Turkestan are Lowland fringed by a girdle of plains, having an altitude of from plaina 1000 to 1500 feet, and these again are skirted by an immense lowland area reaching only 400,300 , and 150 feet, or even sinking below the level of the ocean. These plains and lowlands cover nearly 650,000 square miles. Some geographers divide them into two portions,-the higher plains of the Balkash (the Ala-kul and Balkash drainage areas) and the Aral-Caspian depression, which occupies nearly two-thirds of the whole and has been ably described by M. Mushketoff under the appropriate name of Turanian basin,-the Kara-tau Mountains being considered as the dividing line between the two. The Balkash plains, more than 1000 feet above the sea, and corered with clay, with a girdle of loess at their foot, are well watered by the tli and other feeders of Lake Balkash (see Semiryetchense) and on their rich prairies are the homes of numerous Kirghiz. In the south-west the clayey soil becomes saline. There is the Famine steppe (Bek-pak-data), while in the Ak-kum steppe, which surrounds Lake Kara-kul, large areas are covered with sands, partly shifting. A gulf of clayey plains penetrates up the Ili into the in-

[^273]terior of the mountains, and its thick layers of loess form the Kulja oasis. Another gulf, penetrating much more deeply into the highlands up the trench occupied by Lakes Ebi-Nor and Ayar, and joining the trench of the upper Irtish, leads by an imperceptible gradient up to the plateau of Central Asia. It is known as the "Dzungarian Gate," and a gate it has been since the dawn of history for whole nations of nomads who have migrated from the rapidly desiccating plateau down to the grassy prairies of Siberia and Russia. The plains and lowlands of the Turanian basin are subdivided by a line drawn from north-east to south-west along a slight range of hills running from the sources of the Ishim towards the south-east corner of the Caspian (Bujnurd and Elburz edge of Khorasan). This low range, which most probably separated the lowlands of the Aral-Caspian region (submerged during the Post-Pliocene period) from the higher plains which had emerged by the end of the Tertiary period, now divides the Transcaspian steppes from the somewhat different higher plains (see Transcasplan Region). In the Turanian basin the contrast between desert and oasis is much stronger than in the Balkash region. Fertile soil, or rather soil which can be rendered fertile by irrigation, is limited to a narrow terrace of loess along the foot of the mountains (see Syr$D_{A R I A}$ ), and is surrounded by barren deserts. Even where the loess spreads over terraces at some distance from the mountains, as in the south-east Transcaspian region, it can be cultivated only when irrigated. The dryness of the climate is excessive : rain falls only where the hills cause the clouds to condense, the soil elsewhere being moistened only occasionally by a few showers. Two rivers onlythe Syr and the Amu-succeed in crossing the desert and reaching the Sea of Aral. But their former tributaries no longer run their full course: the glacier-fed Zerafshan dries up amidst the gardens of Bokhara soon after emerging from the highlands; and the Tejer̈, the Murghab, and the Andkho lose thermelves amidst the fields of the Turcomans. The only tributaries which the Amu retains are those which have the whole of their course in the highlands. In the north such formerly important tributaries of the Syr-Daria as the Tchu, with its subtributary the Sary-su, now dry up some hundreds of miles distant from the main stream. The arid desert absorbs every drop of running, water which reaches its borders.
The whole area is now undergoing geological changes on a vast acale. Rivers have changed their courses, and lakes their outlines. Far away from their present shores the geologist finds indubitable traces of the recent presence of the lakes in the shells they have left amidst the sands. Traces of former rivers and channels, which were the main arteries of prosperous regions within the period of written history, have now disappeared. Of the highly developed civilizations which grew up and flourished in Bactriana, Bokhara, and Samarkand the last traces are now undergoing rapid obliteration with the desiccation of the rivers and lakes. The great "Blue Sea " of Ceutral Asia, the Sea of Aral, which at a recent epoch (Post-Glacial) extended eouth-west to Sary-kamysh, and the shells of which are found north and east of its present shores from 50 to 200 feet above its present level ( 162 feet above the ocean, and 245 above the Caspian), now occupies but a small portion of its former extent. It covers a shallow depression, some 23,000 square miles in area, which is drying up with astonishing rapidity, so that the process of desiccation can be shown on surveys separated only by intervals of ten gears; large parts of it, like Gulf Aibughir, bave dried up since the Russians took possession of its shores. Steamers regularly ply on its waters and ascend both its tributaries. The whole country is dotted with lakes, which are rapidly disappearing under the hot winds of the deserts; and the
clayey takyrs of the steppes give evidence of thousanas of lakes which have quite recently ceased to exist, leaving beds of clay kept wet by the condensed moisture of winter and the ferr rain-showers of early spring.
Like the highlands of eastern Asia, those of Turkestan are mostly built up of Azoic gneisses and metamorphic slates, resting upon granites, syenites, old orthoclase porphyries, and the like. These upheavals date from the remotest geological ages; and since the Primary epoch a triangular continent haring its apex turned towards the north-east, as Africa and America have theirs pointing soutliward, rose in the middle of what now constitutes Asis. It is only in the outer foldings of the highlands that Primary fossiliferous deposits sre found, - Devouian, Carboniferous, and Permo-Carbonic. Within that period the principsl valleys were excsvated, snd their lower parts have been filled up subsequently with Jurassic, Cretsceous, and Tertiary deposits. One of the most striking instances of this is the very thick Cretaceous and Tertiary deposits which cover the bottom of the valley of the V sksh (right tributary of the Amu) and are continucd for about 300 miles to the north-east, as far as the Ałai valley,-probably along the edge of the Pamir platesu. The deposits of the Secondary period have not msintained their horizontal position. While upheavals having a north-eastern strike continued to take place after the Carboniferous epoch, ${ }^{1}$ another series of upheavals, having a north-western strike, and occasioned by the expansion of dishases, dolerites, melaphyres, and andesites, occurred later, subsequently at least to the close of the Tertiary period, if not also before it, dislocating former chains and raising rocks to the highest levels by the addition of new uphesvals to the older ones. Throughout the Triassic and Jurassic periods neerly all Turkeetan remained a continent indented by gulfs and lagoons of the south European Triassic and Jurassio ses. Immense fresh-water lukes, in which were deposited layers of plants (now yielding coal), filled up the depressions of the country. Cretaceoue and Tertiary deposits occur extensively along the edge of the highlands. Upper and Middle Cretaceous, containing phosphates, gypsum, naphtha, sulphur, snd alum, attain thicknesses of 2000 and 5000 feet in Hissar. Representatives of all the Tertiary formations are met with in Turkestan ; but, while in the highlands the strata are cosst-deposits, they assume an open sea character in the lowlands, and their rich fossil fuuns furnishes evidence of the gradual shallowing of that sea, until at last, after the Sermasthian period, it became a closed Mediterranean. During the Post-Pliocene period this ses broke up into several parts, united by narrow straits. The connexion of Lake Balkssh with the Sea of Aral can hardly be doubted ; but this portion of the great sea was the first to be divided. While the Sea of Aral remeined in connexion with the Caspian, the desiccation of the Lake Balkash basin, and its break-up into smaller eeparsto basins, were elready going on. The Quaternary epoch is represented by vast morisinic deposits in the valleys of the Tisn-Shan. About Khan-Tengri glaciers descended to 8 level of 6800 feet above the sea, ${ }^{2}$ and discharged in to the wide open valleys or syrts. It is most prohable that, when allowance has been made for the obliteration of glacial markings, and the region hes been better explored, it will appear that the glaciation of Turkestan was on a scale at least as vast as that of the Himalayas. In the lowlands the Arsl-Caspian deposits, which it is difificult to separste sharply from the lster Tertiary, cover the whole of the area. They contain shells of molluscs now inhabiting the Sez of Aral, and in their petrogrsphical festures are exactly like those of the lower V olga. The limits of the Post-Pliocene Aral-Caspian see have not yet been fully traced. It exterded some 200 miles north sud more thsn 90 miles east of the present Aral ehores. A nariow strait connected it with Lake Balkssh. The UstUrt platean and the Mrugojar Mountains (see Turasi) prevented it from spreading north-westward, and a narrow channel connected it along the Uzboi (see p. 512 supra) with the Caspian, which sent 2 broad gulf to the east, spread up to Yolge, and was connected by the Manytch with the Black Sea bssin. Great interest, geological and historical, thus attaches to the recent changes undergone by this bssin ; but much still remains to be done before the numerovs questions arising in connexion with it can be settled. Since the theory of geological cstaclysms was abandoned, and that of slow modificstions of the crust of the earth accepted, new data have been obtained in the Aral-Caspian region to show that the rate of modification after the close of the Glacial period, although still very slow, was faster than had been supposed from the eridence of similar changes now going on in Europe and America. The effects produced by desiccating agencies are beyond all comparison more powerful than those which result from the earthquakes that are so frequent in Turkestan. All slong the base of the highlands, from Khojend ts Vycrnyi, earthquskes are frequent ${ }^{3}$ but, however destructive of life, their effects lie beyond the scope of our observstionsl methods

Musiketoff's Turkestan (pp. 35, 681) seems to justify this conclusion.
${ }^{2}$ See I. Ignatieff, in Izvestic of Russ. Geogr. Soc., pol. xxiii., 1887.
${ }^{3}$ For a list of them, see Izvestio of Russ. Geogr. Soc., vol. xxiii., 1887; also Orloff, in Mem. of Kazan Naturalists, 1873, iii.

The climate of West Turkestan is exceedingly dry and continental. Although the country is comprised within the latitudes of Sicily and Lyons, it has a south Norwegian Janusry and Persian summer. Temperstures of more thsn $100^{\circ} \mathrm{Fahr}$. in the shade are common, and the hest is rendered still more unbearahle by the reflexion from a soil destitute of vegotation. The winter is for the most part so cold that the average tempersture of January is below the freezing point, and even resches $0^{\circ}$ Fshr. Snow falls for several months on the lower Syr-Daris, and, were it not blown away by the winds, sledge-communication would be possihle. This river is frozen for an average of 123 days every year in its lower parts, and nearly 100 days at Perovsk. At Tashkend there is snow during two months and temperstures of $-10^{\circ}$ Fahr. have been measured. In 1876, on 24 th October, almond-trees, vines, snd cotton crops were buried under a heavy snowfall. To the south of Khojend the winter becomes more clement. Absence of rain is tho distinctive feature of the climste. Although it raina and snows hearily on the mountains, only 11 inches of rain and snow fall throughout the year at Tsshkend, at the base of the highlands; and the steppes of the lower Amn have less than 3 inches. A few ohowers are all that fall from the almost invarishly cloudless sky above the Transcaspian ateppes. The following table will illus. frate the climate of Turkestan :

|  | Latl. tude. | Height in feet | Aversge teloperature. |  |  | Raio Io inches. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

The fauna of Turkestan belongs to the great 200 -geographical domain of northern Asia, and is only differentiated by the presence of species which have disappeared from the peripherio parts of the Cld World and now find a refugo in the remotest regions of the nninhabited platesu. From the great Palæoarctic region it is distinguished by the presence of Himslayan species. The distinetive animal of the Psmir plateau is the magnificent Ovis poli (conjectured to be the ancestor of our common sheep), mentioned by Yarco Polo and rediscovered by Syevertsoff, It hreeds by thousands on the Pamir, climbing the lighest ridges, whioh it prefers to the valleys. The region to which it is confined has the shape of an ellipse, vrith its longer sxis running aouth-west to north-east. The animsl is rsre on the upper Naryn, and never penetrates to the west of Sel-su. In tho alpine tracte of the Tian-Shan, on the borders of the Pamir, their horns snd skulls are frequently met with, but there the place of the species is now taken by Ovis karelini. The wild horse, which occurred in Polsud a few centuries ago, hss been discovered by Prejeralsky in the highlands of Dzungaria and described as Eques prjevalskiti by Polyakoff. The wild camel inhabits the lonoly plateaus south of the Ala-Shan ; but no description of it has been puhlished. The other mammals of Turkestsn are mostly those which sre met with elsewhere in north Asia. The large light-coloured Himalayan bear (Ursus isabcllinus) has its home on the Pamir, and the amsller, strong, white-clswed Leuconyx ap to the highest levels on the Tian-Shan. Antelopes, Lcpus Lehmanni, Lagomys rutilus, various species of Arvicols, snd the Himalayan long-tailed marme.t (Arctomys caudatus), the most characteristic inhabitant of the alpine mesdows, are the only memmals of the Pamir proper. In the slpine region sre found the badger (Meles laxius), the ermine (Fotorius ermineus) and air other Mfusulide, the wild dog (Canis alpinus), the common and the blackeared fox (C. melanotis), while the corsac fox (C. corsac) is met with only on the plains. Two species of lynx, the cheatah (Felis jubata), Felis manul, and Felis irbis, this lsst axtending westwards as far as the Persian Gulf and eastwarde as far as the river Amur, must be added to the above. The tiger is met with only on the lower Amu-Daria, except when it wanders to the alpine region in pursuit of the maral deer (Cerves maral). Tho jackal is characteristic of the steppes; it bsnishes the wolves and foxes Hares ere ropresented by aeversl apecies, Lepus lehmanni being the most charscteristic. Both the common and the long-tailed marmot ( $A$. baibacinus and $A$. cauciatus) are found at the foot of the mountains, as also four species of Spcrmophilus, three of voles, two of the mouse, and three of the hamster. The Meriones (four apecies) and the jerbos (five species) are only mat with in the ateppe region. Of ruminsnts, besides the aheop ( $O$. poli, O. Karelini, O. nigrimonlana, O. heinsii), we find one muflon (Musimon vignei), formerly known ouly in the Himslayas, the Chineso sntelope (Antilope subguturosa) and the saiga antelope in the ateppes, the Siherian ibex and another goat, the yal, the zebu or Indian ox, the common ox, the camel,
and the dromedary. The wild boar is common in the reed thickets along the rivers and lakes, where it atays during the winter, migrating to the highlands in summer. The hedgehog and porcupine are common in the plains.

It would be impossible to descrihe in a few words the svifsuna No fewer than 385 species are recorded, most of them being middleEuropean and Mediterranean. A large number were formerly known only in the Himalayas, or in Persia, while others have their origin in east Asia. The commonest are mostly European scquaintances. As for the very rich iusect fauna, of which full descriptions are now accessible, it is worthy of note that among the Lepidoptera of the Pamir there is an interesting mixture of Tisu-Shan with Himalayan apecies. M. Grum-Grzimsilo found on the Psmir the Colias nastes, a apecies characteristic of Labrsdor and Laplsnd; like the alpine plants which bear witness to a Glacisl period flors in the Himalayss, this hutterfly is a survirsl of the Glacial period fauns of the Pamir. ${ }^{1}$

As a whole the fiors of Tukestan belongs to thst of Central Aai:' Which was formerly continued hy geo-hotsnists as far west as thi steppes of Russia, but which must now he considered as a separate region subdivided into two,-the Centrsl Asian proper and tuat of the Gobi. It has its own habitus, notwithstanding the number of species it has in common with Siberis and south-east Russis on the ons hand and with the Himalayas on the other, and this habitus is due to the dryness of the climate and the consequent changes nadergone by the soil. Towards the end of the Glacial neriod the Tian-Shsa Mountaing had a flora very like that of northern Caucasus, combining the characters of the floras of the Europesn Alpe and the Altai, while the prairies had a flora very much like that of the south Russian stoppes. During the Stone Age the human inhabit. ants lired in forests of maple, white beech, and spple trees. But the gradusl desiccstion of the country resulted in the immigration from the Central Asian plateau of such species as could adapt themselves to the dry climate end soil, in the disappearance of European sud Altaic species from sll direr parts of the region, in the survival of steppe spocies, snd in the adaptation of many of the existing apecies to the needs of an srid and extreme climate and a saline soil. At present the flora of Turkestan hss a variety of chsracters, dependiug on the rarious physical aspects of the separate regions, the Pamir vegetation and that of the Aral-Caspian steppes constituting two types with numberless intermediate gradations.
There is no arboreal vegetation on the Pamir, except a few willows sud tamarisks slong the rivers. Mountain and valley alike are covered with soft carpets of grass, various species of Festuca predominating almost to the exclusion of all others. In the immediate vicinity of water the ryang (Carcs physoides) grows, and a few patches are covered with Allium. To these may be added a few Ranunculacex, some Ifyosolis, low Scabioss, the common Taraxacum, one species of Chamomilla, snd \& fer Leguninose. In the north and west the Stipa of the Russian steppes supersedes Festuca and affords splendid pasture for the herds of the KaraKirghiz. In the gorges and on the better-watered slopes of the mountains the herbaceous vegetation becomes decidedly rich. Besides the above-nsmed there sre many other Graminese, such as the beautiful Lasiagrostis splendins, and whole aess of Scabioss. Ercmurus, of a vsriety of colours and 6 to 7 feet in height, forms thickets slong with the tall Scorodosma fotida. The northern alopes of the Atai chain are richer in trees. Up to 12,000 feet fullgrown specimens occur of the artcha (Junipcrus pseudo-Sabina), charscteristic of the whole northern slopes of ihe Turkestan highlands, the poplsr, a very few hirches (B. Sogdiana), and a rich nnderwood of shrubs familiar in European gardens, auch as Rhododendron chrysanthum, Sorbus aucuparia (rowsn), Berberis heteropoda (berberry), Lonicera Tatarica (honeysuckle), and Crategus (hswthorn). Farther esst and north comes the Turkestan pine (Picca Schrenkianc), while at lower levels there grow numerous willows, black and white poplars, tamarisk, large Celtis, as well as shrubs of Eľ'agnus (wild olive), Hippophae rhamnoides (6allow thorn), Rubus fructicasus (black berry), Prunus spinosa (blackthora), snd P. Armeniaca (apricot). The characteristic poplar, Populus diversifolity, which does not aeem to have found yet the shape of leaves best suited to the climate, and therefore produces them in most striking Fariety, snd the dwsrf Acer Lobclii-very different, however, from the European maple-also occur.
The above spplies to most of the highlands of the Tian-Shan. The drier aouthern slopes are quite devoid of arboresl vegetation.

[^274]On the northern slopes, at the higher levels, only the Juniperus pseudo-Sabina growa on the mountains, and rich meadow grasses cover the syrts. Lower down, et about 7500 to 8000 feet the conifer zone begins, characterized by the Picca Schronkiana, which furnishes the inhabitants with timber and fuel. Of course the artcla and a few other deciduous trees also occur. The richest zone is that which comes next, extending downwards to 5000 and 4500 feet. There woods of birch, several species of poplar, the maple (Accr Semenoviri), and a rich underwood spread over the mountain slopes, Orchards of apple and apricot surround the villages. The meadows are covered with a rich vegetation, -numberless bright Pæonix, variegated Scabiosæ, large Convolvulacca, all kinds of Campanula, dark-coloured Eremurus, splendid Umbcllifcræ, yellow-flowered Galliunn, a mass of Rosaccæ, Althcæ, Glycyrrhizæ, ligh-stemmed Scorodosma fotida, and tall Gramincer. But, as soon as the soil loses its fertile humus, it produces only a few of Phlomis, Alhagi camclorum, Psamma, Salsolacea, Arlemisix, Peganunn, and some poppies and Chamomilla, but only in the spring. The invading steppe plants appear everywhere in patches in the Turkestan meadows. Very often-almost invariably on the drier sonthern slopes of the mountains-the steppe vegetation climbs up to the level of the alpine. Nowhere, perhaps, is the effect of various soils-locss, clay, salt clay, and sand-upon vegetation better observable than in the receutly*emerged and arid regions of markestan.
The "culture" or "apricot" zone is folloved by the prairie belt, in which black-earth plants (Stipa and the like) struggle for existence agaiust invading Central Asian forms. And then come the lowlands and descrts with their moving sandy barkhans, shors, and takyrs (seo Transcaspian Region). Two species of poplar ( $P$. pruinosa and $P$. diversifolia), Elæagnus angustifolia, the ash, and a few willows grow along the rivers. Large areas are wholly destitute of vegetation, and after crossing 100 miles of such a desert the traveller will occasionally come upon a forest of saksaut (Anabasis Anmodendron). Contorted stems, sometimes of consider able thickness, very hard, and covered with a grey cracked bark, rise out of the sand, bearing green plumes of thin branches, with small greyish leaves and pink fruit. Sametimes the tree is a mere knot peeping above the sand with a crown of thin branches. But even these fantastic growths are rapilly being destroyed by the Kirghiz berdsmen, who use them for fuel. ${ }^{1}$ In spring, however, the steppe assumes quite another aspect, being covered, except where the sands are shifting, with a rich vegetation. Persian species penetrate into Bokhara and the region of the upper Amu.

As already stated (p.635), the climate of Turkestan varies considerably from north to south. In Akmolinsk and Semiryetchensk most of the kinds of corn which characterize Niddle Russia are grown. South of the Tchu and the Syr-Daria gardening is a considerable industry; and, although rye and wheat continue to be the chief crops, the culture of the apple, and especially of the apricot (uryuk), aciuires importance. Attempts are also made to cultivate the vine. The inhabitants of the neighbourhond of Tash. kend and Samarkand, as well as those of the much more northem but better sheltered Kulja oasis, ald the cultivation of the almond, nomegranate, and fig. Vines are grown and cotton planted in those districts. Finslly, abont Khojend and in Ferghana, where the climate is milder still, the vine and the pistachio tree cover the sills, while agriculture and horticulture have reached a high degrec of perfection. Successful attempte are now being made to grow the tea-plant in the Transcaspian region.

The arable lsod, being limited to the irrigated terraces of loess already spoken of, occupies less than a fiftieth of the whole area of West Turkestan, even when the Transcaspian deserts are left out of account. The remainder is nearly cqually divided between pasture land and desert (sandy steppe and barren mountain). Owing to a very equitalle distribution of irrigation water in accordance with Moslem law, agriculture and gardening have reached a high stage of derclopment in the oases. Two crops are usually taken every yesr. ${ }^{2}$ Wheat, barley, millet, pease, lentils, rice, sorglrum, lncerne, and cotton are the chief agricultural prollucta. Carrots, melons, vegetable marrows, and onions are extensively grown. Rye and oats are cultivated in Kazalinsk and Kopat. Corn is exported. Owing to the irrigation, total failure of crops and consequent famines are unknown, unless among the Kirghiz shepherds. The kitchen gardens of the Mohammedans are, as a rule, adnurably kept. Potatocs are grown only by the Russians. The cultivation of cotton is rapidly extending ( 32,000 acres in 1886), as also is sericulture, which is chiefly carricd on in Ferghana, whence silk cocoons are an important item of export. Cattle-breeding is extensivcly pursuet, and in Russian Turkestan alone recent estimates slow 400,000 camels, $1,600,000$ horses, $1,200,000$ cattle, and $11,000,000$ sheep. This last figure, however, is but a very rongh estimate, -the flocks on the Kirghiz steppe being so large that the proprietors themselves do mot know their

[^275]exact numbers. Murrains are of frequent occurrence; a recent on resulted in a terrible famine among the Kirghiz. Live cattle hides, wool, camel-hair, tallow, felt. and leather are exported to a considerable extent.

The mineral wealth of Turkestan is considerable. Traces of suriferons sands have been discovered at many places, but the per. centage of god is too poor to make the working remunerative. Silver, lead, and iron ores occur at several places; but the want of fuel is an obstacle to their exploitation. The vast coal-beds of Kulja and several inferior obes in Turkestan are not yet serionsly Norked, the total jearly output being only some 120,000 cwts. The naphtha wells of Ferghana and the layers of graphite about Sairam-Nor are also neglected. There are abundant deposits of gypsum, alum, kaolin, marble, and sinilar materials. Notwithstanding the salt springs of Ferghana and Syr-Daris, the salt lakes of the region, and the rock-salt strata of the Alexandrovsk Mountains, salt is imported.

Turkestan bas no manufacturing industry carried on by means of machinery, except a few distilleries and two establishments for dressing raw cotton. But there is a great variety of artisan mork, which, however, has been for some time declining and now stands at a rather low level. ${ }^{3}$ Trade is very actively carried on. Its importance may be julged by the fact that in 1876 27,900 camela nere uscd for the transport of wares to Tashkend. This town and Bokhara are the chicf conmercial centres, the principal articles of export to Russia, ric Orenburg and Semipalatinsk, being raw cotton and silk, cattle and their products, while mantufactured wares are imported in return. There is also an import and export trade to and from Ürumtehi and China, via Kulja and Ak-su.
Turkestan has been the theatre of so many migrations and con- Ethaoquests that its present population could not fail to be very mixed. graphy. Roth Aryans and Mongols (especially the Ural-Altaic branch) have their representatives there, the former settled for the most part, the latter chiefly nomad. The Ural-Altaians, or Turanians, are mmerically the predominant element, and consist of Turcomans, Kirghiz, Uzbegs, and Sarts. The Turcomans inhabit chiefly that part of Turkestan which is now known as the Transcaspian Region (q.v.). They number less than one million. The Kara. Kalpaks ("Black Bonnets") may number about 50,000 in Turke. stan, and some 300,000 in the Russian empire altogether. Very little is known of their history. They are supposed to be bit recent immigrants to Syr.Daria, having come from the former Bulgarian empire on the middle Volga. Their language and haluits are the same as those of the Kirghiz; but for the last century aod a half they have had some acguaintance with agriculture. Their pacifio temper exposed them to the raids of the Kirghiz, who compelled them first to settle in Dzungaria, then to change their dwellings several times, and ultimately (in 1742) to recognize the sovereignty of Russia. Even since that time they lave been driven by the persecutions of their old enemies to cross the Aral-Caspian steppes and seek refuge near Astrakhan. The real masters of the steppes and highlands of Turkestan are the Kirghiz, of whom there are two branches, -the Kazak (Cossack) Kirghiz and the Kara (Black) Kirghiz or Burut (see Kirohiz) The Uzbegs, who played a predominant political part in Turkestan before the Russian conquest, are of Turco-Tartar origin and sjeak a pura Jagatai dialect; but they are mixed to a great extent with Persians, Kirghiz, and Mongols. They are subdivided into clans and lead a semi-nomadic life, ,reserving most of the attractive features of their Turkish congeners-especially their honosty and independedce. When settled they aro mostly designated as Sartg-a name which has reference more to manner of life than to anthropological elassification, althongh a much stronger admixture of Iranian blond is evident in the Sarts, who also speak Persian at Khojend and Samazkañ. Tarantchi or Taranji ("]abourer" in Chinese) is the name given to those Sarts who were settled in the Kulja region by the Chinese Government after the rising of 1758 . They constitute about two-fifths of the population of Knljs. After defeating the Dzungañs in the ycar 1865, they took the political power in Kulja into their own liands, offering shelter to the Kirghiz who made inroads on the Rnssian dominions. This was made a pretext for the andexation of Kulja by Russia in 1871; but it has been since restored to China. The origin of the Dzungañs is somewhat problematical. They number nearly 20,000 , and inhabit the valley of the Ili in Kulja and partly are scttled in Russian 'furkestan. They are Mohammedans, but have adopted Chinese manners of life. The Mongolian brancl is represented in Turkestan by Kalmucks and Torgontes (Torgod) in the north-east and in Kulja, where they are mixed with Solons, Sibos, and Chincse. The Aryan Tajak (sce TAJAK), the aborigines of the fertile parts of Turkeatan, were subdued by the Turco-Nongolian invaders and partly compelled to emigrate to the mountains, where they are now known as Galtchas. They constitute the intellectual element of the country and are the principal owners of the irrigated land, -the Uzbegs being their labourers, -merchants, and mollahs or priests $\frac{\text { They are Sunnite Mussulmans. The other representatives of Aryan }}{\text { B See N. Mayeff"a Turkestan Ezh iblion of } 1886 \text {, Tashkend, } 1886 \text {. }}$
race in Turkestan are a few Persians, mostly liberatid ole res; Indians, who carry on trade and nsury in the citics; a few Gipsies; and the Russians. Among these last two distinct clements must be noticed, -the Cossacks, who are settled on the borders of the Kirghiz steppe and heve assumed many Kirghiz festures, ${ }^{1}$ and the peasant-settlers who sre beginning to colonize the valley of the Ili and to spread farther south. Exclusive of the military, the Russians nnmber about 75,000, nearly two-thirds being in Semiryetcliensk (Cossacks and peasants).

Turkestan has no lack of populous citien, which, notwithstanding reeent vicissitudes, continue to be important for their trade, while several athers are widely famons for the part they Lave played in history. . Khokand, ${ }^{2}$ Margmilan, Namangan, sad Andijan in Ferghans; Tashkend and Khojend in Syr-Daria; Samarkand in Zersfshan; Bokhara sud Kiniva in the independent khsnates have esch from 30,000 to 100,000 inhabitants.

Populous cities adorned with fine monuments of Arabian architecture, nomerous ruius of cities decayed, grand irrigation canals now lying dry, and written monuments of Arabian litersture testify to a time when civilization in Turkestan stood at a mach higher lovel than at present. This period was during the first centuries after its conversion to Islam. Now all is in decay. The beantiful mosques and madrasas are dilapidated; no astronomera watch the sky from the tops of their miasrets; and the scholars of the madrasas waste their time on the most deplorably puerile schnlasticism. The inspiration of early belief has disappesred; the ruling motive of the mollahs (priests) is the thirst for personal enrichment, and the people no longer follow the khojas (see p. 639 below). The agricultural labourer has preserved the nprightness, diligence, and sobriety which characterize the Turkish peasant in Asis as well as in Enrope; but the richer inhabitants of the cities are grossly sensual. Centuries of wars, followed, by massacres and cruel vengesnce, an unceasing civil strife between parties dispoting for supremacy in the name of religion, conspiracies, appesls to foreigners, snd endless intrigues have hastened the decay of Mahammedan civilization in the khanates of Turkestan and paved the way for Russian conquest.

It remains, however, an open question whether the Rinssians will be sble to bring new vigour to the conntry and awaken intellectual life. They have failed to do eo in eastern Rassia, at Kazan, and elsowhere, where both civilizstions-the European and the Asiatic -ramain as tharoughly estranged from one another as they were three centuries ago. This estrangement is not merely religious, but social end economical. The followers of Islam, whose common Isw and religion know only of a temporary possession of the land, which belongs wholly to the Prophet, cannot accept the principles of unlimited property in land which European civilization has borrowed from Roman law; to do so would put an end ta all public irrigstion warks, and to the syatem by which water is nsed accarding to each family's needs, and so wonld be fatal to sgriculture. When taking possession of Turkestan, the Russians began to grant deeds establishing property rights over land in eccordance with Roman law. Butastudy of the Mohsmmedan ayotem soon pat en end to so erraneons a policy, and Mussulman law is still respected. The Russisns have sbolished elavery in Turkestan; and their rule has put an end to the interminable intestine struggles, which had weakened and desolated the whole region. The barbsrnns tartures and executions which rendered Khiva notorious in the Fast ara no longer heard of; and the continual sppeals of the khojas for "holy" war against their rivals find no response. But the Russian rule has imposed many new taxes, in return for which Torkestan only gets troops of Russian merchants and officisls, who, instead of becoming the exponents of what is best in European civilization, toa often eccept the worst festures of the depraved Mnssulman civilization of the higher classes of the country. New tribunals and new justices of the peace are sbout to be introduced (1887) ; schools are being diligently spread; but the wants of the natives are set behind those of the children of the Russian officials and merchants and the supposed necessities of Rnssification. A consulting lospital for Mohsmmedsn momen has recently been opened by women graduates in medicine at Tashkend.

## East Turkestan.

As. already stated, by this name we designate that rast depression in the great plateau of eastern Asia which lies between ihe Tian-Shan Mountains in the north-west; the steep slopes of the Pamir and of the Tibet plateau, bordered by the Kuen-Lun, in the south-west and south; the Attyn-Tagh in the south-east as far as Lake Lob-Nor; and in the north-east the still imperfectly known mountains

[^276]which run east-south-east from the Tian-Shan, having the Bagratch-kul on their northern slope. ${ }^{3}$ F'arther east the Kuruk-Tagh and the steep slope of the Gashuũ Gobi separate East Turkestan from the higher terrace of the plateau, so that about Lob-Nor the Tarim depression is narrowed to a width of about 100 miles ; and on the 98 th meridian, at Lake Tchin-shen-ho, the steep edge of the Gobi meets the spurs of the Nan-Shañ Mountains. ${ }^{4}$ This region has been and still is designated by a variety of names, such as the Tangut Plain, West Gobi (a most inappropriate name, as already pointed out by Ritter), Altyshar or Jity-shar (the land of six or seven cities), Little Bokharia, Kashgaria, and so on. In its physical features it forms a connecting link between the Chinese territories and the Aral-Caspian depression. It covers about 465,000 square miles, but has hardly more than $1,000,000$ inhabitants.

Although lying at a high altitude (Kashgar 4000 feet Puselcer and Yarkand 4120 feet), it has the character of a depres fatura sion in comparison, not only with the mountains, but also with the lofty plateaus which surround it,-Tibet,. Pamir, and the Tian-Shan syrts. It has a general slope towards the east, and its lowest portions (formerly occupied by a great lacustrine basin) are only 2600 feet above the sea. ${ }^{5}$ At its north-east edge, i.e., at the foot of the remotest offshoots of the Tian-Shan, M. Prjeralsky measured an altitude of only 2600 feet. Its average altitude ranges from 3100 to 3700 feet, increasing to 4200 at its outer rim. No mountains or hills diversify its surface, which is that of a high plain. All the mountains which enclose it rise to considerable heights, far above the snow line. The steep slopes of the Pamir culminate in Tagharma Peak ( 25,360 feet). In the north the snowclad Kokshat-tau and Kirghiznyn Ala-tau form a series of uninterrupted chains, which reach a height of 24,000 feet in the KhanTengri and have at their southern base the broad and higt alpine plateaus, or syrts, of which the Yułduz, dotted with lakes, has acquired historical fame as the meeting place of the armies of Timur before his Dzungarian march. On the southern borders of East Turkestan, in the KuenLun and Karakorum Mountains, is the Dapsang-one of the highest peaks of the globe ; and farther east the AttynTagh and the Nan-Shañ (with Humboldt and Ritter ranges), which are among the highest mountains of Asia, separate it from the lofty Chaidam or Tsaidam plateau. ${ }^{6}$ East Turkestan is thus secluded by high mountains and plateaus from the rest of the continent. Even the few Pasmes passes which lead to it climb to altitudes of. 14,000 feet. It is open only towards the east, where it is connected with the Gobi depression. Its position as the highway from China to West Turkestan and the Dzungarian empire bas made it known, though only very imperfectly until lately, through Chinese documents, the narratives of the journeys of Buddhist missionaries, and the travels of Marco Polo, Rubruquis, and a few Jesuits. From a remote antiquity it was crossed by caravans going from China to Lake Balkash, Ferghana, and the Oxus. The route, after crossing the Gobi, proceeded either to the Dzungarian Gate, or, via Kashgar, to the high passes of Terek-Davan and Muz-art, which led to Ferghana and Issyk-kul. Both passes have a wide renown in Central Asia, the latter especially, on account of its difficulties, one of which is a

[^277]nuge gracier, waycn has to be ascended with the help of the ice axe.
One river only, the Tarim-now lost in the marshes of Lob-Nor-and its tributaries, water this region. It is formed by the confluence of several rivers flowing from the semicircle of mountains which fence in East Turkestan on the south, west, and north. The Kashgar-Daria rises under the name of Kizil-su on the Atai. The YarkandDaria has its origin in a high valley between the KuenLun and Karakorum Mountains, at the base of Dapsang, from several streams, such as the auriferous Zerafshan, which is fed by the glaciers of the Karakorum pass; after piercing the Knen-Lun, it enters the plain, where its waters are soon diverted to the fields and gardens of the Yarkand oasis. The Kbotan-Daria rises farther east in the same valley, and also pierces the Kuen-Lun, its two branclesthe Kara-kash and Urung-kash-being renowned for their "black" and "white" jade. This river only reaches the Tarim during the summer. The Tian-Shan Mountains contain the sources of several feeders of the Tarim; but some of them no longer reach the main stream. The Kizil-Kunghei disappears after having watered Uteh-Turfan (Uj-Turfan) ; the Ak-su meets the Khotan-Daria at its junction with the Tarim; but the Baidu-gol and the Kutcha are lost in Lakes Baba-kul and Sary-kamyeh. From the Yułduz plateau comes the Haidu-gol, which flows past Kara-Shar and enters the Bagratch-kul Lake, whence it issues under the name of Kontcha-Daria, and, crossing the east of East Turkestan from north to south, joins the marshes of Lob-Nor ; thus the long-doubted connexion between these two lakes-the northern and the southern-really exists. The Tarim is navigable for steamers from the confluence of the Yarkand and Khotan rivers all the way to Lob.Nor. ${ }^{1}$ These rivers, however, do not bring life to the immense deserts, the aspect of which recalls partly the Aral-Caspian depression and partly the Mongolian Gobi. Their undulating surface is covered with a gravelly soil, ont of which all the finer particles have been winnowed by the wind, and it resounds under the hoofs of the passing hordes; grass covers it only in the beginning of spring. Here and there occur clayey deposits with an efllorescence of salt, which is hard in summer but impassable after rains. Then come immense areas of loose sand, which is raised in clouds by storms of wind, and the hills of which, moving on like waves, invade the cultivated fields that have been conquered by laborious effort from the desert. The features with which the traveller in the Sabara, or on the plateau of eastern Iran about Lake Zareh (Hamun) is familiar, are here reproduced on the same large scale: The Takla-makan desert north of Khotan covers 93,000 square miles-an area nearly equal to that of Great Britain. As one approaches Lob-Nor, and thus touches upon territory that has emerged at a still more recent epoch, the desert becomes still drearier and still less passable on acconnt of the shifting sands. Lob-Nor now consists of two basins: but the largest of them, although it has an area four times as large as that of the Lake of Geneva, can hardly be called a lake, since its greatest depth is less than 20 feet, while reeds rise 20 feet above the thin film of water and extend far beyond its shores. In fact the whole of the region, notwithstanding its considerable altitude above the ocean, has but recently emerged from under water. During the later portion of the Tertiary period it was covered with an immense Mediterranean sea, and even during the Post-Pliocene period was occupied by a lake. But, as we see on a smaller scale in Finland and Sweden, where the higher

[^278]lacustrine depressions are more advanced in ras process of desiccation than those situated at lower levels, so in Central Asia the more elevated Tarim region is more advanced in its desiccation than the Balkash basin, and this latter again is in a more advanced stage of the same process than the Aral-Caspian depression. The desiccation of East Turkestan must have gone on, however, within historical times at a much more rapid rate than geologists seem prepared to admit. East Turkestan has not always been the desert it now is. Many cities, in which Greek and Byzantine coins have been found, lie buried beneath the sands, and in one of these Buddhist statues have been discovered. Indeed it is very probable that the great migration of the first centuries of our era resulted from the necessitv of abandoning East Turkestan.
The clinate is sovere : a cold winter follows a burning summer. Clitasta A few allowers slightly moisten the surface in spring; but the summer and autumn are rainless. The sir.is continuslly chsrged with dust, and often with sand.
The vegetation of the interior of East Turkestan is very poor, Florm being the seme as that of the eteppes of West Turkestan. On the eaudy hilla are some tamarisks and Elxagnus, rapidly being used up as fuel ; along the rivers are copses of poplara, which have diff. culty in maintaining themselves, because no humus gathers in their shade, the dry leaves being hlown away hy the atorma and ecattered as dust over the desert ; and, finally, along the old beds of rivers and lakes grow dense and rank beds of reede, where the wild boar has his habitat. Immense areas are covered with Salsolacees, and the gravelly ground is clothed in spring with a rich carpet of grass The oases possess all the plants which are cultivated in West Turkestan, - the mulberry, walnut, pear, apple, a pricot, olive, and vine. Cotton, rice, maize, millet, and whest are grown; and Middendorffa ${ }^{2}$ remark, that on the edge of the desert we find the hest cultivated fielde and the richest gardens, is atill more applicable to the oasea of East than to those of West Turkeetan. But outside the oases desolation reigns. Wind frcely modifies the surface, carrying away the fincst particles of the gravelly aoil, breaking down the barkhans as soon as man has destroyed the vegetation which grew on them, snd lifting the sand into the air snd whirling it along in columns of the most fantastic shapes
As a rule, the mammals are not numerous, and the faunz closely resemblcs that of the Tian-Shan. It seems to be owing to the loneliness of its deserts that East Turkestan has preserved the wild ancestors of our domestie animals. Besides the wild ass (Equus hcmionus), Prjoralsky discovered in the Dzungarian ateppes the wild horse-the ralal ancestor of our domestic horse-and on the plateau of Tsaidam the wild camel and the wild yak.a
Raw cotton and ailk are exported to a considerable smount; bot Indos. of manufceturcd cottons only s rough mata is sent to Semiryecthenak tries and for the Kirghiz Some silk wares, carpets, and ailk "grain" sre minerah exported from Khotan, leather-ware from Yarkand, polished and copper ware from Ak -sit, and amall iron ware from Kutcha. Stockbrceding is of paramount importance, and cattle, asses, camele, and sheep are reared in considerable numbers. Mineral resources are not wanting, hut the mining industry is in a primitive condition. Gold is obtained from alluvial deposits at Kiria, coal at Kashgar, jade in Khotan, and sulphur and aaltpetre at Utch-Turfan.
It is only along the bass of the mountains, where there is a fringe of loess, and where streama bring the nceessary moisture, that luman aettlements have aprung up, or rather maintained themaslves until now. The eeries of oases akirts the base of the TianShan and the Kuen-Lun. Kashgar stands at the apex of the angle made by those two ranges, while Yanghi-hissar, Yarkand, Khotan, and Kiria lie along the Kuen-Lun, and Utch-Turfan, $\Delta \mathbf{k}$-su, Bai, Kutcha, Kurła, Karaslar, and Turfan along the Tian-Shan. Many miles of desert separate these oases from each othar ; and their population could be, and has been, much greater than it is, for there is no lack of water in the streams which rise beneath the snow covering of the mountains. The various oasee, which are named after their chicf towns, have slwaye been nearly independent of each other. Still, in the course of their much disturbed history, Khotan, Yarkand, Kashgar, and $\Delta \mathrm{k}$-su, one sfter snother acquired a kind of supremacy over the rest. At present Yarkand and Kashgar are the most important. The city of Yarkand has nearly 80,000 inhabitante ; it is surrounded by walls, and has a separate fort, Yanghi-lissar; ruins of old settlements are scattered around. Its Chinese merchants carry on an setive trade, and the Turkish population are bresders of cattlo on gn extensive scale. Wheat, barley, rice, beans, zorghum, mulberries, and a variety of fruit trees are

[^279]grown in the gardens. FASEOAs (q.v.), surrounded by a series of populous villages, is the chief commercial centre, owing to ita position on the highway to Lake Issyk-kul It is surrounded by forts, one standing at the conflnence of the Kasingar and Yarkand rivers. Khoran ( $g . j$. ) or Iltchi (also Iu-thian), o very populous city under the Ban dynasty of China ( $206 \mathrm{~B}, 0.1 \mathrm{~A} . \mathrm{D}$. ), hes much declined of late. It is renowned for its gold mines, nad especially for its jade and its mask. Copper kettles, carpeta, soma silk, and felt waro nro manufectured. Sanju ( 7000 houses), Kilisn, Pialms, Guma, Kargatyk, and Posgan, on the slopes of the Kuen-Lun between Yarkand and Khotan, are the richest parts of the region. Naya, Kiris, Tchira, all on small rivers flowing from the Kuen-Lon, continue the line of oases towards the east, terminsting in Tchertchen, which now consists of but \& few score of houses. The oases st the base of the Tian-Shan are Utch-Turfan (Uat-Turfan), Ak-su (formerly the capital of Sairam), Bai, Kutchs with Shah-yer, Bugur, Kurta, Karashar, and Turfan. Their inhabitants grow corn to a considerable amount, and keep numerous berds of cattle and flocks of aheep. The ehief exports are wool, fowle, and the horns of the maral deer. On the lower Tarim, where s few sottlements, supported chiefly by fishing, continue to etruggle against the encroaching desert, the ruips of formerly populons towns testify that the region was not always the dreary waste it now is.

The popalation is mixed, Aryans and Turanians being thoroughly intermingled. On the elopes of the Pamir, abor, Sary-kol, there is a purely Aryan population of Persian Galtch. Kirghiz and Kars-Kirghiz inhabit the slopes of the Tian-Shan. Kklmucks occur in the north-east ; and in the central parts the population cousista of Turkish Sarts and Uzbegs and of Persian Tajak,-the Mongolian element inereasing towards the north-east. The language ia Turkish, like that spoken in West Turkestan, with several varieties of patois and a considerable sddition of Chinese words. As a rule, the inhabitants of East Turkeetan have an air of poverty. There are no rich mosques in their towns, auch as thoee of Samarkend and Bokhara; the houses are of nubaked brick and poorly furnished. The dross is that customary in West Turkestan. But the habits of the people differ to some extent and the women enjoy greater liberty than in other Mohammedan countries: they go in the atreets unveiled; free marriages, contracted for short terms, sre not unfrequent. As a rule, the position of women is more independent -a fealure noticed even by the earliest travellers in the country.

The aggregate population of East Turkestan, estimated between 575,000 and $1,500,000$ in 1825, is now (1887) hardly more than 1,000,000. Kuropatkin estimatcs it at 1,200,000, Forsyth at 600,000 . The population of the chief towns may be stated approzimately as follows-Yarkand, 60,000; Kashgar, 50,000; Khotan, 40,000; Sanju, 35,000; Ak-8u, 20,000; Kiris, 15,000; Yanghi-hissar. 10,000; Kargatyk, 10,000 ; Kurta, 6000.

It appears very probable that at the dawn of history Esst Turkeatan was inhahited by an Arysn population, the ancestors of the present Slavonic and Teutonie races, snd that a civilization not inferior to that of Bactriana had already developed at that timo in the region of the Tarim Our knowledge, however, of the history of the region is very fingmentary until about the beginning of the Christian era. When the Huns (Hiong-nu) occupied vest and east Mongalia in 177 B. o., they drove before them the Yue-chi (Yutee, Yetes, or Chetes), who divided into two bordes, one of which invaded the valley of the Indus, while the other met the Sacæ in Esat Turkestan and drove them orer the Tian-Shan into the valley of the Ili. Thus by the beginning of our era the Tarim region had a mised population of Aryans and Ural-Altaians, some being settled agriculturista and others nomsds. There were also several independent cities, of which Khotan was the most important. One portion of the Arysns emigrated and settled in what is now Wakhan (on the Pamir platesu), the present language of which seems very old, dating anterior to the separation of the Vedic and Zend languages. In the lat century the Chinese extended their rule westwards over East Turkestan ss far as Kashgar. But their dominion seems to have been merely nominal, for it was coon shaken off. By the end of the 5th century the western parts foll under the sway of the "White Huns" or Ephthalites, while the eastern parts were under Tangut (Thygun) dominion. The Chinese, however, still retained the region about Lob.Nor. Buddhism penetrated into the country at an early date; but in East Turkestan there were also followers of Zoroastrianism, of Nestorian Christianity, and even of Manichrism. An active trade was carried on by means

1 Such ia the conclusion reached by Lassen (Indische Atterthumskunde), aod sapported by M. Grigorieff (Rither"a Asien in Russ. transl. : Addeoda to "East Torkestao, In Russian). In connexinn with the objcetion based upon the onb-boreal character of the regions which were tha cradle of the Aryaus, as proved by tha ao-called palseontology of the Aryan languages, it - 8 g bs observed that by the end of tha Glacial, sod duriog the earijer Lacustrioe (PostGlacial) period, tha vegetation of Turkestan and of Ceotral Asia was qoite different from what it is now. It was Siberiso or oorth Europeas. The researches by M. Krasnoff (sea above, p. 635) as to the characters of the former Alore of tha Tian. Shan, snd the changes it has undergoue in consequence of the ln all apeculations founded apon the testimony of langnage as to the original
home of the aryane.
of nomerous caravans. Tho civilization and political organization of the country were dominated by the Chinese, but were also infuenced to some extent loy Greco-Baetrian civilization. Buddhism spread rapidly in the south-west, and the study of Peli became widely diffused Our information as to the state of the country from the 2d century to the first half of the 7 th is slight, and is chiefly derived from the Journeys of the Buddhist pilgrim Fs-hien in 399 , S.ng-yrn in 518, and Hwen-t'sang in 629 . By this time Buddhism had reached its culminating point: in Khotan there were 100 monasteries and 5000 monks, and the Indian saered litersture was widely diffused; but already there were tokens of its decay. Even then the eastern parts of the Tarim basin seem to have been gr wing less and less populous. To the east of Khotan cities which wero prosperous when visited by Song:yun had a centary latcr fallen into ruins, whils their inhabitants had migrsted westwards. Legend has it that all the ichabitants of Go-lao-lo-tsia were buried in a sandstorm, and this seems to bebut a poetical way of representing a phenomenon which was steadily going on in East Turkestan.

Little is known about these regions during the 7th, 8th, and 9th centuries. In the 7 th century the Tibetan king, Srong-btsan, with the help of the western Turks, subjugated the western part of the Tarim basin. During the following century the Dobammedans under Kotaiba, after several excursious into West Turkestan, took Samarksnd, Ferghans, Tashkend, and Khokand (712-713), and invaded East Turkestan, penetrating as far as Turfan and Shina, The Chinese supremacy was not shaken by these inrasions. But, on the outbreak of internal disturbances in China, the Tibetana took possession of the western proviuees of Clina, and intercepted the communications of the Chinese with Kashgaria, so that they had to send their troops through the lands of the IIui-khe (Hoei-ke, or Hoei-hu). In 790 the Tibetans were masters of East Turkestan; but their rule was never strong, and towards the 9th century we find the country under the Hoi-he. Who these people were is somewhat uncertain According-to Chinese documents, they cams from the Selcaga; but most Orientalists identify them with the Uigurs. In the opiniou of M. Grigorictf, whom we follow in this akoteh, ${ }^{2}$ the Turks who succeeded the Chinese in the western parts of East Turkestan were the Kalluk Turks, who exteuded farther south-west up to Kashmir, while the north-esstern parts of the Tarim region were subdued by the Uigurs. Soon Mongolian hordes, the Kara-Kitais, entered East Turkestan (11th century), and then penetrated into West Turkestan, Khive falling under their dominion. During the following contury Jenghiz Khan overran China, Turke. stan, India, Persia, Hussia, and Hungary; Kashgaria fell under his rule in 1220 , though not without strenuous resistance followed by massacres. The Jongolian rule was, bowever, not vory heary, the Mongols merely exacting tribute. In fact, Kashgaria flourished under them, and the fanatieism of Islam was considerably sbated. Women again ecquired greater independence, and the religions toleration then established permifted Christisnity and Buddhism to spread freely. This state of affairs lasted until the 14 th century, when Tughlak Timur, who extended his dominions to the KuenLun, aceepted Islam. He transferred his capital from Ak-su to Kashgar, and had a summer residence on the bauks of Issyk-kul. His son reigned at Samerkand, but was overtlirown by Timur-lang (see TimणR), and the reign of the great conqueror was a ferci source of suffering to the region. To put an end to the attacks of the wild Tian-Shan tribes, he undertook in 1389 his renowned march to Dzungaria, which was devastated; East Turkestan slse ouffered severely

The re-introduction of Islam was of no benefit to the Tarim region. In the 14 th and 15 th centuries Bokhara and Samarkand lecame centres of Moslem scholarahip, and sent great numbers of their learned doctorg to Kashgaria. Rubruquis, who visited East Turkestsn in 1254, Marco Polo between 1271 and 1275, and Hoils in 1680 , all bore witness to great religious tolerance; but this entirely disappeared with the invasion of the Bokharian mollahs. They created in East Turkestan the power of the khojas, who sfterwards fomented the many intestine wars waged between the rival factions of the White and the Black Mountaineers. In the 17th century a powerful Kalmuck confederation arose in Dzungeria, sad eztended its sway over the Ili snd Issyk-kul basins, having its capital on the Ili. To this power or to the Kirghiz the "Whites" and "Blacks" alternately appealed in their struggles, in which Yarkand supported the latter and Kashgar the former. These otruggles pared the way for a Chinese invasion, which was supported by the White Lhojas of Kashgar. The Chinese entered Dzungaria in 1758 , and there perpetrated a terrible massacre, the victims being estimated $\varepsilon$ t one million. The Kalmucks fled and Danngaria became a Chinese province, with a military colonization of Sibos, Solons, Dahurs, Chinese criminals, and Moslem Dzungars. The Chinese next re-conquered East Turkestan, marking their progress by massacres and transporting 12,500 partisans of independence to the Ili valley. Hereupon the dissentient khojas fled to Khokand snd there gathered armics of malcontents and fanatic followers of ${ }^{2}$ See Rittar's Asicn," East Turkestan" (Russ. trans.), ii. 232; also Kuropatkin's Ľashgaria.

Islam. Several times they succeeded in overthrowing the Chinese rule-in 1825, in 1830, and in 1847-but their auccesses were never permanent. After the "rebellion of the aeven khojas" in 1847 Dearly 20,000 families from Kashgar, Yarkand, and Ak-日u fled to West Turkestan through the Terek-Davan pass, many of them perishing on the way. In 1857 anotber insurrection broke out ; but a few montha later the Chinese again took Kashgar (for the details bee Kashaar). In the course of the Dzungarian outbreak of 1864 the Chinese were again expelled; and Yakub Beg became master of Koshgar in 1872. But five years later he had ggain to sustain wor with China, in which he was defeated, and East Turkastan once more became a Chinese province.

## T U R K E Y

## Part I.-History.

SOMEWHERE about the second decade of the 13th century the little Turkish tribe which in due course was to found the Ottoman enipire fled before the Mongols from its original home in Central Asia, and, passing through Persia, entered Armenia, under the leadership of Suleymán Er-Togl-Shahh, its hereditary chief. His son, Er-Toghrul, who sul. succeeded him as head of the tribe, when wandering about the country with his warriors came one day upon two armies engaged in a furious battle. Er-Toghrul at once rode to the assistance of the weaker party, who were on the point of giving way, but who through the timely aid thus rendered not only regained what they had lost but totally defeated their enemies. The army thus saved from destruction proved to be that of 'Ala-ud-Din, the Seljuk sultan of Asia Minor, and their adversaries to be a horde of marauding Mongols. By way of recompense for this service 'Alá-ud-Dín granted to Er-Toghrul a tract of land on the Byzantine frontier, including the towns of Sugut Dosmán. and Eski Shehr. 'Osmán, the son of Er-Toghrul and the prince from whom the race derives its name of 'Osmanli (see Torks, p. 661 below), corrupted by Europeans into Ottoman, was horn in Sugut in 1258 (A.H. 656). While still young 'Osmán won from the Greeks Karaja Hisisár (Karahissar) and some other towns, on which account he received from his suzerain, the Seljúk sultan of Konya (Konieh), the title of heg or prince, along with the drum and the horsetail standard, the symbols of princely rank.

Early Tarkish princi. palities.

In 1300 (699) the Seljuk empire (see Seljoks) fell to pieces under the onslaught of the Mongols, who were, however, powerless to replace it by any government of their own. Thereupon ten separate Turkish dynasties arose from its ruins : that of Karasi sprang up in ancient Mysia, the houses of Saru Khan and Aydin in Lydia, of Mentesha in Caria, of Tekka in Lycia and Pamphylia, of Hamid in Pisidia and Isauria, of Karaman in Lycaonia, of Kermiyan in Phrygia, of Kizil Ahmedli in Paphlagonia, and of 'Osman in Phrygia Epictetus. These principalities were all eventually merged in that of the "Osmánlis, once the least among them, and the inhabitants assumed the name of Ottoman. Hence by far the greater portion of the people palled Ottomans owe their name to a series of political events. On the collapse of the Seljuk power the Greeks retained hardly any possessions in Asia except Bithynia and Trebizond. Armenia was abandoned for a time to roving Tatar or Turkman trihes, till some sixty or seventy years later one or two petty local dynasties sprang up and founded short-lived states.

The year 1301 (700), in which 'Osmán, who shortly
before had succeeded his father, first coined money and Pourdcaused the khutba, or public prayer for the reigninging of monarch, to be read in his name-the two prerogatives of Ottoman an independent sovereign in the East-may be regarded as the birth-year of the Ottoman empire; and it was about this time that his followers and subjects began to call themselves 'Osmánlis, or, as we might render it, 'Osmanites. Having thoroughly established his authority in his capital of Yeni Shehr, 'Osman began to wrest from the Greeks many of the neighbouring towns and strongholds, among others Ayina Göl and Koyun Hisári, routing before the last named a large Byzantine army. He then turned his attention to the administration of his state, and such was the feeling of security he succeeded in establishing that large numbers of people from the surrounding districts flocked into his dominions and became his subjects. After six years of peace several of the Byzantine castellans of the neighhourhood, instigated by the governor of Brusa (Broussa), made a simultaneous attack upon the Ottomans, but 'Osmán totally defeated them and sent in pursuit Kara 'Ali Alp, who took possession of all their domains. Gházán, the khan of the Mongols, who had entered into an alliance with the emperor of Constantinople, sent to all the Turkish princes an arrogantly worded message forbidding them to do any hurt to the Byzantine territories. .To show how light he held this menace, 'Osmán assembled an army forthwith, marched to Nicæa and thence to the Bosphorus, laying waste the country as he went and taking possession of a number of towns and villages. Michael, called by the Turkish historians Kösa Mikhál or Michael Scantbeard, the governor of one of these, embraced Islam and became one of the most trusted officers of 'Osmán and of his son and successor Orkhan. The descendants of this Michael were the hereditary commanders of the akinjis, a corps of light cavalry who played a great part in the early Ottoman wars. The first service on which Michael was employed was to destroy, along with Orkhan, a Mongol horde that had taken and pillaged the Ottoman town of Karaja Hisár. Meanwhile "Abd-ur-Rahmán and Akcha Koja, two of 'Osmán’s generals, were adding to the Ottoman dominions in the north, capturing several towns and laying siege to the city of Nicæa. The Ottoman chiefs next resolved to acquire Brusa, the natural capital of these parts. So they built round it a series of towers, in which they placed garrisons, with the view of intercepting communications and eventually starving the city into submission. At length, in 1326 (726), after a desultory siege of eight years, the keys were, through the intervention of Mikhál, handed over to Orkhan, who was in command of the Ottomans, and the townspeople were allowed to ransom
themselves for 30,000 sequins. Very soon after this 'Osmán died, aged seventy, at Sugut, whence his remains were carried for burial to Brusa. 'Osmán was distinguished for piety and generosity as well as for equity and courage. He cared nothing for amassing wealth, and on his death his personal efiects were found to consist of two or three suits of clothes, a ferw weapons, some horses, and a flock of sheep. And so high was his reputation for justice that, we are told, many of the Asiatic subjects of the Cæsars fled to him for that protection which their own rulers would not or could not give them.
Orkhan, who succeeded his father 'Osmán, continued the war against the Greeks, taking from them Nicomedia, Nicæa, and many of the towns which they still retained in Asia. Hitherto the Ottomans had not interfered with the other Turkish states; but now Orkhan, granting a short respite to the Byzantines, took advantage of a dispute regarding the succession to the throne of Karasi, entered that principality, and annexed it to his own dominions. To his son Suleymán the Ottomans owe their first establishment in Europe: one night that prince, accompanied by a few companions, crossed the Hellespont on a raft and surprised the town of Galipoli (Gallipoli). The next day he brought over a number of Turkish troops, with whose assistance he possessed himself of many of the neighbouring towns and villages; but his career was cut short by a fatal fall from his horse when out hunting. Orkhan did not long survive his son, grief at whose untimely end is said to have hastened his own death, in 1359 (761). This monarch is celebrated for the number of mosques, colleges, and other public institutions that he founded. During his reign the Ottoman army was thoroughly organized, and a body of regular paid soldiers was raised, which formed the nucleus of the military power of the state, though the old irregular militia was still called out whenever a campaign was to be undertaken. The famous corps of the janissaries (Turkish yeni cheri, i.e., "new troop") was instituted at this time. It consisted of the children of Christian subjects, who were educated as Mussulmans and brought up to a military life.
Having taken the city of Angora from certain territorial lords who, incited by the prince of Karaman, had attacked the Ottoman dominions, Murád I., the son and successor of Orkhan, found himself free to extend his possessions across the Hellespont. He forthwith passed over into Europe, where he and his genezals soon reduced almost all Roumelia, capturing Adrianople, Philippopolis, and many other places of importance. These successes alarmed the Christian princes, who determined to make a vigorous effort to drive the Turks back into Asia. The kings of Bosnia, Hungary, and Servia accordingly marched with a large army upon Adrianople, but were surprised during the night and completely deieated by an inferior Turkish force. Some time after this victory Murad returned to Asia, where he celebrated the wedding of his son Byyezid with the daughter of the prince of Kermiyán, a large portion of whose territory was made over to the 'Osmánli monarch as the dower of the bride. Next year, when Murád set out to inspect his new possessions, he met the prince of Hamid, whom he constrained to sell all his dominions. The Karaman prince, ever the jealous rival of the Ottoman, now stirred up some of the Turkman tribes to ravage his enemy's land; but Murad was beforehand with him, and, entering his country, defeated him and annexed the district of Ak-Shehr to his own kingdon. The Bosnian and Bulgarian princes having allied themselves against the sultan, the Turkish commander in Europe invaded Bulgaria, which was speedily subdued and added to the Ottoman possessions. Murád next entered Servia and advanced to the plain of Kosovo, where he found awaiting him the
levies of Servia, Bosnia, Hungary, Albania, and Walachia. The Turks, though far inferior in number to their adversaries, gained a complete victory, 1389 (791), but it was purchased with their sovereign's life. After the battle Murád was riding over the field with sorne of his people, when a wounded Servian, who was iying among the slain; sprang up and stabbed him so that he died almost immediately afterwards. In consequence of this battle Servia became subject to the Turk.

Báyezid I., surnamed Yildirim, "Thunderbolt,"on accour'九 of the fury of his attack and the rapidity of his movements, received the oath of fealty on the battlefield of Kosovo. He did much to secure the position of the Ottomans, in Europe, taking many of the towns which still remained to the Christians in Roumelia. In Asia he annexed the remaining Turkish principalities, and pushed his conquests as far as Cesarea and Sivás. The Christians made another great effort to free themselves from their Eastern foes: whilst Bayyezid was a'sent in Asia, the king of Hungary led a powerful army, in the ranks of which were many knights of France and Germany, into the Ottoman dominions and laid siege to Nicopolis. Bayezid sped to the rescue, and inflicted an overwhelming defeat on the Christians. He next turned his attention to Constantinople, the reduction and annexation of whick he had long meditated, when he was summoned to meet Timur, the Tatar conqueror, who had invaded his Asiatic. dominions and taken Sivás. The Ottoman and Tatar hosts encountered each other outside Angora, and there the former sustained their first disastrous overthrow, Bayezid being taken prisoner and his army practically annihilated. Next year, 1403 (805), he died in captivity ; the story of his having been imprisoned in an iron cage is not confirmed by the Turkish historians, and is most probably fictitious. After this victory Timúr overran the Ottoman territories in Asia, taking and sacking Brusa, Nicæa, and many other cities. With a view to the complete annihilation of the 'Osmánli power, he restored the independence of the Turkish principalities which Bayezid had annexed, and placed them under the rule of their former emirs.

On the withdrawal of TYmúr from Asia Minor the four surviving sons of Bayezid fought for what was left of their father's kingdom; after ten years of civil war success finally rested with Muhammed, who alone of the four is Muhan reckoned among the Ottoman sovereigns. The attention of the new sultan, whom his people called Chelehi Muhammed or Muhammed the Debonair, was turned rather to the restoration of his father's empire than to the conquest of neighbouring countries. In Europe he lived on amicable terms with the Byzantine emperor, and the Christian kings further north did not venture to make any serious attack upon him. But in Asia he had to contend with many enemies, the most formidable of whom was the emir of Karaman, who, having been defeated and made prisoner, was gencrously pardoned and restored to liberty. Another difficulty with which Muhammed bad to deal was a strange religious outbreak: a vast number of fanatic dervishes, headed by an apostate Jew and a Turkish adventurer of low birth, rose in revolt, and were only dispersed after several bloody battles. This sultan, who was much beloved by his subjects and is spoken of with praise by the Byzantine historians, was stricken wilh apoplexy while riding in Adrianople, and died almost inmediately in the thirt--third year of his age, 1421 (824).

The first care of his son and successor Murád II. was to rid himself of a pretender to the throne who, aided by the Greek emperor, had made a descent upon the Asiatic shore of the Dardanelles. This adventurer was soon defeated and pursued to Adrianople, where he was taken and hanged. In revenge for the assistance rendered to
XXIII. - 8 r
his enemy, the sultan invested Constantinople, but he was compelled to relinquish the siege in order to subdue a revolt headed by his brother, which had broken out in Asia. Murád again annexed all the Turkish principalities which had been restored by Tímúr, except those of Kizil Ahmedli and Karaman, which did not finally become incorporated with the empire till the time of Muhammed II. The Turks were now called upon to face the most formidable Christian enemy they had yet encountered, namely Hunyady, the illegitimate son of Sigismund, king of Hungary. This famous general, after haying inflicted several severe though not very important defeats upon his adversaries, invaded European Turkey with a large army of Hungarians, Poles, Servians, Bosnians, Walachians, and Frankish crusaders, the last-named being under the command of Cardinal Julian. The Ottoman army was utterly routed, Sophia taken, and the chain of the Balkans forced; and Murid was compelled to sign a treaty for ten years, by which he resigned all claims to Servia and gave over Walachia to Hungary. Weary of the cares of state, and thinking that peace was, for a time at least, secured, Murad abdicated in favour of his young son Muhammed and sought a quiet retreat in the town of Magnesia. But he was not allowed to enjoy repose for long: the Christian princes, incited by Cardinal Julian and in direct violation of the treaty, assembled their forces, and, under Hunyady as commander-in-chief, without declaring war, ontered the Turkish dominions and took many of the Ottoman strongholds in Bulgaria. When the news reached Murad he resumed the imperial power, put himself at the head of his troops, and advanced to meet the invaders, who had just captured Varna. Outside that town a great battle was fought, in which a copy of the violated treaty, raised high upon a lance, formed one of the standards of the Ottomans. The conflict, which was long and bloody, resulted in the total overthrow of the Christians, the Polish king, Ladislaus, and Cardinal Julian being among the slain, 1444 (848). Murád again abdicated and sought the retirement of Magnesia ; but once again he had to take up the reins of gevernment. This time the janissaries and sipáhis, accustomed to the firm rule of the victor of Varna, had refused obedience to the young Muhammed. The sultan remained at the head of the state until his death, which occurred in 1451 (855).
Huham- Muhammed II., who now ascended the throue for the mad II. third time, determined to accomplish the long-cherished design of his house, and make Constantinople the capital of the "Osmánli empire. He easily found a pretext for declaring war against Constantine Palæologus and in the spring of 1453 (857) led an immense army to beleaguer Fall of the city. His troops covered the ground before the land-Constan- ward walls between the Sea of Marmora and the Golden tinople.
the Ottomans advanced to storm the city. The Christians offered a desperate resistance, but in vain. The emperor died fighting in the forefront of the battle, and at noon Muhammed rode in triumph into his new capital and went straight to the cathedral of St Sophia; there, hefore the high altar, where the preceding night Constantine had received the Holy Sacrament, he prostrated himself in the Moslem act of worship. The capture of Constantinople is not the only exploit to which Muhammed owes his surname of Fátih, or the Conqueror: he also reduced Servio and Bosnia, overthrew and annexed the Greek empire of Trebizond and the Turkish principality of Karaman, acquired the suzerainty of the Crimea, and won many of the islands of the Greek Archipelago from the Venetians and Genoese. But before Belgrade, which he had besieged as the first step to an attack upon the northern kingdoms, he suffered a serious defeat, leing driven wounded from the field by Hunyady and John Capistran, with the loss of 300 cannon and 25,000 men. Rhodes, whither an Ottoman force was despatched, was the scene of another failure : here the Knights of St John gallantly end suc. cessfully withstood their Muhammedan foes, and compelled them to retire from the island. In Albania a long and for a time, successful resistance was offered to the Turkish arms by the famous George Castriot, the Iskender Beg of the Turks. This chieftain had been in his youth in the service of Murád II., and was by him appointed governor of his native Albania, whereupon he revolted and tried to restore the independence of his country. Among the favourite designs of Muhammed were the subjugation of Italy and the establishment of the Mussulman dominion in the capital of Western Christendom. A Turkish army crossed the Adriatic and stormed the city of Otranto ; but its further progress was stopped, and for ever, by the death of the Conqueror, which occurred a few months later, in 1481 (886). The Muhammedan soldiers besieged in Otranto, being unsupported from Turkey, were, after a long and brave defence, forced to surrender.

Bayezid II. was hardly seated on the throne before he Bay was called upon to face a formidable revolt raised by his IL younger brother Jem. This youthful pretender, who was both talented and high-spirited, was, after a number of adventures, finally compelled to fly the country. He sought the protection of the Knights of St John at Rhodes, who, however, retained him a prisoner, and made an arrangement with Bayezld whereby they received from that monarch a yearly sum of 45,000 ducats as the price of the compulsory detention of his brother. After thirteen years of captivity the unfortunate prince was murdered by Pope Alexander VI. (Borgia), who, it is said, received 300,000 ducats from the sultan as the reward of his crime. Though frequently compelled to engage in defensive wars, Bayezid was of a peace-loving and unambitious disposition, and a few torms in the Morea were all the additions made to the empire while he was on the throue. It was during his reign, however, that the Ottoman fleet began to be formidable to Christendom, the desperate battle off Sapienza, won by Kemál Re's against the Venetians, being the first of the Turkish naval victories over the Mediterranean powers. Báyezid, whose paoific habits had alienated the sympathies of the janissaries, was in 1512 (918) forced by these dreaded guards to abdicate in favour of Sclim, the youngest of his three sons. This prince had already been in open revolt against his father; but his determined and warlike character had won for him the esteem of the Turkish pretorians. Báyezid's hcalth, which had long been failing, gave way under this blow : and the old sultan died three days after his deposition, at a little village on the way to Demitoka, whither he was going to end his life in retirement.
Selím I. was personally the greatest of the Ottoman
monarchs: lis unfinching courage and tireless rigoir were not more remarkable than his political sagacity and his literary and poetic talents; but so merciless was he that he has altrays been known in Turkish history as Yawuz Selím or Selim the Grin. Happily for Europe he turned his attention to the neighbouring Juhammedan states and left the Christian powers in peace. Having caused both his brothers to be put to death, he marched against Persia, the king of which country had given refuge to the family of one of the hapless Turkish princes. The quarrel between them was further embittered by religious hatred: the shath of Persia was the pillar of the Shi'ites, as the Ottoman sultan was of the Sunnites. Selim in his fanatical zeal had ordered a massacre of his Shi'ite subjects, in which forty-five thousand persons suffered death. The sháh was eager to avenge the slaughter of his co-religionists. The janissaries showed signs of insubordination upon the march, but Selím resolutely maintained order and reduced them to submission. At length they came upon the Persian host drawn out on the plain of Chaldiran, where a great battle was fought, which ended in the rout of the Persians and left the way to Tabriz, the residence of the Persian king, open to the sultan. Thither Selím proceeded; but eight days later he set out on his homeward march. The battle of Chaldiran brought no addition of importance to the empire; but the districts of Diyár-Bekr (Diarbehr) and Kurdistan, through which the army bad passed on the way to Persia, were completely suldued and annexed to the Ottoman dominions. Selin's next important campaign was against the Menlúks of Egypt. This hody of Easterif chivalry offered a most gallant resistance to the 'Osmanlis; bur, possessing no artillery, which they disdained as unbeconing men of ralour, they were defeated in a series of ergagements, and Selím and his army entered Cairo as conqueroro in 1517 (923). The results of this war were momentous and far-reaching: the Ottoman empire was greatly increased by the addition of Egypt, Syria, and the Hejaz, of all of which the Memluks lad been lords; the caliphate of Islám was won for the house of 'Osmán, Selím constraining the representative of the old 'Abbasid family, who resided, a purely spiritual prince, at Cairo, to make over to him and his heirs the rights and privileges of the successors of the Prophet. The sultan at the same time acquired from hin the sacred banner and other relics of the fonniler of Islam, which had been handed down to the Arabian prince from his fathers, and which are now preserved in the seraglio at Constantinople. On his return Selím set himself to strengthen and improve his fleet, doubtiess with a view to the conquest of Rhodes. He died, however, in 1520 (926), before his extensive preparations were completed. This sultan reigned only eight years, but in that short time he almost doubled the extent of the Ottoman empire.
Suleymán I., who succeeded his father Selim as sultan, bad not been long on the throne before he fonnd himself involved in a war with the king of Hungary. He marched northwards with a powerful army and wrested from the enemy several places of importance, including the strongly fortified city of Belgrade. Having left a large garrison. in this city, which was regarded as the key to the Christian lands north of the Danube, the sultan returned to Constantinople, where he continued his father's work of creating a strong and efficient Ottoman. fleet. When all was ready Suleymán set out for Rhodes, determined to mipe a way the disgrace of his ancestor's second failure, as he had done clat of his first. The conquest of Egypt had, moreover, rendered the possession of Rhodes necessary to the Turks, as the passage between Constantinople and their nerr acquisition conld never be safe so long as that island reuained in hostile hands. The Knights of St

John met the attack in a manner worthy of their illustrious order; but the overwhelming force of the Ottomans and the hopelessness of any relief compelled them to accept the sultan's terms. These were highly honourable to the defenders, who were permitted to retire unmolested, whilc. Suleymán pledged himself to respect the Christian religiori in the island, which now, 1522 (929), became his. Four years after the conquest of Rhodes the sultan again invaded Hungary, where in the renowned battle of Mohacz he annihilated the army of the Magyars and slew their king. Thence he marched along the Danube to BudaPesth, which opened its gates to him, and there he rested a little while before starting on his homeward way. The disturbed state of Asia Minor hastened Suleymann's departure; but in three years ( 1529 ) he was back at Buda, ostensibly as the ally of Zapolya, an Hungarian who claimed the throne left vacant by Louis, who fell at Mohacz. Ferdinand of Austria bad opposed the claim of Zapolya, who thereon had applied to the sultan for aid, which that monarch was most willing to accord. The troops of Ferdinand being driven from Buda, Suleymán, accompanied by his protégé, adranced upon Vienna. On 27th September 1529 the rast Turkish host, under the personal command of one of the greatest of the family of 'Osman, laid siege to the capital of the German empire, and on the 14th of the following month, after a most desperate assault carried on for four days, the invaders were compelled to retire, leaving the city in the possession of its heroic defenders. The terrent of Turkish military might had now reached its northern limit: once again it vainly swept round the walls of Vienna, but further it never went. Suleymán next directed his arms against Persia, from which country he won a large portion of Armenia and 'Irák as well as Baghdád, the old capital of the 'Abbásid caliphs. In 1542 be was again in Hungary, having been appealed to by the widow of Zapolya on behalf of her infant son against the pretensions of Ferdinand. Suleyman promised to place the child upon the throne when he should be of a proper age ; in the meantime he treated Hungary as an Ottoman province, dividing it into sanjaks or military districts, and garrisoning Buda and other important cities with Turkish troops. Six years later a truce for five years was concluded between the sultan and Ferdinand, whereby almost all Hungary and Transylvania were made over to the former, who was also to receive a yearly present, or more correctly tribute, of thirty thonsand ducats. The Turks, now at the zenith of their power, were the terror of all around them. The achievements of the Ottoman nary during the reign of Suleymán were hardly, if at all, less remarkable than those of the army. Khayr-ud-Din, the Barbarossa of the Europeans, won Algiers for Turkey, and held the Mediterranean against the fleets of Spain and Italy ; Torghud added Tripoli to the empire ; and Piyala routed the gaileys of Genoa, Florence, Naples, and Malta off the isle of Jerba. But fortune did not always smile upon the crescent. In 1565 (973) Suleymán sustained the second great check he was destined to encounter. The Turks once more measured swords with the Knights of St John and drove them from Malta, which had neen given to the order by Charles $V$. on its expulsion from Rhodes. A powerful Turkish army and fleet, commanded by officers of renown, were accordingly despatched to win Mfalta for the Otteman crown ; but so valiantly was it defended that the Turks were forced to withdraw with a loss of twenty. five thousand men. Suleymán died in harness. In 1566 (974), when seventy-six years of age, he entered Hungary for the last time, summoned thither to aid his vassal, young Sigisnıund Zapolya. Sziget, a place which had foiled the Turks on previcus ocrasions, was the first object of attack Count Zrinyi, the eovernor, determined to resist to the last
so the Ottomans found themselves compelled to undertake the siege of this comparstavely unimportant town. There on the night of 4 th Septentber the great sultan died, and a few hours later Count Zrinyi and his brave companions perished amid the smoking ruins of the fortress they had most nobly held. Under Suleymân I., whom European historians call the Magnificent, but whom his own people style Kánunín or the Lawgiver, the Turkish empira attained the summit of its power and glory. The the great disasters, at Vienna and Malta, were eclipsed by the number and brilliancy of the sultan's victories, by which large and important additions were made to the empire in Europe, 'Asia, and Africa.

Selim II., the unworthy son and successor of the Magnificent Suleymán, was the first Ottoman monarch who shran!s from leading his army in person. He was a man of mean and ignoble character, whose sole pleasure seems to have consisted in the indulgence of his degraded tastes and vicious appetites. The first conflict between the Turks and the Russians occurred in his reign. In view of a threatened war with Persia, the grand vizier Sokolli conceived the idea of uniting the rivers Don and Volga by a canal, by means of which an Ottoman fleet could be sent into the Caspian. But in order to carry out this scheme it was necessary that the town of Astrakhan should be in the hands of the Turks. A considerable force was acco Iingly despatched from Constantinople to take possession of that city; but the Russian army which Ivan the Terrible sent to its relief drove back the Turks and their Tatar allies from before the walls, 1569 ( 977 ). Cyprus was the next object of attack. This island, which belonged to Venice, was assailed and taken, though not without heary loss, at a time of peace between the republic and the Porte, 1570-71 (978). The Christian powers of the Mediterranean were roused and alarmed by this act of treachery, and a maritime league was formed through the efforts of Pope Pius V., with Spain, Venice, and Malta for its most important members. On 7th October 1571 the Christian fleet, under the command of Don Joha of Austria, encountered the Ottoman ships, led by the galley of the kapudan pasha, Mu'ezzin-záda 'Ali, just outside the Gulf of Lepanto. A furious conflict ensued, which resulted in the utter defeat of the Turks, their admiral being killed and their fleet almost annihilated. This famous fight, although it brought little immediate material advantage to the victors, was of the highest moral value to them ; for it broke the spell of Barbarossa, and showed that the Ottoman was no longer invincible on the seas. The only other event of importance during this reign was the final conquest of Tunis for Turkey by Kilij 'All, who won it from the Spaniards in 1574 (982). Selím II. died miserably the same year.

Murad III., who now succeeded to the Ottoman throne, was no improvement upon his father; he ruled in name only, all real power being in the hands of worthless favourites. As a natural consequence the empire began rapidly to decay ; corruption infected all ranks of official society, the sultan himself selling his favours for bribes; while the other great curse of old Turkey, military insubordination, showed itself in a more threatening aspect than ever. ;The janissaries mutinied on several occasions, and each 'time compelled the weak Murad to accede to their demand. Notwithstanding this wretched state of affairs, some extensive and important, though not permanent, additions were made to the empire. These, consisting of Azerbijan and Georgix-the latter had been in alliance with Persia-were the risult of a campaign against the last-named country, the muernal condition of which was then even worse than that of Turkey. Transylvania, Moldavia, and Walachia rose in revolt, encouraged by the war which broke out in

1593 between Turkey and Austria. Iu 1594 hostilities with Persia were resumed; and early in the followiug year Murad died, leaving the empire to his eldest son Muhammed III.
Things had been going very badly in the war with Austria, when in June 1596 the grand vizier and the muful, joining their voices with that of Sa'd-ud-Dín the historian, prevailed upon the new sultan, whose character resembled only too closely that of his father, to place himself at the head of the Ottoman army which was about to march into Hungary. Four months later Muhammed met the imperialists under the archduke Maximilian, and the Transylvanians led by Prince Sigismund, on the marshy plain of Keresztes, where a battle lasting three days took place. Although at one time things looked so hopeless for the Turks that the sultan would have fled but for the entreaties and remonstrances of Sa'd-ud-Din, the 'Osmanlis gained a complete and decisive victory. But nothing came of it; for Muhammed, instead of following up his success, hastened back to Constantinople to receive the congratulations of his courtiers and to resume his indolent and voluptuous life. Nothing else worthy of note occurred during his inglorious reign. He died in 1603 (1012).

Muhammed III. was the last heir to the Ottoman throne who was entrusted with the government of a province during his father's lifetime ; henceforth all the sons of the sultan were kept secluded in a pavilion called the Kafes or cage in the seraglio gardens. This new system, which was necessarily very prejudicial to the character of the future rulers, had its origin in the same dread of rivals that caused a sultan in those times to pat all his brothers to death immediately on his accession.
The reign of Ahmed I . is not marked by any event of Abmald importance. The peace of Sitavorok (Zsitvatorok) between Turkey and Austria, 1606 (1015), made no change of any moment in the territorial possessions of either power, but is interesting as being the first treaty in which an Ottoman sultan condescended to meet a Christian prince on a footing of equality. Hitherto the Turkish monarchs had affected to grant merely short truces to their European enemies. But this peace was to be permanent ; the annual payment or tribute of thirty thousand ducats by Austria was to be discontinued; and the ambassadors sent from the Porte were now to be officials of rank, and not, as formerly, menials of the palace or camp.

Ahmed died in 1617 (1026) and was succeeded by his Mustafo brother Mustafa I. Up till this time the succession had I. been regularly from father to son; but, as Mustafa's life had been spared by his brother on his accession, that prince now ascended the throne in preference to 'Osmán, the eldest son of Ahmed I . This arose from the peculiar nature of the Turkish law of succession, which gives the throne to the eldest male relative of the deceased sovereign. Mustafa was, however, imbecile ; so after a reign of three months he was deposed, and his nephew 'Osmán, though only fourteen years of age, seated on the throne in his stead.

An unsuccessful war with Persia, which had been going on for some time, was now brought to an end by a treaty which restored to the shah all the territories conquered since the days of Selim II. In 1621 the sultan !ed nis troops against Poland, partially with the Jiew of weakening the janissaries, whom he justly regarded as the most deadly enemies of his cmpire. This expedition was not attended by any important results, neither Tuiks nor Poles gaining a decisive advantage. On his return 'Osmán formed another plan for freeing himself from his tyrannical soldiery: he gave out that he was going to make the pilgrimage to Mecca, but his real intention was to proceed only as far as ${ }^{5}$ amascus, there place himself at the hear
of an Asiatic army, and march against the janissaries and sipshis in Constantinople. But the janissaries heard of this design and rose in revolt. Incited by a vizier whom -Osmán had deposed, they seized their sovereign and dragged him to the state prison of the Seven Towers, where shortly afterwards he was foully'murdered by the traitor minister, 1622 (1031).

The wretched Mustafa was again raised to the throne, only to be deposed fifteen months afterwards in favour of Murád, the eldest surviving brother of 'Osmán.

In Murad IV., who succeeded to the supreme power in 1623 (1032), when a child of eleven years, Turkey bad once more a sultan of the old 'Osmánli type. Since the death of Suleymán the empire had been cursed with a succession of rois fainéants, under whom it bad rapidly fallen to decay. The vigour and courage of the new sultan stayed it for a while upon its downward course, and reatored to it something of its bygone glory. While still quite young, Murád had been compelled by the mutinous janissaries to deliver into their cruel hands his favourite vizier, Háfiz Pasha. This embittered him against that corps, and, when soon afterwards the soldiers began openly to discuss his deposition, Murad swiftly and suddenly cut off the ringleaders and all others whom he suspected of disloyalty; this struck fear into the bearts of the disaffected soldiers, who, finding themselves without any to organize or direct them, returaed to their allegiance. Murad next turned his attention to checking the intolerable corruption and abuses which pervaded every department of the state. He had but one simple though terribly drastic method of reform,-the execution of every official whom he even suspected of any malpractice. Having restored some sort of order in his capital, Murád marched against Persia and recaptured the city and district of Erivan. In 1638 (1048) he undertook a second and more important campaign against the same power. His object was the recovery of Baghdád, which had been taken by the shâh's troops some sixteen years before. The Persians resisted long and gallantly, but at length the Turks carried the city by storm, when Murad disgraced himself by the slaughter of a vast number of the inhabitants. By the peace which followed Turkey restored Erivan to Persia, but retained Bagbddd, which has been in its hands ever since. Murad on his return entered Constantinople in triumph. This sultan died in 1640 (1049); his death is said to have been hastened by habits of intemperance, which he had contracted towards the close of his life.

Ibrabim, the brother of the late sultan, now mounted the Ottoman throne. He was another of those wretched princes who gave themselves up to the indulgence of their own follies and vices without bestowing a thought upon the welfare of their people or the prosperity of their country. All the evils that had been curbed for a time by the stern hand of Murád broke out afresh and in worse form than before. The sultan himself was the most venal of the venal. Shut up in the seraglio, he thought of nothing but the gratification of his own and his favourites' caprices; gem-encrusted coaches and pleasure-boats, and carpets and hangings of richest sable for his rooms, were among the objects for which he plundered his people and sold every office to the highest bidder. This went on for eight years, till at length his subjects, weary of his cxactions and tyranny, deposed him, and made his son Muhammed, then only seven years of age, sultan in his room. The only events of note that occurred during Ibrahín's tenure of power are the capture of Azoff from the Cossacks and the occupation of Crete. This island, which was then in the hands of Venice, was soon overrun, but it was not till well on in the next reign, after a siege of twenty years, that the Ottomans succeeded in taking Candia the capital.

The mirority of Muhammed IV., who became sultan in 1648 (1058), was marked by all the troubles and evils that might have been anticipated, until the grand vizierate was conferred on Köprili Muhammed in 1656 (1067). This statesman, who was seventy years old when he entered upon the duties of prime minister of Turkey, was the founder of an illustrious family of viziers, whose integrity and strength of character did much to counteract the per nicious influence of degenerate sultans and to prop up for a season the declining empire. Old Köprili accepted the unice of grand vizier only upon condition of receiving absolute power; this be employed much in the same way as Murád IV. had done when he set about the work of reform: he executed every one who fell under his suspicion. He died in 1661 (1072), leaving the vizierate to his son Fázil Ahmed. Alimed was, like his father, a man of great ability, and happily for Turkey he enjoyed the complete confidence of the young sultan, who cared for nothing but the chase, whence he is called in the Ottoman histories Avji Muhammed or Muhammed the Huntsman. Before long Ahmed was called on to lead the Turkish army against Austria. He took Neuhäusel and several places of little importance ; but near the convent of St Gotthard (on the Raab) he was completely defeated in 1664 (1075) by a smaller Christian force under Montecuculi. A truce for twenty years on the basis of the treaty of Sitavorok was the result of this battle; the Ottomans, however, retained Neuhäusel. Ahmed next appeared in arms in Crete, for the purpose of bringing to a close the siege of Candia, which had been going on ever since 1648 ; but it was not till other three years bad passed that the brave garrison opened the gates to the grand vizier, in 1669 (1079). The sultan himself was induced to bead the next campaign, which was undertaken on behalf of the Cossacks of the Ukraine, who had craved the protection of the Porte against Poland. The Turks took the cities of Kamenetz and Lemberg, whereupon King Michael sued for peace, 1672 (1083), and promised to make ove= Podolia and the Ukraine to Turkey and to pay an annual tribute of 220,000 ducats. The sultan accepted these terms and returned home in triumph; but the Poles refused to be bound by them, and under the command of Sobieski they attacked and defeated the troops of Ahmed Pasha. The war lasted till 1676, when it was brought to an end by the treaty of Zurawno, which left the sultan in possession of Podolia and almost all the Ukraine. Three days after this peace was signed Ahmed Pasha died. Few men bave done more to ruin their country than Kara Mustafa, who succeeded Ahmed in the grand vizierate. His pet scheme was the conquest of Germany and the establishment of a great Turkish province between the Danube and the Rhine, with bimself as nominal viceroy but virtual sovereign. He accordingly marched with an enormous army, probably not far off half a million strong, against Vienna. In the summer of 1683 (1094) this mighty host appeared before the walls of the Austrian capital. For an account of the siege, see vol. xix. p. 296. A few weeks after his discomfiture Ķara Mustafa was executed at Belgrade by the sultan's orders." Venice and Russia now declared war against Turkey; misfortune followed misfortune; city after city was rent away from the empire; the Austrians were in possession of almost the whole of Hungary, the Italians of almost all the Morea. At length a severe defeat at Mohacz, where Suleymán had triumphed years before, exhausted the patience of the soldiery, and Muhammed IV. was deposed in 1687 (1039).

The first year of the reign of Suleymann II., who succeeded his brother, was marked by a serious mutiny of the janissarics of the capital, who, aided by the dregs of the population, created a reign of terror_in Coustantinonle.
during which they pillaged the palaces of the principal officers of the government and murdered the grand vizier, along with many of the members of his household. The Anstrians, under Charles of Lorraine, Louis of Baden, and Prince Eugene, were carrying all before them in the norith: Erlau, Belgrade, and Stuhlweissenburg fell into their hands; and by the end of 1689 the Ottomans had lost almost all their former passessions beyond the Danube. Meanwhile the Venctian leader, Morosini, was equally successful in the Morea, completing the conquest of that province, which he added to the dominions of St Mark. When matters had come to this pass, the sultan summoned an extraordinary meeting of the divan to consult on the measures to be taken to mect the danger threatening on every hand. By the unanimous advice of his ministers, Suleymán appointed to the grand vizierate Köprili-zida Musṭafa, another son of old Köprili Muhammed, This statesman, whe had been trained in the duties of office under his father and brother, worthily upheld the high name of his house. He gave up the whole of his gold and silver plate to be coined into money wherewith to pay the troops; he sought out the best men to fill positions of trust and responsibility in the arny and navy ; and he exercised and encouraged a wise and just policy of toleration tewards the Christian subjects of the sultan. Such was the cenfidence which his high character and illustrious connexion inspired that large numbers of volunteers bastened to join the Turkish hosts; and in a very few weeks from the time when he took command of thi army Mustafa had driven the Austrians out of Servia, and Belgrade once more received a garrison of Ottoman troops. Mustafa returned in triumph to Constantinople, where, early in the summer of 1691 (1102), Suleymán II. died, and was succeeded on the throne by his brother Almed II.
The most important event which occurred during the brief and disastrous reign of this monarch was the defeat and death at Slankamen (Szlankament) of Köprili-záda Mustafa, who in Angust 1691 advanced from Belgrade to attack the Austrians under Louis of Baden. The unfortunate result of the battle was in great measure owing to the rashness of the vizier, who, in opposition to the advice of the oldest and most experienced of his officers, refused to a wait behind the lines the attack of the enemy. The Ottomans fought with desperate courage; but the day was decided against them by the death of Mustafa, who was shot while cutting his way through the Christian ranks. Almed II. reigned for four years, during which the hapless empire, besides continuing to suffer defeat at the hands of foreign foes, was visited with the curses of pestilence and domestic insurrection.

On the death of Ahmed II. in the year 1695 (1106) Mustafa II., son of Muhanmed IV., was girt with the sword of 'Osman. The new sultan, aware of the pitiful condition to which the empire had sunk, in part, est least, through the negligence and indifference of bis predecessors, resolved to restore the old Ottoman usages, and placed himself at the head of his armies. His first campaign was altogether successful: he recaptured several important fortresses and totally defeated a great Austrian army. During the following winter he worked hard to repair the finances and bring the forces of the empire into a higher state of efficiency; and, when he set out in the spring against the Austrians, fortune continucd to smile upon his banners. He defeated the duke of Saxe, raised the siege of Temesvar, and strengthened the garrisens of thcse fortresses which Turkey still held in Hungary But in the next year, 1697, all was changed : Prince Eugene was at the head of the Austrians, and on the banks of the Theiss, near Zenta, the Turks sustainod an overwhelming defeat, which compelled the sultan to
retreat to Temesvar. Thence he returned to Constantinople, and never again led an army against the enemy. Recourse was once more had to the house of Köpriii, and Amuja-zàda Huseyn, a nephew of old Köprili Muhammed, was promoted to the grand vizierate. Huseyn raised fresh troops; but he saw that what was really needful was peace, and this he succeeded in bringing about. At Carlowitz on 26 th January 1699 a peace was arranged, through the intervention of England and Holland, between Turkey on the one hand and Austria, Venice, Russia, and Poland on the other. The basis of the treaty, agreed to with certain modifications, was that each power should retain the territories in its possession at the time of opening negotiations. This arrangement left Austria in possession of Transylvania and almost all Hungary and Slavonia; Venice remained mistress of its conquests in Dalmatia and the Morea; Poland received Podolia; and Russia, which under Peter the Great was only now becoming conscious of its strength, retained Azoff. which it had wrested from Turkey three years before. Huseyn Pasha took advantage of the restoration of peace to check the disorders which had sprung up in various parts of the empire, and to endeavour to effect much-needed reforms in many departments of the state. But unfortunately his efforts were thwarted by others less disinterested than himself; and, broken-hearted by the calamities of his country, he retired from office three years after the peace of Carlowitz, and very shortly afterwards died. Musțafa II. very soon followed the example of his minister, and abdicated in 1703 (1115) in favour of his brother Ahmed III.

Although the peace of the empire was often broken during his reign, Ahmed 11I. was not of a warlike disposition, and all the representations and entreaties of Charle XII. of Sweden, who after the disaster of Pultowa had taken refuge in Turkey, failed to induce him to re-open hostilities with the czar. In 1710 Nu'mán Pasha, son of Amuja-zada Hnseyn, and the last of the Köprili family, was appointed grand rizier. Though able and tolerant, he was so much addicted to interfering in the business of his subordinates that he became the object of general dislike, and was dismissed from his office after holding it for fourteen months. The menacing preparations of Russia in the south had more infiuence with the Porte than the prayere of the Swedisi king, and in 1711 the new grand viziti, Baltaji Muhammed, marched into Moldavia to meet the forces of Peter the Great, who had formed an entrenched camp near the village of Hush, on the right bank of the Pruth. Here the vizier blockaded him, and after two days' severe fighting compelled him to surrender nith all his army. By the treaty which followed the czar pledged bimself, a mong other things, to restore the fortress of Azof and all its dependencies to the sultan, and to grant the king of Swedcn a free and safe passage to his own country through the Muscovite deminiens. The lenity of Baltaji Mubammed in not destroying the czar and his army when they were within his grasp caused such discontent at Constantinople that he was dismissed from the vizierate, which was conferred on 'Alí Pasha, known as Dámád 'Ali or "All the Son-in-Law, from ine circumstance of his having married a daughter of the sultan. This vizier distinguished himself by winning back from Venice the whole of the Morea in a single campaign (1715). His next venture, a war against Austria, undertaken in the following year, had a very different issue, he himself being slain and his army routed in a great battle at Peterwardein. Next yeas Prince Eugene, the copqueror of Dámád 'Alí, laid siege to Belgrade, which he forced to capitulate after driving off a large army sent by the Turks to its relief. These events led to the peace of Passarowitz in 1718, by which Austria acquired that portion of Hungary which had remained in
the possession of Turkey, as well as extensive territories in Scrvia and Walachia. The grand vizier Ibrahim, another son-in-law of the sultan, who was at the head of affairs from 1718 to 1730 , conurived to secure for the enpire an unusually long respite from internal disorders; but the sultan's love of costly pomp and splendour and the luxurious magnificence of his court rendered him so unpopular that, in consequence of a riot in the autumin of $1730(1143)$, he voluntarily abdicated the throne, and his nepherw Malunúd I. became pádishâh in his stead.
(Е. J. т. с.)

## History from 1718.

With the treaty of Passarowitz the Tenetian repullic disappears from the scene of Turkish warfarc. Russia gradually becomes a more formidable enemy than Austria; and the subject Christian races imperceptibly enter on the first stages of national consolidation and revival. After the long and resultless war with Tersia hostilities again broke out with Russia in 1736 Marshal Munnich stormed the lines of Perekop and devastated the Crimea; bit he was unable to maintain bis amm there and retreated with greatly diminished forces. Azof was taken by General Lascy; and in the following year Otchakoff fell into the hands of Münnich, while the Crimea was again invaded and ravaged. Austria now joined Russia, and the Porte had to sustain a war in Servia and Bosnia as well as on the coasts of the Black Sea. The double combat was carried on with very different results. While the Russians won victory after victory, and finally penetrated into the beart of Moldavia, the Anstrians were defeated and driven across the Danube. On their advancing from Belgrade in the summer of 1739 they were defeated with great loss at Krotzka, and compelled to sue for peace. The treaty of Bclgrade, which was signed on 1st September 1739, zestored to the Porte Belgrade and Orsova, with the portions of Servia, Bosnia, and Walachia which it had ceded to Austria at the peace of Passarowitz. Russia, unable to continue the war with a victorious Turkish army ready to fall upon its flank, had to conclude peace on very moderate terms. It received Azoff, but under a stipulation that the fortifications should be razed, and that no Russian vessels of war should be kept either on the Black Sea or on the Sea of Azoff. The peace was the last advantageous one made by the Porte without allies; and the succeeding thirty years were on the whole a period of respite from misfortune.
After this followed the wars with the empress Catherine, before whose genius and resources it seemed as if Turkey must inevitably sink into nothingness. The first contest was provoked by the armed intervention of the enp,ress in Polish affairs and her well-known intrigues with rebellious subjects of the Porte. War was rashly declared by Mustafa III. in October 1768. In 1769 the Russians entererl Moldavis and captured the fortress of Choczin (Chotim); in the following year their armies made good the conquest of Moldavia and Walachia, while a fieet from the Baltic entered the Greek Archipelago and landed troops in the Morea. The Greeks of the Morea rose in insurrection; they were, however, overpowered, and the sinall Russian force withdrew, leaving the Greeks to the vengeance of their conquerors. At sea the Turks suffered a scvere defeat near Chios, and their fleet was subseqnently blockaded and set on fire in the Bay of Tchesme, the principal officers in the Russian navy being Englishmen. Assistauce was, moreover, given by the Russians to Ali Bey, a Mameluke chieftain who was in rebellion against the Porte in Egypt, and to Tahir, a sheikh who had made himself indlependent at Acre. In 1771 the Russians intaded and conqnered the Crimea. Anotria now took alarm, and signed a convention with the Porte preparatory to armed interiention.

But the partition of Poland reunited the three neighbouring Cliristian powers and prevented a general war. An armistice was agreed upon between Russia and the Porte, and negotiations followed. These were broken off in 1573. The Russians crossed the Dannbe, and, though unsuccessful in their attempts upon Silistria and Varna, so completely defeated the Turkish forces in the field that on 21st July $1 i$ iit the Porte conclnded peace at KutchukKainardji under conditions more unfarourable than those which it had rejected in the previous year. The Tartar territory of the Crimea, with Kuban and the adjoining districts, was made into an independent state, Russia retaining Azoff, Kertch, and Kinburn. Moldavia and Walachia were restored, but on the condition that, as occasion might require, the Russian minister at Constan tinople might remonstrate in their favour. Russia, in fact, was given a species of protectorate over these provinces. Permission was given to Russia to erect a church in Constantinople, and the following engagenent was made: "The Porte pronises to protect the Christian religion and its churches ; and it also allows the court of Russia to make upon all occasions representations as well in favour of the new church at Constantinople as on belalf of its ministers, promising to take such representations into consideration." Out of this clause arose the clain of Russia to the riglt of protection over all the Christian suljects of the Porte, though the specific right of intervention was clearly attached only to a single church and its ministers. By other clauses in the treaty the obligations restraining Russia from making fortifications and placing ships of war on the Black Sea were annulled. It received the right of free navigation for its merchant ships on all Turkish waters, and the right of placing consuls at all Turkish ports. These last two conditions were of great historical importance through their effect upon Greece. The consuls appointed were usually Greek traders, and permission to carry the Russian flag was indiscriminately given to Greek vessels. Hence there followed that great development of Greek commerce, and of the Greek merchant nary, which in half a century made the insurgent Greeks more than a match for the Turks at sea

The stipulation that the Crimea and adjoining districts should be made into an independent state was of course not inteaded by Russia to be anything more than a reil for annexation; and in 1783 Catherine united this territory to her dominions. She had now definitely formed the plan of extinguishing Turkish sovereignty in Europe and placing her younger grandson on the throne of a restored Greek kingdon. The boy was named Constantine, bis whole education was Greek and such as to fit him for the throne of Constantinople. Joseph II. of Austria threw himself eageriy into the plan for a partition of the Ottoman enpire, and in 1788 followed Russia into war. While the Russians besieged Otchakoff, Joseph invaded Bosnia; but he was unsuccessful and retired ingloriously into IIungary. Otchakoff was stormed by Suwaroff on 16 th December 1788. In the following year the Turkish armies were overthrown hy Suwaroff in Moldaria and by the Austrian Laudan on the south of the Danube. The fate of the Ottoman empire seemed to tremble in the balance; it was, however, saved by the convulsions into which Joseph's reckless allocracy had thrown his own dominions, and by the triple alliance of England, Prussia, and Holland, now formed by Pitt for the preservation of the balance of power in Europe. Joseph died in 1790; his successor Leopold II. entered into negotiations, and concluded peace at Sistova in August 1791, relinquishing all his conquests except a small district in Croatia. Catherine contiqued the war alone. 1smail was captured by Suwaroff with tearful slaughter, and the Russian armies pushed on south of the Danuhe. Pitt, with
the triple alliance, attempted to impose his mediation on the empress Catherine, and to induce her to restore all her conquests. She refused, and both Prussia and England armed for war ; but public opinion declared so strongly against the minister in England that it was impossible for him to pursue his plan. Catherine nevertheless found it in her interest to terminate the war with the Porte. Poland claimed her immediate attention; and, adjourning to a more convenient season her designs upon Constantinople, she concluded the treaty of Jassy in January 1792, by which she added to her empire Otchakoff, with the seaboard as far as the Dniester. The protectorate of Russia over. Tifisis and Kartalinia was recognized.

Catherine's successor Panl (1796-1801) made it his business to reverse his mother's policy by abandoning the attack on Turkey. Bonaparte's invasion of Egypt and the destruction of the French fleet by Nelson at the battle of othe Nile led the Perte to join the second coalition against France. Bonáparee, invading Syria, was checked and turned back at Acre, where Jezzar Pasha was assisted in his strenuous defence by an English squadron under Sir Sidney Smith. A Turkish army was meanwhile transported from Rhodes to the Egyptian coast. This army was destroyed by Bonaparte on his return to Egypt at the battle of Aboukir on 25th July 1799, after which Bonaparte set sail for France, leaving the Egyptian command to Kléber. Kléber, cut off from all communication with France and threatened by superior Turkish forces, entered into a convention at El Arish for the evacuation of Egypt. This convention, however, was annulled by Lord Keith, the English admiral, and Kléber replied by giving battle to the Turks and defeating them at Heliopolis on 20th March 1800. Egypt was finally wrested from the French by the English expedition under Abercromby, and restored to the sultan. The Ionian Islands, which France had taken from Venice at the time of the treaty of Campo Formio, were conquered by a combined Russian and Turkish force, and were established as a repualic, at first under the joint protectorate of Russia and the Porte, afterwards under the sole protectorate of Russia. The former Venetian ports on the mainland of Epirus and Albania were given up to Turkey. Somewhat later, under pressure from St Petersburg, the sultan undertook not to remove the hospodars, or governors, of Walachia and Moldavia without consulting Russia, and to allow no Turks except merchants and traders to enter those territories.

On the restoration of peace France reassumed its ancient position as the friend and ally of the Porte. The sultan now on the throne was Selím III. (1789-1807). Though the results of the war of the second cealition had been favourable to Turkey, the Ottoman empire was in a most perilous condition. Everywhere the provincial governors were making themselves independent of the sultan's authority; a new fanatical sect, the Wahhabees, had arisen in Arabia and seized upon the holy places; the janissaries were rebellions and morz formidable to their sovereign than to a foreign enemy; and the Christian races were beginning to aspire to independence. It had seemed for a white as if the first to rise against the Porte would be the Greeis, among whom the revolutionary influcnces of 1789 and the songs of the poet Rhegas, put to death by the Turks in 1798, stirred deep feelings of hatred against their oppressors. Circumstances, however, postponed the Greek revolt and accelerated that of the Servians. In the country immediately south of the Danube the sultan's anthority was defied by the janissaries settled about Belgrade and by Passwan Oglu, ruler of Widdin in Bulgaria. The pasha of Servia, hard pressed by these rebels, called upon the rayas to take up arms in defence cf the sultan. They did so, and in 1804 the janissaries
answered by a series of massacres in the Servian villages. The Servians now rose as a nation against the janissaries. Kara George became their chief, and in combination with the pasha of Bosnia, acting under the sultan's orders, exterminated the janissaries or drove them out of the country. Victorious over one oppressor, the Servians refused to submit to another. They carried on the war against the sultan himself, and at the suggestion of Russia sent onvoys to Constantinople demanding that for the future the fortresses of Servia should be garrisoned only by Servian troops.
When the third European coalition against France was in course of formation Russian and French influences were in rivalry at Constantinople. The victories of Napoleon in 1805 gave him the ascendency, and his envoy prevailed upon the sultan to dismiss, without consulting Russia, the hospodars of Walachia and Moldavia, who were considered to be agents of the court of St Petersburg. This was a breach of the engagement made by the sultan in 1802, and it was followed by the entry of Russian troops into the principalities. England, as the ally of Russia, sent a fleet under Admiral Duckworth through the Dardanelles to threaten Constantinople. While the admiral wasted time in negotiations, the French ambassador, General Sebastiani, taught the Turks how to fortify their capital The English admiral found that he could do nothing, and repassed the Dardanelles, suffering some loss on the passage. The war on the Danube was not carried on with much vigour on either side. Alexander was occupied with the struggle against Napoleon on the Vistula; Selim III. was face to face with mutiny in Constantinople, having brought upon himself the bitter hatred of the janissaries by attempting to form them into a body of troops drilled and disciplined after the methods of modern armies. While the military art in Europe had been progressing for centuries, Turkey had made no other changes in its military system than those which belonged to general decay. Its troops were a mere horde, capable indeed of a vigorous assault and of a stubborn defence, but utterly untrained in exercises and mancenvres, and almost ignorant of the meaning of discipline. Selím was a reformer in government and administration as well as in military aflairs. He broke from the traditions of his palace, and began a new epoch in Turkish history; but the influences opposed to him were too strong, and a mutiny of the janissaries in Constantinople deprived him of his crown. He was allowed to live, but as a prisoner, while the puppet of the janissaries, Mustafa IV., was placed on the throne (May 1807).
A few weeks after this event the treaty of Tilsit cnded the war between France and Russia, and provided for the nominal mediation of Napoleon between Russia and the Porte. A truce followed between the armies on the Danube. Among the Turkish generals who had understood the necessity of Selím's reforms, and who were prepared to support him against the janissaries, was Bairaktar, commander at Rustchuk. As soon as the truce gave him freedom of action, Bairaktar marched upon Constantinople. Leading his troops against the palace, he demanded the restoration of Selím. As the palace gates were closed, Bairaktar ordered an assault ; but at the moment when his troops were entering Selim was put to death. Besides Mustafa there was only one member of the house of Osman remaining, his brother Mahmúd, who concealed himself in the furnace of a bath until the palace was in the hands of Bairaktar's saldiers. He was then placed on the throne (July 1808). For a while Bairaktar governed as grand vizier. He was rash enough, however, to dismiss $I$ rart of his own soldiers from Constantinople. The janissariey attacked him in his palace. A tower in which he defended himself was blown up, and after a battle in the streets of

Constantinople between the janissaries and the remainder of Bairaktar's troops, during which the dethroned sultan Mustafa was put to death, the janissaries remained conquerors, and Mahmúd was forced to submit to their demands. The innovations of the late reign were abolished, and for a while Mahmúd seemed content to reign as servant of the reaction.
It is well known that plans for the partition of the Ottoman empire occupied Napoleon and Alezander at Tilsit. Austria, though unwilling to see Russia aggrandized, was prepared in the last resort to combine with the dismembering powars, if all attempts to prevent the execution of the plan by diplomatic means should fail. But after a few years the alliance declined and a war between France and Russia was seen to be inevitable. Meanwhile the conflict on the Danube had been resumed, and the Servians were still in arms. The Russians had advanced into Bulgaria and captured Silistria. England, which had made peace with Turkey in 1809, sought to reconcile the belligerents, in order that the czar might be free to employ his whole force against Napoleon. In May 1812 a treaty was signed at Bucharest, by which Bessarabia was ceded to Russia, the river Pruth becoming the boundary of the two empires. The Porte in this treaty promised to grant an amnesty to the Servians, to leave to them the management of their internal affairs, and to impose upon them only moderate taxes. These promises, however, were neither accepted by the Servians as a sufficient concession, nor were they observed by the Porte. The Servians continued to fight, and ultimately secured their autonomy about 1817 without help from Russia.

Mahmúd II. (1808-1839) was the only sultan of modern times who possessed the qualities of a great ruler. Brought up in the seclusion of the seraglio till the age of twentythree, when he was suddenly placed on the throne, it is surprising that he should have shown the power, the resolution, and the intelligence which marked his government. The dificulties of his reign were enormous. He belonged to an epoch when the Ottoman empire might fairly be considered as in actual dissolution. This he to some extent arrested, and the reforms which he effected, partial and imperfect as they were, have prolonged the existence of the Turkish state to our own day. The first and most obvious internal danger to be met was the insubordination of the provincial pashas. Against these rebellious servants Mahmúd waged a persistent and unvearying war, now employing them against one another, now crushing them by his own armed force. One of the most forPashs midable was Ali Pasha of Janina, who lad made himself anion master of Albania and part of Greece. When Mahmúd in 1820 threw his armies upon this chieftain, the outbreak of hostilities in Epirus was the signal for the insurrection of Greece. While Eypsilanti, grandson of a hospodar of Moldavia who had been put to death by tho Porte, raised the standard of revolt in Moldaria, asserting that Russia had promised the Christians its support, the Greeks of the Morea rose and exterminated the Turkish population among them. Hypsilanti was soon crushed; and the rising in the Morea was answered by massacres of the Greeks in the principal cities of the empire, and by the execution of Gregory, patriarch of Constantinople, the head of the Greek Church. These deeds of violence excited the utmost indignation in Russia. A despatch was sent to Constantinople, calling upon the Porte to restore the churshes which had been destroyed, to guarantee the inviolability of Christian worship in the future, and to discriminate in its punishments between the innocent and the guilty. These demands were presented as an ultimatum by the Russian ambassador, who, not receiving an answer within the time allowed, quitted Cosstantinuğle (27坞 July 1821) The
infuence of Austria and England, however, restrained the emperor Alexander from declaring war, and the Greeks were left to sustain their combat by themselves. As long as Ali Pasha was unsubdued, the only forces which the sultan could employ against the Greeks were irregular bands of volunteers. It was by one of these hordes that the fearful massacres of Chios, in the spring of 1822, were perpetrated. In that same spring, however, the overthrow and death of Ali set free the regular troops. Two armies of considerable strength now moved southwards frons Thessaly, with the object of reducing the country north of the Gulf of Corinth and then uniting to conquer the Morea. The western army, commanded by Omer Brionis, was checked by the Suliotes, and subsequently beaten back by the defenders of Missolonghi. The eastern army, after advancing under the command of Dramali into the Morea, was compelled to retreat. But the passes in its rear had been seized by the Greeks; on all sides the enemy closed in upon it; and it was only through the disorders of the Greeks themselves that Dramali's force escaped annihilation. Of those who survived the encounter most perished by sickness and famine in the neighbourhood of Corinth. Nor was the fortune of the Ottomans better at sea. The destruction of their admiral's vessel with all its crew by the fire-ship of the Greek captain, Kanaris, caused such terror that all further attempts to reduce the islands were abandoned, and the fieet returned to the Dardanelles.

After an interval of ineffective land warfare, the sultan determined to call upon Mehemet Ali, pasha of Egypt, for assistance. Mehemet had riser to power in the disturbed period that followed the expulsion of the French from Egypt. He had a more powerful fleet than that of his sovereign, and an army disciplined after the European system. In calling upon his powerful vassal for help the sultan must have been aware of the dangers which his aggrandizement would involve. Mehemet eagerly responded Mehemo to Mahmúd's call ; and his son Ibráhím, in command of a Ali's 88 . powerful armament, set sail in. the spring of 1824 from eistance Alexandria against Crete. This island was rapidly con- Tourkey quered, and Ibráhím, after failing in some combined operations against Samcs, crossed over to the Morea. Here he marched across the peninsula, carrying all before him. Nauplia alone maintained its defence, while the Egyptian sent out his harrying columns, slaughtering and derastating in every direction. From the Morea Ibráhím was summoned to assist the Turks, who had been for nine months unsuccessfully engaged in a seennd siege of Missoionghi. Tbráhím began his siege operations in the beginning of 1826; but it was not for three months more that Missolonghi. fell. The tide of Ottoman conquest moved on eastwards, and the acropolis of Athens capitulated in the following year. But the defence of Missolonghi had lasted long enough to bring the powers of Europe into the field. On the death of the emperor Alexander at the end of 1825, Canning sent th3 duke of Wellington to St Petersburg to negotiate conditions of joint diplomatic action on the part of England and Russia. A protocol signed at St. Petersburg on 4th April 1826 fixed the conditions on which the mediation of Great Britain was to be tendered to the Porte. Greece was to remain tributary to the sultan, but to be governed by its own elected authorities and to be independent in its commercial relations. The surviving Turkish population was to be removed from Greece; all property belonging to Turks, whether on the continent or the islands, was to be purchased by the Greeks. This protocol was developed into the treaty of London between England, Russia, and France, signed in July 1827, by which the three powers bound themselves to put an end to the confict in the East. In pursuance of this treaty the mediation of the
powers was offered to the Porte, and an armistice demanded. It was contemptuously refused. The united fleets of the powers consequently appeared before Navarino, where Ibrâ. him was assembling his forces for an expedition against Hydra. After a vain attempt at negotiation, they entered the harbour and fought the battle of Navarino, on 20th October 1827, in which the Turco-Egyptian fleet was totally destroyed. Canning had just died; his successors could only speak of Navarino as an "untoward event" and withdraw from further interference, leaving Russia and the Porte face to face. After a proclamation by the sultan calling the Mohammedays to arms, war was declared by Russia in April 1828. The moment was siugularly favourable for Russia, for Maḥmúd had, little more than a year before, exterminated the janissaries. After bringing over soldiers from Asia to make him secure of victory in the event of a conflict, he had called upon the janissaries to contribute a certain number of men to the regiments about to be formed on the European pattern. The janissaries refused and raised the standard of rebellion. Mahmúd opened fire on them with cannon, and the slaughter did not cease until the last of them bad perished. The great difficulty in the way of a military reorganization was thus removed, and the newly-modelled regiments were raised to about 40,000 men. Small as the army was with which he had to meet the Russian invasion in 1828, the campaign of that year was honourable to the Turkish arms. Though Varna fell into the hands of the Russians, Silistria and Shumla were successfully defended, and the Russians, after suffering great losses, were compelled to withdraw to winter quarters on the Danube. In the following year they advanced through Bulgaria, defeated the Turks at Kulevtcha, and, after the surrender of Silistria, crossed the Balkans under the command of Diebitsch. They reached Adrianople, which immediately capitulated. Diebitsch, concealing the real weakness of his force, sent out detachments towards the Euxine and the Egean, while the centre of his army marched on Constantinople. Had the sultan known the insignificant number of his enemy, he might safely have defied him. But the wildest exaggerations were current in the capital; Kars and Erzeroum had fallen into the hands of Paskiewitch, commander of the czar's forces in Asia; and in Constantinople the friends of the slaughtered janissaries threatened revolt. Mahmud listened to the adrocates of peace, and on 14th September hostilities were brought to a close by the treaty of Adrianople. This treaty gave Russia the ports of Anapa and Poti on the eastern coast of the Black Sea; but its most important clauses were those which confirmed and extended the protectorate of the czar over the Danubian principalities. The office of hospodar, hitherto tenable for seven years, was now made an appointment for life, and the sultan undertook to permit no interference on the part of neighbouring pashas with these provinces. No fortified point was to be retained by the Turks on the left bank of the Danube; no MFussulmau was to reside or hold property within the principalities. The Bosphorus and the Dardanelles were declared free and open to the merchant ships of all nations. The Porte further gave its adherence to the treaty of London relating to Greece, and accepted the act entered into by the allied powers for regulating the Greek frontier. An indemnity in money was declared to be owing to Russia; and by leaving the amount to be fixed by subsequent agreement Russia retained in its own hands the most powerful means of enforcing its influence at Constantinople. The suzerainty over Greece, which the powers had at first agreed to leave to the sultan, was by common consent abandoned, and Greece became an independent kingdom.

At the close of eight years of warfare Mahmu's's southernimost provinces were even more completely severed from
the empire.than Servia and the Danubian principalities. It was in rain that he had borne the humiliation of calling upon his vassal, Mehemet Ali, for help, and Mehemet's reward had now to be paid. Crete was offered to him; this, however, was far from satisfying his ambition, and in November 1831 he threw an army under Ibráhím into Palestine and began the conquest of Syria. The sultan now declared Mehemet and his son to bo rebels, and despatched an army against them. The first encounter took place in the valley of the Orontes. The Turks were put to the rout, and retired into Cilicia. Ibráhím following gained a second victory at the pass of Beylan, and, after crossing Mount Taurus, destroyed the last army of the sultan at Konieh, on 21 st December 1832. In this extremity Mahmuid looked for help to the European powers, and Russia at once tendered its aid At the request of the sultan a Russian fleet appeared before Constantinople. The French ambassador thereupon threatened to quit the capital ; and finally, under French mediation, terms of peace were signed with Ibrâhm at Kutaya (April 1833), the sultan making over to his vassal, not only the whole of Syria, but also the province of Adana between Mount Taurus and the Mediterranean.

Scarcely had this treaty been concluded when Russian influence again won the ascendency at Constantinople, and a treaty of alliance between Turkey and Russia was signed at the palace of Unkiar Skelessi, which in fact reduced Turkey to the condition of a vassal state. The form of the treaty was skilfully framed to disguise the relation of dependence which it created and the rigbt of intervention in the internal affairs of the Ottoman empire which it gave to Russia. Each power pledged itself to render assistance to the other not only against the attack of an external enemy but wherever its peace and security might be endangered. Another article declared that, in order to diminish the burdens of the Porte, the crar would not demand the material help to which the treaty entitled him, but that in lieu thereof the Porte undertook, whenever Russia should be at war, to close the Dardanelles to the war-ships of all nations. The control of the Dardanelles was thus transferred from Turkey to Russia, and the entrance to the Black Sea converted into a Russian fortified outpost. In this treaty, brilliant as it appeared, Russia had gone too far. The Western powers declared that they would not recognize it, and the most strenuous and systematic efforts were henceforth made both by France and England to diminish Russian influence in the East. France, anxious to gain in Egypt a counterpoise to England's naval power in the Mediterranean, made itself the patron and ally of Mehemet Ali. England adhered to the cause of the sultan, and on many occasions showed its hostility to Mehemet. Thns the two Western powers, though both in antagonism to Russia, were directly in conflict with one another in their Eastern policy. Mahmúd in the meantime was steadily preparing to renew the war with his rival. He obtained the services of Moltke and other Prussian officers in organizing his army, and, after a successful campaign against the rebellious tribes of Kurdistan, assembled his troops in the spring of 1839 on the upper Euphrates, and marched against Ibráhím. In the operations which followed the advice of the European officers was persistently disregarded by the pasha in command; and on 24 th June the Turkish army was annibilated by Ibráhím at Nisib. To complete the ruin of the empire, the Turkish admiral, Achmet Fewzi, sailed into the port of Alexandria arid landed over his fleet to Mehemet Ali. The sultan did not live to hear of the overthrow of his hopes. He died in the same week in which the battle of Nisib was fought, leaving the throne to his son 'Abd-ulMejíd (1839-1861).

The very suddenness of these disasters contributed ultimately to the preservation of the Ottoman envire, inasmuch as it compelled the powers of Europe to take action. The French and English fleets appeared in the Dardanelles. The czar saw that it was impossible to maintain the treaty of Unkiar Skelessi, and this treaty was tacitly abandoned. Russia now addressed itself to the task of widening the existing differences between France and England. France insisted on far more favourable conditions for Mehemet Ali than England would allort, demanding that Egypt and all Syria should be given to him in hereditary dominion, with no further obligation towards the sultan than the payment of an annual tribute. Russia and the other powers took part with England, and ultiinately, without asking the sanction of France, the four powers signed a treaty pledging themselves to enforce upon Mehemet the terms proposed by England, which practically reduced him to the position of an ordinary pasha in Palestine, while leaving him the herefitary governinent of Egypt. On the publication of this treaty Thiers, the French minister, prepared for war. He was, however, dismissed by Louis Philippe, and his successor, Guizot, accepted the situation. As Mrehemet Ali refused to give up his conquests, an Anglo-Austrian naval squadron was seut to co-operate with a Turkish force in attacking the coast-torns of Syria. Acre was captured, and Ibráhím, assailed by the mountain tribes of the interior, was forced to retire to Egypt. A convention made between Mehemet and Sir Charles Napier, who had appeared at Alezandria with part of the fleet, formed the basis of the ultimate settlement, by which Mehemet, after formal submission to the sultan, was recognized as hereditary governor of Egypt. Russia now united with the other powers in a declaration that the ancient rule of the Ottoman empire, forbidding the passage of the Dardanelles to the war-ships of all nations, except when the Porte should itself be at war, was accepted by Europe at large.
The young sultan entered on his reign nominally as an independent soverciga, but really under the protection of the European powers. His minister, Reshid Pasha, who had gained in an unusual degree the confidence of Western statesmen, understood the necessity of bringing the Turkish system of government more into harmony with the ideas of the civilized world. An edict, known as the Hattisherif of Gulhane, announced the speedy establishment of institutions "which should insure to all subjects of the sultan perfect security for their livos, their honour, and their property, a regular method of collecting the taxes, and an equally regular method of recruiting the army and fixing duration of sorvice." Scarcely had this edict been published when Reshid was driven from power by a palace intrigue. His reforming efforts, like those of Mahmúd, were not wholly ineffective ; yet little was realized in consparison with what was promised and what was needed.. The Turkish Government was soon discredited, and the intervention of Europe required, by conflicts between the Christian and Mohammedan tribes in the Lebanon, resulting in massacres of the former. After the convulsions of 1848 the sultan incurred the enmity of the autecratic courts by refusing to give up Kossuth and other exiles who had taken refuge within his dominions. The suppression of the national Hungarian Government by Russia ia 1849 had heightened in the emperor Nicholas the sense of his own power. He now looked forward to the speedy extinction of Turkey, and in 1853 proposed to the British ambassador, Sir H. Seymour, a plan for the division of "the slck man's" inheritance as soon as he should expire. Disputes between France and Russia relating to the rights of the Latin and Greek Churches in certain sacred places were made the occasion for the essertion of a formal claim on the part of
the czar to a protectorate over all Christians in Turkey belonging to the Greek Church. This claim not being acknowledged by the Porte, a Russian army entered the Danubian principalities. After ineffective negotiations war was declared by the sultan on 4 th October 1853. Hostilities commenced in Walachia, and the Turkish fleet was attacked and destroyed at Sinope. Englaud and France allied themeelves with the Porte, and landed an army at Varna in the spring of the following year. Silistria was successfully defended by the Turks; and, on the occupation of the Danubian 1 rincipalities by Austria, the allies took up the offensive and transferred their forces to the Crimea. The siege of Sebastopol followed, ending in its capture in Scptember 1855. Meanwhile Russian and Turkish forces were opposed in Asia. Kars maintained a gallant defence, but succumbed to famine tiro months aiter the fall of Scbastopol. The peace of Paris followed, in which Russia ceded to Turkey the portion of Bessarabia adjacent to the mouth of the Danube. The Black Sea was neutralized, Russia and the Porte alike engaging to keep no war-ships and to maintain no arsenals there. The exclusive protectorate of Russia over the Danubian principalities was abolished, and the autenomy of these prorinces, as tell as of Servia, placed under the guarantee of all the powers. The Porte published a firman, the Hatti-Humaiun, professing to abolish "every distinction making any class of the subjects of the empire inferior to any other class on account of their religion, language, and race," and establishiag complete equality between Christians and Mahommedans; the powers in return declared the Porte admitted to the advantages of the public law and concert of Europe. The absurd stipulation was added that no right should thereby accrue to the powers to interfere either collectively or separately iu the relations of the sultan with his subjects.

The Crimean War gave to part of the Balkan population twenty years more of national development under the slackened grasp of the Porte; and by extinguishing the friendship of Austria and Russia it rendered the liberation of Italy possible. But each direct proviso of the treaty of Paris seemed made only to be mocked by events. Scarcely a year passed without some disturbance among the Christian subjects of the sultan, in which the interference of the powcrs incariably followed in one form or another. A new series of massacres in the Lebanon in 1860 caused France to land a force in Syria. Walachia and Moldavia formed themselves into a single state under the name of Roumania, to which the house of Hohenzollern soon afterwards gave a sovereign. Bosnia and Montenegro took up arms. Servia got rid of its Turkish garrisons. Crete fought long for its independence, and seemed for a moment likely to be united to Grecce under the auspices of the powers ; but it was ultimately abandoned to its Turkish masters. The overthrow of France in the war of 1870 and the consequent isolation of England Ied Russia to declare the provision of the treaty of Paris which excluded its ships of war and its arsenals from the Black Sea to be no longer in force. To save appearances, the British Government denianded that the matter should be referred to a European conference, where Russia's will was duly ratified.
A ferr years later the horizon of eastern Europe risibly darkened with the coming storm. Russian influences were no doubt at nork ; but the development of national feeling which had so powerfully affected every other part of Europe during the 19th century could not remain without effect among the Christian races of the Balkan peniasula. In 1875 Bosnia and Herzegovirre revolted. In the meantime the government of 'Abd-ul-Aziz (1861. 1876) had become worse an.l worse. The state was bank rupt. Ignatieff, the Russian ambassador, gained completo ascendency in the palace, and frustrated every ottempt ob
be part of the better Turkish statesmen to check the larrent of misrule. His creature, Mal!míd Pasha, maintaned his place in spite of universal contempt, until a conspiracy was formed at Constantinople. which cost the sultan his throve (301t May 1876) and a fow days later bis life. His imberile euccessor, Murâd V., gave place efter a reigu of three months to "Abd-ul-Hamid II. The Bosuian insurrection had already extended to Bulgaria, and tlie slaughter of the Turkish inhalitants in certain villages bad been avenged hy massacres of the most feariul character. Servia and Montenegro took up arms. "The resources of European diplomacy were exhausted in fruitless attempts to gain from the Porte some real eecurities ior better government, and in April 1877 Rissia declared war. The neutrality of Austria had been secured by a secret agreennent permitting that country to occupy Bosuia and Herzagovina, if Russia should extend its influence beyond the Ralkans. The Bulgarian massacres had excited sueh Lorror and indignation in England that Lord Beaconsfield was forced to remain neutral. The ministry sontented itself with stating that England would not permit Egypt to be the acens of hostilities, nor acquiesce in any prolonged occupation of Constantinople by Russian troops. Turkey was thus left without an ally. The Russians entered Bulgaria in June ; and, while Rnstchuk was besieged, their advaneed guard under Gourko hurried across the Balkans. Meanwhile Osman Pasha, coming from WIddin, occupied and fortified Plevna on the Russian line of march. Against his redoubts the Russians, ill commanded, threw themselves in vain, and Gourko was compelied to fall back on the Shipka Pass. But in December the capture of Plevna, in which Roumanian troops cooperated, set free the invading army, and the march on Constantinople was resumed. The Balkans were passed in mid-winter ; Adrianople was oecupied; and the Turkish armies were captured or annibilated. The Russians now pressed forward to the very suburbs of Constantinople, and on 3d March 1878 peace was concluded at San Stefano. In Asia the Russians had captured Kars and were besieging Erzeroum, The treaty of San Stefano ceded to Russia the portion of Bessarabia taken from it in 1856, together with the 1)obrudja, and also Kars, Batoum, and the adjoining territory in Asia. It recognized the independence of Servia, Montenegro, and Roumania, and largely estended the territory of the first two. Bulgaria was constituted an autonomous state, thongh tributary to the Pcrte, and was defined so as to extend to the Agean Sea and to include the greater part of the country between the Balkans and the coast. Crete, Thessaly, and Epirus were to receive the neeessary reforms at the hands of a European compmission. To this treaty Great Britain refused to givo its assent, and vigorous preparations were made for war. The fleet was at the Dardanelles, and Indian troops were brought to Malta. Russia could no longer connt ou the neutrality of Austria. Under these circumstances the court of St Petersburg consented to submit the treaty to a European congress, which, after a secret agreement had been made between Russia and England on the principal moints of difference, assembled at Berlin. The treaty of San Stefano received various modifications, the princilal being a reduction of the territory inclnded in Bulgaria and the division of that state into two parts. Bulgarin north of the Balkans was convtituted an autonnmons principality ; Bulgaria eonth of the Balkans was marde into $a$ province, with the title of Fastern Rnumelia, sulject to the authority of the sultan, but with a Christian governor and an autonomous administration. Anstria receised Pusnia and Herzegorina. The territory ceded to Servia and Montenegro ly the treaty of San Stefano. as well as that ceded to Russia in Asta, was somewhat diminished.

The Porte was advised to make some cesssun of territory to Greece, and the line of frontier sulsequently recomi mended gave to Greece Janina as well as Thessaly. The usual promises of organic reform were made by Turkey. By a sep,sarate convention England undertook the defence of Asiatic Turkey and received (yprus. The organization of Eastern Roumelia aras duly taken in hanil hy a European commission and lirought to a favourablo conelusion, but it mas not until a naval demonstration had been mads by England that the final cession of Dulcigno to the Monte negrins was effectel, and that Thessaly, without Epirus, was given up to Grecce. Alexander of Battenberg became prince of Bulgaria. By a popular movement in 188.5 Bulgaria and Eastern Rounmelia were united into a single state. This revolution oceasioned the utmost displeasure at St Petersburg; and under Russian infuence Prince Alexander was kidnapped and forced to abdicatis The Porte offered no armed resistance to the union.

## Part II.-Geography and Statistics.

Turkey, or the Ottoman empire (Osmanli Vilaicti), embraces extensive territories in south-eastern Europe, western Asia, and northern Africs, grouped mainly round the eastern waters of the Mediterranean, and slong both sides of the Red Sea, the west coast of the Persian Gulf, and the southern and western shores of the Black Sea. These territories form an aggregate of provinces and 91 tes, some under the dircct control of the oultan, come enjoying a large share of political sutonomy, some practically independent, either administered by foreign powers or rnled by hereditary ₹sssals or tributary princes. The present (1887) extent of the Ottoman empire is about $1,692,150$ square miles, snd its population $42,346,000$.

## Europran Turtey.

1 Since the Russo-Turkish Wsr of 1878 (see shove), the extremely irregular frontiers of European Turkey are conterminous with Greece in the south, and in the north with Montenegro, Austria, Servia, and Roumsnia, being sepsrated from the last country partly by the Danube, partly by a conventional line drswn from Silistria on that river to Mangalia on the Black Ses. By the Berlin congress Roumsnia and Servia, hitherto vassal states, were made absolutely independent kingdoms, Roumsnia st the same time receiving the district of Dobrudja between the lower Danube sud the Black Sca, and Servia those of Nish and Leskovatz about the upper Morava river. Montenegro was also recognized as an independent principality, with an increase of territory, which gave it a ses frontier limited southwards hy the river Boyana, and including the Albanian ports of Dulcigno snd Antiveri on the Adriatic. The Greco-Turkish frontier was also shifted north, Greece obtaining most of Thessaly and a strip of Epirus (couth Albania), so thst since 1881 the border line runs from nesr Mount Olympus on the Gulf of Saloniki ( $40^{\circ} \mathrm{N}$. lat.) west to the Pindus range, then south. west to the Gulf of Arta on the Ionian Sea. A etill more serious step was taken towards disintegration by the withdrawsl of Bulgaris and Esstern Roumelia from the immediate jurisdiction of the Sublime Porte. The former was constituted s tributary principslity, with representative institutions, and Eastern Roumelia was erected into sn antonomous province, both nuder'the guarantee of the Europesn porsers. But in 1885 the latter province declared for union with Bulgaria, and since then these two territories hsve practically formed one state administered from Sophia, Europe assenting and Turkey consenting (imperial Grman of 6th April 1886) on the retrocession to Turkey of the Moslem districts of Kirjali and the Rhodope. In the year 1878 Austria occupied and assumed the civil sdministrstion of the north-western provinces of Bosnia snd Herzegovina, besides taking military possession of the contiguous strategicsl district of Novi-Bazar. The direct possessions of the sultan have thus been redaced in Europe to a strip of territory stretching continuously 3cross the Balkan Peninsula from the Bosphorus to the Adriatic ' $29^{\circ} 10^{\prime}$ to $19^{\circ} 20^{\prime}$ E. long.), and lying in the east mainly between $40^{\circ}$ and $42^{\circ}$ and in the west between $39^{\circ}$ snd $43^{\circ} \mathrm{N}$. lst. It corresponds roughly to ancient Thrace, Macedonis with Chslcidice, Epirus, and a large part of Illyria, constituting the present administrative divisions of Stambul (Constantinople, including a small strip of the opposite Asiatic coast), Edirneh (Adrianople), Saloniki with Kosovo (Macedonia), Jsnins (parts of Epirus sud Thessaly), Shkodra (Scutari or npper Albania). To these must be added the Turkisl islsnds in the Egean usually reckoned to Europe, that is, Thasos, Ssmothrace, Imbros, and, in the extreme south, Crete or Candis, with estimated (1887) areas and populations as under :-

| Provincea. | Ares in Square Miles. | Populstion. |
| :---: | :---: | :---: |
| Constantinople | 1,100 | 1,200,000 |
| Adrianoplo | 12,800 | 560,000 |
| Saloniki and Kosov | \$2,000 | 1,900,000 |

| Dobrudja, ceded to Roumanis. | 4,200 | 150,000 |
| Nish sud Leskovatz, ceded to Servis | 4,250 | 367,000 |
| Duligno, \&c, ceded to Montenegro $\ldots$......... | 2,000 2,000 | 116,000 100,000 () |
| Total Europead Turkey before 1878.. | 151,020 | 10,940,000 |

For detailed accounts of the physical features, climste, fanna, and flora of these regions, the reader is referred to the articles Albania, Bosnia, Bulgaria, Constantinople, Epirus, Herzegovina, Macedonia, and Thrace. Here it will suffice to remark in a general wsy that the territory still directis administered from

Stambnl comprises one of the most fsvonred rcgions of the temperate zone. The extensive igneous snd metsmorphic system of the Great Balkans and Rhodope (Despoto-Dagh), culminsting in the Rilo Dagh ( 9000 fcet), interspersed in the Pindus range farther west by Permian formstions of unknown sge, snd succeeded in the extreme east (both sides of the Bosphorus) by Lower Devonian sandstones and some mors recent volcsnic rocks, is pierced by the four rich slluvial velleys of the Msritza, Kars-su or "Blackwater," Struma (Strymon), and Vardar. These rivers, flowing in nearly parallel south-casterly courses to the Ægean, collect most of the drainage of Roumelia, as Thrace and Macedonia sre commonly cslled by the Turks. The whole region thus enjoys a somewhst southerly aspect, sheltered from the north by the lofty crests of the Rilo Dagh snd northern Pindus, and in every way admirably suited for the cultivstion of most cereals, ss well as of cotton, tobacco, madder, the mulberry, the vine, snd fruits. Here maize yields snch a bountifnl harvest that, although originslly introduced from America, it hss long been regarded as indigenous, and for the ltalans is simply the Turkish corn ("gran +urco") in a pre-eminent sense. The inhsbitsuts also, Greeks intormingled with Turks in the esst, with Bulgarians in the west, sre intelligent snd industrions, noted for their skill in the manufacture of carpets sud other woven goods, of ssddlery, arms, snd jewellery.

## Asiatic Tureey.

The msinstay of the Ottoman dynssty is the Asiatic portion of the empire, where the Mohsmmedan religion is absolutely predominsnt, and where the naturally vigorous and robust Turki race forms in Asia Minor a compact mass of many millions, far outnumbering any other single ethnical element and probsbly eqnalling sll taken collectively. Here 8lso, with the nnimportant exception of the islauds of Ssmos snd Cyprus and the somewhst privileged district of Lebsnon, all the Turkish possessions constitnte vilayets directly controlled by the Porte. They comprise the geographically distinct regions of the Anatolian plateau (Asia Minor), the Armenian and Kurdish highlands, the Nesopotamian lowlands, the hilly snd partly mountainons territory of Syria snd Palestine, and the coatlands of west and north-east Arsbia. The changes caused by the Russo-Turkish War of 1878 were the cession to Persia of the little district of Kotur on the eastern frontier and to Russia of the districts of Kars and Batoum on the north-east frontier, while to England were conceded the military occupation and adminietration of Cyprus. Asiatic Turkey is conterminous on the esstwith Russia and Persia; in the south-west it encloses on the west, north, and north-east the independent part of Arabia. Towards Egypt the frontier is a conventional line drawn from Akabah at the head of the Gulf of Akabah north-westwards to the little port of El Arish on the Mediterranean. Elsowhere Asiatic Turkey enjoys the ad. vantage of a sea frontage, being washed in the north-west and west by the Euxine, Egesn, snd Mediterranesn, in the oouth-west by the hed Sea, sud in the sonth-east by the Persian Gulf.

The above enumerated five natural divisions of Asistic Turkey are divided for administrative purposes into soout twenty vilsyets, which, however, have been and still are snbject to considersble fuctuations. The subjoined grouping, with areas and populstions, is based mainly on dats lately columunicsted confidentislly to the British Govercment by Mr Redhouse His estimates of population have been strikingly confirmed by the official returns that have fo the first time just been msde for certain provinces in Asis Minor and the Armenian highlands. Thus the censns of the Trebizond vila yet, completed in 1886, gave a total of $1,010,000$, which differs only by 7000 from Mr Redhouse's estimste for $1878(1,017,000)$. So also the juet completed (1887) censue for the Erzeronm vilayet gives 583,000 , or 998,000 inclnding the territory ceded to Russia is 1878, which is 45,000 higher than Mr Redhonse's estimste.

|  | Total Aaiatic Turkey.... | 691,680 | 24,382.000 |

Detailed descriptions of Asiatic Turkey mill be found under the hepazate sticles Arabia, Armenia, Asta Minor, Kurdistan, Mesopotamia, Palestine, and Syria. Of these natural divisions Asia Minor or Anatolia is by far the most inportaut for extent, population, and natural resources. It constitutee an elevated snd fertile plateau enclosed by irregular mountain ranges, which in the Taurus and Antitaurus on the south and east rise to from 7000 ta 10,000 feet, culminating in the volcanic Erjish-Dagh, or Argæus, nearly 12,000 feet high. The platean, which has a meau altitude of some 3000 feet, is depressed iu the centre, where the Tuz-gol (Tatta Palus) and several other lacustrine basins have at present no butfow, but which appear to bave formerly drained through the Sakaria (Sangarius) northwards to the Euxine. In the same direction, and in curiously parallel curves, flow the more easterly Kizil-lrmak (Halys) and Yeshil-Irmak (Iris), which carry off most of the surface waters of the plateau. The western rivers-Grsnicus, Xanthus (Scamander), Hermus, Simois, Meander-although renowned in song and bistory, are comparatively insignificant cosststreams, rushing from the escarpment of the plateau down to their fjord-like estuaries in the Ægean. None of the rivers are navigable to any distance from their mouths, end in the absence of good means of communication the very rich resources of the plateau in minerals and agricultural produce hare hitherto been little dereloped. Owing to the different elevations and varied aspects of tho land towards the Euxine, Egean, and Mediterranesn, the climate is extremely diversified, presenting all the transitions from intense summer heat along most of the eeaboard to severe winters on the lofty tabielands of the interior, which are exposed to biting winds from the Russian stoppes. Anatolia has an endless variety of nstural products, from the hardy boxirood of Lazistan (Trebizond vilayet) to the sub-tropical figs and grapes of the western coastlands. On the platean thrives the famous breed of Angora goats, whose soft, silky fleece (molair) forms a staple export.
Of far less economic importance are the Armenian uplands, forning a rugged plateau of limited extent, above which rise many lofty pcaks, culminating in the tower-cresterl Ararat ( 16,916 feet), the converging point of three empires. The long and terribly severe winters, intolerably hat short summers, aud generally poor soil of Armenia present a marked contrast to the far more temperate climate, rich upland valleys, and densely wooded slopes of the more southern Kurdistan highlands. But these advantages are counterbalanced by the generally inaccessible nature of the country, the want of good highways, and especially the lavless character of its inhahitants, who have undergone little social change since the days of their wild Karduchi forefathers. In the heart of this sovage region lies the magnificent basin of Lake Van, which, like Tuz-gol and the more easterly Urmiya, has no present outlow, but formerly, no doubt, discharged to the Tigris valley.
In the Van district lie the sources of most of the head streams of the Troris (q.v.) and Euphrates (q.v.), which have created tbe vast and fertile alluvial plains of Mesopotamia. This latter region, the seat of the sncient Accadian and Assyrian and the more recent Moslem cultures, forms a continuous plain from the escarpments of the Kurdistan highlands to the Persian Gulf, broken only in the north by the Sinjar Hills, and capable of yielding magnificent crops wherever water is available. But under Osmanli rule the eplendid system of irrigatiou works, dating from the dawn of history, has fallen into decay: the lover Euphrates now overflows its banks and converts much of the region above and below Kurnsh, at the coufluence of the two great arteries, into malarions marshlands. Hence the populous cities and innnmerable rillages fornierly dotted over the Babylouian plains haro been succeeded by the scattered hamlets of the Montefik and other smphibious arab trives.
This lowland region is separated by the more elevated Syrian desert or steppe from the much smalier and less productive provinces of Syria and Palestinc. Here the main physical features are at once simple and yet striking. The narrow, hilly region dis. posed north and south between the Nediterrancan and the desert, and stretching for over 400 miles between Anatolia and the Sinai Peninsula, culminates towards the centre in the parallel Libanus and Antilibanus ( 10,000 to 11,000 feet), enclosing between them the fertile depression of the Beka' (Coele-Syria). The stupendous ruins of Baalbek, standing at the highest point of this depression in $30^{\circ} \mathrm{N}$. lat., mark the parting line between the northern and contherr. watersheds of the region. Northwards flows the El-'Ași (Orontes), southwards tho Litani (Leontes), both through thie Beka in moderately stoping beils to the Mediterranean. For further particulars, see the articles Lebanoy, Jordans, Palestinfe In the Lebanon the Christian Maronite communities enjoy a measure of self-gorernment under the guarantep of France, while their pagan neighbours and hereditary foes, the Druses, are gradually withdrawing to the hilly 1 Tauran district beyond Jordan.
Turkey's Arabian possessions comprise, besides El-Hosa on the Persian Gulf, the low-lying, hot, and insaluirious Tebama and the south- western highlands (vilayets of Hejaz s nd Yemen) stretcling continuously along the cast side of the Red Sea, and including the
two holy cities of Meces and Medina. These are held by military occupation, probably at a loss to the imperial exchequer, and certainly against the wishes of the inhabitauts. But these drawback are supposed to be more than compensated by the political prestig6 derired from the possessiou of the Holy Land of Islam.

## Africas Territories.

Siuce the abandonment of eastern or Egyptian Soudan in 1884, consequent on the revolt of the Mahdi, and the occupstion of Tunis by the French in 1881, Turkey in Africa has been reduced to the two territories of Egypt and Tripolitana with Barca and Fezzan, joiutly occupying the north-east corver of the continent. Of these Tripolitana slone is directly administered, constituting the pashalik or vilayet of Tripoli. Egypt, whose southern frontier Wrss temporarily fixed in January 1887 at the station of Akssho above Wady Halfa, near the second cataract in Lower Nubia ( $22^{\circ}$ N. lat.), has formed a practically iddependent principality under the dynasty of Mehemet Ali since 1841, subject only to an annual tribute of $£ 695,000$ to the Porte. The areas and populations of Turkey in Africa were estimsted as follows in 1887:-

| Tripoli, whth Barca and Fezzan, a vilsyetEgypt, tributary principality ........... | Area In Sq. Miles. | Population. |
| :---: | :---: | :---: |
|  | $\begin{aligned} & 485,000 \\ & 374,000 \end{aligned}$ | $\begin{aligned} & 1,000,000 \\ & 6,500,000 \end{aligned}$ |
| Total Turkey In Africa | 802,000 | 7,800,000 |

The Empire
Turkey is essentially a theocratic absolute monarchy, being sub- Admu; ject in principle to the direct personal control of the sultan, who tratio. is himself at once a temporal autocrat aud the recognized caliph, that is, "successor" of the Prophet, and consequeutly the spiritual head of the Moslem world (see Monammedanism). Eut, although tho attempt made in 1876 to introduce representative institutions proved abortive, this theoreticsl absalutism is yevertheless tempered not only by traditional usage, local privilege, the juridical and spiritual precepts of the Foran and its 'ulema interpreters, and the privy council, but also by the growing force of puhlic opinion and the direct or indirect pressure of the Europeen porers. The "ulemá form a powerful corporstion, whose bead, the sheikhu' 2 Isham, ranks as a state functionary scarcely second to the grend vizier, or prime minister. Owing to their intensely conservative and fanatical spirit, the 'ulemá have always been determined opponents of progress, and are at present one of the greatest obstacles to reform in a political system where the spinitual and temporal functions are inextricably interwoven. Besides these expounders of Koranic doctrine, the sovereign is to some extent bound also by the Mullecka, a legal zode based on the traditional sayings of Mohammed and the recorded decisions of his successors, having the force of precedents.
The grand vizier (sadr-azam), who is nominated by the sultan, presides ex-officio over the privy council (mejliss-i-khass), which, besides the sheikhu 'l-Islam, comprises tho ministers of home snd foreign affairs, war, finance, marine, trade, public works, justice, public instruction, ond warship, with the president of the council of state and the grand master of artillery. For administrativo purposes the immediato possessions of the sulton are divided into vilayets (provinces), which are again subdivided into sanjaks or mutessariks (arrondissements), these iuto kazas (cantons), and the kazas into nahiés (parishes or communes). A vali or governorgeneral, nominated by the sultan, stands at the licad of the vilayet, and ou him âre directly dependent the pashas, affendis, beys, and other administratars of the minor divisions. All these officials unite in their own persons the judicial and executive functions, and all alike are as a rule thoronghly corrupt, venal in the dispeneation of justice, oppressors of the subject, embezzlers of the public revennes, allogether absorbed in anassing woalth during their mostly brief and precarious tenure of office. ${ }^{?}$ Foreigners settled in the country are specially protected from exactions by the so-called "capitulations," in virtue of which they are exempt from the jurisdiction of the local courts and amenabie for trial to tribunals pres 1 See Sungtes, vol. xxii. p. 660 .
\& Major-General F. T. Haig, who travelled through the heart of yemen is the winter of $1586-87$, thms speaka of the adoinistration in that alionct exciusively Maslem provioce: ": The fiscal system of the Turks, if it were really carried into effect, would be by no means bad; but like every other department of the government it is ruined by the utter corruption that prevans in every branch of the administration from top to Zotton. No more elinnuent expounders of the evils and honelessness of their whole system are to be found their own officials " (Proc. R. Geng. Soc., August 1887, M. 487). Mr G. P. Devey also, coosul at Erzeroum, reports that in a part of that provincs the sheep-taz for 1885 was collected three times over: "On the first occasion the real nuniber had been underestimated, ond the collector therefore came again, and, Hoding that such was the case, marle the villagers pay the whole sumof $14,0 n 0$ piastres ( 9000 had been levied on the previous occasion), instead of the difference, on the pround that they had cheated the Government in not leciaring their whole stock. $A$ third time a collector visited the caza, sod, wheo the villagera conles prodice no receipt that the tax hail been pain (for none hail beengiven), a third time the full surn was takea" (Cons. Rep., July 1887, p. 3).
aided over by their respective consuls. Cases between foreigners of different nationalities are heard in the court of the defendant, and between foreigners and Turkish subjects in the local courts, at which a consular drageman atteuds to see that the trial is conducted according to law.
The trade returns for tho last few years show that the country is slowly recovcring from the disastrous consequences of the RussoTurkish War. For the four years $1882-86$ the exports from and imports to Turkey were valued as under:-

|  | Exports. 1 | Imports. |  | Exports. 1 | Imports. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1882-5 | £10,900,000 | 217,000,000 | 1584.5 | £11,326,000 | £18,263,000 |
| 1883-4 | 9,550,000 | 17,350,000 | 1855-6 | 10,690,000 | 17,702,000 |

The ahare of the chief foreign states in these exchanges is shown in the subjoined table ${ }^{2}$ for the years $1884-55$ and 1895.86 :-

|  | Imports from |  | Expores to |  |
| :---: | :---: | :---: | :---: | :---: |
|  | 15S4-5. | 1885.6. | 18S4-5. | 1ss5-6. |
| Grest Britain | 28,304,000 | 1 $£ 7,735,000$ | ¢3,923,000 | 24,031,000 |

Exclnsive of coasting craft, the mercantile fleet of Turkey in 1885 consisted of 14 steamers of 11,000 tons snd 400 sailing vessels of 65,000 tons.

All branches of the foreign trade, together with most of the local traffic and the banking business, are almost exclusively in the hands of Greeks, Armenians, Jews, and foreigners. The Turks and other Mohammedans are engaged nearly altogether in agricnltural and pastoral pursnits. But the land, especially in Anatolia, is gradually passing from its Moslem owners in to the possession of Chistian mortgagees. Scarcely any accurate agricultural returns are avail2hle, except for one or tro districts. In tha Erzeroum vilayet in $1886^{3}$ the live-stock stood as under, -sheep $1,485,000$, goats 645,000 , oxen 470,000 , buffaloes 48,000 , horses 61,000 , asses 42,000 , mules 5000 ; beehives numbered 80,000 . The chief agricultural prodnce for the same jear was-wheat $16,690,000$ bushcla, barley $13,297,000$ bushels, beans 46,250 cwts., melons $17,000 \mathrm{cwts}$., mulberrics 10,000 crits., other fruits 40,000 crits. In the same year of the 12,000 square miles constituting the Trebizon 1 vilayet 2100 were under cultivation, 1860 uncultirated, 2520 woodland, and 5520 highland pasturage, the annual yield being about $2,300,000 \mathrm{cwta}$ of cereals, $1,000,000$ crts. of nuts, fruits, vegetables, \&C., and 500,000 crtts of fodder;

[^280]whilst of live-stock there were 300,000 sheep and goats, 150,000 horses, 25,000 mules and asses, 60,000 oxen. ${ }^{4}$
Previous to 1880 Turkey was commonly regarded as practically Financen banigrupt. But since then a considerable improrement has been cffected. Trustworthy data sre still wanting; bat a careful estimats gave the gross revenue and expenditire of 1884 at £T16,313,000 and $£ T 16,223,000$ respectively, the expenditure including over £T4,000,000 available for atate creditors. The public debt stood at $£ 106,437,000$ in 1882 . The sultan is reported to draw a sum of from $£ 1,000,000$ to $£ 2,000,000$ snnually from the public revenues for the support of the seraglio or imperial household of over five thonsand persons.

Until 1886 the military service, compulsory on all Moslems over 18 years of age, was kept up by 45,000 annual recruits drawn by ballot; but in November of that year universal conscription of the wholo able-bodied male popnlation was decreed. By this measure the army, hitherto reckoned at about $160,000 \mathrm{men}$, with a war strength of from 450,000 to 500,000 , will be probably raised to a permanent footing of $1,000,000$ effectives nnder the flag and in the reserves. These will continue to be grouped in the three categories of the nizam or regulars in active serrice, the redif or first reserve, and the mustahfiz or second reserve. There is to be a considerable increase of cavalry, all conscripts being allowed to join that branch of the eervice who have the means of providing themselves with miunts and equipment. For military purposes the empire is divided into seven divisions, with beadquarters at Constantinople, Adrianople, Monastir, Erzingian, Baghdad, Damascus, and Sanaa, all except Sanaa (for Yemen) hitherto furnishing an army corps for the nizam and two for the redif.

The nary at the begintiing of 1857 comprised 15 large and Nary. several smaller ironclads (monitors, gunboats, \&ic.), a number of mostly ohd-fashioned steancrs, and 14 torpedo boats, and was manned by 30,000 sailors and 10,000 narines (nominal strength), raised by conscription or voluntary enlistment and serving for 12 jears in the active and reserve classes.

Public instruction is much more midely diffused thronghout the Ednce empire than is commonly supposed. This is due partly to the tion Christian coramunitics, notably the Maronites and others in Syria, the Anatolian and Roumelian Greeks, and the Armenians of the castern provinces and of Constantinople. Education is practically limited amongst the Mohammedans to reading and writing and the study of the Koran. But amongst the Christians, especially the Armenians, the Greeks of Smyrna, and the Syrians of Beyrut, it embraces a considerable range of subjects, such as classical Hellenic, Armenian, and Syriac, as well as modern French, Italian, and English, modern history, geography, and medicine. Large sums are freely contributed for the establishment and support of good schools, and the cause of national education is seldom forgotten in the legacies of patriotic Anstolian Greeks. Even the Turks are bestirring themselves in this respect, and Ereat progress has been made dnring the last twenty years in the Erzeroum vilayet. ${ }^{\circ}$ In 1886 that province contained 1216 schools and 163 madrasas (colleges), with a total ettendance of 25,680 , including 1504 girls. Elsewhere few official statistics are available.
Besides administrative and financial reforms, one of the most pressing needs is improved means of communication. In Trebizond the route from the coast at Unieh through Niksar to Sivas has recently been completed to the limits of the vilayet. But the works on the more important road from Eirasun to Kara-hissar for the silver and lead mines at Lijessy are still suspended, owing to disputes between the contiguous provincial administrationa. Many of the great historic highways are also much out of repair. At the end of 1885 only 1250 miles of railway wera completed in the empire, of which 903 were in Europe and 347 in Asia. The chief lines are those connecting the capital with Adrianople ( 210 miles), Adrianople with Saremby (152), Saloniki with Uskub (150), Zenica with Brod (118), Uskub with Mitrovitza (75), and Kulleli with Dégéagatch (70) in Europe, and, in Asia, Scutari with Ismid (40), Smyrna with Ala-Shehr (130), and Smyrna with Denizli (170). By imperial decree (August 1887) a contract was granted to an English syndicate for the extension of the Ismid line and the construction of a system of Asiatic railways to extend to Baghdad within the space of ten jears.

The telegraph system is much more developed, comprising (1885) 14,620 miles, with 26,100 miles of wire and 470 atationa. The yearly arerage of letters and packages of all sorts aent through the 710 post-offices scarcely exceeds 2,600,000. Most of the fareign postal service is conducted through the British, Austrian, German. French, and Russian privileged post-offices.

For the ethnography of the Turks, see Tores.
(A. II. K.)

## Part III.-Literature.

In all literary matters the Ottoman Turks have ahown themselves a singularly nninventive people, the two great schools, the old and the new, in to which we may divide their literature, being closely
modelled, the one after the classics of Persia, tho other after those of modern Europe, aud more especially of Frauce, The old or Porsian school Hourished from the fonudation of the entpire down to about 1830, and still contiunes to drag on a feeble existeuce, though it is now out of fashion and cultivated hy none of the leadiag men of letters. These belong to the new or European scliool, which sprang up some fifty or sixty years ago, aud which, in spite of the bitter oppusition of the partisaus of the olil Oriental system, has succeeded, partly through its own inhereut superiority and partly through the taleuts and courage of its supporters, in expeliing itg rival from the position of uudisputed authority which it had occupsied for upwards of five hundred years, For the present purpose it will be couvenient to divide the old achool iuto threc periods, which may be termed respectively the pre-classical, the classical, and the post-classical. Of these the first extends froms the early days of the empire to the accession of Suleyuáu I., 1301. 1520 ( $700-926$ ); the secoad from that eveut to the accessiou of Mahmúd I, $1520-1730$ ( 926.1143 ) ; and the third from that date to the accession of 'A bil-ul-Aziz, 1730-1851 (1143-1277).
The works of the old echool in all its periods are entirely Persian in tone, seutiment, and form. We find in then tho same leautjes and the eame defects that we observe in the productious of the Iranian authors. The formal elegance and couveutional grace, alike of thought and of expression, so characteristic of persian classical literarure, pervade che works of the beat Ottoman writers, and they are likewise imbued, though in a less degree, with that spirit of mysticism which ruus through so much of the poctry of Irán. But the Ottomans did not stop here: in their romantic poems they chose as subjects tha favourite themes of their Persian masters, such as Leyli and Mejnio, Khusrev and Shírín, Yúsuf and Zuleykhá, and so on ; they congtantly allude to Persian heroes whose stories occur in the Shih-Namr and other storehouses of Iravian legendary lore; and they wrote their poems in Persian metres and in Persian forms. The meanevi, the kasida, aud the ghazel,-all of them, so far at least as the Ottomade are coucerned, Persian, - were the favourite verse-forms uf the old poets. A mesueví is a poem written iu rhymiag couplets, aod is usually uarrative in subject. The kasida and the ghazel are hoth monorliythmic; the first as a rule celelrates the praises of some great mau, while the second discourses of the joys and woes of luve. Why Peraian rather than A rabian or any other literature lecame the mollel of Ottonau writers is explaincd by the early history of the race feee Turks). Some two ceuturiea befora the arrival of the Tarks in Asia Minor the Seljuks, then a mere horde of savages, Lad overrun Persia, where they settled and adopted the civilizatiou of the people they had subdued. Thus Persiau, becaue the laugnage of their court and Government, aud when by and hy they pusherd their conquests into Asia Minor, and fomaded there the Seljuk empire of Rum, they carried with them their Persian culture, aud diffused it asoong the peoples newly brought under their svay. It was the desceudants of those Persianized Seljuks whom the early Otlouans found ruling in Asia Minor un their arrival there. What hatl lisjupeued to the Seljúks two centuries before hajpred 10 the Ottomans now: the less civilized race adopted thu culture of the uore civilized ; and, as the Seljuk empire fell to jieces and the Ottoman cane gradually to occupy its place, the sons of men who had called themselves Seljuks legan theuceforth to look upon themselves as Ottomana. Hence the vast majority of the prople whom we are accustomed to think of as Ottomans ara oo only by adoption, being really the desceudants of Seljnks or Seljukian sulyjecta, who of literary taste. An extraordiuary love of jurecedeut, the result apparently of cunscious want of original power, was sufficient to keep, their writers loyal to their carly guide for centuriea, till at leugth the allegiaoce, though not tha fashion of it, has been changed in our own days, aul Daris has replaced Shiráz as the shrine towards which the Ottoman scholar lurns. While conspicnously lackıng in creative genins, the Ottomaus liave always shown themselves possessed of recentire and assimilative powers to a remarkable degree, the resalt being that the puoblier of their writers both io prose aud verse is euomnons, Of course only a few of the nost probiueut, either throngh the intrinsir jnerit of their work or through the nolluence they have had in guiding or shapiog that of their coutemporaries, cau be soentioned in a brief review like the present. It ought to be premised that the poetry of the old school is greatly superior to the prose.
Ottomau literature may be said to open with a few mystic lines, the work of Sultan Veled, soa of Maulaná Jelál-ud-Dín, the author of the great Peraian poem the Mathnaws. Sultáa Veled flourished during the reign of "Osmáo I., though lie did not reside in the territory under the rule of that prince. Aoother mystic poet of this early time was "Áshik Pasha, who left a loug poem in rhyming couplets, which is called, inspliropriately enough, his Diván. The aocturnal expedition across the Hellesjont ly which Suleyman, the son of Orkhan, won Galipoli and therewith a foothold in Europe for his race, was shared in and celebrated in verse by a Turkisly wolle or cheftain mamed Gháa Fázil. Sheykhí of Keruiyáu, a
conten porary of Muhammad I. and Mrurad II., wrote a lengthy und still esteemed mesnevi ou the ancicut Persian romance of Nibusrev and Shirin; and about the same time laziji-oghlu gave to the world a long versified history of the Prophet, the Muluemmedtya. The writers mentioned above are the loost importaut previous to the capture of Constautinople; but there is little literaiure of rcal merit prior to that event. The unost notable prose work of this period is an old collection of atories, the Mislory of the forty Vezirs, said to lave been compiled Ly a certain Sheyklh-zada and dedicatcd to Murad II. A few years after Constantinople passed into the hauds of the Ottomaus, some ghazels, the work of the coutemporary Tatar prince, Dlir 'Alí Slim, who under the nom de plume of Nevay! wrote much that shows true taleut and poetic feeling, found their way to the Ottoman capital, where they were seen and conied Ly Ahmed Pasla, oue of the viziers of Mulammed II. The poems of this statesman, though possessing little merit of their own, being for the most part mere trauslatious from Nevayi, form oue of the laudmarks io the history of Ottoman literature. They set tho fashion of ghazel-writing; and their appearance was the signal for a more regular cultivation of poetry and a greater attention to literary style and to refiuemeut of language. In Sinán Pasha, another minister of Nuhanmed the Conqueror, Ottoman prose
found itg first exponent of ability; he left a relsgious treatiso found itg first exponent of ability; he left a relggious treatiso entitled Tazarru'at (Supplicatious), which, notwithstanding a too lavish employment of the resources of Persian rhetoric, is as remarkable for its clear aud Jucid style as fo: the veauty of many of the thoughts it contaius. The most noteworthy writers of the Conqueror'e reign are, after Ahmed and Sinán, the two lyric poets Nejátí and Zátí, whose verses show a considcrable improvement ulun those of Alimell Paslia, the romantic poets Jemálf and Hamdi, and the loetesses Zeynet and Mihri. Liko most of his house, $\mathrm{H}_{\mathrm{G}}$ himmed II. was fond of poetry and patronized neen of letters. $\mathrm{H}_{\mathrm{t}}$ hinself tried versification, and some of his lines which havo como down to us appear quite equal to the average work of his coutemporaries. Tweuty-oue out of the thirty-four sovereigos who Lave occupied the throne of 'Oszińn have left verses, aml among theso Selim I. stands out, not merely as the greatest ruler, warrior, aod etatesman, but also as the most gifted and most Persian lauguage; the excelleuce of what be has done in Turkish makes us regret that Le did so litile. The most prominent man of letters under Selín I. was the legist Kemál Casha-záds, frequently called Iln-Keuál, who distingrished limself in both prose aisd verse, He left a romantic poero on the loves of Yisuf and Zuleyklá, and a work cntitled Nigaristin, which is modelled both Mesilhí whose matter ou the Gulistán of Sa'dí. His conteuporary, kuown in Europe than any other Turkish joem, deservcs a vassing meution.
With tho accession of Selinu's son, Suleymán J., the classical Classica jeriod hegius. Hithcrto all Ottoman writiug, eveu the most highly perion. finished, hed been somewhat rude and uncouth; but now a marked inim rovement hecomes visible alike in the manaer and the matter, and authors of greater ability begin to make their appearance. Fuzuli, one of the four great pocts of the old scliool, seeuns to have been a uative of Baghilád or its neighhourliood, and prohably because an Ottonan sukject wheu Suleyináu took possession of tho old rapital of the caliphs. Hig language, which is very jeculiar, seems to be a sort of mixture of the Ottoman and Szerbijan dialecta of Turkish, and was most probahly that of the Persiau Turks of those daya. Fuzuli showed far more originality than auy of lis predecessors; fnr, although his work is uaturally Persisn in form and in gencral claracter, it is far from being a were ecluo from Shíráz or Ispralán. He struck out a new line for himself, and was Persian. An his inspiration to no previous writer. Whether Turk or: Persian. Au intense and passionate ardour brealhes in his rerses, and forms one of the most remarkable as well as oue of the most attractive characteristics of lis style; fur, whilo few cren among Turkish poets are more artificial than be. few seem to write witl grester earuestoess and sincerity. His influence ulou his suc cessors has scarcely been as far-reaching as might lave been expected, -a circumstance which is perhaps in some measure owing to the unfamiliar dialect in which he wrote, Besiles his Divan, he left a beantiful mesneví ou the story of Leylí aud Slejoún, as well as some prose works little inferior to his joctry. Bákí nf Constantinople, though far from rivalling lis contemporary Fuzúlí, Wrote much good jortry, including one piece of great excelleuce. au elegy on Suleymán I. The Ottomans liave as a rule heen juarticularly successful with elegies ; this one Ly Bákí has never been sur passed. Rúli, Lámi'i, Nev'i, the janissary Yalıya Beg, the muftı During the and Selim II. all won deserved distinctiou as joess. During the reign of $A$ hmed I. arose the second of the great poets of the old Ottoman school, Nef'i of Erzerúm, who owes his pye-
enumeace to the hrilliance of his kasidas. But Ner'í conld revile as well as praise, aud such was the bitterness of sone of his revile that certain influential persouages who came muder his lash induced Muríd IV. to permit his execution, Nerí, who, lika Fuzúli.

Jurmel a style of his orn, had many to imitate him, of whom Sabri Shákir, a contemporary, was the most successful. Ná'ilí, Jevrí, and Fehim need not detain us; but Nabi, who flourished under Ibríhím and Mulammed IV., calls for a little more attention. "This prolific antlior copied, and so imported into Ottoman literature, a didactic style of ghacel-writing which was then being antroduced in l'ersia ly the poet Sa'ib; but so closely did the lnpil follow in the fontstepis of his master that it is not always casy to know that his lines are intended to be Turkish. A numbler of jocts, of whon Seyyid Vehbi, Rághib Pasha, Raluni of the Crionoa, Kelim, and S:imi are the most notable, took Nabi for their model. Uf these, Simi is remarkable for the art with whicli le constrncten his ghazels. Among the writers of this tine who dill not copy Nábí are Súbit, Risikh, and Talib, cach of whon endeavoured, with no grcat success, to open up a new path for linnself. We now reach the reign of Aḷmed III., durivg which fourishal Nedín, the greatest of all the poets of the old school. Little appears to be known about his lifa further than that he resided at Coustantinople and was alive in the year 1727 (A.H. 1140). Nedinn stands quite alone: he couied no one, and no one has attempted to copy him. There is ia his peetry a joyonsness and sprightiossa which at once distinguish it from the work of any other Turkish anthor. His ghazels, which are written with great elcganoe and finish, con. tain many graceful and original ideas, and the words he makes use of are always chosen with a view to harmony and cadence. His kasidas are almost equal to his glazels; for, while they rival those of Nefi in brilliancy, they surpass then in beanty of diction, ausl are not so artificial and dependent on fantastic and far-fetched conceits. The classical period cames to $8 a$ end with Nedíns ; its brightest time is that which falls betwecu the rise of Nefi and the eleath of Nedim, or, more roughly, that cxtending from the accession of Ahmed I., 1603 (1012) to the deposition of Al!med III., 1730 (1143).
We will now glance at the prose writers of this period. Under tho name of Humdyün Némui 'Imperial Book) 'Al' Chelcbi made a highly esteened translation of the well-known Pessian classic Anorr-i Suhcyll, dedicating it to Suleymán I. Sa*dul-Din, the preceptor of Murád III., wrote a valuable history of the empire from the earliest times to the death of Selim I. This work, thu Tuj-ut-Tevirikh (Crown of Clisooicles), is reckoned, on acconnt of its ornate yet clear style, one of the masterpieces of the old school, and forms the first of an uubroken serics of annals which are written, especially the later amoug them, with great minuteress and detail. Of Sa'd-ud-Din's successors in the office of imperial historiographer the most remarkable for literary power is Na'imá. His work, which extends from 1591 (1000) tu 1659 (1070), contrasts strongly with that of the earlier historian, being written with great directness and lucidity, combined with much vigour and picturesqueness. Evliyá, who dicd during the reign of Muhammed IV., is noted for the record which he has left of his travels in different countries. Abont this time Tash-köpri-záda began and "Atá-ulláh contunued a celebrated biocriaphy of the legists and sheykhs who latl tlourished under the Ottoman monarchs. Hájí lihalifa (see vol. xi. p.377), frequently termed Kátib Chelehi, was one of the nost famous men of letters whon Tarkey has prodnced. He clied in 1658 (1068), having written a great number of learncd works on history, biography, chronolory, geography, and other subjects. Tho l'ersianizing tenfeacy of this school rearhet its highest point in the proluctions of Veysí, who left a Lifc of the Projhet, and of Nergisi. a miscellaneous writer of prose and verse. Such is the intentiona] obscurity in many of the compositions of these two authors that every seutence becomes a puzzle, over which even a scholatly Ottonati must panse hefore lie can be sure lie has fonnd its trice meaning. The first printiog press in Turkey was established lyy an Hungarian whe had assumed the name of Ibrihim, aud is 1728
(1141) aprearel the first book printell iu that country; it was Vain kuli's Turkish translation of Jevheri's Arabic dictionary.

Coming now to the post-classical period, we find among poets wortly of mention Belígh, Nevres, Ilishınet, aud Sunbuli-záda Vehbi, each of whom niote in a style peculiar to himself. Thrée puets of mate-Pertev, Neshet, and Sheykl Ghalib-flowished puider Selim III. Jhe last-mamed is the fom'th grent paet of the olll school. IIusn is 'Ashl: (Beanty sid Love), as his great noem i: called, is an allegorical romauce full of tenderness and inaginative power. Ghailib's style isins original as that of Fuzuli, Neri, or Nedim. Tho most ilistinguished of the prose writers of this period are perhajs Kislnd, the inperial historiographer, 'Asim, who traing lated into 'lurkish two great loxicons, the Arabic Kímuis and tha l'ersiau Burhin-i Kilit, aud Kani, tho only humorous writer of uerit belonging to the old achool.

When we reach the reigu of Malınúd II., the great transition period of Ottoman history, during which the civilization of the West began to strugglo in earnest witlı tlaat of the East, we find the change which was coming over all thiags Turkish affecting literature aloug with the rest, and prepariug the way for the appearance of the new school. IThe chief pocta of the tiansition are Fízil Bey, Wásif, notable for lis not altogether unlappy atterapt to write verses in the spoken language of the capital, Izzet Molle, Pertev I'asha, "Ákif I'asha, aud the poetegses Fituct and Leylá. In the works of all of these, althongh we occasionally discern a linat of the new style, the olil l'ersian nianner is still supreme.

Moro intimate relations with western Europe and a pretty general stuly of the French langunge and literature, tngether with the steady progress of the reforming tendency fairly started under Malnuxd ll., have resulted in the birth of the new or moidern school, whose objects are truth and simplicity. In the political writings of Reshif nuel 'Ákif J'ashas we lave the first ${ }^{\text {collear note of }}$ clange; but the man to whom more thau to any other the new departure owes its anccess is Shinasí Efendi, who entployed it for poctry as well as for prose. The European stylc, on its introduction, encountered the nost violent opposition, but now it alone is used by living anthors of repute. If ony of these docs mite a pamplilet in the old manner, it is mercly as a tour de force, or to prove to some faithful but clagorous jartisan of the Persian style that it is not, as he sulyoses, lack of ability which causes the modern autlios to adopt the simpler ant more natural fashou of the West. The whole tone, sentiment. aud form of Ottoman literature have been revolutionized liy the uew echool : varieties of poetry liitherto unknown have been allopted from Europe; ou oltogether now branch of literature, the drama, las arisen; while the sciences are now treated and scriously studied after the system of the West. Among writers of this school who lave won distinction are Ziyid Pasha, Jevdet Pasha, the statexman autl histoman, Ekrem Bey, the author of a beautiful serics of mascellaneous poens, Zcməenrct, I İámid Bey, who holds the first place among Ottomen dramatists, and Kemál Bey, the learler of the mociera school and out of the most illustrious men of letters whoni his comatry has prolluced. He lias written mith conspicuous success in nlmost evely brancls of literature, -listory, romance, ethics, poetry, and the drama.
For the Turkish language, see j, 661 below.
There is $1 n$ work in exislence which gives a satisfactory accunst of Oltonaa literatare. Vou Hammer-Yurgstall's Geschichte der Usmunischen Dichtkurst (l'esth, 1836) is not always trustworthy and leaves much to be desired in manly ways. Other works on the puetry are La Muse Ottoniane, by Servau de Sugny (Paris, 1853); On the History, System, and 1'arieties of Turhish l'oetry, hy Redhnuse (Lonalun, 1878): Ottoman Poems, ly Gibb (Lomlon, 1882). of transletiens we bave Bás's Disan, by Haramer (Viensa, 1825); the Truvels of Extiyd, by Hamnser (London, 1834); Rose und A nchtiymdl (a poen of Fazli, a mediocre writer of the time of Suleymán I.), Turkish a and German, by Hammes (Pesth); Jes Conseits cie Nubi JFFendi, by Pavet de Courleille (1’aris, 185T): The II istory of the Forty Tezirs, by Gibj (looudon, 1886). An interesting aud valuable sketch of Ottoman puetry is giver by Eemal Bey in a series of articles in the Twkish Literary jounal M(ymui a-i Lihs-z-Ziyi.

TURKEI, an abbreviation for TUREEY-COCE or TURKEyHen as the case may be, a well-known large domestic gallinaceous bird. How it came by this name has long veen a matter of discussion, for $1 t$ is certain that this valuable animal was introduced to Europe from the New World, and in its introduction had nothing to do with Turkey or with Turks, eveu in the old and extended sense in which that term was aprlied to all Mahometans. But it is almost as unquestionable that the name was originilly applied to ine pird which we know as the Goinea Fowl (q.v.), and'there is no doubt that some authors in the $16 t \mathrm{~s}$ and 17 th coniurics curionsly confounded these twe species. As both birds became more cuminon and better known, the distinctiou was gradually perceived, and the name "Turkey." clare to that from the New Worldnossibly because of, its repeated call-note-to be syllabled
turk, turk, turk; whereby it nay be almost said to hare named itsclf (cf. Notes and Queries, sor. 6, iii. 1p. 23. 369). But eren Linnæus could not clear himself of the confision, and unlappily misapplied the name Meleargris, undeniably belonging to the Guinea-Fowl, as the generic term for what we now know as the Turkey, adding thereto as its suecific designation the word gallopavo, taken from the Gallopava of Gesner, who, though not wholly free from error, was less mistaken than some of his contemporaries and eren successors. ${ }^{1}$
${ }^{1}$ The Freach Coq and I'oule d'Inde (whence Lindon) involve no coutradiction, looking to the general idea of what Iudia then was. One of the carliest German names for the bird, Kalekuttisch Hün (wheuce the Scandinavind Falkon), must hare arisev trrough some mistake at present inexplicable; but this does not refer, as is generally supposcil, to Csleutta, Lut to Calicut on the Malabar coast (cf. Notes and Queries, ser. 6, s. p. 185)

The Turkey, so far as we know, was first described by Oriecho in his Sumario de la N゙atural Historia de las Indias ${ }^{1}$ (cap. xxxvi.), said to have beeu published in 1527. He, not unnaturally, includes both Carasows and Turkeys in one category, calling both "Pavos" (Peafowls); bat he carcfully distiaguishes between them, pointing out among other thiags that the latter make a wheel (hacon la rueda) of their tail, though this was not 60 grand or so beantiful as that of the Spanish "Pavo," and he gives a faithful though ehort description of the Turkey, The chief point of interest in hia account is tbat he speaks of the speciea having been already taken from New Spain (Mexico) to the islands and to Castilla del Oro (Darien), where it bred ln a domestic state among the Christians. Much labour has been given by varions naturalists to ascertaia the date of ita iatroduction to Europe, to which we can at present only make su approximate attempt; ${ }^{2}$ but after all that has been writtea it is plain that evideace concurs to show that the bird was established in Europe by 1530 -a very short time to have elapsed since it became known to the Spaniards, which could liardly have been before 1518 , when Mexico was discovered. The possibility that it had been brought to England by Cabot or some of his slaccessora earlier in the century is not to be overlooked, and reasous will presently be assigned for supposing that one of the breeds of Eaglish Turkeys nay have had a northenn origin; ${ }^{3}$ hut the oftca queted distich first given in Baker's Chronicle (p. 298), asserting that Turkeys came into Eagland in the same year-and that year by reputation 1524-as carps, pickerels, aud other commoditica, is whelly untrustworthy, for we know that both these fishes lived in the country long before, if iadeed they were not indigenous to it. The earliest documentary evidence of ita existence in England is a "constitution" eet forth by Crammer in 1541, which Hearno first printed (Lelaud'a Collcctanca, ed. 2, vi. p. 38). This names "Turkeycocke" as one of "the greater fowlea" of which an ecclesiastic was to have "on one in a dishe," and ita associstion with the Crane and Swan precludes the likelihood of any confusion with the Guinea-Fowl. Bloreover the comparatively low price of the two Turkeys and four Turkey-chicks served at a feast of the serjeants-at-law in 1555 (Dugdale, Origines, p. 135) points to their baving hecome by thst time abundant, and indecd by 1573 Tusser beara witaess to the part they bad already begua to play in "Christmaa husbandlie fare." In 1555 both ecxes were characteristically figured by Belon (Oyseaux, p. 249), as was the cock by Geaner in the same year, and these are the earliest representations of the bird known to exist.
There is no need to dcscribe here a-bird so familiar sad in these days so widely distributed. As a dcuizen of our poultry-yards (see Poultry, vol. xix. p. 640) there are at least two distiact breeds, though crosscs between them are much commoner than purely-bred examples of either. That known as the Norfolk breed is the tsller of the two, and is eaid to be the more hardy. lis plunuage ia almost entircly black, with very little lustre, but the feathers of the tail and some of those of the back have a brownish tip. The chicks also are black, with occasionally white patches oa the head. The other brecd, callad the Cambridgeshire, is much more variegated ia colour, and some parta of the plumage have a hright metallic gloss, while the chicka are generally mottled with browniah grey. White, pied, and buff Turkeys are also often scen, and if care be taken they are commonly found to "brecd true." Occasionally Turkeys, the cocks especially, occur with a top-bnot of feathers, and one of them was figured by Albin in 1738. It has been auggested with some appearance of probability that the Norfolk breed may be desceaded from the northern form, Meleagris gallopavo or amcricana, while tho Cambridgeshire breed may spring from the southern form, the M. mexicana of Gould (Proc. Zool. Sociely, 1856 , p. 61), which indced it very wuch resembles, especi-
${ }^{1}$ Purchas (Pilgrimes, iii. p. 995) in 1625 qnoted both from thia and from the amme suthor's IIystoria General, said to have been published a few years later. Oviedo's earlier work is only known to the present writer by the repriat of 1852.

2 The bibliography of the Turkey is so large that there is here no room to name the various works that might be citcd. Recent research has failed to add anything of importance to what has becn said on this point by Buffon (Oiscaux, ii pp. 132-162), Peanant (Arctic Zoology, 1p. 291-300), -an admirable summary, -and Broderip (Zoological Recreations, pp. 120-137) -not that all their statements can be wholly accepted. Earrington'a essay (Miscellanies, pp. 127-151), to prove that the bird nas known before the discevery oi Americs and was trausported thither, is an ingenious plece of special y, leading which his friend Pennant did him the real hindoess of ignoring.
${ }^{3}$ In 1872 Josselin ( Nelo Eaglaid's Raritics, p. 9) speaks of the settlers hringing up "great store of the wild kiod" of Turkeys, "which remain about their houses as tame as ours in England." The bird was evidently plentiful down to the very seabosrd of Massachusetts, and it is oot likely to have been domesticated by the Indian tribea there, as, according to Hernandez, it acema to have been by the Mexicans. It was probably easy to take alive, and, as we know, capahle of enduring the royage to England.
ally in having its tail-coverts and quills ripped with white or light ochreous, - poiats that recent North-American ornithologists rely upon as cliatinctive of this form. If this smpposition be true, there would be reason to beljeve in the double introduction of the bird iato England at least, as already hinted, but positive information is almost wholly wanting. The northern form of wild Turkey, whose habits have been described in mach detail by all the chicf writers on North-American birds, is now extinct in the settled parts of Canada and the eastern States of the Union, where it was once so numerous; and in Mexico the southern form, which would seem to have been never abundant siace the conquest, has been for many years rare. Further to the south, ou the bordera of Guatemala and British Houduras, there exists a perfectly distinct species, M. ocellata. whoso plumage almost vies with that of a Peacock in splendour. while the bare ckia which covers the head is of a deep blue studded with orange caruaclea (Proc. Zool. Socicty, 1861, pl. xl.).

The genus Meleagris is considered to enter into the Family Phasianidæ, in which it forrss a Subfamily Meleagrinx, peculiar to North and Central America. The fessil remains of three species, have been described by Prof. Marsh-one from the Miocene of Colorado, and two, one much taller and the other smaller than the existing species, from the Post-Pliocene of New Jersey. Both the last had proportionally long and slender legs.
(A. N.)

TURKS. The use of the name "Turks" has never been limited in a clear and definite way from the time of the Byzantine authors to the present day. To the former, as also to the Arabs, it has a collective sense like Scythians or Huns; ${ }^{5}$ at the present day we are wont to restrict the name to the Osmanli Turks, though they themselves refuse to be called Turks, having, as they hold, ceased to be such in becoming imbued with Arabo-Persian culture. On the other band, when we speak of Uiguró and Patars, we mean tribes who style themselves Turks and really are such. It is only by the aid of historical and linguistical cvidence that we can determine the true limits of the Turkish name.

The national Turkish traditions, preserved by the Origin Persian historians Rashid ed-Din and Jowaini from Uigurian books which are now lost, point to the region watered by the river Selenga and its affluents, the Orkhon and the Tugila, as the primitive seat of the Turkish peeple. Pashid ed-Din combines this tradition with that of the Mohammedan descendants of Oghuz, who, in accordance with Moslem traditions, derive the whole Turkish stock from Japhet, the son of Noah, or more accurately from Turk, the son of the former (Yafiz-oglan), and pretend that he pitched his tents in the vicinity of Lake Issyk-kul (in Semiryetchensk). But, though Turkish tribes did Ethoo wander so far to the west, and even farther, in remotelogica antiquity, it seems pretty certain that the Uigurian tradi- affines. tion has preserved the memory of the true origin of the race, that Turks and Mongols were originally different stems of a single people, and that these two members of the Ural-Alitaic (q.v.) family were more closely related to each other than to any other member of the same family (FinnoUgrians, Samoyedes, Tungus-Manchus). The evidence for this rests, not on the ethnological system of Rashid ed-Din, though it affords a secondary argument, but on the indubitable affinity of the Mongolian and Turkish languages and the similarity of the ethnological characters of the two races. Here, of course, we do not argue from the Osmanlis, who have lost all their original race-characters and have become "Caucasians" of the best type, but rather, for instance, from the Kirghiz, who are considered as the typical Turks of the present day, and are described by Ujfalvy as being midray betreen tho Mongol and the Caucasian. We must now turn our attention to the wanderings of the Torks and their subsequent fate, - a rather difficult task,

[^281]owing to the want of accurate information. The enly truly historical recerds are to be feund in the Chincse chironicles and encyclepædias, ${ }^{1}$ where, however, the Turkish preper names appear in such distorted forms as to bo unrecegnizable; yet, till the 6th century of our era, no other accounts are agailable.
It is generally admitted that the first. Turkish people mentioned by the Chincse aro the Hieng-nu, who, wandering to the west, occupied the country south of the Altai Mountains and expelled (about 177 B.c.) the former occupants of those regions, the Yue-chi, ${ }^{2}$ Kan-goi, and Usun ( $($-ssun), 一tribes of. unknown nationality, but possibly also Turks. ${ }^{9}$ The Hiong-nu were identified by Deguignes with the Huns, this denemination being used in a political or collective sense, and including, besides the Huns preper, the Ephthalites or White Huns, Avars, Bulgars, Magyars, Khazars, and Petchenegs, who are styled by several scholars Hunnic or Scythian peoples, -a term of no scientific value whatever, as the main body of these peoples censisted really of Mongol-Turks or Finne-Ugrians. As, however, separate articles have been devoted to most of these ethnical names, we alstain from further details, as alse from discussion of the question of the Turkish erigin of the Magyars and the Khazars, though that of the fermer seems to us as improbable as that of. the lattcr is certain. ${ }^{4}$ Be this as it may, the Hiong-nu are, so to speak, proteTurks, and the histery of the Turks proper begins with the Tu-kiu, the Chinese equivalent of the word Turk. Originally a division of the Hiong-nu, almost extirpated by wars, but miraculously saved from complete destruction, the Tr-kiu settled seuth of the Kin-Shan (Altai ?) Mountains, and were miners and iron-smelters in the service of the Juen-Juen " ("les Tartares Geou-gen" of Deguignes). About 552 A.D., hewever, they conquered their fermer masters and founded 2 mighty empire under princes who took the title of Tli khan. In these Tu-kiu Deguignes recogaized the Turks whe entered into friendly relations with Byzantium, and to whom Justin II. sent two ambassaders, -Zemarchus (568) and Valentinus (575). The narratives of these ambassaders are preserved in the fragments of Menander Protecter; and (comparing the variations of the corrupt text with the record of Tabari) from him we learn that at the first date the reigning prince was Sinjibulns (Arabic Sinjibu). ${ }^{6}$ From the Greek and the Arabo-Persian accounts it seems that Sinjibu put an end to the empire of

[^282]the Ephthalites or Haitals in these regions. He shared the conquered country with Khosrau I., the Oxus becoming the frontier between Irān and Turān. The memory of the empire of Sinjibu and of its political strength has been preserved by the Arabic authors Ibn Khordandbeh and Mas'udi, who inform us that the Turkish tribe of the Karluks, scttled in the provinces of Ferghāna and Shāsh (Tashkend), were of eld the mightiest of all the Turks, and that their sovereign, the khakan of khakans, was obeyed by all the neighbonring princes. To them they reckon the mythical Afrāsiāb and the historical Shāwa. ${ }^{7}$ It is.uncertain at what epoch the empire of the Karluks cane to an end; but the Chinese assert that about 650 they reduced the inhabitants of the Ili and Jaxartes territory, thoagb they wero unable to protect them afterwards against tho inroads of the Arabs under Kotaiba b. Moslim (706-714). The latter defeated the armies ecat to their aid under Kurbogha Noyon, a sister's son of the Chinese emperor. ${ }^{\text {Q }}$ It is also doubtful if the so-called Afrassiāb kings or Ilckkhans, whe reigned in the 10 th century at Käshgar and Balāsāghun and conqucred. (999) the dominiens of the Samanids in Transoxiana, belonged to the Karluks, as is supposed by Grigorieff and Lerch. or to the Uigurs, as others think.

The namo Uigurs is very common during the Mongolian period, and Rashid ed-Din aud others use it (by an ana chronism) in speaking of remote antiquity, though it is wholly unknown to the Arabic geographers, and, as Vambéry has shown, to the Uigurs themselves,-nay, even inpossible in the old Turkish language, in which the form would be Utkur. The name Ugur, Ogur, or Oger of Byzantine authors is really different; but Grigorieff has recognized the name in the corrupt Arabic form of Tagazgaz, which must be read Teguz-Ugur, ${ }^{9}$ the "Nine Ugnrs," to distinguish them from another division of the same tribe, the On-Ugur or "Ten Ugurs." In the time of Ibn Khordadbeh and Mas'udi these Turks had gained the snpremacy amongst their brethren, and had their residence at Kushän, which has been identified with the Kiao-chang of tie Chinese. According to their accounts, the Kiao-chang form the southern division of the Hui-khe (Hoei-ke of Deguignes), and were settled before the Christian era south and east of the Tian-Shan up to the Pamir plateau and the Kuen:Lun. The Arabic authers make them adherents of Manichreism; but, as the origimal Turkish Shamanism has developed into a dualistic system, this statement may rest on a partial misapprehension. It seems, $h o w e v e r$, certain that Buddhism reachcd these Turks on its way towards China, for we know that this religion spread in the $2 d$ century b.c. throughout the adjacent kingdom of Bactria, and was still flourishing when Hwen-T"sang visited (7th century) those regions. Thus we can understand why the old Ural-Altaic religion bears a Sånskrit namo. The northern division of the Hui-khe, which remained unknowis to the Arabs, wandered from the Selenga region to tuc sources of the. Yenisei, ranquished the Tu-kin (745): anc founded an empire from the Selenga to Lake Balkasti. till they were overthrown (841) by the Ha-kas (idealitied with the Kirghiz). These northern Uigurs are called by the Chinese Kao-che, Chi-le, Di-li, and Te-le. The histery of the southern branch is unknown, for the chronoiogicai data of Rashid ed-Din and Abn-1-Gbazi are contradictory and useless, though their statements that the prince bore the title of Idi-kut and submitted te the Mongols have full historical weight. That the Uigurs rose during the

7 Cp. Mas'udi, ed. Paris, i. 288 ; Nöldeke, ut $8 u p .$, 耳. 20e, $n_{0} 1$.

- The title Noyon, if the present writer's conjacture on the text of Tahari, ii. 1195, is right, proves that Karbogha was a Mongolian prines.
- Before this Reinaud had conjectured that the Tagazgaz were tlio same as the Uicurs. but failed to correct the Arabic comption.

Mongolian epoch to a certain supremacy by higher culture is attested by Rashid ed-Din and Jowaini, who often mention Uigurian books.

The Petchenegs (Gr. Пarछıvaкаи, Пат $\xi$ เvaкıтаь; Magyar Besenyö; Lat. Bisseni) were of old, as Constantine Porphyrogenitus tells us, settled about the lower Ural and Volga, but were driven thence $(894-899)$ by the Ghuzz (Ouzoi). A part of them returned afterwards to their ancient abode, but the great majority wandered westward and settled on both sides of the Dnieper, driving the Hungarians before them to the Carpathians. Here they annoyed the neighbouring peoples by their raids, and engaged readily in the Russian expeditions against the Greck empire, till the policy of the Byzantine court incorporated large numbers of them with its own armies, sometimes with fatal result, as was experienced by Romanus Diogenes, when these auxiliaries passed to the camp of his antagonist Alp Arslan. At the period of the first crusade the Christian armies met with them on their march through Servia and Bulgaria; but the Petchenegs are not mentioned after the 13 th century. The learning of Orientalists has discovered faint traces of the language once spoken by them in the Turkish dialect of the Bosnians. ${ }^{1}$

Comans or Cumani (Russ. Polowtze, Magyar Palocz and Kun) is a term chiefly used by Europeans for the Turkish tribes that occupied Moldavia and the adjacent regions of south Russia. The origin of the name is uncertain; but it seems to be Turkish, though it rarely occurs in Oriental records. The most probable conjecture regarding the people denoted by it is that they were a mixture of Ghuzz and Petchenegs. Oriental authors know much more of their neighbours to the east, the Kipchaks, a very common mame of Turkish clans down to the present day. Sometimes both names are combined: Rubruquis speaks of the Coman Kipchaks. Anna Comnena informs us that the Comans spoke the same dialect as the Petchenegs, a dialect well known to European scholars from the so-called Codex Cumanicus. ${ }^{2}$ On the arrival of the Mongols in these regions, the Kipchaks suffered great lardships, and large numbers of them were sold as slaves throughout the Mohammedan world. From them sprang the Bahrite Mameluke sultans of Egypt (1250-1380). The Comans sought refuge amongst the Hungarians and became Christians; but their arrival, causing internal dissensions in Hungary, greatly favoured the adrance of the Mongolian arms. The remnants of the Comans, Kipchaks, and other Turkish tribes coutinued to dwell in southern Russia under Mongolian rule (see Mongols), whilst others became merged with the Hungarians.

The Ghuzz dwelt originally in the far East amongst the Toguz-Ugur, but migrated in the reign of the caliph AlMahd (755-785) to Transoxiana, where they adhered to the cause of the famous Al-Mokannae, not from religious predilection, but to satisfy their love of war and plunder. In the same manner they afterwards served every warlike prince in their neighbourhood, and entered like other Turks into the service of the caliphs. The main body of the life-guard of the 'Abbãsids consisted of Turks, and seme individuals rose very soon to high commands. Entrusted with the administration of distant provinces, they founded independent princely houses, such as those of the Tulunids and Ikhshids in Egypt (rol. vii. p. 750) and the Ghazntids (see Ghazni). In the meantime fresh bands of the Ghuzz poured from the east and the vorth into Turkestan, the region becoming overstocked with a nomadic population. Some of them sought and found an outlet to the west by occupying the territory of the Petchenegs and joining the Turkish population of southern Russia; but

[^283]the great majority, seeing the ruined state of the empire of the caliphs, crossed the Oxus and overran the northeru and eastern provinces of Persia. How these loose desultory bands were guided to subsequent victories, and moulded with the peoples amongst whom they settled into regular political bodies, bas been already narrated undeı SeljuEs (q.v.).

Meanshile they underwent a great change in their outward appearance, habits, \&c., as Rashid ed-Din relates, owing to the influence of the air and the water, and, we may add, to frequent intermarriage with the inhabitants of the countries invaded by them. After somo generations the change was great enough to strike their Iranian neighbours, who called them Turkmans (Turcomans), ${ }^{3}$ a term implying resemblance to Turks. It is therefore quite natural that the modern Osinanlis should have become Caucasians; for, if Rashid ed-Din in the 13 th century noticed the difference between a Turkman and a genuine Turk, the six centuries which have elapsed since amply suffice to have obliterated all original Ural-Altaic characteristics. The old name Ghuzz, originally, as it seems, the Turkish Oghuz (an eponymous hero of whom Turkish chronicles tell many fables) was wholly superseded by the new name Turkman and by other political names.

During the Seljukian period there arose in Transoxiana the empire of the Khārizm shahs, founded by Mohammed b. Anushtegin, upon whom the government of Kharizm (Khiva), -which down to 995 had belonged to princes of Iranian descent-was conferred (1097) by the Seljuk prince Barkiyārok. His son Atsiz became independent (1138), but his empire seemed destined to early ruin by the arrival of the Kara-Chitai, who defeated the Seljuk prince Sinjar (1141) and became for a time supreme masters of Turkestan. Nevertheless the Kharizmian dynasty held its place as a tributary sovereignty, and developed great power under the princes Takash and Mohammed his son. The former defeated and killed (1194) the last Seljuk prince of 'Irak, and the latter extended his dominion from the Caspian to the Indus and from the Jaxartes to the coast of "Omān. His cunning antagonist, the 'Abbāsid caliph An-Nāsir, invoked the aid of Jenghiz Khān, who scarcely required this invitation to attack Mohammed. The sack of Bokhära was followed in the same year (1220) by that of the other principal cities of Transoxiana and by the persecution of the unhappy prince, who died in a forgotten island of the Caspian. His son Jelal-ed-Din was driven towards India, but by a change of fortune ascended once more the throne of his fathers, till the new Mongol khān, Ogdai, sent fresh armies against him and forced him to seek refuge in the Kurdish Mountains, where he was murdered (1231). The fate of the Turks of Transoxiana was shared by their brethron in Asia and Europe, and new Mongol-Turkish empires arose, of which an outline has been given under Mongols. As the Mongol rule grew weaker, there arose in Persia and on the frontiers of Asia Minor the Turkman dynasties of the Ak Koyun-lu, the Kara Koyun-lu, the Zu'l-kadria, and the Ramazān Oglu, whose history is closely connected either with that of the rise of the Ottoman power (see below) or with the history of Persia (see rol. xviii. p. 632 sq.).

At the present day the Turkish people occupy a very extensive area, the centre of which lies in Khiva, Boklara, and Khokand, and which stretches from the lower Lena in Siberia to the Dannbe and from the Crimea to Kermann aud India. Politically they be-
${ }^{3}$ The term "Turkman" occurs in Arabic chrouicles of the Seljukian period, and even in Mokaddasi, p. 274. Rashid ed-Din therefore exaggerates in stating that it only came into use in his lifetime. Bnt Vamber'y's statement that it was applied of old to the descendants of Oghuz is contradicted by the genuine Persian text of Rashide ed-Din and the unanimous testimony of history. His objections against the popular etsmelog meutioned above are, however, not quite unfounded.

Jong to Russia, Turkey, Persia, China, end Afghauistan. In religion the grest majority are Mohammadans; a few tribes in Russia are baptized Christians; and some others adhere to the originsl Shemanism, which bas also influenced the religions conceptions of the Christian and Mohammedsn Turks. The principal Turkish peoples are the following. (I.) By a popular distinction the Turks of Siberia and Russia, with some colqnies in Turkey, are styled Tatars (see Tartars), though the Yakuta of northern Siberis are not usually iucluded in this term. The Yakuts, who are perhaps a mixture of Turkish and Tungus tribes, deviating from the ordinary course of Turkish wsnderings, are settled ahout the lower Lena, and number probsbly 200,000 (Rittig, 80,000; Lansdell, 210,000). ${ }^{1}$. They are nominslly Christians. (II.) On the Kirghiz (Kara-Kirghiz and Kazāks) and Kara-Kalpaks see Kirghiz ; but note that the Kipchaks, named there as a separate tribe, really form a subdivision of the Kazāk-Kirghiz, and are perbaps akin to the Kitai-Kipchaks, who are reckoned to the Uzbegs. (III.) Uzbeg is a political, not an ethnological denomination, originating from Uzbeg Khān of the Golden Horde (1312-1340). It was used to distinguish the followers of Shaibāri Khān (16th contury) from his antagonists, and became finally the name of the ruling Turks in the khenstes as opposed to the Sarts, Tajiks, and such Turke as entered those regions at a later date and are known to be Kirghiz, Kara-Kalpaks, or Taranjis. The Uzbegs ere therefore a mixed race of different Turkish tribes. According to Kostenko, ${ }^{2}$ they number 201,972 in the Russisn provinces of Sir-Daria, Ferghāna, Zerafshan, and Amu-Daria, andVambéry conjectures that there are 1,000,000 more in Bokhare, 700,000 in Khivs, and 200,000 under Afghan supremacy, giving a total number of about $2,000,000$. They are agriculturists or inhabit the cities; a few are semi-nomads. (IV.) The eastern Turks on the eouthern elopes of the Tian-Shan Mountsins at Kasbgar, Ustturfan, Ak-su, Sairam, Kutchs, Yarkand, Khotan, \&c., are the remnants of the ancient Uigurs; and of the same origin are the Taranjis (=agriculturists), gettled in the Ili valley and elsewhere. The nomber of the latter is given as about 50,000 ; that of the former may bo estimated from the statements of Forsyth ${ }^{3}$ and Kuropatkin ${ }^{4}$ at about $1,000,000$ for the whole district, the great majority being Turks and the rest Mohammedan Chinese (Sungans). (V.) The Turcomans (properly Turkmans) inhabit the steppe east of the Caspian and south of the Oxus from Astrabad to the Paropamisus. The term is sometimes takeu to include their brethreu in Persia and Asia Minor, who will be treated separately. The following ore the principal tribes:-(1) the Tchaudors and Imrailis, in the northwestern part of the Ust-Urt to the Gulf of Karaboghaz; (2) the Yomuts, extending from Khiva across the Ust-Urt to the Caspian, sud along the sea-board to Persia; (3) the Göklen, on Persian territory, between the upper Gorgen and Atrek; (4) the Tekkes, the most numerous tribe at the present day, divided into the Akhal Tekkes and the Merp Tekkes, 60 named after the centres where their greatest numbers are found; (5) the Sakars, on the left bank of the Oxus, to the east of Tcharjui, considered by Vambéry as a division of the Tekkes; (6) the Sariks, at Penjdeh and Yul-utan on the nortb-western elopes of the Paropamisus; (7) the Salors, ono of the oldest Turkman tribes, who suffered grestly from the Tokkes, till they finally migrated (1857) to Zurahàd in Persia, and left their former districts to the Tekkes and Sariks; (8) the Ersaris, on the Orus about Khoja Salih; and (9) the Ali-elis, ahout Andkhui. Their total number, inclusive of some Turkmans who do not belong to any of these tribes, and are scattered throughout the provinces of Syr-Daria, Amu-Daris, Zerafshan, and Astrakhen (about 16,000), is estimated by Vambéry at about $1,000,000$, and by Grodekoff at 1,170,000. The Turkmans are, with few exceptions, nomads, and were formerly the terror of their neighbours, who feared them as the "man-stealing Turks"; but since Merv bas been ennexed to Russia (1884) they bave been compelled to abaudon their predatory habits. ${ }^{\circ}$ (VI.) The Turkish nomads scattered throughout Persia are partly the descendants of the Ghuzz tribes that invaded the cotuntry at the Seljukian period; others hare migrated thither in the following centuries. They are known by the name of Ilat or Iliyāt (meaning tribes or neoples) and consist of several trihes, having each its own chieftain, the Ilkhāni, appointed by the shah. An accurate list of tho names of these tribes does not exist; but the most powerful and most numerous are the following. (1) The Kajars, who dwelt in Transcaucasia down to the time of Abbas the Great, by whom one division of them was compelled to settle at the south-east corner of the Caspian near Astrabad. To this division belongs the present dynasty of Persia. (2) The Afshars or Aushars, a very numerous tribo, in the province of Adarbaijăn (Azerbijon). A division is slso settled in the mountainous regions of the Antitaurus; its members are nominally subjects of the Ottoman empire $h_{t}$ really independent. (3) The Shekakis and Shah-sewen. 3 Report of $G$ Mission to Yarkant.

4 Koshgaria, translated by W. E. Cowan, Calcutta, 1852.
The Merv. Nasis, London, The Turcomuns, trauslated by R. Michell ; O' Donoran, Yambery, Sh, London, 1882 ; and the jouruals of travellers in these regions, Vambéry, Schuyler, Lessar, sc.
latter is not a tribal, but a political name, meaning those who lora the ehah, i.e., partisans of the Șafari dynasty (1499-1736) and the Shīite faith. (4) Therkers Koyun-ln, near the town of Khon, the remnants of the once powerful tribe named sbove. Besides these, many other names are recorded of tribes wandering in the Trans csucasian regions and in the provinces of Adarbaijen and Mazenderan, but many of them are very uncertsin. All these Turks are comprehended nnder the general denomination of Adarbaijāni Turks; they are nomade or seni-nomads and speak a peculiar Turkish dlalect, the Turk Azeri or Adarbsijāni Turkish. Some specimens of it hsve been published by Chodzko, Bergé, Melgunoff, and Barbier de Meynard. Iu the southern provinces of Persis are settled the (5) Kashksis, (6) Abul-werdis, (7) Kara-Gözlüs, (8) Bahsr-lu, and (9) Inan-lu. To the first named are reckoned by some the Khalaches, ${ }^{\text {ban }}$ old Turkish tribe which was already settled near Herst before the Se?jukian period and has given rise to some Indian dynasties. Vambery thinks that the total number of Iraniau Turks msy emount to about two millions, or, if wo sdd the Csncasian Turks under Russian supremacy, three millions. ${ }^{7}$ (VII). The Osmanlis, under which term ate comprehended sll the Turkish subjects of the sultan of Turkey, consist chiefly of the following elements. (1) Turkmanian tribes and Turks of every description, who poured into Asia Minor after the defeat of Romanus Diogenes (1071); to these we may also reckon the Ottomans proper, though they did not enter the country till after the downfall of the Kharizmian empire. The Mongolian invasion drove the obscure ancestors of this the most illustrions Turkisb dynssty to Asia Minor, whence they gradually epread to the province of Khodawendikyār (Bithynis). (2) Tatara scattered amongst the rest of the population, but forming a large colony in the Dobrudja. In part they occupied their present settlements before the conquest of Constontinople; but others have immigrated into Asia Minor during the last two centuries from the Crimea and Caucasus, since the Russian conquests of those regious. They have fared very badly under Turkish rule, as is attested by Captain Wilson. That tribes of Turkish origin were settied in Europe long before the rise of the Ottoman power is known from the Byzantine authors, who mention a colony of them (about 30,000 ) as esrly as the 10th century in the Vardsr valley in Macedonia. ${ }^{9}$ (3) The so-called Kizil-bashis or "Red Heads," a nickname of the Sbitic Turkish immigrants from Persia, who are found chiefly in the plains from Kara-hissar along Tokat and Amasia to Angora. During the wars with Persia the Turkish sultans forced them to settle here. They are agriculturists and highly praised by several travellers for their honesty and laborious bsbits. (4) Turkmenian tribes-Yuruks and Götchebes (words meaning "nomads" and characteristic of their most distinctive quality), -who occupy the mountains in summer and descend into the plsins in winter, though some are settled iu the plains of Cilicia near Tsrsus and Adaua, the rest being semi-nomsds. Reclus estimates the total number of Turks in Europe at 1,500,000 and 35,000 Tatars. For Asia Minor statistics are wanting; but P. de Tchihatchef, the chief authority for matters relating to this peninsula, thinks that $6,000,000$ is a fair estimate for the total population, including Greeks, Armenians, Kurds, \&c., but excluding the islands. It appear's therefore necessary to reduce the already moderate number of Osmanlis given by Yambéry $(10,000,000)$ to about $6,000,000$.

## Language.

The Turkish, or, as some prefor to say, the Turco-Tatar language, Dialedy is a member of the Ural-Altaic family (see UraL-Altalc) and cal raf comprehends many dialects, which differ considerably in their ties. vocabulary and in a less degree also in their grammar. The study of these dialects has made sreat advances during the 19 th century. Abel Rémasat in. 1820 Enew only of four, viz, the Uigurian, Jagatai, Tatar, and Osmanli. Béresine in 1848 distinguished wine. teeu, grouned round three types, viz., (1) Jagatai dislects (Uigur, Coman, Jagatsi, Uzbegian, Turknasni, Kazani literary lsnguage); (2) Tatar dialects (Kirgbizian, Bashkiri, Nogai, Kumi, Karatchai, Kara Kalpaki, Meshtcheryaki, and Siberiau) ; (3) Turki dialects (Derbendi, Adarbaijāni, Krimmi, Anadoli, and Rumili). Böhtlingk (1851) added the Yakuti, and Shaw (1877) the Eestern Turki. Radloff (1882) subdivided tho one Siberisn dialect of Béresino into more than 3 dozen different dialects. On phonetic principles the last-name? proposes the following classification, which seems, however, not quite satisfactory: (1) Oriental dialects (Altsi, Baraba, Lebed, Tuba, Abakan, Kitarik, Soyon, Karagass dialects, and Uigur) ; (2) Occidental (Kirghizi, Irtish, Bashkir, and Volga dialcets, with numerous subdivisions) ; (5) Central-Asiatic (Taranji, Jagatai, \&c.) ; and (4) southern (Turkmani, Adarbaijāni, Caucasian, Anadoli, Krimmi, and Osmanli). It would be premature to criticise this systera till the author publisbes the second part of his grammar, which will treat of the real etymological phenomens of the north Turkish dialects. ${ }^{6}$ Cp. tho Tabakot i. Nâsiri, by Major Raverty, p. 553 sq., where the name is incorrectly writtea Khalj.

Cp. Lady Sheil, Glimpses of Life and Manners in Persin (London, 185é), and various articles by'Von Seillitz in the Bussischo Rivue, \&c

On the phenetical characteristics of each of these dialects ample information is given in his Phonetik der norrdichen Turk. Sprachen. These crent dialectical variaties are aasily accounted for by the want of a commen Turkish litarary languase nnderstood everywhere. The soost developed and refined Turkish tongue, that of the Osmanlis, which is rery rich in literary nonuments, has admitted too many Arabic and Parsian words, grammatical formo, and even whola sentences, and has been too much spoiled by the precepts of Persian rhatoric, to produce a popular literature. With tha exception of some talee and novels, this literature has remained an exotic production, unintelligible even to the poople who are snppused to apeak the sams language (see TUreEEY, p. 656 above). The Jagatai and Uzbegian dialects would have answared the purpose better, and preseat tha best typo of a (lypothetical) general Turkish languaso, of which the most prominent fastures masy ba here given.

The Arabic alphabet is in general nse, thongh come tribes in Rnssia make use of Russian and others in Asia Minor of Armenian and Greek characters. But the oldest Turkish alphabet, the Uigurian, is a direct transformation of the Syriac, and has foarteea charactars. When and by whom it was invantad is uncertain; the Arabic author of the Finrist does not mention it, and the Uigurian MISS. which $\pi \theta$ possess date for the most pert from the 15th cantory. It is commonly supposed to lee the rork of Nestorian missionaries, who may have preached the Gospel amongst the Turks as early as the 6 th or 7 th century. In the aga of Sinjibn the Turks aeem to have used the Sogdian characters in their political intercourse with Byzantium; but as a rule they remsincd illiterate till their convarsion to Islam. As the Semitic languages are charactarized by the threa-radical system and the constancy of the congonsats, all Ural-Altaic languages ara dominated by the law of vowel harmony snd agglutivation. We bave therefore in Turkish a double range of vowels, commenly eight in number, of which $a, i, 0, u$ denuta the hard or guttural and $a, k, b, t$ the soft or palatal vewels, the remels in every separate word beiag of the same range. The $i$ only is in most dialects indifferent. The lam of agglatination is derived from tho same principle, but has regard, not only to the vorsels, bnt also to the censonants and the syllables; it is an abose of the term if it is taken to mean that in Tarkish no real etymology exists, but only an agglutination of themes and roots.

As regards the etymology wo observe the absence of gender, of a coparate form for the dual, and of the nominativa in the neuns. There are commonly five oblique cases-genitive, dative, accusative, commorative, and ablative-though Bolitlingk has shown that in the Yalat dialect, which distinguishes ten cases, the genitive is wanting. The adjective, naless used as substantive, is uninflected both as attribute and as predicare; the comparativs is formed by tho suffix -rak (-rck), and takee the compared nean in the ablative; the superlative has no apecific form, thongh a peculiar intensive is formed by prefixing to the edjective (though in writing always as two words) a syllable beginning with the same consonant, and onding in a labial $p$ or $m$ : for instance, kap kera, "intensely black"; kip kizil, "intensaly red." The decimal syatem has prevailed over an original septimal eybtam. The article does not exist. The relative pronoun has bean borrowed from the Persian in many dialects ; it is absent in the original Tarkiah. The theme of the verb is seen in the imperative, from which are derived rarious narticiples and gerunds, asad either separately or combined with pronominal suffixes. Thase combinations onpply the forme of the simple tensas and moods, though different dialecta use different forms of participle and gernud for this purposs. Compond tenses and moods are expressed by meens of anxiliary verbs. The theme of the imperative may, by the addition of a simple consonant, vowel, or eyllable, be modified into a negative, passive, reflexive, raciprocal, impossible, causative, or doubly cansative form, which are con. jogated in the same manner as the erigiaal form. The causative forms again admit of a passive negative, sce, so that in fact the number of possible rerbal forms derived from a single theme bas been calcnlated by Shaw at 29,000 . There are ne prepositions, only postpositions.
In ayntax the order of the Fords and clauses of a period is almost the incarse of what seams natural to us, the snbject and its predicate being placed st the ond, while all hypothetical, causal, prohibitive, -in chert all subordinate-clauses come first. In the simple style of illiterate peasants, and in popnlar romances and tales, this method presents no inconveaience as regards easy understanding, but in the artificial, often excessively logg periods of an Osmanli etylist, is presents serious difficulties to a European reader. TURJIERIC, the tuberons root of Curcuma longa, L. an herbaceous perennial plant belonging to the natural order Zirgiberacex. It is a native of southern Asia, being cultivated on a large scale both on the maiuland and in the islands of the Indian Ocean. Turincric bas been used from a remote period both as a condiment and as a dye stuff, and to a more limited extent as a medicine. In Europe it is employed chiefly as a dye, also as an ingredient in curry powder and as a chemical test for alkalies. The root is prepared by cleaning it and drying it in an oven. There are several varieties (Madras, Bengal, Gopalpur, Java, China, and Cochin turmeric), differing chiefly in size and colour and to a slight degree in flavour. Some of these consist exclusively of the ovate central tubers, technically known as "bulbs," and others of the somewhat cylindrical láteral tubers, which are distinguished in trade as "fingers." Poth are hard and tongh, but break with a short resinous or waxy fracture, which varies in tint from an orange brown to a deep reddish brown.

Turmerio has a characteristio odour and an aromatic taste. The aroms it owes to a complex essential oil, which consisto principally of en alcohal called turmerol (formula $\mathrm{C}_{19} \mathrm{H}_{29} \mathrm{O}$ ), which differs from carvol in being unable to combine with hydrogen sulphide; the other constituents of the oil have not been datermined. The colonr is due to curcumin, $\mathbf{C}_{14} \mathbf{H}_{14} \mathrm{O}_{4}$ of which the drag containg about 0.3 per cant. It possesses the properties of an acid, forming red-brewn salts with alkalies and boing precipitated from alkaline solations by acids. When pure it forms yellow crystals hering a ranille odour and exhibitiag a fine blue colour in reflected light. It is soluble in alcohol, in chloroform, and in alkaline colutions, but anly sparingly in water. Paper tinced with a tincture of turmario exhibits on the addition of an alkali a reddish brown tint, which becomes violat on drying. This peculiarity was pointed ont by Vogel in 1815, and eince that date turmeric hos been otilized as a chemical test for detecting alkalinity. In India the drug is considered to possess cordial and stomachic properties : a decoction made with milk and oweetened is used as a remedy for colde. Externally it is employed in skin diseases and in the form of a cooling lotion for rclieving the pain of conjunctivitis; the fumes of the burning tubers diracted into the nostrils relieve congestion in cases of coryza. The cultivation of turmeric is carried on most successfully in light rich soil in well-watered districts. The plant is easily propagated by offsets. An acre yields abont 2000 Ib . Turmeric is baid to grow in large quantitiee on the slopes of hills bordering the plaine of the Beni in Bolivia and also in Panama. Several species of Curesma and of ellied genera yield yellowish aromatic roots. In Sierra Ieone a kind $0^{7}$ turmeric is obtained from a species of Canra.

TURNER, Charles (1773-1857), an English engraver, was born at Woodstock in 1773. He entered the schools of the Royal Academy in 1795 ; and, engraving in stipple in-the manner of Bartolozzi, he was employed by Alderman Boydell. .His finest plates, however, are in mezzotint, a method in which he engraved J. M. W. Turner's Wreck and twenty-four subjects of his Liber Studiorum, Reynolds's Marlborough Family, and many of Raeburn's best portraits, including those of Sir Walter Scott, Lord Nowton, Dr Familton Profe. Dugadd Stewart and John Robison, and Dr Adam. He also worked after Lawrence, Shoe, and Owen. He was an admirable ongraver, large, broad, and masterly in touch; and he reproduced with great fidelity the characteristics of the various painters whose works he translated into black and white. In 1828 he was elected an associate engraver of the Royal Academy. He died in London on Ist August 1857.

TURNER, Josepe Mallord William (1775-1851), one of the greatest painters of the English school, was born In London on 23d April 1775. His father, William Turner, a native of Devonshire, kept a barber's shop at 26 Maiden Lane, in the parish of St Paul's, Covent Garden; he was "a cheerful, talkative little man, with small blue ojes, a parrot nose, projecting chin, and a fresh complexion indicative of bealth." Of the painter's mother, Mary Marshall or Turner, little is known; she is said to have been a persou of ungoveruable temper and towards the end of her life became insane. Apparently the home in which Turner spent his childhood was not a happy one, and this may account for much that was unsociable and eccentric in bis character. The earliest known drawing by Turner, a view of Margate Church, dates from his ninth year. It was also about this time that he was sent to his first school at New Brentford. Of educaison, as the term is generally understood, he received but little. His father taught him to read, and this and a few months at New Brentford and afterwards at Margate were all the schooling he ever had; he never mastered his native tongue, nor was he able in after lifo to learn any foreign language. Notwithstanding this lack of scholarship, one of his strongest characteristics was a taste for associating his works with personages and places of legendary and historical interest, and certain stories of antiquity seem to have taken root in his mind very strongly. By the time Turner had completed his thirteenth year his school days were over and his choice of an artist's career settled. In 1788-89 he was receiving lessons from Palice, "a floral drawing master," from T. Malton, a perspective draughtsman, and from Hardwick, an architect. Ho also attended Paul Saudby's drawing school in St Martin's Lane. Part of his time was emplojed in making drawings at home, which he exhibited for salo in his father's shop window, two or three shilliugs being the usual price. He coloured prints for eugravers, washed in backgrounds for architects, went out sketching with Girtin, and made drawings in the evenings for Dr Munro "for half a crown and his supper." When pitied in after life for the miscellaneous character of his early work, his reply was "Well! and what could be better practice?" In 1789 Turner became a student of the Royal Academy. He also worked for a short time in the house of Sir Joshua Reynolds, with the idea, apparently, of becoming a portrait painter; but, the death of Reynolds occurring shortly afterwards, this intention was abandoned. Jn 1790 Turner's name appears for the first time in the catalogue of the Royal Academy, the titlo of his solitary contribution being "View of the Archbishop's Palace, Lambeth." About 1792 he received a commission from Walker, the engraver, to make drawings for his Copper-Plate Magazine, and this topographical work took him to many interesting places. Tho natural vigour of his constitution enabled him to cover much of the ground on foot. Ho could walk from 20 to 25 miles a day with ease, his baggage at the end of a stick, making notes and memoranda as he went. He rose early, worked hard all day, wasted no time over his simple meals, and his homely way of living made lim easily contented with such rude accommodation as he chanced to find on the road. A year or two after he accepted a similar commission to make drawings for the Pocket Magazine, and before his twentieth year he had travelied over many parts of England and Wales. None of these magazine drawings are remarkable for originality of treatment or for artistic feeling.

Up to this time Turner had worked in the back room above his father's slop. His love of secretiveness and solitude had already begun to show itself. An architect who often employed him to put in backgrounds to his drawings says, "ho would never suffer me to see him draw, but concealed all that he did in bis bed-room."

On another occasion, a visitor entering unannounced, Turner instantly corered up his drawings, and, in reply to the intimation, "I've come to see the drawings for -_," the answer was, "You shau't se0 'em, and mind that next time you come through the shop, and not up the back way." Probably the increase in the number of his engagements induced Turner about this time to set up a studio for himself in Hand Court, not far from his father's shop, and there ho continued to work till he was elected an associate of the Royal Academy (1799).

Until 1792 Turner's practice had becn almost exclusively confined to water colours, and his early works show how much he was indebted to some of his contemporaries. There are few of any note whose style ho did not copy or adopt. His first exhibited oil juicture appeared in the Academy in 1793. In 1791-95 Canterbury Cathedra:. Malvern Abbey, Tintern Abbey, Lincoln and Peterborough Cathedrals, Shrewsbury, and King's College Chapcl, Cambridge, were among the subjects exhibited, and during the next four years ho contributed no less than thirty-nino works to the Academy. In the catalogue of 1798 he first began to add poetic quotatious to the titles of his pictures; one of the very first of these-a passage from Milton s Paradise Lost-is in some respects curiously prophetic of one of the future characteristics of his art.
> " Yo mists and exhalations that uow riso From hill or steaming lake, dusky or grey Till the sun paints your fleecy skirts with gold, In honour of the world's great author rise.'

This and several other quotatious in the following jears show that Turner's mind was now occupied with something more than the merely topographical element of landscape, Milton's Puradise Lost and Thomson's Seasons being laid under frequent contribution for descriptions of sunrise, sunset, twilight, or thunderstorm. Turner's first visit to Yorkshire took place in 1797. It seems to have braced his powers and possibly helped to change the student into the painter. Until then his work had shown very little of the artist in the higher sense of the term: he was little more thau a painstaking and tolerably accurato topographer, but ereu under these conditions he had begun to attract the notice of his brother artists and of the critics. England was, at the time, at a low point both in literature and art. Among the artists De Loutherbourg and Morland were almost the only men of nute left. Hogarth, Wilson, Gainsborough, and Reynolds luad passed away. Beechey, Bourgeois, Garvey, Farington-names well-nigh forgotten now-were the Academicians who painted landscape. The only formidable rivals Turner bad to contend with wero De Loutherbourg and Girtin, and after the death of the latter in 1802 he was left undisputed master of the field.

It is not therefore surprising that the exhibition of his works in 1798 was followed by his election to the associateship of the Royal Academy. That he should have attained to this position before completing his twentyfourth jear says much for the wisdom and discernment of that body, which further showed its recognition of his talent by electing him an Academician four years later. Turner owed much to the Academy. Mr Ruskin saya, "It taught him nothing." Possibly it had little to teach that he had not already been able to learn for himself; at all events it was quick to see his genius aud to confer its honours, and Turner, naturally generous and grateful, never forgot this. He enjoyed the dignity of Acadennician for nearly half a century, and during nearly the whole of that period he took an aclive share in the direction of the Academy's affairs. His sueeches are descrihcd as "confused, tedious, obscure, and extremely difficult to follow"; but at council meetings he was ever anxious to allay anger end bitter controversy. His oviaions on art were always
listened to with respect ; out on matters of business it was often difficult to know what he meant. His friend Chantrey used to eay, "He has great thoughts, if only be could express them." When appointed professor of perspective to the Royal Academy in 1808, this painful lack of expression stood greatly in the way of his usefulners: he was often at a loss for words to express his ideas, and when he had recourse to his notes he found difficulty in reading them. Mr Ruskin says, "The zealous care with which Turner endeavoured to do his duty is proved by a series of large drawings, exquisitely tinted, and often completely coloured, all by his own hand, of the most difficult perspective subjects, illustrating not only directions of line, but effects of light, with a care and completion which would put the work of any ordinary teacher to utter shame." In teaching he would neither waste time nor spare it. "If a student would take a hint, Turner was delighted and would go on with him giving bint after hint; if he could not follow, he left him. Explanations are wasted time; a man who can see understands a touch; a. man who cannot misunderstands an oration." With his clection to the associateship of the Academy in 1799, Turner's early struggles may be considered to have ended. He had emancipated himself from hack work, had given op making topographical drawings of castles and abbeys for the engravers-drawings in which mere local fidelity was the principal object-and bad taken to composing as he drew. Local facts had become of secondary importance compared with effects of light and colour. He had reached manhood, and with it he abandoned topographical fidelity and began to paint his dreams, the visionary facultythe true foundation of his art-asserting itself, nature being used to supply suggestions and materials.

His pictures of 1797-99 had shown that he was a painter of no ordinary power, one having much of the poet in him, and able to give expression to the mystery, beauty, and incxhaustible fulness of nature. His work at this period is described by Mr Ruskin as "stcrn in manner, reserved, quiet, grave in colour, forceful in hand."

Turner's visit to Yorkshire in 1797 was followed a year or two later by a second, and it was on this occasion that he made the acquaintance, which afterwards ripened into a long and staunch friendship, of Fawkes of Farnley Hall. From 1803 till 1820 Turncr was a frequent visitor at Farnley. The large number of his drawings still preserved there-English, Swiss, German, and Italian, the studies of rooms, outhouses, porches, gatcways, of birds shot while he was there, and of old places in the neighbour-hood-prove the frequency of his visits and his affection for the place and for its hospitable master. A caricature, made by Fawkes, and "thought by old friends to be very like," shows Turner as "a little Jewish-nosed man, in an ill-cut brown tail-coat, striped waistcoat, and enormous frilled shirt, with feet and hands notably small, sketching on a small piece of paper, held down almost level with his waist." It is evident from all the accounts given that Turner's personal appearance was not of a kind to command much attention or respect. This may have pained his sensitive nature, and led him to seek refuge in the solitude of his painting room. Had he been inclined he had abundantopportunity for social and fricndly intercourse with his fellow-men, but he gradually came to live more and more in a state of mental isolation, keeping himself to hinself, entirely absorbed in his art. "This man must be loved for his works, for his person is not striking nor his conversation brilliant," is the testimony of Dayes, the watcr-colour painter (and Girtin's master), in 1804. Turner could never make up his mind to visit Farnley again after his old friend's death, and his voicề would falter when he spoke of the shores of the Wharfe.

Turner visited Scotland in 1800, and in 1801 or 1802 L made his first tour on the Continent. In the following year, of the seven pictures he exhibited six were of foreign subjects, among them Bonneville, the Festival upon the Opening of the Vintage of Matcon, and the well-knowe Calais Pier in the National Gallery. The last-named picture, although heavily painted and somewhat opaque in colour, is magnificently composed and full of energy A better idea of its masterly composition can be formed from Mr Seymour Haden's vigorous etching than from the picture itself, which is now greatly darkened by time.

In 1802, the jear in which Turner became a Royal Academician, he took his old father, who still carried on the barber business in Maiden Lane, to live with him. The powder tax, imposed in 1795, drove out wigs and spoiled the old man's trade. "It is precisely," says Mr Hamerton, "when the painter wins the full honours of the Academy-honours which give a recognized and envied position in London society-that he takes his father home; a meaner nature wonld have tried to keep the old man at a safe distance." Turner's relations with his father were of the most dutiful and filial kind to the last. ${ }^{1}$

In 1804 Turner made a second tour on the Continent, and in the following year painted the Shipwreck and Fishing Boats in a Squall (in the Ellesmere collection), seemingly in direct rivalry of Vandervelde, in 1806 the Goddess of Discord in the Garden of the Hesperides (in rivalry of Poussin), and in 1807 the Sun rising through Vapour (in rivalry of Clande). ${ }^{2}$ The last two are notable worke, especially the Sun. In after years it was one of the works he left to the nation, on the special condition of its being lung beside the Claudes in the National Gallery. In this same jear (1807) Turner commenced his most serious rivalry. Possibly it arose out of a desire to break down Claude worship, the then prevailing fashion, and to show the public that there was a living artist not un worthy of taking rank beside him. That the Liber Studiorum was suggested by the Liber. Veritatis of Claude, and was intended as a direct challenge to that master, is beyond doubt. There is, however, a certain degree of unfairness to Claude in the way in which the challenge was given. Claude made drawings in brown of his pictures as they left the easel, not for publication, but merely to serve as private memoranda. Turner's Liber drawings had no such purpose, but wre intended as a direct appeal to the public to judge between the two artists. The first of the Liber drawings were made in the autumn of 1806, the others at intervals till about 1815. They are of the same size as the plates and carefully finished in sepia. About fifty of them are now to be seen in the Turner rooms of the National Gallery. The issue of the Liber began in .1807 and continued at irregular intervals till 1819, when it stopped at the fourtcenth number. Turner had resolved to manage the publishing business himself, but in this he

[^284]was not very successful. He soon quarrelled with his engraver, F. C. Lewis, on the ground that he had raised his charges from five guineas a plate to eight. He then employed Charles Turner, who agreed to do fifty plates at the latter sum, but, after finishing twenty, he too wished to raise his price, and, as a matter of course, this led to another quarrel. Reynolds, Dunkarton, Lupton, Say, Dawe, and other engravers were afterwards employedTurner himself etching and mezzotinting some of the plates. Each part of the Liber contained five plates, the oubjects, divided into "historical," "pastoral," "marine," Sc., embracing the whole range of landscape art. Seventyone plates in all were published (including one as a gift of the artist to his subscribers); ten other plates-more or less completed-intended for the fifteenth and sixteenth numbers were never published, the work being stopped for want of eucouragement. Absence of method and business babits may account for this. Turner is said to have got up the numbers in his own house with the help of a female servant. The plates, which cost the subscribers only five shillings apiece, were so little esteemed that in the early quarter of the 19th century they were sometimes used for lighting fires. So much has fashion, or public taste, changed since then that a fine proof of a single plate has sold for $£ 210$. The merit of the plates is unequal ; some-for example, Solway Moss, Inverary Pier, Hind Head Hill, Ben Arthur, Rizpah, Junctiou of the Severn and Wye, and Peat Bog-are of great beauty, while a few are comparatively tame and uninteresting. Among the unpublished plates Stonehenge at Daybreak and Sheep Washing, Windzor Castle take a high place. The Liber shows strong traces of the influence of Cozens and Girtin, and, as a matter of cousse, of Claude. In most of the designs the predominant feeling is serious; in not a few, gloomy, or even tragic. A good deal has been written about Turner's intention, and the "lessons" of the Liber Studiorum. Probably his only intention in the beginning was to show what he could do, to display his art, to rival Claude, perhaps to educate public taste, and at the same time make money. If lessons were intended they might havo been better conveyed by words. "Silent elways with a bitter silence, disdaining to tell his meaning,"-such is Mr Ruskin's explanation; but surely Turner had little reason for either silence or contempt because the public failed to see in landscape art the means of teaching it great moral lessons. The seventy plates of the Liber contain an almost complete epitome of Turner's art. Already in this work aro seen strong indications of one of his most remarkable characteristics-a knowledge of the principles of structure in natural objects: mountains and rocks are drawn, not with topographical accuracy, but with what appears like an intuitive fetling for geological formation; and trees have also the same expression of life and growth in the drawing of stems and branches. This instinctive feeling in Turuer for the principles of organic structure is treated of at considerable length in the fourth volume of Modern Painters, and Turner is there contrasted with Claude, Poussin, and some of the Dutch masters, greatly to their disadvantage.

After 1797 Turner was little concerned with mere topographical facts : his pictures might be like the places represented or not; much depended on the mental impression produced by the scene. He preferred to deal with the spirit, rather than with the local details of places. A curious example of the reasonableness accompanying his exercise of the imaginative faculty is to be found in his creations of creatures he had never seen, as, for example, the dragon ${ }^{1}$ in the Garden of the Hesperides and the python

[^285]in the Apollo, exhibited in 1811. Both these monsters are imagined with such vividness and reality, and the sense of power and movement is so completely expressed, that the spectator never once thinks of them as otherwise than representations of actual facts in natural history. It needs but a little comparison to discover how far Turner surpassed all his contemporaries, as well as all who preceded him, in these respects. The imaginative faculty he possessed was of the highest order, and it was further aided by a memory of the most retentive and unerring kind. A good illustration of this may be seen at Farnley Hall in a drawing of a Man-of-XVar taking in Stores. Some one, who had never seeu a first-rate, expressed a wish to know what it looked like. Turner took a blank sheet of paper one morning after breakfast, outlined the ship, and finished the drawing in three hours, Fawkes sitting beside him from the first stroke to the last. The size of this drawing is about 16 in . by 11 in . Mr Ruskin thus describes it :
"The hull of s first-rate occupies nearly one half of the picturs to the right, her hows toward the spectator, seen in sharp perspective from stem to stern, with all her port-holes, funs, anchors, and lower rigging elaborately detailed, two other ships of the line in the middle distance drawn with equal precision, a noble breezy sea, full of delicate drawing in its waves, a store ship beneath the hull of the larger vessel and several other boats, and a complicated cloudy sky, ali drawn from memory, down to the smallest rope, in a drawiug-room of a mansion in the middle of Yorkshire."

About the year 1811 Turner paid his first risit to Devonshire, the county to which his family belonged, and a curious glimpse of his simple manner of life is given by Redding, who accompanied him on some of his excursions. On one occasion they spent a night together in a small road-side inn, Turner having a great desire to see the country around at sunrise.
"Turner was content with bread and cheese and beer, tolerably good, for dinner and supper in one. In the little sanded room we conversed by the light of an attenuated candle and some sid from the moon until nearly midnight, when Turner laid his head upon the table and was soon fast asleep. Three or four hours rest was thus obtained, and we went out as soon ss the sun was up to explore the eurrounding neighbourhood. It was in that early morning Turner made a sketch of the picture Crossing the Brook." In another excursion to Borough Island, "the moruing was squally and the sea rolled boisterously into the Sound. Off Stakes Point it became stormy ; our Dutch hoat rode bravely over the furrows. Two of the party were ill. Turner was all the while quiet, watching the troubled scene. Bolt Head, to seaward, against which the waves broke with fury, seemed to absorb his entire notice, and he scarcely spoke a eyllable. While the fish were getting ready Turner mounted nearly to the highest point of the island rock, and seemed writing rather than drawing. The wind was almost too violent for either purpose."

This and similar incidents show how careless of comfort Turner was, and how devoted to his art. The tumult and discomfort by which he was surrounded could not distract his powers of observation; and some thirty years later there is still evidence of the same kind. In the catalogue of the exhibition of 1842 one of his pictures bears the following title, "Snow-Storm: steam-boat off a harbour's mouth making signals in shailow water, and going by the lead. The author was in that storm the night the 'Ariel' left Harwich."

From 1813 till 1826, in addition to his Harley Street residence, Turner had a country house at Twickenham. He kept a boat on the river, also a pony and gig, in which he used to drive about the neighbouring country on sketching expeditions. The pony, for which Turner had a great love, appears in his well-known Frosty Morning in the National Gallery. He appears to have had e great affec-
fish-eater, to show his sea descent (and this in the year 1800, when hardly a single fossil saurian skeleton existed within 'Tumer's reach), renders the whole conception one ol the mast curious exertions of the imaginative intellect with which I am acquainted in the arts" (Ruskin. Mord. Painters, vol. r. p. 313).
tion for animals, and one instance of his tenderness of beart is given by one who often joined him in the amusement of fishing, of which Turner was very fond. "I was often with him when fishing at Petworth, and also on the banks of the Thames. His success as an angler was great, although with the worst tackle in the world. Every fish he caught he showed to me, and appealed to me to decide whether the size justified him to keep it for the table or to return it to the river; his hesitation was often almost touching, and he always gave the prisoner at the bar the benefit of the doubt."

In 1813 Tumer commenced the series of dramings, forty in number, for Cooke's Southern Coast. This work was not completed till 1826. The price he at first received for these drawings was $£ 7,10$ s. each, afterwards raised to $£ 13,2 \mathrm{~s} .6 \mathrm{~d}$.

Crossing the Brook appeared in the Academy of 1815. It nay be regarded as a typical example of Turner's art at this period, and marks the transition from his earlier style to that of his maturity. It represents a piece of Devonshire scenery, a view on the river Tamar. On the left is a group of tall pine-trees, beautifully designed and drawn with great skill and knowledge of structure, in the foreground a couple of children, with a dog carrying a bundle in its mouth across the brook, and beyond, a vast expanse of richly-wooded country, with glimpses of a winding river, an old bridge, a mill, and other buildings, and, in the far distance, the sea. Both in design and execution this work is founded upon Claude. Some critics consider it one of Turner's greatest works; but this is open to question. ${ }^{1}$ It can hardly be called a work in full colour: it is limited to greys and quiet greens for the earth and pale blues for the sky. It is a sober but very admirable picture, full of diffused daylight, and in the painting of its distance better than any master who had preceded him. The fascination of the remote, afterwards 30 distinctive an element in Turner's pictures, shows itself here. Perhaps nothing tests the powers or tries the skill of the landscape-painter more severely than the representation of distant effects. They come and go so rapidly, are often in a high key of light and colour, and so full of mystery and delicacy, that anything approaching to real imitation is impossible. Only the most retentive memory and the most sensitive and tender feeling will avail. These quatities Turner possessed to a remarkable degree, and his powers matured there was an ever-increasing tendency in his art to desert the foreground, where things were detiaite and clear, in order to dream in the infinite suggestiveness and space of distances. Dido Building Carthage also belongs to this period. It hangs beside the Claudes in the National Gallery. It pertains to the old erroneous school of historical painting. Towering masses of Claudesque architecture piled up on cither side, portiooes, vestibules, and stone pines, with the sun in a yellow sky, represent the Carthage of Turner's imagination. With all its faults it is still the finest work of the class he ever painted. Carthage and its fate had a strange fascination for him. It is said that he regarded it as a moral example to England in its agricultural decline, its increase of luxury, and its blindness to the insatiable ambition of a powerful rival. He returned again to this theme in 1817, when he exhibited his Decline of the Carthaginian Empire: Hostages Leaving Carthage for Rome,-a picture which Mr Ruskin describes as "little more than an accumulation of academy student's outlines coloured brown."

In 1818 Turner was in Scotland making drawings for

[^286]the Provincial Antiquities for which Sir Walter Scots supplied the letterpress, and in 1819 he visited Italy for the first time. One of the results of this visit was a great change in his style, and from this time his works became remarkable for their colour. Hitherto he had painted in browns, greys, and blues, using red and yellow sparingly. He had gradually been advancing from the sober grey colouring of Vandervelde and Ruysdael to the mellow and richer tones of Claude. His works now begin to show a heightened scale of colour, gradually increasing in richness and splendour and reaching its culminating point in such works as the Ulysses, Childe Harold's Pilgrimage, the Golden Bough, and the Fighting Teméraire. All these works belong to the middle peried of Turner's art (182939), when his powers were entirely developed and entirely unabated. Much of his most beantiful work at this period is to be found in his water-colour dramings: those executed for Whitaker's Mistory of Richmondshive (1819-21), for Cooke's Southern Coast (1814-26), for The Rivers of Englund (1824), for England and Trales (1829-38), Provinciul Antiquities (1826), Rogers's Ituly (1830), Scott's Works (1834), and The Rivers of France (1833-35) are in many instances of the greatest beauty. Of the Richmondshire drawings Mr Ruskin says, "The foliage is rich and marvellous in composition, the rock and hill drawing insuperable, the skies exquisite in complex form."

But perhaps one of the greatest services Turner rendered to the art of England was the education of a whole school of engravers. His best qualitics as a teacher came from the union of strength and delicacy in his work; subtle and delicate tonality was almost a new element for the engraver to deal with, but with Turner's teaching and careful supervision his engravers by degrees mastered it more or less successfully, and something like a new development of the art of engraving was the result. No better proof cau be found of the immense advance made than by comparing the work of the landscape engravers of the pre-Turnerian period with the work of Miller, Goodall, Willmore, Cooke, Wallis, Lupton, C. Turner, Brandard, Cousen, and others who worked under his guidance. The art of steel engraving reached its highest development in Englaud at this time. Rogers's Italy (1830) and his Poems (1834) contain perhaps the most beautiful and delicate of the many engravings executed after Turner's drawings. They are vignettes, ${ }^{2}$ a form of art which Turner understood better than any artist ever did before,-perhaps, we might add, since. The Alps at Daybreak, Columbus Discovering Land, and Datur Horct Quieti may be given as examples of the finest.

In 1828 Turner paid a secoud visit to Italy, this time of considerable duration, on the way visitiug Nimes, Avisnon, Marseilles, Geuoa, Sperzia, and Siena, and in the following year he exhibited the Ulysses Deriding Polyphemus, now in tho National Gallery. It marks the beginning of the central and best period of Turner's power. This work is so well known that description is hardly needed. The galley of Ulysses occupies the centre of the picture; the oars are being thrust out and the sailors flocking up the masts to unfurl sail, while Ulysses wares the blazing olive tree in defiance of the giant, whose huge form is seen high on the cliffs above; and the shadowy horses of Phcebus are traced in the slanting rays of the rising sun. The impression this picture leares is one of great power and splendour. The painting throughout is magnificent, especially in the sky. Leslie speaks of it as "a poem of
${ }^{2}$ "Of all the artists who ever lived I think it is Turner who treated the vignette most exquisitely, and, if it wore necessary to find some particular reason for this, I should say that it may have been because there was nothing harsh or rigid in his gevius, that forms and colours nelted into each otber tenderly in his dream worid, and that his sense of gradation wre the most delicate ever possessed by man" (Hamertan).
mátchless splendour and beauty." From this period onward till about 1840 Turner's life was one of unceasing activity. Nothing is more astonishing than his prodigious fertility; he rose early, worked from morning till night, entirely absorbed in his art, and gradually became more and more solitary and isolated. Between $\cdot 1829$ and 1839 he sent fifty-five pictures to the Royal Academy, painted many others on private commission, māde over four hundred dramings for engravers, besides thousands of studies and sketches from nature. His industry accounts for the immense quantity of work he left behind him. There is not the slightest evidence to show that it arose from a desire to make money, which he never cared for in comparison with his art. He has been accused, perbaps not without some cause, of avarice and meanness in his business dealings, and many stories are told to his discredit. But in private he often did generous things, although owing to his reserved disposition his virtues were known only to a few. His faults on the other hand-thanks to the malice, or jealousy, of one or two individuals-were freely talked about and, as a matter of course, greatly exaggerated. "Keep it, and send your children to school and to church," were the words with which he declined repayment of a considerable loan to a poor drawing-master's widow. On another occasion, when interrupted in his mork, he roughly chid and dismissed the applicant, a poor moman; but she had hardly left his door before he followed her and slipped a $£ 5$ note into her hand. His tenants in Harley Street were in arrears for years, but he would never allotr his lawyer to distrain; and if further proof of his generosity were needed his great scheme for bettering the condition of the unfortunate in his own profession should suffice. On one occasion he is known to have taken down a picture of his own from the walls of the Academy to make room for that of an unknown artist.
The first of Turner's Venetian pictures (Bridge of Sighs, Ducal Palace and Custom House, Venice, Canaletti Painting) appeared in the Academy in 1833. Compared with the sober, prosaic work of Canaletti, Turner's pictures of Venice appear like poetic dreams. Splendour of colour and carelessiess of form generally characterize them. Venice appeared to him " $a$ city of rose and white, rising out of an emerald sea against a sky of sapphirc blue." Many of these Venetian pictures belong to his later manner, and some of thefn, the Sun of Venice Going to Sea (1843), Approach to Venice (1844), and Venice, Evening, Going to the Ball (1845), to his latest. As Turner grew older his love of brilliant colour and light became more and more a characteristic. In trying to ohtain these qualities he gradually fell into an unsound method of work, treating oil as if it had been water-colour, using both indiscriminately on the same canvas, utterly regardless of the result. Many of his finest pictures are already in a ruined state, mere wrecks of what they once were.
The Fighting Tėméraire Tugged to her Last Berth to be Broken up (see vol. xxi. p. 441, fig. 43) was exhibited in the Academy of 1839. By many it is considered one of his finest works. Turner had all his life been half a sailor at heart : he loved the sea, and shipping, and sailors and their ways; many of his best pictures are sea pieces; and the old ships of Collingwood and Nelson were dear to him. Hence the pathetic feeling be throws around the fighting Téméraire. The old three-decker, looking ghostly and wan in the evening light, is slowly towed along by a black, fiery little steam tug,-a contrast suggesting the passing away of the old order of things and the advent of the new; and behiad the sun sets red in a thick bank of smoke or mist. The Slave Ship, another important sea picture, was exhibited in the following year, and in 1842 Peace: Burial ot Sea, commemorative of Wilkie.

Turner had now reached his sixty-serenth year, but no very marked traces of declining power are to be seen in his work. Many of the water-colour drawings belongisg to this period are of great beauty, and, although a year or two later his other powers begarf to fail, his faculty for colour remained unimparred alnust to the end. He paid his last visit to the Continent in 1843, wandering abous from one place to another, and avoiding his own countrymen, an old and solitary man. . At his house in Queen Anne Street they were often ignorant of his whereabouts for months, as he sellom took the trouble to write to any one. Two years later (1845) his health gave way and with it both mind and sight began to fail. The works of his declining period exercised the wit of the critics. Turner felt these attacks keenly., He was naturally kindhearted and acutely sensitive to censure. "A man may be weak in his age," he once remarked, "but you should not tell him so."

After 1845 all the pictures shown by Turner belong to the period of decay,-mere ghosts and shadots of what once had been. In 1850 he exhribted for the last time. He had given up. attending the meetings of the Academicians; none of his friends lad seen him for months; and evca his old housekeeper had no idea of his whereabouts. Turner's mind had evidently given way for some tilue, and with that love of secrecy which in later years had glown into a passion he had gone away to hide himself in a corner of London. He had settled as a lodger in a suall house in Chelsea, overlooking the river, kept by his old Margate landlady, Mrs Booth. To the children in the neighbourhood he was known as "Admiral Bootl.," His short, sailor-like figure may account for the idea that he was an impoverished old naval officer. He had been ill for some weeks, and when his Queen Aune Street housekeeper at last discovered his hiding-place she found him sinking, and on the following day, the 19th Deceniber 1851, he died. He was buried in St Paul's cathedral, in deference to a wish te had himself expressed.

Fo left the large fortune he had amassed (about $£ 140,000$ ) to found a charity for the "maiutenance and support of male decayed artists, being born in England, and of English parents only, and of lawful issue." His pictures he hequeathed to the nation, on condition that they were to be exhibited in rooms of their owu, and that these rooms were to he called "Turner's Gallery." The will and its codicils were so confused that after years of litigation, during which a large part of the money was wasted in legal expenses, it was found impossible to decido what Tumer really manted. A compromise was effected in which the wishes of everybody, sare those of the testator, were consulted, his next-of-kin, whom he dil not mean to get a single farthing, inheriting the lonk of his property. The nation got all the pictures and drawings, and the Royal Academy £20,000.

It is unnecessary here to do more than allude to the charerg Which have heen brought against Turner's moral character. Like most men of note he had his enemies and detractors, and it is to be regretted that so many of the steries they aet in circulation shonld have been repeated by one of his biograpleers, who candidly admits having 'spared none of lris faults," and excuses himself for so doing by "what he hopes" is his "undeviating love of truth." The immense quantity of work accomplished by Turner during his lifetime, work full of the utmost delicacy and refinement, proves the singularly fine condition of his nervous system, and is perhafs the best answer that can be given to the charge of being excessively addicted to senanal gratification. In his declining years he possibly had recourse to stimulants to help his failing powers, but it by no means follows that he went habitually to excess in their nse. Ho never lost an opportunity of doing a kindness, and under a rough and cold exterior there was more gool and worth hidden than the world imagined. "During the ten years I knew him," says Mr Ruskin, "years in which ho was suffering most from the evilopeaking of the world, I never heard him say ore depreciating word of any living man or man's work; I never saw him look an onkiud or blamefnl look; I never knew him let pass, without sorrowfu] remonstrance, or endeavour at mitigation, a blameful word spoken by another. Of no man but TurDer, whom I have ever known, could I say this." Twice during his earlier days there are circumstances leading to the belief that he had thoughts of
marriage, but on both occasions it ended in dissppointment, and his home after his father died was cheerless and solitary, without rolace or comfort of any kind.
If Turner had died early his repatation as an artist would havo l.een very different from what it ultimately became. He wonld hot bave been recognized as a colourist. It was only after the year 1820 that colour began to assert itself strongly in his work. He painted for many a year in greys and greens and browns, went steadily through " the subdued golden chord," and painted yellow mists and suns rising through vapour ; but as time went on that was no longer enough, sud he tried to paint-the sun in his strength end the full glories of sunshine. The means at the painter's disposal are, howerer, limited, and Turner, in his efforts after brilliancy, hegan to indulge in reckless experiments in colour. He could not cndure even the slightest restraints which technical limitations impose, but went on trying to paint the unpaintable. As a watercolour painter Torner stands pre-eminent; he is unquestionably the greatest master in that branch of art that ever lived. If his work is compared with that of Barrett, or Varley, or Cozeus, or Sandby, or any of the earlier masters, so great is Turner'a superiority that the art in his hands seems to bo lifted altogether into a higher region.

In 1843 a champion, in the person of Mr Ruskin, arose to defend Turner against the unjust and ignorant attecks of the press, and what at first was intended as a "short pamphlet, reprobating the manner aud style of these critics," grew into the five volumes known as AFodern Painters. The writer employs all his eloquence a ad his great critical faculty to prove how immeasurably euperior Turner was to all who had ever gone before, hardly restricting his sapremacy to landscape art, and placing him amoug the "seven supreme colonrists of the Forld." Two lives of Turner have been written, one by Mr Thornbury, the other by Mr Hamerton. The work of the latter deserves the highest commendation; it gives a clear and consistent history of the great artist, and is characterized by refined thought and critical insight. An excellent little book by Mr W. C. Monkhouse should also be noticed.
(G. RE.)

TURNHOUT, a town of Belgium, in the province of intwerp, 25 miles east-north-east from Antwerp and 6 from the Dutch frontier, stands in the middle of a wide lain. It is a prosperous manufacturing and commercial centre, the chief industries being the weaving of cottons and linens (especially ticking), lace-making, paper-making, brick-making, dyeing, bleaching ; there is also an establishment for the rearing of leeches. The population of the commune in 1876 was 15,743 .

TURNING. Sce Lathe.
TURNIP. See Agriculture, vol. i. pp. 365-368, and Horticulture, vol. xiu. p. 288.
turnip-Fly, Tornip-Flea, or Earth Flea-Beetle, the name applied to several species of Haltica which infest turnip fie!ds and do considerable damage to crops. The genus belongs to the family Chrysomelidx, and includes about 100 species. The turnip-fly mest usually" met with, Haltica nenorum, is scareely 2 mm . in length and of a shining black colour, with two ochreous yellow longitudinal bands runuing along each wing-case; the bands are slightly sinuous and bend inwards at the hinder end. Of the elevenjointed antenre the first three segments are yellow and the remainder black. The coxx are black, the rest
 $\underset{\substack{\text { Turnip fly (IIIaltica } \\ \text { nemorum). }}}{\text { Y. }}$ of the legs having a yellowish hue. The coxe and tibize are stout and formed for leaping, especially in the posterior pair of legs. The remarkable power of jumping las given rise to the name turnip-flea. The females are slightly longer and decidedly stouter than the males.
Another species, H. concinna, has a greenish yellow or brassy appearance, and the tibie of the two posterior legs are armed with a thorn-like hook. A third species, $H$. consobrina, is of a dark bluo colour above, whilst another species, $H$. obscurella, often very abundant, is of a lighter btue colour, and iarger than those-mentioned above.
The life-history of Hallicu nomorum may be takeo as an example of that of the genus. The beetles begin pairing during April, and continue all through the summer. The female lays but few egrs, usually one a day. The egga are depositod on the under surface of \& itaf, close under one of the projectirg reius; they possess a pro-
tective colouring. The development withon the egg asts ten days, at the end of which a small larva creeps out, and at once eats its way through the lower epidermis of the leaf into the mesophyll and there forms long winding burrows. The larra or maggot is of a yellowish colour and somewhat cylindrical in form. It has three pairs of legs antcriorly and a pair of pro-legs at its hinder ead. The most anterior and the most posterior segment bear a black spot. The month is provided trith a pair of mandibles, by means of which the larva eats its way through the sol't tissue of the leaf. This larval condition lasts about six days; the maggot then leaves the leaf and bnries itself somo one or two inches beneath the surface of the earth; here it turns into a chrysalis. From this the fullgrown beetle emerges after an interval of fourteen days, and it is in this stage of its life-bistory that it proves most destructive to the turnip crop. Seversl broods may be produced each season; the beetle lives through the winter sheltered under fallen leaves, pieces of mood, clods of earth, \&c., until the warmoth of spring awakens it, when it boon begins to lay eggs.

Since the chief damage to the crop is due to the perfect bectle devouring the foung leaves of the turnip plant, ono of the most important methods of dealing with the pest is to ensure a strong and healthy growth of the plant, by means of manuring, watering, \&c. Another preventative is the removal of such weeds as the ohepherd's purse and charlock, which harbour the insect in great numbers, and the removal of any stubble in which it might pass the winter. When a crop is badiy attacked dressings of soot and gas-lime mixed with sulphur and lime, or of soot or lime alone, prove efficacions, but these must be applied whilst the dew is on the leaves or the "fly" will escape.
TURNSTONE, the name long given ${ }^{1}$ to a shore-bird, from its habit of turning over with its bill such stones as it can to seek its food in the small crustaceans or other animals lurking beneath them. It is the Tringa interpres ${ }^{2}$ of Linnæus and Strepsilas interpres of most later writers, and is remarkable as being perhaps the most cosmopolitan of birds; for, though properly belonging to the northern hemisphere, there is searcely a sea-coast in the world on which it may not occur: it has been obtained from Spitzbergen to the Strait of Magellan and from Point Barrow to the Cape of Good Hope and New Zealandexamples from the southern hemisphere being, however, almost invariably in a state of plumage that shows, if not immaturity, yet an ineptitude for reproduction. It also, though much less commonly, resorts to the margins of inland rivers and lakes; but it is very rarely seen except in the neighbourhood of water, and salt water for preference.
The Turnstone is about as big as an ordinary Snipe ; but, compared with most of its allics of the group Limicola, to which it belongs, its form is somowhat heavy, and its legs are short. Still it is brisk in its movements, and its variegated plumage makes it a pleasing bird. Seen in front, its white face, striped with black, and broad black gorget attract attention as it sits, often motionless, on the rocks; while in flight the white of the lower part of the back and white band across the mings are no less conspicuous even at a distance. A nearer view will reveal the rich chestnut of the mantle and upper wing-coverts, and the combination oi colours thus exbibited auggests the term "tortoise-shell" often applied to it-the quill-feathers being mostly of a dark brown and its lower parts pure white. The deeper tiots are, however, peculiar to the nuptial plumsge, or are only to be faintly traced at other times, so that in wiuter the adults-and the young always-have a much plainer appearance, ashy-grey and white bcing almost the ooly lines observable. From the fact that Turnstones may be met with at almost any season in various parte of the world, ${ }^{8}$ and especially on islands as the Cansries, Azores, and many of those in the British seas, it has been inferred that these birds may breed in such places. In some cases this may prove to be true, bnt in most evidence to that effect is wanting. In America the breediog-range of this apecies has not been defined. In Europe there is good reason to euppose that it

[^287]includes Shetland; but it is on the north-western coast of the continent, from Jntland to the extreme north of Norway, that the greatest number are reared. The nest, contrary to the hahits of most Livicolm, is generally placed under a ledge of rock which abelters the bird from observation, ${ }^{1}$ and therein sre laid four egge, of a light olive-green, closely blotched with brown, and hardly to be mistaken for those of any other bird. A second species of Turnstone is sdmitted by some authors and denied by othera. This is the S. melarocephalus of the Pecific cosst of North Americs, which is said to be on the sverage larger than $S$. interpres, snd it never exhibits sny of the chestnut colouring.

Though the genus Strepsilas seems to be rightly placed among the Charadridx (cf. Plover), it occupies a somewhat abnormal position among them, and in the form of its pointed beak and its rariegated coloration has hardly any very near relative.
(A. N.)

TURPENTINE consists of the oleo-resins which exude from certain trees, especially from some conifers and from the terebinth tree, Pistacia Terebinthus, L. It was to the product of the lattcr, now known as Chian turpentine, that
 of Theophrastus) and its resin ( $\dot{\rho} \eta$ riv $\eta \tau \in \rho \mu i v \theta(v \eta)$ were well known and highly prized from the carliest times. The tree is a native of the islands and shores of the Mediterranean, passing eastward into Central Asia; but the resinous exudation found in commerce is collected in the island of Scio. Chian turpentine is a tenacious semi-fluid transparent body, yellow to dull brown in colour, with an agreeable resinous odour and little taste. On exposure to the air it becomes dry, hard, and brittle. In their general characters, turpentines are soft solids or semi-fluid bodies, consisting of a mixture of one or more resins with essential oils, which, although differing in physical properties, have a composition corresponding to the formula $\mathrm{C}_{10} \mathrm{H}_{10^{\circ}}$.They adso contain minute quantities of oxygenated oils. Formerly they had considerable reputation in medicine, and they still continue to be employed in plasters and ointments; but their great use is in the arts, for which they are separated by distillation into rosin or colophony (see Rosin, vol. xx. p. 852) and oil or spirit of turpentine.

Crude or common lurpentine is the commercisl neme which embraces the oleo-resiu yielded by several coniferons trees, both Enropesp and American. The principal Europesn product, bometimes distinguished as Bordeaus turpentine, is obtained from the sea pine, Pinus maritima, in the Lendes department of France. Crude turpentine is further yielded by the Scotch fir, $P$. sylvestris, throughout northern Europe, and by the Corsican pine, P. Laricio, in Austria and Corsica. In the United States the turpentineyielding pines are the swamp pine, P. palustris, and the loblolly, P. Teda, both inhabiting North and South Carolina, Georgia, and Alabama: Venice turpentine is yielded by the larch tree, Larix curopea, from which it is collected principally in Tyrol. Strasburg turpentine is obtained from the bark of the silver fir; but it is collected only in small quantities. Less known turpentines are obtained from the mountain pine, $P$. Pumilio, the stone pine, P. Cembra, the Aleppo pine, P. halepensis, \&c. The so-called Canada balsam, from Abies balsamcia (see Balsam, vol. iii. p. 293), is also a true turpentine.

Oil of turpentine as a commercial product is nbtained from all or any of these oleo-resins, but on a large scale only from crude or common turpentine. The essential oil is rectified by redistillstion with water and alkaline carbonates, and the water which the oil carries over with it is removed by a further distilletion over calcium chloride. Oil of tufnentine is a colonrless liqnid of oily consistence, with a strong characteristic odoar and a hot disagree. able taste. Its boiling point ranges from $152^{\circ}$ to $172^{\circ} \mathrm{C}$. st ordinsry temperature ; its sp. gr. is between 0.856 and 0.870 ; and in optical properties it rotates the plane of polarized light both to right and left in rarying degrees according to its sources. It is soluble in slcohol, ether, benzol, other essential oils, and the fixed oils, snd itself is a solvent of resins snd caoutchouc. On exposure to the air it dries to s solid resin, and when oxidized in the presence of water gives off perozide of hydrogen-a resction utilized in the preps ration of a disinfectant called "sanitas." Oil of turpentine is largely used in the preparation of vernishes, and as a mediura by paint rs in their "flat" colours.

[^288]TURPIN, archbishop of Rheıms and the supposititious author of Historia Raroli Magni et Rotholandi, is probably to be identified with Tilpin, who was archbishop of Rheims towards the end of the 8th century. This Tilpin is alluded to by Hincmar (845-882), his third successor in the see. According to Flodoard (ob. 969), Charles Martel drove Ragobert, bishop of Rheims, from his office, putting in his place a warrior-clerk, Milo. The same writer represents Milo as discharging a mission among the Vascones or Basques, the very people to whom authentic history hes ascribed the great Carolingian disaster at Roncesvalles. It is possible that we owe the warlike legends that have accumulated round the name of Turpin to some confusion of his identity with that of his martial predecessor. Flodoard says that Tilpin was originally a monk of St Denis; and we know from Hincindr that, after his appointment to Rheims, he occupied himself in securing the restoration of the metropolitan rights and landed property of his church, whose revenue and prestige had been impaired under Milo's rule. He was, according to the latter authority, elected in the days of Pippin, the son of Charles Martel, i.e., betreen 752 and 768 . He died, if we may trust the evidence of a diploma alluded to by Mabillon, in 791. Hincmar, who composed his epitaph, makes hira bishop for forty years and more, from which it is evident that he was elected somewhere about 754. Flodoard, howerer, states that he died in the forty-serenth year of his bishopric. Tilpin was present at the synod of Pome in 769 ; and Pope Hadrian, at the request of Charlemagne, sent him a pallium and confirmed the rights of his church (Gallia Christiana, ix. 28-30). According to Flodoard, he substituted monks for canons in the monastery of St Remigius; and 17th-century tradition ascribed to him an ancient pontificale, still extant in Marlot's days (17th century).

Tho sbove is a summary of sll that authentic history and trast. worthy tradition tesch about the anthor to whom the common voice of the Middle Ages escribed the Historia Caroli Magni. A short scconnt of the work bes been given elsewhere (Roland, Leoend of). But, populer es this production was during the Middle Ages, it was rather the crystalization of earlier Roland legende than the source of later ones. Potthast has enumerated about fifty codices rithout by sny mesns, according to M. Gaston Paris, exlaustisg the list. The latter writer has made the Historia Karoli the subject of a special study ( $D e$ Pseudo. Turpino, Paris, 1865), which may bo recommended as a model of brilliant though cantious scholerehip. The great popularity of the pseudo-Tarpin seens to dste from the latter half of the 12th century; end M. Paris enumerstes at least five French translations belonging to the 13 th, and one into Latin-Ferse of about the same ege. Mr Ward (Cat. of Romances, 549) has recently expressed e doubt es to whether tho Turpin chronicle wbs completed at Vienne.

TURQUOISE, a blue or bluish green mineral, ralued, when;cut and polished, as an ornamental stone. The finest variety occurs in Persia, whence it originally reached western Europe by way of Turkey, and thns came to be called by the Venetians, who imported it, turchesa, and by the French turquoise. It is chemically a hydrated phosphate of aluminium, associated with a variable proportion of hydrated phosphate of copper, to which it owes much of its colour. The green tints of certain varieties appear to be due to admixture with salts of iron. A fine blue Persiah turqnoise, analysed by Prof. A. H. Churcl, yielded-alumina $40 \cdot 19$, phosphorus pentoxide $32 \cdot 86$, water $19 \cdot 34$, cupric oxide $5 \cdot 27$, ferrous exide $2 \cdot 21$, and manyranous oxide 0.36 . The most ralued tint of the turquoise is a delicate blue, inclining slightly to green; in mauy speci mens the green becomes more pronounced with age. Although the turquoise is practically opaque, sections may be ground so thin as to admit of examination by transmitted light. Its microscoplc structure was first studied by Prof. Fischer of Freiburg (Baden), afterwerds by H. Bücking of Strasburg, and recently by Clarke and Diller.

Thin sections are almost colourless. Between crossed Nicols they showe either a fibrous texture or a finely-granular aggregate of doubly-refracting particles without definite crystalline outlines. The mineral has never been found crystallized, but occurs as veins, nodules, stalactitic masses, and incrustations. Large pieces are exceedingly rare. The specific gravity of turquoise is about 2.75 , and its herdness below 6 ; it takes a fair polish and exhibits a feeble lustre. It is usually cut en cabochon or with a low convex surface, and in the East is frequently engraved with Persian and Arabic Enscriptions, generally passages from the Koran, the incised characters being in many cases gilt. Such objects are worn as amulets. The turquoise bas always been associated with curious superstitions, the most common being the notion that it changes colour with variations in the state of its owner's health, or even in sympathy with his affections.
Persia is the chief centre of the turquoise trade, where the same mines have beon worked for at least eight centuries. The finest atones are found near Nishápúr in Khorásan (see Persid, vol. zviiu. p. 822). Taveruier, writing in the 17 th century, atates that the best turquoise, reserved for the sole use of the shah, was obtained from the mine which he describes as the Vieille Roche, while inferior stones were got from the Nouvelle Roche. These terms still aurvive, ell turquoise of fine colour being said in trade to be from the "old rock," and that which is pale, or changes tint on exposure, is from the "now rock". According to a recent raport by Cansul Benjamin at Teheran the best turquoise is found at Abu Riáh, and all the Khorásan miles are farmed by a few prominent officials, who pay to the shah an annual rent of about £6500. Dr Tietze has lately described apecimens of the matrix of the mineral brought to Fienna from Persis by General Schindler. These show that the turquoise occurs, nat in clay-slate, as is often stated, but in a parphyritic trachyte or trachytic breccia, and in loose fragroents in the neigh. bouriug alluvium, The mineral is slso faund in Kerman in bouthern Persia, but the stons is of pale coloar, tending to fade, and the mines which yield it are now nearly ahandaned. In 1849 Major C. Blacdonald found turquoise in Wady Maghara and Wady Sidreh, near Sinal (q.v.), where, according to Mr H. Baverman, it lines the open joints of a ferruginous sandstone, and is also embedded in small ochreous nodules in the rock itself. The redder the rock the finer the colour of the associated turquoise. As the colour is liable to fade, the Arabian turquoise has not a good name among jewellers, and the workings were abandoned by Discdonald in 1865. In Wady Maghara there are relice of extensive mining operations, presumably for turquoise, of so early a date that the rock was wrought by fint iroplements. The early inhabitants of Mexico made much nse of this mineral far inlaying obsidian ornaments, and for mosaic work with iron-pyrites. It was probably one of the atones known es chalchihuill. In 1858 Prof. W. P. Blake called attention to the occurtonce of turquoise at Cerillos, sbont 22 miles southwest of Santa Fé, in New Mexico, where mining operations for this mineral were carried on two centurios ago. The turquoise varies in colour from oky-blue to apple-green, snd is found as nodules and small veins in a felspathic rock of microgranitic texture, probably of eruptive origin. The mines of Cerillos are no longer worked. A similar green mineral is found at Turquoiso Mountain in Cochise connty and at Mineral Park, Mohave county, Arizona. It also occurs to s emall bxtent in sonthern Nevada, where it is found es blue grains disseminated through a sandstone. In Europe, the turquoise is found at Oolsnitz in Saxony and near Jordansuinihl in Silusia, occurring at the latter locality in clay-Blate. Under the nsmes of callais and callaina Pliny described a green mineral which, if not our turquaise, aeems to have been very closely related to it. A bright groen mineral, wrought into boads, and found with stone hatchets in sncient graves at Men-er Hroeck (Rock of the Fairy) in Mrittany, was described in 1864 by M1. Demour, who, eeeking to \dentify it with Pliny's callais, revived this name. Dansafterwerds brought the word into harmany with our mineralogical nomenclature is writing it callainite. The mineral in question is a hyäated ,hosphate of alnminium, apparently identical with Breithauptie variscite. By many mineralogists the true torquoise is called calaite (aee Vol. xvi p. 405).
Turquoise is commonly imitated by ensmels, but of late some ingenious counterfeits have been made with the same chemical composition as the natural stone. To increase the deception, pieces of ochreous matter are inserted at the back of the artificial turquoise, to initato the netural matrix. In order to distinguieh between the genuine stone and its imitations, Pohl recommends that a splinter ohould be strongly heated in a platinum capoule, when the true turquaise is reduced to a brownish bleck powder or a friable mase with s decrepirating sound; the false turquoise does not desrepitete, but either fuses to a glass or is reduced to a frit.

TURRETIN, or Turretini. Three theologians of this name figure in the history of Genevan theology.

1. Benort Turpetin (1588-1631), the son of Francesco Turretini, a native of Lucca, who settled in Geneva in 1579, was born in that town on 9th November 1588. He was ordained a pastor in Geneva in 1612, and became professor of theology in 1618. In 1620 he represented the Genevan Church at the national synod of Alais, when the decrees of the synod of Dort were introduced inte France; and in 1621 he was sent on a successful missiou to the states general of Holland, and to the autherities of the Hanseatic towns, with reference to the defence of Cenera against the threatened attacks of the duke of Savoy. He published in 1618-20 a defence of the Genevan translation of the Bible. Benoit Turretin died at Genera on 4th March 1631.
2. François Turretin (1623-87), son of the preceding, was born at Gcneva oa 17th October 1623. After studying theology in Geneva, Hollandi: and France, be became a pastor in Genera in 1647. after'a brief pastorate at Leyden, he again returned to Geneva as professor of theology in 1653. He was one of the most influential supporters of the Formula Consensus Helvetica, drawn up chielly by Heidegger, in 1675, and of the particular type of Calvinistic theology which that symbol embodied. His Institutio Theologise Elenctice (3 vols. 4to, Geneva, 1680-83) has passed through frequent editions, the last reprint having been made in Edinburgh in 1847. F. Turretin died at Genera on 28th September 1687. He was also the author of volumes entitled De Satisfactione Christi Disputationes (Ceneva, 1666) and De Necessaria Secessionte Nostra ab Ecclesia Romana (Geneva, 1387).
3. Jear Alphonse Turretin (1671-1737), sou of the preceding, was born at Geneva on. 13th August 1671. He was educated at Geneva and in Holland, and after travelling in England and in France was received into the "Vénérable Compagnie des Pasteurs" of Geneva in 1693. In 1697 he became professor of church history. During the next forty years of his life he enjoyed great influence in Geneva as the adrocate of a more liberal theology than bad prevailed under the preceding generation, and it was largely through his instrumentality that the use of the Formula Consensus Helvetica as a symbol was discontinued in 1725. He also wrote and laboured for the promotion of union between the Reformed and Lutheran Churches, his most important work in this connexion being Nubes Testium pro Afoderato et Pacifico de Rebus Theologicis Judicio, et Instituenda inter Protestantes Concordia (Geneva, 1719). Besides this he wrote Cogitationes et Dissertationes Theologica, on the principles of natural and revealed religion (Geneva, 1737); and commentaries on Thessalonians and Romans were published posthumously. He died at Geneva on 1st Mav 1737.
tURTLE. See Tortoise.
TUSCANY (Ital. Toscana), one of the sixteen compartimenti of the kingdom of Italy, contains eight previncesArezzo, Florence, Grosseto, Leghorn, Lucca, Massa-Carrara, Pisa, and Siena-and has an area of 9287 square miles with \& population of $2,208,869 \mathrm{in} 1881$. In 1859, im. mediately before it united with the kingdom of 'Sardinia, the grand-duchy of Tuscany, exclusive of Massa-Carrara, which then belonged to Modena, but including the islands of Gorgona, Elba, Pianosa, Formica, Montecristo, Giglia, and Gianutre, as well as the duchy of Lucea (united to it
in 1847 ), had an area of 8625 square miles and a population of 1,806,940. See Italy, vol. xiii. pp. 489-490.

Etruria (q.v.) was finally annexed to Roma in 351 b.c. (sea Rome), and constituted the seventh of the eleven regious into which Italy was, for administrative purposes, divided by Augustus. Under Constautive it was united into one province mith Umbria, an arrangement which subsisted until at least 400 , as the Notitia epeaks of a "consularis Tuscie et Umbrix." In Ammianius Marccininus there is implied a distinction between "Tuscia suburbicaria" and "Tuscia annonaria," the latter being that portion which lies to the north of the Arno. After the fall of the Western empire Tuscia, with other provinces of Italy, came successively under the aray of Herulians, Ostrogoths, sud Greek and Lombard dukes. Under the last-named, "Tuscia Langobardorum," comprising the districts of Viterbo, Corneto, and Bolsena, reas distinguished from "Tuscia Regni," which lay more to the north. Under Charlemague the name of Tuscia or Toscana became restricted to the latter onl5. Oue of the earliest of the Frankish marquises was Boniface, either first or second of that name, who about 823 fought with success against the Saracens in Africa. Adalbert 1., who succeeded him, in 878 espoused the cause of Carloman as against his brother Louis 1II. of France, and suffored excommunication and imprisonment in consequence. Adalbert II. (the Rich), who married the ambitious Bertha, daughter of Lothair, king of Lorraine, took a prominent part in the politics of his day. A subsequent marquis, Hugo (the Great), became also duke of Spoleto in 989. The male line of marquises ended with Boniface II. (or III.), who was murdered in 1052. His widow, Beatrice, in 1055 married Godfrey, duke of Lorraine, and governed the conntry till her death in 1076 , when she was succeeded by Matilda (q.v.), her only child by her first husband. Matilda died in 1114 without issue, hequeathing all her extcnsive posscssions to the church. The consequent struggle between the popes, who claimed the inheritance, and the emperors, who maintained that tho countess had ro right to dispose of imperial fiefs, enabled the principal cities of Tuscany gradually to assert their independence and govern themselvea under consuls and elders of their own selection. The most important of these Tuscan republics or sell.goveracd communes were Florence, Pisa, Siena, Arczzo, Pistoia, and Lucca. Some account of the manner in which they were all gradually absorbed by Florence will be found under Florevice and Mlenici. The title of grand-duke of Tuscany was conferred on Cosmo de' Medici by Pius V. in 1567, and the emperor (Maximilian 11.), after withholding his consent for some years, nutimately confirmed it to Cosmo's successor in 1576. In 1735, in view of the childlessucss of Giovan Gastone, the last of the Medici, the succession of Francis, duke of Lorraine, afterwards emperor Francis I., was arranged for by treaty. In 1765 he was succeeded as grand-duke by his second son Leopold (seo Leopoln II.), who, on becoming enperor in 1790, handed Tuscany over to his second son Ferdinand, third grand-duke of the zaine. The duchy was occupied by the French in 1799, ceded to Louis, prince of Parma, by the consention of Madrid in 1801, and annesed to the French empire in 1803. Ferdinand, however, was reinstated in 1814, and on his death iu 1824 was succeeded by his son Leopold, second grand-duke of the name, who was deposed by the constituent assenibly on 16 th August 1860 . See Italy.

TUSCULUM, an ancient Latin city, situated in a commanding position on one of the eastern ridges of the Alban Hills, near the site of the modern Frascata (q.v.). It has a very beautiful and extensive view of the Campagna, with Rome lying fifteen miles ${ }^{1}$ distant to the north-west, on the west the sea near Ostia, and the long range of the Sabine Hills on the north-east. According to tradition, the city was founded by Telegonus, the son of Ulysses and Circe; hence Horace (Epod., i. 30) speaks of it as "Circæa mœnia" and Ovid (Fast., iii, 91) as "L'elegoni mœnia" (sce also Prop., iii. 30, 4, and Sil. Ital., xii. 535). The legendary descent of one of the chief Tusculan families, the gens Mamilia, from Ulysses through Telegonus is commemorated on some denarii struck by the Mamilian gens in the later years of the Roman republic; these have on the reverse a figure of Ulysses recognized by his dog Argo. Then Tarquinius Superbus was expelled from Rome his cause was espoused by the chief of Tusculum, Octavius. Manilius, who took a leading part in the formation of the Latin League, composed of the thirty principal cities of Latium, banded together against Rorae. Mamilius commanded the Latin army at the battle of Lake Regillus, a

[^289]piece of water which then lay immediately below the Colles Tusculani, but is now dried up. At this battle ( 497 8.c.) Mamilius was killed, and the predominance of Rome among the Latin cities was practically established. From that time Tusculum became an ally of Rome. and on that account frequently incurred the hostility of the other Latin cities. In 378 в.c., after an expression of complete submission to Rome, the people of Tusculum received the Roman franchise, and thenceforth the city continued to hold the rank of a municipium. Several of the chief Roman families were of Tusculan origin, e.g., the gentes Mamilia, Fulvia, Fonteia, Juventia, and Porcia; to the last-named the celebrated Catos belonged. During the imperial period little is recorded about Tusculum ; but soon after the transference of the seat of empire to Constantinople it became a very important stronghold, and for some centuries its counts occupied a leading position in Rome and were specially infuential in the selection of the popes. During the 12 th century there were constant struggles between Rome and Tusculum, and towards the close of the century the Romans, supported by the German emperor, gained the upper hand, and the walls of Tusculum, together with the greater part of the city, were destroyed.

Extensive remains still exist of the massive malls, which surronnded the city, and of its arx-a separata citadel-which stood ou an abrupt rock, approached only on one side, that towards the city, with which it was connected by long walls. "The walls are built of large blocks of the native "lapis Albanus" or peperino, some of them as much as 5 feet long by 3 feet thick. They probably belong to the early republican period; restorations in concrete faced witli "opus reticulatum" of the 1st century B.c. can ba traced in many places.

During the latter gears of the republic and under tha empire Tusculum was a farourite site for the country villas of weslthy Romans. That of Lucullus was very large and magaificent ; other handsome houses were built thera by Julius Casar, L. Crassus, Q. Metellus, Marcus Brutus, and others. A palace was erected by Tiberius near Tuscuium on the way to Rome, close to the Yia Latinz.
Tha most interesting associations of the city are those connected with Cicero, whose farourite residence and retreat for study and literary work was at Tusculum. It was here that he composed his celebrated Tusculan Disputations and other philosophical morks. Much has bcen writteu ou the position of his villa, but its true site still remains donbtful. Its grounds are known to have adjoined the more splendid villas of Lucullus and the consul Gabinius (see Cic., De Fin., iii. 2, and Pro Dom., 24). The most probable site is that now marked by the Villa Rufinclla to the west of Tusculum, where the hill is divided into two ridges. The scholiast on Horace, Epod., i. 30, states that Cicero's rilla was "ad latera superiora," the plural probably being used in allusion to the double ridge. The other theory, which places the site at Grotta Ferrata, some distance farther to the west, has little evidence to support it. Although Cicero (Pro Sestio, 43) speaks of his orn house as being insignificant in size compared to that of his neighbour Gabinius, jet wa gather from other notices in various parts of his works that it was a building of no mean size and pretension. It comprised two gymnasia (Div., i. 5), with covered porticus for exercisa and philosophical discussion (Tusc. Disp., ii. B). One of thesa, which stood on higher ground, was called "the Lyceum," and contained a library (Div, ii. 3); the other, on a lower site, shaded by rows of trees, was called "the Academy." The main building contained a covered porticus or cloister, with apsidal recesses (exedra) containing seats (sca Ad Fam., vii. 23). It also bad bath-rooros (Ad Fan., xiv. 20), and contained a number of works of art, both pictures and statues in bronzo and marble (Ep. ad Alt, i $1,8,9,10$ ). The central strium appears to have been small, as Cicero speaks of it as an atriolum (Ad Quint. Fr., iii. 1). The cost of this and the other house which he built at Pompeii led to his being burdened with debt ( $E_{p}$. ad All., ii. 1). Nothing now exists which can be asserted to be part of Cicero's villa with auy degree of certainty. The so-called "scuola di Cicerone," near the line of tha ancient Wall of Tusculam, is the substructure of some building formed in the usual Roman way by a series of raulted chambers, and is clearly later in date than the time of Cicero. Other remains of houses exist in and ncar the city, Lut nothing is known as to their history or ownership.

Ruins of two theatres still exist. One of then, which is not earlier than the beginning of the 1st century, between the city and the arr, is fairly perfect, and still possesses most of its ancient seats, divided in to four cunci by three flights of steps. Only traces remain
of the other theatre, which abutted against the long malls that defended the road from the city to the arx. Remains of an amphitheatre of no great size can be traced, dating probably from the 3d century. There is also a large piscina, near the first-mentioned theatre. In the vicinity of Tusculum a number of interesting tombs have been discovered at various times; some, as for example that of the Furii, contained valuable inscriptions of the 4 th and 3 d senturies B.C.

The city was supplied with water by the Aqua Crabra, and near it were the springs which fad two of the Roman aqueducts- the iAqua Tepula and Aqua Virge (Front., De Aq., 8).
For further information the reader is referred to Compagni, Memorie Storiche Hell Antico Tuscuio: Canina, Descr. dell Antico Tusculo; Gell, Topogr. of Rome land.its Vicinity ; and Nibby, Dintorni di Roma, vol, iii.

TUSSER, Thomas (c. 1527-1580), poet, was the son of William Tusser by Isabella, daughter of Thomas Smith of Rivenhall, Essex, where he was born about 1527. Notwithstanding strong reluctance on his part he was sent in his early years to a music school, and became chorister in the collegiate chapel of the castle of Wallingford. He was afterwards admitted into the choir of St Paul's, and went thence to Eton, where he was under the tuition of Nicholas Udall. In 1543 ho was elected to King's College, Cambridge, and soon afterwards exchanged to Trinity Hall. On leaving the university he was for about ten years at court; probably in some musical capacity. He then settled as a farmer in Suffolk, near the river Stour, an omployment which he seems to have regarded as combining the chief essentials of human felicity. Subsequently he lived successively at Ipswich, West Dereham, Norwich, and London. There he died in April 1580, and was buried in the church of St.Mildred in the Poultry. His monument was destroyed in the fire, but the quaint epitaph is preserved in Stor's Survey of London. A marble tablet, on which the epitaph is inscribed, has been erected to him in the church of Manningtree, Essex.
Tusser's peems on husbandry have the charm of simplicity and directness, and their practical sarss were arparently relished, for in his lifetime they went through a number of editions. They are $A$ Hundreth Good Pointes of Husbandrie, 1557, 1561, 1562, 1564, and 1570; A Diulogue Wyuyngcand Thryuynge, 1562; A Hzandrethe Good Pointes of Husbandrie lately married unto a Hundrethe Good Pointes of Hiswijry, 1570 ; Five Hundreth Pointes of Good Husbandrie united to as many of Good Wiferie, $1573,1576,1577,1585$, 1586, 1590, 1593, reprinted with memeir by William Mavor, 1812, by Auber, 1873, and by the Englislı Dialect Society, 1879. His metrical autobiography, priuted in the Appendix to Five Hundreth Pointes, 1573 , was republished in 1846 along with his will, which would seem to refute the sarcasms which became current, that he had not been successful in practising his own maxims. One of these references is contained in a volume of epigrams by H. P., The More the Merrier, 1608. Ono of the epigrams entitled Ad Tusserum, begins thus:-
" Tusser, they tell me, when thou wert alive,
Thou, teaching thrift, thyselfe could'st never thrive."
Possibly Tusser obtained the reputation of being.poor from his practice of thrift ; but in any case, if his will represents his worldly condition at the time of his death, he was not in poverty in his later years.

TVER, a government of central Russia, on the upper Volga, bounded by Pskoff and Novgorod on the W. and N., Yarostarl and Vladimir on the E., and Moscow and Smoleusk on the S . ; it has au area of 25,225 square miles. Lying on the southern slope of the Valdai plateau, and intersected by deep ralleys, it has the aspect of a hilly region, but is in reality a plateau ranging from 800 to 1000 feet in height. Its highest parts are in the northwest, where the Volga, Western Dwina, and Mista rise in narshes and lakes. The plateau is chiefly built up of Carboniferous limestones, Lower and Upper, underlain by Devonian and Silurian deposits, which appear only in the denudations of the lower valleys. The whole is covered by a thick sheet of boulder-clay (the bottom-moraine of the Scandinavo-Russian ice-sheet) and subsequent lacustrine deposits. A number of asar (see vol. x. p. 368) occur ou the slopes of the plateau. Ochre, brick, and pottery clays, as also limestone for building, are obtained, and there are
chalybeate springs. The soil, which is clayey for the most part, is not fertile as a rule.
Nearly the whole of Tver is watered by the upper Yolga (350) miles) and its tributaries, several of which (Vazuza, Dubua, Sestra, Tvertsa, and the tributaries of the Mologa) are navigable. The Vyshnevototsk system of canals connects the Velga (navigable some 60 miles from its source) with the Baltic, and the Tikhin syatem connects the Mologa with Lake Ladoga. The Msta, which flows into Lake Ilmeñ, and its tributary the Tsna, water Tver in the north-west, and the Western Dwina rises in Ostashkof: This netwerk of rivers highly favours navigation : as many as 3000 toats yearly pass through the Vyshnevototsk system, and corn, linseed, apirits, flax, hemp, timber, metals, and manufactured ware to the annual value of $1,500,000$ are shipped from, or brought to, the river ports of the government. Lakes, ponds, and marshes are numerous in the west and north-west, Lake Seliger-the soures of the Volga-and Lake Mstiue being the most important. The forests-coniferous in the north and decidueus in the south-rare rapidly disappearing, but still cover 890,000 acres. The climato is continental; the average yearly temperature at TVer ( $41^{\circ} \cdot 5$ Fahr.) is the same as that of Orel and Tanboff (January $11^{\circ}$, July $67^{\circ}$ ). The population ( $1,646,683$ in 1883 , as against $1,567,300$ in 1872 ) is unequally distributed, and in the districts of Kalyazin and Kasl in attains a density not much less than that of the more highly faveured black-earth provinces of south east Russia ( 16 and 17 pir square mile). Apart frem sone 100,000 Karelians and a few Poles and foreigners, the people are all Great Russians. Some traces of Finnish Ves and of Lithuanians are found in the north-east and aouth. The official returns give the number of Raskolniks as 25,000 . Only 157,110 are urban ; but agriculture is not the chief occupation. While barley and oats are exported, rye is imperted. The crops for 1883-1885 averaged 2,889,400 quarters of corn and 4,078,400 bushels of potatoes. Cattle-rearing does not prosper, and tbe in crease shown by the returns for 1883 ( 351,630 horses, 583,670 cattle, and 373,780 sheep) as against those of 1872 is simply due to better registration. Cheese-making has recently been introduced on the co-eperative principle ( 2168 cwts . of cheddar exported to Britaiu in 1881). The fisheries in the lakes and rivers are productive. The peasants are principally engaged in various manufactures. The total production of the larger manufactures in 1883 was valued at $£_{£ 2,237,250 \text { (tanneries } £ 244,460 \text {, cottous } £ 803,270 \text {, distilleries }}$ $£ 320,010$, flour-mills $£ 263,5000$, and that of the petty trades carried on in combination with agriculture (preparation of pitch, tar, and turpentine, beat-building, construction of cars, sledges, wheels, boxes, tubes, and wooden ressels, and cabinet-making) was estimate. 1 in 1884 at $£ 3,000,000$, giving occupation to 101,400 persons. Certain branclies of the leather industry aro important, Kimry and Ostash. koff sending to the market $£ 650,000$ worth of boots annually. Tle small workshops of Tyer and the surrounding district work some 4500 ewts. of iren into nails every year, and the Ostashk off smiths use some 7000 cwts . of iren annually in the manufacture of hatchet 3 , scythes, sickles, and different agricultural implements. Weavin $\%$, lace-making, leather embroidcry, stocking-making, felting, aud tiie like are also inpertant petty trades, several of these being organiz.d on co-operative principles by the zemstzos. The railway from St Petersburg to Moscow crosses Tper, and sends off two branches to Rzheff and to Rybinsk, all three lines being amiong the busiest in Russia: The river traffic alse is considerable. The chief centres of trade, besides the city of Tver, are Byezhetsk, Rzheff, Kashin, Ostashkoff, Torshok, Krasnyi Kholm, and Vesiegonsk during its fair. The provincial assembly of Tver is one of the nest prominent in Russia for its efforts in the cause of education and sanitury improvement. Iu 1883 there were 997 primary schools with 47,680 scholars ( 8500 girls), 17 gymnasia and progymnasia ( 1697 beys und 1263 girls), and tro normal schools for teachers. The government is divided into twelve distriets, the chief towns of which, with their pepulations in 1884, are-TVER (see below), Byezhetsk (5890), Kalyazin (5200), Kashin (5730), Kortcheva (2275), Ostashlkof (9900), Rzheff (26, 480), Staritsa ( 2700 ), Torshok ( 12,910 ), Vesiegonsk (3870), Vyshuiy V Vototchok ( 11,590 ), and Zubtsoff (3160).
TVER, capital of the above government, lies 102 miles by rail to the north-west of Moscow, on both banks of the Volga (here crossed by a floating bridge) at its junction with the Tvertsa. The low right bank is protected from inundations by a dam. As a whole the town is but poorly built. The oldest church dates from 1564, and the cathedraI from 1689. An imperial palace, the ccurts, and the postoffice rauk among its best buildings. A public garden occupies the site of the former fortress. The population was 39,100 in 1884. The manufactures, chiefly of cotton, employ 5900 workmen ( 5710 at the cotton mills), and a number of nail-making workshops employ some 800 men, while more tilin 1000 women are engaged in the domestic
manufactory of hosiery forrexport to Moscow and St Petersburg. The traffic of the town is considerable, Tver being an intermediaté place for the trade of both capitals with the provinces of the upper. Volga.

Tver dates its origin from 1180, when a fort was erected at the mouth of the Tvertsa to protect the Suzdal principality againat Novgorod. In the 13th century it became the capital of an independent principality, and remained so natil the end of the 15 tb century. Dilkhail Yaroslavovitch, princaof Tver, was killed fighting ngainst the Tatars, as also was Alexander Mikhailovitch, who boldly fought for the independence of Tver against Moscow. It long renuaioed an open question whether Moscow or Tver would ultinately gain the supremacy in Great Russia, and it was only with the help of the Tatars that the princes of the former eventually succeeded in breaking down the independence of Trer. In 1486, when the city was almost entirely burued dowa by tho Muscovites, the son of [van III. became prince of Trver; the final annexation to Moscow followed four years later. In 1570 Tver had to endure, for some reason now difficult to understand, the vengeance of Ivan the Terrible, who ordered the massacre of 90,000 inhabitants of the priacipality. In 1609-12 it was pluadered both by the followers of the second false Demetrius and by the Poles.

TWEED, a river in the south of Scotland, has its rise iu the south-west coruer of Peeblesshire, not far from the Devil's Beef Tub in Dumfriesshire. The stream flowing from Tweed's Well, about 1500 feet above sea-level, is generally regarded as its source, although the honour is also claimcd for other streams issuing from a higher elevation. For the first 36 miles of its course it intersects the county of Peebles-frequently on this account called Tweeddale-in a north-easterly virection, passing between verdant hills separated by valleys watered by its numerous affluents. Having passed several picturesque keeps and castles, it reaches the town of Peebles, shortly before which it receives the Lyne Water from the north and the Manor Water from the south. The valley now widens; the scenery becomes softer and richer; and the river, bending in a more easterly direction, passes Innerleithen, where it receives the Leithen from the north and the Quair from the south. It then crosses Selkirkshire in a south-easterly direction, and, having received the Ettrick from the south on the borders of Roxburghshire, flows northward past Abbotsford, forming for about 2 miles the boundary between the counties of Selkirk and Roxburgh. After receiving the Gala, the Tweed crosses the north-western corner of Roxburghshire past Melrose and its abbey, and, after heing joined by the Leader from the north, winds past Dryburgh abbey round the south-western corner of Berwickshire. The remainder of its course is in a northeasterly direction through Roxburghshire past Kelso, where it receives the Teviot from the south, and then between the counties of Berwick and Northumberland, past Coldstream and Norham castle to the town of Berwick, where it reaches the North Sea. It receives the Eden Water from the north at Edenmouth, the Leet Water from the north at Coldstream, and the Till from Northumberland between Coldstream and Norham castle. The last 2 miles of its course before reaching Berwick are in England. Though the latter part of its course is through a comparatively level country, the scenery along the river is full of charm, owing to the picturesque variety of its finely wooded banks. The associations connected with the keeps and castles of the Tweed have supplied materials for several of Sir Walter Scott's poems and romances; and its varied beauties have been sung by Hogg, Leyden, Thomson, and many others. The bed of the river is pebbly and sandy, and, notwithstanding discolorations from manufactures, the stream, from its clear and sparkling appearance, is still well entitled to the name of the "silver Tweed." The total area drained by it is about 1870 square miles, and its total length is 97 miles. Next to the Tay it is the largest river in Scotland. The Tweed has, however, no estuary, and its traffic is chiefly confined to Berwick. But for a short dis-
tance up the river some navigation is carried on by barges. The river is one of the best in Scotland for trout and salmor fishing.

See Sir Thomas Dick Lander'a Scollish Rivers and Prof.'TVitç"' River Tweed, 1884.

TWELVE TABLES. See Roman Law, vol. xx. v. 679 sq., and Rome, vol. xx. p. 737.

TWENTY-FOUR PARGANAS, the metropolitan district of the lieutenant-governorship of Bengal, India, takes its name from the territory originally ceded to the East India Company, which contained twenty-four pargánas or sub-districts. The district lies between $21^{\circ} 55^{\prime} 20^{\prime \prime}$ and $22^{\circ}$ $57^{\prime} 32^{\prime \prime}$ N. lat. and $88^{\circ} 6^{\prime} 45^{\prime \prime}$ and $88^{\circ} 20^{\prime} 51^{\prime \prime}$ E. long. It has an area of 2124 square miles, and is bounded on tho rorth by Nadiý, on the north-east by Jessore, on the south and south-east hy the Sundarbans, and on the west by the river Hugli (Hooghly). The country consists for the most part of a vast allurial plain within the delta of the Ganges, and is everywhere watered by numerous rivers, all branches of the Hugli. In the northern portion the soil is very rich, but the southern or seaboard part consists of the network of swamps and inland channels known as the Sundarbans. The Húgli and six other streams are navigable by the largest boats throughout the year. The district is well supplied with canals, the most important being Tolly's Nala ( 10 miles long), which connects the Húglif with the Bidyádhári. The Twenty-Four Pargánàs was once famous for its sport, but owing to the extension of cultivation game is now scarce. Tigers are seldom met with; leopards are more numerous; there are several varieties of deer. The district has many roads, and is traversed by the Eastern Bengal Railway and the Calcutta and South-Eastern State Ravilway.

In 1881 the population of the district, exclusive of Calcitta, numbered $1,869,859$ (males 975,430 , fomales 894,429 ), embracing 1,153,040 Hiadus, 701,306 Mohammedans, and 13,976 Christiaus. The ten following municipalities had each a-populatiou of upwards of 10,000-Sonth Suburban, 51,658; Agarpara, 30,317; Baraogar, 29,982; Naihati, 21,533; Nawabganj, 17,702; Basurhat, 14,843; South Durn Dum, 14,108; Baduria, 12,981; Rajpore, 10,576 ; and Barasat, 10,533 . The administrative headquarters of the district are at Alipur, a southern suburb of Calcutte. Rice forms the staple crop of the district; other crops are pulses, oil seeds, sugar-cane, tobacco, \&c. Its principal exports are rice, sugar, pin leaf, fish, pottery, \&c. ; the imports comprise pulses of all kinds, oil-seeds, spices, turmeric, chillies, cloth, cotton, \&c. The objects of the rural manufactures are sugar, cotton curtains, brass and iron work, horn sticks, and cotton ard tasar silk cloth. The gross revenue of the district in 1885-S6 amounted to $. £ 338,595$, of which the land-tax contributed $£ 155,181$. The district was ceded to the East India Compauy by treaty by the nawáb vázien of Bengal in 1757. Since then several changes have heeu made in its boundaries, the latest in 1863.

TWICKENHAM, a town of Middlesex, England, is situated on the north bank of the Thames and on the London and South-Western Railway, $11 \frac{1}{4}$ miles south-west of London by rail. It is a straggling and irregular town, but has many fine suburban villas, and the district is noted for its sylvan beauty. Opposite the town there is an eyot in the river about 8 acres in extent, called Eel Pie Island, much resorted to by boating parties. The parish church of St Mary was rebuilt in red brick in very plain style after the fall of the old one in 1713, but the picturesque western tower of the I4th century still remains. It contains many interesting monuments, including one to Pope! who was buried in the nave. The principal public build ings are the town-hall and assembly rooms (built in 1876, and containing the free library established in 1882), the economic museum, the royal naval female school for the daughters of naval and marine officers, the Montpellier lecture hall, the metropolitan and City of London police orplatage, the almshouses of the London Carpenters ${ }^{3}$ Com =
pany, and a brancl of the national refuge for the homeless and destitute. The population of the urban sanitary district (aren 2415 acres) in 1871 was 10,533 , and in 1881 it was 12,479 .
Twirkenham at Domestlay was included in Isleworth. Anciently it was calleal Twittenhan or Twicaunham. The manor was given iu 941 by King Edmund to the monks of Christ Charch, Canterbury, from whom it hall been previonsly taken, lut it was again alicinatecl, for it was restored to the same noonks by Elled in 948 . In the reign of Henry YIII. it came into the possession of the erovin, mind by Charles I. was assigned to Hemrietta Maria as jart of her jointurc. - It was sold during the Protectorate, Lut after the Restoration the quecn mother resumed possession of it. In 1670 it was settlecl for life on Catlocriue of liraganza, quiten of Charles II. It still remains in possession of the crown, lunt since the dentlo of Catherino las been let on leases. In the neighbourlinol arc many residences of literary or historical interest. I'ope's villa, where he lived from 1717 till his dleath in 1744, has been rvinoval. Among old mansions of interest still remaining are strawherry 1fill, the resilence of Horace Walpole, now much alterect ; Marble Hill, buit by Gcorge III. for the countess of Sulfolk, aul subsequently residell in ly the maryuis of Wellesley; Orlemins Honse, built in the reign of Cuneen Anne by Jolnstone, ocenpicd for some tine by the iluke of Orlenns, and from 1879 to 1383 as a club honse ; York House, ssiil' to liave been the residence of Janes II. when duke of York, bestowed hy Charles 11. on Loril Clarenton when lic mnarricd the duke of York's danghter, and in modern times resilesl in ly the Comto de Paris; and Twickenlaan Honse, formerly the resilence of Sir Jolm Hawkins, author of thic $I$ Iistory of MILsic, and tho nnecting place of the "Literary Club." of the olit manor house of Twickenhan, to which Catherino of Arafon is said to have retired after hees divorre from Henly VIlI., :tnd which was sulbsequently the resilenice of Catherine of liragan\%a, uneon of Charles 11., thic only renains are a ruin called the Aragon tower. Twickenham Park ITouse, for some time the residence of Lort Chancellor Bacon, las becn demolished.
TWILIGHT. The light of what is called the "sky" depends upon the scattering or reflexion of direct sunlight in the earth's atmosphere, mainly if not entirely due to those fine dust particles which (as we have recently learned) form the necessary nuclei for condensation of aqueous vapour. Were it not for these particles the sky would appear by day as it does in a clear winter night, and the stars would be alway's visible. Alpine climbers and aeronauts, when they have left the grosser strata of the atmosphere below then, find this state of things approxinated to; and even at the sea-level the blue of the sky is darker when the air contains but few motes. After the sun has set, its rays continue for a time to pass through parts of the atmosphere above the spectator's horizon, and the scattered light from these is called twilight. It is, of course, inost brilliant in the quarter where the sun has set. Before sunrise we have essentially the same phenomenon, but it goes by the name of "dawn." The brilliancy of either dejends upon several conditions, of which the chief is, of conrse, the degree by which the sun has sunk below the horizon. But the amount of dust in the air affects the phenomenon in two antagonistic ways: it diminishes the amount of sunlight which reaches the upper air after passing close to the earth and it increases the fraction of this light which is scattered to form twilight. Hence no general law can be laid down as to the duration of twilight; ; but it is usual to state (roughly) that it lasts until the sum is about $18^{\circ}$ under the horizon. If we make this assumption, it is a simple matter of calculation to solve questions as to the duration of twilight at a given place at a given time of year, the maximum duration of twilight at a given place, \&c. In the older works on astronomy such questions were common enough, but they have now little beyond antiquarian interest. The more complex phenomena of twilight, such as the "after-glow," de., probably depend upon the precipitation of moisture on the dnst particles as the air becomes gradually colder. This will of course alter the amount of scattering ; but it may also lead (by reflexion from strata of such particles) to an increase in the amount of light to be scattered.

## tycho minhe. See Brahe.

TYLDESLEY with Shakeliley, a town of Lancashire, England, is situated on a considerable eminencc, 11 miles west-north-west of Manclester and 199 north-west of London (by the London and Nortl-Western Railway). The church of St Gcorge, a handsonte building in the Early Pointed style, erected in 1827, has lately undergone restoration. Public baths were built in 1876 . A public cemetery was formed in 1878. The tuwn is the growth of the 19th century and depends unon its cotton-mills and the large collieries in the neighbourhood. It is governed by a local board of health of sixtecn members. The population of the urban sanitary district (area 2490 acres) in 1871 was 6408 and in 1881 it was 9954.
At Domesday Tyllesley formoll part of the manor of Warrington. One of its proprictors, Sir Thomas Tyhlesley, was a distinguisished Royalist. His son Edward in 1672 solit the manor to Raljh Asticy, and from the Astleys it passed in 1728 to Thomas Joluson of Bolton. In 1823 it becane the property of Cieorge Orucrod, anthor of the History of Cheshire.

TYLER, Jонn (1790-1869), tenth president of the United States, was accustomed with pride, but with the support of conjecture rather than evidence, to claim re: lationship with Wat Tyler of the reign of Riclard II. The earliest of his American ancestors was Henry Tyler, a reputed native of Shropshire, England, who in 1652 settled at Middle Plantation, Va., on the outskirts of what is now the city of Williamsburg. Joln Tyler was the son of Judge John Tyler, some time governor of Virginia, and was born at Greenway in that State, 29th March 1790. In 1802 he entered the grammar school of William and Mary, where, though fond of fun and frolic and cultivating an inherited taste for the violin, he mado good progress in his studies, "After graduating in 1806 he entered on the study of law, and in 1809 was called to the bar, where his progress from the first was rapid. He becane a member of the State legislature in December 1811. In 1813 he raised a company in defence of Richmond, in command of which he subsequently served with the fifty-second regiment at Williamsburg and Providence Forge. In December 1816 he was elected to the house of representatives at Washington, where he displayed much readiness and skill in debate as an uncompromising advocate of popular rights. In 1825 he was elected governor of Virginia by a large majority, and the following year was re-elected unanimously. .- In 1827 Ihe was: chosen a senator. He opposed Clay on the tariff question in 1832, delivering a speech against 'the 'protective dulies which lasted three days; but, he jvoted for Clay's Cornpromise Bill of 1833. He was the only senator who voted against the Force Bill on 20th February of this year, a singularity of conduct which somewhat damaged his reputation in Virginia. Although opposed to the establishinent of the United States Bank, he supported the resolutions in 1835 censuring President Jackson for the removal of the deposits, on the ground that the procedure was unconstitutional. In consequence of a vote of the Virginia legislature instructing him to vote for the expurgation of these resolutions from the senate journal he resigned, 21 st February 1836. His action led the Whigs to bring him forward as a candidate for the vice-presidency, but he only received forty-seven votes. For some time after this he ceased to take an active part in politics; removing in the end of the year from Gloucester to Williamsburg, where he had better opportunities for legal practice, he devoted his chicf attention to his professional duties. At the Whig convention which met at Harrishurg, Pennsylvania, 4 th December 1839, he was nominated again for the vice-presidency on the Harrison ticket, and elected in November 1840. On the death of Harrison, soon after his inauguration in 1841, Tyler succeeded him. His elp-
vatiou to the presidency was thus accidental in a double sense, for he had been nominated for the vice-presidency to reconcile the extreme faction. His policy in office (sse United STates) was opposed to the party who nominated him and was on Democratic lines. In 1845 he was succeeded by Polk, and he spent the remainder of his life in retirement from active duties. He was nominated in 1861 for the lower house of the permanent congress, but died at Richmond on the 18th of the following January.
See L. G. Tyler, Lijc and Tines of the Tylcrs, 2 vols,, 1884 .
TYNDALE, Wilumam (c. 1484-1536), translator of the New Testament and Pentateuch (see Englise Brble, wol. riii. pp. 384, 385), was born in Gloucestershire, possibly in the parish of Slimbridge, about the year 1484. Of his early educatiou nothing is known; abont his twentieth year he went to Oxford, where tradition has it that he was entered of Magdalen Hall. He afterwards resided at Cambridge. Ordained to the priesthood, probably towards the close of 1521 , he entered the household of Sir Johu Walsh, Little Sollbury, Gloucestersi:ire, in the capacity of chaplain and domestic tutor. Here he spent two years, and in the course of lis private studies began to contemplate seriously the work of translating the Nevr Testament into English. His sympathy with the "new learning," which the had not concealed in conversation with the higher clergy of the neighbourhood at Sir John's table, led to his being summoned before the chancellor of Worcester as a suspected beretic ; and "with the goodwill of his master" he left for London in the summer of 1523 . There he preached a little at St Dunstan-in-the-West, and worked at his translation, living for some months in the house of Humplrey Monnouth, an alderman; but finding pullication impossible in England he sailed for Hamburg in \$ay 1524. After visiting Luther at Wittenberg, he settled in Cologne, where he mado some progress with .a quarto edition of his Nevv Testament, when the interference of the authorities of the town compelled his fight to Worms. The octavo edition (see vol. viii. p. 384) was here completed in 1526 . Where Tyudale resided in the interval batween 1526 and 1530 - the year of publication of his translation of the Pentatench-is not known; his Parable of the Wicked Mammon (1527), Obedience of a Christian Man (1528), and Practice of Prelates (1530), all bear to ha e been printed at "Marlborowe in the land of Hesse" or "Marborch." From 1530 onwards he appears to have lived chiefly in Antwerp, but of his life there hardly anything is recorded, except that as a marked man he was continually the subject of plots and intrigues, and that at last he was arrested and thrown into prison in the castle of Vilvorde, some six miles from Brissels, in 1535. Haring been found guilty of heresy, he was put to death by straugling, and his body afterwards burnt at the stake on October 6, 1536.
The $\Pi^{F}$ orks of Tyndale were first published along mith those of Frith ( $q, v$. ) and Barnes, "three worthy Martyre and principal Tcachers of the Church of Englaud," by Johu Daye, in 1573 (folio). His Doctrinal Treatises and Introduclions to Different Portions of the Holy Scripturc were publislied by the Parker Society in 1848 . For biography, see Demaus, Williain Tyndale (London, 1871); also the Introlluction to Mounbert's critical reprint of Tyndale's Pentateuch (New York, 1884), where a full bibliography is given. There seenis no reason to donbt that the translation of Joshua, Judges, Samuel, Kings, and Chronicles in Mattlev's Bible is substantially the work of Tyndale.
TYNE, a river in the north-east of England, is formed of two branches, the North Tyne, rising in the Cheviots on the borders of Roxburgh, and the South Tywe, rising at Tynehead Fell, at the south-eastern extremity of Cumberkand. The North Tyne flows south-eastwards by Bellingbau, a short distance below which it receives the Rede from the north, and 2 miles above Hexham it is joined by the South Tyne, which before the junction flows north-
ward to Haltwhistle, and then eastward, receiving the Allen from the right a short distance above Haydon Bridge. The united streams then have a course of abou: 30 miles eastwards to the sea at Tynemouth. For a considerable part of its course the Tyne flows through a pleasant and richly cultivated country, but in its lower reaches the presence of coal pits has almost completely robbed the scenery of its natural charms, and the former sylvan retreats of noonks and abbots are now occupied by blast furnaces and shipbuilding yarde, and similar scenes of busy industry, which line both banks of the river from Newcasile to the sea. The river is navigable to Blaydon for small craft, and to Newcastle. 8 miles from its nouth, for large vessels.
Tbe coal trade of the Tyne is the most important in Engianh, and for its general shipping trade the river janks next in inportance to tne Thanes and the Mersey. The principal ports are Newcastle and North and South Shields, but below Newcastle the river is everywhere studded with piers and jetties. $A$ bout a seventh of the whole tonage of vessels built in England is built ou the Tyne, the most important works being those of Jarrow. For boat-racing the Tyne vies in celebrity with the Thames.
TYNEMOUTH, a municipal and parliamentary borough of England, in Northumberland, includes the townships of Chirton, Cullercoates, North Shields, Preston, and Tynemouth. This last, the principal watering-place on this part of the coast, is picturesquely situated on a promontory on the north side of the Tyne at its mouth. It is connected with Newcastle, 8 miles to the west-south-west, by a branch of the North-Eastern Railway; its distance from London is $273 \frac{1}{2}$ miles by rail. The town has rapidly increased within recent years, and contains many well-built streets, squares, and villas. On the point of the promontory there is a small battery called the Spanish battery, and near it a monument has been erected to Lord Collingwood. Within the grounds to which the gateway of the old castle gives entrance are the ruins of the ancient priory of St Mary and St Oswin-the principal remains being those of the church. A pier, half a mile long, serves as a breakwater to the harbour. Among the principal public buildings are the assembly rooms and the aquarium (1872). The municipal buildings of the borough of Tynemouth are situated in North Shields, where are also the custom house, a master mariners' home, à seamen's institute, and a sailors' home founded by the late duke of Northumberland. Shipbuilding is carried on, and there are rope and sail works. The fish trade is of considerable importance and employs several steam and sailing boats. The population of the municipal and parliamentary borough of Tynemouth (incorporated in 1849; area 4303 acres), divided invo the three wards of North Shields, Percy, and Tynemouth, was 38,941 in 1871, and 44,118 in 1881.

Tynemoutlı was a fortress of the Sarons, and mas aucicntly known as Penlal Crag, "the head of the rampart on the rock." From remains fonnd in 1783 it is supposed to have been a Roman station. The first chureh was built of wood by Edwin, king of Northumbria, about 625, and was rebuilt in stono by his successor Oswald in 634. The hody of Oswiu, king of Deira, was brought hither for burial in 651, and on this accourut Tynemouth came to be in great repute as a place of burial both for rojal and ecclesiastical persons. The monastery was repeatedily plundered and burnt by the Danes, especially during the 9th centary. After its destruction by Healfdeane in 876 it was rebuilt by Tostig, earl of Northumberland, who endowed it with considerable revenue; but, baviog been granted in 1074 to the monks of Jarrow, it became a cell of Duraam. Malcolm III., king of the Scots, and his son Edward, who were slain in battle at Alnwick on 13th November 1093, were both interred in the monastery. In 1095 Earl Morrbray, haring entered into a conspiracy against William Rufus, conrerted the monastery into a castle, which he strongly fortified. By William Rufus the priory was conferred on St Albans abbev, Hertfordshire. It was surrendered to Henry TlII. on 12th January 1539 , and the eite and remains were granted by Edward YI. in 1550 to the earl of Warwick, afterward. duke of Northumberland. In 1644 the castle was taken by the Scots under tie earl of Leven. The town enjoyed various immunities at a very early period, which wero
aftermards the subject of some dispute. Edward I. restored to it several fiee customs of which it had been deprived. Afterwards it received a contirmation of its various former charters by Edward !I and Richard II.

TYPHON, or Typhoeve, son, according to Hesiod (Theog., 820 sq .), of the Earth and Tartarus, is described as a grisly monster with a bundred dragons' heads who was conquered and cast into Tartarus by Zeus. According to I!iad ii. 282, he lies in the land of the Arimi (Cilicia). Other legends place his prison under Etna or in other volcanic regions and make him the cause of eruptions. The myth, therefore, as we lave it, rests on a personification of volcanic forces. He is the father of dangerous winds (typhoons), and by later writers is identified with the Egyptian Set (see vol. vii. p. 717).
TYPHUS, TYPHOID, AND RELAPSING FEVERS. These are conveniently considered together, as they constitute the important class of continued fevers, having certain characters in common, although each is clearly distinguishable from the others. The following is a general account of the more salient features of each.

## Typhos Fever.

Typhus ${ }^{1}$ is a continued fever of highly contagious nature, lasting for about fourteen days and characterized mainly by great prostration of strength, severe nervous symptoms, and a peculiar eruption on the skin. It has received numerous other names, such as spotted, pestilential, putrid, jail, hospital fever, \&c. It appears to have been known for many centuries as a destructive malady, frequently appearing in epidemic form, in all countries in Europe, under the conditions to be afterwards referred to. The best accounts of the disease are those given by English writers, who narrato its ravages in towns and describe many "black assizes," in which it was communicated by prisoncrs brought into court to the judges, jurymen, court-officials, \&c., with fatal effect, producing oftentimes a widespread consternation. Typhus fever would seem to have been observed in almost all parts of the world; but, although not unknown in warm countries, it has most frequently prevailed in temperate or cold climates.

The causes concerned in its production include both the

## Predis.

 predisposing and the exciting. Of the former the most powerful of all are those influences which lower the health of a community, especially overcrowding and poverty. Hence this fever is most frequently found to affect the poor of large cities and towns, or to appear where large numbers of persons are living crowded together in unfavourable hygienic conditions, as has often been seen in prisons, workhouses, \&c. Armies in the field are also liable to ouffer from this disease; for instance, during the Crimean War it caused an enormous mortality among the French troops. Some high authorities, including Dr Murchison, have held that such conditions as these referred to are capable of generating typhus fever by themselves, and the apparent occasional de novo origin of this disease has doubtless the support of many striking facts which would appear to favour this view (seo Pathology, vol. xviii. p. 803). In the light, however, of recent researches into the relation of specific disease germs to the production of fevers and other infectious maladies, there is increasing difficulty in maintaining this position; and the direction of opinion is decidedly towards the view that, however much insanitary conditions and overcrowding act as causes prediaposing to the reception of the disease, the introduction into the system of a living organism or germ is necessary to the manifestation of the phenomena of the fcver. Nevertheless no specific organism has yet been clearly identified[^290]in the case of typhus fever. This disease is now much lesz frequently encountered in medical practice than formerly. -a fact which must mainly be ascribed to the greak attention which in recent times has been directed to improvement in the sanitation of towns, especially to the opening up of crowded localities so as to allow the frew circulation through them of fresh air. In most large cities, however, limited epidemic outbursts of the distasa occur from time to time, under the conditions of overcrowding and poverty, although the increased facilities possessed by local authorities for recognizing such nut breaks, and for the prompt isolation or removal of infected persons to hospitals, operate in general effectually ta prevent any extensive spread of the fever. All ages are liable to typhus, but the young suffer less severely than the old. The disease appears to be communicated by the exhalations given off from the bodies of those suffering from the fever, and those most closely in contact with the sick are most apt to suffer. This is shown by the frequency with which nurses and physicians take typhus from cases under their care. As in all infectious maladies, there is often observed in typhus a marked jroclivity to suffer in the case of individuals, and in such instances very slight exposure to the contagion may conrey the disease. Typhus is highly contagious throughout its wholo course and eves in the early period of convalescence. The contagion, hosiever, is rendered less active by the access of fresh air; hencs this fever rarely spreads in well-aired rooms or houses where cases of the disease are under treatmel.u. As a rula one attack of typhus confers immunity from risk of others, but numerous exceptions have been recorded.

The course of typhus fever is characterized by certaiz. well-marked stages. (1) The stage of incubation, or thi period elapsing between the reception of the fever poisor. into the system and the manifestation of the special ovidence of the disease, is believed to vary from a week to ten days. During this time, beyond feelings of languor, no particular symptoms are exhibited. (2) The invasios of the fever is in general well marked and severe, in the form of a distinct rigor, or of feelings of chilliness lasting for hours, and a sense of illness and prostration, together with headache of a distressing character and sleeplessness. Feverish symptoms coon appear and the temperature of the body rises to a considerable height ( $103^{\circ}-105^{\circ}$ Fahr.) at which it continues with but little daily variation until about the period of the crisis. It is, however, of impoitance to observe certain points connected with the teraperature during the progress of this fever. Thus abous the seventh day the acme of the fever heat has beer reached, and a slight subsidence ( $1^{\circ}$ or less) of the tem-

Temperature chart of typhus fever.
perature takes place in favourable cases, and no furthor subsequent rise beyond this lowered level occurs. When it is otherwise, the case often proves a severe one. Again, when the fever has adranced towards the end of the second week, slight falls of temperature are often observed, prior to the extensive descent which marks the attainment of the crisis. The pulse in typhus fever is rapid (100-120.
or more) and at first full, but later on feeble." Its condiLion as indicating the strength of the heart's action is watched with anxiety. The tongue, at first coated with a white fur, soon becomes brown and dry, while sordes (dried mucus, ©c.) accumulato upon the teeth ; the appetite is gone and intense thirst prevails. The bowels are as a rule fonstipated, and the urine is diminished in amount and high-coloured The physician on examination may make ont distince enlargenent of the spleen. (3) The third stage is characterized by the appearance of the eruption which senerally shows jitself about the fourth or fifth day or later, and consists of dark red (mulberry coloured) spots or blotches varying in size from mere points to three or four lines in diameter, very slightly elevated above the skin, at first disappearing on pressure, but tending to become both darker in hue and more permanent. They appear chiety on the abdomen, sides, back, and limbs, and occasionally on the face. Besides this, the characterustic typhus rash, there is usually observed a general faint mottling all over the surface. The typhus rash is rarely absent and is a very important diagnostic of the disease. In the more severe and fatal forms of the fever, the rash has all through a very dark colour, and slight subcutaneous hemorrhages (petechix) are to be seen in abundance. After the appearance of the eruption the patient's condition weems to be easier, so far as regards the headache and discomfort which marked the outset of the symptoms; lut this is also to be ascribed to the tendency to pass into the typhous stupor which supervenes about this time, and becomes more marked throughout the course of the second week. The patient now lies on his back, with a dull dusky countenance, an apathetic or stupid expression, and contracted pupils. All the febrile symptoms already mentioned are fully developed, and delirium, usually of a low muttering kind, but sometimes wild and maniacal (delirium ferox) is present both by night and day. The peculiar condition to which the term "coma vigil" is applied, in which the patient, though quite unconscious, lies with eyes widely open, is regardod, especially if persisting for any length of lime, as an unfavourable omen. Throughout the second week of the attack the symptoms continue unabated; but there is in addition great prostration of strength, the pulse becoming very feeble, the brcathing shallow and rapid, and often accompanied with bronchial sounds. (4) A rrisis or favourable change takes place about the end of the second or beginning of the third week (on an average the 14 th day), and is marked by a more or less abrupt fall of the temperature (vide chart) and of the pulse, t.ogether with slight perspiration, a discharge of loaded nrine, the return of moisture to the tongue, and by a clange in the patient's look, which clears up and shows signs of returning intelligence. Althrough the senso of weakness is extreme, convalescence is in general steady and comparatively rapid.
Tyrhus fever may, however, prove fatal during any stage of its pregress and in the early convalescence, either from sudden failure of the heart's action-a condition which is specially apt to arisefrom the supervention of some neryous symptems, such as meningitis or of deepening ceina, or from some other complicatien, such as bronchitis. - Further, a fatal result sometimes takes place hefore the crisis from shecr exlaustion, particularly in the casc of those whose physieal or nervous energies have been lowered by hard work, inadequate nourishment and sleep, or intemperance, in all which conditions typhus fever is apt to assume an unusually serions form.
Occasionally troubleseme sequele remain belind fer a greater or iess length of tiine as the effects of the fever. Among these may he mentionell mental wenkiness or irritability, occasionally some form of paralysis, an inflamed condition of the lymphatic ressels of one leg whe swilted leg of fever), prolonged weakness and ili heas'th, \&cc. Cradual improvement, liowever, may, be confidently onticipated and even ultimate recosery.
The mertality from tyithins forer is estimated by Nurchison and ethers as averaging about is por cent. of'the sases, Litt it raries
much according to the severity of type (particularly in epidemics), the previous health and habita of the individual, and very specially the age,-the proportion of deatho being in striking relation to the adrance of life. Thus, while in children under fifteen the death-rate is only 5 per cent., in persons over fifty it ia about 46 per cent.
The treatment of typhus fever includes the prophylactic measures of attention to the sanitation of the more densely populated portiens of towns. The opening up of cross streets intersecting those Which are close-huilt and narror, whereby fresh air is freely admitted, has done much to benish typhus fever from districts Where previously it was endemic. Further, the enforcement of the law regulating the number of persons accommodated in common longing-houses, and the application of the powers now vested in local authorities for dealing with cases of evercrowding everywhere, and for isolation and treatment of the infected, have had a like salutary effect. Where typhus has broken out in a crowded district the prompt removal of the patients to a fever hospital and the therough disinfection and cleansing of the infected houses are to be recommended. Where, on the other hand, a single case of accidentally caught typhus occurs in a member of a family inhabiting a well-aired house, the chance of it being communicated to others in the dwelling is but small; neverthcless every precaution in the way of isolation and disinfection should be taken.
The treatment of a typhus patient is conducted upen the same general principles as have heen illustrated in other fevers (see Scarlet Fever, Smallpox). Complete isolation should be maintained throughout the illness, and the services of a day and a night nurse procured, who should keep a strict wateh and preserve a record of the temperature and other observations, the times of feeding and the form of nourishment administered, as well as every other fact noticed, for the physician's information. Due attention should be given to the rentilation and cleansing of the sick chanber. The main element in the treatment of this fever is good nursing, and especially the regular administration of nutriment, of which the best form is milk, although light plain soup may also he given. The food should be administered at atated intervals, not, as a rule, oftener than once in one and a half or two heurs, and it will frequently be necessary to rouse the patient from his stupor for this purpose. Sometimes it is impossible to administer food by the mouth, in which case recourse must be had to nutrient enemata. Alcoholic stimulants are not often required, except in the case of elderly and weakly persons tho have become greatly exhausted by the attack and are threatening to collapse. The hest indication for their use is that furnished by the condition of the circulation : when the pulse shows unsteadiness and undue rapidity, and the first sound of the heart is but indistinctly heard by the stethoscope, the prempt administration of stimulants (of which the best form is pure spirit) will often succeed in averting danger. Shonld their use appear to increase the restlessncss or delirium they should be discontinued and the diffusible (ammoniscal or ethereal) forms tried instead.

Many other symptoms demand special treatment. The healaclie, which persists for days at the commencemeut and is with many a very distressing symptom, may be nitigated by remeving the hair and applying cold to the heal. The slecplessness, with or without delirium, may bo combsted by quictness, by a moderately darkeued room (although a distiuction between day and night should bo made as regards the amount of admitted light), and by soothing and gentle dealing on the part of the nurse. Opiate and sedative medicines in any form, although recommended by many high autherities, must io given with great caution, as their use is often attended with danger in this fever, where coma is apt to supervenc. When resorted to, prohably the safest form is a combination of the bromide of potassium or anımonium with a guarded amomt of chloral. The writer has seen alarming effects follow the administration of opium. Occasionally the deep stuper calls for remedies to rouse the patieut, and these nay be employed in the form of mustard or cantharides to the surface (calves of legs, nape of neck, over region of heart, \&c.), of the cold affusion, or of cnernata containing turpentine. The beight of the temperature may bo a serions synptom, and antipyretic remedics appear to have but a slight influ. ence over it as compared to that which they possess in ty phoid fever, aeute rheumatism, \&c. The cold bath treatment, which has bech recommended, cannot be carried ont without serious risk to life in the necessary movement of the patient. It is a well-recognized rule that persons suffering from typhis fever ought not to be movel up in bed for any purpose after the first few days. Cold sjonging of the hands and foet and exposed parts, or cold to the leasd, may often considerably lower the temperature. Flyoughout the whole progress of a case the condition of the bladder requires specia? attention, owiug to the patient's cirowsiness, and the legular use of the catheter becomes, as a rule, nccessary with the advance of the symptoms.
The complications and result of this fever fall to bo dealt with acenrding to the methods of treatment applicalle to their character an! cxtent.

## Typhold or Enteric Fever.

Typhoid or enteric fever (évrepov, the intestine) is a continued fever characterized mainly by its insidious onset, by a peculiar course of the temperature, by marked abdominal symptoms occurring in connexion with a specific Iesion of the bowels, by an eruption upon the skin, by its uncertain duration, and by a liability to relapses.

This fever has received various names, sush as gastric fever, abdominal typhus, infantile remittent fever, slow fever. nervous fever, \&c. Dr Murchison, in reference to its supposed origin in putridity, uses the term "pythogenic fever," but this designation has not been generally adopted. Up till a comparatively recent period typhoid was not distinguished from typhus fever. For, although it had been noticed that the course of the disease and its morbid anatomy were different from those of ordinary cases of typhus, ithnas believed that they merely represented a variety of that inalady The distinction between the two diseases appears to have been first accurately made in 1836 by Messrs Gerhard and Pennock of Philadelphia, and still more fully demonstrated by Dr A. P. Stewart of Clasgow (afterwards of London). Subsequently all doubt upon the subject was removed by tho careful clinical and pathological observations made by Sir William Jenner at the London fever hospital (1849-51). A clear distinction has been established between the two fevers, not only as regards their phenomena or morbid features, but equally as regards their origin. While typhus fever is a disease of overcrowding and poverty, typhoid may occur where such conditions are entirely excluded; and the connexion of this malady with specific emanations given off from decomposing organic or fæculent matters, or with contamination of food or water by the products of the disease, is now alinost universally admitted. Alike in sporadic cases and in extensive epidemic outbreaks the existenee of insanitary conditions in house drainage, water supply, \&c., can in the majority of instanees be made out. The question whether such conditions alone will suffice to beget this fever-or, in other words, its de novo origin-has, as in the case of typhus, been much discussed, and an affirmatire opinion expressed by some bigh authorities. But the same remark must again be made as to the difficulties in the way of maintaining such a position in view of the evideuce of the part played by microbes in infective processes.
canses of That all insanitary conditions in respect of drainage of
bouses and localities furnish the most ready means for the introduction of the contagion of typhoid there is a general agreement, as there is equally that the $m$-边certain means of preventing its appearance or spread are those which provide a thoroughly trustworthy and secure drainage, a safe method of disposal of sewage, and a pure and abundant water supply. Typhoid fever is much less directly communicable from the sick to the healthy than typhus. The infective agent appears to reside in the discharges from the bowels, in which, particularly when exposed and undergoing decomposition, the contagium seems to multiply and to acquire increased potency. Thus in sewers, drains, \&rc., in association with putrefying matter, it may increase indefinitely, and by the emanations given off from such decomposing material accidentally escaping into houses, or by the contamination of drinking water in places where wells or cisterns are exposed to fecal or semage pollution, the contagion is conveyad. Of the precise nature of the contagious prisciple we bave as yet 110 fnll information, ${ }^{1}$ but there appears to be strong reason for believing that a specific microbe or organism plays a part in the propagation of the disease. Still it is obvions that for its successful

[^291]implantation in and effect upon the system a peculiar condition of preparedness or receptivity to the morbific agent must be presupposed to exist in the individual, regarding which also our knowledge is of the vaguest. Thera is abundant evidence that one of the vehicles for the conveyance of the contagion is food, especially milk, which may readily become contaminated with the products of the disease where an outbreak of the fever has occurred in a dairy.

Typhoid fever is most common among the young, the majority of the cases occurring between the ages of fiftecn and twenty-five (Murchison). But children of any age may suffer, as may alse, theugh more ravely, persons at or beyond middled life. It is of as frequent occurrence among the well-to-do ss among the poor. The greater number of cases appear to occur in autumn. In all counties this fever seems liable to prevail; and, while some of its features may be medified by climate and lecality, its main characters and its results are essentially the same everywhere.
The more inportant phenomena of typhoid fever will be better understood by a brief reference to the principal pathelogical changes which take place during the disease. These relate for the most part to the intestines, in which the morbid precesses are lighly characteristic, both as to their nature and their locality. The changes (to be presently specified) are evidently the result of the action of the contagium on the system, and they begin to show themselves from the very commencement of the fever, passing through various stages during its continnance. The portion of the bowels iu whicls they occur most ahundantly is the lower part of the small intestine (ileum), where the "solitary glands" and "Peyer's patches" on the mucous surface of the canal become affected by diseased action of a definite and progressive character, which stands in distinct relatien to the eymptoms exhibited by the patient in the course of the fever. (1) These glands, which in health are comparatively indistinct become in the commencment of the fever eularged and prominent by infiltration due to inflammatory action in their substance, and consequent cell proliferation. This change usually affects a large extent of the ileum, but is more marked in the lower portion near the ilco-cæcal value (see Anatomy). It is generally held that this is the coudition of the parts during the first eight or ten days of the fever. (2) These enlarged glands next underge a process of sloughing, the inflammatory products being cast off either in fragments or en wasse. This usually takes place in the second week of the fever. (3) Ulcers are thus formed varying in size according to the gland masses which have sloughed away. They may be few or many in number, and they exbibit certain characteristic appearances. Thus they are frequently, but not always, oblong in shape, with their long axis in that of the bowel, and they have somewhat thin and ragged edges. They may extend through the thickness of the intestine to the periteneal coat and in their progress erode bloed-vessels or perferste the bowel. This stage of ulceration exists from the sceond week ouwards during the remaining period of the fever, and even into the stage of convalescence. (4) In most instances these ulcers lucal by cicatrization, leaving, however, no contraction of the calibre of the bowel. This stage of liealing evidently occupies a considerable time, since the process dees not advance at an equal rate in the case of all the ulcere, some of which have been later in forming than others. Even when convalescence has been apparently completed, somo uuliealed ulcers may yet remain and prove, particularly in connexion with errors in diet, a cause of relapse of some of the symptoms, and even of still more serions or fatal consequences. The mesenteric glands external to, but in functional relation with, the intestine, become enlarged during the progress of the fever, but usmally subside after recovery.

Besides these changes, which are well recomnized, others mere or less important are often present. Among these way be mentioned one which the present writer has repeatedly observed in the severe and protracted forma of this fever, namely, marked atrophy, thinning, and softness of the coats of the intestines, even after the ulcers have healed,-s condition which may not improbably be the cause of that long-continued impairment of the function of the howels so often complained of by persens who have passed through an attack of typhoid fever. Other changes common to most fevers are also to be observed, such as softening of the muscular tissues generally, and particularly of the heart, and evidences of complica. tions affecting chest or other organs, which net unfrequently ariae. The swelled leg of fever sometimes follows typheid, as does also periosteal inflammation.

The symptoms characterizing the onset of typhoid fever are very much less marked than those of most other ferers, and the disease in the majority of instances sets in somerrhat insidionsly. Indeed, it is no uncommon thing for patients with this fever to go about for a conslderable time after its action has begun. The most marked of the early symptems are headache, lassitude, and discomfort, together with sleeplessness and feverishness, particularly at night; this last symptom is that by which the disease is most readily delected. in its early stages. The peculiar cou'sc of the temperature
is also one of the most important diagnostic evidences of this fever. Dring the first week it has a morning range of moderate febrile rise, bot in the evening there is a marked ascent, with a fall again towards morning, each morning and evening, however, showing respectively a higher point than that of the provious day, unti abont the eighth day, when in an arerage case the highest paint is attained. This varies according to the severity of the attack;

Temperature chart of typhoid fever.
but it is no unusual thing to register $104^{\circ}$ or $105^{\circ}$ Fahr. in the even. ing and $103^{\circ}$ or $104^{\circ}$ in the morming. During the second week the daily range of temperature is comparatively small, a slight morning remission being all that is observed. In the third week the same condition continnes more or less; but frequently a slight tendency to lowering may be discerned, particularly in the morning temperature, and the febrile action gradually dies down as a rule between the twenty-first and twenty-eighth days, althongh it is liable to recur in the form of a relapse. Althongh the patient may, during the earlier days of the fever, be able to move about, he fecls languid and uneasy ; and usually before the first week is over he has to take to bed, and soon the effects of the attack become more apparent. $H_{\theta}$ is restless, hot, and uncomfortable, particularly as the day ad vances, and his cheeks show a red fosh, cspecially in the evening of after taking food. , The aspect, however, is different from the oppressed stupid look which is present in typhus, and more resembles the appearance of hectic. The pulse in an ordinary case, althongh more rapid than normal, is not accelerated to an extent corresponding to the height of the temperature, and is, at least in the earlier stages of the fever, darely above $100^{\circ}$. In severe and protracted cases, whero there is ovidence of extensive intestinal ulceration, the pulse becomes rapid and weak, with a dicrotic charactur indicative of cardiac fcebleness. The tongro has at first s thin whitish fur and is red at the tip and edges. It tends, however, to become dry, brown or glazed looking, and fissured transversely, while sordes may be present about the lips and teeth. There is much thirst and in some cases romiting. Splenic and hepatic enlargement may be made out. From an early period in the disease abdominal symptoms show themselres with greater or leas distinctress and are frequently of highly diagnostic significance. The abdomen is somewhat distended or tumid, and pain accompanying somo gurglinc sounds may be elicited on light pressure about the lower part of the right side close to the groin, - the region corresponding to that portion of the intestine in which the morbid changes already referred to are prog'essing. Diarrhcea is a frequent but by no meads constant symptom. When present it may be slight in amount, or, on the other hand, extremely profuse, and it corresponds as a rula to the severity of the intestinal ulceration. The discharges are highly characteristic, baing of light yellow colour resembling pea soup in appearance. Should intestinal hemorrhage occur, as is not unfrequently the case during some stage of the ferer, they may be dark brown, or composed entirely of blood. The urine is scanty and high-coloured. About the beginning, or during the course of the second week of the fever, an eruption frequently makes its appearance on the skin. It cousists of isolated spots, oval or round in shape, of a pale pink or rose colour, and of about one to ono and s half lines in diameter. They are seen chiefly upon the abdomen, chest, and back, and they come out in crops, which continue for four or five days and then fade array. At first they are slightly elevated, and disappear on pressure. In some cases they are very fow in number, and then presence is made out with difficulty; but in others they are nuraerous and sometimes show themselves upan the limbs as well as upon the body. They do not appear to have any relation to the severity of the attack, and in a very consider. able proportion of cases (particularly in children) they are entircly sbsent. Besides this cruption there are not unfrequently numerous very faint bluish patclics or blotches about half an inch in diameter, chiefly upon the body and thighs. When present the rose-coluured spots contiuse to come out in crops till nearly the end of the fever, and they may reappear ohould a relapse subsequently occur. These various symptoms persist throughout the third week, usually, however, increasing in intensity. The patient becomes prostrate, and emaciated; the tongue is dry and brown, the pulse quickeneal and feeble, and the abdominal symptoms more coarked; while nervous disturbance is exhibited in delirium, in
tremors and jerkings of the muscles (subsultus tendinum), in drowsiness, and occasionally in "coms vigil." In serero cases the ezhaustion reaches an extremo degree, although oven in euch instances the condition is not to be regarded as hopeless. In favourable cases a change for the better may be anticipsted between the twenty-first and twenty-eighth daye, more usually the latter. It does not, how. ever, take place as in typhus by a well-marked crisis, but rather by what is termed a "lysis" or gradual subsidence of the febrile symptoms, especially naticeable in the daily decline of both morning and ovening temperature, the lessening of diarrhoea, and improvement in pulse, tongue, \&c. Convalescence proceeds slowly and is apt to be interrupted by relapses (due not unfrequently to errors in diet), which are semctimes as severe and prolongad as the original attack, and are attended with equal or cren greater riske. Should such relapses repeat themse!ves, the case may be protracted fer tro or three months, but this is comparatively rare.

Death in typhoid fever usually takes place from one or other of the following causes. (1) Exhanation, in the secont or third weeks, or later. The attending symptoms are increasing emaciation, weak ness of the pulse, and cadaveric aspect. Sonetimes sinking is sudden, partaking of some of the charactera of a collapse. (2) Hamorrhage from the intestines. The evidebce of this is exhibited, not only in the evacuations, but in the sudden fall of temperature and rise in pulse-rate, together with great pallor, faintness, and rapid sinking. Sometimes hæmorrhage; to \& dangerous and even fatal extent, takes place from the nose. (3) Perforation of an intestinal ulcer. This gives $1 i s e$, as a rule, to sudden and intenso abdominal pain, together with vomiting and sigus of collapse, viz., a rapid fickering pulse, cold clammy skin, and the marked fall of temperature. Symptoms of peritonitis (see Peritonitas) quickly supervene and add to the patient's distress. Death usually takes place within 24 bours. Occasionally peritonitis, apart from perforation, is the cause of death. (4) Occasionally, but rarely, hyperpyrexia (excessive fever). (5) Complications, such as pulmonary or cerebral inflamma. tion, bedsores, \&c.

Certain sequelæ are sometimes observed, the most important being the swalled leg, periostitis affecting long bones, geceral illlocalth, and anemia, with digestive difficulties, often lasting for a long time, and sometimes issuing in phthisis. Occasionally, after sovere cases, mental weakness is noticed, but it is usually of comparatively ehort duration.

The nortality in typhoid fever varies with the character of the Moroutbreak, the general health and surrouudings of the individuals tality. attacked, and other conditions. At one time it was regarded as, on an average, about the samo as that of typhus; but under modern methods of treatment the chances of recovery are much greater, and the death-rate may be stated as about 12 per ceat. or perhaps some. what less.

The treatment embraces those proplylactic measures which sim Treat at preventing the escape of sewer gases into drelling-houses by ment careful attention to the drainage and plumber-work, and also secure an abundant supply of pure water for domestic use (see Hrgiene, Severaoe, and Ventilation). When an outbreak of the fever occurs in a family, all such matters should be specially inquired inte, and the sources of milk supply carefully scrutinized. The discluarges from the bowels of the typhoid patient should be at once disinfected with carholic acid or other similar agent, and the grestest care taker as to their disposal, with the vien of obviating any risk of contamination of drinking-water, \&c. The general managenent is conducted upon the same principles ae $a^{\circ} \theta$ observed in the case of typhus, except that in typhoid fever very special care is necessary in regard to diet. Milk, the great valne of which as a fever food was first clearly set forth by Prof. Gairdner, is of eminent service in typhoid, but it must bo administered with due regard to time and to the digestive powers of the patient. When given too frequently or in too great quantity it may; by its imperfect digestion, prove a source of irritation to the bewcls. Even when given with every care it may fail to agree, as is proved by the presence of mdigested curd in the evacuations. In such a case its admixture with lime water or with poptonizing agents may render its digestion less dificult, but sometimes its use most for a time be suspended. It is, however, rare that milk cannot be borne when carcfully edministered. Barley water or simple soups, such as chicken broth, bcef-tea, \&c., aro ocossionally usefnl either as substitutes for or adjuvants to milk. All through the fever the patient should be fed at regular periods-not, as a rulc, oftener than once in one and a half or two lours-although in the iotervals water or other fever drink may be given from time to time. In convalescence the diet should still be largely milk andosoft matters, auch as custards, light nuddings, meat jellics, boiled bread and milk, \&c., but other solid foods, with the exception of fish, should be for a long time avoided In changing the diet it is of importance to note its effect upon the temperature, which may sometimes be considerably disturbed from this cause, even after the apparent subsidence of all febile action. Stimulants, although unnecessary in a largo proportion of cases, are occasionally called for when there is great exhaustion, ard in prolonged attacks. Thcir effect, lowever, should ba care-
fully watched. They are usually best administered in the form of pure spirit.
The more prominent symptoms which mark the course of typhoid fever frequently call for special treatment. Thus, when the fever continues long, with little break in its course, the employment of remedies to coutrol its action (antipyretics) may often be resorted to with benefit. Such drugs as quinine, salicin, salicylic acid, and salicylate of soda, kairin, antipyrin, antifebrin, \&c. (in ten to thirty grain deses of one or other), may frequently break in upen the centinnity of the fever, and by markedly lowering the temperature relieve for a time the bedy from a source of raste, and aid in tranquillizing the excited nerveus system. The times for their administration are cither one or two hours before the usual maximnn temperature or during the period of remission. These remedies may, however, fail, or by inducing sickncss or great prostration and lepression of the circulation require to be discoutinned. For a similar purgose the cold bath is recommended by many bigh authorities and is regularly employed is Germany. The method recommendel by Liebermeister is this: "When the temperature rises above $104^{8}$ Fahr., the patient should be placed in a bath of about $94^{\circ}$, which is gradually cooled down by the addition of coll water to $68^{\circ}$ Fahr., and remain imunersed for twenty or thirty minutes, the liubs being all the while gently rubhed. He sheuld then he put back into bed." Another method is that of Dr Rrand of Stettin: "When the patient's temperature attains $102^{\circ}$ Fahr., he should be placed in a tepid bath of $70^{\circ}$ and allowed to romain till a sense of coldness or shivering is preduced, which usually occurs in 'from five to twenty minutes." By such means no doubt Whe tempersture can often be reduced $2^{\circ}$ or $3^{\circ}$ Fabr., but it is very apt to rise again and the bath must then be repeated. It is claimed by the adrocates of this method of treatment that it has been successful in diminishing greatly the mertality of typhoid fever, but they held at the same titne that its success in large neeasure depends upon its employment from an early stage in the disease. British physicians are much divided upon the point, many high authorities agrecing in its marked ntility, while others no less eminent regard it as fraught with danger from the frequent morement of the patient from bed, the shock to the system, and the risk of hæmorrhage, pnoumenia, or other complications, and as a plan of treatment difficult of being carried out in ordinary practice. Although employed in some fever hospitals and with apparent success, it has not yet commended itself for general adoption. Other methods of applying cold, while probably less effectual than the bath, are much more available, as, for example, the tepid or cold pack, the frequent spongiug of portions of the body with cold water, or the application of icchags to the head. The present writer has resorted to these metheds in many cases of typhoid fever, with the effect of markedly lowering a high temperature. When diarrhcea is oxcessive it may be restrained by such remedies as chalk, bismuth, Dover's powder, sc. Hemorringe is dealt with by preparatione of ergot, or by acetate of lead, gallic acid, or other styptios. In the event of perforation of the bewel opium is the only means available to lessen the distress attending that fatal occurrence.
In the convalescent stage, and oven after apparently complete recovery, the utmost care should be observed by the patient as to liet, all hard and indigestible substances being dangerons from their tendency to irritate or reopen unhealed ulcers, and bring on a relapse of the fever or cause a sudden perforation. Lastly, the general health demands careful attention for a length of time, alluded to.

## Relafsing Fever.

This is a contunued fever occasionally appearing as an epidemic in communities suffering from scarcity or famine. It is characterized mainly by its sudden in rasion, with violent febrile symptoms, which continue for about a week and end in a crisis, but are followed, after another week, by a return of the fever.
This disease has receirea many other names, the best known of which are famine fever, short fever, synocha, bilious relapsing fever, recurrent typhus, and spirillum ferer. As in the cass of typhoid, relapsing fcyer was long believed to be simply a form of typhus. The distinction betreen theru appears to have been first clearly established in 1826 , in connexion with an epidenic in Ireland. Outbreaks of relapsing fever have occurred in all parts of the world at times and in places where famine has arisen; but the disease has been most closely observed and studied in epidemics in Great Britain and Ireland, Germany, Poland, Russia, America, and India. It has frequently been found to prevail along with an epridemic of typhus fever.

Relapsing fever is highly contagious, and appears, ike typhus, to be readily communicated by the exhalations from the body. With respect to the nature of the contagion, certain important and inter: esting observations have been made. In 1873 Obermeier discovered in the blood of persons suffering from relapsing fever minuto organisms in the form of spiral filaments of the genus Spirochate (see vol. xxi. p. 399, fig. 1, n), measuring in length ro\% to ${ }^{1}{ }^{1}$ inch and in breadth $\frac{1000}{}$ to botoo inch, and possessed of rotatory or twisting mevements. This erganism has receired the name of Spirillun obcrmeieri. It appears to be present in abundance during the height of the febrile symptoms, and is not seen during the interval until the relapse is impending, when it is again present as before. This observation has been confirmed by numcrous investigators, and it has been found that inoculation with the blood containing these Spirilla produced the symptoms of relapsing ferer in both men and anionals. Comparatively little is as yet kuorn of the life-history of these organisms, and the question whether they are to be regarded as the prime sonrce of the disease or as mere accompaniments affords ground for difference of opinion (see Pate ology, val. xviii. p. 403); nevertheless their discovery and the conditions of their presence already mentioned. are noteryorthy facts in refereuce not only to the pathology of this fever but also to tha general doctrine of infectiveness in discase-processes. The most constautly recognized factor in the origin and spread of relapsing fever is destitution; but this cannot be regarded as more than a predisposing cause farouring the reception and propagation of the norbific agent, since in many lands widespread and destructive famines have prevailed without any outbreak of this fever. Instances, too, bave been recorded where epidemics were distinctly associated with overcrowding rather than with privatiou. Relapsing fever is most commonly met with in the young. One attack dees not appear to protect from others, but rather, according to some authorities, engenders liability.
The extreme contagiousness of relapsing fever has occasionally Its eco been shown by ite syrcading widely when introduced into a district, tagiou even among those who had not become predisposed by destitution ness, or other depressing conditions. The contagion, like that of typhus, appears to to most active in the immediate vicinity of the patient and to be greatly lessened by the access of fresh air. It is capable of being conveyed by clothing. The incubation of the disease is with one week. The symptoms of the fever then show themselves with great abruptness and violence by a rigor, accompanied with pains in the limbs and severe headache. The febrile phenomena
are very marked, and the temperature quickly rises to a high point

Temperature chart of relapsing fever.
( $105^{\circ}-107^{\circ}$ Fahr.), at which it continues with little variation, while the pulse is rapid ( $100-140$ ), full, and strong. There is intense thirst, a dry brown tongue, bilious vomiting, tenderness over the liver and spleen, and occasionally jaundice. Sometimes a peculiar bronzy appearanee of the skin is noticed, but there is no characteristic rash as in typhus. There is much prostration of strength. After the continuance of these symptems for a period of from fire to seven days, the ternperature suddenly falls to the normal point or below it, the pulse becomes correspondingly slow, and a profuse perspiration occurs, while the severe headache disappears and the appetite returns. Ezcept for a sense of weakness, the patient feels a condition of great detility, work, but in some cases there remains a condition of great debility, accompanied with rbeumatic pains in the limbs. This state of freedom from fever continues for about a abruptness and severity than in the first attack, and the whele abruptness and severity than in the first attack, and the whole symptoms are of the same character, but they do not, ss a rule, continue so leng, and they terminate in a crisis in three or four third, after which convalescence proceeds satisfactorily. Second, third, and even fourth relapses, however, may occur in exceptiona'
cases.

The mertality in relapsing fever is comparatively small, about per cent. being the average death-rate in epidemics (Murchison). The fatal cases occur mostly from the complications cemmon to continat ferers. The treatment is essentially the same as that
for typhus fever (see above).
(J. O. A.)

## TYPOGRAPHY

## Part I.-Historical.

TIVPOGRIAPHY (writing by types) is the art of printing (cast-metal) movable types on paper, vellum, \&c. $t$ is quite distinct, not only from writing, but from xylography or wood-engraving, i.e., the art of cutting figures, etters, or words on blocks of wood and taking impressions from such blocks, by means of ink or any other fluid coloured substance, on paper or vellum.
Possibly the earliest attempt to describe the art of typagraphy is that in the Donatus issued by Peter Schoeffer, perhaps before 1456, the colophon of which says that it was finished "Arte neva imprimendi seu caracterizandi [from character $=$ letter] . . . absque calami exaratione." Fust and Schooffer in the Mainz psalter of 1457 said that it was formed by an "adinventio artificiosa imprimendi ac caracterizandi absque calami ulla exaratione." The colophon of the Catholicon of 1460 is more precise, and says that the book was printed " "on calani, stili, zut pennex suffragio, sed mira natronarum formaruraque coucordia, proporcione, ac modulo." Io 462 Albrecht Pfister had "gedrucket" the Four Histories. In the Liber Sextus Decretalium, published in 1465, Fnst and Schoeffer say that it was completed "non atramento ["atramento communi," in the Justinianus of 1468 and 1472], plumali canna neque ærea, oed artificiosa quadam adinventione imprimendi seu caracterizasti," opbrase which they slightly varied in Cicero's officia, issued in. the eame year: "non atramento, plumali canoa neque ærea, sed arte quadan perpulcra." The edition of St. Jerome's Epistlics of 1470 is said to have been completed by an "ars impressoria," the Decrectum Gratiani of 1472 by an "ars quædam ingeniosa imprimandi," the Dyalogus of 1478 by an "ars magistra." We ind further-"ars sancta " or "dirina," "מova ars scribendi," "मovum pascribendi genus prope divisum," " gcnlpteria archety porum ars,"," "ars mirifica formandi," "ars excusoria," "nura imprimendi ratio," "ars pressurx," "chalcotyns ars," "chalcographia" (14i2 and tater), "chalcographia excusoria impressoriaque," "libratia impressio," "empryntynge" (Caxten, 1482), "prenterei " (Schoeffer, 1492), "truckery" (1505), "impression des livres" (1498), and "prenten."
The early printers called themselves, or were called by others, "librorum prothocaragmatici" (Gramm. Rhythm., 1463), "impres6ores librorum," "exsculptor librorum" (Jenson, 1471), "chalcographrus" (1473; Hain, 13036), "masmister artis impressorie,", "hoeckprinter"; and during the 16 th century we find them still frequently called "chalcotypus" and "chalcographns."
The types were at first designated more Ly negative than positive expressions. In 1468 they were called "caragma," later on "caraxter" or "charscter," "archetipe note" (1473, ; Hain, 13036), "scalptoria archetyporum ars," "chalcotypa ars," "formæ," "artificiosissimæ imprimenderum librorunn forme." We soon hear slso of the process and material by which they were produced. The Grammatica of 1468 , published by Schoeffer, says that it was "cast" (sum fusus libellus). In 1471 "xenex formulx" are spoken of ; and Bernardus Cenninus and his son eay that they had printed the Virgil "ex pressis ante calibe caracteribus et deinde fusis literis " (with letters first cut into steel and then cast). In 1473 Friedrich Creusner at Nuremberg says that he had "cut" (sculpsit) the werk of Diogenes (Haiu, 6192). Johan Zciner of Ulnt says in 1474 that he had perfected a book, not with the pen, but with letters of metal Tstagneis caracteribus.). In 1474 Joh. Pl. de Lignamine speaks of "metallicx forme." In 1476 Husner of Strasburg represents the Nider as being printed with "letters cut of metal (littcris sculptis grtificiali certe conatu ex ære)." Nicolas Jenson printed in 1480 "qith lettera "cut and cast" (sculptis ac conflatis).
The word typographus does not seem to occur before 1438, when $i$ was nsed in the preface of P. Stephanus Dulcinius Scalx to the Astronomicon of Manilius, printed in that yeer at Milan by Antonius 'arotu8; ; in 1498 Erasmus uses it in a letter (dated 13th Feb.) to Shristianus, a Liibeck merchant; ${ }^{2}$ and in 1517 Jehan Schoeffer applies the word to himself in the colophon of the Æneas Sylvius published by him. But of the use of the word typographia no parlier instance is known then 1520, in which year Gerardus Noviomagus (=Geldenhaurius) in his Lucubratizncula de Batavorum Znssela (pref. to Nicol. Buscoducensis, dated 1520) says: "'inventa Germanorum :. . bombarda ridelicet, typographia, pyxis chartaque nautica;" end Johan Schott, a printor of Strasburg, in the Greogr. Piolem. published by him, describes his, grandfather, Johan Mentelin, as "primus typographixe inventor." Gerardus, it may bo added, borrowed the whole passage from Pet. Montanu.s (hi. 1 Adag., published a. 1504), who has chalcographia instead of typo-
graphia. Meerman indeed" speaks of a use of the reord typographia (or at least of typographus) earlier than 1520 , and refers to the preface of Bernardiuns Veronensis in the edition of Tibullus, Catullus, and Propertius published at Venice in 1493 by Symon Bevilaqua, "al least," Mcernisn adds, "ss it (the preface) is read in the Annal. Typogr. of Maittaire, i. $560,2 \mathrm{~d}$ ed.". But an page 560 Maittairo quotes the first two lines of Bernardinus'e preface (till dicii) and then adds: "Grecis characteribus destitutus, typegraphus necesse habnit hiatus in commentario hic illic relinquere," which is eridently Maittaire's own remark, not that of Bernardinus. The present writer at least has been unuble to find auch a passage in the Tibullus.

Although the art of writing and that of block-pronting both differ widely from printing with movable metal types, yet this last process seems to have been such a gradual transition from block-printing, and block-printing in its turn to have been such a natural outcome of the many trials that were probably made to produce books in some more expeditious manner than could be done with handwriting, that a cursory glance at these two processes will not seem out of place, all the less as a discussion on the origin and progress of typography could hardly be understood without knowing the state of the literary development at the time that printing appeared.

The art of printing, i.e., of impressing (by means of First certain forms and colours) figures, pictures, letters, words, attemp lines, whole pages, \&c., on other objects, as also the art of at print engraving, which is inseparably connected with printing, ing existed long before the 15 th century. Not to go back to remoter essays, there is reason to suppose that mediæval kings and princes (among others William the Conqueror) had their monograms cut on blocks of wood or metal in order to impress them on their charters. Such impressions from stamps are found instead of seals on charters of the 15 th century. Manuscripts of the 12 th century show initials which, on account of their uniformity, are believed to have been impressed by means of stamps or dies. ${ }^{4}$ But the idea of multiplying representations from one engraved plate or block or other form was unknown to the ancients, whereas it is predominant in what we call the art of blockprinting, and especially in that of typography, in which the same types can be used again and again.

Block-printing and printing with mavable types seem to have East been practised in China and Japan long before they were known in Asiatie Eurpe. It is said that in the year 175 the text of the Chinese printind classics was cut upon tablets, which were erected outside the university, and that impressions were teken of tlam, sone of which are said to be still in existence. Priuting from rooden blocks can be traced as far back as the 6th century, when the foupder of the Suy dynasty is said to hava had the remains of the classical books engraved on wood, though it was not mutil the 10th century tlat printed books became common. In Japaz the carliest exanplc of block-printing dates from the period $764-750$, when the enyress Shiyan-taku, in pursuance of a vow, had a million small wrooden toy pagodas made for distribution among the Buddhist temples and nionasteries, each of which was to contain a dhâraní ont of the Buddhist Scriptures entitled "Vimala nirhhasa Sítra," printed on a slip of paper about 18 inches in length and 2 in width, which was rolled up and deposited in the body of the pagoda under the spire. In a journal of the period, under the year 987 , the expression "printed" book" (seri.hon) is found applied to a copy of the Buddhiat canon brought back from Chine by a Buddhist priest. This, of course, must have been a Chinese edition; but the use of the term implies that printed books were already known in Japan. Il is said that the Chinese printed with movable types (of clay) from the middle of the 11 th century. The anthorities of the British Nuseum exhibit as the earliest instance of Corean books printed with movable types a work printed in 1337. To the Corcans is attributed the invention of copper types in the beginning of the 15 th century; and an inspection of books bearing dates of that

[^292]period seems to show that they ased such types, even if they did not invent them.

From such evidence as we have it would seem that Europe is not indebted to the Chinese or Japanese for the art of block-printiug, nor for that of printing with movable types.

In Europe, as late as the second half of the 14 th century, every book (including school and prayer books), and every problic and private document, proclamation, bull, letter, \&c., was written by band; all figures and pictures, even playing-cards and images of saints, were drawn with the pen or painted with a brush. In the 13 th century there already existcd a kind of book trade. The organization of universities as well as that of large ecclesiastical establishments was at that time incomplete, especially in Italy, France, and Germany, without a staff of scribes and transcribcrs (scriptores), illuminators, lenders, sellers, and custodiane of books (stationarii librorum, librarii), and pergamenarii, i.e., persons who prepared and sold the vellum or parchment required for books and documents. The books supplied were for the most part legal, theological, and educational, and are calculated to have amounted to above one bundred different works. As no book or document was approved unless it had some ornamented and illuminated initials or capital letters, there was no mant of illuminators. The workmen scribes and transcribers were, perhaps without exception, caligraphers, and the illuminators for the most part artists. Beautifully written and richly illuminated manuscripts on vellum became objects of luxury which were eagerly bought and treasured up by princes and people of distinction. Burgundy of the 15 th century, with its rich literature, its wealthy towns, its love for art, and its school of painting, was in this respect the centre of Europe, and the libraries of its dukes at Brussels, Bruges, Antwerp, Ghent, dc., contained more than three thousand beautifully illuminated MSS.

In speaking of the writing of the manuscripts of the 15 th and two preceding centuries, it is essential to distinguish, in each country, between at least four different classes of writing, and two of these must be again subdivided each into two classes. All these different kinds of writing were, in the first instance, taken as models for cutting sucin portions of text as were intended to illustrate and explain the figures in block-books, and afterwards as models for the types used iu the printing of books and documents.
(1) The book hand, that is the ordinary writing of legal, theological, and devocional books, was used by the official transcribers of the universities and churches. These men had received a more or less learned education, and consequently wrote or transcribed baoks with a certain pretence of understanding them and of being able to write with greater rapidity than the ordinary caligrapher. Hence their writing may be called (a) the current or cursive boolt hand, of which a good many illustrations may be found in Wilh. Schnm, Exempla Codicurr, Amplon. Erfurtensium. Quite distinct from this current writing, and much clearer and moro distinct, is (b) the upright or set book hand, which was employed by some writers who worked for universities and churches, and also by a goad many who may be presnmed to have worked in lavge cities and commercial towns for echools and the people in general without nniversity connexion. (2) In the chureh hani (Gothic or black letter) were praduced transcripte of the Bible, missals, psalters, and other works intended for usein churches and private places of worship. This writing we may again subdivide into two classes,-(a) the orna. mental or caligraphic writing, fonnd exclnsively in books intended for use in chmrches or for the private ase of wealthy and distinguished persons, and (b) the ordinary uepright or set church hand, employed for less ornamental and less expensive books. (3) The letter hand may be said to be intermediate between the set literary book hand and the set literary chureh hand, and to differ but little from either. It was employed in all public documents of the nature of a letter. (4) The court or chaster hand was used for charters, title-deeds, papal bulls, \&c.
${ }^{1}$ See Ern. Satow, "On the Early Hist. of Printing in Japan," in Trans. A siat. Soc. of Japan, x. 48 sq.; and Stan. Julien, "Documents our l'Art d'Imprimer," \&c., in Journ. Asiat., 4 we ser., ix. 505.

Uypold Läber (Lauber), a teacher and transcriber at Hagenau in Germany, is kuown to have carried on a busy trade in manuscripts just about the time of the invention of printing. His prospectuses, in handwriting of about the middle of the 15 th century, 2nnounce that whatever books people wish to have, large or small, "geistlich oder weltlich, hübsch gemolt," are all to be found at Dypold Laubor's the scribe. Ho had in stock Gesta Romanomum, mit des Viguren gemolt; poetical warks (Parcixal, Tristan, Freidank) ; romances of chivalry (Der Witfarn Ritter; Vón eime Getruwen Ritter der sin cigen Hertze gab umb ciner schönen Frowen willen; Der Ritter unter dem Zubcr) ; Biblieal and legendary works (A Rimed Bible; A Psalter, Latin und German; Episteln und Evangelien durch das Jor; Vita Christy; Das gantze Passional, winterteil und summerteil; devotional books (Bellial ; Der Selen Trost ; Der Rosenkrantz ; Dic zehn Gebot mit Glosen; Small Bette-Buieher) ; and books for the people (Gute bewehrte Artznien-Bücher; Gemolte Loss-Bücher, i.e., fortnne-telling books; Schachtzabel gemolt). The lower edncational books consisted for the most part of the Abecedaria, containing the alphabet, the Lord's prayer, the creed, and one or two prayers; the Donatus, a short Latin grammar oxtracted from the work of Elits Donatus, a Roman grammarian of the ath centary, and distinctly mentioned in a school ordinance of Bantzen of 1418 ; the Doctrincil, a Latin grammar in leonine verse, compiled by Alexander Gallus (or De Villa Dei), a minorite of Brittany of the 13 th century; the Summula Logica of Petrus Hispanus (afterwards Pope John XXI.), used in the teaching of logic and dialectics; and Dionysins Cato's Disticha de Moribus, and its supplement called Facetus, with the Floretus of St Bernard, used in the teaching of morals. As helps to the clergy in their attempts to educate the lower classes, and as a means of assisting and promoting private devotion, there were picture books accompanied with an easy explanatory text, for the most part representations of the mystic relation between the old and New Testaments (typology). Among these books the Biblia Pauperum ${ }^{2}$ stands first. It represents pictorially the life and passion of Christ, and there exist MSS. of it as early $2 s$ the 13 th contury, in some cases beantifully illuminated. ${ }^{3}$ A richly illuminated MS. of it, execnted in the Netherlands c. 1400 , is in then British Museum (press-mark, King's, 5), and also fragments of one of the 14 th century (press-mark, 31,303 ). A remodelling and development of this work is the Spceulum Humana Soliationis, a work is rliyme of the 14th century, which in forty-five chapters represents the Bible history interworen with Mariolatry and legend. Of this work the Paris national library and arsenal hbrary cach possesses a MS. composed in 1324, whereas the British Jluseum bas nine MSS. (six being illuminatcd) of the 14 th and 15 th centurics, written in the Netherlands, Germany, France, and England, one (press-mark, 16,578 ) bearing the distinct date 1379 and another (press-mark, Egerton, 878) that of 1436. A work of a similar nature is the Apocalypsis, ofwhich at least two recensions with illustrations maje be pointed out. One gives the text as we know it, with or without commentary, for which of. Brit. Mus., 17,333 (French), 18,633 (French, but written in England), Reg. 2 D. xiii., and 22,49s (French), -all four early 14 th century. Another is more a short history or biography of St. John, but the illustrations follow those of the former work very closely; cf. Brit. Mns., 19,896 (15th century, German). It is this last recension which agrees with the blockbook to he mentioned hereafter. Other devotional works aro the Ars Moriendi, the Antichrist, and other works which will be found mentioned among the block-books.

## Block-Printing or Xylography.

When all this writing, transcribing, illuminating, \&c, had reached their period of greatest devclopment, the art of printing from wooden blocks (block-printing, xylography) on silk, cloth, de., vellum, and paper made its appearance in Europe. It seems to have been practised, so far as we have evidence, on cloth, dec, and vellum as early as the 12 th century, ${ }^{4}$ and on paper as far back as the second half of the l4th century, while it was largely employed in the early part of the 15 th in the production of (1) separate leaves (called briefs, from breve, scriptum), containing either a picture (print, prent, shortened from the Fr. emprint, empreinte, and already used by Chaucer, C. T., 6186, sixtext, D. 604, printe, prente, preente, and in other early English documents ; also called in colloquial German Helge, Helglein, or Halge) or a piece of text, or both together;

[^293]and of (2) whole block-books, sometimes consisting of half picture and half text, or wholly of text, or altogether of picture. ${ }^{2}$ It is, however, certain that pbout 1400 xylograplyy was known all over Germany, Flanders, and Holland.
In thesa blocks, as in wood-engraving now, the lines to be printed were in relief. Tbe block, after the picture or the text had been engraved upon it ${ }_{\mathrm{s}}$. was first thoronghly wetted with a thin, watery, pale brown material, much resembling distemper; then a sheet of damp paper was laid upon it, and the back of the paper was carefully rubbed with some kind of dabber or burnigher, usually called a frolton, till an impression from the ridges of the carved block had been transferred to the paper. In this fashion a sbeet could only be printed ou one side (anopisthographic); and in some copics of block-books we find the sides on which there is no printing pasted tngether so as to give the work the appcarance of an ordinary book. There aro only a few hlock-books which do not posesss this characteristic, as the Legend of St Servalius-in the royal library of Brussels, Das Zeilglocklein in the Eamberg library (of. Falkenstein, p. 49), Das geistlich und vecltlich Rom at Althorp and Gotha (cf. Falkenstein, p. 46) ; but these belong to the end of the 15 th century, and therefore to a later period than the ordinary block-booke. Consequently, if a man wanted to set up as a printer of briefo or books, he needed no apparatus but a set of wood-blocks and a rubber.
Formerly it was the general opinion that playing-cards had been the first products of xylography; but the carliest that have been preserved to us are done by hand, while the printed ones date from the 15 th c. ntury, therefore from a period in which woodeuts were alrcady used for other purposes. It is believed that some of the wood engravings and bloch-books were printed in monasteries. In a necrology of the Franciscan monastery at Nördlingen, which comes down to the heginning of the 15 th century, this entry occure: "VII. ld. Augusti, obiit Frater h. Luger, laycus, ontimns incisor lignorum "; and on some of the engravings we find the arms of certaiu monastcries, which may, however, merely mean that they were printed for, not in, those monasteries. The registers of Ulm mentiun several wood-engravers (formschneider), - in 1398 a certain Ulrich; in 1441 lleinrich Peter von Erolzbeim, Joerg, and anotber Heinrich; in 1442 Ulrich and Lienhart; in 1447 Clans (Nicola9), Stoffel (Christopher), and Johan』; in 1455 Wilhelm; in 1461 Meister Ulrici, \&c. In a register of taxcs of Nördlingen we find from 1528 to 1452 a certain Wilhelm Eegeler mentioued as brieftrucker; in 1453 his widow is called alt brieftruicherin; sad in 1461 his brother Wilhelna is reqistered for the ameme craft. At Mainz there was a printer, Henne Cruse, in 1440. At Nuremberg we find in 1449 Hans, a formschncider, while his son Junghans exercised the same industry from 1472 te 1490 . Hans von Pfedersheim printed at Frankfort in 1459, and Peter Schott at Strasburg in 1464. A certain George Glockendon exercised the same trade at Nuremberg ['ll 1474, when lie dien, being oucceeded by a son and afterwards hy a grandson. In Flanders a Jande Printere was eatablished at Autwerp in 1417; and printers and wood engravers (houte bildsnyters) worked there in 1442 (Privileges of the Corporalion of $S t$ Luke at Antwerp). At Brnges printers and becldemakers (makers, engravers of images) were enumerated in 1454 among the members of the fraternity of St Jolin the Evangelist. The printers of playing rards seen to hare constituted a separate class. These entries show that about the middlo of the 15th century thero were men who exercised the art of wood-engraving and printing as a trade or craft. It seems also certain that wealthy persons and religious institutions were wont to possess sets of blocks, and, when occasion arose, they printed a set of sheets for presentation to a friend, or in the case of monasteries for sale to the passing pilgrim. A printer of briefs or block-books had no nced to serve an apprenticeship; any neathanled man could print for himself. We learn from tho inventory of the possessious of Jean de Hinsberg, bishop of Liége (1419-1455), anil his sister, a nun in the convent of Bethany, near Mechlin, that thry possessed "unum instrumentum ad imprimendas scripturss et ymagines," and "novem printe lignes ad imprimendas ymagiacs cum quatuordecim aliis dapideis printis." These entries would seem to indicate that people purchased engraved blocks of wood or of stone from the woodcutter rather than books from a printer.
The earliest dated woodcut that we know of is the St Christopher of 1423, preserved in the library of Lord Spencer at Althorn. The fary engraving, which is preserved at Brussels and epparently ears the date meccexviii., is now declared to be of 1468 , the date . aving been falsified. The next date after that of the St Christopher is 1437 , found on a woodent prescrved in the imperial library at Vienna. It was discovered in 1779 in the moustery of St Blaise in the Black Forest, and represents the martyrdom of St Scbastian, with fourteen lines of text. The date, however, is said by others to refer to a concession of iudulgences. A woodent, preserved in the library at Vienna, which represents St Nicolas do Tolentino, has the dato 1440 , but written in by hand; as the saint was canonized
I We have also evidence that sometlmes the picture or flgures were printed from hooks, space tenng reseryed for the text, to bo added afterwards by hand we Bernard. Irigin. 1. 1(S)
in that jear, it-may refer to that erent. Another in the Wefgel collection representing the bearing of the cross, St Dorothea and St Alezis, has the date 1443, also written in by hand, thougb the woodcut is considered to belong to that period. These are the only known wood-engravings with dates anterior to the second half of the'15th ceptury. But there exist a good many woodcuta which, from the style of the engraving, are presumed to be of an earlier date, and to have been printed partly in the fourteenth and partly in the frst half of the 15th century. -J. D. Passavant ${ }^{2}$ enumerstes twenty-seven, ell of German ongin snd preserved in various libraries in Germany, while in the Collectio Weigeliana (vol. i.) no fewer than 154 are recorded, sonse of which are to be ascribed to the Netherlands. We know of the existence of at least five ongravings Which may be ascribed to the Netherlands:-(1) representing the Virgin Mary, with Dutch inscriptions, in the museum at Berlin, (2) representing the Virgia Mary spoken of above, in the library at Brussels; (3) representing St Anthony and St Sebastian, in the Weigel collection; (4) a St Hubert and St Enstatius, in the royal library at Brussels; (5) representing the Child Jesus, in the library at Berln (6) the Mass of St Gregory, with indulgence, in the Wergel collection ( $f f$. i. 195).
Of block-books of probable German origin the following are known:-
(1) The Apocalypsis, or Ḧistorza S. Johannis Evangcliste cjusque Visiones Apocalypticz (Germ. 'Das Buch ader haymichea Offenbarungen Sanct Johans). Of this work eix or eeven editions are said to exist, each containing forty-eight (tbe 2d and 3d edition fifty) illuetrations, on as many anopisthographac leaves, which seem to havo been divided into three quires of eight sheets each. The first edition alone is without signatures.
(3) Ars Mreriendi. Of this work some authors think that there are early German editions, among others that snoken of belows as the 2d Dutch edition. CertainIy German is the edition of Hans Sporer of Nuremberg, 1473, in the public library at Zwickan, of another by Ludwig zu Ulm, in the Paris national library, and of that described in Collcctio Weigel. (ii. 16), where also other, but opistlographic, editions are described.
(3) Ars Memorandi; thirty lesres, folio, printed on one side, fifteen leaves being letter-press and fifteen plates.
(4) Salve Regina, bears the nume of its engraver, Lienhart czu Regenspurck. It is composed of sixteen leaves; troo leaves (signsture a) are manting in the only copy known of it, which was in the Weigel collection (ii. 103).
(5) Vita Christi; thirty-two leaves, am. 8vo. Two copies in the Paris library (Sothoby, ii. 143).
(6) The Ten Commandments for Unlearned People (Die z-hn Botl fiur die ungelernte Leut). Ten leaves are preserved in the library at Heidelberg bound up with a manuscript (No. 438). ${ }^{3}$
(7) The Passion of Our Lord; sixteen leaves, in the Weigel collection (Sotheby, ii. 141).
(8) The Antichrist (Der Enndchrist); twenty-six leates, amall follo (Sotheby, ii. 38; Weigel, ii. 111). Copies, Lord Spencer and coll. Weig.
(9) The Fiftecn Signs of the Last Judgment; twelve engravings, usually bound up with the engravings of The Antichrist (Sotheby, ii. 42). Copy, Lord Spencer. There is also an edition published at Nuremberg in 1472 by Junghannss Prifimaler.
