2582. For the Corinthian order, we must seek examples rather in Rome than in any part of Greece. The portico at Athens, and the arch of Hadrian at Athens, do not furnish us with specimens of art comparable with the three columns in the Campo Vaccino, belonging, as is generally supposed, to the temple of Jupiter Stator. Those in the temple near Mylassa, and the Incantata, as it is called, at Salonica, do not satisfy the artist, as compared with the examples in the remains of the temple of Mars Ultor at Rome, the temple of Vesta at Tivoli, and others, for which the reader may refer to Desgodetz.

2583. The reader is again here reminded that the module or semidiameter is to be

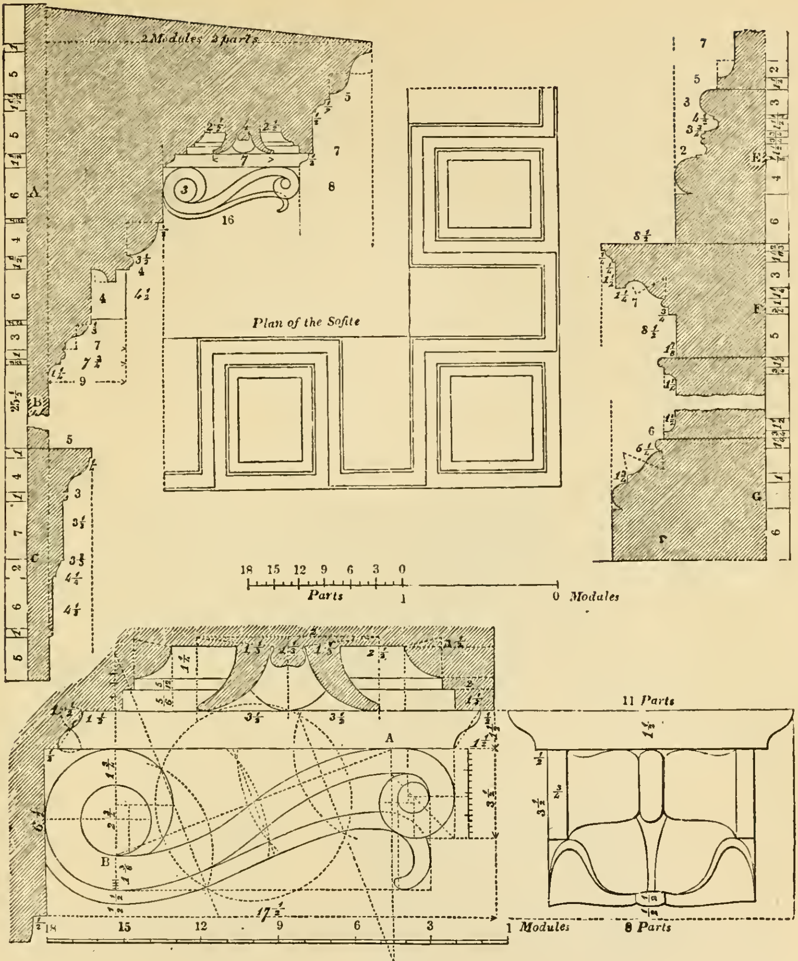

Fig. 889.

2584. *Fig.* 889. shows the details of the entablature, &c. and also the profile and front of the Corinthian modillion to a larger scale. On the profile is shown the caisson or sunk panel on the sofite of the corona. The height is six parts, and the projection sixteen. As seen in the figure, a distance equal to three parts and a half is taken for the height of the smaller volute, and on this distance a scale of sixteen equal parts is made; the figure shows the dimensions to be given to the small squares, whose angles serve as centres to describe the curves. Having drawn the line AB, it is divided into four equal parts by lines perpendicular to it, which, meeting vertical lines from A and B, give the points, which serve as centres for striking the curve of the modillions. The acanthus leaf which supports it, as well as the curves which form the profile of the roses in the caisson, are also struck by compasses.

2285. In *fig.* 890., which exhibits the method of drawing the Corinthian capital, one half of the plan shows the capital in plan, and the other half of it laid down diagonally. Having drawn the axis of the plan correspondent to the axis of the elevation of the capital, with a radius equal to two modules, describe a circle, which divide into sixteen equal parts Their lines of division will each correspond to the centre of each leaf. The vase of the capital is determined by a circle whose radius is $14\frac{1}{2}$ parts. The figure shows the circles which bound the leaves upwards on the vase.

2586. The elevation shows the heights whereon are carried the projections of the plan.

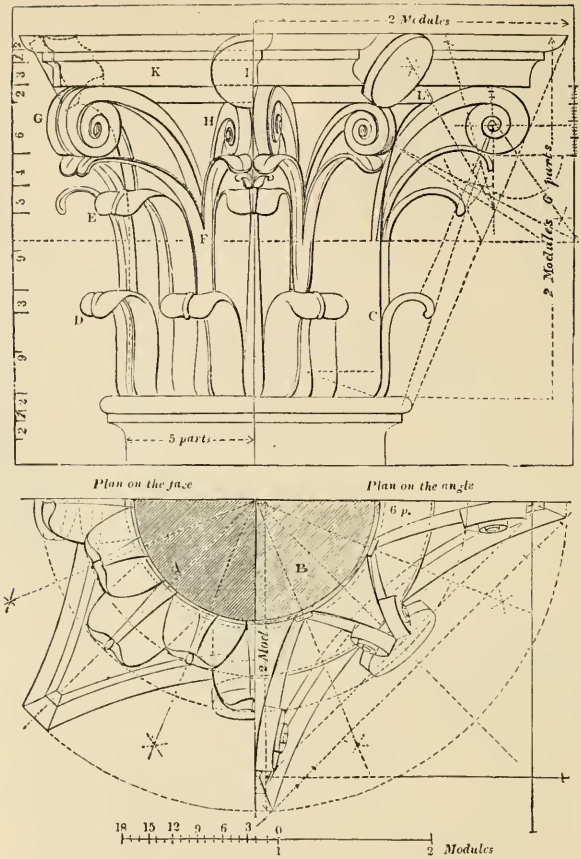

Fig. 890.

Above the leaves come the sixteen volutes, whereof the eight larger ones support the four angles of the abacus, and the eight smaller ones support the flowers which decorate the middle of the abacus. The volutes seen in profile may be drawn geometrically with the compasses, but they are always more agreeable and easy when drawn by the eye with a hand which feels the contours.

The different parts of the capital are as follow: A, plan of the leaves and abacus; B, plan of the larger and smaller volutes; C, the vase or body of the capital; D, the first tier of leaves; E, the second tier of leaves; F, the caulicolus; G, the larger volute; H, the smaller volute; I, the flower; K, the abacus; L, the lip of the vase.

2587. Vitruvius is scanty in the information he gives on the Corinthian order, and what he says respecting it relates more to the origin of the capital and the like than to the proportions of the detail. He makes the capital only 1 diameter high, and then forms upon the plan a diagonal 2 diameters long, by means whereof the four faces are equal according to the length of the arc, whose curve will be the ninth part in length and its height the seventh part of the capital. He forms the order with a pedestal, with base and cornice, as Daniel Barbaro would have it. The whole height given to it in our measures is about 27 modules and 2 parts.

2588. Palladio uses the pedestal with its ordinary subdivisions, making it between a third and fourth part of the height of the column, including its base and capital. To the base he gives 1 module, the shaft of the column a little less than 8 diameters, and places twenty-four flutes upon it, which two thirds downwards are channelled, and on the other or lower third neatly fitted with convex pieces of segments of cylinders called *cablings.* He makes the capital 1 diameter and a sixth in height, giving it two tiers of leaves, caulicoli, and abacus. To the architrave, frieze, and cornice he assigns a little le s than a fifth part of the column, including the base and capital. The whole height given to the order by this author is about 27 modules and 10 parts of our measures.

2589. Serlio makes his pedestal pretty nearly as the rest. To the base of the column he assigns half a diameter for the height, when that is about level with the eye, but when much above it he directs all the members to be increased in height accordingly, as where one order is placed above another, he recommends the number of parts to be diminished. To the shaft of the column he gives a little more than 7 diameters, and to the capital the same height as that given by Vitruvius, whom, nevertheless, he considers in error, or rather that some error has crept into the text, and that the abacus ought not to be included in the height. The height of the architrave, frieze, and cornice he makes a little less than a fourth part of the column, including its base and capital. The whole of the order, according to him, is 28 modules and a little more than 1 part of our measures.

2590. Scamozzi gives to the pedestal of this order the height of 3 diameters and one third, composing it with the usual parts of base, die, and cornice; to the base of the column the same height and mouldings as Palladio. To the shaft of the column he assigns the height of 8 diameters and one third, and diminishes it on each side an eighth part of its thickness at bottom. The capital is of the same height as that by Palladio. The architrave, frieze, and cornice he directs to be a little less than a fifth part of the height of the column. By our measures the whole height of his order is 30 modules and 20 parts.

Sect. VII.

THE COMPOSITE ORDER.

2591. The Composite order, as its name imports, is a compound of others, the Corinthian and Ionic, and was received into the regular number of orders by the Romans. Philander, in his notes on Vitruvius, has described its proportions and character. Its capital consists, like the Corinthian, of two ranges of acanthus leaves distributed over the surface of a vase, but instead of the stalks or branches, the shoots appear small and as though flowering, adhering to the vase and rounding with the capital towards its middle. A fillet terminates the vase upwards, and over the fillet an astragal is placed, and above that an echinus, from which the volutes roll themselves to meet the tops of the upper tier of leaves, on which they seem to rest. A large acanthus leaf is bent above the volutes, for the apparent purpose of sustaining the corner of the abacus, which is dissimilar to that of the Corinthian order, inasmuch as the flower is not supported by a stalk seemingly fixed on the middle of each face of the abacus. The principal examples of

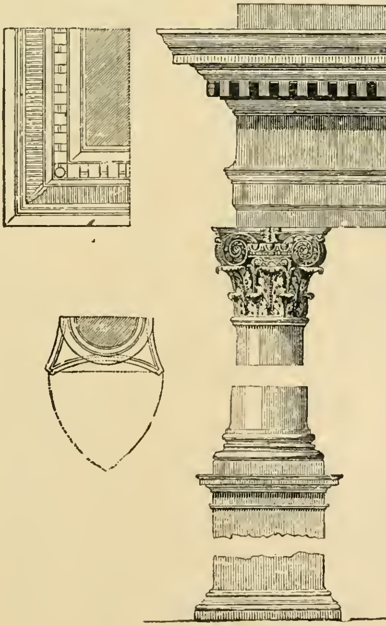

Fig. 891.

the order are at Rome, in the temple of Bacchus, the arches of Septimius Severus, of the Goldsmiths, and of Titus; also in the baths of Dioclesian.

2592. *Fig.* 891. (see preceding page) is a representation of Vignola's profile of the order. Its measures are subjoined in the following table: —

Members composing the Order.		Heights in Parts of a Module.	Projections from Axis in Parts of a Module.
ENTABLATURE.

2593. The flutes in this order are separated by a fillet between them, and are, when used, twenty-four in number.

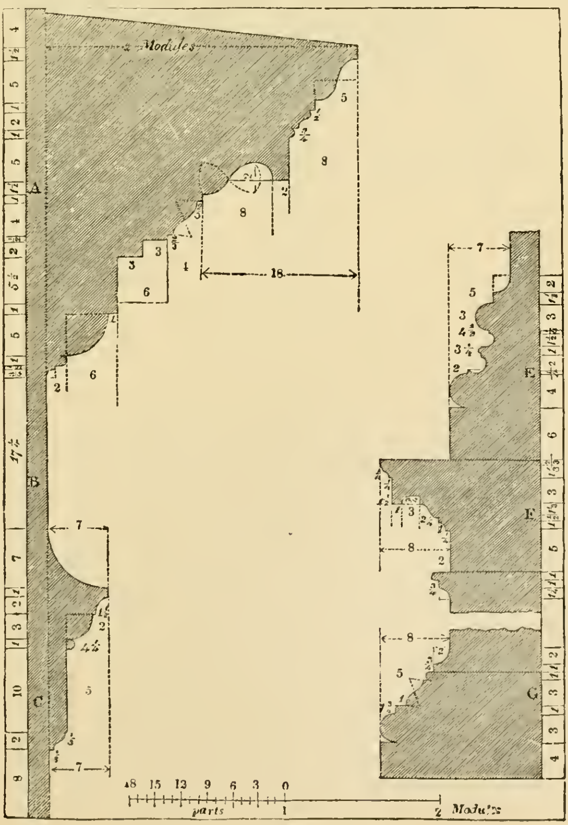

Fig. 892.

2594. *Fig.* 892. (see preceding page) shows the parts of the entablature. base. and pedestal to a larger scale, and *fig.* 893. gives, similarly, a more intelligible, because larger, represent-

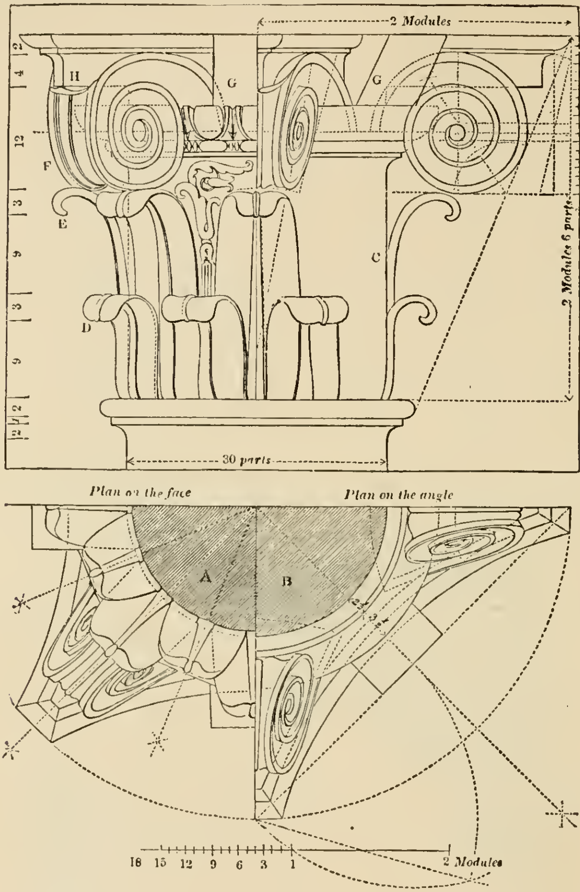

Fig. 893.

ation of the mode of setting up the capital, which, as we have already observed, has only eight volutes. In this figure A is the plan, as viewed frontwise; B, that of the capital, viewed diagonally; C, the vase or body of the capital; D, the first tier of leaves; E, the second tier of the same; F, the volutes; G, the flower; H, the abacus.

2595. Vitruvius has not given any instructions on this order; we are therefore obliged to begin our parallel, as in the other orders, with —

2596. Palladio, whose examples of it are light and much decorated. To the pedestal's height this master assigns 3 diameters and three eighths of the column, adding to it a lower plinth of the height of half a diameter. He makes the base of the column half a diameter in height, and assigns to the shaft 8 diameters and a little more than one fourth, and cuts on it twenty-four flutes. The height of this capital is 1 diameter and a sixth, his volutes being very similar to those he prescribes for his Ionic. The architrave, frieze, and cornice he makes a little less than a fifth part of the height of the column. The whole height of his profile in our measures is 30 modules and 12 parts.

2597. Serlio seems to have founded his profile of this order upon the example in the Coliseum at Rome. He makes the height of the pedestal a little less than 4 diameters of the column. To the shaft of the column he assigns 8 diameters and a half. To the height of the capital he gives 1 diameter, differing therein from his profile of the Corinthian order in the disposition of the volutes and leaves. His entablature, which is a little less in height than one fourth of the column, he divides into three equal parts for the architrave, frieze, and cornice The total height of his profile in our measures is 32 modules and 9 parts, being much higher than that of Palladio.

2598. Scamozzi's profile greatly resembles that of Palladio. His pedestal is 3 diameters, and the base of his column half a diameter in height. The shaft of his column without base or capital, is 8 diameters and one twelfth high, and the capital 1 diameter and a sixth. The entablature is one fifth part of the column in height, and the whole of the profile in our measures is nearly 29 modules and 7 parts.

Sect. VIII.

PEDESTALS.

2599. We think it necessary to devote a small portion of our labour to the consideration of pedestals, on account of the great difference which exists in the examples of the orders, and this we shall place in a tabular form, previous to the general remarks it will be necessary to make.

Table showing the Height of Pedestals in ancient and modern Works.

		Plinth in Minutes.	Mouldings above Plinth in Minutes.	Die in Minutes.	Cornice in Minutes.	Total Height in Minutes.
Doric	Palladio - -	26	14	80	20	140
	Scamozzi - -	30	15	$68\frac{4}{7}$	$22\frac{1}{2}$	$136\frac{1}{14}$
Ionic	Temple of Fortuna Virilis - -	44	$19\frac{3}{4}$	$93\frac{3}{4}$	$23\frac{1}{4}$	$180\frac{3}{4}$
	Coliseum - -	$33\frac{1}{4}$	$9\frac{1}{2}$	$81\frac{5}{6}$	17	$141\frac{1}{2}$
	Palladio - -	$28\frac{2}{3}$	$14\frac{1}{3}$	$97\frac{3}{4}$	$21\frac{1}{2}$	$162\frac{1}{4}$
	Scamozzi - -	30	15	$82\frac{1}{2}$	$22\frac{1}{2}$	150
Corinthian	Arch of Constantine -	$17\frac{1}{2}$	29	153	$29\frac{1}{2}$	228
	Coliseum - -	23	$11\frac{1}{2}$	78	$19\frac{1}{4}$	$131\frac{3}{4}$
	Palladio - -	$23\frac{1}{2}$	$14\frac{1}{2}$	93	19	150
	Scamozzi - -	30	15	$132\frac{1}{2}$	$22\frac{1}{2}$	200
Composite	Arch of Titus -	55	30	141	29	255
	Arch of the Goldsmiths - -	46	$25\frac{1}{4}$	$144\frac{1}{2}$	$25\frac{1}{4}$	241
	Arch of Septimius Severus - -	30	$30\frac{5}{6}$	$140\frac{1}{2}$	$29\frac{5}{6}$	$182\frac{1}{6}$
	Palladio - -	33	17	133	17	200
	Scamozzi - -	30	15	$112\frac{1}{2}$	$22\frac{1}{2}$	180

2600. The minutes used in the above table are each equal to one sixtieth of the diameter of the shaft.

2601. Whether the pedestal is to be considered a component part of an order is of little importance. There are so many cases that arise in designing a building, in which it cannot be dispensed with, that we think it useful to connect it with the column and entablature, and have consequently done so in the examples already given of the several orders. Vitruvius, in the Doric, Corinthian, and Tuscan orders, makes no mention of pedestals, and in the Ionic order he seems to consider them rather as a necessary part in the construction of a temple than as belonging to the order itself.

2602. A pedestal consists properly of three parts, the base, the die, and the cornice. "Some authors," says Chambers, "are very averse to pedestals, and compare a column raised on a pedestal to a man mounted on stilts, imagining they were first introduced merely through necessity, and for want of columns of a sufficient length. "It is indeed true," he continues, "that the ancients often made use of artifices to lengthen their columns, as appears by some that are in the baptistery of Constantine at Rome; the shafts of which, being too short for the building, were lengthened and joined to their bases by an undulated sweep, adorned with acanthus leaves; and the same expedient has been made use of in some fragments which were discovered a few years ago at Nismes, contiguous to the temple of Diana. Nevertheless, it doth not seem proper to comprehend pedestals in the number of these artifices, since there are many occasions on which they are evidently necessary, and some in which the order, were it not so raised, would lose much of its beautiful appearance. Thus, within our churches, if the columns supporting the vault were placed immediately on the ground, the seats would hide their bases and a good part of their shafts; and in the theatres of the ancients, if the columns of the scene had been placed immediately on the stage, the actors would have hid a considerable part of them from the audience; for which reason it was usual to raise them on very high pedestals, as was likewise necessary in their triumphal arches; and in most of their temples the columns were placed on a basement or continued pedestal (*stylobata*), that so the whole might be exposed to view, notwithstanding the crowds of people with which these places were frequently surrounded. And the same reason will authorise the same practice in our churches, theatres, courts of justice, or other public buildings where crowds frequently assemble. In interior decorations, where, generally speaking, grandeur of style is not to be aimed at, a pedestal diminishes the parts of the order, which otherwise might appear too clumsy; and has the farther advantage of placing the columns in a more favourable view, by raising their base nearer to the level of the spectator's eye. And in a second order of arcades there is no avoiding pedestals, as without them it is impossible to give the arches any tolerable proportion. Sometimes, too, the situation makes it necessary to employ pedestals, an instance of which there is in the Luxembourg at Paris; where, the body of the building standing on higher ground than the wings, the architect was obliged to raise the first order of the wings on a pedestal, to bring it upon a level with that of the body or *corps de logis* of the building, which stands immediately on the pavement."

2603. The dies of pedestals are occasionally decorated with tablets or with sunk panels whose margins are moulded; but, generally speaking, such practices are to be avoided. In very large pedestals the surface may be thus broken, as in single monumental columns, which, at best, are but paltry substitutes for originality. Habit has reconciled us to view with pleasure the Trajan and Antonine columns, the monument of London, and the column of Napoleon in the Place Vendôme at Paris, in each of which the pedestals are ornamented in some way or other, so as to tell in some measure the story of the person in whose honour they were erected, or, as in the basso-relievo of the London column, the event which it records. But care must be taken when inscriptions are used to preserve a rigid adherence to truth, and not to perpetuate a lie, as was the case in the monument just named, against a most worthy portion of the people of the British empire.

2604. As respects the employment of pedestals, we should advise the student, except under very extraordinary circumstances, to avoid the use of them under columns which are placed at a distance from the main walls of an edifice, as, for example, in porches peristyles, or porticoes, — a vice most prevalent in the Elizabethan architecture, or rather the cinque-cento period, which the people of this day are attempting with all its absurdities to revive. Here we must again quote our author, Sir William Chambers, whose excellent work we have used above, and on which we shall continue to draw largely. "With regard," he says, "to the application of pedestals, it must be observed, that when columns are entirely detached, and at a considerable distance from the wall, as when they are employed to form porches, peristyles, or porticoes, they should never be placed on detached pedestals, as they are in some of Scamozzi's designs, in the temple of Scisi (Assisi) mentioned by Palladio, and at Lord Archer's house, now Lowe's hotel, in Covent Garden; for then they indeed may be compared to men mounted on stilts, as they have a very weak and tottering appearance. In compositions of this kind, it is generally best to place the columns immediately on the pavement, which may be either raised on a continued solid basement, or be ascended to by a flight of fronting steps, as at St. Paul's, and at St. George's Bloomsbury; but if it be absolutely necessary to have a fence in the intercolumniations, as in the case of bridges or other buildings on the water, or in a second order, the columns may then, in very large buildings, be raised on a continued plinth, as in the upper order of the western porch of St. Paul's, which in such case will be sufficiently high: and in smaller buildings, wherever it may not be convenient or proper to place the balustrade between the shafts, the columns may be placed on a continued pedestal, as they are in Palladio's designs for Signor Cornaro's house at Piombino, and at the villa Arsieri, near Vicenza, another beautiful building of the same master." The same author continues: "The base and cornice of these pedestals must run in a straight line on the outside throughout, but the dies are made no broader than the plinths of the columns, the intervals between them being filled with balusters, which is both really and apparently lighter than if the whole pedestal were a continued solid." The author quoted then proceeds to caution the student against the employment of triangular, circular, and polygonal pedestals, and such as are swelled and have their die in the form of a baluster, or are surrounded by cinctures.

These extravagances were rife in the age of Louis XV., but notwithstanding the zeal of the jobbing upholsterers and decorators of the present day, who are the curse of all architectural art, we hope they will never be permanently revived in this country, though their introduction has already proceeded to a considerable extent

Sect. IX.

INTERCOLUMNIATIONS.

2605. An intercolumniation is the clear distance between two columns measured at the lower diameter of their shafts. This distance must depend principally on the order employed: in the Tuscan, for example, the nature of its composition allows a greater width between columns than would be admissible in the Corinthian order, independent of what has already been stated in Sect. II. (2524, *et seq.*) in respect of supports and loading; and this because of the enrichments of the several orders requiring that they should take their departures (to use a phrase borrowed from another science) from the axes of their respective columns. The ancient names (which are still preserved) of the different intercolumniations are described by Vitruvius in his second and fourth books. They are — the *pycnostyle*, wherein the space between the columns is 1 diameter and a half, as its etymology from *πυκνος* and *στυλος* imports (thick in columns), an intercolumniation used only in the Ionic and Corinthian orders; the *systyle* (*συστυλος*, with columns a little more apart), wherein the interval between the columns is a little greater; the *eustyle* (*ευστυλος*, or well-contrived interval), wherein the intercolumniation is of 2 diameters and a quarter; the *diastyle* (*διαστυλος*, with a more extended interval between the columns), having an intercolumniation of 3 diameters; and the *aræostyle* (*αραιοστυλος*, with few columns), wherein the interval is 4 diameters. In the Doric order the triglyphs necessarily regulate the intercolumniations, inasmuch as the triglyph should fall over the axis of the column; hence the intercolumniations in this order are either systyle monotriglyph (that is, with a single triglyph in the intercolumniation), or $1\frac{1}{2}$ diameter; diastyle, or of $2\frac{3}{4}$ diameters; or aræostyle, which will make the interval 4 diameters, as will be immediately understood on reference to *fig.* 894.; wherein A is the sysytle monotriglyph intercolumniation of 3 modules; B, that of the diastyle, or 6 modules; and C, the aræostyle, or of 8 modules. The intercolumniation marked D serves for the application of coupled columns, wherein the rule seems necessarily to be that the space between the columns may be increased, so that the requisite number of supports according to the order and intercolumniation is preserved.

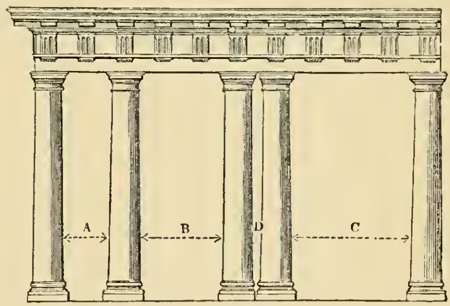

Fig. 894.

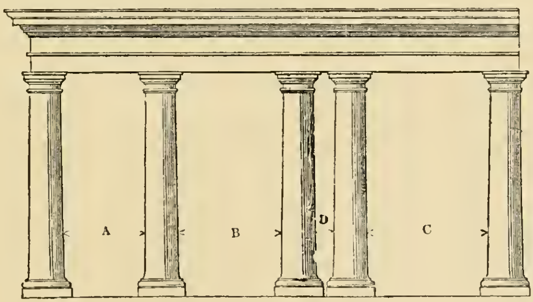

Fig. 895.

2606. The intervals of the Tuscan order are indicated in *fig.* 895., wherein A shows the intercolumniation called eustyle of $4\frac{1}{2}$ modules; B, the diastyle of 6 modules; and C, the aræostyle of 8. D, of 1 module, is the space of coupled columns.

The intercolumniations in this order are scarcely susceptible of rules other than those we have indicated in our previous discussion on the orders generally in Sect. II. (2523, *et seq.*), wherein we have entered on the subject at such length that we refrain from saying more in this place. We may, however, observe, that the application of the principles there mentioned are so intimately connected with this section, that the separation of one from the other would destroy all our scheme for keeping the student in the right path. Hereafter the principles in question will be applied to and tested on arcades.

2607. In *fig.* 896., of Ionic intercolumniations, A is the eustyle arrangement; B, that of the diastyle; C, that of the aræostyle; and D, that of coupled columns.

2608. *Fig.* 897. is a similar application of the intercolumniations to the Corinthian order, wherein also A exhibits the eustyle; B, the diastyle; and C, the aræostyle intervals: D also showing the space used of 1 module for coupled columns.

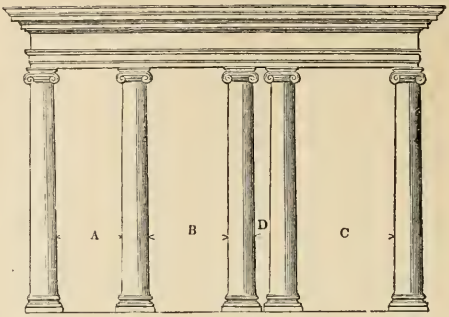

Fig. 896.

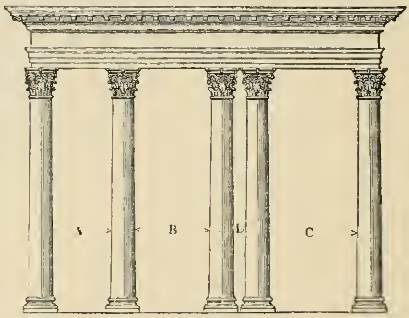

Fig. 897.

2609. Sir William Chambers, for whose observations we have much respect, — and, indeed, to whose valuable labours we acknowledge ourselves much indebted, — seems to have had a distant glimpse of the doctrine of equal weights and supports, but knew not exactly how to justify his notions on the subject. He therefore avoids the main question by attributing the pycnostyle intercolumniation rather to necessity than choice; observing, that "as the architraves were composed of single stones or blocks of marble, extending from the axis of one column to that of another, it would have been difficult to find blocks of a sufficient length for diastyle intervals in large buildings." But this is a reason altogether unsatisfactory, inasmuch as we know that they were sufficiently masters of masonry to have conquered any such difficulty. We are much more inclined to agree with him when he says (always, however, reverting to the principle of equal supports and weights), "With regard to the aræostyle and Tuscan intercolumniations, they are by much too wide either for beauty or strength, and can only be used in structures where the architraves are of wood, and where convenience and economy take place of all other considerations: nor is the diastyle sufficiently solid in large compositions." These considerations, however, may be always safely referred to the doctrines laid down in Section II. of this Chapter, already alluded to; and, indeed, that reference is justified by the instructions of Vitruvius in the second chapter of his third book, wherein he directs that the thickness of the column should be augmented in an enlarged intercolumniation: as, for example, supposing the diameter of a column in the pycnostyle species to be taken one tenth of the height, it should in an aræostyle be one eighth; arguing, that if in an aræostyle the thickness of the columns exceed not a ninth or tenth part of their height, they appear too slender, and in the pycnostyle species the column at one eighth of its height is clumsy and unpleasant in appearance. Upon this passage Chambers observes, "that the intention of Vitruvius was good, but the means by which he attempts to compass it insufficient. His design was to strengthen the supports in proportion as the intervals between them were enlarged; yet according to the method proposed by him this cannot be effected, since one necessary consequence of augmenting the diameter of the column is enlarging the intercolumniation proportionably. Palladio and Scamozzi have however admitted this precept as literally just, and by their manner of applying it have been guilty of very considerable absurdity." We are not at all inclined to admit the truth of the opinion of Chambers; for, again reverting to the doctrine of the supports and loading, which was unknown to him, it is to be remembered that increase in the space of the intercolumniation immediately involves increase of weight in the load or entablature, and therefore seems to demand increase of diameter to the supports. Palladio and Scamozzi were not therefore guilty of the absurdity laid to their charge.

2610. Among the other reasons for our adopting the practice of Vignola is that he has observed so much uniformity in his intercolumniations, except of the Doric order, wherein the triglyphs prevent it, aware as we are that the practice has by many able writers been much condemned. Chambers even says that his practice in this respect is "preferable to any other, as it answers perfectly the intention of Vitruvius, preserves the character of each order, and maintains in all of them an equal degree of real solidity."

2611. With the exception of the Doric order, wherein the most perfect arrangement of the detail results from the interval produced by the ditriglyph, there can be no doubt that, abstractedly considered, the diastyle and eustyle intercolumniations are very convenient in use, and may be employed on most occasions, except, as just mentioned, in the Doric order.

2612. In setting out the intervals between columns especial care must be taken that the centres of modillions, dentils, and other ornaments in the entablature fall over the axes of the columns. It is on this account that Vignola gives about two diameters and a third to the intervals in all the orders except the Doric, instead of two diameters and a quarter, as required by Vitruvius; an alteration which removes the difficulty and greatly simplifies the rules.

2613. Cases from many circumstances often occur where greater intercolumniations than the eustyle and diastyle are too narrow for use, and the moderns, headed by Perrault, have adopted an interval which that master has called aræosystyle. This disposition is obtained without infringing on the law of weights and supports, to which we have already so often alluded. In it the columns are *coupled*, as shown in the preceding figures, the interval being formed by swo systyle intercolumniations, the column separating them being, as Chambers observes, "approached towards one of those at the extremities, sufficient room being only left between them for the projection of the capitals, so that the great space is 3½ diameters wide, and the small one only half a diameter." One of the finest examples of this practice is to be seen in the façade of the Louvre, (see *fig.* 176.) which in many respects must be considered as the finest of modern buildings. The objections of Blondel to the practice are not without some weight, but the principal one is the extra expense incurred by it; for certain it is that it requires nearly double the number of columns wanted in the diastyle, besides which it cannot be denied that it causes considerable irregularities in the entablatures of the Doric, Corinthian, and Composite orders, which, however, are not apparent in the other two. It is, nevertheless, so useful in cases of difficulty which constantly arise, that we should be sorry to exclude the practice altogether, though we cannot recommend it for unlimited adoption.

2614. A great many expedients have been employed to obviate the irregularity of the modillions in the Corinthian and Composite orders, arising from the grouping of columns. We, on this head, agree with Chambers, whose instructions we subjoin in his own words: "The simplest and best manner of proceeding is to observe a regular distribution in the entablature, without any alteration in its measures, beginning at the two extremities of the building, by which method the modillions will answer to the middle of every other column, and be so near the middle of the intermediate ones, that the difference will not easily be perceivable. The only inconvenience arising from this practice is, that the three central intercolumniations of the composition will be broader by one third of a module than is necessary for eleven modillions: but this is a very trifling difference, easily divided and rendered imperceptible if the extent be anything considerable." In the Doric order, the grouping of columns is not so easily managed, and therein our author recommends the expedient employed by Palladio, in the Palazzo Chiericato, and in the Basilica at Vicenza. In the last-named, the coupled columns are only 21 minutes apart, thus making the space between the axes 2 modules and 21 minutes, that is, 6 minutes beyond the breadth of a regular metope, and 2 half-triglyphs. To conceal the excess, the triglyphs are 31 minutes broad, and their centres are carried 1 minute within the axis of the column, and the metope is 3 minutes broader than the others. These small differences are not perceptible without a very critical and close examination of the distribution. In this arrangement the attic base of Palladio should be employed, because of its small projection, and the larger intercolumniation must be aræostyle.

2615. Intercolumniations should be preserved of equal width in all peristyles, galleries, porticoes, and the like; but in loggias or porches, the middle interval may be wider than the others by a triglyph, a modillion or two, and a few dentils, that is, if there be no coupled columns at the angles nor groupings with pilasters, in which cases all the other intervals should be of the same dimensions. It has been observed by Blondel, that on occasions where several rows of columns are used, as, for instance, in the curved colonnades of the piazza of St. Peter's, the columns ought as much as possible to be in straight lines, because otherwise the arrangement can only be understood by viewing it from the centre of the figure employed. The observation is well worth the student's consideration, for the resulting effect of a departure from this rule, as Chambers has properly observed, is "nothing but confusion to the spectator's eye from every point of view." The same author condemns, and with justice, though in a smaller degree, the use of "engaged pilasters or half columns placed behind the detached columns of single, circular, oval, or polygonal peristyles, as may be seen in those of Burlington House. Wherefore," he says, "in buildings of that kind, it will perhaps be best to decorate the back wall of the peristyle with windows or niches only." We can hardly suppose it here necessary to caution the student against the use of intercolumniations without reference to the absolute size of them: they must not be less than three feet even in small buildings, because, as Sir William Chambers seriously says, "there is not room for a *fat* person to pass between them."

2616. Before leaving the subject which has furnished the preceding remarks on intercolumniations, we most earnestly recommend to the student the re-perusal of Section II. of this Book. The intervals between the columns have, in this section, been considered more with regard to the laws resulting from the distribution of the subordinate parts, than with relation to the weights and supports, which seem to have regulated the ancient practice: but this distribution should not prevent the application generally of the principle, which may without difficulty, as we know from our own experience, be so brought to bear upon it as to produce the most satisfactory results. We may be perhaps accused of bringing a fine art under mechanical laws, and reducing refinement to rules. We regret that we cannot bind the professor by more stringent regulations. It is certain that, having in this respect carried the point to its utmost limit, there will still be ample opportunity left for him to snatch that grace, beyond the reach of art, with the neglect whereof the critics are wont so much to taunt the artist in every branch.

Sect. X.

ARCADES AND ARCHES.

2617. An arcade, or series of arches, is perhaps one of the most beautiful objects attached to the buildings of a city which architecture affords. The utility, moreover, of arcades in some climates, for shelter from rain and heat, is obvious; but in this dark climate, the inconveniences resulting from the obstruction to light which they offer, seems to preclude their use in the cities of England. About public buildings, however, where the want of light is of no importance to the lower story, as in theatres, courts of law, churches, and places of public amusement, and in large country seats, their introduction is often the source of great beauty, when fitly placed.

2618. In a previous section (2524.) we have spoken of Lebrun's theory of an equality between the weights and supports in decorative architecture: we shall here return to the subject, as applied to arcades, though the analogy is not, perhaps, strictly in point, because of the dissimilarity of an arch to a straight lintel. In *fig.* 898. the hatched part AEMFDCOB is the load, and ABGH, CDIK the supports. The line GK is divided into six parts, which serve as a scale to the diagram, the opening HI being four of them, the height BH six, NO two, and OM one. From the exact quadrature of the circle being unknown, it is impossible to measure with strict accuracy the surface BOC, which is necessary for finding by subtraction the surface AEMFDCOB; but using the common method, we have

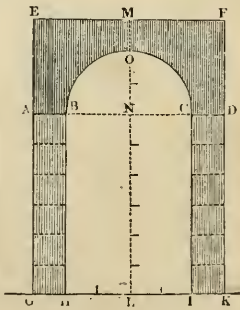

Fig. 898.

$$AD \times AE - \frac{BC^2 \times \cdot 7854}{2} = \text{to that surface; or, in figures,}$$

$$6 \times 3 - \frac{4 \times 4 \times \cdot 7854}{2} = 11 \cdot 72.$$

Now the suports will be $IK \times IC \times 2$ (the two piers) = the piers; or, in figures,
$1 \times 6 \times 2 \quad = 12 \cdot 00.$

That is, in the diagram the load is very nearly equal to the supports, and would have been found quite so, if we could have more accurately measured the circle, or had with greater nicety constructed it. But we have here, where strict mathematical precision is not our object, a sufficient ground for the observations which follow, and which, if not founded on something more than speculation, form a series of very singular accidents. We have chosen to illustrate the matter by an investigation of the examples of arcades by Vignola, because we have thought his orders and arcades of a higher finish than those of any other master; but testing the hypothesis, which we intend to carry out by examples from Palladio, Scamozzi, and the other great masters of our art, not contemplated by Lebrun, the small differences, instead of throwing a doubt upon, seem to confirm it.

2619. In *fig.* 898. we will now carry, therefore, the consideration of the weights and supports a step further than Lebrun, by comparing them with the void space they surround, that is, the opening HBOCI; and here we have the rectangle $HBCI = HB \times HI$, that is, $6 \times 4 = 24$, and the semicircle BOC equal, as above, to $\frac{4 \times 4 \times \cdot 7854}{2} = 6 \cdot 28$. Then $24 + 6 \cdot 28 = 30 \cdot 28$ is the area of the whole void, and the weight and support being $11 \cdot 72 +$

12 = 23·72, are a little more than two thirds the areas of the whole void; a proportion which, if we are to rely on the approval of ages in its application, will be found near the limits of what is beautiful.

2620. We shall now refer to the examples of Vignola alluded to; but to save the repetition of figures in their numbers, as referred to, each case is supposed in what immediately follows as unconnected with the entablatures which they exhibit, it being our intention to take those into separate consideration.

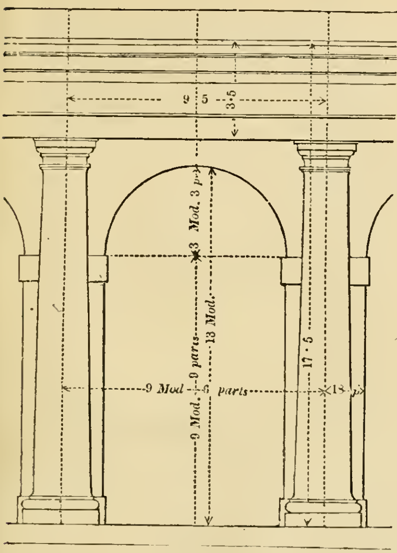

Fig. 899.

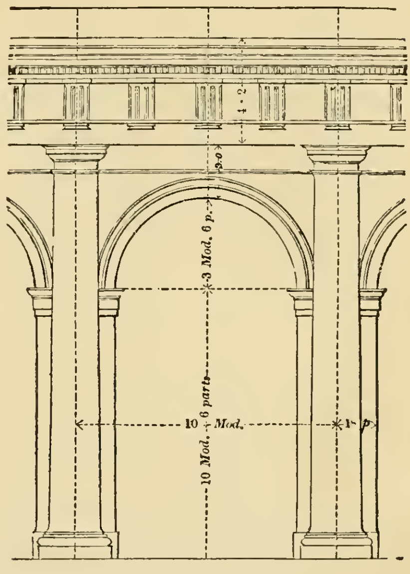

Fig. 900.

2621. Suppose the Tuscan example (*fig.* 899.) without an entablature, we have the

Supports, $9·75 \times 3 =$ 29·25

The whole of rectangle above them, $4·25 \times 9·5 = 40·375$

Less semi-arch, $\frac{6·5 \times 6·5 \times ·7854}{2} = 16·6$

23·775

53·025 solid parts.

The area of the void is $16·6 + \overline{9·75 \times 6·5} = 79·97$, whereof 53·025, the portion of solid parts, is not widely different from two thirds.

In Vignola's Doric example, (*fig.* 900.), again without the entablature, we have

Supports, $10·5 \times 3 =$ 31·50

The whole rectangle above them, $5·5 \times 10·0 = 55·00$

Less semi-arch, $\frac{7 \times 7 \times ·7854}{2} = 19·24$

35·76

67·26 solid parts.

The area of the void is $19·24 + \overline{10·5 \times 7} = 92·74$, whereof 67·26, the portion of solid parts, is not much different from two-thirds.

In the Ionic example (*fig.* 901.), still without considering the entablature, the following will result: —

Supports, $12·64 \times 2·66 =$ 33·61

The whole rectangle above them, $10·88 \times 5·2 = 56·57$

Less semi-arch, $\frac{6·4 \times 6·4 \times ·7854}{2} = 16·08$

40·49

74·10 solid parts.

The area of the void is $16·08 + \overline{12·64 \times 7·1} = 105·82$, whereof 74·10, the portion of solid parts, differs little in amount from two thirds of the void.

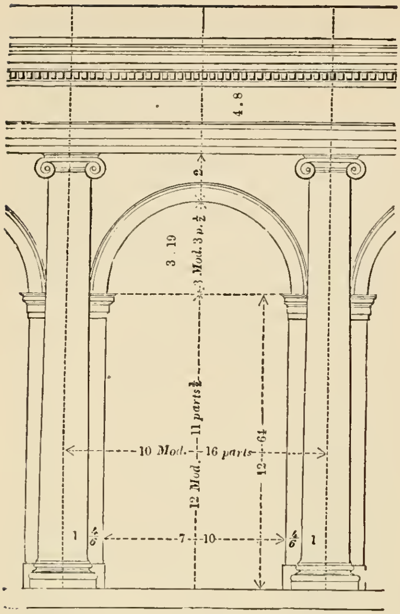

Fig. 901.

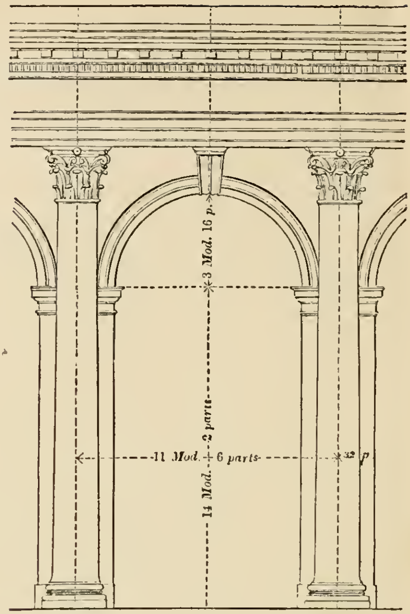

Fig. 902.

In the Corinthian example (*fig.* 902.), not taking into consideration the entablature, the following is the result: —

Supports, $14 \cdot 11 \times 3 \cdot 55 =$ 50 09

The whole rectangle above them, $11 \cdot 33 \times 5 \cdot 88 = 66 \cdot 62$

Less semi-arch, $\frac{7 \cdot 76 \times 7 \cdot 76 \times \cdot 7854}{2} = 23 \cdot 65$

$= 32 \cdot 97$

83·06 solid parts.

The area of the void is $23 \cdot 65 + \overline{14 \cdot 111 \times 7 \cdot 76} = 133 \cdot 15$, whereof 83·06, the portion of solid parts, is somewhat less than two thirds of the void.

2622. The result which flows from the above examination seems to be that, without respect to the entablature, the ratio of the solid part to that of the void is about ·666. Bearing this in mind, we shall next investigate the ratio of the supports and weights, considering the entablature above the arcade as a part of the composition; and still following Vignola, whose examples, as we have above stated, do not so much differ from those of other masters as to make it necessary to examine those of each, we will begin with that architect's Tuscan arcade, without pedestals, exhibited in *fig.* 899. on the preceding page. In this example, from centre to centre of pier,

The whole area, in round numbers, $17 \cdot 5 \times 9 \cdot 5$ - - - $= 166 \cdot 2$

Area of semi-arch, $\frac{6 \cdot 5 \times 6 \cdot 5 \times \cdot 7854}{2}$ - - $= 16 \cdot 6$

Rectangle under it, $9 \cdot 75 \times 6 \cdot 5$ - - $= 63 \cdot 3$

Total void, therefore, $= 79 \cdot 9$

86·3

Entablature, $9 \cdot 5 \times 3 \cdot 5$ - - - - - - $= 33 \cdot 2$

Leaves for the supporting parts - - - - - 53·1

In this example, therefore, the supporting parts are 53, those supported 33, and the voids 79. The ratio between the solid and void parts = ·9, and the ratio of the supports to the weights is $\frac{33}{53} = 62$.

The distance between the axes of the columns is 9 modules and 6 parts; the height of the semi-arch, 3 modules and 3 parts; and between the crown of it and the under side of the architrave is 1 module; the whole height, including entablature, being 17 modules and a half.

2623. Following the same general method, we submit the Doric arcade (*fig.* 900.) without pedestal. Measuring, as before, from centre to centre of piers,

The whole area, in round numbers, 20·2 × 10 - - -		= 202·0
Area of semi-arch $\frac{7 \times 7 \times \cdot 7854}{2}$ - -	= 19·2	
Rectangle under it, 10·5 × 7 - -	= 73·5	
	Total void, therefore, =	92·7
		109·3
Entablature, 10 × 4·2 - - - - - -		42·0
Leaves for the supporting parts - - - - -		67·3

In this example, therefore, the supporting parts are 67, those supported 42, and the voids 92. The ratio between the solid and void parts is ·85, and the ratio of the supports to the weights is $\frac{42}{67} = \cdot 63$.

The distance between the axes of the columns is 10 modules, the height of the semi-arch is 3 modules and 6 parts, and between the crown of it and the underside of the architrave is 2 modules; the whole height, including the entablature, being 20 modules $3\frac{1}{2}$ parts.

2624. The Ionic arcade, without pedestal, is shown in *fig.* 901. The measurements, as above, from centre to centre of pier,

The whole area, 22·64 × 10·88 in round numbers - - -		= 246·3
Area of semi-arch, $\frac{6\cdot 4 \times 6\cdot 4 \times \cdot 7854}{2}$ - -	= 16·1	
Rectangle under it, 12·64 × 7·1 - -	= 89·7	
	Total void, therefore, =	105·8
		140·5
Entablature, 10·88 × 4·8 - - - - - -		52·2
Leaves for the supporting parts - - - - -		88·3

Hence, in the example, the supporting parts are 88, those supported 52, and the voids 105; so that the ratio of the voids to the solids, in this order, is ·8, and the ratio of the supports to the weights does not materially differ from the other orders, being $\frac{52}{88} = \cdot 6$.

The distance between the axes of the columns is 10 modules 16 parts, the height of the semi-arch is $3\frac{1}{2}$ modules 3 parts, and between the crown of it and the under side of the architrave is 2 modules; the whole height, including the entablature, being 22 modules $13\frac{1}{2}$ parts.

2625. *Fig.* 902. represents the Corinthian arcade without pedestal. The measurement, as before, is from centre to centre of pier.

The whole area, 25·2 × 11·33, in round numbers - -		= 288·5
Area of semi-arch, $\frac{7\cdot 76 \times 7\cdot 76 \times \cdot 7854}{2}$ =	23·6	
Rectangle under it, 14·11 × 7·76 =	109·5	
	Total voids, therefore, =	133·1
		155·4
Entablature, 10·36 × 5·6 - - - - - -		58·0
Leaves for the supporting parts - - - -		97·4

In the Corinthian example, therefore, the supporting parts are 97, those supported 58, and the voids 133. The ratio between the solid and void parts = ·8, and the ratio of the supports to the weights $\frac{58}{97} = \cdot 59$. The distance between the axes of the columns is 11 modules and 6 parts, the height of the semi-arch is 3 modules 16 parts, and between the crown of it and the under side of the architrave is 2 modules $3\frac{1}{2}$ parts; the whole height, including the entablature, being 25 modules $3\frac{1}{2}$ parts.

2626. The laws laid down by Chambers for regulating arcades are as follow: — "The void or aperture of arches should never be much more in height nor much less than double their width; the breadth of the pier should seldom exceed two thirds, nor be less than one third of the width of the arch, according to the character of the composition, and the angular piers should be broader than the rest by one half, one third, or one fourth." . . . "The height of the impost should not be more than one seventh, nor need it ever be less than one ninth of the width of the aperture, and the archivolt must not be more than one eighth nor less than one tenth thereof. The breadth of the console or mask, which serves as a key to the arch, should at the bottom be equal to that of the archivolt, and its sides must be drawn from the centre of the arch. The length thereof ought not to be less than one and a half of its bottom breadth, nor more than double."

2627. The ratios that have been deduced by comparing the void and solid parts, if there be any reason in the considerations had, show that this law of making arches in arcades of the height of 2 diameters is not empirical, the following being the results of the use of the ratios in the arcade without, and that with pedestal, of which we shall presently treat. Thus in the

		Diameters.		Diameters
Tuscan arcade without pedestal,	$\frac{13\cdot5 \text{ height}}{6\cdot5 \text{ width}}$	$=2\cdot0$;	with pedestals,	$\frac{17\cdot5}{9\cdot5}=1\cdot84$
Doric arcade without pedestal,	$\frac{14\cdot0}{7}$	$=2\cdot0$	—	$\frac{20\cdot0}{10\cdot0}=2\cdot00$
Ionic arcade without pedestal,	$\frac{15\cdot83}{7\cdot10}$	$=2\cdot2$	—	$\frac{22\cdot0}{11\cdot0}=2\cdot00$
Corinthian arcade without pedestal,	$\frac{18\cdot00}{7\cdot76}$	$=2\cdot3$	—	$\frac{25\cdot0}{12\cdot0}=2\cdot08$

2628. In the examples of the arcades with pedestals, we shall again repeat the process by which the results are obtained, first merely stating them in round numbers. *Fig.* 903 is a

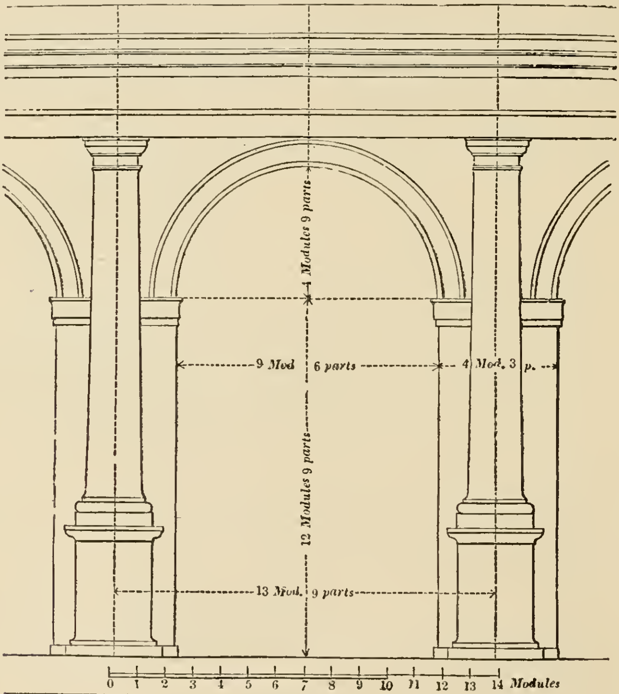

Fig. 903

Tuscan arcade from Vignola's example, as will be the following ones. In this the whole area is 306, omitting fractions, the area of the void is 156, that of the entablature 50, and the supports 100. The ratio of the supported part (the entablature), therefore, is $\frac{50}{100}=\cdot5$, and the supports and weights are very nearly equal to the void The height of the pedestal is almost 3 modules and 8 parts, the opening 9 modules 6 parts, and the width of the whole pier 4 modules and 3 parts.

The detail of the above result is as follows. —

The whole area, $22\cdot30 \times 13\cdot75$ - - - - -		$=306\cdot62$
Area of semi-arch, $\frac{9\cdot5\times9\cdot5\times\cdot7854}{2}$	$=35\cdot43$	
Below that, $12\cdot75 \times 9\cdot75$ -	$=121\cdot12$	
	Total voids, therefore,	$=156\cdot55$
		$150\cdot07$
Entablature, $13\cdot75 \times 3\cdot66$ - - - - -		$=50\cdot32$
Leaves for supporting parts - - - -		$99\cdot75$

It will be seen that we have taken the numbers in the preceding paragraph without supplying strictly the decimal parts that arise from the multiplication and subtraction of the several portions compared. The coincidence of the hypothesis with the apparent law is no less remarkable in this example than it will be found in those that follow; and, sceptical as we at first were on the appearances which pointed to it, we cannot, after the examination here and hereafter given, do otherwise than express our conviction that, in carrying out the principles, no unpleasant combination can result.

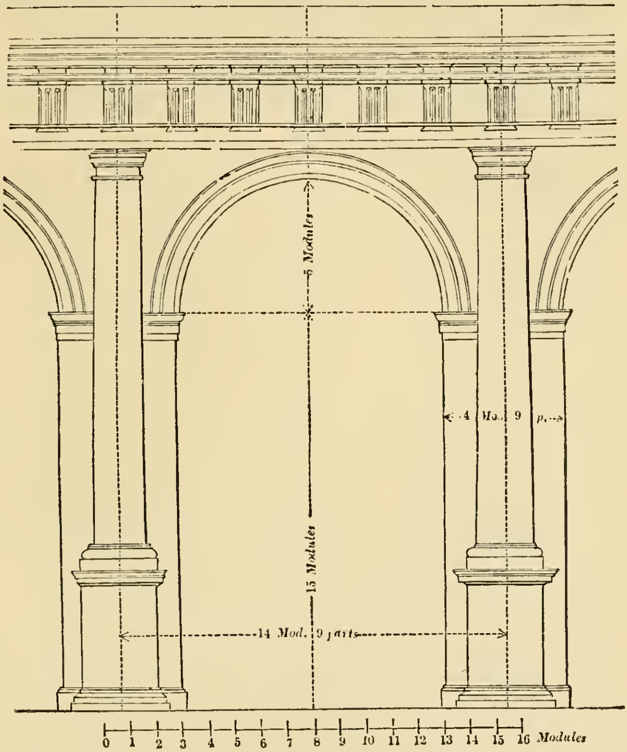

Fig. 904.

2629. *Fig.* 904. exhibits the Doric arcade, whose whole area from centre to centre of columns is 374. The area of the void is 189, that of the entablature 62, and of the supporting parts 112. The ratio of the entablature to the supports is therefore $\frac{62}{112} = \cdot 55$, and that of the supports and weights to the voids ·9. The height of the pedestal is almost 5 modules and 4 parts, the opening 10 modules, and the width of a pier 4 modules and 9 parts.

As in the preceding example, we think it will be useful to detail the process by which the general results stated have been arrived at. It is curious and interesting to observe the similarity between the cases. It is scarcely possible to believe that accident could have produced it. May not the freemasons of the middle ages have had some laws of this nature which guided their operations? But we will now proceed to the calculation.

The whole area, 25·4 × 14·75 - - - - -		= 374·65
Area of semi-arch, $\frac{10{\cdot}0 \times 10{\cdot}0 \times {\cdot}7854}{2}$ = 39·27		
Below that, 12·75 × 9·75 - = 150·00		
	Total voids, therefore, -	= 189·27
		185·38
Entablature, 14·75 × 4·25 - - - - - -		= 62·68
Leaves for supporting parts - - - - - -		122·70

Herein, as before, the general result in the preceding paragraph has been given in round numbers, that the mind of the reader may not be distracted from the general proportions. The detail again corroborates the hypothesis, as in the preceding subsection was predicated, and the further we proceed, as will be presently seen, its truth becomes more manifest.

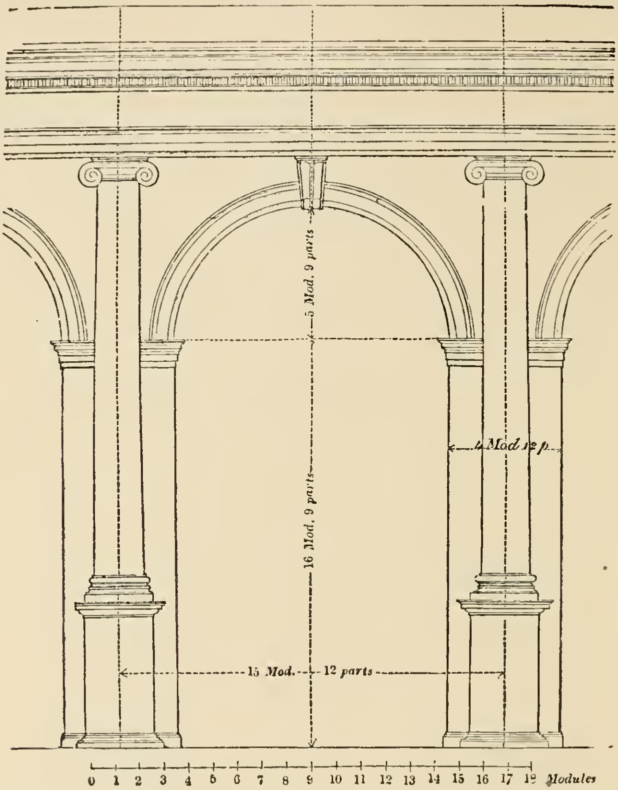

Fig. 905.

2630. The Ionic arcade with a pedestal is shown in *fig.* 905. The whole area is 448 between the axes of the columns; that of the void, 228. The entablature's area is 73, and the supporting parts 146. The ratio, therefore, of the load to the support is $\frac{73}{146} = \cdot 5$, and supports and weights are very nearly equal to the void. The height of the pedestal is 6 modules, the opening 11 modules, and the width of a pier 4 modules and 12 parts.

Once more returning to the detail on which the above proportions are based, and which in this as in the following example we think it better to supply, observing, as before, that the numbers above stated are given roundly, we shall have in the Ionic arcade,

Whole area, 28·66 × 15·66 - - - - - -		= 448·81
Area of semi-arch, $\frac{11 \times 11 \times \cdot 7854}{2}$	= 47·01	
Below it, 16·5 × 11 -	= 181·50	
Total area of voids, therefore,		= 228·51
		220·30
Entablature, 15·66 × 4·7 - - - - - -		= 73·50
Leaves for supporting parts - - - - - -		146·80

Whence it will be seen that the round numbers first given are shown to be sufficiently accurate for exemplification of the law, and that the further we examine the hypothesis the more closely we find it connected with the theory of weights and loads that has occupied a very considerable portion of this Book, and which we hope may not have had the effect of exhausting the reader's patience. We trust we shall have his pardon for pursuing the course we have taken.

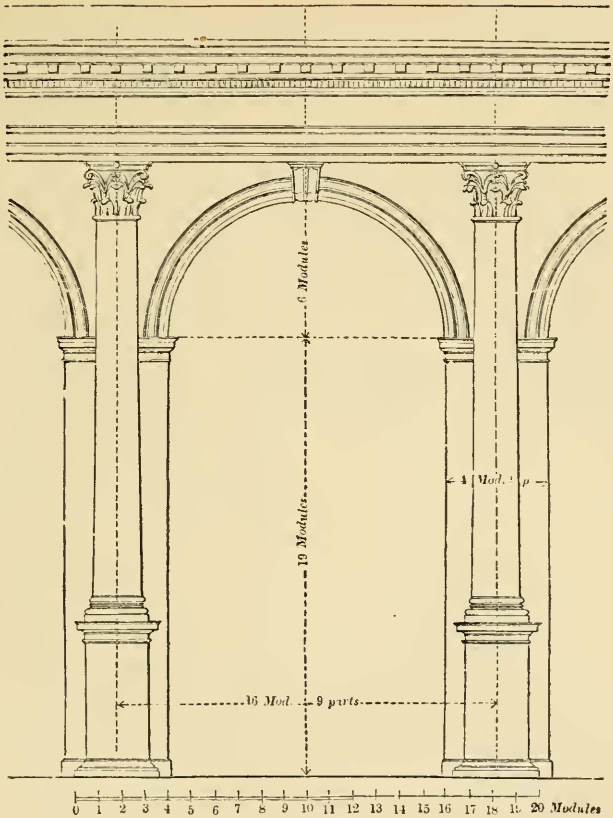

Fig. 906.

2631. *Fig.* 906. is an arcade with pedestals of the Corinthian order. Its total area is 528, that of the void 284, the area of the entablature 84, and that of the supporting parts 159. Hence, the ratio of the load to the support is $\frac{84}{159} = \cdot 52$, and the supports and weight are equal in area to the void within a very small fraction. The height of the pedestal is $6\frac{1}{2}$ modules, the opening is 12 modules wide, and the width of a pier is 4 modules and 9 parts.

We here close the curious proofs of a law whose existence, we believe, has never been suspected by modern architects. It was clearly unknown to Rondelet, and but for the work of Lebrun already quoted, we might never have been led to the investigation of it. That author himself, as we believe, did not entertain any notion of it.

In the Corinthian arcade with pedestal we have

Whole area, 32 × 16·5 - - - - - -		= 528·00
Area of semi-arch, $\frac{12 \times 12 \times \cdot 7854}{2}$	= 56·05	
Below it, 19 × 12 -	= 228·00	
Total area of voids, therefore,		= 284·05
		243·95
Entablature, 16·5 × 5·09 - - - - -		= 84·10
Leaves for supporting parts - - - - -		159·85

Thus, again, the law seems to be borne out, and to prove that the assumptions we have been making are not those of empiricism.

2632. In *fig.* 907. are collected the imposts and archivolts used in the arcades of the different orders.

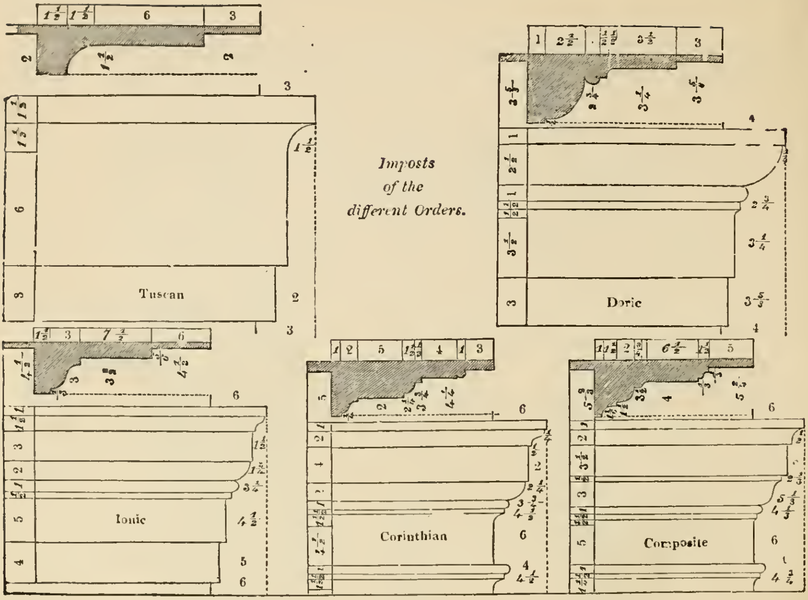

Fig. 907.

2633. We are not of the opinion of Sir William Chambers in respect of the arcades which Vignola has given; that author had not, we think, critically examined their composition, and we confess we do not think his own examples are improvements on those of the master in question; but we are willing to admit that in the examples of arcades with pedestals, they would have been much improved by assigning a greater height generally to the plinths of the pedestals, which are, doubtless, much too low, and might be well augmented by adding to them a portion of the dies of the pedestals.

2634. Great as is our admiration of Palladio, we do not think it necessary to say more relative to his arcades, than that he has given only designs of arches with pedestals, and that their height is from one and two thirds to two and a half of their width. His piers are generally $3\frac{3}{4}$ modules, except in the Composite order, wherein they are $4\frac{4}{5}$ modules.

2635. Scamozzi makes his Tuscan arch a little less than double its width, increasing the height gradually to the Corinthian arch with pedestals to nearly twice and a half the width. He diminishes his piers as the delicacy of the order increases, his Corinthian piers being only $3\frac{3}{4}$ modules in width. We do not, however, think it necessary to dwell longer on this part of the subject, and shall close it by observing that the impost of the arch should not much vary from half a module in height, and that the width of the archivolt, which should touch the shaft of the column or pilaster in the geometrical elevation, at its springing, is necessarily prescribed by the width of pier left after setting out the column upon it. Where columns are used on piers, their projection must be such that the most prominent member of the impost should be in a line with the axis of the column on the transverse section. In Ionic, Composite, and Corinthian arcades, however, it may project a little beyond the axis of the columns, to avoid the disagreeable mutilations which are otherwise rendered necessary in the capitals. Arcades should project not less than their width from the front of the wall which backs them." With regard to their interior decoration," says Chambers, " the portico may either have a flat ceiling or be arched in various manners. Where the ceiling is flat, there may be on the backs of the piers, pilasters of the same kind and dimensions with the columns on their fronts; facing which pilasters there must be others like them on the back wall of the portico. Their projection as well as that of those against the back of the piers may be from one sixth to one quarter of their diameter. These pilasters may support a continued entablature, or one interrupted and running across the portico over every two pilasters to form coffers; or the architrave and frieze only may be continued, while the cornice alone is carried across the portico over the pilasters as before, and serves to form compartments in the ceiling, as is done in the vestibule of the Massini palace at Rome, and in the great stable of the King's mews, near Charing Cross," — no longer in existence, having been destroyed to make way on its site for the execrable mass of absurdity to which the government who sanctioned it have facetiously given the name of National Gallery. Chambers thus continues: — "Where the portico is arched, either with a semi-circular or elliptical vault, the backs of the piers and the inner wall of the portico may be decorated with pilasters, as is above described, supporting a regular continued entablature, from a little above which the arch should take its spring, that no part of it may be hid by the projection of the cornice. The vault may be enriched with compartments of various regular figures, such as hexagons, octagons, squares, and the like, of which, and their decorations, several examples are given among the designs for ceilings." Of these we shall hereafter give figures in the proper place. "But when the vault is groined, or composed of flats, circular or domical coves, sustained on pendentives, the pilasters may be as broad as are the columns in front of the piers, but they must rise no higher than the top of the impost, the mouldings of which must finish and serve them instead of a capital, from whence the groins and pendentives are to spring, as also the bands or *arcs-doubleaux* which divide the vault."

2636. In the examples of arcades, we have followed those given by Chambers, as exhibiting a variety which may be instructive to the student, and at the same time afford hints for other combinations. *Fig.* 908. is one of the compositions of Serlio, and is an

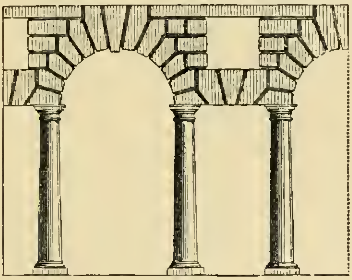

Fig. 908.

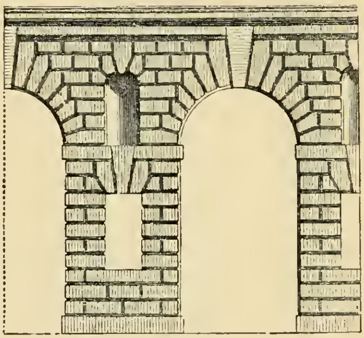

Fig. 909.

expedient for arching in cases where columns have been provided, as in places where the use of old ones may be imposed on the architect. The larger aperture may be from $4\frac{1}{2}$ to 5 diameters of the column in width, and in height double that dimension. The smaller opening is not to exceed two thirds of the larger one, its height being determined by that of the columns. Chambers thinks, and we agree with him, that this sort of disposition might be considerably improved by adding an architrave cornice or an entablature to the column, by omitting the rustics and by surrounding the arches with archivolts. It is not to be inferred, because this example is given, that it is inserted as one to be followed except under very peculiar circumstances. Where an arrangement of this kind is adopted, care must be used to secure the angles by artificial means.

2637. *Fig.* 909. is given from the cortile of the castle at Caprarola by Vignola, a structure which in the First Book of this work we have (346.) already mentioned. The height of the arches is somewhat more than twice their width. From the under side of the arch to the top of the cornice is one third of the height of the arch, the breadth of whose pier is equal to that of the arch, and the aperture in the pier about one third of its breadth.

2638. A composition of Bramante, executed in the garden of the Belvedere at Rome, is given at *fig.* 910. The arch in height is somewhat more than twice its width, and the

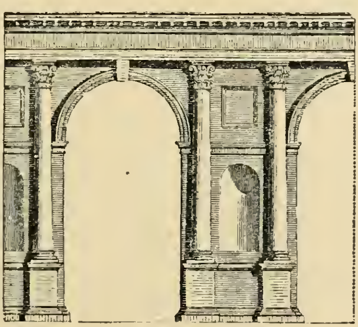

Fig. 910.

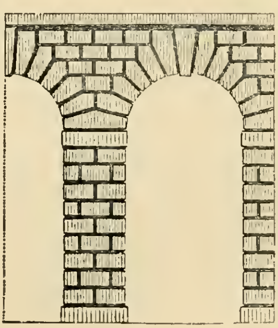

Fig. 911.

breadth of the pier equal to the opening. By dividing the latter into twelve parts we have a measure which seems to have prevailed in the mind of the architect, inasmuch as two of them will measure the parts of the pier supporting the archivolts, four the space for the two columns, two for the intervals between the niche and the columns, and four for the niche. Half the diameter of the arch measures the height of the pedestal; the columns are of the height of ten diameters, and their entablature one quarter of the height of the columns. The impost and archivolt are each equal to half a diameter of the column.

2639. *Fig.* 911. is an example whose employment is not uncommon in the designs of Palladio, and was considered by our great countryman Inigo Jones to be worthy of his imitation. The arch may be taken at about twice its width, and the pier not less than one nor more than two thirds of the width of the aperture.

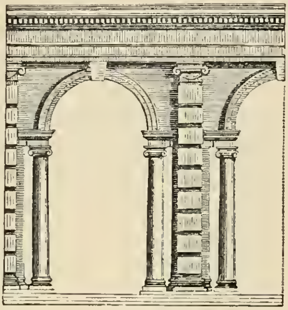

Fig. 912.

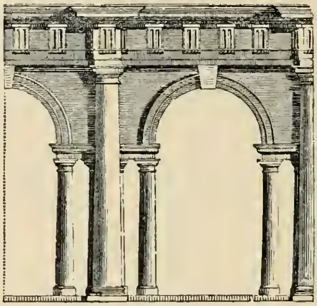

Fig. 913.

2640. The example in *fig.* 912. is from the hand of Vignola, and was executed for one of the Borghese family at Mondragone, near Frascati. In it the arch is a little more in height than twice its width, and the breadth of the pier columns supporting the arch includes a little less than the width of the arch itself. We are not quite satisfied in having here produced it as an example, though, compared with the following one, we scarcely know whether we should not on some accounts prefer it.

2641. The last example (*fig.* 913.) is one by that great master, Palladio, from the basilica at Vicenza. From the figure it is impossible to judge of its beauty in execution, neither can any imitation of it, unless under circumstances in every respect similar, produce the sensation with which the building itself acts on the spectator; yet in the figure it appears meagre and nothing worth. We can therefore easily account for the conduct of the critics, as they are called, who, never having seen this master's works, indulge in ignorant speculations of the pictorial effects which his compositions produce. Though not entirely agreeing with Chambers in his concluding observations on arcades and arches, we may safely transfer them to these pages. "The most beautiful proportion," he observes, "for compositions of this kind is, that the aperture of the arch be in height twice its width; that the breadth of the pier do not exceed that of the arch, nor be much less; that the small order be in height two thirds of the large columns, which height being divided into nine parts, eight of them must be for the height of the column, and the ninth for the height of the architrave cornice, two fifths of which should be for the architrave and three for the cornice. The breadth of the archivolt should be equal to the superior diameter of the small columns, and the keystone at its bottom must never exceed the same breadth."

Sect. XI.

ORDERS ABOVE ORDERS.

2642. Vitruvius, in the fifth chapter of his book "On the Forum and Basilica," in both which species of buildings it is well known that orders above orders were employed, thus instructs his readers: — "The upper columns are to be made one fourth less than those below" (*quarta parte minores quam inferiores sunt constituendæ*), "and that because the latter, being loaded with a weight, ought to be the stronger; because, also, we should follow the practice of nature, which in straight-growing trees, like the fir, cypress, and pine, makes the thickness at the root greater than it is at top, and preserves a gradual diminution throughout their height. Thus, following the example of nature, it is rightly ordered that bodies which are uppermost should be less than those below, both in respect of height and thickness." It is curious that the law thus given produces an exactly similar result to that laid down by Scamozzi, p. 2. lib. v. cap. ii., whereon we shall have more presently to speak. Galliani, Chambers, and others have considered the above-quoted passage of Vitruvius in connection with another in chap. vii. of the same book, which treats of the portico and other parts of the theatre, wherein the author states, after giving several to this question unimportant details, "The columns on this pedestal" (that of the upper order) "are one fourth less *in height*" (quartâ parte minores *altitudine* sint) "than the lower columns." The reader will here observe the word *altitudine* is introduced, which does not appear in the passage first quoted; and we beg him, moreover, to recollect that the last quotation relates entirely to the scene of the ancient theatre, in which liberties were then taken with strict architectural proportion as much as they are in these later days. Those who think that because Vitruvius interlarded his work with a few fables, he is therefore an author not worth consulting, as ephemeral critics have done in respect of that great master of the art, Palladio, may opine we have wasted time in this discussion; but, adopting the old maxim of Horace, "Non ego paucis offendar maculis," we shall leave them to the exposure which, with the instructed architect, their own ignorance will ultimately inflict on them, and to the enjoyment of the felicity attendant on a slight knowledge of the subject a person is in the habit of handling.

2643. We will now place before the student our own reading and explanation of the passage of Vitruvius relative to the use of orders above orders, and attempt to show what we conceive to be its real meaning. In *fig.* 914. the diagram exhibits an Ionic placed above a Doric column: the entablature (which however does not belong to the consideration) being in both cases one fourth of the height of the column. Inasmuch as in our previous rules (following Vignola) it will be recollected that the module of the Doric order is subdivided into twelve, whilst that of the Ionic is subdivided into eighteen parts, we must, for the purpose of obtaining an uniformity of measures in both orders, reduce those of either to the other to obtain similar dimensions. Instead, therefore, of measuring the upper order by itself, which would not afford the comparison sought, we shall have to reduce its established measures to those of the lower one, or Doric, and this, as well as the measurement of the lower order itself, is taken in modules and decimal parts of its semidiameter. Thus, the lower order being 2 modules at its bottom diameter and 1·666 modules at its upper diameter, the mean, without descending to extreme mathematical nicety, may be taken at 1·833, which multiplied by the height, 18 modules = 32·994, the area of a section through the centre of the column. Now if the upper columns are to be the same thickness at the bottom as the lower ones are at the top, that is, 1·666 module of the lower order, their upper diameters will be 1·387 (that is, five sixths of the lower diameter), and the mean will be 1·526, which, multiplied by 16, the height, = 24·416 the area of a section down the centre of the column, and just one fourth less than that of the lower column. The investigation tends to show us that we should not lightly treat the laws laid down by Vitruvius and his followers at the revival of the arts, for we may be assured that in most cases they are not empirical, but founded on proper principles. We cannot, however, leave this point without giving another reason, which is conclusive against Chambers's construction of the passage; it is, that supposing the upper column's lower diameter to be the same or nearly so as the lower column's upper diameter, if the *fourth* part had relation to the height instead of the bulk, we should have had the absurdity in the illustration above given, of an Ionic column in the second order only six and three quarters diameters high, whilst the lower or Doric is nine diameters in height.

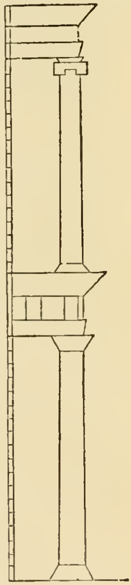

Fig. 914.

2644. Scamozzi, we doubt not, thought as we have expressed ourselves on this subject, and we here translate the words he uses in the eleventh chapter of his sixth book (second part). "Hence it is more satisfactory, and they succeed better and are more pleasing to the eye, when these columns (the upper ones) are made according to their proper diminution, so that the lower part of the upper column may be just the thickness of the upper part of the lower one, and so from one to the other, as may be seen in the Ionic order of the Theatre of Marcellus and other edifices; and this is the reason and natural cause that it is the same as though out of a long and single tree the shafts were cut out one after the other."

2645. The laws of solidity seem to require that where more than one order is used, the strongest is to occupy the lower situation; thus the Doric is placed on the Tuscan, the Ionic on the Doric, the Corinthian on the Ionic, and the Composite on the Corinthian; though, with respect to the last, we find examples of importance wherein the reverse has been the case. Two tiers of columns should not be of the same order, neither should an intermediate order be omitted; such, for instance, as placing the Ionic on the Tuscan column, or the Corinthian on the Doric; for by this practice many irregularities are introduced, especially in the details of the members.

2646. Frontwise the axes of the upper and lower columns must be in the same vertical plane, but viewed in flank this is not absolutely necessary; they should not, however, deviate too much from it. In the theatre of Marcellus the axes of the upper columns are nearly a foot within those of the Doric below them; but circumstances required this, and there is no great objection to the practice if the solidity of the structure be not lessened by it. Chambers observes that the retraction should never be greater than at the theatre of Marcellus, where the front of the plinth in the second order is in a line with the top of the shaft in the first. When the columns are detached, they should be placed centrally over each other, so that the axes of the upper and under ones may form one continued line, by which means solidity is gained as well as a satisfactory result to the eye. As to the false bearings of the bases of the upper order on the profile, this is a matter neither really affecting stability nor the appearance of the design.

2647. In England there are not many examples of orders above orders, while on the Continent the practice has not been uncommon; but it is always a matter of great difficulty so to arrange them as to avoid irregularities where triglyphs and modillions in the same design meet in the composition. We have used the figures of Chambers for our illustration here, because they are nearly coincident with the rules of Vitruvius and Scamozzi, and we shall now place them before the reader, observing that the irregularities alluded to are almost altogether avoided.

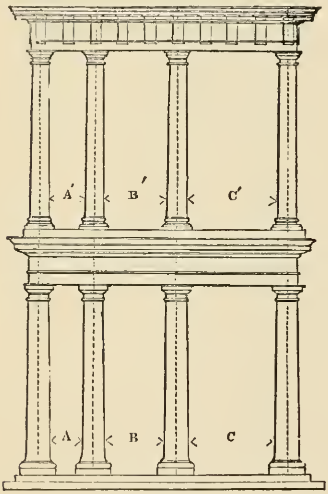

Fig. 915.

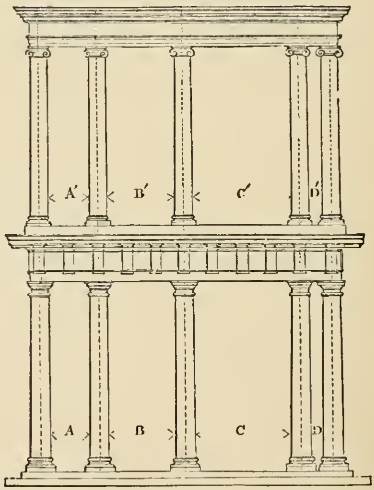

Fig. 916.

2648. *Fig.* 915. exhibits the Doric over the Tuscan order. The intervals A, B, and C are respectively $2\frac{1}{6}$, $4\frac{1}{4}$, and $6\frac{1}{3}$ modules; and A′, B′, and C′, 3, $5\frac{1}{2}$, and 8 modules of their order. The entablature of the lower order is $3\frac{1}{2}$ modules, the column, including base and capital, being 14 modules high; and the entablature of the upper order is 4 modules high, the column with its base and capital being 16 modules in height.

2649. The distribution of the Doric and Ionic orders is given in *fig.* 916., wherein the intervals A, B, and C are respectively 3, $5\frac{1}{2}$, and 8 modules; D, ·7 module; and A′, B′, C′, and D′ respectively 4, 7, 10, and $1\frac{1}{4}$ modules. The Doric order in this example is 20 modules high, whereof 4 are assigned to the entablature; the Ionic 22 modules high, whereof 4 belong to the entablature.

2650. In *fig.* 917. is represented the Corinthian above the Ionic order; the intervals A, B, C, D are respectively 5, 6, 7, and 1 modules, and those of A′, B′, C′ D′ respectively 6·4, 7·6, 8·8, 1·6 modules; the lower order is $22\frac{1}{2}$ modules high, 18 being given to the column with its base and capital; and the upper or Corinthian order is $24\frac{1}{2}$ modules high, whereof 20 belong to the height of the column, including its base and capital.

2651. The last (*fig.* 918.) is of the Corinthian order above and Composite below. In the lower order the intervals A, B, C, D are $4\frac{2}{3}$, 6, 7, and 1 modules respectively, and A′, B′, C′, and D′, in the upper order, 6, 7·6, 8·8, and 1·6 modules respectively. The whole height of the Corinthian order is 25 modules, whereof 5 are given to the entablature; the Composite order here is $24\frac{1}{2}$ modules, of which 20 belong to the column, including the base and capital.

2652. We insert the observations of Chambers relative to the above four figures, which

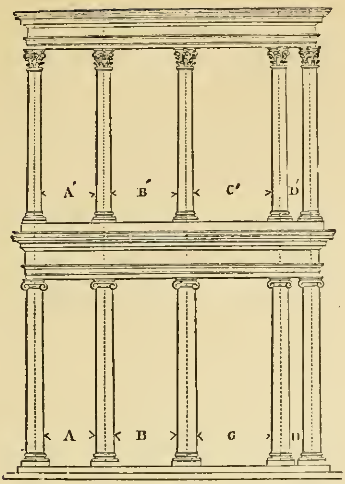

Fig. 917.

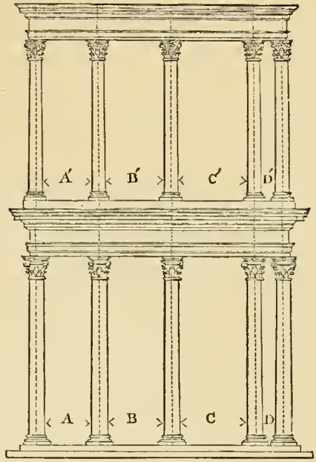

Fig. 918.

as we have adopted them, shall be in his own words. "Among the intercolumniations there are some in the second orders extremely wide, such as the Ionic interval over the Doric aræostyle; the Composite and Corinthian intervals over the Ionic and Composite aræostyle, which, having a weak meagre appearance, and not being sufficiently solid, excepting in small buildings, are seldom to be suffered, and should seldom be introduced. The most eligible are the eustyle and diastyle for the first order, which produce nearly the diastyle and aræostyle in the second." Speaking of the use of pedestals in orders above orders, the author thus proceeds: — "Many architects, among which number are Palladio and Scamozzi, place the second order of columns on a pedestal. In compositions consisting of two stories of arcades this cannot be avoided, but in colonnades it may and ought; for the addition of the pedestal renders the upper ordonnance too predominant, and the projection of the pedestal's base is both disagreeable to the eye and much too heavy a load on the inferior entablature. Palladio, in the Barbarano palace at Vicenza, has placed the columns of the second story on a plinth only, and this disposition is best; the height of the plinth being regulated by the point of view, and made sufficient to expose to sight the whole base of the column. In this case the balustrade must be without either pedestals or half balusters to support its extremities, because these would contract and alter the form of the column; its rail or cap must be fixed to the shafts of the columns, and its base made level with their bases; the upper torus and fillet of the columns being continued in the interval, and serving as mouldings to the base of the balustrade. The rail and balusters must not be clumsy; wherefore it is best to use double-bellied balusters, as Palladio has done in most of his buildings, and to give the rail a very little projection, that so it may not advance too far upon the surface of the column, and seem to cut into it. In large buildings the centre of the baluster may be in a line with the axis of the column; but in small ones it must be within it, for the reason just mentioned. The height of the balustrade is regulated in a great measure by its use, and cannot well be lower than three feet, nor should it be higher than three and a half or four feet. Nevertheless, it must necessarily bear some proportion to the rest of the architecture, and have nearly the same relation to the lower order, or whatever it immediately stands upon, as when a balustrade is placed thereon chiefly for ornament. Wherefore, if the parts are large, the height of the balustrade must be augmented, and if they are small it must be diminished; as is done in the Casino at Wilton, where it is only two feet four inches high, which was the largest dimension that could be given to it in so small a building. But that it might, notwithstanding its lowness, answer the intended purpose, the pavement of the portico is six inches lower than the bases of the columns, and on a level with the bottom of the plat-band that finishes the basement."

We must here leave this subject, recommending the student to an intimate acquaintance with the various examples that have been executed, and further advising him to test each of the examples that may fall under his notice by the principles first adverted to in this section, as the only true means of arriving at a satisfactory result.

Sect. XII.

ARCADES ABOVE ARCADES.

2653. As the disposition of one arcade upon another is, under certain regulations, subject to the same laws of voids and solids as the simple arcade of one story, which has formed the subject of a previous section, we shall no further enter into the rules of its combination than to offer a few general observations on the matter in question; and herein, even with the reproach of a want of originality, we shall draw largely on our much-quoted author, Chambers, whose language and figures we are about to use. So sound, indeed, is the doctrine of Chambers in this respect, and so well founded on what has been done by those whom we consider the greatest masters, that we should not be satisfied without transferring his dicta to these pages, and that without any alteration.

2654. "The best," says Chambers, "and, indeed, the only good disposition for two stories of arcades, is to raise the inferior order on a plinth, and the superior one on a pedestal, as Sangallo has done at the Palazzo Farnese; making both the ordonnances of an equal height, as Palladio has done at the Basilica of Vicenza."

2655. "Scamozzi, in the thirteenth chapter of his sixth book, says that the arches in the second story should not only be lower, but should also be narrower, than those in the first; supporting his doctrine by several specious arguments, and by the practice, as he says, of the ancient architects in various buildings mentioned by him. In most of these, however, the superior arches are so far from being narrower, that they are either equal to or wider than the inferior ones. In fact, his doctrine in this particular is very erroneous, entirely contrary to reason, and productive of several bad consequences; for if the upper arches be narrower than the lower ones, the piers must of course be broader, which is opposite to all rules of solidity whatever, and exceedingly unsightly. The extraordinary breadth of the pier on each side of the columns in the superior order is likewise a great deformity; even when the arches are of equal widths it is much too considerable. Palladio has, in the *Carità* at Venice, and at the Palazzo Thiene in Vicenza, made his upper arches wider than the lower ones, and I have not hesitated to follow his example; as by that means the weight of the solid in the superior order is somewhat diminished, the fronts of the upper piers bear a good proportion to their respective columns, and likewise to the rest of the composition."

2656. "In a second story of arcades there is no avoiding pedestals. Palladio has, indeed, omitted them at the Carità, but his arches there are very ill proportioned. The extraordinary bulk and projection of these pedestals are, as before observed, a considerable defect; to remedy which in some measure they have been frequently employed without bases, as in the theatre of Marcellus, on the outside of the Palazzo Thiene, and that of the Chiericato in Vicenza. This, however, helps the matter but little; and it will be best to make them always with bases of a moderate projection, observing at the same time to reduce the projection of the bases of the columns to ten minutes only, that the die may be no larger than is absolutely necessary; and in this case particular care must be taken not to break the entablature over each column of the inferior order, because the false bearing of the pedestal in the second order will by so doing be rendered far more striking, and in reality more defective, having then no other support than the projecting mouldings of the inferior cornice. There is no occasion to raise the pedestals of the second order on a plinth, for as they come very forward on the cornice of the first order, and as the point of view must necessarily be distant, a very small part only of their bases will be hid from the eye."

2657. "The balustrade must be level with the pedestals supporting the columns; its rail or cornice and base must be of equal dimensions, and of the same profile with theirs. It should be contained in the arch and set as far back as possible, that the form of the arch may appear distinct and uninterrupted from top to bottom; for which reason, likewise, the cornice of the pedestals must not return nor profile round the piers, which are to be contained in straight perpendicular lines from the imposts to the bases of the pedestals. The back of the rail may either be made plain or sunk into a panel in form of an open surbase, for so it will be most convenient to lean upon, and it should be in a line with or somewhat recessed within the backs of the piers. The back part of the balustrade may be adorned with the same mouldings as the bases of the piers, provided they have not much projection; but if that should be considerable, it will be best to use only a plinth crowned with the two upper mouldings, that so the approach may remain the more free."

2658. In *fig.* 919. is a Doric above a Tuscan arcade, from the example given by Chambers, whereon, before giving the dimensions of the different parts, we shall merely observe of it that the voids or arcades themselves are in round numbers to the solids as 295 to 205, being vastly greater. We are inclined to think that the voids in this case are rather too great in volume, and that, had they been reduced to one half their height exactly, the proportions would have been somewhat more pleasing. It is true that a trifling irregularity would have been introduced into the triglyphs of the upper order, or rather the metopæ between them; but that might have been easily provided against by a very trifling alteration in the height of the frieze itself. This fault of making the voids too large pervades Chambers's examples, and but that we might have been thought too presuming we should have slightly altered the proportions, little being requisite to bring them under the laws which we have thought to be founded on reason and analogy. We have indeed throughout this work refrained from giving other than approved examples, preferring to confine ourselves to observations on them when we have not considered them faultless.

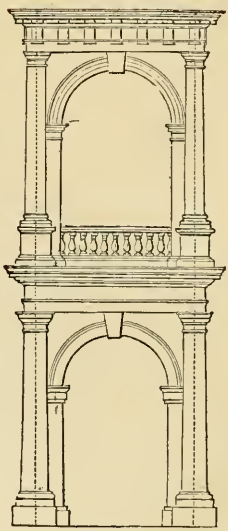

Fig. 919.

2659. In the figure the clear width of the lower arcade is $7\frac{2}{3}$, and its height $14\frac{1}{2}$ modules. The width of each pier is 1 module. Of the upper arcade the width is $9\frac{1}{2}$, and the height 18·233 modules. The width of the piers is $1\frac{1}{4}$ module each. The height of the plinth of the lower order is $1\frac{1}{2}$ module, that of the column, including base and capital, $14\frac{1}{2}$ modules, the entablature $3\frac{1}{3}$. The height of the pedestal of the upper order is 3·733 modules, of the column with its base and capital 16, and of the entablature 3·733 modules. In the proportions between the voids and solids above taken the balustrade is not considered as a solid, because, in fact, it is nothing more than a railing for the protection of those using the upper story. As we have expressed our desire to give the examples of others rather than our own, we feel bound to recommend the student to set up the diagram in question, with the simple alteration of reducing the solids nearly to an equality with the voids, which may be done with sufficient accuracy by assigning to the lower arcade a module less in width than Chambers has done; and we venture to say that he will be surprised at the difference, as regards grace and elegance, which will result from the experiment. It is to be understood that no change is proposed in the other dimensions of the ordonnance, the width of piers, orders, entablatures, all remaining untouched.

2660. In *fig.* 920. we give another example from Chambers, which, in our opinion, requires a rectification to bring it into proper form. Herein the Ionic is used above the Doric arcade, and the voids to the solids are as 3·33 to 2·98, being much more than equal to them. In this, as in the former example, we should have preferred a greater equality between the solids and voids, though in that under consideration there is a nearer approximation to it.

2661. In the figure the clear width of the lower arch is $8\frac{1}{3}$, and its height $16\frac{1}{6}$ modules; the width of each pier is 1 module. Of the upper arcade the width is $10\frac{1}{2}$, and the height $20\frac{1}{2}$ modules. The width of the piers is $1\frac{1}{4}$ module each. The height of the plinth of the lower order is $1\frac{1}{2}$ module that of the column, including the base and capital, $16\frac{1}{6}$ modules, and of the entablature 4 modules. The height of the pedestal of the upper order 4 modules, of the column, including base and capital, 18 modules, and of the entablature 4, and of the balustrade above it $3\frac{1}{3}$.

2662. The dimensions of the Ionic and Corinthian arcades in *fig.* 921. are as follow : — Clear width of lower arch 9 modules, its height $18\frac{1}{6}$ modules. The width of each pier is 1 module. Of the upper arcade the width of an arch $15\frac{3}{5}$ modules, and its height 23 modules. The width of

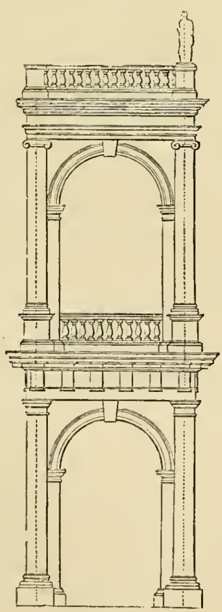

Fig. 920.

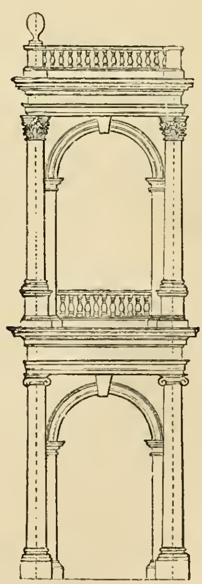

Fig. 921.

the piers is $1\frac{1}{4}$ module each. The height of the plinth to the lower order is $1\frac{2}{3}$ module; of the column, including base and capital, 18 modules; the entablature $4\frac{1}{2}$ modules. The pedestal of the upper order is $4\frac{1}{2}$ modules high; column, including base and capital, 20 modules; entablature $4\frac{1}{2}$ modules; and, lastly, the balustrade is $3\frac{3}{5}$ modules in height.

2663. *Fig.* 922. is an arrangement adopted by Palladio in his basilica at Vicenza, being the dimensions, or nearly, of the arcades on the flanks. The intermediate ones are much wider. In the basilica, however, the entablature breaks round the columns of the orders. The width between the axes of the columns of the lower order is 15 of their modules. The arch is 15 modules high and $7\frac{5}{6}$ wide. The order wherefrom the arch springs is $10\frac{5}{6}$ modules high; from axis to axis of the small columns in the lower arcade is 9 modules. The height of the plinth is $1\frac{1}{2}$ module, of the principal columns, including bases and plinths, $16\frac{1}{4}$ modules, and of their entablature 4 modules. In the upper arcade the distance between the axes of the principal columns is 18 of their modules. Their pedestals are 4 modules high, the columns, including bases and capitals, 18 modules, and entablature 4 modules high. The width of the arch is $9\frac{2}{3}$ modules, and its height $20\frac{5}{6}$ modules. The height of the small columns is 11·733 modules high, including their entablature.

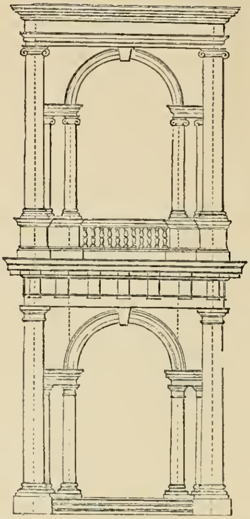

Fig. 922.

2664. The use of arcades above arcades seems from its nature almost confined to public buildings, as among the ancients to their theatres and amphitheatres. In the interior quadrangles or courts of palaces they have been much employed on the Continent, and in the magnificent design made by Inigo Jones for the palace at Whitehall are to be found some very fine examples.

Sect. XIII.

BASEMENTS AND ATTICS.

2665. When the order used for decorating the façade of a building is placed in the middle or second story, it is seated on a story called the *basement.* The proportion of its height to the rest must in a great measure depend on the use to which its apartments are to be appropriated. "In Italy," observes Chambers, "where their summer habitations are very frequently on that floor, the basements are sometimes very high. At the palace of Porti, in Vicenza, the height is equal to that of the order placed thereupon; and at the Thiene, in the same city, its height exceeds two thirds of that of the order, although it be almost of a sufficient elevation to contain two stories; but at the Villa Capra, and at the Loco Arsieri, both near Vicenza, the basement is only half the height of the order; because in both these the ground floor consists of nothing but offices." It may hence be gathered that no absolute law can be laid down in reference to the height of a basement story. Yet we may state, generally, that a basement should not be higher than the order it is to support, for it would in that case detract from the principal part of the composition, and, in fact, would be likely to interfere with it. Besides which, the principal staircase then requires so many steps that space is wasted for their reception. "Neither," says Chambers, "should a basement be lower than half the height of the order, if it is to contain apartments, and consequently have windows and entrances into it; for whenever that is the case the rooms will be low, the windows and doors very ill formed, or not proportional to the rest of the composition, as is observable at Holkham: but if the only use of the basement be to raise the ground floor, it need not exceed three, four, or at the most five or six feet in height, and be in the form of a continued pedestal."

2666. Basement stories are decorated generally with rustic work of such various kinds, that we fear it would be here impossible to describe or represent their varieties. Many are capriciously rock-worked on their surface, others are plain, that is, with a smooth surface. The height of each course, including the joints, should on no account be less than one module of the order which the basement supports; their length may be from once and a half to thrice their height. As respects the joints, these may be square or chamfered off. When square joints are used, they should not be wider than one eighth part of the height of the rustic itself, nor narrower than one-tenth, their depth not exceeding their width. When the joints are chamfered, the chamfer should be at an angle of forty-five degrees, and the whole width of the joint from one third to one fourth of the height of the rustic.

2667. The courses are sometimes (often on the Continent) laid without showing vertical joints; but, as Chambers says, this "has in general a bad appearance, and strikes as if the building were composed of boards rather than of stone. Palladio's method seems far preferable, who, in imitation of the ancients, always marked both the vertical and the horizontal joints; and whenever the former of these are regularly and artfully disposed, the rustic work has a very beautiful appearance." We shall presently make a few remarks on the subject of rustics; but here, to continue and finish that more immediately under consideration, have to add, that when a high basement is used, it is not uncommon to crown it with a cornice, as may be seen in *fig.* 909.; but the more common practice is to use a platband only (as in *fig.* 911.), whose height should not be greater than that of a rustic exclusive of the joint. Of a similar height should be made the zoccolo or plinth; but this may, and ought, perhaps, to be somewhat higher. When arches occur in basements, the platband, which serves for the impost, should be as high as a course of rustics, exclusive of the joint; and if the basement be finished with a cornice, such basement should have a regularly moulded base at its foot; the former to be about one thirteenth of the whole height of the basement, and the base about one eighteenth, without the plinth.

2668. The Attic — which is used instead of a second order where limits are prescribed to the height of a building, examples whereof may be seen at Greenwich Hospital, and in the Valmarano palace, by the great Palladio, at Vicenza — should not exceed in height one-third of the order whereon they are placed, neither ought they to be less than one quarter. Bearing some resemblance to a pedestal, the base, die, and cornice whereof they are composed may be proportioned much in the same way as the respective divisions of their prototypes. They are sometimes continued without, and sometimes with, breaks over the column or pilaster of the order which they crown. If they are formed with pilasters, such ought to be of the same width as the upper diameter of the order under them, never more. In projection they should be one quarter of their width at most. They may be decorated with sunk moulded panels if necessary; but this is a practice rather to be avoided, as is most especially that of using capitals to them — a practice much in vogue in France under Louis XV.

2669. We now return to the subject of the rock-worked rustic, whereof, above, some notice was promised. The practice, though occasionally used by the Romans, seems to have had its chief origin in Florence, where, as we have in a former Book (329.) observed, each palace resembled rather a fortification than a private dwelling. Here it was used to excess; and if variety in the practice is the desire of the student, the buildings of that city will furnish him with an almost infinite number of examples. The introduction of it gives a boldness and an expression of solidity to the rustics of a basement which no other means afford. In the other parts of Italy it was sparingly applied, but with more taste. Vignola and Palladio seem to have treated it as an accident productive of great variety rather than as a means of decoration. The last-named architect has in the Palazzo Thiene carried it to the utmost extent whereof it is susceptible. Yet, with this extreme extent of application, the design falls from his hands full of grace and feeling. To imitate it would be a dangerous experiment. De Brosse failed at the Luxembourg, and produced an example of clumsiness which in the Palazzo Pitti does not strike the spectator.

2670. Rustics and rockwork on columns are rarely justifiable except for the purpose of some particular picturesque effect which demands their prominence in the scene, or street view, as in the gateway at Burlington House in Piccadilly,—of which a good view, with the house itself, is to be seen in the "Builder" for 1854, p. 559. It was pulled down about 1867.

SECT. XIV.

PILASTERS.

2671. Pilasters, or square columns, were by the Romans termed *antæ*, by the Greeks *parastatæ*. This last word implies the placing one object standing against another, a sufficiently good definition of the word, inasmuch as in ninety-nine cases out of a hundred they are engaged in or backed against a wall, or, in other words, are portions of square columns projecting from a wall.

2672. It is usual to call a square column, when altogether disengaged from the wall, a *pillar* or *pier*; and we are inclined to think, notwithstanding the alleged type of trees, that the primitive supports of stone buildings were quite as likely to have been square as round, and that the inconvenience attendant upon square angles may have led the earliest builders to round off the corners, and gradually to bring them to a circular plan. Isolated pillars are rarely found among the examples left us by the ancients; the little temple at Trevi furnishes, indeed, an example, but not of the best period of the art. The principal points to be attended to in their use are their projection, diminution, the mode of uniting the entablature over them with that of their columns, and their flutings and capitals.

2673. In respect of the projection of pilasters, Perrault says they should project one half, and not exceed that by more than a sixth, as in the frontispiece of Nero, unless circumstances require a different projection. The pilasters of the Pantheon project only a tenth part of their width; and sometimes, as in the forum of Nerva, they are only a fourteenth part. But when pilasters are to receive the imposts of arches against their sides, they are made to project a fourth part of their diameter; and this is a convenient proportion, because in the Corinthian order the capital is not so much disfigured. Hence, when pilasters are made to form re-entering angles, they should project more than half their diameter. Many and various opinions have been formed on the propriety of diminishing pilasters. Perrault, with whom we incline to agree, thinks that when one face only projects, pilasters should not be diminished. Those at the flanks of the portico of the Pantheon are without diminution. But when pilasters are on the same line as columns, we want to lay the entablature from one to the other without any projection, in which case the pilaster must be diminished in the same degree as the column itself, speaking of the front face, leaving the sides undiminished, as in the temple of Antoninus and Faustina. When the pilaster has two of its faces projecting from the wall, being on the angle, and one of those faces answers to a column, such face is diminished similarly to the column, as in the portico of Septimius, where the face not corresponding to the column receives no diminution. There are, however, ancient examples where no diminution is practised, as in the interior of the Pantheon, where it is so small as not to be very apparent, being much less than that of the column, as is also the case in the temple of Mars Ultor, and in the arch of Constantine. In these cases, the custom of the ancients is sometimes to place the architrave plumb over the column, which brings it within the line of the pilaster. This may be seen in the temple of Mars Ultor, in the interior of the Pantheon, and in the portico of Septimius. Sometimes this excess is divided into two parts, one whereof goes to the excess of projection of the architrave above the column, and the other half to the deficiency of extent above the pilaster, as in the forum of Nerva. The whole matter is a problem of difficult solution, which Chambers has avoided, but which, with reference to the examples we have cited, will not be attended with difficulty to the student in his practice.

2674. We have above seen that pilasters, when used with columns, are subject to the form and conditions of the latter. As to their flutings we are left more at liberty. In the portico of the Pantheon we find the pilasters fluted and the columns plain. This, however, may have been caused by the difficulty of fluting the latter, which are of granite, whilst the pilasters are of marble. On the other hand, we sometimes find the columns fluted and the pilasters plain, as in the temple of Mars Ultor, and the portico of Septimius Severus. Generally, too, it may be observed that when pilasters project less than half their diameter, their return faces are not fluted. In respect of the number of the flutes, if the examples of the ancients were any guide, there could have been no fixed rule; for in the portico of the Pantheon, the arch of Septimius Severus, and that of Constantine, seven flutes only are cut on the pilasters, whilst the flutes of the pilasters in the interior of the Pantheon are nine in number. This, however, is to be observed, that the flutes must always be of an odd number, except in re-entering pilasters, wherein four are placed instead of three and a half, and five instead of four and a half, when the whole pilaster would have nine. This is done to prevent the ill effect which would be produced in the capital by the bad falling of the leaves over the flutes.

2675. We shall hereafter give from Chambers some representations of pilaster capitals, which, except as regards their width, resemble those of the order they accompany. The practice of the ancients in this respect was very varied. Among the Greeks the form of the pilaster capital was altogether different from that of the column, seeming to have no relationship to it whatever; but on this point the student must consult the works on Grecian antiquities, an example whereof will be found in *fig.* 883.

2676. A pilaster may be supposed to represent a column and to take its place under many circumstances; and, notwithstanding all that was said on the subject by the Abbé Laugier, many years ago, against the employment of pilasters altogether, we are decidedly of opinion that they are often useful and important accessories in a building. It would be difficult to enumerate every situation wherein it is expedient to use pilasters rather than insulated or engaged columns. In internal apartments, where the space is restricted, a column appears heavy and occupies too much room. The materials, morever, which can be obtained, often restrict the architect to the use of pilasters, over which the projections of the entablature are not so great; indeed, as the author in the *Encyclopedie Methodique* observes, a pilaster may be considered as a column in bas-relief, and is thus, from the diminished quantity of labour and material in it, simpler and more economical in application. That in houses and palaces of the second class the decoration by pilasters is of great service may be amply shown by reference to the works of Bramante, San Gallo, Palladio, and the other great masters of Italy, no less than in this country to those of Jones, Wren, and Vanbrugh.

2677. In profiling the capitals of Tuscan and Doric pilasters there can of course arise no difficulty; they follow the profiles of those over the columns themselves. In the capitals, however, of the other orders, some difficulties occur: these are thus noticed by Chambers. "In the antique Ionic capital, the extraordinary projection of the ovolo makes it necessary either to bend it inwards considerably towards the extremities, that it may pass behind the volutes, or, instead of keeping the volutes flat in front, as they commonly are in the antique, to twist them outwards till they give room for the passage of the ovolo. Le Clere" (*Traité d'Architecture*) "thinks the latter of these expedients the best, and that the artifice may not be too striking, the projection of the ovolo may be considerably diminished, as in the annexed design" (*fig.* 923.), "which, as the moulding can be seen in front only, will occasion no disagreeable effect."

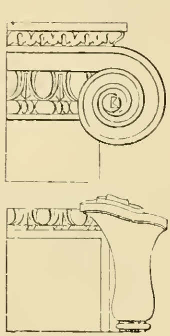

Fig. 923.

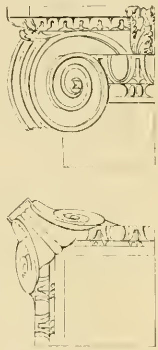

Fig. 924.

2678. "The same difficulty subsists with regard to the passage of the ovolo behind the angular Ionic volutes. Le Clere therefore advises to open or spread the volutes sufficiently to leave room for the ovolo to pass behind them, as in the design" (*fig.* 924.) "annexed; which may be easily done, if the projection of the ovolo is diminished. Inigo Jones has in the Banqueting House made the two sides of the volutes parallel to each other, according to Scamozzi's manner, and at the same time has continued the ovolo in a straight line under them, so that the volutes have an enormous projection; which, added to the other faults of these capitals, renders the whole composition unusually defective and exceedingly ugly."

2679. "What has been said with regard to the passage of the ovolo behind the volutes in the Ionic order is likewise to be remembered in the Composite; and in the Corinthian the lip or edge of the vase or basket may be bent a little inwards towards its extremities, by which means it will easily pass behind the volutes. The leaves in the Corinthian and Composite capitals must not project beyond the top of the shaft, as they do at San Carlo in the Corso at Rome, and at the Banqueting House, Whitehall; but the diameter of the capital must be exactly the same as that of the top of the shaft. And to make out the thickness of the small bottom leaves, their edges may be bent a trifle outwards, and the large angular leaves may be directed inwards in their approach towards them, as in the annexed design" (*fig.* 925.), "and as they are executed in the church of the Roman college at Rome. When the small leaves have a considerable thickness, though the diameter of the capital is exactly the same as that of the shaft, in each front of the Composite or Corinthian pilaster capital, there must be two small leaves with one entire and two half large ones. They must be either of olive, acanthus, parsley, or laurel, massed, divided, and wrought, in the same manner as those of the columns are, the only difference being that they will be somewhat broader."

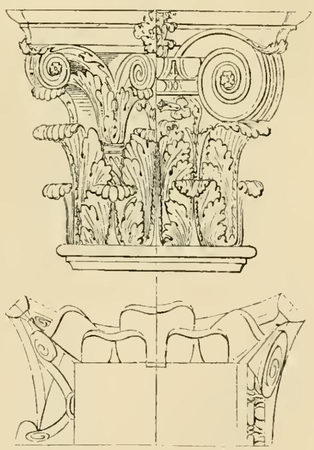

Fig. 925.

2680. It is desirable to avoid the use of pilasters at inward angles penetrating each other, because of the irregularity such practice produces in the entablatures and capitals. One break is quite as much as should be ever tolerated, though in many of the churches in Rome they are multiplied with great profusion of mutilated capitals and entablatures; "than which," observes Chambers, "nothing can be more confused or disagreeable."

2681. Neither should columns be allowed to penetrate each other, as they do in the court of the Louvre, inasmuch as the same irregularity is induced by it as we have above noticed in the case of pilasters.

Sect. XV.

CARYATIDES AND PERSIANS.

2682. The origin of caryatides we have in the First Book (165, *et seq.*) so far as regards our own opinions, explained, and in that respect we shall not trouble the reader. Our object in this section is merely to offer some observations on the use of them in modern practice. The figures denominated Persians, Atlantes, and the like, are in the same category, and we shall not therefore stop to inquire into their respective merits; indeed, that has already been sufficiently done in the book above alluded to. The writer of the article in the *Encyclopedie Methodique* has, we think, thrown away a vast deal of elegant writing on the subject of caryatides; and using, as we have done, to some extent, that extraordinary work, we think it necessary to say that we cannot recommend anything belonging to that article to the notice of the reader, except what is contained in the latter part of it, and with that we do not altogether agree.

2683. The object, or apparent object, in the use of caryatides is for the purpose of support. There is no case in which this cannot be better accomplished by a solid support, such as a column, the use of the attic order, or some other equivalent means. But the variety in quest of which the eye is always in search, and the picturesque effect which may be induced by the employment of caryatides, leads often to their necessary employment. The plain truth is, that they are admissible only as objects necessary for an extreme degree of decoration, and otherwise employed are not to be tolerated. There can, as we imagine, be no doubt that the most successful application of these figures as supports was by Jean Gougeon in the Louvre; as was the most unfortunate in the use of them in a church in the New Road, which at the time of its erection was much lauded, but which we hope will never be imitated by any British architect.

2684. As to the use of what are called Persians or male figures, originally in Persian dresses, to designate, as Vitruvius tells us, the victory over their country by the Greeks, the observations above made equally apply, and in the present day their application will not bear a moment's suspense in consideration.

2685. We have been much amused with the gravity wherewith Sir William Chambers, not with his usual sound sense, treats the claims of the personages whose merits we are discussing: he says, "Male figures may be introduced with propriety in arsenals or galleries of armour, in guard-rooms and other military places, where they should represent the figures of captives, or else of martial virtues; such as strength, valour, wisdom, prudence, fortitude, and the like." He writes more like himself when he says, "There are few nobler thoughts in the remains of antiquity than Inigo Jones's court" (in the design for the great palace at Whitehall), "the effect of which, if properly executed, would have been surprising and great in the highest degree." (See *fig.* 207.)

2686. What is called a *terminus*, which is, in fact, nothing more than a portion of an inverted obelisk, we shall not observe upon further than to say that it is a form, as applied to architecture, held in abhorrence. For the purpose, when detached and isolated, of supporting busts in gardens, it may perhaps be occasionally tolerated: further we have nothing to say in its favour. Those who seek for additional instruction on what are called termini, may find some account of them, as the boundary posts of land among the Romans, in books relating to the antiquities of that people.

2687. We shall now proceed to submit some examples of caryatides for the use of those whose designs require their employment. *Fig.* 926. is from a model of Michael Angelo

Fig. 926.

Fig. 927.

Fig. 928.

Fig. 929.

Buonarotti, and is extracted from the *Treatise on Civil Architecture*, by Sir William Chambers, as are the succeeding examples.

2688. *Figs.* 927. and 928. are also designs by Michael Angelo, which, though not designed for a building, are well adapted for the purpose under certain conditions.

2689. *Fig.* 929. is the design of Andrea Biffi, a sculptor of Milan, in the cathedral of which city it is one of the figures surrounding the choir. The statue possesses much grace, and was admirably suited to the edifice wherein it was employed.

2690. *Fig.* 930. comes from Holland, having been executed by Artus Quellinus in the judgment-hall of the Stadthouse at Amsterdam.

Fig. 930.

Fig. 931.

Fig. 932.

Fig. 933.

Fig. 934.

2691. *Fig.* 931. is by Michael Angelo, and is at the Villa Ludovisi at Rome.

2692. *Fig.* 932. is from the design by the last-named master for the monument of Pope Julius, whereof we have had occasion already to make mention in the First Book of this work. (335.)

2693. *Fig.* 933. is a representation of one of the celebrated caryatides by Jean Gougeon in the Swiss guard-room of the old Louvre at Paris, and does not deserve less admiration than it has received. The scale on which this and the preceding figures are given does not admit of so good a representation as we could wish.

2694. *Fig.* 934. is from the arch of the goldsmiths at Rome, being thereon in basso rilievo, but considered by Chambers as well as ourselves a suitable hint for carrying out the purpose of this section.

Sect. XVI.

BALUSTRADES AND BALUSTERS.

2695. A baluster is a species of column used as an ornamental railing in front of windows, or in arcades, or on the summit of a building, whose professed object is the protection of its inhabitants from accidents: analogously, too, it consists of a capital, shaft and base.

2696. The baluster is not found in the works of the ancients, and we believe it owed its introduction in architecture to the restorers of the arts in Italy, in which country a vast variety of examples are to be found. They made their first appearance in the form of stunted columns, not unfrequently surmounted by a clumsily-shaped Ionic capital. The term is said to have had its rise (with what truth we cannot pronounce) from the Latin *balaustium*, or the Greek *βαλαυστιον*, the flower of the wild pomegranate, to which in form the architectural baluster is said by some to bear a resemblance. The writer in the *Encyclopedie Methodique* has taken the opportunity, in the article " Balustre," of launching his anathema against the use of it, but we by no means agree with him; and instead of calling it, as he does, " *une invention mesquine*," we incline to think that it was almost the only invention of the modern architects that deserves our admiration. It is true that the form has been abused in every possible shape; but we are not, in art more than in morals, to arrive at the conclusion that anything is bad because it has been abused and misapplied. Such, then, being the case, we shall proceed in a serious vein to consider its proportions, founded on the best examples that have come to our hands. We must first premise with J. F. Blondel, that balusters and balustrades, which last are a series of the first, should in form and arrangement partake of the character of the edifice. They have even been in their species so subdivided as to be arranged under as many classifications as the orders themselves, a distinct sort having been assigned for employment with each order. We are not quite certain that such an arrangement is necessary, but are rather inclined to think it fanciful; though we are quite willing to allow that where the lighter orders are employed, the balustrades to be used over them are susceptible of a more minute and lighter subdivision of their parts.

2697. The general rules to be observed in the use of the balustrade are, that its balusters be of an odd number, and that the distance between them should be equal to half their larger diameter, from which will result an equality between the open and solid spaces. Blondel disapproves of a half baluster on the flanks of a subdivision of a balustrade: in this we dissent from him, and would always recommend its adoption if possible. In respect of the detailed proportions of the balusters themselves, we are to recollect that the subdivisions are of the capital, the shaft or vase of the baluster, and its base. For proportioning these to one another, Chambers (and we think the proportions he uses not inelegant) divides the whole given height into thirteen equal parts, whereof the height of the baluster is eight, that of the base three, and of the cornice or rail two. If the baluster is required to be less, he divides the height into fourteen parts, giving eight to the baluster, four to the base, and two to the rail. He calls one of these parts a module for the measurement of the rest, and that measure we think convenient for adoption in this work. The module he divides into nine parts.

2698. Balusters intended for real use in a building, as those employed on steps or stairs, or before windows, or to enclose terraces, should not be less than three feet in height, nor more than three feet six inches; that is, sufficiently high to give security to the persons using them: but when merely used as ornamental appendages, as in crowning a building, they should bear some proportion to the parts of the building. Chambers says that their height never ought to exceed four fifths of the height of the entablature on which they are placed, nor should it ever be less than two thirds, without counting the zoccolo or plinth, the height of which must be sufficient to leave the whole balustrade exposed to view from the best point of sight for viewing the building. We can scarcely admit these rules to pass without noting the examples in Palladio's works, which give a much greater latitude for variety. When balusters fill in between the pedestals, as in the façade of the Palace Chiericato at Vicenza, the balustrade's height is of course regulated by that of the pedestal itself; but in the court of the Porti palace the crowning balustrade is not higher than the cornice of the entablature on which it stands. The same proportion is observed in the atrium of the Carità at Venice. In the Valmarana palace the height of the balustrade is equal to that of the entablature of the small order. It is true that in a few instances this master made the height of the balustrade equal to that of the whole entablature, and Inigo Jones has in some instances followed his example; but this was not the general practice either of the one or the other.

2699. We have already said that the baluster generally varies in form, so as to be appropriate to the order over which it is used. It is moreover to be observed that the baluster is susceptible of a pleasing variety of its form by making it square instead of circular on the plan, whereof examples are given in *figs.* 938, 939, and 940.; but when the situation requires an expression of solidity, almost all the circular examples we submit to the reader may be changed from a circular to a square form on the plan, and thus as required we may obtain the character suitable to their respective situations. These changes, from one to another form in details of this description, are in their adoption much more the index to the capacity and genius of the architect than the restless and capricious longing after variety recently exhibited in some of the latest works produced in the city of London, works which reflect no credit on the age in which we live. In *fig.* 935. is given a baluster

Fig. 935.

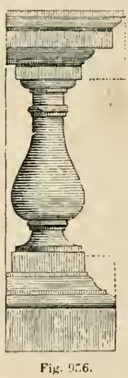

Fig. 936.

Fig. 937.

suitable to the Tuscan order; and using the module of nine parts above mentioned, the following is a table of its dimensions:—

Members.		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Rail, 2 modules.	Fillet	3	$27\frac{1}{2}$
	Corona	$8\frac{2}{3}$	$24\frac{1}{3}$
	Quarter round	$4\frac{2}{3}$	
	Fillet	$1\frac{2}{3}$	
Baluster, 8 modules.	Abacus	$5\frac{2}{3}$	$11\frac{1}{2}$
	Cyma reversa	4	
	Neck	5	$5\frac{1}{4}$
	Astragal, Fillet	$3\frac{1}{3}$	
	Centre of belly	27	13
	From same to astragal	9	
	Astragal, Fillet	$2\frac{1}{3}$	$10\frac{1}{2}$ fillet
	Inverted cyma	$6\frac{1}{3}$	
	Plinth	$7\frac{1}{3}$	13
Pedestal, 3 modules.	Inverted cavetto	5	
	Fillet	2	
	Astragal	5	
	Plinth	15	24

2700. In *fig.* 936. is given the form of a baluster suited to the Doric and Ionic orders, of which also the table of dimensions is subjoined: —

Members.		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Rail, 2 modules.	Fillet	2	27
	Cyma reversa	$3\frac{2}{3}$	
	Corona	7	22
	Quarter round	4	
	Fillet	$1\frac{1}{3}$	
Baluster, 8 modules.	Abacus	$5\frac{2}{3}$	11
	Echinus	$3\frac{1}{3}$	
	Fillet	1	
	Neck	5	5
	Astragal, Fillet	3	
	Centre of belly	27	$12\frac{1}{2}$
	From same to astragal	9	
	Astragal	2	
	Fillet	1	
	Inverted cavetto	6	10 (upper part)
	Fillet	$2\frac{1}{3}$	
	Plinth	$7\frac{1}{3}$	$12\frac{1}{2}$
Pedestal, 3 modules.	Fillet	$1\frac{1}{3}$	
	Inverted ogee	5	
	Fillet	$1\frac{2}{3}$	
	Astragal	$4\frac{1}{3}$	
	Plinth	15	$23\frac{1}{2}$

2701. A suitable baluster for the Corinthian or Composite order is exhibited in *fig.* 937., whereof the measures are as follow: —

Members.		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Rail, 2 modules.	Fillet - - - -	$1\frac{2}{3}$	$26\frac{1}{2}$
	Echinus - - - -	$2\frac{2}{3}$	
	Fillet - - - -	1	
	Corona - - - -	$6\frac{1}{3}$	$21\frac{1}{2}$
	Cyma reversa - - -	$3\frac{2}{3}$	
	Astragal, Fillet - - - -	$2\frac{2}{3}$	
Baluster, 8 modules.	Abacus - - - -	5	$10\frac{1}{2}$
	Echinus - - - -	3	
	Fillet, Cavetto - - - -	$2\frac{1}{3}$	
	Neck - - - -	5	$4\frac{3}{4}$
	Astragal, Fillet - - - -	$2\frac{2}{3}$	
	Centre of belly - - -	27	12
	From same to astragal - -	9	
	Astragal, Fillet - - - -	$2\frac{2}{3}$	
	Scotia - - - -	$4\frac{2}{3}$	$4\frac{3}{4}$ (at top)
	Fillet - - - -	1	
	Astragal - - - -	$3\frac{2}{3}$	
	Plinth - - - -	6	12
Pedestal, 3 modules.	Fillet, Astragal - - - -	$2\frac{2}{3}$	
	Inverted cyma recta - - -	$4\frac{1}{3}$	
	Fillet - - - -	1	
	Astragal - - - -	4	
	Plinth - - - -	15	23

2702. The Tuscan baluster (*fig.* 938.) is suitable for terraces and basements: its rail

Fig. 938.

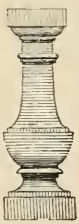

Fig. 939.

Fig. 940.

Fig. 941.

Fig. 942.

Fig. 943.

and pedestal may be the same height as in the *fig.* 935. Its principal measures being as follow: —

Members		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster 5 modules.	Abacus - - - -	3	6
	Cyma reversa - - -	2	
	Neck, Fillet - - - -	4	3
	Rustic belly, at top - -	- -	$4\frac{1}{2}$
	Rustic belly - -	27	
	Rustic belly, at bottom - -	- -	$7\frac{1}{2}$
	Bottom of belly, Fillet - - -	$2\frac{1}{2}$	
	Inverted cavetto and fillet - -	8	3
	Plinth - - - -	$8\frac{1}{3}$	$7\frac{1}{2}$

Other forms of Tuscan balusters are given in *figs.* 939. and 940., but it is not necessary to give the detail of the parts, as the proportions are sufficiently preserved in the figures.

2703. The double-bellied baluster is used in situations where greater lightness is required from the smallness of the parts and the delicacy of the profiles. The proportions for the bases and rails need not vary from those already given. Perhaps they need not be quite so large.

2704. *Fig.* 941. is an example of a double-bellied baluster. suitable to the Doric order. Its parts are as follow: —

Members.		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster, 8 modules.	Abacus - - - -	4½	8
	Echinus, Fillet - - - -	4½	
	Upper part - - - -	24¾	4 neck; 8 belly
	Middle part - - - -	4½	6 centre
	Lower part - - - -	24¾	8 belly; 4 neck
	Fillet, Inverted echinus - - -	4½	
	Plinth - - - -	4½	8

2705. In *fig.* 942. we give an example of the double-bellied baluster for the Ionic order, and its measures are subjoined: —

Members.		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster, 10 modules.	Abacus - - - -	4½	9
	Fillet and cyma reversa - -	4½	
	Upper part - - - -	30½	4½ neck; 9 belly
	Middle part - - - -	9	7½ centre
	Lower part - - - -	30½	9 belly; 4½ neck
	Inverted cyma and fillet - -	4½	
	Plinth - - - -	4½	9

2706. The last example we shall give of the double-bellied baluster (*fig.* 943.) is suitable to the Corinthian order. The measures are as follow: —

Members.		Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster, 12 modules.	Abacus - - - -	5	11
	Echinus and fillet - - -	4	
	Neck - - - -	5½	5½
	Astragal and fillet - - -	3½	
	Upper part - - - -	29	5½ at top; 11 at belly
	Middle - - - -	6	
	Lower part - - - -	29	11 at belly; 5½ at bottom
	Fillet and astragal - - -	3½	
	Neck - - - -	5½	5½
	Fillet and inverted echinus - -	4	
	Plinth - - - -	5	11

2707. We do not deem it necessary to give any examples of the scroll and Guiloche balustrades, which were so much in vogue during the reigns of Louis XIV. and Louis XV., though the present taste seems almost to require it. As that taste has been mainly generated by house decorators, as they are called, and upholsterers, these gentry will soon find out another means of amusing the public, by driving them out of fashion and finding all that is beautiful in some renovated and equal absurdities.

2708. We have already observed that the intervals between balusters should not be more than half the diameter of the baluster at its thickest part; to this we may here add, that they should not be less than one third of that diameter. The pedestals for supporting the rail ought neither to be too frequent nor too far apart; for in the first case they impart a heavy appearance to the work, and in the last the work will seem weak. Seven or nine balusters are good numbers for a group, besides the two half ones engaged in the pedestals. The disposition, however, and number of the pedestals depend on the places below of the piers, columns, or pilasters, for over these a pedestal must stand; and when, therefore, it happens that the intervals are greater than are required for the reception of nine balusters, the distance may contain two or three groups each, flanked with half balusters, and the width of the dies separating the groups may be from two thirds to three quarters the width of the principal pedestals. The rail and base should not be broken by projections, but run in unbroken lines between the pedestals.

2709. When the principal pedestals stand over columns or pilasters, their dies should not be made wider than the top of the shafts, and on no account narrower; indeed, it is better to flank them on each side when the ranges are long with half dies, and give a small projection to the central pedestal, and to let the base and rail follow the projection in their profiles. This practice will give real as well as apparent solidity to the balustrade.

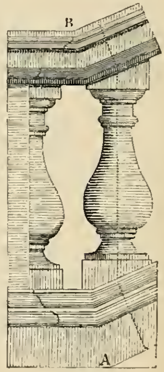

Fig. 944.

2710. *Fig.* 944. shows the application of a balustrade to a portion of a staircase, and herein the same proportions are observed as on level ranges. Some masters have made the mouldings of the different members of the baluster, follow the *rake* or inclination of the steps; but the practice is vicious: they should preserve their horizontality, as exhibited in the figure, in which, at A and B, is also shown the method in which the horizontal are joined to the inclined mouldings of the base and rail. In the balustrades of stairs the spaces between the balusters are usually made narrower than they are on level beds; and Le Clere recommends that the height of the plinth should be equal to that of the steps; but this is not absolutely required, though it must on no account be less.

2711. The bulbs or bellies of balusters and their mouldings may be carved and otherwise enriched: indeed, in highly decorated interiors, this seems requisite.

2712. The following observations as to the height of statues placed upon balustrades are from Sir William Chambers: — "When statues are placed upon a balustrade their height should not exceed one quarter of the column and entablature on which the balustrade stands. Their attitudes must be upright, or, if anything, bending a little forwards, but never inclined to either side. Their legs must be close to each other, and the draperies close to their bodies, for whenever they stand straddling with bodies tortured into a variety of bends, and draperies waving in the wind, as those placed on the colonnades of St. Peter's, they have a most disagreeable effect, especially at a distance, from whence they appear like lumps of unformed materials, ready to drop upon the heads of passengers. The three figures placed on the pediment of Lord Spencer's house, in the Green Park, which were executed by the late ingenious Mr. Spang, are well composed for the purpose."

2713. "The heights of vases placed upon balustrades should not exceed two thirds of the height given to statues," says the same author. We are not altogether averse to the application of either statues or vases in the predicated situations, but we think the greatest discretion is required in their employment. When it is necessary to attract the eye from an indispensably obtrusive roof, they are of great value in the composition; but we shall not further enter on this point of controversy, for such it is, inasmuch as many object to their use altogether, and have considerable reason on their side. We must, however, briefly state the ground of objection, and Chambers's answer as respects statues. There are, he says, some "who totally reject the practice of placing statues on the outsides of buildings, founding their doctrine, probably, upon a remark which I have somewhere met with in a French author, importing that neither men, nor even angels or demi-gods, could stand in all weathers upon the tops of houses or churches."

2714. "The observation is wise, no doubt," (we doubt the wisdom of it,) "yet, as a piece of marble or stone is not likely to be mistaken for a live demi-god, and as statues, when properly introduced, are by far the most graceful terminations of a composition, one of the most abundant sources of varied entertainment, and amongst the richest, most durable, and elegant ornaments of a structure, it may be hoped they will still continue to be tolerated." We fear that if the only reasons for their toleration were those assigned by the author, their doom would soon be sealed.

Sect. XVII.

PEDIMENTS.

2715. A pediment, whose etymology is not quite clear, consists of a portion of the horizontal cornice of the building to which it is applied, meeting two entire continued raking cornices, and enclosing by the three boundaries a space which is usually plain, called the *tympanum*. It is not, however, necessary that the upper cornice should be rectilinear, inasmuch as the cornice is sometimes formed by the segment of a circle. The arrangement in question was the Roman *fastigium*, and is the French *fronton*. The Greeks called pediments αετοι, or eagles; why, this is not the place to inquire. The origin of the pediment, according to authors, seems to have arisen from the inclined sides of the primitive hut. This is a subject, however, which in the First Book (subsec. 5.) has been already considered, and we shall therefore in this section confine ourselves to its employment in the architecture of the day.

2716. Of the varied forms which, by masters even of acknowledged talent, have been given to the pediment, whether polygonal, with curves of contrary flexure, with mixed forms, broken in the horizontal part of the cornice or in the raking parts of it, or reversed in its office with two springing inclined sides from the centre, we propose to say no more than that they are such abuses of all rules of propriety, that we shall not further notice them than by observing that in regular architecture no practice is to be tolerated where the pediment is composed otherwise than of two raking unbroken and one horizontal unbroken cornice, or of the latter and one continued flexure of curved line. To these only, therefore, we now apply ourselves.

2717. Generally, except for windows and doors, the pediment ought not to be used, but as a termination of the whole composition; and though examples are to be found without number in which an opposite practice has obtained, the reader, on reflection, will be convinced of the impropriety of it, if there be the smallest foundation for its origin in the termination of the slant sides of the hut.

2718. The use of the pediment in the interior of a building is, perhaps, very questionable, though the greatest masters have adopted it. We think it altogether unnecessary: if the pyramidal form is desirable for any particular combination of lines, it may be obtained by a vast number of other means than that of the introduction of the pediment. Hence we are of opinion that the attempted apology for them in Sir William Chambers's work, is altogether weak and unworthy of him, and only to be explained by that master's own practice.

2719. Vitruvius ordains that neither the modillions nor dentils which are used in the horizontal cornice should be used in the sloping cornices of a pediment, inasmuch as they represent parts in a roof which could not appear in that position: and the remains generally of antiquity seem to bear him out in the assertion; but the Roman remains seem to bear a different testimony to the validity of the law, and to our own eyes the transgression affords pleasure, and we should recommend the student not to feel himself at all bound by it; for, as Chambers most truly observes, "The disparity of figure and enrichment between the horizontal and inclined cornices are such defects as cannot be compensated by any degree of propriety whatever, and therefore to me it appears best, in imitation of the greatest Roman and modern architects, always to make the two cornices of the same profile, thus committing a trifling impropriety to avoid a very considerable deformity."

2720. Different sized pediments in the same façade are to be avoided; but as respects their forms in ranges of windows and niches a pleasing variety is often obtained by making them alternately curved and rectilinear, as in the temple at Nismes and in the niches of the Pantheon at Rome.

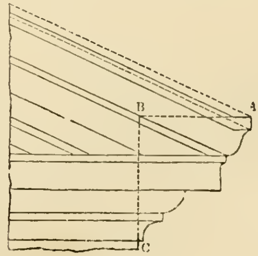

Fig. 945.

2721. In the horizontal part of a cornice under a pediment the two upper mouldings are always omitted, and the intersection of the inclined with the horizontal lines, supposing the inclined members of the cornice to be of the same height as those which are horizontal, will not fall into the profile (*fig.* 945.) whereof AB and BC are the leading lines. To obviate this inconvenience, some architects have made a break in the cymatium and fillet, as shown in the figure. But this is a bad practice, and to it we prefer either making the cyma and fillet higher, as the dotted line AD indicates, or altogether lowering the height of the cyma on the horizontal line. If the inclined cornice is joined on each side by horizontal ones, the best expedient is to give only such small projection to the cyma as that it may meet the inclined sides.

2722. The heights of pediments should be regulated by their lengths, independent of the consideration of climate. (See Book II. Chap. III. Sect. IV. 2027.) Thus, when the base of the pediment is short, the height of the pediment may be greater; and when long, it should be diminished; for in the former case the inclined cornice leaves but scanty space for the tympanum, and in the latter case the tympanum will appear overcharged. From one fifth to one quarter of the length appears to have been agreed on as the limits; but we subjoin, from a work by Stanislas L'Eveillé (*Considerations sur les Frontons*, 4to. Paris, 1824), the method which we consider the best for determining the height of a pediment, observing, by the way, that a strict adherence to the ordinary rules for finding the height may produce the absurdity of a pediment higher than the columns by which it is borne, a condition which would not at all accord with the view we have taken of the orders in Sect. II.

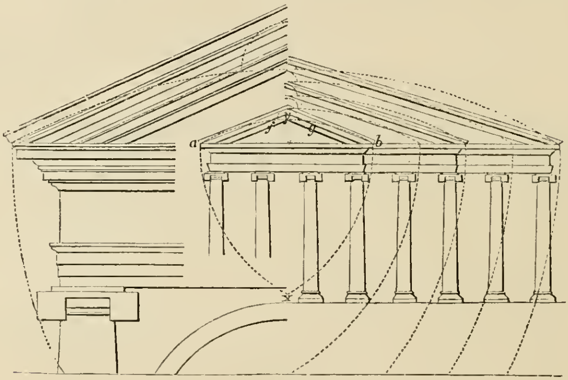

Fig. 946.

Chap. I. of this Book. In fig. 946. we have a synoptical view of pediments of various extents, and as the letters applied to the central pediment will apply to all the rest, we shall restrict our description to that. Suppose the points *a* and *b* to be the extremities of the fillet of the corona. Then, with a radius equal to *ab*, from the points *a* and *b*, describe the arcs *ax*, *bx*, and from their intersection *x* with the same radius let the arc *ayb* be described. From *y*, as a centre, with a radius equal to the height of the horizontal part of the cornice, describe the portion of the circle *f g*, and from *a* and *b* draw thereto tangents intersecting in *y*. Then *yb* and *ya* will be the proper inclination of the fillet of the corona to which the other members of the inclined parts will necessarily be parallel.

2723. We conclude this section by the words of Chambers. "The face of the tympan is always placed on a line perpendicular with the face of the frieze; and when large, may be adorned with sculpture, representing the arms or cypher of the owner, trophies of various kinds, suited to the nature of the structure, or bas-reliefs, representing either allegorical or historical subjects; but when small it is much better left plain."

Sect. XVIII.

CORNICES.

2724. In many cases the façades of buildings are erected without any of the orders appearing in the design, other, perhaps, than those which are applied as the dressings of windows, niches, or doors. The palaces of Florence and Rome abound with such examples, in most of which the edifice is crowned with a cornice, which adds dignity to the building, producing a play of light and shadow about it of the utmost importance as regards its picturesque effect. The moderns have generally failed in this fine feature of a building, and it is only within the last few years, in this country, that a return to the practice of the old masters, a practice properly appreciated by Jones, Wren, Vanbrugh, and Burlington, has manifested itself. If a building be entirely denuded of pilasters and columns, and there are very few common instances that justify their introduction, it seems rational to deduce the proportion of the height and profile of its cornice from the proportions that would be given to it if an order intervened.

2725. If we consider the height of the crowning cornice of a building in this way, and as the portion of an entablature whose height is, as in the case of an order, one fifth of that of the building, we should immediately obtain a good proportion by dividing the whole height into 25 parts and giving two of them to the height of the cornice. For the entablature being one fifth of the whole height, and its general division being into 10 parts, four whereof are given to the cornice, we have for its height the $\frac{4}{10}$ of $\frac{1}{5} = \frac{4}{50} = \frac{2}{25}$, or the twelfth and a half part of the total height of the building $= 0{\cdot}08$. Now there are circumstances, such as when the piers are large, and in other cases when the parts are not very full in their profiles, which may justify a departure from the strict application of this rule; but it will be seen that in the following ten well-known examples the practice has not much differed from the theory, nearly the greatest deviation being in the celebrated cornice of the Farnese palace, which is here placed (*fig.* 947.) as an extraordinary work of art in connection with the building it crowns. The examples alluded to are as follow, and we shall begin with those of earlier date, the diminution in height being almost a chronological table of their erection, with the exception of those by Palladio: —

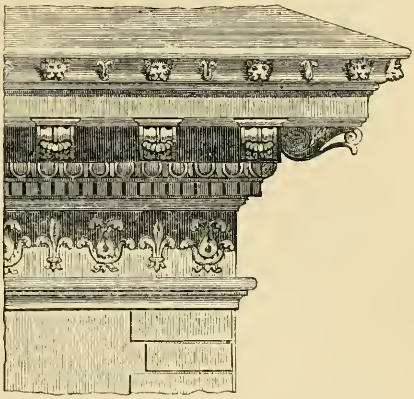

Fig. 947.

In the Spannocchi palace, at Siena, the cornice is $\frac{81}{1000}$ of the whole height of building, or $\frac{3}{37} = {\cdot}081$.

In the Picolomini palace, at Siena, the cornice is $\frac{74}{1000}$ of the whole height of building, or $\frac{2}{27} = {\cdot}074$.

In the Pojana palace, built by Palladio, at Pojana, in the Vicentine territory, the cornice is $\frac{71}{1000}$ of the whole height of building, or $\frac{1}{14} = 071$.

In the Strozzi palace, at Florence, the cornice is $\frac{69}{1000}$ of the whole height of building, or $\frac{2}{29} = {\cdot}069$.

In the Pandolfini palace, at Florence, by Raffaelle, the cornice is $\frac{69}{1000}$ of the whole height of building, or $\frac{2}{29} = {\cdot}069$.

In the Villa Montecchio, by Palladio, the cornice is $\frac{69}{1000}$ of the whole height of building, or $\frac{2}{29} = {\cdot}069$.

In the Villa Caldogno, by Palladio, the cornice is $\frac{69}{1000}$ of the whole height of building, or $\frac{2}{29} = {\cdot}069$.

In another villa by Palladio, for the family of Caldogno, the cornice is $\frac{66}{1000}$ of the whole height of building, or $\frac{1}{15} = {\cdot}066$.

In the Farnese palace, at Rome, the cornice is $\frac{59}{1000}$ of the whole height of building, or $\frac{1}{17} = {\cdot}059$.

In the Gondi palace, at Florence, the cornice is $\frac{57}{1000}$ of the whole height of building, or $\frac{2}{35} = {\cdot}057$.

From these examples it appears that the mean height of the cornices under consideration is something more than one fifteenth of the height of the building, and experience shows that, except under particular circumstances, much more than that is too great, and much less too little, to satisfy an educated eye. The grace beyond the reach of art is, if we may use an Hibernicism, in the power of few, but the bounds have been passed with success, as is testified in the Farnese palace. It may be objected to the system that we have generally adopted in this work, that we are too much reducing the art to rules. But this is a practice of which the painter is not ashamed in the proportions of the human figure, and we must remind our reader and the student that all rules are more for the purpose of restraining excess than bounding the flights of genius.

2726. *Fig.* 948. is an entablature by Vignola, which possesses great beauty, and has been often imitated in various ways for crowning a building; this must be con-

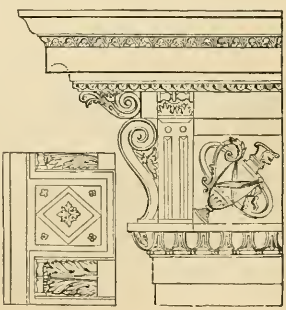

Fig. 948.

sidered more in relation to a building than a mere cornice, and requires rustic quoins, if possible, at the angles when used. Chambers, speaking of this example, says, that "when it is used to finish a plain building, the whole height is found by dividing the height of the whole front into eleven parts, one of which must be given to the entablature, and the remaining ten to the rest of the front." We suspect that the smallness which is assigned by this author to its height has been induced by some error, and that a better rule would be induced by assigning to the cornice its proper height, according to the laws above hinted at, and proportioning the rest of the entablature from the cornice thus obtained.

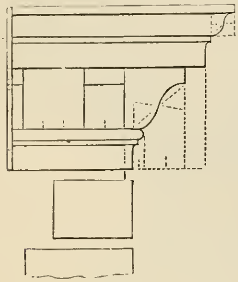

Fig. 951.

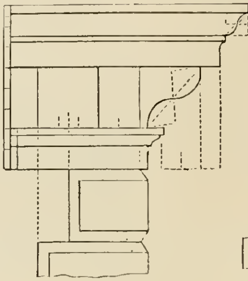

Fig. 950.

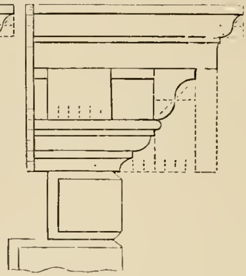

Fig. 949.

2727. In *figs.* 949, 950, and 951. are given three examples of block cornices (the second being by Palladio), whose proportions the figures sufficiently show without here giving a detail of their parts. The height of either should not be less than one fifteenth of the height of the building.

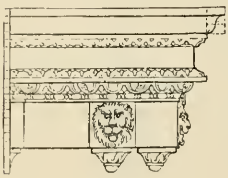

Fig. 952.

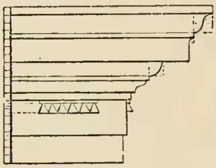

Fig. 954.

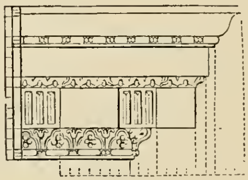

Fig. 953.

2728. *Figs.* 952. and 953. are block cornices, which we have adopted from Chambers, the first being from a palace at Milan, and the other, by Raffaelle, in a house in the Lungara at Rome. The height of these, says the author, and we agree with him, need not exceed one sixteenth part of the whole front, nor should either be less than one eighteenth. *Fig.* 954. is what is called an architrave cornice, which was frequently employed by the old masters. It seems well adapted to the entablatures of columns bearing arches, being rather in the nature of an impost; but it is useful, changing it to suit the order in cases where the height does not admit of the whole of the entablature being used over the order.

Sect. XIX

PROFILES OF DOORS.

2729. One of our objects in this work has been to impress throughout on the minds of our readers that architecture does not depend on arbitrary laws; and though we may not have proved satisfactorily to the student that the precise laws have been exactly stated, we trust we have exhibited sufficient to show and convince him that there was a method and limit in the works of the ancients which in the best times prevented the artists from falling on either side into excess.

2730. In *fig.* 955. we give a door with its architrave, frieze, and cornice, without relation to mouldings, but merely considered in the masses. Its proportions correspond with those most usually adopted; that is, its height is twice its width, the entablature is one fourth of the height of the opening, and the architraves on each side, together, two sixths of the width. The opening, therefore, measuring it in terms of the width of the architrave, will be 6 parts wide and 12 high, and its area consequently 72 parts. Now

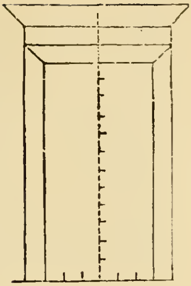

Fig. 955.

t will be found that the solid parts of this are exactly on their 'ace two thirds of this area; for up to the top of the opening each ırchitrave being equal to 12, the sum will be 24; and the entabla- :ure being 8 wide and 3 (one fourth of twelve) high, $8 \times 3 = 24$; which added to 24 for the architraves gives 48 for the solids, and $\frac{48}{72} = \frac{2}{3}$, as above stated. The same analogy does not seem to hold n respect of doors and windows, of making the voids equal to the supports and weights, as in intercolumniations; nor indeed ought we to expect to find it, for the conditions are totally different, nasmuch as no door can exist except in a wall, whereas the office of columns is connected with the weight above only. We trust, therefore, we have shown enough to keep the reader's mind alive to some such law as above developed, without insisting very strongly on a minute attention to it in detail.

2731. We shall now, before submitting any examples of doorways to the reader, touch upon some important points that must be attended to; the first of which is, that all gates and doors, independent of all other considerations, must be of sufficient size for convenient passage through them. Hence internal doors must never be reduced under 2 feet 9 or 10 inches, and their height must not be under 6 feet 10 inches or 7 feet, so as to admit the tallest person to pass with his hat. These are minimum dimensions for ordinary houses in the principal floors; but for houses of a superior class, which are provided with what may be called state apartments, widths of 4, 5, and 6 feet, folding doors and the like, will not be too great for the openings, and the heights will of course be in proportion. The entrance doors of private houses ought not to be under 3 feet 6 inches, nor ordinarily more than 6 feet in width; but in public buildings, where crowds of people assemble, the minimum width should be 6 feet, and thence upwards to 10 or 12 feet. No gate should be less than 9 feet wide; and when loaded waggons or carts are to pass through it, 11 or 12 feet will not be too much. As a general observation we may mention that all doors should open inwards, for otherwise the person entering pulls the door in his face, which is an inconvenient mode of entering a room. Also when the width of a door is greater than 3 feet 8 inches it should be formed in two flaps, by which three advantages accrue: first, that the door will not occupy so much space for opening; second, that each door will be lighter; and, third, that the flaps will more nearly fold into the thickness of the wall. Chambers properly says, "That in settling the dimensions of apertures of doors regard must be had to the architecture with which the door is surrounded. If it be placed in the intercolumniation of an order, the height of the aperture should never exceed three quarters of the space between the pavement and the architrave of the order; otherwise there cannot be room for the ornaments of the door. Nor should it ever be much less than two thirds of that space, for then there will be room sufficient to introduce both an entablature and a pediment without crowding; whereas if it be less it will appear trifling, and the intercolumniation will not be sufficiently filled. The apertures of doors placed in arches are regulated by the imposts, the top of the cornice being generally made level with the top of the impost; and when doors are placed in the same line with windows, the top of the aperture should be level with the tops of the apertures of the windows; or if that be not practicable without making the door much larger than is necessary, the aperture may be lower than those of the windows, and the tops of all the cornices made on the same level."

2732. To say that the principal door of a building should if possible be in the centre of the front would seem almost unnecessary; but it is not so, perhaps, to inculcate the necessity of its being so situated in connection with the internal arrangement of the building as to lead with facility to every part of it, being, as Scamozzi observes (Parte Secunda, lib. vi. c. 4.), like the mouth of an animal placed in the middle of the face, and of easy communication with the *inside*. In the internal distribution the doors should as much as possible be opposite one another on many accounts, not the least whereof is the facility thus given to ventilation; but such a disposition also gives the opportunity of a far better display of a series of rooms, which on occasions of fêtes imparts great magnificence to the apartments. In this climate it is well to avoid too great a number of doors, and they should never, if it can be avoided, be placed near chimneys, because of subjecting to draughts of air those who sit near the fire. Generally the doors in a room should be reduced to the smallest number that will suit the distribution, and the practice of making feigned or blank doors, though sometimes necessary, should if possible be excluded.

2733. The ornaments with which doors are decorated must of course depend on the building in which they are used; and as this is a matter in which common sense must direct the architect, it is hardly necessary to say that the ornaments applied to them in a theatre would ill suit a church.

2734. The composition and designing of gates and their piers must of necessity suit the occasion, as well as the folding gates attached to them, for the enclosure of the parks, gardens, and other places they are to serve. There are few finer examples in the highe class of this species of design than the celebrated gates at Hampton Court.

2735. The evil days on which we have fallen in this country, in respect of the arts, pre cludes the hope of again seeing the doors of our buildings ornamented with bassi relievi an bronze ornaments, a practice common among the ancients no less than among the reviver of the arts; witness the doors of St. Peter's, and, above all, those monuments of the art, th doors of the baptistery at Florence by Lorenzo Ghiberti, wherein art rises by being mad only subservient to the holy purpose to which it is the mere handmaid. In the mentio of doors those of San Giovanni Laterano at Rome must not be omitted; they have the credi of having been the enclosures to the temple of Saturn in the ancient city.

2736. The manufacture of doors has been already sufficiently noticed in the Secon Book; and it therefore only remains for us to subjoin a few examples, which, we think among many others, deserve the attention of the student.

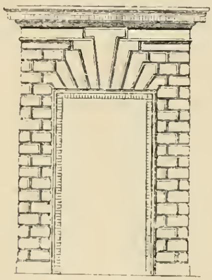

Fig. 957.

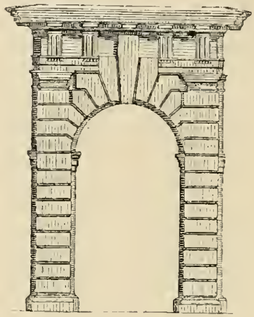

Fig. 956.

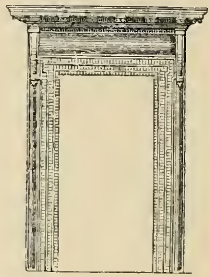

Fig. 958.

2737. Fig. 956. is an external doorway designed and executed by Vignola, at Caprarola not a great distance north of Rome; it must speak for itself: if the reader be of on mind, he will see in it a beautiful handling of the subject; but we cannot further answer fo our opinion, knowing as we do that some of the reviewers of these days may find out tha it possesses no *æsthetic* beauties. There are cases where imitation has been permitted; an the sanction for our opinion is, that it has been imitated by one whom we and all other hold in reverence at Greenwich Hospital, though, as we think with Chambers, for th worse. "The aperture is in the form of an arch, and occupies somewhat more than tw thirds of the whole height. It is adorned with two rusticated Doric pilasters and a re gular entablature. The height of the pilasters is 16 modules, that of the entablature 4. The width of the aperture is 7 modules, its height 14, and the breath of each pier i 3 modules." To the detail of Chambers we have to add that the void in this example which has no analogy to that which as a general rule we gave in the commencement o the section, is about one third of the area of the whole design, the void being to such are as 7·57 to 20·88.

2738. *Fig.* 957. is a design by the last-mentioned master, in which the void is as nearly as possible equal to one third of the area, the supports another, and the weights the othe third: in other terms, the aperture occupies two thirds of the whole height and one hal of the whole breadth, being, in fact, a double square. Its entablature has an alliance with the Tuscan order, and the cornice is equal to one fifteenth of the whole height of the door. These two examples are especially external; those which follow are from their nature applicable in general form to either external or internal doorways.

2739 *Fig.* 958. is a doorway in the Cancellaria at Rome, and is from the design of Vignola. The width is one half the height, and the height of the entablature is equal to one third of the height of the aperture. The breadth of the architrave is one fifth of the aperture's width, and the pilasters below the consoles are half as broad as the architrave. It is heavy, as might have been expected from the proportion between the voids and the solids.

2740. *Fig.* 959. is a design by Michael Angelo Buonarotti, and its aperture may be twice its height,

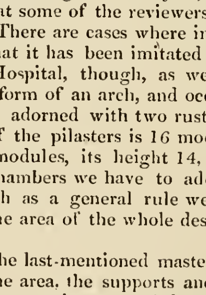

Fig. 959.

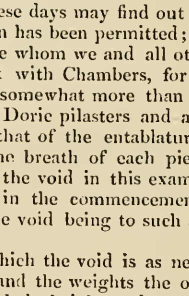

Fig. 960.

he whole entablature a quarter of its height, and the architrave one sixth of the width of the aperture. The face of the pilasters or columns at the sides must be regulated by the lower fascia of the architrave, and their breadth is to be a semidiameter.

2741. *Fig.* 960. is by Vignola, and is in the Farnese palace at Rome. The opening is twice the width in height, and the entablature is three elevenths of the height of the aperture, one of the foregoing elevenths being given to the architrave. The whole of the ornament on the sides is, including architraves and pilasters, equal to two sevenths of the width of the aperture. The cornice is Composite, with modillions and dentils, and the frieze is enriched with a laurel band.

2742. *Fig.* 961., another of the examples given by Chambers, is believed to be by Cigoli. The void is rather more in height than twice its width. The impost of the arch is equal to half a diameter, the columns are rather more than nine diameters high, and rusticated with five square cinctures. The entablature is not so much as one quarter of the height of the column, and its tablet is equal to the width of the aperture.

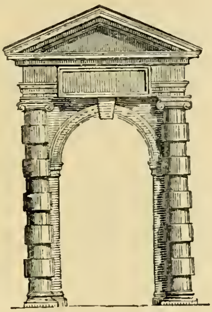

Fig. 961.

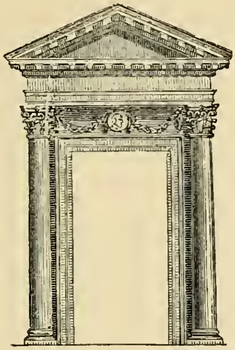

Fig. 962.

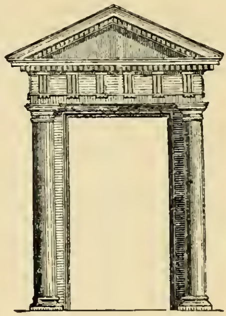

Fig. 963.

2743. *Fig.* 962. is by Inigo Jones, and the aperture may be twice as high as it is wide. The architrave may be a sixth or seventh of the width of the aperture, the top of it being level with the astragal of the columns, which are Corinthian, and ten diameters in height. They must be so far removed on each side from the architrave as to allow the full projection of their bases. The entablature may be from two ninths to one fifth of the column, and the pediment should be regulated by the rules given in Sect. XVII. (2722.).

2744. *Fig.* 963. is by Serlio. The aperture may be a double square, or a trifle less; the diameter of the columns a quarter of the width of the aperture, or a trifle less; their height 8 to 8½ diameters; the entablature about a quarter of the height of the columns, and the pediment should be drawn in conformity with the directions in Sect. XVII.

Sect. XX.

WINDOWS.

2745. Windows, of all the parts of a building, are those which require the greatest nicety in adjustment between the interior and exterior relations of them. The architect who merely looks to the effect they will produce in his façades has done less than half his work, and deserves no better name or rank than that of a mere builder. It seems almost useless to observe that the windows of a building should preserve the same character, that those in each story must be of the same height, and that the openings must be directly over one another. Blank windows are, if possible, to be avoided. they always indicate that the architect wanted skill to unite the internal wants of the building with its external decoration. Windows, moreover, should be as far removed as the interior will permit from the quoins of a building, because they not only apparently, but really, weaken the angles when placed too near them.

2746. Vitruvius, Palladio, Scamozzi, and Philibert de l'Orme, besides many other masters, have given different proportions to them as connected with the apartments to be lighted. That these should be different is indicated by the different places in which those masters have written. Nothing, indeed, seems so much to disallow general laws as the proportion of windows to an apartment; according to the climate, the temperature, the length of the days, the general clearness of the sky, the wants and customs of commerce and of life generally. In hot climates the windows are always few in number and small in dimension. As we approach those regions where the sun has less power and the winter is longer, we observe always an increase in their size and number, so as to enable the inhabitants to take as much advantage as possible of the sun's light and rays. It seems, therefore, almost impossible to give general rules on this subject. We shall on this account endeavour, in the rules that this section contains, to confine ourselves to the sizes which seem suitable in this climate, as respects the proportion of light necessary for the comfort of an apartment.

2747. It is a matter of experience that the greatest quantity of light is obtained for an apartment when lighted by an horizontal aperture in the ceiling. Of this a very extraordinary verification is to be found in the Pantheon at Rome. This edifice, whose clear internal diameter is 142 feet 6 inches, not including the recesses behind the columns, is nearly 74 feet high to the springing of the dome, which is semicircular. The total clear number of cubic feet in it may therefore be taken in round numbers at 1,934,460 cubic feet. Those who have visited it well know that it is most sufficiently and pleasingly lighted, and this is effected by an aperture (the *eye*, as it is technically called,) in the crown of the dome, which aperture is only 27 feet in diameter. Now the area of a circle 27 feet in diameter being rather more than 572 feet, it follows that each superficial foot of the area lights the astonishing quantity of nearly 3380 cubic feet. Independent of all considerations of climate, this shows the amazing superiority of a light falling vertically, where it can be introduced. But in a majority of cases the apertures for light are introduced in vertical walls; and the consequence is, that a far greater area of them for the admission of light becomes necessary. In considering the question it must be premised that a large open space is supposed before the windows, and not the obstructed light which it is the lot of the inhabitants of closely-built streets to enjoy. Again, it is to be recollected that in the proportioning of windows it is the apartments on the principal floor that are to be considered, because their width in all the stories must be guided by them, the only variety admissible being in the height. In this country, where the gloom and even darkness of wet, cloudy, and foggy seasons so much prevails, it is better to err on the side of too much rather than too little light, and when it is superabundant to exclude it by means of shutters and blinds. We are not very friendly to the splaying of windows, because of the irregularity of the lines which follows the practice; but, it must be admitted, it often becomes necessary when the walls are thick, and in such cases a considerable splay on the inside increases the light in effect by a great diminution of shade. It is well, if possible, to have an odd number of windows in an apartment: nothing wherein contributes more to gloom than a pier in the centre.

2748. We do not think it necessary to advert to the rule of Palladio for the dimensions of windows given in the first book of his work, chap. 25.; because, were it true for the climate of northern Italy, it would not be so for that of Great Britain; neither are we at all satisfied with that which in his practice Sir William Chambers says he adopted, and which is as follows, in his own words:—" I have generally added the depth and height' we suppose width " of the rooms on the principal floor together, and taken one eighth part thereof for the width of the window; a rule to which there are few objections: admitting somewhat more light than Palladio's, it is, I apprehend, fitter for our climate than his rule would be." This rule is empirical, as indeed is that on which we place most dependence, and to which we shall presently introduce the reader, being ourselves inclined to the belief that in the lighting a room there is a direct relation between the area of the aperture admitting the light and the quantity of cube space in the room. Indeed the law which we are about to give is one founded on the cubic contents of the apartment; and if the results bore a regular ratio to that quantity, the discussion would be at an end, for we should then have only to ascertain the cubic contents, and, knowing how much an area of light one foot square would illuminate, the division of one by the other would supply the superficies of windows to be provided. Our own notion on this subject is, that 1 foot superficial of light in a vertical wall, supposing the building free from obstruction by high objects in the neighbourhood, will in a square room be sufficient for 100 cube feet if placed centrally in such room. It will, however, immediately occur to the reader, that this rule cannot in many cases satisfy the requirements of an apartment as respects the quantity of light necessary for its proper illumination. The subject is beset with numerous difficulties, which to overcome requires the greatest skill. In the case of an apartment, long as compared with its width, it is well known to every practical architect that windows of the same collective area at either of the narrow ends of such apartment will light it much more effectively than if the same area of light were admitted on either of the long sides, and most especially so, if it should happen that on such long side there were a pier instead of a window in the centre of such side. In illustration of what we mean, let us refer the reader to the ball room at Windsor Castle, an apartment 90 feet long, 34 feet wide, and 33 feet high. This room is lighted from the northern narrower side by a window nearly occupying the width, and is supplied by an abundance of light. But had the same quantity of light been admitted from either of the long sides of the room, so many masses of shadow would have been introduced through the interposition of piers, that its effect would have differed most widely from the cheerful and airy aspect it now presents. We have taken this as an example that more presently occurs to us, but the reader from his observation will have no difficulty in supplying instances in corroboration of our impressions on this subject.

But we shall now proceed to give, in the author's own words, the rules of which we have spoken. That author is Robert Morris, and the work quoted is *Lectures on Architecture, consisting of Rules founded on Harmonick and Arithmetical Proportions in Building*. London, 8vo. 1734. "There are rules, likewise, for proportioning of light according to the magnitude of the room by which any room may be illuminated, more or less, according to the uses of them, and at the same time preserve an external regularity; which, as it is on an uncommon basis, I shall explain to you as well as I conveniently can. Let the magnitude of the room be given, and one of those proportions I have proposed to be made use of or any other; multiply the length and breadth of the room together, and that product multiply by the height, and the square root of that sum will be the area or superficial content in feet, &c. of the light required."

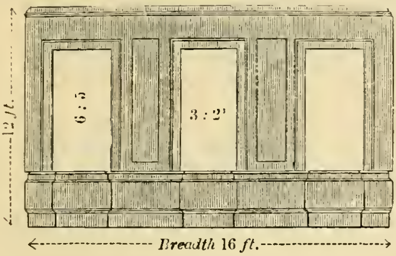

Fig. 964.

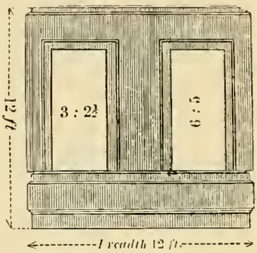

Fig. 965.

2749. "Example. Suppose a room (*fig.* 964.), whose magnitude is the arithmetical proportion of 5, 4, and 3, and is 20 feet long, 16 feet broad, and 12 feet high, the cube or product of its length, breadth, and height multiplied together is 3840, the square root of which sum is 62 feet. If the height of the story is 12 feet as before mentioned, divide that 62 feet into three windows; each window will contain 20 feet 8 inches of superficial light, and those will be found to be 3 feet 2½ inches broad, and 6 feet 5 inches high, which are windows of two diameters."

2750. "Let us now suppose another room on the same range whose height is 12 feet, as the preceding example is, and its proportion (*fig.* 965.) shall be the cube. The product of that cube is 1728, and its root is 41 feet 4 inches, or thereabouts: divide that 41 feet 4 inches in two parts for two windows, and each will be 20 feet 8 inches of superficial light, and those will be two diameters in height, and the magnitude the same as the preceding room."

2751. "For example sake, I will only suppose one more room (*fig.* 966) upon the same range, and 12 feet in height, whose proportion shall be the arithmetical of 3, 2, and 1; that is, its height being 12 feet, the breadth will be 24 and length 36, the product of those numbers multiplied together will be 10368, and its root 101 feet 8 inches, or thereabouts: divide this room into five windows, each window will have 20 feet 4 inches superficial light, and the magnitude will be near or equal to the others, and if the proportion be 6, 4, and 3, and coved, the light is the same."

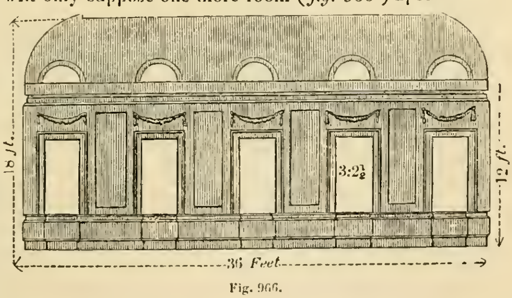

Fig. 966.

2752. "There is," says the author, rather perhaps simply, "but one objection to this rule to make it universal for all kinds of proportioned rooms on the same floor, and that is, the square root doth not always happen to be exact enough for to make them alike; but as the variation will be so small, it may be made use of; and if the area something exceeds the standard of the principal room, that room may be converted to a use which requires more than standard light, and the necessities of families sometimes require it. But, however, the rule will serve for the purpose near enough for any practice."

2753. "If you extend the rule to larger rooms, the same methods will be preserved even if the height be continued through two stories, if the upper windows be made square

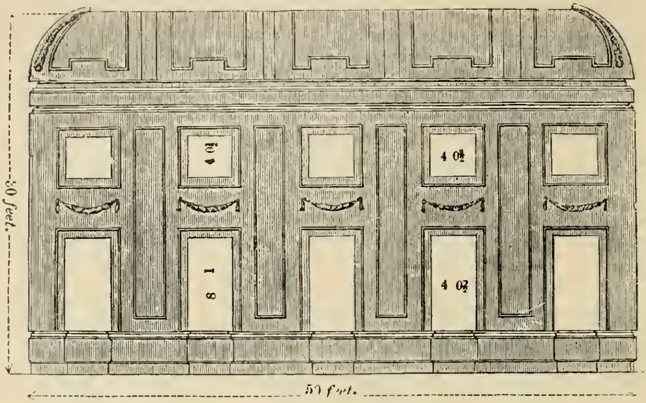

Fig. 967.

and to have two tire" (tiers) "of windows. Let us suppose the room (*fig.* 967.) with two tire of windows in height, to be 50 feet long, 40 feet wide, and 30 feet high, the arithmetical proportion of 5, 4, and 3, the product of those numbers multiplied together will be 60000, the square root of which sum is 245 superfical feet; divide that sum for the tire" (tiers) "of windows into three parts, or take one third of it, and that makes the attic or square windows 81 feet 8 inches superficial light; divide this into 5 windows, and they are 4 feet and half an inch square, and the five lower windows, consisting of 163 feet 4 inches superficial light, being what remains out of the 245 feet, the root, each of these windows is 4 feet and half an inch by 8 feet 1 inch, or two diameters, which 245 feet, the whole sum of the square root of the room, will sufficiently illuminate the same."

2754. The extreme piers should not, if possible, be less than half the width of the principal piers. This cannot always be obtained, but a much less width causes great irregularity, and that more especially when one of such end piers falls opposite a chimney breast, besides causing a great mass of shadow on the other side of the chimney, which has a tendency towards making the room dark and gloomy.

2755. Windows in the same story should be similar. There may be an occasional deviation for a great central window, but such deviation must be used with much caution. Another practice, most properly reprobated by Chambers, is that of intermitting the architrave and frieze of an order in the intervals between the columns to make room for windows and their enrichments, as on the flanks of the Mansion House in the city of London; a practice from which Sir Christopher Wren was, unfortunately, not exempt, as may be noticed in St. Paul's Cathedral.

2756. What are called Venetian windows are occasionally allowable, when so ranged and introduced as not to interfere with the composition, — a task often difficult to effect. They should not be much repeated, as in the front at Holkham, where they become actually disgusting. Though in the examples which follow there be two which are composed with semicircular-headed centres, we do not approve of the general use of examples designed on such principles, and would advise the student rather to study the composition of the Venetian window, when required, as in *fig.* 968., which we do not present as one of beauty, but rather of propriety, where the want of light to the apartment renders a Venetian window expedient. The method of making sashes, shutters, and the other accessories of windows has been described in a previous section; we therefore proceed to offer a few of the most celebrated examples of windows. It is not necessary, after the investigation relative to the voids and solids of doors, to pursue the inquiry into the relative proportions of windows as respects that part of the subject. They are, in a measure, in regard to windows, subject to the same principles, and this, by trial, will be immediately apparent to the student; and we therefore shall not stop for such investigation.

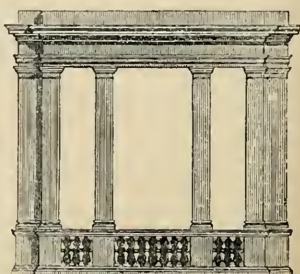

Fig. 968

2757. *Fig.* 969. is after the lower story of windows at St. Peter's at Rome, by Michael Angelo, and is rather less than the double square in height. The architrave is one seventh

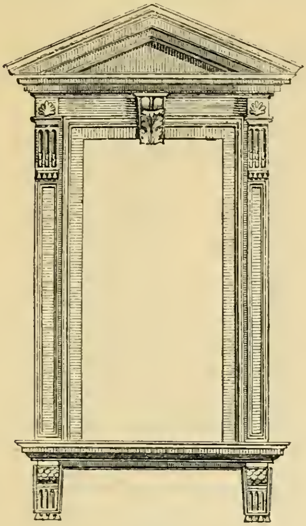

Fig. 969.

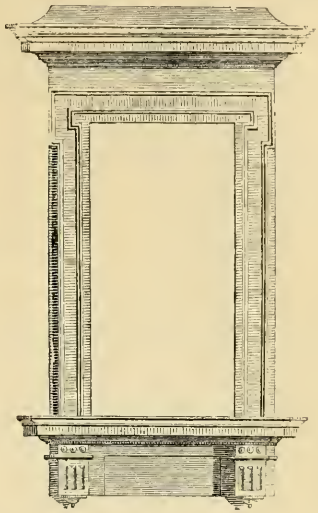

Fig. 970.

of the aperture's width, being the same as that of the pilasters. The length of the consoles is one third of the width of the aperture, and the entablature one quarter of its height.

2758. *Fig.* 970. is from the Mattei palace at Rome, and is the design of Bartolomeo Ammanati. It possesses, though rather heavy, considerable beauty, and well deserves the attention of the student. Chambers, from whom we have selected many of our examples in this and others sections, says, "the parts made somewhat less would succeed better, as would also a pediment instead of the sloped covering at top:" but we entirely disagree with him, and are of opinion that what he proposes would ruin the design.

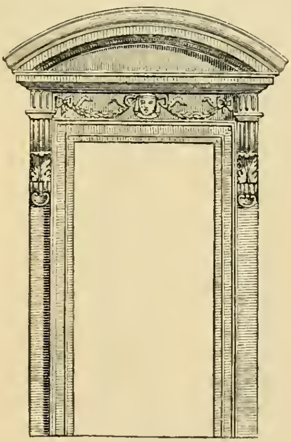

Fig. 971.

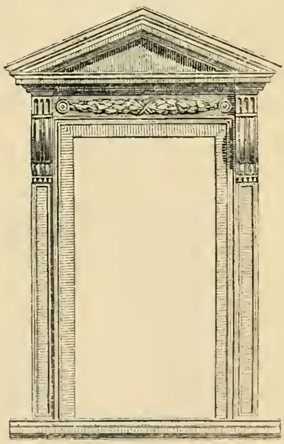

Fig. 972.

2759. *Figs.* 971. and 972. are the compositions of Bernardo Buontalenti. The apertures are a double square, or something less, the architraves a sixth or seventh of the apertures, and the pilasters may be about the same. The height of the entablature should not be more than a quarter that of the aperture, nor much less. The greatest length of the consoles should not exceed half the width of the aperture, nor should their least length be less than one third of it.

2760. *Fig.* 973. is from the old Louvre at Paris, and is by the celebrated Pierre Lescot.

abbot of Clugny in the reigns of Francis I. and Henry II. Its proportions are not much dissimilar from the two last examples.

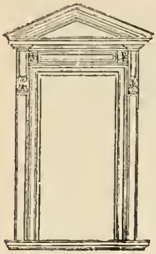

Fig. 973.

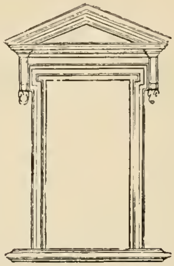

Fig. 974.

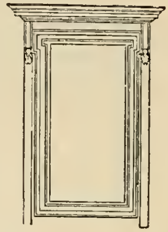

Fig. 975.

2761. *Fig.* 974. is a window constantly used by Palladio. The opening is a double square, the breadth of the architrave equal to one sixth of the aperture, and the frieze and cornice together equal to double the height of the architrave. The breadth of the consoles equal to two thirds the width of the architrave. The breaks over the consoles in the bed mouldings of the cornice are perhaps not strictly correct, but are deviations from propriety which may be tolerated. The breaks in the upper vertical parts of the architrave would perhaps be better omitted. The practice generally should be avoided, except in cases where a greater length of cornice is wanted for the purpose of filling the bare walls to which the windows are applied.

2762. *Fig.* 975. is from the Banqueting House at Whitehall, by Inigo Jones. The aperture is a double square, the entablature one fourth of its height, and the architrave somewhat more than one sixth of its width.

2763. *Fig.* 976. is by Michael Angelo, and executed at the Farnese palace at Rome. It possesses all the wildness and fancy of the master, and though abounding with faults, is redeemed by its grandeur and originality.

2764. In *fig.* 977. is given the design by Ludovico da Cigoli of a window from the ground floor of the Renuccini palace in Florence. It can scarcely be properly estimated without its connection with the façade, to the character whereof it is in every respect suitable.

2765. *Fig.* 978. is a design of Palladio, nearly resembling that executed in the Barbarano palace at Vicenza. It has been imitated by Inigo Jones, and perhaps improved on by him, in the flanks at Greenwich Hospital.

Fig. 976.

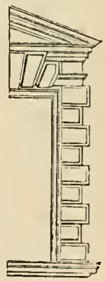

Fig. 977.

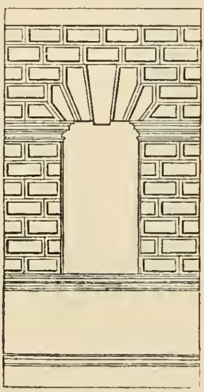

Fig. 978.

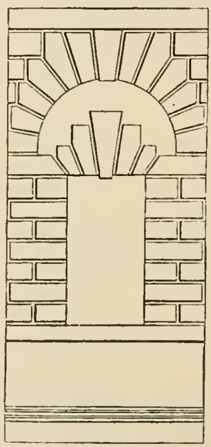

Fig. 979.

2766. *Fig.* 979. is also by Palladio, and executed by him in the Porto palace at Vicenza.

2767. *Fig.* 980. is the design of Raffaelle Sanzio, and worthy of the reputation of that great painter and architect. It is executed in the Pandolfini palace at Florence, on the principal floor. The height of the aperture is a very little more than twice its width, the architrave is one seventh the width of the aperture. The columns, which are Ionic, are

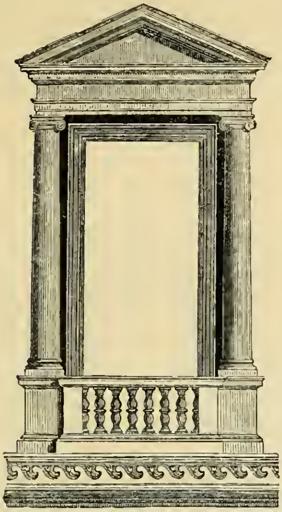

Fig. 980.

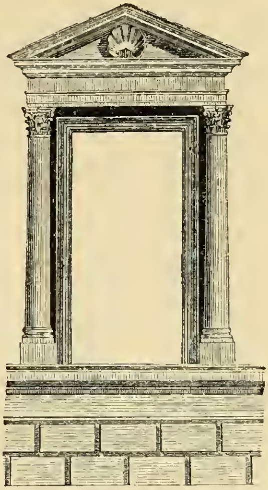

Fig. 981.

9 diameters high, and should be as much detached from the wall as possible. The distance of them from the architrave of the window is a quarter of a diameter, which is also the distance of the entablature from the top of the same architrave. The total height of the entablature is two ninths of that of the column, and the height of the pediment is one quarter of its base or somewhat less. The pedestals are one quarter of the height of the whole order.

2768. *Fig.* 981. is one of the windows of the Bracciano palace at Rome, by Bernini. The aperture is more than a double square, and the architrave about one sixth the width of the aperture. The entablature is only one fifth of the height of the columns, including their sub-plinths, and the pediment is less in height than one quarter of its extent.

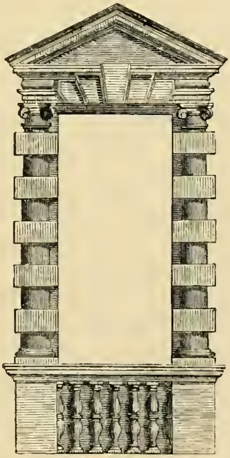

Fig. 982.

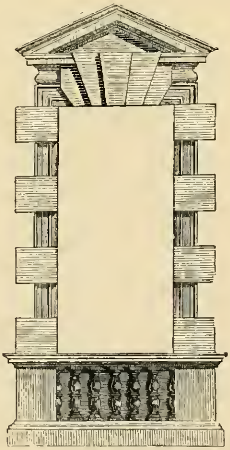

Fig. 983.

2769. *Fig.* 982. is from the principal floor of the Palazzo Thiene at Vicenza. The aperture is two and two tenths of its width in height; the columns are nine diameters high, and one quarter engaged in the wall. The under sides of the Ionic capitals are level with the top of the aperture, having angular volutes with an astragal and fillet below the volute. The bases are Tuscan, and there are on each shaft five rustic dies of an equal breadth.

whose inner sides are on a line with the sides of the aperture, and their projection equal to that of the plinth of the base, that is, one fifth of a diameter of the column. The keystones incline forwards towards the top, and they are hatched, only the surface being left rough, as are likewise the dies on the columns, except at their angles, which are rubbed smooth. The entablature is Ionic, the architrave consisting of only two fasciæ, the frieze swelled, and the dentil band placed immediately on the frieze, without any intervening mouldings, a practice not very unusual with Palladio. The pedestals are rather more than one third the height of the columns. The dies and balusters stand on the platband of the basement, which was done to diminish the projection.

2770. *Fig.* 983. is a design by Inigo Jones, which has been much used in this country. It is rather higher than a double square. The width of the architrave is one fifth that of the aperture, and the rustics are a trifle less than the third of it. The entablature is two ninths of the height of the opening, and the height of the pedestal is $\frac{27}{100}$, or nearly so, of the height of the aperture and pedestal taken together.

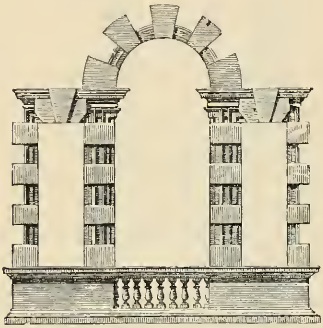

Fig. 984.

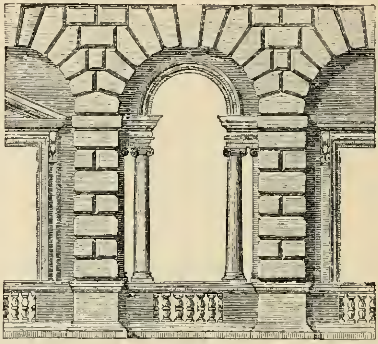

Fig. 985.

2771. *Fig.* 984. is the design of a Venetian window by Colin Campbell, the compiler of the three first volumes of the *Vitruvius Britannicus*; and

2772. *Fig.* 985. is very similar to the Venetian windows in the west façade of the Horse Guards, executed by Kent. It is perhaps as favourable an example of this species of window as can be produced.

Sect. XXI.

NICHES AND STATUES.

2773. A niche is a recess constructed in the thickness of a wall for the reception of different objects, such as statues more especially, but occasionally also for that of busts, vases, and tripods. Vitruvius makes no mention of niches, and but for an inscription published by Visconti in the *Monumenti Gabini* we should not have known that they were by the ancients called *zothecæ*, or places for the reception of a figure. Our English word niche is evidently derived from the Italian *nicchio*, a shell.

2774. In the early Greek temple the niche is not found; at a later period, as in the monument of Philopappus, we find a circular and two quadrangular-headed niches occupied in the time of Stuart by statues; and it does not seem improbable that in the Gymnasia, Agora, Stadia, &c. of the nation mentioned, the use of the niche was not uncommon. But the different forms of the ancient tomb, and the early methods of sepulture, would soon suggest to the Greeks and Romans the use of the niche, especially in such tombs as were devoted to the use of a particular family. These sepulchres, whose subdivisions were called *columbaria*, had their walls ornamented with small niches for the reception of cinerary urns, or those containing the ashes of the dead. In these, a large-sized niche occupies the principal place in the apartment, and in this was deposited the urn or sarcophagus of the head of the family.

2775. The small temples (*ædicula*) of the Romans are often found decorated with niches; and in the small building on the Lake of Albano, generally supposed to have been a Nympheum, we find each side of the interior dressed with six niches, whose height sufficiently indicates that they were provided for the reception of statues. In the temple of Diana, at Nismes, in the South of France, which is now considered to have been a portion of Thermæ, as the great aqueduct ran near it, the interior has two sides decorated with six Corinthian columns, and in the wall between each column is a niche (called tabernacle by the moderns). Each is placed on a pedestal, and at the sides have pilasters alternately surmounted by segmental and triangular pediments. We do not, however, consider it necessary to enumerate the various Roman works wherein the niche finds a place, and shall therefore do no more than refer the student to the Pantheon, the temple of Peace, the arch of Janus, at Rome, and to its exuberant employment at Palmyra, Baalbec, and Spalato. The buildings cited will furnish him with examples of all sorts and characters.

2776. The dresses of niches seem to bear an analogy to those of windows and doors in their form and decoration; the niche may really be considered as an opening in a wall, and indeed there are, in the arch of Claudius Drusus, now the Porta Maggiore, at Rome, openings used as niches, in which an object placed may be seen from either side of the wall. It therefore appears not improper to dress the niche with the ornaments which custom has sanctioned for doors and windows. The author of the article "Niche" in the *Encyclopedie Methodique*, has divided niches into three classes. The first are such as are square on the plan, and either square or circular-headed. These are the simplest, and are without dressings of any sort. Second, such as are square on their plans, and with square heads, but ornamented with dressings, or crowned with a simple platband supported by two consoles. In the third class are included all niches whose plan and heads are semicircular, either ornamented with festoons, or with dressings, or with columns and entablature. These, says the author, are to be introduced into buildings according to their several characters, from simple to highly enriched, as requisite.

2777. Some architectural authors have laid down positive rules for the proportions of niches. According to others the proportion is found in a niche twice and a half its width in height; and indeed this produces a proportion not inelegant. But in considering the classes separately, they have divided the width of the niches invariably into twelve parts. To a niche of the first class they give twenty-eight of such parts; to one of the second class, thirty; and to one of the third class, thirty-one parts. This reduction, however, of the proportions of a niche seems to us to partake of empiricism; and we would rather always trust to an educated eye than to rules which seem to have no basis on fitness and propriety. It is, moreover, to be recollected that all rules of art can be considered only as *mean terms*, serving more as approximations than positive laws for the guidance of the artist in the different combinations he imagines.

2778. The use of tiers of niches over each other is condemned by J. F. Blondel, unless separated by a line of entablature between them, which may seem to indicate the existence of a floor; otherwise, he observes, one figure seems to stand on the head of another. This, however, is an abuse of reasoning; not that it is to be understood that we think the practice very allowable. The recommendation of this master in respect of the relation between niches and the statues that are to occupy them is worthy of attention. He opposes, and we think with great propriety, the placing a statue without a plinth in the niche. The plinth is, indeed, necessary to the good effect of every statue; and to pretend that the imitation in marble could or ever was intended to be mistaken for the object it imitates, would be to leave behind all those matters of convention in art for which the spectator is well prepared. In architectural decoration, no less than in the abstract imitation of the objects of sculpture, no one is desirous of believing them natural and living, but only as models of imitation.

2779. The following observations are from Chambers, relative to the size of the statues used in niches. "The size of the statue depends upon the dimensions of the niche; it should neither be so large as to seem rammed into it, as at Santa Maria Maggiore, in Rome, nor so small as to seem lost in it, as in the Pantheon, where the statues do not occupy above three quarters of the height of the niche, and only one half of its width. Palladio, in arched niches, makes the chin of his statues on a level with the top of the impost (springing), so that the whole head is in the coved part. In the nave of St. Peter's, at Rome, the same proportion has been observed, and it has a very good effect. The distance between the outline of the statue and the sides of the niche should never be less than one third of a head, nor more than one half, whether the niche be square or arched; and when it is square, the distance from the top of the head to the soffite of the niche should not exceed the distance left on the sides. The statues are generally raised on a plinth, the height of which may be from one third to one half of a head; and sometimes, where the niches are very large in proportion to the architecture they accompany, as is the case when an order comprehends but one story, the statues may be raised on small pedestals, by which means they may be made lower than usual, and yet fill the niche sufficiently, it being to be feared lest statues of a proper size to fill such niches should make the columns and entablature appear trifling. The same expedient must also be made use of whenever the statues in the niches, according to their common proportions, come considerably larger than those placed at the top of the building. A trifling disparity will not be easily perceived, on account of the distance between their respective situations; but if it be great, it has a very bad effect; and therefore this must be well attended to and remedied, either by the above-mentioned method, or by entirely omitting statues at the top of the building, leaving the balustrade either free, or placing thereon vases, trophies, and other similar ornaments." Further on in the same work, the author says that "niches, being designed as repositories for statues, groups, vases, or other works of sculpture, must be contrived to set off the things they are to contain to the best advantage; and therefore no ornaments should ever be introduced within them, as is sometimes injudiciously practised, the cove of the niche being either filled with a large scollop shell, or the whole inside with various kinds of projecting rustics, with moulded compartments, either raised or sunken, or composed of different coloured marbles, for all these serve to confuse the outline of the statue or group. It is even wrong to continue an impost within the niche, for that is of considerable disadvantage to the figures, which never appear so perfect as when backed and detached on a plain smooth surface. An excess of ornaments round the niche should likewise be avoided, and particularly masks, busts, boys, or any representation of the human figure, all which serve to divide the attention, and to divert it from the principal object."

2780. "The depth of the niche should always be sufficient to contain the whole statue, or whatever else it is to contain, it being very disagreeable to see statues, or any other weighty objects, with false bearings, and supported on consoles or other projections, as is sometimes done, and in the case of niches, the side views become exceedingly uncouth; for in these a leg, an arm, a head, in short, those parts alone which project beyond the niche appear and look like so many fragments, stuck irregularly into the wall." We trust we shall be excused for this and many other long quotations from Chambers, on account of the strong common sense with which they abound, though not always expressed in the most elegant language that might have been selected.

2781. We conclude the section with a few examples of niches, whose general proportions are sufficiently to be derived from the figures which represent them, and which, therefore, will not require our more minute description in this place, the diagrams themselves being the more useful mode of submitting the subject to the student.

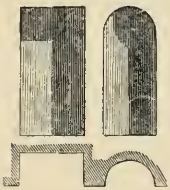

Fig. 986.

Fig. 987.

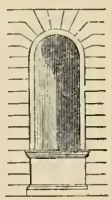

Fig. 988.

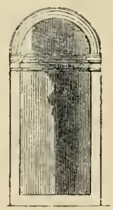

Fig. 989.

2782. *Fig.* 986. is the simple niche, square and circular in the head and in the plan; in the latter we have before, as a general rule, given the proportion of its height as twice and a half that of its width; but the former, or the square-headed one, may be a double square, yet it never should exceed in height twice and a half its width.

2783. *Fig.* 987. is a common form of using the niche where the opening of windows with which it is accompanied requires a correspondent square recess for the niches, as also in interiors where the leading lines may require such an expedient.

2784. *Fig.* 988. shows the method of introducing niches in a rusticated basement, which is often requisite. The rustics are received on a flat ground, in which the niche is formed. The reader is not to understand that any of the figures are intended as models for imitation, but merely as modes on which, in using them, he may so work as to reduce them to his own views in the design whereon he is engaged.

2785. *Fig.* 989. is from the plate of Palladio's Egyptian Hall, and exhibits the violation of Chambers's excellent maxim of not allowing the impost to be continued round the springing of the niche. If niches are merely introduced for play of light and shadow without reference to their reception of statues, the practice of this abuse may be tolerated; but certainly not in cases where statues are to be placed in them.

2786. *Fig.* 990. is the niche accompanied by entablature, pediment, architraves, consoles, and pedestals, as in the windows which have already

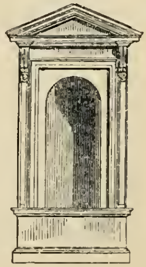

Fig. 990.

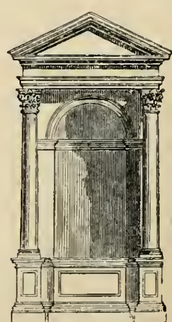

Fig. 991.

been given, and their proportions will serve as a guide in this; the only difference being that a niche is inserted within the architrave of the opening.

2787. *Fig.* 991. is imitated from one of the niches of the Pantheon, for the details whereof the reader may refer to Desgodetz.

Sect. XXII.

CHIMNEY PIECES.

2788. It is not our intention to devote much of a space, necessarily restricted, to the consideration of designs for chimney pieces; not because we consider them unworthy of the serious attention of the student, nor because the ever-varying fashion of the day seems to create a desire for new forms, but because they come under the category of doors and windows (strange as it may seem) in respect of the relation of the void to the solid parts. We are not aware that any view of this nature has heretofore been involved in the consideration of them. but we are not the more on that account to be driven from our hypothesis. The examples of chimney pieces that have been given by Chambers, and, before him, by old Serlio, were but fashions of their respective days; and if it be possible to establish something like a canon on which they might be designed, we apprehend it would be useful to the student.

2789. A chimney piece is the ornamental decoration applied to the aperture of a chimney opening, and it seems but reasonable that in its general distribution it should be subject to those laws which regulate the ornaments of other openings. The forms and fancies into which this ornament of a room may be changed are infinite, and we therefore consider that if its appendages can be drawn into a consistent shape we shall be of service in the few

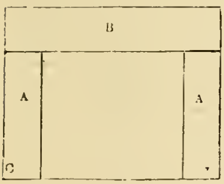

Fig. 992.

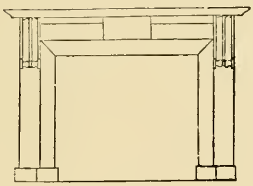

Fig. 993.

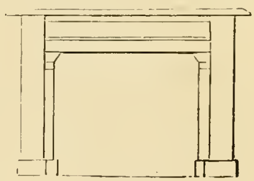

Fig. 994.

remarks subjoined. In *fig.* 992. the chimney opening to be decorated is 4·0 wide and 3 feet 6 inches high; its area is therefore equal to 4 : 0 × 3 : 6 = 14 feet. The principle here recommended is to make the two supporting pieces equal to one half of that area, or seven feet, and the supported piece B equal to the other half. Now, as the height is 3 : 6, we shall have $\frac{7}{3\cdot5}=2$ for the width of the two piers, that is, each will be one foot wide. By the addition of these to the width of the opening, the dimension becomes six feet; and as B is to contain seven feet superficial, it follows that $\frac{7}{6}=1\frac{1}{6}$ is the height of B that it may contain 7 feet.

2790. In *fig.* 993. we have shown the method of developing the principle; in it the supports, load, and void bear the same relation to each other as in the preceding figure. The entablature is divided into three equal parts for the architrave, frieze, and cornice, and trusses are placed on the pilasters by the sides of the architrave. The tablet is of course not absolutely required, and the trusses may be formed of leaves instead of being plain, as here shown.

2791. *Fig.* 994. is another mode of using the proportions given in *fig.* 992., and upon it, as well as that last given, we have only to observe, they are not introduced as specimens of design, but solely with the view of illustrating a principle. The projection of chimney-pieces should not generally be greater than the whole width of the support, nor less than half.

2792. We wish we could give some rule for adjusting the size of a chimney opening to that of the room it is to warm. Morris, in his *Lectures on Architecture*, before quoted, imagined that he had found out one, and he speaks with confidence on the results which follow its use; but we confess we are not satisfied with them. We nevertheless should be wrong in omitting it, and therefore give his words for the consideration of the student. The first rule is as follows: — "To find the height of the opening of the chimney from any given magnitude of a room, add the length and height of the room together, and extract the square root of that sum, and half that root will be the height of the chimney." The second rule is as follows: — "To find the breadth of a chimney from any given magnitude of a room, add the length, breadth, and height of the room together, and extract the square root of that sum, and half that root will be the height of the chimney." The third rule he gives is, "To find the depth of a chimney from any given magnitude, including the breadth and height of the same, add the breadth and height of the chimney together, take one fourth of that sum, and it is the depth of the chimney." His fourth and last rule is, "To find the side of a square or funnel proportioned to clear the smoke from any given depth of the chimney, take three fourths of the given depth, and that sum is the side of the square of the funnel. Observe, only, that in cube rooms the height is equal to the breadth, and the foregoing rules are universal." The rules given by Chambers are extremely vague and general. He says that "in the smallest apartments the width of the aperture is never made less than from three feet to three feet six inches; in rooms from twenty to twenty-four feet square, or of equal superficial dimensions, it may be four feet wide; in those of twenty-five to thirty, from four to four and a half; and in such as exceed these dimensions, the aperture may be extended to five or five feet six inches; but should the room be extremely large, as is frequently the case of halls, galleries, and salons, and one chimney of these dimensions neither afford sufficient heat to warm the room nor sufficient space round it for the company, it will be much more convenient, and far handsomer, to have two chimney pieces of a moderate size than a single one exceedingly large, all the parts of which would appear clumsy and disproportioned to the other decorations of the room." It is well so to place the chimney as that persons on entering a room may at once see it. In this climate a cheerfulness is imparted by the sight of a fire; but it is not to be so placed as to be opposite a door, neither ought it, if possible to be avoided, to be so placed as to have a door on either side of it. There are, however, circumstances under which even the last-named category cannot be avoided, but it is always well if it can. The fact is, that the further the door can, generally speaking, be removed from a chimney, the better; and the architect must, if the plan admit it (and he ought so to distribute his parts), avoid all cross draughts of air in a room. Angular chimneys are only admissible in small rooms where space and other considerations permit no other means of introducing a chimney. We can hardly think it necessary to say, with Chambers, that "whenever two chimneys are introduced in the same room they must be regularly placed, either directly facing each other, if in different walls, or at equal distances from the centre of the wall in which they both are placed. He observes, however, with a proper caution to the student, that "the Italians frequently put their chimneys in the front walls, between the windows, for the benefit of looking out while sitting by the fire; but this must be avoided, for by so doing that side of the room becomes crowded with ornaments, and the other sides are left too bare; the front walls are much weakened by the funnels, and the chimney shafts at the top of the building, which must necessarily be carried higher than the ridges of the roofs, have, from their great length, a very disagreeable effect, and are very liable to be blown down." All these objections, however, may be easily answered, and the funnels collected, or shafts, as they then become, be, with skill, made even ornamental to a building. It is in cases like these that the power of the architect above the artisan is manifest.

2793. Where the walls of a building are sufficiently thick, their funnels rise within the thickness of the walls, but in walls of a mean thickness this cannot be accomplished, for under such circumstances the walls and chimney pieces will necessarily project into the rooms, and if the break be great, the effect is unpleasant; but this may always be obviated by making arched recesses on each side, which, in commoner rooms, may be occupied by presses or closets, thus enabling the architect to carry the cornice unbroken round the room, a point which should never be forgotten, inasmuch as by the cornice or entablature of the apartment being carried round it without a break, which gives the ceiling an unbroken and regular form, a regularity is preserved infinitely more satisfactory to the eye than the disagreeable appearance of a broken, and, we may say, disjointed cornice.

2794. Of the materials employed in the construction of chimney pieces, nothing more is requisite than to say that the costliness of the material must follow the wealth of the founder of the building. Marble, however, is the material usually employed, and the various sorts known are not unfrequently intermixed, so as to produce a pleasing effect. When the aid of the sculptor is called in, much latitude is allowed in the proportions; but on this head we hope we may, without prejudice, deliver our opinion, that the effect has never amounted to anything like what might have been expected from his extraneous aid; and the solution is easy: his object is not to produce a work in harmony with the apartment, but rather to exhibit his own powers.

2795. In the external appearance of chimney shafts, so as to group them with the building to which they belong, no architect can be put in competition with Sir John Vanbrugh. Those of Blenheim, Castle Howard, and other of his buildings, exceed all praise, and deserve the closest investigation of the student. They become in his works, as they always should do, parts of the building, inseparably connected with it, and their removal would detract from the majesty of the structure with which they are connected. On this point we are certain that the best advice that can be given to the student is a constant contemplation of the works of Vanbrugh. In these days there seems to be a return to good feeling in this respect; and we hope it will, for the credit of the English school, be followed up.

Sect. XXIII.

STAIRCASES.

2796. A staircase is an enclosure formed by walls or partitions, or both, for the reception of an ascent of stairs, with such landings as may be necessary. Of the construction of stairs we have treated in previous sections; this will be confined to general observations on them and their enclosures.

2797. Scarcely any subdivision of a building is of more importance, as respects the character of the architect and the comfort and pleasant occupancy of it by his employer, than its principal and subordinate staircases. There is, moreover, no part, perhaps, in which more room is left for architectural and picturesque display. In our own country there are some extraordinary examples of great beauty produced in staircases on comparatively small scales; whence the student may learn that without great space he may produce very imposing effects. One of these may be still seen, though in a very neglected state, as are most of the buildings attached to the collegiate church of Westminster, at one of the prebendal houses there built by our great master Jones. It is a specimen of his consummate skill as an artist, and well worth the attention of the student, if he can obtain admittance to view it; but if he cannot, we may refer him to some plates executed from drawings made by us many years since, and published in the first and best edition of *Illustrations of the Public Buildings of London* (Lond. 1828). The extreme space occupied by the staircase in question does not exceed 24 by 23 feet; and within these small dimensions he contrived a staircase fit for a palace. So highly did the late Sir John Soane think of this bijou that he had a series of drawings made to illustrate its parts, and exhibited them in his lectures at the Royal Academy.

2798. It is almost unnecessary to impress upon the student that an excess rather than a deficiency of light is requisite in a staircase, and that it should be easily accessible from all parts of the building. Those laws upon which the ease of persons ascending and descending depend will form the subject of two subsections shortly following (2804. and 2814.), to which we particularly recommend the reader's attention. They are of the utmost importance, and we record with surprise that they have not been attended to by architects generally of late years. We have crept up staircases in houses of consequence, which deserved little more than the name of ladders, and we are sorry to say that this defect is found even in the works of Chambers himself; but never in those of Jones and Wren. We shall with these remarks proceed to further observations on the subject, which has already been partially touched upon in 2176. *et seq.*

2799. We know little of the staircases of the Greeks and Romans, and it is remarkable that Vitruvius makes no mention of a staircase, as an important part of an edifice; indeed his silence seems to lead to the conclusion that the staircases of antiquity were not constructed with the luxury and magnificence to be seen in more recent buildings. The best preserved ancient staircases are those constructed in the thickness of the walls of the pronaos of temples for ascending to the roofs. Of this sort remains are found in several peripteral temples. That of the temple of Concord at Agrigentum is still entire, and consists of forty-one steps. According to Pausanias, similar staircases existed in the temple of the Olympian Jupiter at Elis. They were generally winding and spiral, like the inside of a shell, and hence are called *scale a lumaca* by the Italians, and by the French *escaliers en limaçon*. Sometimes, as in the Pantheon at Rome, instead of being circular on the plan, they are triangular; so were they in the temple of Peace, and in the baths of Dioclesian.

2800. Very few vestiges of staircases are to be seen in the ruins of Pompeii; from which it may be inferred that what there were must have been of wood, and, moreover, that few of the houses were more than one story in height. Where they exist, as in the building at the above place called the country house, and some others, they are narrow and inconvenient, with steps sometimes a foot in height. Occasionally, too, we find private staircases mentioned, as in the description of Pliny's Tusculan villa, where one was placed by the side of the dining room, and appropriated to the use of the slaves who served the repast.

2801. The author of the article "Escalier" in the *Encyc. Méthod.* observes that the magnificence of the staircase was but tardily developed in modern architecture, and that it owed much of its luxury to the perfection to which a knowledge of stereotomy brought the science of masonry. The manners too and the customs of domestic life for a length of time rendered unnecessary more than a staircase of very ordinary description. Thus in the earliest palaces the staircases seem to have been constructed for the use of the inhabitants only, possessing in fact no more beauty than we now give to a back staircase. They are for the most part dark, narrow, and inconvenient. Even in Italy, which in the splendour of its buildings preceded and surpassed all the other nations of Europe, the staircase was, till a late period, extremely simple in the largest and grandest palaces. Such are the staircases of the Vatican, Bernini's celebrated one being comparatively of a late date. The old staircases of the Tuilleries and of the Louvre, though on a considerable scale, are, from their simplicity, construction, and situation, little in unison with the richness of the rest of these palaces. And this was the consequence of having the state apartments on the ground floor. When they were removed to a higher place, the staircase which conducted to them necessarily led to a correspondence of design in it.

2802. It will be observed that our observations in this section are confined to internal staircases. Large flights of steps, such as those at the *Trinità de' Monti* and *Araceli* at Rome, do not come within our notice, being unrestricted in their extent, and scarcely subject to the general laws of architectural composition. In these it should however be remembered that they must never rise in a continued series of steps from the bottom to the summit, but must be provided with landings for resting places, as is usually the case in the half and quarter spaces of internal stairs. An extremely fine example of an external flight of stairs may be cited in those descending from the terrace to the orangery at Versailles. For simplicity, grandeur, design, and beauty of construction, we scarcely know anything in Europe more admirable than this staircase and the orangery to which it leads.

2803. The selection of the place in which the staircase of a dwelling is to be seated, requires great judgment, and is always a difficult task in the formation of a plan. Palladio, the great master of the moderns, thus delivers the rules for observance in planning them, that they may not be an obstruction to the rest of the building. He says, "A particular place must be marked out, that no part of the building should receive any prejudice by them. There are three openings necessary to a staircase. The first is the doorway that leads to it, which the more it is in sight the better it is; and I highly approve of its being in such a place that before one comes to it the best part of the house may be seen, for although the house be small, yet by such arrangement it will appear larger: the door, however, must be obvious, and easy to be found. The second opening is that of the windows through which the stairs are lighted; they should be in the middle, and large enough to light the stairs in every part. The third opening is the landing place by which one enters into the rooms above; it ought to be fair and well ornamented, and to lead into the largest places first."

2804. "Staircases," continues our author, "will be perfect, if they are spacious, light, and easy to ascend; as if, indeed, they seemed to invite people to mount. They will be clear, if the light is bright and equally diffused; and they will be sufficiently ample, if they do not appear scanty and narrow in proportion to the size and quality of the building. Nevertheless, they ought never to be narrower than 4 feet" (4 feet 6 inches English *), "so that two persons meeting on the stairs may conveniently pass each other. They will be convenient with respect to the whole building, if the arches under them can be used for domestic purposes; and commodious for the persons going up and down, if the stairs are not too steep nor the steps too high. Therefore, they must be twice as long as broad. The steps ought not to exceed 6 inches in height; and if they be lower they must be so to long and continued stairs, for they will be so much the easier, because one needs not lift the foot so high; but they must never be lower than 4 inches." (These are Vicentine inches.) "The breadth of the steps ought not to be less than a foot, nor more than a foot and a half. The ancients used to make the steps of an odd number, that thus beginning to ascend with the right foot, they might end with the same foot, which they took to be a good omen, and a greater mark of respect so to enter into the temple. It will be sufficient to put eleven or thirteen steps at most to a flight before coming to a half-pace, thus to help weak people and of short breath, as well that they may there have the opportunity of resting as to allow of any person falling from above being there caught." We do not propose to give examples of other than the most usual forms of staircases and stairs; their variety is almost infinite, and could not even in their leading features be compassed in a work like this. The varieties, indeed, would not be usefully given, inasmuch as the forms are necessarily dependent on the varied circumstances of each plan, calling upon the architect almost on every occasion to invent *pro re natâ*.

2805. Stairs are of two sorts, straight and winding. Before proceeding with his design, the architect must always take care, whether in the straight or winding staircase, that the person ascending has what is called *headway*, which is a clear distance measured vertically from any step, quarter, half-pace, or landing, to the underside of the ceiling, step, or other part immediately over it, so as to allow the tallest person to clear it with his hat on; and this is the minimum height of headway that can be admitted. To return to the straight and winding staircase, it is to be observed, that the first may be divided into two *flights*, or be

* The Vicentine foot is about 13·6 inches English.

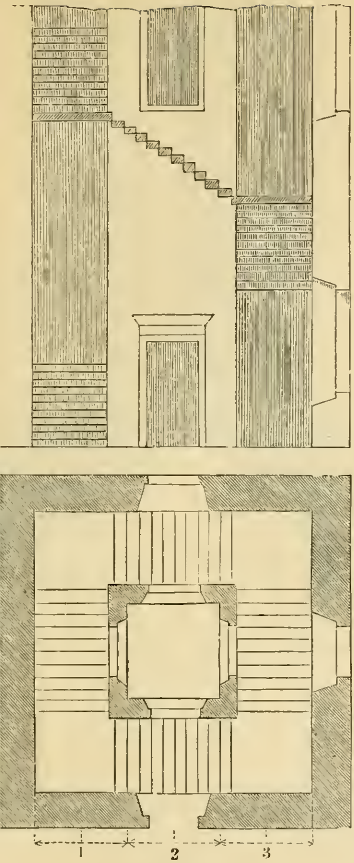

Fig. 995.

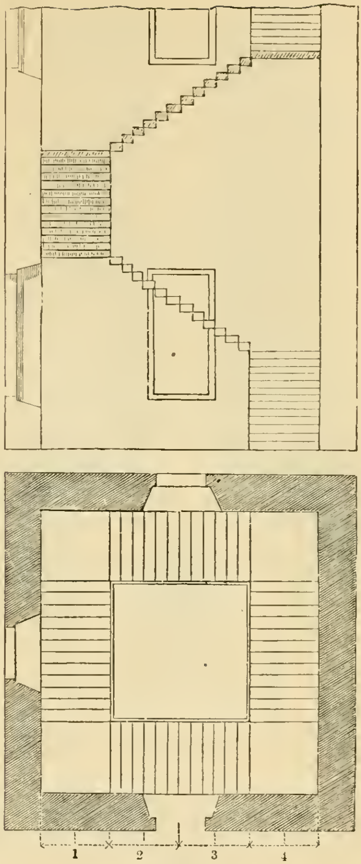

Fig. 996.

ıade quite square, so as to turn on the four sides round a close or open newel, as in *fig.* 995. ı which the former is the case, light being obtained by windows in the walls which enclose he newel ; or, as in *fig.* 996. : in which case, the newel is open, and the light may be received ither from a vertical light above, or from side windows in the walls. Palladio says these wo sorts of stairs were invented by Sig. Ludovico Cornaro, a gentleman of much genius, vho erected for himself a magnificent palace at Padua.

2806. Of winding or spiral stairs. some are circular on the plan, either open or with a olid newel ; others elliptical, also with open or solid newels. Those with the open newel re preferable, because of their allowing the staircase to be lighted additionally, if requisite, y the light obtainable from above ; besides which, persons passing up and down may see ach other. Palladio thus directs the setting out of spiral staircases. " Those," he says, ' which have a newel in the middle are made in this manner. The diameter being divided nto three parts, two are given for the steps, and the third is for the newel ; or, otherwise, he diameter may be divided into seven parts, three of which are for the newel and four or the steps. " Thus," he says, " was made the staircase of the column of Trajan at Rome ; nd if the stairs are made circular," (that is, the treads segments of circles on the plan,) ' they will be handsomer and longer " (of course) " than if made straight."

2807. " But as it may happen that the space will not give room for these measures, he diameter may be reduced and divided according to the plates." The essence of these lans, omitting the step whose plan is segmental, we here subjoin.

2808. *Fig.* 997. is a plan and section of a staircase with a solid newel, in which the vhole diameter is divided into twelve parts, and of these four are given to the newel, nd the remainder divided equally between the steps.

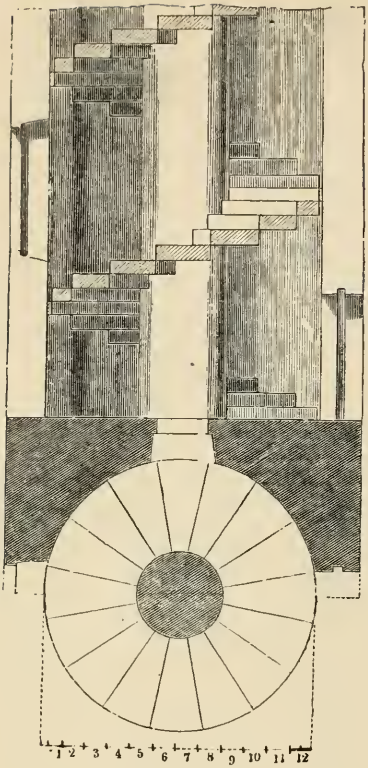

Fig. 997.

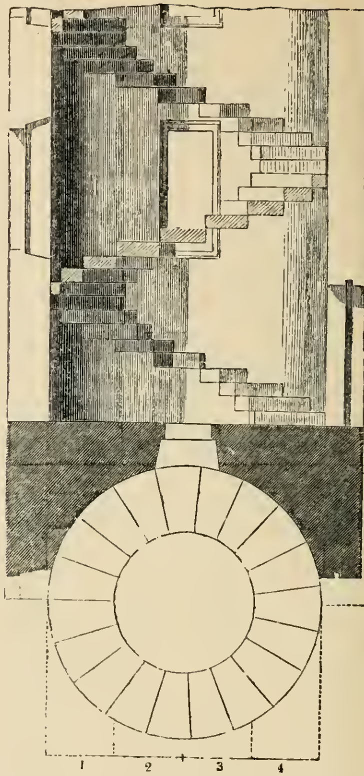

Fig. 998.

2809. *Fig.* 998. is the plan and section of a spiral staircase with an open newel, wherein the diameter is divided into four parts, two being given to the newel, and the remainder equally divided between the steps.

2810. *Fig.* 999. is the plan and section of an elliptical staircase with an open newel. The conjugate diameter is divided into four parts, whereof two are given to the conjugate diameter of the newel, and the remainder one on each side to the steps.

2811. In *fig.* 1000. the same staircase is given, but with a solid newel, and of course requiring many openings on the sides to light it.

2812. It is not the difficulty of multiplying the examples of staircases which prevents our proceeding on this head, but the space into which our work is to be condensed. Enough of example has been given, by using portions of the examples, to meet every case, the decoration being dependent on the design of the architect, and the distribution on his good sense in the application of what we have submitted to him.

2813. There is, however, one important point in the construction of a staircase to which we must now advert, and that is easiness of ascent. Blondel, in his *Cours d'Architecture*, was, we believe, the first architect who settled the proper relation between the height and width of steps, and his theory, for the truth whereof, though it bears much appearance of it, we do not pledge ourselves, is as follows.

2814. Let x = the space over which a person walks with ease upon a level plane, and z = the height which the same person could with equal ease ascend vertically. Then if h be the height of the step, and w its width, the relation between h and w must be such that when $w=x$, $h=0$, and when $h=z$, $w=0$. These conditions are fulfilled by equations of the form $h=\frac{1}{2}(x-w)$ and $w=x-2h$. Blondel assumes 24 (French) inches for the value of x, and 12 for that of z. We are not sufficiently, from experiment, convinced that these are the proper values; but, following him, if those values be substituted in the equation $h=\frac{1}{2}(24-w)$, and $w=24-2h$: if the height of a step be 5 inches, its width should be $24-10=14$ inches, and it must be confessed that experience seems to confirm the theory, for it must be observed, and every person who has built a staircase will know the fact, that the merely

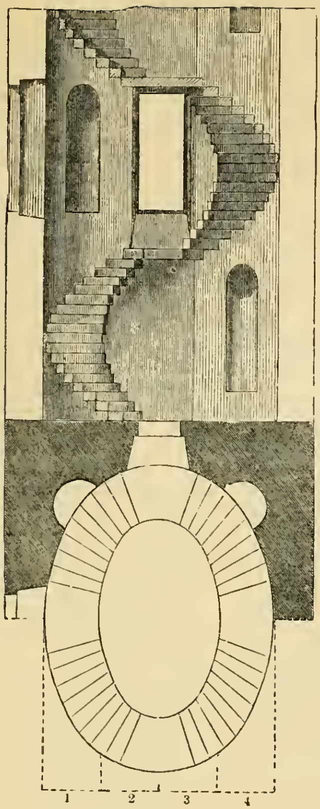

Fig. 999.

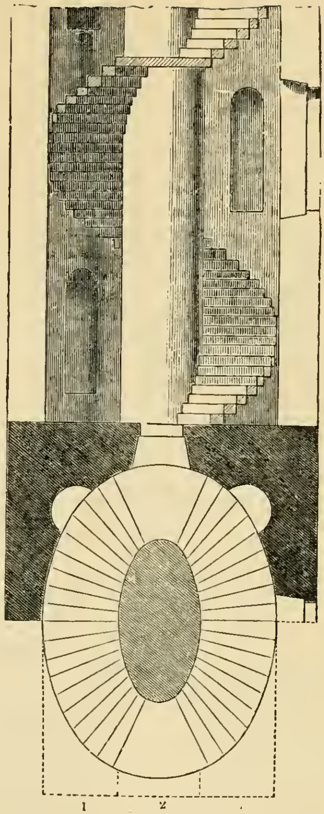

Fig. 1000.

reducing the height of the risers without giving a correspondent width of tread to the step is inconvenient and unpleasant.

Sect. XXIV.

CEILINGS.

2815. Economy has worked so great a change in our dwellings, that their ceilings are, of late years, little more than miserable naked surfaces of plaster. This section, therefore, will possess little interest in the eye of speculating builders of the wretched houses erected about the suburbs of the metropolis, and let to unsuspecting tenants at rents usually about three times their actual value. To the student it is more important, inasmuch as a well-designed ceiling is one of the most pleasing features of a room.

2816. There is, perhaps, no type in architecture more strictly useful in the internal distribution of apartments than that derived from timber-framing; and if the reader has understood our section on floors, he will immediately see that the natural compartments which are formed in the carpentry of a floor are such as suggest panels and ornaments of great variety. Even a single-framed floor with its strutting or wind-pieces between the joists, gives us the hint for a ceiling of coffers capable of producing the happiest effect in the most insignificant room. If the type of timber-framing be applied to the dome or hemispherical ceiling, the interties between the main ribs, diminishing as they approach the summit, form the skeletons of the coffers that impart beauty to the Pantheon of Agrippa. We allude thus to the type to inculcate the principle on which ornamented ceilings are designed, being satisfied that a reference to such type will insure propriety, and bring us back to that fitness which, in the early part of this Book, we have considered one of the main ingredients of beauty. If the panels of a ceiling be formed with reference to this principle, namely, how they might or could be securely framed in the timbering, the design will be fit for the purpose, and its effect will satisfy the spectator, however unable to account for the pleasure he receives. Whether the architrave be with plain square panels between it and the wall, as in the temples of the Egyptians, or as at a later period decorated with coffers, for instance in the Greek and Roman temple, the principle seems to be the same, and verifies the theory. The writer of the article "Plafond" in the *Encyc. Meth.* has not entered into the subject at much length, nor with the ability displayed in many other parts of that work; but he especially directs that where a ceiling is to be decorated on the plane surface with painting, the compartments should have reference to the construction. With these preliminary observations, we shall now proceed to the different forms in use. Ceilings are either flat, coved, that is, rising from the walls with a curve, or vaulted. They are sometimes, however, of contours in which one, more, or all of these forms find employment. When a coved ceiling is used, the height of the cove is rarely less than one fifth, and not more than one third the height of the room. This will be mainly dependent on the real height of the room, for if that be low in proportion to its width, the cove must be kept down; when otherwise, it is advantageous to throw height into the cove, which will make the excess of the height less apparent. If, however, the architect is unrestricted, and the proportions of the room are under his control, the height of the cove should be one quarter of the whole height. In the ceilings of rooms whose figure is that of a parallelogram, the centre part is usually formed into a large flat panel, which is commonly decorated with a flower in the middle. When the cove is used, the division into panels of the ceiling will not bear to be so numerous nor so heavy as when the ceiling appears to rest on the walls at once, but the same sorts of figures may be employed as we shall presently give for other ceilings. If the apartment is to be highly finished, the cove itself may be

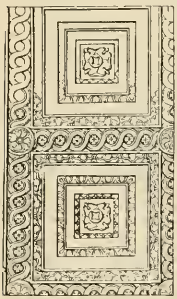

Fig. 1001.

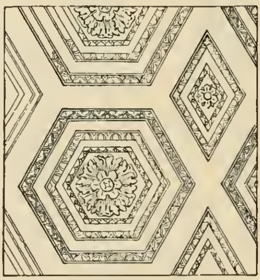

Fig. 1002.

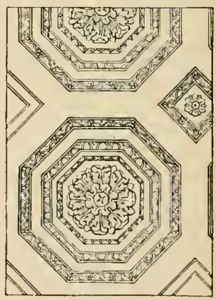

Fig. 1003.

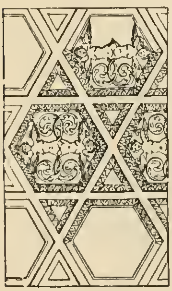

Fig. 1004.

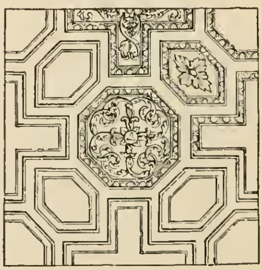

Fig. 1005.

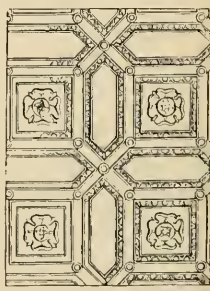

Fig. 1006.

decorated with enriched panels, as in the *figs.* 1001, 1002, 1003, 1004, 1005, 1006. In all ceilings it is desirable to raise the centre panel higher than the rest, and the main divisions representing the timbers in flat ceilings should, if possible, fall in the centre of the piers between the windows.

2817. *Fig.* 1007. shows the ceiling of a square room in two ways as given on each side of the dotted line, or it may be considered as representing the ends of a ceiling to a room whose form is that of a parallelogram. The same observation applies to *figs.* 1008. and 1009. The soffites of the beams should in all cases approach the width they would be,

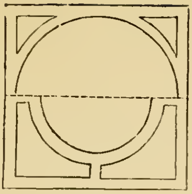

Fig. 1007.

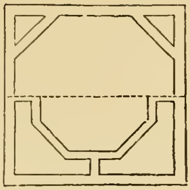

Fig. 1008.

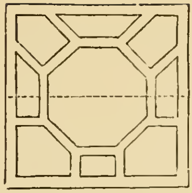

Fig. 1009.

considered as the sofites of architraves of the columns of the order to which the cornice belongs, and they may be decorated with guiloches, as in *fig.* 1010., or with frets. (See the word "Fret" in Glossary.)

Fig. 1010.

2818. In the two following figures (1011. and 1012.) are given four examples of rooms which are parallelograms on the plan, and above each is a section of the compartments.

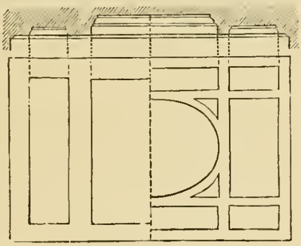

Fig. 1011

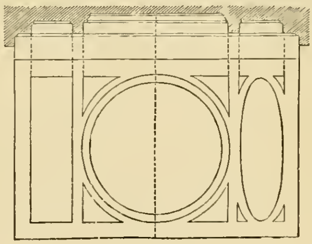

Fig. 1012.

2819. As to the proportion of the cornice, it ought in rooms to be perhaps rather less than in halls, salons, and the exterior parts of a building; and if the entablature be taken at a fifth instead of one fourth of the height, and a proportional part of that fifth be taken for the cornice, it cannot be too heavy. Perhaps where columns are introduced it will be better to keep to the usual proportions. Chambers, if followed, would make the proportions still lighter than we have set them down. He says that if the rooms are adorned with an entire order, the entablature should not be more than a sixth of the height nor be less than a seventh in flat-ceiled rooms, and one sixth or one seventh in such as are coved; and that when there are neither columns nor pilasters in the decoration, but an entablature alone, its height should not be above one seventh or eighth of those heights. He further says that in rooms finished with a simple cornice it should not exceed one fifteenth nor be less than one twentieth, and that if the whole entablature be used its height should not be more than one eighth of the upright of the room. In the ceilings of staircases the cornices must be set out on the same principles; indeed in these, and in halls and other large rooms, the whole of the entablature is generally used. In vaulted ceilings and domes the panels are usually decorated with panels similar to those in *figs.* 1001, 1002, 1003, 1004, 1005, 1006., but in their application to domes they of course diminish as they rise towards the eye of the dome. (See 2837.)

Sect. XXV.

PROPORTIONS OF ROOMS.

2820. The use to which rooms are appropriated, and their actual dimensions, are the principal points for consideration in adjusting the proportions of apartments. Abstractedly considered, all figures, from a square to the sesquialteral proportion, may be used for the plan. Many great masters have carried the proportion to a double square on the plan; but except the room be subdivided by a break the height is not easily proportioned to it. This objection does not however apply to long galleries which are not restricted in length, on which Chambers remarks, "that in this case the extraordinary length renders it impossible for the eye to take in the whole extent at once, and therefore the comparison between the height and length can never be made."

2821. The figure of a room, too, necessarily regulates its height. If a room, for example, be coved, it should be higher than one whose ceiling is entirely flat. When the plan is square and the ceiling flat the height should not be less than four fifths of the side nor more than five sixths; but when it leaves the square and becomes parallelogramic, the height may be equal to the width. Coved rooms, however, when square, should be as high as they are broad; and when parallelograms, their height may be equal to their width, increased from one fifth to one third of the difference between the length and width.

2822. The height of galleries should be at least one and one third of their width, and at the most perhaps one and three fifths. "It is not, however," says Chambers, "always possible to observe these proportions. In dwelling-houses, the height of all the rooms on the same floor is generally the same, though their extent be different; which renders it extremely difficult in large buildings, where there are a great number of different-sized rooms, to proportion all of them well. The usual method, in buildings where beauty and magnificence are preferred to economy, is to raise the halls, salons, and galleries higher than the other rooms, by making them occupy two stories; to make the drawing-rooms or other largest rooms with flat ceilings; to cove the middle-sized ones one third, a quarter, or a fifth of their height, according as it is more or less excessive; and in the smallest apartments, where even the highest coves are not sufficient to render the proportion tolerable, it is usual to contrive mezzanines above them, which afford servants' lodging-rooms, baths, *powdering-rooms*," (now no longer wanted!) "wardrobes, and the like; so much the more convenient as they are near the state apartments, and of private access. The Earl of Leicester's house at Holkham is a masterpiece in this respect, as well as in many others: the distribution of the plan, in particular, deserves much commendation, and does great credit to the memory of Mr. Kent, it being exceedingly well contrived, both for state and convenience."

2823. In this country, the coldness of the climate, with the economy of those who build superadded, have been obstacles to developing the proper proportions of our apartments; and the consequence is, that in England we rarely see magnificence attained in them. We can point out very few rooms whose height is as great as it should be. In Italy, the rules given by Palladio and other masters, judging from their works, seem to be sevenfold in respect of lengths and breadths of rooms, namely, — 1. circular; 2. square; 3. the length equal to the diagonal of the square; 4. length equal to one third more than the square; 5. to the square and a half; 6. to the square and two thirds; or, 7. two squares full. As to the height of chambers, Palladio says they are made either arched or with a plain ceiling: if the latter, the height from the pavement or floor to the joists above ought to be equal to their breadth; and the chambers of the second story must be a sixth part less than them in height. The arched rooms, being those commonly adopted in the principal story, no less on account of their beauty than for the security afforded against fire, if square, are in height to be a third more than their breadth; but when the length exceeds the breadth, the height proportioned to the length and breadth together may be readily found by joining the two lines of the length and breadth into one line, which being bisected, one half will give exactly the height of the arch. Thus, let the room be 12 feet long and 6 feet wide, $\frac{12+6}{2} = 9$ feet the height of the room. Another of Palladio's methods of proportioning the height to the length and breadth is, by making the length, height, and breadth in sesquialteral proportion, that is, by finding a number which has the same ratio to the breadth as the length has to it. This is found by multiplying the length and breadth together, and taking the square root of the product for the height. Thus, supposing the length 9 and the breadth 4, the height of the arch will be $\sqrt{9 \times 4} = 6$, the height required; the number 6 being contained as many times in 9 as 4 is in 6.

2824. The same author gives still another method, as follows: — Let the height be assumed as found by the first rule ($=9$), and the length and breadth, as before, 12 and 6. Multiply the length by the breadth, and divide the product by the height assumed; then $\frac{12 \times 6}{9} = 8$ for the height, which is more than the second rule gives, and less than the first.

CHAP. II.

PRINCIPLES OF PROPORTION.

SECT. I.

GENERAL REMARKS.

2825. In undertaking to point out some of the mechanical methods of obtaining proportions of length, breadth, and height, in plans and elevations, as traceable upon geometric representations of the design, we would recall the reader's attention to the admirable remarks on the true nature of proportion made by the author of this Encyclopædia in Sect. I of the first chapter in this book.

2826. But, however just those remarks may be, they do not, any more than any of the mechanical means, result in success in the building as executed and seen in perspective. The ever varying relation between the sides of a mass, such as a Greek temple, can hardly be supposed to be at every moment equally beautiful in proportion, and the finest mediæval structure equally owes the satisfactory effect which it produces to the spectator's judicious choice of his point of view. Some very judicious observations on the rectification of proportions according to the position of the spectator are given by James Pennethorne, in his *Elements and Mathematical Principles of the Greek Architects*, 8vo , London, 1844.

2827. Before the probable effect in execution of an intended design can be ascertained, the designer must have well mastered the routine of drawing, as explained in the several sections on DRAWING, PERSPECTIVE, and SHADOWS, given in this work. He should likewise have familiarised himself with the varying effects of the changes resulting from points of view and alteration of light upon some building of which he may have opportunities to make studies in the usual GEOMETRIC DRAWINGS (explained 2490*a. et seq.*), so as to become imbued with that sense of general fitness of parts to the whole, which is meant by having the "compasses in one's eye."

2828–2837. The simpler such a building may be, the easier it will be at first to begin to acquire the power of anticipating correctly the effect in a design if it be executed: that power can then be applied to designs of more complicated character resulting from the various methods, which we are about to point out, of obtaining proportions.

SECT. II.

HORIZONTAL AND VERTICAL COMBINATIONS OF BUILDINGS.

2838. The different elements of a building are ranged by the side of or above each other, and in designing an edifice both these combinations must be kept in mind, though in the study of the subject, in order to lighten the labour, they may be separately considered. The two species of disposition are horizontal, as in plans, and vertical, as in sections and elevations.

2839. As respects horizontal disposition of the elements of a fabric, beginning with columns, their distance in the same edifice should be equal, but that distance may be varied as circumstances require. In buildings of small importance, the number is reduced as much as possible, on the score of economy, by increasing the distance between them; but in public buildings they should be introduced in greater number, as contributing to the greater solidity of the edifice by affording a larger number of points of support. They ought not, however, to be at all introduced except for the formation of porticoes, galleries, and the like subdivisions. The least distance at which they can be properly placed from a wall is that which they are apart from one another. This distance, indeed, suits well enough when the columns are moderately wide apart; but when the intercolumniations are small compared with their height and the diameter of the columns, their distance from the walls in porticoes must be increased, otherwise these would be much too narrow for their height, affording shelter neither from the sun's rays nor from the rain. On this account, under such circumstances, they may be set from the walls two or three times the distance between the axes of the columns. From this arrangement will result an agreeable and suitable proportion between the parts.

2840 The ceiling of a portico may be level with the under side of the architrave, or it may be sunk the depth of the architrave, which may return in a direction towards the walls, thus forming sunk panels in the ceiling, or the sinking of the panels may be as much as the whole height of the entablature, whose mouldings should then be carried round them. When several ranks of columns occur in a portico the central part is sometimes vaulted, the two central columns of the width being omitted. The method of disposing pilasters in respect of their diminution has been treated of in a former part of this work. (2671, *et seq.*)

2841. The exterior walls which enclose the building should run as much as possible in straight continued lines from one angle to another; a straight line being the shortest that can be drawn. The internal walls, which serve for subdividing the building into its several apartments, should, as much as may be, extend from one side to the opposite one. Where they are intercepted by openings, they should be connected again above by lintels or other means.

2842. In *fig.* 1013. is shown the method of forming a plan or horizontal distribution, and combining it with the vertical distribution in the section and elevation. The thing is so simple that it can hardly want explanation. The equidistant parallel axes being drawn and cut at right angles by similarly equidistant ones, the walls, according to the required accommodations, are placed centrally upon the axes; and the columns, pilasters, &c. upon the intersections of the axes. The doors, windows, niches, and the like are then placed centrally in the interaxes, which must be bisected for that purpose. Above and below the horizontal combination the section and plan are to be drawn. These vertical combinations are infinite, and from every plan many sections and elevations may be formed. The figure exhibits a building of one story only, with a central apartment occupying the height of two stories. But on the same plan a building of two or more stories may be designed. These may have two tiers of porticoes, one above the other, or one only on the ground story, forming by its covering a terrace on the first floor; or a portico might receive on its columns the walls of the next story, and thus become recessed from the main front. So, again, the stories may be equal in height, or of different heights, as circumstances may require. The most usual practice is, above a basement to make the succeeding story higher; but above a principal floor the height of succeeding ones is diminished. The method of placing orders above orders does not require that any addition should be made to what has been said on that subject in Chap. I. Sect. 11. of this Book, and by the same methods arcades over arcades may be conducted.

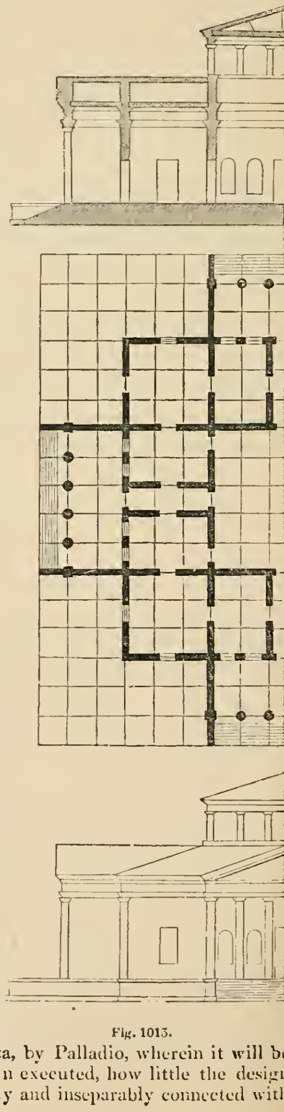

Fig. 1013.

2843. Not the least important of the advantages resulting from the method of designing just submitted to the reader is the certain symmetry it produces, and the prevention, by the use of these interaxal lines on each floor, of the architect falling into the error of false bearings, than which a greater or more dangerous fault cannot be committed, more especially in public buildings. The subterfuge for avoiding the consequence of false bearings is now a resort to cast iron, a material beneficially enough employed in buildings of inferior rank; but in those of the first class, wherein every part should have a proper point of support, it is a practice not to be tolerated. Neither should the student ever lose sight, in respect of the ties he employs in a building, of the admirable observation of Vignola on the ties and chains proposed by Tibaldi, in his design for the baptistery at Milan: "Che le fabbriche non si hanno da sostenere colle stringhe;" — Buildings must not depend on ties for their stability. The foregoing figure is from Durand's *Precis d'Architecture.* We now submit, in *fig.* 1018., an illustration of the principles of interaxal division from the celebrated and exquisite Villa Capra, near Vicenza, by Palladio, wherein it will be seen, on comparing the result with what has actually been executed, how little the design varies from it. It will from this also be seen how entirely and inseparably connected with the horizontal are the vertical combinations in the section and elevation, the voids falling over voids, and the solids over solids. Whatever the extent of the building, if it is to be regular and symmetrical in its composition, the principles are applicable, and that even in buildings where no columns are used; for, supposing them to exist, and setting out the design as though they did exist, the design will prove to be well proportioned when they are removed. The full application of the principles in question will be seen in the works of Durand, the *Précis* and *Cours d'Architecture*, which we have used freely; and where we have had the misfortune to differ from that author, we have not adopted him.

2844. The student can scarcely conceive the infinite number of combinations whereof every design is susceptible by the employment of the interaxal system here brought under his notice; neither, until he has tested it in many cases, will he believe the great mastery in design which he will acquire by its use. In the temples and other public buildings of the ancients, it requires no argument to prove that it was the vital principle of their operations, and in the courts, cavædia, &c. of their private buildings it is sufficiently obvious that it must have been extensively used. That its use in the buildings of those who are called the Gothic architects of the middle ages was universal, a glance at them will be sufficient to prove. The system of triangles which appears to have had an influence on the proportions of the early cathedrals may be traced to the same source (see the early translation of Vitruvius by Cæsar Cesarianus), and indeed, followed up to that source, would end in the principle contended for.

2845. It is impossible for us to prove that the interaxal system was that upon which the revivers of our art produced the astonishing examples many whereof are exhibited in our First Book; neither can we venture to assert that it was that upon which our great master Palladio designed the example above given, unquestionably one of his most elegant works; but, to say the least of the coincidence which has been proved between the actual design and the theory upon which it appears to have been founded, it is a very curious, and, if not true, a most extraordinary circumstance. Our belief, however, is, that not only Palladio but the masters preceding him used the system in question, and that is strengthened by the mode (not strictly, we allow, analogous) in which Scamozzi, in the tenth chapter of his third book, directs the student to adopt in buildings seated on plots of ground whose sides are irregular.

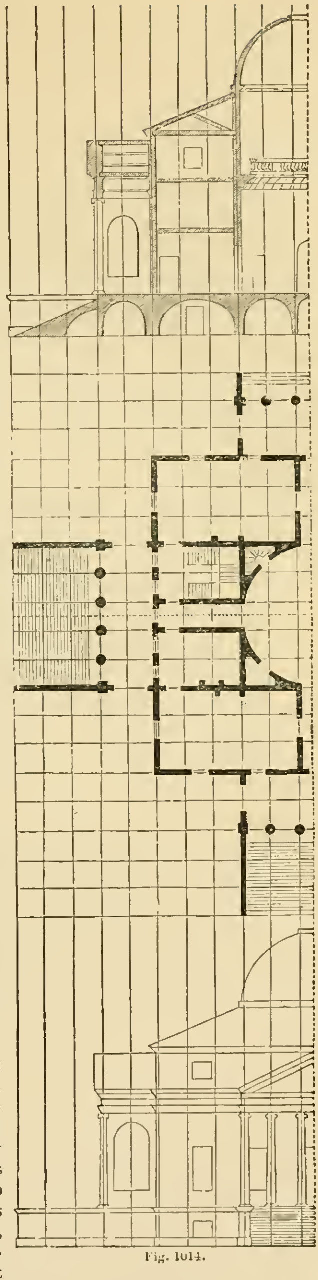

Fig. 1014.

2846. To Durand, nevertheless, the public is greatly indebted for the instruction he has imparted to the student in his *Précis d'Architecture* more especially, and we regret that in our own country the art is treated by its professors too much in the manner of a trade, and that the scramble after commissions has prevented their occupation upon works similar to those which have engaged the attention of professors on the continent. The fault, however, is perhaps not, after all, so much attributable to them as to a government, whatever the party in power, till within the last five years (nay perchance even now) totally indifferent to the success of the fine arts, whose palmy days here were under the reign of the unfortunate Charles. Our feelings on this subject, and love for our art, betray us perchance too much into expressions unsuitable to the subject under consideration, and thereon we entreat, therefore, the patience of our readers, knowing "we have a good conscience."

2847 Our limits preclude the further enlargement on this part of the subject, which in detail would occupy the pages of a separate work, and which, indeed, from its nature, could not be exhausted. We trust, however, enough has been given to conduct the student on the way to a right understanding of this part of the laws of composition.

Sect. III.

SUBDIVISIONS AND APARTMENTS OF BUILDINGS AND THEIR POINTS OF SUPPORT.

2848. The subdivisions, apartments, or portions whereof a building consists are almost as many as the elements that separately compose them: they may be ranked as porticoes, porches, vestibules, staircases, halls, galleries, salons, chambers, courts, &c. &c. All these are but spaces enclosed with walls, open or covered, but mostly the latter, as the case may require. When covered, the object is accomplished by vaults, floors, terraces, or roofs. In some of them, columns are employed to relieve the bearing of the parts above, or to diminish the thrust of the vaulting. The horizontal forms of these apartments — a general name by which we shall designate them, be their application what it may — are usually squares, parallelograms, polygons, circles, semicircles, &c.; their size, of course, varying with the service whereto they are applied. Some will require only one, two, or three interaxal divisions; others, five, seven, or more. It is only these last in which columns become useful; and to such only, therefore, the system is usefully applied. The parts whereof we speak may belong to either public or private buildings: the former are generally confined to a single story, and are covered by vaults of equal or different spans; the latter have usually several stories, and are almost invariably covered with roofs or flats.

2849. When columns are introduced into any edifice to diminish the action of the vaults and increase the resistance to their thrust, the choice of the species of vault must be well considered. If, for example, the vault of a square apartment (*fig.* 1015.) of five interaxal

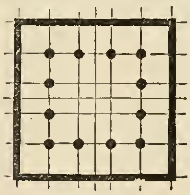

Fig. 1015.

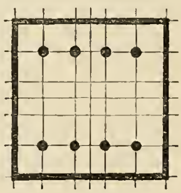

Fig. 1016.

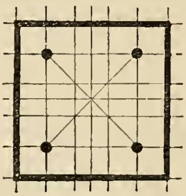

Fig. 1017.

divisions be covered with a quadrangular dome, or, in other words, a quadrantal cove, mitred at each angle, twelve columns would be required for its support. If the vault were cylindrical (*fig.* 1016.) eight columns only would be necessary; but if the form of the covering be changed to the groined arch (*fig.* 1017.), four columns only will be required. Supposing a room of similar form on the plan contained seven interaxal divisions each way, twenty columns must be employed for the coved vault, twelve columns for that whose covering was semi-cylindrical, and still but four for the groined vault. It is obvious, therefore, keeping economy in mind, that the consideration and well weighing of this matter is most important, inasmuch as under ordinary circumstances we find it possible to make four columns perform the office of twelve and even twenty. Here, again, we have proof of the value of the interaxal system, whose combinations, as we have in the previous section observed, are infinite. But the importance of the subject becomes still more interesting when we find that economy is inseparable from that arrangement whose adoption insures stability and symmetry of the parts. These are considerations whereof it is the duty of the architect who values his reputation and charactèr never to lose sight. If honour guide him not, the commission wherewith he is intrusted had better have been handed over to the mere builder, — we mean the respectable builder, who will honestly do his best for his employer.

2850. What occurs in square apartments occurs equally in those that are oblong, for the first or square is but the element of the last. If it happen that from the interaxal divisions contained in the length of an oblong or parallelogram, the subdivisions will not allow of three bays of groins, it does not follow that the arrangement must be defective, for one may be obtained in the middle bay. In subdivisions of width, allowing five interaxes, at least four columns would be saved, and in those of seven interaxes eight columns might be dispensed with. (See *fig.* 1018.)

2851. When the subdivisions on the plan, supposing it not square, take in five interaxes which in the longitudinal extent of the apartment include several bays of groins, whose number must always be odd, one column is sufficient to receive each springing of the arch, but in those of seven interaxal divisions two columns will be necessary. (See *fig.* 1019, A.)

2852. If the vaulting be on a large scale, its weight and thrust are necessarily increased, and the columns may be changed into pilasters connected with the main walls, as in *fig.* 1020., or as I I in the preceding figure.

2853. The height of the apartment from the floor to the springing of the arches will be found three interaxes in apartments whose horizontal combination is of five interaxes, and four and a half for the height to springing of such as are of seven interaxal divisions on the plan. Where the combinations are different in the adjoining apartments the heights just mentioned afford the facility of lighting the larger one above the crown of the lower one, as at B in *fig.* 1019.

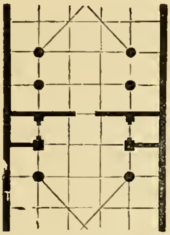

Fig. 1018.

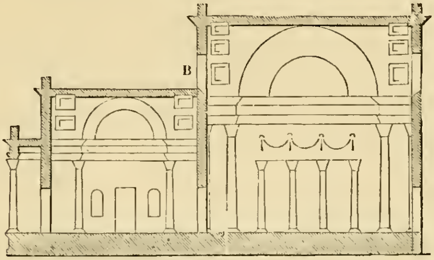

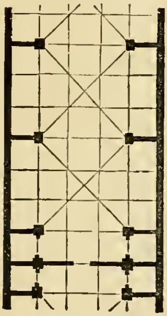

Fig. 1020.

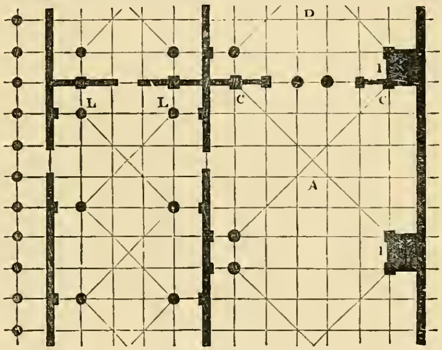

Fig. 1019

2854. Sometimes the springing is from the walls themselves, as at C, *fig.* 1019., instead of from the columns as at L. The first of these arrangements should be permitted only when *en suite* with the apartment there is another, D, wherein the springings are from columns. When the apartment is the last of the suite, the springings must be from piers or columns, one interaxis at least from the wall. If all these matters are well understood, as also the sections upon the orders, and upon the different elementary parts of a building, a graphic combination has been established by which we shall be much aided in the composition or design of all sorts of buildings, and enabled, with little trouble, and in a much shorter period of time than by any other process, to design easily and intelligently. To do more distinguishes the man of genius from the man who can be taught only up to a certain point.

Sect. IV.

COMBINATION OF THE PARTS IN LEADING FORMS.

2855. Having shown the mode whereby the parts of a building are horizontally and vertically combined in the several apartments, which may be considered the grammar of composition, we shall now show its application in the leading forms or great divisions of the plan. Keeping in mind the advantage, upon which we have before touched, of arranging the walls of buildings as much as possible in straight lines, we should also equally endeavour to dispose the principal apartments on the same axes in each direction. Upon first thoughts the student may think that a want of variety will result from such arrangement, but upon proper reflection he will in this respect be soon undeceived. The combinations that may be made of the different principal axes are, as above stated, numberless, that is, of those axes whereon the parts may be advantageously placed so as to suit the various purposes to which the building is destined, paying also due regard to the nature of the ground whereon the fabric is to be erected

2856. Let us, for example, take a few only of the combinations which may be formed from the simple square, as in the first sixteen diagrams of *fig.* 1021., by dividing it in both directions into two, three, and four parts. The thick lines of the diagrams may be considered as representing either walls or suits of apartments, in which latter case the open spaces between them become courts. In reference also to the vertical combinations connected with the dispositions in question, some parts of them may consist of one, other parts of two and three stories, as well for additional accommodation of the whole building to its purpose as for producing variety of outline in the elevation. If, as in some of the diagrams, we omit some of the axes used for the division, such omissions produce a new series of subdivisions almost to infinity. By this method large edifices may be most advantageously designed; it enables us to apply to the different leading axes the combinations suitable to the destination of the building. Considered however as merely an exercise for the student, the use of it is so valuable that we do not believe any other can be so beneficially employed by those masters who profess to teach the art. We have not gone into the subdivisions of the circle in detail, contenting ourselves with the two most obvious dispositions. These are susceptible of as great variety as the square, observing however that the leading axes must be concentric.

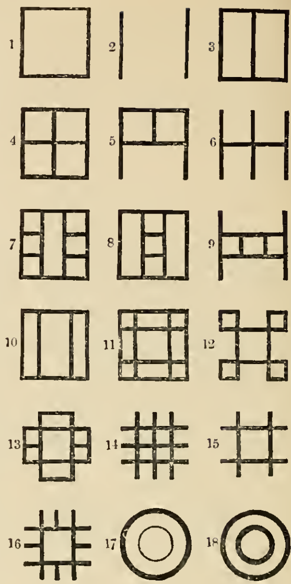

Fig. 1021.

2857. Following up the method just proposed, let us imagine a design consisting of a certain number of similar and dissimilar parts placed in certain relations to each other. Now, having fixed clearly in our mind the relative situations of the several parts and the mode by which they are connected with each other, we shall have a distinct perception of the work as a whole. We may abbreviate the expression of a design by a few marks, as in *fig.* 1022., wherein the crosses represent square apartments, and the simple lines are the expressions of parallelograms, whose relative lengths may be expressed by the lengths of the lines. The next step might be to expand these abbreviations into the form given in *fig.* 1023., on which we may indicate by curves and St. Andrew's crosses, as dotted in the diagram, the way in which the several apartments are to be covered.

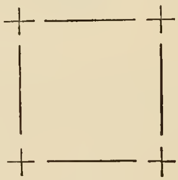

Fig. 1022.

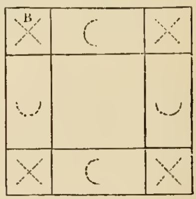

Fig. 1023

2858. We may now proceed with the design; but first it will be well to consider one of the apartments, for which let one of the angles B be taken (see *fig.* 1024. and 1025.). Suppose it, for instance, to be five or any other number of interaxal parts square. This, then, will be the width of the apartments whose forms are that of a parallelogram; and inasmuch as in this apartment the diameter of the vault will be diminished by two interaxes, which results from the use of the four angular columns, the groined vault will be of the width of three interaxes, and the same arrangement will govern the rest of the apartments. In the centre an open court is attendant on the disposition, as indicated by the diagram. The section which is the result of the combination, subject however to other regulation in the detail, is given under the plan of the figure, and the elevation above it entirely depends upon, and is regulated by, the joint combination of the plan and section. The example is given in the most general way, and with the desire of initiating the student in the theory of his art. The building here instanced might serve some public purpose, such as a gallery for the reception of painting or sculpture, or at least give the hint for one; but our object is not to be misunderstood, — we seek only to give the tyro an insight into the principles of composition.

2859. It is not our intention to enter further on the variety which follows the method of designing, of which the foregoing are only intended as hints; but we cannot leave the subject without submitting another example for the study of the reader. Our desire is that of establishing general principles, whereof *fig.* 1026. is a more complete illustration than those that have preceded it. The abbreviated form of the horizontal disposition is shown at A, and in B it is further extended, and will be found to be very similar to that of No. 15. in *fig.* 1021. In the example the interaxal divisions are not drawn through the

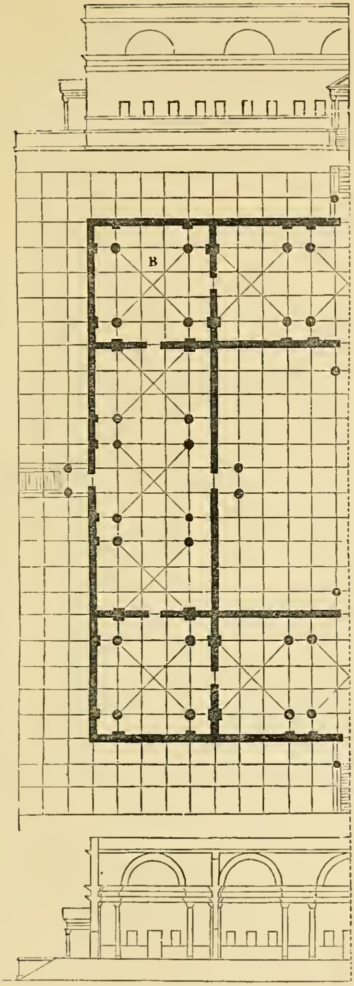

Fig. 1024.

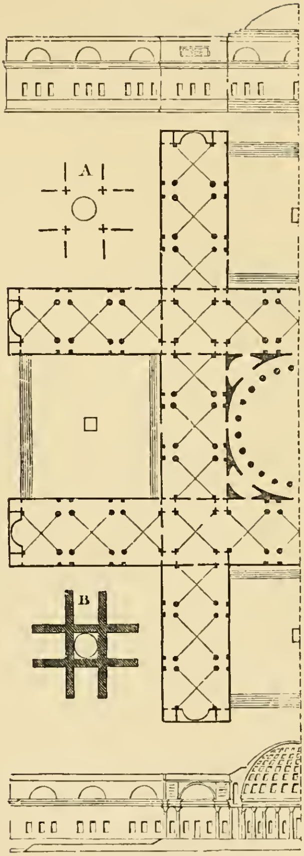

Fig. 1025.

plan, but it will be immediately seen that the space allotted to the whole width of the apartments is three in number. In the centre a circular apartment is introduced and covered with a dome, which might have been raised, in the vertical combination, another story, and thus have added more majesty to the elevation. And here we repeat, that in

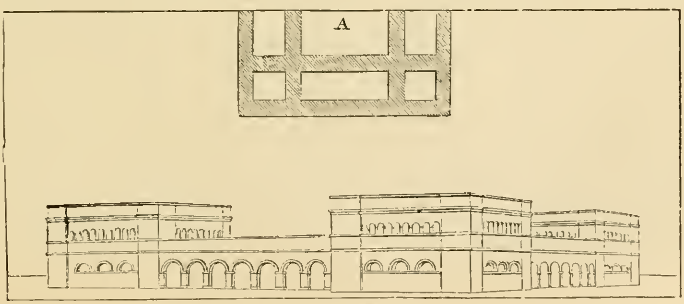

Fig. 1026.

designing buildings of more than one story, (for it cannot be too often impressed on the mind of the student), the combination of the vertical with the horizontal distribution will suggest an infinite variety of features. which the artist may mould to his fancy, although it must be so restrained as to make it subservient to the rules upon which fitness depends.

2859*a*. We close this portion of the subject with an example in perspective from Durand. The general plan, A, *fig*. 1026., will be found similar to No. 11 in *fig*. 1021., and the distribution may be a good practice for the student to develope. It is an excellent example for exhibiting of what plastic nature are the buildings which the vertical combinations will admit as based on those which are horizontal.

Sect. V.

GENERAL PRINCIPLES OF PROPORTION.

(The following pages of this section were originally compiled by the late Edward Cresy for his *Encyclopædia of Civil Engineering*, published by Messrs. Longmans, who have now deemed it preferable to place it in this edition of Gwilt's *Encyclopædia of Architecture*, as being in every respect a more suitable place for it.) (1867).

That branch of the principles of architecture which is most intimately connected with the architect's practice, the *proportioning of masses*, or the arrangements for the supports of an edifice, must be the objects of his unwearied study and attention. We shall, therefore, here endeavour to point out, as briefly as possible. the general features which in this respect belong to the two oldest divisions, viz. the Greek, and the Roman, architecture.

That part of Greece which lies to the south of Thessaly, near the foot of Mount Othrys, is supposed to have contained the capital of Hellen, who left his kingdom to his three sons Æolus. Dorus, and Xuthus, the second son becoming the founder of the Dorian race, and the youngest that of the Ionian.

Architecture can hardly be said to have existed as a science until the Dorians perfected that style, which we find in the temples and other buildings scattered throughout those islands and countries in the Mediterranean Sea which received Doric colonies. The dwellings of these early civilisers of mankind were plain and simple; the laws of Lycurgus forbade the use of any carving or decoration, their doors being fashioned only with the saw, and their roofs by the axe; but in their temples and public edifices, they were encouraged to bestow more labour and superior workmanship: the Dorian architecture appears never to have undergone any great change; the same style, and almost the same proportions, are found in most of the examples that have been spared us.

These people spread a knowledge of the arts of construction wherever they settled; and we find them at a very early period in the northern districts of Greece, under the Olympian chain of mountains, in the island of Crete, on the eastern side of the northern coast, on which is situated the town of Cnossus with its harbours, Heracleum and Apollonia, at which latter places their religious rites were celebrated. After having overrun Thessaly, they sent from thence a colony to the district of Driopis, called the Doric Tripolis, between Œta and Parnassus, from the union of the three cities Bæum, Cytinium, and Erineus, and, subsequently, when Acyphas was added, Tetrapolis.

The country next occupied by the Doric tribes extended from the river Sperchius beyond Œta to Parnassus and Thermopylæ, but the most important of their migrations was that called the Return of the Heraclidæ. After this period they were for a short time driven into Attica, where they received protection from Theseus, and when again settled in the Peloponnesus, they sent out colonies to Rhodes, Cnidus, and Cos, led by princes of the Heraclidæ from Argos and Epidaurus. Another colony from Trœzen was established at Halicarnassus. The towns which composed the Tripolis of Rhodes, together with Cnidus, Cos, and Halicarnassus, formed the Doric league called Hexapolis, but after the separation of the latter place, Pentapolis: this league met on the Triapian promontory to celebrate the rites of Apollo and Ceres. A colony was sent from Lindos to Telos; others from Cos, Nisyrus and Calydna; from Argos to Carpathus, now the island of Scapanta; from Cnidus to Syme, a town of Asia Minor; from Megara a migration took place, which settled at Astypalea, one of the Cyclades; and others to Anaphe, Thera, Phalegandros, Melos, Myndus, Mylasa, Cryassa, Synnada, and Noricum in Phrygia.

The Rhodians founded Gagæ, and Corydalla in Lycia, on the shores of Asia Minor; Phaselis on the confines of that country; Pamphylia; and Soli in Cilicia. According to Thucydides, about 713 years before Christ, Antiphemus led a colony from Lindus, and founded the town of Gela in Sicily.

Corinth sent out numerous colonies from Lechæum in the Cresæan Gulf, which founded Syracuse about 760 years before Christ; Molycrion, Chalcis, towns of Æolia; Salicum in Acarnania; Ambracia and Anactorium in Epirus; Leucadia, now the island of St. Maura, which was formerly joined to the continent by a narrow isthmus; Corcyra, on the coast of Epirus; Epidamnus in Macedonia; Apollonia Potidæa, with several others.

Issa, an island in the Adriatic, was peopled from Syracuse. Megara, situated between Corinth and Athens on the Sinus Saronicus after it became a part of the territory of the Heraclidæ, sent colonies to Astacus in Bithynia and Chalcedon, another city in that province opposite to Byzantium, Selymbria in Thrace, and Heraclea in Pontus, celebrated for its naval power.

Megara also colonised Hybla in Sicily, famous for its wild thyme and honey, which people founded Selinus. Sparta founded Tarentum about 700 years before Christ, which at one time comprised thirteen tributary cities within its government, and could muster 100,000 foot and 3000 horse.

From Gela, which was colonised from Lindus in the Island of Rhodes, originated Agrigentum, a place of considerable importance at the time the Cretan Phalaris obtained the sovereignty; indeed Crete and Rhodes jointly may be said to be the founders of Agrigentum.

In following the progress of the Heraclidæ along the shores of the Mediterranean to the Pillars of Hercules, we find wherever they settled those beautiful examples of construction in masonry which we can never be weary of admiring and studying. The temples in the Doric style in Sicily are of great beauty, and they may be some years anterior to those now remaining in Greece, but the difference cannot be very great: those at Syracuse and Agrigentum were constructed from the spoils obtained when Hiero defeated the Carthaginian general Hamilcar at Himera, and those at Athens were not built till some time after the defeat of Xerxes; but by some of the historians it is said that both battles were fought on the same day, that whilst Hiero was obtaining his independence, the Persians were overthrown at Salamis. Some time, however, elapsed after these victories before the Athenians and other states of Greece which had been engaged in the war recovered their prosperous condition; and it was not until the time of Pericles, which is nearly 50 years after the building of the temples at Agrigentum and Syracuse, that the restoration of the Parthenon and other public buildings throughout Greece was undertaken. The temples at Selinus are said to have been built when the city was founded, 620 years before Christ, and it is asserted they were entirely destroyed when the inhabitants deserted the city 250 years after its foundation: could this be proved, they would rank among the first erected.

The Propylea at Athens was built by Mnesicles in the 85th Olympiad; and a few years afterwards, when Pericles governed, Ictinus completed the Parthenon, and probably the temple of Theseus. The temples at Sunium and Phygalia were also the work of that renowned architect, and are deservedly ranked for their proportions and execution among the most graceful productions of Greek architecture. The temple of Jupiter Panhellenius in the Island of Egina was founded by Eacus before the Trojan war, but the ruins we now admire no doubt may be referred to the time of Pericles.

The source of those beautiful effects which have received the almost instinctive admiration of every age and country can only be traced by correct measurement, and a careful observation of the proportions of the masses, which will almost irresistibly convince us that in temples and fronts of porticoes one general law prevailed, and was applied to all tetrastyle, hexastyle, and octastyle arrangements, based upon the proportion of a cube. This is found to govern most of the designs executed from the time of Pericles to the death of Alexander, the golden age of Greek art, when sculptors, painters, architects, and engineers were called forth to vie with each other in their several branches, and workmen of skill and ingenuity were found to embody the suggestions of their imagination; and the results would lead us to suppose that the acmé of perfection was attained, for since that period none of the productions either in sculpture or architecture have equalled those of the Greeks in the simple elegance of their design, or the excellence of their execution.

Tetrastyle Porticoes with four columns exhibit the simplest, and perhaps the earliest, application of the Doric order; the entire façade is comprised within a square, the height being divided into three portions, the upper constituting the entablature, and the other two-thirds being divided equally between the supports and their three intercolumniations, making the latter a little more than a diameter. We may imagine the square divided in its height and width by 8, making altogether 64 compartments of equal area; the upper 8 devoted to the pediment will have, when the inclined sides are set out, a diminution of one-half their area, four whole squares being rejected in those parts above the pediment, the area of the tympanum being only equal to four. The entire mass is thus reduced to the area of 60 of these squares, which are thus disposed of; 20 are given to the supports, or 5 cubes to each column, 20 are divided between the three intercolumniations, and the remaining 20 constitute the load supported; the columns are 5 diameters in height, and bear no more than their own weight, a due harmony being obtained throughout; the eye is satisfied that the load cannot distress its supports, and the spaces between the supporting masses are again proportioned and made equal to either, so that we have a triple division, — one, the perpendicular arrangements of the supports, another their just distribution or equal distances, and the third, the entablature proportioned to the strength that is to carry it, all of which are comprised within the boundary of a square. The tetrastyle porticoes that remain are not numerous, and none are perfect; three have been selected, which will enable us to test the idea we have attempted to define. First, that at Eleusis, the entire width of which is 20 feet 6 inches, the height 21 feet 6 inches; and if we reject half the height of the pediment we shall have a square: the united diameter of the columns only varies 5 inches in width from those of the intercolumniations.

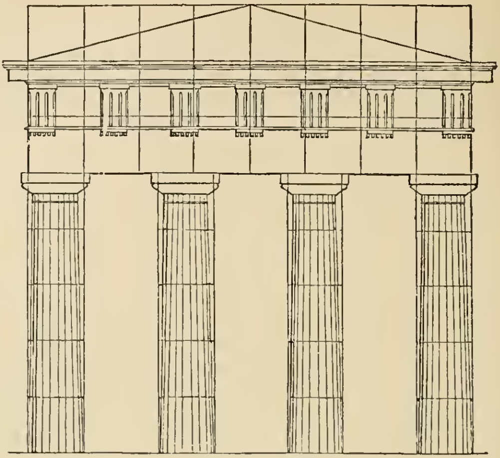

Fig. 1027. TETRASTYLE PORTICOES.

If we divide the height into three, rejecting, as already observed, half the pediment, which in this case is 1 foot 1½ inch, we have for the height of the square 20 feet 4 inches, whilst the entire width is 20 feet 6 inches, a difference not very great: this divided into three, and giving two-thirds to the height of the columns, would make them only 13 feet 6 inches and 8 seconds, whilst they really are 14 feet 2½ inches in height. In this example the entire height, which we may call 21 feet 5¼ inches, is divided into three, two parts of which constitute the height of the columns.

In the Temple of Themis at Rhamnus, the width is 20 feet 11 inches, and the height the same, the diameters of the columns being in excess 3 inches only above the width of the intercolumniations.

In the Doric Portico at Athens, the entire height equals nearly the width.

Hexastyle Porticoes. — The practice of the Dorian architects, in setting out a temple with six columns in front, appears sometimes to have been to divide the width into twelve parts, the height without the pediment being made equal to eight of them; thus forming a façade within a parallelogram or a square and a half: as the ninth division in height cuts the pediment in half, we have thirty-six squares for the entablature or mass supported, being the same quantity found in the six columns and the five intercolumniations; at other times we find the entire width divided into nine parts, and six given to the height, one of which indicates the pediment, thus rising a ninth: if a circle be described in the tympanum, and a horizontal line drawn through the centre, cutting off a twelfth of the height, the remaining $\frac{11}{12}$ being divided into three equal parts, the upper third, or entablature, being the part supported, the remaining $\frac{2}{3}$ are divided between the columns and their interspaces; thus making the columns equal to $\frac{2}{3}$ of the height comprised between the centre of the tympanum and the platform upon which they were placed.

If we take each of these nine parts as 5 feet, we have 45 feet for the width, 30 for the height, including the 5 feet for the rise of the pediment, which if we divide by the horizontal line, to obtain its true area or quantity, we shall have 2 feet 6 inches for its mean height, and 6 feet 8 inches for that of the level entablature: for as we have observed, these two dimensions, which make 9 feet 2 inches, must be equal to half the height of the columns, or the whole will not be divided into three parts; or, which is the same thing, the height from the centre of the pediment must be divided into three parts, and the upper division taken for the entablature. These proportions are exceedingly simple in their application; if it were intended that the columns and the spaces between them should be equal, half the width of the façade, or 22 feet 6 inches, should be distributed among the intercolumniations, and the other half divided among the columns.

The Temple of Theseus at Athens is one of the best preserved as well as the most admired, and was probably erected soon after the Parthenon; it is of Pentelican marble, adorned with admirable sculptures. The total width of its hexastyle portico is 45 feet, and its height, instead of 30, is 31 feet; the extra foot, which prevents it being an exact square and a half, is given to the pediment, which probably has undergone some change, as it rises much more than the ninth of its whole extent.

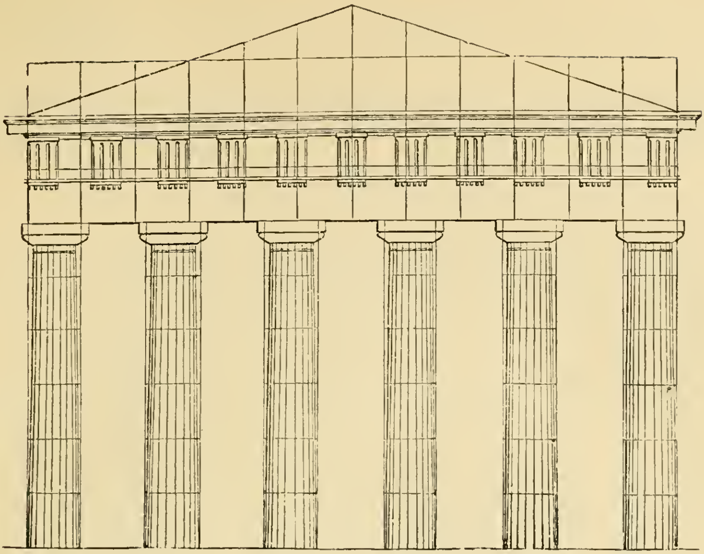

Fig. 1028. HEXASTYLE PORTICOES.

	Feet.	In.
The height of the pediment is	5	9·75
level cornice	1	0·45
frieze	2	8·55
architrave	2	8·9
columns	18	8·8
and of the entire façade	31	0·4

	Feet.	In.		
half the pediment	2	10·875		
the level entablature	6	5·9		
making together a dimension nearly equal to half the height of the columns.			9	4·775

The façade of this beautiful temple is divided equally into three parts; ⅓ is given to the entablature, and the other two to the columns and their intercolumniations. The outer columns are 3 feet 4·85 inches in diameter, and all the others 3 feet 3·4 inches. The middle intercolumniation is 5 feet 3·95 inches, the next two each 5 feet 4·05 inches, and those towards the angles 4 feet 6·35 inches. The diameters taken together are 20 feet, and the intercolumniations 25 feet, so that the columns and their spaces are not in equal proportions: the former would have required a diameter of 3 feet 9 inches, which would have made them nearly five diameters in height, instead of what they are; they would have been heavier, it is true, but more in accordance with the early examples.

The Hexastyle Temples at Rhamnus, Sunium, Egina, Eleusis, and Phygalia, are not sufficiently perfect to enable us to decide whether our principles would apply to them: but from the judgment we can form from their remains, they appear to have been all comprised in a square and a half, and their entablatures and pediments in the proportion of a third of the whole.

The Hexastyle Temple at Segesta in Sicily is sufficiently perfect to enable us to judge of its entire proportions.

	Feet.	In.
Its total length is	76	0
and height	50	8

or the whole façade is bounded by a square and a half.

	Feet.	In.
The height of the columns is	31	0
entablature	11	4
pediment	8	4
Total	50	8

	Feet.	In.
Half the height of the pediment is - - - -	4	2
entablature - - - -	11	4
Total height of superincumbent mass - - -	15	6

which is exactly one-half of 31 feet, the height of the columns; so that we have, as far as height is concerned, $\frac{1}{3}$ for the superincumbent mass or entablature, and $\frac{2}{3}$ for the columns and their intercolumniations.

	Feet.
The columns have their united diameters - - -	37
The intercolumniations ditto - - - - -	39

so that they are not in exact equality, although the difference is not considerable.

At Agrigentum are the remains of four Hexastyle Temples.—That of Juno Lucina is without its cornice and pediment: the diameter of the columns is 4 feet 6 inches, and the entire width is 55 feet. The united diameter of the six columns is 26, and of the five intercolumniations 29 feet.

The Temple of Concord is in width 57 feet, and in height 38; or it is comprised within square and a half.

	Feet.	In.
The height of the columns is - - -	23	0
entablature - - -	8	0
pediment - - -	7	0
	38	0

	Feet	In
Half the height of the pediment is - - - -	3	6
The height of the entablature - - - -	8	0
which is equal to half the height of the column - -	11	6

Thus one-third of the entire height is given to the entablature or mass supported. The united diameter of the columns is 28 feet, and that of the intercolumniations 29 feet, the latter being a little in excess.

Temple of Hercules.—The total width is 84 feet, and height 56, which is a square and a half.

	Feet.	In.
The height of the columns is - - - - - -	33	6
entablature - - - -	13	0
pediment - - - - - -	9	6
Making a total height of - - - - -	56	0

The united diameter of the columns is 43 feet, and that of the intercolumniations 41 feet. The height of the entablature and half pediment is in this case 17 feet 9 inches, instead of 16 feet 9 inches, as it should have been to have equalled half the height of the columns.

Temple of Castor and Pollux is imperfect, but the total width is 45 feet, of which the diameters of the six columns occupy 24 feet, and the intercolumniations 21. The height of the columns is about 20 feet, and that of the entablature 8 feet, as measured on the flank. This temple nearly agrees in width with the temple of Theseus at Athens, but its proportions vary; there is not sufficient remaining to judge of its entire form.

At Selinus are the remains of five hexastyle temples. In one the total extent is 51 feet, of which the united diameters of the columns occupy 24, and that of the five intercolumniations 27 feet. The height of the entablature is about 11 feet, but that of the columns and pediments has not been yet ascertained.

The second temple is in width 77 feet 6 inches, the diameters of the columns occupying 37 feet, and the five intercolumniations 40 feet 6 inches; the height is 50 feet 8 inches, so that the whole façade is included in a parallelogram, having a height not quite equal to two-thirds its extent, or a square and a half.

	Ft.	In.
The height of the columns is - - - -	29	4
entablature - - - -	13	4
pediment - - - - -	8	0
In all - - - - -	50	8

which is a foot less than the required height.

In this example there is not an exact correspondence between the columns and what they support: the entablature and pediment occupy 13, the intercolumniation 12, and the columns 11 parts out of the whole number, 36, into which the parallelogram may be supposed to be divided.

The third temple is not sufficiently measured to enable us to examine into its proportions; the total width is 79 feet, of which the united diameters of the six columns occupy 36 feet, and the five intercolumniations 43 feet.

The fourth temple is in width 84 feet 9 inches, and in height 56 feet 6 inches or a square and a half.

	Feet.	In.
The height of the columns being - - -	34	0
entablature - - -	11	6
pediment - - -	11	0
In all the height is - - -	56	6

	Ft.	In.
The height of half the pediment is - - - -	5	6
the level entablature - - - -	11	6
Making a height equal to half that of the columns, viz. -	17	0

Thus the heights are in just proportion, one-third being given to the entablature and pediment, and the other two-thirds to the columns and their intermediate spaces, which are in the proportions of 44 feet 9 inches for the columns, and 40 feet for the five intercolumniations.

The fifth temple is 81 feet in front, the six columns occupying 37 feet 8 inches, and the five intercolumniations 43 feet 4 inches. The height of the column is 31 feet, and the entablature 15 feet 6 inches, or one-half the height of the column, so that, without the pediment, the entablature in this example would constitute a third; and if the pediment had only risen 7 feet 6 inches, to make the general proportion a square and a half, these columns would have had more to sustain than any other example we have yet referred to.

Octastyle Temples.— We will now apply these principles to a façade with eight columns, and endeavour to follow the same system. We have already had a square, and a square and a half, as the form or figure within which the design was comprised; the portico of four columns being circumscribed by the one, and that of six by the other; and as in the octastyle there are double the number of columns contained in the first, a double square is required to comprise it, that the same relative proportions may be obtained.

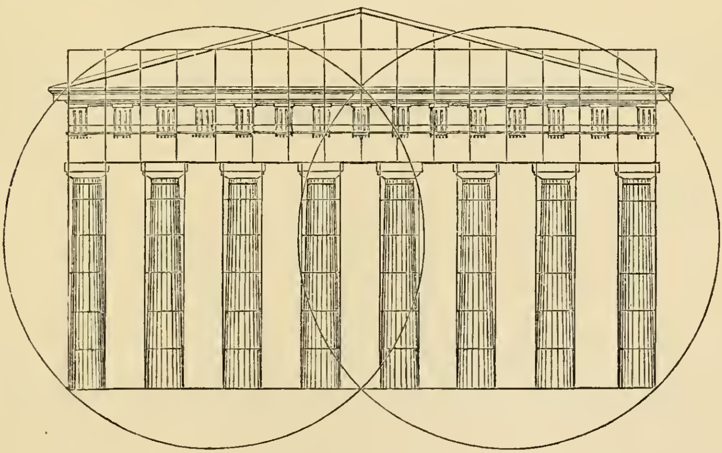

Fig. 1029. OCTASTYLE PORTICOES.

After the width of the façade is determined, it is divided into sixteen parts, and ten are set out for the height to the top of the tympanum of the pediment; which generally rising a ninth of the extent, two divisions will serve to denote it, and if a circle be inscribed in the tympanum, and a horizontal line drawn through the centre, we shall have a parallelogram 16 squares in width, and 9 in height.

Six squares in height will determine the under side of the entablature, which, if divided equally between the columns and their intercolumniations, would give 48 squares to each, which are precisely the proportions of the example we are about to examine.

The Parthenon or Temple of Minerva at Athens is admitted to have the most beautiful proportions of all octastyle Greek examples; its entire width, measured in the front of the columns at the base, is 100 feet 9 inches, and its height to the centre of the tympanum, from the level of the platform on which the columns are placed, 51 feet $2\frac{1}{2}$ inches, 20 inches only beyond what it should be to accord with the rules laid down. Dividing this height into three parts, we have in round numbers 17 feet 1 inch for each: the height of the entablature and half pediment is 17 feet, and that of the columns 34 feet 2 inches, precisely one-third of the height being devoted to the entablature, the lower two-thirds being divided between these and their intercolumniations; adding all the diameters together, we have 49 feet 6 inches; the intercolumniations being 51 feet 3 inches, or only 1 foot 9 inches in excess for the latter: hence if a parallelogram or double square be divided into $40\frac{1}{2}$ squares, and $13\frac{1}{2}$ be given to the columns, the same quantities to the intercolumniations, the entablature and its pediment, we should have the general proportions of the Parthenon, the difference before alluded to being too slight to produce any effect on the eye in so large a mass. The height to the centre of the pediment is 51 feet $2\frac{1}{2}$ inches, consequently the width to make it an exact double square should have been 102 feet 5 inches, instead of 100 feet 9 inches; and this difference may have been occasioned by the difficulty of setting out the triglyphs or from the idea that the width, as measured along the corona, should have some consideration, and a mean be established.

As we have before observed that the Parthenon is considered perfect both in its design and execution, a more detailed account of its construction and mouldings will be the best illustration that can be offered on the subject of Greek masonry, premising that in the present instance it is all of the finest marble from Pentelicus.

The Doric Column varies considerably in its proportions, some not being more than four diameters in height, whilst in other examples they are from that to six and a half: those we are now considering are formed of twelve blocks; on the upper and lower bed of each are described two circles, the circumference of the outer being 9 inches from the edge, whilst the inner circle is only 20 inches in diameter. The space between these is not polished, but left rough as from the chisel, and a little sunk for the purpose of retaining

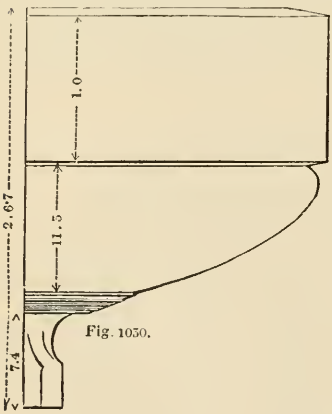

Fig. 1030.

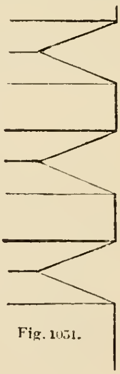

Fig. 1031.

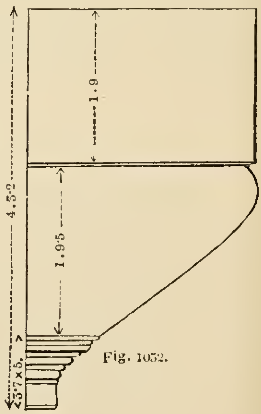

Fig. 1032.

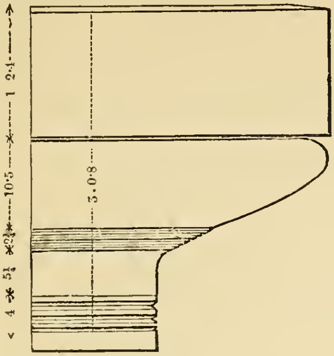
DORIC CAPITALS, SELINUNTUM.

a fine mortar or cement. In the centre of each block is a square hole, measuring $5\frac{1}{2}$ inches on each side, sunk 3 inches in depth; in these were inserted pieces of hard wood, 6 inches in length, to steady the blocks, and keep them from being displaced, particularly at the time the flutes were worked, or the exterior was undergoing the process of polishing. The outer columns are 6 feet $3\frac{6}{10}$ inches in diameter at bottom, and the others 6 feet $1\frac{8}{10}$ inch, the upper diameter of the latter being 4 feet $9\frac{3}{4}$ inches: their total height is 34 feet $2\frac{8}{10}$ inches, or nearly five diameters and a half; the diminution is not regular, there being at a certain height a swelling or entasis, which improves the outline, and destroys that meagreness which is the result of a straight line. The angular column is a little more in diameter, that it may not appear less than the others, which are not so surrounded by air.

The shafts have generally twenty flutes, uniting in an arris, and not with a square fillet between them, as in the other orders; they are elliptical in some examples, as at Pæstum, where their number is 16 and 24; the heads are variously finished. The capital of this order varies in its height from $\frac{1}{3}$ to $\frac{2}{3}$ of the lower diameter of the columns, and the abacus is sometimes more than ¼ longer than that width, all these proportions depending more upon the height of the column than upon its lower diameter.



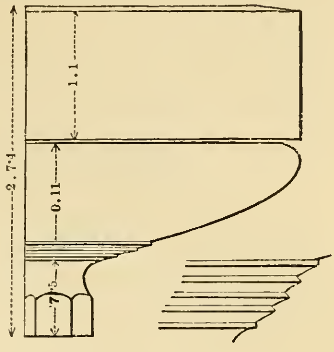


Fig. 1033. SELINUNTUM. Fig. 1034.

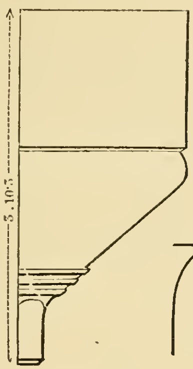
Under the abacus is the *echinus* or *ovolo*, which is beautifully turned, or cut like the bell or profile of a flat cup, under which are usually from 3 to 5 annulets. The contour



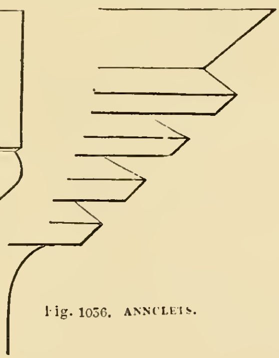


Fig. 1036. ANNULETS.

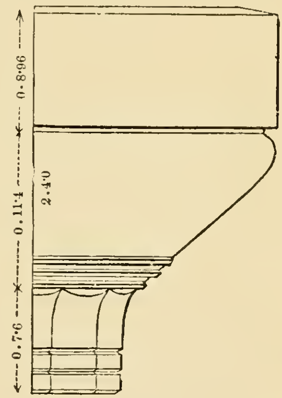

Fig. 1035. DORIC CAPITALS. SELINUNTUM. Fig. 1037. DORIC CAPITALS.

or profile of the echinus is a portion of a curve formed by the section of a cone. Where the capital is placed on the column is another sinking, and sometimes three; and the true and delicate manner in which these lines are cut gives a charm that more elaborate sculpture fails in attaining.

The architrave of the Parthenon, which extends from the centre of one column to that of the other, is in three thicknesses, showing two joints on the soffite. The frieze is admirably contrived not to overload the architrave: the triglyphs are each in a single block, 3 feet wide and 2 feet 3 inches in thickness. On each side is a perpendicular groove 1½ inch deep, into which the sculptured metopes are slipped, the clear width between the triglyphs being 4 feet $3\frac{15}{100}$ inches, and the angular one 3 inches less: at the back of the metopes, and between the triglyphs, is a hollow space, from 8 to 14 inches deep. The metope is held to the back of the frieze by a metal cramp in the form of an H, 2 feet long, and attached on each side to the adjoining triglyph by others 17 inches in length. The cornice is in one thickness; the angular block covers two mutules, each of the others one space and a mutule. For further particulars of the construction of the Parthenon, and for several dimensions omitted by Stuart, the writer must refer to some notes he added a few years after his return from Athens to his wife's (Mrs. Cresy) translation of "The Lives of celebrated Architects, ancient and modern, by Francesco Milizia," 2 vols. 8vo. 1826.

In the Doric Order we may trace a reason for the direction given to the several lines, whether perpendicular or horizontal; and although there is great variety in the form of the members, yet when examined in detail, nothing will be found to disturb the unity of the design. The voids are nicely adjusted to the solids, and all those parts, as the columns and triglyphs, intended as supports, are striated perpendicularly, whilst those supported are decorated with members and mouldings running horizontally, and indicating rest or repose. The inclined lines of the pediment are the only exception to this rule, and they are composed of longitudinal members, placed consistently with their use, viz. that of throwing off the water from the roof: so well-combined a whole, consisting of parts all expressing their utility, deserves our admiration: even the annulets under the echinus of the capital indicate so many cinctures to bind the tops of the perpendicular flutes together, before the elegant tazza or cup-like vase is placed between the shaft and the abacus.

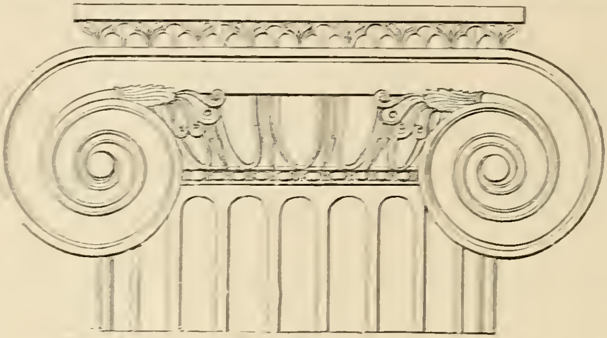

Fig. [illegible] IONIC CAPITAL.

Ionic Proportions. — This style seems very nearly coeval with the Doric: it is supposed by some commentators to be of Achaic origin, by others of Persian; both Greeks and Persians may have contributed to its formation; the term Ionic was applied to it by Vitruvius from its being first used by the inhabitants of Ionia; the few perfect examples remaining are of the greatest beauty, both in design and execution.

The shores of Asia Minor, in the reign of Medon, the son of Codrus, were taken possession of by a number of Greeks, who commenced their migration about a thousand years before Christ; after they had passed from Attica, they first mixed with the inhabitants of Caria and the Leleges. Helen the son of Deucalion, who reigned in Phthia, situated between the rivers Peneus and Asopus, having left his kingdom to his eldest son, the others sought for settlements elsewhere: Dorus established himself in the neighbourhood of Parnassus and Xuthus in Attica, where he married the daughter of Erechtheus, the sovereign of Athens, and had by her two sons Achæus and Io.

Io with a number of followers from Athens went into the Peloponnesus and established himself at Ægialus, a place on the sea-shore lying between Elis and Sicyonia; here he married the daughter of Selinuntus, king of that district, at whose death he succeeded to his dominions; Io built Helice, and called the inhabitants Ionians. Some time after Io was recalled to Athens to command the troops in a war against the Thracians, over whom he obtained a victory: the Athenians in consequence designated themselves Ionians. Attica was divided by Io among four tribes, the Geleontes, the Argades, the Ægicores, and the Hopletes, the names of his four sons, or according to Strabo, labourers, artisans, priests, and guards.

When Erechtheus died, Cecrops, his eldest son, succeeded, and Xuthus, his other son, was driven out of Attica; in the country he afterwards inhabited he built four towns, Œnoe, Marathon, Probalinthus, and Tricorythus, after which he died at Ægialus; his son Achæus then passed into Laconia and Thessaly, when he recovered his father's dominions; his two sons Archander and Architeles went into Argos, where they married two daughters of Danaus, one of the royal family of Argos. The Lacedæmonians and Ægeans were called after Achæus Achæans, until the return of the Heraclidæ, when they were driven out, and obliged to flee to Ægialus and into Attica, where the Ionians again received them on account of their common origin.

At the death of Codrus, his youngest son Nileus embarked with all the Ionians into Asia, where they occupied eight of the Ionian cities, viz. Miletus, Ephesus, Myus, Teos, Priene, Lebedos, Erythræ, and Clazomenæ; the other four founded by the Ionians were Colophon, Phocæa, Samos, and Chios. The Ionians formed themselves into twelve states, because, according to Herodotus, they were previously so divided in the Peloponnesus; the names of the cities from whence they were ejected were Pellene near Sicyon, Ægira and Ægæ, Bura, Helice, Ægium, Rypæ, Patræ, Pharæ, Olenus, Dyme and Tritæa, the last being an island.

The inhabitants of Athens who migrated from the Prytaneum were the most noble among the Ionians, though all who celebrated the Aplurian festival, from which alone the Ephesian and Colophonians were excluded, were afterwards called Ionians.

The appellations Doric, Ionic, and Corinthian are derived from Vitruvius: but it appears doubtful whether these terms were current among the Greeks: that author asserts that the first is the most ancient; "for Dorus, the son of Hellen, and the nymph Orseis, built the temple of Juno at Argos of this order when he reigned over the whole of Achaia and Peloponnesus; that many temples afterwards erected throughout Greece were of the Doric order, but by command of the Delphic oracle in a general assembly of the different states of Greece, thirteen colonies were sent into Asia, who built the cities before mentioned, and erected temples; among the first they dedicated was one to Apollo Panionios, having Doric proportions, and another to Diana, in which some variations was made. The first was of a masculine proportion, the other feminine, and the latter was the invention of the Ionian settlers, and afterwards called from them Ionic.

But if it be difficult to trace the Ionic order to its origin, we may analyse its proportions, and compare them with that order which prevailed so universally in Greece, which will lead us to remark that a very great change took place when the rules that guided the Doric builders were laid aside; at no other period were such material alterations made in the proportions of the masses, the columns, entablatures, and intercolumniations; to the Corinthian, so universally used in later times by the Romans, the feminine proportions were applied which are stated by Vitruvius to have commenced with the Ionians.

There is of course much fable in all the accounts that have reached us upon these important changes, but among them is one which seems to carry with it some semblance of truth, and which is as follows:—"when Hermogenes was employed to erect the temple of Bacchus at Teos, according to Vitruvius, the marble was prepared for one in the Doric style; but the architect changed his mind, from the idea that other proportions, afterwards called Ionic, were more suitable for the purpose, almost inducing the inference that Hermogenes was the inventor of those delicate proportions; he appears unquestionably to have displayed great skill and ingenuity in all his designs, and to have entertained the opinion that sacred buildings should not be constructed with Doric proportions, as they obliged the adoption of false and incongruous arrangements."

To obtain more delicate proportions, without sacrificing the great principle of making the weight supported equal to its supports, would seem at first difficult; in the example of the Doric order we have seen this practice universally adopted, and it is equally evident in the Ionic, though not exactly after the same method; the columns and their entablatures, or what they carry, agree in quantity, but their distribution is different. The square or figure which bounds the Ionic façade is divided into four parts, one of which is given to the entablature, a second to the columns, and the other two, or one half, are distributed among the intercolumniations.

In the quantity of material for constructing the two varieties of temples there is a considerable difference, the Doric requiring one-third more than the Ionic; for example, in a Doric tetrastyle portico where the area was 12, four parts would be given to the entablature, four to the columns, and four to the intercolumniations. In the Ionic three parts would be required for the entablatures, and three for the columns, six being allowed for the intercolumniations; thus one temple would have eight, and the other six parts solid out of twelve, consequently, with a given quantity of materials, two very different porticoes might be built, without making any change in the proportions which the columns bear to their entablatures. Hermogenes could construct with the same material a much larger temple in the Ionic style than in the Doric; and supposing the dimensions already decided upon, there would be a saving of labour and material: from the imperfect state of the Ionic temples remaining, it is scarcely possible to enter into a thorough examination of their proportions; that on the Ilissus at Athens, measured by Stuart, no longer exists, but its dimensions, given by that very accurate delineator, may serve our purpose as an example of a tetrastyle portico. Its entire width was 18 feet 7¾ inches, and height to the top of the level cornice in front 18 feet 4½ inches, to which must be added that of the tympanum of the pediment: multiplying the width by the height of the entablature and half the pediment, which together is 5 feet 7 inches and 10 parts, we have for the area of the portions supported 105 feet 4 inches and 9 parts: the quantity contained in the four columns is found by multiplying their united diameters, 7 feet 1 inch and 7 parts, with their height, 14 feet 9 inches and 4 parts, giving a product of 105 feet 4 inches and 9 parts as their area. The united intercolumniations in this example are 11 feet 6 inches and 2 parts, which multiplied by the height of the columns is 170 feet 1 inch and 9 parts for the area; 40 feet 7 inches and 9 parts less than it would have been had it equalled the quantity contained in the columns and their entablature, or been one-half the entire area of the façade.

The portico of this elegant example of Ionic was nearly a square without the pediment, and the supports and supported are in exact accordance as to quantity, whilst the intercolumniations are about 1½ times the quantity contained in the columns, instead of double. Departing a little from the proportions before us, let us endeavour to set out a

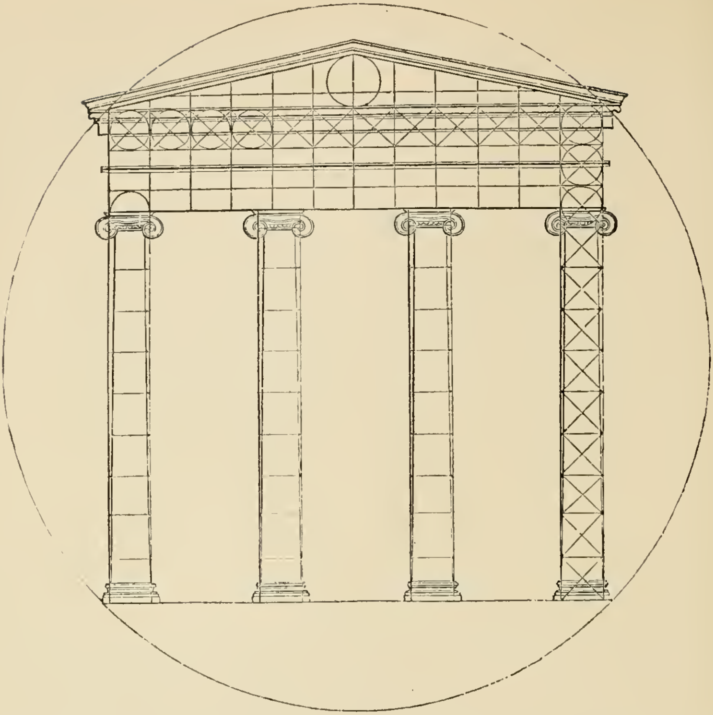

Fig. 1039. IONIC TETRASTYLE TEMPLES.

portico, as already done for the Doric order, having the same number of columns, and like the tetrastyle eustyle of Vitruvius, divide each side of the square which circumscribes it into $11\frac{1}{2}$ parts, premising that the pediment rises a ninth and one side of the square passes through its centre. The side of the square being divided into $11\frac{1}{2}$ parts, 1 is given to the diameter of the columns, 3 parts to the middle intercolumniation, and $2\frac{1}{4}$ to each of the others; thus the sites for the columns are obtained: dividing the upright sides of the square into the same number of parts, $8\frac{1}{2}$ are given to the height of the column, and the remaining 3 to the entablature and half pediment.

Multiplying $11\frac{1}{2}$ by the same, we have for the entire area $132\frac{1}{4}$, which if divided into 4 is 33 and a fraction for the columns, the same for the entablatures, and double that for the intercolumniations: the columns being four in number and $8\frac{1}{2}$ diameters in height, their area will be 34 parts; the intercolumniations being $7\frac{1}{2}$ in their united width, that multiplied by $8\frac{1}{2}$, their height, gives $63\frac{3}{4}$ for their area, and the entablature being 3 high and $11\frac{1}{2}$ in width, we have for its contents $34\frac{1}{2}$ parts, giving a result of nearly a fourth for the entablature as well as for the columns, and a half for the intercolumniations. By making some allowance for the diminution of the columns, an exact agreement between the quantities might be obtained; those in the intercolumniations would then be found equal to those in the entablature and its supports, or half the entire square devoted to solid and the other half to voids: had the columns of the temple on the Ilissus been about 1 inch less in diameter, its proportions would have been in close accordance with those of the figure, where the 4 columns occupy 38 squares, the entablature the same number, and the intercolumniations 76.

Ionic Hexastyle. Temple of Erechtheus at Athens.—This highly-enriched example, executed in the finest marble, is in height without the pediment 26 feet $6\frac{3}{4}$ inches, and in width, measured along the front of the corona, 40 feet 6 inches, so that this portion is comprised within a square and a half or nearly so: the lower diameter of the columns is 2 feet $3\frac{8}{10}$ inches, and the upper 1 foot $11\frac{2}{10}$ inches, giving a mean of 2 feet $1\frac{5}{10}$ inches; their collected diameters are 12 feet 9 inches, whilst that of the intercolumniations at the same level is 23 feet $1\frac{5}{10}$ inches, nearly double the space occupied by the columns. The height of the entablature without the pediment is 4 feet $11\frac{1}{4}$ inches, and its superficial content on the face 190 feet, and adding 85 feet for the area of the tympanum, we have altogether 275 feet.

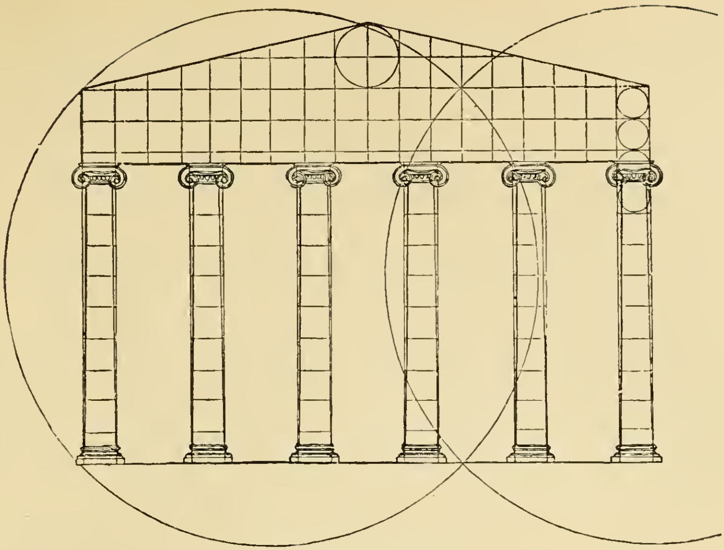

Fig. 1040. IONIC HEXASTYLE TEMPLES.

supposing the tympanum to rise a ninth of its base; the height of the columns is 21 feet $7\frac{1}{2}$ inches, and their united mean diameter 12 feet 9 inches, which being multiplied together produce 275 feet 8 inches, or nearly equivalent to the area of the mass they support. To obtain the exact quantity of mass and void, the mean diameters of the columns as well as of the intercolumniations should be taken; the greater the probable delicacy of execution, the greater is the necessity for the architect to balance his quantities exactly. In the subject now under consideration the whole is comprised within a square and a half; the supports and the entablature are equal, and the intercolumniations as much as the two together or one-half the whole. The height of the architrave is 2 feet $1\frac{5}{100}$ inches; that of the frieze 1 foot $11\frac{3}{4}$ inches, and the level part of the cornice $10\frac{45}{100}$ inches.

Roman Tetrastyle. Ionic Temple of Fortuna Virilis.—The width is 33 feet 6 inches, and height, including half the pediment, 37 feet 1 inch, comprising an area of 1242 feet 4 inches, one quarter of which, 313 feet 1 inch, nearly agrees with the quantity contained in the entablature as well as in the columns which support it; their height is 27 feet, and their united diameters 12 feet 4 inches, which multiplied together produce 333 feet for the area of the supports. The height of the entablature with half the pediment is 10 feet 1 inch: this multiplied by its width, 33 feet 6 inches, gives 337 feet 10 inches for the area of that supported: the intercolumniations are together 21 feet 2 inches, which multiplied by their height, 27 feet, gives 571 feet 6 inches for their area, about 100 feet less than the quantity comprised in the columns and entablature.

Without the pediment this façade is nearly square; its proportions rank very high in the estimation of all admirers of Roman architecture; it has, however, undergone many reparations before the stucco was put upon the columns; they were lighter, as was the entablature, the upper members of the cornice being somewhat heavier than is usual in the early examples of this order; if divested of these additions, and giving a trifle more to the intercolumniations, we shall obtain half the area for the columns, and a quarter for each of the other divisions; at present the columns equal in quantity the mass they carry.

If it be required to draw a tetrastyle portico in exact accordance with the rules laid down, after forming the square each side should be divided into 12 parts, or 144 squares, arranged like those of an abacus: one of these divisions on the base would become the diameter of the column, and nine their height, the other eight on the base would be devoted to the intercolumniations, and the upper three of the height to the entablature. The columns, 9 diameters in height, would thus comprise 36 squares, the intercolumniations 72, and the entablature and half pediment 36; consequently the columns and entablature would be equal in quantity, and the intercolumniations half the whole, or equal to the contents of the supports and supported.

Roman Hexastyle. Corinthian, Maison Carrée at Nismes. — This beautiful temple has undergone several restorations; its entire width and height to the apex of the pediment is 43 feet 8 inches, from whence it has derived its name. The height of the columns, including base and capital, is 29 feet 6 inches, that of the entablature 6 feet 9 inches, and of the pediment 7 feet 5 inches; taking away half the height of the pediment, we have 39 feet 11 inches and 6 parts, which may be considered as 40 feet; this multiplied by the width produces for the entire area 1746 feet 8 inches. The superficial content of pediment and entablature, 456 feet 8 inches, is obtained by multiplying the entire width by 10 feet $5\frac{1}{4}$ inches, the height of the entablature and half the pediment, which superficies is only 20 feet 2 inches more than a quarter of the whole. The united diameter of the six columns is 17 feet 6 inches, and that of the intercolumniations 26 feet 2 inches, so that they are in the proportions to each other of 2 and 3, the whole being 5, one having an area of 515 feet 9 inches, the other 772 feet; when added together they are nearly three times the area of the part supported.

The proportion between the columns and intercolumniations of the temple at Assissi is also similar, the height of the columns is 32 feet 10 inches, and the total width of the six 52 feet, which dimensions multiplied together produce 1707 feet 4 inches, one-fifth being 341 feet 6 inches nearly.

The area of the columns is 684 feet, and that of the intercolumniations 1023 feet 4 inches, giving a proportion of two-fifths and three-fifths. The entablature, pediment, and pedestals upon which the columns are placed seem to have undergone a change since their erection. If the whole extent of an hexastyle portico be divided into 18 parts, and one be called the diameter, to obtain the same proportions as those laid down for a tetrastyle portico, the height up to the centre of the pediment must include 12 only of those parts, which would give a portico of a square and a half, comprising 216 squares; the 6 columns, each 9 diameters in height, would require 54; the 5 intercolumniations, double that number, or 108, and the entablature and half pediment 54.

Roman Octastyle. — The Pantheon at Rome, which has a portico of 8 columns, is one of the best examples that can be selected for examination. The total width is 109 feet 10 inches; the diameters of the eight columns 39 feet 5 inches, and the seven intercolumniations 70 feet 5 inches, or nearly in the proportion of 1 to 2. The height of the columns is 46 feet 5 inches, and that of the entablature and half pediment 23 feet $2\frac{1}{2}$ inches, together 69 feet $7\frac{1}{2}$ inches, nearly a square and a half, the area of which is 7647 feet 2 inches.

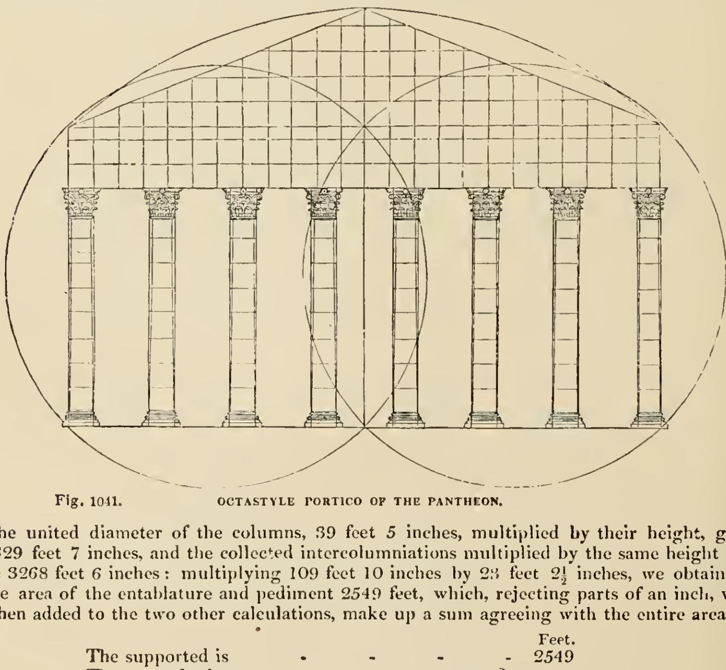

Fig. 1041. OCTASTYLE PORTICO OF THE PANTHEON.

The united diameter of the columns, 39 feet 5 inches, multiplied by their height, gives 1829 feet 7 inches, and the collected intercolumniations multiplied by the same height will be 3268 feet 6 inches: multiplying 109 feet 10 inches by 23 feet $2\frac{1}{2}$ inches, we obtain for the area of the entablature and pediment 2549 feet, which, rejecting parts of an inch, will, when added to the two other calculations, make up a sum agreeing with the entire area.

			Feet.
The supported is	- - - -		2549
The area of columns	-	1829·7	5098
of intercolumniations	-	3268·6	
Together	-		7647

A line drawn through the centre of the pediment, another at half the height of the columns, and a third under the entablature, would divide the height into three equal portions, proving that, in this example, the Romans made the part supported one-third of the whole, and divided the other two between the columns and their intercolumniations. The shaft of each column is cut out of a single block of granite ; they are not sufficiently delicate to be exactly in the proportion of half the quantity contained in the intercolumniations ; but if allowance be made for their diminution, the difference is not very great. The whole width being 109 feet 10 inches, the third, 36 feet 7 inches and 4 parts, is nearly a mean between the collected diameters of the top and bottom of the shaft, making the intercolumniations double the quantity contained in the supports, or equal to that of the supports added to the mass they carry. The whole would then be divided into four, as in the previous examples of the Ionic, and two portions given to the intercolumniations.

The Pantheon Portico is a double square without the pediment, or nearly so, the length of the level cornice, which crowns the entablature, being double the height of the order : this, no doubt, was the outline of the proportions before the heavy pediment was placed upon it, which in all probability was heightened beyond the ordinary rise of a ninth, for the purpose of concealing the wall behind it. The Roman proportions are frequently made independently of the pediment; the tetrastyle porticoes are a square, the hexastyle a square and a half, and the octastyle, as in this instance, a double square without it.

To set out an octastyle portico, in which half the pediment should be comprised within the double square, after dividing the width into 24 and the height into 12, which multiplied produce 288 squares, 72 are given to the column, the same to the entablature and half pediment, and double that, or 144, to the intercolumnations, or proportions similar to those laid down for the tetrastyle and hexastyle porticoes. The columns in such a case would be nine diameters in height, the entablature and half pediment three : supposing the latter to rise a ninth of the span, the remainder would be distributed among architrave, frieze, and cornice.

We have endeavoured to show the proportions required in a tetrastyle, hexastyle, and octastyle portico among the Dorians, the Ionians, and their followers the Romans: the square and a half, or the double square, were the outlines or boundary figures from whence the other proportions were deduced.

The great difference of character in the Doric and Ionic designs arises from the distance at which the columns are placed, which affects the proportions of the entablature laid upon them, as well as that of the columns themselves ; where these are six diameters in height or consist of six cubes, they are made to carry the same quantity, whatever may be their distance apart, and where drawn out to nine diameters, they have only their own weight to support ; but the form given to this weight, or the proportions of architrave, frieze, and cornice, vary, as the intercolumniations are of one or more diameters.

It has been too generally considered that the orders derived their proportions from the lower diameter of the columns, without reference to their application : this has produced a variety of design, but at the same time occasioned a great departure from the true principles, and led to very important errors. The Tuscan, the Doric, the Ionic, the Corinthian, and Composite orders have been laid down in modules or measures of various kinds, which the young architect has adopted as mere isolations, regardless of the many other considerations which have stamped beauty on his model ; hence we have imitations, but soul is wanting.

The Doric order is treated of as so many diameters in height according to its age, and the entablature is said to be heavy or light, as it was of early or late execution ; the other orders have been chronicled in a similar manner, and architecture has been fettered, and its great principles lost, or at least neglected : it is true that the outline which bounds the figure has undergone but few changes, but the subordinate parts or the filling-in are susceptible of interminable variety. An object inscribed within a circle is perhaps the most easily compassed by the eye, next that within the square, and when a building is vast, and distance is necessary to comprise a view of the whole, the double square ; beyond this the ancients seem seldom to have gone for the proportions of their façades, or of a portico intended to be seen in front. After the masses were proportioned, their decorations were more various than the buildings themselves ; no two are perfectly alike, but the great difference is in their ornaments and enrichments, or in the number of diameters contained in the height of the columns.

The Parthenon and Pantheon porticoes are both octastyle, each admitted to be as beautiful as they can be — one the perfection of sober grandeur, the other of cheerful lightness ; one Greek Doric, the other Corinthian, both comprised within a double square, and having their columns equal in quantity to the mass of entablature they support : where, then, is the difference between the two examples? It results, as we have already seen, from the material in the one occupying two-thirds, and in the other only half the entire area. In the façade of the Parthenon the eye has one-third void only to contrast with the solid matter, and in the Pantheon half, which proportions seem to have been established by the Ionians, and usually adopted by the Romans.

In proportioning the architrave, frieze, and cornice, care must be taken that no more is laid upon the columns than their own bulk: when the latter are one diameter apart, this quantity will be greater in height than when they are further distant; so that the greater the intercolumniation, the lighter in appearance will be the entablature, the columns still bearing the same weight, nor need they be increased after it is ascertained that they are competent to their duty: to do so would be to employ material in excess, which it should be the aim of an architect to avoid.

If we now examine the portico of the Pantheon, we cannot fail to perceive the agreement existing between the parts supported and their supports.

The solid content of entablature	5918	11

which leaves little more than 100 cubical feet of difference between one and the other; and if the crown moulding returned on the flank be comprised, the quantity contained in the entablature would equal that of the eight columns.

The pediment is omitted altogether in this calculation, it being in reality, though not in appearance, an additional load for the eight columns beyond their regular entablature, which is of marble, and weighs probably 452 tons; the granite columns with their marble bases and capitals are something more than that quantity, and these, including the entablature and pediment, probably contain upwards of 1000 tons of material.

The Capitals of the Columns of the Pantheon are admitted to rank among the best examples found in Rome: though not so highly and elaborately worked as those which decorate the columns of the temple of (Jupiter Stator) the Dioscuri, yet they are remarkable for the

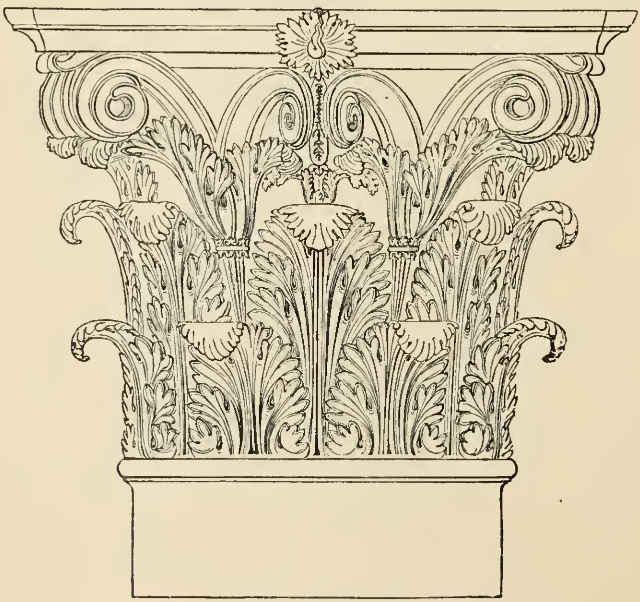

Fig. 1042. CAPITALS OF THE PANTHEON.

elegant arrangement of the ornaments: further details will be found in Taylor & Cresy's *Architectural Antiquities of Rome*, whence the details here given have been selected

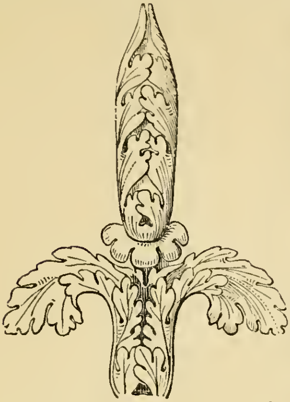

Fig. 1043.

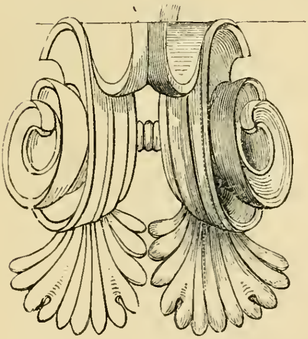

Fig. 1044.

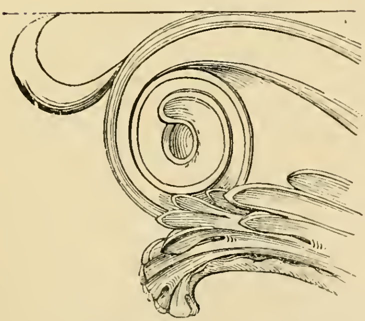

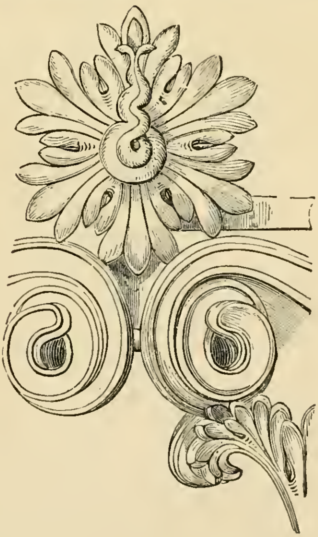

Fig 1045. CAPITALS OF PANTHEON. Fig. 1047.

Although the Romans did not improve the arts which the Greeks had spread among them, by the introduction of the arch they materially altered the character of the architecture practised before the time of the Republic: this feature alone produced entirely different construction, and the several changes it has since undergone in form have served to establish a variety of styles, as we shall afterwards find.

Sewers, aqueducts, bridges, theatres, amphitheatres, baths and triumphal arches, all exhibit the arch in its most useful application, and as did the halls of the baths vaulting of stupendous span; the dome of the Pantheon being 142 feet 6 inches in diameter internally, covered by a hemispherical dome.

Symmetry, as understood by Vitruvius, seems to relate more to the proportions of the façade than to those of the detail; but he doubtless intended it to be understood that

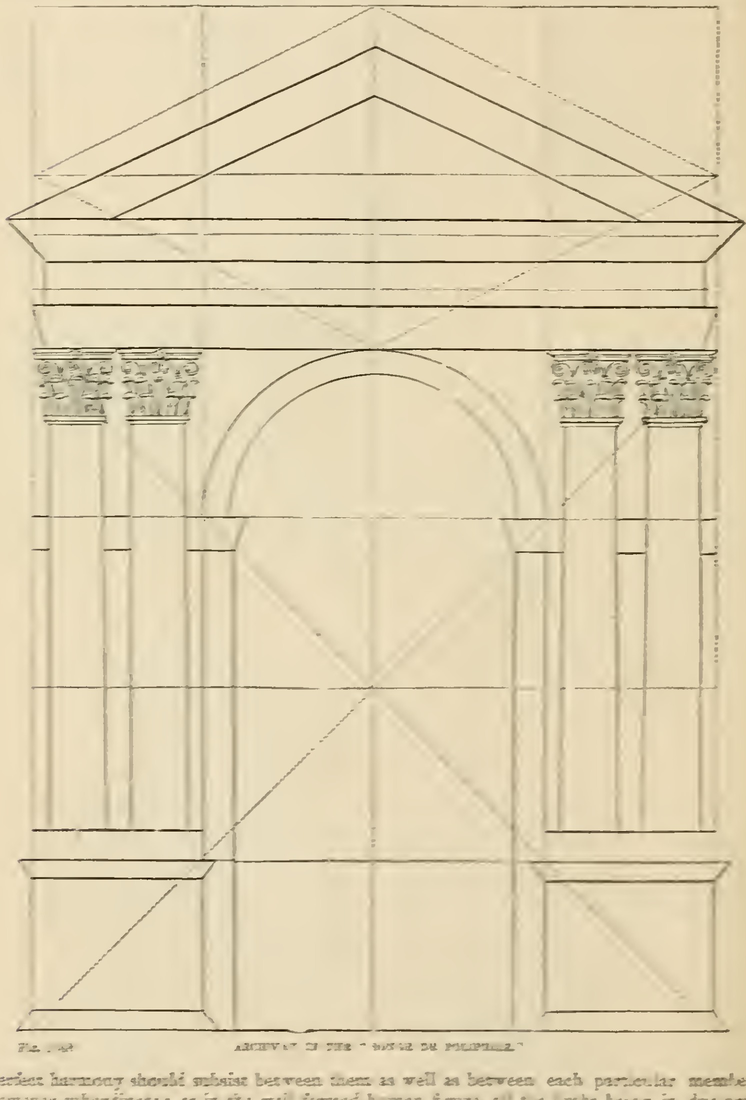

Fig. [illegible] ARCHWAY IN THE "[illegible]."

perfect harmony should subsist between them as well as between each particular member, however subordinate; as in the well-formed human figure, all the limbs being in due proportion, the whole when combined produces true symmetry: and the same author insists very strenuously on a careful study of the rules upon which this is founded, proving that the effect desired cannot be produced by a mere effort of fancy, or what is commonly called taste.

A building, though entirely devoid of ornament, may be rendered beautiful by the justness of its proportion, and the richest edifice wanting in this never can excite admiration: façades having but height and breadth, these two dimensions must be equal to each other, if we adopt the symmetrical proportions prescribed by Vitruvius, for he observes "the square includes the human figure either lying down or standing in an erect posture, the arms being stretched out." Temples, triumphal arches, and other buildings left us by the Greeks and Romans were decidedly designed upon this principle, as were most of the façades of the religious structures erected since the fall of the Roman empire.

In the "Songe de Poliphile," originally published in Italian by Aldus in the year 1499, are some observations on setting out a façade, which convey some idea of the principles adopted for the formation of a perfect and harmonious design on the revival of Roman architecture.

"Draw a square figure, divided by three perpendicular and three horizontal lines, at equal distances from each other, forming sixteen squares: on the top of the square add a half square, which, similarly divided, makes altogether twenty-four squares: in the lower square draw two diagonals, crossing eight squares in the same manner: then form a lozenge above the great square, tracing within it four lines on the four principal points that separate the four sides of the void."

After understanding this figure, I thought within myself what can modern architects do, who esteem themselves so learned without letters or principles? They neither know rules nor dimensions, and therefore corrupt and deform all sorts of buildings, both public and private, despising nature, who teaches them to do well if they would imitate her: good workmen, besides their science, may enrich their work either by adding to or diminishing therefrom, the better to please the eye, but the mass should remain entire, with which all should be made to harmonise. By the mass is understood the body of the edifice, which, without any ornament, shows the knowledge and spirit of the master, for it is easy to embellish after any invention: the distribution and arrangement of the parts is also a matter of consideration; hence we may conclude that any workmen or their apprentices know how to ornament a work, but to invent lies only in the heads of the wise.

Taking from the square and a half, the lozenge and the diagonal lines leaves the three perpendicular and the three horizontal, except that in the middle, which terminates in the centre of the perpendicular, cutting it into four parts or portions: by this rule will be found two perfect squares, one above and one below, each containing four small squares, which form the opening or doorway; now if you take the diagonal of the lower square, it will show you what thickness must be given to the centre of the portico; if you carry it straight, the line will serve to denote the architrave: and the point of the centre of the upper square will show you the centre of the arch or curve to be given to the door; turning a semicircle it will rest on the transverse line, which cuts the square and a half into two equal parts: but if done by any other means I do not esteem it perfect. This method was invented by ancient and expert masons, and observed in their arches and vaults, to give them both grace and solidity: the pedestal on which the columns rest commences at the level of the pavement by a plinth, and the whole is a foot high, furnished with mouldings; one portion is divided into architrave, frieze, and cornice, the latter being something more than the others; that is to say, if the architrave and frieze contained five parts, the cornice should be six. The whole twenty-four squares form a square and a half; then divide the upper half into six parts by five horizontal and five perpendicular lines, and draw a line from the centre of the fifth transverse to the corner of the great perfect square, where the architrave commences; then draw it perpendicular on the key of the archivolt, and it will show you the height to be given to the frontispiece above, the extremities of which should unite and relate to the projection of the cymatium and its mouldings.

General Principles.—It would appear that all the principal Roman triumphal arches with single openings were a square, either comprising or excluding their attics: that the centre from whence the archivolt was struck was the centre of the square or if the façade was more than a square, as the arch of Trajan at Ancona, then where the two diagonals crossed the centre was fixed. The width of the opening is generally half the entire extent, sometimes three parts out of seven.

These triumphal arches were generally surmounted by a group of figures, or the car and horses of the conqueror, accompanied by his companions in arms and the trophies obtained from the enemy; these, as shown on several medals, appear to be equal in height to $\frac{1}{3}$ of the entire edifice upon which they are placed, the attic and entablature representing $\frac{1}{3}$, and the columns and pedestals the other $\frac{1}{3}$: and as the former are nearly equal in their height, it follows that the horse and his rider, or the car and its triumphant hero, were double the height of the pedestal on which they were placed, for so we may consider the attic which contained the inscription, the body of the arch being a perfect square, and in correct proportion, without the attic. The depths of these arches varied; that of Constantine at Rome is nearly the same as the width of the great centre opening; many of the others are less than that proportion; but it seems that the cube was the measure that

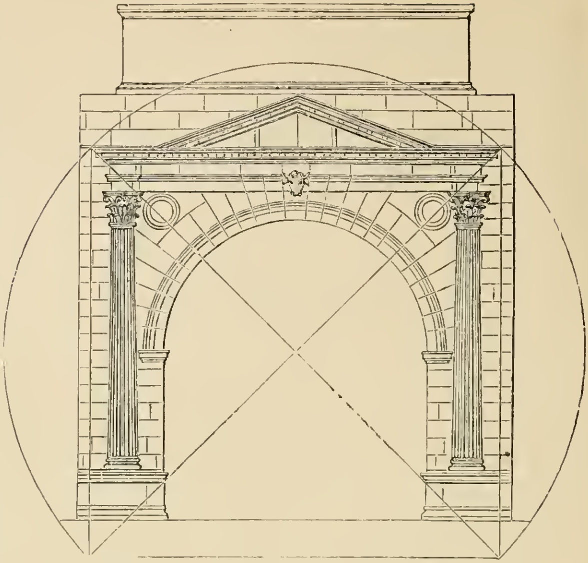

Fig. 1049. ARCH OF AUGUSTUS AT RIMINI.

bounded the proportions, as shown in fig. 1053. The several Roman examples selected differ in arrangement, but not in principle, from the description given by Poliphile: take away the pedestals on which the columns are placed, and then four squares in height include half the tympanum, and eighteen squares the entire figure, 6 of which may be considered as devoted to the arch, and the other 12 to supports: or, if we comprise the whole façade in 20 squares, and abstract the 8 which belong to the opening between the pedestals, we have 4 for each pier or support, and 4 for the entablature, the supported being only ½ the quantity contained in the two supports: resistance to the arch, or its thrust, requires a different arrangement from that of a portico, but we nevertheless find definite proportions made use of, and a double quantity given to masses which have to bear weight as well as resist thrust.

The Arch of Augustus at Rimini has the height of its order determined by the length of the frieze.

The Arch of Augustus at Aosta resembles that of Titus in arrangement; it is a perfect square comprising the attic.

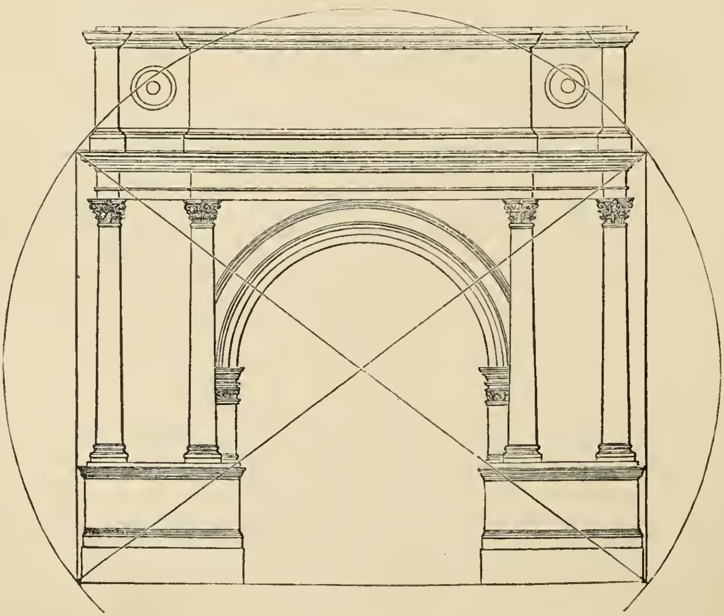

Fig. 1050. ARCH OF AUGUSTUS, AT AOSTA.

The Arch of Sergius at Pola is a perfect square, without attic, like that of Titus.

The Arch of Titus at Rome, raised by the senate and Roman people to commemorate the conquest of Judæa, is one of the best examples of proportion that remain: built of white marble, it is a monument of constructive art, some of the blocks being 9 feet square, and 2 feet thick; the arch is composed of eleven voussoirs 16 feet deep. For a detailed account of its construction and ornament the reader is referred to the "Architectural Antiquities of Rome."

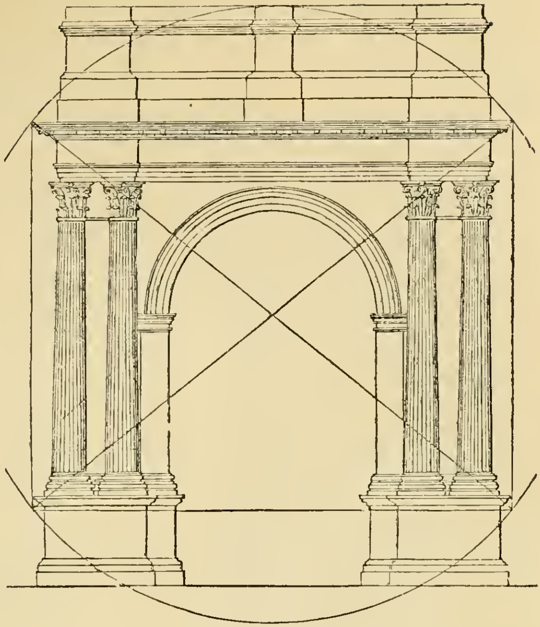

Fig. 1051. ARCH OF SERGIUS AT POLA.

The proportions are a square, as is the opening of the archway, up to the springing; and not a double square, as described by Serlio. The pedestals are in height nearly half the opening of the archway, which Palladio observes was the ordinary proportion given by the ancients. The entire length of the upper member of the cornice in this example is 48 feet, which dimension corresponds with the entire height, almost to a fraction: the width of the opening is 17 feet 6 inches, a trifle more than one-third of the entire width: bounding the façade by a parallelogram, excluding the attic, and drawing two diagonals, we obtain the centre from which the arch is struck, which rule will apply to the other

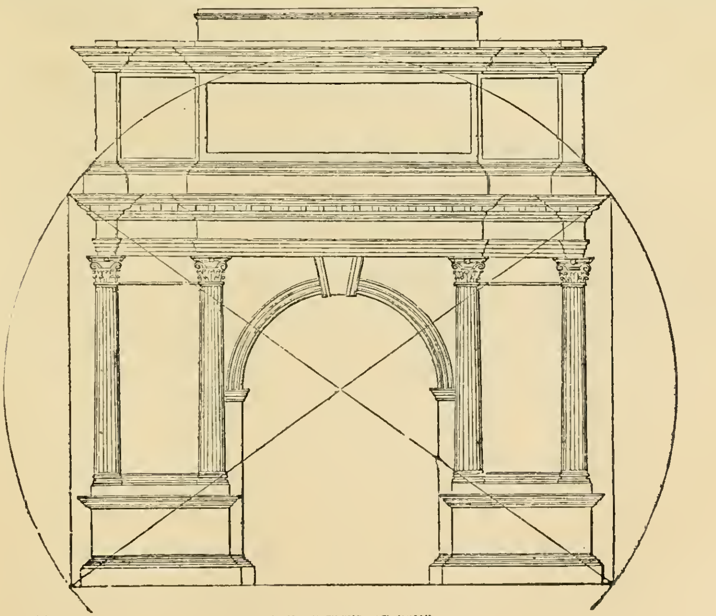

Fig. 1052. ARCH OF TITUS, AT ROME.

triumphal arches with a single opening, though varying materially from the principles laid down by Poliphile, and adopted by Serlio and other architects at the revival of Italian architecture. The Arch of Titus is a square comprising its entire façade; that of Poliphile a square up to the under side of the entablature; consequently, the opening of the triumphal way is in width half the height to the top of the impost upon which the archivolt rests, while in the more ancient the entire aperture without the arch is a square.

In the Arch of Poliphile the entablature and pediments are nearly equal in quantity to each of the piers upon which they are carried; and the piers themselves are in width only one quarter of the whole breadth of the façade: it will be found, however, that nearly the same proportions exist between supports and supported in both examples.

The Arch of Augustus at Susa has a single arch: proportion a square to the top of the entablature, opening a square to the springing: width divided into four, two given to the opening and one to each pier, which has a three-quarter column at the angle: attic as high as piers are wide.

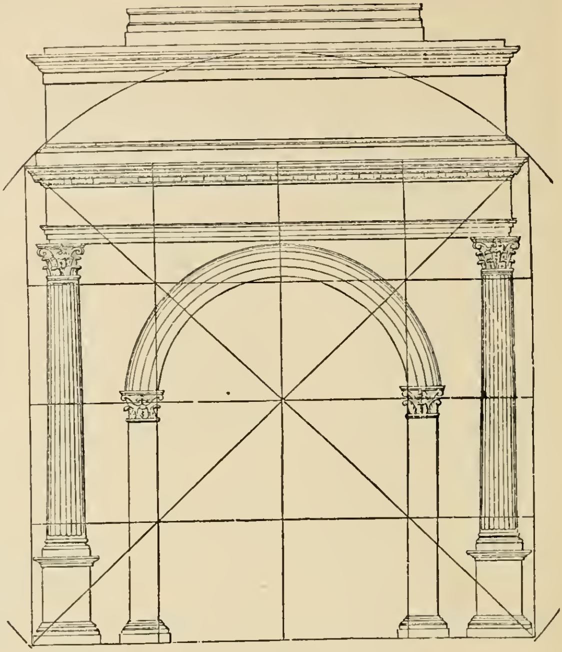

Fig. 1053. ARCH OF AUGUSTUS AT SUSA.

In arches with three openings, as those of Septimus Severus and Constantine, these

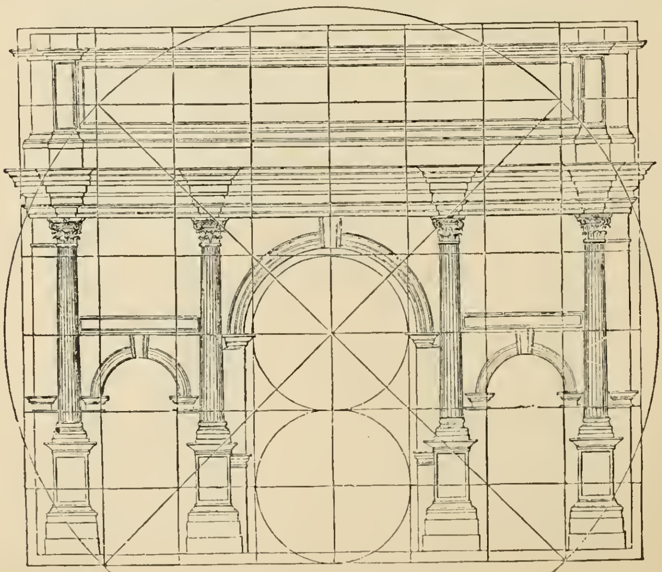

Fig. 1054. ARCH OF SEPTIMUS SEVERUS, AT ROME.

occupy one-half the width, and the piers the other: where the diagonals of the figure cross is the centre, from which the principal arch is struck.

The Arch of Trajan at Beneventum.—Circle struck from the centre which describes the archivolt; comprises all within it except the attic: division of width into seven, two for each pier, three for centre; attic half the height of the order.

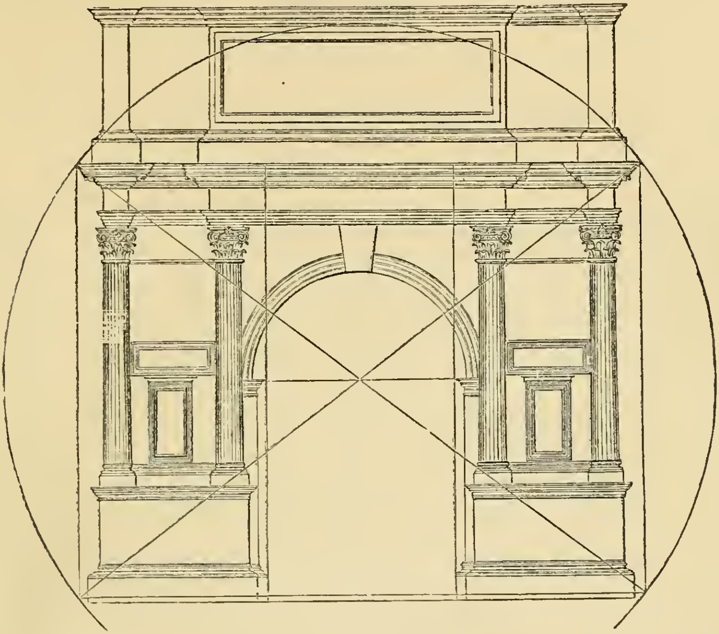

Fig. 1055. ARCH OF TRAJAN AT BENEVENTUM.

In the foregoing examples, we have attempted to show that the beauty which belongs to form in architecture rests upon one principle based on the laws of nature, and that the first element in a good design is the proportion of the parts as well as the whole: nothing has more misled the critics upon this subject, as well as architects themselves, than implicitly following the rules laid down for drawing the orders. In treating upon the antique, they have frequently been right as far as regards the letter, but essentially wrong in the spirit. The laws of nature do not vary, nor do our organs of sense or perception, and what was apparently fit and proper in the opinions of the Greeks is equally so at the present day: in their sculptures we never find a man represented carrying more than his own weight, and such laws ought to be our guide.

After the destruction of the Roman empire, the character impressed upon architecture by the Greeks was lost: other styles arose in succession, which have been designated as Byzantine, Romanesque, Lombardic, Saxon, Norman, Saracenic, and Pointed. The five first retained the semicircular arch, and only differed in the quantity of material employed: for examples of the three first-mentioned we must refer to a work entitled "Architecture of the Middle Ages at Pisa," by Edward Cresy and G. L. Taylor, containing measurements made in 1817.

CHAP. III.

MEDIÆVAL ARCHITECTURE.

Sect. I.

THE STYLE IN GENERAL.

The question that first naturally arises is, What is Gothic or Mediæval architecture? Although Rickman, in his essay mentioned on page 971, gave a sketch in which he wished to show the differences between Classic and Gothic architecture, the first real attempt at defining the character of Mediæval art seems to have been made by the late A. W. Pugin, who, in his *True Principles of Pointed or Christian Architecture*, 1841, enunciated the following principles, which have formed the keynote for the various works and lectures on the subject since written and delivered: —

I. There should be no features about a building which are not necessary for convenience, construction, or propriety. II. All ornament should consist of enrichment of the essential construction of the building. III. The smallest detail should have a meaning or serve a purpose. IV. The construction itself should vary with the material employed. V. The design should be adapted to the material in which it is executed. VI. Pointed architecture does not conceal her construction, but beautifies it. VII. Plaster, when used for any other purpose than coating walls, is a mere modern deception. VIII. A flat roof is contrary to the spirit of the style. IX. A splayed form is necessary for piers, arches, basemoulds, strings, and copings. X. All mouldings of jambs are invariably sunk from the face of the work. XI. Large stones destroy proportion. XII. The jointing of masonry should not appear to be a regular feature. XIII. A joint in tracery should always be cut to the centre of the curve where it falls. XIV. The external and internal appearance of an edifice should be illustrative of, and in accordance with, the purpose for which it is destined. XV. It is a defect to make the two sides of a design correspondent if their purposes differ. XVI. The picturesque effect of the ancient buildings results from the ingenious methods by which the old builders overcame local and constructive difficulties. XVII. The elevation should be subservient to the plan. XVIII. Details are multiplied with the increased scale of the building.

These principles, with the addition of the subject mentioned in the next paragraph, seem to form the creed of the most advanced foreign archæologists, such as M. Viollet le Duc, for the consideration of the spirit of the style has been neglected in favour of an investigation of details by French and German writers on architecture.

"Internal altitude," writes Pugin in the same work (p. 66.), "is a feature which would add greatly to the effect of many of our fine English churches, and I shall ever advocate its introduction, as it is a characteristic of foreign pointed architecture of which we can avail ourselves without violating the principles of our own peculiar style of English Christian architecture, from which I would not depart in this country on any account. I once stood on the very edge of a precipice in this respect, from which I was rescued by the advice and arguments of my respected and revered friend Dr. Rock, to whose learned researches and observations on Christian antiquities I am highly indebted and to whom I feel it a bounden duty to make this public acknowledgment of the great benefit I have received from his advice. Captivated by the beauties of foreign pointed architecture, I was on the verge of departing from the severity of our English style, and engrafting portions of foreign detail and arrangement. This I feel convinced would have been a failure; for although the great principles of Christian architecture were everywhere the same, each country had some peculiar manner of developing them, and we should continue working in the same parallel lines, all contributing to the grand whole of Catholic art, but by the very variety increasing its beauties and its interest."

This author claimed for pointed architecture the merit of its having been the only phase of art in which the "principles" had been carried out, and is supported, with some reservations, by Viollet le Duc. Our space is too limited to discuss that assertion; the student who desires to investigate the subject must refer to Pugin's publication for his arguments, and must guard against being captivated by the one-sided illustrations given as "contrast." For an assertion of the same general principles in regard of Classic and Modern architecture, the reader is referred to the chapter on Beauty in Architecture, in the present work (*par.* 2492, *et seq.*), written, we are inclined to consider, before the publication of Pugin's propositions.

A more strictly architectural definition of the term *Gothic architecture* has been deduced from the writings of various investigators, as being that combination of art and science in building which followed the adoption, during the middle ages, of broken arches for vaults, openings, and ornaments, in lieu of the previously existing arches of continuous lines. The term Gothic architecture, according to such writers, does not acknowledge as its legitimate productions any structures that are point vaulted and point arched, point vaulted but not arched, point arched but not vaulted, or neither arched nor vaulted, unless they conform to rules approved by the builders in north-western Europe (and especially in England) during the middle ages. These regulations are, in effect, nine :— I. Daylight must not fall upon any apparently *horizontal plane surface*, however small, except pavements, steps, seats, and tables. II. Every *arch* must be moulded within a chamfer, or at least be chamfered. III. Every *impost* must follow the plan of the arch or arches which it receives. IV. Every *pillar* must be an assemblage of juxtaposed shafts or mouldings. V. Every *pier* must be polygonal, or at least circular in plan. VI. Every *base* must follow the plan of the pillar or pier to which it belongs, or at least be either polygonal (preferably octagonal), or cylindrical if under a shaft. VII. All *decoration* must be worked within the plane of the walling to which it belongs, except in the cases of bases, bands, capitals, cornices, copings, and dripstones. VIII. *Roofs* of high pitch and flying buttresses, spires, and pinnacles, tracery and foliation, are incidental, rather than peculiar, features. IX. The *continuous arch* may be exceptionally employed when it, with the rest of the building in which it occurs, exhibits submission to the preceding regulations.

These regulations were observed to the north of the Loire and of the Alps, which was the seat of what may be designated *original Gothic*. South of those boundaries we have to deal with what may be designated *imitative Gothic*, to which, as a matter of course, appends itself one of the two divisions, Christian and Mahomedan, of *Pointed* art. We take it for granted that the reader is already convinced that the Romanesque and Byzantine perfect developments of Roman construction do not become transitional to *original* or *imitative Gothic* architecture merely by the introduction of the pointed arch as a mere form, independent of the regulations above enumerated. On the contrary, they become new *styles*, with their own periods of transition and development; which, by those writers who do not feel that the architecture of the Mahomedans has been as consistent as that of north-western Europe, are at present considered as mere solecisms, deserving to have the epithets of *pointed Romanesque* and *pointed Byzantine* given to them.

These regulations, therefore, define the difference between *Gothic* and *Pointed* architecture. They exclude from the title of *Gothic* those branches of the transition from Romanesque art which, in Germany, Italy, and the Spanish peninsula, were, whatever the period might be, merely imitation Gothic ; as they also exclude any branch of the pointed Byzantine school, which was employed by the Normans in Sicily, or by other Christian communities.

The readers who are desirous of considering this subject more in detail are referred to Freeman, *History of Architecture*, 1849, wherein Chapter I. Part II. treats upon the "Definition and Origin of Gothic Architecture;" and concludes with the observation: "We may then define Gothic architecture as a style whose main principle is verticality, a principle suggested by the pointed arch, and carried out in its accompanying details." A writer in the *Archæological Journal*, for February 1847, has expressed his notion that "it would be very possible to build a *thoroughly good* Gothic church, taken entirely from ancient examples, without a single pointed arch throughout ;" a principle which would astonish most of the talented practitioners of the present day.

An eminent amateur has written a very studied and elaborate explanation of what he considers to constitute Gothic architecture. "I believe," says Mr. Ruskin, in *Stones of Venice*, Vol. II. Chap. VI., after a short inquiry into the mental power or expression, "that the characteristic or moral elements of Gothic are the following, placed in the order of their importance: — I. Savageness ; II. Changefulness ; III. Naturalism ; IV. Grotesqueness ; V. Rigidity ; and VI. Redundance. These characters are here expressed as belonging to the building. As belonging to the builder they would be thus expressed :— I. Savageness, or rudeness ; II. Love of change ; III. Love of nature ; IV. Disturbed imagination ; V. Obstinacy ; and VI. Generosity. The withdrawal of any one, or any two, will not at once destroy the Gothic character of the building ; but the removal of a majority of them will." He then proceeds to examine them in their order ; but our limited space prevents our following him word for word, and we have found it necessary to curtail some of the following paragraphs.

In defining its outward form, he states that the most striking feature is that it is composed of pointed arches. "I shall say then, in the first place, that Gothic architecture is that which uses, if possible, the pointed arch for the roof proper ;" and subsequently adds, "Our definition will stand thus ; Gothic architecture is that which uses the pointed arch for the roof proper, and the gable for the roof mask."—"All good Gothic is nothing more than the development in various ways, and on every conceivable scale, of the group formed by the *pointed arch for the bearing line* below, and the *gable for the protecting line* above (*fig.* 1056.). The subject of the masonry of the pointed arch has been discussed in Chapter XI. of Volume I. (of his work), and the conclusion deduced, that of all possible forms of the pointed arch (a certain weight of material being given), that generically represented in *fig.* 1057. is the strongest. But the element of foliation *must* enter somewhere, or the style is imperfect; and our final definition of Gothic will, therefore, stand thus:—Foliated architecture, which uses the pointed arch for the roof proper, and the gable for the roof mask."

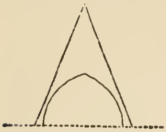

Fig. 1056.

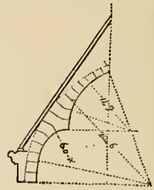

Fig. 1057.

The figure 1057, though of the outline as given by Mr. Ruskin, really exhibits the stone arch erected in granite across the chancel of the Bruen Testimonial Church at Carlow, designed by the late J. Derick (*Builder*, 1854, p. 34.). The trefoiled arch exercises a force within the building neutralising the outward thrusting force of the lancet arch, the two forces producing a state of rest.

"A few plain and practical rules," continues Mr. Ruskin, "will determine whether a given building be good *Gothic* or not, and if not Gothic, whether its architecture is of a kind which will probably reward the pains of careful examination:—I. Look if the roof rises in a steep gable, high above the walls. If it does not do this, there is something wrong; the building is not quite pure Gothic, or has been altered. II. Look if the principal windows and doors have pointed arches, with gables over them. If not pointed arches, the building is not Gothic; if they have not any gables over them, it is either not pure or not first-rate. If, however, it has the steep roof, the pointed arch, and gable all united, it is nearly certain to be a Gothic building of a very fine time. III. Look if the arches are cusped, or apertures foliated. If the building has met the first two conditions, it is sure to be foliated somewhere; but, if not everywhere, the parts which are not unfoliated are imperfect, unless they are large bearing arches, or small and sharp arches in groups, forming a kind of foliation by their multiplicity, and relieved by sculpture and rich mouldings. If there be no foliation anywhere, the building is assuredly imperfect Gothic. IV. If the building meets all the first three conditions, look if its arches in general, whether of doors and windows, or of minor ornamentation, are carried on true shafts with bases and capitals. If they are, then the building is assuredly of the finest Gothic style. It may still, perhaps, be an imitation, a feeble copy, or a bad example, of a noble style; but the manner of it, having met all these four conditions, is assuredly first-rate. If its apertures have not shafts and capitals, look if they are plain openings in the walls, studiously simple, and unmoulded at the sides. If so, the building may still be of the finest Gothic, adapted to some domestic or military service. But if the sides of the window be moulded, and yet there are no capitals at the spring of the arch, it is assuredly of an inferior school."

"The next tests to be applied are in order to discover whether the building be *good architecture* or not; for it may be very impure Gothic, and yet very noble architecture; or it may be very pure Gothic, and yet, if a copy, or originally raised by an ungifted builder, very bad architecture:—I. See if it looks as if it had been built by strong men; if it has the sort of roughness, and largeness, and nonchalance, mixed in places with the exquisite tenderness, which seems always to be the sign-manual of the broad vision and massy power of men who can see *past* the work they are doing, and betray here and there something like disdain for it. If it has not this character, but is altogether accurate, minute, and scrupulous in its workmanship, it must belong to either the very best or the very worst of schools: the very best, in which exquisite design is wrought out with untiring and conscientious care, as in the Giottesque Gothic; or the very worst, in which mechanism has taken the place of design. On the whole, very accurate workmanship is to be esteemed a bad sign. II. Observe if it be irregular, its different parts fitting themselves to different purposes, no one caring what becomes of them so that they do their work. III. Observe if all the traceries, capitals, and other ornaments, are of perpetually varied design. IV. Lastly, *Read* the sculpture. Preparatory to reading it, you will have to discover whether it is legible (and, if legible, it is nearly certain to be worth reading). The criticism of the building is to be conducted precisely on the same principles as that of a book; and it must depend on the knowledge, feeling, and not a little on the industry and perseverance of the reader, whether, even in the case of the best works, he either perceives them to be great, or feels them to be entertaining."

"The *variety* of the Gothic schools," says Mr. Ruskin, in another portion of the same work, "is the more healthy and beautiful, because in many cases it is entirely unstudied, and results, not from mere love of change, but from practical necessities. It is one of the chief virtues of the Gothic builders, that they never suffered ideas of outside symmetries and consistencies to interfere with the real use and value of what they did. If they wanted a window they opened one; a room, they added one; a buttress, they built one; utterly regardless of any established conventionalities of external appearance. Every successive architect employed upon a great work built the pieces he added in his own way, utterly regardless of the style adopted by his predecessors. These marked variations were, however, only permitted as part of the great system of perpetual change which ran through every member of Gothic design, and rendered it as endless a field for the beholder's inquiry as for the builder's imagination; change, which in the best schools is subtle and delicate, and rendered more delightful by intermingling of a noble monotony, in the more barbaric schools is somewhat fantastic and redundant; but, in all, a necessary and constant condition of the life of the school. Sometimes the variety is in one feature, sometimes in another: it may be in the capitals or crockets, in the niches or the traceries, or in all together, but in some one or other of the features it will be found always. If the mouldings are constant, the surface sculpture will change; if the capitals are of a fixed design, the traceries will change; if the traceries are monotonous, the capitals will change; and if ever, as in some fine schools, the early English for example, there is the slightest approximation to an unvarying type of mouldings, capitals, and floral decoration, the variety is found in the disposition of the masses, and in the figure sculpture."

SECT. II.

PERIODS OF GOTHIC ARCHITECTURE.

The divisions of Gothic architecture in England, as made by King, Dallaway, Millers and others, have been used in Book I. Chap. III.; but their subdivisions and nomenclature have been discarded by later investigators; and many tables have been put forward of divisions and subdivisions. Thus, Britton's nomenclature (1807) was, English 1189–1272; decorated English 1272–1461; highly decorated, or florid, English 1461–1509; debased English 1625. Millers's division (1807) was early English 1200–1300; ornamented English 1300–1460; and florid English 1460–1537, as adopted herein in Book I. E. Sharpe classifies the style as, *Romanesque*—Saxon period until 1066; Norman 1066–1145, *Gothic*—transitional 1145–1190; lancet 1190–1245; geometrical 1245–1315; curvilinear 1315–1360; and rectilinear 1360–1550.

The following table introduced by Rickman, *Attempt to Discriminate, &c.*, shows his nomenclature and the duration of the periods; these names have maintained themselves, in consequence of their general appropriateness, from 1819 to the present time:—

Kings.	Date.	Name of Period.	Remarks.
William I. William II. Henry I. Stephen. Henry II.	1066 1087 1100 1135 1154 to 1189	NORMAN.	Prevailed little more than 124 years; no remains really known to be more than a few years older than the Conquest.
Richard I. John. Henry III. Edward I.	1189 1199 1216 1272 to 1307	EARLY ENGLISH.	Prevailed about 118 years.
Edward II. Edward III.	1307 1327 to 1377	DECORATED ENGLISH.	Continued perhaps 10 or 15 years later; prevailed little more than 70 years.
Richard II. Henry IV. Henry V. Henry VI. Edward IV. Edward V. Richard III. Henry VII. Henry VIII.	1377 1399 1413 1422 1461 1483 1483 1485 1509 to 1546	PERPENDICULAR ENGLISH.	Prevailed about 169 years. Few, if any, whole buildings executed in this style later than Henry VIII. This style used in additions and rebuildings, but often much debased, as late as 1630 or 1640.

The reign of Richard I. was the chief period of the transition from the Norman to the early English style; that of Edward I. for the change from the early English to the decorated style (the Eleanor crosses belonging rather to the latter, than to the former, style); while in the latter part of the long reign of Edward III. the transition to the perpendicular style commenced, and was almost completed by the time of the accession of Richard II.

Similar tables of the duration of styles in foreign countries have been given in the section Pointed Architecture, in Book I.

Rickman, in describing the style to which he gives the name "decorated," especially classes under that style the tracery in which "the figures such as circles, trefoils, quatrefoils, &c., are all worked with the same moulding, and do not always regularly join each other, but touch only at points; this," he says, "may be called geometrical tracery." The Rev. G. A. Poole, *Ecclesiastical Architecture*, 1848, remarks that "a very large proportion of the buildings in which this kind of tracery is used, belongs to the previous period, called early English. The examples which might have been supposed to clear up the difficulty only make it greater. Thus, in speaking of the chapter-house at York, which has splendid geometric tracery, he says, "The chapter-house is of *decorated* character;" yet the chapter-house is clearly of a character which prevailed during a considerable part of that period which Rickman assigns to the early English style. The general tendency has likewise been, of late, to range with the early English by far the greater proportion of those examples which answer to Rickman's definition of geometrical decorated; a few of the later examples only being treated as transition from early English to decorated. The mouldings, it is true, are generally of perfectly early English character, and so are the clusters of foliage, the bosses, and other ornamental appendages. Instances occur in which the simple early English lancet was used during the period of the geometrical tracery. How, then, are the two styles, if they be two, to be separated, in a system which is in part chronological? How are they to be united, in a system which is also in part founded on similarity of parts?

"It is, however, perhaps the most perfect of all the styles; for its tracery has the completeness and precision of the perpendicular, without its license and exuberance; while its minor details partake of the boldness and sharpness of the early English, which need not fear to be compared with the ornamental accessories of any subsequent style. Besides the intrinsic beauty of this style, it is important as affording the first full development of tracery and of cusping, with all their power of enriching large windows, and of bringing together several lights as one whole."

"In pursuing the study of mediæval architecture, it may be held as an axiom," writes Brandon, *Analysis of Gothic Architecture*, "that personal inspection of the old churches of England is the *only means* by which it can be possible now, either to appreciate the genius of our mediæval architects, or to sympathise with the spirit which animated them. But it is probable that even experienced observers may sometimes be misled by a practice of occasionally assimilating work in a later style to some already existing portion of an incomplete general design. Indeed it forms a strongly marked exception to the usual practice; for it was a general rule with the builders of the middle ages never to fall back upon a past era of their art, even when engaged in completing structures of a bygone age." He then describes the proceedings in this respect at St. Alban's Abbey Church, at Westminster Abbey, and at Fotheringay Church, Northamptonshire.

The early English character of Westminster Abbey Church has been so well preserved throughout, that in many cases it requires a close inspection before it is possible to detect the presence of decorated or of perpendicular work. Thus the windows in the aisles erected by Henry V. are very decidedly of early decorated character; the customary octagonal and moulded cap of the perpendicular period occupy the place of the corresponding circular and foliated members, which, had the windows really been erected some hundred years earlier, would assuredly have surmounted the boltels placed in their jambs.

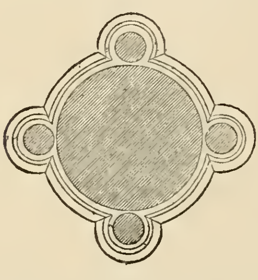

Fig. 1058. WESTMINSTER ABBEY; TRANSEPT AND CHOIR. EARLY ENGLISH.

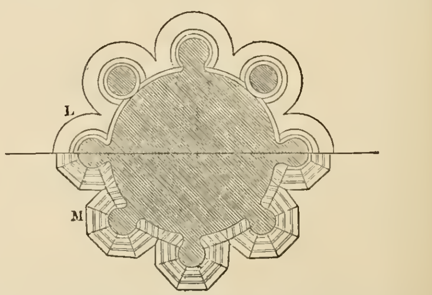

Fig. 1059. WESTMINSTER ABBEY; PILLARS OF NAVE (L, EASTERN BAYS, DECORATED—M, WESTERN BAYS, PERPENDICULAR.)

In the earlier plans of the nave piers four shafts stand clearly detached from the main body of the pier, *fig.* 1058.; but subsequently the pier was worked with eight shafts, *fig.* 1059. (L); and, later still, with eight shafts, *fig.* 1059. (M) all attached to the central mass, indicative of the altered fashion of the day, in which detached shafts, once such a favourite feature, were entirely discarded. In the piers they worked the bands of the 13th century (N) with the mouldings peculiar to the 15th (O). *Figures* 1060, both drawn to the same scale, show how they departed both from the outline and size of the original. In the triforia, the early English design is equally apparent in the earlier and later portions of the work; but the mouldings in each are true to their styles. Although the groining is tolerably in keeping throughout, yet in the aisles and in the later portion of the vaulting, the original spring and height of the ridge rib has been preserved, while to the elegant acutely pointed lancet of the earlier groining an obtusely pointed arch has been preferred, which, consequently, it has been necessary to stilt. Brandon gives illustrations of the early English and perpendicular arcades under the windows, a feature which, though long disused and supplanted by a system of panelling, is yet followed out. "I am not aware," writes the Rev. J. L. Petit, "whether sufficient attention has been given to the attempts occasionally made by the mediæval architects to assimilate their work to the portions erected in an earlier style. In some instances, as in the choirs at Ely and Lincoln, this is done without sacrificing any of the distinctive features of the style then in use; but in Beverley Minster, and in Whitby Abbey, the case is different. In the latter, the whole of the early English arrangement of the choir, as regards its lancet windows, is continued in the transept, though the ornaments with which it is enriched show that this part clearly belongs to the decorated period. The triforium in the former is uniform throughout the whole church, for the same is continued in the decorated work, except the disuse of marble in the shafts."

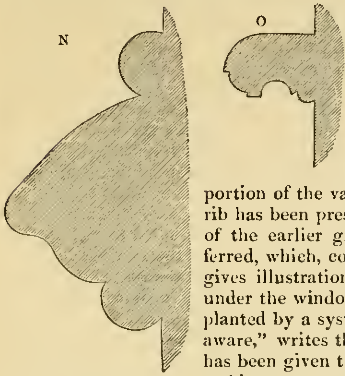

Fig. 1060.
WESTMINSTER ABBEY.

The same system of using previous ideas, but working them out with later details, is exemplified in the *Sketch Book* of Wilars de Honecort, an architect of the middle of the 13th century. In comparing his sketches with drawings from the original works, their extreme inaccuracy and contempt of detail is evident. He sketched them because he saw there was something in the general arrangement which, with alterations, might become useful. He therefore drew each with his own improvements to it. As to the details, Wilars did not want them, for he was perfectly convinced that those of his own time were better than anything previously executed. The reader will find reviews of this work in the *Builder* for 1858, with some woodcuts of the illustrations.

Besides this question of assimilation of style, there arises that of *similarity of work* in different buildings, resulting from the superintendence or design of one master mind; but this is so extensive a subject that in our limited space we dare not do more than name it for the attention of the student or reader. Another interesting important point is that of the *transition* from one period into another, such as the decorated into the perpendicular. A curious example of this exists in the church at Edington, in Wiltshire, an account of which, with woodcuts, is given by Parker, in the 6th edition of Rickman's *Attempt*, 1862.

SECT. III.

MOULDINGS.

It will probably surprise many of our readers that even so late as 1845, the statement was made that "but little acquaintance with mouldings is evinced in the works of most modern architects." Such was the opinion expressed by F. A. Paley, when he published his very useful *Manual of Gothic Mouldings*. "Viewed as an inductive science," he writes, "the study of Gothic mouldings is as curious and interesting in itself as it is important in its results. Any one who engages actively in it will be amply repaid, if only by the enlarged views he will acquire of the ancient principles of effect, arrangement, and composition. But the curves, the shadows, and the blending forms, are really in themselves extremely beautiful, and will soon become the favourites of a familiar eye; though viewed without understanding they may seem only an unmeaning cluster of holes, nooks, and shapeless excrescences. Perhaps few are aware that any group can be analysed with perfect ease and certainty; that every member is cut by rule, and arranged by certain laws of combination. The best work on Gothic mouldings which could possibly be written will do no more than set him in the right way to obtain a knowledge of the subject by his own research. The look of a moulding is so very different in section, projected in a reduced size on paper, from its appearance in perspective reality, that the same form seen in the one may scarcely be recognised in the other.

"Gothic architecture revelled in the use of mouldings;—and yet, mouldings are merely the ornamental adjuncts, not the essentials, of architecture. Some buildings of the best periods were quite devoid of them, whence it is evident that they are not necessary even to a perfect design. Boldness and simplicity produce effects, different indeed in their kind, yet not less solemn and striking than richness of detail. If the uniformity in their use had not been very strict and close, it had been a hopeless task ever to master the subject; indeed, if there had not been a *system* of moulding, there would have been nothing to investigate. But so little did the mediæval masons depart from the fixed conventional forms, that we often find a capital, a base, or an arch mould of perfectly the same profile in an abbey or a cathedral which we had copied in our note-book from a village church at the other end of the kingdom, so that we might almost suspect that the very same working drawing had been used for both."—Thus far we have quoted from Paley, to whose work we shall again have recourse in the further development of this section; but in so condensed a form, that it should not prevent the student from himself possessing so invaluable a work, of which a third edition was issued in 1865, with an accession of illustrations.

We must now attempt to give some idea of the *nomenclature* of mediæval mouldings. "The most complete specimen," writes Professor Willis, in his *Architectural Nomenclature of the Middle Ages*, 1844, "is that preserved to us by William of Worcester, or Botoner," who was born in Bristol, in 1415, and is now best known by a manuscript note book remaining in the library of Corpus Christi College, Cambridge; it was printed in 1778 by Nasmith. Two of its pages contain lists of technical words attached to roughly drawn outlines of jamb mouldings, the one showing the *north* door of St. Stephen's Church, the other the west door of St. Mary's Redcliffe Church, both at Bristol. These doors are still in existence; on comparison, the former agrees perfectly with the mouldings of the *south* porch of the church in question, except that two little boltels have been scraped clean off. The west door of Redcliffe Church has undergone a much severer *skinning*. *Fig.* 1061. represents the outline of the former door; "the names given to the mouldings by Botoner are, A, a cors wythoute; B, a casement, C, a bowtelle; D, a felet; E, a double ressaunt;

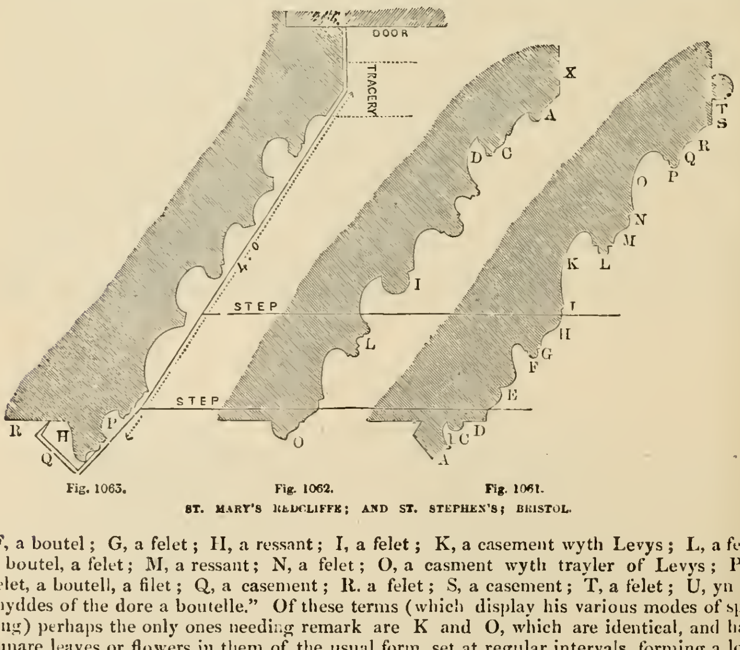

Fig. 1063. Fig. 1062. Fig. 1061.

ST. MARY'S REDCLIFFE; AND ST. STEPHEN'S; BRISTOL.

F, a boutel; G, a felet; H, a ressant; I, a felet; K, a casement wyth Levys; L, a felet, a boutel, a felet; M, a ressant; N, a felet; O, a casment wyth trayler of Levys; P, a felet, a boutell, a filet; Q, a casement; R. a felet; S, a casement; T, a felet; U, yn the myddes of the dore a boutelle." Of these terms (which display his various modes of spelling) perhaps the only ones needing remark are K and O, which are identical, and have square leaves or flowers in them of the usual form, set at regular intervals, forming a long continuous train. "Benet le Ffremason" appears to have worked the original mouldings.

The section of the mouldings of the west door of Redcliffe Church is shown in *fig.* 1062., to which the names were also attached, the additional terms obtained being "A, a chamfer; C, a double Ressant wyth a filet; O, a Ressant lorymer; M, a lowryng casement; and I, a grete bowtelle." "I cannot help pointing out," writes Professor Willis, "how imperfect a nomenclature must be, which can make no stronger distinction between the combinations E and C, than by calling one a 'double ressant,' and the other a 'double ressant with a fillet.' The universal moulding O, in fig. 1062, is a 'ressant lorymer.'" *Fig.* 1063. is an outline of the jamb mouldings as they appear at present, engraved from a drawing made expressly for us by Mr. T. S. Pope, of Bristol, and exhibits the skinning they have undergone.

Mouldings of an arch or jamb are said to be *grouped* when they are placed in combination as they are generally found; but a *group* is a branch of mouldings or separate members, standing prominent or isolated, either on a shaft, or between two deep hollows. An arch of two or more *orders* is one which is recessed by so many successive planes or retiring arches (see *fig.* 1065. &c.), each placed behind or beneath the next before it, reckoning from the outer wall line. The accompanying figures exhibit both groups and orders.

We have adopted the usual architectural system of exhibiting the mouldings in the manner of a mould or pattern, and it likewise carries out the principle of this work. It is also preferred to the popular way of engraving sections, that is, by an apparently perspective representation of a stone cut out of an arch. The several sets of figures are all drawn to scale. The examples selected are, Fountains Abbey, Yorkshire, for the transition and for the early English period; Tintern Abbey, Gloucestershire, for the geometric period; Howden Church, Yorkshire, for the late decorated period; and Henry VII.'s Chapel, Westminster, for the perpendicular period. For those from the three first buildings, we have to express our grateful acknowledgment to E. Sharpe's *Architectural Parallels*, 2 vols. fol. 1845–48, a work combining technical precision, without which it would be useless to the *architect*, with artistic character, by which it will recommend itself to every one interested in such antiquities. The illustrations of Tintern are valuable examples of the geometric period. The work contains many geometrical plans, elevations, and sections of 14 buildings, with all the principal mouldings to a large scale (those herein are all reduced, and therefore less useful), with an additional valuable volume of the mouldings engraved full size. For the illustrations of the fourth period we are indebted to Cottingham's work on the Chapel, fol. 1822–29, perhaps the only perfect monograph of a large structure yet published in England.

One reason for selecting the illustrations in this manner has been that, with the very limited space at our disposal for so extensive a subject as the detail of Gothic architecture, we could not emulate either the very satisfactory work which now, with its useful illustrations, passes as Rickman's *Attempt to Discriminate the Styles of Architecture in England*, 8vo. 1865, 6th edit., or Brandon's *Analysis of Gothic Architecture*, which is full of examples of detail drawn to scale. Another reason was, to give the means of comparing the use of details in similar parts of edifices of nearly the same general dimensions; otherwise we could merely have given the prettiest selection that it had been possible to have made for the purpose.

" During the period in which the so-called *Anglo-Saxon* architecture prevailed, little decorative work was done. The very rude carvings are extremely shallow, being such as could be worked with the hammer or pick, and without the chisel. In some doors and larger arches there is a regular impost at the springing, having a rude resemblance to Roman mouldings; otherwise the jambs and arch stones are merely returned square. The tower of Sompting Church possesses early carved work, and boltels at the angles of the window openings, and also a very peculiar ornamented string course. The chancel arch at Wittering Church, Northamptonshire, is among the early attempts at moulding observed in this country, being rough and coarsely chiselled members, generally semi-cylindrical. A square-edged reveal soon became a boltel, by first chamfering, and then removing indefinitely the angles. Thus, a square-edged arch with its sub-arch or soffit rib, was either worked into rounds at each angle or into pointed rolls; or some edges were chamfered, others worked into rolls, and the sub-arch cut away into a broad semi-cylindrical rib.

ARCH PLANES.

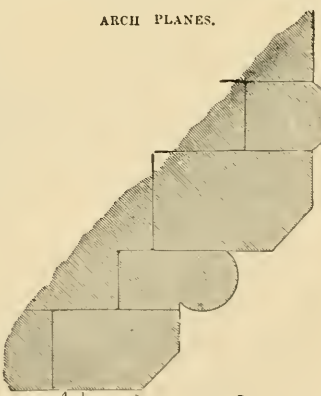

Fig. 1064. FOUNTAINS ABBEY; NAVE.

"The *Norman* architects never got much beyond the plain semi-cylindrical roll (*fig.* 1064. does not show even so much work). They paid more attention to surface sculpture and shallow ornamental work in the archivolts and soffits. Some of the early mouldings and ornaments are illustrated in *fig.* 188., in Book I.

"The invention of the pointed boltel, contemporaneously with the pointed arch, opened the way to a great number of new forms, all more or less referable to this common origin, in varying the members of complex *early English* groupings. The first and by far the most important of these is the *roll and fillet*, as A in *figs.* 1065. and 1066. It is the keynote of almost all the subsequent formations. The characteristics of the mouldings of this style may be defined to be, deep undercut hollows between prominent members, which comprise a great variety of pointed and filleted boltels, clustered, isolated, and repeated at certain intervals, a great depth or extent of moulded surfaces, and the general arrangement in rectangular faces. The hollows, giving the effect of a series of detached arches or ribs, rising in succession, are seldom true circles (A, *fig.* 1067.); and, like the projecting parts, they assume a great number of capricious forms. They are not always arranged in exact *planes*; the student must be fully prepared to find great irregularity in this respect.

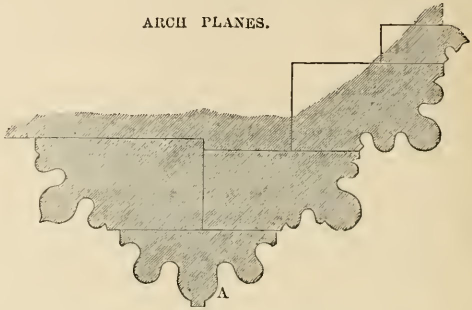

Fig. 1065. FOUNTAINS ABBEY; CHOIR.

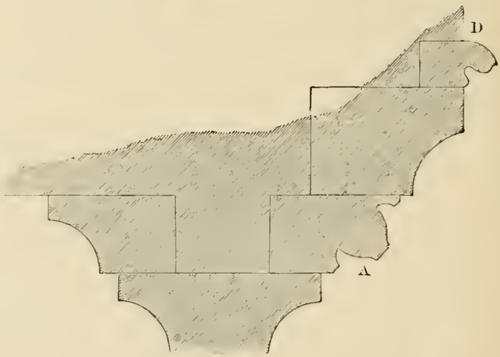

Fig. 1066. TINTERN ABBEY; NAVE.

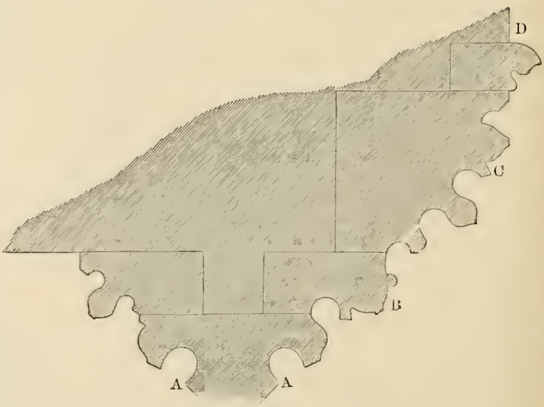

Fig. 1067. TINTERN ABBEY; CHOIR.

"Early English mouldings may be said to comprise the following members:—I. The plain boltel or edge roll; II. The pointed boltel; III. The roll and fillet; IV. The scroll moulding (rare); and V. Angular forms, consisting of chamfered ridges and intervening projections of irregular character. The other forms chiefly consist of capricious modifications of the roll and fillet. The *roll and triple fillet* (of which B, *fig* 1067., is a modification), is much used in the more advanced buildings of the style, and was the favourite form during the reigns of Edwards I. and II. Sometimes only one side has a fillet attached, as at C, and others. Three pointed rolls, placed together somewhat in the shape of a fleur-de-lis, form a combination of very frequent occurrence (as *figs.* 1097. and 1104.), with many minor varieties of shape. The fillet is almost always a narrow edge line. The irregular shape and the freely undulating curve of the roll and fillet moulding has been commonly preferred. Almost every conceivable modification of the plain roll, peaked, depressed, elliptical, grooved at the end, threated, isolated, and combined, might be found and catalogued by a careful observer. The *scroll* moulding, also called *edge* moulding or *ressant lorymer*, as O in *fig.* 1062. and D in the above figures, was used in advanced early English work; it is so called from its resemblance to a roll of thick paper, the outer edge of which overlaps the side exposed to view. It was extensively used in the decorated period."

The exquisite skill, taste, and patient labour invariably evinced in the working of early English mouldings, are truly admirable. The deepest hollows are all as clearly and perfectly cut as the most prominent and conspicuous details; and as much so in the village church as in the cathedral. Some examples (of doorways) occur at Bolton and Furness Abbeys, whose arch mouldings extend 5 to 6 feet in width.

"The details of *decorated* mouldings are for the most part identical with those of the preceding style, with the addition of some new members, and several important modifications of grouping. The latter will be found to produce an entirely different effect, though in description the distinction may appear very trifling. Much greater geometrical precision in drawing both the hollows and the projecting members prevailed. Segments of circles, both convex and concave, were much used, with an avoidance of strong contrasts of light and shade, which imparted a more pleasing, though much less striking, effect. The perfection of moulding, as of all architectural detail, is considered by many to have been attained in this period; yet rich mouldings in it are of rather rare occurrence. Very often plain chamfers are used in all the windows, doorways, and pier arches, while minor parts, such as bases, sedilia, and the like, have fine and elaborate details.

"There appear to be three distinct kinds to which decorated mouldings may be generally referred:—I. The plain or hollow chamfer of two or more orders, which, properly speaking, is only the step preparatory to moulding. II. Roll and fillet mouldings, and fillets with hollows between each group. III. A succession of double ogees, or double ressants, divided by hollows of three-quarters of a circle. Sometimes the mouldings of II. are combined with those of III. The mouldings of class II. are generally borne by jamb shafts, now engaged in, and not detached, from the wall. Those of III. are almost always continuous, except in pier arches, where they constantly occur. Four or five of these together give a very deep and rich effect to a doorway. One member of a double ogee is often considerably larger than the other, or those of one order of different size from the others.

"The principal forms found in decorated work are:—I. The roll and fillet, the fillet being extremely broad, often as much as 3 and 4 inches. II. The roll and triple fillet, invariably producing a fine effect. Its edge lines are sharp and delicate, and the profile beautifully relieved by the deep side hollows with which it is necessarily connected. III. The ogee. IV. The double ogee, or *double ressant.* V. The scroll moulding, or *ressant lorymer.* VI. The wave moulding, which may be cal'ed the *undy-boltel* (A in *fig.* 1068.), from its gently undulating surface: scarcely any method of moulding is so common in, or so characteristic of, this period, as two orders of the wave moulding, with a hollow between them: all the varieties of this moulding appear to occur without any definite distinction throughout the decorated and perpendicular periods; it is wider and shallower in early than in late work; the wavy line is even at times very faint. VII. The plain, or hollow, chamfer; and VIII. The sunken chamfer. The boltel, or three-quarter round, is used very sparingly. The hollows are usually of larger size than those of the early English; and there is this general difference in their use, that *in this style they divide groups, in the early English, individual members.* A few exceptional instances occur of a tongue-shaped member projecting from the inner side of the principal roll and fillet; this is a very characteristic detail of the class II.

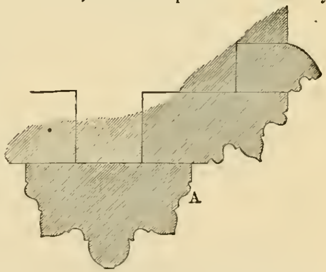

Fig. 1068. BOWDEN CHURCH; CHOIR.

"In windows, the plane in which the mouldings of the jamb lie is seldom coincident with that on which the side of the mullion is arranged, for this would in most cases give too great thickness to the latter. The difference of inclination may be very slight, but it requires attention.

"In mouldings of the *perpendicular period*, a comparatively meagre save-trouble method of working them is perceived. Large and coarse members, with little of minute detail: wide and shallow hollows; hard wiry edges in place of rounded softened forms, are all conspicuous characteristics. Their general arrangement on the chamfer plane (*figs.* 1061. and 1062.), which is a marked feature of this period, gives a flatness unpleasing to the eye in comparison with the rectangularly recessed grouping of the two preceding styles. Three peculiarities are so common, that their absence almost forms the exception to the general usage. These are:—I. A wide shallow hollow, usually occupying the centre of the group, and equal to about one third of the entire width. When the hollow is deep and narrow, it is generally a mark of early work; of late, when wide and shallow; and of debased, when sunken but little below the chamfer plane. One or both ends of the hollow are sometimes returned in a kind of quasi-boltel (as I. *fig.* 1062.). The boltel is often formed from a plane by sinking a channel on each face; and occasionally it stands like an excrescence on the surface of a plane (as in *figs.* 1061. and 1062.); but this is a departure from the usual practice, as well as from the principle of mouldings. II. The constant use of boltels, or beads of three-quarters of a circle, resembling small shafts. And III. The frequency of the double ogee, and some varieties of it peculiar to the period, as shown in the figures above-named. This double ogee appears to be composed of a semi-circular hollow continued in a boltel. All varieties may be considered distinctive criteria of the period. The *double ressant* is sometimes of a large and clumsy size. The roll and fillet was not extensively used; its form is that of B, *fig.* 1071.

"Rich and good perpendicular mouldings are not very common, most examples consisting but of three or four very ordinary members, offering nothing either novel or interesting to the view. The doorways are, however, often very deeply recessed, and the engaged jamb shafts bear isolated groups of considerable delicacy. The distinction of the *orders* is often completely lost in this period, while it is seldom undefinable in the previous one. The chamfer plane in many cases is either more or less than an angle of 45°. Sometimes two parallel chamfer planes are taken for the basis of the arrangement of the mouldings."

Among the characteristics of the tertiary French style, or the Flamboyant, which has been described and illustrated in *pars.* 546, *et. seq.*, is that called by Professor Willis, in a most ingenious and valuable paper, read in 1840 before the Institute of British Architects, *penetration* or *interpenetration* of the different mouldings and parts. The French antiquaries have called the system in question *moulures prismatiques.* Neither of these terms seem satisfactory, but of the two we are inclined to prefer the first as most significant. In the paper above mentioned, he observes that the practice is very rarely to be seen in English buildings, but produces an instance of it in the turrets of King's College chapel, at Cambridge (*fig.* 1069.), where the cornice A of the pedestal seems to pierce the plinths of the angle buttresses, and appears at B. This is, however, by no means a capricious, but rather an indispensable arrangement, by which the solidity of the octangular base was obtained without the necessity of the multitude of re-entering angular mouldings, which would have otherwise been carried round the buttresses.

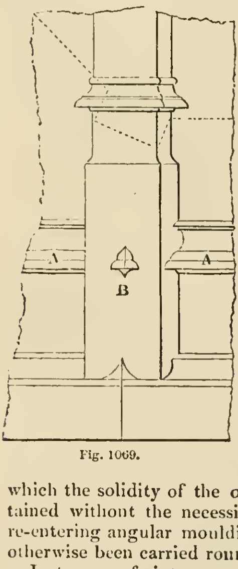

Fig. 1069.

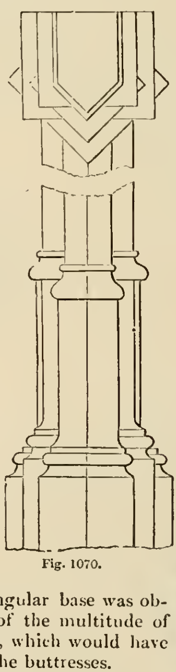

Fig. 1070.

Instances of interpenetration are abundant in France. Amongst those selected by him is one from a screen, in the cathedral at Chartres; it is given here geometrically (*fig.* 1070.). *Fig.* 1071. is from the stone cross at Rouen, in which the interpenetration principle is displayed in many of the vertical as well as horizontal members of the structure. The parts A A, mark where the fillet of the mullion pierces the chamfered and moulded parts of the sill. "In many Flamboyant examples, small knobs and projections may be observed, and on a superficial

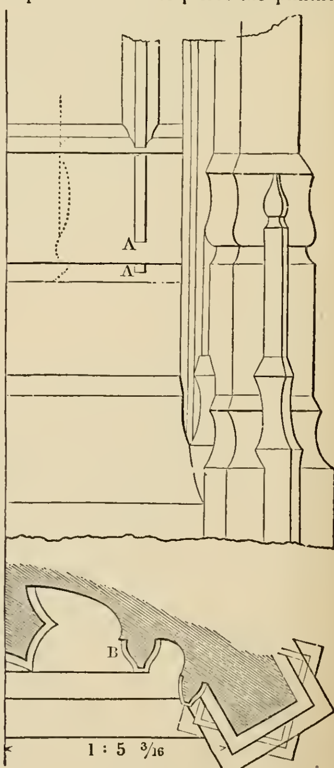

Fig. 1071.

view might pass for mere unmeaning ornaments, but will be found explicable upon this system of interpenetration." *Fig.* 1072, "is a window from a house near Roanne, at the base of whose mullions, knobs may be observed, which really represent the Gothic base of a square mullion on the same plinth with the hollow chamfered mullion, and interpenetrating with it." The Professor also states that, "it may perhaps be found that this character belongs to one period, or one district, of the Flamboyant style;" but from our own observation, we are inclined to believe it to have been universal from the middle of the fifteenth century to the period when the style of the Renaissance superseded it. The principles on which it is conducted certainly prevailed in Germany and in the Low Countries, as Professor Willis afterwards states. A notion to what extent it proceeded may be perceived by *fig.* 1073, taken from Möller's *Denkmäler der Deutschen Baukunst*, 1821, and exhibits on the plan a series of interferences contrived with great ingenuity and a consummate acquaintance with practical geometry. The subject is the plan of a tabernacle, or canopy, such as is not unfrequent in churches on the Continent. It shows, says Möller, how the simple and severe architecture of the 13th and 14th centuries had been debased. The square BCDE is the commencing figure.

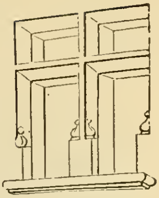

Fig. 1072.

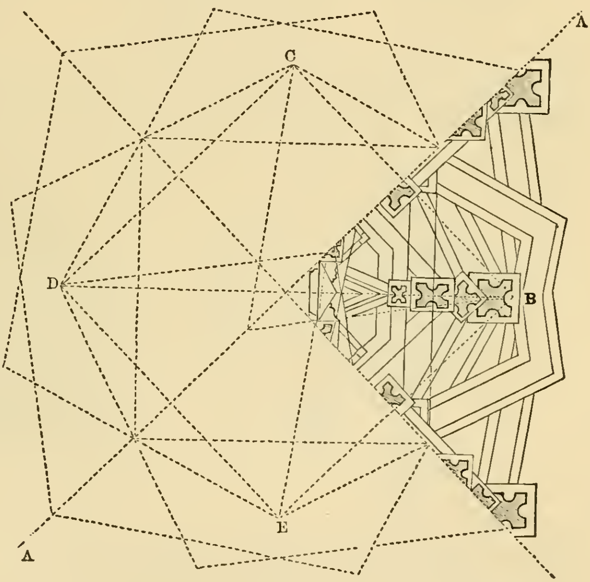

Fig. 1073.

A comparison of English and French mouldings has been made, with illustrations, by the Rev. J. L. Petit, in his work, *Architectural Studies in France*, 8vo. 1854, page 141. Of course Viollet le Duc's *Dictionnaire* has now become a well of information on this as on many other details. Some few examples are given at the end of the ensuing chapter of this Book. Venetian details have been carefully elucidated by J. Ruskin, in *Stones of Venice*, Vol. III., 1853, wherein pp. 221–249 are devoted to the examination in succession of the bases, doorways and jambs, capitals, archivolts, cornices, and tracery bars, of Venetian architecture. We do not, however, perceive that any scale or dimension is given to the examples illustrated, the absence of which materially lessens the usefulness of the examples. German details may be sought in Möller's work before quoted; in King, *Study Book of Mediæval Architecture and Art*, 1860; in Statz, Ungewitter, and Riechensperger, *Gothic Model Book*, 1859; and in Hoffstadt, *Gothisches ABC buch*, 1840.

Sect. IV.

PIERS AND COLUMNS.

The general plans of the piers supporting the principal arches are either simple or compound: simple, when composed of one plain member; and compound, when consisting of a core surrounded by smaller shafts, detached or engaged. Piers of the earliest period for carrying walls were square, as at the cathedral at Worms. These were relieved by engaged shafts, as in *fig.* 1074. In the 12th century the shaft begins to take the form on its plan of a Greek cross (*fig.* 1075.), with engaged columns in its angles as well as on its principal faces.

For the benefit of those making surveys of buildings, we think it useful to subjoin the following recommendation from the "Remarks" of Professor Willis:—"In making architectural notes, the plan of a pier should always be accompanied with indications of the distribution of its parts to the vaulting ribs and arches which it carries. The mere plan of the pier by itself conveys but small information; for it often happens that the identical pier may be distributed in many different ways, and that these differences constitute the only characters that distinguish the practice of one age or country from another. *Fig.* 1075*a*. shows one way in which the plan alone may be made to convey these particulars. The dotted lines, drawn from the respective members of the pier, mark the direction of the ribs and arches; and upon each of these, at a small distance from the pier, are placed vertical sections of these ribs, as at ABCD."

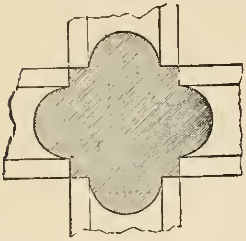

Fig. 1074.

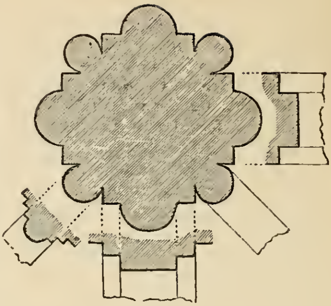

Fig. 1075.

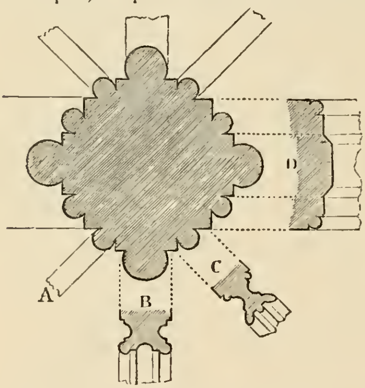

Fig. 1075*a*.

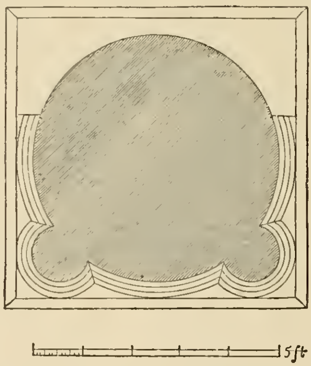

Fig. 1076. FOUNTAINS ABBEY; NAVE.

Norman piers are, in their earlier form, mostly masses of wall, with rectangular nooks containing attached shafts, as at Winchester, *figs.* 1267 and 1268. The circular (*fig.* 1076.) and octagonal columns seem to have been introduced about the time of the transition; and continued common in ordinary parish churches throughout the early English and decorated periods. Complex early English piers are so varied in arrangement that it would be impossible here to do more than notice their general characteristics, which consist principally in the number of smaller isolated shafts clinging to a central column, to which they are at intervals attached, in reality as well as in appearance, by moulded bands or fillets (Westminster Abbey, *fig.* 1278.), wherein a circular shaft is found, with four detached colonnettes (*fig.* 1058.), and with eight small detached shafts at Ely. *Fig.* 1077. is a gracefully designed pier. One without the colonnettes, and with broader fillets, is a very common form in the early English and decorated periods, with some varieties.

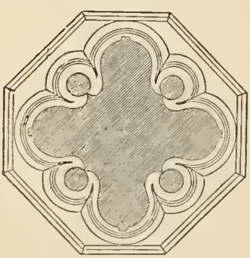

Fig. 1077. FOUNTAINS ABBEY; CHOIR.

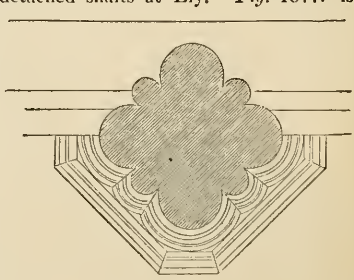

Fig. 1078. TINTERN ABBEY; PIER.

Geometric and decorated piers have their shafts engaged (*figs.* 1078. and 1079.), so that a clustered column is formed by working out the surfaces of the mass in lines and hollows. The example (*fig.* 1059.), from Westminster Abbey, has four detached, and four attached, colonnettes to the central shaft, but the reason for this exceptional arrangement has been explained...

and extent of the great piers in cathedrals and abbeys. Piers in the perpendicular period are generally of oblong or parallelogrammic plan, the longitudinal direction extending from north to south (*fig.* 1316.). On the east and west sides half shafts are attached, which bear the innermost order or soffit mouldings of the arch; the rest, including the great hollow, being usually continuous, without the interruption of any impost. The plan of the pier in Henry VII.'s Chapel is a fine example (*fig.* 1324.) of such an arrangement; and *fig.* 1059. shows the continued adoption of the decorated piers in the later portion of the nave of Westminster Abbey. Sometimes the ground plan is a square, set angleways (as in the nave of Canterbury Cathedral, *fig.* 1299., and at Bath Abbey Church, *fig.* 1320.), and each angle may have an engaged shaft of a circular or ogee form.

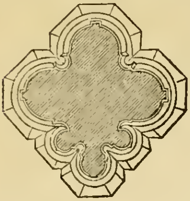

Fig. 1079. HOWDEN CHURCH.

Sect. V.

CAPITALS.

The mouldings of capitals and bases are more definitely marked in the various periods than any other kind of mouldings. "It is by no means impossible, even for an experienced eye, to mistake the details of a decorated for those of a perpendicular arch; but no one moderately acquainted with the subject could hesitate in pronouncing the style of a capital or base, provided it possessed any character at all. In the Norman period, when the shaft was round, the highest and lowest members only were square, the parts immediately next them being rounded off to suit the shape of the shaft (*fig.* 1266.). This is seen in the ordinary form of the *cushion capital.* We may observe the lingering reluctance to get rid of the square plinth, in the tongue-shaped leaves or other grotesque excrescences which are often seen to issue from the circular mouldings of transition Norman bases." *Fig.* 1080. is a curious example of the square form in front (N), and the circular moulded form in rear, of the shaft, shown on plan, *fig.* 1076. As soon as a sub-arch was introduced the corners of the capitals were either cut off or cut out: the former process produced the octagonal form; the shape of the shaft produced

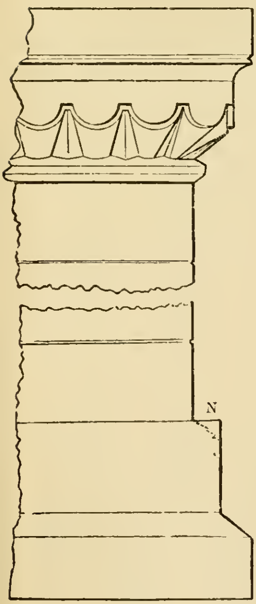

Fig. 1080.
FOUNTAINS ABBEY; NAVE.

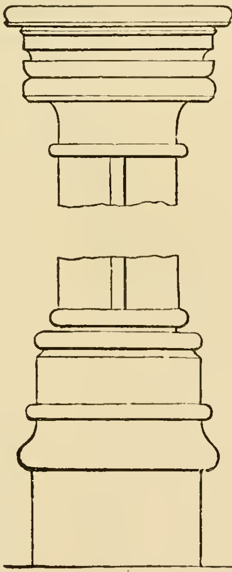

Fig. 1081.
FOUNTAINS ABBEY; CHOIR.
Scale, the same as to fig. 1064.

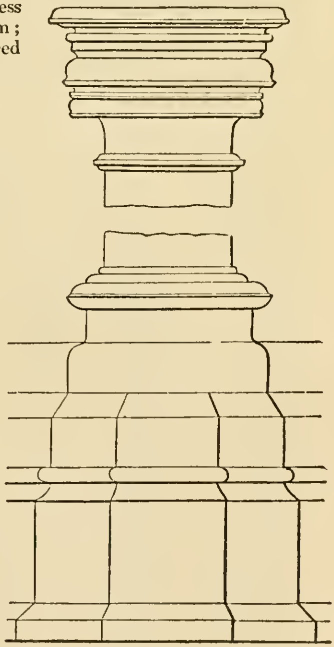

Fig. 1082.
TINTERN ABBEY.

the circular capitals and base. But capitals became octagonal before plinths: and similarly octagonal plinths were retained long after circular capitals had become universal.

Fig. 1081. is the front face of the shaft shown in *fig.* 1077., as is also *fig.* 1082. of that of *fig.* 1078., &c.

"Capitals may be divided into moulded and floriated. In the latter, the foliage in the transition Norman and early English period is arranged vertically, in the decorated it twines horizontally, or rather transversely, round the capital (*fig.* 1083.). In the perpendicular, more frequently small leaves or pateræ are set like studs at intervals round the shaft above the neck. The capital consists of three parts, the abacus, the bell, and the neck. In the early English period the abacus is almost invariably undercut. In the decorated it consists of the scroll moulding with a cylindrical roll of less size below it. The bell, in early English caps, is sometimes double, with a very handsome effect, while in decorated work it is seldom so deeply undercut. It is also much more varied by elaborate and capricious forms, as by a number of fine edge lines; and the underpart of the bell is often composed of a roll and fillet. The necking forms an important detail in judging of the dates of the work. In the early English it is usually of a bold angular outline; or a semihexagon. The neck during the decorated period is almost always the scroll moulding, but many other forms will be found to occur. Even a practised eye may occasionally be deceived in the date of capitals of the two early periods.

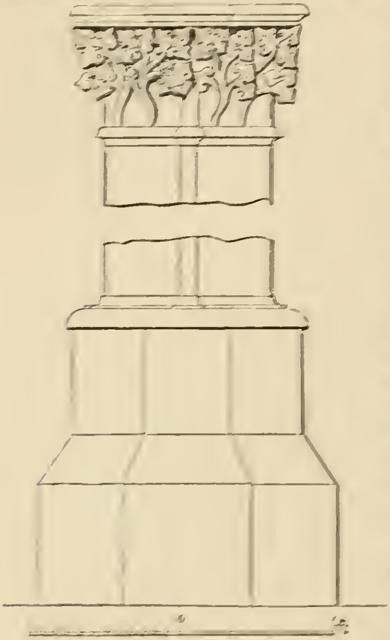

Fig. 1083. [illegible] CAPITAL.

"The capitals in the perpendicular period present such marked features that they are seldom liable to be mistaken. The mouldings are large, angular, meagre and few. Neither abacus nor bell is clearly defined. The latter is reduced to a meagre chase, although it sometimes still remains. The upper part of the abacus is usually sloped off to a sharp edge, and the section of the moulding below resembles the letter S inverted, being a

[illegible]

mere corruption of the decorated scroll moulding; *above all*, the capital is octagonal, while that of the preceding styles is round. The shaft, however, is circular in the perpendicular work, while octagonal capitals most generally occur in the other styles in the case of large single columns of the same shape. The base in the later style is generally circular in its upper members and octagonal below. The capitals are often embattled. The astragal or neck is either a plain round or a kind of debased scroll moulding with the upper edge chamfered as in the abacus. It will be found that a much greater license was taken in designing the mouldings of this style than in any other. *Fig.* 1092. is the section of the capital of the shaft to the arch between the nave piers in Henry VII.'s Chapel, (as at C, *fig.* 1825.). *Fig.* 1093. is the base of shaft to nave piers, as E, *fig.* 1824. and B, in *fig.* 1825. *Fig.* 1094. the base, and capital 8 inches high, to the vaulting shafts in the aisles; the capitals in the small chapel at the end of the building are nearly the same in section.

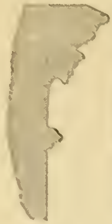

Fig. 1092.

Fig. 1093. Fig. 1094. HENRY VII.'S CHAPEL. Scale, the same as to Fig. 1093.

Sect. VI.

BASES.

The bases of the shafts in the 11th and 12th centuries are often chamfered and frequently moulded in the Attic form, more or less modified and debased. In the latter period the Attic base is sometimes found almost pure. In early work the base consists of the plinth or lower step, of solid masonry, generally square (*fig.* 1080. see the curious modifications of it in the plan *fig.* 1076.), but in early English often octangular (*fig.* 1077. and 1081.); and the base mouldings, a series of annular rolls, slopes, or hollows taking the form of the column. In decorated and perpendicular columns, the plinth is apparently omitted, and the base is divided into heights, stages, or tables, by gradually spreading courses, each separated from the next by a plain, or by a moulded, order. The lower part of the base is sometimes octagonal or polygonal. A cavetto above a quarter round is a very common form in early work. A bold annular roll, quirked on the under side, often divides the shaft from the plinth.

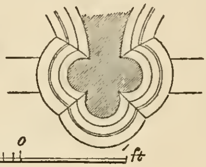
The early English base is very similar to the Attic form, the chief peculiarity consisting in the hollow being cut downwards and extended from half to three quarters of a circle, so that it is capable of containing water (*figs.* 1081., 1084., and 1085.). The earlier the base is in the period, the shallower, as a general rule, is this water-holding hollow (*fig.* 1086.). A common form is obtained by omitting the hollow altogether, and thus bringing the rolls into contact (like *fig.* 1088.). In very rich early English bases there are often double hollows between filleted rolls, and below these occur other bold annular rolls, single, double, and even triple, as at the beautiful Galilee porch at Ely, where the bases are worked out of Purbeck marble and were polished. The spread of the base in the uppermost members generally equals that of the capital, or nearly so. By far the commonest decorated base is that shown in *fig.* 1087. and *fig.* 1089., the number of rolls being generally three, but often only two. A few modifications may be perceived, but they are seldom very complex. The large spreading roll is worked out of the block, with which it usually stands flush, and is separated by a quirk or angular nook. This is also observable in the previous style. A simple form of base is shown in *fig.* 1091.

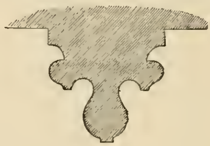
The prevailing characteristic of the bases of perpendicular columns is a large bell-shaped spread in the upper part, often double, forming the contour of a double ogee in section, as *fig.* 1093.; and is one of the ordinary kind. The lower part is almost invariably octagonal, the upper being generally round, but also frequently octagonal, irrespective of the shape of the shaft (*fig.* 1800.). It has either one or more stages sloping off by a hollow chamfer, or by a second bell-shaped slope. The first member of the base is always an annular roll, resembling the neck of capitals; this is often in the form of the debased roll and fillet. Edge lines scarcely ever occur. Other examples of bases are given in the last section of this book. The usual distribution of the table mouldings of a late base consist of a plain slope F (*fig.* 1820.), reckoning upwards from the ground line C, a flat surface E, and a projecting moulding D. In more elaborate structures, the number of these base tables and intermediate *champs* or *fasciæ* is increased, and the latter are often carved in panels, &c. Thus a second table, B, is introduced above the ground line G. Professor Willis applies the term "ground table, grass table, or earth table," to the slope B, and states that to such tables as D the term "ledgement tables" were probably applied.

Sect. VII.

VAULTING SHAFTS AND RIBS.

When the main shaft supporting the clerestory had an attached circular shaft in front, the latter was often carried up as a shaft to the roof (*fig.* 1266.) The point





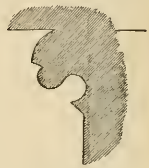


Fig. 1095. CHOIR. Fig. 1096. CHOIR AISLES.

Fig. 1097. Fig. 1098.
Transverse and Diagonal Rib; and Wall Rib—CHOIR AISLE.
FOUNTAINS ABBEY. VAULTING RIBS

has not yet been settled whether this shaft in some early buildings was, or was not, so carried up to receive the cross-rib of a vault, or simply to bear the beam of the roofing. When vaulting became more general, the purpose of the shaft was undisguised (*fig.* 1278.), and being made correspondent with the vaulting ribs, the groups of the latter were received on a colonnette or on small columns. The vaulting ribs at St. Saviour's (Southwark) Church, are given in *fig.* 662*e*. In the latter part of the 15th century engaged colonnettes for receiving the vault ribs rise from corbels placed on or above the capitals of the shafts, and sometimes the ribs themselves spring from the corbels (*figs.* 1274. and 1275.), and later, or in the perpendicular period, the older form was, as it were, reverted to, and the attached circular shaft was carried up to, and received the vaulting ribs, as in *figs.* 1302., 1307., 1314., 1317., and 1325.

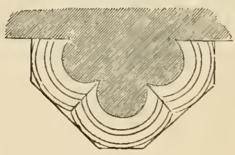

Fig. 1099. NAVE AND CHOIR. Fig. 1100. AISLE.
TINTERN ABBEY. VAULTING SHAFTS.

Corbels very frequently supplied the place of capitals both for the springing of arch mouldings and for vaulting. These corbels were either moulded or carved to correspond with the capitals (*fig.* 1109.), or they were fashioned into a mass of foliage, into heads of males and females, or of animals. Even whole figures were introduced, occasionally deformed if not purposely so carved for admission within the

space. In the vaulted sacristy at Winchester College, its "springers present an archbishop in benediction, a bishop, and a king, and over the door a guardian angel. Bosses of oak leaves and roses alternately, carved with great taste and 'subtilitè,' enrich and cover the junction of the ribs.—The uncouth and barbaric heads in the corbels which surround the principal figures contrast with their graciousness, and form that antithesis which the great masters in fine arts of the succeeding centuries employed so abundantly. The virgin patroness presides over the western pinnacle of the chapel; the angel Michael at the other termination of the building menaces with his flaming falchion the several demons which might approach the hall, refectory, cellar, and kitchen; the angel Raphael points out the entrance to the house of prayer at New College; the king and the bishop support the label of the gateways to the college at Winchester, and the entrance of the chapel; and as the appointed guardians and supporters of temporal and spiritual things, they sustain alternately the corbels or springers of the ceiling of the chapel. At the entrance of the hall and kitchen, the recreating psaltery and bagpipes are affixed; over the kitchen window is 'excess,' a head vomiting; and opposite is 'frugality' in the figure of a bursar with his iron-bound money chest. Over the master's windows are the pedagogue instructing, and a listless scholar, scarcely attentive to the book he holds in his hand. Elsewhere we recognise the soldier, the scholar, the clergyman, &c., as suggesting the various professions in which the inmates may occupy themselves in after life. The inept substitutions for these significant and appropriate ornaments are amongst the most palpable evidences of the insufficiency and inaptness of our mimicry of this style, in most instances in the present day; and they betray great ignorance of the poetical mind and spirit of mediæval sculpture."—Cockerell, *The Wykeham Buildings.*

SECT. VIII.

HOOD MOULDINGS AND STRING COURSES.

"The strings consist of projecting ledges of stones carried below windows, both within and without a building, round buttresses, and other angular projections, and to cornices, parapets, tower stages, and other parts of edifices, being used as dividing lines. Though subordinate, they are of the greatest possible importance in imparting a character to a building. They at once relieve naked masonry, and bind into a whole the seemingly detached portions of a rambling or irregular construction. In most cases, especially to windows, a string course forms a real drip or weathering, and adapts its upper surface especially to this end, thus becoming what is termed a hood moulding, which when used

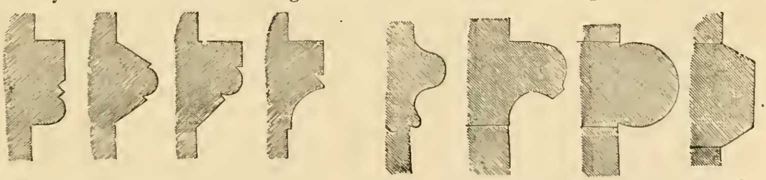

Fig. 1110. Fig. 1110*a*. Fig. 1110*b*. Fig. 1110*c*. Fig. 1113. Fig. 1114. Fig. 1111. Fig. 1112.
NORMAN PERIOD. FOUNTAINS ABBEY. CHOIR AISLES. NAVE CLERESTORY. AISLE.

internally, cannot be said to have any real use; but they form a decorative finish of too important a kind to be neglected with impunity."

Norman string courses are generally full of edges or hard chamfered surfaces (*fig.* 1110.). In most cases they have some sculptured decoration of the style, as the billet, the chevron,

Fig. 1115. Fig. 1116 Fig. 1117. Fig. 1118. Fig. 1119. Fig. 1120.

The scale of the last ten Sections is the same as that attached to fig. 1085.

the hatched or serrated moulding, or the like (*fig.* 188.). *Figs.* 1111. and 1112. are among the simplest, being the latest in the period. The commonest early English strings are like *figs.* 1114. and 1115.; the under-cutting giving a bold projection is a striking feature of this moulding as of all others of the style. The most frequent decorated form is *fig.* 1116. That shown on *figs.* 1179. and 1181. is also very common. The scroll, with a half-round next below it, *fig.* 1115. is very characteristic. The rounded form of the upper side, or weathering (*fig.* 1118.), is peculiar to the two first styles; the angular or chamfered, of the last (*figs.* 1119. and 1120.). String courses follow the principle of the abacus of the capitals, from which indeed they are often continued along the wall of the building.

Fig. 1121.—HENRY VII'S CHAPEL.

Perpendicular strings and hood mouldings are generally marked by the plane slope of the upper surface. The details of the parts underneath are so varied as to render it impossible here to give any account of them. A characteristic mark of the style is a small boltel in the lower part (*fig.* 1121.). The wall often recedes above the string, or even overhangs it. *Fig.* 1122. is the section of the "Angel cornice" over the arches in Henry VII.'s chapel, as shown in the elevation, *fig.* 1325., at D. *Fig.* 1123. is the cornice and base over it, over the panelling above the octagon windows. The scale is the same as to *fig.* 1085.

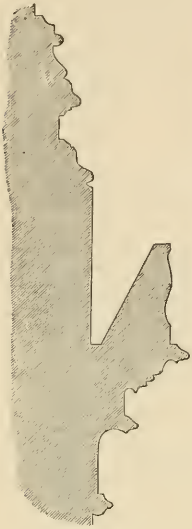

Fig. 1122. Fig. 1123.

Sect. IX.

BASE COURSES OR PLINTHS.

This term is applied to that series of mouldings formed at the base of a wall, which leads the eye from the upright face gradually into the ground. The lowest course of them is even called the "earth table." The early examples are very plain, consisting of one or of more chamfered set-offs at various heights, as *fig.* 1124.

In the early English period, the roll moulding was introduced at the upper edge of a deep chamfer, as *figs.* 1125. and 1272., and with one or two chamfered set-offs. They then became very similar, as in the transepts of Beverly Minster, to *fig.* 1126., of the geometric or decorated period, in which the tablet or slope took a curved or ogee outline, and was generally only one in number, finished at top by a scroll moulding, with occasionally a string above it, as at Ewerby. The height of

Fig. 1127.
HOWDEN CHURCH.
CHOIR.

fig. 1126 is very small for so large a building. The basement to Lichfield Cathedral is not much more defined. *Fig.* 1277. is a richer example.

The basement in the perpendicular period is one of the glories of the style. That shown in *fig.* 1306. from Winchester, may be considered very plain, as is also that at Bath, *fig.* 1319. Reversed ogees and hollows, variously disposed, are the principal members. *Fig.* 1128. being the basement round the outside of Henry VII.'s chapel, will afford some idea of the work bestowed upon this feature. Yelvertoft Church, Northamptonshire, has four rows of diagonal, square, and circular panelling, one above the other (Rickman, page 213., 6th edit.). In Norfolk, where flint work was used in the erection of the building, it was introduced in upright panelling in the lowest face, above an ogee moulding (*ibid*, page 214.).

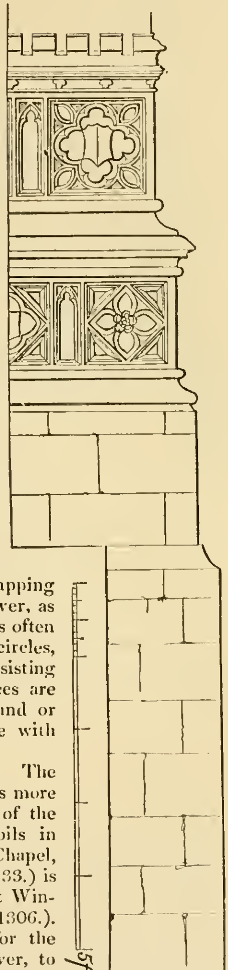

Fig. 1128. HENRY VII.'S CHAPEL.

Sect. X.

PARAPETS.

The Norman period may be said not to have exhibited any parapet, the roof being finished by the tiles or lead work projecting over the wall and supported by a corbel blocking.

During nearly the whole of the early English period, the parapet in many buildings was often plain, as *figs.* 1129. and 1126.; or with a series of arches and panels; or with quatrefoils in small panels, as *fig.* 1277., which is of the next period; or plain, with a rich cornice under it.

In the decorated period it was still plain but with moulded capping and cornice, as *figs.* 1130. and 1131., and with the ball flower, as in *fig.* 1128., but also closer and connected by tendrils; it is often pierced in various shapes, of which quatrefoils (*fig.* 1277), in circles, or without that enclosure, are very common; but another, consisting of a waved line, is more beautiful and less usual; the spaces are trefoiled. Pierced battlements are very common, with a round or square quatrefoil. The plain battlement most in use is one with small intervals, and the capping moulding only horizontal.

They continued to be used in the perpendicular period. The trefoiled panel with waved line is seen, but the dividing line is more often straight, making the divisions regular triangles. One of the finest examples of a panelled parapet, consisting of quatrefoils in squares with shields and flowers, is that at the Beauchamp Chapel, Warwick. The pierced parapet on Henry VII.'s Chapel (*fig.* 1133.) is a fine example, with its angle pinnacle. That on the choir at Winchester Cathedral consists of upright panelling only (*fig.* 1306.). Early period *battlements* frequently have quatrefoils either for the lower compartments or on the top of the panels of the lower, to form the higher. The later examples have often two heights of panels, or richly pierced quatrefoils in two heights, forming an indented battlement. They have generally a running cap moulding carried round the indentations.

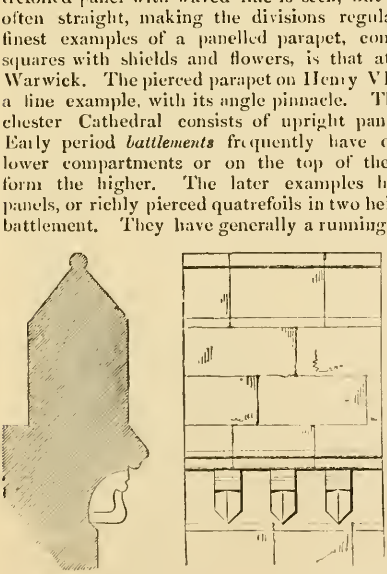

Fig. 1129. FOUNTAINS ABBEY; NAVE.

0 1 2 3 ft

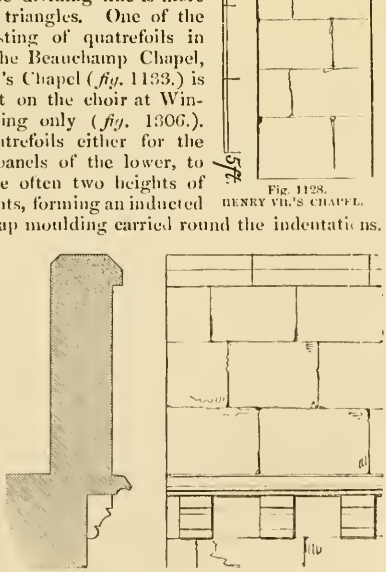

Fig. 1130. FOUNTAINS ABBEY; CHOIR.

In a few late buildings the capping is ornamented, somewhat like a cresting: and in a few instances figures resembling soldiers on guard have been carved on the battlements.

Plain battlements have been divided into four descriptions. I. Of nearly equal divisions, having a plain capping running round the outline. II. Of nearly equal intervals,

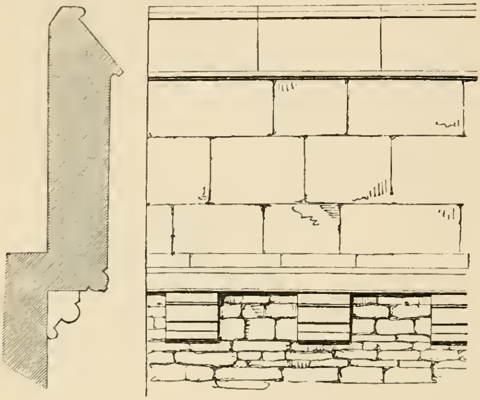

Fig 1131. TINTERN ABBEY; CHOIR.

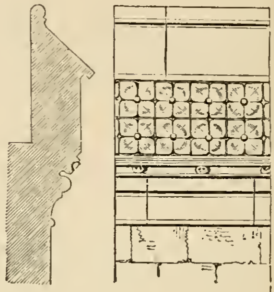

Fig. 1132. HOWDEN CHURCH; CHOIR.

and sometimes with large battlements and small intervals, the capping being only placed on the top, and the sides cut plain. III. Like the last, but with a moulding running round the outline, the horizontal capping being set upon it. And IV. The most common late battlement, with the capping broad, of several mouldings running round the outline, often narrowing the intervals (Rickman). It is seldom that the battlements will tell the age of the building, as they have been so often rebuilt. A small battlement differing to these four descriptions, is shown in *fig.* 1128., under the windows of Henry VII.'s chapel. A few more words may be said in the section Towers and Spires.

Sect. XI.

MOULDINGS IN WOODWORK.

"If this kind of work be attentively examined, it will be seen that it was wrought altogether on the same principles as the corresponding sculpture in stone. We see the thoroughly conventional early school, the naturalesque middle-pointed school, and the again conventional third-pointed school of carvers, succeeding each other in exactly the same way, the main difference between the two being that the work in wood is ordinarily very much more thin, flat, delicate, and sharp, than the work in stone; that it has always some limits set to its exuberance by the nature of the framework in which it was wrought. In carpenter's work, it was always the rule only to mould the useful members, and so it was also as regards the carving. It was not useful or convenient to put on to a piece of oak framing a mass of oak to be carved as a boss or a stopping to a label (this sort of device was reserved for the ingenuity of nineteenth century architects), and so it will be found that most of the old wood-carving is so contrived as to be wrought out of the same plank or thickness as that which is moulded. or else is a separate piece of wood —in a spandril, for instance, enclosed within the constructional members. The spandrils in the arcades behind the stalls at Winchester Cathedral are an admirable example; they are carved in thin oak, perforated in all directions, and then set forward about half-an-inch in advance of the back panelling. The effect of this is, as may be supposed, to give the

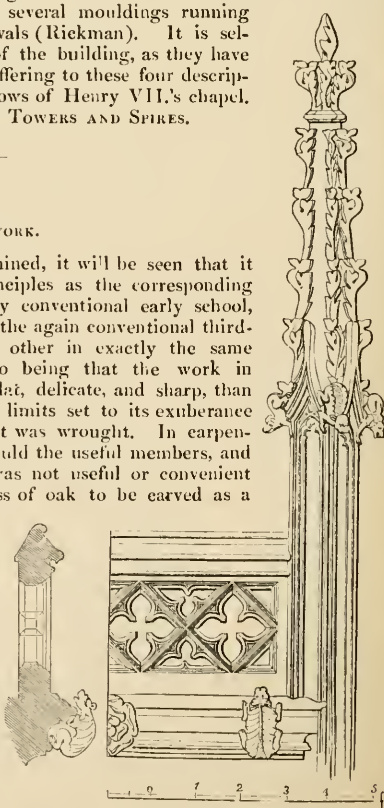

Fig. 1133. HENRY VII.'S CHAPEL.

carving the most distinct relief; and it is an effect strictly lawful, because it was impossible in other material, and yet natural in woodwork. The same attention to the material will be found exemplified very remarkably in all old wooden mouldings. The accompanying illustrations (*figs.* 1134. and 1135) will show how extraordinarily minute, delicate, and sharp they were. In the stalls at Selby we see an elaborate cap, only $1\frac{3}{4}$ inches high; at Winchester, a band $\frac{7}{8}$ths of an inch in height, and yet consisting of four distinct members, and showing in elevation as many as eight

Fig. 1134. STALLS; WINCHESTER CATHEDRAL.

Fig. 1135. SCREEN; ST. MARY'S HOSPITAL, CHICHESTER.

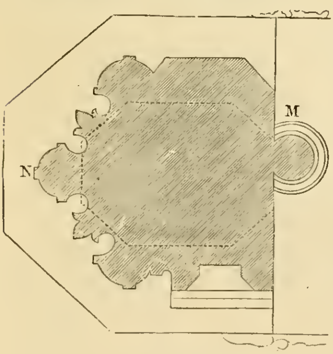

Fig. 1137. Scale 2 in. to 1 ft.

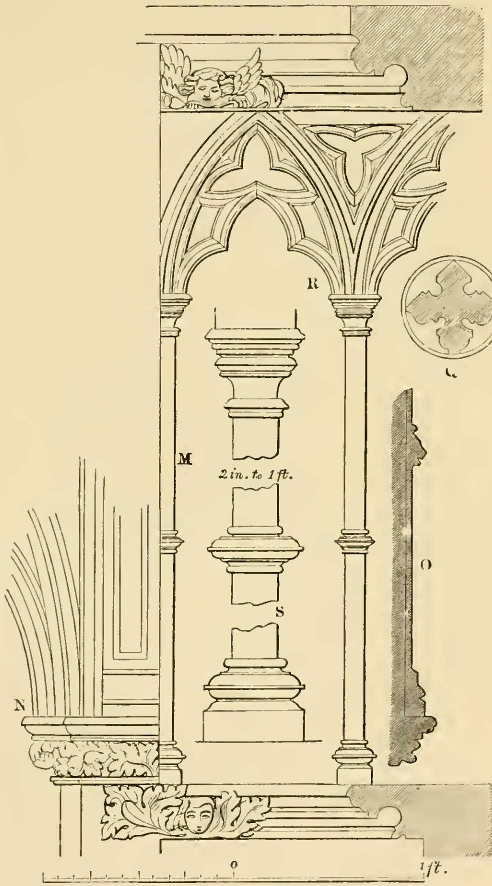

Fig. 1136. SCREEN; NORTHFLEET.

distinct lines. The finish of the wall plates in the porch at Horsemonden, and the carving of the miserere seat, so curiously preserved in the midst of woodwork some three hundred years later in date, in Henry VII.'s chapel, are fair illustrations of the goodness of the earlier sculpture."

"The whole of the early mouldings are sharp, delicate, minute, and quaintly undercut. They are very often unlike any stone mouldings, just as many wooden traceries (e g. those of the screen at St. Mary's hospital, at Chichester (*fig.* 1135.), and the stalls at Lancaster), are quite unlike what could conveniently be executed in stone. In spite of a bad fashion which obtains just now," among some of the present mediæval architects, "of ignoring the value of mouldings, I maintain that they prove conclusively the existence of a school of art in this country of almost unsurpassable excellence." Street, *On English Woodwork in the 13th and 14th centuries*, read at the Royal Institute of British Architects, 20th February, 1865.

As an example of early work we give *figs.* 1136. and 1137., from Bury, *Woodwork*, being the details of the screen in Northfleet Church, Kent. M, in the first figure, is the first column (the details being given to a larger scale at S) in the screen abutting upon the centre opening, the arch of which is shown at N. The corresponding positions on plan are exhibited in *fig.* 1137. The section O, represents the face of the buttress P, while the plan Q is that of the arch mouldings at R.

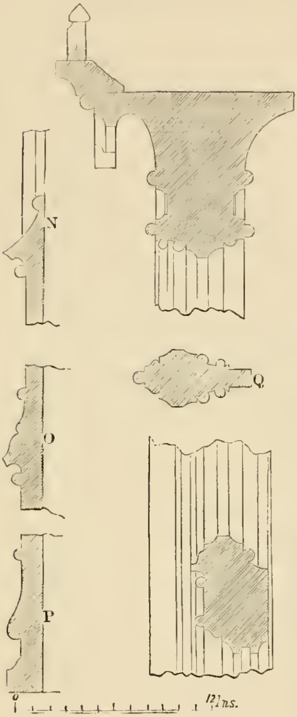

Fig. 1138. LAVENHAM, SUFFOLK.

Fig 1138. is a section of the screen on the south side of the chancel at Lavenham Church, Suffolk, wherein the details N, O, and P, are those belonging to the buttress Q, which even in late mediæval carpentry was not omitted, though somewhat out of accordance with the "true principles" attributed to design in that style.

Fig. 1139, being the capital and base mouldings from the screen in Aldenham Church, Hertfordshire, are of the perpendicular period. These examples are all further illustrated in Bury's work above-mentioned, as well as *figs.* 1140. to 1144., showing the general style of mouldings adopted for seats and bench ends, as noticed in *par.* 2192*b*. *Fig.* 1140. is the rail of the bench; *fig.* 1141. the division under the seat; and *fig.* 1142. the section of the arm of the stall and of a bench end, all at Bridgenorth Church, Somersetshire. *Fig* 1143. is the arm of the stalls at Wantage Church, Berkshire; and *fig.* 1144. the rail and stall mouldings at Swinbrook Church, Oxfordshire. The ends of the stall even in Henry VII.'s chapel are worked out of only 3-inch planks, and formed into three attached shafts, similar to *fig.* 1143. Other notices of the thickness of stuff are given in *par.* 2175*d*.

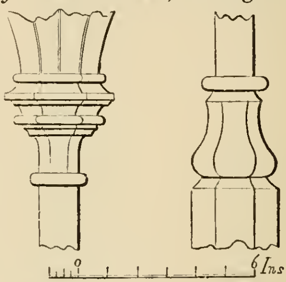

Fig. 1139.
SCREEN; ALDENHAM, HERTS.

Having given illustrations of the principles of constructing timber roofs during the mediæval period, we now append some of their details, which, on comparison with the

Suffolk, from which building the screen in *fig.* 1138. was also derived. *Fig.* 1156. is the cornice; *fig.* 1157. the wall strut, and *fig.* 1158. the purline. *Fig.* 1159. is the cornice in the chancel aisle. These are likewise derived from Bury, *Woodwork*.

Sect. XII.

WINDOWS.

In the body of the work we have, under each period of Gothic architecture, given a description in general terms of the windows prevailing at the several times. The examples here brought together, are inserted merely for the purpose of showing the gradual change in their forms and combinations, which are almost infinite in number, and yet that the latter are far from exhausted, is conclusively shown by R. W. Billings, in his work on *Geometric Combinations*; and by E. Sharpe, in *Decorated Window Tracery*.

The earliest windows are extremely small, always semi-circular headed, or nearly so, and without moulded archivolts. They are usually with a single light (*fig.* 1266.), except in belfry towers, where we often find them divided into two by a shaft with a capital, as in the tower at St. Alban's (*fig.* 1160.). The simple plain head, however, in the latter part of the early period, was more or less ornamented with the chevron or zigzag, and other orna-

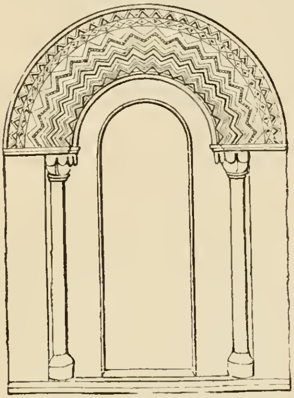

Fig 1161. BEAUDESERT.

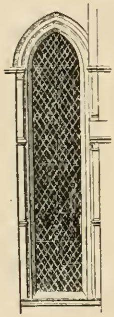

Fig. 1162. CANTERBURY.

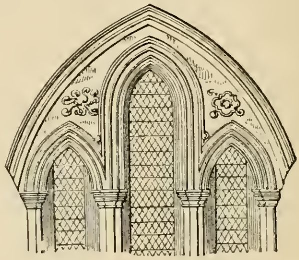

Fig. 1163. SALISBURY.

ments of the time, as in *fig.* 1161. One of the greatest and most striking changes brought in by the pointed style was that of introducing, from the suddenly elongated dimensions of its windows, a blaze of light into its edifices, which, from the low and narrow sizes of their predecessors, were masses of gloom. From the beginning of the 12th century we see them lengthened in a surprising manner, and terminating with a lancet-head, which sometimes became occasionally cusped. An instance of the simple lancet-head is given in *fig.* 1162., from the Trinity Chapel at Canterbury Cathedral. Sometimes an elegant combination is obtained by grouping lancet-headed windows under one hood, the centre rising above the side ones, as at Salisbury Cathedral (*fig.* 1163.), where the spaces between the heads are ornamented, or have a sunk panel or device. These spaces are frequently pierced with foliated circles, or with trefoils or quatrefoils not enclosed. In an example at Lincoln (*fig.* 1164.), the height of the group is equal, but the light of the centre being wider than the two side lights, the curvature of the arches of the latter is necessarily much less than that to the former, and the effect is not satisfactory. There were, however, many other arrangements in designing these lancet-headed windows than the single and triple ones just mentioned. Two, four, and five, lights occasionally form the group. Of the last-named, are windows at Irthlingborough, in Warwickshire, and at Oundle, in Northamptonshire, in which the lights on the sides gradually rise up to the centre one. In the latter part of the period, heads finish with trefoils; the mullions are moulded and finished, both inside and outside, with shafts or colonettes, from the capitals of which spring the mouldings of the subdivisions.

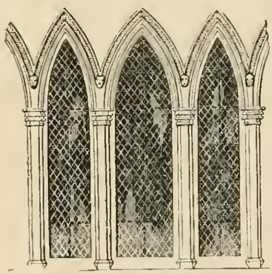

Fig. 1164. LINCOLN.

The finest and largest group of early English lancets in the kingdom is the five, commonly called 'the five sisters,' in the north transept at York Cathedral, completed 1250. They are each about 5 feet 7 inches wide, and nearly 60 feet high, and in the interior have a beauty altogether their own, not surpassed, if it be equalled, by any decorated or perpendicular window in the kingdom. The rich effect of the arrangement of the two stories, each having three lights, at the east end of Southwell Minster, is well deserving of attention. Ely cathedral has internally five lights over three, while externally three more are observed over the five.

At Kilkenny Cathedral there are three huge early English lancets, the centre one being

62 feet high and 8 feet wide. The detached shafts are filleted in four rows; the mouldings over are formed into trefoil arches. In the south side of the choir of St. John's Priory, in the same city, is a continuous arcade of 54 feet of lancets, the largest pier being only 9 inches wide.

These filleted bands are an interesting work, as they are found in many parts both of Ireland and England. Perhaps the most remarkable example in England is that at Walsoken Church, near Wisbeach, where the chancel arch has four small shafts in each pier, all banded five or six times It is additionally striking from its greater antiquity than any of the Irish examples, being, as at St. Alban's, romanesque. These banded columns and roll mouldings find their counterpart at Margam Abbey, in Glamorganshire, the west front of which shows a fine triplet, and a doorway below banded in this peculiar manner. *Transactions* of the Institute of British Architects, 1865–66, pp. 80–86.

The *foliations* seen in windows belonging to the earlier examples of this style in England are not generally cut out of the same stone as the head of the arch to which they belong, but form the tracery, in small pieces, and these enter into the class of *plate tracery*, i.e. they belong to the flat soffit, and not, like *bar tracery*, to the outer mouldings.

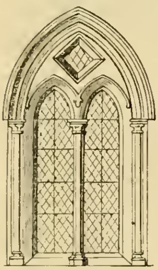

Fig. 1165. PAINTED CHAMBER.

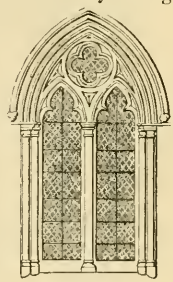

Fig. 1166. ELY.

By perforating the space between the heads of two adjoining lancet-headed windows, as in the old painted chamber at Westminster (*fig.* 1165), the elements of the ornamented window are obtained. To cover it, however, ornamentally, the enclosing arch must be depressed and modified; and at Ely (*fig.* 1166), we find an example for illustrating the remark. The lozenge-shaped form between the heads of the arches is converted into a circle which, as well as the heads of the lights is foliated. Instead of a single circle inserted in the head of the window, we then have them with three foliated circles, as

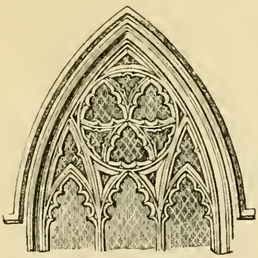

Fig. 1167. MERTON COLLEGE.

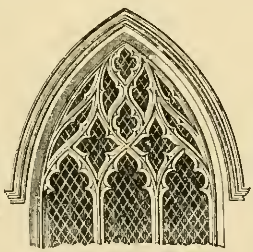

Fig. 1168. CATHEDRAL, OXFORD.

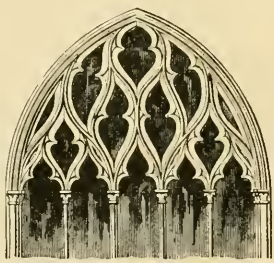

Fig. 1169. ST. OUEN, ROUEN.

at Lincoln, one above and two below; the same cathedral furnishing an example in the east window of its upper part having one large circle inclosing seven smaller foliated ones, besides its containing similar ones in the heads of the two leading divisions below. The windows just described belong to a transitional style between the early English Gothic and the decorated; but the ornamented windows of the 14th century exhibit in their general form and details a vast variance from them in the easy unbroken flow of the tracery with which they abound.

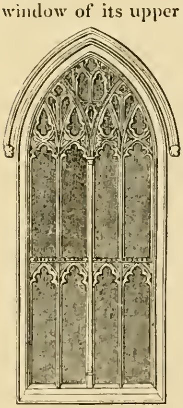

Fig. 1170. CAWSTON.

In the next stage come the examples shown by *fig.* 1167., Merton College Chapel, and *fig.* 1168., the Cathedral, both at Oxford; the latter whereof has a tendency towards the Flamboyant style, which has been before mentioned, and which, in the 14th century, had thoroughly established itself in France, as may be seen in the windows of the church of St. Ouen, at Rouen, exhibited in *fig.* 1169. It may be observed that the principal lights are seldom divided by transoms; when they, however, occur they are mostly plain, and rarely embattled. Though the ogee head is often found, the usual form is that of the simple-pointed arch. In the clerestory, square-headed windows are often seen, but more often in other parts of the edifice. In the preceding, as well as in this period, occurs the window bounded by three equilaterally segmental curves foliated more or less as the date increases. The arrangement of the tracery of windows has, by the French antiquaries, been divided into two classes — *rayonnant* and *flamboyant*. Their *rayonnant*, so called on account of the great part the circle plays in it, and on whose radii its leading forms are dependent, was flourishing throughout the 14th century in France.* The *flamboyant* or tertiary pointed style followed it. We have already observed that the Continent preceded us in each style as much as half a century.

After this comes the Florid style, in which the edifices seem to consist almost entirely of windows, and those of the most highly ornamented description. It is scarcely necessary to do more than exhibit the figures for a comprehension of the nature of the change which took place; in short the introduction of the Tudor arch alone was sufficient hint for a totally new system. In the example (*fig.* 1170.) of a window at Cawston Church, Norfolk, we may observe the commencement of the use of transoms, which at length were repeated twice and even more in the height of the window, and indeed became necessary for affording stays to the lengthy mullions that came into use. *Fig.* 1171. is an example of the square-headed window of the period, and *fig.* 1172. of a Tudor-headed window at Aylsham Church, Norfolk. Another example may be referred to in *fig.* 200., and in the several illustrations given under the section PRINCIPLES OF PROPORTION, at the end of this chapter.

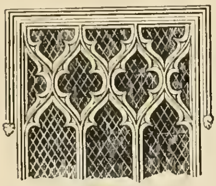

Fig. 1171. NORWICH.

Fig. 1172. AYLSHAM.

Mullions appear to have been introduced about the end of the 12th century as substitutes for iron frames, and were at first built in courses that corresponded with the other work of the wall in which they stood, or were in small pieces. But as early as 1235 they were *face-bedded* stones dowelled with iron. As the oxidation of the metal proved injurious, iron was superseded, after the end of the 14th century, by dowels made from the bones of sheep or from the horns of deer. *Fig.* 1173., from the west windows in the tomb-house at Windsor, temp. Henry VII, illustrates the arrangement usually adopted in drawings to show the distance from centre to centre, as at M, N and O, that is to be allowed in forming the length of radius employed in striking the curves for the tracery. Other examples of such sections are given from the clerestory of the nave of Winchester Cathedral, *fig.* 1303; Rouen Cathedral, *fig.* 1290; King's College Chapel, *fig.* 1312.; St. George's Chapel, Windsor, *fig* 1316.; and from Amiens Cathedral, *fig.* 1329.

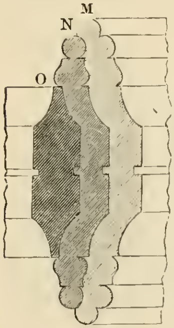

Fig. 1173. WINDSOR.

The simplest *mullion* or *monial* or *tracery bar* would be a plain rectangular block of stone. The next, with the edges chamfered, varied by substituting a hollow for a plain chamfer; by giving an ogee form to the chamfer; and by cutting out a hollow in the chamfer with receding angles instead of a receding curve; this last is perhaps peculiar to the early decorated style. The hollowed chamfer is the only moulding ordinarily made to carry the ball flower ornament of the 14th century, and the four-leaved flower of the 15th century. When the tracery becomes at all elaborate, the subordination of the parts is effected by giving to the jambs and mullions, or perhaps to some of the mullions only, and to some of the tracery bars, an additional *order of mouldings*. Then the fillet or boltel of the outer moulding (N, in *fig.* 1173.) describes the greater lines; that of the inner moulding (O) the smaller lines of the tracery and the whole of the cusping. In like manner a third order is often added by the same means and for the same purpose (as M). Each of these orders

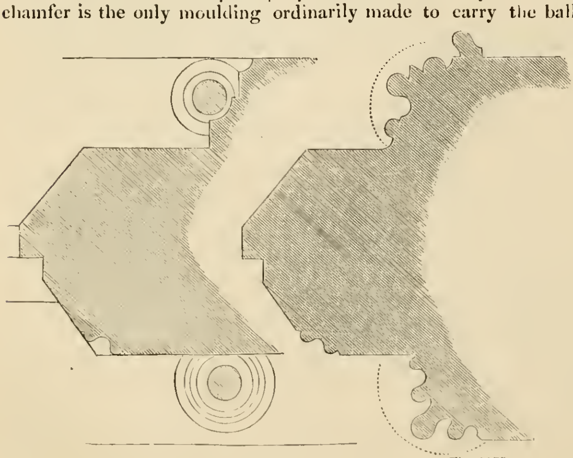

Fig. 1174. FOUNTAINS ABBEY. CHOIR. Fig. 1175.

may be as varied as was the first. Perhaps the most common form for the first is the hollowed chamfer, and for the second and third, the ressant with a fillet. In a very few instances, the outer fillet becomes a sharp edge, i.e. the mullion is chamfered to an arris.

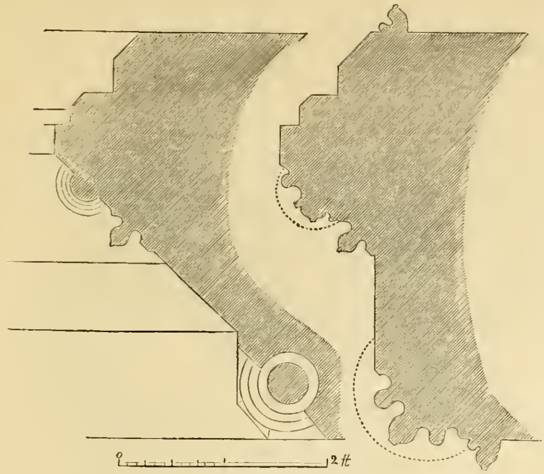

Fig. 1176. TINTERN ABBEY. CHOIR Fig. 1177.

"Nothing is more essential to the good effect of windows (except where the mullions are treated as shafts under a mass of tracery without glazing), and nothing is so much neglected by modern architects, as making the mullions of adequate thickness," writes Mr. Denison, in *Church Building.* "The modern works are very seldom more than $\frac{1}{6}$th of the width of the lights; probably about 4 inches in the ordinary side windows, and sometimes less, and perhaps a few as much as 7 or 8 inches in large east and west windows. In the east window of Tintern Abbey, which has eight lights (*fig.* 1178.), the principal mullion is 15 inches thick, and the two secondary ones are 11 inches, and the four smallest very nearly 8 inches. At Guisborough Priory, of the geometrical period, a window of only seven lights had two principal mullions, both as thick as the middle one at Tintern. The great mullion of the east window at Lincoln is about 2 feet thick. Even the two small east windows of Guisborough, with only three lights, has 9-inch mullions, and those at Tintern 7-inch. Some four-light windows at Whitby have the middle mullions about 13 inches, and the short clerestory windows of Bridlington are above a foot thick. No mullion ought to be much less than one-third of the width of the adjacent light. The *lights* of the small Guisborough windows are exactly three times the width of the mullions; the aisle windows of Selby are about the same; where there are more lights than these, and therefore two or more classes of mullions are required, the larger ones must be considerably more than this. In all cases the depth from back to front ought to be at least twice the width or thickness from side to side. There are a few old geometrical windows, with 'thin' mullions, but they are exceptions, and do not look well.

Fig. 1178. TINTERN ABBEY. EAST WINDOW. Fig. 1179.

"The difference between good and bad windows, strikingly exhibited in the same church, may be seen in the north aisle of the choir at Selby, where a set of windows of no more than three lights, and those rather short ones, having tracery of the simplest possible pattern, only three quatrefoils in the head, are perhaps the most beautiful windows of the size to be found anywhere. Above them in the clerestory are windows of four lights and much more elaborate tracery, and yet almost as ill-looking as any modern ones. The reason is that the lower ones are deep set, and have thick mullions and tracery, and high arches, whereas the others are very shallow, on account of the passage in the wall; the

Sect. XIII.

WINDOW JAMBS AND ARCH PLANES.

The following details of window jambs and mouldings, are reduced from those given in the valuable publication already mentioned, namely Sharpe's *Architectural Parallels*. *Fig.* 1174. is the plan of the jambs, and *fig.* 1175. of the mouldings of the arch over them, to the early English choir at Fountains Abbey, Yorkshire. *Figs.* 1176. and 1177. are the similar portions to the geometric choir at Tintern Abbey, Monmouthshire. The same publication gives, amongst its numerous details, the elaborate grouping of mouldings to the magnificent east (*figs.* 1178. and 1179.) and west (*figs.* 1180. and 1181.) windows of this building, which is somewhat transitional to the decorated period, and of very great beauty. *Fig.* 1182. is the jamb mouldings to the decorated east window at Howden Church, Yorkshire, showing a passage in the wall, which materially deteriorates from the good effect of the window.

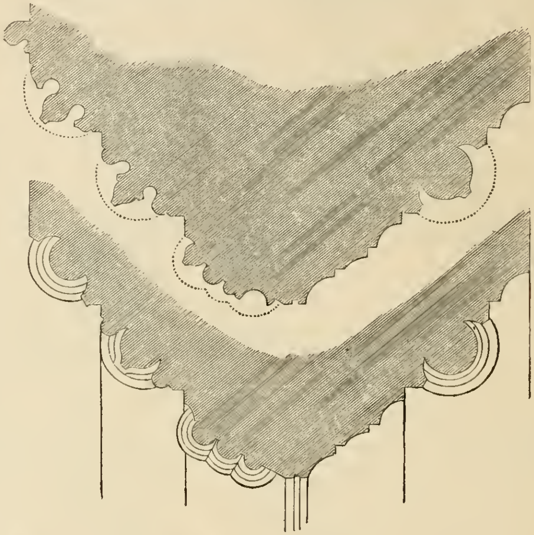

Fig. 1181. Fig. 1180. TINTERN ABBEY; WEST WINDOW.

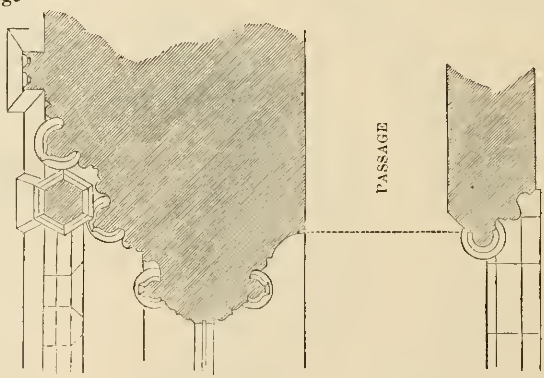

Fig. 1182. HOWDEN CHURCH; EAST WINDOW.

The following illustrations are from Henry VII's Chapel. *Fig.* 1183. is the wall jamb to the first cant of the angular windows to the aisles. *Fig.* 1184. is the first angle mullion of the circular or bow windows; it also shows the arrangement for the mullions or monials, and (L) the mitring

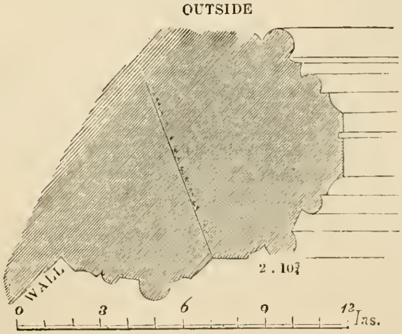

Fig. 1183. HENRY VII.'S CHAPEL.

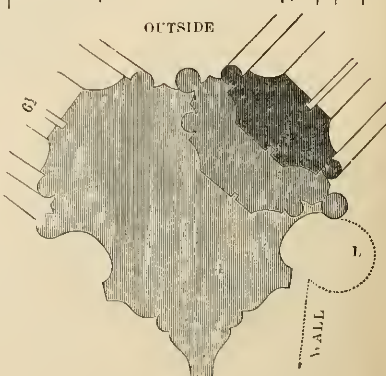

Fig. 1184. HENRY VII.'S CHAPEL.

with the wall-work inside. *Fig.* 1185. is the jamb mouldings of the upper range, or the clerestory windows. These are all reduced from Cottingham's work on this building, and are, to some extent, shown in the interior elevation of the bay, given in *fig.* 1325.

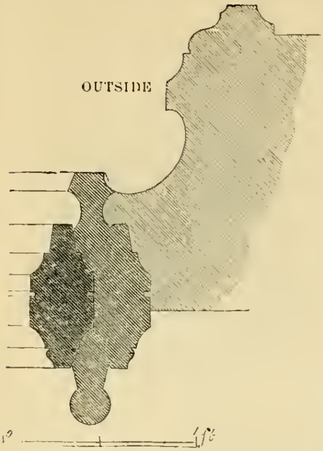

Fig. 1185. HENRY VII.'S CHAPEL.

The section of the jambs to the windows of the clerestory at Winchester Cathedral is given in *fig.* 1303. ; to the windows of King's College Chapel, Cambridge, in *fig.* 1312. ; to those of St. George's Chapel, Windsor, in *fig.* 1316. ; and to those in the clerestory at Amiens Cathedral, in *fig.* 1329.

The arch planes worked in the same buildings, have been placed on pages 971., 972., and 973., while the series of mouldings to the arches of Henry VII.'s Chapel will be found very poor in comparison, as may be observed in *fig.* 1325.

Sect. XIV.

CIRCULAR WINDOWS.

The large circular windows so frequently seen in the transepts of churches, and sometimes at the west ends of them, and going by the general name of rose windows, seem to have originated from the *oculi* with which the tympana of the ancient basilicæ were pierced, and which are still observable in monuments of the 11th century. For the study of this species of window the edifices of France furnish the most abundant means, many of them being of exquisite composition, and in our opinion far surpassing any elsewhere to be seen. Many of these, from Rouen, Beauvais, and Amiens, will be found illustrated in the following chapter of this work.

It is scarcely previous to the 12th century that they can be fairly called *rose* windows; before that period they are more properly denominated *wheel* windows, the radiating mullions resembling the spokes of a wheel and being formed of small columns regularly furnished with bases and capitals, and connected at top by semicircular arches or by trefoils. By many the more decorated circular window has been called the *marigold* window, but we scarcely know why that should have been done. The rose windows are used in gables, but their dimensions are then generally smaller and they are often enclosed in segmental curves whose versed sines form an equilateral triangle or a segmental square.

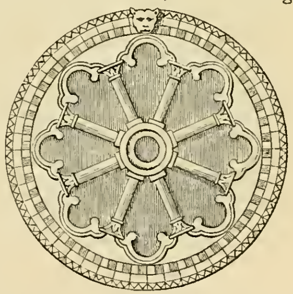

Fig. 1186. PATRIXBOURNE.

An early specimen of the wheel window is in Barfreston Church (*fig.* 180.), wherein it is manifestly later than the other parts of the front. The example from Patrixbourne Church, Kent (*fig.* 1186.), is a curious and early example of the wheel window; herein, and indeed in all the minor examples, a single order of columns is disposed round the centre;

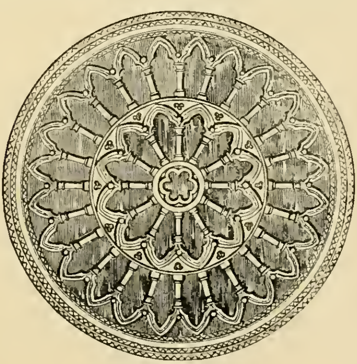

Fig. 1187. YORK. 1269. A.D.

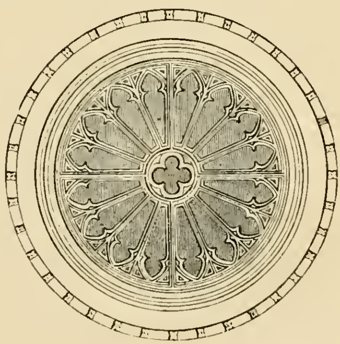

Fig. 1188. ST. DAVID'S. 1350. A.D.

but in the south transept at York Cathedral we have a noble instance of this species (*fig* 1187.)—a double order of columns being employed, connected by foliation above the capitals of the columns; this example is of the 13th century. As the early style came in, the columns would of course give place to the mullion, as in the elegant specimen from St. David's, shown in *fig.* 1188. The two following examples (*figs.* 1189. and 1190.) from Westminster, and Winchester Palace, Southwark, are both of the 14th century. The first

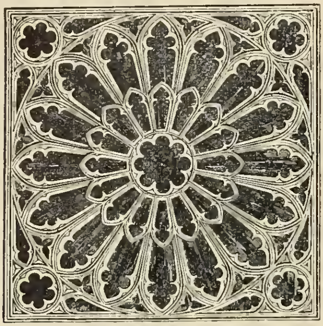

Fig. 1189. WESTMINSTER ABBEY CHURCH.

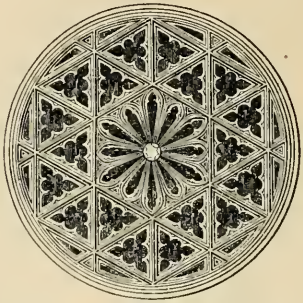

Fig 1190. WINCHESTER PALACE, SOUTHWARK.

is not the original window, but we have reason to believe it was accurately remade from the original one. The latter is a most elegant arrangement flowing from the continued sides of the central hexagon, and consequently forming a series of equilateral triangles decorated with foliation. It was placed in the gable of the great hall of the palace, which hall was spanned by a timber roof of very beautiful and ingenious construction, a few years since destroyed by fire, after which the wall containing the window was taken down.

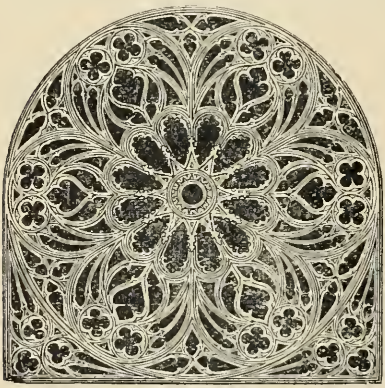

Fig. 1191. ST. OUEN, ROUEN.

During the period of the three last examples in this country, the French were making rapid strides towards that era in which their flamboyant was to be stifled and extinguished by the introduction of the renaissance style, about which we have already submitted some remarks, and produced some examples. In the church of St. Ouen, at Rouen, the circular window (*fig.* 1191.), middle of the 14th century, exhibits the extraordinary difference between French and English examples of the same date. Beautiful as many of the English examples undoubtedly are, we know of none that is equal to this for the easy and elegant flow of the tracery composing it. The leading points it will be seen are dependent on the hexagon, but, those determined, it appears to branch off from the centre with unchecked luxuriance, preserving, nevertheless, a purity in its forms quite in character with the exquisite edifice it assists to light. The details of this window may be advantageously studied in Pugin's *Antiquities of Normandy*, and in the larger woodcut given in the subsequent chapter.

Besides these examples of circular windows, others will be found of varying patterns, forming the centre pieces in the heads of large windows, as at the churches of Easby, Howden, Wellingborough, and at St. Alban's Abbey.

Sect. XV

TRACERY OF WINDOWS.

As the perpendicularity of the style changed, at the beginning of the 13th century, from that which might be termed horizontal, so did the comparatively rude and clumsy form of its ornament assume a lightness founded on a close observation of nature. Its sculpture is endowed with life, and its aspiring forms are closely connected with the general outlines bounding the masses. The models used for decoration are selected from the forest and the meadow. Among the flowers used for the angular decorations of pinnacles and spires, on crockets, and in similar situations, an ornament very much resembling the *Cypripedium calceolus*, or lady's slipper, and the iris, are of constant occurrence. The former plant, however, appears to be found only in the woods in the north of England, and now, at any rate, it is very rare.

These models, however, though closely and beautifully imitated (says Ramée), are submitted to reduction within such boundaries as brought them to a regular and geometrical form. Thus is found every conceivable description of ornament brought within the limits of circles, squares, and triangles, as well as within the more varied forms of the many-sided polygons; the latter, as in the marigold and rose windows, being again subject to the circumscribing circle; these polygonal subdivisions having always reference to the regulating subdivisions of the apsis, as will be further referred to in Chap. IV.

The circle obviously presents a boundary for a very extended range of objects in nature. In the vegetable world, a flower is scarcely to be found which, within it, cannot be symmetrically arranged. Its relations afford measures for its subdivisions into two, three, four, and six parts, and their multiples, by the diameter and radius alone; the last being an unit, upon which the equilateral triangle and hexagon are based; moreover, as the interior angles of every right-lined figure (*Euclid*, prop. 32. b. 1.), together with four right angles, are equal to twice as many right angles as the figure has sides, it will be immediately seen that the interior angles in the equilateral triangle, the pentagon, the hexagon, the nonagon, and the dodecagon, are divisible by the sides so as to clear the result of fractions. Thus, in the equilateral triangle, the number of degrees subtended by the sides is 60°. In the pentagon the number is 108°; in the hexagon, 120°; in the nonagon, 140°; and in the dodecagon, 150°. (See *par.* 1219.). Independent, therefore, of the service of the circle in construction, we are not to be surprised at its being so favourite a figure in architecture, from the period at which the art was to become truly serviceable to mankind.

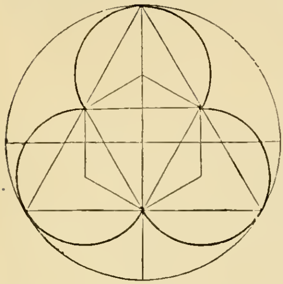

Fig. 1192.

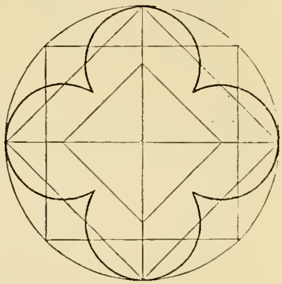

Fig. 1193.

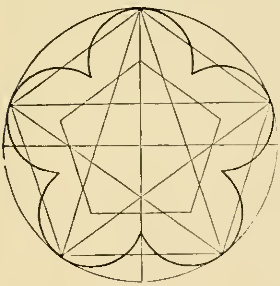

Fig. 1194.

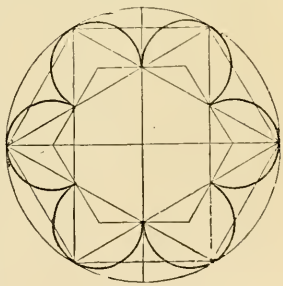

Fig. 1195.

In respect of the pentagon (*fig.* 1194.), if lines be drawn from each angle so as to connect every two of its sides, the pentalpha results; a figure in much esteem in the 13th and 14th centuries, and used among the Pythagoreans as a symbol of health, centuries and centuries before.

The heptagon and undecagon, whose interior angles are not divisible without a fraction or remainder, were rarely used by the Freemasons; an instance of either does not occur to us.

An inspection of *figs.* 1192. to 1198. will show the mode of generating from the several polygons the lobes of circular windows, as also the way of obtaining the centres for the lobes in a simple and symmetrical manner. In *fig.* 1192. the basis of formation is the equilateral triangle, and three lobes are the result. Those of four lobes, or quatrefoils (*fig.* 1193.), originate from the square; and the Cruciferæ, or cruciform plants, Tetradynamia of Linnæus's system, seem to be their types in nature.

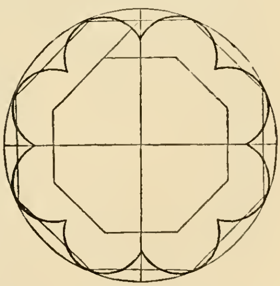

Fig. 1196.

For those of five lobes, resulting from the pentagon (*fig.* 1194.), types are found in the classes Pentandria, Decandria, and Icosandria, of Linnæus. They comprise the rose, the apple, cherry, and medlar blossoms; those of the strawberry, the myrtle, and many others.

For circular windows consisting of six lobes, and based on the hexagonal formation (*fig.* 1195.), the class Hexandria seems to furnish the type, under which are found almost all the bulbous-rooted flowers, pinks, &c. These observations might be extended to a great length; but the writer does not feel inclined to pursue the system to the extent to which it has been carried by a German author (Metzger), who bases the principles of all pointed architecture on the formations of the mineral and vegetable kingdoms. In *fig.* 1196. the octagon is the base; in *fig.* 1197. the nonagon; and in *fig.* 1198. the dodecagon. Beyond the last, the subdivision is very rarely, if ever, carried. It was not that all these types were selected from a mere desire of assimilating to nature the decorations of the 13th century, but it sprung from that deep impression of the utility of geometrical arrangement, which sought in the vegetable kingdom, and elsewhere, such forms as fell in with the outlines adopted. Similar formations based upon the arrangement of squares, triangles, and polygons, are exhibited in *figs.* 1335. to 1339., in the latter portion of this chapter, as obtained from the decorations of Amiens Cathedral.

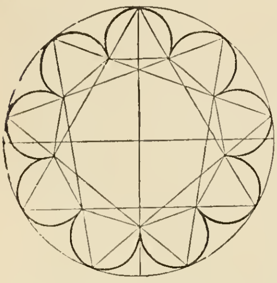

Fig. 1197.

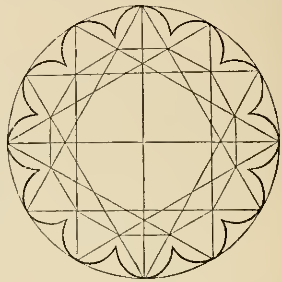

Fig. 1198.

Mr. Denison comments upon a particular figure in window tracery, which appears to him to be very bad, and often adopted. He calls it the "broken-backed cusp," (*fig.* 1199.) because it gives the feeling that it is always going to break (like *fig.* 1205., doorway). By it, the cusps are made a principal instead of an accessory; the proper way being to make a sub-arch at the back of the lower pair of cusps (*fig.* 1200.), and to thicken the trefoil above until it looks like a piece of solid stonework, and having a real bearing on each other, and capable of resisting pressure.

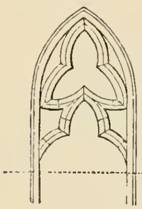

Fig. 1199.

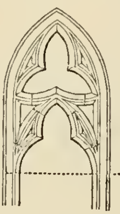

Fig. 1200.

Few attempts have been made to point to the origin of tracery and its ramifications. As the spaces of window openings went on increasing, until at last they became gigantic, in several instances exceeding 40 feet, a construction of stone framework became absolutely necessary. This framework, as we find in examples of the early decorated period, was at first unornamented—mere pillars or mullions below, with segmental curves, crossing each other, to fill the arch. But by degrees these curves changed their character, and assumed all the infinite variety we now know under the term tracery. From great windows, this class of decoration descended to the minor parts of buildings; and at last we find that light, fragile, screen-work, to be the great depository of this kind of knowledge. Fixed geometric forms, rather than mere fancy, as the foundation of composition, are ever to be preferred as of the utmost importance to the designer, if he wishes or intends to arrive at a successful result.—Billings, *Infinity of Geometric Design.*

Our limited space warns us to refrain from the further elucidation of this subject; but before quitting it, we can refer to the many illustrations of the further development of "tracery and geometric forms," forming a portion of the PRINCIPLES OF PROPORTION, treated hereafter, wherein examples are given from Westminster Abbey, Beauvais, Rouen, and other cathedrals.

To aid in the formation of tracery a perfect knowledge of practical geometrical drawing is requisite; we therefore refer the reader to that section in Book II. where, commencing at *par.* 1007., he will find other more useful problems that will assist him in his designs. We append another application of the problem "to inscribe a circle in a given triangle," as being one of those more generally required in circular forms, and perhaps a quicker method than those above described. If a five-lobed figure be required, as in *fig.* 1201., obtain the triangle A B C from the five divisions, on a base line B C at a tangent to the circle; bisect B C and join A D. Bisect the angle A B C by a line B E, and

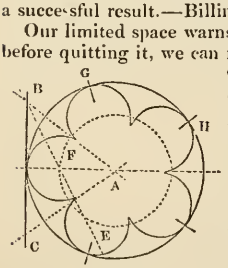

Fig. 1201.

where it crosses the line A D, as at F, will be the centre of the required circle or lobe. A circle with the radius A F being drawn, the other centres on the lines of division, as A G, A H, &c., are readily found.

Another usual geometrical problem in tracery work consists in finding the centre of a circle placed in the head of an arch. This has been elucidated by E. W. Tarn, in the *Builder* for 1863, p. 221. Let A B C in *fig.* 1202. be an equilateral arch, and the width A B be divided into three equal portions A D E B. Let the arches D F and E G be drawn with the same radius as those of A and B, as D H. Then it is required to find the centre of the circle which shall touch the four arcs. Make E I equal to $\frac{1}{6}$th of E B, and with the centre A and radius A I draw an arc cutting the perpendicular or centre line of the window in K; then K is the required centre, and K L the radius of the circle.

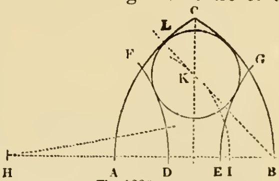

Fig. 1202.

SECT. XVI.

DOORWAYS.

It is almost needless to observe that through the several changes of style the doorways followed their several forms; our duty will, therefore, be to do little more than present the representations of four or five examples to the notice of the reader. The Prior's entrance at Ely (*fig.* 187.) is a fine specimen of a highly decorated Norman doorway. The earlier Norman doorways had but little carving. They are, as in *fig.* 1203., generally placed within a semicircular arch, borne by columns recessed from the face of the wall, and the whole surmounted with a dripstone. In *fig.* 187. it will be seen that the semicircular head of the door is filled in level with the springing, and sculptured with a figure of our Saviour in a sitting attitude; his right arm is raised, and in his left is a book. What is termed the *vesica piscis* surrounds the composition, which is supported by an angel on each side. These representations are frequently met with in Norman doorways. Many examples are composed of a series of recesses, each spanned by semicircular arches springing from square jambs, and occupied by insulated columns; though sometimes the columns are wanting and the recesses run down to

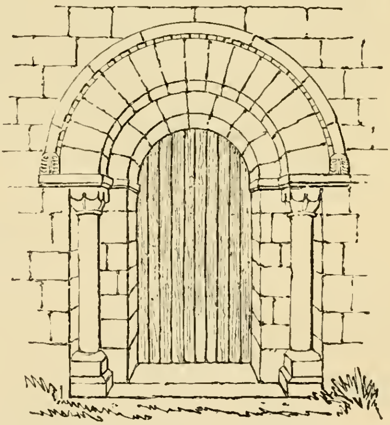

Fig. 1203. WYKEN CHURCH, WARWICKSHIRE.

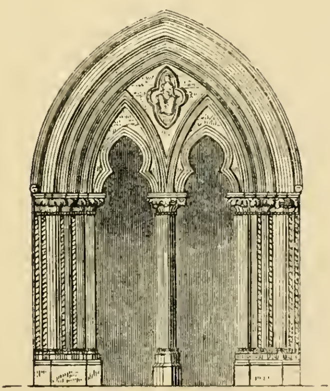

Fig. 1204. LICHFIELD.

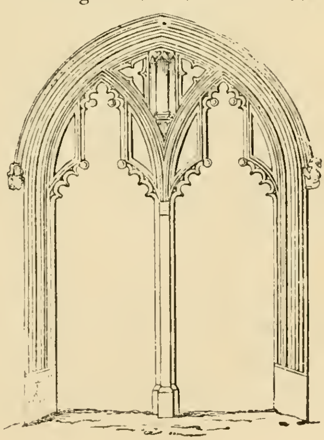

Fig. 1205. ST. NICHOLAS, LYNN.

the plinth. The arches are very often decorated with the chevron, zigzag, and other Norman ornaments.

The early English doorways have the same character as the windows of the period; the smaller ones are often recessed with columns, from which a pointed arch is twined with a cut moulding on it and a dripstone over it. The more important doors, however, are mostly in two divisions, separated by a pier column, and with foliated heads. These are generally grouped under one arch, springing from clustered columns on each side, and the space over the openings is filled in, and decorated with a quatrefoil, as in the doorway to the chapter-house at Lichfield (*fig.* 1204.). Sculpture often occurs in the arrangement. The door to the chapel of St. Nicholas, at Lynn (*fig.* 1205.), is a curious example of the latter part of the decorated period. *Fig.* 1206., from Tattershall Castle, Lincolnshire, belongs to the Florid English or perpendicular period, whose simplest doorways usually had the depressed or Tudor arch, and without the square head which appears in the example. The more ornamental ones were crocketed, and terminated with finials, as appears in the face of the porch at King's College Chapel, Cambridge (*fig.* 1208.). The doorway at St. George's Chapel, Windsor (*fig.* 1207.), though later in date, is more simple than the last, notwithstanding the exuberance of ornament and tracery which had then very nearly reached its meridian.

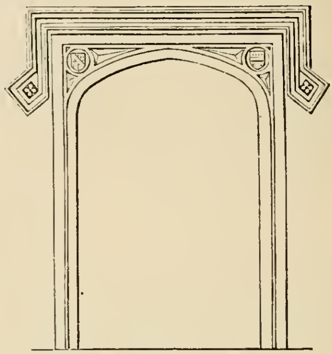

Fig. 1207. ST. GEORGE'S CHAPEL.

Sect. XVII.

PORCHES.

The porch is a distinguishing feature both in ecclesiastical and domestic architecture throughout northern Europe during the whole of the mediæval period. In the case of the smaller churches it was usually attached to the north and south doors. When to the north, it was generally built of stone, while the south porch was more often of timber. In France the porches are usually of very grand proportions and of elaborate structure.

A Norman porch, with an upper story or *parvise*, a chamber which appears to have been variously appropriated, occurs on the north side of Southwell Minster, Nottinghamshire, and is arched (Rickman, p. 81.); and another at Sherborne, Dorsetshire, which is groined. The example at Malmesbury Abbey Church is perhaps the finest of the few that exist of this period. An early English porch with a chamber remains on the north side of St. Cross Church, Hampshire. The porch at Felkirk, in the West Riding of Yorkshire, of late early English or early decorated date, has a roof formed of stone ribs 1 foot in breadth by 10 inches in depth, plain chamfered at the angles, placed about 18 inches apart, springing from a string or impost about 4 feet from the floor. A complete illustration of this interesting example is given in Robson, *Mason's Guide*. The same simple plan is followed in those at Barnack, Northamptonshire, and at Middleton Cheney, Northamptonshire. The south porch at St. Mary's Uffingdon, Berkshire, is groined. This feature was extensively used in this period, as at Salisbury and Wells.

A beautiful example of a vaulted roof to a shallow porch occurs in the decorated church at Higham Ferrars, Northamptonshire (Rickman, p. 111., also giving a plain vault with richly moulded door jambs at the west porch of Raunds Church, Northamptonshire). Stone ribs are employed in the vestry or chapel at Willingham Church, Cambridgeshire (Rickman, p. 179., decorated); the chapel is 14 feet 1 inch long, and 9 feet 9 inches wide, as shown in Lysons' *Cambridgeshire*, p. 285. In this, and in the following, periods, the groined roof became common, and partook of all the varied enrichment exhibited in larger roofs. The porches exceed in profuseness of decoration those of the preceding style: they were almost universally adopted. The south porch of Gloucester, and the south-west porch of Canterbury are beautiful examples. In the former, canopied niches occupy the front over the doorway, the front being crowned with an embattled parapet of pierced panelling, and at the quoins are turrets embattled and finished with crocketed pinnacles.

The example here given of the shallow porch at King's College Chapel, Cambridge (*fig.* 1208.), is beautiful in design and in proportion. The north porch at Beverley Minster rises somewhat higher than the aisle, the upper part forming a *parvise*. The door has a fine feathered straight-sided canopy, over one of ogee form, both crocketed. It is flanked with niches, buttresses, and pinnacles; the whole front is panelled and crowned with a lofty central pinnacle, having a niche. An idea of it will be gained from the illustration given as a frontispiece to the present edition. The south porch of Leverington Church, Cambridgeshire, is groined, and also has carved bosses. Over it is a *parvise* 10 feet 1 inch wide and 14 feet 4 inches in length. The covering (of slabs of stone?) is supported by six arched stone ribs, placed 2 feet 1 inch apart, and 9 feet 5 inches span; the rib is 4 inches wide, 6 inches in depth, and chamfered on the lower edge. It has a richly perforated stone ridge ornament. The section and details are given in *Builder* for 1848, p. 91, which also (iii. 598.) illustrates the south porch at North Walsham Church, Norfolk, which is lofty and open to the roof, it not having been divided into stories. It is a specimen of the mixture of flint with stone details. The south porch of a church near Evesham, in Worcestershire; the sacristy, also at Felkirk: and the porches at the churches of Strelly, in Nottinghamshire; of All Saints, at Stamford; and of Arundel, in Sussex, have interesting stone roofs.

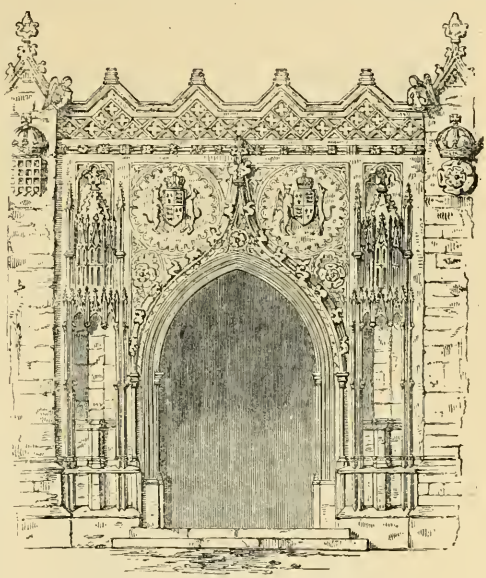

Fig. 1208. KING'S COLLEGE CHAPEL, CAMBRIDGE.

In the case of domestic buildings, the porch, as at Wingfield Manor House, Derbyshire, has a story over the entrance, differing from those at Eltham, Croydon, Cowdray (which has an elaborate groined stone roof), and many others, having only one story. That at Porchester Castle hall was the whole height of the building, having a room above the entrance to the hall, which was elevated on a basement story, and was reached by a flight of steps occupying the lower story of the porch. At Dartington Manor House, Derbyshire, and at East Barsham, Norfolk, there are two stories above the entrance, an arrangement frequently observed in similar erections, as at Thorpland Hall, Norfolk, and at Eastbury House, Essex, erected cir. 1572. From the architectural prominence given to this feature in domestic buildings, the designation "porch house" was often employed.

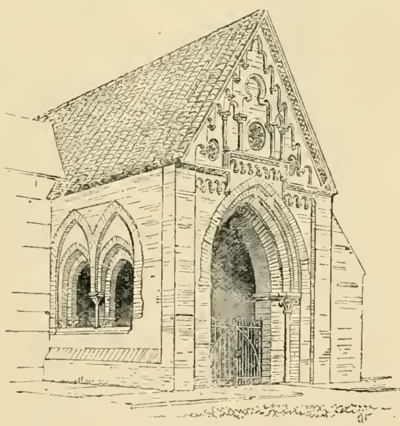

Fig. 1209. PORCH, AT LUBECK.

So very exceptional is the use of *brickwork* in England in mediæval work, at any rate until the common brick porches, which were added in the 17th century, that we are induced to notice one of the many examples in this material executed abroad, in Germany especially. The north porch of Lübeck Cathedral (*fig.* 1209.), is described by G. E. Street, as "a 13th century addition, of two bays in depth, with groining piers of clustered shafts with sculptured capitals, and a many-shafted doorway of the best character. Its interior is probably mainly of stone, but the exterior is all of brick. The archway is boldly moulded, and above it is a horizontal arcaded corbel table, stepped up in the centre to admit the arch. The gable is boldly arcaded upon shafts, and has a stepped corbel table, with a double line of moulded bricks above it next to the tiles. A couple of simple open arches are pierced in each side wall, and there are flat pilasters at the angles. In the gable, enclosed within the arcading, are some circular openings, one of which is cusped with small foliations formed of brick. The moulded bricks in the main arch are of two kinds only, one a large boltel, the other a large hollow, and these arranged alternately with plain square-edged bricks, produce as much variety as is needful. The jamb of the door-way is of plain bricks, built with square recesses, in which detached stone shafts are placed. The capitals throughout are of stone, and carved with simple foliage. Perhaps no other example is more completely all that it should be in the use of its materials. The exterior is simple in all its details, yet sufficiently enriched by their skilful arrangement to be thoroughly effective; whilst in the interior, where more adornment was naturally required, brick is frankly abandoned, and the richly moulded and sculptured ribs and archivolts are all of stone, though I have no doubt the vaulting and walls are, as on the outside, of brick. The only tracery which can be properly executed in brick is in fact the simplest *plate tracery* (and even this requires great skill and care in its execution), or that simple fringe of cusping round an opening which occurs in the porch, and which may be executed with ease with a single pattern of moulded brick often repeated." *Church Builder*, 1863, p. 56. We have somewhat altered the arched entrance as shown in Mr. Street's sketch, understanding that this porch has been lately restored in this manner.

Sect. XVIII.

TOWERS AND SPIRES.

Europe has been considered by J. H. Parker, *Transactions* of the Institute of British Architects, to be indebted to Caen and its neighbourhood for that very interesting feature, the Gothic spire of stone. He has also traced its history from the low pyramid of Thaon Church, Normandy, dating about the end of the 11th century, shown in *fig.* 1210., whereof the stones are left rough within and overhang one another, while at the base a large piece of timber was introduced as if to bind the whole together (*fig.* 1211.), which has now entirely decayed. The apex has also decayed or been removed. The spires of Comornes near Bayeux; Basly near Caen, middle of 12th century; and Rosel, are of the same character, and are followed by those at Huppeau near Bayeux, which is considerably taller, but of about the same date; Vaucelles, near Caen; St. Loup, near Bayeux; St. Contest, near Caen; and Bougy, which is of a fine transitional character, as is that at Douvres; the small square spires at the east end of St. Stephen's at Caen; and the elegant lofty octagonal spire with square pinnacles at Ducy, which is a little earlier than the elegant western spires of St. Stephen's at Caen. On that building are altogether eight spires, varying in date from one of about the middle of the 12th century on a stair turret; the two pairs of early Gothic work of the choir; to the light western spires which possess pinnacles of open work at the angles and in the centre of each face; these date about 1230. The fine spire on St. Peter's Church, at Caen, dates at the beginning of the 14th century, and is commonly quoted as the perfection of a spire (*figs.* 1212. 1213.). It is octagonal, with openings pierced in the flat sides. That of St. Saviour's is later and not so good. Nearly all the spires in this district have the surface of the stone cut to imitate shingles, a clear proof of their having had a timber prototype. The spires at Bayeux Cathedral were probably being built at the same time as those at St. Stephen's Church, which they resemble. Secqueville Church has one of nearly the same date.

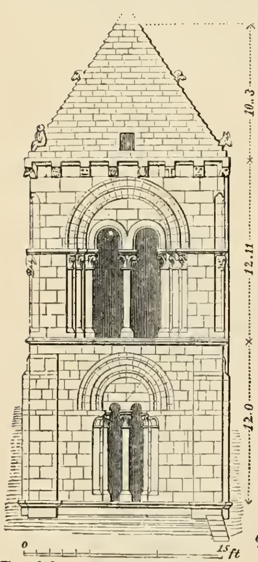

Fig. 1210. THAON, NORMANDY.

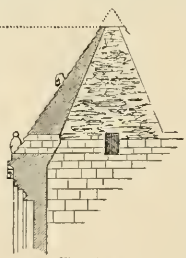

Fig. 1211. SECTION OF SPIRE.

Of later date are the spires at Bretteville, Bernières, and Langrune, coming up to the middle of the 13th century. They are all of elegant design, and light construction. After these are the unfinished spires of Norrey and Audrieu, closing the century. Illustrations of several of these buildings will be found in Britton's *Normandy*. Mr. Fergusson considers that the spire took its origin from the gable termination seen in some early foreign towers.

A chronological sketch of the gradual development of the spire in Germany, has lately been attempted by W. H. Brewer, in the *Builder* for 1865, to which we can here only refer the reader, as well as for its very peculiar illustrations.

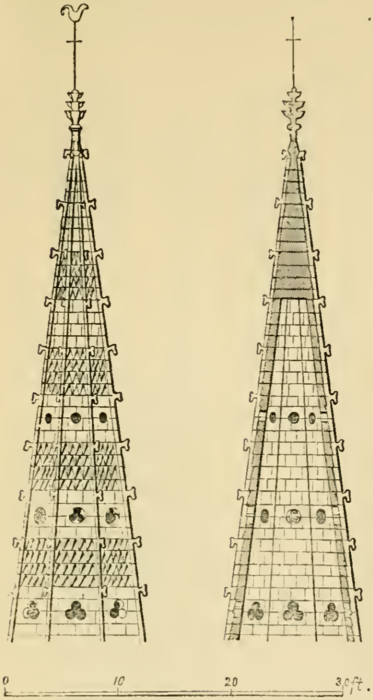

Fig. 1212. Fig. 1213.
ST. PETER'S AT CAEN.

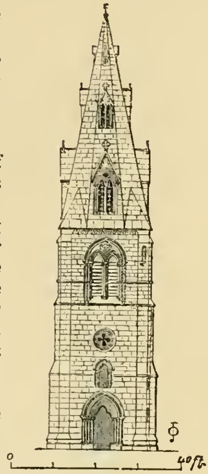

Fig. 1214. WARMINGTON.

In England, during the Norman period the west end of the larger churches sometimes had towers terminating the aisles. Another tower rose from the intersection of the cross (the smaller churches had but this one), while it was only of sufficient elevation to break the long line of nave, choir, and transepts, all of equal height. The roofs of the towers were of but little higher pitch than the rest. The nearest approach to spires, in form if not in height, were found in the pinnacles surmounting the angle buttresses in the larger churches. During the early English period, towers rise to a greater elevation, and are very generally finished with a spire, sometimes of great height. The most frequent spire is that called a *broach* when it does not rise from within parapets, but is carried up on four of its sides from the top of the square tower, the diagonal faces resting on *squinches*, or arches thrown across the corners within, and finished on the outside in a slope, as shown in *fig.* 1214. of Warmington Church, Northamptonshire, which has been published in detail by W. Caveler. A great many spires consisted of wooden frames, covered with lead or with shingles; and these in general, as well as stone spires in a few instances, were connected with the tower in a different way; the spire itself being at first only four-sided, and the angles being canted off a little above the base, to form the octagon. The early English spire, completed in 1222, to Old St. Paul's Cathedral was the highest in Europe, being 500 feet high, according to Stow, or 489 feet as calculated by Mr. E. B. Ferrey.

In the decorated period, Heckington Church, Lincolnshire, one of the most beautiful and perfect models in the kingdom shows, says Rickman, "a very lofty tower and spire situated at the west end (*fig.* 1215.), the four pinnacles which crown the tower are large and pentagonal. This unusual shape has, at less cost, an effect fully equal to an octagon, and the pinnacles are without crockets, but have rich finials; the spire is plain, with three tiers of windows on the alternate sides. The whole arrangement of this steeple is peculiarly calculated for effect at a distance." The details of this work are given in Bowman and Crowther's useful publication. The elaborately arranged octagon at Ely Cathedral, the design of Alan de Walsingham, is of this period. The work entitled *Churches of the Archdeaconry of Northamptonshire*, 1849, illustrates in small pictorial views several of the fine lofty west towers and spires of this and the succeeding period, erected in that locality.

The perpendicular period is distinguished by the splendour and loftiness of its towers and spires. That at Salisbury, for example, rises to the height of about 387 feet. That at Norwich, rebuilt soon after 1361, is 318 feet high. St. Michael's spire, at Coventry, built 1373–95, is the most beautiful one in the kingdom; it does not rise, like those at Salisbury and Norwich, from the centre of a transeptal church, but from the ground; and its flying buttresses, and extremely taper form, give it great advantage over every spire which rises from within battlements. The *broach* is not unfrequent in this style, and examples are chiefly to be found in Northamptonshire. Of other remarkable spires of this style we should name Whittlesea, in Cambridgeshire (*fig.* 1216.); Rushdon, in Northamptonshire; the two spires of St. Mary and St. Alkmund, at Shrewsbury; Laughton-en-le-Morthen, in Yorkshire; Chester-le-Street, in Durham; and finally, Louth, in Lincolnshire, of which latter structure the building accounts are given in the *Archæologia*, vol. x., showing its completion between 1501 and 1518.

The spire of the tower of St. Nicholas Church, at Newcastle-upon-Tyne, from its peculiarity of standing on arched ribs, holds a high place in the series; it is the type of which there are various imitations. The best known are St. Giles's, at Edinburgh; the church at Linlithgow; the college tower at Aberdeen, and its modern imitation by Sir C. Wren, at St. Dunstan's-in-the-East Church, in London. Of another class of towers of this period, that of Fotheringay Church is the type. The ordinary square tower is surmounted by an octagonal lantern of much smaller dimensions, connected with the tower, in composition,

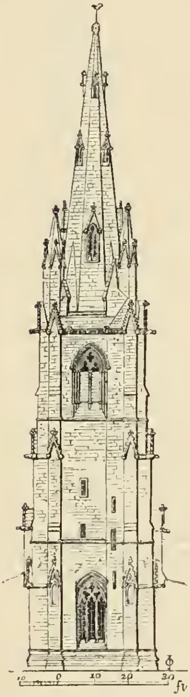

Fig. 1215. HECKINGTON.

Fig. 1216. WHITTLESEA.

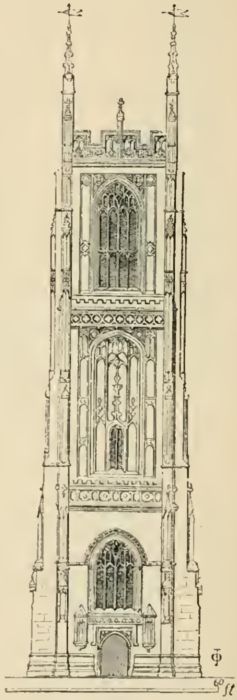

Fig. 1217. ALL SAINTS', DERBY

by flying buttresses from the bases of the angle pinnacles. The tower of All Saints' Church, at Derby, has deservedly a very high reputation (*fig.* 1217.). It is late in the style; as is also the fine detached campanile at Evesham. The tower of St. Peter Mancroft, at Norwich, is a good specimen of flint building with stone panels. The most remarkable of the perpendicular towers, both in itself and for its influence in the ecclesiastical architecture of a large district, is that of Gloucester, erected about 1455. This noble tower rises above 200 feet from the ground and about 100 feet above the roof of the choir. It is surmounted by a crenellated parapet flanked by four turret-like pinnacles, all of delicate open work, to the very finials, of a light and graceful character almost beyond the natural capacity of stonework. Among the more important imitations of it are St. John's, at Glastonbury; St. Stephen's, at Bristol; St. Mary, at Taunton; and that at North Petherton; the two last are said to have been designed by the same architect.

Beacons were sometimes added to towers; such is the lantern of All Saints' Pavement, at York, which is an octagon erected upon the tower. Hadleigh Church, in Essex, has a beacon in an iron framework placed on the top of an angle turret.

By far the finest west front, comprising two towers of the perpendicular period, is that of Beverley Minster. What the west front of York is to the decorated style, this is to the perpendicular, with the addition, that in this front nothing but one style is seen—all is harmonious. (See frontispiece, *fig.* 1218.) Each of the towers has four large and eight small pinnacles, and a very beautiful battlement. The whole front is panelled, and the buttresses, which have a very bold projection, are ornamented with various tiers of niche-work of excellent composition and most delicate execution. We may here incidentally notice that the east front is fine, but mixed with early English, which style extends to the transepts, while the nave and aisles are decorated, terminating with perpendicular, and finished with the west façade above noticed.

In concluding this portion, we cannot withhold naming the most elaborate work on the subject of this section, published from drawings made by C. Wickes, in 3 vols. fol. 1853–59. Its chief drawback is that the illustrations are pictorial and not geometric, which might have been obviated by a plan and section to each. Our sketch of the varieties of towers and spires will be found filled up, in Rev. G. A. Poole's *History of Ecclesiastical Architecture.*

In Ireland, the Dominican Abbey, commonly called the Black Abbey, at Kilkenny, had a tower placed on the south of the altar in a most singular way. At the Franciscan Church, the tower was placed at the east end of the nave, with a chancel at the end; the tower was much narrower than the nave, but exactly the width of the lofty arch supporting it, so that now the roof has gone, the construction appears extremely bold and hazardous. This building was one of a numerous class. Except the round towers, which ceased to be built when the English went to Ireland, and the low Cistercian towers, the Irish churches up to that period were almost towerless. In a few instances other towers could be named, as the fine massive one of the Trinitarian Friary, at Adare; but suddenly, in the 15th century, it became the practice to build to the Franciscan and Dominican structures these lofty and slender additions The nave was shut out from the choir by two transverse walls placed close together and pierced each with a narrow arch; above them rose the slender tower, standing as it were on the apex of the gables, instead of spreading over the width of the nave. They were finished with a peculiar battlemented parapet. There is no instance of two western towers to the mediæval churches in Ireland; and a mediæval spire is not known to exist in that country.

In Scotland, the spires are chiefly of the middle pointed period, but not erected until about the middle of the 15th century. Short octagonal stone spires form a very common termination to towers of late date; they generally carry small pedimental headed lights either on all or on the cardinal faces, and are for the most part plain, though, as at Corstorphine, at Aberdeen, and at Crail, in Fifeshire, they are banded by two or three embattled strings or coronæ into stages. Sometimes, as at the two former places, there are small pinnacles at the angles; while at Corstorphine, and St. Andrew's at Aberdeen, a lumpish semi-pyramidal abutment on the angles is extremely suggestive of the *broach.*

The *construction* of the tower and spire is of such importance as to require much attention. A tower built for the reception of bells intended to be rung, should have a solid foundation, not merely four arches nearly as wide as the tower itself, leaving four piers not much bigger than the thickness of the wall which they support. Bells require a tower to themselves, for it is known that they will spoil the best clock ever fixed. In Sir C. Wren's towers, and others built by his imitators, the substance of the walls was concentrated at the angles, leaving a moderate sized arch on each side, and only the same internal area as would exist in the case of four straight walls. This is sound construction, and is well displayed in the tower of Antwerp Cathedral. Such an arrangement also admits of a staircase being carried up in the substance of the wall, without diminishing strength, besides, a desirable object in some large towers, doing away with the necessity for buttresses. The tower, if thus carried up its whole height, will be more fit to support an octangular or circular spire or lantern. The mean internal area should be half the external area, and then, if well built and of good materials, the tower will safely bear as many bells as can be hung on one level.

There should be an offset to support the ringing floor and the bell floor, so that no timber be run into the wall to act as battering rams. Neither should a bell be hung on cross beams resting on the walls, but always in a trussed cage. As regards sound, one level of bells is considered better than two tiers. It is wonderful that some of the early brick or stone cones or pyramids (shown in *fig.* 1211.) have stood, for they were evidently built in level but gathering courses, even in the 11th century, around a light frame of timber, which was either removed or left to decay. As soon as the principle of diminution upward was acknowledged, two systems of construction presented themselves; the first is direct carriage of the upper storey from the basement floor; the other is a false-bearing; the weight being, in either case, thrown as much as possible upon the angles, even to the extent upon each floor of an opening in the centre of each side, which is the weakest part of a blank tower. In the first case there are two varieties, one being the pyramidal roof square on plan; the other being the pyramidal roof octagonal on plan. The latter, whether completed externally as a *broach* or otherwise, requires to be carried as low down the tower for support as possible; and in some cases, as at St. Léonard, in France, the octagon is more judiciously placed with four angles over the centres of the sides of the tower, than with four faces over the corners of the tower, which then require to be loaded by pinnacles. These are set diagonally more advantageously than when square with the tower, because they thus have a larger base. The greater height given in the middle of the 12th century to the spire rendered such precaution inevitable; and at the same time it became evident that if the spire were to be no longer square on plan, it must not seem to rise abruptly out of a square.

Octagonal steeples, with octagonal spires not built through, but resting upon them, seem to be considered now as dangerous experiments in construction. Yet one at Guebwiller, in France, is a central steeple of four stages, including the pendentives. At Schelestadt is another of the same kind. This plan does not seem to have been in favour after the commencement of the 13th century.

When the French architects determined to trust their octagonal spires to the upper storeys of their steeples, they seem to have been careless about allowing the pendentives to approach points of weakness. The student will gather a good lesson on this point from the section of the steeple at the Abbaye de la Trinité, at Vendôme, given in Viollet le Duc's *Dictionnaire*. In the steeple of the cathedral at Chartres, the pendentives of the octagon sit upon the four pinnacles, which are thus each obliged to take a part of the weight of the spire; the other part being thrown upon the four faces of the octagonal drum, which are weighted by heavy gables. At the bottom the spire is 31½ in. thick, and at top 11¾ in. in a length of 156 ft. 8 in., built of hard Berchère stone. The roofs of the pinnacles are 19¾ in. thick. It is to be noticed that the danger of a fall, which was so imminent as to cause the destruction of the steeple at St. Denis, is attributed in great part to the increase of weight given to it during a course of restoration, by using the stone of St. Pierre instead of that of Vergelé. Some French spires have a very curious effect, due to the presence of a simulated hip in the centre of their sides for the whole or part of the height: but still more extraordinary were the slits in that of St. Denis, and the slit with two transoms in that of St. Nicaise, at Reims.

The spire of the church at Langrune, near the sea-coast, north of Caen, in Normandy, has at its base in the interior, a sort of buttress of thin stone resting on the thicker walls of the tower, which runs up for a great height to each of the angles and sides of the spire. They are pierced so as to afford a free passage all round at the base of the spire; and may have been provided to assist in strengthening it on account of its exposed position. It has been drawn by Rev. J. L. Petit in his *Architectural Studies*.

It will be found that the stone spires of the 12th century were high in regard to the rest of the steeple. The *proportions* at St. Denis were 38½ to 35; those at Chartres are 60 to 42; but in time these proportions were altered so much that the spires of St. Nicaise at Reims (end of 13th century), and those of the front of the cathedral in that city, are scarcely half the height of the tower instead of equal or superior to it. Murphy, in his account of the *Batalha*, remarks that no settled proportion seems to have been observed in the dimensions in general; they varied from four times the width of the base to eight times.

As regards the jointing of the stones of which spires are composed, their security seems to be wholly the result of an accurate working of the beds and vertical joints, and the adhesion of naturally good and properly applied mortar. In modern work it is questionable whether such aids as dowelling and cramping should be altogether dispensed with. Iron must not be used, for reasons given in an earlier portion of this work. One method used at present to steady and tie in the spire, is that of the insertion of an intermediate stage or floor of timber framing. Sir C. Wren, when rebuilding the upper portion of the (former) spire of Chichester Cathedral which had been forced out of the upright, placed two intermediate stages connected with a pendent beam of timber about 80 feet in length attached to the finial stone; each stage was about 3 inches less in diameter than the spire at their levels; these restored the spire if it departed from the upright. A similar pendulum, with two stages, to act in like manner, has been introduced by Gibbs in his spire of St. Martin's in the Fields, London. Iron rods have of later years been used to effect this purpose.

When the beds of the stones are horizontal, one course of binders secured with dovetailed dowels will perhaps be enough in the height; but when the beds are inclined, two or three of these courses in its height would be an effectual means of preventing its spread. It has been considered that a spire is stronger when the beds are set at right angles to the face, but if not well set, water gets in, and sudden frosts do much injury. It is probable, however, that a large number of steeples would, were examination possible, be found to have been well chained with timber or with metal. The former material appears to have been employed in the church at Châteauneuf (Sâone et Loire).

The spire, built *cir.* 1315, of St. Aldate's Church, Oxford, had to be taken down in 1865. The tower is about 56 feet high; the spire, about the same height to the weathercock, was for 10 feet down from it of solid stone, similarly to that shown in *fig.* 1213. The cause of its failure was that a 1½-inch iron bar coupled at the angles and inserted in the first course of stone 7 inches thick at the base of the spire, had rusted, in some place, entirely through, bursting the stone inside and out. The angle pinnacles alone sustained the spire for many years.

Nearly all the spires of Normandy are said to have been executed in thin slabs of stone ; they are all about 7 inches thick at the bottom, and about 4 inches thick at the top, and are almost all executed in the Creuilly stone. In Caen, especially, that stone was employed in the steeples, though it had to be brought about 12 or 14 miles. The joints are (probably) set at right angles to the face of the stone. The spire at Batalha is about 7 inches thick, independent of the carved work, though almost a fourth part of its superficies is perforated : its stones are said to be keyed together by means of dovetailed pieces of pine wood (Murphy). The slender stone ribs of the octagonal spire of Freiburg Cathedral are girded together at intervals of about 15 feet by means of double horizontal ribs or bands of limestone; in the middle of each of these bands an iron cramp is inserted, so that one half of the thickness of the metal is fixed in the under course of the stone-work, and the other half in the upper course, in order to prevent all thrust. The space between the rib and the horizontal bands is filled up with perforated tracery, so that the appearance of great lightness, united with great boldness, is imparted to the whole. Plate XI. of Moller's work shows a careful representation of the joints, explaining in what manner the stones are connected together, both in the principal members and the ornamental parts. The spires of Strasburg and Constance Cathedrals, and that of St. Stephen's Church at Vienna, present other examples of open work spires. The thickness of the decorated spire to the staircase in the north tower of the west front of Peterborough Cathedral, is about 11 inches at 2 feet above the wall of the tower, where the octagon commences, and is about 10 feet diameter (shown in Robson, *Masons' Guide*). The methods adopted of strengthening Salisbury spire and tower, are related by Price in his work published in 1750, who states that it is 400 feet high from the pavement to the extreme top, but to the top of the capstone or ball only 387 feet as previously noticed. It is only 9 inches thick at the bottom, diminishing to 7 inches.

The outline of a tower in elevation should be a parabolic curve, for strength as well as appearance, as it will not then present a top-heavy appearance. The difficulty in designing a tower and spire in the Roman or Italian style is to prevent a telescopic effect ; and in the mediæval style the appearance of an extinguisher is too often obtained. The entasis to the spire, and due diminution of the tower (though the former is usually held not to have existed, some spires being formed of two and even three lines at different angles), are desirable both for appearance and strength. They are common features in Essex and Middlesex, and the absence of them may be noticed by any one going from Essex into Suffolk, the round towers in which county have the entasis, but not those of later date. The tower of All Saints' Church, Colchester, possesses it, and diminishes from 21 feet to 19 feet, having internally an offset at each floor and at the roof, so that no timbers run into the walls.

A mathematical method of setting out the entasis for a spire was furnished by Mr. Thomas Turner, of Hampstead, to the *Builder* for 1848, through the late Professor Cockerell, R.A. But as he states that the ordinates may be obtained very nearly true by taking a thin lath and bending it to the extent required, we do not consider it necessary here to do more than to refer to the paper. In the reconstruction of the spire to St. Stephen's Church, at Vienna, an iron framework was introduced to support the light stone ribs, until near to the summit, which was made wholly of iron.

The iron spires at Rouen, Bruxelles, and Auxerre, are the only three we have noted.

CHAP. IV.

MEDIÆVAL PROPORTION.

SECT. I.

EFFECT OR USE OF NUMBERS.

The introduction into this work of the investigation of the principles of proportion, as propounded by the late E. Cresy, renders it necessary that some preliminary details should be considered, before the student passes on to those pages. These details will consist of the result of the use of numbers, as given by the late Mr. Gwilt and appended to the previous editions, and of the enquiry by modern investigators into the use of the *triangle* and of the *square* during the mediæval period. The subject is interesting, and a very enticing one, and we regret that our limited space will not allow us to do more than merely enter upon it. We would warn the student that should he feel inclined to devote any time to this subject himself, he must not be content with the measurements he may usually find in publications, but must found his theories on those taken by himself to be in any degree certain of his deductions.

The plan on which the earlier Christian churches were constructed, wrote Mr. Gwilt, was that of a cross: he omitted to notice, however, the Italian basilican plan and the domical Greek plan; but he justly observes that (in western Europe) after the 10th century it would perhaps be difficult to find a cathedral deviating from a cruciform plan. At the beginning of the 9th century, in an inauguration (of a church) sermon, the preacher observes, "In dextro cornu altaris quæ *in modum crucis* constructa est;" and again, "In medio ecclesiæ quæ est instar *crucis constructa.*" (Acta SS. Benedict.) Round churches, as at Aix la Chapelle, in Germany, Rieux and Merinville, in France, with Little Maplestead, Cambridge, Northampton, and the Temple Church, London, in England, are not enough in number to affect the rule. It was in the 13th century that the termination of the choir was changed from a circular to a polygonal form. The general ordonnance of the plan was, however, not changed, and seems almost to have sprung from the laws and proportions upon which surfaces and solid bodies are dependent. The square and its diagonal, the cube and its sides, appear, at least the latter or the side of the former (*fig.* 1219.), to furnish the *unit* on which the system is based. Hence the numbers 3, 5, and 7, become the governing numbers of the different parts of the building. The unit in the Latin cross, placed at the intersection of the nave, gives the development of a perfect cube, according to the rules of descriptive geometry. Here are found the number 3, in the arms of the cross and the centre square; the number 5, in the whole number of squares, omitting the central one; and the number 7, counting them in each direction. The foot, however, of the cross was, in time, lengthened to repetitions of five and six, and even more times. In monumental churches, formed on such a system, there necessarily arises an unity of a geometrical nature; and the geometrical principles emanating therefrom guided not only their principal, but their secondary, detail. Even before the 13th century there seems to have been some relation between the number of bays into which the nave was longitudinally divided, and the exterior and interior divisions whereof the apsis consisted; but after the introduction of the pointed style, this relation became so intimate, that from the number of sides of the apsis the number of bays in the nave may be always predicated, where the work has been carried out as it was originally designed. From the examination of many, indeed most, of the churches in Flanders, this circumstance had been long known to us; but for its first publicity, the antiquary is indebted, we believe, to M. Ramée, in 1843.

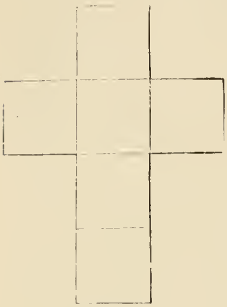

Fig. 1219.

The connection of the bays of the nave with the terminating polygon of the choir was such, that the polygon is inscribed in a circle, whose diameter is the measuring unit of the nave, and generally of the transepts, and forms always the side of the square intercepted by them. It is most frequently octagonal (*fig.* 1220.), and generally formed by three sides of the octagon. When this is used, the governing number will be found to be 8, or some multiple of it. Thus, in the Abbaye aux Hommes, at Caen (this, however, is previous to the 13th century), the termination of the choir is by a double octagon, and the number of bays in the nave is eight. The same occurs at St. Stephen's, at Vienna; in the Church of St. Catherine, at Oppenheim; at Lichfield Cathedral; at Tewkesbury Abbey, and at almost every example that is known.

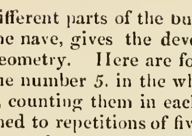

Fig. 1220.

It may be well here to observe, that English cathedrals, partly from their great deficiency in symmetry, on account of their not having been finished on their original plans, do not afford that elucidation of the theory that is found in those on the Continent. In twenty-four instances of them we have sixteen in which the terminations are *square* instead of polygonal; when polygonal, the rule seems to have been always followed. It must be noted, however, that in contradistinction to the rest of Europe, England kept steadily, as a rule, to a square east end; and though at Canterbury and Tewkesbury, and a few other noted examples, the circular form appears, yet often, as at Peterborough and Westminster, the curved apse was capped with a rectilinear addition, protesting, as it were, against the foreign element.

An eastern termination of the choir in three bays may be produced from the octagon, by omitting the sides in the direction of the length of the building, as in *fig.* 1221. In *fig.* 1222. the three sides will be found to be those of a hexagon; and in this case the number 6 governs the other parts. Examples of this arrangement are, the minster at Freiburg-im-Breisgau; the cathedral at Cologne, where the apsis is dodecagonal, and there are six bays in the nave; and the abbey at Westminster, where the eastern end is hexagonal, and there are found twelve bays in the nave. In respect of a nonagonal termination, the most extraordinary instance of a coincidence with the above-mentioned rules occurs in the duomo of Milan, commenced at the end of the 14th century. Its apsis is formed by three sides of a nonagon, and the bays in the nave are nine in number. One third of the arc contained under the side of an equilateral triangle seems to be the governing dimension. The number 3, submultiple of 9, pervades the structure. There are three bays in the choir, and the like number in the transepts The vault of the nave is subtended by an equilateral triangle. The lower principal windows are each designed in three bays. The plan of the columns in the nave in each quarter contains three principal subdivisions, and, in a transverse section of the nave, the voids are just one-third of the solids. These are curious points, and much more worthy of investigation than many of the unimportant details which now-a-days so much occupy the attention of archæologists. If the stem of the plant is right, the leaves and fruit will be sure to grow into their proper forms.

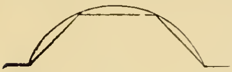

Fig. 1221.

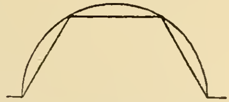

Fig. 1222.

Figs. 1223. and 1224. show the decagonal terminations of an apsis. In the first, a side of the polygon faces the east; in the second, the angle of the polygon is on the axis of the church. The last case is of rare occurrence. Examples of it are, however, found in the church at Morienval, and in the choir of the dom-kirche of Naumburg. The first case is illustrated by a variety of examples—such are the cathedrals at Reims, Rouen, Paris, Magdeburg, and Ulm, with the churches of Ste. Elizabeth at Marburg, that at St. Quentin, &c., and, in this country, the cathedral at Peterborough; all of which have either five or ten bays in the nave. The dodecagon, as a termination, is subject to the same observations as the hexagon: indeed they were anticipated by the mention of the cathedral at Cologne. Under the figure of the heptagon must be classed the magnificent cathedral of Amiens, wherein seven chapels radiate round the choir end, and there are as many bays in the nave (*fig.* 237.). The choir at Beauvais is terminated by a double heptagon; and, had the church been completed, it would doubtless have had seven or fourteen bays in the nave. At Chartres, the choir is also terminated by a double heptagon, and the nave contains seven bays. In the duomo at Florence, the eastern termination is octagonal, and there are four bays in the nave; this is an example of the expiring Gothic style in Italy.

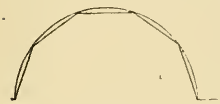

Fig. 1223.

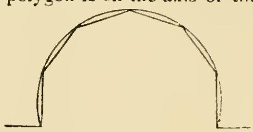

Fig. 1224.

On an examination of the principal churches on the Continent, in and after the 13th century, it would appear that the practice of regulating the details was dependent on the number of sides in the apsis, or of bays in the nave. Thus, if the choir is terminated by three bays, formed on an octagonal plan, we find 3, or a multiple of it, is carried into the subdivision of the windows. So, if the number 5 is the dominant of the apsis, that number will be found transferred to the divisions of the windows; and in like manner the remainder is produced. There are two or three other matters affecting the monuments of art erected in and after the 13th century. The aisles are usually half the width of the nave, though instances occur where the width is equal. Many churches have two apsides—such are the cathedrals at Nevers, and at St. Cyr; and in Germany, St. Sebald at Nuremberg; the dom-kirche at Mayence; the abbey church at Laach; the cathedrals of Bamberg, Worms, and others. So far Mr. Gwilt.

"It remains to observe," writes Professor Cockerell, in the *Archæological Journal*, 1845 "upon the mysterious *numbers* employed by Wykeham in the plans of his chapels at Winchester and Oxford, which are divided longitudinally by 7, and transversely by 4, equal parts. In the first, the chapel consists of 6 of these parts, and the ante-chapel of 1; in the second, the chapel consists of 5, and the ante-chapel of 2; the width being equal to 4, corresponding with the entire figure of the *vesica piscis*."

The recurrence of the number 7, "a number of perfection," is constant; accordingly we find it employed in the following remarkable instances, sometimes in the nave, and sometimes in the choir. In the cathedrals of York, Westminster, Exeter, Bristol, Durham, Lichfield, Paris, Amiens, Chartres, and Evreux; in the churches of Romsey, Waltham, Buildwas, St. Alban's (Norman portion), and Castle Acre; and in St. George's Chapel, at Windsor, Roslyn Chapel, and many others. See also the notice on page 1011.

Sect. II.

EARLY USE OF GEOMETRY AND OF A MEASURE.

The idea is now generally sanctioned, that the mediæval architects had some settled system of proportioning their designs either by simple geometric forms or by combinations of them. It will be our endeavour to indicate the sources whence the facts on this subject can be drawn, and to notice such of the details as our space will permit.

The knowledge of geometry previous to, and in, the 12th century has been commented upon in par. 309, *et seq.* The *Album* of Wilars de Honecort, an architect living in the middle of the 13th century, exhibits the use of geometry in various ways. This manuscript was published in facsimile by M. Lassus in 1858, and an English translation was edited by Professor Willis in 1859. The sketches also show a certain mastership of figure drawing, besides many designs of portions of buildings. Some original drawings still exist of Reims Cathedral, known to be before 1270, thus of the same period as those of Wilars, and two of them have been published in the *Annales Archéologiques*, vol. v. page 92. The drawings were traced with a masterly line; they only showed how the design was to be arranged; and by means of *axial lines only*, the whole was set out as regularly as could be done for the most classical building. Scarcely any of the later original drawings still existing in many continental cities show the use of geometric figures (see *fig.* 1073.). Yet, on the 14th of February, 1321, during the erection of the cathedral at Siena, five persons who had been appointed for the purpose reported that "the *new* work ought not to be proceeded with any further, because if completed as it had been begun, it would not have that measure in length, breadth, and height, which the rules for a church require." The *old* structure, it also appears, "was so justly proportioned, and its members so well agreed with each other in breadth, length, and height, that if in any part an addition were made to it under the pretence of bringing it to the right measure of a church, the whole would be destroyed." Della Valle, *Lettere Sanesi*, ii. p. 60; noticed in Hawkins, *Gothic Architecture*, 1813, p. 183. This statement would seem to prove that some system had existed.

In *par.* 620, we have already mentioned the disputes on the great question of proportioning the cathedral at Milan, 1387–1392, by the foreign system of *squares*, or by the native theory of *triangles*. The first notice in England of this unique instance of a dispute appears to have been taken by J. W. Papworth, who presented in 1854 to the Institute of British Architects some extracts from the Records of the Board of Works for Milan Cathedral, published by Giulini, *Memorie di Milano*, 4to. Milan 1776, part 2, pp. 448–60 of the *Continuazione*. These notes further condensed show, that on the 1st of May, 1392, fourteen of the artists employed upon the works made affidavit of their opinion on ten points submitted to them, on the part of the German Enrico di Gamondia, who was one of the number. On the third point, thirteen declared that the said church, not including the intended cupola, should be raised *non al quadrato ma fino al triangolo*, that is to say, on the triangular proportion. The same opinion is given on the fifth point as to the versed sine of the vaulting. Enrico, who on all the points held a contrary opinion to the thirteen, was thereupon dismissed. Another meeting of similar character, held 26th of March, 1401, of thirteen artists employed on the building, and two amateurs, was not so nearly unanimous upon the question of the alterations proposed by the Frenchman Giovanni Mignotto, and upon that occasion Guidolo della Croce (one of those employed) declared that the alterations were correct, and that Mignotto was a *verus operarius geometra*, because his ratios were like those of the dismissed *maestro* Enrico. The dismissal of this Jean Mignot, 13th of October, 1401, was accompanied by a charge for the expense of pulling down the work that he had erected during two years. Although the chronicle makes the curious mistake that the magister Enricus and the magister Annex (i.e. Johann von Fernach, 1391–92), also a German, had advocated the *triangular* system, it rightly adds that the triangular system prevailed over that of the square; and the lines may be supposed to have been truly given by Cesare Cesariano. The conclusion we have arrived at in the matter is that the plan was designed on the principle of the *square* (exhibited in *fig.* 1231.), while the elevation was designed on that of the *triangle* (shown in *fig.* 1232.).

Cesare Cesariano, the first translator of *Vitruvius*, Como, 1521, terms the geometric principle of design, "Germanic symmetry," and "rule of the German architects." Rivius, who translated this work (Nur. 1548), names the order resulting from the *triangle* as "the highest and most distinguished principle of the stonemasons." One principle rested on the arrangement of the *square*, or of the octagon which proceeds from it, in the same way as that of the equilateral *triangle* was based upon the hexagon or dodecagon which resulted from it. On this law of the *square* is founded the work by M. Roriczer, *On the Ordination of Pinnacles*, 1486, which was printed by Heideloff, in *Die Bauhütte des Mittelalters in Deutschland*, Nuremberg, 1844; and also by Reichensperger, who translated it into modern German, Trier, 1845. It was noticed in the *Journal* of the Archæological Institute of Great Britain, 1847; and translated in a concise manner by J. W. Papworth for the Architectural Publication Society, *Detached Essay*, 1848, with woodcuts. An appendix follows *On the Construction of a Canopy*, which was also given in Heideloff's publication.

The *square*, or octagon system, maintained itself among the German stonemasons until the commencement of the 19th century. Heideloff relates that the *chef-d'œuvre* of Kieskalt, the last city architect of Nuremberg (1806), was founded on the rules used in Roriczer, and those in the book of instructions written 1506 by Laurenz Locher, architect of the Count Palatine, on the art of the stonemason, *nach des Choresmaass und Gerichtigkeit*, "according to the measure and ordination of the choir."

"The system depending on the equilateral *triangle* for its variety of form," states E. Cresy, *Stone Church*, 1840, "continued in use till the beginning of the 15th century in France, when it underwent a great and important change by the introduction of the isosceles triangle and its compound the pentagon. A pupil of Berneval, the designer of the Church of St. Ouen at Rouen, proved that these figures could furnish novelties in design. We can well imagine how displeasing this innovation must have been to the whole fraternity of masons; their mystery was invaded." Pommeraye, in his *History* of the Abbey of St. Ouen, mentions that the master was so incensed at the clergy preferring the rose window of the northern transept (*fig.* 1293.) executed by his pupil, where this innovation was first introduced, to that of the south (*fig.* 1288.), of his own execution, upon the ancient triangular system, that in a fit of jealousy he killed his rival, and was himself condemned to be hanged. (See page 1036.)

In the year 1525, Albert Duerer published in German his *Geometrical Elements*, showing therein clustered columns, and a few other details of Gothic architecture. In 1532 a Latin edition was published at Paris, entitled Albertus Durerus, *Institutionum Geometricarum*; and in 1606 a second edition was printed at Arnheim. It is this author who first brings to our notice the use of a figure called the *vesica piscis*, which is explained in Sect. III. In 1589 Spenser published his *Faëry Queene*, and in it allusion is made to the proportion of a building in words which deserve attention (b. 2, canto 9, v. 21). In 1593 Sir Thomas Tresham erected the curious lodge at Rushton Hall, Northamptonshire, entirely constructed on the equilateral triangle; it contains one room of an hexagonal form; the upper windows are mostly triangular openings (*Builder*, iii. 538. 550.).

Stieglitz, in *Altdeutscher Baukunst*, 4to. Leipzig, 1820, records the possession of a manuscript *Treatise on Architecture*, giving the rules and instructions according to which the ancient *werkmeisters* and *steinmetzen* worked. Judging from the character of the handwriting, it must belong to the middle of the 17th century, and this is also indicated by the drawings which exhibit the Italian style of that epoch. But the rules for the construction of churches belong to a more remote period, and the author of the manuscript states that these rules were never described, but were transferred in a traditional way to, and kept by, the artists, who called them, like the ancients, Measure of the Choir and Justice. It seems to be the *only* written directions for a building which has come down to us. The drawings in it, which are only shaded, are finely executed by a steady and practised hand. They show the formation of the several cornices, mouldings, jambs for doors and windows, plinths, and arches, and also the formation and the arches of the vaulting. The building is proved to have strict rules and an established module, according to which all the members are regulated by the ensemble of the structure, and the whole is again regulated by the members. The choir is considered as the key, and after its breadth is regulated, the thickness of the enclosure-wall, and also all the dimensions for the cornices and other members are obtained. Thence the saying, "Measure of the Choir and Justice."

At first, from a given circle an octagon is to be constructed, and according to it, the ground-plan and the pentagonal projection of the choir are to be devised. Should the choir contain 20 feet in the clear, its wall would be 2 feet thick; and if 30 feet wide, then 3 feet. The pillars of the choir are commonly 2½ feet thick at their base, exclusive of the ground table (*schrägesims*), and the depth is double of the thickness. The width of the windows is regulated by the space between the columns, which is divided into 5 parts: 3 are given to the window in the clear, together with the mullions. If the choir be very extensive, and therefore the lights of the windows be too wide, in such case intermediate mullions are introduced; but small windows have only one main or two subsidiary mullions.

The nave and aisles are regulated after the manner of the choir, being made equal to it in width, yet in such a manner that the pillars, although equal in thickness to the wall of the choir, do not run in the same line of the opening, but project with three sides of their octagonal form. The breadth of the choir being divided into 3 equal parts, 2 are to be given to each aisle, including the wall of the choir. The same dimension of two such parts is applied to the pillars from one centre to the other, which shows at the same time the space for the buttresses on the enclosure-wall. As, in consequence of the aisles, the nave portion requires a wider vaulting than the choir, the enclosure-wall of the nave ought to be constructed one-third thicker than that of the choir. The buttresses are the same in thickness and breadth as for the choir. The windows are kept of the same width throughout the whole structure. The transept projects as far as the breadth of the aisles, and its wall has the same thickness as the wall of the choir. The length of the church is for the most part regulated according to the requirements of the population.

The towers, erected on both sides of the façade, are devised from the width of the inner shafts and external pillars, which width formed into a square gives the external enclosure-line of the towers. If only a single tower be constructed, it ought to be regulated after the choir, and agree with the same. The thickness of the tower-wall is regulated by the height of the tower itself. Thus for every 100 feet of height, 5 feet in thickness is required for the wall. Then, to this thickness one half more is to be given for the foundation. But if the ground be firm and good, this thickness need only be kept as far as the base, and thence gradually reduced. The formation of the groining is not so clearly developed by the editor, and we therefore omit it.

The outline and elevation of the choir are also calculated from its width. A choir which is 20 feet broad, ought to be one and a half or twice as high. The latter height was called the real height. An ordinary choir requires only four tables or strings. The ground table (*schrägesims*) rises from the floor or ground to a height equal to the thickness of the counterforts. The string course (*kaffsims*) above is placed as high as the distance between the pillars. The supporting string (*tragesims*) ought not to rise higher than the capital of the pillars in the interior of the choir. The top, or roof-cornice (*dachsims*) ought to be placed at least half a foot higher than the vaulting. The pillar-cornice is measured by taking the thickness of the pillars twice down from the top cornice. A choir of greater height requires more cornices and decorations. The height of the nave portion is fixed by taking twice the width of the choir, and this is measured from the ground-table to above the top-cornice. The ground floor of the tower ought to be as high as the whole tower is broad, and the upper floors to be regulated accordingly. We have only to add that the form given to the towers by the author of the MS. shows the Italian style of his epoch, whilst the church itself is constructed in German fashion, that is, with high pointed-arched windows and buttresses, which are drawn without any mouldings.

Sect. III.

THE VESICA PISCIS.

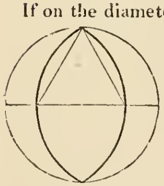

Fig. 1225.

If on the diameter of a circle (*fig.* 1225.), with an axis perpendicular to it, an equilateral triangle be described, whose vertical height shall be equal to the semi-diameter of such circle, and from the angles of the triangle on the diameter, with a radius equal to one side of the triangle, arcs of circles be described cutting each other superiorly and inferiorly, the figure described is that which is called the *vesica piscis*, or fish's bladder.

The Greek word ἰχθὺς, signifying a fish, seems to have been in early ages a mystical word, under which Christ was denominated, "Eò quod in hujus mortalitatis abysso, velut in aquarum profunditate, sine peccato esse potuerit, quemadmodum nihil salsedinis a marinis aquis pisci affricatur;" that is, Because in the unfathomed deep of this mortal life he could exist without sin, even as a fish in the depths of the sea is not affected by its saltness. The term, too, at a very early period, furnished an anagram, whose parts were expanded into the expression, Ἰησοῦς Χριστὸς Θεοῦ Υἱὸς Σωτήρ. The initials of these words were, in their turn, expanded into a long acrostic (to which reference may be had, *sub voce Acrostichia*, and also under the term *Ichthys*, in Hoffmann's incomparable Lexicon) on the Day of Judgment, said to have been delivered, *divino afflatu*, by the Erythrean sybil, but much more resembling the hard-spun verses of a learned and laborious man than the extemporaneous effusions of a mad woman. This acrostic is recognised by Eusebius, and by St. Augustine, *Civ. Dei.*, &c. There is nothing, declared Mr. Gwilt, to afford any proof of the connection of this monogram with the form and plan of the churches erected during the mediæval period of the art. Apology, perhaps, would be due for any digression upon it, had it not been for an opinion in favour of its use expressed by the late Professor C. R. Cockerell, whose talents and learning deservedly ranked high in the eyes of the public, in his essay on the *Architectural Works of William of Wykeham*, read 1845, before the Archæological Institute of Great Britain and Ireland. Ramée, in his *Histoire*, has also gone more at length into this subject. Professor Cockerell likewise noticed that the writers of the 16th century, Cesariano 1521, Caporali 1536, and De Lorme 1576, recommend this figure, chiefly as that geometrical rule by which "two lines may be drawn on the ground at right angles with each other in any scale, according to the conception of Euclid's mind."

From an early time the *triangle* seems to have been associated with as much mystery and veneration as the number 3. Without here touching on symbolism, in its use, whether equilateral or isosceles—we cannot but perceive, both in one and the other, a tendency to the production of the pointed arch. The geometrical law for describing it is, as every one knows, founded on the intersection of two circles of the same radius (*fig.* 1226.) The Pythagoreans called the equilateral triangle, Tritogeneia. It was, according to Plutarch, the symbol of justice. The subdivision of the arcs bounding an equilateral triangle by other arcs of equal radius, gives other modifications of the pointed arch, and by their intersections are obtained the skeleton lines of ornamented windows of an early period, which, at a later date, branched out into the most luxuriant forms. Mrs Jameson, in *Sacred and Legendary Art*, 3rd edition, 1857, vol. i. p 93, gives a drawing from an ancient Greek picture, wherein the upper part of the representation of the Infant Christ is placed in a figure formed of four equilateral triangles (which produce the dodecagon). The head of the infant may be supposed to occupy in the diagram the site of a chancel, the body in the place of a nave, and the hands, being held forth, assume the place of the transepts.

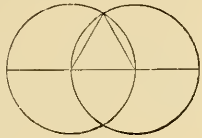

Fig. 1226.

SECT. IV.

MODERN INVESTIGATIONS.

Among the investigators early in the present century was C. L. Stieglitz, who published his *Altdeutschen Baukunst*, 1820, as already mentioned. Therein he states that, "with regard to the ground-plans of churches, it seems that two sorts have been employed. With the first, the nave of the church was in *breadth* equal to that of each of the aisles. With the second, if, for instance, such a breadth be taken as an unit, the breadth of the nave would be the diagonal line of the square, and the breadth of each aisle an unit. The length of the interior of the churches of these two sorts, measured from the entrance to the choir, contains usually nine units The church of St. Stephen, at Vienna, is an illustration of the first system ; and the Münster at Strassburg of the second. The cathedral at Cologne is a variety of the first plan. In this instance the nave is the breadth of its aisle, but each aisle is divided into two by a row of columns in the middle. The fore-part of the church has usually three diagonals of the square for its breadth, wherefrom the unit, should it be unknown, can easily be deduced. According to this principle, if the whole inner breadth of the church be considered as the root of a square, the diagonal of the same will be equal to the whole breadth of the front on the outside.

In the first sort of plan, the nave of the church is raised either to an equal height with the aisles or a little higher. In the second, however, the nave is constructed far higher. Owing to the first disposition, both the nave and the aisles are brought under a single roof, as in St. Stephen's at Vienna. In those of the second sort, the nave and the choir (which was equal in breadth to the nave) had each, as well as the aisles, a separate roof. The wall of the nave and of the choir, on account of its small thickness, comparatively with its height, required some support at the sides, and this was provided for by arched counterforts or flying buttresses from the enclosure-wall of the aisles. The cathedral at Cologne shows a similar disposition, although the nave is equal in breadth to one of the aisles, wherefore the aisles are divided into two rows by pillars, for the purpose of giving to this portion of the vault (when it will be finished), on account of its smaller arching, a less height than the one intended for the vault of the nave and of the choir. The ground-plan of this cathedral is a Latin cross. The aisles surround the choir, which rises high above them, and therefore the enclosure-wall of the choir is connected with the pillars of the outer wall by means of arched buttresses. According to Boecker's observations, the number 7, consecrated by religion and philosophy, is applied all over the parts of this edifice, not only in the measures of length, in the proportions of height, in the pillars of the nave, as well as in those of the choir, but also in the decorations and details."

The inner height of the choir is stated to be 161 feet; the height to the gable, corresponding to the entire width of the west front, is 231 feet ; the (proposed) height of the towers is equal to the entire length of the building, 532 feet ; the height of the side aisles 70 feet, and so forth. In a similar manner, at the entrances on either side, are pedestals for seven statues ; in each of the entrances as many spaces for statues ; there are 14 corner tabernacles on the southern tower ; and with attention, the same combination may be traced in all the details. Twenty years appear to have elapsed, and then Hoffstadt published the *Gothisches ABC Buch*, Frankfort, 1840, which enters fully into the formation of details by a geometric system.

In England, the subject was not thoroughly taken up until 1840, when R. W. Billings published his *Attempt to Define the Geometric Proportions*, &c. He therein considers that during the Norman period, no intricate figures were used for regulating the proportions of the various parts of buildings. He exhibits the early simplicity of proportion, in the elevation of a compartment of the Norman nave of Gloucester Cathedral, as in the annexed *fig.* 1227. Something of the same sort of equality may be perceived at Winchester Cathedral, as shown in *fig.* 1266., where the width K L gives the heights L M and M N ; the diagonal of this square gives the height L O ; and O P is a square in height ; but we are at a loss to regulate the upper part, unless the triangle be used, when P Q will give the upper point at R, the centre of the head of the semicircular window.

Fig. 1227.

In the projection of the plans of the nave and choir of Carlisle Cathedral (*fig.* 1228.), the architect, says Mr. Billings, was guided by the repetition of a *circle* whose diameter in the first or Norman part was the extreme width of the building ; and in the second part, erected 200 years subsequently, it was the width between the internal walls. The distribution and even the substance of the columns was regulated by some recognisable subdivision of the circle ; and a circle, or arc of a circle regulated by the width of each compartment thus formed, was the basis upon which the heights of the different portions of the interior were framed. The woodcut must suffice to show this principle as regards the plan. The precise divisions will not probably answer in any other building, but must be modified. The east wall, it will be perceived, is included within the boundary lines; this is also the case at the Temple Church, London. From the result of calculations, the scale for the *choir* was made 8 parts of the radius of the principal circle, or $\frac{1}{16}$th of the diameter ; this sixteenth part is equal to 4 feet 6 inches (or a yard and a half), and the dimensions of the building may be calculated therefrom. In the *nave*, the piers are exactly 5 feet 8 inches, or $\frac{1}{12}$th of the diameter, and it was this exact division, states Mr. Billings, which induced the application of the scale of twelve parts to the diagram of that end of the building.

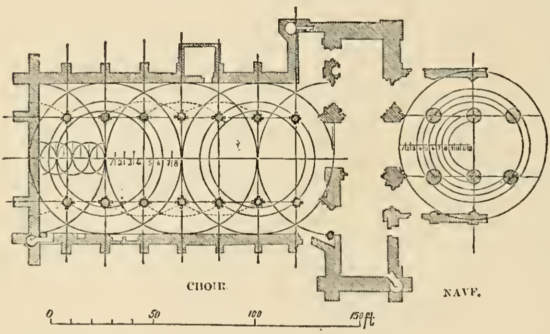

Fig. 1228. PLAN OF CARLISLE CATHEDRAL.

In every portion of the elevation of a compartment of the choir (*fig.* 1229), there is evidence of its geometric formation. The student must have recourse to the publication itself for the further detailed development of the system in connection with this figure, but it is necessary to state that from the dimensions of the arch Mr. Billings divided the width between the centres of the piers into 6 parts for a scale ; this gives all the remaining proportions. The same scale of 6 parts of the width was applied by Mr. Billings to a bay of the presbytery of the choir at Worcester, and finding it satisfactory, though totally at variance in its proportions, with the exception of the principal arch, it was considered as confirmatory of the theory. These two examples are of nearly the same period in the style.

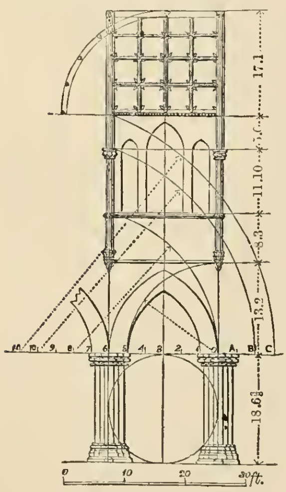

Fig. 1229. BAY IN CHOIR; CARLISLE.

In 1846 Mr. Billings published his *Architectural Antiquities of the County of Durham*, and in collecting the measurements of its churches he was led to compare their proportions. The result is given by him in two tables, proving a groundwork of *squares*, and this he states "would at once account for the non-existence of ancient working drawings, for the designer would only have to communicate a rough diagram of his plan, bounded by series of equal squares, and give the dimensions of one, to be properly understood by a practical man. Most singularly, the measure is in each case one square yard (as above noticed). No less than six of the chancels are 15 feet ; three others are 18 feet ; and three of 21 feet. At Houghton, the widths of the chancel, of the transept and the distance between the columns of the nave, are all 15 feet."

The next investigator was the late Prof. Cockerell, R.A., who, in his essay before noticed (pages 1007, 1010), considers that Cesare Cesariano "may be said to have done to a great extent in that style what Vitruvius did in the Greek, namely, in discovering many of its fundamental doctrines and principles. More especially does he reveal the estimation in which Vitruvius was held during the middle ages; and the interpretations of his rules attempted by the architects and commentators of that period." Thus, the church in the Castle of Nuremburg, built by Barbarossa in 1158, and the Frauenkirche, probably of later date, in the centre of that city, are exact illustrations of the temple "in Antis" of Vitruvius, as given by Cesariano, lib. iii. fol. 52. The use of the work of Vitruvius, about 1284, is also recorded in Galiani's edition of the author, by an amusing story connected with the building of the Castel Nuovo at Naples.

"It is needless to produce any further proofs of resemblance," writes J. S. Hawkins, in his *History of the Origin of Gothic Architecture*, 1813, p. 223, "than to say that, in every Gothic cathedral as yet known, the extent from north to south of the two transepts, including the width of the choir, if divided into ten, as Vitruvius directs (for Tuscan buildings, lib. iv. cap. 7), would exactly give the distribution of the whole. Three arches form the north and three the south transept; the other four give the breadth from one transept to the other. One division of the four being taken for each of the side aisles of the nave, and two left for its centre walls, the complete distribution of the nave is also given. Of the proportion of one-third of the whole width as the height of the columns, the cathedral of Milan is a decided instance. The two transepts together are 110 cubits, the breadth of the choir 28, making together 138; and the height of the columns is 46 cubits."

The rules named by Cesariano occur in his *Commentary*, fols xiv. and xv., and he illustrates them by the plan and section, of Milan Cathedral, which was commenced in 1386. The figures are entitled "ichnographia,"—"orthographia,"—"scenographia,"—"sacræ Ædis Baricephalæ, Germanico more, a Trigono ac Pariquadrato perstructa," and, "secundum Germanicam symmetriam," and again, "per symmetriæ quantitatem ordinariam ac per operis, decorationem ostendere, Germanico more," &c.

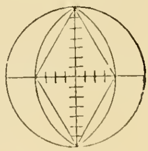

Fig. 1230.

The first rule, "a Trigono," establishes the respective proportions of the length and breadth of the cross, which are included within the two arcs of 102°, constructed according to the first proposition of Euclid. The *fig.* 1230. has been commented upon (page 1010) as involving the *vesica piscis*. Mr. Cockerell continues his remarks by noticing Mr. Kerrich's paper in the *Archæologia*, xix. p. 353–61, wherein that author uses the figure but does not confess his debt. In all the examples given by him the vesica is applied to the internal length and breadth.

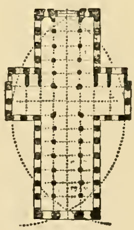

Fig. 1231.

The second rule, "a Pariquadrato," is effected by dividing the area comprehended in the *vesica*, into commensurate squares or bays, on the intersections of which the columns and buttresses are placed. The number of them will be determined by the extent of the plan. *Fig.* 1230. represents the illustration of the rule in which 14 by 8 are used; in the chapels of Wykeham we have 7 by 4. The plan, *Fig.* 1231., explains the determination (by the symbol of the *vesica piscis*) of the length and breadth of a church; the subdivision into squares, the position of its piers, &c. *Fig.* 1232. explains the rule by which the heights of the vaulting, the roof, the spire, &c., are determined, namely, by equilateral *triangles* erected upon the plan. The woodcut exhibits both a single and a double aisled church.

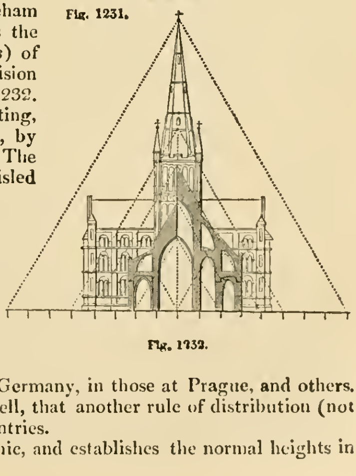

Fig. 1232.

This important fundamental rule will be found to be applicable to cathedrals in England, as at York, Winchester, Worcester, Lichfield, Hereford, Salisbury, Norwich, Exeter, Westminster, Romsey, and others: in Italy, in the church of San Petronio at Bologna, and in most of the works of the architects Lombardi, as San Zaccaria and San Salvatore, at Venice: in France, in the cathedral at Rouen, and in others: and in Germany, in those at Prague, and others. But it is to be noted, continues Professor Cockerell, that another rule of distribution (not yet discovered) is more frequent in the latter countries.

The third rule, also "a Trigono," is orthographic, and establishes the normal heights in the elevations and sections by equilateral *triangles*, according to Cesariano, fol. 15. "The application of the first and second rules in New College Chapel is exact; the whole and the parts are commensurate, as well in the bays or squares as in the subdivision of the bays of the windows; of the flanks, as also of the west end. While in All Souls' and Magdalene Chapels, the two copies of the former, the divergences are extreme. *Fig.* 1233. is the plan and its subdivisions of New College Chapel, Oxford. To our author's own work we must refer the student for the apt remarks and comparison of the three plans, merely adding that the first is three diameters long, while the other two are less than three diameters, by which Professor Cockerell apprehends that the rule had been lost, or was disregarded, although Chichele's chapel was built by "the King's masons." The chapel at Winchester is upon the same principle, the number 7 including the vestibule, which only occupies one of the divisions instead of two, as at New College; the relation of three diameters is obtained without making the diagram, as in New College Chapel, inclusive of the walls.

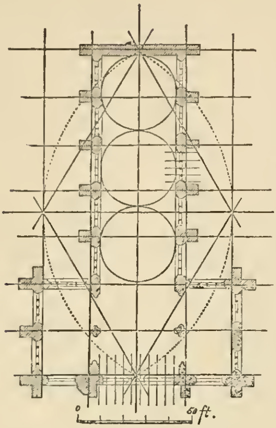

Fig. 1233. PLAN; NEW COLLEGE CHAPEL; OXFORD.

"The application of the third, the orthographic rule, is not traced so distinctly in the elevations and interior of New College Chapel, though more exactly in that of Winchester, and we also perceive the value of the principle of the extension of these squares laterally, for the purpose of establishing the height of the ceiling, and of the pinnacles in the east and west fronts."

The next exponent of this instructive subject was R. D. Chantrell, who in 1847 read a paper on the *Geometric system*, before the Institute of British Architects. It was printed, with cuts of the two chief keys of the system, in the *Builder* for the same year. He first refers to Mr. Kerrich's use of the *vesica piscis*, explaining it, as in *fig.* 1234. Where the

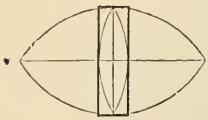

Fig. 1234.

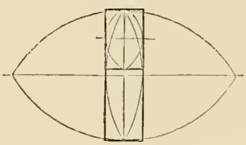

Fig. 1235.

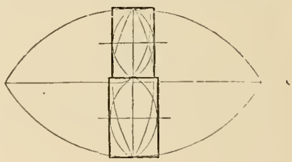

Fig. 1236.

chancel is separated by an arch, the plan is subdivided by taking the breadth as radius (*fig.* 1235.), as at Routh Church, near Beverley, the *vesica* coming sometimes within the walls and western arch, and at others extending to the western face of the arch in the nave, in many works of the 13th century. The apse is sometimes included in, and sometimes excluded from, the *vesica*. Where the nave and chancel vary in breadth, the base of the triangles equal the breadth of the chancel (*fig.* 1236.), its length being determined by the *vesica*, and in each of these cases the breadth of the nave is obtained by framing a similar *vesica* upon the remaining length.

The Anglo-Norman church at Adel, in Yorkshire, is defined upon the extreme length internally, as shown in *fig.* 1237., and subdivided by the proportions of smaller *vesicæ* and other proportions.

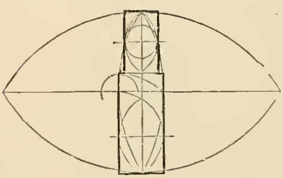

Fig. 1237.

The *equilateral triangle* alone has been tried, but no great variety, he considers, can be produced, as, like the former system, it is but a minor portion of the great system in which most others will be found combined. He notices that in 1830, J. Browne,

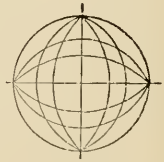

Fig. 1238.

of York, produced a system on the circle. By placing a square or cross on the centre of the circle, dividing it into four equal parts, centres are obtained for *vesicæ* (*fig.* 1238.) of different proportions to those formed by the double triangles. By striking these radial lines upon each of the four points on the circumference, centres are produced in abundance for quatrefoils, crosses, and other figures applying more especially to tracery. The first *vesica* gives the proportions of the naves and their aisles of the cathedrals at Durham, Ely, Peterborough, Canterbury and Salisbury, but no others, and cannot therefore be considered an universal system.

In 1842 Mr. Chantrell developed a system which includes that of Kerrich's. Its formation is detailed in the journal named, to which we must refer the investigator, as the essay has not otherwise been published. *Fig.* 1239. will at once show the principle, and if it be drawn out to a very much larger scale it will not appear so complex. Besides the triangles, the points are obtained for many polygons. The six divisions, A A, B B, from the semidiameter are first obtained; and straight lines drawn to each alternate one give triangles. On their intersections, as C C, if lines be continued to the circumference, six centres are given, D D, F F, upon which, with the first radius A B (or of the semi-diameter), strike a second series of segments, and a third set of 12 centres is obtained. The second centres will give two intersecting triangles, completing the *first* part of the design. Upon the 24 points of the intersecting *inner arcs*, a circle inscribed will determine the inner triangles upon the centres of the first, and the diagram is perfected. For more complex forms, an additional number of centre lines may be drawn upon the remaining intersections.

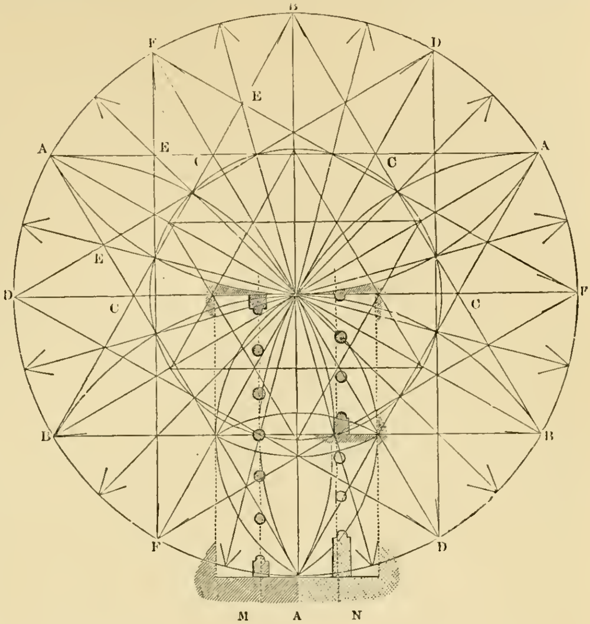

Fig. 1239. MR. CHANTRELL'S SYSTEM.

The number 10 was, according to Vitruvius, Plato's perfect number; but the anti-Platonists, with their 6 or the radial division of the circle (A to B, *fig.* 1239.), could, by the working of their centres, without the necessity of dividing with the compasses, produce the 10, showing that they were the more perfect, as their system combined with all others. The examples named by Mr. Chantrell, in which "the system is clearly exhibited," are the rose window in the south transept of York Cathedral; that of Winchester Palace in Southwark (*fig.* 1190.), but slightly varied and almost undisguised; and the east window of Hawkhurst Church, Kent. Walkington Church, near Beverley, using the entire diagram, affords a simple illustration; whereas Kerrich's plans are proportioned upon the second radial figure produced by the division of the circle, they should be placed upon the base of the great triangle, thus facilitating the operation of giving proportion to a plan. In the composition of the cathedrals at Ely, Lincoln, Canterbury, Norwich, Salisbury, Worcester, Durham, Peterborough, and Winchester, the general proportion is determined by the first of the 24 subdivisions on each side of the centre intersecting the great triangle. The abbeys are all produced on the intersections of the triangles and their centres, and the subdivisions for the piers are found in the centre portion of the diagram, with this occasional difference, that transversely the radial lines may either pass through the *centres of the piers* or *come on the outer or inner faces*, to conceal the principle on which they were based. Thus M (*fig.* 1239.) is part of the plan of the nave of Boston Church, Lincolnshire, arranged on the former principle, while N is part of that of Middleton-on-the-Wolds Church, Yorkshire, where the lines come on the inner face of the piers.

"For the elevation, proceeding with the double spherical triangle upon the centres longitudinally, and the variations before noticed, transversely, the various heights were obtained for the pillars; and the subdivisions by the spherical triangles upon them gave arches, capitals, and bases, triforia, tracery, mouldings of every description, and due proportion to each feature. I have every reason to believe," concludes Mr. Chantrell, "that this system will apply to the works of all ages that can be tested by sound geometric principles."

The results of the investigations published by E. Cresy in 1847 are added in Sect. VI.

F. C. Penrose, in his investigations at Lincoln Cathedral in 1848, for the Archæological

Institute of Great Britain and Ireland, urges that "the tendency towards the system of designing on the *square*, with greater or less degree of approximation, is found to occur in so many churches that it is a law which had great authority with, at least, the more orthodox of the middle age architects, although they did not scruple to modify it when they saw occasion." He decides that the nave of Lincoln Cathedral was formed on this system on the intersection or intended intersection of the piers, and coinciding with the *outside* of the main walls. The choir seems to be built upon the true system of squares, which are of the same size as those of the nave, but the greater width of the former allows of the squares coinciding with the *inside* of the walls. "The height of the choir appears to be obtained, as is so frequently the case, from that of an equilateral *triangle*, whose base lies within the walls. The height of the nave is obtained by a square placed within the same limits, which, though less symbolical, is more commensurate." He thinks that if the length of St. Hugh's choir could be recovered, the whole length from east to west was then such that it included the transepts within a *vesica piscis*. He also conceives (for reasons he states) that the architect to the presbytery had access to the original drawings prepared for the earlier parts of the building.

The ratio of the voids to solids appears to be more remarkable than is to be found in any vaulted building in Europe, at least among the larger structures. Very careful measurements taken immediately above the plinths give voids 1056, supports 107, or the former nearly ten times the supports, including in the latter, the external buttresses and walls; and including in the voids, the clear internal area of the church.

Mr. Penrose gives the measurements of the heights of various parts taken by him with great exactness, and this height he divides into 26 parts, which will be found "to agree in an exceedingly accurate manner with the principal divisions of the bays. In Bourges Cathedral, he states the height of the vaults agrees with that of an equilateral triangle whose base occupies the breadth from centre to centre of the external walls. Some of the heights may be obtained from parts of this triangle, and others from integral numbers of French feet. In the cathedral at Metz, the height is 130 French feet = 138·6 English feet. If this be divided into 300 parts, various proportions of them determine heights. The cathedral of Ratisbon appears to be founded on the triangle taken as that at Bourges. The ratio of its height to length is as 3 to 8; and is 104·2 English feet high, or 110 Bavarian feet. These results are well worth further consideration, from the well-known conscientious manner of taking measurements adopted by Mr. Penrose.

An early investigator, Mr. W. P. Griffith, published in 1847-52, numerous essays on this subject, as named in the list of books in the Glossary addendum. He exhibits the adaptation of the *square*, set square and diagonally, one upon another (as in *fig.* 1073.) to the church of the Holy Sepulchre at Cambridge, *fig.* 1240.; and also of the *triangle*, for early churches, as at Little Maplestead, *fig.* 1241. Westminster Abbey Church, and the cathedrals at Salisbury, Winchester, and Rochester, are based upon a triangle whose base being the width of the nave, including the walls, is placed upon the centre of the central tower, and three of these triangles will include the length of the nave. Ely Cathedral, Redcliffe Church, Bristol, and Bath Abbey Church, are proportioned in a similar manner. "We must insist," he writes, "after a primary figure of form or unit has been given, that each part produced shall bear a proportion to each other, and to the original unit.—Although the equilateral triangle dictated the general proportions, the square and pentagon were found very useful in the details. The chapter houses of Wells, York, Salisbury, and Westminster, are proportioned by joint squares forming an octagon; and those of Lincoln, Westminster, Worcester, and others, by two conjoint pentagons, forming a decagon." He illustrates the formation of the plan of Salisbury Cathedral, both on the *square* and on the *triangle*; but, as noticed respecting Milan Cathedral, although the square appears to suit best for the plan, the elevations appear to have been set out upon the *triangle*. *Fig.* 1242. shows the system applied by him to the plan of Sefton Church, Lancashire.

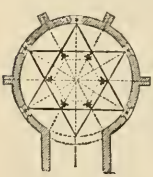

Fig. 1241. CHURCH AT LITTLE MAPLESTEAD.

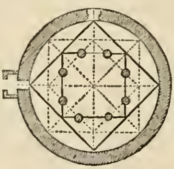

Fig. 1240. CHURCH OF THE HOLY SEPULCHRE, CAMBRIDGE.

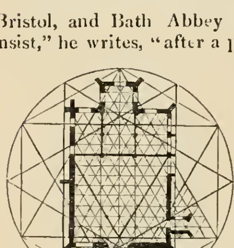

Fig. 1242. SEFTON.

A comparison of the number of equilateral triangles, as named by Mr. Griffith, in fixing the *height* of buildings, will be as follows, viz., Westminster Abbey, 6; King's College Chapel, 4; Lincoln, $3\frac{1}{2}$; Hereford Cathedral, 4; Peterborough; $3\frac{1}{2}$; Lichfield, $3\frac{1}{2}$; Exeter, 4; Worcester, $3\frac{1}{2}$; Bristol, 3. The loftiness of Westminster Abbey is attributed to the cause that the cloisters adjoining (similar to double aisles, as originally intended) being included in the base of the triangle of the transverse section, therefore the height of the abbey is *more* than the cathedrals. The chancel of Bristol Cathedral has no triforium, and is accordingly *less* in height. These buildings having been based upon the equilateral triangle, that figure will alone be a key to them, and it will be futile to try the square. In Westminster Abbey that figure mostly abounds (in trefoils, hexafoils, dodecafoils, &c.); while Salisbury Cathedral, being based on the *square*, that figure and its products will be found chiefly employed (in tetrafoils, octafoils, &c.). This building is 4 squares high.

Dr. Henszlmann, in his *Remarks* on his alleged discovery of the constructional laws of mediæval church architecture, read at the Institute of British Architects, 1852, states that "the architects of old did not employ much reckoning in their constructions, but used geometric forms.—In studying the churches, I became persuaded that out of a ground-line or sum, considered as a basis, there can be developed, either by a geometrical or algebraical method, between 30 and 60 sums or lines, corresponding to the size, age, and importance of the building, and there is, with very few exceptions, not a structural member, be it large or small, the proportions of which are not defined by one of these lines or sums, or exceptionally by their multiples or divisions." He published the first portion of his elaborate system in 1860; this, together with the extensive system put forward by D. R. Hay, of Edinburgh, must be left to the reader to investigate from the books themselves.

The last of the investigators with whose system we shall trouble the student is W. White, who published it in the *Ecclesiologist* for 1853. He has perceived that each architectural period has its own appropriate order of rules, and this in minute accordance with an intelligible system of development. Thus, in the Norman period, the general proportions of the plan are reducible to the *square*, and the relative proportions and positions of the minor parts chiefly by the equilateral *triangle*. As architecture progressed the square disappeared, and to the outline and detail was applied the *triangle*. In the middle of the 14th century, as art declined, the triangle was forgotten, and a system of a diagonal square was taken up. Since then mathematical proportions have been chiefly employed, especially that of the diagonal of the square, *fig.* 1243.

"The figures applicable to the setting out of mediæval buildings are these: 1. the square; 2. the equilateral triangle; and 3. certain arcs described upon diagonals and

I.

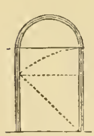

Fig. 1243.

II.

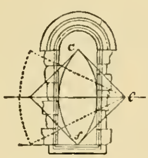

Fig. 1244.

III.

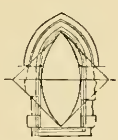

Fig. 1245.

IV.

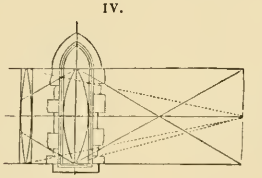

Fig. 1246.

V.

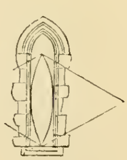

Fig. 1247.

bases of the same." Thus, in Norman work, the proportion of a square placed lozengeways from the ends of which a *vesica piscis* is struck (*fig.* 1244.) is in common use. In first pointed work, the proportion is that of a square touching the head and sill (*fig.* 1245.). The system shown in *fig.* 1246. seems chiefly used in lancet windows and works of that period, the height being first determined. The proportion in *fig.* 1247. is used in traceried first pointed, the *vesica*, giving the width, being obtained from the apex of an equilateral triangle.

VI.

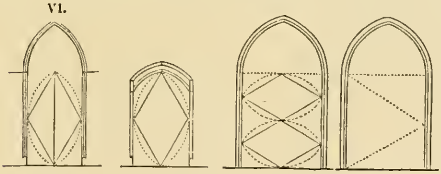

Fig. 1248. Fig. 1249. Fig. 1250. Fig. 1251.

The proportions *figs.* 1248. to 1251. predominate in middle pointed; those of II. and V. the same, only in the latter period the rule is applied to the determining of the lights or bays instead of the whole opening, and is applied to the centres of the mullions and not to the sides only. All these proportions appear to have been equally well known in all early times, but in the middle pointed period they gradually became more complicated, and are consequently more difficult to trace out. In third pointed they can hardly be found, and in obtuse third pointed they quite disappear, the proportions shown in *figs.* 1243. and 1252. taking their place. The equilateral triangle of 60°, D E F (*fig.* 1253.) used to obtain one point, is often accompanied by the angle formed of 30°, E F G, to obtain another relative point; each equal subdivision

VII.

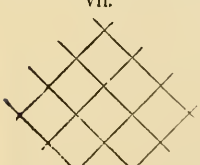

Fig. 1252.

VIII.

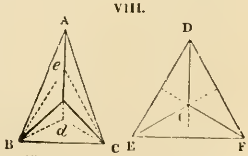

Fig. 1254. Fig. 1253.

F D and F G; F G and F E, having the corresponding angles of each equal; whereas in other triangles (as *fig.* 1254.) this is not the case.

We give one of his illustrations of the theory as applied to Steyning Church, Sussex, a Norman building. The plan (*fig.* 1255.) is set out by equal *squares*, and also the exterior (*fig.* 1256.) to some extent. The interior (*fig.* 1257.) is set out by squares and triangles. The diagrams will explain themselves. The diameter of the columns is determined similar to *c e f* in Rule II. The lower window is set out by II. and the upper one by VI.

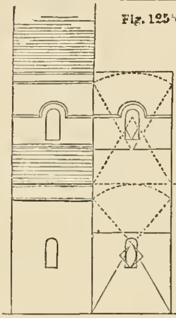

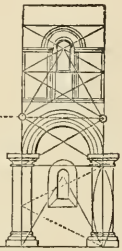

Fig. 1256. Fig. 1257.
STEYNING CHURCH.

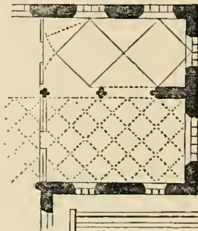

Fig. 1262.

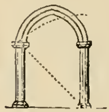

Fig. 1261.

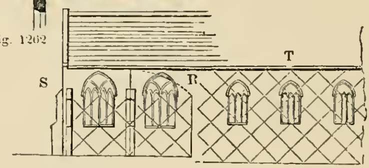

Fig. 1263. PROBUS CHURCH.

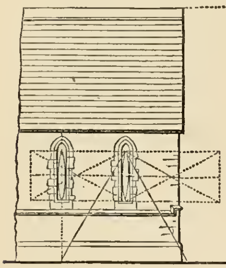
Fig. 1258. is the ground-plan, and *fig.* 1259. the elevation of the east end: and *fig.* 1260. the elevation of part of the side, of the church of St. John, Wappenbury, Warwickshire. The relation of the lines one with another is well exhibited in the diagrams. At Itchenor Church, Sussex, the width is divided externally. In the west window of the north aisle of the church of St. Andrew's at Ewerby, the centres of the mullions obtained on the plan by squares diagonally divided, exactly coincide with the same points on the elevation as developed according to Rule VI. This system is shown in *figs.* 1287. and 1303. *Figs.* 1262. and 1263. explain the method of setting out the proportions for third pointed work; the height of the bay (R) being first determined by the diagonal of a square.



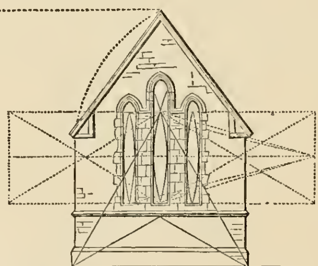


Fig. 1259.

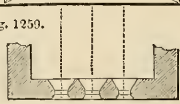

Fig. 1260. Fig. 1258.
WAPPENBURY CHURCH.

The example is the church at St. Probus, Cornwall. The windows S are a square wide to the outer edge of the moulding, and are fixed by a square on the base of the bays. The windows T have their points fixed much in the same way, but their width is determined by the diagonal of a square. The height of the arches in the interior are also determined by the diagonal of a square (*fig.* 1261.).

"No one," writes Mr. White, "seems to have carried out upon the equilateral triangle any definite theory of design, or to have reduced the application of it to any tangible shape.—The theory is that the several parts of a perfect building must be in certain relative proportions to each other,—so that all parts may be brought into an entire and unmistakable harmony with each other,—hence it is not a definite application of these principles that is insisted on, but only a systematic observance of them in some way or other.—In secular and domestic buildings, we do not look for the same amount or kind of beauty, nor is the same exactness of proportion of equal importance as in an ecclesiastical building, where every line ought to be in its proper place, and every form distinctly marked to convey an idea of perfection. In common dwelling-houses, where it is directly evident that the external form is entirely dictated by certain requirements of internal arrangement, a sort of natural beauty always results, and so there is not the same need to have recourse to exactness of proportion to produce some degree of good effect.

"The advantage of a mechanical process for defining proportions and forms would be immense in the mere practical carrying out of the work; for by its means we could, by taking one leading dimension, transcribe, reduce, or enlarge drawings with the greatest accuracy, and with less than half the labour of using scales and compasses. A large body of men, working apart from each other, but under certain and very rigid restrictions, must produce diversity as well as similarity. Their works must all possess the same general character, though the details and form in the application of them must vary in every instance with the circumstances of the case and the workings of the different minds."

This system is developed by Mr. White, on numerous plans, details, towers, &c. taken from his own dimensions.

Sect. V.

PROPORTIONS OF MOULDINGS.

To enable us to decide that mouldings may have been also designed according to a measure, there is a very interesting notice recorded by Llaguno, *Noticias de los Arquitectos y Arquitectura de España*, edited by Cean-Bermudez, 1829, wherein, under the life of Pascual Iturriza, he states that that architect designed, 8th of May, 1541, the *capilla mayor* to the parish church at Plasencia in Guipuzcoa. While the work was in hand, complaints arose from the townspeople, voters, that he was decorating it with work that was too minute and could not be seen from the floor. To this assertion he replied, according to an entry in the archives of the town, that they might bring some persons, *peritos en la gimetria*, who could give a judgment in the matter. Such skilled persons were brought to the building and approved the work in debate. Whereon the town council requested the vicar, as being a person who was always in the building, to oversee the remainder of the work. The church is in the Gothic style, with a nave and chancel only, and is executed in cut stone. Iturriza was further employed at Santa Marina de Oxirondo in 1559.

We have given in the section Masonry an illustration (*fig.* 662*h.*) of a mode of setting out the ribs for vaulting, found on an incised block of stone. Such specimens of mediæval work are very rare. Prof. Willis, in his paper on *Vaulting*, gives another example, and perhaps only two more could be quoted. But these do not show how the mouldings were proportioned.

We insert from the appendix to Roriczer's work, quoted on page 1008, the method of making the template or mould for working the mouldings for a canopy. The directions are:— In a given square A B C D (*fig.* 1264.) inscribe a circle and draw the diagonal and centre lines. With the centre Z, and a radius equal to the given line A B, describe a circle, and therein inscribe a square E F G H parallel to the diagonals of the first square. This gives the size of the horizontal measurement of the four leaves of the great flower or finial of the canopy. In the same circle inscribe a square I K L M of equal size to the last mentioned square, but parallel to the sides of the square A B C D, and let the line I K intersect the line F G in N, and the line F G intersect K L in O, and the line K L intersect the line G H in P, and the line G H intersect the line L M in Q. Bisect the line B K in R, and with the centre B and the radius B R describe a circle; and with the same radius describe a similar circle about the centre C. With the centre G, and the same radius, cut off from the line G Z a portion G T, and through the point T draw a line S S of indefinite length; and from the points O and P draw lines perpendicular to the line S S and joining it. This gives the outline of the template for the arched mouldings; for M Q will be the internal face of the wall, Q P the external splay, with one hollow moulding C therein; the rectangular parallelogram under P O will contain the jamb mouldings from which the template of the mullion is found, &c.

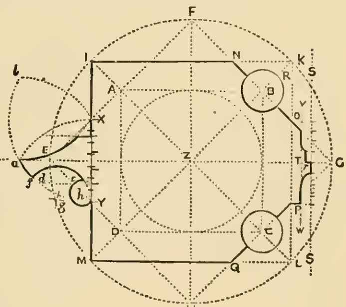

Fig. 1264.

The jamb and hood mouldings are not described by Roriczer, but probably the back of the hood is obtained by the radius X Y cutting Z E at *a*, and from *a* and X the same radius will give the point *b*, from whence the curve X *a* is obtained. The curved line Y *a* is obtained from X. Divide X Y into 5 equal parts, and at 1 draw a line parallel to Z *a*. The length *a f* will be equal to the diameter *e* Y. With a radius equal to *d e*, and the centres *f* and Y, describe arcs of circles intersecting in the point *g*, and with the centre *g* and the same radius describe the arc *f* Y. The roll moulding appears to be formed by the length *e* Y on the line E Y, cutting the line Y X at 1.

The jamb moulding is probably obtained by dividing the line S S into 8 equal parts; a radius equal to one of the parts struck from 2 and 6 will give the curves, and the line V W. T *r* will be equal to half T 4, and the jamb is completed. For the remainder of the construction of the canopy we must refer the reader to the publication in question.

"It is in vain," states Cresy, *Stone Church, Kent,* 1840, "that we attempt to imitate the tracery or mouldings belonging to this (the 13th century) style correctly, unless we consider them to emanate from some simple figure. However numerous the mouldings, they never appear confused, which entirely arises from the order observed in their arrangement." This he illustrates by the mouldings forming the trefoil arches round the chancel. "The points of intersection of the two equilateral triangles are the centres for the hollows, and the more prominent parts of the moulding are set out with the same radius at the points of the triangles; or, in other words, four circles are encircled within a circle, and by omitting each alternate one the figure is formed."

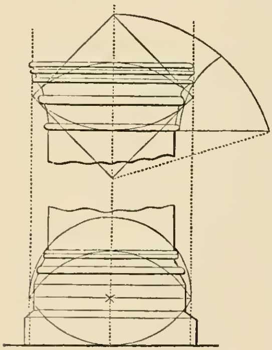

Fig. 1265*a*. CAP AND BASE AT STEYNING.

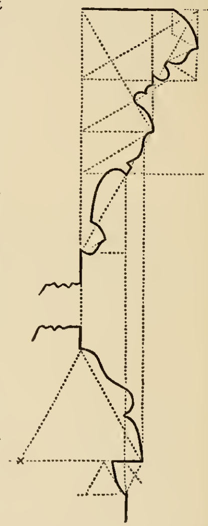

Fig. 1265. HECKINGTON.

Fig. 1265. is from Mr. White's essay, and represents his system applied to a cap and base of the porch doorway at the church of St. Andrew, at Heckington, in Lincolnshire. The mouldings are reduced from full size drawings whereon the diagrams coincide very accurately with the several members, the whole being set out by subdivisions of the equilateral triangle, or angles of 30° and 60° &c. (as *fig.* 1253.). *Fig.* 1265*a.* illustrates another cap and base from Steyning church, previously selected as an example. The cap of the columns is formed on the principle of Rules II. and III., and the base upon that of VI.

A remarkable circumstance connected with this subject is, that although the German archæologists appear to have reduced the proportioning of mouldings and details to a system, as illustrated and explained by Hoffstadt, *Gothisches A B C Buch*, Frankfort, 1840, which has been translated into French by T. Aufschlager, *Principes du Style Gothique*, Paris and Frankfort, 1847, no one has translated it into English, or prepared a corresponding publication on English work (certainly not since the well conceived but lamentably produced system by Batty Langley in 1742), not even the author of the *Analysis of Gothic Architecture*, from whom it might have been expected. In fact, a true system of mediæval architecture being still unknown in England, designs are made at random, and the school, in disregard of its professed principles, continues disunited. For the satisfaction of those who may desire to subject the mouldings given in Chap. III. to a system, we add that the plans of Fountains, Tintern, and Henry VII.'s Chapel, appear to be designed on the system of the square; that of Howden on the triangle.

Sect. VI.

PRINCIPLES OF PROPORTION.

The following portion of the elucidation of this subject was originally published in 1847 by E. Cresy in his *Encyclopædia*, as referred to at page 900 of this work, who noticed, while introducing it, that "our attention must not be directed to the decorative portions of the style, but to the construction, from the study of which some valuable lessons may be deduced."

The Saxon manner of Building. — A division of the transept of the cathedral at Winchester has been selected as the best authenticated example of the style in use previous to the Norman Conquest. In a paper read before the British Archæological Association at their second annual congress, held at Winchester in August, 1845, the author gave his reasons for supposing it to be the work of St. Athelwold, for which the reader is referred to its "Transactions."

Arches upon arches enabled the Saxons to continue their walls to a considerable height, the openings between the piers being proportioned as those of the Roman buildings in the time of the emperors. The plans of the piers differ from those previous to the introduction of Christianity: in Britain both the Greek cross and the circle are applied to them.

At Winchester Cathedral the columns of the triforium recede within the pier, and are set round a circle, (fig. 1267.); the passage in the walls of the clerestory is shown at the side; in another portion of the same building is a similar arrangement in less massive piers. (fig. 1268.)

The Saxon churches were generally divided into three tiers or stories, viz. a lower arcade, a triforium, and clere-story above; and such was the solidity and thickness of the walls, that buttresses were altogether omitted, the outer face of their buildings in this particular bearing a closer resemblance to the Roman than the Norman, although the workmanship was rude, and the decoration scanty.

The proportions found in Saxon buildings are the same as in the Roman, which, without doubt, they took for their models. The circular temple of the Pantheon at Rome, 142 feet 6 inches diameter internally, and 183 feet 8 inches externally, contains the proportions of two-fifths wall and three-fifths void; the area of the latter being 15,948 superficial feet, and of the former 26,493 superficial feet; the difference of these areas giving 10,545 feet for the area of the walls.

We have already seen that in the Coliseum at Rome the points of support are about one-sixth of the entire area of the plan; and the proportions of both these buildings have been admired for nearly 2000 years, the one vaulted, the other uncovered.

Generally the walls and piers of our Saxon cathedrals occupy from one-third to two-fifths of the entire area; in their sections one-third is devoted to walls and piers, and the remainder divided between the nave and side aisles.

The division of the cathedral at Winchester exhibits very perfectly the Saxon manner of building; the piers that support the lower arches are 10 feet wide, and the clear openings between them 12 feet 1 inch. The nave and transepts retain their original construction; in the former under the casing executed by William of Wykeham, and in the latter it is seen in its full purity. The choir stands over the crypts built by St. Athelwold, and though

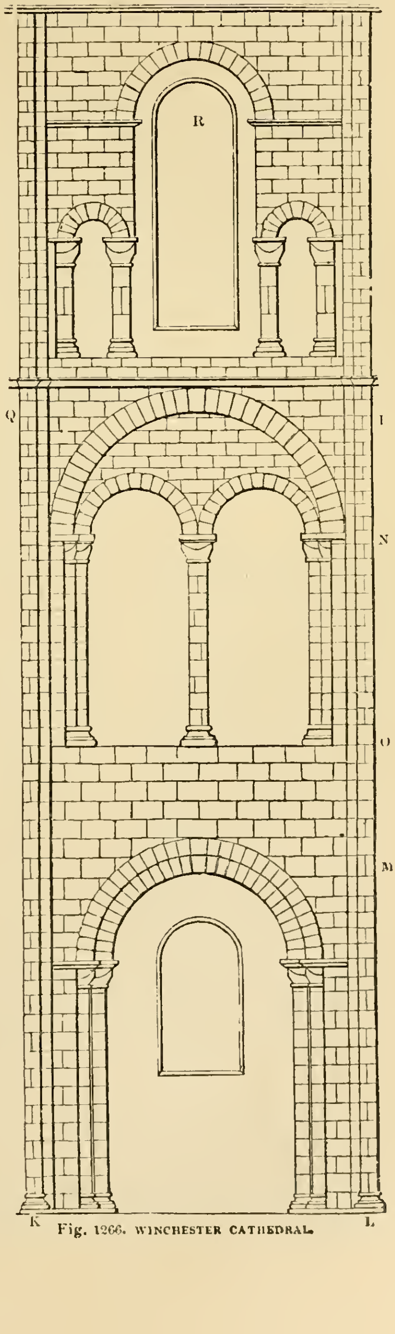

Fig. 1266. WINCHESTER CATHEDRAL.

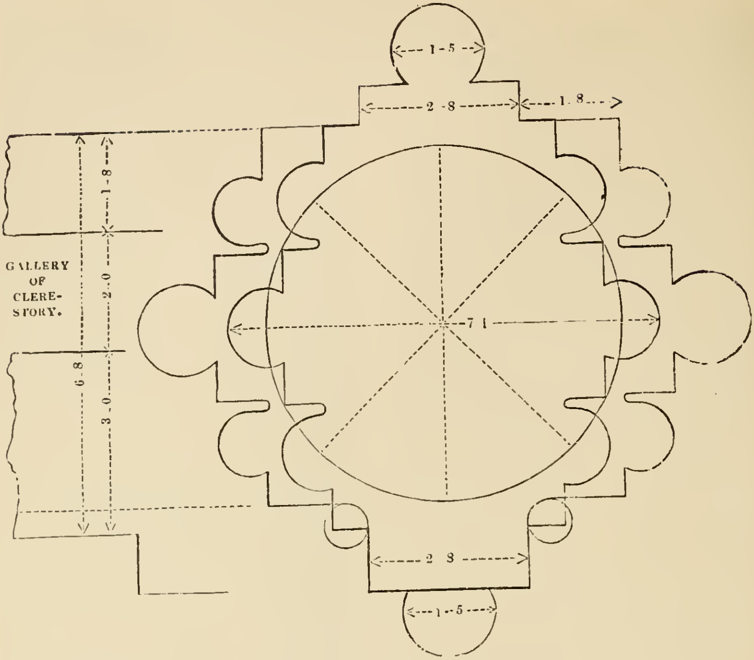

Fig. 1267. PIER IN NAVE AT WINCHESTER CATHEDRAL.

somewhat changed by the Normans, it yet retains the dimensions given to it by its celebrated Saxon constructor.

The small piers, one of which, in the south transept, is nearly perfect, are set out with great regularity, and measure 9 feet 8 inches from west to east, and 8 feet 2 inches from north to south; their form is that of the Greek cross, composed of five cubes, each 2 feet 7 inches in width, with large and small columns placed around them to receive the mouldings that decorate the arches: six of these columns have their centres on the same circle: it is evident that the hexagon, or the duplication of the equilateral triangle, was applied, and that the whole was set out by one conversant in geometry, and acquainted with the proportions of the cube. The Greek cross, which defines the solid mass, is continued through the triforium and clerestory up to the timber roof. The columns of the triforium, set round the inner circle, are partly cut into the lateral arms of the Greek cross, but the face of the shafts of the columns are in a line

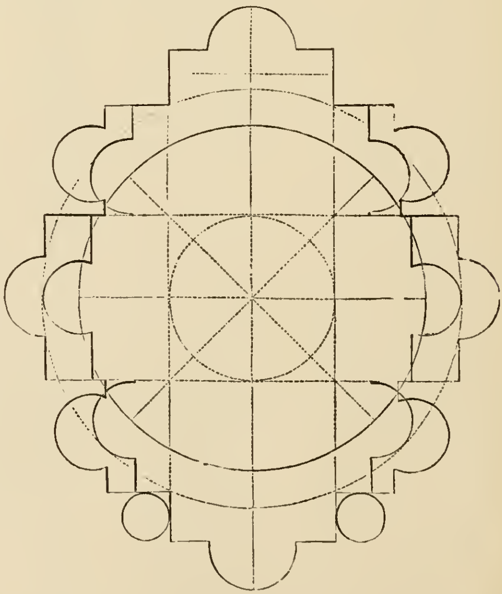

Fig. 1268. PIER AT TRANSEPT AT WINCHESTER CATHEDRAL.

with its outer side. The centre of the pier is preserved throughout, and so placed as always to balance the masses around it equally. The circular shafts at Gloucester Cathedral, Tewkesbury Abbey Church, and several others, were probably of earlier date than pillars formed of several shafts; those in the church of Saint Germain des Prez, at Paris, are delicate examples of the former style.

That aisles, galleries, and passages, belonged to the construction of a Saxon church, we have sufficient evidence in the accounts left us by contemporary historians; but the present subject is almost conclusive on this point, there being a preparation for a wall 6 feet 8 inches in thickness, containing the passage 2 feet in width, indicated by the plan of the pier at fig. 1267. The arrangement of the columns shows that there was no intention of vaulting the side aisles, for the two which carry the cross springers appear to have been added some time after the original construction, as were also those in the pier, fig. 1268.

Athelwold is supposed to have executed the whole of this work before the year 980: the mouldings throughout are rudely cut, the capitals of the main pillars being the only portions which are at all enriched by sculpture, and they are very simply carved.

The Norman manner of Building can scarcely be said to differ from the Saxon, though the masons employed after the Conquest certainly acquired a superior knowledge in their art. The ornaments which we find in Norman buildings had all been previously used by the Saxons; hence the difficulty of distinguishing the works of one from the other: where written authority is not handed down to us, we can only judge by the difference of the workmanship; it cannot be denied that there were many very able masons among the Saxons, who were qualified to raise buildings and enrich them with sculptured ornament.

The finest examples of Norman work may be seen at Caen and its neighbourhood, and have been engraved from measurements taken by the late Mr. Pugin.

In England the same style prevailed throughout our religious structures; there is a great similarity of arrangement, and little variety of ornament. The Norman style was generally adopted after the Conquest, but that named by the monkish historians the "Opus Romanum" was continued in many of our parish churches, as well as in some larger buildings. The Norman pillar was sometimes composed of a cylinder with four small half columns attached, as at Amiens, which is 7 feet 2 inches diameter.

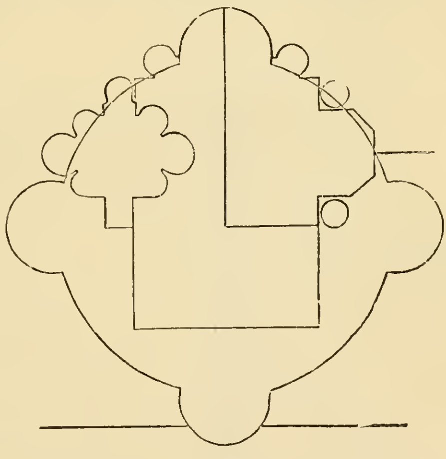

Fig. 1269. PIER AT AMIENS.

For the Saracenic or Arabian Styles we must refer to the beautiful work recently published by Mr. Owen Jones, where the decorative parts of this curious and highly ornamented architecture are admirably given, and proceed to the description of the principles which guided the constructors of pointed architecture.

The Lancet Style succeeded the Norman, and we find it well defined in many churches and cathedrals as early as the year 1180; in it decoration was sparingly introduced, and throughout every part of the design there was simple uniformity, and a display of a considerable knowledge of geometry: the heads of the windows and doors were formed of a pointed arch, constructed upon an equilateral triangle; all the mouldings which surrounded those apertures were delicately formed, and had both capitals and bases; this style was practised till 1230, when it was followed by another, which by some writers has been termed

The Early English or the Geometric Style, from the manner in which the several portions of a building were set out; and we find it adopted generally up to the year 1280.

Salisbury Cathedral, founded by Bishop Richard Poore, in the year 1220, was finished in 1260. Its plan is that of a Greek or patriarchal cross, the extreme length being 480 feet, that of the great transept from north to south 232 feet, and that of the lesser transept 172 feet: the stone used for the external walls and buttresses was brought from the quarries at Chelmark, which lies about 12 miles distance, westward from the city. The middle of the walls is filled in with rubble, and the shafts of the columns are of marble, from the Purbeck quarries. At the intersection of the nave with the great transept rises a noble stone tower and octagonal spire, the total height of which is 400 feet; the stone of the spire is in thickness about 2 feet to the height of 20 feet above the tower, after which it is only 9 inches in thickness to the summit: this spire, though braced and strengthened throughout by timbers and ironwork, has declined from the perpendicular $22\frac{1}{2}$ inches; but since 1681, when the observation was made, there has been no further declination.

The walls, after they were carried up to the floor of the triforium, appear to have been increased by corbelling, as if it had been doubted whether, as originally set out, there would be sufficient strength to carry the cross springers of the vaulted nave; the total width is exactly 100 feet. The clear width of the nave, as measured on a level with the triforium, is 33 feet 3 inches, and that of each side aisle half that dimension, or 16 feet 9 inches; had this last been 16 feet $7\frac{1}{2}$ inches only, the proportions shown by a section would have been exactly one-third for walls and two-thirds for voids; after appropriating the third of the 100 feet to the walls, half the remainder is given to one side, and half to the other; we also find that each of these dimensions of 16 feet 8 inches is divided into three, two parts of which are given to the outer wall and buttress, and the other to the main pillar that divides the nave and side aisles, or nearly so.

The inclination of the arched buttresses is not such as to resist the spreading of the vault at its base, the knowledge of their use not having then been attained The height of the vaulting of the nave from the pavement is 81 feet.

Wells Cathedral has some peculiarities in its construction, particularly in the application of its arched buttresses: they pitch against a stone corbel inserted below the springing of the

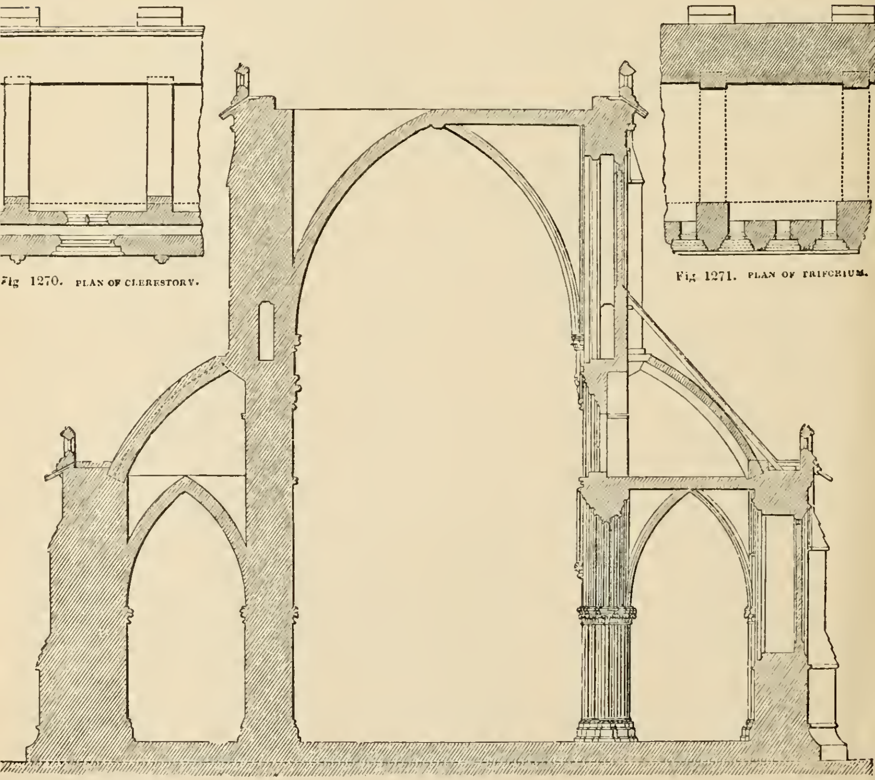

Fig 1270. PLAN OF CLERESTORY.

Fig 1271. PLAN OF TRIFORIUM.

Fig. 1272. SECTION OF WELLS CATHEDRAL.

middle vault, and a tangent drawn at the back of the vault and elongated determines the inclination of the top of the flying buttress: here some improvement is shown upon those at Salisbury. The masonry of the arches is admirably constructed, and the joints all radiate to a common centre.

The total width of this cathedral from face to face of the buttress is 86 feet 5 inches, and that of the nave 31 feet 10 inches, instead of 28 feet $9\frac{1}{2}$ inches, as it would have been if a third had been adopted; the side aisles are also diminished in consequence, being only 13 feet $7\frac{1}{4}$ inches in the clear; they are, however, equal to the buttress, outer wall, and main pillar added together, the first projecting 2 feet 8 inches, the second or outer wall being 6 feet in thickness, and the piers 5 feet diameter; whilst the width of the side aisle measures 13 feet $7\frac{1}{4}$ inches, an approximation sufficiently near to suppose that the proportions of thirds was still adopted in practice. The nave has been increased at the expense of the side aisles, and its height is 68 feet 9 inches to the top of the vaulting from the pavement.

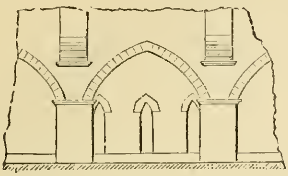

Fig. 1273. TRIFORIUM, INSIDE.

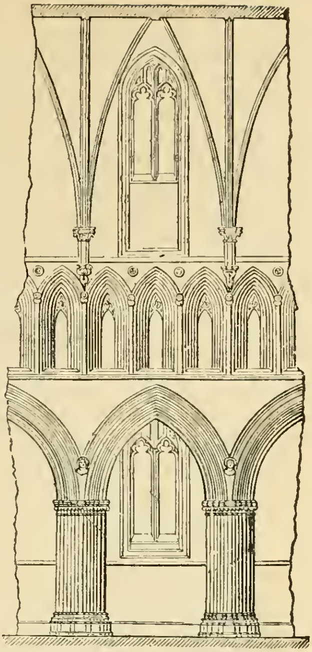

Fig. 1274. DIVISION OF WELLS CATHEDRAL.

Chapter House at Wells, erected between the years 1293 and 1302, is an octangular building of great beauty. A section through the buttresses shows that two equilateral triangles crossing each other have determined the mass and void, which are in the proportion of one to two, or the thickness of the two walls is equal to one-third the entire diameter: the base line of the triangle, on which the supports of the crypt are placed, clearly indicates this arrangement. Of the twelve equilateral triangles comprised in the parallelogram formed by uniting the bases of the two larger, each outer wall and buttress occupy two, or the two walls and their buttresses four of the twelve divisions, leaving eight for the space between them.

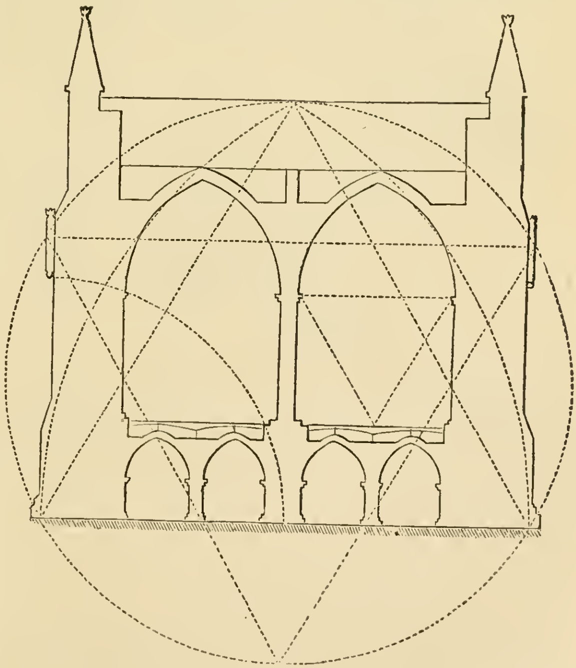

Fig 1275. CHAPTER-HOUSE AT WELLS.

Where it is determined that the walls shall occupy one-third of the section of a building, no figure is so well calculated for such a distribution as the equilateral triangle; it enables the architect at once to limit and fix the proportions of his design; hence its universal application: and the mysterious qualities attached to it by the freemasons no doubt arose from the extraordinary facility it afforded them in setting out their several works. What can be more simple or more beautiful than the distribution of this edifice? Within a circle a hexagon is set out, the perpendicular sides of which mark the outer faces of the buttresses; the junctions of the angles, by forming a base to every two sides, produce the two equilateral triangles, which sub-divided not only enable us to arrange the other portions accurately, but also to measure with the greatest nicety their relative dimensions. The quantities of material employed in construction can be estimated by such means much more easily than by measuring each portion separately, cubing it, and adding the numerous dimensions so obtained together; there is decidedly more simplicity in the former than in the latter system: the area of one triangle being found, we at once know that of all the rest,

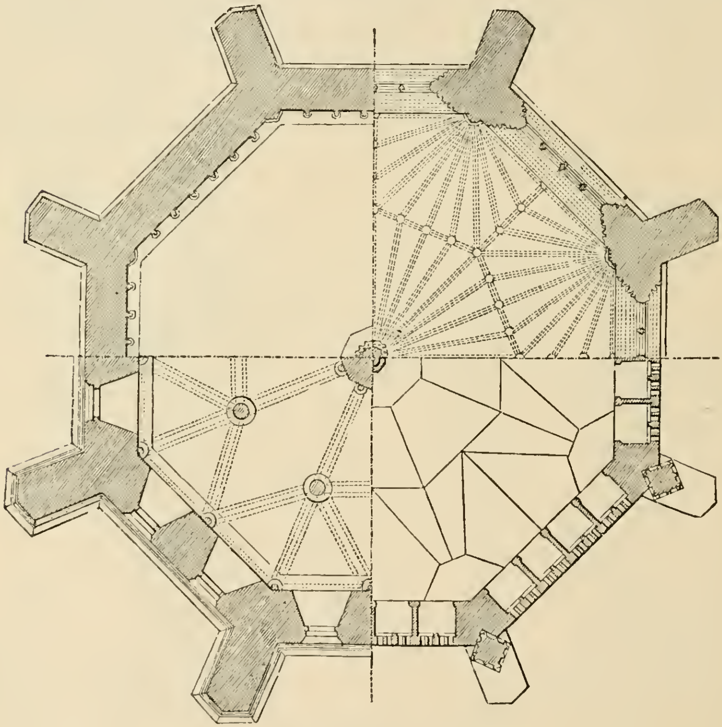

Fig. 1276. CHAPTER-HOUSE, WELLS: PLAN.

or of any portion. In the subject before us the distance from the middle of one buttress to that of the other is 31 feet 6 inches, and the diameter taken through them at this level is 92 feet; omitting the buttresses, the outer side measures 26 feet, and the inner 21 feet 6 inches, the respective radii of the circles which comprise the octangular outer walls and the void being 38 feet and 31 feet 5 inches. Hence we find that the entire area of the building without the buttress is - - - - 3264 feet.

The area of the void - - - - - -	2176 feet.
And of the walls or points of support - - - -	1088 feet.

At the level of the crypt, above the outer plinth, we have these regular proportions, two-thirds void and one-third walls.

The height of the entire building, from the pavement to the top of the parapet, is 72 feet 6 inches, and to the top of the pinnacles 92 feet, the total height being equal to the extreme diameter taken above the plinth moulding on the outside. The interior of this chapter-house exhibits the most perfect proportions as well as appropriate decorations; the eight windows, divided into four days, have their heads filled in with circles set out upon equilateral triangles; the vaulted stone roof rests partly upon the octangular central pillars, 3 feet in diameter, surrounded by sixteen small columns, one at each angle and another between: the height of the pillar is 22 feet 8 inches.

Thoroughly to comprehend the expression, as well as use of the various members found in the architecture of the middle ages, we must trace the progress made in vaulting, and observe the changes it underwent, from the simple cylindrical to the more complex and difficult display of fan tracery or conoidal arches. The ridge ribs, or *liernes*, as they are termed, in the crypt of the Chapter-house at Wells, pass from the centre of the building to the middle of each buttress; the diagonals, or *croissées*, mitre into them as well as into the *formerets* or ribs against the outer walls.

In the vaulting of the Chapter-room, we have evidence of greater refinement, and an

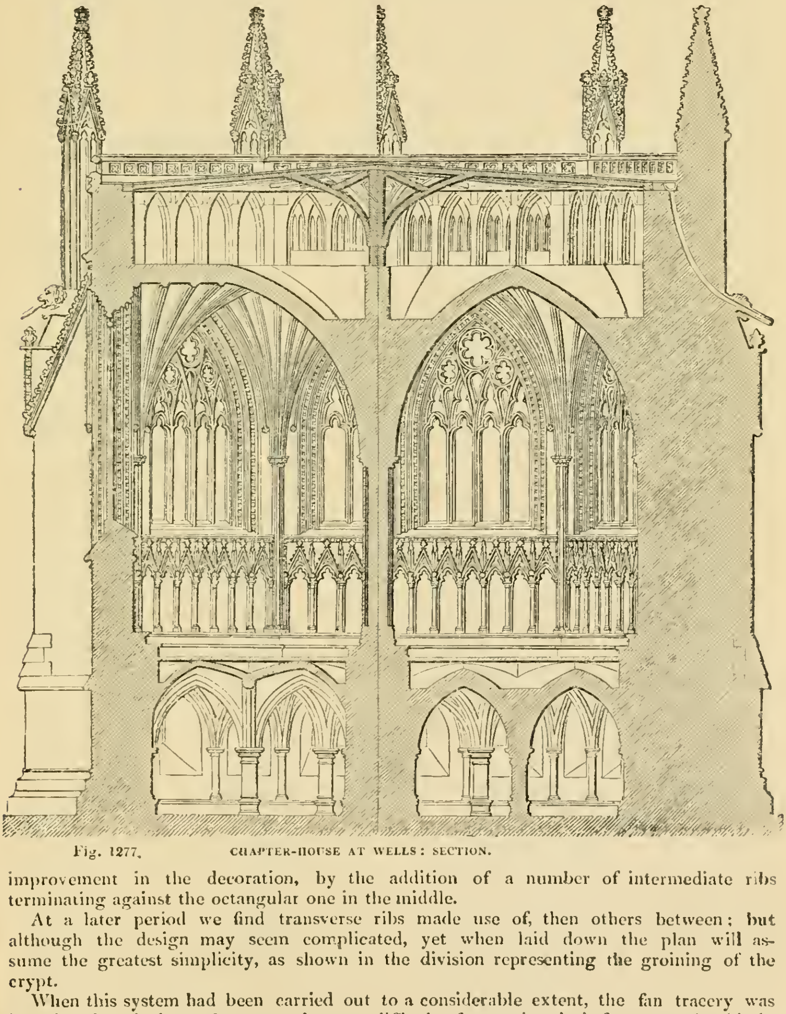

Fig. 1277. CHAPTER-HOUSE AT WELLS: SECTION.

improvement in the decoration, by the addition of a number of intermediate ribs terminating against the octangular one in the middle.

At a later period we find transverse ribs made use of, then others between; but although the design may seem complicated, yet when laid down the plan will assume the greatest simplicity, as shown in the division representing the groining of the crypt.

When this system had been carried out to a considerable extent, the fan tracery was introduced, and although apparently more difficult of execution, it is far more scientific in its application and arrangement, evincing a higher knowledge of mathematical principles and geometry, and is another evidence of the gradual progress of the mind towards perfection in this style of architecture.

Westminster Abbey, commenced in the year 1245, is in that style which for many years prevailed in France: the fine church at St. Denys, near Paris, is exactly similar in all its detail. The windows are wide, divided by mullions, and have their heads filled in with plain circles, the origin of the cusp, or that kind of decoration which every pointed arch afterwards received. This style, which succeeded the Lancet, is found throughout England, and many of the parish churches exhibit fine examples of it. Stone Church, in Kent, of which the writer has published an account, may be cited as one of the best; its ornament shows the skill and taste that prevailed among the free-masons at that period. Salisbury, Wells, and York Cathedrals abound with rich foliage and sculptures of the highest merit executed at the same time, and it is wonderful to observe to what a state of perfection the artists of this country had arrived. The effects of the chisel of the Pisan school were displayed upon marble, but our sculptors worked upon an inferior material; yet the draperies of their figures, as seen in the front at Wells, and elsewhere, are quite equal to those wrought by the pupils of Italian masters at the same time. The circle and its intersections at this period were alone employed for the plans of piers, sections of mouldings, and the filling in of windows and doorways: from them we trace the origin of the style which immediately succeeded.

The cathedrals of Cologne, Amiens, Beauvais, the Sainte Chapelle at Paris, and numerous other examples on the continent, exhibit the same proportions and style with that of Westminster; the lofty pointed arches, which rest upon the main cluster, are decorated with numerous small mouldings; the triforium, in some instances glazed, have their pointed arches filled in with trefoils, cinquefoils, or sexfoils, and the clerestory, carried up to the very apex of the vaulting, is similarly adorned. Westminster Abbey is one of the finest examples of building executed in the thirteenth century.

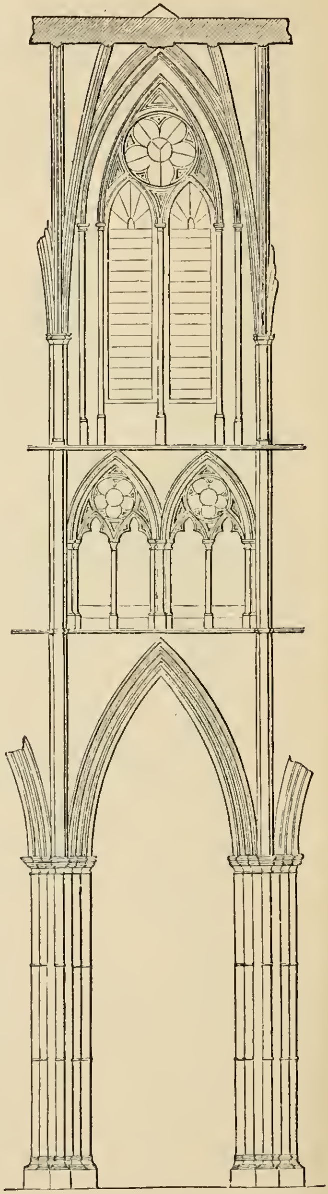

Fig. 1278. WESTMINSTER ABBEY.

Tracery and Geometric Forms.—To comprehend thoroughly the principles which directed the free-masons of the middle ages in the execution of all their works would require far greater illustration than can be bestowed upon the subject in the present volume: it must be sufficient if we point out a few which influenced the design of some of their best examples, and show that it is a perfectly erroneous opinion to suppose they were executed without a thorough knowledge of certain rules, originating with themselves, and perfected by a constant study of what was not only useful, but productive of the best effect. Those who inquire into this subject must collect the data upon which an opinion can be formed, for it is scarcely possible, without positive measurement, to arrive at any conclusion upon the matter: the admirer of the Greek, or the commentator upon Vitruvius, alone can scarcely hope to be successful: it is true that in one of the early printed Italian editions of the valuable author quoted, there are several diagrams which seem to point to the subject, but the student will find only the nucleus around which the lovers of geometry in the middle ages arranged their varying and beautiful forms; this is the equilateral triangle, and by inclosing the plan, section, or elevation of a building within it, the several proportions can be accurately measured, and if sub-divided into a number, either of the triangles would show the proportion it bore to the whole area.

In one of the tracery heads of the windows in the cloister at Westminster, the date of which is about 1348, we have two figures that resemble the plans given to clustered pillars, indicating at once that the same principles were applied to the setting out of both windows and points of support. When the circumference of a circle is divided into twelve equal parts, the points which divide them form the termination of four equilateral triangles, and we have at their intersections, not only the centres of the circles that constitute the filling in, but also the several mitres and other portions of the figure.

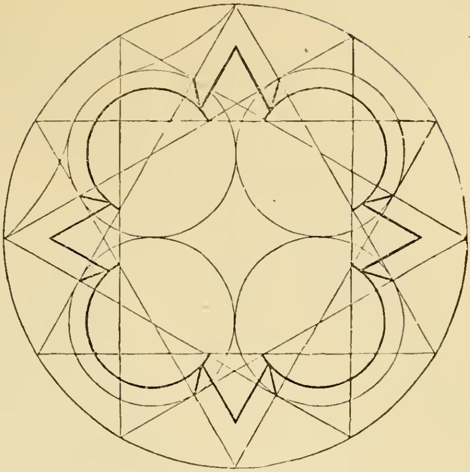

Fig. 1279. CLOISTERS AT WESTMINSTER ABBEY.

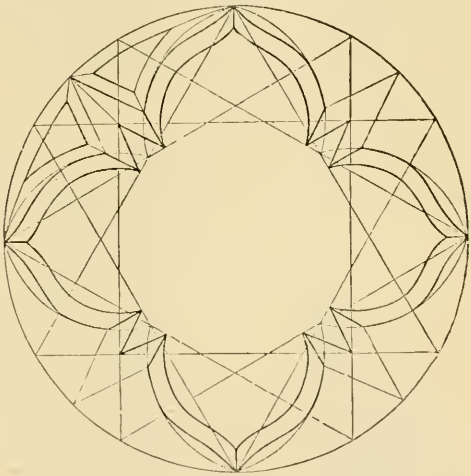

Fig. 1280. CLOISTERS AT WESTMINSTER ABBEY.

These rules were evidently applied to windows, and to tracery of every description, executed at the end of the thirteenth and commencement of the fourteenth centuries; also to the plans of the main cluster of pillars in many cathedrals and churches. For nearly a century, circles and their intersections formed the ornamental portions of every kind of panel and window head; they were afterwards blended into other figures, and apparently set out upon different principles; but the hexagon and equilateral triangles were necessary to produce the flowing lines which succeeded. The change which took place in design no doubt arose from the facility which had been attained by the practice of this method, and if it were possible to exhibit each variety in England alone, there would be ample evidence of the inventive power of the freemasons, and the progressive improvement in their school for depicting form. The quatrefoil in fig. 1279. is met with in the panels of several altar tombs, in the spandrills of the arches of doorways, and it is worthy of observation that all the mitres, where the figures change their form, are perfect for each: had these considerations been neglected, we should not have had the graceful flowing lines found in these designs: no other triangles crossing are so universally applicable, or require less skill in their adoption. The student of the present day might occupy a life in the collection of these subjects, and they are most excellent models for the application of the rules of theoretical geometry to practice.

Windows of three Days or Divisions are met with, having heads of singular beauty, inclosed within an equilateral triangle, and so numerous are the designs, that it is rare to meet with two exactly similar. In

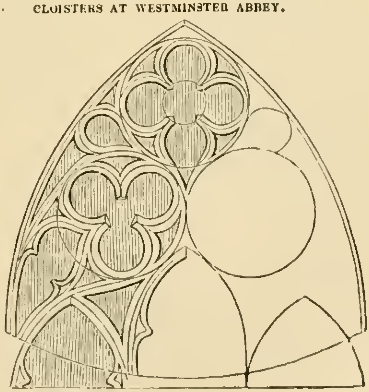

Fig. 1281.

the more simple of three days or lower divisions, the head is occupied by three circles, each of which contains a trefoil constructed upon the crossing of either three or four equilateral triangles.

A very extraordinary design, composed of intersecting circles, is to be seen at the east end of the chancel of the church at Sutton, at Hone, in Kent; although much dilapidated, it still preserves many of its original flowing lines, all struck from the same radius, through points previously determined by crossing the primitive circle by four equilateral triangles.

At half the height of the head of the window a horizontal line may be supposed to be drawn from one side to the other, on which are three circles: the two outer touching, are crossed by the third, struck from the point of their junction; with the same radius several spherical triangles are struck from the points of intersections, producing the lines, which unite and divide the window head into several compartments, differing in pattern and dimension. After the circles were struck, the lines that did not play into each other were left out, and those only retained which flowed on gracefully; by these nice considerations and just application of principles, the masons were certain of producing a perfect effect, without rigidly adhering to any particular form.

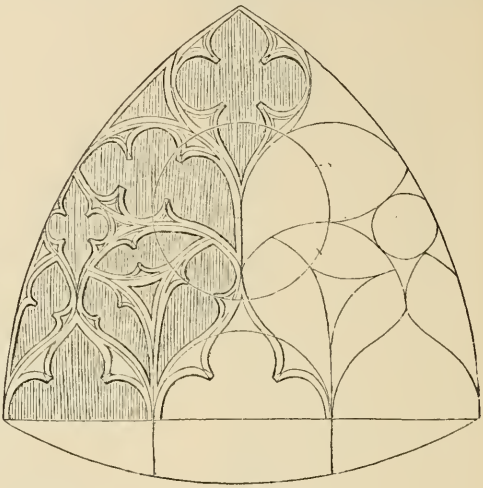

Fig 1282. HONE CHURCH, KENT.

Windows of four Days or Divisions. — Among the heads of a more simple character are those which contain one large circle, subdivided by three equilateral triangles, each

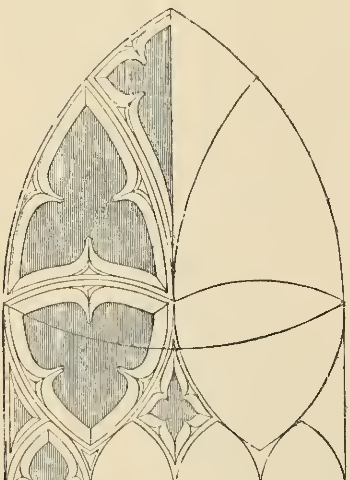

Fig. 1283.

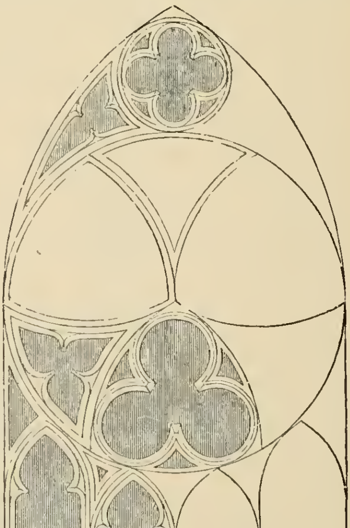

Fig. 1284.

inclosing a trefoil. Others contain, in addition to the one great equilateral triangle, two smaller, constructed upon the points of its base, and dropping into the space comprised between the heads of the divisions below.

Windows of Six Divisions are far more complicated, and, though exhibiting greater skill in geometry, are set out precisely upon the same principle. The two equilateral triangles inclosed within the great circle mark out the prominent features of the design, and their terminations are the centres of as many spherical triangles, which, by their crossing, constitute the elaborate filling in.

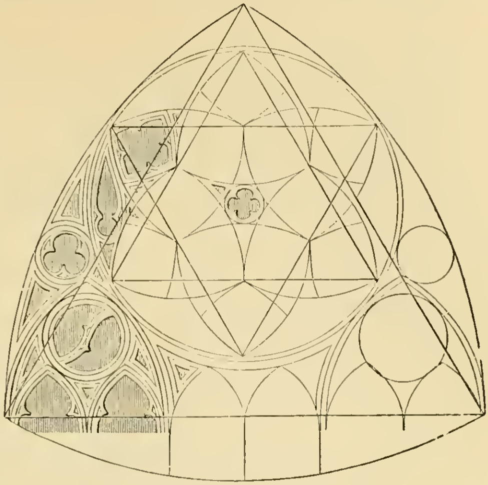

Fig. 1285.

In some examples, above the two main lower divisions is a circle divided by several others, the twelve which are indicated in the figure serving to proportion the tracery of this compartment.

At the latter end of the fourteenth century, these designs were so multiplied that almost every cathedral and church had its peculiar windows: in Amiens cathedral, the chapels constructed at this same time receive their light from windows, the heads of which are filled in with tracery exceedingly varied, but the general principles of setting out the work are preserved; the circle and the equilateral triangle were subdivided almost to infinity, and at no period of the arts do the inventive faculties appear so fertile as in that we are now considering. The great west window of York Cathedral is the finest example of the improvement made in this mode of decoration; the geometric forms are there so concealed by the blending of the several curves, as to produce continued flowing lines, which is partly shown in fig. 1282.; they are, however, all set out in the same manner, and the centres upon which they are struck are established by the crossing of equilateral triangles.

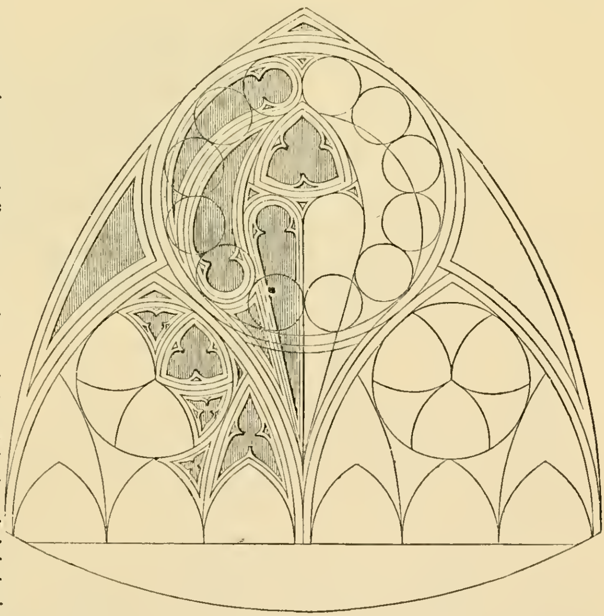

Fig. 1286.

During the episcopacy of John Grandisson, from the year 1327 to 1369, Exeter Cathedral was undergoing an entire change in its architecture. To this bishop we are indebted for the great west window, of nine days, and several smaller of four and five, in which are introduced tracery showing a great variety of design: some are composed of equilateral triangles, each containing a trefoil, some of circles with six turns, others have four and three; but the heads of all, varied as they are, belong to the same school as fig. 1285.

The great east window at Bristol Cathedral is another fine example of nine days, executed about the middle of the 14th century; the centre of the head of the window, or rather the nucleus to the tracery, is an octagon, six sides of which are retained, the other two being suppressed, to allow of a better combination with the three centre divisions of the lower part.

The equilateral triangle also defined the form and magnitude of the several mullions, as shown by *fig.* 1287., constructed upon measurement of the windows of the clerestory of the nave at Winchester: a line drawn from the apex of one mullion to the other is the base of the triangle, and the space inclosed by the two is divided into ten other equilateral triangles, two of which agree in dimensions and form with each mullion. Of the twelve equilateral triangles embracing two half mullions, ten are given to the day or space to admit the light, and two, or one-sixth of the whole, is comprised by the mullion; such appears to have been the manner of proportioning the parts of windows in the middle ages.

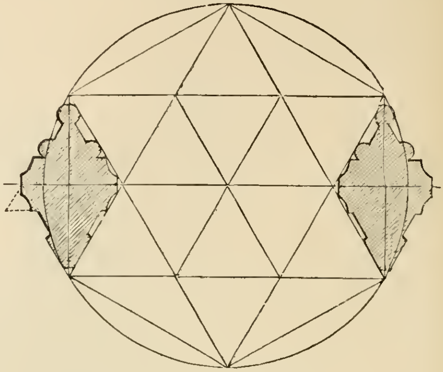

Fig. 1287. See also fig. 1303. WINCHESTER.

Rose Windows in the West Transept of the Church of St. Ouen at Rouen is 29 feet 6 inches in diameter, and composed of seven equal circles, one of which occupies the centre: each of those, which surround it, are again subdivided by others; two only of the outer six are preserved in the figure, and form the quatrefoils, whilst the intersections of the others serve as centres to the rest of the design.

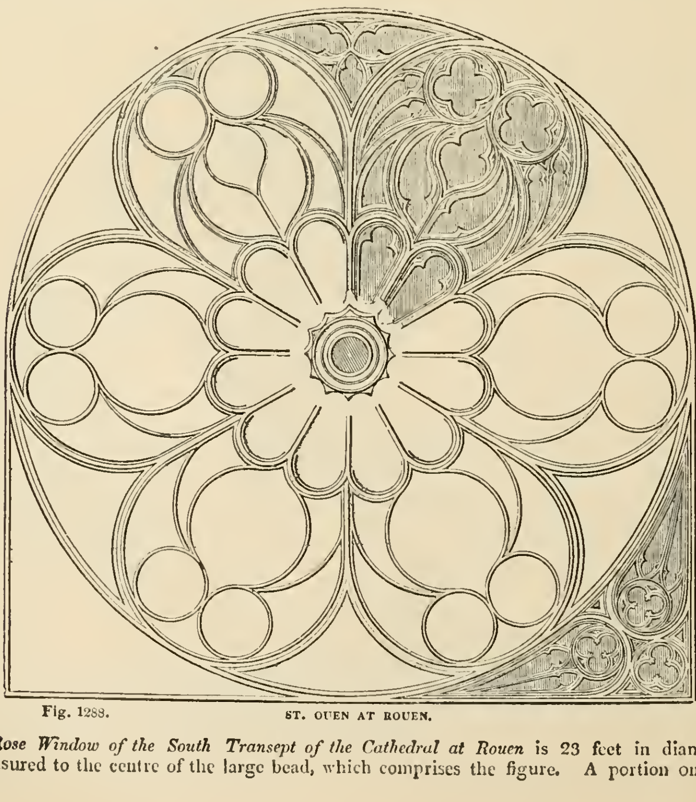

Fig. 1288. ST. OUEN AT ROUEN.

Rose Window of the South Transept of the Cathedral at Rouen is 23 feet in diameter, measured to the centre of the large bead, which comprises the figure. A portion only of this beautiful example is given, for the purpose of exhibiting the principle upon which it is set out: it will be evident that the nucleus of the design is composed of two equilateral triangles, and the sides of each continued, constitute the alternate divisions.

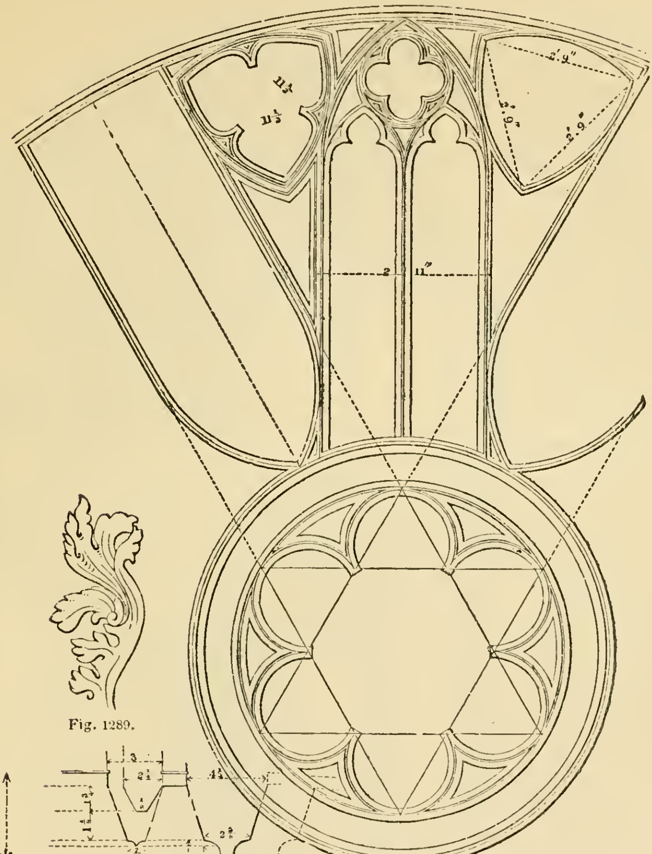

Fig. 1289.

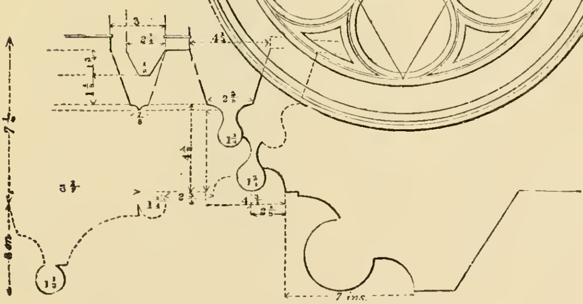

Fig. 1290. ROUEN CATHEDRAL: SOUTH TRANSEPT.

The internal hexagon has its parallel sides prolonged, to mark the position of the four divisions that have their pointed heads attached to the small circle, which forms the eye of the pattern; and the length of these prolonged lines is limited to the extent of the sides of an equilateral triangle, which is again divided regularly, the triangular spaces between being filled in with trefoils. The small mullions are in width $2\frac{1}{2}$ inches, the next size 3 inches, and those which mark out the figure and have a bead for their termination are $4\frac{1}{2}$ inches: another bead and bold projecting label, or rim, circumscribe the whole rose window, the hollow around which is enriched with a curved leaf. On each side of the internal hexagon an equilateral triangle is constructed, around which a circle is struck, uniting elegantly with the next, and forming the six turns which characterise the filling in of circles at this period; these were the principal decorations after the Lancet style was abandoned, and were continued until succeeded by more flowing and varied designs.

Rose Window of the South Transept at Beauvais, 34 feet 4 inches in diameter, is composed of six large circles and their intersections.

To set out this window the great circle expressed by the outer bead is divided into twelve parts, each being equal to half the radius; twelve equilateral triangles are then inscribed, the points of which touch each of the divisions, and where they cross nearest to the outer circle, the twelve pointed arches that surround the figure are struck; the other points of intersection of the triangles are centres, from which the other curves are drawn. It must at once be evident, that in a circle so divided, or by any other equal number of equilateral triangles, the portions contained between the smaller angles must be equal to each other; the six circles around the centre have their curves blended into the outer, and if it be required to fix centres for each of these flowing lines, they can only be obtained by covering the entire rose window with lines in the manner already described. The radius being equal to the side of a hexagon, and that figure being composed of two equilateral triangles, was probably the chief reason of its first preference over all others; it certainly affords the most extraordinary powers of combination, and there is carcely a moulding or form in the architecture of this period but is set out from it. The mullions that bound the divisions are all portions of this figure, as are the mouldings, which sweep round the arches of the buildings themselves. Nothing can surpass the brilliant effect of these marigold windows when glazed with rich colours, and exposed to either a rising or setting sun; in the example now described, this effect is still further heightened by making nearly the whole end of the southern transept a continuation of the same design, the glass descending almost to the tops of the doors which afford access to the cathedral. The construction of such works must excite our highest admiration, for it appears scarcely possible to excel the perfect manner in which the parts are put together and worked off, the execution being in every particular worthy the design.

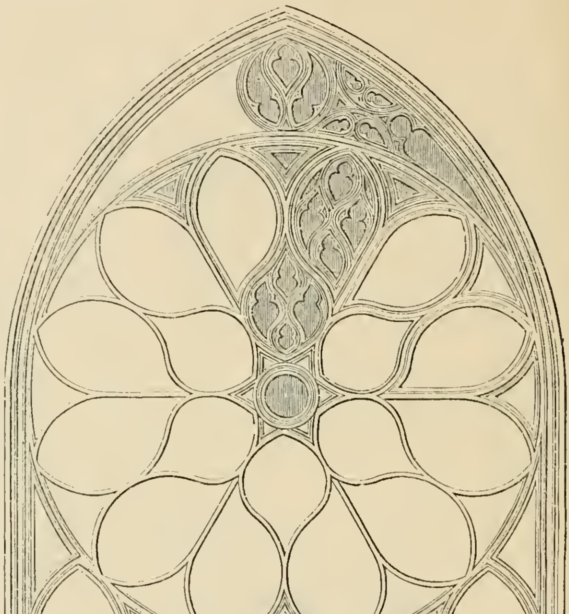

Fig. 1291. BEAUVAIS CATHEDRAL: SOUTH TRANSEPT.

The Rose Window in the South Transept at Amiens, 29 feet 6 inches in diameter is set out upon two squares, which cross each other diagonally.

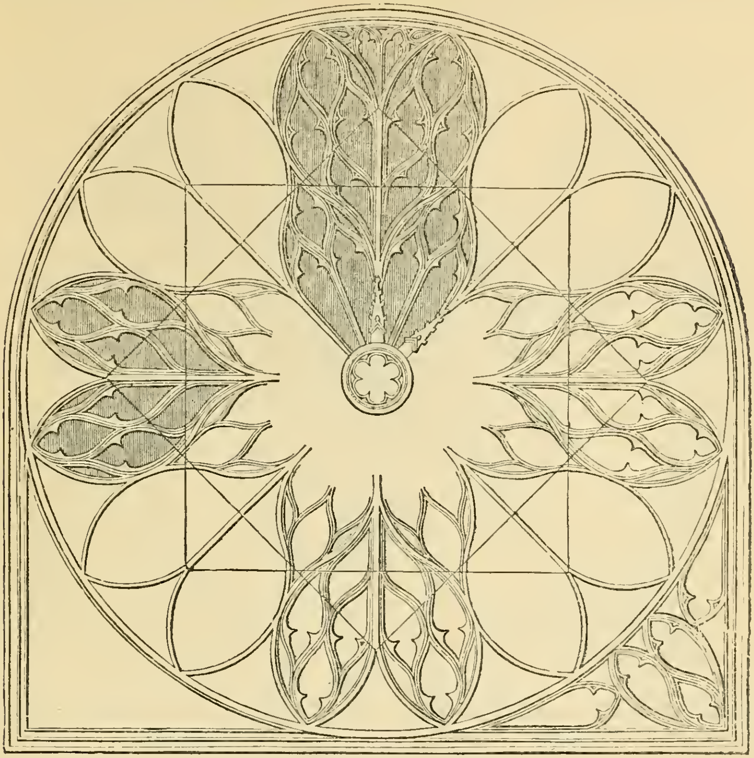

Fig. 1292. AMIENS CATHEDRAL : SOUTH TRANSEPT.

Sixteen divisions are employed in this figure, and by crossing as many squares, we arrive at the method by which it is set out; each side of the square is equal to the radius by which the master line on the outer bead or circle is struck: where the squares cross each other are the divisions of the pattern, and their several points are the centres upon which the pointed arches are struck, which surround the outer portion of the rose.

Where the lines of the squares cross, in the interior of the figure, the smaller divisions are established, and their points of intersection serve for centres to strike the lesser curves; to show this clearly the whole must be set out, and drawn to a large scale.

The architecture of France underwent a material change after the thirteenth century; the heads of the windows were no longer filled with tracery composed of six foils, generally three in each window, but branched out into a more running pattern, as practised in several parts of England. The fourteenth century not only exhibits windows of more difficult design, but an apparent absence of the principles by which the several parts were proportioned to each other. Before the Perpendicular style appeared, great progress had been made in the groining of the spacious vaults of the naves, as well as those of the side aisles. After the fan tracery was substituted in England, the windows had straight mullions ascending till they intersected the arch; and we have no further display of the varied figures that everywhere prevailed before: geometry was now exercised upon the intricacies which their surprising vaults exhibited. It is somewhat singular that we never find the beauties of a previous era retained, and blended with that which succeeded.

For the 300 years during which the Pointed style continued to flourish, each half century gave to it a new character; hence we have seldom any difficulty in establishing its date · all these changes resulted from an improved knowledge in the art of construction. The lodges of freemasons were gradually approaching the principles which directed the efforts of the architects of the Byzantine school, and which were found too refined and delicate to be practised out of Italy after the eleventh century.

The Rose Window in the Northern Transept of the Church of St. Ouen at Rouen, 28 feet 6 inches in diameter, is an example of the pentagonal setting out.

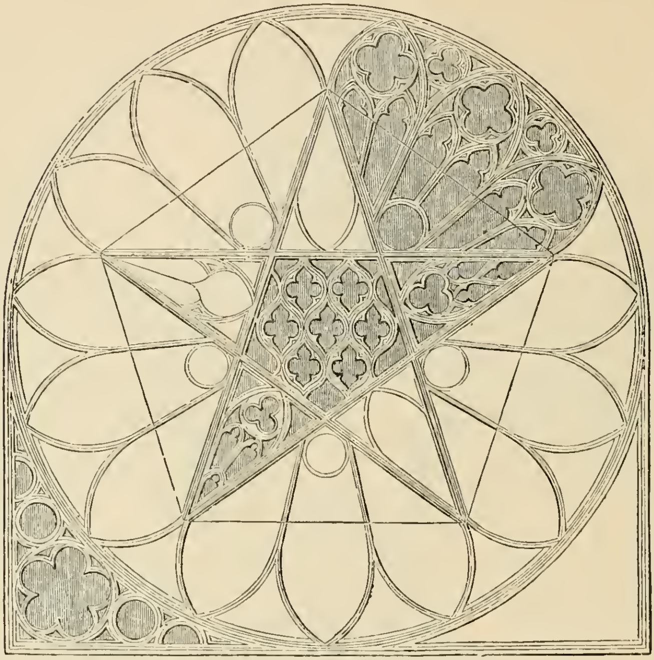

Fig. 1293. ST. OUEN AT ROUEN.

When the sides of a pentagon are prolonged, they unite and form five isosceles triangles, each having for its base a side of the original pentagon. The equilateral triangle, the square, and the pentagon may have been adopted by different confraternities of freemasons; the first can be formed into hexagons, duodecagons and their multiples; the squares, by crossing diagonally, into octagons; they may be also tripled and quadrupled: the mitre of the equilateral triangle is in the direction of its centre of gravity, as is that of the square and the isosceles triangles; consequently to unite the mouldings around either, the plummet would indicate the direction of the line, when dropped from the angles and suffered to cross, the point of intersection being the centre of gravity common to the several lines.

In the chapel of St. Cecile is the monument of Alexander Berneval, the master mason of the works at St. Ouen, at the time the rose window was executed by his pupil, whom it is reported he murdered from jealousy: such an application of triangles was then called the *pentalpha*.

The foundations of this church were laid by Marcdargent, about 1318, by whom it was built as far as the transept; but probably the rose window of the northern transept was not inserted till many years after, for the memorial of Berneval bears the date of 1440: this monumental stone is 8 feet 6 inches in length, and 4 feet in width, and in it is represented the architect and his pupil, each employed tracing with his compasses his respective design; these beautiful brasses with their rich tabernacle work were in the highest state of perfection when the writer was last at Rouen, and around the master figure was inscribed in German letters: —

Cy gist Maistre Alexandre de Berneval, Maistre des oeuvres de Maconnerie du Roy, notre Sire, du Baillage de Rouen, et de ceste Eglise, qui trespassa, l'an de grace mil. ccccxl. le v jour de Januier.

Prie's Dieu pour l'ame de luy.

The date of the pupil's death is not commemorated, which has led some to imagine the tale of his murder untrue, and that he erected the monument to his master with the intention of being buried by his side.

The North Rose Window at Amiens, 37 feet 8 inches in diameter, is a magnificent example of the application of the pentagon, with 5 isosceles triangles around it.

This window, probably executed in the fourteenth century, has a great resemblance to the last described; the fan tracery, of which we have early specimens in the cloisters at Gloucester, required the same knowledge of geometry to perfect their design. In 1482 Euclid was first printed at Venice from the Greek text; but geometry had been studied in England from the time that Adhelard, in 1130, had introduced a translation of that author from the Arabic versions which he met with during his travels in Spain. In 1256 Campanus of Navarre translated Euclid, who seems to have been commented upon by several eminent writers, and no doubt it was the text-book of the freemasons, who diligently applied the problems it contained to every purpose of their art. In 1486 the Editio Princeps of Vitruvius appeared, and the commentaries of Cæsare Cæsariano followed in 1521; the latter author published three plates of the Cathedral at Milan, covered with equilateral triangles, which have not been described so as to be useful or understood. The compartments which have the flat sides of the original pentagon for their base, and parallel sides throughout till they terminate in the pointed arch, have their mullions proportioned to their opening, the larger being double the size of the smaller, whilst the latter are equal to half the open space between them: the mullions in these examples, which divide two spaces, 6 inches in width, are usually 3 inches in thickness, and the others are in the same proportion. The next sized mullion is $4\frac{1}{4}$ inches, with a bead of $1\frac{1}{4}$ inch diameter, which runs round the whole pattern of the figure, the centre of which may be called the master line, by which all the rest are set out; the several mullions are all twice as much in depth as in width.

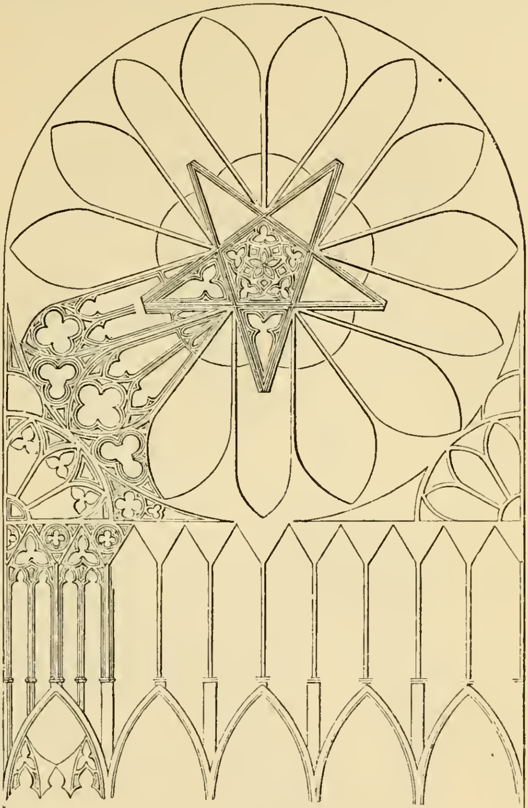

Fig. 1294. AMIENS: ROSE WINDOW.

Baptistery of Pisa. — The internal diameter of this circular building is 100 feet, and the thickness of its outer walls and columns 10 feet 6 inches; its external diameter is 121 feet, the area of which is 11,499 superficial feet, that of the interior being 7854; if we deduct from it what is occupied by the four piers and eight columns, or 188 feet, we have 7666 feet for the void, exactly two-thirds of the entire area. To find these proportions in an edifice commenced about the middle of the twelfth century in Italy, is a curious corroboration of the opinions already advanced, the same rules as those described for the Chapter House at Wells being apparently followed: the conical brick dome was the work of an after period, and may have been the prototype for that of St. Paul's at London; the pointed architecture belonging to the exterior of this edifice, of the same character as that which adorns the crosses of Queen Eleanor in England, was added in the fourteenth century.

The section shows how the equilateral triangle governs the proportions of this celebrated building; the extreme diameter is the base, and its apex the level on which the more recent conical and hemispherical domes are placed: the intersection of the two great triangles fixes the diameter to be given to the internal void, around which the side aisle, its walls and pillars should be formed. The circle which has its diameter comprised between the apex of the two equilaterals determines the clear width between the

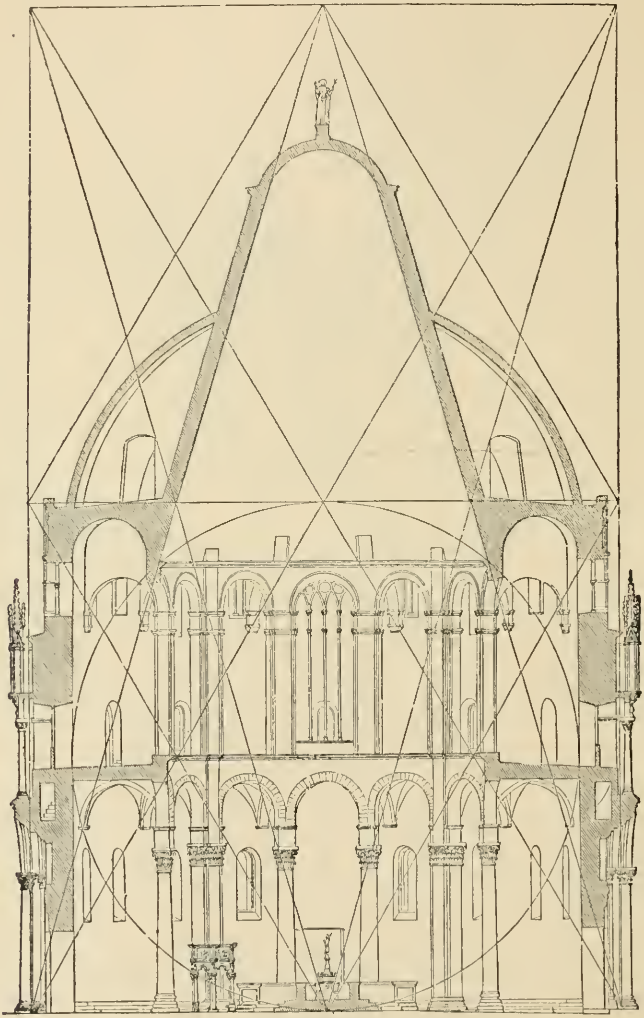

Fig. 1295. BAPTISTERY OF PISA.

outer walls. That the architects of those days delighted in the forms produced by the several intersections of the circle in combination with the equilateral triangle, we are assured by viewing the several designs they have left us in mosaic upon the walls of the Duomo, and at the cathedrals of Florence, Sienna, and elsewhere.

Roslyn Chapel, Scotland, commenced about the year 1446, has its buttresses well suited to give aid to the walls, and to enable them to resist the thrust of its nearly semicircular vault, which they receive below the springing. The extreme width from face to face of the buttresses is 48 feet 4 inches; the span of the nave is 15 feet 8 inches, being 5 inches less than the proportion of a third; the two side aisles together are 15 feet, or within a few inches of the width of the nave; consequently the walls and piers in this beautiful example are 17 feet 8 inches, or 15 inches more in extent than they would have been if the proportion of one-third had been adopted. The height from the pavement to the under side of vault is 41 feet 10 inches.

After the examples described, we cannot doubt of the great proficiency that had been made in the application of the rules of geometry to architecture; every feature, whether the simple moulding or the most elaborate tracery, was set out either upon the equilateral triangle, square, or pentagon, and these regular figures seem to have been chosen on account of the facility by which they are subdivided. From the introduction of the style each fifty years that succeeded brought with them new and improved principles, and at the very commencement of the fourteenth century, we see the clustered pillar and

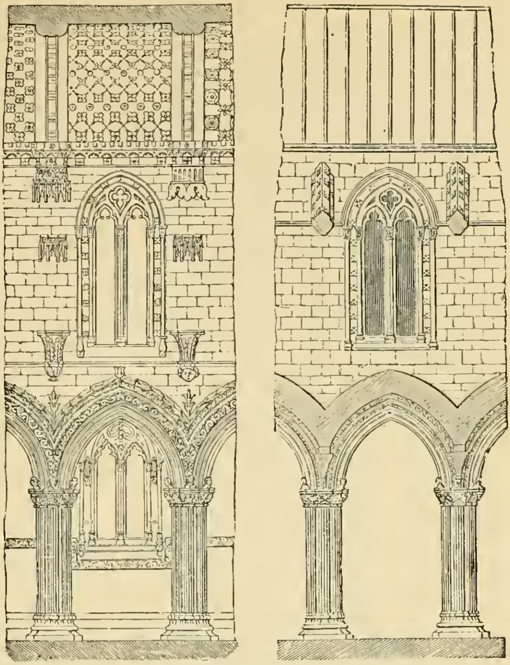

Fig. 1296. ROSLYN CHAPEL. Fig. 1297.

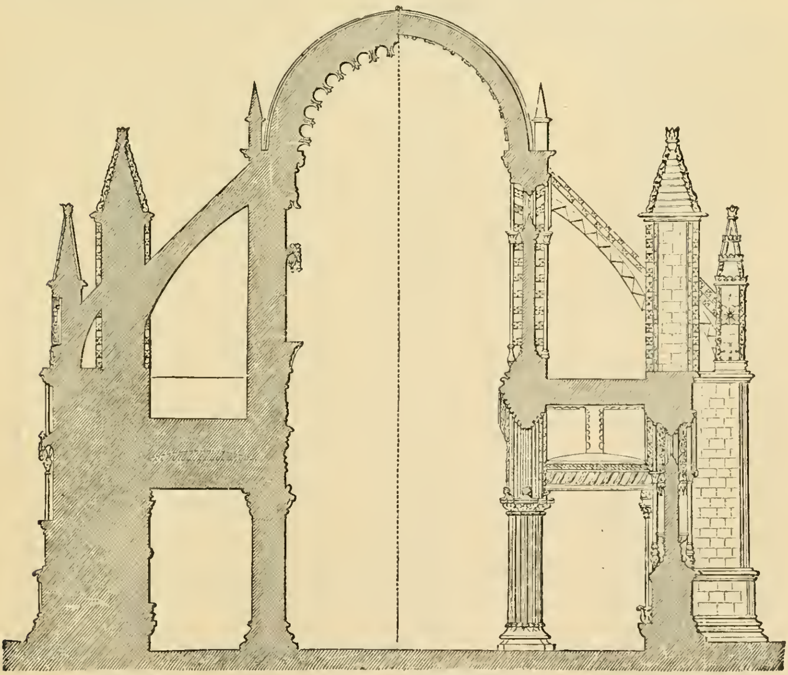

Fig. 1298. SECTION OF ROSLYN CHAPEL.

its many moulded arches yielding to a style that combined greater simplicity with a more thorough knowledge of construction, which will be evident upon an examination of St. Stephen's Chapel, Westminster, (now destroyed,) begun in 1348, the nave of Canterbury and Winchester Cathedrals, and several others. In these examples we have elegantly formed arches resting on well-proportioned piers, the mouldings of which so combine that they form a perfect figure, and show that the points of support were designed to carry all that is placed above them; the same contour of moulding that surrounds the pier performs its useful part in the upper portions of the building, constituting one entire whole. This style, simple as well as elegant, was executed by masons fully qualified to advance it to the greatest perfection, and deserves both our study and admiration.

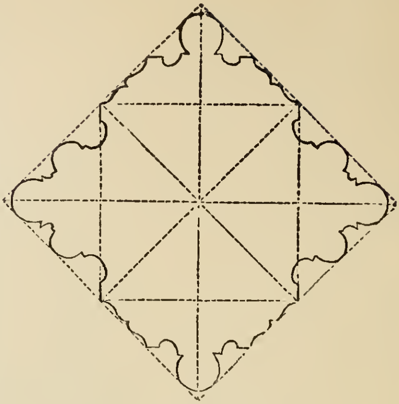

Fig. 1299. CANTERBURY CATHEDRAL.

Canterbury Cathedral exhibits every variety of style found in mediæval architecture; its history has been published by Mr. Britton: to that work, to which the writer contributed some measurements in 1820, he must refer for a detailed and elaborate account of the several changes made in the decoration of the edifice. It is only to the pillars of the nave we are desirous of drawing the attention, and that merely to show their simple form, and the manner of setting them out: four squares are so placed that their diagonals and sides are united in the centre, thus constituting a form capable of the greatest resistance at the four points of the entire pier, where the several thrusts and pressures are received: the O G mouldings of the piers run round the arches, whilst the columnar mouldings towards the aisle and nave support the ribs of their respective vaults. Greater simplicity can hardly be obtained, and every line and indentation of the plan has its use and appropriation: there is no profusion, or member for the sole purpose of decoration; in this arrangement we have the commencement of good taste, and the indication of a more harmonious and perfect style.

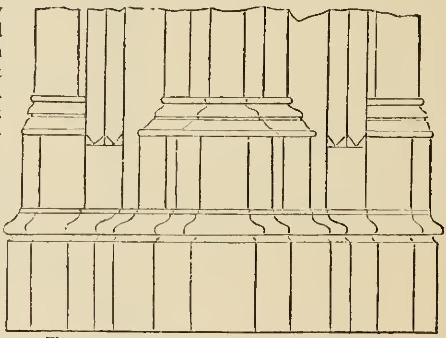

Fig. 1300. CANTERBURY CATHEDRAL.

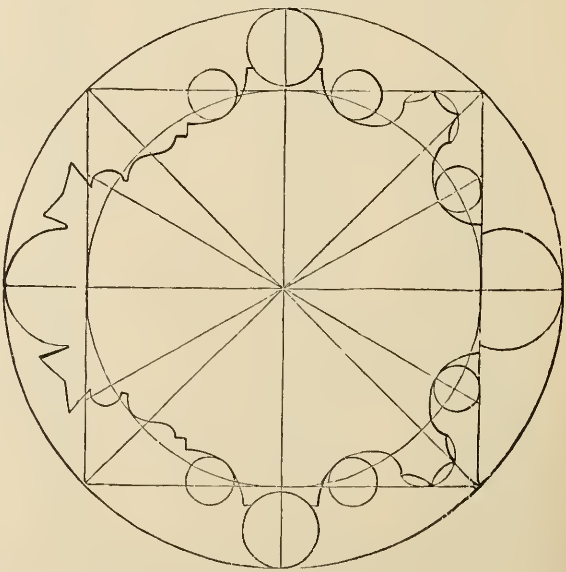

Fig. 1301. ST. OUEN AT ROUEN.

In the Church at St. Ouen at Rouen, we have a very different arrangement, and by no means so solid a form.

Winchester Cathedral. — One division of the nave has been selected to show the peculiar style practised at the latter end of the fourteenth century, and also the skill exhibited in changing the form of a Saxon edifice, and giving it its present character. The plan, fig. 1303. is that of the pillar, as well as of the mouldings and walls of the triforium and clerestory above. When William of Wykeham effected the changes in the nave of this cathedral, he preserved all above the arches of the triforium, cutting away only the masonry of each division below that level which intervened between the main pillars; he then caused the whole to be cased with an ashlar, so that the original Saxon masonry and proportions of the mass remain within the casing. The dotted semicircular arch is the same as that in fig. 1266., and in the roofs above the groining the Saxon walls are traceable, — another proof that when any alteration was made in a building by our mediæval masons, they did not think it necessary entirely to demolish it. We have in this example the decorative character which belongs to the architecture of the latter end of the fourteenth century, though somewhat heavy in its proportions, which arises from the mass constituting the original fabric being preserved, or having undergone so little change. The thickness of these pillars from north to south is 10 feet 8 inches, and from east to west 10 feet, whilst the width of the opening from east to west is only 14 feet.

If we examine the area of one severy of the nave, as left by Wykeham, and calculate the points of support, we shall see that the proportions are not those found in the nave at Canterbury, or in other cotemporary buildings; comprising the space between the buttresses, the entire area of the parallelogram contained between lines drawn through the middle of the piers from north to south is 2228 feet; while the points of support within that area are 557 feet, or one-quarter of the whole.

On the section, shown at fig. 1304., the buttresses on the north side project 6 feet; the north wall is 5 feet 6 inches in thickness, the half piers attached project internally 2 feet 1 inch; the north aisle is in width 13 feet 1 inch, the pier 10 feet 8 inches; the clear width of the nave 32 feet 5 inches; the pier 10 feet 8 inches; the south aisle 13 feet 1 inch, the half-pier which projects from the south wall 2 feet 1 inch, and the thickness of the south wall 7 feet 2 inches; there are no buttresses, as the cloister, now removed, served their purpose. The width from east to west, measured from the centres of the piers, being 22 feet 1 inch, and the width of

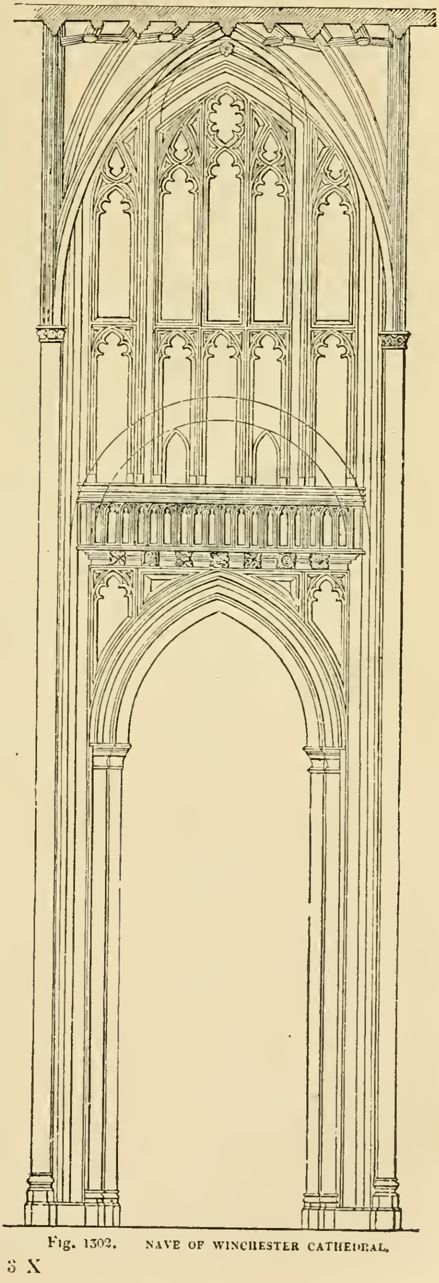

Fig. 1302. NAVE OF WINCHESTER CATHEDRAL.

buttresses outside 3 feet 2 inches. The cathedral or duomo at Pisa presents a very different result; the total width of the nave is 113 feet 6 inches, and the width of a severy 17 feet 1 inch, the area of which is nearly 1930 feet, the points of support being only a twelfth of that quantity on the plan, and one-sixth as regarded upon the section. Hence we see the necessity of ascertaining the proportions of mass and void in a building, before we can accurately judge of its merits as a style, each having its peculiar quantity, which marks its character.

The section or rather plan of the walls, on the level with the gallery of the triforium, shows the method adopted to proportion the openings to the mass. The thickness of the clerestory walls is included within the eight equilateral triangles, and where their sides cross, the position of the mullions is established. In fig. 1287. the circle which comprises the two that divide the window into three days shows their proportion and their size, which in this example is one-third of the opening: in a window of three days we have six triangles for space, and three for mullions: the splays at the sides of these windows, uniting them with the faces of the wall, are cut parallel with the sides of the several triangles. The main pier is set out by uniting the bases of two equilateral triangles with perpendicular lines, or forming the whole into the figure of a hexagon. By a comparison of this plan with that of fig. 1267., the additions made by William of Wykeham to the original Saxon pillar will be readily perceived.

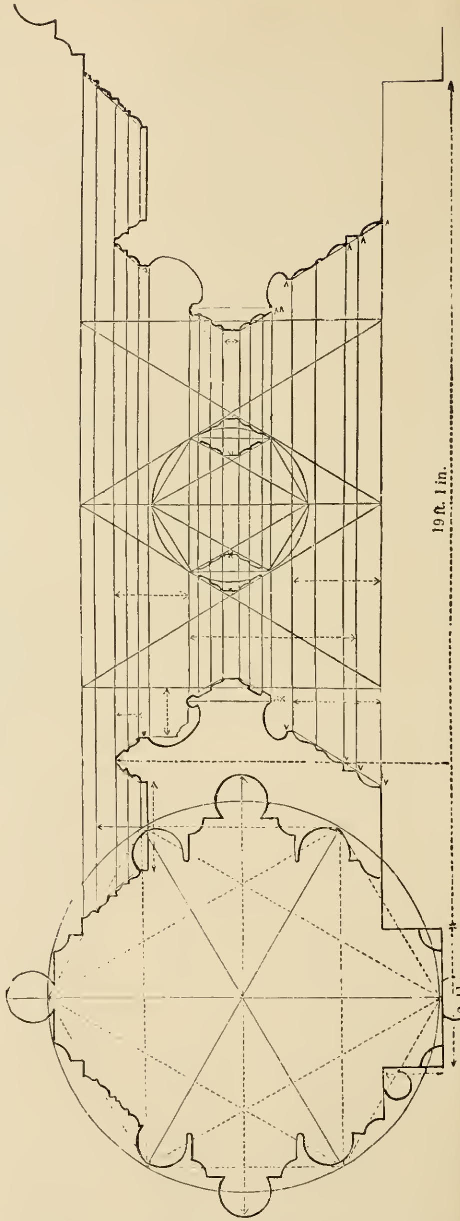

Fig. 1303. PIER AND WINDOWS OF CLERESTORY, WINCHESTER.

The width of one of the divisions of the nave at Winchester, measured from the centres of the piers from west to east, is 22 feet 1 inch, and the same dimension taken in the nave at Canterbury is 20 feet only. In the former example the opening between the piers is 12 feet 1 inch, and in the latter 14 feet; there is consequently no comparison, with regard to lightness, in these two works of the same period; the pier being comprised $2\frac{2}{3}$ times in the entire division at Winchester, and $3\frac{1}{3}$ times at Canterbury, or on the pavement the plinths around the base seem to fall within one-third of the entire width. It would almost appear that in setting out the pillars of several cathedrals, the same system was practised as shown for the mullions of windows at fig. 1287.: but the plinths, and not the cluster of columns and mouldings, must be regarded as occupying the third. Bath Abbey church is 20 feet 2 inches from centre to centre of pier from east to west, and the clear width between the plinths about two-thirds of that dimension, and this is the case with many examples.

The Section through the Nave of Winchester Cathedral is highly deserving of our attention: the clear width of the side aisles is 13 feet 1 inch, and that of the nave 32 feet 5 inches; the clear width of the building between the outer walls is 80 feet, the thickness of the walls 16 feet 10 inches, the projection of the buttress 6 feet, and the thickness of the piers 10 feet 8 inches, making for the entire width from north to south 102 feet 8 inches.

The width between the walls forms the base of an equilateral triangle, the apex of which determines the height of the vaulting of the nave; a semicircle struck upon this base, with a radius of 52 feet, determines the intrados of the arches of the flying buttresses on each side, which are admirably placed to resist the thrust opposed to them.

On this section we have endeavoured to apply the principles of *Cesare Cesariano,* before referred to, to the measurement of mass and void by a method far more simple than that usually adopted.

By covering the design with equilateral triangles we see the number occupied by the solids, and can draw a comparison with those that cover the voids: to prevent confusion in the diagram a portion only of three of the triangles has been subdivided, to show with what facility the quantities of the entire figure might be measured, if the several large equilaterals were subdivided throughout in a similar manner. The band which extends

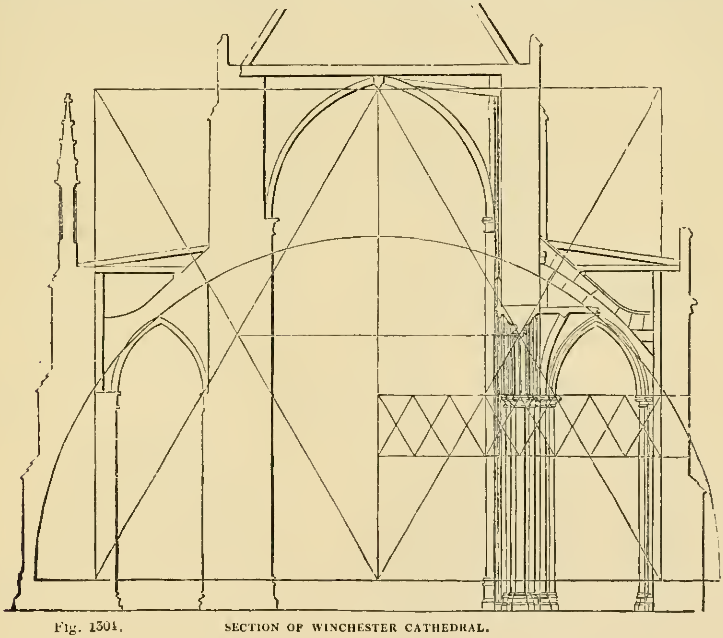

Fig. 1301. SECTION OF WINCHESTER CATHEDRAL.

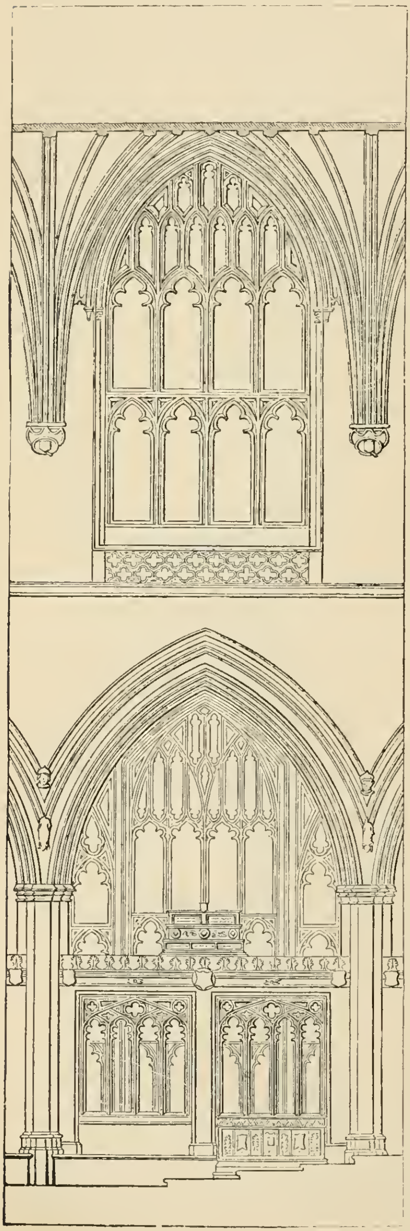
from the face of the outer buttress to the centre of the section contains 36 small equilateral triangles, six of which cover the pier; consequently it occupies on the section one-sixth of that quantity; no further calculation is requisite to find the proportion it bears to the whole: in like manner the other parts of the section may be compared. Such was the use of equilateral triangles in the middle ages for ascertaining quantity.

The two equilateral triangles which occupy the nave and a portion of the piers are comprised within the figure called a Vesica Piscis; if the horizontal line drawn at half the height, uniting the base of the upper and lower triangles, be taken as a radius, and its extremities as centres, it will be evident that parts of circles may be struck, comprising the two triangles within them. Euclid has shown that a perpendicular may be raised or let fall from a given line by a similar method, the space between the segments being called afterwards a nimbus; and there can be no doubt that from time immemorial all builders have used it: the bee adopts for its honied cell a figure composed of six equilateral triangles, and this is proved to be the most economical method of construction; the sides of each hexagon are all common to two cells, and no space is lost by their junction. The nearer the boundary line of a figure approaches the circle, the more it will contain in proportion to it, but circles could not be placed above and under each other, or side by side, without interstices occurring, and the equilateral triangle, or a figure compounded of it, is the only form that will admit of it being so arranged.

The interior and exterior division of the choir at Winchester exhibits two styles; the latter is a fine example of the decorated elegance to which architecture had arrived at the commencement of the sixteenth century.



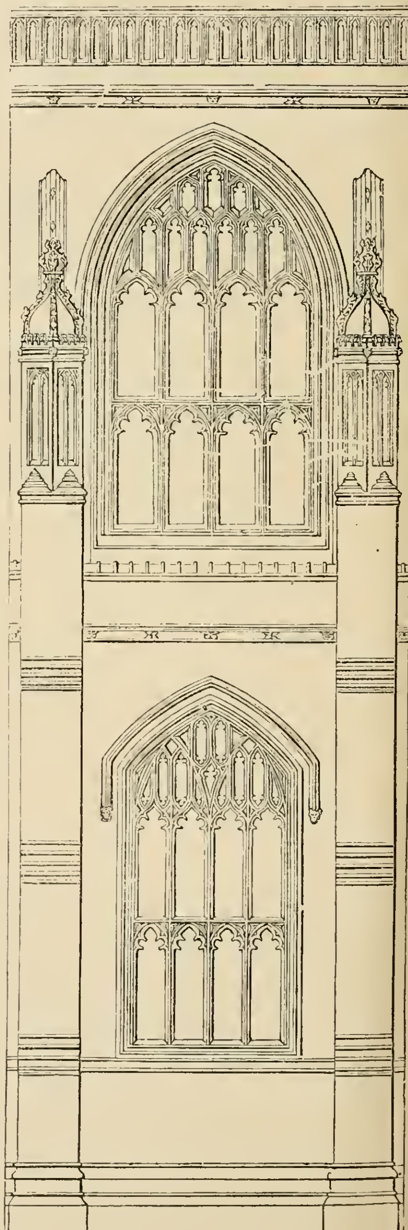


Fig. 1305. WINCHESTER CATHEDRAL: CHOIR. Fig. 1306.

King's College Chapel, Cambridge, has no side aisles, but in lieu of them are small chapels between the buttresses, which are not interrupted in their depth, their whole strength being requisite to maintain in equilibrio the highly wrought stone vault; this they have hitherto perfectly done, to the admiration of all who have studied its principles of construction. The chapel is divided in its length into twelve equal divisions or severies, each of which is formed of four quadrants of a concave parabolic conoid standing on their apex, and is bounded by a main rib or arch of masonry which has its abutments secured by the weighty buttresses added to the outer walls. The width of each severy from centre to centre is 24 feet, the thickness of the buttresses being 3 feet 7 inches, and the length of the chapel between them 20 feet 6 inches; their depth is 13 feet 6 inches in the clear.

The transverse section shows more particularly the proportion of mass and void, which are here equal: the total extent or width from the face of one buttress to that of the other is 84 feet, and the clear width 42 feet; the height from the pavement to the top of the stone vault is 80 feet 1 inch, though this varies from the pavement being out of the level; the thickness of the walls at top is 5 feet 7½ inches; in it is a gallery 2 feet 1½ inch wide, and 7 feet high, communicating entirely around the building.

The height of the cluster column, whose capital receives the points of the inverted cones, is 59 feet 3 inches, so that the arch, which is struck from four centres, does not rise more than 18 feet 6 inches, and the intersections take place at one quarter of the span when the height is 15 feet 6 inches: this arch or stone rib is 2 feet in depth and 18 inches in breadth, formed of twelve voussoirs on each side, the joints radiating to the centres respectively; it abuts at its extremities against the ponderous buttresses. and remains steadfast and immovable, dividing, as before stated, the vault into several severies.

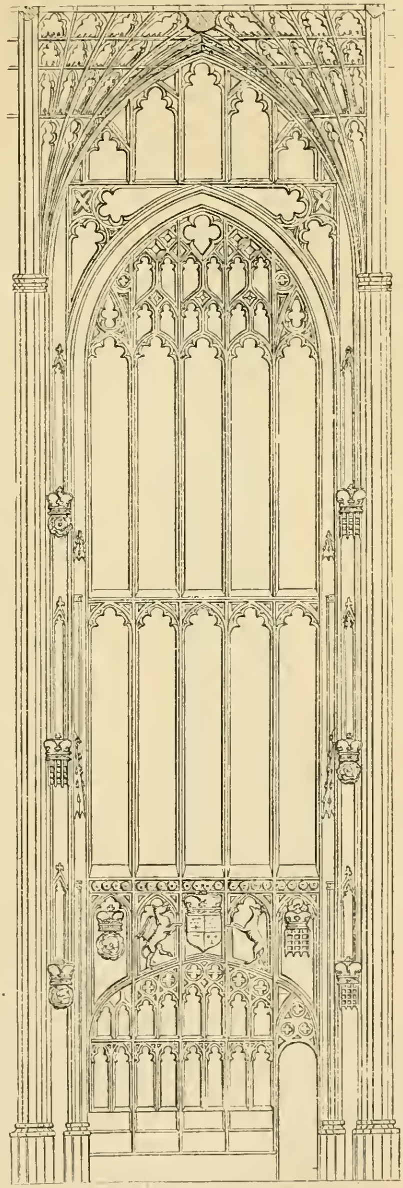

Fig. 1307. KING'S COLLEGE CHAPEL.

The plan of the main piers shows that there has been no after-thought grafted upon the original design, which, in all probability, was commenced soon after the year 1446, as we find that a stone quarry at Haselwode, and another at Huddlestone, in Yorkshire, were granted, for the works to be carried on here. The stone roof does not appear to have been commenced till about 1512, the indenture concerning it bearing date the fourth year of King Henry VIII.; in this document Thomas Larke is called the "surveyor," John Wastell the "master mason," and Henry Semerk one of the "wardens," the two latter agreeing to set up a sufficient vawte, according to a plat signed; the stone to be from the Weldon quarries: the contracting parties were also to provide "lyme, scaffoldyng, cinctores, moles, ordinaunces," and "every other thyng required for the same vawting: the timbers of two severies of the "great scaffolding" were given them for the removal of the whole; and they were to have the uses of all "gynnes, whels, cables, hobynatts, saws, &c.;" they were to pay for the stone, and to have 100*l.* for each severy, or 1200*l.* for the whole, money being advanced for wages as the works proceeded: the "chare roff," as the vault is called was to be sufficiently buttressed, and the whole performed in a perfect manner.

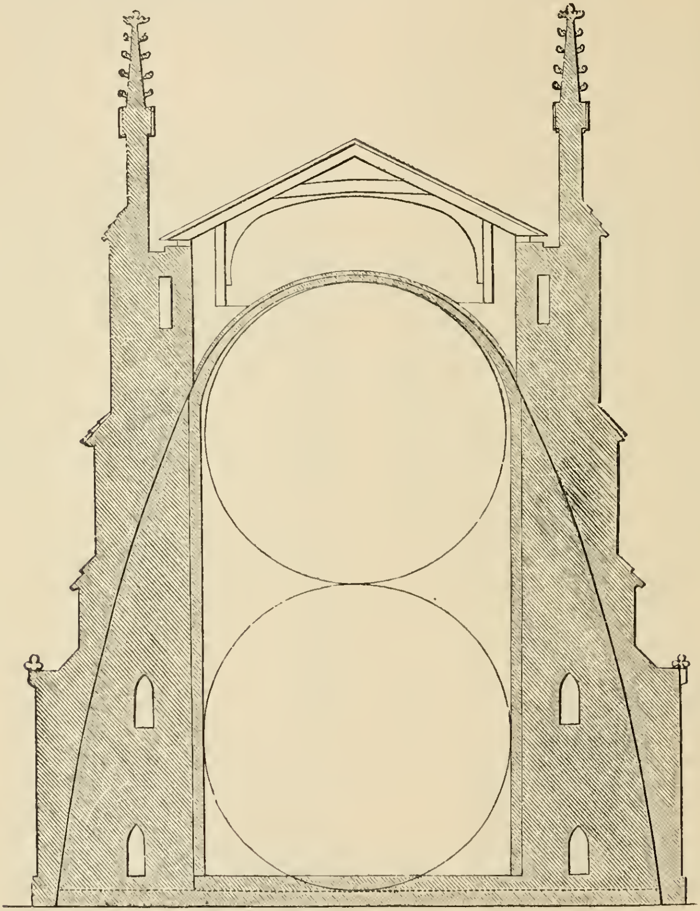

Fig. 1308. SECTION OF KING'S COLLEGE CHAPEL.

The extreme width, measured from the face of one buttress to that of the other, is 84 feet, and from north to south, from the centre of one pier to that of the other, 24 feet; thus the area comprised in a severy, or space between two lines drawn through the centres of the buttresses on the plan, is 2016 feet, exactly double the area of one of the severies of St. George's Chapel, Windsor: the extreme width is the same, but the difference arises from the divisions in the one being double that of the other, as measured from east to west.

	Feet.
The area of the nave, 42 × 24 - - - - -	1008
of the chapel on one side - - - -	336
ditto on the other - - - -	336
of the walls on one side - - - -	168
ditto on the other - - - -	168

Hence we have for the areas of the space or void on the plan 1680 feet, and for the walls and pier 336 feet, or one-sixth of the whole 2016 feet, similar proportions to those which we shall afterwards find in St. George's Chapel, Windsor. In King's College the nave comprises half the entire area of a severy, and the remaining half is divided into three, one of which is given to each of the chapels, and the other divided between the points of support: in this beautiful building, with its majestically contrived roof of stone, the lightest construction is adopted. The catenarian curve exhibits the direction of the thrust of the vault, which falls within the base.

The stone roof we are now examining differs somewhat from that of Henry VII.'s chapel at Westminster; the area of the points of support is only one-half of those in the latter elegant example; in no instance have we so much effect produced by the mason's art, with so small a quantity of material: it is evident that the gradual changes made in the architecture of the mediæval period led at last to the greatest perfection, beyond which it seems impossible for us to advance.

In selecting a style of any one period, it may be fairly asked whether the principles found in the latter, or the economy adopted in the constructions of the 15th century, might not be applied to it, and the same effect produced,—the section of the chapter-house at Wells, for instance, lightened of half its material: undoubtedly it might, for the lofty pointed arch, not having the thrust which the latter, struck from four centres, had, would exert less thrust, and be in favour of such a change.

But at the present day, when copies are rigidly made of the finest examples of each style, it would seem a bold innovation to suggest such an adoption; still it might be introduced, and probably would have been, had the freemasons continued an operative fraternity, and been required to build in the Lancet or other style, which superseded it. The same decorations and form of arch may be used in the later styles as in the earlier, as far as construction is concerned, and we have evidence of sufficient strength in the example before us; the principles are the same in each, though they may differ in form; there would be no more difficulty in transforming one style to that of another, than was experienced by William of Wykeham, when he changed the Saxon nave of Winchester to the Perpendicular.

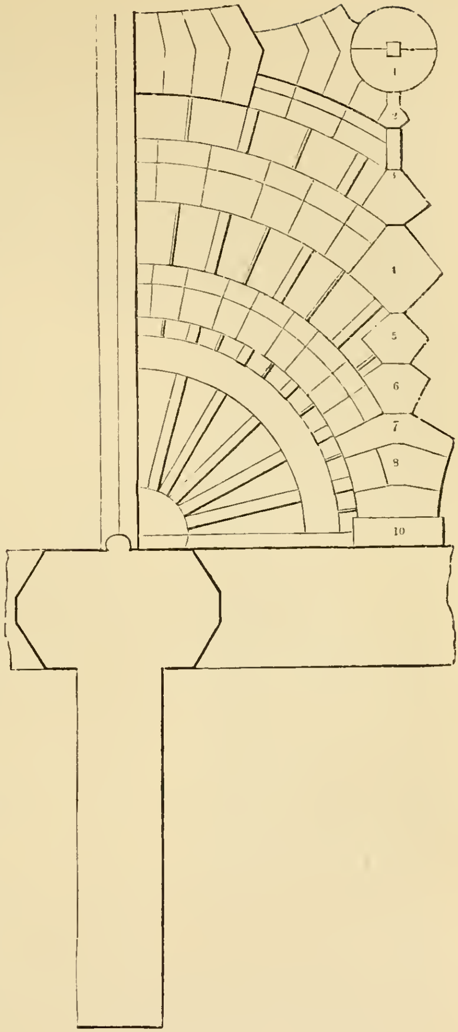

Fig 1309. VAULTING OF KING'S COLLEGE CHAPEL.

On the section shown at *fig.* 1308. a line is drawn exhibiting the catenarian curve, for the purpose of showing that the abutment piers are set out in correspondence with its principles; it is not contended that a knowledge of this curve guided the freemasons in proportioning their piers, or that their flying buttresses were always placed within it; but it is singular that in those structures where their true position seems to have been decided, the catenarian passes through them.

Bath Abbey section (*fig.* 1319.) is an example which exhibits this most perfectly; and by a comparison of its section with that at Wells (*fig.* 1272.), it will be perceived that the struts are differently placed, and that the earlier example is defective: *fig.* 1298. represents Roslyn

Chapel, in which there is evidently some improvement; but at the time of its construction perfect knowledge on this subject had not been attained. In a catenarian chain formed of links of equal length, every side is a tangent to the curve, and the direction of each link is at right angles to it, acting in a direction perpendicular to the line it forms in the catenaria; and hence its useful application to the science of construction. It is quite clear that wherever the curve passes through the section of a building, stability is obtained; and where it does not, it is doubtful: certainly the best application of flying buttresses is that which can be tested by this principle.

The main arches of the roof abut against the outer buttresses, and spring from a cluster of mouldings set round a circular pier; the situation of the small columns and hollows which decorate it being determined by the crossing of equilateral triangles. The ribs of each severy abut in the centre upon a circle 3 feet 6 inches in diameter, formed of two stones, and indicated by No. 1.: in the middle is a mortise-hole 9 inches square; No. 2. is in width 17 inches in the widest part; No. 3. is 2 feet 2 inches; No. 4., 3 feet 8 inches; No. 5., the same; No. 6., 3 feet 3 inches; No. 7. 4 feet 3 inches; No. 8., the same; No. 9., 3 feet 2 inches, and No. 10., which abuts against the outer wall, 4 feet.

By a reference to the plan on fig. 1312., it will be understood how the several rings of voussoirs which compose the quarter of the parabolic conoid abut and are locked one into the other: the construction of this vault is somewhat similar to that adopted by Soufflout at the Church of St. Geneviève at Paris, although his manner of applying it materially differs.

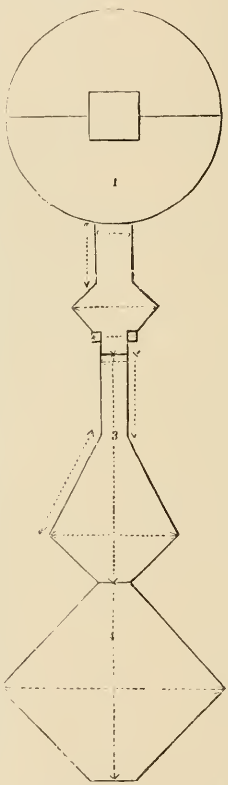

Fig. 1310. KING'S COLLEGE CHAPEL: RIBS OF VAULT.

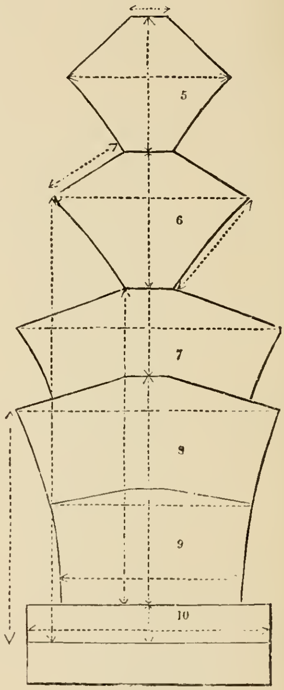

Fig. 1311.

The buttress in the present example has an area of 56 feet, equal to that of the piers, to which it is attached; or the two piers and buttresses together have an area of 224 feet: it is curious to find that of the 336 feet before given to the points of support, one-sixth should be applied to the piers, one-sixth to the buttresses, and the other portion to the walls between; for 55 ft. 6 in. × 6 = 336 feet — the area of the points of support taken on both sides; so equally are the parts even distributed.

When the Normans first used flying buttresses, as at the Cathedral at Chartres, the Abbaye aux Hommes at Caen, and several other buildings, they abutted them against the ordinary outside wall; but it was soon discovered that a greater resistance was necessary to oppose the thrust, and prevent the abutments from yielding. Salisbury Cathedral was probably one of the earliest where flying buttresses were used; and the opinion of Sir Christopher Wren is worthy of quoting upon this subject, as it applies more particularly to the first constructed, and not so immediately to those erected in the fourteenth or fifteenth centuries. "Almost all the cathedrals of the Gothic form are weak and defective in the poise of the vault of the aisles; as for the vaults of the nave, they are on both sides equally supported and propped up from spreading by the bowes or flying buttresses, which rise from the outward walls of the aisles: but for the vaults of the aisles, they are indeed supported on the outside by the buttresses; but inwardly, they have no other stay but the pillars themselves, which, as they are usually proportioned, if they stood alone, without the weight above, could not resist the spreading of the aisles one minute: true, indeed, the great load above of the walls and vaulting of the nave should seem to confine the pillars in their perpendicular station, that there should be no need of butment inwards, but experience hath shown the contrary, and there is scarce any Gothic cathedral, that I have

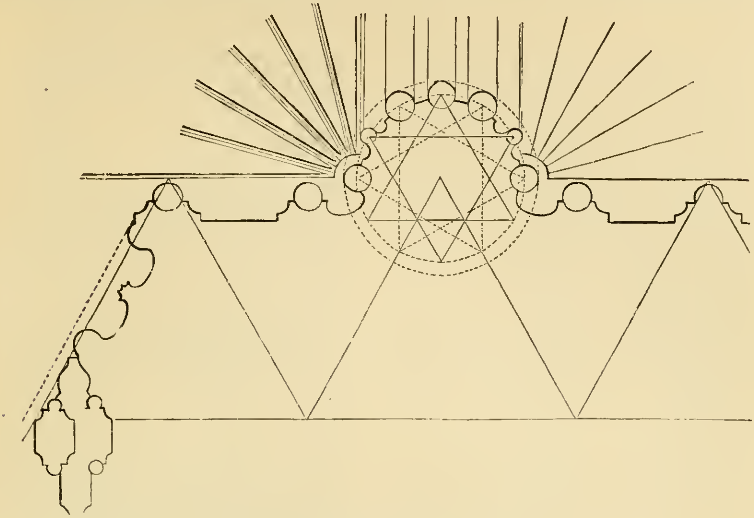

Fig 1312. KING'S COLLEGE CHAPEL: PIERS.

seen at home or abroad, wherein I have not observed the pillars to yield and bend inwards from the weight of the vault of the aisle; but this defect is the most conspicuous upon the angular pillars of the cross, for there not only the vault wants butment, but also the

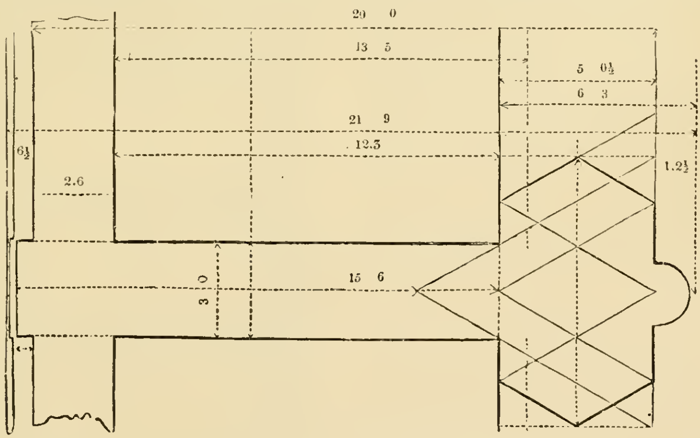

Fig. 1313. KING'S COLLEGE CHAPEL: BUTTRESSES, ETC.

angular arches that rest upon that pillar, and therefore both conspire to thrust it inwards towards the centre of the cross."

At King's College chapel, flying buttresses are dispensed with, and happily the knowledge of construction had arrived at such perfection, when its astonishing vault was projected, that we have no evidence whatever of its yielding in any part.

It may seem extraordinary that the Pointed style made so little progress in Italy, the Byzantine being always preferred: the architects of that country were probably unwilling to relinquish a mode of construction so economical, half only of the material employed in the lightest, and a quarter in the earliest of the Gothic style, being required for the basilica: for example, where 100 rods of stonework would be used in the latter, 200 would be necessary for the style practised at King's College, St. George's Chapel, and Bath Abbey Church, and 400 for that of the Chapter-house at Wells; this result would lead to the conclusion, that no style is so well adapted for the wants of the present day as the Byzantine.

St. George's Chapel, Windsor. — If we suppose a line on the plan to pass through the centre of the buttresses and piers, and one severy of the nave to be defined, we shall have a width of 12 feet, and a length of 84 feet, the area of which is 1008 feet: after this we shall find the area of the walls and piers comprised within this severy to be 168 feet, or one-sixth of the whole; such are the proportions of mass and void found in this chapel. The clear width of the side aisles between the columns is 11 feet 9 inches; that of the nave 34 feet 10 inches, and between the outer walls 69 feet 2 inches: the height of the top of the vaulting of the nave is 54 feet 2 inches. The height up to the springing line of the great vault over the nave being equal to half the entire width, it is evident that two squares must comprise within them the entire building beneath this line; upon setting them out we find the nave and its pillars occupy one, whilst the other is given to the side aisles, external walls, and buttresses.

The Rev. John Milner, in his admirable treatise on the Ecclesiastical Architecture of England, which has been the text-book for all modern writers, states that "its rise, progress, and decline, occupy little more than four centuries in the chronology of the world: as its characteristic perfection consisted in the due elevation of the arch, so its decline commenced by an undue depression of it. This took place in the latter part of the 15th century, and is to be seen, amongst other instances, in parts of St. George's Chapel, Windsor, commenced by Edward IV. in 1482; in King's College Chapel, Cambridge, and in the Chapel of Henry VII. at Westminster. It is undoubtedly true that the architects of these splendid and justly admired erections, Bishop Cloose, Sir Reginald de Bray, &c. displayed more art and more professional science than their predecessors had done; but they did this at the expense of the characteristic excellence of the style itself which they built in."

"In St. George's Chapel we have the work covered with tracery and carvings of the most exquisite design and execution, but which fatigue the eye, and cloy the mind by their redundancy:" but we have also a building constructed with one-half the materials that would have been employed had the style practised in the chapter-house of Wells been adopted. The admirers of the Pointed style have not sought for the true principles which mark its several changes; they have not examined into its constructive arrangements; had they done so, they would have perceived that, as the skill of the freemasons advanced, and their workmanship improved, they economised material, constructed more solidly, and produced a richer and more harmonious effect, without sacrificing any of the principles which governed their practice; the improvements they made were as great as those noticed when the

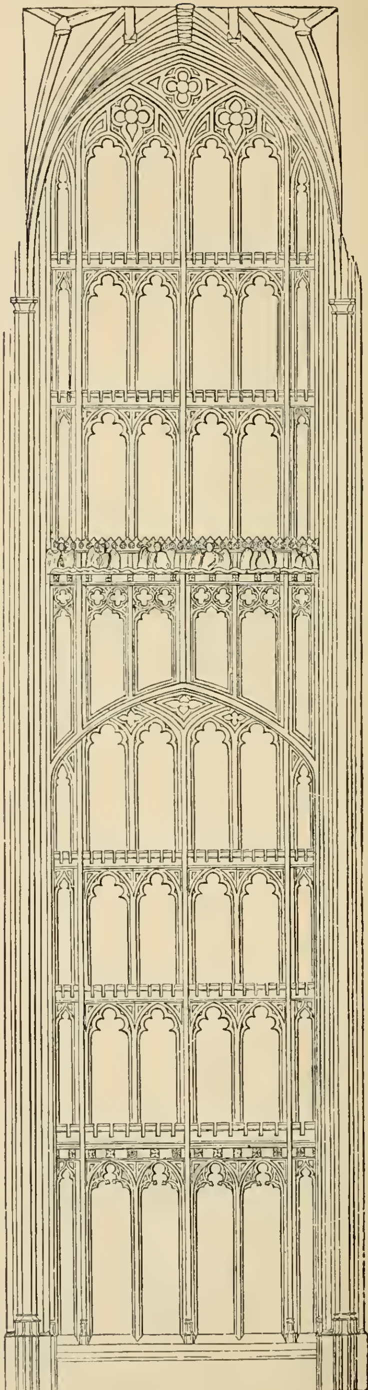

Fig. 1311. ST. GEORGE'S CHAPEL, WINDSOR.

Doric proportions were changed to the Ionic. In the Doric we had two-thirds mass, one-third void; in the Ionic half mass, half void; at Wells Chapter-house one-third mass, two-thirds void; in St. George's Chapel, one-sixth mass and five-sixths void.

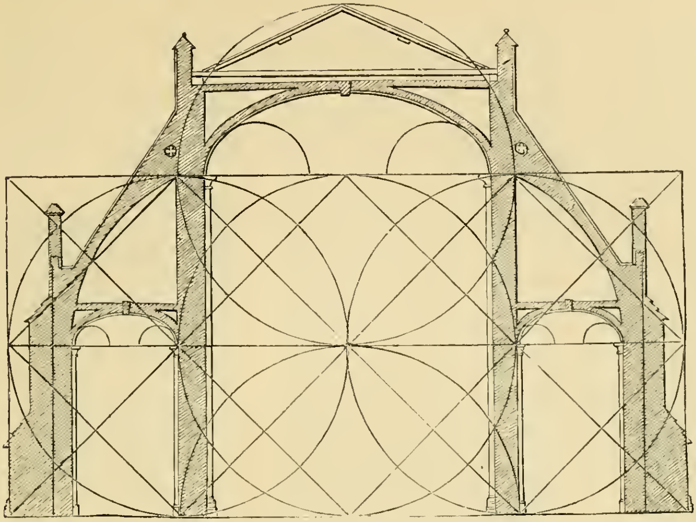

Fig. 1315. ST. GEORGE'S CHAPEL, WINDSOR.

The plan of the pillars is that of a double square, or parallelogram, the diagonals of which latter figure become the sides of equilateral triangles that serve for the setting out

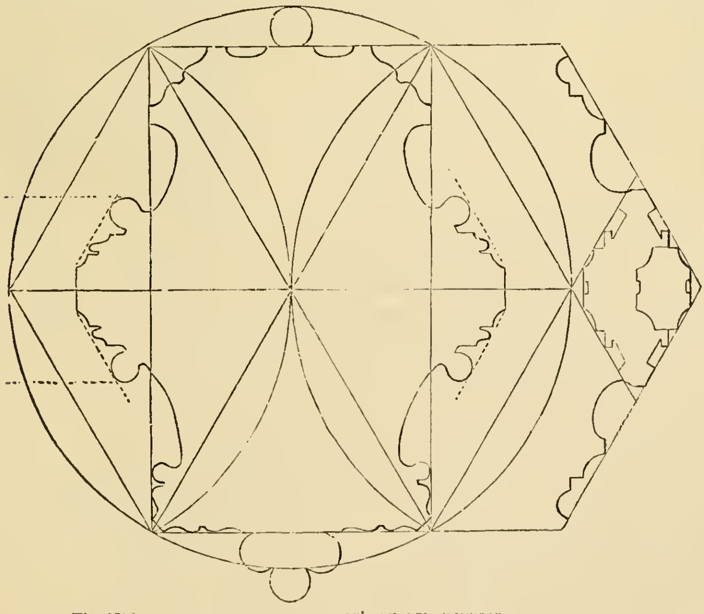

Fig. 1316. PIER OF ST. GEORGE'S CHAPEL, WINDSOR.

the splays, upon which the several mouldings are cut: from east to west these piers are 3 feet 1 inch, from north to south 3 feet 6 inches, not comprising in this last dimension the three small columns on the fall towards the nave, or the single column on that towards the side aisles, the first of which projects 6½ inches, and the latter 4 inches.

The mouldings around the windows and their mullions are shown at the side of the pier in their proper position.

Division of the Nave of St. George's Chapel. — The mouldings set around the plan of the pier are continued up to the vaulting of the roof, without any other interruption except where they are mitred round the arches.

Bath Abbey Church is 89 feet 5 in. wide from face to face of the buttresses to the nave: whose clear width is 29 feet 10 in., or one-third of the whole; and each of the side aisles is a trifle more than the half of the width of the nave, being 15 feet 8 inches; the walls and piers added together are not quite equal to a third, as they amount only to 14 feet 2 inches on each side, or together to 28 feet 4 inches, the difference being given to increase the side aisles.

The section of this beautiful building presents to us all the improvements made in vaulting, and the right proportions as well as directions to be given to the flying buttresses: in the first application of those supports, as at Salisbury, they are evidently misapplied, but in the example before us we find that the constructors had arrived at a knowledge of the principles of the catenarian curve, which is traceable through the solid masses of the section: it was by slow degrees that the freemasons arrived at a knowledge of the peculiar properties of this figure; had it been known at the first commencement of the introduction of flying buttresses, we should have had a better application of them; in several instances we find them adopted where no advantage, or very little, could be derived from them.

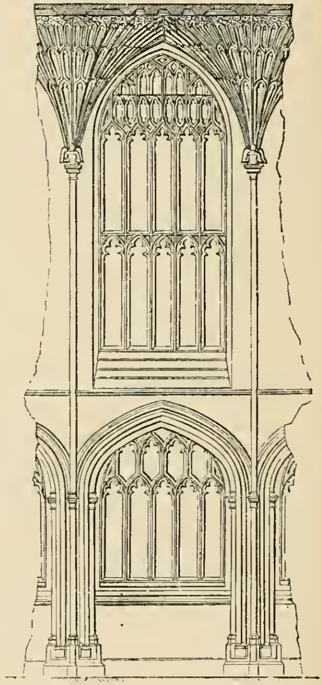

Fig. 1317. BATH ABBEY CHURCH.

Division in Bath Abbey Church differs from all other examples of this period, by the height given to the clerestory and the omission of the triforium: the judicious and excellent arrangement of the flying buttresses permits of the greater display of glass, which in the sixteenth century had arrived at its most gorgeous state, rich in every colour, and beautiful from the drawing of the patterns, and figures with which it was covered.

Bishop King commenced this building about the year 1500, on an entirely new site, near the old church: from the centre of one pier to that of the other is 20 feet 1 inch; the thickness of the outer buttresses 3 feet, and their projection 4 feet; one severy of building contains 1650 feet, and the area of the points of support is 275 feet, or one-sixth. The pillars are square, though set diagonally, their width from north to south and from east to west being 5 feet, and the opening of the arches between them 15 feet 1 inch; half their plan and base is shown at fig. 1320.: the height from the pavement to the top of the capitals, where the sculptured angel is placed, is 56 feet 3 inches, and to the top of the vaulting 73 feet 6 inches, within 7 feet as much as the clear width between the outer walls.

Fig. 1321. shows the plan of the stone vaulting, which is perfectly geometrical in its setting out; the cloisters at Gloucester, the aisle at the east end of Peterborough cathedral, and St. George's Chapel, Windsor, have vaults of a similar kind.

The thickness of the stone which comprises the vaults of fan tracery varies according to its position, but in no instance is it considerable, or more than absolutely necessary to resist crushing. The spire of Salisbury, 180 feet in height, of an octangular form, measures from east to west internally 33 feet 2 inches, and from north to south 6 inches more; the thickness of the spire at bottom is only 2 feet, or the area of its base is half that of the void, the void containing two parts, and the solid around it one; this spire diminishes in thickness for the first 20 feet, after which it is 9 inches in thickness throughout; at about 30 feet from the summit is a hole, by which an exit from the interior may be made, and by means of the crockets and irons on the outside the top of the spire may be attained: in 1816 the writer examined the position of the vane, and the manner in which the capping stone was placed, and descended astonished at the perfection of the masonry, and the thinness of the stone with which it was constructed.

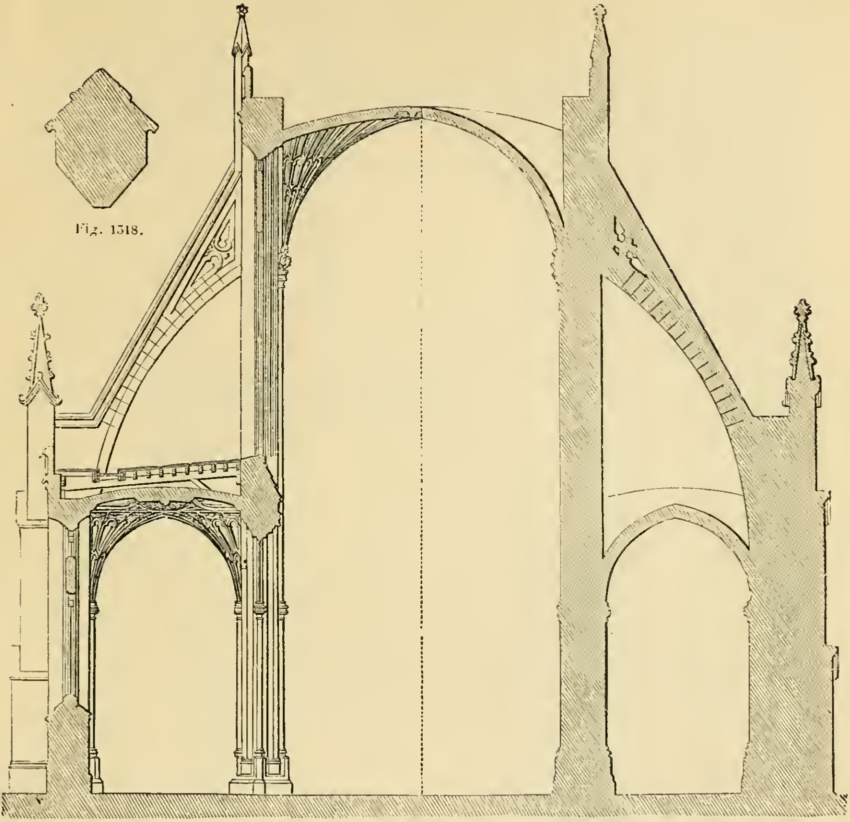

Fig. 1318.

Fig. 1319. SECTION OF BATH ABBEY CHURCH.

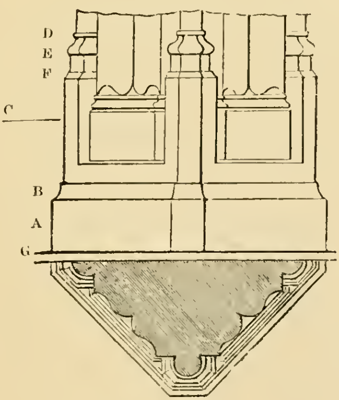

Fig. 1320. PIER.

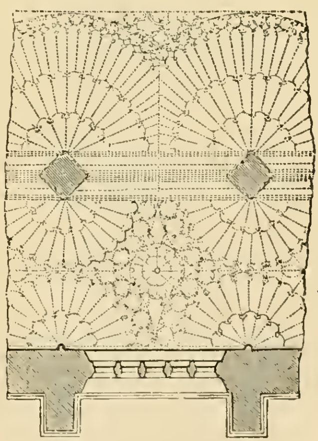

Fig. 1321. GROINING.

The Lady chapel at *Caudebec, near Rouen, Normandy*, exhibits the manner of suspending a keystone by locking it between the voussoirs of a strong semicircular arch. The length of this pendent stone is 17 feet 6 inches, and its thickness at the top, where locked, is 30 inches: the voussoirs are 3 feet in length; the small pointed arches or ribs that form the groining of the hexagonal vault spring from the side walls and the ornamental knob of the pendentive, and are perfectly independent. The abutments of the semicircular arch, which has a radius of 12 feet, are formed by solid walls continued for some length in the direction of its diameter. This sacristy is hexagonal; each side internally measures 12 feet, and the height from the pavement to the springing of the ribs is 18 feet.

Henry the Seventh's Chapel, Westminster. — The first appearance of the pointed arch was probably a little before the termination of the twelfth century; the pillars and mouldings which then accompanied it were of Saxon origin: to its acute form was

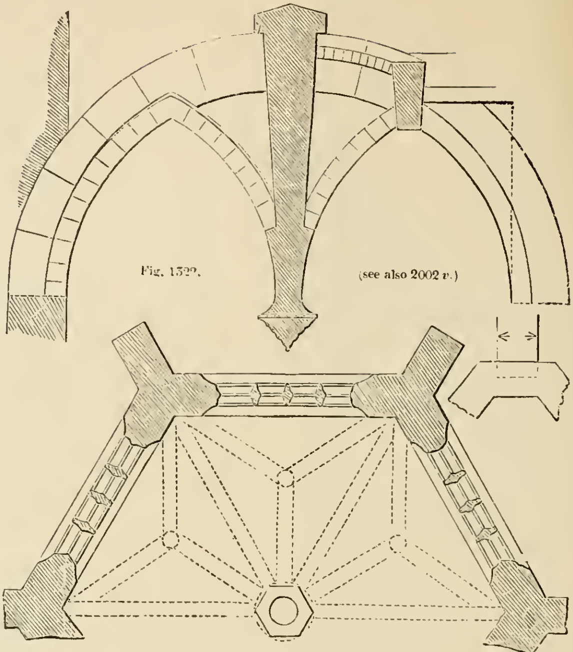

Fig. 1522. (see also 2002 v.)

Fig. 1523. CAUDEBEC SACRISTY.

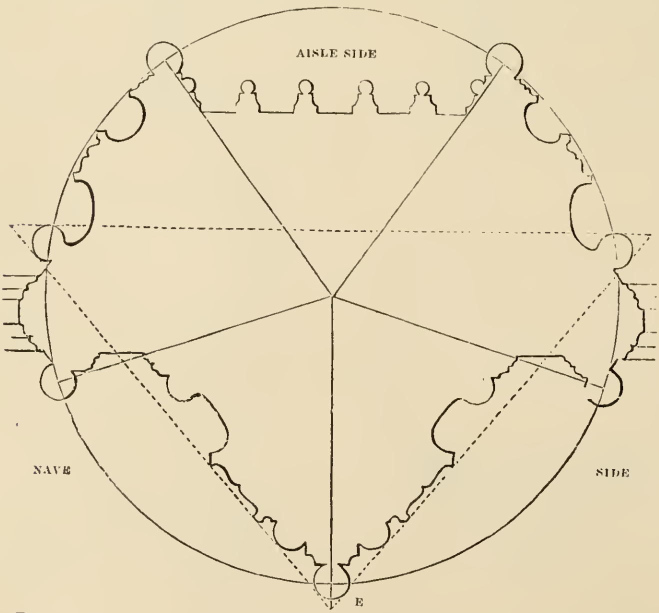

Fig. 1524. PIER OF HENRY VII.'S CHAPEL.

afterwards added the slender Purbeck columns and simple groining, producing that unadorned majesty which reigns throughout the cathedral of Salisbury. This style underwent several changes, and was succeeded at the latter end of the thirteenth century by another, in which the arch was struck from more than two centres: the naves of York, Canterbury, and Winchester Cathedrals have been cited as among the best examples. But we have now to describe the principles of a style founded upon the others, and applied to all buildings in England from the middle of the fifteenth to the middle of the sixteenth century; it is not met with on the continent, the Italian architecture having th

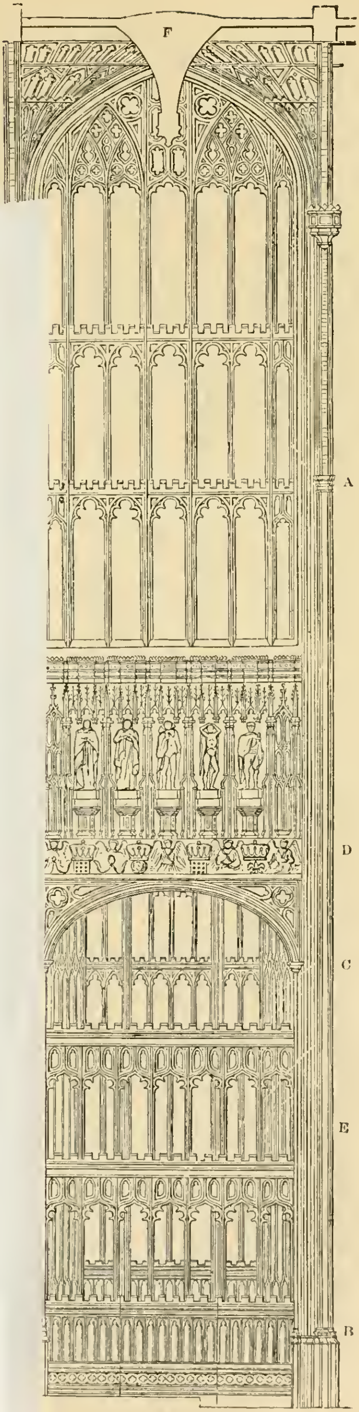

Fig. 1325. HENRY VII.'S CHAPEL.

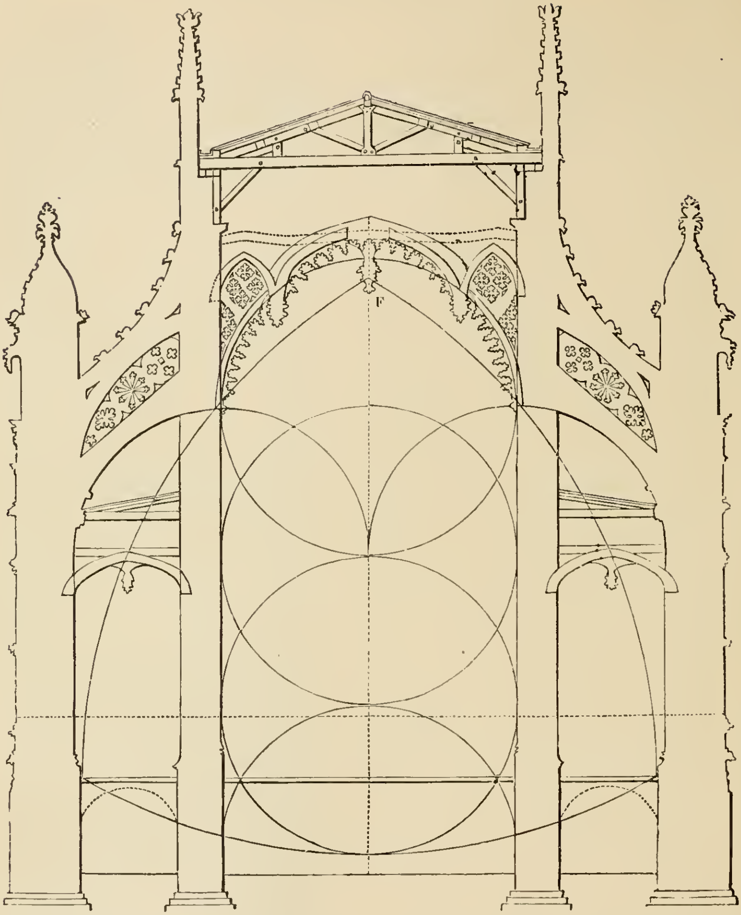

Fig. 1526. SECTION OF HENRY VII'S. CHAPEL.

6 inches, and the clear width of the nave 33 feet. The entire width, at the basement or level of the pavement of the crypt, is 79 feet: $26\frac{1}{3}$ feet, or $\frac{1}{3}$, is devoted to points of support, and $52\frac{2}{3}$ feet, or $\frac{2}{3}$, to the side aisles and nave; the area of a severy shows $\frac{1}{3}$ applied to walls and piers, and $\frac{2}{3}$ to the void, which proportions accord with the early rather than with the late examples; the great weight of the vaulting, which is 62 feet high from the pavement of the chapel, requiring additional strength, the proportions of St. George's Chapel at Windsor would not have been equal to the necessary resistance. (See *par.* 2002*w.*)

Our limits will not permit a more extended inquiry into the principles of proportion, the study of which is calculated to produce an important improvement in the noble art, for the practice of which the young architect must prepare himself by careful measurement, not only of the ruins of the Acropolis and of the Capitol, but of all that remains of mediæval architecture: he must be a pilgrim seeking after truth, not bowing before any favourite shrine, but returning with a devotion as enlarged as his subject. The stupendous works which antiquity has transmitted to us, it is hoped, may excite the attention of the general reader, nor will his interest be diminished by the contemplation of the astonishing development of modern industry. The writer cannot but feel the importance and variety of his subject, and, while he is conscious of his own imperfections, he must often accuse the deficiency of his materials: but the results of his labour, however inadequate to his own wishes, he finally delivers to the candour of the public.

The Figure of the Cube has from time immemorial been selected by the architect and engineer as best suited for every variety of edifice; and it is remarkable that the multiplying of the cube constitutes the design of the Greek temple, the Gothic cathedral, and the modern iron structure at Sydenham, the variety of effect depending upon the mode of its application. Reviewing the temples of the ancients, we find that those composed of a portico of four columns, and six intercolumniations on the flank, or seven columns; that the whole constituted a double cube, or two cubes side by side. A cube of 32 feet 4 inches in height, breadth, and length, placed behind another of the same dimensions, would represent the entire mass of the temple of Fortuna Virilis at Rome.

The temple of six columns, or the Hexastyle, is composed of nine half cubes, or three entire, placed one behind the other, with the addition of three half cubes against the sides of the first, making altogether four cubes and a half.

The Octastyle temple is composed of nine whole cubes, or four cubes and a half in depth, repeated twice, placed side by side. The Parthenon is thus formed of cubes, whose sides each measure 50 feet 6 inches; two occupy the front, of 101 feet; the depth of the four and a half cubes are a trifle more than 227 feet, the true extent being 227 feet 7 inches.

Six cubes, placed one above the other, form the design of the Campanile, at Florence, commenced by the celebrated Giotto in the year 1334; and on the breaking up of these cubes into ornament, the perpendicular lines are lengthened out, whilst in the Greek temple the horizontal are made to preponderate; repose in the latter, and lofty aspiration in the former, marks the distinction between them.

The *Tower of Rochester Castle,* usually supposed to be of Norman construction, perfectly resembles the far-famed Coliseum at Rome, in the manner in which the spiral vaults are executed. and in the general method adopted in carrying up the massive walls. The cement employed was evidently manufactured on the spot, as it is entirely composed of the materials found close at hand, and the stone such as could be brought down the Medway, and quarried on its shores. If this enduring structure was the work of Gundulph in the 12th century we have the strongest evidence that the Roman arts of construction were continued without any change either in the art or mystery of building up to that period at least.

The building is a cube and a half nearly, being about 74 feet square without the entrance porch, and its height to the top of the angular turrets is 112 feet. A square divided into twenty-five equal squares exhibits its plan; the sixteen outer squares represent the thickness of the walls, in which are galleries, recesses, and contrivances necessary for its protection against an enemy; the nine inner squares of the plan are divided into two spacious rooms, one being 45 feet by 19 feet, the other 45 feet by 21 feet; the wall that divides them is 5 feet 6 inches in thickness. The height comprises a basement story and three others beneath its roof, which has been vaulted, and which is 90 feet to the top of the battlement, and 112 feet to the top of the turrets.

Rules adopted by the Freemasons in setting out their Buildings, from the Tenth to the Fifteenth Century:—

In the foregoing remarks on Proportion some general rules have been suggested as to mass and void, and more particularly the principles of setting out the windows and tracery of the English and French cathedrals. On referring again to this interesting subject, the writer was led to inquire why the structures of the latter country should be so uniformly larger than those of the former, from which they differed but little in style, preserving the same relative proportions, though differing in dimensions. Guided by the supposition that the buildings of the above period were the works of fraternities of freemasons, it seemed conclusive that they should have some standard of measurement, either of their own or peculiar to each country; and. on testing the measurements with that view, it resulted that those of England were set out with the English perch of 16 feet 6 inches, and no doubt by an English lodge; while in those of France the French perch royal, of 22 *pieds du roi*, equal to 23·452 English feet, was employed; the few exceptions at Bayeux, Caen, St. George Bocherville, and some others with round arches, and the elegant church of St. Ouen at Rouen, in the flamboyant style, are set out with the English perch of 16 feet 6 inches, and are universally attributed to English constructors; they certainly most curiously agree in proportion and dimension with the English cathedrals, which have two cubes given to the nave, producing on the plan a Latin cross. instead of the Greek so usually found in France. It would seem that the standard measures referred to were well and wisely chosen, as if intended to apply to all times and all varieties of structure; for it is singular how nearly the dimensions of the cubes of the fairy palace at Sydenham, 24 feet, correspond to 23 feet 6 inches of the royal French perch.

To illustrate this subject fully is not within our present narrow limits; a very few examples must suffice, out of the numbers which might be adduced in support of the proposition; and it is earnestly hoped that the young architect may be sufficiently interested to test the theory practically, that while he admires their picturesque beauties, he will examine by measurement their plans and sections.

Of the French Cathedrals, we must be content to refer to Chartres, Reims, and Amiens as those most admired, and which serve as examples of the application of the French perch in setting out their various parts as well as the whole.

Chartres Cathedral, in which the pointed arch first appears, is a structure of the 11th century, and one of the most remarkable, as well as beautiful, erected after the first introduction of the pointed style by those who had journeyed with the Crusaders, and had an opportunity of studying their craft in the East.

The proportions are simple in the extreme. A cube is devoted to the nave, two to the transept, one to the choir; in addition to which, at the eastern extremity, is a semicircular termination with six polygonal chapels attached, forming on the plan a Greek cross of admirable design.

The nave, comprising six divisions of pointed arches on each side, is in its length and width six royal perches, the distribution of which will enable the reader to comprehend the setting out of the entire plan, which he can refer to in several publications.

The clear width of the nave is two royal perches between the clerestory walls; each side aisle is one royal perch, and the distance from the middle of one pier to that of the other, from west to east, is also a royal perch.

The entire width of the nave from out to out, that is to say, from the face of the exterior buttresses, is six royal perches, four perches being given to the two side aisles and nave for their clear widths, and the other two to the projection of the buttresses, thickness of the two outer walls, and those of the clerestory of the nave.

If the royal perch be divided into three, one part constitutes the diameter given to the pillars, and another the thickness of each of the walls of the side aisles.

The internal height of the nave is the same as its clear internal width with side aisles; so justly is all proportioned that the perch royal, and its division into three, enables us to comprehend the dimensions of the parts, as well as that of the entire mass of construction.

Reims Cathedral was similarly set out. The clear width of the nave is two royal perches, and each of the side aisles is one perch. The extreme width of the nave, comprising the projection of the buttresses, is six royal perches; the diameter of the piers, one-third of a royal perch, as in the example of Chartres.

It must be observed that the dimensions do not apply to the clear distances between the pillars, but to the space between the walls, which in the clerestory are peculiar for the contrivances of a gallery, which usually continues around the entire cathedral, and which will be better understood when we treat upon Amiens Cathedral, reserved for a fuller description. That the perch was the standard of measurement there can be no doubt; for in the smaller churches of Great Britain, as that of Roslyn, for example, the nave is a single perch in width, and the side aisles half a perch; the proportions of the parts being also those of the third of an English perch.

Salisbury Cathedral, a contemporary structure with Amiens, is set out with the English perch, and affords the best commentary upon the two standard measures made use of in the same century by the French and English freemasons.

The Nave of Amiens Cathedral is usually admired for its elegant proportions, and by several eminent critics has been cited as the *beau ideal* of that style of architecture so universally practised during the middle ages, or after the Romanesque had been discontinued. It is one of the most simple in its arrangement, though at first sight, removing all idea of simplicity, and appearing so complicated from its variety of parts, as to defy the application of any ordinary rules; the numerous arcades, the narrow and lofty compartments, the vaulted divisions, the diagonal and curved lines, blending one into the other, and apparently without limit, it is some time before the eye can acqui see in the idea that such an edifice can be brought under the same laws as a Greek temple, or that the cube could be the measure of its parts or its whole. In taking the measurements, however, of this rare example, the dimension of 23 feet 6 inches so frequently occurred that it seemed to denote a standard by which to arrive at the length, breadth, and height of the whole, and that if considered after the manner of Sebastian Serlio where he describes Bramante's plan of St. Peter's, we might arrive at something like a clue to the whole design.

It is curious to note, in the work of the above mentioned architect, several allusions to the cube, in the defining the parts as well as the whole of a design, and there can be little doubt that this simple figure served as the means of measuring the quantities, of either solid or void, in every period of the constructive arts; certainly none presents to the architect a better means of comprehending or of measuring quantity, and none is more readily subdivided, or rendered subservient to the taste of the designer, whatever may be the architecture he is anxious to imitate.

Within an isometrical cube may be placed the entire nave of Amiens Cathedral; and the better to understand its proportions, we must suppose each square or cube into which it is divided to measure 23 feet 6 inches each side, or the isometrical figure to contain 216 such cubes; the total height, width, and length being 141 feet, or six times the 23 feet 6 inches. (See *fig.* 1327.)

On the plan are six divisions in length and width, or altogether 36 squares; each measure 23 feet 6 inches on each of their sides. The six outer divisions of the principal figure are devoted to walls and buttresses; the adjoining six on each side show the situation

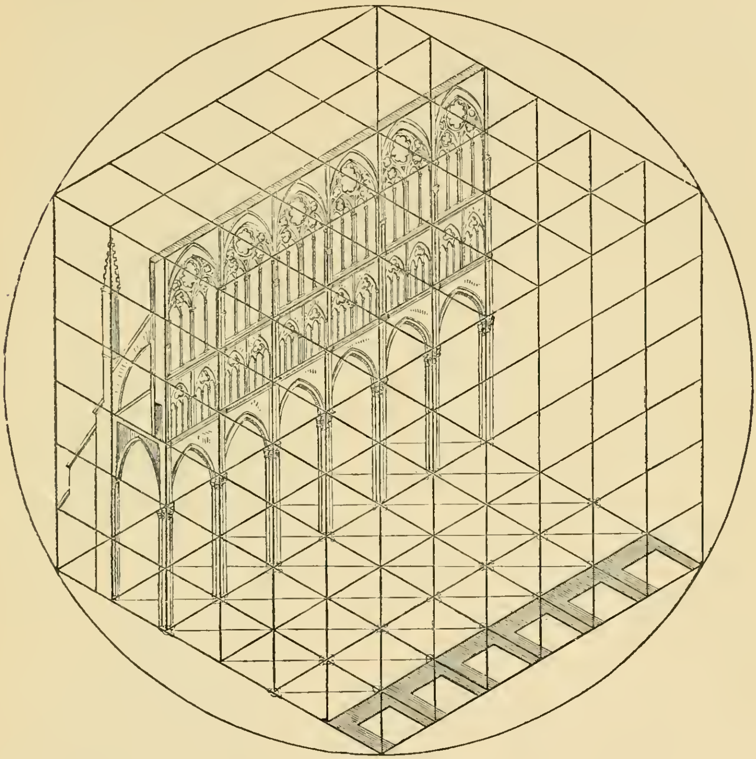

Fig. 1327. NAVE OF AMIENS CATHEDRAL.

of the side aisles; and the two middle divisions that of the nave. The two side aisles occupy together 12 squares, as does the nave; the remaining 12 being devoted to outer walls and their buttresses.

The entire area, therefore, has 24 squares to represent its interior distribution, and half that number its external walls; or one third walls, two-thirds void. Such are the general arrangements of its plan, and its extreme simplicity has enabled the constructors to execute the vaulting of the side aisles and that of the centre nave by diagonal ribs, which in the former extend over one square, and in the latter two, thus giving to the nave its due proportion of height, without changing the principle of its construction.

The freemasons of the middle ages were so perfectly acquainted wi h geometry that there is seldom any defect in their vaulting; it is evident that they laid down their plans for its execution before they decided upon the form of their main piers; in their setting out, every part had its due function; and the column, which was intended to be connected with the vaulting, either of nave or side aisle, was peculiarly adapted by its position for its use.

The master mason Robert de Luzarche commenced the building of this nave about the year 1220, the founder being Bishop Evrard. The pillars of the nave were raised to the height of their capitals in 1236, but it was not till 1236 that the vaulting was comp'eted; and about eight or nine years afterwards the lateral chapels were added.

To the top of the battlement of the nave there is not quite so much height as the outer wall of the Coliseum at Rome, which is 157 feet; but it is curious to observe that one division of this renowned building does not differ very materially in its proportions from that at Amiens; the division of the ampitheatre being seven cubes in height; the piers occupy one third of the width of a compartment, as is usual in Roman structures of the same period. The masonry of Amiens Cathedral is executed after the Roman models, consequently the pointed arch makes the chief difference between the two styles.

To render the application of the theory of the cube to the nave of Amiens Cathedral more evident, or how the 216 cubes which the isometrical figure contains are placed, somewhat more of detail must be entered into.

The six main divisions shown in the figure, with the side aisle behind them, have their points of support at the four angles of each of the six squares; then each square, with its 23 feet 6 inches sides, shows the position of the lowest cube of the six placed one above the other, forming the entire height of each division or severy.

At the top of the second cube is the level upon which the main arches spring, and that upon which the ribs of the vaulting of the side aisles rest.

The top of the third cube indicates the level upon which the triforium is based, and consequently contains the vaulting of the side aisle.

The fourth cube is the triforium, and the fifth and the sixth the clerestory.

On examining the section, the side aisles are three cubes in height, including the vaulting, and the nave six; the entire open space of the interior has 18 cubes for each aisle, or 36 for the two side aisles, and 72 for the nave; in all 108 cubes, or exactly one half the entire number contained in the isometrical cube.

It must be remarked that considerable alterations have been made since the building was constructed; between the buttresses, chapels have been formed, and the original windows, which lighted the side aisles, removed to the extent, or somewhat beyond the outer face of buttresses, as represented. The interior is therefore increased materially in width, and its effect greatly improved, making the entire internal width and height more in conformity with each other, or each 141 feet.

In the elevation of the divisions the boundary of each of the six cubes is more clearly marked. The width from centre to centre of each pillar, indicated by the seven circles (*fig.* 1328.) is 23 feet 6 inches; to the top of the capitals from the pavement A B, the height is twice that dimension; to the bottom of the bases of the column of the triforium B C, the same; thence to the bottom of the glass of the clerestory windows C D, the same; to the tops of the capitals or spring of the arches D E, the same; and above that line to the underside the vaulting E F, the same; thus, six times 23 feet 6 inches, or 141 feet, is the total height from the pavement, of the division represented in *fig.* 1328.

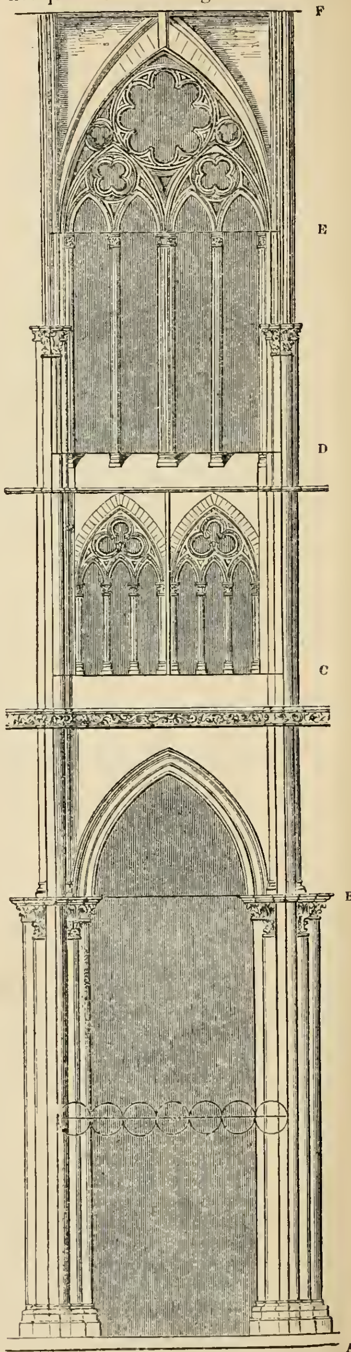

Fig. 1328. ELEVATION OF NAVE; AMIENS.

As the groined vaults of the side aisles are set out upon a square, and the width from the centres of piers is the same as these towards the nave, we have three perfect cubes of 24 feet in each severy up to the bottom of the triforium story, and the same number from thence to the top of the vaulting of the nave.

The main pillars are 7 feet, and 7 feet 2 inches in diameter, composed of a large cylindrical column, with others attached for the support of the vaulting. Towards the nave there are three columns which are carried up to the height of about the middle of that of the clerestory windows; on the capitals which terminate them rest the cross springers and diagonal ribs of the vaulting. The arches of each division are 4 feet 9 inches in thickness, and rest on the side columns, of 18 inches diameter. The faint line on the plan *fig.* 1329. represents the pier and mullions of the division of the clerestory window.

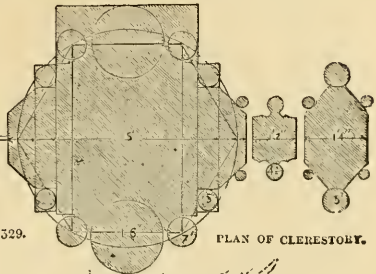

Fig. 1329. PLAN OF CLERESTORY.

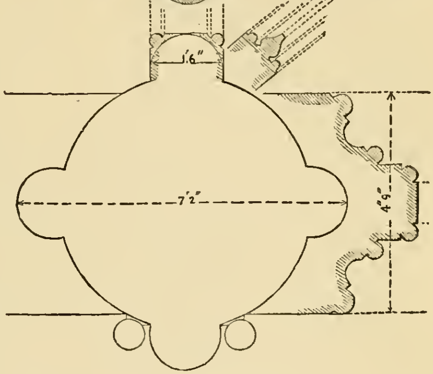

Fig. 1330. PLAN OF COLUMNS; AMIENS.

The seven circles shown in *fig.* 1328. exhibit the proportion each pier bears to the opening, namely, that of two-sevenths for piers, and five-sevenths for the space between them. The dimensions vary a little as taken throughout the six severies, as in some instances the diameter of the piers varies as above stated.

It may be remarked that the contour of the torus and scotia in the base, are not sections of cylinders or their portions, but partakes of the elliptical. The mouldings below, are contoured differently to those above, the eye, and consideration is given to their position, to produce proper effect.

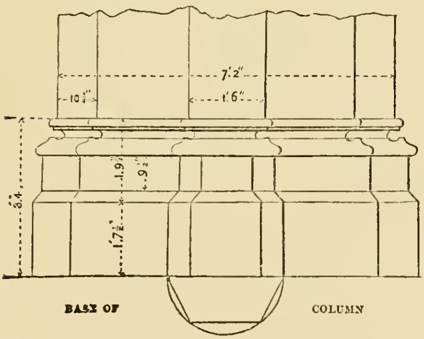

Fig. 1331.

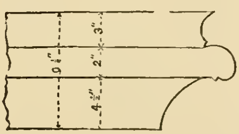

Fig. 1332. AMIENS.

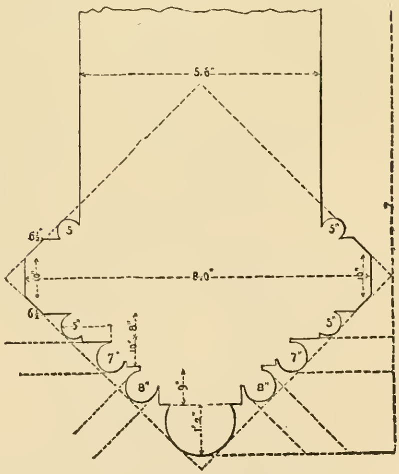

Fig. 1333. PIERS IN SIDE AISLES.

The base and capital of the main pillars, as here shown with their dimensions, is the same as the front view towards the nave, with the exception that the two 7-inch columns at the side of that in the middle are omitted.

The piers that divide the side chapels, and the original outer buttresses, have been changed probably from their original design; they are now 8 feet wide.

The clerestory window with its piers and mullions being already given (*fig.* 1329.) it remains to show the plan of the piers and mullions of the triforium, and its gallery or passage, which has a clear width of 20 inches between the main pier and the outer wall, which is about 10 inches in thickness (*fig.* 1334.) The middle mullion, or that which divides the triforium into two principal arches, is 2 feet 6 inches in width, and composed of seven small columns, as shown attached to the main pillar, which has a depth of 6 feet 8 inches.

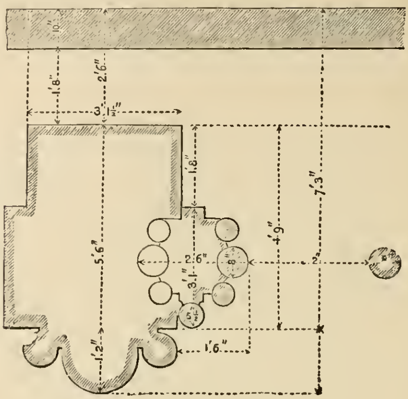

Fig. 1334. PLAN OF TRIFORIUM.

The ordinary decoration in this cathedral is very simple, consisting of a circle, comprising either three, four, five, six, or eight others; the centres of which and their portions may be understood by reference to the five diagrams *figs.* 1335. to 1339. Sculptured foliage occurs in the capitals and along the string mouldings; figures, however, of the most elaborate execution and design decorate the exterior, and particularly around the chief entrances; perhaps few buildings excel the Cathedral of Amiens in the richness of these portions, or the magnificence of its porches. In describing the *figs.* 1292. and 1291., an attempt was made to convey an idea of the geometrical style of the tracery in the rose windows, as well as those of the side chapels.

We cannot quit this part of our subject without regretting the want of further space for the treatment of this very interesting reference to the arts as displayed by the builders of this period, particularly as the principles upon which they practised are so little known. Simple as they were, their system seems to have been forgotten after the lodges of the freemasons were broken up, and the new era appeared. The *renaissance*, or the return to the Greek models, at once set aside all knowledge of that architecture which had attained such perfection in Europe for four centuries.

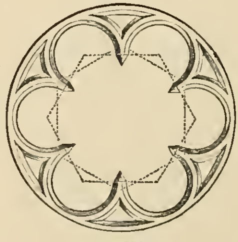

Fig. 1339.

THE BUILDING FOR THE EXHIBITION OF THE INDUSTRY OF ALL NATIONS, 1851.

This building was stated to have been suggested to the Society of Arts in June 1845 by his Royal Highness Prince Albert, and it was not long ere the plan for its adoption was developed. The public quickly responded to an appeal by subscribing 75,000*l.* to enable the commissioners to erect a suitable building, to be completed by the 1st of May 1851; the site being granted by Her Majesty, on the south side of Hyde Park; and all that was required of the exhibitors was, to deliver their various specimens of art and manufacture at the building which would be provided for them. Mr. Paxton, after some other designs had been set aside, submitted a design composed chiefly of glass and iron, which Messrs. Fox, Henderson, & Co. tendered to construct for 79,800*l*. This was immediately carried into effect.

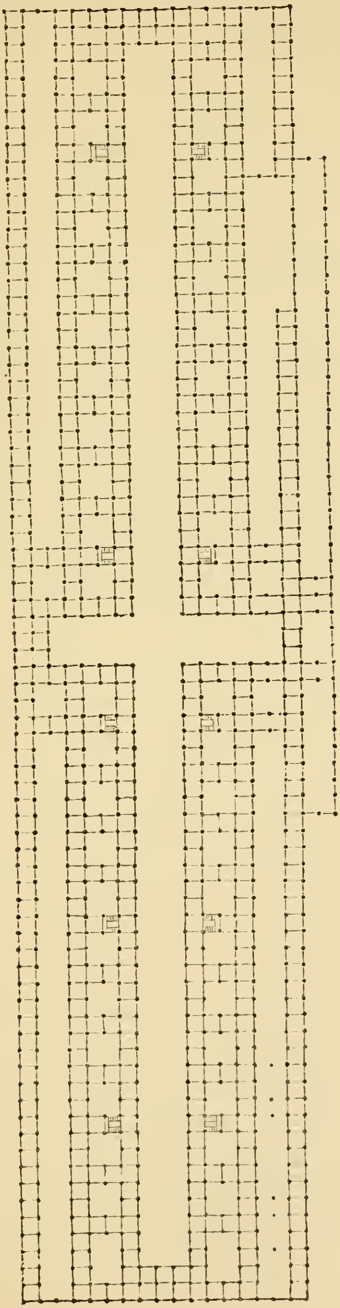

Fig. 1340. GROUND PLAN.

THE BUILDING FOR THE EXHIBITION OF ALL NATIONS, 1851, COMMONLY CALLED THE CRYSTAL PALACE.

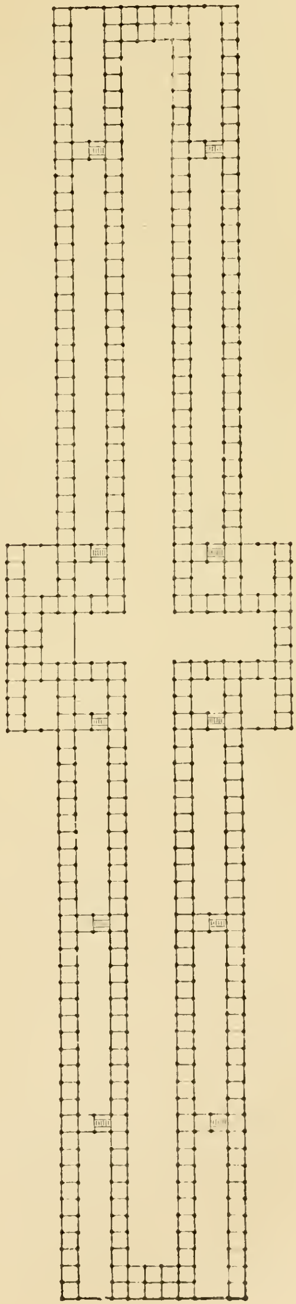

Fig. 1341. UPPER PLAN.

The site for the building contained about 26 acres, being 2,300 feet in length, and 500 feet in breadth; the principal front extending from west to east. The total area of the ground-floor was 772,784 superficial feet, and that of the galleries 217,100 square feet. The length of these galleries extended nearly a mile. The cubical contents of the building were estimated at 33,000,000 feet.

There were used in its construction 2,300 cast iron girders, 358 wrought iron trusses for supporting the galleries and roof, 30 miles of gutters for carrying water to the columns which served as water-pipes, 202 miles of sash-bars, and 900,000 superficial feet of glass.

On the ground-floor, 1,106 columns of cast iron, rested on cast iron plates, based upon concrete; these columns were 8 inches in diameter, and 18 feet $5\frac{1}{2}$ inches in height; they were cast hollow, the thickness of the metal varying from $\frac{5}{8}$ to $1\frac{1}{8}$ in., according to the weights they were destined to support. The sectional area was increased by four broad fillets or faces, $3\frac{1}{2}$ inches in width, and a little more than a sixth of an inch in thickness.

The principal entrance was in the centre of the south side; passing through a vestibule 72 feet by 48, the transept was entered, which was covered by a semi-cylindrical vault 72 feet in diameter, springing from a height of 68 feet from the floor; and this vault of iron and glass was in length 408 feet from north to south. On each side of the transept was an aisle 24 feet wide.

Standing in the middle of the transept, the vista or nave, at right angles, extended east and west 900 feet in each direction; the total length being 1,848 feet. This nave was 72 feet wide, and 64 feet high; and on each side was an aisle 24 feet in width; and above, at a height of 24 feet from the floor, were galleries which surrounded the whole of the nave and transept.

Beyond these side aisles and parallel with them, at a distance of 48 feet, were second side aisles, of an equal width to those already mentioned, and also covered with galleries on a similar level to the others. Bridges of communication were made at convenient distances, to allow of an unbroken promenade, and from which a view of the several courts might be obtained. These courts were roofed in, at the height of 2 stories, and were 48 feet in width. Ten double staircases 8 feet wide gave access to the several galleries.

After the transept and nave were marked out, the general arrangement consisted of a series of compartments 24 feet square, and as much in height; these bays or cubes were each formed of 4 columns, supporting girders put together very ingeniously. One of these bays or gallery-floors, 24 feet square, containing 576 superficial feet, was calculated to support as many cwts., or 30 tons.

The symmetry and strength of this vast building depended upon the accuracy with which the simple plan was drawn out, and much credit is due to Mr. Brounger, who superintended this portion of the work. He had to establish a series of squares of 24 feet, and this was admirably effected by rods of well-seasoned pine, fitted with gun-metal cheeks.

Stakes were driven into the ground to mark the position of the columns, their precise centres being afterwards found by the theodolite, and marked by a nail on the top of the stake or pile; and when the digging commenced for the foundations, and there was a necessity to move the pile, a right-angled triangle was formed in deal, and previous to the removal of a stake, a nail indicating the position of the column was placed at the apex of the triangle; two other stakes were driven in, and the first withdrawn. The entire ground plan may be considered as composed of 1,453 squares, each containing 576 superficial feet. The south front occupied 77, the east and west fronts each 17, so that the entire parallelogram contained 1,309 of these squares; on the north side were 48 others, 3 divisions in depth, making an additional 144, thus completing the number stated. The nave, transept, and courts were formed by the omission of the columns, where their width required to be either 48 or 72 feet, and girders of sufficient strength were substituted to span the space where such columns were omitted. Had each of the 1,387 squares of which the plan consists had its complement of columns to have perfected each cube, 1,502 would have been required; but the formation of the wider openings occasioned only 1,106 to be employed, so that, by the omission of a third, the courts, nave, and transepts acquired their admired proportions. Each of the 1,387 squares was 576 superficial feet, or a total of 798,912 superficial feet. The columns being 8 inches in diameter, the area of the section of the whole 1,106 was 380 superficial feet, or the points of support were a trifle more than a 2,000th of the entire area, for $\frac{798912}{380}=2,102$.

When we compare the Crystal Palace with one of the lightest constructed basilicas of ancient Rome, we are astonished at the difference in the proportions. For instance, the total area of the basilica of St. Paul without the walls of Rome, was 108,000 superficial feet; while the points of support were 12,000, or one ninth. The Crystal Palace, which was seven times the area of the basilica of St. Paul, had it been constructed in a similar manner, would have required 84,000 superficial feet for the points of support, instead of 380 superficial feet.

In the Saxon cathedrals, one third of the entire area was employed for walls and piers; in the Pantheon at Rome, one quarter; in St. Paul's, London, one sixth; and in most of the cathedrals constructed from the 12th to the 15th century, the same proportions are practised; but we have never hitherto seen any attempt to lessen the proportions of the supports beyond a twentieth of the entire area, when the ordinary building materials, as brick or stone, have been employed, whilst in this instance iron columns are found sufficiently strong, when they have the proportion of a 2,000th part of the whole, or are one hundred times less in section than their points of support, estimated as a twentieth of the whole, and which we have considered as the lightest of the constructions hitherto practised; the round Temple of Claudius at Rome being the example. Tredgold calculated that an iron column of cast iron 8 inches in diameter, and 24 feet high, will carry nearly 50 tons, or 1,106, 55,300 tons; so that, if each of 1,387 squares had to sustain 30 tons, there would be ample strength, this not amounting to more than 41,610 tons.

In preparing the foundations for the columns, great care was taken to arrive at the gravel, upon which a bed of concrete was thrown; and it was estimated that a pressure per superficial foot of $2\frac{1}{2}$ tons should be provided for. The concrete varied in depth from 8 to 4 feet, and was finished by covering the top with a surface of fine mortar, worked even and with a level face. On this was laid a base plate for each column, the lower part consisting of a horizontal plate having attached to it a vertical tube of the form of the column it was to carry. The length of these base plates was from north to south, so that the water brought down by the columns from the roof might run in the direction from east to west. Into the sockets, cast iron pipes 6 inches in diameter were inserted, for the purpose of conveying the water into the cisterns and tanks provided to receive it.

At the upper portion of the base plate four holes were cast, in as many projections, which answered to others at the foot of the column to be placed upon it, which, when fixed, was secured by nuts. Between the shaft and its base, pieces of canvas dipped in white lead were introduced before the joints were secured, which were thus rendered water-tight. The columns were 8 inches in diameter, and those on the ground floor 18 feet $5\frac{1}{2}$ inches in height, being cast hollow to allow of a current for the rain water; the strength of these columns was increased by four projecting ribs, and by the form of angular additions made to receive the nuts and screws.

The Crystal Palace at Sydenham had also the *simple cube* as the nucleus of which this vast edifice was composed; and the simplicity of its form enabled the constructors, by a small variety of castings, to execute the whole. It was to this locality that the materials of the Hyde Park building were removed and readapted to a much more extensive erection. Three cubes, placed one on the other, formed the side galleries, as seen in the section, *fig.* 1342 The omission of six such cubes measures the width and height of the nave to the level of the springing of the arched covering; such are the simple proportions composing this vast structure. On the ground-floor is laid boarding $1\frac{1}{2}$ inches in thickness, $\frac{1}{2}$ an inch apart, upon joists 7 inches by $2\frac{1}{2}$ inches, which rest upon sleepers 13 inches by $3\frac{1}{4}$ inches, placed 8 feet apart. The second tier of columns are 16 feet $7\frac{1}{4}$ inches long, with connecting pieces 3 feet $4\frac{1}{2}$ inches deep, and a similar girder to those below. The third tier of columns and connecting pieces in every case are the same as the second.

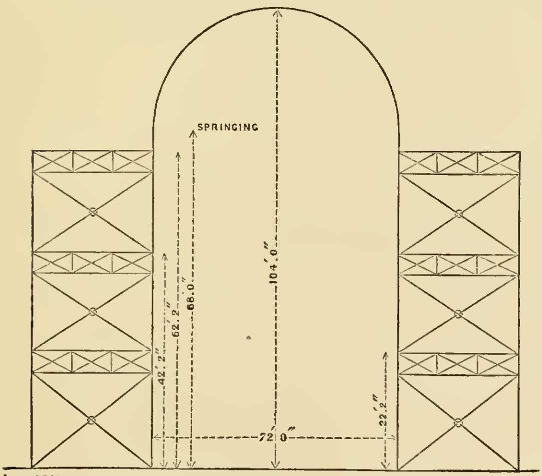

Fig. 1342. Section of the Crystal Palace, Sydenham.

CHAP. V.

SPECIAL SUBJECTS.

2861 to 2946. Mr. Gwilt wrote, in 1842, Chapter V., Public and Private Buildings. The several sections were revised and enlarged and additional ones inserted in 1867, and again in 1876. The progress in most of the subjects, as well as of others, has been so great of late years that a volume for each might well be written, giving the later examples and principles of arrangement. As it is a convenient place in this work for specially treating some subjects, the chapter is retained under a new heading. The sections Ventilation of Buildings and Warming of Buildings are taken to Use of Materials or Practical Building, Chapters XIII. and XIV., and most of the other sections are inserted in the Glossary. The student will find in the List of Books many works relating to the subjects, of which he may be in search.

Sect. I.

THEATRES.

2947. A taste for dramatic representations prevailed at a very early period among the people of antiquity, and this was not diminished by the introduction of Christianity, even when the temples were deserted and paganism seemed extinct. The destruction of these, however, was its concluding triumph. It would be a difficult matter to fix the precise date of the abolition of the pagan theatre, but it seems likely to have resulted rather from the falling into decay of the old theatres than from a disinclination on the part of the people to the pleasure they received at them. With the revival of the arts, the taste for scenic representations appeared with the literature on which they are dependent. In Italy we find, therefore, the drama at this period represented in very large enclosures, such as the amphitheatre constructed by Bramante in the large court at the Vatican, whence the taste soon spread over all the nations of Europe.

2948. The pleasure which flowed from this renewal of an ancient art was at first confined to few, and those were either men of learning or select societies, who bore the expenses, and again raised in the country a renewal of a theatre much resembling those of the ancients as respected the form and disposition. To prove this, we need only cite the example of the celebrated theatre at Vicenza, built by Palladio in 1583, and designed in imitation of the ancient theatres. A full account of this building is given in *L'Origine dell' Academia Olympica, &c. Opera di Ottavio Bertotti Scamozzi*, Vicenza, 1690. For dramatic representations this theatre is no longer used, and at present it is only recognised as a monument of the extraordinary skill of the architect, and a memorial of the dramatic buildings of its period. The theatre at Parma, built by Aleotti, is another building belonging to the same class, and preserved, like the last-mentioned, as a curiosity.

2949. When, however, the taste for scenic amusements began to spread, the sovereign princes, who alone could support the expense of such establishments, began to make them a necessary part of their palaces; and the theatre, no longer a public and essential building, became what it now is, a place which served for the habitual amusement of those who could afford it. The drama again revived, and its history is an index to the edifices that rose for its representation. Becoming thus necessary for the amusement of the better classes of society, the establishment of theatres was undertaken by individuals in almost every city, and competition was the natural consequence. Then began the division of the theatre into different parts, the entry to which was marked by different prices, and the separation of the common people from those of rank and fortune.

2950. Italy does not contain so many theatres, nor of such consequence, as might be predicted from the taste of its inhabitants. Among the earliest of consequence was that built at Bologna in 1763 by Antonio Galli Bibiena (not to mention that built at Verona under the direction of the celebrated Scipio Maffei by Francesco Galli Bibiena), with a noble portico in front and salons in the angles, possessing moreover great merit in its interior distribution. In the Italian theatres there is almost invariably a certain feeling of grandeur and unity about the interior little to be expected from the exterior, which in no way leads the spectator to the suspicion of a fine *Salle de Spectacle* behind it.

2951. France has the credit of having erected the first modern theatre that can be denominated an example in this species of monumental architecture. That to which we allude is the theatre at Bordeaux, which is 325 feet in length, and half that measure in width. Whether we consider the exterior or interior of this edifice, everything is grand; the accessories are worthy of the whole, and the richness of the interior decoration is only equalled by the fine forms whereon the decorations are used. The ingress and egress are admirable; and a splendid concert-room and magnificent staircases complete the destination, to which it is so suited, as to afford the finest model of a theatre to which we can refer the student. The plans, &c. of this work were published by its architect, V. Louis, under the title of *Salle de Spectacle de Bordeaux*, atlas folio, Paris, 1782.

2952. The principal points for the consideration of the architect in the composition of a theatre may be classed under the heads of utility, suitableness for the purpose, and taste in combining them. Under the first head must be placed the accomplishment of two main objects, those of seeing and hearing what passes on the stage. These, indeed, are intimately connected with each other, and are entirely dependent on the form adopted for the plan of the interior, that is, the general form given to the boxes which surround the part before the curtain. We are not aware of any plan which, in this respect, is not based on a quadrangular, elliptical, or circular form.

2953. The quadrangular form, besides its want of beauty, is not well adapted for fulfilling the objects with which we set out. In this, the greater number of spectators or audience who occupy the side boxes are so inconveniently placed, that, to observe what is going on, their heads must be turned sidewise, and they are hence in a false position for the object. The actor being generally the point to which all eyes are directed, the spectator opposite the proscenium will look at him in a right direction; but as the spectator removes to the extremity of the side, it is manifest that the angle in which the head must be turned becomes sharper, and the position is then painful. Besides this objection, the form is known to be unfavourable to hearing or to the propagation of sound.

2954. The truncated oval is in some measure subject to the same inconveniences on the sides as the last-mentioned figure. It removes also a large portion of the spectators to a considerable distance from the centre of the scene, besides which, in the boxes near the proscenium, their seats tend in opposite directions to the actor. It has been to remedy these faults that the form of the horseshoe has been adopted, which is a sort of mean between the quadrangular and oval forms: and where the plot of ground is much longer than it is wide, it is a suitable figure, and one which affords the opportunity of increasing the number of boxes.

2955. When, however, the circumstances concur in allowing it, the adoption of the semicircular plan is doubtless the best. It is a figure which allows each spectator to be at an equal distance from the scene, that also by which the spectators in adjoining boxes less interfere with one another, that which affords the means of all seeing equally well, that in which the sound is most equally distributed, and that whose uniformity and simplicity seem to engender the best decoration. The semi-elliptic, with the transverse axis parallel to the proscenium, has interior advantages in some respects over the semicircle; but it induces great difficulty in connecting the proscenium itself with the auditory part of the house, and, by increasing the width of the proscenium, increases the perplexity in framing (as formerly) the roof conveniently for the painting rooms, and securely as respects the walls.

2956. Upon the destruction by fire of Drury Lane Theatre a pamphlet appeared, entitled *Observations on the Principles of a Design for a Theatre*, by Benjamin Wyatt, London, 8vo. 1811. These observations are so well worth the notice of the student that we shall close this section by giving the substance of them. The heads for consideration, says the author, are:—

2957. *First.* The size or capacity of the theatre, as governed by the width of the proscenium or stage opening; and by the pecuniary return to be made to those whose property may be embarked in the concern. *Second.* The form or shape of the theatre, as connected with the primary objects of sound and vision. *Third.* The facility of ingress and egress, as materially affecting the convenience of those who go to every part of the house respectively, as well as their lives, in cases of sudden accident or alarm. *Fourth.* Decorum amongst the several orders and classes of the visitants to the theatre, as essential to the accommodation of the more respectable part of those visitants, and consequently of great importance to the interests of the theatre. *Fifth.* Security against fire, as well in regard of insurance, as with relation to the lives of individuals going to the theatre.

2958. The size or capacity will necessarily depend very much on the width of the proscenium or stage opening, inasmuch as it is from the extremities of that opening that the form of the theatre must spring. The annexed is a statement of the width of the proscenium at the theatres named in that publication:—

Argentino, at Rome	36 feet	Parma	40 feet
Old Covent Garden (burnt 1856)	38 feet	Milan	40 feet
Théâtre Italien, Paris (burnt)	38 feet	San Benedetto, at Venice	40 feet
Turin	39 feet	Théâtre Français, at Paris	40 feet
Bordeaux	39 feet	Drury Lane	40 feet 6 in.

Table prepared by Mr. E. M. Barry, 1860, for his description of New Covent Garden Theatre, London.	San Carlos, Naples.	La Scala, Milan.	Bologna Theatre.	Turin Theatre.	London. Her Majesty's.	London. New Covent Garden.
Width of proscenium	53 feet	43 feet	51 feet	42 feet	37 feet	50 feet
Number of boxes in each tier	29	41	25	29	43	36
Number of tiers of boxes	6	5	5	6	6	4
Width between the boxes	70 feet	66 feet	57 feet	52 feet	59 feet	63 feet
Length from curtain to centre box	70	88½	78	61	88	81
Height from pit to ceiling	70	69	63½	53½	51	65½

A width beyond 40 feet seems to have been considered by the performers as inconvenient, from the space they would have to pass over in the business of the drama, but 50 feet appears now to be the maximum adopted. A greater width, indeed, than that stated prevents the easy and secure working of the scenes, for the machinery is increased in magnitude and weight as the height and breadth of the scenes increase. In mere *spectacle* and scenic grouping a reduction in the width of the proscenium, and depth of the stage, reduces the number of extra performers, or supernumeraries as they are called, which become necessary for filling the stage. Again, every additional foot given to the stage opening increases the quantity of canvas used in the scenes, as well as the framing whereon they are fixed.

2958*a*. In the *Edinburgh New Philosophical Journal*, vol. xxvii., Mr. J. S. Russell gives some elementary considerations of certain principles in the construction of buildings designed to accommodate spectators and auditors, well worth the architect's notice. In every large room, says the writer, a perfectly good seat is one in which, without uneasy elevation of the head or eye, without straining or stretching, we can calmly and quietly take any easy position, or variety of positions, which we may be disposed to assume, and yet may in all of them see and hear the speaker with equal clearness and repose, so as to give him patient and undisturbed attention. The object, then, is to ascertain in what manner the interior of a building for public speaking should be formed, so that throughout the whole range which the voice of a man is capable of filling, each individual should see and hear without interruption from any of the rest of the audience, with equal comfort in an easy posture,

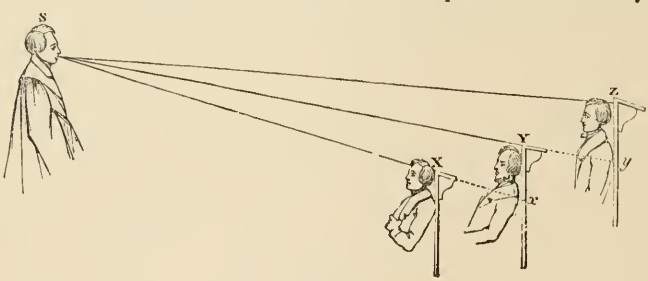

Fig. 1347.

and as clearly as if no other individual auditor or spectator were present. (See *figs.* 1347. and 1348.) The position of the seats is first investigated. In the usual variety of station

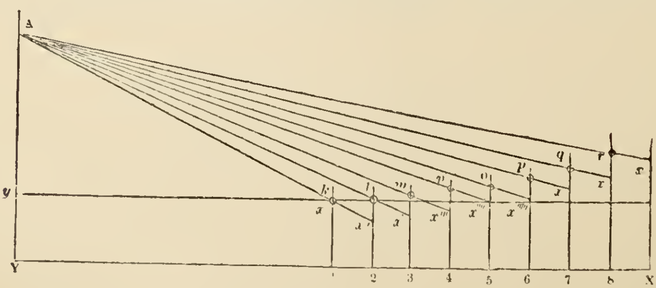

Fig. 1348.

and of position, it appears from experiments that the range required for the purpose is more than a foot and less than 18 inches, so that these may be taken as the limits; that is, over the head of the person before you there must be a clear range of 12 or 18 inches, through which the head may be moved upwards or downwards without interruption. In other words, that a straight line drawn from the speaker's head over that of the anterior spectator shall intercept the straight line which forms the back of the seat of the posterior observer, so as to cut off a height of 12 or 18 inches, within which the head of the spectator shall at times be comprehended while sitting in a comfortable position. Thus let S (*fig.* 1347) be the speaker and XYZ be three successive ascents; then the line SX must fall below SY, so as to leave the space $Yx = 18$ inches $= Zy$.

2959. Applying this formula to every individual place in the room or building, we shall have the form required to satisfy the auditors. Let $2\frac{1}{2}$ feet be assumed as a constant representing the distance of one spectator behind another, measured horizontally; and $1\frac{1}{4}$ feet as the clear space, measured on the vertical line, for the mean range of comfortable vision for each. If the level of the floor, that is, of the lowest seats, be already determined, the form of the interior accommodation may be thus described. AY (*fig.* 1348.), the height of the speaker, YX the level floor. From Ay take $Yy = 4$ feet. Draw yx parallel to YX. Take Ay to yx as $1\frac{1}{4}$ to $2\frac{1}{2}$, that is, as h, the range of position of the spectator, to d, the distance between the seats. Take horizontal distances 1, 2, 3, 4, &c. $= 2\frac{1}{2}$ feet, prolong Ax to x', then the height x' to $l = 1\frac{1}{4}$ feet. Join Al and prolong it to x'', and take a distance x'' to $m = 1\frac{1}{4}$ feet. Through m draw Am, and prolong it to x''', and take $x'''n = 1\frac{1}{4}$ feet. Continue the process in the same manner to p, q, r, s, t, &c., and the points will be found of the successive places which the heads of the auditors should occupy.

2960. But it is not only in receding that the back seats must rise; those too far forward may be also unpleasant. They are too low; they also should be raised: but this must be done so as not to interrupt those who are behind. It may be accomplished in a similar way; for, as formerly set off, 1, 2, 3, 4, 5, 6, &c. $= 2\frac{1}{2}$ feet (*fig.* 1349.), 1 is the first anterior point. Join A1, and let it cut the vertical line through 2 in x', the portion downwards $x'l = 1\frac{1}{4}$ feet; then l is the point found. Join Al, make $x''k = 1\frac{1}{4}$ feet; join Ak and $x'''i = 1\frac{1}{4}$ feet; and so on. g, h, i, k, l, are the places found which the heads of the spectators should occupy, and show the elevation to be given to the seats successively.

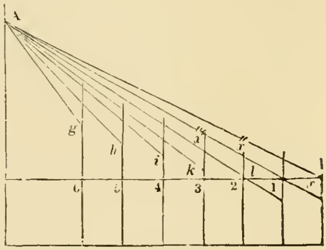

Fig. 1349.

2961. If the simple process described be accurately performed, the points which indicate the places of the spectators will lie in the branches of a very beautiful curve, which may be termed the *iseidomal* or the *isacoustic* curve, that is, *one of equal* seeing or hearing: it will be of the form in *fig.* 1850. A being the place of the speaker, and the heads of the spectators being placed on the line Amn, continued as far as the voice will reach, XAX being the axis of the curve, and YY its parameter. This curve has two branches on opposite sides of A, showing that if the building extend behind the speaker, or if the spectacle be visible or the sound audible on every side, the same may be continued all round. By means of this curve, the position of seats in a theatre may be satisfactorily determined.

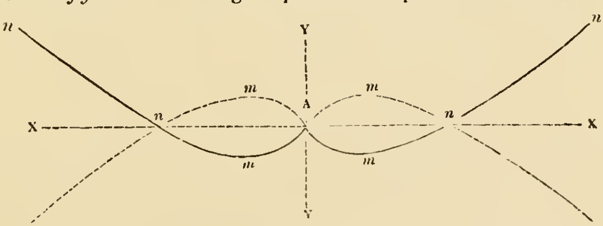

Fig. 1350.

2962. For any great assemblage, where it is desirable that one individual or group of individuals should be seen or heard, an amphitheatre of this form might be constructed from the surface of revolution generated by moving the curve round its axis, which would perfectly accommodate 10,000 individuals.

2963. According to the arrangement of London audiences, Mr. Wyatt calculates that a theatre consisting of three fourths of a circle on the plan, with a stage opening of 35 feet, will contain, in boxes in four tiers, four other boxes next the stage, a pit and two galleries, 2,869 persons, exclusive of four boxes in the proscenium, and fourteen immediately under the dress boxes. Perhaps no modern theatre can be required to hold above 2,500 people.

2964. We have already given some general hints relative to the form; we shall here add the author's view of this matter; and thereon he very properly says that, with reference to distinct sound, the safest method is to adopt a form known to be most capable of conveying sound with facility, to construct that form of materials that are conductors of sound, and to avoid all breaks and projections on the surface of that form, because they obstruct and impede the progress of the sound. It is well known that a circular enclosure without breaks possesses the power of conveying sounds with facility, as the whispering gallery in St. Paul's Cathedral; and that wood is an admirable conducting material for the purpose. Count Algarotti, in his treatise on the Opera, says, daily experience teaches us that in a box whose walls are naked, the singer's voice is reverberated in a particular manner; it sounds crude and harsh, and by no means flattering to the ear; the accents are quite lost if the box be hung with tapestry; whereas they are reflected full, sonorous, and agreeable to the ear when the boxes are only boarded, which is an obvious proof, and confirmed by experience, that the best lining for the interior part of a theatre is wood, as is said to have been the case in Her Majesty's Theatre, burnt in 1867.

2965. Whatever be the form of the theatre, it ought in every part to be limited in extent to such distance as the voice will distinctly reach; and the nearer that figure conforms to the proportions wherein the natural voice is heard in each direction, the more equally will the sound be heard in every part of the theatre. The experiments tried by Mr. Wyatt proved that the reach of the voice when moderately exerted was in the proportion of about two ninths further in a direct front line than laterally; and that being distinctly audible on each side of the speaker at a distance of seventy-five feet, it will be as plainly heard at a distance of ninety-two feet in front of him, declining in strength behind him so as not to be clearly heard at much more than thirty feet. "According," says Mr. Wyatt, "to these data, it would appear that the geometrical figure, which comes the nearest to the extreme limits of the natural expansion of the voice, is a semicircle of 75 feet radius, or 150 feet in diameter, continued on each side to the extent of 17 feet, or in the proportion of about two ninths of its lateral expansion (*fig.* 1351.) beyond the limits of the semicircle, and then converging suddenly until the two lines meet at C, behind the back of the speaker." But though the voice may be heard at these distances, it does not follow that a theatre of this extent should be erected; indeed, it would be absurd to do so, for the actor varies his place almost every moment; and as he removes from the centre, from which it has been assumed he is speaking, he would become inaudible to some parts of the audience as he receded from it. It is evident, therefore, in planning a theatre, the radius or semi-diameter must be so reduced as to bring the extreme distance at which he may in any case be placed within the space of 75 feet, that is, that when the speaker is placed at the extremity of either side of the stage, his voice may be heard by those seated on the opposite side of the house. In the diagram, the widest part of the theatre inscribed in the larger figure is 58 feet upon the level of the dress boxes; and allowing 9 feet 6 inches for the depth of the boxes on that floor, by means of a projection of 18 inches more than the boxes above, there will be 67 feet 6 inches between the extreme part of the stage on one side and the back wall of the boxes on the opposite side: but as the speaker is in no case placed at either extremity of the stage, and even if so situated, the distance between him and the opposite side of the house would be within 8 feet of the reach of his voice in its lateral direction, and 25 feet within its limits in a direct line, it hence appears that the circular is preferable to any other form; and if we fix a limit for the diameter of that form, we are in possession of the rules which limit the length of the theatre, or the distance from the front line of the stage to the boxes immediately in front of that line. Taking 75 feet for the distance at which the voice can be heard laterally, as the space between the front line of the stage and its immediately opposite boxes may occasionally be in the lateral direction of the voice, the greatest distance from the front wall of the stage to the back wall of the boxes opposite the stage should not exceed 75 feet, the limit of the voice in its lateral direction, because of the turns of head which he must often make for the business of the scene, when that which was opposite might become lateral; and thus those persons sitting in the opposite boxes would be 92 − 75 feet = 17 feet beyond the reach of his voice.

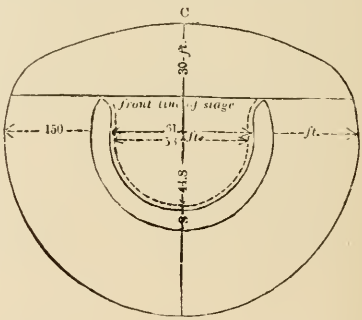

Fig. 1351.

2966. The use of a semicircle without modification would, however, involve the extension of the stage opening to an inconvenient width; and Mr. Wyatt very properly considers that the whole area of a theatre should contain little more than one-third of the space over which the voice can reach; "the one," he says, "being (independently of the space behind the back of the speaker) a superficies of 11,385 feet, and the other of 4003." This, he thinks, will compensate for the absorption of sound consequent on the number of the audience, the woollen garments they wear, and the state of the atmosphere, and would ensure a good hearing in every part of the house.

2967. According to the author's statement, he recommends that the distance from the front of the stage to the back wall of the boxes immediately opposite should be about 54 feet; in the old Drury Lane it was 74 feet, and in the old Covent Garden Theatre, built about 1730, it was 54 feet 6 inches. In the Opera House, built by Vanbrugh, it was 66 feet. At Milan it is 78 feet. At the old San Carlos, at Naples, 73 feet; and at Bologna, 74 feet. The distance in the late Covent Garden Theatre was 69 feet 8 inches, or nearly 16 feet more than it ought to have been. How, then, can people wonder at not seeing and hearing in such theatres? See also the Table given in subsect. 2958.

2968. In an opera house the band as it were sustains the voice, and the *spectacle* of the ballet is more addressed to the eye than to the understanding; but even in that the theatre is universally too large for the pleasure of those who appreciate properly what is transacted in the scene. It is satisfactory to know that the theatre, which in our introductory remarks was selected as a model, should coincide in the main points here in question with Mr. Wyatt's project. We are not certain whether he had visited it, but are certain that if he had he would not change his opinion.

2969. In respect of vision in a theatre, there can be no question that the semicircle gives the best chance for the whole of the audience; but the objections to it are, that it requires that either the stage opening should be of inconvenient width or that the size of the house should be too small. It is therefore, without modification, inadmissible. It is on this account that the ellipse, the horseshoe, and other flat-sided forms, have in later theatres been adopted, though it is manifest that a large proportion of the audience, says our author, "must be placed with their backs inclining towards the scene, and that in *all* of them (if the house be not of extremely *small* dimensions) the front boxes must be at a great distance from the stage; for in proportion as the sides shall approximate each other the front must recede, provided the circumference be not varied." The summing up of the question on this head is thus given by Mr. Wyatt: "There is no object connected with the formation of a theatre which, in all its bearings, is of more importance than that the part of the house which faces the scene should be within a moderate distance from the stage. Unless that be the case, it is obvious that a very large proportion of the spectators must be excluded from a clear and distinct view of that play of the features which constitutes the principal merit of the actor in many of the most interesting scenes." Mr. Wyatt does not believe that the height of the ceiling injures or affects the sound of the voice in the lower parts of the theatre, and observes that it must in every theatre "be much too high to act as a reverberator or sounding board to the lower parts of the house." But we do not agree with him on this point, and think we could refer him to more than one theatre in the metropolis which is defective in the conveyance of the sound from this cause alone. Besides this, we do not feel quite certain that the diagonal line drawn from the actor to the upper tier of boxes should not be the regulating distance, instead of the horizontal one which has been mentioned above.

2970. The following include many of the late suggestions for improving a theatre for the public, with those named in the former edition of this work. The mode of securing an exit free from fear, as well as from actual danger, has not been sufficiently faced; to provide against the disastrous results of a panic is a work of greater physical difficulty than to render a building fireproof. For a stage manager to appear every night and explain the available means of egress, the attendant at special doors to shout "here" on being named (and then to vanish for the rest of the evening), might satisfy some persons. The paramount consideration is a sufficiency of exits. Ingress and egress should be provided on each side of the house, so that whatever doors, passages, and staircases are placed on one side, there will be corresponding ones on the other. The spectators are thus divided and pressure avoided. The various tiers may in large theatres require more than one exit. It is important to prevent two crowds meeting in the street, such as the pit and the gallery, for the pathway becomes blocked. The difficulty on the ground floor is not great.

A "crush" room and waiting room are wanted, where those having carriages may wait, and those who are going to walk should be let out clear of them.

Whenever two passages meet, by which an exit takes place, from that point onwards the passage should be double the size, in order to let the crowd pass easily. The passages and staircases should be made direct, so that the crowd need not hesitate or stop the way at all. Large halls and staircases give rise to much lounging about, which is bad. Angles should as much as possible be avoided, as well as steps in passages, for which no excuse can be offered.

Sloping corridors have been advocated, but these are not praticable in some localities.

2970*a*. Every opening should be instantly and always practicable. All obstructions should be forbidden by law. Doorways ought not to be less than 6 feet wide, and the doors in most cases are best made sliding, or should open both ways, whether made of wood, wrought iron, cement, or terra-cotta. Messrs. Chubb have lately invented a clever contrivance for dispensing with an attendant at extra exit doors, consisting of a superimposed spring panel on the inside of the door, in which the lock is embedded; with a slight pressure the double doors fly open outward, and it is impossible to open them from the outside except by a key. Another invention is Walker's new safety and escape door, consisting of an inner frame of a door which will open outwards, the usual outer frame opening inwards. Present doors can be adapted to the invention.

2970*b*. Two stone or cement staircases to the galleries are essential, although one need only be used as an entrance. The staircases for the upper parts should be as wide and as easy as possible. Staircases should never be less than 5 feet wide (some writers say not more than 3 feet wide), the steps to be all straight, no winders, 12 inches in the tread, and not less than 6½ inches rise. They should be square, and be formed along an enclosed wellhole, if any; no windows should be permitted. A series of staircases absolutely disconnected with each other has lately been urged; the only doors on to it being at the top and bottom; an iron hand rail on each side. It has also been suggested that "there should be an equal number of steps to each flight, say thirteen for headway and space; the half-landing should be elliptical, every door should open both ways, and folding, with an easy fastener. All these, in any case, ought to be provided in new buildings, and as much as possible in old buildings" (W. H. White, F.S.A.) In large staircases, which consist of a centre and two side flights, the central one should be equal in width to the two side flights together. In calculating the width, regard should in some measure be had to the number of persons which the part they serve will contain. The broad, long gallery stairs at the Italian Opera House, Covent Garden, with the door near the top, show a good arrangement; they serve a double purpose, being at once a stairs and a waiting-hall. Communication with the wardrobe and the property rooms should be effected only by iron spiral stairs.

2971 The "crush room" or saloon at the Italian Opera House, Covent Garden, is situated at the top of the grand staircase, and forms an ante-room for all those passing to the boxes. At each end of the room are refreshment bars, to which all classes can thus resort, to the exclusion of none. Proper cloak rooms, with lavatories and water-closets, and refreshment rooms or bars, are necessary adjuncts. The various rooms required for the different departments will differ in every theatre, and the architect must obtain this information from the manager, before he sets to work. Near the orchestra is a waiting-room for the musicians, with cupboards for their instruments and coats, lavatories, &c. The music library should not be far away. A painting room over the ceiling of the auditorium was formerly usual, also at the back of the stage, where the artist can paint against the upright wall. The carpenters' shops are near to it. The property and armoury rooms must be near the stage; and a very well ventilated property shop. The theatre at Warsaw is said to be very complete in its wardrobes. The dressing-rooms for men and women should be kept apart; the tailors' and dressmakers' shop and wardrobes just above them, and fitted with lifts to send costumes up and down. Supernumeraries' and soldiers' dressing-rooms are also required. A large magazine near the stage, to keep the stock, scene cloths, and wings, properly fitted with racks and grooves, to stow them away in good order. Green-rooms, or waiting-rooms for men and women, so that no one should be on the stage who is not immediately concerned in the acting. The passages to have plenty of swing doors to prevent draughts. Proper apartments for firemen, hall porter, and housekeeper; kitchen and cellars; rooms for the manager, secretary, treasurer, chorus and solo practice; and lavatories, &c., throughout the house. A box office is usually provided near the chief entrance. Large and dry cellarage is a desideratum, in which to stow unused properties.

2971*a*. With the exception of the dressings and interior ornaments of the building, it would be possible, though perhaps somewhat inconvenient, to erect a theatre, though not perhaps absolutely fireproof, yet very secure against fire. Small theatres can be constructed of concrete and cement and terra-cotta, from its rude form as common brick, to stair treads; all the finishing touches would be of the ordinary materials of theatre building. Iron should never be depended upon except as a stiffener, and then buried in concrete. Stone should be excluded. Floors to be of cement floated on concrete, such as Wilkinson's improved granite concrete, having arched under surface between iron girders; also with iron ⊥ joists forming a parallel landing about 6 inches thick for landings and corridors; and for paving, &c.; steps can be formed of it singly for fixing, or formed *in situ* with moulded or plain sofite. As a matter of primary importance, the *auditorium* and the *stage*, with its accessory apartments, should be, as far as possible, two distinct structures, by making the wall between them of brick or concrete of sufficient thickness, and carrying it considerably above the roofs; it should have as few openings in it as possible, and all of them should be fitted with fireproof doors.

2971*b*. The proposed iron *curtain* or door to this opening, as at the Prince of Wales's Theatre, has been taken exception to, on the grounds that it is cumbersome, costly, absorbs heat rapidly, and is slow in working. A single plated curtain may be liable to buckle and to become a sheet of red-hot metal. At several theatres Messrs. Clarke, Bunnett & Co. have made a curtain of two screens of wrought iron plate $\frac{1}{8}$th of an inch thick, having an air space of 6 inches between them. The framework is formed of longitudinal and transverse T and angle iron, with external channel iron frame perforated, so that a current of air is continually passing between the two screens The top portion of the curtain is riveted to double wrought iron girders, secured to the head of an hydraulic ram, which, with the cylinders, are fixed and bolted to the proscenium wall, which varies in thickness from 14 to 18 inches. The movement of the curtain occupies about 30 seconds, in ascending or in descending; it is caused by pulling a lever, and the curtain stops automatically as it reaches the stage level. The lever can be worked from the stage or in the box-office, where it would be under the control of persons remote from the fire. The new iron curtain for the Comédie Française, by M. Edoux, can be set in motion from various parts of the theatre

2971*c*. A simpler form of curtain is composed of *asbestos*, at a less cost. At Manchester it has been applied at the Queen's Theatre, and at the Comedy Theatre. At the latter, the curtain runs in an iron groove closely fixed to each side of the brickwork. Being used nightly in place of the green curtain, it is constantly in working order, and can be dropped instantly. As to the curtain invented by Max Clarke, Mr. Emden considers that the *silicate cotton*, with which it is lined, has "no texture," and would consequently be liable "to sink down and become dense at the bottom of the curtain, while the top would be thin" and inefficient. He also considered that "no curtain has been invented which, in the ordinary theatre, would readily cut off the auditorium from the stage for more than a limited time." Messrs. Jones, however, state that with "a curtain properly constructed and lined with silicate cotton, the auditorium would be cut off from the stage for any length of time"—say a whole week (*British Architect*, March 30, 1888). A fireproof curtain put forward by Capt. W. E. Heath is described as "to be of asbestos cloth quilted on a strong canvas, rolled on a roller over a narrow tank of water, and in unrolling it passes under another roller at the bottom of the tank, thus rising perfectly saturated." A further description is given in the *Proceedings* of the Inst. of Brit. Architects of February 23, 1888, p. 174; and in the *Architect*, February 17, p. xiv. of Supplement.

Sufficient has perhaps not been said in this work as to the use of *silicate cotton* or *slag wool*, a pure mineral fibre, manufactured from iron slag, and quite incombustible. The best non-conductor of heat or sound yet discovered; as a non-radiator of heat or cold it is well established; and acts well in preventing the transmission of rarefied air, and arresting the spread of fire. It may be applied in a loose or natural form, as packing; woven with yarn or wire into sheets and strips; or felted in conjunction with wire netting, and put on similarly to ordinary felt. One ton will cover 1800 square feet of one inch thickness. It has been referred to, s.v. "Pugging," par. 2247. The advantages of this useful material are well described in the *British Architect*, April 6, 1888, on the reports of W. H. Stanger, F.C.S., with the experiments on its fire-resisting qualities.

2971*d*. Johnson's patent fireproof *wire lathing*, by which any partition or ceiling is rendered practically fireproof. *Metal laths*, on Edwards's patent, for use in the construction of fire-resisting ceilings, partitions, and doors. With his *dove-tailed corrugated iron sheets* (Hyatt's patent), for the same purpose, partitions are formed of Portland cement, concrete, and iron only two inches thick, the metal being completely protected. The "fibrous plaster" slabs of Wilkinson and Co., and of Hitchens, are intended for lining walls, ceilings, and floors for fireproof purposes, as noticed par. 2246*b*. Fireproof flooring of various sorts are noticed par. 1903*l*. *et seq.*

2971*e*. Wood can now be protected by various paints, for which reference can be made to the previous chapter, s v. PAINTING. Among them are, *Asbestos* fireproof paint, also water-resisting; colourless fireproof liquid "antiflame" for fireproofing fabrics; also a fireproof stain. Griffith's *pyrodene* fireproof paint is stated to render wood of all kinds and fabrics absolutely flame-proof by being simply soaked with it, and can be applied by anyone (par. 2273*j*). It was supplied to the Manchester Exhibition, 1887. Sir Seymour Blaine's fireproof paint was used (1887) at Edward Terry's new theatre in the Strand.

2971*f* The flimsiest material, as canvas, hangings, dresses, gauzes, &c, can now, by some solution, or by chemical treatment, also be rendered incapable of bursting into flame. The chemicals now most commonly used for this purpose are alum, borax, phosphate of soda, sal-ammoniac, and tungstate of soda (a "fireproof starch" prepared with it was first introduced by Donald Nicoll, ex-sheriff of London). This tungstate is considered the best, but as, if used singly, it is apt to become insoluble and to rub off, the addition of about 3 per cent. of phosphate of soda will diminish the risk. After the ordinary washing the goods should be immersed, before wringing and drying, in a solution containing 20 per cent. of tungstate, with a proportionate quantity of phosphate. Alum acts injuriously on the fabrics, especially if coloured. The others are cheap and commonly harmless.

2971*g*. The electric lighting system should be used in preference to the common gas system. It has been put up at the Savoy and the Criterion Theatres in London. Any gas burners should be properly protected, and no inflammable substance used.

2971*h*. An exit for smoke is advocated to be formed over the stage and over the proscenium. Firemen to be always in attendance with hose capable of being attached to hydrants fixed at convenient points, the water being supplied from a tank, and also from the water mains. The supply of water from large reservoirs provided in the upper parts of the building is a precaution which should never be omitted, though late fires have shown they are never in order when required. Pipes may be laid on from them to those parts, such as the carpenters' room, scene room, and painting-room, where fires would be most likely to break out, and where if they did break out they would probably be most dangerous. The necessary fireman's arrangements, with tell-tale clocks, &c., must be duly provided.

2971*i*. The "automatic sprinkler" is advocated by many, to be fixed over the flies and over the roof of the auditorium. They have been introduced at Mr. E. Terry's new theatre in the Strand. A hollow girder was advertised in 1861 by William Hood for holding water, which could be played on a fire without opening doors and windows to get at it. This was objected to for many reasons. This is now stated to have been "the ingenious invention of Jethro Robinson, who introduced the system to E. T. Smith, who used it at Astley's Theatre." Sinclair's "automatic sprinkler" has found favour lately in America, where it was adopted in various ways in warehouses. Insurance offices are said to have reduced the premiums in consequence of the use of the system. The water jets leave not a space outside the range of action. Once fixed they work of themselves when a temperature of 155 degrees arises where they are placed. All the apparatus is tested to a pressure of 500 lbs. to the square inch. Hannay's patent pneumatic principle is applied for charging the tubes with air as a protection against frost. Dick's *Fire Queen* extincteur is portable and self-acting; a gallon of its contents (water super-saturated with carbonic acid gas) is stated to be of more value than 30 gallons of water.

2971*k*. Mr. R. S. Ash, of Monaco, in a letter to the *Times*, August 1887, suggested that each theatre should have a fire-guard room, disconnected from the main building. From it a series of water pipes should pass to those parts specially menaced with fire. In response to an electric summons, the man in charge would be enabled to turn on one or more or all the pipes. One pipe should be specially prepared to saturate the curtain, or to act as a falling sheet of water if the curtain be up. People are rarely burnt to death in a fire, but are suffocated by the carbonic acid gas, the want of air, the smoke, or the intense heat. The pipes are not exposed to rust, it is stated, but unless they are used occasionally, it is feared they will rust. The guardian, it is supposed, will not experience the feelings of panic, and so will be prepared to obey the summons, and, "if the town supply of water is working satisfactorily, water would be delivered immediately where needed." The Asphaleia Company, on whose system the new Opera House in Buda-Pesth, and the Stadt Theatre at Hallé, have been rebuilt, have sent over a model of their system for exhibition; it was explained by Mr. Walter Emden, in his paper on *Theatres and Fireproof Construction*, read at the Society of Arts, January 25, 1888.

2971*l*. *A Modern Fireproof Theatre.* Edward Terry's, in the Strand. Almost the whole of the structural portions are of incombustible materials, and the limited amount of woodwork has been coated with fireproof paint. Ironwork has been thoroughly cased in concrete; the flights of stairs are generally of concrete, the corridors and floors chiefly of mosaic and cement, the panelling is in fibrous plaster, the gallery seats are of concrete. The isolation of the auditorium from the stage is complete. The proscenium wall rises some 20 feet above the auditorium roof, and iron doors close the openings between the two parts of the house, while an asbestos drop curtain, stretched on a metal framework, fills the proscenium opening, and is to be used as an ordinary green curtain. Behind this curtain, besides the fireproof nature of the materials used, all the woodwork has been coated with the fireproof solution called Pyrodene, prepared by Messrs. Griffiths Brothers. A thoroughly efficient system of automatic sprinklers and the electric light have been introduced. In both the roofs direct exhausts have been formed so as to carry off the ordinary heat, and in case of fire to draw up and extract the smoke and gases generated. An efficient hydrant service is provided all over the house. Although the theatre is only estimated to accommodate about 800 persons, exits have been provided for an assembly of 3,500 persons. Each part of the house has two or more exits, on two sides of the building. The corridors and gangways generally average 3 feet 6 inches to 4 feet in width. Plain directions are painted over each opening out of the auditorium, which openings can be available for ordinary use. The doors are fitted with a specially constructed lock, invented by Messrs Chubb and Mr. Walter Emden, the architect, which can only be opened from the outside with a key, a push from within opening it without difficulty. (*British Architect* for October 21, 1887, p. 295.)

2971*m*. There are now two new theatres in London which are considered fairly fireproof, and the "Court" at Sloane Square may be a third, as regards inflammability. As to any advance in plans and sections, there have been two plans prominently put forward this year (188-). One fathered by Mr. Henry Irving and Alfred Darbyshire, architect, drawings of which were published in the *Daily Telegraph* of October 29, 1887. Another was brought forward by R. Nevill, architect, in an extensive paper read at the Royal Institute of British Architects, Dec. 9, 1887 (discussion); and reported in *Proceedings* of Jan. 26 following. Another is by R. M. Roe, architect, printed in the *Proceedings* of Feb. 23. One by J. G. Buckle, architect, described in his work, and dedicated to Wilson Barrett. And lastly, by E. J. Tarver, architect, whose drawing is given in the *British Architect* for March 23. "Managers who contemplate new structures will have to form their own judgments and selections according to what may be the individual characteristics of the ground and neighbourhood. The Darbyshire plan is for a house detached all round, and with one gallery only. The Buckle plan is for a place where an underground house is needed. The Tarver plan is for a theatre above ground, adaptable to any site with one side open and the pit partly or wholly sunk."

2971*n*. Many of the bad features of construction and arrangement in modern theatre building are stated to be often due to the proprietors or managers; the architect has not his entire way in the matter. The expenses of a theatre are very great, and the amount of the ground rent is an inducement to the site being made as small as possible. Any extraneous provision must necessarily entail cost and occupy space.

2972. Foreign theatres are not considered good examples for the study of an Englishman, as the habits of the nations are so different. Abroad, too, theatres usually stand in open squares, as at Hanover, Munich, Berlin, Dresden, and Darmstadt; not in back streets and crowded thoroughfares. The new Opera House in Paris is essentially a government establishment, and would be wholly useless in England, where a theatre is a private speculation. It is an exaggerated and badly proportioned copy of Munich theatre, with which it will not compare for compactness. It seats only 2,000 people. One of the best studies of a house on the balcon principle is that at Mayence, given in Fergusson's *Handbook*. The theatre at Darmstadt has been the type for those at Munich, Berlin, Moscow, and other places. But their passages and front arrangements are all bad for use in England; the idea being to collect the people into the entrance hall for show. The Victoria theatre at Berlin is a double theatre, one for winter, with another for summer. The theatre at Dresden is round, following the form of the interior. It has been lately suggested that the orchestra floor should be much deeper than is usual, so as to hide the movement of the instruments, which often spoils the illusion of the scene. In England the stage is always made on the incline; in Germany it is flat, which arrangement has become very general abroad; as in the double theatre at Berlin.

2972*a*. We have availed ourselves largely of papers read at the Royal Institute of British Architects, in which will be found further remarks upon the lighting, ventilation, and fittings required for these structures: *On the Construction and Rebuilding of the Royal Italian Opera House, Covent Garden*, by its architect, Mr. E. M. Barry, Feb. 6, 1860; and *On the Construction of Theatres*, by Mr. Warington Taylor, Dec. 19, 1864. The *Builder*, *Building News*, *Architect*, and *British Architect* journals, contain descriptions of most of the numerous theatres erected at home and abroad of late years, and to these publications the architect can resort for further views on the several important points touched upon by us herein. The Metropolitan Board of Works has issued regulations for the proper working of theatres for the safety of the public. The Home Secretary, it is stated (1887–88), is preparing a measure of reform in respect of theatre construction and management, in consequence of the late serious accidents.

Sect. II.

HOSPITALS.

2973. The buildings called hospitals are devoted to the reception of those persons who may be suffering from disease or accidental injuries. To this sort of building will this section be chiefly devoted. The same name has been given to a building for the reception of travellers; for the temporary accommodation of the destitute; for the maintenance and education of youth; and for the support of meritorious and indigent persons; the hospitals of Greenwich and Chelsea are good examples of establishments of this latter class; the former building, indeed, adds to its other excellencies a magnificence in the architecture worthy the object, though not so originally intended. The Hôtel des Invalides at Paris is another monument worthy of all praise; and indeed we scarcely know a quadrangle more imposing than the court of this edifice with its double tier of arcades. This hospital contains 7,000 veterans, and has attached to it a library of 20,000 volumes. The building erected for the alleviation of incurable diseases is properly an *infirmary*, and might be termed an almshouse.

2973*a*. To the honour of most of the nations, but few cities are now unprovided with one or more hospitals. In Milan there are so many of such buildings that it has been remarked that no one has need to pay for advice. The governments of France, Russia, Germany, and Turkey support these institutions; but in England, with the exception of Chelsea and Greenwich Hospitals, they depend upon the charity and foundations of benevolent individuals, as at Guy's, St. Thomas's, Bartholomew's, and the many other hospitals of London. There is great reluctance often on the part of the poor to enter an hospital; and on this account we do not think that money ill bestowed which tends to impart to it an agreeable and cheerful exterior. It is almost unnecessary to insist upon the thorough warming and ventilation of the edifice: no means should be omitted to render the place wholesome, and to prevent infection spreading from one part to another. The hospitals of a city should be seated in the least populous part, if the health of the city be consulted, or in each suburb; in which latter case the establishment would be nearer the quarter it is to serve, and more accessible in a short time in the case of accidents.

2974. The plans of some of the finest (but old) hospitals in Europe are given in Durand's *Parallèle d'Édifices*, 1801-9. Among them is that of Milan. It was commenced by Filarete in 1457, and is of course in a half-Gothic style. The men are placed to one side of a central cloistered court, which is 210 feet wide and 243 feet long in the clear, in a quadrangle 263 feet wide and 279 feet long, the cells being placed in the form of a cross of that size and 30 feet wide. In the intervals of the cross are four courtyards, on whose remaining sides are rooms for the assistants. On the opposite side of the cloistral court are placed the women. In the middle of the narrow side of the great cloister, opposite the entrance, is a church, which serves for the whole establishment. The cloisters of the large court and main body of the building are in two stories, so that they form galleries of communication. This edifice has served for a model to many others of an early date, but it is perhaps now considered good only for the pleasant promenades supplied by the corridors. The hospital of La Roquette, in the suburbs of Paris, designed by Poyet, was conceived on a magnificent scale, and was admirably planned. In this design each room, as well those on one side of the establishment for the males as those on the other side for the females, is appropriated to one particular disease. Each of these rooms is about 32 feet wide and 30 feet 6in. high. Behind the beds (which are in two rows in each room) runs a passage about 3 feet 4 in. wide, which removes them so much from the walls, and allows therefore of the necessary waiting on the invalids, and hides the wardrobe attached to each bed in the window recesses. Above these passages, which are about 6 feet 6 in. high, is arranged on each side a row of windows, by which ventilation as well as light is obtained. The ground floor contains the halls and offices necessary for such an establishment. The designs for this building were made about 1788, on the instructions drawn up, after several years' investigation, by a number of the most skilful and learned medical men of France, so as best to unite health and convenience in such an edifice. One of the conditions prescribed by their programme was the complete insulation of each apartment, as well as an easy communication by covered galleries round the building, and these were required to be of such extended dimensions that the air around should be unobstructed and circulating in every part with freedom, thus affording a wholesome promenade for the patients. The plan, however, was not continued.

2975. In France the hospital of St. André at Bordeaux, designed 1825-9 by J. Burguet for 728 patients, was considered so good in its arrangements, that they were followed in the hôpital du Nord, afterwards Lariboisière, at Paris, designed 1846-54 by M. P. Gauthier for 606 beds. This plan of making a distinction between dormitories for the comparatively healthy, and wards for the sick, and abolishing all communications by passages and stairs between wards, was the important feature of such establishments. This hospital has been the model for those designing later works.

2975a. The erection of the Victoria general military hospital at Netley, commenced in 1856 by Mr. Mennie, led to so much correspondence, investigation, and contradiction, that the student is best referred to the journals between 1856 and 1858, when a plan was finally adopted, which met with the approval of Miss Nightingale. It is said to have provided averages of 1,315, 1,406, and 1,800 cubic feet per patient. The communication of the wards with a general corridor and with the water-closets has been alleged as its chief fault, but its plan should be compared with others regarded as models at the time, to obtain a notion of the great stride in the planning of these buildings. The controversy continued with great advantage, as it produced plans of other hospitals considered as models on various points, up to 1862, when the military authorities issued their official plans for hospitals.

2975b. In 1865 the Société Chirurgicale de Paris issued the then recent exposition of scientific views with regard to the reconstruction of the hôtel-Dieu and of hospitals generally. It demanded a minimum of 538 square feet per bed as clear space of site *outside* the building; a maximum of two stories of wards, and of 200 to 300 beds in each hospital, considering that two small hospitals are preferable to one equal to their united capacity, because the periodical and regular vacancy of wards has been attended with good results. It considered that small wards of 15 to 20 beds are to be preferred to larger wards, and that the building should not only possess a day ward for convalescents, but another for their meals. The wards should be separated by landings and rooms for attendants. They should be completely isolated blocks, all having the same aspect, and being exposed without any obstruction to the rays of the sun, to the effects of rain, and to the action of the wind; and they should be arranged in a single line or in parallel lines at intervals of 260 feet or 330 feet, in order to obtain an efficient separation and a sufficient current of air. Finally it declares that no emanation from refuse or effluvium is to be tolerated; and that no abundance of artificial ventilation compensates for an insufficient natural ventilation. (The *Builder* journal, 1865, vol. xxiii. p. 170.)

2975c. It has been strongly recommended that ward space for each patient, approaching as near as circumstances allow to 2,000 cubic feet, with 144 square feet of floor, should be allowed for each bed; the ventilation to be obtained on the *natural* system; yet others are in favour of artificial ventilation with an *ascending* current; others for a *descending* current, which is adopted at the hôpital Lariboisière to the extent of 12 to 14 cubic feet per minute; at the hôpital Beaujon 24 to 36 feet, which was inefficient; and at Guy's hospital 40 to 60 feet, which was successful. Fireplaces alone are considered inefficient for the purpose.

2975d. The opinions expressed by the writers in the *Builder* journal during 1856-61, result in describing the correct plan as consisting of detached wards separated at least by lawns twice as wide as the height of the buildings, each ward being enclosed by four separate walls, and having windows on two sides that open from the ceiling with double sashes glazed; water-closets under a separate roof and divided from the wards by a corridor; the corridors continuous and close for 7 feet high, but open above with piers or columns; galleries, with seats in the gardens; comfort of nurses' rooms; and care as to finish of floors, &c. Besides the above publication and various parliamentary reports, the works by Husson, *Études sur les Hôpitaux*, 4to. Paris 1862, and by Jaccoud, *Nouveau Dict.* &c., vol. xvii., 8vo. Paris, 1873, both contain plans and valuable suggestions.

2975e. The new building of St. Thomas's Hospital in London, designed 1865-71 by Mr. Henry Currey, has been described by him in a lecture read at the Royal Institute of British Architects, January 23, 1871. It may be supposed to exhibit all that is requisite to be provided in an hospital of a metropolis, for the accommodation of 600 patients. It is arranged on the pavilion principle, now generally admitted to be the best for hospital purposes, and being placed in a row is specially suitable for the space of ground on which the edifice is erected. The corridor, of two stories, with a flat roof over, connecting the ends of each of the six pavilions, is 900 feet long; they are placed at the distance of 125 feet from each other, their axis being due east and west. The wards are 28 feet in width by 120 feet in length, and 15 feet high, in which are placed twenty-eight beds on each of five floors, giving a cubic capacity of 1,800 feet for each patient, the beds being placed 8 feet from centre to centre: small wards for two beds, contiguous thereto, separate special cases from the others. Adjoining the passage are placed the sisters' room, the ward kitchen, and a room for medical officers. The staircases are wide, and have a tread of $12\frac{1}{2}$ in., with a rise of $5\frac{7}{8}$ in. The well-holes are occupied by lifts and ventilating shafts. The water-closets, lavatories, and a bath-room are attached to each ward, and cut off from it by intercepting lobbies, with windows on both sides. There also are the foul linen and dust shoots communicating with the basement for external removal. Dormitories for the nurses and servants are placed in the attic story. The wards have flat ceilings, and the windows are carried up to it, to ensure a thorough change of air in the upper part. The sixth or last pavilion is designed for special diseases, and the wards are therefore smaller. The floors of the wards are laid with wainscot as being non-absorbent, and tongued with hoop iron, and prepared for waxing and polishing; the walls are plastered with Parian cement with the same object, the finishing coat of which is tinted to avoid the glare of the white. The windows are constructed in three divisions, the lower part being hung to open in the usual way, and the upper sash drops to the depth of the transom. They are glazed with plate glass.

2975*f*. The general entrance to the hospital is placed in the centre, and the hall forms the substructure of the chapel. Near to it is the kitchen department. On the first floor are the resident medical officer's department, two operating theatres, &c., placed between the ends of the blocks next the side public thoroughfare. The administrative department is placed at the end, adjoining the bridge, in a detached building, and comprises the governors' hall, committee room, counting-house, clerk and surveyor's offices, the treasurer's residence, and many other apartments necessarily required for so large an establishment. The training institution for nurses adjoins the matron's residence between the first and second wards, and affords accommodation for forty probationers, each having a separate bedroom.

2975*g*. *The Warming and Ventilating Arrangements.*—For the latter, the natural system is depended upon as much as possible, but in order to change the air during cold and boisterous weather and at night, a main extracting shaft is carried up in the well-hole of the staircase, and in this is placed the smoke flue from the boiler, consisting of a wrought iron tube 15 in. in diameter. In the upper part of this shaft is also placed the hot-water cistern. Shafts are carried from the ends of all the wards, both at the ceiling and floor level, and from the centre of the stove hereafter mentioned, communicating with a horizontal trunk in the roof, which trunk is connected with the heated shaft previously referred to. To replace the air thus extracted, fresh air is introduced by means of zinc tubes laid between the "Dennett arching" and the floor boards, communicating with the stoves and hot-water coils, the whole admitting of regulation by valves. The wards generally are warmed by three open fireplaces, aided in cold weather by an auxiliary system of hot water. These stand in the middle of the wards, with vertical shafts, an inner one of wrought iron 15 in. diameter, and an outer case of cast iron, the space between forming a ventilating shaft, which is connected with the main trunk in the roof. The smoke tube is carried down to the basement, from whence it can be swept. The ventilation of the lavatories and water closets is entirely independent of the wards, and is carried up the shaft in the river turret. That of the medical museum and school buildings, placed beyond the hospital buildings, is on the same general principle. the ventilating and smoke shaft being contained in the tower at the southern end of the building. There is an hydraulic lift to each pavilion.

For the numerous other details the student must be referred to the paper itself, which contains a plan and perspective view of this admirably designed building.

2975*h*. The sixth report of the Local Government Board contains the report made by Dr Bristowe and Mr. Holmes on the inspection of all hospitals in Great Britain and Ireland.

2975*i*. The first *circular hospital* erected in England was the Miller Memorial Hospital, at Greenwich, designed by Messrs. Keith D. Young and Henry Hall. The Burnley hospital was another, and then the Hastings, St. Leonard's, and East Sussex hospital, which was opened in September, 1887 (illustrated in *British Architect*, January 28, 1887; and *Builder*, p. 180). The Antwerp hospital, the hospital at Hampstead, and the circular hospitals for the army deserve inspection; but this Hastings hospital is the most typical, and probably the most complete building on the circular principle which has yet been erected in this country, or indeed anywhere.

2975*j*. In the *rectangular* ward, where the nurse's room is at one end, while at the other is possibly placed the worst "case," that is, the patient who is most severely ill, the nurse, as the day goes on, must find the whole length of that ward a great strain upon her physically. In the *circular* ward, the nurse can see all the beds except one—certainly except two—in the whole ward from any point in it; and she has to travel the shortest possible distance to get to any one patient who may need her services at any given time. It must not be regarded as the most perfect system of hospital construction; it is one type of construction suited to special cases, and one which deserves a fair and prolonged trial. (Henry C. Burdett). Professor Marshall and P. Gordon Smith, *Circular System of Hospital Wards*, 8vo. 1878.

2975*k*. Village Hospitals.—Each village ought to have the means of accommodating instantly, or at a few hours' notice, say four cases of infectious disease, in at least two separate rooms, without requiring their removal to a distance. A decent four-room or six-room cottage, at the disposal of the authorities, would answer the purpose. When such provision as this has been made, and cases of disease in excess of the accommodation occur, the sick should not be crowded together, but temporary further provision be made for them. The most rapid and the cheapest way of obtaining this further accommodation may often be to hire other neighbouring cottages; or, in default of this, tents or huts might be erected upon adjacent ground. The regulation bell tent is 14 feet diameter, 10 feet in height, the area of base is 54 square feet, and cubic space 513 feet. The regulation hospital marquée is 29 feet long, 14 feet wide, with side walls 5 feet 4 in., height to ridge 11 feet 8 in., giving a cubic capacity of a little over 3,000 feet.

Mr. Geo Buchanan's report (1888) to the Local Government Board, containing suggestions as to the provision of isolation hospital accommodation, with plans, is of high importance.

2975*l*. Convalescent Hospitals, erected in the country for the recovery of patients after they have been treated for their diseases in town hospitals, and then only requiring a short time of change and fresh air before returning to work, are now considered desirable adjuncts to hospital treatment.

2975*m*. An *Imbecile asylum* is provided at the Poplar and Stepney sick asylum; Austin Bros., architects.

Sect. III.

INFIRMARY.

2976. The word infirmary appears to have two opposite meanings. In one it designates a place for aged, blind, or impotent persons; the other, a place for the cure of wounded or diseased persons; such are hospitals, which buildings were originally called infirmaries. The infirmary proper is the place appropriated to the sick in a large establishment, such as an asylum, a prison, a workhouse or a school. Greenwich Hospital has an infirmary attached to it.

2976*a*. Workhouse infirmaries were until lately greatly condemned for the want of accommodation; the want of classification and separation; imperfect ventilation, owing to the insufficient supply of cubic space, sometimes aggravated by essential defects in construction: 500 cubic feet per bed only being provided where 1,000 feet at least is required; insufficient washing arrangements; and other comforts for the patients, as well as for the nurses, and officers, neglected.

2976*b* The requirements of the Local Government Board at Whitehall for a provincial workhouse sick ward or infirmary, comprise a separate building from the workhouse itself. The sick should be divided into: 1. Ordinary sick of both sexes; 2. Lying-in women, with a separate labour room adjoining the lying-in ward; 3. Itch cases of both sexes; 4. Dirty and offensive cases of both sexes; 5. Venereal cases of both sexes; 6. Children of both sexes; and, lastly, 7. Fever and small-pox cases of both sexes. Classes 1 to 6 may be accommodated in the infirmary; separate entrances for 3 and 5; a detached building with separate rooms for 7. In the case of large infectious wards, there should be a detached washhouse, otherwise a shed containing a copper, in which the linen may be disinfected by boiling before being taken to the general laundry. The length of dormitory wards should be calculated according to the following minimum wall-space for each bed, in addition to that occupied by doors or fireplaces, viz.: for *inmates in health*, adults 4 feet; women with infants 5 feet; children, single beds 3¾ feet, double beds 5 feet; and for sick, itch, and venereal cases, 6 feet; for lying-in, offensive, fever, and small-pox cases. 8 feet. The day rooms should afford accommodation for not less than one-half of those who occupy the day and night rooms. A minimum of 20 feet floor space should be allowed for each sick person. Sick wards should be 24 feet wide and 10 to 12 feet in height. Infectious wards should be 20 feet wide and 12 feet in height, and should have external windows on their opposite sides. The gangways should be in the centre of the wards; but if a sick ward holds only one row of beds, which is not recommended, it should be at least 12 feet in width, and have the gangway and fireplace on the side opposite to the beds. The dimensions above given are considered the most economical, and at the same time the most convenient for the various classes of wards. But where they are not so constructed, there should be

	Floor space.	Cubic space.
In ordinary dormitories	36 feet	360 feet
In sick wards	60 ,,	600 ,,
In lying-in, offensive, and infectious wards .	80 ,,	960 ,,

One room or a suite of rooms communicating by a gangway should rarely exceed 90 feet in length. Such a room or suite of rooms may be connected with a similar suite in the same line by the central part of the building, in which would be placed the apartments of the nurses, and other offices; or they may be placed in blocks, parallel or otherwise, connected by a corridor. Nurses' rooms and suitable kitchens and sculleries should be provided. Special means of ventilation, apart from the usual means of doors, windows, and fireplaces, should be secured. Air bricks are suggested, 9 in. by 3 in. or 9 in. by 6 in., covered on the inside with metal, having perforations of about one-twentieth of an inch in diameter inserted about 8 feet or 10 feet apart in the upper and lower parts of the external wall. The lower set may be fitted with hit-and-miss gratings, made to lock so that they may be regulated only by the proper authorities. Ventilating fireplaces are useful. Where hot-water pipes are used, they should run round the wards, and a portion of the fresh air pass over them. If no other system of warming be adopted, fireplaces should be provided in all inhabited rooms, say a fireplace to each 30 feet of length. The walls of all sick wards should be plastered internally.

2976*c*. The infirmary for the Central London District Schools at Hanwell, designed 1865 by Mr. Gale, accommodates 100 children of each sex. It forms three sides of a quadrangle, and consists of ten wards, five on each floor. Each ward has a nurses' room, two fireplaces, and set of bath room, water closets, &c.; six of the wards have double sets with two entrances for the convenience of subdivision. The corridors are all provided with open fireplaces and draw-off sinks, with supply of hot and cold water. In each corridor, at a central point between the various wards, is a lift by which provisions, &c., are sent up direct from the kitchen.

2976*d*. The infirmary at Blackburn, erected 1858 by Messrs Smith and Turnbull, may be described as arranged on the pavilion principle, consisting of a main corridor, on each side of which are placed eight wards alternating, each holding 8 beds in a ward, with their own set of bath rooms and water-closets. In the middle and separating the set is the building devoted to a chapel, the necessary offices and apartments, and the operating room, with two wards of four beds in each.

Sect. IV.

PRIVATE BUILDINGS.

GENERAL OBSERVATIONS.

2983. Private buildings differ in their proper character from public buildings as much as one public building differs in character from another not of the same kind. The ends in both, however, in common, are suitableness and utility. The means are the same, namely, the observance of convenience and economy. The same elements are used in the formation of one as of the other; hence they are subject to the same principles and the same mechanical composition. Distribution, which is usually treated distinct from decoration and construction, and very improperly so, as applied to private edifices, is conducted as for public buildings, that is, as we have said, with a view to utility and economy.

2984. If the student thoroughly understand the true principles of architecture,—if he possess the facility of combining the different elements of buildings, or, in other words, fully comprehend the mechanism of composition, which it has in a previous part of this Book (III.) been our object to explain, nothing will remain for him in the composition of private buildings, but to study the special or particular conveniences required in each. There are some quaint old aphorisms of Dr. Fuller, prebendary of Sarum, which are so applicable to all private buildings, that we shall not apologise for transferring them to our pages.

2985. "First," he says, "let not the common rooms be several, nor the several rooms common; that the common rooms should not be private or retired, as the hall (which is a pandochæum), galleries, &c, which are to be open; and the chambers, closets, &c., retired and private, provided the whole house be not spent in paths. Light (God's eldest daughter) is a principal beauty in a *building*; yet it shines not alike from all parts of the heavens. An east window gives the infant beams of the sun, before they are of strength to do harm, and is offensive to none but a sluggard. A south window in summer is a chimney with a fire in it, and stands in need to be screened by a curtain. In a west window the sun grows low, and over familiar towards night in summer time, and with more light than delight. A north window is best for butteries and cellars, where the beer will be sour because the sun smiles upon it. Thorough lights are best for rooms of entertainments, and windows on one side for dormitories."

2986. "Secondly, as to capaciousness, a house had better be too little for a day than too big for a year; therefore houses ought to be proportioned to ordinary occasions, and not to extraordinary. It will be easier borrowing a brace of chambers of a neighbour for a night, than a bag of money for a year; therefore 'tis a vanity to proportion the receipt to an extraordinary occasion, as those do who, by overbuilding their houses, dilapidate their lands, so that their estates are pressed to death under the weight of their house."

2987. "Thirdly, as for strength, country houses must be substantives, able to stand of themselves, not like city buildings, supported and flanked by those of their neighbour on each side. By strength is meant such as may resist weather and time, but not attacks; castles being out of date in England, except on the sea-coasts, &c. As for moats round houses, 'tis questionable whether the fogs that arise from the water are not more unhealthful than the defence that the water gives countervails, or the fish brings profit."

2988. "Fourthly, as for beauty, let not the front look asquint upon a stranger, but accost him right at his entrance. Uniformity and proportions are very pleasing to the eye; and 'tis observable that freestone, like a fair complexion, grows old, whilst bricks keep their beauty longest."

2989. "Fifthly, let the offices keep their due distance from the mansion-house; those are too familiar which presume to be of the same pile with it. The same may be said of stables and barns; without which a house is like a city without works, it can never hold out long. It is not only very inconvenient, but rather a blemish than a beauty to a building, to see the barns and stables too near the house; because cattle, poultry, and suchlike must be kept near them, which will be an annoyance to a house. Gardens ought also to be disposed in their proper places. When God planted a garden eastward, he made to grow out of the ground every tree pleasant to the sight and good for food. Sure he knew better what was proper for a garden than those who now-a-days only feed their eyes and starve their taste and smell." The same honest old dignitary (would we had some such in these days!) says, "He who alters an old house is ty'd as a translator to the original, and is confined to the fancy of the first builder. Such a man would be unwise to pull down a good old building, perhaps to erect a worse new one. But those who erect a new house from the ground are worthy of blame if they make it not handsome and useful, when method and confusion are both of a price to them."

Sect. V.

PRIVATE BUILDINGS IN TOWNS.

2990. The common houses of the town are not those which will engage our attention. In London, and indeed throughout the towns of England, the habits of the people lead them to prefer separate houses for each family, to one large one in which several families may be well lodged, or, in other words, they prefer rows of mean-looking buildings, with holes in the walls for windows, to the palatial appearance which results in Paris and most of the other cities in Europe, from large magnificent buildings with courts, and capable of accommodating a number of different establishments. The section will be confined chiefly to the arrangement of a house of the first class; and from what will be said, sufficient hints may be drawn for the composition of those in a lower class.

2991. The private buildings in a town are often in their composition beset with difficulties which do not occur in those of the country, where the extent of site is freer and ampler. These, therefore, may be isolated, and receive light from every side. Their offices may be separated from the main house, and the parts may be disposed in the simplest possible manner; but in cities the site is generally more or less restricted, often very irregular in form, and generally bounded by party walls. Yet, with all these obstacles, it is necessary to provide almost as many conveniences as are required in a country house; whence the disposition cannot be so simple in its application as where there is no retraint. All that can be done is to make it as much so as the nature of the spot will permit, and to produce the maximum of comfort which the site affords.

2992. Nothing must be considered below the attention of an accomplished architect, nor anything above his powers; he ought as cheerfully to undertake for the proprietor the conduct of the meanest cottage as of the most magnificent palace. Little will be requisite to be said on the common houses of London, or other cities and towns, in which there are seldom more than two rooms and a closet on a floor, with an opening behind. These may be varied; but the general mode is to construct them with a kitchen in a floor sunk below the ground, and a room behind, serving for a variety of purposes; an area in front, with vaults under the street, and the same often in the rear of the house. The space opposite the descending stairs will form a dark closet; and the privies, and wine and beer cellars, with other small offices, are provided in the vaults. On the ground floor there is rarely more than a passage on one side, which conducts to a staircase; and this requiring more width than the passage itself, the best room on this floor is placed in front, and the back is a smaller room, often opening on a small light closet still further in the rear. A yard is supposed behind, by which light is obtained for the back room. On the one-pair and other floors the passage becomes necessary as an access; the drawing or front room therefore runs over it, and becomes larger, capable, in the upper floors, of subdivision for bedrooms, or other purposes, as may be required; and the back rooms with their closets, if carried up, follow the form of those on the ground floor. Though little variety may be the result of the restricted space to which this species of house is usually confined, the addition of four or five feet either way will enable an intelligent architect to throw in closets and other conveniences which are invaluable, as relieving a small house from the pressure which otherwise will exist in the different apartments. But this will be obvious to the practical man, unless he walks about blindfold. The houses we have just described may stand upon a site of about twenty feet by thirty feet, independent of the vaults in front and rear, and the back light closet, which is an invaluable appendage to a house of this description; which is the scale of a second-rate house.

2993. Of the next higher rate of house the varieties are too great to be described, because the extent of the largest arrives at what would be called a palace on the continent. But, taking a mean between that just described and that last named, we may take one similar to a moderate one in Portland Place for example In such a one must be provided, on the basement or sunk story, vaults under the street for beer, coals, wood, privies, and the like, the refuse or dust of the house. The body or corps de logis on this floor must contain housekeeper's room, servants' hall, rooms for butler and head footman, wine cellar, closets for linen, strong room for plate, with closets and other conveniences for the household. The ascending staircase must also have a space set apart for it. In the rear, under the open area behind, will be placed a kitchen, scullery, and the larder, with the other appendages of this part of the household; an area, covered, where the communication with the rest of the floor is made between the body of the house and the offices in question Beyond the kitchen are often vaults (though the disposition is sometimes otherwise), over which the stables and coachhouses are placed, opening on the ground floor on to a mews parallel to the street in which the house is situate. The ground floor of this disposition has usually a dining-room in front, with a good-sized hall at its side, leading to a staircase which ascends in direction of the long side of the house; and this is necessary when the rooms above are to communicate by folding doors. In some old houses, however, the staircase ascends between the front and back rooms, and a back staircase is provided by the side of it. But more commonly this is placed beyond the principal stairs, to allow of throwing the drawing-rooms into one. In rear of the dining-room is often placed a library for the gentleman of the house; and beyond this, and further than the back stairs, when the lateral staircase is used, a waiting-room, at the rear of which a water-closet may be placed, with a door from it to the area over the kitchen; or there may be a communication of this sort from the waiting-room, which may serve the purpose of access to the stables. On the one-pair floor the disposition will be two drawing-rooms, a boudoir over the waiting-room, and beyond this a water-closet. On the two-pair floor two bed-rooms, each with a dressing-room, or three bed-rooms and one dressing-room, and a bath-room and water-closet. Above this four bed-rooms and closets may be obtained; and, if necessary, rooms in the roof in addition. For a good house of this class, with the offices, the plot of ground should not be much less than 100 feet by 30.

2994. Of the first-class of houses, as a model may be taken the town-house, in Piccadilly, of his Grace the Duke of Devonshire, which, with the offices and court-yard in front, covers an area extending about 231 feet towards the street, and 188 feet in depth, whereof the house itself occupies a frontage of 163 feet and a depth of 188 feet, and opens on to a large garden in the rear. On the east side of the court-yard are disposed the kitchen and other domestic offices, opposite whereto, on the west side, stand the coach-houses and stabling. The basement of the house contains apartments for the various persons attached to such an establishment. The principal floor, to which the ascent is by an external staircase, contains an entrance-hall, 35 feet by 30 feet, and communicates to an apartment on the west side, 33 feet by 22 feet, leading to the south-western corner room, which is 20 feet square. On the north of the last is a room, making the north-west angle of the building, and this is 40 feet by 20 feet. On the east side of this last, and facing the north, is a room 33 feet by 23 feet, and in the centre of the north front, corresponding with the width of the hall, is an apartment 30 feet by 23 feet 6 inches. To the east of the last is a room 33 feet by 24 feet, and east of that, forming the north-east angle, is a small room 20 feet square. Thus far these rooms, seven in number, are all *en suite*, but this is in some measure interrupted by the remainder of the east flank, which is filled with three smaller rooms. To that of them, however, at the south, which is 20 feet square, a passage is preserved, and from that you enter another room, 23 feet by 22 feet, which once more brings you back to the hall. The staircases are between the north and south rooms on each side of the hall. Above this floor are the lodging rooms, &c. The superficial area of all the reception rooms on the principal floor, added together, amounts to 5708 feet. Plans and elevations are given in the *Vitruvius Britannicus*, which contains other town houses of importance of the period, well worth the student's attention.

2995. Burlington house, Piccadilly, before its late partial demolition, was in some respects—for instance, in its beautiful semicircular colonnade in the front court—considered superior to that just described. It can be hardly necessary to add that, in such edifices, rooms must be provided for steward, butler, housekeeper, stillroom-maid, valets, ladies' maids, servants' hall of good dimensions, &c., for a muniment room and for plate, both of which must be fire-proof. Baths also should be provided on the chamber floor, with other conveniences which will occur to the architect. The rooms for pictures, if possible, should be on the north side of the building. The illustrated journals of the present day show the great changes which have been made in the requirements, and the size and number of the apartments, of all grades of society.

2995*a*. During the last thirty years, however, flats, or residences in flats, have been largely adopted, and the system appears to be gaining ground in large towns for many classes of society. The paper by Mr. W. H. White, *On Middle-class Houses in Paris and Central London*, read November 19, 1877, at the Royal Institute of British Architects, is suggested for perusal.

Sect. VI.

PRIVATE BUILDINGS IN THE COUNTRY.

2996. Of first-class private buildings in the country, we apprehend we cannot furnish better hints than by describing that of Kedlestone, in Derbyshire, erected for Lord Scarsdale by Robert Adam. There are others which are larger, but we do not think any superior in distribution and effect. The plans and elevations of it are to be seen in the *Vitruvius Britannicus* above mentioned. The main body of the house M (*fig.* 1352), is about 136 feet by 105 feet; and at each angle are quadrants of communication to the four wings A, B, C, and D, which are each about 70 feet by 54 feet. On the basement story of the main building are a large and small sub-hall in the centre, the former 67 feet 3 inches by 42 feet, and the latter 42 feet by 40 feet 7 inches. On the right of these are disposed a butler's room, 22 feet 6 inches by 17 feet 9 inches; a housekeeper's room, and a steward's room, 30 feet by 21 feet 3 inches. On the left, a bath, a gun-room, 23 feet

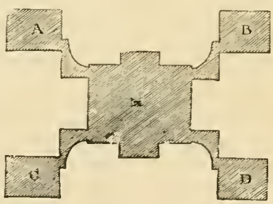

Fig. 1352.

9 inches by 23 feet 7 inches; a smoking parlour, 28 feet by 17 feet 9 inches; a boot-room, 22 feet 6 inches by 17 feet 9 inches, besides closets, staircases, &c., on either side. The wing B contains the stables, a chapel, and other apartments. C, sleeping and other rooms, eight in number, with a staircase which conducts to the corridor in the corresponding quadrant. D contains the kitchen and its requisite accessories, and a servants' hall. This wing has also a staircase to its corresponding corridor in the quadrant, which attaches it to the main body. On the principal story, the main body M has at the entrance, which is in the centre, and approached by a noble flight of steps, a magnificent hall, 69 feet 3 inches by 42 feet, at the end whereof is a saloon 42 feet diameter. To the right, entering from the hall, is the principal staircase, beyond which, laterally, is a bed chamber 33 feet by 22 feet, with its accessories; and on its end, towards the back front, are ante-rooms, and towards the front the dining-room, whence by the corridor is access to the kitchen in the wing D, and from the ante-rooms above mentioned the corresponding corridor on that side leads to a conservatory in the back front of the wing, and the upper part of the chapel. On the left-hand side of the hall, with windows in the left flank of the main body, is the drawing-room, 44 feet by 28 feet; at the end towards the rear is a library, which is continued in the corridor leading to the wing A, wherein is a music *gallery*, 66 feet by 18 feet, with other rooms and a staircase. On the end of the drawing-room, towards the front, is a music *room*, 36 feet by 24 feet, whence the corridor leads to Lord Scarsdale's bedroom, 18 feet square, with dressing-rooms, and the lady's library, which, on this floor, are in the wing C. The wing D is occupied by the upper part of

the kitchen, a laundry, 35 feet by 18 feet, and some bedrooms, to which access is by a gallery over part of the kitchen. The main body and wings contain a story over what has been last described, chiefly for chambers. We have before (in the First Book, *figs.* 221, 222) noticed the splendid hall and saloon, which occupy the height of the whole building, and are, though somewhat faulty in detail, very finely-conceived and well-proportioned apartments. The former is 40 feet high to the top of the cove, and the latter 55 feet to the level of the eye of the dome. Though the elevations exhibit defects, we are not inclined to quarrel with them in a dwelling which deserves rather the name of a palace than of a country house.

2997. England abounds with country seats of this class; among them is Holkham, which has already been mentioned in the First Book (511); but we know none for disposition that can claim superiority over that which we have above described at length, from which the student may derive much information on the requirements in a mansion of the first class. It is to be understood that we here intend modern buildings. The houses of the times of Elizabeth and James are many of them magnificent structures, but the comfort introduced into houses of later date leaves them, independent of their picturesque beauty, far behind the buildings of Kent, Carr, James, and many others. Blenheim is monumental in its design, and properly so, and hence does not fall within the category of this section.

2998. There are, of course, many intervening degrees between the mansion we have just described and the villa of the retired banker or merchant: it would be impossible to state them in detail. We have given the maximum in the above case, and we shall now give the minimum for the class last mentioned.

2999. The smallest site of ground on which a villa can be well designed is, supposing it an oblong, about 80 feet by 56 to 60 feet. This on the principal floor will admit of a hall, a saloon or ante-room, which may lead to the principal apartments, a drawing-room, two secondary drawing-rooms, one whereof may be appropriated to the reception of a billiard table, a good dining-room, not less than 30 feet by 20 feet, a library of equal size, with other rooms, suitable to the particular taste of the proprietor, and the conveniences and accessories which such a building requires. The ground, supposing the domestic offices to be under the principal floor, should be raised, so that they need not be much sunk below the general level of the land. If the building be seated on rising ground, a little more sinking may be allowed than under other circumstances, provided the lower story be protected by dry drains all round the building, to prevent the earth lying against the walls, because drainage, the most important of all things in a building, may then be obtained easily by the natural fall of the ground. But a villa need not be compelled to have its domestic offices underground; then their combination with the apartments will test the architect's capabilities. The plot we have mentioned will admit of all the offices below which are necessary for the service of a good-sized family, and above, with only one story above the principal one, will afford a pretty fair allowance of dormitories; but if a concealed story for servants be practised in the roof, there are few establishments on a common scale for which, on the plot, accommodation may not be provided by a skilful artist. The stables and coach-houses and the greenhouses should stand apart. Some persons like to have these communicating with the villa itself; but the practice is destructive of symmetry, and very injurious (except in the villa on an irregular plan, which then rather approaches to the *cottage orné*) to the general effect of the architecture.

3000. The villas at Foot's Cray and Mereworth, imitations of Palladio's Villa Capra, so often mentioned in this volume, and represented in *fig.* 1018, are the maxima of villas; beyond this the villa becomes a mansion, and must be treated as one on a scale more or less grand, as the means of the proprietor allow the architect to provide for his wants. All precepts, however, on this head are valueless, because the architect is regulated so much by the convenience required. He must possess himself fully of that, and, attending to the general rules given throughout this work, but especially in this Third Book, he will find little difficulty in fulfilling the commission with which he is intrusted. Among other matters let him well inform himself of what has been done, and make himself master of the points involved in domestic economy, from the lowest to the highest grade, and he cannot, using that information, fail of giving his employer that satisfaction which is the first care that should animate him.

3001. The *cottage orné*, as it is called, is a building subject only to rules which the architect chooses to impose upon himself. The only point to be attended to, after internal comfort has been provided for, is to present picturesque effect in the exterior. The student should consult the work of Professor Kerr, *The English Gentleman's House*, 8vo. London, 3rd edition, 1871, in which will be found a selection of the best examples of house planning, with a fund of useful observations; while the illustrated journals of the present day exhibit plans and views of villas designed in the many peculiarities of architecture adopted by the various professors of the art.

Sect. VII.

FARM-HOUSE.

3002. The mere building denominated a farm-house is simple enough in its distribution, and scarcely justifies a section here, because the persons engaged in agriculture have generally the best notion of the mode of suiting it to their own particular business and the nature of the farm they occupy. It is first to be considered whether it is expedient to place it close to the other buildings of the farm, such as the barns, stables, and stalls for cattle, &c. If so, it should be designed in character with them, and a large space of ground is enclosed for the formation of a farm-yard; which, notwithstanding the seemingly repulsive nature of the subject, may be made a very picturesque composition as a whole. The farm-house itself, though it must be sufficiently large to accommodate the family of the farmer, should be restricted in the size of its rooms and the extent of its plan by the magnitude of the farm, it being altogether an absurdity to plant a large house on a small farm, not only because of the original cost, which the rent of the land will not justify, but because of the cost of the annual repairs which a large building entails beyond those of a smaller one. The same observation applies to the farm buildings themselves, which in extent must be regulated by the size of the farm cultivated. It is moreover to be considered, in respect of the latter, whether the farm be grazing or arable. In the first case more provision of cattle sheds must be afforded; in the latter case more barns must be allotted to the cultivator. These, however, are matters upon which the architect receives his instructions from the proprietor, and whereon, generally speaking, he is himself incompetent to form a correct judgment.

3003. In the commonest farm-houses the external door may open to a plain passage, at the end whereof the staircase may be placed. On one side of the passage may be a common kitchen, and on the other side the better or larger kitchen, serving also as a parlour for the farmer and his family. Beyond these, on one side, may be placed the pantry, and on the other side the dairy-room, the last being much larger than the former, and being on the side of the parlour or best kitchen, not so liable to the heat. To these, as needful, may be added more rooms on the ground floor; the upper story being divided into bed-chambers for the family, with garrets over them for the servants. The kitchens should be placed upon arched cellars on several accounts, not the least of which is that the farmer should have the means of preserving in good condition the malt liquor or cyder which is the principal beverage of his establishment. It is a sad mistake on the part of landed proprietors, though common enough, to think that such buildings are not only below the care of an architect, but that he is too ignorant of the wants of the farmer to be competent to the task; if, however, he will reflect for a moment, he must admit that the artist who can make the most of a large plot of ground, with numberless requirements in the accommodation, is not less able to turn to the greatest advantage for the comfort of the occupier even a small farm-house.

3004. In the erection of a larger farm-house the choice of the site, as before, must depend on the nature of the ground and the situation of the farm Health and convenience are the primary governing matters. It must never be placed where it cannot be well drained. It should be central to the land, and as near the road as the conditions will admit. For such a building the principal door may open into a moderately wide passage, having therein a staircase to the upper rooms. On the right of the passage a common kitchen may be provided for the family, and on the left a room somewhat larger, which in very small farm-houses used to be called the best kitchen, but which in this may be really the parlour, where the family may sit retired from the servants. Under these, cellars, as above mentioned, may be provided. On the ground floor we may now add a bakehouse and scullery to the pantry and dairy provided in the first scheme, as also closets and such conveniences for the housewife. The floor above may be extended over the additional rooms just mentioned, thus giving lodging room to a larger number of persons than to those contemplated in the first scheme. "In this manner," says Ware, in his *Complete Body of Architecture*, folio, London, 1756, "the young architect will very easily see how to enlarge or contract his plan for the building of farm-houses, according to the intended bigness." . . . "They all consist of the same number of rooms, and in general of the same number of offices; this is where the bare article of convenience for farming is concerned. Where the inhabitant is grown rich, and intends to live in another manner, he may add what he pleases, which the architect may adopt." . . . "It is then no longer to be considered a farm-house, but as the house of some person of fortune, who intends to live as those independent of business do, but withal to have some farming in his eye." When the farm-house comes to this extent it trenches hard upon the condition of the villa, though not quite reaching it, because the latter includes many provisions for a refined mode of living which the yeoman, the pride of England, does not require; a class which, we fear, the manufacturing and commercial classes are fast annihilating.

Sect. VIII.

COTTAGES.

3005. "Estates," observes Kent, (*Hints to Gentlemen of Landed Property*, 8vo. London, 1776,) "being of no value without hands to cultivate them, the labourer is one of the most valuable members of society: without him the richest soil is not worth owning." It follows, then, that his condition should be most especially considered, and it is a duty of every country gentleman to take care that the labourers on his estate are so considered as to be made at least comfortable. "The shattered hovels," says the same author, "which half the poor of this kingdom are obliged to put up with, is truly affecting to a heart fraught with humanity." . . . "The weather penetrates all parts of them, which must occasion illness of various kinds, particularly agues; which more frequently visit the children of cottagers than any others, and early shake their constitutions." . . . "We are careful of our horses, nay, of our dogs, which are less valuable animals; we bestow considerable attention upon our stables and kennels, but we are apt to look upon cottages as incumbrances and clogs to our property, when, in fact, those who occupy them are the very nerves and sinews of agriculture." We fear the neglect of the comfort of the cottager has given a greater impulse to poaching and other crimes than his natural propensities have induced. This, however, is not a matter for discussion here. It is not to be supposed that we mean the labourer is to be placed in an expensive dwelling; a difference of rank must exist; and if the whole revenue of the country were divided among the population per head, it would be seen (as M. Dupin has recently shown in a most eloquent and sound address delivered in Paris as respects France) that the division of it per day, after allowing for the expenses of the most economical government that could be devised, would be such as would not satisfy the lowest class of labourer, much less the ingenious mechanic. This is a matter so susceptible of proof, and so proper to be generally promulgated, that we have here gone a little out of our way lest we should be considered too urgent with respect to the cottager.

3006. No cottage ought to be erected which does not contain a warm, comfortable, plain room, with an oven to bake the bread of its occupier; a small closet for the beer and provisions, two wholesome lodging rooms, one whereof should be for the man and his wife, and the other for his children. It would be well always, if possible, that the boys and girls in a cottage should be separated; but this unfortunately entails an expense, and perhaps is not so materially necessary, because the boys find employment at an early age. A shed for fuel should be attached.

Cottages should always be placed in sheltered spots, and as near as possible to the farm where the labourer is employed. The wear and tear of a man is not very dissimilar to that of an engine, and it tends as much to the interest of the farmer as it does to the comfort of the labourer that all unnecessary fatigue be avoided.

3007. In the erection of cottages it is not only more economical, but more comfortable to the occupiers, that they should be built double, or in twos at least. In those provinces where brick or stone can be obtained they should never be constructed with timber, and tiles, if they can conveniently be had, should always supersede thatch. Further observation on this subject will be unnecessary, for we have ill delivered the principles of our art if the student be not now prepared to carry out the few hints on the subject of cottages, — buildings, in point of fact, of importance paramount to the palace which the sovereign inhabits.

The following remarks are by J. C. Loudon, and are extracted from a "Report to Her Majesty's principal Secretary of State, from the Poor Law Commissioners, on an Enquiry into the Sanitary Condition of the Labouring Population of Great Britain," 1842.

"The *essential requisites* of a comfortable labourer's cottage may be thus summed up: —

"1. The cottage should be placed alongside a public road, as being more cheerful than a solitary situation and in order that the cottager may enjoy the applause of the public when he has his garden in good order and keeping.

"2. The cottage should be so placed that the sun may shine on every side of it during the day throughout the year, when he is visible. For this reason, the front of the cottage can only be parallel to the public road in the case of roads in the direction of north-east, south-west, north-west, and south-east; in all other cases the front must be placed obliquely to the road, which, as we have previously shown, is greatly preferable to having the front parallel to the road.

"3. Every cottage ought to have the floor elevated, that it may be dry; the walls double or hollow, or battened, or not less than eighteen inches thick, that they may retain heat; with a course of slate or flagstone, or tiles bedded in cement, six inches above the surface, to prevent the rising of damp; the roof thick or double, for the sake of warmth; and projecting eighteen inches or two feet at the eaves, in order to keep the walls dry, and to check the radiation of heat from their exterior surface.

"4. In general, every cottage ought to be two stories high, so that the sleeping rooms may not be on the ground floor; and the ground floor ought to be from six inches to one foot above the outer surface.

"5. The minimum of accommodation ought to be the kitchen or living room, a back kitchen or wash-house, and a pantry, on the ground-floor, with three bedrooms over; or two rooms and a wash-house on the ground floor, and two bedrooms over.

"6. Every cottage, including its garden, yard, &c., ought to occupy not less than one sixth of an acre; and the garden ought to surround the cottage, or at all events to extend both before and behind. In general, there ought to be a front garden and a back yard, the latter being entered from the back kitchen, and containing a privy, liquid manure tank, place for dust and ashes, and place for fuel.

"7. If practicable, every cottage ought to stand singly, and surrounded by its garden; or at all events not more than two cottages ought to be joined together. Among other important arguments in favour of this arrangement, it may be mentioned that it is the only one by which the sun can shine every day on every side of the cottage. When cottages are joined together in a row, unless that row is in a diagonal direction with reference to a south and north line, the sun will shine chiefly on one side. By having cottages singly or in pairs, they may always be placed along any road in such a manner that the sun may shine on every side of them, provided the point be given up of having the front parallel to the road, a point which in our opinion ought not for a moment to be put in competition with the advantages of an equal diffusion of sunshine.

"8. Every cottage ought to have an entrance porch for containing the labourer's tools, and into which, if possible, the stairs ought to open, in order that the bedrooms may be communicated with, without passing through the front or back kitchen. This, in the case of sickness, is very desirable, and also in the case of deaths, as the remains may be carried down stairs while the family are in the front room.

"9. The door to the front kitchen or best room should open from the porch, and not from the back kitchen, which, as it contains the cooking utensils and washing apparatus, can never be fit for being passed through by a stranger, or even the master of a family, where proper regard is had by the mistress to cleanliness and delicacy.

"10. When there is a supply of clear water from a spring adjoining the cottage, or from some other efficient source, then there ought to be a well or tank, partly under the floor of the back kitchen for drawing it up for use, as hereafter described in detail. The advantages of having the tank or well under the back kitchen are, that it will be secure from frost, and that the labour of carrying water will be avoided.

"11. The privy should always be separated from the dwelling, unless it is a proper water-closet, with a soil-pipe communicating with a distant liquid manure tank or cesspool. When detached, the privy should be over or adjoining a liquid manure tank, in which a straight tube from the bottom of the basin ought to terminate; by which means the soil basin may always be kept clean by pouring down the common slops of the house. No surface being left from which smell can arise, except that of the area of the pipe, the double flap, to be hereafter described, will prevent the escape of the evaporation from this small surface, and also ensure a dry and clean seat.

"12. The situation of the liquid manure tank should be as far as possible from that of the filtered water tank or clear water well. It should be covered by an air-tight cover of flagstone, and have a narrow well adjoining, into which the liquid should filter through a grating, so as to be pumped up or taken away without grosser impurities, and in this state applied to the soil about growing crops.

"13. In general, proprietors ought not to intrust the erection of labourers' cottages on their estate to the farmers, as it is chiefly owing to this practice that so many wretched hovels exist in the best-cultivated districts of Scotland and in Northumberland.

"14. No landed proprietor, as we think, ought to charge more for the land on which cottages are built than he would receive for it from a farmer if let as part of a farm; and no more rent ought to be charged for the cost of building the cottage and enclosing the garden than the same sum would yield if invested in land, or, at all events, not more than can be obtained by government securities.

"15. Most of these conditions are laid down on the supposition that the intended builder of the cottage is actuated more by feelings of human sympathy than by a desire to make money; and hence they are addressed to the wealthy, and especially to the proprietors of land and extensive manufactories or mines."

3008. To the foregoing fifteen essential requisites we have only to add a few observations on the design of a cottage. The plan should not be straggling, or such as to render a variety of roof-lines necessary, and although its arrangement should be compact, it should not be cramped. Shapeless nooks and corners do not become convenient cupboards and closets or because they are enclosed and possess a door, but rather convenient hiding-places for mice and dirt. Too many projections make a small building look smaller by depriving it of breadth; and too great a diversity of colour gives it a vulgar appearance, and frequently destroys the effect of really good proportions. The temptation to build picturesquely and to try experiments with new materials and methods of construction, is much greater in the country than in town. Coloured bricks, bands of ornamental tiles, glazed patera, and other similar attractions, may give variety to elevations, but they must be adopted with considerable caution in small buildings. New inventions and pseudo-economical devices too often prove miserable and expensive delusions. As the details of construction, &c., which are given in the next section, are equally applicable to those in the country, this subject will be now dismissed.

3009. In the autumn of 1863 two premiums of 25*l.* each were offered through the Society of Arts for the most approved designs for cottages, to be built singly or in pairs, at a cost not exceeding 100*l* each. It was essential that each cottage should fulfil the following requirements. On the ground floor, a living-room of about 150 feet superficial; a scullery or kitchen of not less than 70 feet superficial; with a ventilated pantry. On the upper floor, three bedrooms, one to be not less than 100 feet superficial; fire-places to be provided in two of the rooms. The height from the ground to the first floor to be 9 feet, and the bedrooms to be 8 feet in the clear. The memorandum of the Inclosure Commissioners with respect to the substantiality of agricultural buildings to be adhered to. In the estimate, brickwork was to be taken at 8*l.* per rod reduced; Countess slates at 23*s.*; and Baltic timber at 2*s.* 3*d.* per foot cube. An allowance of 20 per cent. was to be made for contingencies and builder's profit on the cost prices of labour and materials, with 5 per cent. for superintendence. The prime cost, therefore, of each house was not to exceed 80*l.*, including not only the cottage, but the fixtures, water supply or well, fencing, paving, and all those necessary addenda which the owner must supply.

3010. An able report was drawn up on the 134 designs submitted, by the three appointed judges (given in *Builder*, 1864, p. 359), towards the conclusion of which they observe "that although good cottages may possibly be erected, under favourable circumstances, in some parts of England for a lower sum, we consider the probable average cost of a pair of cottages built with the conveniences enumerated, would be about 280*l.* to 300*l.*, and that the attempt to erect them at any considerable reduction upon this amount must result in some inferior kind of buildings, discreditable to the owner, and wanting in much of the necessary accommodation for a labourer and his family." The premiated design is given in the same volume, p. 952. On p. 295 of the following volume, six builders' estimates are given for erecting six cottages on the premiated plan, ranging from 397*l.* 13*s.* 4*d.* to 527*l.* the pair; a difference somewhat accounted for by the designer in his observations at p. 319, where he states that 260*l.* the pair would be the price of some he was then erecting, with modifications. On p. 394 is given a design estimated at 200*l.*, and tendered for at 180*l.* the pair, which is deserving of comparison.

3011. The Central Cottage Improvement Society, London, stated in 1865, that "reports from different parts of the country, of the actual cost of building, prove that on the average, each room containing 100 superficial feet, or 10 feet square, of a cottage or block of buildings, costs from 20*l.* to 25*l.*, exclusive of land; this is equivalent to 3*d.* per foot cube. In the five sets of plans published by the society, No. 1, of four rooms, has been built for 162*l.*; No. 2, slightly larger, for 168*l.*; No. 3, same as No. 1, with a scullery, for 175*l.*; and No. 4, more commodious, for an artizan, for 220*l* per pair. The *Journal* for 1858, of the Bath and West of England Society, vol. vi., details a cottage of five rooms, built on Exmoor, for 60*l.*, with a living room 15 feet by 13 feet.

Sect. IX.

TOWN DWELLINGS FOR THE INDUSTRIAL CLASSES.

3012. The leading features of construction and detailed arrangement which may be considered peculiarly applicable to dwellings intended for working men whose wages range from 12*s.* to 24*s.* per week will be described herein. Workmen of this class have been hitherto strangers not only to the conveniences which render home attractive, but to the barest accommodation necessary to render social life tolerably decent. Unfortunately, the nearer an improved dwelling approaches its miserable predecessor in general aspect and character, the more popular it will be. The difficulty, therefore, in designing new homes for the poor consists in the introduction of improvements which shall lead to the gradual abandonment of injurious habits, and to give no sudden offence to jealously cherished prejudices. To do this effectively it is desirable to ascertain the leading requirements of the inhabitants of the district in which it is proposed to build.

3013. A poor man's town dwelling should consist of a living room and bedroom; a plentiful supply of water; a water-closet, sink, and lavatory, distinct but not far removed from his tenement; a wash-house, with the means of drying clothes in any weather without artificial heat; and, when practicable, a play-ground for children.

3014. The living-room should be 12 feet by 10 feet clear of all obstructions or projections, and 8 feet high, giving 960 cubic feet at least. The rooms should be of a square form, as being easily kept clean and made comfortable. *Fig.* 1353. presents a general plan of the arrangements. The door should open into a porch or vestibule, and be placed at the end of the wall opposite to the window, so that when both are open the air in the dwelling may be effectively changed. The window should be sufficiently large to light every part of the room. It should be fitted with sashes, to insure top and bottom ventilation; and its sill should not be more than 2 feet 9 inches from the floor, to prevent high furniture being placed under it. Tolerably large panes of glass will be found to last longer than if the panes be small. The fire-place should be as near the centre of its own wall as possible, and be furnished with a range containing a boiler, with a tap of the best description fixed 2 inches above the bottom; an oven; and a cooking place at least 10 inches wide from side to side, with sliding bars, flap and catch, all of which ought to be of wrought iron. The living-room should have a good serviceable closet the entire height of the room, the front flush with the chimney breast, to contain shelves for cooking utensils and crockery, &c., and a large covered box for coal; this closet should be lighted by a small window hung upon centres and to be easily opened.

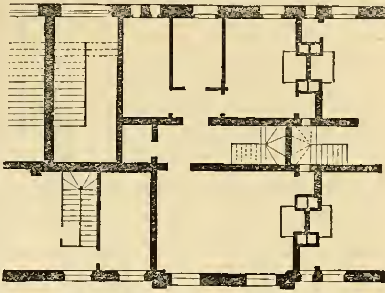

Fig. 1353. PEABODY DWELLINGS, COMMERCIAL STREET.

30 5. The bedrooms should be 12 feet by 8 feet, and 8 feet high, communicating with the living room by a door in the wall opposite to the fire-place at the end nearest to the window, so that enough wall space may be secured for the bed. As these rooms would be sufficiently warmed from the living-room, fire-places can be dispensed with where space is limited or expense of much importance.

3016. The walls should be well-built with sound stock bricks (the partitions being half a brick thick) and coloured with two coats of well sized distemper colour of a warm cheerful tint. Such walls offer no harbour for vermin; they are uninjured when nails are driven into them; and their freshness and colour are easily renewed at a trifling expense. The ceilings should be plastered, not only for a clean appearance, but also as a preventive against the spread of fire. The floor is best made of wood, though it is apt to get dirty and tolerably difficult to clean. If firewood or coal be broken upon any other floor than a wooden one the concussion is injurious to it. Tile and asphalte floors are often recommended as the best; but though they have a clean appearance, they are cold to the feet when uncovered by a carpet; are more liable to injury; and are more troublesome to repair. Asphalte and cement floors depend in a great measure upon their rigidity for their efficiency, and require iron beams and brick arches, which are expensive.

3017. As regards ventilation, beyond supplying doors that do not fit too close, windows that will open at top and bottom, and fire-places with air-channels underneath the floor, it is extremely difficult to know how to proceed further without detection. A ventilator once discovered is instantly rendered useless by being pasted over. Perforated bricks placed throughout the length of the wall in which the window is set, and in that opposite to it, causes the air to be so diffused by its passage through the narrow channels with which the bricks are provided, that the paste-brush is seldom used.

3018. The lavatory should contain a water-closet fitted with a strong galvanized iron valve; a lead trough, for washing purposes, supplied with a high-pressure loose valve cock, and an enamelled iron basin. A smaller lead trough or waste, for the discharge of dirty water, should have an inch service cock above it for supplying pails and kettles. The walls, coloured as those of the dwelling, should be well painted to the height of 18 inches above each trough, for frequent and easy washing. The floor is best covered with thick 9-inch square tiles, which bear a good deal of wear and tear and slopping in one spot without injury. The lavatory should have two windows at least, one in the external wall of the water closet and one at the furthest end of the wall at right angles to it.

3019. To attach a laundry to an extensive range of such dwellings becomes a positive duty. A washing tub and rinsing tub are necessary, about 3 feet 3 inches long by 1 foot 9 inches wide, with washer, plug, and chain, and a separate cold water service to each. The top of the tubs should be 3 feet 3 inches above the foot-board, or the floor, if not provided. A 10-gallon copper, with cold water service, and a tin ladle. The flue of the copper is to be carefully constructed to insure the heat being well distributed over the sides and bottom, and to afford facilities for regulating it and for cleaning. Wringing machines might be provided if hydrometers are not used; they are easily attached to the tubs. Artificial means of drying clothes, as adopted with advantage in public wash-houses, are to be avoided in small laundries, because they cannot be maintained without considerable expense. Clothes are more easily and effectively dried when protected from rain, and suspended in strong cross currents of air.

3020. The water-cistern should be as close to the laundry as possible, in order that the piping may be short, with very few joints and bends so as to be free from the risks which attend a variety of levels. More attention is desirable to the dimensions of the iron piping, and the nature and position of the services, than they usually receive. Thus means should be provided for filling, emptying, and cleaning the cistern or tank; also for regulating the supply during the time that any portion of the piping is under repair. Every rising main should be furnished with at least two valves. The first is best fixed in the junction between the rising main and the company's street main, so as to regulate the entire supply of the building. The second should be fixed at the bottom of the rising main, so as to release the water which remains in the pipe after the cistern has been filled. In some cases an additional cock, 2 feet above each floor level, for the supply of buckets, or for the connexion of hose in case of fire, may be desirable.

3021. A few square yards of *play-ground* is of inestimable value for the labouring man's children. One large play-ground to a block of buildings is of much greater use than many small yards to as many cottages, and has tended as much as anything to ensure the success of the large blocks of dwellings in London.

3022. The drain-pipes should be of the best description, and their diameters larger than those employed under ordinary circumstances, because their liabilities to obstruction are very much greater. The main drains should be external to the building, and supplied with examination holes at intervals for repair and cleansing, and should possess the means of being regularly flushed with water. When the ground is soft, the drains, both large and small, should be laid upon beds of concrete, to preserve them in their proper falls. Soil and other pipes should be ventilated by being taken above the roof of the building.

3023. The *site* for a block of associated dwellings should be as open and in a situation as public as possible, not only to receive the advantages of light and ventilation, but that it may be easily found and readily accessible, and that its residents may have contact with neighbours whose habits and appearance are superior to their own. The ends of the site should face north and south, so that its east and west sides should have the morning and evening sun. It should offer every facility for good drainage; the nature of the subsoil should be well ascertained, and every necessary precaution taken to avoid, or to clear out, any accumulation of foul refuse that may have been carted into the vacant site. The most economical dimensions for a site within the jurisdiction of the Metropolitan Board of Works in London, are 108 feet long by 60 feet wide. This area will accommodate a building 108 feet long by 34 feet wide, and admit of a playground 26 feet deep in its rear. The multiple of 108 by 34 = 3600 in round numbers, is the area allowed by Act of Parliament for a building containing several distinct tenements, and possessing only one entrance and staircase. The height of the building is best kept at 46 feet from the ground-line to the eaves of the roof; it admits of as many stories of dwellings as can be occupied with comfort to the tenants, and it requires no unnecessary thickness of walls. If made five stories in height it will contain 40 or 45 dwellings, about 16 water-closets, 8 lavatories, 8 wash tubs and coppers.

3024. The following paragraphs comprise a brief description of the dwellings lately built or now constructing. In the basement, only a small cellar need be provided for dust, access to it is to be obtained by a small external staircase under its first landing, but distinct, so that the dust may be removed without annoyance. The ground, first, second, and third floor plans may be divided throughout their entire length into two equal portions, by a corridor 4 feet 2 inches wide, on each side of which are arranged the dwellings (*fig.* 1354.).

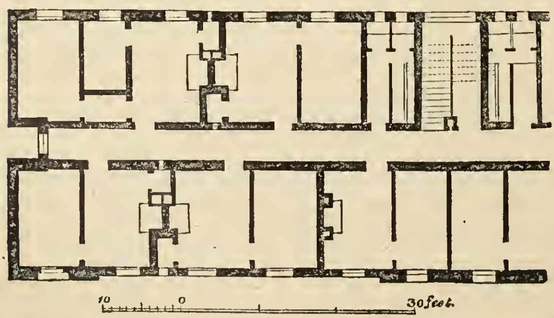

Fig. 1354. PEABODY DWELLINGS, COMMERCIAL STREET.

In the centre is the principal entrance, which is 5 feet 6 inches wide, and furnished with external and internal folding-doors under the immediate supervision of the porter whose office adjoins it. The staircase, placed immediately opposite to the entrance, is 8 feet wide, with solid square stone steps having a 10-inch tread, and an average rise of 7 inches. The side furthest from the corridor has an arch 7 feet wide, and extending from the ground-line to within a few feet of the eaves of the roof. It is separated from the corridor by two arches, whose centre pier contains a dust shaft, traversing the entire height of the building, and communicating with the cellar above named in the basement. It is 14 inches wide within, open above the roof for ventilation, and is furnished with a hopper, which receives the dust, and closing flush with the wall at each floor level.

3025. The lavatories adjoin the staircase, those for the men on one side, for the women on the other. The fourth or topmost floor contains a laundry, about 22 feet long by 12 feet wide, covered with an open timber roof, the tie-beams having standards helping to support it, and serving as clothes posts. It is lighted by a range of small casements, admitting air sufficient to remove any unpleasantness that might arise from the laundry, and to thoroughly dry the clothes. It is furnished with eight sets of wash tubs, some being separated by slate partitions, for privacy; eight 10-gallon coppers; eight wringing machines, or a patent hydrometer; trellis framed standing boards; stools (as being better than tables) for clothes baskets; soap boxes and ladles. This floor also contains a bathroom for each sex, placed over the lavatories; it is furnished with one of Rufford and Finch's stoneware baths, and has a service of cold water. Hot water is supplied from the laundry when required. A cistern lined with lead adjoins each bath-room, and also supplies the lavatories below it; this position secures a direct fall to the several services, and avoids the necessity for frequent bends and joints.

3026. The main drains are 12 or 9 inches in diameter; the smaller drains, kept as short as possible, are 6 and 4 inches, according to their requirements. The ventilation is secured by the side corridor having a window at each end of it, and by the open staircase in the middle of its length, all which forbid stagnation and remove impurities. These very practical observations are mainly due to the paper by H. A. Darbishire, who has designed several blocks of dwellings in the metropolis, as given, with illustrations of those in Commercial Street, Whitechapel Road, in the *Civil Engineer*, &c. for 1864.

SECT. X.

SANITARY ASPECT OF HOUSE CONSTRUCTION

3027. This subject may usefully be referred to. Granting that a house is well drained and that the plumber's work is properly carried out, there are yet other matters to be considered, so that a house may be a healthy residence. It should have plenty of light, plenty of air at all times, pure and dry, or at least as much so as possible. During the period when the number of windows and the glass in them were each taxed, large windows were advocated; but as soon as both were taken off, a change of fashion occurred, and small windows and small panes were again introduced. As regards street architecture, it is important that the houses should be erected of a height bearing a direct relation to the breadth of the street in which they are situated. Perhaps the height of the house should not exceed two-thirds of the width. As regards the direction of a street, the best is one nearly north and south, as the sun shines on a house on the west side from morning till mid-day in the front, and from mid-day till the evening on the back of it. In the other case, the houses on the south side get scarcely any direct sunlight, in winter none at all in front; while those on the north side get none to the back rooms. Hence, large windows are necessary to compensate, by giving as much light as possible, for the direct sunlight which is necessary to make an apartment wholesome.

3028. Purity of air cannot be maintained in a house unless it be thoroughly dry. Setting aside the not inconsiderable quantity of water in the atmosphere produced by those living in it, and by the combustion of gas, oil, and candles, the air in a house is liable to be rendered moist, 1, by absorption from the soil below it; and 2, from the porous material of which it may be built.

3029. The porosity of most building stones and bricks is remarkable. A cubic foot of stone will absorb from 5 to 9 lbs. of water, or from half a gallon to nearly one gallon. The absorption by certain kinds of stone is so rapid that in slight showers the water is all imbibed; and if the surface be kept wet by constant rains, a large portion must find its way inwards, Freestone also allows of the passage of air or other gas by transpiration and diffusion; also bricks, unless these have been exposed to a temperature high enough to flux the material. The quantity of air diffused into and out of a house by the walls is very considerable. If the stone be coated with oil, paint, or any silicate solution, and the absorption be prevented, the valuable property of diffusing air into the house is prevented. *Hollow walls* may secure these advantages. These may be of brick, or of concrete, or of stone outside and brick inside. In some parts of the country the material is laid with beds slightly sloping upwards somewhat to counteract the effects of the rain, especially when blown from the south-west; perhaps the two inches of the bed of the stone on the outside might be bevelled, and the remainder be worked level.

3030. Where rubble walls are used, the best thing to be done is perhaps to point them with a mixture of 1 of Portland cement to 2 of sand, and then to colour the whole with cement wash. But this should not be done until after one summer's sun has assisted in drying the stone, or the damp may dry inwards. It is considered that a 2-feet stone will not dry thoroughly, even under favourable circumstances, in less than two years.

3031. Plaster, whether on brick or lath, is exceedingly porous, and permits of a ready diffusion of gases. A wall merely whitewashed or coloured is better in a sanitary point of view than one that is covered with oil paint, which is then practically impervious to the passage of gases. Wall papers are probably not so bad in this respect as oil paint, but inferior to colouring or distemper work.

3032. The foundation of a house is an important part of it. The most perfect is a solid platform of concrete extending over the entire area of the building, from 2 to 3 feet in thickness, and coated on the top with nearly pure cement. Damp cannot penetrate this, it is considered. The joists should be laid on sleepers, so as to obtain ventilation to the space; in case of the bursting of a water-pipe or of water getting into the concrete bed, it should be laid sloping, so that water could be carried off by outside gratings. This would be expensive, it is true. Another system would be, to build the walls and dwarf-walls to a certain level, and then to fill in with hard dry rubbish, and cover the whole with cement 3 inches thick, composed of 1 of cement and 2 of coarse sand. Or, this might be covered with asphalte, also over the walls, or the usual damp course take its place. This damp course must be put to main and dwarf walls.

3033. Gratings should be placed all round the building, thoroughly to ventilate the space under the basement floor, about 10 feet apart. If a town house, then about 5 or 6 feet apart and each about 10 by 6 inches. Cross walls should have good openings in them to obtain this circulation of air. The floor may be considered cold by this ventilation; if so, the floor can be pugged, or the boards be grooved and tongued.

3034. In this wet climate, where occasionally half an inch of rain falls in a day, it is well to cover the tops of the chimneys, in order to prevent rain from coming down the straight flues into the grate, or down others into the gable walls and keeping them damp, preventing the smoke rising; and this cover can be combined with some means for preventing downdraughts.

3035. A simple method of ventilating a room is to drill a series of smallish holes vertically through the lower frame or meeting bar of the top sash of the window, say six or eight to the sash; the air rises through them into the room in the same manner as in a Tobin's tube. This is an old custom, and often tends to cure a smoky chimney caused in a room. Another is to have a bar of 3 or 4 inches in height to fit in between the frame on the sill of the lower sash, when raised for the purpose; there will then be a space left at the meeting rails for inlet of air.

3036. At the meeting of the Sanitary Institute of Great Britain, held at Bolton, Mr. R. E. Middleton, C.E., read a paper on the then proposed *Sanitary Registration of Buildings Bill*, 1887, in which he quoted a specification where *water-closets* are used. It is here given, as showing the present views, extreme or otherwise, of many sanitary officials.

"1. Every drain or part of a drain inside a house and all soil pipes shall be water-tight throughout.

"2. The main drain of the house shall be ventilated at its upper extremity by means of a continuation of the soil pipe, or by a special pipe provided for the purpose; such ventilating pipe, whether connected with the soil pipe or otherwise, having a clear sectional area of 10 square inches throughout, and being carried to such a height that its outlet shall be at least 3 feet above the eaves of the roof, and the same distance above any window or opening in the roof, not being a chimney, and not less than 6 feet distant from any chimney or opening in the roof, whether of the house to which it belongs or of the next adjoining house, measured in any direction. The main soil pipe shall be similarly ventilated, and if there be more than one soil pipe, then each such soil pipe which shall be longer between the basin of the closet and the main drain than 8 feet shall be similarly ventilated. The main drain shall be disconnected from the sewer or cesspit by means of a syphon trap of approved construction, provided with means for cleaning the trap and the portion of the drain between the trap and the sewer or cesspit; and it shall be ventilated by an inlet air-pipe or ventilating disconnecting manhole; and if there be more than one outlet ventilating pipe connected with the house drain, then each such portion of drain and outlet ventilating pipe shall be provided with a suitable syphon trap and an inlet air-pipe or disconnecting manhole, as already described; and the area of the inlet air-pipe shall in all cases be at least double that of the outlet ventilating pipe in the clear.

"3. No pipe which passes through any part of a house, not being a soil pipe or soil drain, shall be connected directly with the main drain.

"4. No water-closet shall be situated next to a larder or place where food is stored. No pan-closet or D trap shall be used, and every water-closet shall be trapped, and shall be arranged so as to prevent syphonage.

discharged into the open air in an exposed position, and shall not be connected with the soil drain or rain-water pipes, either directly or indirectly, but shall act as detectors.

"6. All sinks, baths, lavatories, and urinals shall be trapped with suitable traps, and the discharges from them shall be carried outside the walls of the house. and shall not be connected directly with any soil drain, nor shall they be introduced under the grating of any trap, but they shall terminate in the open air, and not near any window or other opening.

"7. All water-closets, urinals, and slop sinks shall be provided with suitable flushing cisterns, and the flushing pipe for any closet shall not have a less internal diameter than $1\frac{1}{4}$ inches, and the height of the flushing cistern above the closet, urinal, or slop sink shall not be less than 4 feet. It shall be impossible to draw water from any cistern used for flushing purposes for any other purpose than that of flushing.

"8. The cisterns used for general purposes shall be easily accessible, and shall be provided with covers ventilated into the open air outside the house by a rising pipe other than the overflow pipe, and no pipe from them shall be connected in any way with any soil pipe, drain, or with any pipe receiving the discharge from any bath, lavatory, urinal, sirk, or flushing cistern.

"9. No rain-water pipe used to receive the waste from any bath, lavatory, sink, or urinal shall be placed near a window or other opening; and no rain-water drain shall connect directly with a soil drain ; and no rain-water pipe shall be used as or connected with the soil pipe, nor as a ventilating pipe.

"10. No cesspit shall be constructed in such a manner, nor placed in such a position, as to endanger the water supply ; and every cesspit shall be ventilated by an inlet air pipe and by an outlet ventilating pipe rising to an elevation above the ground level of not less than 20 feet, and having a clear sectional area of not less than 10 square inches, the area of the inlet pipe being double that of the outlet ventilating pipe."

Sect. XI.

TECHNICAL SCHOOL AND COLLEGE BUILDINGS.

3037. The remarkable movement in favour of more efficient technical training has called for an exact treatise on the peculiarities of plan and structural arrangements and fittings of buildings required for its development. Foreign nations have been beforehand with us in this matter, and have long since provided noble buildings, specially created and admirably fitted up for the purpose, and well stored with singularly complete industrial and fine art collections.

3038. Mr. E. C. Robins, F.R.I.B.A., F.S.A., has, besides the lectures delivered by him, brought together a large amount of information on the subject of technical education as taught both in England and abroad, and on the adaptation of architecture to the requirements of this teaching. This new volume is entitled, *A Treatise on the Design and Construction of Applied Science and Art Buildings, and their suitable Fittings and Sanitation, with a Chapter on Technical Education*, 4to. 1887. It contains full descriptions of such institutions as the Bonn, Berlin, and Munich chemical laboratories ; Du Bois-Reymond's Physiological Institute at Berlin; the laboratories at Charlottenburg, Zurich, Paris, Strassburg. Most of these are accompanied with cuts and diagrams, so that their interior arrangements may be studied in minutest detail. Descriptions of the laboratories at South Kensington, Finsbury, Leeds, Bristol, Manchester, Huddersfield, Oxford, Cambridge, and other English cities, are given ; with chapters devoted to the fittings of these buildings, giving detailed information concerning the hundred and one minor things which go to make up the perfect laboratory ; as the working benches, demonstration tables, drawing rooms, and so on. The heating, ventilation, and sanitation of applied science buildings are also elaborately treated and profusely illustrated. An appendix gives statistics as to the technical schools in Great Britain : as particulars of the area occupied by buildings, their cubical contents, the cost of land, cost of fittings, annual expense of maintenance, number of students, and so forth. One chapter embraces the planning of schools for middle class education generally, as at South Hampstead, Gravesend, Sevenoaks, Caterham, Battersea, Wapping, Haverstock Hill, Stepney, with the Camden School for Girls, and the North London Collegiate School for Girls

3039. It has lately been pointed out that technical education was not meant to be a substitute for apprenticeship. The object is rather to teach boys and young men *how* to learn a trade rather than to teach them the trade itself. As a comparison of the views held by some continental states, and by England, on this subject, it has been stated that the Finsbury College, London, cost 37,000*l.* to build, and requires 6,000*l.* per annum from the City Guilds for maintenance ; and that the City and Guilds Central Institute cost 90,000*l.* to build, and receives 10,000*l.* per annum ; while at Berlin, a building has been erected twice the size of Buckingham Palace, which cost 690,000*l.* to build, and it receives 37,380*l.* per annum from the state!

BOOK IV.

VALUATION OF PROPERTY.

CHAP. I.

The valuations in which the architect is consulted are properly only those wherein buildings have been or may be erected; from which if he wander, the probability is that he will create difficulty for himself, tending to exhibit him as a pretender to knowledge not within the regular course of his occupation. The general principles, therefore, on which we propose to touch, are confined to the species of property above named, as distinguished from that in which the resident valuator near the spot in the different provinces is the best adviser, from the local knowledge he possesses. The auctioneers who with unblushing effrontery pretend to a knowledge of the value of property in the metropolis, are utterly incompetent to the duties they undertake, from an ignorance of the durability and cost of buildings, which can be attained by the practice and experience of the architect only.

Buildings may be so disadvantageously placed on their sites as to realise nothing like a proper interest on the money expended in their erection; and, indeed, so as altogether to destroy even the great value of the ground on which they are built. Thus, to place before the reader extreme cases, which generally best illustrate a subject, let him suppose a row of hovels built in Piccadilly, and a house like Apsley House placed in Wapping High Street. In both cases the productive value of the ground is destroyed, there being no inhabitants for such dwellings in the respective quarters of the town.

From this it must be evident that the value of town or city property, which consists principally of buildings, is divisible into two parts; namely, —

That arising from the value of the soil or site; and

That which arises from the value of the buildings placed upon it.

We will suppose for a house which is fairly let at a rent of 100*l.* per annum, no matter what the situation of it be, that it could be built for 1000*l.*, and that the proprietor or builder would be content with 7 per cent. for the outlay of his money, a rate by no means larger than he would be entitled to claim, seeing that the letting, after it is built, is a matter of speculation, and that loss of tenants and other casualties may temporarily deprive him of the interest of his capital. In this case, then, the rent of the mere building would be 70*l.*; and as the full rent assumed is 100*l.*,

$100-70=30$, which is manifestly the value of the ground or ground rent.

Thus in the cases of valuation of freeholds, wherein the gross rent can be accurately ascertained, there can be no difficulty in coming at the real value of the ground rent, because the building rent, or that arising from the expenditure of money on the soil, can be immediately ascertained by the architect, with the rate of interest on it which it is fit the builder should have. The remainder of the rent is that inseparably attached to the value of the soil, and belongs to the ground landlord.

The reason for thus separating the two rents is this: the ground rent, attached as it is to the soil, is imperishable. It is true that the value of ground is constantly fluctuating from the power of fashion over certain localities; but with this the valuator cannot deal. The changes are slow; and the Lord Shaftesbury in the time of Charles II. would have little thought it possible, when he placed his residence in Aldersgate Street, that his successors would have dwelt in a house in Grosvenor Square; neither, even five and twenty years ago, did it cross the mind of the then possessor of the Grosvenor property that the Five Fields at Chelsea contained a mine of wealth in the ground rents of Belgrave and Eaton Squares. Such are the mutations of property, with which the present question is not involved, unless the gift of foresight, in a degree not to be expected, be given to the valuator. The other portion of the value of house property is strictly the result of the perishable part of it, namely, the building itself; and this is limited by the durability of the building, which has great relation to the time it has already existed, and to the substantiality with which it has been constructed. The durability, then, or the number of years a building will continue to realise the rent, is the second ingredient in a valuation, and is a point upon which none but an experienced person can properly decide.

The rate of interest which the buyer is content to obtain in the investment of his money in buildings, or, in other words, in the purchase of the perishable annuity arising from the building, will necessarily vary with the value of money in the market. In the compensation cases under public improvements, wherein it is obligatory on the owner to part with his property, the 6 per cent. rate of the table is generally used, by which the buyer makes too little interest on the perishable part of the property. Few would be inclined to invest money in such property at so low a rate, for a rent which every year, from wear and tear, becomes less valuable. Individuals understanding the subject would scarcely be found to purchase, unless they could make at least 8 per cent. for this part of the capital. In the cases above mentioned, twenty-five years' purchase, that is, 4 per cent., is the usual price at which the ground rent is taken.

Having thus prepared the student, we will present an example of a valuation conducted on the principles named. Thus, suppose a building and the ground on which it stands to be together worth 150*l.* per annum, and that its durability is such that a purchaser may count on receiving that rent during a term of fifty years. We will suppose the house to stand upon a plot of ground 24 feet in frontage and 60 feet in depth; that the size of the house is 24 feet by 40 feet, and that to build a similar one would cost 1,440*l.*, which, at a rate of 7 per cent. upon the expenditure, would produce a building rent of 100*l.* 16*s.* per annum.

	£	*s.*	*d.*	£	*s*	*d.*
Now the total rent being - - - -	150	0	0			
The rent arising from the building itself - -	100	16	0			
The value of the mere ground must be - - -	49	4	0			
We therefore here have the imperishable part, viz. the ground, of the value of 49*l.* 4*s.* per annum, which, giving the purchaser 4 per cent. interest for his money, is twenty-five years' purchase for the fee-simple by the Fourth Table, that is - - - - -				1230	0	0
An annuity (from the building) of 100*l.* 16*s.*, to continue for fifty years, is, by the Fourth Table at 5 per cent., worth 18·256 years' purchase, that is - - - - - - - -				1840	0	11
The value of the old materials at the end of the term, if taken to be pulled down and sold for 150*l.*, will be that sum at the end of fifty years to be received at the present time, discounting at 4 per cent. from the Second Table ·1407 × 150 - - - =				21	2	0
Total value of the freehold - - -				3091	2	11

In the above valuation the ground estimated by its frontage would be $\frac{49l.\ 4s.}{24 \text{ feet}}$ = 41*s.* per foot, and ground is usually let by the foot when demised for building. In the chief parts of great cities ground is now usually sold and let at per foot superficial.

The next case of valuation is that of a beneficial lease, in which the rent paid by the lessee is less than the actual value of the premises. The difference between them, therefore, is an annuity for the term of the lease, which is so much benefit to the lessee, and is estimated by the Fourth Table; thus—

Suppose the actual value of given premises be - - - -	£100
Rent reserved by the lessor - - - - - -	50
Beneficial annuity belonging to the lessee - - - - - -	£50

If the term of the lease be twenty-one years, such is the length of the annuity, and the question stands as under :—

An annuity for twenty-one years, discounting at 5 per cent., is by the Fourth Table worth 12·8211 years' purchase, which multiplied by 50*l.* = 641*l.* 1*s.*

It is to be observed that the annuities must be clear after the deduction of all outgoings which may be necessary to keep it unencumbered.

Let us take another case.

A man takes a lease of ground at 10*l.* per annum, and lays out 1,000*l.* on a sixty-one years' lease, interest being 3 per cent. How much must he receive as rent to replace the principal at the end of the term?

1000*l.* at 3 per cent. = 30*l.* + 10*l.* ground rent = 40*l.* improved rent.

1*l.* per annum for sixty-one years at 3 per cent. will amount to 169*l.* (See Third Table.)

$\frac{1000}{169}$ = 5*l.* 9*s.* = the sum to be laid out yearly.

And 30*l.* + 5*l.* 9*s.* = 35*l.* 9*s.*, or 3·59, is the rate of interest to secure or replace the principal at the end of the term without consideration of repairs, loss of tenants, insurance, &c.

We now subjoin some observations on the valuation of *house property*, which claim the architectural student's attention. Inwood's *Tables for the Purchasing of Estates, &c.* have long been in general use; they are founded on the elaborate Tables by Baily and Smart. A series are given hereafter. W. D. Biden, *Rules, Formulæ, and Tables for the Valuation of Estates, &c.*, with his smaller work, *Practical Rules for Valuers*, 1862, are useful, and have furnished the outline for the following remarks.

It is generally considered that the value of a *freehold* house ranges, according to situation, style, condition, &c., from 10 to 20 years' purchase. It naturally follows that purchasers, and some valuators indeed, imagine that house property, as a rule, pays from 5 to 10 per cent. interest on the purchase-money. This is a great error, as many have experienced who have endeavoured to realise and to expend yearly 8 per cent. on the cost of house property. The valuation should be made at 5 per cent. (if the purchaser will be content with that interest); and the present value of *all* the costs, charges, and losses incident to house property should be fairly stated and deducted in the valuation, and then the purchaser will not be deluded with the idea that he is to net a very large interest, which may be spent unconcernedly. Such is the expectation of many of those who are induced to join Building Societies, and who buy, what appears to them, a bargain, as they will be receiving for years double or treble the amount of interest obtainable from the funds. A change of tenants, or other cause, soon shows the difference. Where, however, the buyer himself occupies the house, whether freehold or leasehold, he may make a very advantageous investment of his money. In the latter case, that is, of a leasehold, he must bear in mind the result of the occupation of the premises, namely, dilapidations, for which he will be called strictly to account by his landlord at the expiration of his term of lease.

Compare the following valuations, made in two ways, of a *freehold* house, which will last for about 80 years, the tenants paying the rates amounting to about £7 per annum. One valuator may make out his calculations thus:—

	£ s. d.	£ s. d.
Gross rent received by the landlord - - - - -		63 0 0
Deduct Insurance - } when paid by him - -	1 10 0	
„ Land Tax - } when paid by him	1 2 6	
„ Sewers Rate } when paid by him	0 15 9	
„ General repairs, 10 per cent. - - -	6 6 0	
„ Collection, &c. - - - - - -	4 14 6	
		14 8 9
		48 11 3
(In a leasehold valuation, the ground rent would also have to be deducted.)		
To pay 8 per cent., at years' purchase (Fourth Table) - -		12½
Presumed value of the property, according to this rough valuation -		£607 0 8

Another valuator will make out his calculations as follows:—

	£ s. d.	£ s. d.
Gross rent - - - - - - - -		63 0 0
Annual deductions, as before - - - - -		14 8 9
Net rent - - - - - - - -		48 11 3
But property is usually subject to various depreciating contingencies, which must be provided against by an annual reserve according to the class of building, thus:—		
Deduct for losses by bad tenants, say 1 year's rent in 6 =	10 10 0	
And, for extra repairs and expenses contingent upon such frequent changes, say an equal sum - - -	10 10 0	
Deduct a sum for rebuilding (say about £630), which, put by each year in the funds at 3 per cent. compound interest, will produce that amount at the end of the life of the house, say 80 years, i.e., £1 per annum for 80 years (Third Table) - - - - - = £321·363 × 2 = £642·726	2 0 0	
		23 0 0
Clear income from the property - - - -		25 11 3
If the purchaser elects to have 5 per cent. for his speculation, the amount to be paid for the property will be - - - - -		£512 0 0

The value of the ground in these calculations is included in the rental; when of some importance, it must be valued upon its own merits, as shewn in the previous page.

But there may be a further expenditure for surveyors' charges, solicitors' charges for transferring the property, and loss of capital by selling out of the funds, which it may be often necessary to deduct from that amount. A matter also of consideration is whether the building is in a good state of repair, both in structure and decoration, as ready for a tenant.

When the property is *leasehold*, then, as soon as the clear income has been ascertained, it will have to be multiplied by the number of years' purchase at the rate of interest required for the term (Fourth Table), to find the amount that the property is worth. The number of years' purchase provides for the percentage and to get back the principal, the annual instalments of which must be invested at the same rate of interest to produce the total sum at the end of the term (in lieu of the rebuilding fund in the *freehold* property). Among Inwood's *Tables*, 16th edition, 1855, is one (p. 177), whereby to calculate " the present value of an income for a certain number of years, which is to pay during its continuance a given rate of interest on the purchase-money, and to replace the purchase-money at the end of the same number of years at a rate of interest to be selected."

From the former method of expressing the valuation, it would appear that a purchaser may realise 8 per cent. upon his outlay; and so indeed he may, for a few years, if everything connected with the property be very favourable; but the latter calculation shows exactly what may be expected, namely, that on capitalising a further sum to form a sinking fund for certain repayments, then 5 per cent. per annum may be appropriated as *income*, the remainder of the rent being set aside to supply a fund to meet exigencies of no uncommon occurrence. The real value of the property, moreover, is found to be much less than what the rough calculation would show it to be worth.

The deductions for losses depend entirely upon the class of house. First class houses in good situations let so readily to responsible tenants, who for their own comfort and display maintain the fabric, that the sums to be deducted for the occasional want of occupants and expenses of reletting are reduced to a minimum. On the other hand, a much lower class of house, together with the present unsatisfactory mode of letting houses on three years' agreements, and the still more ineligible arrangement by the year, throw so much larger amounts for repairs, decorations, and change of tenancy, upon the landlord, that the total of the sums to be deducted is raised to a very high estimate. Herein the best judgment of the valuator is called into requisition, and it requires the knowledge obtained by the practical architect to assist his judgment in such matters.

After the actual value has been ascertained, another item for consideration is the additional sum that a purchaser will be induced to give for some reason—such as the property being in a fashionable neighbourhood; the house possessing arrangements peculiarly suited to his wishes, and so on: this amount may be called a " fancy price," and when paid had better be considered as money sunk.

For making rough calculations, according to the first instance, the value of *freehold land* in the country is generally considered worth from 30 to 33 years' purchase, being calculated on the 3 per cent. tables. In a few very exceptional cases as much as 40 years' purchase has been given; but the difference constituted a " fancy price." For town plots from 25 to 30 years' is more usual. *Freehold houses and buildings*, 1st and 2nd class, from 18 to 20 years' purchase, or 5 per cent.; 3rd and 4th class, about 16 years' purchase, or 6 per cent.

For *Leasehold property* :—

1st and 2nd class,	from 15 to 16	years' purchase	or 6 per cent.
2nd and 3rd ,,	14 to 15	,,	7 ,,
3rd and 4th ,,	12 to 13	,,	8 ,,
4th and 5th ,,	11 to 12	,,	9 ,,
5th and 6th ,,	10	,,	10 ,,

Freehold *Ground-rents* are valuable in proportion to the extent to which they are covered by the rack-rent and by the period of reversion. A good ground-rent ought to be six times covered, that is, five parts are brick and mortar rent, and one part ground-rent. A reversion, however, unless within forty years, is not much taken into account. Some ground-rents in the City of London (where the ground-rent is larger in proportion) have sold for 31¼ years' purchase; those only covered by three times the rack rent, sold for 25 years' purchase. Leasehold and freehold ground-rents can only be valued according to locality, circumstances, length of holding, &c. Unsecured ground-rents are usually valued at 25 years' purchase, but those well-secured at from 30 to 33 years' purchase. *Improved ground-rents* are not worth so much as the freehold ground-rent, in consequence of the covenants of superior leases, danger of breaches of covenants, &c.

In the valuation of *leases* held on lives, the operation, after bringing the rent to a clear annuity, is conducted by means of the sixth, seventh, and eighth tables, given hereafter, as the case may require.

In the valuation of *warehouses*, the only safe method of coming at the value of a rental is by the quantity of goods or tonnage they will contain after leaving proper gangways, and not overloading the floors. In corn warehouses, however, the grain being distributed over the surface of the floor, the squares of floor are taken to come at the contents. Goods warehoused are paid for to the warehouseman usually at a weekly or monthly rent; and it is commonly considered that the profit he should make ought to be one half of the rent he pays to the landlord, so that in fact two-thirds of the actual rent realised goes to the proprietor, and the other third to the warehouseman or lessee. Tables of the weight and space occupied by different goods are given in the Glossary Addendum.

We have noticed at the commencement of this chapter that valuations depending upon building or building land are essentially within the province of the architect. But as valuations for *Railway* and *Improvement compensations* ramify into one and the other, as well as into agricultural land, a portion of the subject into which we do not consider it desirable here to enter, we will only notice that, as regards the former, there are several items, beyond those already mentioned, to be taken into consideration. A man holding a property, and dispossessed against his will, has a right to be paid for his interests being so injuriously affected, hence an item for "compulsory sale" is allowed; this was formerly as much as 30 per cent. for house property, now it is only 10 per cent.; while for land, from 10 to 25 per cent. is obtained, according to circumstances. With certain exceptions, the purchase of lands compulsorily is placed under the provisions of the Statute 8 Vict. cap. 18, "The Land Clauses Act." The assessment of the items usually consists of the following heads:—I. The value of the property taken. II. Any reversionary or prospective advantage the owner may be likely to receive at any time; to be estimated in present money. III. Any advantage the owner may have by carrying on a trade, business, or profession, in a locality; whether the same would be utterly destroyed, or a portion be taken with him. IV. The cost of removing, or loss by forced sale. V. The value of the portion only of the property (if so taken), and amount of damage the remainder may sustain in consequence of the severance; this is usually called *consequential damage.* VI. If a portion only be taken, and that portion injuriously divides the remainder of the property, the estimated amount of damage is known as *severance.* VII. Compensation for loss of time, trouble, and expense, in finding a new investment; loss of interest; the parting with property to which one is attached to and has an interest in; and other losses by being forced to give up a property and seek new. This forms the item of *compulsory sale.*

CHAP. II.

CIVIL AND ECCLESIASTICAL DILAPIDATIONS.

The architect, in the course of business, may be commissioned to ascertain the extent of neglect on the part of an occupant in keeping premises in proper order according to the terms upon which the property is held by him. In civil cases it is not usual for the lessor to exercise a power, generally reserved to him in leases, of causing his architect to inspect the premises from time to time to detect dilapidation; but it is usual for the lessor to cause such an inspection (at a reasonable period, so that the repairs may be done) before the expiration of the term: this reasonable period may vary from two to twenty-six weeks, more or less. After such inspection or survey, a notice to repair dilapidations according to its appended schedule is served upon the tenant, who may either execute the works within the term, or (unless he can compound with the lessor for a sum to be ascertained under arbitration) take the responsibility of paying the charges of the tradesmen employed by the lessor after the premises have been surrendered, to which a compensation for loss of rent is naturally added; but this arrangement, if adopted, is a very exceptional procedure. It will be evident that in cases where a lease expires and is not to be renewed before other suitable premises can be obtained, the latter method of action may be desirable; but generally, and especially in the case of a dwelling-house, the cheapest, if the most inconvenient, course is for the tenant to have a survey made for himself and to get the repairs executed within the term. In ecclesiastical cases the survey previous to the end of occupancy is rarely, if ever, practicable; and a sum must be ascertained under arbitration. According to the usual tenor of leases, the lessor expects that the premises shall be delivered, at the expiration of a term, in as good condition as the *use and wear* during the time will permit, and the lessee undertakes to make good any injury which the premises may have suffered through accident, neglect, or intention; these conditions apply, not only to what was originally demised, but to whatever may have been erected during his occupation. In ecclesiastical cases the principle, as will hereafter be explained, is rather different. It may be noticed here that the term *wear and tear* is a popular mistake which the law does not support; use and wear is legitimate, tear is dilapidation.

In civil dilapidations a tenant is bound, according to his covenant, specific or general, but never beyond maintaining and upholding, unless the conditions of repair are so bad that no measures short of reconstruction are consistent with safety, or possible from the extent of decay. His liability is not supposed to extend to such defects as only indicate age, so long as the efficiency of the part still remains. But if the effects of use or age have proceeded so far as to destroy the part, or its efficiency in the structure, the tenant is liable, it being the presumption that at the commencement of the term the tenant was satisfied that every part was sufficiently strong to last to the close. On the same presumption the degree of liability of the tenant is regulated by the actual condition of the premises at any time, as specified in his covenant, and admits of no extenuation by reason of dilapidations existing at the commencement of his term, as he is presumed to have taken the proper course to guard himself against the occurrence of undue liability. In extreme cases, the liability of a tenant extends to the rebuilding of a party wall condemned as unsafe, to reconstruction after fire, &c., unless specially excepted. In fact, under the natural and the legal favour which the lessor enjoys, the person proposing to become the lessee should employ a professional surveyor, not only to inspect the apparent, and as far as he can the hidden, state of the building, but also to check the conditions contained in the draft of the lease, which are sometimes extravagant when applied to an old and worn-out fabric, though they might be reasonable as regards a new structure.

Whatever the tenant has power to remove during the term cannot be chargeable with dilapidations. Upon this point the old rule is, that whatever is *fixed* to the freehold cannot be removed by the tenant: thus a lessee may erect barns or sheds or any building upon wooden or stone or other blocks laid on the surface of the ground, and take them down, if he please, without substituting anything in their place; but if the barns are fixed into the ground, they immediately become the property of the lessor. There seems, however, to be an exception in respect of buildings erected for the purposes of trade: hence not only coppers and ovens may be taken away, but workshops and the like erected by the tenant for his particular trade. This exception seems at first to have applied only to wooden buildings; but Lord Kenyon held that a brick chimney would prevent a tenant from removing a building, and decided that its being on a brick foundation would not do it. Though this opinion was not held by Lord Ellenborough, yet it was not because the buildings were of brick, but because they were erected for the purposes of agriculture, and not of trade. It is to be remembered, in all cases, that a lessee is bound to leave the premises in as good condition after the removal of fixtures as though they had never existed: thus, if a marble be substituted for a wooden chimney-piece, when the former is removed, the latter, or one of equal value, must be replaced. If a partition be put up and taken away, all damages to the adjacent work must be repaired.

The general rule for determining what injuries are considered dilapidations, is to ascertain what is *fair wear* without dilapidation arising from accident or neglect. Injury by accident is that which happens suddenly, and perceptibly differing from wear, which occurs only by lengthened use. Thus the nosing of a step worn away is not dilapidation; but if such be broken away instead of worn, it is a dilapidation. It may be said that accident is defined here with too much latitude, inasmuch as it takes account of that which occurs without apparent reason at any particular time; but we use the term in common language, and may cite as an example, that if the timbers of a floor decay, the floor will yield, even without a load upon it. When accident occurs, such alone does not limit the extent of the dilapidation, but also such injuries to the building as follow in its train. Thus, if the weather-boarding of a building decay from age, so long as the covering will keep out wet, it is no dilapidation; but if broken in any part, that is a dilapidation; and if from want of reparation any of the internal parts of the building be injured, such injury is a dilapidation: so if timber or timbers belonging to any part of a house merely decay, if it or they be still sufficient for the support of the house, no dilapidation can be chargeable; but if such timber or timbers give way, they must be replaced, and all parts made good which suffered by their failure. *Waste*, in law, is insufferable, even in freeholds which are held for lives only. According to Woodfall (*Landlord and Tenant*), "waste may be done in houses by pulling them down or suffering them to be uncovered, whereby the rafters and other timbers of the house become rotten; but the bare suffering them to be uncovered, without rotting the timber, is not waste: so if a house be uncovered when the tenant cometh in, it is no waste in the tenant to suffer the same to fall down." In external covering, however, it seems that decay arising from inattention to it is dilapidation, even though no accident be the cause. It is always considered that though painting neglected is not itself a dilapidation, yet where decay arises from it, it is one. Broken glass is not considered a dilapidation, unless there be more than one crack in the pane. Some, however, contend that while the glass is sufficiently entire to exclude the wind and weather, no waste is assignable. Generally it seems then to be the rule, that where accident occurs, it is a dilapidation.

In the preceding paragraph the word *neglect* has naturally occurred; dilapidation from neglect being very often followed by dilapidation by *accident*: the latter term is still more nearly connected with the word *misuse*, which occupies the place here given to "accident" in the Report upon Dilapidations, published in 1844 by the Royal Institute of British Architects. This Report does not define its meaning of the word *misuse*; it is clearly not the meaning in which the term is generally employed; for the Report says, "If the effects of use or age have proceeded so far as to destroy the part or its efficiency in the structure, this argues neglect or misuse." The student will find it advantageous to study the Report, and especially the specification contained therein.

This specification instructs the mason "in cases of broken nosings, or of the treads being worn to such an extent as to render the passing up and down dangerous," to piece as described the step; and also directs the joiner "to put nosings to stairs where partially defective, and treads where wholly so." There is in appearance a contradiction between these views upon worn steps and that given in the commencement of this chapter; but the practised surveyor will see that they are easily reconciled, and that his judgment must decide which is, and which is not, fair use and wear. It is to be regretted that the clear and discriminating section on dilapidations in Chambers and Tattersall, *Laws relating to Building*, 1845, contains a sweeping condemnation of this Report, which is in no way authorised by the evidence adduced.

We have added to the usual definition of dilapidation, namely any injury through *accident*, *misuse*, or *neglect*, the word *intention*; and the propriety of the addition, as meaning something different from wilful waste, will be obvious. The erection of a photographer's room on the top of a house in one street may be deemed an injury, and be claimed as dilapidation by a lessor, who would demand the removal of it and the restoration of the roof; while in another street, and within a few yards of this dilapidation, the same lessor might consider the same work (if judiciously executed) an improvement which he would not allow to be removed. So also a grated iron door, instead of the common wooden one, and similar alterations, may become dilapidations of intention at the pleasure of the lessor. There is another point on which surveyors have frequently differed, namely the insertion of nails and screws for the suspension of frames of pictures, &c. This may be now considered to be determined by the judgment in the case of Martin and another *v.* Roe (1857), where hot house frames, bedded in mortar on brick walls, had been removed without damage except what was unavoidable to the mortar. Lord Campbell said that, "in considering this question, we treat the removal by the plaintiff as having been in fact effected without injury to the freehold. In all cases of this kind, injury to the freehold must be spoken of with less than legal strictness. A screw or a nail can scarcely be drawn without some injury; and when all the harm done is that which is unavoidable to the mortar laid on brick walls, this is so trifling that the law, which is reasonable, will regard it as none." Among surveyors it has been held that what is nailed belongs to the freehold, but that which can be unscrewed does not, the careful withdrawal of the screw enabling the tenant to make good the hole.

Although there is a general impression that only damage of broken glass can be claimed from a yearly tenant, he is to use the building in a husbandlike manner, and is bound to fair and tenantable repairs so far as to keep it wind and water tight and to prevent waste or decay.

It used to be supposed that the judgment in the case of Wise *v.* Medcalf (1829) contained an exposition of the whole law on the subject of ecclesiastical dilapidation as far as regarded incumbents; and the decision, which is contained in the following words, should be always in the mind of the surveyor:—"Upon the whole, we are of opinion the incumbent was bound to maintain the parsonage (which we must assume upon this case to have been suitable in point of size and other respects to the benefice) and also the chancel, and to keep them in good and substantial repair; restoring and rebuilding when necessary, according to the original form, without addition or modern improvement; and that he was not bound to supply or maintain anything in the nature of ornament, to which painting (unless necessary to preserve exposed timbers from decay) and whitewashing, and papering belong." This decision is held to establish the principle that the executors of a deceased incumbent are bound to perform those repairs which are necessary to prevent decay, and to use all reasonable means for preventing any future decay. The case of Mason *v.* Lambert (1848) showed that perpetual curates were liable as incumbents for these dilapidations. We have therefore to add, in ecclesiastical cases, any provision against prospective injury; such as paint necessary to preserve exposed woodwork from decay, the insertion of ties to plates taking the feet of rafters, the underpinning of walls at cracks showing continual settlement: these might be entitled dilapidations of precaution, and ought to include the immediate destruction of any erections made by a late incumbent which were suitable to his private fortune rather than to the benefice, as seems to be indicated in the judgment given in the case of Martin and another *v.* Roe (1857), wherein it is observed that, "as to any matter of needless expense or luxury or ornament by which the present incumbent has gratified his own taste or increased his own comfort, he is not only not bound. but he ought not, to transmit it to his successor." The principle thus stated is directly opposite to that which, as we have above observed, regulates civil cases, namely, that the occupier must keep in repair whatever may have been erected during his occupation. The judgment just cited continues in these words: "If the successor may recover damages from the executor after such things have been removed by the testator, there can be no doubt he in his turn must maintain it; and if he maintain it he must also restore, and even rebuild when decayed; so that the benefice might become permanently saddled with a useless burden." The duty to remove such erections does not, however, appear quite to have been thrown upon the estate of the erector: the same judgment says, "the case now supposed is that of an erection, which, if the deceased had left out of repair, his successor could not have maintained any action for dilapidations, which he himself therefore would not be bound to keep in repair, which imposes no burden on him, and which he may remove; for it would be unreasonable to hold that he might not remove, however useless or unsuitable to the living, or even inconvenient to the occupation of the parsonage or glebe, that which for one of these reasons he was not bound to keep in repair." Finally we would quote from the same judgment: "with regard to an ecclesiastical benefice, the character and object of the building to which the chattel is attached, and the manner in which it has been so attached, seem of very great consequence in determining whether there was any intention to separate it permanently and irrevocably from the personal estate." In this case the plaintiffs (executors) were held justified in removing the framework and sashes, valued at 300*l.*, of two hot houses, and might apparently have removed also the brickwork, repairing any waste or damage to the freehold. With respect to that damage we have already referred to this case.

The real difference between civil and ecclesiastical dilapidations may be thus stated:— One man takes certain premises, engaging to pay a rent in order to derive advantages out of them, but having no interest in the freehold. The other man receives a salary to do certain services, the *use* of the house being a portion of that salary. In the latter case, if for a man's own private convenience he lays out a large sum on the freehold, that expenditure will seriously affect his successor, if he have to be burdened with large and expensive erections or decorations suitable perhaps for one of an aristocratic family, but quite foreign to the habits of a future rector of the village coming in as an ordinary occupant.

Such are the general principles of the law of dilapidations; these, in their application, generally impose upon the out-going occupant or his representatives the payment of a sum for which special provision is rarely made during the occupancy: the misery thus entailed is sometimes evaded in civil cases by the lessee, who parts with the remainder of a lease to any one who will give something for it; or who (if the lessor be not careful) assigns it to a man of straw.

CHAP. III.

CALCULATION OF INTEREST.

Interest, or the value of the use of money, is usually expressed *per cent.*, or after the rate per hundred on the principal lent. Thus, if we put out 500 pounds sterling at 5 per cent., it signifies that for every hundred pounds the lender is to receive five pounds per annum during the continuance of the loan. The solution of this question, which is one merely of *simple interest*, is so obvious, that it is unnecessary further to detain the reader upon it; and we therefore pass on to *compound interest*, or interest upon interest, which arises from the principal and interest taken together, as it becomes due at the end of each stated time of payment.

In the resolution of this question, we are to consider that 100*l.* at the end of a year becomes 105*l.* Let a = principal. Its amount at the end of the year is found by saying, if 100 gives 105, what will a give? and we answer $\frac{105a}{100}=\frac{21a}{20}$, which may be also expressed $\frac{21}{20}\times a$, or $a+\frac{1}{20}\times a$.

Thus, by adding its twentieth part to the original principal, we have the principal at the end of the first year; adding to this last its twentieth, we know the amount of the given principal in two years, and so on. Hence the annual increases to the principal may be easily computed. Suppose, for instance, the principal of 1000*l.* Expressing the values in decimal fractions, it will be worth—

After 1 year - - -	£1050	
	52·5	One year's interest on £1050.
After 2 years - - -	1102·5	
	55·125	— 1102·5
After 3 years - - -	1157·625	
	57·881	— 1157·625
After 4 years - - -	1215·506	
	60·775	— 1215·506
After 5 years - - -	1276·281 &c.	

The method above exhibited would, however, in calculations for a number of years, become very laborious, and it may be abridged in the following manner.

Let the present principal $=a$; now, since a principal of 20*l.* will amount to 21*l.* at the end of a year, the principal a will amount to $\frac{21}{20}\times a$ at the end of that time. At the end of the following year the same principal will amount to $\frac{21^2}{20^2}\times a=(\frac{21}{20})^2\times a$. This principal of two years will, the year after, amount to $(\frac{21}{20})^3\times a$, which will therefore be the principal of three years; increasing in this manner, at the end of four years the principal becomes $(\frac{21}{20})^4\times a$. After a century it will amount to $(\frac{21}{20})^{100}\times a$, and in general $(\frac{21}{20})^n\times a$ is the amount of the principal after n years; a formula serving to determine the amount of principal after any number of years.

The interest of 5 per cent., which has been taken in the above calculation, determined the fraction $\frac{21}{20}$. Had the interest been reckoned at 6 per cent. the principal a would at the end of a year be $(\frac{106}{100})\times a$; at the end of two years to $(\frac{106}{100})^2\times a$; and at the end of n years to $(\frac{106}{100})^n\times a$. Again, if the interest be at 4 per cent. the principal a will, after n years, be $(\frac{104}{100})^n\times a$. Now all these formulæ are easily resolved by logarithms; for if, according to the first supposition, the question be $(\frac{21}{20})^n\times a$, this will be $L.(\frac{21}{20})^n+L.a$, and as $(\frac{21}{20})^n$ is a power, we have $L.(\frac{21}{20})^n=nL.\frac{21}{20}$: so that the logarithm of the principal required is $=n\times L.\frac{21}{20}+L.a$, and the logarithm of the fraction $\frac{21}{20}=L.21-L.20$.

We shall now consider what the principal of 1000*l.* will amount to at compound interest of 5 per cent. at the end of 100 years. Here $n=100$. Hence the logarithm of the principal required will be $=100L.\frac{21}{20}+L.1000$, calculated as under:—

$$L.21=1{\cdot}3222193$$
$$\text{Subtracting } L.20=1{\cdot}3010300$$
$$L.\tfrac{21}{20}=0{\cdot}0211893$$
$$\text{Multiply by } 100$$
$$100\,L.\tfrac{21}{20}=2{\cdot}1189300$$
$$\text{Add } L.1000=3{\cdot}0000000$$
$$5{\cdot}1189300=\text{Logarithm of the principal}$$

required, from the characteristic whereof the principal must be a number of six figures, and by the tables it will appear to be 131,501*l.* In the case of a principal of 3452*l.* at 6 per cent. for sixty-four years, we have $a=3452$ and $n=64$. Principal at the end of the first year therefore $=\frac{106}{100}=\frac{53}{50}$. Hence the logarithm of the principal sought $=64\times L.\frac{53}{50}+L.3452$, which will be found to amount to 143,763*l.*

When the number of years is very great, errors of considerable magnitude may arise from the logarithms not being sufficiently extended in the decimal places; but as our object here is only to show the principle on which these calculations are founded, we do not think it necessary further to pursue that subject.

There is another case which now requires our consideration; it is that of not only adding the interest annually to the principal, but increasing it every year by a new sum $=b$. The original principal a would then increase in the following manner:—

After 1 year, $\frac{21}{20}a+b$

After 2 years, $(\frac{21}{20})^2a+\frac{21}{20}b+b$

After 3 years, $(\frac{21}{20})^3a+(\frac{21}{20})^2b+\frac{21}{20}b+b$

After 4 years, $(\frac{21}{20})^4a+(\frac{21}{20})^3b+(\frac{21}{20})^2b+\frac{21}{20}b+b$

After n years, $(\frac{21}{20})^na+(\frac{21}{20})^{n-1}b+(\frac{21}{20})^{n-2}b+\dots\frac{21}{20}b+b$

This principal evidently consists of two parts, whereof the first $=(\frac{21}{20})^na$, and the other, taken inversely, forms the series $b+\frac{21}{20}b+(\frac{21}{20})^2b+(\frac{21}{20})^3b+\dots(\frac{21}{20})^{n-1}b$. This last series is evidently a geometrical progression, whose exponent $=\frac{21}{20}$. Its sum, therefore, will be found by first multiplying the last term $(\frac{21}{20})^{n-1}b$ by the exponent $\frac{21}{20}$, which gives $(\frac{21}{20})^nb$. Subtract the first term b, and we have the remainder $(\frac{21}{20})^nb-b$; and lastly, dividing by the exponent minus 1, that is, by $\frac{1}{20}$, we have the sum required, $=20(\frac{21}{20})^n b - 20b$. Wherefore the principal sought is $(\frac{21}{20})^n a + 20(\frac{21}{20})^n b - 20b = (\frac{21}{20})^n \times (a + 20b) - 20b$.

To resolve this formula we must separately calculate its first term $(\frac{21}{20})^n \times (a + 20b)$, which is $n\text{L}.\frac{21}{20} + \text{L}.(a + 20b)$, for the number which answers to this logarithm in the tables will be the first term, and if from this we subtract $20b$ we have the principal sought.

Suppose a principal of 1000*l.* placed out at 5 per cent. compound interest, and to it there be annually added 100*l.* besides *its* compound interest, and it be required to know to what it will amount at the end of 25 years. Here $a=1000$, $b=100$, $n=25$· and the operation is as follows: —

$$\text{L}.\tfrac{21}{20} = 0{\cdot}021189299$$

$$\text{Multiply by 25 we have } 25\text{L}.\tfrac{21}{20} = 0{\cdot}5297324750$$
$$\text{L}.(a+20b) = 3{\cdot}4771213135$$
$$= 4{\cdot}0068537885$$

The first part or number which answers to this logarithm is 10159·1*l.*; from which if we subtract $20b = 2000$ we find the principal in question to be after 25 years 8159·1*l.*

If it be required to know in how many years a principal of 1000*l.* under the above conditions would amount to 1,000,000*l.*; let n be the number of years required, and since $a=1000$, $b=100$, the principal at the end of n years will be $(\frac{21}{20})^n(3000) - 2000$, which sum must make 1,000,000*l.*; whence results this equation: —

$$3000\ (\tfrac{21}{20})^n - 2000 = 1000000$$

$$\text{Adding to both sides 2000 we have } 3000\ (\tfrac{21}{20})^n = 1002000$$
$$\text{Dividing both sides by 3000 we have } (\tfrac{21}{20}) = 334$$

Using logarithms we have $n\text{L}.\frac{21}{20} = \text{L}.334$, and dividing by $\text{L}.\frac{21}{20}$, we obtain $n = \frac{\text{L}.334}{\text{L}.\frac{21}{20}}$. Now $\text{L}.334 = 2{\cdot}5237465$ and $\text{L}.\frac{21}{20} = 0{\cdot}0211893$, wherefore $n = \frac{2{\cdot}5237465}{0{\cdot}0211893}$. If, lastly, the two terms of this fraction be multiplied by 10000000, we shall have $n = \frac{2{\cdot}5237465}{211893}$, equal to one hundred and nineteen years one month and seven days, which is the time wherein the principal of 1000*l.* will be increased to 1,000,000*l.* In the case of an annual decrease instead of increase of the capital by a certan sum, we shall have the following gradations as the values of a, year after year, the interest being at 5 per cent., and, representing by b the sum annually abstracted from the principal,

After 1 year it would be $\frac{21}{20}a - b$
After 2 years — $(\frac{21}{20})^2 a - \frac{21}{20}b - b$
After 3 years — $(\frac{21}{20})^3 a - (\frac{21}{20})^2 b - \frac{21}{20}b - b$
After n years — $(\frac{21}{20})^n a - (\frac{21}{20})^{n-1} b - (\frac{21}{20})^{n-2} b \ \ldots\ldots - (\frac{21}{20})b - b.$

This principal evidently consists of two parts, one whereof is $(\frac{21}{20})^n a$, and the other to be subtracted therefrom, taking the terms inversely, forms a geometrical progression, as follows: —

$$b + (\tfrac{21}{20})b + (\tfrac{21}{20})^2 b + (\tfrac{21}{20})^3 b + \ \ldots\ldots\ (\tfrac{21}{20})^{n-1} b$$

The sum of this progression has already been found $= 20\ (\frac{21}{20})^n b - 20b$; if, therefore, this be subtracted from $(\frac{21}{20})^n a$, we have the principal required after n years $= (\frac{21}{20})^n (a - 20b) + 20b$.

For a less period than a year, the exponent n becomes a fraction; for example, 1 day $= \frac{1}{365}$, 2 days $= \frac{2}{365}$, and so on. It often happens that we wish to know the present value of a sum of money payable at the end of a number of years. Thus, as 20 pounds in ready money amount in a twelvemonth to 21 pounds, so, reciprocally, 21 pounds payable at the end of a year can be worth only 20 pounds. Therefore, if a be a sum payable at the end of a year, the present value of it is $\frac{20}{21}a$. Hence, to find the present value of a principal a at the end of a year, we must multiply by $\frac{20}{21}$; to find its present value at the end of two years, it must be multiplied by $(\frac{20}{21})^2 a$; and, in general, its value n years before the time of payment will be expressed by $(\frac{20}{21})^n a$.

Thus, suppose a rent of 100*l.* receivable for 5 years, reckoning interest at 5 per cent., if we would know its value in present money, we have

For £100 due after 1 year, the present value is		£95·239
after 2 years	—	90·704
after 3 years	—	86·385
after 4 years	—	82·272
after 5 years	—	78·355
Sum of the five terms		£432·955

So that in present money, the value is 432*l.* 19*s.* 1*d.*

But for a great number of years such a calculation would become laborious. It may be facilitated as follows: — Let the annual rent $=a$, commencing directly and continuing n years, it will be worth $a+(\frac{20}{21})a+(\frac{20}{21})^2a+(\frac{20}{21})^3a+(\frac{20}{21})^4a \dots +(\frac{27}{21})^na$, which is a geometrical progression whose sum is to be found. We have therefore only to multiply the last term by the exponent, the product whereof is $(\frac{20}{21})^{n+1}a$, then subtract the first term, and the remainder is $(\frac{20}{21})^{n+1}a-a$. Lastly, dividing by the exponent minus 1, that is, $\frac{1}{21}$, or, which is the same, multiplying by -21, we have the sum required, $=-21(\frac{20}{21})^{n+1}a+21a$, or $21a-21^{n+1}a$, the value of which second term is easily calculated by logarithms.

CHAP. IV.

COMPOUND INTEREST AND ANNUITY TABLES.

As the architect is often called on to value property, we here add some practical observations on the subject, and a set of Tables for the ready calculation of such matters, which we shall at once explain.

Table First contains the amount of 1*l.* put out to accumulate at compound interest for any number of years up to 100, at the several rates of 3, 4, 5, 6, 7, and 8 per cent. The amount of any other sum is found by multiplying the amount of 1*l* found in the table at the given rate per cent., and for the given time, by the pro osed sum.

Example :—Required the amount of 755*l.* in 51 years, at 5 per cent.

Amount of 1*l.* for 51 years. at 5 per cent. is - - - -	12·040769
Given sum - - - - - - - - - -	755
or 9090*l.* 15*s.* 7$\frac{3}{10}$*d.*	£9080·780595

Table Second contains the present value of 1*l.* payable at the end of any number of years up to 100. The present value of any given sum payable at the expiration of any number of years is found by multiplying the present value of 1*l.* for the given number of years, at the proposed rate per cent., by the given sum or principal.

Example: — Required the present value of 9090*l.* payable 51 years hence, compound interest being allowed at 5 per cent.

By the table, the present value of 1*l.* payable at the expiration of 51 years at 5 per cent. is - - - - - - - -	·083051
Given principal - - - - - - - - -	9090
or 754*l.* 18*s.* 7$\frac{4}{10}$*d.*	£754·933590

Table Third contains the amount of an annuity of 1*l.* for any number of years, and is thus used. Take out the amount of 1*l.* answering to the given time and rate of interest: this multiplied by the given annuity will be the required amount.

Example :—Required the amount of an annuity of 27*l.* in 21 years, at 5 per cent. compound interest.

Annuity of 1*l.* in 21 years at 5 per cent. - - - - - -	35·719251
Annuity given - - - - - - - - -	27
or 964*l.* 8*s.* 4$\frac{7}{10}$*d.*	£964·419777

Table Fourth shows the present value of an annuity of 1*l.* for any number of years, at 3, 4, 5, 6, 7, and 8 per cent., and is used as follows:—

First, when the annuity commences immediately. Multiply the tabular number answering to the given years and rate of interest by the given annuity, and the product will be the value required. (This table provides for the percentage and to get back the principal.)

Example:—Required the present value of an annuity of 45*l.*, which is to continue 48 years, at the rate of 5 per cent.

Under 5 and opposite to 48 years is (years' purchase) - -	18·077157
Annuity given - - - - - - - - -	45
or 813*l.* 9*s.* 5$\frac{3}{10}$*d.*	£813·472065

Second, when the annuity does not commence till after a certain number of years. Multiply the difference between the tabular numbers answering to the time of commencement and end, at the proposed rate of interest, by the given annuity, the product will be the present value required.

Example.

An annuity of 40*l.* is to commence 20 years hence, and is to continue 30 years; required its present value, the rate of interest being 4 per cent.

Under 4 per cent. and opposite to 20 is - - - - -	13·590326
Under 4 per cent. and opposite to 50 (20 + 30) is - - -	21·482184
Difference - - - - - - - - - - - -	7·891858
Annuity given - - - - - - - - - - -	40
	£315·674320

or 315*l.* 13*s.* $5\frac{8}{10}$*d.*

Table Fifth contains the annuity which 1*l.* will purchase, compound interest being allowed. The manner of using this table is obvious, from what has been said relative to the preceding tables.

Example.

What annuity for 10 years will 500*l.* purchase, the rate of interest being 5 per cent.?

Under 5 and opposite to 10 is - - - - - - - - -	·129504
Principal given - - - - - - - - - - -	500
	£64·752000

or 64*l.* 15*s.* $0\frac{5}{10}$*d.*

Tables Sixth, Seventh, and Eighth are for finding the value of annuities on single and joint lives, and were constructed by Simpson, on the London bills of mortality.

To find the value of an annuity for a single life, at a proposed rate of interest, within the limits of the table, take from Table VI. the number answering to the given age and proposed rate of interest, which multiplied by the given annuity, the product will be the value required.

Example.

What is the value of an annuity of 50*l.* upon a single life aged 40 years, according to the London bills of mortality, the rate of interest being 4 per cent.?

The value of an annuity of 1*l.* for 40 years at 4 per cent. is - - -	11·5
Annuity - - - - - - - - - - - - -	50
Value - - - - - - - - - - - -	£575

To find the value of an annuity of two joint lives, multiply the number in Table VII. answering to the given ages, and at the proposed rate of interest, by the given annuity, and the product will be the required value.

Example.

What is the value of an annuity of 60*l.* for two joint lives, the one being 30 and the other 40 years, interest at 4 per cent.?

The number answering to 30 and 40 years at 4 per cent. is - - -	8·8
Annuity - - - - - - - - - - - - -	60
Value - - - - - - - - - - -	£528·0

To find the value of an annuity for the longest of two given lives, proceed as directed in the case immediately preceding, but using Table VIII., and the product will be the value.

Example.

What is the value of an annuity of 60*l.* for the longest of two lives, the one being 30 and the other 40 years, interest at 4 per cent.

The tabular number answering at 4 per cent. is - - - - -	15·9
Annuity - - - - - - - - - - - - -	60
Present value - - - - - - - - - - - -	£954·0

The first five tables which follow are printed from those of Smart; the remainder are from Simpson.

The calculations involving the valuation of annuities on lives are not very frequently imposed on the architect, but it is absolutely necessary he should be capable of performing them, as in the case of valuations of leases upon lives, which sometimes occur to him.

Table VI.*a*. Expectation of Life.

De Moivre's Hypothesis on the duration of human life, namely, that of 86 persons born one dies every year till all are extinct, has led to an empirical rule of easy recollection for the expectation of life, namely, to subtract the age from 86 and halve the difference for an answer. In the left hand side of the subjoined table is shown the number of persons out of 10,000 who may be expected to die in the year following their attaining the age marked in the first column, according to the Hypothesis, to the Northampton and Carlisle tables, and to the Belgian one of Quetelet. The table on the right shows the values of annuities on lives at 3 per cent. in years' purchase, whence it appears that in money results the Hypothesis curiously agrees with the celebrated Northampton tables.

Age.	Hypothesis.	Northampton.	Carlisle.	Belgium.	Age.	Hypothesis.	Northampton.	Carlisle.

A BRIEF SYNOPTICAL LIST OF THE PRINCIPAL

ARCHITECTS,

ANCIENT AND MODERN,

WITH THEIR CHIEF WORKS,

REVISED BY WYATT PAPWORTH

NOTE.—Many of the Names herein are more fully noticed in the body of this work, and some few others will be found by reference to its Index.

BEFORE CHRIST.

7th. Century.

I. AGAMEDES and TROPHONIUS of Delphi.—Mentioned only in mythology; temple to Apollo at Delphi; a temple to Neptune near Mantinæa.

II. THEODORUS and RHŒCUS, of Samos.—Labyrinth at Lemnos; some buildings at Sparta; the temple of Jupiter at Samos; foundations of one of the temples of Diana at Ephesus.

III. HERMOGENES of Alabanda.—Temple of Bacchus at Teos; and that of Diana at Magnesia.

6th. Century.

IV. DEMETRIUS and PÆONIUS, of Ephesus.—Continuation of one of the temples of Diana, at Ephesus, which had been begun by CHERSIPHRON or Ctesiphon and his son Metagenes.

V. DAPHNIS of Miletus.—With PÆONIUS, temple of Apollo at Miletus.

VI. EUPALINUS of Megara.—Tunnel for the aqueduct, and some edifices at Samos.

VII. CHIROSOPHUS of Crete.—Temple to Ceres and Proserpine; another to the Paphian Venus, and one to Apollo; all at Tegea.

VIII. MANDROCLES of Samos.—Bridge of boats over the Thracian Bosphorus, for King Darius.

IX. MEMNO of Persia.—A magnificent palace at Ecbatana for Cyrus.

5th. Century.

X. PYTHIUS of Priene.—Mausoleum at Halicarnassus; the temple of Minerva at Priene, and wrote a treatise on it. In the former he was assisted by Satyrus.

XI. SPINTHARUS of Corinth.—Rebuilt the temple of Apollo at Delphi, which had been destroyed by fire.

XII. LIBO of Elis.—Temple of Jupiter Olympius at Olympia.

XIII. ICTINUS of Athens.—Parthenon at Athens, and wrote a treatise upon it; perhaps the temple of Ceres and Proserpine at Eleusis; temple of Apollo Epicurius near Phigaleia.

XIV. CALLICRATES of Athens.—Assisted Ictinus in the erection of the Parthenon.

XV. MNESICLES of Athens.—Propylea of the Acropolis at Athens.

XVI. ANTISTATES of Athens.—A temple of Jupiter at Athens.

XVII. SCOPAS of Paros.—One side of the Mausoleum at Halicarnassus; a column of the temple at Ephesus. Employed on temple of Minerva at Tegea.

XVIII. HIPPODAMUS of Miletus.—Laid out Munychia in the Piræus and Rhodes.

XIX. CORŒBUS and METAGENES XYPETIUS of Athens.—Perhaps the temple of Ceres at Eleusis.

XX. POLYCLITUS.—A theatre with a dome at Epidaurus, highly praised by Pausanius.

XXI. ARCHIAS of Corinth.—Many temples and other edifices, at Syracuse.

XXII. CALLIAS of Aradus.—Machinery.

XXIII. TARCHESIUS and ARGELIUS.—Wrote treatises on Architecture; the former is supposed to have erected the temple to Æsculapius at Tralles.

XXIV. MNESTHES.—Pseudodipteral temple of Apollo at Magnesia.

BEFORE CHRIST.

4th. Century

XXV. DEINOCRATES or DINOCHARES of Macedonia.—Rebuilt the last temple of Diana at Ephesus; laid out the city of Alexandria, and designed many edifices there; proposed to transform Mount Athos into a colossal figure of Alexander.

XXVI. CALLIMACHUS of Corinth.—Reputed inventor of the Corinthian order. Vitruvius, b. iv. chap. 1.

XXVII. SOSTRATUS of Cnidus.—The Pharos near Alexandria.

XXVIII. EUPOLEMUS of Argos.—Several temples and a theatre at Argos. The Heræum near Mycenæ.

3rd. Century.

XXIX. PHÆAX of Agrigentum.—Various buildings at Agrigentum.

XXX. CLEODAMAS of Byzantium.—Restored, with Athenæus, the cities destroyed by the Scythæ and others.

2nd. Century.

XXXI. COSSUTIUS of Rome.—Additions to the temple of Jupiter Olympius at Athens, for Antiochus Epiphanus, king of Syria, and afterwards destroyed.

XXXII. PHILO of Athens or of Byzantium.—Enlarged the arsenal and the Piræus at Athens; erected the great theatre, rebuilt by order of Hadrian. Wrote on Architecture.

XXXIII. HERMODORUS of Salamis.—Temple of Jupiter Stator in the Forum, and temple of Mars in the Circus Flaminius, at Rome.

XXXIV. CAIUS MUTIUS of Rome.—Temples to Honour and Virtue near the trophies of Marius at Rome.

1st. Century.

XXXV. and XXXVI. BATRACHUS and SAURUS, of Laconia.—These two architects built the temple enclosed by the portico of Octavia, at Rome. The name of the first (βατραχος) signifies a frog; and that of the latter (σαυρος), a lizard. They are considered to have perpetuated their names by the representation of those animals in the eye of the volutes of the Ionic order, of which a capital has been found; and in the churches of St. Eusebius and of St. Lorenzo fuori le Murà, at Rome, are pedestals sculptured with them.

XXXVII. DEXIPHANES of Cyprus, or Cnidos.—A causeway; and rebuilt or repairéd the Pharos at Alexandria, erected by Sostratus.

XXXVIII. VALERIUS of Ostium.—Covered in a theatre at Rome.

XXXIX. CYRUS of Rome.—Architect to Cicero and his brother.

XL. POSTHUMIUS of Rome.—Many works at Rome and Naples.

XLI. LUCIUS COCCEIUS AUCTUS of Rome.—Grotta della Sibella from Lacus Avernus to Baiæ; a temple at Pozzuoli; tunnel of Cumæ, near the Lacus Avernus.

XLII. FUSSITIUS or FUFITIUS of Rome.—Several buildings at Rome. The first Roman who wrote copiously on architecture.

XLIII. MESSIDIUS and PHILOXENUS.—Formed an aqueduct near Rome for Cicero's brother.

XLIV. NUMISIUS.—Theatre at Herculaneum; buried A.D. 79.

AFTER CHRIST.

1st. Century.

1. MARCUS VITRUVIUS POLLIO of Fano.—Basilica Justitiæ at Fano. Writer on architecture, the oldest work extant on the art.
2. VITRUVIUS CERDO of Verona.—Triumphal arch at Verona.
3. CELER of Rome.—Golden house of Nero, with SEVERUS of Rome.
4. RABIRIUS of Rome.—Palace of Domitian and works connected therewith, on Mount Palatine.
5. MUSTIUS of Rome.—Temple to Ceres at Rome.

2nd. Century.

6. JULIUS FRONTINUS of Rome.—He has left a work on aqueducts.
7. APOLLODORUS of Damascus.—The forum of Trajan, the column of Trajan, and other buildings at Rome; a stone bridge over the Danube in Lower Hungary, the remains of which are still visible.

AFTER CHRIST.

8. Caius Julius Lacer of Rome.—Bridge over the Tagus at Alcantara, in Spain; a temple there, now dedicated to San Giuliano.
9. Detrianus of Rome.—Moles Hadriani and the Pons Aelius; now called the Castello and Ponte Sant' Angelo; removed the colossal statue of Nero for Hadrian.
10. Antoninus, Senator, of Rome.—Pantheon at Epidaurus; baths of Æsculapius, in the same city.

4th. Century.

11. Metrodorus of Persia.—Many buildings in India, and some at Constantinople. The first known Christian architect.
12. Alypius of Antioch.—Employed by Julian to lay the foundation of a new temple at Jerusalem.

5th. Century.

13. Cyriades, Consul, of Rome.—A basilica and bridge for Theodosius, carried on by Auxentius, senator, Symmachus, prefect, and Afrodisius, consul.
14. Sennamar of Arabia.—Sedir and Khaovarnack, two celebrated palaces in Arabia.

THE SCYTHIAN DEVASTATIONS.

15. Aloisius of Padua or Rome.—Buildings for Theodoric; assisted Daniel in the erection of the celebrated mausoleum at Ravenna, the cupola of which is of one stone, 36 feet diam. outside, 30 feet inside, and hollowed within.

6th. Century.

16. Ætherius of Constantinople.—The vestibule called Chalce in the Imperial Palace at Constantinople, for Anastatius I; and a wall in Thrace 54 miles long.
17. Anthemius of Tralles.—Sta. Sophia at Constantinople; he was assisted by Isidorus of Miletus.
18. Chryses of Alexandria.—Constructed the embankments along the Euripus, near Dara, in Persia, to keep the river in its channel, and to keep out the sea.

7th. Century.

19 and 20. Isidorus of Byzantium, and Joannes of Miletus.—The city of Zenobia, on the river Euphrates, in Syria, for Justinian.

8th. Century.

21. Abdelrahaman I. of Spain.—Gave the designs for the mosque at Cordova.

9th. Century.

22. Romualdus of France.—Cathedral at Rheims, the earliest example of Gothic architecture.
23. Magnus Eginhardus of Odenwald, in Germany.—Præfect of buildings to Charlemagne. The monastery at Mulinheim, now Seligenstadt; drawing of monastery for Gozpertus, abbot of St. Gall in Switzerland.
24. Tioda of Spain.—Palace for King Alphonso the Chaste, at Oviedo, now the episcopal palace; churches of St. Salvador (since destroyed), St. Michael, and St. Mary, and St. Julius outside the walls.

10th. Century.

25. Eberhard, abbot, of Switzerland.—Church and monastery at Einsiedlen, in Switzerland, and completed by Tietland, abbot.
26. Abdallah ben Said of Spain.—Eastern aisles of the mosque at Cordova.

11th. Century.

27. Busketus or Buschetto.—Church of S. Paolo at Pistoja, 1032. Duomo at Pisa, the earliest example of the Lombard style of architecture. It was built in 1063.
28. Humbert, archbishop, of Lyons.—Erected the stone bridge over the Saone at Lyons, and is recorded as the architect.
29. Pietro di Ustamber of Spain.—Crypt of the cathedral at Chartres, or by bishop Fulbert; rebuilt the church of St. Isidorus at Leon, and erected a bridge there.
30. Carilepho, bishop of Durham, of England.—Began the cathedral church of Durham, "on a plan which he had brought with him from France," where he had been abbot of St. Vincent, in Normandy.

12th. Century.

31. Lanfrancus of Italy.—The cathedral at Modena, 1099-1108.
32. Landfridus of Normandy.—Erected the castle of Pithiviers in Normandy, and then that of Ivry; after which this "architect" was beheaded, that he might not erect another elsewhere.

33. Gundulphus, bishop of Rochester, of England.—Considered to have designed Rochester Castle; his house, and the abbey for nuns at Malling in Kent; White Tower of the Tower of London, and western portion of Rochester Cathedral; the eastern portion erected later by Bishop Ernulf.
34. Odo, prior of Croyland, of England.—Church of Croyland Abbey. Arnold, a lay brother of the abbey, was employed as mason.
35. Lalys of the Land of Canaan.—Neath Castle, Glamorganshire, and other castles, monasteries, and churches; built Lalyston; appointed architect to King Henry I.
36. Raymundo of Montfort, of France.—Cathedral at Lugo, in Spain, all but the belfry and facade.
37. Dioti Salvi, or D. de Petroni, of Italy.—Baptistry at Pisa, in the Lombard style.
38. Buono of Ravenna.—Palaces and churches at Ravenna; tower of St. Mark at Venice, which is 330 feet high, and 40 feet square, built 1148-54; the Castel del Uovo and the Castle Capuano, at Naples; and palazzo de' Signori at Arezzo.
39. Gruamons of Pistoia.—Part of churches of St. Andrea and of St. Giovanni at Pistoia.
40. Alvar Garcia of Estella, in Spain.—The reputed designer of the cathedral at Avila del Rey, in Spain.
41. Sugger, of France.—Built parts of his abbey church of St. Denis, near Paris.
42. Pietro Cozzo of Limena in Italy.—Sala della Ragione at Padua, which is about 261 feet long, 88 feet wide, and 87 feet high inside. The roof was burnt in 1420, and restored by Rizzio and Piccino, of Venice; it was dismantled by a whirlwind in 1756, and restored by B. Ferracina.
43. Wilhelmus of Germany.—Campanile at Pisa, 178 feet high, with Bonano of Pisa. Tomaso, also of Pisa, completed it in the 14th century.
44. William of Sens.—Choir of Canterbury Cathedral, after the fire of 1174; completed by William the Englishman.

13th. Century.

45. Isenbert of Xainctes, in France.—Bridges at Xainctes and Rochelle. Recommended by King John to the citizens of London as a proper person to finish London Bridge, begun by Peter of Colechurch, in 1176.
46. Helvas de Berham or Derham, canon of Salisbury, of England.—Overseer for twenty years of the works at Salisbury Cathedral, from its foundation. He was succeeded by a certain Robert. He may be the same person who is called Elyas the Engineer, in records of the reigns of Kings Richard I. and John, relating to the repair of the king's houses at Westminster.
47. Edward Fitz-Odo of England.—Supposed master of the works at Westminster Abbey Church for King Henry III.
48. Robert de Luzarches of France.—Cathedral of Amiens; continued by Thomas de Cormont, and finished by his son Regnault, as stated in the labyrinth in the nave.
49. Estienne de Bonnueill of Paris.—Church of the Trinity at Upsala, in Sweden, built after the model of Notre Dame at Paris, with ten companions and as many pupils.
50. Wilars de Honecort of France.—Author of a vellum sketch book, preserved at Paris; published by Lassus and Darcel in 1858, and translated by Professor Willis 1859. Church of St. Elizabeth at Cassovia, now Kaschau, in Hungary; and of St. Yved de Braine; and one at Cambray.
51. Pierre de Corbie of France.—Many churches in Picardy, and perhaps the apsidal chapels at Rheims Cathedral.
52. Jacopo or Lapo of Florence (there were several other artists of this name).—Church de' Monaci Cassinensi (afterwards the Vescovado, and now the cathedral) at Arezzo, continued by Margaritone. The piers of the ponte della Carraja at Florence.
53. Jean de Chelles of France.—Gabled fronts of the transept and first chapels of the choir at the cathedral of Notre Dame at Paris.
54. Pierre de Montereau or de Montreuil, in France.—The first Sainte Chapelle at Vincennes; the refectory, dormitory, chapter-house, and chapel of the Virgin in the monastery of St. Germain des Prés, near Paris; the Sainte Chapelle at Paris, and other churches.
55. Hues Libergiers of Rheims, in France.—Church of St. Nicaise at Rheims, now destroyed. He was succeeded by Robert de Coucy. It is one of the early specimens of pure Gothic in France.
56. San Gonsalvo of Portugal.—A bridge and a church at Amaranto.
57. San Pietro Gonsalvo of Tui, in Portugal.—Stone bridge at Tui.
58. San Lorenzo of Portugal.—Stone bridge at Cavez.

AFTER CHRIST.

59. Jacopo of Germany.—Remodelling the buildings of the monastery of St. Francisco at Assisi; the Palazzo del Barjello; and the façade of the archbishop's palace, both at Florence.
60. Nicola of Pisa.—Monastery and church of the Dominicans at Bologna; church of San Micheli; some palaces; and the octagonal campanile of the Augustins at Pisa; church del San Antonio at Padua; church of Santa Maria at Orvieto; church de' Fratri Minori at Venice; abbey in the plains of Tagliacozzo, near Naples, as a memorial of the victory by Charles I. over Conrad; design for the church of San Giovanni at Siena, and for the church and monastery della Santissima Trinita at Florence; Dominican monastery at Arezzo, carried out by Maglione, his scholar. Repairs and alterations to the duomo at Volterra, and the Dominican monastery at Viterbo.
61. Henri de Narbonne of France.—Cathedral at Gerona, in Spain, which city he undertook to visit six times a year.
62. Jacobus de Favariis of Narbonne, in France.—Succeeded him at Gerona.
63. Fuccio or Fucius of Italy.—Perhaps restored the church of Santa Maria sul' Arno at Florence. The gate and towers near the river Volturno at Capua. Finished the Castel Capuano, now the Vicaria, and Castello dell' Uovo, at Naples, commenced by Buono.
64. Ferrante Maglione of Pisa.—Cathedral and church of San Lorenzo at Naples. Palazzo Vecchio and many churches at Naples, in conjunction with Giovanni Benincasa. Dominican monastery at Arezzo, from the designs of Nicolo da Pisa.
65. Masuccio of Naples.—Completed the Castel Nuovo, and the church of Santa Maria della Nuova; designed the churches of San Domenico Maggiore and San Giovanni Maggiore; restored the cathedral of San Gennaro; designed the Palazzo Sant' Angelo and Palazzo Colombrano; all at Naples.
66. Giovanni da Pisa, in Italy (son of Nicola da Pisa).—Campo Santo or public cemetery, and the tribune of the Duomo, at Pisa; Castel Nuovo, and the church of Santa Maria della Nuovo at Naples; façade of the cathedral at Siena; many buildings at Arezzo and other towns in Italy. He was the first architect in the modern style of fortification.
67. Erwin von Steinbach, in Germany.—The portail of the cathedral at Strasbourg, from 1277 till his death in 1318. His son continued the work.
68. Stefano Masuccio of Naples.—Church of Santa Chiara at Naples. The lower part of the campanile is attributed to him or to his pupil Giacomo de Sanctis.
69. Pedro Perez of Spain.—Commenced the cathedral at Toledo.

14th. Century.

70. Arnolfo di Cambio or Arnolfo di Lapo of Florence.—Restoration of the ponte di Trinità; the church of Santa Croce; the walls of the city, with the towers; the loggia of the Or San Michele; the principal chapel of the Badia, enlarging the church and the campanile; Palazzo della Signori, now Pallazzo Veccnio; design, model, and foundation of the cathedral of Sta Maria del Fiore, with the Loggia and the Piazza dei Priori; all at Florence.
71. Johannes de Middelton, of Durham.—As mason erected the lower part of the dormitory of the monastery; completed by Peter Dryng in 1401.
72. Andrea da Pisa in Italy.—Designed the Castello della Scarperia at Mugello, at the foot of the Apennines; designed the church of San Giovanni at Pistoja; fortified and enlarged the ducal Palazzo Gualtieri at Florence.
73. Agostino da Siena, or da Pisa, in Italy, and his brother Angelo da Pisa.—North and west façades of the cathedral at Siena, and two gates; church and monastery of San Francisco; Palazzo de' Nove Magistrati; grand fountain in the piazza opposite the Palazzo della Signoria; hall of the council chamber, and Palazzo Publico; church della Santa Maria in Piazza Manetti, all at Siena, and all built by him in conjunction with his brother; also several works at Assisi, Orvieto, and other towns.
74. William Boyden of England.—Chief architect (or master mason) for the chapel of the Virgin at St. Albans Abbey Church.
75. Henry (*Latomus*, or stonemason) of Evesham, in England.—Chapter-house, refectory, abbot's hall, and kitchen of the monastery at Evesham.
76. Walter de Weston of England.—Clerk of the works at Westminster, kept the rolls of expenses of the erection of St. Stephen's Chapel.
77. Thomas of Canterbury, in England.—Master mason, 1330, at St Stephen's Chapel, Westminster.

78. RAIMOND DU TEMPLE of France.—Great staircase at the Louvre at Paris.
79. RICHARD DE FARLEIGH of England.—Master mason at Bath and Reading; at Salisbury Cathedral he worked with ROBERT, the mason. (See No. 46).
80. NICOLAS BONAVENTURA of Paris.—Employed on cathedral at Milan 1388, followed by Jean Campomosia of Normandy, and by JEAN MIGNOT in 1399.
81. GIACOMO LANFRANI of Italy.—Church of San Francesco at Imola; church of San Antonio di Castello at Venice, and some tombs at Bologna.
82. JEAN RAVY or RAUT of France.—Finished the church of Notre Dame at Paris.
83. HANS HILTS, HILTZ, or HÜLTZ, of Cologne.—Conducted the works, after the death of the Steinbachs, at Strasburg Cathedral, to the four winding staircases up to the cupola. His son Hans completed the tower.
84. JOST DOTZINGER of Worms.—Succeeded Hiltz; he made the font, repaired the choir and the vaulting. He had sufficient influence to cause, 1452, the confederacy of the masons' lodges in Germany, and is considered by many as thus commencing the modern Freemasonry.
85 ALFONSO DOMINGUES of Lisbon.—Said to be the first architect engaged on the monastery at Batalha in Portugal.
86. DAVID HACKET, or AQUETE, or OUGUET, of Ireland.—Commenced the chapel of the founder at the Batalha, in Portugal.
87. WILLIAM OF WYKEHAM, bishop of Winchester, in England.—Supposed to have designed New College, Oxford, and the College at Winchester, both founded by him; rebuilt or cased the nave of Winchester Cathedral; and erected some portions of Windsor Castle.
88. WILLIAM DE WYNFORD, of England.—Master mason; was employed by Wykeham on many of his buildings.
89. ALAN DE WALSINGHAM, sacrist and prior at Ely, in England.—The Lantern Tower and accessory portions, and the Lady Chapel, at Ely Cathedral.
90. WILLIAM READE, bishop of Chichester, of England.—First library at Merton College, Oxford; Amberley Castle, Sussex; an eminent mathematician.
91. ANDREA DI CIONE, called Orcagna, of Florence, and his brother JACOPO DI CIONE.—Additions to the Gran-ducal palace, and the Loggia de' Lanzi, at Florence. His brother built the tower and gate of San Piero Gattolino at Florence.
92. GAINSBOROUGH, or GAYNISBURG, of England.—Employed at Lincoln Cathedral, where his gravestone still exists.
92*a*. HENRY YEVELE or ZENELEY, and STEPHEN LOTE, of London.—Contracted for the stonework of the tomb of the first wife of Richard II.; and devised the form and model for raising the walls of Westminster Hall, London.

15th. Century.

93. FILIPPO DI SER BRUNELLESCO DEI LAPI of Florence.—Dome of the cathedral of Santa Maria del Fiore at Florence. A council of artists from all parts was held in 1420, to advise on this scheme. The Palazzo Pitti, begun and half built by him, completed by Luca Fancelli; great part of the church of San Spirito; chapter-house and a chapel to the church of Ste. Croce; the church degl' Angeli, never completed; the fortress of Milan, and several works about that city; a model for the fortress of Pesaro; the old and new citadels at Pisa; some other works there, as well as at Trento, and in other parts of Italy; and the drainage of the country round Mantua. He set the first example of a purer style in the architecture of Italy.
94. MICHELOZZO MICHELOZZI of Florence.—Palazzo di Medici, now Riccardi, the first building in Florence on modern rules; Palazzo Cafaggiolo, at Mugello; Dominican monastery and church of S. Marco; Noviziata della Santa Croce; chapel in the church dei Servi; Villa Medicea di Careggi, now Orsi; Palazzo Tornabuoni, now Corsi; with several other buildings at Florence. Library at the monastery of the Black Benedictines at Venice; Palazzo at Fiesole; some buildings at Trento; a beautiful fountain at Assisi, the old citadel at Perugia; alterations to the palace at Milan presented by Francisco Sforza to Cosmo di Medici; and other great works in various towns in Italy.
95. JUAN ALONSO or ALFONSO of Spain.—Directed the construction of the castle of Mouraon in the Alemtejo; and designed the sanctuary church of the monastery at Guadalupe in Spain.
96. GIULIANO DA MAJANO, near Fiesole.—Succeeded Lapi at the Duomo at Florence; Palazzo del Poggio Reale at Naples, and many works in that city, besides fountains. An edifice in the first Cortile in the Vatican at Rome; palace of San Marco at Rome; and restored the church. Began to enlarge the church of Sta. Casa, at Loreto, completed by his nephew Benedetto da Majano.

AFTER CHRIST.

97. Norton or Morton, of England (fellow and warden).—Restored St. Mary Redcliffe church, Bristol, after the fall of the spire in 1446.
98. John Dryell or Dayell or Druell, of England.—Surveyor at the erection of All Souls' College, Oxford, of which he was a fellow.
99. Roger Keyes, of England.—Fellow and warden of the college, succeeded to Dryell; he had been master of the works of Eton college, Berkshire.
100. William Horwod (freemason) of England.—Nave, aisles, and tower of the Collegiate chapel at Fotheringay, Northamptonshire.
101. Nicholas Cloos, or Close (afterwards bishop of Lichfield) of England.—Supposed to have designed King's College chapel, Cambridge; though, according to some, his father was the architect.
102. Christodoulos.—Mosque of Mahommed II. on the site of the church of the Apostles with eight schools and eight hospitals, all at Constantinople.
103. Baccio Pintelli of Florence.—Church and monastery of Santa Maria del Popolo; the celebrated Capella Sistina in the Vatican; the hospital of Santo Spirito in Sassia; Ponte Sisto; the church of San Sisto; the church of St. Agostino; the church of San Pietro in Vincola; palace for the Cardinal del Rovere in Borgo Vecchio, all at Rome. Repaired the church and monastery of San Francesco at Assisi. The palace for the Duke Federigo Feltre at Urbino is attributed to him. He first set the example of grandeur in the architecture of chapels.
104. Bartolomeo Suardi, Il Bramantino, of Italy.—Many works at Milan, and other parts of Italy.
105. Giovanni del Pozzo, of Cuenca, in Spain.—Dominican monastery, and a great bridge over the Huexar, near Cuenca.
106. Andrea Ciccione of Naples.—Monastery and church of Monte Oliveto, now San Carlo Borromeo; great portal of the church of San Lorenzo; church of Sta. Marta; Palazzo of Bartolomeo Riccio, now Ercolense; and several other convents and palaces, all in the city of Naples.
107. Aristotile Alberti or Ridolfo Fioravanti of Bologna.—Restored the tower of the church of S. Biagio, at Cento, to its perpendicular position; removed the Campanile of Santa Maria del Tempio, at Bologna, several feet; rebuilt a bridge over the Danube in Hungary; built the Church of the Assumption at Moscow, in which city he is supposed to have built the Kremlin, and other works.
108. William Orchyearde of England.—Master mason of Magdalen College, Oxford.
109. Francesco di Giorgio of Siena.—The ducal palace at Urbino, attributed also to Alberti, Luciano, and Pontelli.
110. Tommaso Formentone of Brescia.—Palazzo Municipale or Della Loggia, at Brescia, one of the four chief town-halls in Italy; continued by Sansovino and completed by A. Palladio.
111. Luciano di Martino or L. di Lauranna.—Palazzo for the Duke Federigo Feltre at Urbino, completed by Pontelli.
112. Leone Battista Alberti of Florence.—Church of San Francisco at Rimini; churches of San Sebastiano and of San Andrea, at Mantua. The principal façade of Santa Maria Novella, at Florence, has been attributed to Alberti, but from the circumstance of its being Gothic, it is more probably by Bettini; the gate and Corinthian loggie are, however, from the designs of Alberti. Palazzo Rucellai; and the choir and tribune of the church della Nunziata, both at Florence. At Rome he altered the papal palace for Pope Nicholas V., and repaired the aqueducts of the Aqua Vergine, and decorated the fountain of Trevi. Many buildings in Italy are attributed to him, but are by his pupils.
113. Jan Keldermans of Germany.—Completed the old Hotel de Ville at Louvain, now the council chamber.
114. Mathieu de Layens of Louvain.—Hotel de Ville at Louvain; choir of the church of Ste. Waltrude at Mons; Tabernacle, baptistry, and altar of the Virgin in the church of S. Leonard at Léau; completed the church of S. Sulpice at Diest, begun by S. van Vorst, and erected the tower.
115. Hans Boeblinger and Matthaeus Boeblinger.—Commenced the Frauenkirche at Esslingen, near Stuttgart, continued by his son, who built the Katherinenkirche and the Spitalkirche. Employed on the cathedral at Frankfort-sur-Maine, and on that at Ulm.
116. Richard Beauchamp, bishop of Salisbury, in England.—Built the great hall, parlour, and chamber of the palace at Salisbury; appointed master and supervisor of the works of St George's Chapel at Windsor Castle (where he was succeeded by Sir Reginald Bray, who was comptroller of the royal works to Henry VII); and built a chantry chapel in Salisbury Cathedral.

117. John Kendale of England.—Supervisor of the king's works throughout the realm. 1 Edw. IV.

118. John Ashfield of England.—Master of the new works, 1473, at Bristol Cathedral. Prior John Martyn succeeded him.

119. Donato Lazzari, usually called Bramante d'Urbino, from the town near his birthplace.—The octagonal church of Sta. Maria Incoronata at Lodi; two churches and a palace at Casale; church at Canobbio. At Milan, the church and sacristy of St. Satiro; chapel of the large lazaretto, and part of that building itself; the monastery of San Ambrogio and its cloisters, and the cupola of the church of Sta. Maria della Grazie. Designed and commenced the building of St. Peter's at Rome; many works in the Vatican, particularly the library and the Belvedere court, &c., for Julius II.; the circular Doric chapel in the convent of San Pietro Montorio; the palaces of S. Giacomo Scossacavalli, afterwards Giraud and Torlonia, del Duca de Sora, della Cancelleria (if not due to the brothers Giamberti Sangallo), dell' Nuovo dell' Imperiale; the churches of SS. Euloy de' Orfani, Lorenzo, and Damaso; cloisters of the monastery della Pace, &c., at Rome; the Strada Julia in that city; ducal palace at Urbino; Palazzo Publico at Brescia; church of Sta. Maria del Monte, near Forli; cathedrals at Città di Castello, Faenza, and Foligno; fortress at Civita Vecchia, and other engineering works at Milan; marble exterior to the Santa Casa at Loreto; Villa Imperiale near Pesaro, churches of San Sepolcro and of Santa Maria della Campagna at Piacenza; church of the Madonna, outside Todi, in the form of a Greek cross, in imitation of his design for St. Peter's; and many other works.

120. Ventura Vitoni of Pistoja.—Church dell' Umiltà at Pistoja, after the design of Bramante, whose pupil he was.

121. Martino Lombardo of Venice.—Scuola or confraternità di San Marco at Venice, and perhaps the church of S. Zaccaria in same city, but the interior is considered earlier. Other palaces there are attributed to him.

122. Simone Pollajuolo, or Il Cronaca, of Florence.—Façade and additions in the cortile to the Palazzo Strozzi, begun by Majano; convent of the Padra Serviti; sacristy of Santo Spirito; and the Council Hall, all at Florence; church of San Francisco, at S. Miniato, near Florence.

123. Novello da San Lucano of Naples.—Palace of Prince Robert Sanseverino, duke of Salerno, now a church; and restored the church of San Domenico Maggiore, both at Naples.

124. Pietro Lombardo of Venice.—Tomb of Dante, the poet, and its chapel in the church of San Francisco; the two great columns in the piazza, at Ravenna; clock tower to the church of San Marco; Palazzo Loredano-Vendramin-Calergi; church of Sta. Maria de' Miracoli; works at the ducal palace; besides many others at Venice; a cloister in the monastery of Santa Giustina at Padua; the Cathedral at Cividal del Friuli.

16th. Century.

125. John Alcock (bishop of Ely) of England.—Comptroller of the royal works, temp. Henry VII.; his chapel in Ely Cathedral; supposed to have designed St. Mary's, or the University Church, Cambridge; Collegiate Church of Saint Giles at Malvern.

126. William Bolton, prior of St. Bartholomew, Smithfield, in London.—Master of the works at the chapel of King Henry VII., at Westminster, and is supposed to have designed it.

127. Gabriello d'Agnolo of Naples.—Church of S. Giuseppe; church of Santa Maria Egiziaca; palace of Ferdinando Orsini, duke of Giavina, at Naples.

128. Gian Francesco Mormando of Mormanno.—Church of San Severino; Palazzo Filomarini; Palazzo Cantalupo; the small church della Stella, at his own expense; all at Naples.

129. John Cole of England.—Master mason of the spire at Louth church, Lincolnshire.

130. John Hylmer and William Vertue of England.—Freemasons, erected the vaulting of the choir of St. George's Chapel, Windsor.

131. Giuliano Giamberti, called San Gallo, of Florence.—Part of the cloister of the monastery of Santa Maddelena de' Pazzi at Florence; cloister for the Fratri Eremitani di S. Agostino; the Poggio Imperiale; fortress near the Porto a Prato, and other works, at Florence; a magnificent palace at Poggio a Cajano for Lorenzo di Medici, with a hall 163 feet by 68 feet by 65 feet high, having a ceiling the widest then known; repaired the cupola and roofed the church della Madonna at Loreto; restored the roof and decorations of the ceiling of the church of Santa Maria Maggiore; restored the church dell' Anima; Palazzo Rovere, near San Pietro in Vincolà, and other works at Rome; church of Madonna delle Carceri at

AFTER CHRIST.

Prato; Palazzo Rovere at Savona; an unfinished palace at Milan; fortress and Doric gate of San Marco at Lucca; works at Pisa; fortifications at Ostia.

132. MARTIN CHAMBICHES or CHAMBIGES of Cambrai, in France.—Employed to construct the portail of the cathedral at Troyes. Directed with Jean Vast the erection of the transepts to the cathedral at Beauvais, and was succeeded by M. LALVE.

133. PIERRE GADYER of Paris.—Probably designed for Francis I. the Château de Boulogne or Madrid, near Paris, now destroyed.

134. DOMENICO BOCCADORO, called Dominique de Cortone.—Remodelled the Hôtel de Ville at Paris to an Italian design.

135. TULLIO LOMBARDO of Venice.—Assisted his father Pietro in the Cappella Maggiore in the Cathedral at Treviso. At Venice, the palazzo Corner-Spinelli; the church of Sta. Maria de' Miracoli, and several other buildings and fine tombs. Cathedral at Belluno. The transept, if not the whole of the church of the Madonna della Grazie at Treviso, completed with the help of his kinsmen Giulio and Sante.

136. LEONARDO DA VINCI, near Florence.—Aqueduct of the Adda and other engineering works at Milan; various machines, plans, and works on architecture.

137. FRA GIOVANNI GIOCONDO of Verona, called Joconde in France.—"Diviseur des batimens"; bridge of Notre Dame at Paris; fortifications at Treviso; built the Foadaco de' Tedeschi, cleansing of the Lagunes, and made a design for the Ponte Rialto, all at Venice. After the death of Bramante, he was engaged with Raffaele and G. da San Gallo in erecting St. Peter's at Rome. Several works at Verona are attributed to him.

138. HANS HOLBEIN of Basle.—Gateway at Whitehall; ceiling of Chapel Royal at St. James's Palace; Wilton House, Wiltshire. Died 1543.

139. ROMBAUT KELDERMANS, of Malines.—Staircase to Hôtel de Ville at Oudenaarden; works to the lower portion of Hôtel de Ville at Gand; house for Grand Conseil at Malines; and chapel of the palace of the dukes of Brabant at Brùxelles.

140. LUDOVICO BERETTA of Brescia (?).—Façade of the church of Santa Maria dei Miracoli at Brescia, in a florid cinquecento arabesque style.

141. RAFFAELLO SANZIO of Urbino.—Continued the church of St. Peter at Rome, after the death of Bramante, his master in architecture; engaged at the Palazzo Farnese, and stabling near thereto; repaired and altered the church of Santa Maria in Navicella; Palazzo Caffarelli, now Stoppani; the gardens of the Vatican; the façade of the church of San Lorenzo, and of the Palazzo Uggoccioni, now Pandolfini, all at Florence.

142. JOHN OF PAUDA in Italy.—Deviser of buildings to Kings Henry VIII. and Edward VI. of England. Supposed to have designed Somerset House; and Sion House, Middlesex. Also attributed to J. Thorpe (175), and J. Shute (200).

143. HECTOR ASHELEY of England.—Master mason and supervisor in the erection of Hunsdon House, Hertfordshire.

144. ROGER AMICE of England.—Surveyor to King Edward VI.; Almes Knight's lodgings at Windsor Castle.

145. ANDREA CONTUCCI of Monte Sansavino, in Italy.—The cappella del Sagramento in the church of Santo Spirito at Florence; palazzo della Canonica, and fortifications at Loreto; church della Nunziata at Arezzo; chapel for the monks of St. Agostino, and his own house at Sansavino; buildings at Venice; and a palace at Evora, with some other buildings in Portugal.

146. BARTOLOMMEO BUONO of Bergamo, in Italy.—Three chapels in the church of S. Rocco; bell chamber, attic and spire to the Campanile of San Marco; and superintended the works at the Procurazie Vecchie, all at Venice.

147. GUGLIELMO DI BERGAMO, called Il Bergamasco, of Italy.—Cappella Emiliana, near the Camaldolese in the island of Murano; palazzo di Calmerlenghi, near the ponte Rialto at Venice; palace at Portagruaro, at Friuli; porta di Santo Tommaso at Treviso; porta del Portello at Padua.

148. GIOVANNI DI OLOLZAGO of Biscay, in Spain.—Cathedral of Huesca, in Arragon.

149. PEDRO DE GUMIEL of Alcala, in Spain.—Monastery of Sta. Engraçia at Saragossa; college of S. Ildefonso at Alcala de Henares; and church of SS. Justo y Pastor.

150. JUAN CAMPERO of Spain.—Church and convent of S. Francis at Torrelaguna, in Spain; commenced the cathedral at Salamanca, under Gil de Hontanon; and the aqueduct. Removed a cloister at Segovia to the site of the new cathedral; and heightened the tower of the monastery of St. Maria del Parral, in that city.

151. ANTONIO GIAMBERTI (DA SAN GALLO) of Florence.—Churches of the Madonna at Montefiascone; the Canonicà, with a double loggia; fortifications at Civita Vecchia, Civita Castellana, Montefiascone, Perugia, and many other strong plàces in

Italy. Altered the tomb of Hadrian at Rome to its present form as the castle of S. Angelo, and its fortifications

152. Antonio Picconi (da San Gallo) of Mugello, near Florence.— Completed the church of Sta. Maria di Loreto, near Trajan's column at Rome; the cupola is by G. del Duca. Palazzetto of the Counts of Parma. near the gate of Venice, and other palaces in Rome and repaired some rooms in the Vatican. Palazzo at Gradoli, and restored the fortress of Capo di Monte near thereto. Made a design for the fortress at Caprarola. Palaces for Bart. Ferratino, and Cardinal di Santa Prassedia; church for Cardinal Alborense; continued the erection of St. Peter's on a new plan, after the death of his uncle Giuliano da San Gallo; church of the Florentines, and of Santa Maria di Monferrato, all at Rome. Fortifications at Civita Vecchia, Parma, Ancona, Placenza, Perugia, and Florence. Church of the Madonna at Loreto, nearly rebuilt. At Castro he built the fortress, Palazzo l'Osteria, and the Mint. At Rome, triumphal arch of wood at the palace of S. Marco for the entry of Charles V.; the bastions to the walls and the gate of Santo Spirito; the Cappella Paolina; the staircase at the Sistine Chapel, and the Palazzo Farnese near the Campo di Fiore, are among his numerous works.

153. Baldassare Peruzzi of Volterra.—Plan and model of the cathedral at Carpi; designs for the façade of San Petronio, and for the gate of San Michele in Bosco at Bologna; fortifications at Siena. At Rome, the little palace for Agostino Chigi, now called the Farnesina, in the Lungara; palazzo Massimi, near the church of San Pantaleo; villa di Papa Giulio III.; cortile of the palazzo d'Altemps; casino at the palazzo Chigi; tomb of Pope Hadrian IV. in the church dell' Anima; palazzo Spinosa, now the hospital degli Eretici convertiti; and assisted in the erection of St. Peter's.

154. Marco di Pino of Siena.—Modernised the church della Trinità di Palazzo, and built the church and convent of Gesù Vecchio at Naples.

155. Pietro Berretini, or Pietro da Cortona.—Portico of the church of Sta. Maria della Pace at Rome; made a design for the façade of the Louvre; palazzo Sacchetti at Ostia; several chapels; the façade of the church of Sta. Maria in Via Lata, and the church of SS. Maria Martina and Luca Evangelista, his masterpieces; and the cupola and other parts of the church of San Ambrogio and Carlo in the Corso.

156. Andrea Briosco, or Riccio, of Padua.—Church of Sta. Giustina, and loggia and council house in the Piazza degli Signori, at Padua.

157. Giovanni Merliano of Nola, in Italy.—At Naples, Strada di Toledo; churches of S. Giorgio de' Genovesi and of S. Giacomo degli Spagnuoli; palazzo of the Principe di Sansevero, and palazzo of the Duca della Torre; the Castel Capuano, altered to a court of law; a fountain at the extremity of the Mole; and triumphal arches at Naples for the entrance of Charles V.

158. Ferdinando Manlio of Naples.—Third cortile to the palazzo Reale; church and hospital della Nunziata; Strada di Porta Nolana, and di Capua, with other streets and palaces at Naples; a bridge at Capua.

159. Juan Gil de Hontanon of Rasines, in Spain.—" Maestro principal" at the cathedral of Salamanca, erected from the designs of A. Rodriguez and A. de Egas.

160. Rodrigo Gil de Hontanon of Spain.—Continued the cathedrals of Salamanca and of Segovia; works at Seville; church at Valladolid; rebuilt the dome of the cathedral at Seville; and commenced the cathedral at Segovia.

161. Baccio d'Agnolo of Florence.—Several triumphal arches for the visit of Pope Leo X., and of Charles V., at Florence. Campanile of San Miniato in Monte was executed, and that of Santo Spirito commenced, by him; designed the entablature and gallery round the bottom of the cupola of Sta. Maria del Fiore, the great altar and choir of which was built by his son Giuliano; palazzo for Giovanni Bartolini on the Piazza della Santa Trinità, and the palaces, all at Florence.

162. Giovanni Maria Falconetto of Verona.—Loggia of two storeys at the palazzo Cornaro; and a music hall; commenced the church of Sta. Maria delle Grazie; Doric portal to the palazzo del Capitanio; gates of S. Giovanni, and of Savonarola, all at Padua; palazzo Savorgnano at Usopo in Friuli.

163. Pietro de Uria of Spain.—Bridge of Almaraz, over the Tagus, having two arches, one about 150 feet, and the other 119 feet

164. Alonzo de Covarrubias de Leiva of Spain.—Worked for, or was consulted upon the cathedrals at Toledo, Salamanca, Plasencia, Segovia, and Seville. Archiepiscopal palace at Alcala de Henares. With Luis de Vega rebuilt and enlarged the palaces at Madrid and Toledo for Charles V With Vidana he designed the celebrated

Hieronymite church and monastery of S. Miguel de los Reyes at Valencia, and commencen the cloister of it; and other works.

165. Diego Siloe of Toledo.—Cathedral and Alcazar at Granada; church and convent of S. Jerome in the same city.

166. Girolamo Genga of Urbino.—Repaired the ducal palace at Urbino; built another on the Monte Imperiale, near Pesaro; church of San Giovanni Battista at Pesaro; façade of the cathedral, and restored the bishop's palace at Mantua; convent de' Zoccolanti at Monte Baroccio; and the church of St. Maria delle Grazie, and the episcopal palace, at Sinigaglia. His son Bartolomeo assisted him, and also practised at Pesaro, Urbino, and other places.

167. Michele San Micheli of Verona.—Cathedral at Montefiascone; church of S. Domenico at Orvieto; fortresses in the Venetian territory, in Corfu, Lombardy, and the ecclesiastical states, as at Legnani, Orzi Nuovo, and Castello; palazzo di Canossa, dell'Gran Guardia on the Bra; Pellegrini de' Verzi; the prefecturate and façade of the palazzo Bevilacqua; chapel Guareschi in the church of S. Bernardino; design for the campanile of the Duomo; churches of Santa Maria in Organo de' Monaci, di Monte Oliveto, di S. Giorgio, and della Madonna della Campagna; gates Nuova, del Pallio, di S. Zenone, del palazzo Pretorio, and del palazzo Prefettizio, all at Verona; as well as fortifications of the same city, where triangular bastions were first introduced, that of della Madellena being erected in 1527.

168. Philibert de L'Orme of France.—Commenced the Tuileries; built the châteaux of St. Maur, Anet, Meudon, and many others. Wrote on architecture.

169. Galeazzo Alessi of Perugia in Italy.—Directed the works at the monastery of S. Pietro; entrance gateway of the fortress and the governor's residence; chapel del Sacramento in the cathedral, and the front of the church of Sta. Maria del Popolo, and several palazzi, all at Perugia. Works at the arsenal and the haven and mole at Genoa, where he executed the public granaries; loggia dei Banchi with a large hall; Palazzo Reale; cupola, choir, and other works of the duomo of S. Lorenzo; the church of Sta. Maria di Carignano; the Stradi nuova and nuovissima, with most of the palazzi in them, and other palaces in the Borgo di S. Pier d'Arena. At Bologna, at Milan, and other cities, he designed many palaces and churches; later he made a design for the church del Gesù at Rome, and for the Escurial in Spain.

170. Sante Lombardo of Venice.—Assisted his father Giulio in the Scuola di S. Rocca; palazzi Trevisani and Gradenigo; the church of S. Georgio de' Greci with Chiona; all at Venice.

171. Michel Agnolo Buonarroti Simone of Florence.—Chapel and cupola of the new sacristy to the church of San Lorenzo; part of the façade of the church; library of the Medici, generally called the Laurentian Library; all at Florence. Church of San Giovanni, which he did not finish; Fortifications at Florence, and at Monte San Miniato. Monument of Julius II. in the church of San Pietro in Vincolà; the Campidoglio, with the palazzo de' Conservatorj, the building in the centre, and the flight of steps; the celebrated cornice and other portions to the palazzo Farnese; and several gates, particularly the Porta del Popolo and the Porta Pia, all at Rome. Plans for many other palaces, churches, and chapels. He was employed on St. Peter's, after the death of Ant. Picconi da San Gallo, making many alterations in the design, and giving the model for the great dome, which was followed out, except as to the lantern.

172 Giacomo Barozzi, of Vignola in Italy.—Various buildings at Bologna; Farnese palace; church of S. Agostino; palazzo di S. Giorgio dei Scotti, all at Piacenza. Received the charge of the Acqua Vergine at Rome, and the works at the Vigna of Pope Julius III. (or his villa), and other buildings for him and his family. Constructed the celebrated palace at Caprarola, near Viterbo, for Cardinal Alessandro Farnese. Became architect to S. Peter's after the death of Buonarroti, when he designed the lateral cupolas; and many other works in that city, including the church del Gesù up to the cornice. The large church of Sta. Maria degli Angeli at Assisi. Consulted on the designs for the Escurial in Spain, and made one which was highly approved.

173. Giulio Pippi of Rome, called Giulio Romano.—Villa Madama; Palazzo Lante at San Pietro; church della Madonna del Orto; Palazzo Ciccia porci alla Strada di Banchi; Palazzo Cenci sulla Piazza S Eustachio, and other buildings in Rome. The celebrated Palazzo del Té at Mantua; palace at Marmiruolo near that city; modernised the ducal palaces, the Duomo, and many other buildings in Mantua; façade of San Petronio at Bologna; and works at Vicenza.

174. Eustace Mascall or Marshall or Malcolm of England.—Clerk of the works at

the building of Christchurch College, Oxford; and chief clerk of accounts for all the buildings of Henry VIII. within twenty miles of London.

175. John Thorpe of England.—A long list of his supposed works will be found in Book I., England.

176. Henricx of Flanders.—Foreman at the first Royal Exchange, London, erected for Sir T. Gresham, who "bargained for the whole mould and substance of his workmanship in Flanders."

177. Damian Forment or Morlanes, of Valencia, in Spain.—Façade of the church of Sta. Engraçia, at Saragossa.

178. Martin de Gainza of Navarre, in Spain.—Carried out works at the Cathedral at Seville, and made the design for the capilla real attached to it, and finished by F. Ruiz.

179. Alonso Berruguete, of Paredes de Nava, in Spain.—Has given his name to that phase of the Renaissance style, which was the fashion of the sixteenth century in Spain, also called the Plateresque style; but it is unknown what works he designed other than shrines, altar-pieces, and tombs.

180. Juan Sanchez of Spain.—"Maestro mayor" of the works of the city of Seville, is supposed to have designed the Casa del Ayuntamiento in it.

181. Pedro di Valdevira of Spain.—Chapel of S. Salvador, at Ubeda; palace in the same place; hospital and chapel of S. Jago at Baeza.

182. Pedro Ezguerra of Ojebar, in Spain.—Works at the cathedral at Plasencia; church of S. Mateo at Caceres; that at Robledillo; and commenced that at Malpartida.

183. Ferdinando Ruiz of Cordova, in Spain.—Continued the capilla real, and heightened the Torre della Giralda of the cathedral, at Seville.

184. Pedro Machuca of Spain.—Royal Palace of the Alhambra at Granada. Succeeded by his son Luis.

185. Antonio Fiorentino of Dello Cava near Florence.—Church of Santa Catterina a Formello at Naples.

186. Jacopo Tatti, called Sansovino, of Florence.—Commenced the church of S. Marcello, and built that of S. Giovanni de' Fiorentini; Loggia on the Via Flaminia, close to the Porto del Popolo; Palazzo Gaddi, now del Nicolini, at Rome. Church of San Francesco della Vigna, finished by Palladio; continued the Scuola begun by M. Lombardo; the Zecca or mint; Palazzo Cornari on the Grand Canal; and other public buildings; besides repairing many domes of the churches of San Fantino, of San Martino, of the Incurables, and of San Geminiano; all at Venice.

187. Theodore Haveus or Heave, of Cleves.—Caius Court of Caius College, Cambridge, with its gateways.

188. Domingo Teotocopuli of Greece.—College of the Donna Maria d'Arragona at Madrid; church and convent of Dominican nuns; also of the Ayuntamiento at Toledo; church and convent of the Bernardine nuns at Silos.

189. El Padre Bartolomé Bustamente of Spain.—Gave the plans for the Jesuits' college at Cadiz, Caravaca, Segura, Trigueros, and Murcia; and hospital of San Juan Bautista, near Toledo.

190. Juan Bautista de Toledo in Spain.—Designed the Escurial completed by Juan de Herrera; assisted in planning the Strada di Toledo at Naples; church of San Giacomo degli Spagnuoli in the same city; and palace at Posilippo.

191. Juan de Herrera, of Mobellan, in Spain.—Continued the Escurial after the death of his master, Juan Bautista; bridge of Segovia at Madrid; palace at Aranjuez; south façade of the palace at Toledo; cathedral at Valladolid; exchange at Seville. He was consulted on designs for many works in Spain and Portugal.

192. Pierre Lescot of Paris.—Fontaine des Innocents in the Rue St. Denis, at Paris, carved by Jean Gougeon. His design for the court of the old Louvre was preferred by S. Serlio to one of his own. He executed the part showing a Corinthian order with a Composite one over it.

193. Sebastiano Serlio of Bologna.—Employed by Francis I. of France at Fontainebleau and at the Louvre. Was the first to publish the Ancient Edifices of Italy and wrote a treatise on architecture

194. Jean Cambiche of Paris.—The salle du Centaure, and the lower storey of the petite galerie at the Louvre. Master of the Masons at the hôtel de ville at Paris.

195 Bartolommeo Ammanato, of Florence, in Italy.—Palazzi Rucellai and Mattei at Rome; ponte della Trinità; continued the Palazzo Pitti; church of San Giovanni, at his own expense; all at Florence; and many works at Pisa, Lucca, and other cities.

196 Nicolo Abate or Nicolo da Modena.—Old château of Meudon; tomb of Francis I., at S. Denis, both usually attributed to de l'Orme; and decorated the apartments of the palace of Fontainebleau.

AFTER CHRIST.

197. Andrea Palladio, of Vicenza, in Italy.—Arcades to the Sala della Ragione; erected the Olympic Theatre after the ancient type, and many other edifices; with the Palazzi Tiene, Chiericati, and Valmarana, all at Vicenza; Villa Capri near that city, and numerous other buildings in neighbouring towns. The church Il Redentore and other works at Venice. Published a treatise on architecture, and a book on the ancient ruins.

198. Bernardo Timante Buontalenti of Florence.—Villa of Marignolla, now Capponi; the casino behind San Marco; the corridor half a mile long extending to the palazzo Pitti; palazzo for the Acciajuoli, now the Corsini; a façade to the Strozzi palace, and to the palazzo Ricardi; the façade of the church della Santissima Trinità, all at Florence; the loggia de' Banchi. ducal palace, and façade of the church of San Spirito at Pisa; the palazzo at Siena; and works in other parts of Italy.

199. Domenico Fontana, of Como, in Italy.—Raised, transported, and fixed, the four great obelisks in Rome, with many improvements there; the Doric arcade and loggia to the front of the church of S. Giovanni Laterano; a palazzo on one side of it for the use of the Popes; enlarged the papal palace; built the palazzo Mattei, now Albani; the library at the Vatican and other works there; and restored the columns of Antonine and Trajan. The Royal palace and other works at Naples.

200. John Shute of England.—A painter and architect, temp. Queen Elizabeth. Wrote the first work on architecture in England.

201. Henry Hawthorne, of England.—Surveyor of the works to Queen Elizabeth; designed the gallery now part of the library at Windsor Castle, "a fine specimen of Anglo-Italian architecture."

202. Sir Thomas Tresham of England.—Liveden House, Northamptonshire; Rushton Lodge and the triangular lodge, in the same county. Also given to J. Thorpe (175).

203. Robert and H. Smithson of England.—Wollaton, Nottinghamshire.

204. Louis de Foix of France.—New mouth to the river Adour; Tour de Cordouan, the lighthouse at the mouth of the Gironde, near Bordeaux.

205. Jean Baptiste Androuet du Cerceau of Orleans, in France.—Pont Neuf at Paris; hôtels de Sully, de Mayenne, and des Fermes or hotel Sequier Made more drawings for monastic buildings, churches, &c., than any architect in France during half a century. Rebuilt church of Notre Dame at Clery; and S. Étienne du Mont at Paris.

206. Jacques Androuet du Cerceau of France.—Finished the works at the Louvre next the river for King Henry IV. There were four architects of the name of *du Cerceau*, and their works are not well separated. Wrote on architecture.

207. Vincenzo Scamozzi of Vicenza.—Additions to the library of S. Mark at Venice; finished the Olympic theatre by Palladio at Vicenza; theatre at Sabionetta; and other buildings. Wrote on architecture.

208. Jacques de Brosse of Paris.—Palais du Luxemburg at Paris and other works; château de Monceaux, near Meaux; château of Colomier, near Paris; façade of the church of SS. Geronis and Protais; and the great hall of the Palais de Justice, both at Paris.

209. Carlo Maderno, of Bissone, Largo di Como.—Altered Michael Angelo's design for S. Peter's at Rome, from a Greek to a Latin cross; began the palace of Urban VIII., and many churches and palaces.

17th. Century.

210. John Warren of England—Tower of St. Mary's Church, Cambridge, designed by John Alcock.

211. Inigo Jones of London.—Banqueting House, Whitehall, being part of his design for a noble Palace; Chapel, Lincoln's Inn; Surgeons' Hall; arcade to Covent Garden and the Church; the grand portico to old S. Paul's Cathedral; and many other important works.

848. Philip Hardwick of London.—House and Warehouses at St. Katherine's Docks; New Hall of the Goldsmiths' Company; Entrance portico, the large hall, and hotels, at the Railway Station, Euston Square; New Hall and Library for Society of Lincoln's Inn; all at London.

849. Charles Texier of Versailles, in France.—Restored Arch at Rheims. Published "Description de l'Asie Mineure," and "L'Arménie, la Perse, et la Mésopotamie." Sent to Algeria, he measured all the Roman works in that country. Published "Byzantine Architecture," and "Principal Ruins of Asia Minor," both with R. P. Pullan.

850. Sir James Pennethorne of Worcester.—Assisted Mr. J. Nash in carrying out in London, the improvements in the Strand; Carlton House Terrace; St. James's Park; various improvements in the streets of the Metropolis, for the Government. The St. James's Bazaar; St. Julian's, Sevenoaks, for C. J. Herries; Dillington House, Ilminster, for Mr. J. L. Lee; Swithland Hall for Mr. Butler Danvers; Christ Church, Albany Street; and Trinity Church, Gray's Inn Road. Formed and laid out Victoria and Battersea Parks, and Kensington Palace Gardens. Museum of Economic Geology, Piccadilly. General Record Office, Chancery Lane. State Ball Room, Supper Room, and Galleries, at Buckingham Palace. Additions to Somerset House, fronting Lancaster Place. Alterations at the National Gallery; and at Marlborough House for the Prince of Wales. University of London, Burlington Gardens; and many other works for the Government.

851. Sir Thomas Deane of Monkstown, near Dublin.—Banks, with other buildings, and the Court house with a fine portico, at Cork; Queen's College, Cork; Lunatic Asylum at Killarney; addition to Trinity College, Dublin, in the Venetian style; Museum at Oxford with his son Thomas and Mr. Woodward.

352. Edward Walters of London.—Many large warehouses in the Renaissance style at Manchester; and numerous houses in the suburbs; Free Trade Hall; Manchester and Salford Bank; stations on the Midland Railway; church in Cavendish Street; Fire Insurance Office, King Street; Warrington Public Hall, &c.; all at Manchester. Died January 22, 1872, aged 63.

353. Sir William Tite of London.—Restored, with David Laing, the church of St. Dunstan's-in-the-East. Designed the Scotch Church, Regent Square; the Royal Exchange; London and Westminster Bank, Lothbury, with C. R. Cockerell, R.A.; several railway stations; all in London. The termini and most of the stations on the Caledonian and Scottish Central Railways; and on the line from Havre to Paris Memorial Church, Gerrard's Cross. Largely employed in the valuation, purchase, and sale of the land required for the extensive railway and improvement works of his time. Died April 20, 1873, aged 75.

354. Owen Jones of London.—Designed St. James's Hall and its decoration; the decoration of the Hall of the Fishmongers' Company; that of Fonthill House, near Salisbury, for Mr. Alfred Morrison, and of his residence in Carlton House Terrace; of Preston Hall, for Mr. Henry Brassey; of the Exhibition of Industry of All Nations, 1851; and of the Crystal Palace, Sydenham. Designed furniture, &c. Published "Plans, &c., with Details, of the Alhambra," in colours, fol. 1836-45; "Designs for Mosaic and Tesselated Pavements," 4to. 1842; "An Apology for the Colouring of the Greek Court at the Crystal Palace," 8vo. 1854; "The Grammar of Ornament," 100 plates, fol. 1856; 112 plates, 1865. Many other works on colour and ornament. Died May 1 (?), 1874, aged 65.

355. Alexander Thomson of Balfron, Scotland, called "Greek Thomson," after the style to which the bent of his studies entitled him.—Designed the Caledonian Road United Presbyterian Church; the St. Vincent Street U.P. Church; and Queen's Park U.P. Church; the Egyptian Hall, Union Street; two buildings on north side of Sauchiehall Street; all at Glasgow. Died March, 22, 1875, aged nearly 58.

356. Pierre François Henri Labrouste of Paris.—With Visconti, superintended the decorations for the funeral ceremony consecrating the return of the remains of the Emperor Napoleon I. to Paris. Opened an atelier. Designed the Library of Ste. Geneviève; the enlargement of the National Library, with new reading room, &c. Appointed general inspector of diocesan edifices. Died June 24, 1875, aged 74.

357. David Bryce of Edinburgh.—Designed many public offices, banks, &c., in Edinburgh, in various styles; as Fettes College; the Sheriffs' Court; Edinburgh Royal Infirmary; Lanark Infirmary; several churches in Edinburgh, Dalkeith, Dundee, Falkland, St. Mungo's, &c. In a long list of mansions, and of additions and alterations, are mentioned Panmure, for Earl of Dalhousie; Kinnaird Castle, for Earl of Southesk; Langton, for Marquis of Breadalbane; and the mausoleum for the Duke of Hamilton. Died May 7, 1876, aged 73.

358. Raphael Brandon of London.—With his brother Arthur, who died December 1847, published "Parish Churches," sixty-three in number, 8vo. 1848. Then "Analysis of Gothic Architecture," seven hundred examples, 4to. 1849; "Open Timber Roofs of the Middle Ages," thirty-five examples, 4to. 1849. Designed the church in Gordon Square for the members of the Catholic Apostolic Church, in conjunction with Mr. Ritchie. Church in Great Windmill Street, Haymarket; and one at Knightsbridge. Died October, 1877.

359. Sydney Smirke of London.—With his brother Sir Robert, designed the Oxford and Cambridge Club, Pall Mall. He restored the Temple Church, and published an account of it, 1845. A block of buildings in the Temple; the Conservative Club, St. James's Street; Carlton Clubhouse, Pall Mall; the circular Reading Room, and other parts, at the British Museum; the Exhibition Rooms for the Royal Academy of Arts, Burlington House. Died December 8, 1877, aged 77.

360. Sir Matthew Digby Wyatt of Devizes.—Travelled for two years, and on his returned published "The Geometric Mosaics of the Middle Ages," fol. 1849. Reported, 1849, on the Industrial Exposition at Paris. Published "Industrial Arts of the Nineteenth Century," fol. 1853; "Metal Work and its Artistic Design," fol. 1852. As superintendent of the Fine Arts department at the erection of the Crystal Palace, he, with Owen Jones, designed several of the Courts, and wrote the descriptions. He designed the Court and interior finishings of the new India Office, Whitehall; Addenbroke's Hospital, Cambridge; the Royal Indian Civil Engineering College at Cooper's Hill; restored the hall of Clare College, Cambridge; designed the Crimean Memorial Arch at Chatham, for the Royal Engineers, &c.; the mansion for Louis Huth, Esq.,

at Possingworth, Sussex; the red brick house for Lady Marian Alford at Kensington Gore. He published his "Lectures" as Slade Professor in 1870. Died May 21, 1877, aged 57.

361. Sir George Gilbert Scott of Gawcott, near Buckingham.—W. B. Moffatt was partner for some years; they designed, 1841, the Martyrs' Memorial at Oxford; St. Giles's Church, Camberwell; and the Infant Orphan Asylum, Wanstead. He designed the St. Nicholas Church at Hamburg; Cathedral at St. John's, Newfoundland; 1854, the Parish Church of Doncaster, Yorkshire; from 1849, as architect to the dean and chapter of Westminster, he continued the restorations of the church, and restored the chapter-house. Designed the Foreign Office, including the exterior of the India Office, Whitehall; the Memorial to the Prince Consort, Hyde Park; and the new Cathedral at Edinburgh. Restored portions of nearly every cathedral in England, and some in Wales; Tewkesbury Abbey choir, &c., and St. Alban's Abbey. Designed the Albert Memorial Chapel, at Windsor; St. Mary Abbott's Church, Kensington; chapel of St. John's College, Cambridge; Glasgow University Buildings; Leeds Infirmary; Preston Town Hall; houses in the Broad Sanctuary, Westminster; and very numerous new churches; also numerous rebuildings and restorations. He wrote "Gleanings from Westminster Abbey," 1861; "Remarks on Secular and Domestic Architecture," 1857; "Lectures on the Rise and Development of Mediæval Architecture," 2 vols., 1879; and many papers and essays. Died March 27, 1877, aged 67.

362. Edward Blore of Derby.—Designed, 1816, Abbotsford, for Sir Walter Scott; was employed for many years in making drawings for antiquarian and other publications; and published "The Monumental Remains of Noble and Eminent Persons," 1824–26; and was among the first to stimulate the revival of Gothic architecture. Restorations at Peterborough, Glasgow, Ely, and Winchester Cathedrals; Merton College Chapel, Oxford; Barfreston Church, Kent; Thorney Church, Cambridgeshire; Ramsey, Huntingdonshire; and several others. Rebuilt the residence, restored the hall and chapel of Lambeth Palace. Designed the Palace of Aloupka, in the Crimea, for Prince Woronzow; Worsley Hall, Lancashire; Haveringland Hall, Norfolk; Cranford Hall, Dorset; and others. Made extensive alterations at Wadham and St John's Colleges, Oxford; and at Windsor Castle. Designed the new front, &c., to Buckingham Palace; and works of restoration, &c., at Westminster Abbey for several years. Died September 4, 1879, aged nearly 90.

363. Joseph Louis Duc of Paris.—Designed, 1833–40, the Colonne de Juillet; and after 1840, the buildings of the Palais de Justice, including the new Salle des Pas Perdus, all at Paris. In 1869 he received the Grand Prix of 100,000 francs decreed every five years by Napoleon III. Died January, 1879.

364. Gottfried Semper of Altona, in Denmark.—Designed, 1834, the Court Theatre, and the Synagogue, at Dresden; and 1847, began the new Museum. He retired to Paris, and then to London, where, 1853, he designed the Wellington funeral car. After some years he went to Zurich as Professor of Architecture; designed the large Polytechnic School; the town hall; the railway station. The rebuilding of the Court Theatre, at Dresden, was carried out by his son Manfred. Designed the Exchange; new Museum; additions to the Imperial residence; and, with von Hasenauer, the Imperial Court Theatre; all at Vienna. Died at Rome May 15, 1879, aged 76.

365. Eugène Emmanuel Viollet-le-Duc of Paris.—In 1840 he was nominated, with Lassus, in the restoration of the Ste. Chapelle, at Paris. He restored the Abbey Church of Vézelay; the churches of St. Pierre, Montréale; the Hôtel de Ville, at Narbonne; the church at Poissy, of St. Nazare in Carcassonne, and at Semur. With Lassus, 1846, the restoration of Notre Dame, at Paris; works at the Abbey of St. Denis; 1849, commenced the restoration of the fortifications at Carcassonne; at the Cathedral at Amiens, and the Syndical Hall at Sens; Notre Dame, at Châlons-sur-Marne; the Cathedral at Laon; the Château de Pierrefonds. Designed the Protestant Cathedral at Lausanne; and the Château d'Eu, for the Comte de Paris. Besides the important "Dictionnaire Raisonné de l'Architecture Française," 1853–68, he published "Essai sur l'Architecture Militaire," 1854; "Dictionnaire du Mobilier Français," 1855; "Entretiens sur l'Architecture," 1858–68; and others. Died September 17, 1879, aged 65.

366. Edward Middleton Barry of London.—Designed, 1857, St. Saviour's Church, Haverstock Hill; the schools in Endell Street, for St. Giles's-in-the-Fields; 1857, Covent Garden Theatre, for Mr. Gye, with the Floral Hall adjoining; was appointed, 1860, to complete the new Palace at Westminster, after the death of

Sir C. Barry. Designed the Halifax Town Hall; new Opera-house at Malta; the staircase to the Royal Academy rooms at Burlington House; the new chambers, "Temple Gardens"; the Cannon Street and the Charing Cross Hotels, with the Queen Eleanor Cross; the Hospital for Children, Great Ormond Street; the Birmingham and Midland Institute. Rebuilt Crewe Hall, Cheshire; designed the decoration of St. Stephen's Chapel, Westminster; and the additional galleries to the National Gallery of Pictures. Died January 27, 1880, aged 49.

367. Jean Pierre Cluysenaar of Liège.—Designed the Marché de la Madeleine; the Hôtel du Conservatoire; and the Galeries St. Hubert, all at Bruxelles. He published "Bâtiments des Stations, &c.," 4to., 1862; "Maisons de Compagne, Châteaux, &c.," 4to., 1862. Died January (?), 1880, aged 69.

368. Johann Heinrich Strack of Bückeburg, in Holstein.—As a student of Schinkel's he assisted in designs for the then Crown Prince, afterwards Frederick William IV., at the new Palace at Berlin; 1828, in the erection of the Palace of Prince Carl, and the Palace of Prince Albrecht. He completed the Palace of Babelsberg, near Potsdam, as well as the present Imperial Palace. At Berlin, he designed the Palais Raczynski, 1843; the churches of St. Peter and St. Andrew; the National Gallery, 1866–76; the Column of Victory in the Thiergarten, 1871–75; and the Villa Borsig. He published several works, including his discovery, 1862, of the Theatre of Dionysius at Athens. He was lecturer at the Academies, and also "baumeister" from 1838 to the Emperor of Germany. Died June 13, 1880, aged 75.

369. Benjamin Ferrey of Christchurch, Hampshire.—Laid out the estate of Sir Geo. Gervis, and designed the Bath Hotel, with several rows of villas, at Bournemouth. Restored the nave and transepts and the Lady Chapel of Wells Cathedral; and the Bishop's palace and chapel. Designed the Church of St. James, at Morpeth; of St. Stephen, Rochester Row, Westminster; the town halls at Dorchester and Luton; the church at Buckland St. Mary; Wynnstay, for Sir W. W. Wynn; Bulstrode, for Duke of Somerset; mansion for the Duke of Connaught at Bagshot Park, &c. His invention of stamping plaster was carried out at Macclean Church, near Ampthill; at All Saints', Blackheath; at Streatham Parish Church, and other churches. Died August 22, 1880, aged 70.

370. Thomas Henry Wyatt of Loughlin House, Roscommon.—He practised in London in partnership with David Brandon from 1838 to March 17, 1851, and designed the Assize Courts at Winchester, Devizes, Usk, Brecon, and Cambridge. Among numerous hospitals, &c., those at Malta; for Norfolk and Norwich; Wiltshire Lunatic Asylum; and the Buckingham Lunatic Asylum; the Exchange Buildings at Liverpool; the cavalry barracks at Knightsbridge, London; railway station at Florence; Adelphi Theatre, London; St. Aidan's College, Birkenhead; Oatland Park Hotel, Surrey; mansion in Park Lane, for Sir Dudley Majoribanks; with many others; and alterations. Among the numerous new churches, in Wiltshire, that of Wilton, near Salisbury; memorial church to George Herbert at Bemerton, &c.; in Dorsetshire, in London, in Cambridgeshire, &c.; the Garrison Church at Woolwich; also the earlier restorations at Llandaff Cathedral, and at Wimborne Minster. Died August 5, 1880, aged 73.

371. William Burges of London.—Gained, in conjunction with Mr. Clutton, the first premium for Lille Cathedral; was occupied in the decoration of the Chapter House at Salisbury; also the first premium for the Memorial Church at Constantinople; designed Brisbane Cathedral, and the Cathedral at Cork; restorations at Waltham Abbey; at Cardiff Castle, for the Marquis of Bute; decoration of chapel of Worcester College, Oxford; designed the Art School at Bombay; made designs for Hartford College, United States; carried out his own house in Melbury Road, Kensington; designed Worcester College Hall; and new churches at Studley and Skelton, near Ripon. Died April 20, 1881, aged 53.

372. Decimus Burton of London.—Designed, 1824–26, the Colosseum, Regent's Park, and the Hyde Park improvements, including the Ionic façade and the triumphal arch; the Calverley Park estate at Tunbridge Wells, for Mr. John Ward; Grove House, Regent's Park; Royal Naval Club, and the Athenæum Club, Pall Mall; Holford House, St. Dunstan's Villa, and St. John's Lodge, Regent's Park; Worth Park, Sussex; Stapleton Palace, near Bristol; the new town, church, hotel, lighthouse, &c., at Fleetwood; the Union Club, United Service Club, and Junior United Service Club, London; palm house, winter garden, &c., at Kew; and numerous private houses. Died December 14, 1881, aged 81.

373. Anthony Salvin of Sunderland Bridge, Durham.—Designed Mamhead, near Exeter; Morby Hall; restored the hall at Brancepeth Castle; designed Methley Hall;

Parham Court, and many others; Peckforton Castle; restored the Beauchamp Tower and Traitors' Gate at the Tower of London; also Carnarvon Castle, with numerous others; the Curfew Tower and other works at Windsor; Alnwick Castle, Northumberland. Designed Keele Hall, Staffordshire; Thoresby Hall, Nottinghamshire. Restored Petworth House; Birdsall House; Fernhurst Church, Sussex; Kilndown Church; the Church of the Holy Sepulchre, Cambridge, &c.; and Dunster Castle. Died December 17, 1881, aged 82.

374. George Edmund Street of Woodford, Essex.—Designed Hadley Church, Essex; others at Constantinople, Rome, Genoa, Lausanne, Vevay, Mürren, and Paris; All Saints' Church, parsonage, and schools, at Boyne Hill, Berkshire; Church of St. James the Less, Garden Street, Westminster; St. Peter's Church, Bournemouth; and the nave to Bristol Cathedral. Restored south transept and the reredos at York Minster. Designed the Courts of Justice, London; the churches of St. Margaret at Liverpool; All Saints at Clifton; St. Mary Magdalene at Paddington; St. Saviour at Eastbourne; St. John at Torquay; St. Philip and St. James at Oxford; the Theological College at Cuddesdon; Dulecht House and Chapel. Restored Christ Church Cathedral, Dublin. He published "Brick and Marble Architecture in Italy," 8vo., 1855; "Gothic Architecture in Spain," 8vo, 1865; and wrote numerous papers and lectures. Died Dec. 18, 1881, aged 57.

375. Conte Commendatore Virginio Vespignani of Rome.—Architect to the Church of St. Peter's at Rome. Died December 3, 1882.

376. David Rhind of London.—At Edinburgh, designed the Commercial Bank Buildings; Life Association of Scotland; Normal School, Chambers Street; Stewart's Hospital; addition to the Assembly Hall on Castle Hill; and the Commercial Bank, Glasgow. Died April 26, 1883.

377. Signor Emilio de Fabris of Florence.—Designed the new façade to the Cathedral of Santa Maria, at Florence, ordered 1869. Died (on the eve of the day appointed for uncovering this great work) June 28, 1883.

378. Heinrich Freiherr von Ferstel of Vienna.—At Vienna, the Votivkirche; the new University; the Palace of the Grand Duke Charles Ludwig Victor; and several other works therein. Died July 15, 1883, aged 55.

379. Jean Baptiste Cicéron Lesueur of Clairefontaine, near Rambouillet, France.—Designed the Parish Church at Vincennes; Conservatoire de Musique at Geneva; at Paris, a great number of princely mansions; 1840, extension and completion of the Hôtel de Ville (burnt 1871), &c. Published, with F. Callet, "Edifices Publiques, &c., de Turin et de Milan," 1855; "Vues Choisies des Monuments Antiques de Rome," 1827; "Chronologie des Rois d'Egypte," 4to., 1848; "Histoire et Théorie de l'Architecture," 1879. Died December 25 (?), 1883, aged 89.

380. Théodore Ballu of Paris.—At Paris, he completed the Church of St. Clotilde (by Gau); carried out the reconstruction of the Hôtel de Ville after 1873; designed the churches of La Trinité and St. Ambroise; restored the ancient Tower of St. Jacques de la Boucherie; and the ancient Church of St. Germain l'Auxerrois. Died May 23, 1885, aged 68.

381. Thomas Leverton Donaldson of London.—Designed the Church of the Holy Trinity, South Kensington; the town mansion of Mr. H. T. Hope, in Piccadilly, with M. Dusillion of Paris; mansion for Mr. H. Hippisley at Lambourn, Berkshire; University Hall, Gordon Square; the library and laboratory at University College, Gower Street; Gordon Street Church; Scotch Church, Woolwich; and Scottish Corporation Hall, Crane Court, Fleet Street. He published "Examples of Doorways from Ancient and Modern Buildings in Italy and Sicily," 4to., 1833–36; "Lime, Mortar, Stucco, &c.," 4to., 1840; "Architectura Numismatica," 4to., 1859; read a vast number of papers at the Royal Institute of British Architects, of which he was the first secretary, and one of the chief founders in 1835; and was for many years Professor of Architecture at University College. Died August 1, 1885, aged 90.

382. Théodore Labrouste of Paris.—Designed the Maison Municipale de Santé, Faubourg St. Denis. Died November 28, 1885, aged 86.

383. James Fergusson of London.—Designed the picture gallery for Miss North's paintings in Kew Gardens, illustrating his theory of lighting temples. Published "Rock-cut Temples of India," 1845; "True Principles of Beauty in Art," 1849; "Picturesque Illustrations of Ancient Architecture of Hindostan," 1847; "Handbook of Architecture," 2 vols. 1855; "Modern Styles," 1862; "History of Architecture," 2 vols. 1865; "History of Indian and Eastern Architecture," 1876; "Topography of Jerusalem," 1847; "Palaces of Nineveh and Persepolis restored," 1851; "Mausoleum of Halicarnassus," 1862; "Rude Stone Monu-

ments," 1873; "Tree and Serpent Worship," 1873; "Temples of the Jews," 1878; "Cave Temples of India," 1880, with Mr. James Burgess; "The "Parthenon, an Essay on Lighting Temples," 1885; and many lectures and papers. Died January 9, 1886, aged 78.

384. Henry Hobson Richardson of Louisiana, U.S.A.—Educated at Harvard University, he proceeded, 1859, to Paris, where he studied; settled at New York for three years, and then at Boston, where he designed Trinity Church and two others; 1878, Sever Hall, and 1881, Austin (Law School) Hall, both for Harvard University; the New York State Capitol at Albany from 1868, at an estimated cost of four million dollars, but will probably cost double that amount; in 1878, Messrs. Eidlitz, Richardson, and Olmsted were appointed joint architects, but to Richardson is due, after 1875, the south side, with a central staircase seventy feet square, and the Senate chamber, opened March 1881. He also designed, 1884, the County Buildings and the Jail at Alleghany, Pennsylvania; 1885, the Field Building or Store at Chicago, 325 feet long; the Cincinnati Chamber of Commerce, Ohio; with several libraries, dwelling-houses (including his own), railway stations, &c. He exercised great influence upon the architectural art of his country. Died April 27, 1886, aged 48.

385. R. Kyrye Penson of Oswestry.—He held several appointments in Carmarthenshire and Cardiganshire, and designed a large number of churches, residences, schools, bridges, and other works, especially St. Mark's Church, Wrexham; and Dynevor Castle, Llandilo, for Lord Dynevor; with numerous restorations of churches, &c. Died May 22, 1886, aged 70.

386. John Prichard of Llandaff.—Was a pupil of A. W. Pugin, and held the position of diocesan architect for nearly forty years. Superintended the restoration of many churches, as well as that of the cathedral in conjunction with Mr. J. P. Seddon, the general restoration with Mr. T. H. Wyatt, and subsequently by himself. He remodelled, about 1865, Eatington Hall, Warwickshire; and designed the mausoleum of the Bute family at Cardiff Castle. Died Oct., 1886, aged 68.

387. George Vulliamy of London.—A pupil of Sir C. Barry; travelled much abroad, returned in 1843. Succeeded Mr. Marrable at the Metropolitan Board of Works as superintending architect in 1861, and for whom he designed the group of buildings on the south side of Queen Victoria Street, near Bucklersbury; additional story, &c., to the offices of the Board; several of the Fire Brigade stations, &c. Amongst his private works are the French Protestant Church, Bloomsbury; church, &c., at Queenhithe; the memorial tower to the Earl of Ellesmere; Dyffryn in Merionethshire; the restoration of the north transept of Rochester Cathedral; All Saints' Church, Ennismore Gardens; the pedestal and sphinxes for the Cleopatra's Needle, &c. Died November 12, 1886, aged 69.

388. George Goldie of York.—He was pupil, and then partner with Messrs. Hadfield and Weightman of Sheffield. He removed to London, and designed the Church of St. Wilfrid, at York; the Pro-Cathedrals at Kensington, at Durban in Natal, and at Middlesborough; the Cathedral at Sligo; the Church of St. John of Jerusalem, in Great Ormond Street; Upsall Castle, and Weston Manor in the Isle of Wight; and many Roman Catholic churches, &c. Died March 1, 1887, aged 59.

389. Victor Marie Charles Ruprich-Robert of Paris.—He designed the Church of Flers; the restoration of the Château d'Amboise; the Church of Ste. Trinité at Caen; the Church of Ouistreham in the Calvados diocese. Besides "Flore Monumentale," 1866, and the monograph on the Church and Monastery of Val de Grâce, 1875, he had nearly completed a great work on "Norman Architecture in Normandy and England." Died May 7, 1887, aged 67.

390. Sir Horace Jones of London.—Commencing practice in 1846, he designed the British and Irish Magnetic Telegraph Company's offices, Threadneedle Street; the Sovereign Assurance office, Piccadilly; Royal Surrey Music Hall; Cardiff Town Hall; Caversham Park, and other buildings, warehouses, residences, &c.; and was surveyor to several estates. In February 1864 he was appointed architect to the Corporation of the City of London, which office he held for twenty-three years, for whom he designed, 1868, the Central Meat Market; 1875, the Poultry and Provision Market; 1883, the Fruit Market; 1871, the Foreign Cattle Market at Deptford; 1877, the reconstruction and enlargement of Billingsgate Market; and 1882, the rebuilding of Leadenhall Market, with large additions, &c., to the Islington Cattle Market. He also completed, 1864, the City Lunatic Asylum at Dartford; designed, 1864, the new roof and other works to the Guildhall; 1872, the library and museum, and 1884, the new council chamber. Several stations for the City police; artizans' dwellings in Farringdon Road; the bascule bridge over the river Thames beyond the Tower, commenced 1885, with

J. W. Barry as engineer; the Guildhall School of Music, on the Embankment; and the Temple Bar Memorial, are among his later designs. In 1882–83 he was President of the Royal Institute of British Architects. Died May 21, 1887, aged 68.

391. Daniel Ramée of France —Much occupied for the "Monuments Historiques" of France. Restored the Palais de Justice at Beauvais; the Church of St. Vulfran at Abbeville, Notre Dame de Noyon, the Church of St. Riquier, that at Senlis, and many others. He published many works, especially "Histoire Générale de l'Architecture," 8vo, 1843; 2nd edit. 1862; and others named in the list of publications. Died September, 1887, aged 81.

392. Edward I'Anson of London.—President of the Royal Institute of British Architects at the time of his death, January 30, 1888, aged 76.

393. George Godwin of London.—Edited "The Builder" from 1845 (vol. iii.), for nearly forty years, retiring in October 1883.—Died January 27, 1888, aged 73.

As great use was made of this work by Gwilt, we notice here that he had the edition of 1835. It was first published in 1805–10, which edition is in the library of the Institution of Civil Engineers; the second, of 1812–14, is in the library of the Institute of British Architects, and in Sir John Soane's Museum; while the British Museum contains the edition dated 1830–2. In this one some of the plates have been re-engraved and rearranged. [Paris, 1814.
——— Mémoire Historique sur le Dôme du Panthéon François. 10 plates, 4to.

A

GLOSSARY OF TERMS

USED IN

ARCHITECTURE AND IN BUILDING.

[Note.—Further explanations, illustrations, &c., of many of the terms herein will be obtained in the Encyclopædia by reference to the Index; and many publications on the subjects described will be found in the List prefixed hereto.]

A.

Abaciscus. A word sometimes used as synonymous with abacus, but more correctly applied to a square compartment enclosing a part or the entire pattern or design of a Mosaic pavement.

Abacus. (Gr. Αβαξ, a slab.) The upper member of the capital of a column, and serving as a crowning both to the capital and to the whole column. It is otherwise defined by some as a square table, list, or plinth in the upper part of the capitals of columns, especially of those of the Corinthian order, serving instead of a drip or corona to the capital, and supporting the nether face of the architrave, and the whole trabeation. In the Tuscan, Doric, and ancient Ionic orders, it is a flat square member, well enough resembling the original title; whence it is called by the French *tailloir*, that is, a trencher, and by the Italians *credenza*. In the richer orders it parts with its original form, the four sides or faces of it being arched or cut inwards, and ornamented in the middle of each face with a rose or other flower, a fish's tail, &c.; and in the Corinthian and Composite orders it is composed of an ovolo, a fillet, and a cavetto. The word is used by Scamozzi to signify a concave moulding in the capital of the Tuscan pedestal.

Abaton. (Gr. Αβατον, an inaccessible place). A building at Rhodes, mentioned by Vitruvius, lib. ii., entrance to which was forbidden to all persons, because it contained a trophy and two bronze statutes erected by Artemisia in memory of her triumph in surprising the city.

Abattoir. (Fr. Abattre, to knock down.) A building appropriated to the slaughtering of cattle. All private slaughtering-houses, in large towns at least, should be abolished, and public ones, under proper supervision, established, as lately effected at Edinburgh, Manchester, and a few other towns.

Abbey. (Fr. Abbaïe.) Properly the building adjoining to or near a convent or monastery, for the residence of the head of the house (abbot or abbess). It is often used for the church attached to the establishment, as also for the buildings composing the whole establishment. In such establishments the church was usually grand, and splendidly decorated. They had a *refectory*, which was a large hall in which the monks or nuns had their meals; a *guest hall*, for the reception and entertainment of visitors; a *parlour* or *locutory*, where the brothers or sisters met for conversation; a *dormitory*, an *almonry*, wherefrom the alms of the abbey were distributed; a *library* and *museum*; a *prison* for the refractory, and *cells* for penance. The *sanctuary* was rather a precinct than a building, in which offenders were, under conditions, safe from the operation of the law. *Granges*, or farm buildings, and *abbatial* residences. *Schools* were usually attached for the education of youth, with separate accommodations for the scholars; a *singing school*. A *common room*, with a fire in it, for the brothers or sisters to warm themselves, no other fire being allowed, except in the apartments of the higher officers. A *mint* for coining, and a room called an *exchequer*. The abbey was always provided with a *churchyard*, a *garden*, and a *bakehouse*. The *sacristy* contained the garments of the priests, and the vessels, &c.; *vestiaria* or wardrobes being assigned for the monks. Many of the ordinary duties of these persons were performed in the cloisters where they delivered their lectures.

Abreuvoir. (Fr.) In masonry, the joint between two stones, or the interstice to be filled up with mortar or cement, when either are to be used.

Absciss, or Abscissa. A geometrical term, denoting a segment cut off from a straight line by an ordinate to a curve.

Absis. See Apsis.

Absorption. The penetration of a gas or liquid into any substance; or the taking up of moisture by capillary attraction. A principle seriously affecting the durability of all building materials. The rapidity of absorption is not a criterion as to durability, but the comparative durability of stones of the *same kind* may be tested by the smallness of the weight of water which a given weight of stone is capable of absorbing. The actual absorption of water by *bricks* of various qualities has thus been stated:—Malm place brick, 62 ounces of water; white Surrey, 58 oz.; white seconds, 52 oz.; red facings, 51 oz.; pickings, 50 oz.; stocks, 27 oz.; Workman's waterproofed, 2 oz. The following table of the absorbent powers of certain *stones*, when saturated under the exhausted receiver of an air-pump is given in the *Report* of the Commissioners on Building Stones, 1839:—

Sandstones.		Oolites.		Magnesian Limestones.		Limestones.	
Craigleith	0·143	Ancaster	0·180	Bolsover	0·182	Barnack	0·204
Heddon	0·156	Bath Box	0·312	Huddlestone	0·239	Chilmark	0·053
Kenton	0·143	Portland	0·206	Roach Abbey	0·248	Ham-Hill	0·147
Mansfield, red	0·151	Ketton	0·244	Park Nook	0·249		

The *granites*, though closely granulated, take up much more than the *grauwaeke*, but less than the *sandstones*; while the *grauwacke* resists the water four times that of *granite*, and thirty-six times that of *Yorkshire sandstones.*

Abstract. A term in general use among artificers, surveyors, &c. to signify the collecting together and arranging under a few distinct heads the various small quantities of different articles which have been employed in any work, and the affixing of a price to determinate portions of each, as per square, per foot, per pound, &c. for the purpose of more expeditiously and conveniently ascertaining the amount.

Abuse. A term applied to those practices in architecture which, arising from a desire of innovation, and often authorised by custom, tend to unfix the most established principles, and to corrupt the best forms, by the vicious way in which they are used. Palladio has given a chapter on them in his work. He reduces them to four principal ones: the first whereof is the introduction of brackets or modillions for supporting a weight; the second, the practice of breaking pediments so as to leave the centre part open; third, the great projection of cornices; and, fourth, the practice of rusticating columns. Had Palladio lived to a later day, he might have greatly increased his list of abuses, as Perrault has done in the following list:—the first is that of allowing columns and pilasters to penetrate one another, or be conjoined at the angles of a building. The second that of coupling columns, which Perrault himself in the Louvre has made almost excusable; the third, that of enlarging the metopæ in the Doric order, for the purpose of accommodating them to the intercolumniations; the fourth, that of leaving out the inferior part of the *tailloir* in the modern Ionic capital; the fifth, that of running up an order through two or three stories, instead of decorating each story with its own order; the sixth, that of joining, contrary to the practice of the ancients, the plinth of the column to the cornice of the pedestal, by means of an inverted cavetto; the seventh, the use of architrave cornices; the eighth, that of breaking the entablature of an order over a column, &c., &c.

Abutment. The solid part of a pier from which an arch immediately springs. Abutments are artificial or natural: the former are usually formed of masonry or brickwork, and the latter are the rock or other solid materials on the banks of the river, in the case of a bridge, which receive the foot of the arch. It is obvious that they should be of sufficient solidity and strength to resist the thrust of the arch.

Abuttals. The buttings or boundings of land.

Acanthus. (Ακανθος, a spine.) A spiny herbaceous plant found in various parts of the Levant. Its leaf is said by Vitruvius to have been the model on which the Grecian architects formed the leaves of the Corinthian capital.

Acer. A genus of trees comprehending the maple and sycamore, the wood of which is not of much value. That of the acer campestre furnishes the cabinet makers with what they call bird's-eye maple.

Access. See Passage; also Adit.

Accidental Point. In perspective, the point in which a straight line drawn from the eye parallel to another straight line cuts the perspective plane. It is the point wherein the representations of all straight lines parallel to the original straight line concur when produced. Its name is adopted to distinguish it from the principal point or point of view.

Acoustics. (Gr. Ακουω, to hear.) The doctrine or theory of sounds, as applicable to buildings. See Theatres, book iii., chap. v., and Churches in the same book. The subject is one presenting great difficulty. The statements of various professors, and a comparison of buildings themselves, have been collected in a work by Mr. T. R. Smith. It was stated by Professor Lewis, at a lecture given in 1864–65, that in consulting one of the most eminent Scottish philosophers respecting the plan for a church, the reply was, that in his opinion the principle adopted would most probably answer; but he added that he had studied acoustics probably as much as any man, and the conclusion he arrived at was that in applying theory to actual practice he knew nothing about it, and he believed nobody else knew more.

Acropolis. (Gr. Ακρος and Πολις, city.) The upper town or citadel of a Grecian city, usually the site of the original settlement, and chosen by the colonists for its natural

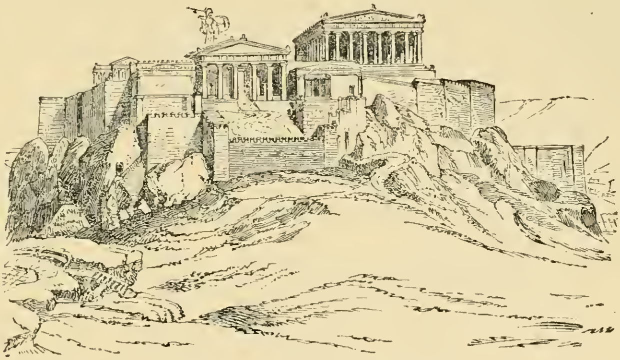

Fig. 1361. The Acropolis at Athens.

strength. The most celebrated were those at Athens, Corinth, and Ithome; the two latter were called the horns of the Peloponnesus, as though their possession could secure the submission of the whole peninsula.

Acroteria. (Gr. Ακρωτηριον, the extremity of anything.) The pedestals, often without base or cornice, placed on the centre and sides of pediments for the reception of figures. Vitruvius says that the lateral acroteria ought to be half the height of the tympanum, and the apex acroterium should be an eighth part more. No regular proportion, however, is observable in Grecian buildirgs.

The word acroterium is applied to the ridge of a building; it has also been used to signify the statues on the pedestals; but it is only to these latter that it is strictly applicable. The word has, moreover, been given to the small pieces of wall in balustrades, between the pedestal and the balusters, and again to the pinnacles or other ornaments which stand in ranges on the horizontal copings or parapets of buildings.

Acute Angle. A term used in geometry to denote an angle less than 90°, that is, less than a right angle.

Acute-angled Triangle. A triangle having all its angles acute. Every triangle has at least two acute angles.

Adhesion. (Lat. Adhæreo.) A term in physics denoting the force with which different bodies remain attached to each other when brought into contact. It must not be confounded with cohesion, which is the force that unites the particles of a homogeneous body with each other. The following is an account of some experiments recorded in the *Technical Repository* for 1824:—'The insertion of a nail is accomplished by destroying the cohesion of the wood, its extraction by overcoming the force of adhesion and friction. We will consider it here solely as a case of adhesion. Fine sprigs, of which 4560 weighed one pound, $\frac{44}{100}$ of an inch long, forced four-tenths of an inch into dry Christiania deals at right angles to the fibre, required a force of 22 lbs. to extract them. The same description of nail having 3200 in the pound, $\frac{53}{100}$ of an inch long, and forced $\frac{44}{100}$ of an inch into the same kind of wood, required 37 lbs. to extract it. Threepenny brads, 618 to the pound weight, one and a quarter inch long, forced half an inch into the wood, required a force of 58 lbs. to draw them out. Fivepenny nails, 139 to the pound weight, two inches long, and forced one inch and a half into the wood, required a force of 320 lbs. to extract them. Sixpenny nails, 73 to the pound, two inches and a half long, and forced one inch into the wood, required 187 lbs. to extract them. The same kind of nail forced one inch and a half into the wood required 327 lbs. to draw it out; and one forced two inches into the wood required 530 lbs. to extract it. In this last experiment the nail was forced into the wood by a hammer of cast-iron weighing 6·275 lbs. falling from a height of twelve inches, four blows of which were necessary to force the nail an inch and a half into the wood. It required a pressure of 400 lbs. to force the nail to the same depth. A sixpenny nail driven one inch into dry elm across the grain or fibres required 327 lbs. to draw it out by direct force; driven endwise into dry elm, or parallel with the grain, it required only 257 lbs. to extract it. The same sort of nail driven into dry Christiania deal was extracted by a force equal to 257 lbs., and by one of 87 lbs. from a depth of an inch. The adhesion, therefore, of a nail driven into elm across the grain, or at right angles to the fibres of the wood, is greater than when it is driven with the grain, or parallel with the fibres, in the proportion of 100 to 78, or 4 to 3. And under the same circumstances, in dry Christiania deal, as 100 to 46, or nearly 2 to 1. The comparative adhesion of nails in elm and deal is between 2 and 3 to 1. To extract a sixpenny nail driven one inch into green sycamore required 312 lbs.; from dry oak, 507 lbs.; and from dry beech, 667 lbs. A common screw of one-fifth of an inch had an adhesion about three times as great as that of a sixpenny nail. A common sixpenny nail driven two inches in dry oak would require more than half a ton to extract it by pressure.'

Adit (Lat. Adeo), or Aditus. The approach or entrance to a building, &c. Among the ancients the *aditus theatri*, or adits of a theatre, were doorways opening on to the *stairs*, by which persons entered the theatre from the outer *portico*, and thence descended into the seats. Upon the same principle were the adits of a circus.

Adjacent Angle, in geometry, is an angle immediately contiguous to another, so that one side is common to both angles. This expression is more particularly applied to denote that the two angles have not only one side in common, but likewise that the other two sides form one straight line.

Adytum. (Gr. Ἄδυτον, a recess.) The secret dark chamber in a temple to which none but the priests had access, and from which the oracles were delivered. Seneca, in his tragedy of Thyestes says—

"Hinc orantibus
Responsa dantur certa, dum ingenti sono
Laxantur adyto fata."

Among the Egyptians the *secos* was the same thing, and is described by Strabo. The only well-preserved ancient adytum that has come to our knowledge is in the little temple at Pompeii; it is raised some steps above the level of the temple itself, and is without light.

Adze or Addice. An edged tool used to chip surfaces in a horizontal direction, the axe being employed to chop materials in vertical positions. The blade, which is of iron, forms a small portion of a cylindric surface, in both its sides, and has a wooden handle fixed into a socket at one of its extremities, in a radial direction, while the other extremity, parallel to the axis of the cylinder, and therefore at right angles to the handle is edged with steel, and ground sharp from the concave side. The adze is chiefly employed for taking off thin chips from timber or boards, and for paring away irregularities at which the axe cannot come. It is also used in most joinings of carpentry, particularly when notched one upon another, scarfings, thicknesses of flooring boards opposite to the joists, &c.

Aerial Perspective. The relative apparent recession of objects from the foreground owing to the quantity of air interposed between them and the spectator. It accompanies the recession of the perspective lines.

Æsthetics. (Gr. Αισθητικος, having the power of perception by means of the senses.) It is in the fine arts that science which derives the first principles from the effect which certain combinations have on the mind as connected with nature and right reason. See pp. 795 and 922.

Ætiaioi. (Gr. Αετος, an eagle.) The name given by the Greek architects to the slabs forming the face of the tympanum of a pediment. This word occurs in the Athenian inscription now in the British Museum, brought to England by Dr. Chandler, and relating to the survey of some temple at Athens.

Ætoma, or Ætos. (Gr. Αετος.) A name given by the Greek architects to the tympanum of a pediment. It seems derived from the custom of decorating the apex or ridge of the roof with figures of eagles, and that the name thence first given to the ridge was afterwards transferred to the pediment itself.

Air Drains, or Dry Areas. Cavities between the external walls of a building protected by a wall towards the earth, which is thus prevented from lying against the said walls and creating damp. They may be made with the walls battering against the ground, and covered over with paving stones, or with their walls nearly perpendicular, and arched on the top. This covering should be above the ground, and sloped to throw off the wet. The bottoms should be paved, and the areas should be well ventilated.

Air Holes. Holes made for admitting air to ventilate apartments: also for introducing it among the timbers of floors and roofs for the prevention or destruction of the dry rot.

Air Trap. A trap formed so as to prevent foul air from rising from sewers or drains into the atmosphere. There are various sorts, all depending upon a certain amount of water in them.

Aisle, or Aile. (Lat. Ala.) A term chiefly used by the English architect to signify the side subdivisions in a church, usually separated from the nave or centre division by pillars or columns. Among different nations, as applied to architecture, it bears different significations. Strabo states that among the Egyptians the *alæ* of the temple were the two walls that enclosed the two sides of the pronaos, and of the same height as the temple itself. The walls, he observes, from above ground, were a little further apart than the foundations of the temple, but as they rose, were built with an inclination to each other. The passage, however, is not clearly to be understood.

In Gothic, as well as in many modern, churches, the breadth of the church is divided into three or five parts, by two or by four rows of pillars running parallel to the sides; and as one or other is the case, the church is said to be a three-aisled or five-aisled fabric. The middle aisle is called the nave or chief aisle, and the penthouse, which joins to each side of the main structure containing the aisles, is called a wing. St. Mary's, Taunton; Chichester Cathedral; St. Helen's, Abingdon; and Elgin Cathedral, perhaps comprise all the five-aisled churches in Great Britain, except a building at the west end of the cathedral at Durham. On the Continent there are many such buildings, among which is the cathedral at Milan. It is somewhat remarkable that in Westminster Abbey and in Redcliff Church at Bristol the aisles are continued on each side of the transept, and in Salisbury Cathedral on one side only, a circumstance not met with in any other churches in this country.

Ajutage. (Fr.) Part of the apparatus of an artificial fountain, being a sort of *jet d'eau*, or kind of tube fitted to the mouth or aperture of a vessel, through which the water is to be played, and by it determined into the form to be given to it.

Alabaster. A white semi-transparent variety of gypsum or sulphate of lime, a mineral of common occurrence, and used for ornamental purposes, as screen work, and for sculpture. It was much used formerly for monuments in churches and the like, and has been re-introduced of late years for similar purposes.

Albarium Opus. (Lat.) In ancient Roman architecture a term imagined by some to have been nothing more than a species of whitewash applied to walls, but, as we think, incorrectly. In the passage of the tenth chapter of the fifth book of Vitruvius, where he recommends the use of the albarium opus for the ceilings of baths, he allows *tectorium opus* as a substitute; so perhaps it was a species of stucco. Its employment at the baths of Agrippa, seems to prove it to have been superior to the other, and it is by no means improbable that it was susceptible of a high polish.

Alcove. A wide and deep recess in a room. That part of a sleeping chamber wherein the bed is placed. The use of alcoves, though not by that name, is ancient. They were frequently designed in the form of a niche; such, for instance, as those that Winkelman notices at Hadrian's villa at Tivoli, of which sort are some at Pompeii. They were often formed by enclosures or balustrades, of various heights, and by means of draperies the alcove was separated from the large chamber of which it was a part. Some idea may be formed of it from many of the ancient bassi relievi, especially from the celebrated one known by the name of the *Nozze Aldobrandini*. In modern works this part of a room differs according to the rank and taste of the proprietor. In England it is rarely introduced, but in France and Italy it often forms a beautiful feature in the sleeping apartments of palaces and large houses.

Alder. (Ang. Sax. Ellarn.) A tree belonging to the order Betulaceæ. It is used for piling and any similar work under water.

Aleatorium. In ancient Roman architecture, a room in which games at dice were played.

Alipterion. In ancient Roman architecture, a room used by the bathers for anointing themselves.

Alkoranes. In Eastern architecture, high slender towers attached to mosques, and surrounded with balconies, in which the priests recite aloud at stated times prayers from the Koran, and announce the hours of devotion to worshippers. They much embellish the mosques, and are often very fantastical in form. They are also called Minarets.

Alley. (Fr. Allée.) An aisle, or any part of a church left open for access to another part. In towns, a passage narrower than a lane. An enclosed walk in a garden.

Almery or Aumbrye. A recess or cupboard for holding the sacred vessels, &c., used in the mass. An example, dating circa 1200, is seen in Lincoln Cathedral.

Almonry. Properly a closet or repository for the reception of broken victuals set apart as alms for the poor. It is more generally used to denote a house near the church in abbeys, or at their gates, provided with various offices for distributing the alms of the convent, and for the dwelling of the almoner.

Almshouse. A house devoted to the reception and support of poor persons, and generally endowed for a particular description of persons.

Altar. The name given to a flat stone found in Celtic erections.

Altar. (Lat. Altare.) A sort of pedestal whereon sacrifice was offered. According to Servius there was among the ancients a difference between the *ara* and *altare*, the latter being raised upon a substruction, and used only in the service of the celestial and superior divinities, whereas the former was merely on the ground, and appropriated to the service of the terrestrial gods. Altars to the infernal gods were made by excavation, and termed *scrobiculi*. Some authors have maintained that the *ara* was the altar before which prayers were uttered, and that the *altare* was used for sacrifices only. There is, however, from ancient authors no appearance of such distinctions, but that the words were used indiscriminately. The earliest altars were square polished stones, on which were placed the offerings to the gods. Whilst the sacrifice consisted only of libations, perfumes, and offerings of that nature, the altar was small, and even portable; when man, however, began to consider he was honouring the divinity by an offering of blood, the altar necessarily expanded in dimensions. Different forms of it were adopted, according to the nature of the sacrifice, and on it the throat of the victim was cut and the flesh burnt. Of this sort is the circular altar of the Villa Pamphili at Rome, one of the largest and most elegant of the class. On it appears the cavity for holding the fire, and the grooves for carrying off the blood. The varieties of altars were suitable in form, ornament, and situation to the service to which they were appropriated: some, as we have already observed, being for sacrifices of blood, others for receiving offerings and the sacred vessels; some for burning incense, others for receiving libations. Many were set up as mere monuments of the piety of a devotee, whilst others were raised to perpetuate some great event. They served for adjuration as well as for an asylum to the unfortunate and evil doer. In form they varied from square to oblong, and from triangular to circular. Those of metal were commonly tripodial. When of brick or stone their plan is generally square. According to Pausanias they were occasionally made of wood. They do not appear to have been of any regular standard height, for they are sometimes found on bassi relievi reaching but little above a man's knee, whereas in others they appear to reach his middle; but it seems that in proportion to its diameter the circular altar was generally the highest. Vitruvius says that they should not be so high as to intercept the statues of the gods, and he gives the relative heights of those used for different divinities. Thus, he says, those of Jupiter and the celestial gods are to be the highest; next, those of Vesta and the terrestrial gods; those of the sea gods are to be a little lower, and so on. On festivals they were decorated with such flowers and leaves as were sacred to the particular divinity. But besides this casual decoration, the ancient altars furnish us with some of the most elegant bassi relievi and foliage ornaments that are known. According to Vitruvius, their fronts were directed towards the east, though very frequently but little regard was paid to their position, as they were occasionally placed under the peristyle of a temple, and not unfrequently in the open air. In the larger temples were often three different altars. The first was in the most sacred part, in front of the statue of the god; the second before the door of the temple; and the third (called *anclabris*) was portable, and on it the offerings and sacred vessels were placed.

The altars of the Catholic church are either attached or isolated. The former generally stand against a wall, and are so decorated as to appear quite independent of it. The decorations are either of painting or sculpture, or both. The isolated altar has no sort of connection with any part either of the building or of its decorations. The high altar is always isolated, whether placed at the end of the church or in its centre, as in the well-known example in St. Peter's at Rome. Whatever the situation of the high altar, it should be grand and simple, and raised on a platform with steps on every side. The holy table of the Protestant churches of England was generally of wood, but some of stone (but not affixed) have been put up of late years; they are usually covered with a cloth more or less decorated. Above it is the Reredos.

The altars of the Greek church, though in other respects the religion vies in splendour with the Romish church, are destitute of painted or sculptured ornament. In Calvinistic churches the name as well as the uses of an altar are unknown either as an appendage or a decoration.

Altar Piece. The entire decorations of an altar. See Reredos.

Altar Screen. The back of an altar, or the partition by which the choir is separated from the presbytery and Lady chapel. The date of its introduction into English churches we believe to have been about the close of the thirteenth century. It is generally of stone, and composed of the richest tabernacle work, of niches, finials, and pedestals, supporting statues of the tutelary saints. Those to the high altars of Winchester Cathedral, of St. Alban's Abbey, and of New College at Oxford, are fine examples. Many were destroyed at the Reformation, or filled up with plaster and covered with wainscot. In many altar-screens a door was placed on each side of the altar for the officiating priests, whose vestments were deposited in an apartment behind the screen.

Altar Tomb. A tomb of a square box-like form, raised some 3 to 6 feet in height above the ground. On it is usually seen a sculptured recumbent representation of the deceased. These effigies are often placed under an arch, sometimes richly canopied.

Alto Relievo. See Relievo.

Alure. A gutter, passage, or gallery, as on the top of a wall or building, being one in which a person could walk. Lydgate used the word for covered walks in the streets.

Ambitus. A space which surrounded a tomb, and was held sacred. In descriptions of subterranean tombs, it denoted a small niche made in the wall for the reception of an urn or body. When the corpse was placed in it, to the mouth of the niche a slab was fixed, so fitted and cemented as to prevent noisome effluvia. The slabs were sometimes inscribed with the name and quality of the party. If they received an urn, either upon that or over the niche the inscription was placed. Much decoration was occasionally used in the recesses themselves.

Ambo. (Gr. Αμβων.) The elevated place or pulpit in the early Christian churches, which, according to Ciampini, fell into disuse about the beginning of the fourteenth century. The last erected ambo in Rome is supposed to have been that of S. Pancrazio, on which appears the date of 1249. It was an oblong enclosure, with steps usually at the two ends. Two ambones are described by Eustace in the cathedral at Salerno. They are placed on each side of the nave before the steps of the chancel, and are both of marble, the largest being covered with mosaic work and supported by twelve Corinthian granite columns.

Ambrey. See Aumbrye.

Ambulatio. (Lat.) See Pteroma.

Ambulatory. (Lat.) A sheltered place for exercise in walking; a cloister; a gallery.

Amphiprostyle. (Gr. Αμφι, both or double, προ, before, στυλος, a column.) A term applied to a temple having a portico or porch in the rear as well as in the front, but without columns at the sides. This species of temple never exceeded the use of four columns in the front and four in the rear. It differed from the temple in *antis*, in having columns instead of antæ at the angles of the portico. Such was the temple of Nike Apteros at Athens. See Temple.

Amphitheatre. (Gr. Αμφι, about, and θεατρον, a theatre.) An edifice formed by the junction of two theatres at the proscenium, so as to have seats all round the periphery, a contrivance by which all the spectators being ranged about on seats rising the one above the other, saw equally well what passed on the *arena* or space enclosed by the lowest range of seats, whose wall towards the arena was called the *podium*. The origin of the amphitheatre seems to have been among the Etruscans, to whom also are attributed the first exhibitions of gladiatorial fights. It was from this people that the Romans acquired a taste for such shows, which they communicated to every nation which became subject to their dominion. Athenæus says, "Romani ubi primum ludos facere cœperunt, huic asciti artifices ab Etruscis civitatibus fuerunt, sero autem ludi omnes qui nunc a Romanis celebrari solent sunt instituti." Lib. iv. c. 17. The most extraordinary edifice remaining in Rome, we may indeed say in the world, is the amphitheatre generally called the Coliseum. It was commenced by Vespasian, and completed by Titus his son. Words are inadequate to convey a satisfactory idea of its stupendous and gigantic dimensions. Ammianus says that it was painful to the eye to scan its summit; "ad cujus summitatem ægrè visio humana conscendit." Martial, in one of his epigrams says,

> "Omnis Cæsareo cedat labor amphitheatro,
> Unum pro cunctis fama loquatur opus."

The greater axis of the ellipsis on which it is planned is about 627 feet, and the lesser 520 feet, the height of the outer wall about 166 feet, such wall being decorated by the Doric, Ionic, and Corinthian Orders, and pierced with arcades between the columns. Covering five English acres and a quarter, it was capable of containing the vast number of 87,000 persons. It has suffered much from having been used actually as a quarry for many of the modern edifices of the city; but in the present day its preservation is strictly attended to by the papal government. A description of this building has been given in p. 94 *et seq.* Besides the Coliseum, there were three other amphitheatres in Rome: the Amphitheatrum Castrense, on the Esquiline, built probably by Tiberius; that of Statilius Taurus, and that built by Trajan in the Campius Martius. The other principal amphitheatres were those of Otricoli; on the Garigliano, of brick;

Puzzuoli, Capua, Verona, at the foot of Monte Casino, Pæstum, Syracuse, Agrigentum, Catanea, Argos, Corinth, Pola in Istria (see *fig.* 1362.), Hipella in Spain, Nismes, Arles, Frejus, Saintes, and Autun. This last has four stories, in that respect like the Coliseum. That which remains in the most perfect condition is at Verona; its age has not been accurately determined, some placing it in the age of Augustus, and others in that of Maximian; of these, Maffei thinks the first date too early, and the latter too late. The silence of Pliny upon it, seems to place it after the time of his writing. In the reign of Gallienus, it was not only built, but began to suffer from dilapidation, for many of the stones belonging to it are found in the walls of Verona, which walls were erected in the time of that emperor Many of these were keystones, and the numbers cut upon them still remain. From the silence of authors that it was the work of any of the emperors, it seems probable that, like that at Capua, it was erected at the expense of the citizens. The length is about 514 feet, and the breadth about 410; the long diameter of the arena 242 feet, the short diameter 147 feet. The audience part or *visorium* contained forty-seven tiers of seats, and the building was capable of containing about 22,000 seated spectators. In the profile of the walls of this amphitheatre the diminution in thickness upwards is made on the inside, which is also the case in that at Pola. In the Coliseum the diminution is on the outside. The amphitheatre at Nismes contained about 17,000 persons, and was about 400 feet in length and 320 feet in breadth.

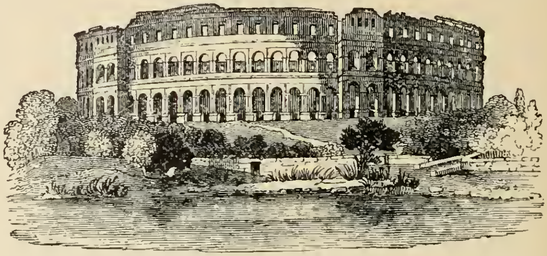

Fig. 1362. Amphitheatre at Pola.

The first amphitheatres, as we learn from Pliny, were constructed of wood, and usually placed in the Campus Martius, or in some place out of the city. Accidents occurring from their insecurity, they were abandoned for the more substantial species of fabric of which we have been speaking. The first person who is said to have erected an amphitheatre in Rome was Caius Scribonius Curio, on the occasion of the games he gave to the people at the funeral obsequies of his father. Determined to surpass all that had hitherto been seen, he constructed two theatres of wood, back to back, which, after the theatrical representations had been finished, were turned round with the spectators in them, leaving the stages and scenery behind. By their opposite junction, they formed a perfect amphitheatre, in which the people were gratified with a show of gladiators.

The part in which the gladiators fought was called the *arena*, from being usually covered with sand to absorb the blood spilt in the conflicts, for which it was used. It was encompassed by a wall called the *podium*, fifteen or sixteen feet high, immediately round which sat the senators and ambassadors. As in the theatres, the seats rose at the back of each other; fourteen rows back from the podium all round being allotted to the equites, and the remainder to the public generally, who sat on the bare stone, cushions being provided for the senators and equites. Though at most times open to the sky, there were contrivances for covering the whole space with an awning. The avenues by which the people entered and retired were many in number, and were called *vomitoria*.

Anamorphosis. (Gr. Ανα, backward, and μορφη form.) A term employed in perspective to denote a drawing executed in such a manner that when viewed in the common way it presents a confused and distorted image of the thing represented, or an image of something entirely different; but when viewed from a particular point, or as reflected by a curved mirror, or through a polyhedron, it recovers its proportions and presents a distinct representation of the object.

Anchor. In decoration, an ornament shaped similarly to an anchor or arrow head. It is used with the egg ornament to decorate or enrich mouldings. By some it is called a tongue, from its supposed resemblance to the forked tongue of a serpent. It is used in all the orders, but only applied to the moulding called the echinus or quarter round.

Ancones. (Gr. Αγκων, the joint of the elbow.) The trusses or consoles sometimes employed in the dressings or antepagmenta of apertures, serving as an apparent support to the cornice of them at the flanks. In ancient doors the ancones were sometimes broader at the top than at the bottom, and were not in contact with the flanks of the architrave, but situated a small distance from them. The term is also used to signify the corners or quoins of walls, cross beams, or rafters.

Andron. (Gr. Ανηρ.) In ancient architecture, the apartment appropriated to the reception of the male branches of the establishment, and always in the lower part of the house; the *gynæcia*, or women's apartments, being in the upper part.

ANGLE. (Lat. Angulus.) The mutual inclination of two lines meeting in a point, called indifferently the angular point, vertex, or point of concourse: the two lines are called legs.

ANGLE BAR. In joinery, the upright bar at the angle of a polygonal window.

ANGLE BEAD, OR STAFF BEAD. A vertical bead, commonly of wood, fixed to an exterior angle and flush with the intended surface of the plaster on both sides, for the purpose of securing the angle against accident, serving also as a guide for floating the plaster. The section of these beads is about three-quarters of a circle, with a projecting part from the other quarter, by means whereof they are made fast to the wood bricks, plugging, or bond timbers. Angle beads of wood round the intradosses of circular arches are difficult to bend without cutting or steaming them. The former has a very unsightly appearance, and the latter method is at once inconvenient and troublesome. The plaster itself is the best material in this case, and at the height generally placed will be out of the reach of accident. In good finishings, corner beads which are unsightly should not be used, but the plaster should be well gauged and brought to an arris.

ANGLE BRACE. In carpentry, a piece of timber fixed to the two extremities of a piece of quadrangular framing, making it partake of the form of an octagon. This piece is also called an *angle tie* and a *diagonal tie*. By the use of this piece wall plates are frequently braced. In constructing a well hole of a circular section through a roof or floor for a skylight, &c. the framing is first made in a quadrangular form; braces are then fixed opposite to each angle, and the aperture becomes of an octagonal form; finally, pieces are fixed at each angle of the octagon, meeting each other in the middle of its sides, so as to transform the section of the aperture into a circle, or oval.

ANGLE BRACKET. A bracket placed in the vertex of an angle, and not at right angles with the sides. See BRACKETING.

ANGLE CAPITAL. In ancient Greek architecture, the Ionic capitals used to the flank columns which have one of their volutes placed at an angle of 135° with the planes of the front and returning frieze. As an example may be cited the angle capitals of the temple of Minerva Polias at Athens. This term is also applied to the modern Ionic capital, in which the whole of the four volutes have an angular direction.

ANGLE CHIMNEY. A chimney placed in the angle of a room.

ANGLE IRON. A plate of iron rolled into an L shape, and used for the purpose of securing two iron plates together by rivets, as Y Y in the beam of the plate girder, *fig.* 1363, and the box-beam, *fig.* 1364.

ANGLE MODILLION. A modillion placed in a direction parallel to a diagonal drawn through a cornice at its mitring. It is an abuse seen only in the buildings erected during the decline of Roman architecture, as in the ruins of Balbec and Palmyra, and in the palace of the Emperor Dioclesian at Spalatro.

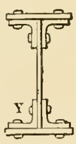

Fig. 1363.

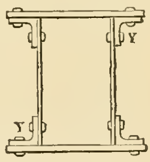

Fig. 1364.

ANGLE OF VISION. In perspective, that angle under which an object or objects are seen, and upon which their apparent magnitudes depend. In practical perspective it should not exceed sixty degrees.

ANGLE OF A WALL. The angle contained by the vertical planes of two walls which form the angle of the building. The term is sometimes used to denote the line in which the two sides of the angle meet, which by workmen is commonly called the *arris*: the arris, however, is not the angle, but the line of concourse formed by the two sides or planes which contain the angle.

ANGLE RAFTER. The piece of timber in a hipped roof placed in the line of concourse of the two inclined planes forming the hip. It is more often called a hip rafter.

ANGLE RIB. A piece of timber of a curved form placed between those two parts of a coved or arched ceiling or vault which form an angle with each other so as to range with the common ribs on each side or return part.

ANGLE STAFF. See ANGLE BEAD.

ANGLE STONES. A term used by some authors to denote *quoins*.

ANGLE TIE. See ANGLE BRACE.

ANGLO-SAXON ARCHITECTURE. Bede mentions one Benedict called Biscop, as the first person who introduced builders of stone edifices and makers of glass into England, A.D. 672. The principal characteristics of the style is a debased imitation of the Roman works, long and short masonry, absence of buttresses, semi-circular and triangular arches, rude balusters, hammer-dressings, and unchiselled sculptures.

ANGULAR CAPITAL. See CAPITAL.

ANNULAR MOULDINGS. Generally those having vertical sides and horizontal circular sections.

ANNULAR VAULT. A vault springing from two walls each circular on the plan; such as that in the temple of Bacchus at Rome.

Annulated Column. Slender shafts clustered together or joined by bands of stone, sometimes of metal, to a central pier or to a jamb. They were much employed in Early English Gothic architecture, and were very often of Purbeck marble.

Annulet. (Lat. Annulus.) A small fillet whose horizontal section is circular. The neck or under side of the Doric capital is decorated with these thin fillets, listels, or bands, whose number varies in different examples. Thus in the Doric of the theatre of Marcellus there are three, whilst in the great temple at Pæstum they are four in number, and in other cases as many as five are used.

Anta, æ plur. (Lat. Anta.) The jambs or square posts supporting the lintels of doors The term antæ we think only applicable to pilasters or pillars attached to a wall, though some authors, as Perrault, have thought otherwise. Vitruvius calls square pilasters when insulated *parastatæ*. There are three kinds of antæ: those of porches or jamb ornaments; angular antæ, being such as show two faces on the walls of a temple; and those on the longitudinal walls of its cell. Antæ are only found in temples as wings to the ends of the walls of the pronaos to give a finish to the terminations the ends of the walls would otherwise present. It might have been this view which led the Greeks to treat them rather as distinct objects than to assimilate their finishings to those of columns. The pilasters in Roman architecture differ only from the column in being square instead of round. A rule in the use of antæ was, that their projection should always be equal to that at least of the mouldings used on them. Some beautiful examples of antæ capitals exist in the temple of Minerva Polias, and the temple of Apollo Didymæus, in Ionia.

Ante-chamber or Ante-room. An apartment through which access is obtained to another chamber or room. One in which servants wait and strangers are detained till the person to be spoken with is at leisure. In the distribution of many houses the peculiarity of the plan forces upon the architect the introduction of ante-rooms: in most cases, indeed, they add both elegance and dignity to a design.

Ante-cour. A French term, sometimes, however, used by English authors. It is the approach to the principal court of a house, and very frequently serves for communication with the kitchen, cellar, stables, &c.

Antefixæ. (Lat. Anti and Figo.) The ornaments of lions' and other heads below the eaves of a temple, through perforations in which, usually at the mouth, the water is cast away from the eaves. By some this term is used to denote the upright ornaments above the eaves in ancient architecture, which concealed the ends of the *harmi* or joint tiles.

Antepagmenta. (Lat.) In ancient architecture, the jambs or moulded architraves of a door. The lintel returning at the ends with similar mouldings down upon the antepagmenta was called *supercilium*.

Antependium. The frontal hangings of the altar.

Anterides. In ancient architecture, buttresses or counterforts for the support of a wall. The Italians call them *speroni* (spurs).

Anthemion. (Gr. Ανθεμιον.) It is considered to mean the honeysuckle, palmetto, or fleuron ornament in the necking of some columns of the Ionic order.

Anticum. (Lat.) A porch to a front door, as distinguished from *posticum*, which is the porch to a door in the rear of a building. It was the space also between the front columns of the portico and the wall of the cella. The word has been sometimes improperly used for *anta*.

Antiquarium. Among the ancients an apartment or cabinet in which they kept their ancient books and vases.

Antique. A term applied to pieces of art worked by the Greeks and Romans of the classical age.

Apartment. (Lat. Partimentum.) A space enclosed by walls and a ceiling, which latter distinguishes it from a court or area.

Aperture. (Lat. Aperio.) An opening through any body. In a wall it has usually three straight sides, two whereof are perpendicular to the horizon, and the third parallel to it, connecting the lower ends of the vertical sides. The materials forming the vertical sides are called *jambs*, and the lower level side is called the *sill*, and the upper part the *head*. This last is either a curved or flat arch. Apertures are made for entrance, light, or ornament. In Greek and Egyptian architecture, but especially in the latter, the jambs incline towards each other. Sometimes apertures are made circular, elliptical, or portions of those figures. "Apertures," says Sir Henry Wotton, "are inlets for air and light; they should be as few in number, and as moderate in dimensions, as may possibly consist with other due respects; for, in a word, all openings are weakenings. They should not approach too near the angles of the walls; for it were indeed a most essential solecism to weaken that part which must strengthen all the rest."

Apiary. (Lat. Apis.) A place for keeping beehives. Sometimes this is a small house with openings for the bees in front, and a door behind, which is kept locked for security. Sometimes it is an area wherein each particular beehive is chained down to a post and padlocked.

Apodyterium. (Ἀποδύσθαι, Gr., to strip oneself.) The apartment at the entrance of the ancient baths, or in the Palæstra, where a person took off his dress, whether for bathing or gymnastic exercises. In the baths of Nero, these apartments were small, but in those of Caracalla the apodyterium was a magnificent room with columns and other decorations.

Apophyge. (Gr., signifying flight.) That part of a column between the upper fillet or annulet on the base and the cylindrical part of the shaft of a column, usually moulded into a hollow or cavetto, out of which the column seems as it were to fly or escape upwards. The French call it *congé*, as it were, leave to go.

Apotheca. (Gr.) A storehouse or cellar in which the ancient Greeks deposited their oil, wine, and the like.

Approach. A curved or graduated road leading to a building situated some distance within the grounds.

Apron, or Pitching Piece. A horizontal piece of timber, in wooden double-flighted stairs, for supporting the carriage pieces or rough strings and joistings in the half spaces or landings. The apron pieces should be firmly wedged into the wall.

Apsis, or Absis. (Gr., signifying an arch.) A term in ecclesiastical architecture, denoting that part of the church wherein the clergy was seated or the altar placed. It was so called from being usually domed or vaulted, and not, as Isidorus imagines, from being the lightest part (apta). The apsis was either circular or polygonal, and domed over; it consisted of two parts, the altar and the presbytery or sanctuary. At the middle of the semi-circle was the throne of the bishop, and at the centre of the diameter was placed the altar, towards the nave, from which it was separated by an open balustrade or railing. On the altar was placed the ciborium and cup. The throne of the bishop having been anciently called by this name, some have thought that thence this part of the edifice derived its name; but the converse is the fact. The *apsis gradata* implied more particularly the bishop's throne being raised by steps above the ordinary stalls. This was sometimes called *exhedra*, and in later times *tribune*.

Aquarium. A case to contain sea or fresh water, in which to preserve living objects of natural history. From a small glass case for a drawing-room, they have increased in size until buildings are erected to contain a number of crystal tanks for the purpose of exhibition—such are those at Brighton, and at the Crystal Palace, in England; and at Hamburgh. London, Liverpool, and other cities are now seeking to establish them. The term is also used for the tanks formed for growing the Victoria Regia and other plants, as at Syon, Kew, Botanic Gardens in the Regent's Park, and elsewhere.

Aqueduct. (Lat. Aquæ ductus.) A conduit or channel for conveying water from one place to another, more particularly applied to structures for the purpose of conveying the water of distant springs across valleys, for the supply of large cities. The largest and most magnificent aqueducts with the existence of which we are acquainted, were constructed by the Romans, and many of their ruins in Italy and other countries of Europe still attest the power and industry of that extraordinary nation. The most ancient was that of Appius Claudius, which was erected in the 442nd year of the city, and conveyed the Aqua Appia to Rome, from a distance of 11,190 Roman paces (a pace being 58·219 English inches), and was carried along the ground, or by subterranean lines, about 11,000 paces, about 190 of which were erected on arches. The next, in order of time, was the Anio Vetus, begun by M. Curius Dentatus, about the year of Rome 481. The water was collected from the springs about Tivoli; it was about 43,000 paces in length. In the 608th year of the city, the works of the Anio Vetus and Aqua Appia had fallen into decay, and much of the water had been fraudulently abstracted by individuals, the prætor Martius was therefore empowered to take measures for increasing the supply. The result of this was the Aqua Martia, the most wholesome water with which Rome was supplied. It was brought from the neighbourhood of Subiaco, twenty miles above Tivoli, and was 61,710 Roman paces (about 61 miles), whereof 7,463 paces were above ground, and the remainder under ground. A length of 463 paces, where it crossed brook and valleys, was supported on arches. To supply this in dry seasons, was conducted into it another stream of equal goodness by an aqueduct 800 paces long. About nineteen years after this was completed, the Aqua Tepula was brought in, supplied also from the Anio; but not more than 2,000 paces in length. In the reign of Augustus, Agrippa collected some more springs into the Aqua Tepula, but the latter water flowing in a separate channel, it preserved its name. This was 15,426 paces long, 7,000 above ground, and the remainder of the length on arcades. To this was given by Agrippa the name of Aqua Julia. In the year 719 of the city, Agrippa restored the dilapidated aqueducts of Appius, of Martius, and of the Anio Vetus, at his own expense, besides erecting fountains in the city. The Aqua Virgo, which receives its name from a girl having pointed out to some soldiers the sources of the stream from which it was collected, was brought to Rome by an aqueduct 14,105 paces in length, 12,865 of which were under ground, and 700 on arches, the remainder being above ground. The Aqua Alsietina, called also Augusta, was 22,172 paces from its source to the city, and 358 paces of it were on arcades. The seven aqueducts above mentioned being found, in the time of Caligula, unequal to the supply of the city, this emperor, in the second year of his reign, began two others, which were finished by Claudius, and opened in the year of the city 803. The first was called Aqua Claudia, and the second Anio Novus, to distinguish it from one heretofore mentioned. The first was 46,406 Roman paces, of which 10,176 were on arcades, and the rest subterranean. The Anio Novus was 58,700 paces in length, 9,400 whereof were above ground, 6,491 on arches, and the rest subterranean. Some of the arches of these are 100 Roman feet high. All the aqueducts we have mentioned were on different levels, and distributed accordingly to those parts of the city which suited their respective elevations. The following is the order of their heights, the highest being the Anio Novus, 159 feet above level of Tiber; Aqua Claudia, 149 feet; Aqua Julia, 129 feet; Aqua Tepula, Aqua Martia, 125 feet; Anio Vetus, Aqua Virgo, 34 feet; Aqua Appia, 27 feet; and the Aqua Alsietina on the lowest level. The Tiber at Rome being 91·5 feet above the level of the Mediterranean, the mean fall of these aqueducts has been ascertained to be about 0·132 English inches for each Roman pace (58·219 English inches), or 1 in 441. Vitruvius directs a fall of 1 in 200, but Scamozzi says the practice of the Romans was 1 in 500. The quantity of water furnished by six of the aqueducts, as given by Frontinus from a measurement at the head of each aqueduct, is as follows:—

*Anio Vetus	4,398 quin.	Aqua Virgo	2,524 quin.	Aqua Claudia	4,607 quin.
†Aqua Martia	4,690 „	Aqua Julia	1,368 „	*Anio Novus	4,738 „

The whole supply is given as 14,018 quinariæ, after much fraudulent diversion of the water by individuals; but the diminished quantity is supposed to have been 27,743,100 English cubic feet, or, estimating the population of Rome at one million of inhabitants, 27·74 cubic feet per diem for each inhabitant, or about 170 gallons English. * These were used for the street and sewer flushings, the baths, and scenic representations. † This was used for drinking purposes, and is still so used.

Parker, *Aqueducts of Rome*, says 24,805 quin. was the exact quantity of water daily poured into Rome in Trajan's time, equal to a stream 20 feet wide by 6 feet deep constantly running in, at a fall six times as rapid as that of the river Thames. He calculated that when the Trajan and the Aurelian aqueducts were finished, the daily supply was quite 332¼ millions of gallons, or at least 332 gallons per head.

There are remains of Roman aqueducts in other parts of Europe even more magnificent than those we have mentioned. One, or the ruins of one, still exists at Metz, and another at Segovia in Spain, with two rows of arcades, one above the other. This last is about 100 feet high, and passes over the greater part of the houses of the city. The Romans do not appear to have been aware of the fact of water rising at a distance to its level at the fountain head.

Arabesque. The term is commonly used to denote that sort of ornament in Saracenic architecture consisting of intricate rectilinear and curvilinear compartments and mosaics which adorn the walls, pavements, and ceilings of Arabian and Saracenic buildings. It is capricious, fantastic, and imaginative, consisting of fruits, flowers, and other objects, to the exclusion in pure arabesques of the figures of animals, which the religion forbade. This sort of ornament, however, did not originate with the Arabians; it was understood and practised by the ancients at a very early period. Foliage and griffins, with ornaments not very dissimilar to those of the Arabians, were frequently employed on the friezes of temples, and on many of the ancient Greek vases, on the walls of the baths of Titus, at Pompeii, and at many other places. To Raffaele, in more modern times, we are indebted for the most elaborate and beautiful examples of a style of decoration called Arabesque, which he even dignified, and left nothing to be desired in it. Since the time of that master it has been practised with varying and inferior degrees of merit, especially by the French in the time of Louis XVI. Arabesques lose their character when applied to large objects, neither should they be employed where gravity in the style is to be preserved.

Arabian Architecture. See Saracenic Architecture.

Arabo-Tedesco. A term used chiefly by the Italians. An example of this style may be quoted in the baptistery at Pisa (*fig.* 152), erected by Dioti Salvi in 1152. It is a circular edifice, with an arcade in the second order composed of columns with Corinthian capitals and plain round arches. Between each arch rises a Gothic pinnacle, and above it is finished by sharp pediments enriched with foliage, terminating in a trefoil.

Aræostyle. (Gr. Αραιος, wide, and στυλος, a column.) One of the five proportions used by the ancients for regulating the intercolumniations or intervals between the columns in porticoes and colonnades. Vitruvius does not determine precisely its measure in terms of the diameter of the column. His commentators have tried to supply the deficiency; and, following the progression observable in the intercolumniations he does describe, each of which increases by a semidiameter, the aræostyle would be three diameters and a half. Perrault, in his translation of Vitruvius, proposes that the interval be made equal to four diameters, which is the interval now usually assigned to it. It is only, or rather ought only to be, used with the Tuscan order.

Aræosystyle. (Gr. Αραιος, wide, συν, with, στυλος, a column.) A term used by the French architects to denote the method of proportioning the intervals between columns coupled or ranged in pairs, as invented by Perrault, and introduced in the principal façade of the Louvre. It was also adopted by Sir Christopher Wren in the west front of St. Paul's.

Arc. In geometry, a portion of a circle or other curve line. The arc of a circle is the measure of the angle formed by two straight lines drawn from its extremities to the centre of the circle.

Arc-boutant. (Fr.) An arch-formed buttress, much employed in sacred edifices built in the Pointed style, as also in other edifices, and commonly called a *flying buttress*, whose object is to counteract the thrust of the main vault of the edifice; it is also called *arched buttress* and *arched butment*. It was used in the Baths of Diocletian.

Arc Doubleau. (Fr.) An arch forming a projection before the sofite of a main arch or vault, in the same manner as a pilaster breaks before the face of a wall.

Arcade. (Fr.) A series of apertures or recesses with arched ceilings or sofites. But the word is often vaguely and indefinitely used. Some so designate a single-arched aperture or enclosure, which is more properly a *vault*; others use it for the space covered by a continued vault or arch supported on piers or columns; and, besides these, other false meanings are given to it instead of that which we have assigned. Behind the arcade is generally a walk or ambulatory, as in Covent Garden, where the term piazza is ignorantly applied to the walks under the arcade instead of to the whole *place* (Ital. *piazza*) or square.

The piers of arcades may be decorated with columns, pilasters, niches, and apertures of different forms. The arches themselves are sometimes turned with rock-worked, and at other times with plain rustic, arch stones or voussoirs, or with a moulded archivolt, springing from an impost or platband; and sometimes, though a practice not to be recommended, from columns. The keystones are generally curved in the form of a console, or sculptured with some device. Scamozzi made the size of his piers less, and varied his imposts or archivolts, in proportion to the delicacy of the orders he employed; but Vignola made his piers always of the same proportion.

Arcade. In mediæval architecture, an ornamental dressing to a wall, consisting of colonnettes supporting moulded arches. Sometimes they stand sufficiently forward to admit of a passage behind them.

Arcæ. In ancient Roman architecture, the gutters of the cavedium; *arca* signifying a beam of wood with a groove or channel in it.

Arcella. (Lat.) In mediæval architecture, a cheese room.

Arch. A mechanical arrangement of blocks of any hard material disposed in the line of some curve, and supporting one another by their mutual pressure. The arch itself is formed of *voussoirs* or arch stones cut in the shape of a truncated wedge, the uppermost whereof is called the *keystone*. The seams or planes, in which two adjacent voussoirs are united, are called the *joints*. The solid extremities on or against which the arch rests are called the *abutments*. The lower or under line of each arch-stone is called the *intrados*, and the superior or upper line the *extrados*. The distance between the piers or abutments is the *span* of the arch, and that from the level line of the springing to the intrados its *height*, or versed sine. The forms of arches employed in the different styles and periods of architecture will be found described under the several heads.

Architect. (Gr. Αρχος and τεκτων, chief of the works.) A person competent to design and superintend the execution of any building. The knowledge he ought to possess forms the subject of this work; whatever more he may acquire will be for the advantage of his employers; and when we say that the whole of the elements which this work contains should be well known and understood by him, we mean it as a *minimum* of his qualifications. To this we may add, that with the possessions indicated, devotedness, faithfulness, and integrity towards his employer, with kindness and urbanity to those whose lot it is to execute his projects, not however without resolution to check the dishonesty of a builder, should he meet with such, will tend to insure a brilliant and happy career in his profession.

Architecture. The art of building according to certain proportions and rules determined and regulated by nature and taste.

Architrave. (Gr. Αρχειν to govern, and Lat. Trabs, a beam.) The lower of the three principal members of the entablature of an Order, being, as its name imports, the chief beam employed in it, and resting immediately on the columns. It is called in Grecian architecture, *Epistylium*, from επι, upon, and στυλος, a column. The height of the architrave varied in the different Orders, as also in different examples of the same Order.

Architrave Cornice. An entablature consisting of an architrave and cornice only, without the interposition of a frieze. It is never used with columns or pilasters, unless through want of height. It is, however, allowable.

Architrave of a Door or Window. A collection of members and mouldings round either, used for the decoration of the aperture. The upper part, or lintel, is called the *traverse*, and the sides the *jambs*. See Antepagmenta.

Archivolt. (Lat. Arcus volutus.) The ornamental band of mouldings round the voussoirs, or arch-stones of an arch, which terminates horizontally upon the impost. It is decorated, as to the members, analogously with the architrave, which, in arcades, it may be said to represent. It differs in the different Orders.

Archivoltum. In mediæval architecture, an arched receptacle for filth. A cesspool or common sewer.

Arch Mouldings. The series of mouldings forming the decoration of an arch as used in mediæval architecture. The illustration of the Early English period, is from St. Mary's Church, Lincoln.

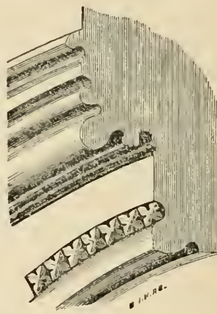

Fig. 1365.

Archway. An aperture in a building covered with a vault. Usually an arched passage or gate wide enough for carriages to pass.

Arcus Ecclesiæ. In mediæval architecture, the arch dividing the nave of the church from the choir or chancel.

Arcus Presbyterii. In mediæval architecture, the arch over the tribune marking the boundaries of its recess.

Arcus Toralis. In mediæval architecture, the lattice separating the choir from the nave in a basilica.

Area. In Architecture, a small court or place, often sunk below the general surface of the ground, before windows in the basement story. It is also used to denote a small court or yard, even when level with the ground.

Area. In Geometry, the superficial content of any figure. The "area" of every building shall be deemed to be the superficies of a horizontal section of such building made at the point of its greater surface, including the external walls and such portion of the party walls as belong to the building, but excluding any attached building the height of which does not exceed the height of the ground story. Metropolitan Building Act, 1855.

Arena. The central space in a Roman amphitheatre, wherein the gladiators fought.

Armoury. An apartment destined for the reception of instruments of war.

Aronade. Embattled; a junction of several lines forming indentations like the upward boundary of an embattled wall, except that the middle of every raised part is terminated by a convex arch, which arch does not extend to the length of that part.

Arrière Voussure. A secondary arch. An arch placed within an opening to form a larger one, and sometimes serving as a sort of discharging arch.

Arris (probably abbreviated from the Ital. *a risega*, at the projection, or from the Sax. apipan, to rise). The intersection or line on which two surfaces of a body forming an exterior angle meet each other. It is a term much used by all workmen concerned in building, as the arris of a stone, of a piece of wood, or any other body. Though, in common language, the edge of a body implies the same as arris, yet, in building, the word *edge* is restrained to those two surfaces of a rectangular parallelopipedal body on which the length and thickness may be measured, as in boards, planks, doors, shutters, and other framed joinery.

Arris Fillet. A slight piece of timber of a triangular section, used in raising the slates against chimney shafts, or against a wall that cuts obliquely across the roof, and in forming gutters at the upper ends and sides of those kinds of skylights of which the planes coincide with those of the roof. When the arris fillet is used to raise the slates, at the eaves of a building, it is then called the *eaves' board*, *eaves' lath*, or *eaves catch*.

Arris Gutter. A wooden gutter of this V form fixed to the eaves of a building.

Arsenal. A public establishment for the deposition of arms and warlike stores.

Artificer. (Lat. Ars and Facio.) A person who works with his hands in the manufacture of anything. He is a person of intellectual acquirements, independent of mere operation by hand, which place him above the *artisan*, whose knowledge is limited to the general rules of his trade.

Artificial Stone. A material produced by the use of cement and other substances, such as Austin's artificial stone, which is not burnt.

Asarotum. In ancient architecture, a species of painted pavement used by the Romans before the invention of Mosaic work.

Ashlar or Ashler. (Ital. Asciare, to chip.) Common or free-stones as brought from the quarry of different lengths and thicknesses.

Also the facing given to squared stones on the front of a building. When the work is smoothed or rubbed so as to take out the marks of the tools by which the stones were cut, it is called *plain ashlar*. *Tooled ashlar* is understood to be that of which the surface is wrought in a regular manner, like parallel flutes, and placed perpendicularly in the building. But when the surfaces of the stones are cut with a broad tool without care or regularity, the work is said to be *random-tooled*. When wrought with a narrow tool, it is said to be *chiselled* or *boasted*, and when the surface is cut with a very narrow tool, the ashlar is said to be *pointed*. When the stones project from the joints, the ashlar is said to be *rusticked*, in which the faces may have a smooth or broken surface. In superior work, neither pointed, chiselled, nor random-tooled work are employed. In some parts of the country herring-bone ashlar and herring-bone random-tooled ashlar are used.

Ashlaring. In carpentry, the short upright quartering fixed in garrets about two feet six inches or three feet high from the floor, being between the rafters and the floor, in order to cut off the acute angle formed by the rafters. The upright quarterings seen in some open timber roofs between the inner wall plate and the rafters, is also so called.

Aspect. (Lat. Aspicio.) The quarter of the heavens which the front of a building faces. Thus a front to the north is said to have a north aspect.

Asphalte. A bituminous substance found in various places. When used for floors or roadways, it is either poured on in a liquid state, forming when set a hard substance, impervious to damp; or it is placed on the ground in powder, in a hot state, and pressed down by hot iron rammers.

Assemblage. The joining or uniting several pieces together, or the union of them when so joined. Carpenters and joiners have many modes of accomplishing this, as by framing, mortise and tenon, dovetailing, &c.

Assemblage of the Orders. The placing of columns upon one another in the several ranges.

Assyrian Architecture. Little more is known of the buildings of Assyria and Babylonia than the thick walls forming halls and chambers lined with carvings, and having carved stone pavements. The roofing is supposed to have been formed with wood pillars supporting the framework of the roof, the spaces between the pillars allowing the entry of light and of fresh air.

Astragal. (Gr. Αστραγαλος, a die or huckle bone.) A small moulding of a semicircular profile. Some have said that the French call it *talon*, and the Italians *tondino*; but this a mistake, for the term is properly applied only to the ring separating the capital from the column. The astragal is occasionally cut into representations of beads and berries. A similar sort of moulding, though not developed in its profile as is the astragal, is used to separate the faces of the architrave.

Astylar. A design made without the introduction of columns or pilasters is termed an astylar composition.

Atkinson's Cement. A quick-setting cement similar to Parker's or Roman cement, formerly obtained from nodules found near Whitby in Yorkshire.

Atlantes or Atlantides. Figures of males used instead of columns for the support of an entablature. In some modern works figures resembling *Persians* have been introduced, and hence that name has been applied to them. Caryatides.

Atrium. In ancient Roman architecture, a court surrounded by porticoes in the interior part of Roman houses. According to Scaliger it is derived from the Greek *αἴθριος* exposed to the air. By some it has been considered the same apartment as the *vestibule*, and Aulus Gellius intimates that in his time the two words were confounded.

Attic, or Attic Order. It is employed to decorate the façade of a story of small height, terminating the upper part of a building; and it doubtless derives its name from its resemblance in proportional height and concealed roof to some of the buildings of Greece. Pliny thus describes it after speaking of the other orders: "Præter has sunt quæ vocantur Atticæ columnæ quaternis angulis pari laterum intervallo." We, however, find no examples of square pillars in the remains of ancient art, though almost all the triumphal arches exhibit specimens of pilastral attics, having no capitals save the cornice breaking round them. In modern architecture the proportions of the attic order have never been subject to fixed rules, and their good effect is entirely dependent on the taste and feeling of the architect. The attic is usually decorated with antæ or small pilasters.

Attic Base. The base of a column consisting of an upper and lower torus, a scotia and fillets between them. It is thus described by Vitruvius, "It must be so subdivided that the upper part be one-third of the thickness of the column, and that the remainder be assigned for the height of the plinth. Excluding the plinth, divide the height into four parts, one of which is to be given to the upper torus; then divide the remaining three parts into two equal parts; one will be the height of the lower torus, and the other the height of the scotia with its fillets. See figure s. v. BASE OF A COLUMN.

ATTIC STORY. A term frequently applied to the upper story of a house when the ceiling is square with the sides, to distinguish it from garrets.

ATTRIBUTES, in decorative architecture, are certain symbols given to figures, or disposed as ornaments on a building, to indicate a distinguishing character; as a lyre, bow, or arrow to Apollo; a club to Hercules; a trident to Neptune; a spear to Pallas, &c. For attributes given to Saints and others in mediæval architecture, see SYMBOLS.

AUGER. A carpenter's and joiner's tool for boring large holes. It consists of a wooden handle terminated at the bottom with steel. The more modern augers are pointed and sharpened like a centre-bit, the extremity of one of the edges being made to cut the wood clean at the circumference, and the other to cut and take away the core, the whole length of the radius.

AULA. (Lat.) In ancient Roman architecture, a court or hall.

AUMBRYE. A recess in the wall of the chancel for the preservation of the sacred vessels.

AVIARY. (Lat. Avis.) A house or apartment, set apart for keeping and breeding birds.

AWNING. (Fr. Aulne.) Any covering intended as a screen from the sun, or protection from the rain.

AXE. (Sax. Eax.) A tool with a long wooden handle and a cutting edge situate in a plane passing longitudinally through the handle. It is used for hewing timber by cutting it vertically, the edge being employed in forming horizontal surfaces. The axe differs from the *joiner's hatchet* by being much larger, and by its being used with only one hand. Axes of various sizes, depending upon the quality of the material, are used by stone-cutters and bricklayers. The *adze* is used to horizontal surfaces.

AXIS. The spindle or centre of any rotative motion. In a sphere a line passing through the centre is the axis.

B

BABYLONIAN ARCHITECTURE. See ASSYRIAN ARCHITECTURE.

BACK. The side opposite to the face or breast of any piece of architecture. In a recess upon a quadrangular plane, the face is that surface which has the two adjacent planes, called the sides, elbows, or gables. When a piece of timber is fixed in a horizontal or in an inclined position, the upper side is called the back, and the lower the breast. Thus the upper side of the handrail of a staircase is properly called the back. The same is to be understood with regard to the curved ribs of ceilings and the rafters of a roof, whose upper edges are always called the *backs*.

BACK OF A CHIMNEY. The recessed face of it towards the apartment, &c. See CHIMNEY.

BACK OF A HAND-RAIL. The upper side of it.

BACK OF A HIP or other RAFTER. The upper side or sides of it in the sloping plane of the side of the roof.

BACK FILLET. The return to the face of the wall, of the margin of a projecting quoin; as in a plain architrave to an opening.

BACK LINING OF A SASH FRAME. That parallel to the pulley piece and next to the jamb on either side.

BACK PUTTYING. The cleaning off of the putty in the rebate of a sash bar on the inside after the glass has been put in, and the outer putty left a while to harden.

BACK SHUTTERS. Those folds of a shutter which do not appear on the face being folded within the boxing.

BACK OF A STONE. The side opposite to the face. It is generally rough.

BACK OF A WALL. The inner face of it.

BACK OF A WINDOW. The piece of wooden framing in the space between the lower part of the sash frame and the floor of the apartments, and bounded at its extremities right and left by the *elbows* of the window. The number of panels into which it is framed is dependent on what may be necessary for carrying out the design; it rarely, however, consists of more than one.

BACKING OF A RAFTER or RIB. The formation of the upper or outer surface of either in such a manner as to range with the edges of the rafters or ribs on either side of it. The formation of the inner edges of the ribs for a lath and plaster ceiling is sometimes called *backing*, but improperly, since contrary to the true meaning of the word.

BACKING OF A WALL. The filling in and building which forms the inner face of the work. In this sense it is opposed to facing, which is the outside of the wall. In stone walls the backing is unfortunately too often mere rubble, while the face is ashlar.

BADIGEON. A mixture of plaster and freestone sifted and ground together, used by statuaries to repair defects in their work. The joiner applies this term to a mixture of sawdust and strong glue, with which he fills up the defects of the wood after it has been wrought. A mixture for the same purpose is made of whiting and glue, and sometimes with putty and chalk. When the first of these is used it is allowed to remain until quite hard, after which it may be submitted to the operation of planing and smoothing. Without this precaution it may shrink below the surface of the work.

BAGNIO. (It.) An Italian term for a bath, usually applied by the English to an establishment having conveniences for bathing, sweating, and otherwise cleansing the body: and now called a Turkish bath. The term is applied by the Turks to the prisons where their slaves are confined, in which it is customary to have baths.

BAGUETTE. (Fr.) A small moulding of the astragal species. It is occasionally cut with pearls, ribands, laurels, &c. According to M. Le Clerc, the baguette is called a *chaplet* when ornaments are cut on it.

BAILEY. See CASTLE.

BAKEHOUSE. An apartment provided with kneading troughs and an oven for baking.

BALANEIA. A Greek term for a bath.

BALCONY. (It. Balcone.) A projection from the external wall of a house, borne by columns or consoles, and usually placed before windows or openings, and protected on the extremity of the projection by a railing of balusters or ironwork. In the French theatre, the *balcon* is a circular row of seats projecting beyond the tier of boxes immediately above the pit.

BALDACHINO. (It.) A canopy supported by columns, generally placed over an altar in Roman Catholic places of worship. Sometimes the baldachino is suspended from the roof, as in the church of St. Sulpice at Paris. It succeeded to the ancient CIBORIUM, which was a cupola supported on four columns, still to be seen in many of the churches of Rome. The merit of its invention seems to belong to Bernini. That erected by him in St. Peter's is 128 feet high, and being of bronze weighs near 90 tons. It was built by order of the Pope Barberini, from the robbery of the Pantheon, and occasioned the bitter observation, "Quod non fecerint Barbari fecerunt Barberini." The decision of the Arches Court against issuing a faculty for the erection of a baldachino in St. Barnabas Church, Pimlico, is given in the journals of the early part of 1874.

BALECTION or BOLECTION MOULDINGS. Mouldings which project beyond the surface of a piece of framing.

BALISTRARIA. An opening, sometimes in the form of a cross, in the wall of a Gothic castle or turret, through which archers could discharge their missiles without being perceived. They were usually in the form of a cross, the vertical slit or opening being made longer than the horizontal one which crossed it in the middle. Sometimes the ends were formed circular instead of square.

BALKS or BAULKS. (Dutch.) Pieces of whole fir, being the trunks of small trees of that species, rough-squared for building purposes. In the metropolis the term is applied to short lengths, from eighteen to twenty-five feet, mostly under ten inches square, tapering considerably, and with the angles so left that the piece is not exactly square.

BALL FLOWER. An ornament resembling a ball inclosed in a flower of a circular shape, the three petals of which form a cup round it. It is usually placed in a hollow moulding, and is considered one of the chief characteristics of the Decorated period of Gothic architecture.

Fig. 1366.

BALLIUM. In the architecture of the middle ages, the open space or court of a fortified castle. This has acquired in English the appellation Bailey; thus St. Peter's in the Bailey at Oxford, and the Old Bailey in London, are so named from their ancient connection with the sites of castles.

BALLOON. A round ball or globe placed on a column or pier, by way of crowning it. The same name is given to the balls on the tops of cathedrals, as at St. Peter's, which is 8 feet in diameter, and at St. Paul's in London.

BALTEUS. (Lat. a girdle.) The wide step in theatres and amphitheatres, which afforded a passage round them without disturbance to the sitters. No one sat on it; it served merely as a landing-place. In the Greek and Roman theatres, every eighth step was a balteus. Vitruvius gives the rules in the third chapter of his fifth book, for properly setting it out.

The term *balteus* is also used by Vitruvius to denote the strap which seems to bind up the coussinet, cushion, or pillow of the Ionic capital.

BALUSTER. A species of small column belonging to a balustrade. See COLUMELLÆ. This term is also used to denote the lateral part of the volute of the Ionic capital. Vitruvius calls it *pulvinata*, on account of its resemblance to a pillow.

Baluster Shaft. A small shaft or pillar in the shape of a baluster dividing an opening, seen in the window of belfries in the Romanesque towers in England. They have generally an elliptical or pear-shaped entasis or swelling in the lower half. The illustration is from Wykham Church, Derbyshire.

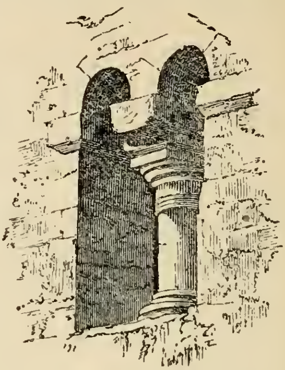

Fig. 1367. Wykham Church, Derbyshire.

Balustrade. A parapet or protecting fence formed of balusters, sometimes employed for real use, and sometimes merely for ornament.

Band. (Fr. Bande.) A flat member or moulding, smaller than a fascia. The face of a band is in a vertical plane, as is also that of the fascia; the word, however, is applied to narrow members somewhat wider than fillets; and the word *fascia* to broader members. The cinctures sometimes used round the shafts of rusticked columns are called bands. In this case the column is called a *banded column*.

Bandages. A term applied to the rings or chains of iron inserted in the corners of a stone wall, or round the circumference of a tower, at the springing of a dome, &c., which act as a tie on the walls to keep them together.

Bandelet, or Bandlet. A small band encompassing a column like a ring.

Banding Plane. A plane intended for cutting out grooves and inlaying strings and bands in straight and circular work.

Banister. A vulgar term for baluster, which see.

Banker. A bench, on which masons prepare, cut, and square their work.

Banquet. (Fr.) The footway of a bridge when raised above the carriage-way.

Baptistery. (Gr. βαπτίζω.) A detached building, or a portion of a church, destined for administration of the rite of baptism. It has been contended by some that the baptistery was at first placed in the interior vestibules of the early churches, as are in many churches the baptismal fonts. This, however, was not the case. The baptistery was quite separate from the basilica, and even placed at some distance from it. Until the end of the sixth century, it was, beyond doubt, a distinct building; but after that period the font gradually found its way into the vestibule of the church, and the practice became general, except in a few churches, as at Florence, Ravenna, of S. Giovanni Laterano at Rome, and in those of all the episcopal cities of Tuscany, and some few other places. The Roman example is perhaps the most ancient remaining. There was a baptistery at Constantinople, of such dimensions that, on one occasion, it held a very numerous council. That at Florence is nearly ninety feet in diameter, octagonal, and covered with a dome. It is enclosed by the celebrated bronze doors by Lorenzo Ghiberti, which Michel Angelo said were fit to be the gates of Paradise. The baptistery of Pisa, designed by Dioti Salvi, was finished about 1160. The plan is octagonal, about 129 feet in diameter and 179 feet high.

Bar. In a court of justice, an enclosure, three or four feet high, in which the counsel have their places to plead causes. The same name is given to the enclosure, or rather bar before it, at which prisoners are placed to take their trials for criminal offences.

Bar. A piece of wood or iron used for fastening doors, window shutters, &c.

Bar or Barred door. The term used in Scotland for a *ledged* door.

Bar of a Sash. The light pieces of wood or metal which divide a window sash into compartments for the glass. The *angle bars* of a sash are those standing at the intersection of two vertical planes.

Bar Iron. Iron made of the cast metal after it comes from the furnace. The sows and pigs, as the shapes of the metal are technically termed, pass through the forges and chaufery, where, having undergone five successive heats, they are formed into bars.

Bar-posts. Posts driven into the ground for forming the sides of a field gate. They are mortised, to admit of horizontal bars being put in or taken out at pleasure.

Bar-tracery. A name given to the completely developed form of Gothic tracery, from its fancied resemblance to bars of iron wrought and bent into the various forms exhibited.

Barbacan. A watch-tower for descrying an enemy; also the outer work or defence of a castle, or the fort at the entrance of a bridge. Apertures in the walls of a fortress, for firing through upon the enemy, are sometimes called by this name. The etymology of the word has been variously assigned to French, Italian, Spanish, Saxon, and Arabian origin. See Castle.

Barge Boards. The inclined projecting boards placed at the gable of a building, and hiding the horizontal timbers of a roof. They are frequently carved with trefoils, quatrefoils, flowers, and other ornaments and foliage.

Barge Couples. (Sax. Bẏꞃᵹan. to bar.) Two beams mortised and tenoned together for the purpose of increasing the strength of a building.

Barge Course. The part of the tiling which projects over the gable of a building, and which is made good below with mortar.

Barn. (Sax. Beꞃn.) A covered farm-building for laying up grain, hay, straw, &c. The situation of a barn should be dry and elevated. It is usually placed on the north or north-east side of a farm-yard. The barns, outhouses, and stables should not be far distant from each other. They are most frequently constructed with wooden framing of quarters, &c., and covered with weather boarding; sometimes, in superior farms, they are built of stone and brick. The roofs are usually thatched or tiled, as the materials for the purpose are at hand; but as the grain should of all things be kept dry, to prevent it from moulding, the gable ends should be constructed of brick, and apertures left in the walls for the free admission of air. The bays, as they are called, are formed by two pairs of folding doors, exactly opposite to each other, and, as well as for thrashing, afford the convenience of carrying in and out a cart or waggon load of corn in sheaves, or any sort of bulky produce. The doors in question must be of the same breadth as the threshing-floor, to afford light to the threshers, and air for winnowing the grain. It is a good practice to make an extensive penthouse over the great doors sufficiently large to cover a load of corn or hay, in case of the weather not permitting it to be immediately housed.

Barrack. A building erected for the housing of soldiers.

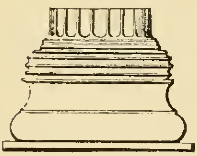
Ba'rrack-room. A name given to a long room in some houses in the country, and intended for the sleeping place of a number of men who may have to stay a night or two, the house not affording a room for each.

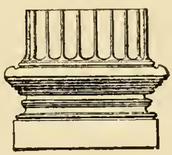
Barrel Drain. One in the form of a hollow cylinder.

Barrel Vault. A cylindrical vault, presenting a uniform concave surface not groined or ribbed.

Barrow. In Celtic antiquities a sepulchral mound, and called by different names according to the shape of it.

Bartisan. A turret on the summit of a tower, castle, or house, whereon was generally hoisted the standard or flag proper to the place.





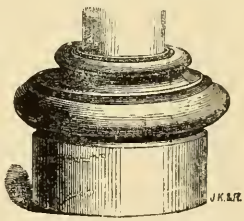


Fig. 1368. Temple on the Ilyssus. Fig. 1369. Temple at Priene. Fig. 1370. Early English Period.

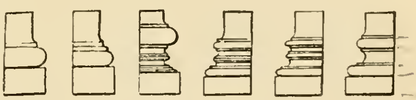
Barycæ or Barycephalæ. (Gr. Βαρυς. low or flat, and κεφαλη, head.) The Greek name for an aræostyle temple.

Base. (Gr. Βασις.) In geometry, the lower part of a figure or body. The *base of a solid* is the surface on which it rests.

Base of a Column. The part between the shaft and the pavement or pedestal, if there be any to the order. Each column of the Romans has its particular base, for which see Fig. 1371. For the Attic base, see also under that word. The Grecian Doric order did not have a base, the shaft standing on the pavement. Two examples of Greek Ionic bases are given in Figs. 1368 and 1369. Bases are also used to the shafts in mediæval architecture, of which Fig. 1370 illustrates an example.



Tuscan, Doric, Ionic, Corinthian, Composite, Attic, Fig. 1371. Roman bases.

Base of a Room. The lower projecting part. It consists of two parts, the lower of which is a plain board adjoining the floor, called the plinth, and the upper of one or more mouldings, which, taken collectively, are called the base-mouldings. In better sort of work the plinth is tongued into a groove in the floor, by which means the diminution of breadth created by the shrinking never causes any aperture or chasm between its under edge and the floor, and the upper edge of the plinth is rebated upon the base. Bedrooms, lobbies, passages, and staircases are often finished without a dado and surbase, and indeed the fashion has extended the practice to rooms of the higher class, as drawing-rooms, &c.

Basement. The lowest story of a building, whether above or below the ground.

Basil. Among carpenters and joiners the angle to which the edge of an iron tool is ground so as to bring it to a cutting edge. If the angle be very thin the tool will cut more freely, but the more obtuse it is the stronger and fitter it is for service.

Basilica. (Gr. Βασιλευς, a king.) Properly the palace of a king; but it afterwards came to signify an apartment usually provided in the houses of persons of importance, where assemblies were held for dispensing justice. Thus in the magnificent villa of the Gordian family on the Via Prenestina there were three basilicæ, each more than one hundred feet long. A basilica was generally attached to every forum, for the summary adjustment of the disputes that arose. It was surrounded in most cases with shops and other conveniences for traders. The difference between the Grecian and Roman basilica is given by Vitruvius in the fifth chapter of his first book.

The term basilica is also applied by Palladio to those buildings in the cities of Italy similar in use to our town halls.

Basis. See Base.

Basket. A term often applied to the vase of the Corinthian capital, with its foliage, &c.

Basket-handle Arch. (Fr. Anse de panier.) An arch whose vertical height is less than half its horizontal diameter, such as an elliptic arch.

Bass. A trough containing mortar, used in tiling, &c.

Basse Cour. (Fr.) A court destined in a house of importance for the stables, coach-houses, and servants attached to that part of the establishment. In country houses it is often used to denote the yard appropriated to the cattle, fowls, &c.

Basso-relievo. See Relievo.

Bastard Stucco or Trowelled Stucco. Fine stuff mixed with sand to form a surface in plastering to receive paint.

Bat. In bricklayer's work, a piece of a brick less than one half of its length.

Batardeau. (Fr.) The same as Coffer Dam.

Batement Light. A window having upright sides, but the bottom of which is not level.

Bath. (From the Saxon, Baδ,) An apartment or series of apartments for bathing. Among the ancients the public baths were of amazing extent and magnificence, and contained a vast number of apartments. These extraordinary monuments of Roman magnificence seem to have had their origin in many respects from the gymnasia of the Greeks, both being instituted for the exercise and health of the public. The word *thermæ* (hot baths) was by the Romans used to denominate the establishment, although it contained in the same building both hot and cold baths. In later times a house was incomplete unless provided with hot and cold baths; and, indeed, it was not till the time of Augustus that public baths assumed the grandeur which their remains indicate. Different authors reckon nearly eight hundred baths in Rome, of which the most celebrated were those of Agrippa, Antoninus, Caracalla, Diocletian, Domitian, Nero, and Titus. It appears from good authority, that the baths of Diocletian could accommodate no less than eight hundred bathers. These stupendous edifices are indicative of the magnificence, no less than the luxury, of the age in which they were erected. The pavements were mosaic, the ceilings vaulted and richly decorated, and the walls encrusted with the rarest marbles. From these edifices many of the most valuable examples of Greek sculpture have been restored to the world; and it was from their recesses that the restorers of the art drew their knowledge, and that Rafaelle learnt to decorate the walls of the Vatican. See p. 96.

Batten. (Probably from the Fr. Bâton, from its small width.) A scantling or piece of stuff from two to six inches broad, and from five-eighths of an inch to two inches thick. Battens are used in the boarding of floors and also upon walls, in order to receive the laths upon which the plaster is laid. See Boarded Floor.

Battening. The fixing of battens to walls for the reception of the laths on which the plaster is to be laid. It also signifies the battens in the state of being fixed for that purpose. The battens employed are usually about two inches broad and three-fourths of an inch thick; the thicknesses, however, may be varied according to the distances that the several fixed points are from each other. Their distance in the clear is from eleven inches to one foot. To fix the battens, equidistant bond timbers were formerly built in the wall: the wall is now plugged at equal distances, and the plugs cut off flush with its surface, or the battens are spiked into the wall. The plugs are generally placed twelve or fourteen inches from centre to centre in the length of the batten. Battens upon external walls, the ceiling and bridging joists of a naked floor, also the common joists for supporting the boarding of a floor, are fixed at the same distance, viz. from eleven to twelve inches in the clear. When battens are fixed against flues, iron holdfasts are of course employed instead of bond-timbers or plugs. When they are attached to a wall they are generally fixed in vertical lines, and when fixed to the surface of a stone or brick vault, whose intrados is generated by a plane revolving about an axis, they ought to be placed in planes tending to the axis; as in this position they have only to be fixed in straight lines, in case the intrados is straight towards the axis, which will be the case when it is a portion of a cone or cylinder; and when the intrados is curved towards the axis they will bend the easiest possible. Great care should be taken to regulate the fans of the battens, so as to be as nearly as possible equidistant from the intended surface of the plaster. Every piece of masonry or brickwork, if not thoroughly dry, should be battened for lath and plaster, particularly if executed in a wet season. When windows are boarded, and the walls of the room not sufficiently thick to contain the shutters, the surface of the plastering is brought out so as to give the architrave a proper projection, and quarterings are used for supporting the lath and plaster in lieu of battens. This is also practised when the breast of a chimney projects into the room, in order to cover the recesses and make the whole side flush, or all in the same surface with the breast.

Batter. (Probably from the Fr. Battre.) A term used by artificers to signify that a body does not stand upright, but inclines from a person standing before it; when, on the contrary, it leans towards a person, its inclination is described by saying it overhangs.

Battlement. An indented parapet on the top of a wall. They were first used in ancient fortifications, and subsequently applied to other buildings as mere ornament. Their outline is generally a conjunction of straight lines at right angles to each other, each indentation having two interior right angles, and each raised part two exterior right angles. The solid parts are called *merlons* and cops; the intervals *crenelles* or embrasures. In Irish architecture a battlement occurs very frequently, the merlons being graduated in height.

Battle-embattled. A term applied to the top of a wall which has a double row of battlements formed by a conjunction of straight lines at right angles to each other, both embrasures and rising parts being double, the lower part of every embrasure less than the upper, and therefore the lower part of each riser broader than the upper.

Baulk. See Balk.

Baulk Roofing. Roofing in which the framing is constructed of baulk timber.

Bay. (Dutch, Baye.) The division of a barn or other building, generally from fifteen to twenty feet in length or breadth. For the bay of a nave or choir of a mediæval church, see Nave.

Bay. In plasterer's work, the space between the screeds prepared for regulating and working the floating rule. See Screed.

Bay of Joists. The joisting between two binding joists, or between two girders when binding joists are not used.

Bay of Roofing. The small rafters and their supporting purlins between two principal rafters.

Bay Window. A window placed in a bay or projection in a room. It is also called an *oriel* window. See Bow Window.

Bay of a Window. See Day.

Bazar. A species of mart or exchange for the sale of divers articles of merchandize. The word is Arabic, signifying the sale or exchange of goods or merchandize. Some of the Eastern bazars are open, like the market-places of Europe, and serve for the same uses, more particularly for the sale of more bulky and less valuable commodities. Others are covered with lofty ceilings and even domes, which are pierced for the admission of light. It is in these that the jewellers, goldsmiths, and other dealers in rich wares have their shops. The bazar or *meidan* of Ispahan is one of the finest in Persia.

Beacon Turret. The turret of an angle of a tower, sometimes in Border counties used for containing the apparatus for kindling at the shortest possible notice the *need-fire*.

Bead. (Sax. Beade.) A moulding whose section is circular. It is frequently used on the edge of each fascia of an architrave, as also in the mouldings of doors, shutters, skirtings, imposts, and cornices. When the bead is flush with the surface it is called a *quirk bead*, and when raised it is called a *cock-bead*.

Bead and Butt Work. Framing in which the panels are flush, having beads *stuck* or run upon the two edges; the grain of the wood being in the direction of them.

Bead, Butt, and Square Work. Framing with bead and butt on one side, and square on the other, chiefly used in doors. This sort of framing is put together square, and the bead is *stuck* on the edges of the rising side of the pannel.

Bead and Flush Work. A piece of framed work with beads run on each edge of the included pannel.

Bead, Flush, and Square Work. Framing with bead and flush on one side, and square on the other, used chiefly in doors.

Bead and Quirk. A bead stuck on the edge of a piece of stuff, flush with its surface, with only one quirk or without being returned on the other surface. *Bead and double quirk* occurs when the bead appears on the face and edge of a piece of stuff in the same manner, thus forming a *double quirk*.

Beak. A little pendent fillet left on the edge of the larmier, forming a canal behind to prevent the water from running down the lower bed of the cornice. The beak is sometimes formed by a groove or channel recessed on the soffite of the larmier upwards.

Beak-head. An ornament often used in Norman mouldings, resembling the beak of a bird.

Beak Moulding. See Bird's-beak Moulding.

Beam. (Sax. Beam, a tie.) A piece of timber, or sometimes of metal, for supporting a weight, or counteracting two opposite and equal forces, either drawing it or compressing it in the direction of its length. A beam employed as a lintel supports a weight; if employed as a tie beam, it is drawn or extended; if as a collar beam, it is compressed. The word is usually employed with some other word used adjectively or in opposition, which word implies the use, situation, or form of the beam; as *tie beam, hammer beam, dragon beam, straining beam, camber beam, binding beam, girding beam, truss beam, summer beam,* &c. Some of these are, however, used simply, as collar for collar beam, lintel for lintel beam, &c. That which is now called the collar beam was by old writers called *wind beam*, and strut or *strutting beam*. A beam is lengthened either by building it in thicknesses, or by lapping or splicing the ends upon each other and bolting them through, which is called *scarfing*. See Collar Beam.

Beam Compasses. An instrument for describing large circles, and made either of wood or metal with sliding sockets, carrying steel or pencil points. It is used only when the circle to be described is beyond the reach of common compasses.

Beam Filling. The brickwork or masonry brought up from the level of the under to the upper sides of the beams. It is also used to denote the filling up of the space from the top of the wall plate between the rafters to the under side of the slating, board, or other covering.

Bearer. That which supports any body in its place, as a wall, a post, a strut, &c. In gutters they are the short pieces of timber which support the boarding.

Bearing. The distance or length which the ends of a piece of timber lie upon or are inserted into the walls or piers; thus joists are usually carried into the walls at least nine inches, or are said to have a nine-inch bearing. Lintels of an aperture should in like manner have a similar bearing, the object being to prevent any *sagging* of the piece acting on the inner horizontal quoins of the wall.

Bearing of a Timber. The unsupported distance between its points of support without any intervening assistance. A piece of timber having any number of supports, one being placed at each extremity, will have as many bearings, wanting one, as there are supports. Thus a piece of timber extended lengthwise, as a joist over two rooms, will have three supports and two bearings, the bearers being the two outside walls and the partition in the midst between them.

Bearing Wall or Partition. A wall or partition built from the solid for the purpose of supporting another wall or partition, either in the same or in a transverse direction. When the latter is built in the same direction as the supporting wall, it is said to have a *solid bearing*; but when built in a transverse direction, or unsupported throughout, its whole length is said to have a *false bearing*, or as many false bearings are there are intervals below the wall or partition.

Beater. An implement used by plasterers and bricklayers for beating, and thereby tempering or incorporating together the lime, sand, and other ingredients of a cement or plaster.

Beaufet. See Buffet.

Bed. (Sax. Beð.) The horizontal surface on which the stones, bricks, or other matters in building lie. The under surface of a stone or brick is called its *under bed*, and the upper surface its *upper bed*. In general language the beds of a stone are the surfaces where the stones or bricks meet. It is almost needless to inculcate the necessity of every stone being worked quite straight, and not dished or hollowed out, which masons are very apt to do for the purpose of making a fine joint. Stones thus worked are very liable to flush and break off at the angles.

Bed Chamber. The apartment destined to the reception of a bed. Its finishings of course depend on the rank of the party who is to occupy it.

Bed-mouldings. The mouldings under a projection, as the corona of a cornice.

Bed of a Slate. The under side of a slate, or that part in contiguity with the boarding or rafters.

Beds of a Stone, in cylindrical vaulting, are the two surfaces intersecting the intrados of the vault in lines parallel to the axis of the cylinder. In conic vaulting, where the axis is horizontal, they are those two surfaces which, if produced, would intersect the axis of the cone. In arching the beds are called *summerings* by the workmen.

Bedding of Timbers. The placing them properly in mortar on the walls.

Beech. One of the forest trees, but not often used in building.

Beetle. (Sax. Býtel.) A large wooden hammer or mallet with one, two, or three handles for as many persons. With it piles, stakes, wedges, &c., are driven.

Belection Moulding. See Balection Moulding.

Belfry. The upper part of the steeple of a church for the reception of the bells. It is the campanile of the Italians, though amongst them a building often altogether unconnected with the body of the church. It is sometimes used more especially in respect of the timber framing by which the bells are supported.

Bell. The naked vase or *corbeille* of the Corinthian and Composite capitals round which the foliage and volutes are arranged. Its horizontal section is everywhere a circle.

Bell Roof. One whereof the vertical section, perpendicular to the wall or to its springing line, is a curve of contrary flexure, being concave at the bottom and convex at the top. It is often called an ogee roof from its form.

Bell Turret. A small tower formed specially for holding a bell. A "bell-gable" is a gable-like wall perforated to hold a bell.

Belt. In masonry, a course of stones projecting from the naked, either moulded, plain, fluted, or enriched with pateras at regular intervals.

Belvedere (It.) A raised turret or a lantern for the enjoyment of a prospect; also a small edifice in gardens, not uncommon in France and Italy.

Benatura. The holy water vessel placed at the entrance of churches, generally on the right hand of the outer, or inner, porch door, or both. The sprinkler, originally made of the herb hyssop, is called *aspergillum.*

Bench. A horizontal surface or table about two feet eight inches high, on which joiners prepare their work.

Bench Hook. A pin affixed to a bench for preventing the stuff in working from sliding out of its place.

Bent Timber Roof. A roof of large span, in which the principals are formed of timber bent to the required form, and secured by bolts or bands.

Beton. (Fr.) Concrete made according to the French system.

Bevel. (Lat. Bivium.) An instrument used by artificers, one leg whereof is frequently curved according to the sweep of an arch or vault. It is moveable upon a pivot or centre, so as to render it capable of being set to any angle. The make and use of it are much the same as those of the common square and miter, except that those are fixed, the first at an angle of ninety degrees and the second at forty-five; whereas the bevel being moveable, it may in some measure supply the office of both, and yet supply the deficiency of both, which is, indeed, its principal use, inasmuch as it serves to set off or transfer angles either greater or less than ninety or forty-five.

Any angle that is not square is called a *bevel angle*, whether it be more obtuse or more acute than a right angle; but if it be one half as much as a right angle, viz. forty-five degrees, the workman calls it a *miter.* They have also a term *half miter*, which is an angle one quarter of a quadrant or square, that is, an angle of twenty-two degrees and a half.

Bier. A portable carriage for the dead. Hearse or Herce.

Billet Moulding. (Fr. Billet.) A moulding used in Norman architecture, in string courses and the archivolts of openings. It consists of short, small, cylindrical pieces, two or three inches long, placed in hollow mouldings at intervals equal to about the length of the billet. See fig. 1372.

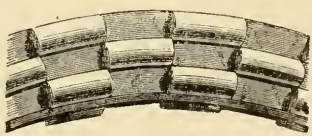


Fig. 1372. Billet Moulding.

Binding Joists. Those beams in a floor which, in a transverse direction, support the bridging joists above, and the ceiling joists below. When they are placed parallel to that side of a room on which the chimney stands, the extreme one on that side ought never to be placed close to the breast, but at a distance equal to the breadth of the slab, in order to allow for the throwing over the brick trimmer to support the hearth.

Binding Rafters. The same as purlins.

Binn for Wine. The open subdivision in a cellar for the reception of wine in bottles. The average diameter allowed for green bottles is 3·56 inches. Thus a binn 6 ft. $2\frac{3}{4}$ in. long will take twenty-one bottles. If they are laid in double tiers the depth should be 32 inches.

Bird's-beak Moulding. A moulding which in section forms an ovolo or ogee with or without a fillet under it, followed by a hollow. It is usual in Greek work, especially in the cap of the *anta* of the Doric order.

Bird's-eye Maple Wood. The wood of the acer macrophyllum, or broad-leaved maple. It is scarcely inferior in grain to the finest satin wood. It is largely used in cabinet work.

Bird's-eye Perspective. A representation of any place or building taken from a great height. The lines can only be found geometrically. It differs from the ordinary perspective representations only in that the horizontal line is very much above the object to be shown.

Bird's Mouth. An interior angle cut on the end of a piece of timber, for the purpose of obtaining a firm rest upon the exterior angle of another piece.

Bit. An instrument for boring holes in wood or any other substance, so constructed as to admit of being inserted or taken out of a spring. The handle is divided into five parts, all in the same plane; the middle and the two extreme parts being parallel. The two extreme parts are in the same straight line, one of them having a brass end with a socket for containing the bit, which, when fixed, falls into the same straight line with the other end of the stock; the further end has a knob attached, so as to remain stationary, while all the other parts of the apparatus may be turned round by means of the projecting part of the handle.

There are various kinds of bits; as *shell bit*, used for boring wood, and having an interior cylindric concavity for containing the core; *centre bit*, used to form a large cylindric hole or excavation; *countersink bit*, for widening the upper part of a hole in wood or iron, to take in the head of a screw or pin, so that it may not appear above the surface of the wood; *rimer bit*, for widening a hole; and *taper shell bit*, used also for the last-named purpose.

Bitumen. A mineral pitch used in former ages instead of mortar. The bricks of the walls of Babylon are said to have been cemented together with it.

Blade. (Sax. Blæd.) A name sometimes given to the principal rafter of a roof.

Blade of a Chisel. The iron or steel part of it as distinguished from the wooden handle.

Blade of a Saw. The thin steel part on the edge of which the teeth are cut. The chief properties of a good saw are, that it should be stiff and yet bend equally into a regular curve, well tempered, equally thick on the cutting edge, and thinner towards the back edge.

Blank Door. A door either shut to prevent a passage, or one placed in the back of a recess, where there is no entrance, having, nevertheless, the appearance of a real door.

Blank Window. One which has the appearance of a real window, but is merely formed in the recess of the wall. When it is necessary to introduce blank windows for the sake of uniformity, it is much better to build the apertures like the other and real windows, provided no flues or funnels interfere; and instead of representing the sashes by painting, real sashes should be introduced with the panes of glass painted black on the back.

Blind. The ordinary white linen material for draw-down blinds, now also made buff, blue, or red in colour. Also quadrangular forms of wood or metal, covered with an opaque substance, stretched between the framing, so as to cover either the whole or part of the sashes of a window. They are used for the purpose of diminishing the intense effects of the sun's rays, or of preventing persons from seeing into the interior of an apartment. Helioscene. Venetian.

Block (Teutonic) of Wood. A piece of wood cut into some prescribed form for a particular purpose.

Block of Stone or Marble. A piece rough from the quarry before it has received any form from the hand of the workman.

Blocking or Blocking Course. In masonry, a course of stones placed on the top of a cornice and forming the crown of a wall.

Blockings. Small pieces of wood fitted in and glued to the interior angle of two boards, or other pieces, for the purpose of giving additional strength to the joint. In gluing up columns the staves are glued up successively and strengthened by blockings; as also the risers and treads of stairs and all other joints that demand more strength than their own joints afford. Blockings are always concealed from the eye.

Board. (Sax. Bord.) A piece of timber of undefined length, more than four inches in breadth, and not more than two inches and a half in thickness. When boards are of a trapezoidal section, that is, thinner on one edge than the other, they are called *feather-edged boards*. Boards when wider than nine inches are called *planks*. The fir boards called *deal* (because they are *dealt* or *divided* out in thicknesses) are generally imported into England ready sawn, being thus prepared cheaper by saw mills abroad than they can be here. Fir boards of this sort, one inch and a quarter thick, are called *whole deal*, and those a full half inch thick, *slit deal*. See Batten.

Board for Valleys or Valley Board. A board fixed on the valley rafters, or a piece for the leaden gutter of the valley to rest on.

Boarded Floor. A floor covered with floor-boards. The laying of floors usually commences when the windows are in and the plaster dry. The boards should be planed on their best face and set up to season, till the natural sap is expelled. They are then to be planed smooth, shot, and squared on the edge. The opposite edges are brought to a breadth by drawing, with a flooring gauge, a line on the face parallel to the other edge. After this they are gauged to a thickness, and rebated down on the back to the lines drawn by the gauge. The next thing is to try whether the joists be level, and if not, either the boards must be cut on the under side to meet the inequality, or the joists must be *furred* up by pieces to bring the boards, when laid, to a level. The boards employed in flooring are either battens or deals of greater breadth. The quality of battens is divided into three sorts. The best is that free from knots, shakes, sap wood, or cross-grained stuff, well matched, and selected with the greatest care. The second best is that in which only small but sound knots are permitted, but it is to be free from sapwood and shakes. The most inferior kind is that left from the selection of the other two.

BOARDING JOIST. In naked floorings the joist to which the boards are to be fixed.

BOARDING FOR LEAD FLATS AND GUTTERS. That which immediately receives the lead, rarely less than one inch and an eighth, or one inch and a quarter thick. It is usually laid merely with rough joints.

BOARDING FOR PUGGING OR DEAFENING, also called SOUND BOARDING. Short boards disposed transversely between the joists of floors to hold some substance intended to prevent sound being transmitted from one story to another. These boards are supported by *fillets* fixed to the sides of the joists, about three-quarters of an inch thick and an inch wide. The substance, often plaster, placed between them to prevent the transmission of the sound, is called the *pugging*.

BOARDING FOR SLATING. That nailed to the rafters, in place of laths, for the reception of the slates, usually $\frac{3}{4}$ to $\frac{7}{8}$ of an inch in thickness; the sides commonly rough; the edges either rough, shot, ploughed and tongued, or rebated and sometimes *sprung*, so as to prevent the rain from passing through the joints. The boarding for slating may be so arranged as to diminish the lateral pressure or thrust against the walls by disposing the boards diagonally on the rafters. On the lower edge of the boarding is fixed the *eaves board*, as also against all walls either at right angles to or forming an acute angle with the ridge, or a right or obtuse angle with the wall plate. The eaves board is for raising the lower ends of the lower row of slates that form the eaves. Those placed against walls are for raising the slates to make the water run off from the wall. The boarding for slates should be of yellow deal without sap.

BOARDING FOR LINING WALLS. The boards used for this purpose are usually from five-eighths to three-quarters of an inch thick, and are ploughed and tongued together.

BOASTER. A tool used by masons to make the surface of the work nearly smooth. It is two inches wide in the cutting part.

BOASTING IN MASONRY. The act of paring the stone with a broad chisel and mallet, but not in uniform lines.

In CARVING, it is the rough cutting round the ornaments, to reduce them to their contours and profiles, before the incisions are made for forming the raffels or minuter parts. See ASHLAR.

BODY OF A NICHE. That part of it whose superficies is vertical. If the lower part be cylindrical and the upper part spherical, the lower part is the *body* of the niche, and the upper part is termed the *head*.

BODY OF A ROOM. That which forms the main part of the apartment, independent of any recesses on the ends or sides.

BODY RANGE OF A GROIN. The wider of two vaults which intersect and form a groin.

BOLECTION MOULDING. See BALECTION MOULDING.

BOLSTER OR PILLOW. The baluster part of the Ionic capital on the return side. See BALUSTER.

BOLT. (Gr. Βολις, a dart.) In joinery, a metal fastening for a door, and moved by the hand, catching in a staple or notch which receives it. Bolts are of various sorts, of which *plate spring* and *flush bolts* are for fastening doors and windows.

This name is also given to large cylindrical iron or other metal pins, having a round head at one end and a slit at the other. Through the slit a *pin* or *forelock* is passed, whereby the bar of a door, window shutter, or the like is made fast. These are usually called round or window bolts.

The bolt of a lock is the iron part that enters into a staple or jamb when the key is turned to fasten the door. Of these the two sorts are, one which shuts of itself when the door is shut to, called a *spring bolt*; the other, which is only acted upon by applying the key, is called the *dormant bolt*.

In carpentry, a bolt is usually a square or cylindrical piece of iron, with a knob at one end and a screw at the other, passing through holes for its reception in two or more pieces of timber, for the purpose of fastening them together, by means of a nut screwed on the end opposite to the knob. The bolt of carpentry should be proportioned to the size and stress of the timbers it connects.

BOLTEL. See BOULTINE.

BOND. (Sax.) Generally the method of connecting two or more bodies. Used in the plural number, it signifies the timbers disposed in the walls of a house, such as *bond timbers*, *lintels*, and *wall plates*. The term *chain bond* is sometimes applied to the bond timbers formerly placed in one or more tiers in the walls of each story of a building, and serving not only to tie the walls together during their settlement, but afterwards for nailing the finishings thereto. These bond timbers are now not allowed to be used in buildings in the metropolis.

In masonry or brickwork, is that disposition of stones or bricks which prevents the vertical joints falling over one another. *Heart bond* is that bond which occurs when two stones being placed in a longitudinal position extending the exact thickness of the wall, another stone is put over the joints in the centre of the wall.

Bond Masonry. See Bound Masonry.

Bond Stones. Those whose longest horizontal direction is placed in the thickness of the work.

Boneing, or Boning. (Etym. doubtful.) The act of judging of, or making, a plane surface or line by the eye. It is also performed by joiners with two straight edges, by which it is seen whether the work is out of *winding*, that is, whether the surface be plane or twisted.

Booth. (British, Bwth.) A stall or standing in a fair or market. The term is also applied to any temporary structure for shade and shelter, as also for wooden buildings for itinerant players and pedlars.

Border. (Fr. Bord.) A piece of wood put round the upper edges of any thing, either for use or ornament. Such are the three pieces of wood, to which the term is more usually applied in architecture, which are mitred together round the slab of a chimney.

Boring. The art of perforating any solid. For wood, the various sorts of bits are described under Bit.

Boss. (Fr.) A projecting mass or prominency of material, to be afterwards cut or carved. It is placed at the intersection of the ribs in groined vaulting. The bosses in the later mediæval styles were beautifully carved with foliage and figures. See Orb.

Boss. Among bricklayers, a wooden vessel used by the labourers for the mortar used in tiling. It has an iron hook, by which it hangs on the laths or on the rounds of a ladder.

Bossage (Fr.) Projecting stones laid rough in building to be afterwards cut into mouldings or carved into ornaments. The term is also used to signify rustic work, which seems to advance before the naked of a building, by reason of indentures or channels left at the joints. The cavities or indentures at the joints are sometimes bevelled or chamfered, and sometimes circular.

Boudoir. A French term used in England to designate a room in a large mansion especially appropriated to the mistress of the house as her sitting-room.

Boulder Walls. Such as are built of round flints or pebbles laid in strong mortar. This construction is used where there is a beach cast up by the sea, or where there is an abundance of flints in the neighbourhood.

Boultine or Boltel. A name sometimes given by workmen to a convex moulding, such as an ovolo. See Bowtel.

Bound or Bond Masonry. That wherein the stones of each succeeding course are laid so that the joint which mounts and separates two stones always falls directly over the middle of the stone below.

Bow. (Sax. Buȝen.) The part of any building which projects from a straight wall. It is sometimes circular and sometimes polygonal on the plan, or rather formed by two exterior obtuse angles. Bows on polygonal plans are called *canted bows*.

Bow. Among draughtsmen, denotes a beam of wood or brass, with three long screws that direct a lath of wood or steel to an arch. It is used in drawing flat arches of large radius.

Bow Compasses. Instruments for describing small circles.

Bow Room. A room having a bow on one or more sides of it.

Bow Saw. One for cutting the thin edges of wood into curves.

Bow Window. A semicircular or polygonal projection from a building, and containing a window. The supports are either carried up from the ground, or in the case of an upper story, they are formed of projected suites of mouldings springing from a corbel. They are most frequently seen in the later mediæval and the Italian styles.

Bowlers or Bolders. See Pavement.

Bowtel or Boltel. The mediæval term for a plain moulding or shaft of a circular shape. See Boultine.

Box. (Sax.) Generally, a case for holding anything.

Box for Mitering. A trough for cutting miters. It has three sides, and is open at the ends, with cuts on the vertical sides at angles of forty-five degrees with them.

Box of a Rib Saw. Two thin iron plates fixed to a handle, in one of which plates an opening is made for the reception of a wedge, by which it is fixed to the saw.

Box of a Theatre. One of the subdivisions in the tiers round the circle.

Boxed Shutters. See Boxings of a Window.

Boxings of a Window. The cases opposite each other on each side of a window, into which the shutters are folded or fall back. The shutters of principal rooms are usually in two divisions or halves, each subdivided into others, so that they may be received within the boxings. The subdivisions are seldom more in number than three, and are so contrived that the subdivision whose face is visible, which is called the front shutter, is of the exact breadth of the boxing, and also flush with it; the next, hidden in the boxing, is somewhat less in breadth than that last mentioned, and the third still less. Suppose, for instance, a window four feet wide, standing in a two-brick or eighteen-inch wall; we may thus find the number of leaves each of the halves must have, as follows:— To the thickness of the wall add that of the plastering, say 2 inches, and we have 20 inches. Now the sash frame = 6 inches in thickness, being added to the *reveal* or distance = $4\frac{1}{2}$ inches of the sash frame from the face of the wall = $10\frac{1}{2}$ inches, which, subtracted from 20, the thickness of the wall and plaster, leaves $9\frac{1}{2}$ inches. This will give three leaves, or subdivisions, and as it is usual to make the *back flaps*, or those folded within the boxings, less than the front shutter, whose face is visible and flush with and of the exact breadth of the boxings, the arrangement may be as follows:—Front shutter $9\frac{1}{2}$ inches, the next 8 inches, and the third $6\frac{1}{2}$ inches; in all, 24 inches, the half of the opening of the window. It will be perceived that no allowance has been made for the shutters being rebated into each other, as is usually the case; and for this half an inch more must be allowed for the two rebates of the three leaves, and one-eighth of an inch for the rebate at the meeting of the two principal divisions in the middle of the window, making, with the breadth of the three subdivisions, $24 + \frac{5}{8}$; the flaps, therefore, may be thus disposed:—Front leaf $9\frac{1}{2}$ inches, second leaf $8\frac{1}{2}$ inches, and the third leaf $6\frac{5}{8}$ inches; in all $24\frac{5}{8}$ inches, being fully the width of each principal division. To find the depth to be given to the boxings, to the thickness of each of the leaves add one-sixteenth of an inch, and if there be a back lining add also the thickness of that. The second and third flaps are almost always thinner than the front leaf; thus, say front leaf $1\frac{1}{2}$ inch, second leaf $1\frac{1}{4}$ inch, and third leaf $1\frac{1}{4}$ inch; to which add $\frac{3}{16}$ for the three leaves, and the amount will stand thus:—$1\frac{1}{2} + 1\frac{1}{4} + 1\frac{1}{4} + \frac{3}{16} = 4\frac{3}{16}$ inches for the depth of the boxings. If the walls are only a brick and a half thick, or the window very wide, the architrave is made to project before the face of the plaster, for the purpose of obtaining width for the boxings, or the plaster is brought out from the internal face of the wall by means of battening.

Brace. (Fr. Embrasser.) An inclined piece of timber used in trussed partitions and in framed roofs, in order to form a triangle, by which the assemblage of pieces composing the framing are stiffened. When a brace is used to support a rafter, it is called a *strut*. When braces are used in roofs and in partitions, they should be disposed in pairs, and introduced in opposite directions. See Angle Brace.

Bracket. (Lat. Brachium.) A supporting piece for a shelf. When the shelf is broad the brackets are small trusses, which consist of a vertical piece, a horizontal piece, and a strut; but when narrow the brackets are generally solid pieces of board, usually finished with an ogee figure on their outer side.

Bracket for Stair. It is sometimes used under the ends of wooden steps next to the well-hole, for the sake of ornament only, for it gives only the appearance of a support.

Bracketing to a Cornice. The wooden ribs nailed to the ceiling, joists, and battening for supporting the cornices of rooms when too large for security, by the mere dependence on the adhesive power of plaster to the ceiling. It consists of vertical ribs whose rough outline is that of the cornice, and to which the laths are nailed for sustaining the plaster in which the mouldings are run. The bracketing for coves is only an enlargement of the scale which occurs in ordinary cornices, the operation being that of obtaining a set of ribs to which the laths may be nailed for the reception of the plastering. The ribs in question are usually cut out of deals, whose thickness must necessarily vary with the weight of plaster they have to support.

Brad. (Etym. uncertain.) A thin nail used in joinery without the spreading head which other nails have, the projection of the head being only on one side. There are various sorts of brads, such as *joiners' brads* for hard woods; *batten brads*, for softer woods; and *bill*, or *quarter brads*, used for a hastily laid floor. When brads are used they are generally driven below the surface of the wood through the medium of a *punch*, and the hole is filled up with putty to prevent an appearance of the nailing.

Branches. The ribs of a Gothic vault, rising upwards from the tops of the pillars to the apex. They appear to support the ceiling or vault.

Brandering. Covering the underside of joists with battens about an inch square and from twelve to fourteen inches apart, to which to nail laths, in order to secure a better key for the plastering of the ceiling.

Brandrith. A fence or rail round the opening of a well.

Brass. A metal much used in building. It is an alloy of copper and zinc, whose proportions vary according to the required colour. Four parts of copper and one of zinc form a good brass. The common process for making it is by heating copper plates in a mixture of native oxide of zinc, or calamine and charcoal.

Brass. A sepulchral metal plate, generally sunk into a grave-stone; sometimes with a mere inscription, but very frequently with effigies, armorial bearings, and other devices engraved upon it.

Brattishing. An ornamental cresting. The carved open work over a shrine.

Brazing. The union of pieces of copper by heating and hammering them. See Soldering and Welding.

Breadth. The greatest extension of a body at right angles to its length.

Break. The recess or projection of any part within or beyond the general face of the work. In either case it is to be considered a break.

Break in. In carpentry, it is the cutting or breaking a hole in brickwork with the ripping chisel for the purpose of inserting timber, or to receive plugs, the end of a beam, or the like.

Breaking down. Sawing a baulk of timber into boards.

Breaking Joint. In masonry or brickwork, it is the placing a stone or brick over the course below, in such a manner that the joint above shall not fall vertically immediately above those below it.

Breast of a Chimney. The projecting or facing portion of a chimney front towards a room which projects into it, or which, from other construction, may not have a break. It is, in fact, the wall carried up over the front of a fireplace, whether projecting or not. See Chimney.

Breast of a Window. The masonry or brickwork forming the back of the recess or parapet under the window sill.

Breeze. Small ashes and cinders used instead of coal in the burning of bricks.

Bressummer or Breast Summer. That is, a summer or beam placed breastwise for the support of a superincumbent wall, performing in fact the office of a lintel. It is principally used over shop windows to carry the upper part of the front and supported by iron or timber posts, though sometimes by stone. In the interior of a building the pieces into which the girders are framed are often called summers.

Brewhouse. An establishment for the manufactory of malt liquors. A brewhouse is generally provided as an appendage to dwelling-houses in the country, for brewing the beer used by the family.

Brick. (Dutch, Bricke.) A sort of fictitious stone, composed of an argillaceous earth, tempered and formed in moulds, dried in the sun, and finally burnt to a proper degree of hardness in a clamp or kiln. The method pursued by the ancients in making unburnt bricks is described by Vitruvius, book ii., chap. iii. That author describes the three different sorts in use:—Didoron (διδωρον), being one foot long and half a foot wide; the other two sorts are called Pentadoron and Tetradoron. By the word *Doron* the Greeks mean a palm, because the word δωρον signifies a gift which can be borne in the palm of the hand. That sort, therefore, which is five palms each way is called Pentadoron; that of four palms Tetradoron. The former of these two sorts is used in public buildings; the latter in private. Each sort has half-bricks made to suit it. Towards the decline of the Republic, the Romans made great use of bricks as a building material. According to Pliny, those most in use were a foot and a half long, and a foot broad. This agrees nearly with the Roman bricks used in England, which are generally found to be about seventeen inches in length, by eleven inches in breadth. Ancient bricks are generally very thin, being often no more than one inch and a half thick, and are often called tiles. From the article in the *Encyc. Méthodique*, it appears that in the researches made among the buildings at Rome, bricks of the following sizes were found. The least were 7½ inches (French) square and 1½ inch thick; the medium one 16½ inches square and from 18 to 20 lines in thickness. The larger ones were 22 inches square by 21 or 20 lines thick. The smaller ones were used to face walls of rubble work; and for making better bond with the wall, they were cut diagonally into two triangles, the longer side being placed on the outside, and the point towards the interior of the work. To make the tie more effectual between the rubble and the facing, there were placed at intervals of four feet in height, one or two courses of large square bricks. The larger bricks were also used for the arches of openings to discharge the superincumbent weight.

Bricklayer's Work. The art of bricklaying.

Brickwork. Any work performed with bricks as the solid material.

Bridge. (Sax. Bricge.) A structure for the purpose of connecting the opposite banks of a river, gorge, valley, &c., by means of certain materials, forming a roadway from one side to the other. It may be made of stone, brick, iron, timber, suspended chains or ropes, or the roadway may be obtained by means of boats moored in the stream. In the bridges of the ancients the arches were semicircular; in those erected during the mediæval period the arches were obviously made pointed, and generally of small spans, although there are a few good exceptions; while in those of modern date they have been segmental or semi-elliptical. The last two forms are very much more suitable, because of the freer passage for the stream, especially in the case of floods. We would refer the student to the brick railway bridge at Maidenhead, over the river Thames, carried out in 1835, by Sir I. Brunel, as a daring effort of work; the two largest arches, elliptical in form, are each 128 feet span, with a rise of 24 feet 3 in.

only; to the elliptical stone bridge over the Arno at Florence, 1567–70, by Bart. Ammannato, for its acknowledged beauty, the largest arch of which is 95 feet 10 in., with a rise of 15 feet 2 in.; and to the Grosvenor bridge at Chester, over the Dee, executed 1825–27, by Thomas Harrison, architect, for its design and good construction, as well as for being the largest span of any bridge yet erected in Great Britain, and almost in the world, consisting of only one segmental arch of 200 feet span, with a rise of 42 feet. In the brick bridge at Pavia, over the Ticino, which is of an early period, and also a covered bridge (a practice useless perhaps, but not uncommon in Italy and other parts of the Continent), the arches, 70 feet in span, are Pointed; a form very favourable in every respect and most especially so in rivers subject to sudden inundations, but unfavourable certainly in cases where the span of the arch (here having a rise of 64 feet) is required to have a large width in proportion to its height.

There are two rules respecting bridges which ought not to be neglected: the principal one is, that their direction must, if possible, be at right angles to the stream; the other that they must be placed in the line of the streets which they connect on the opposite banks of the stream. From a want of regard to these points many unfortunate blunders have been committed, which a prodigal expenditure will not afterwards rectify. The position of a bridge should be neither in a narrow part nor in one liable to swell with tides or floods, because the contraction of the waterway increases the depth and velocity of the current, and may thus endanger the navigation as well as the bridge itself.

It is the common practice to construct a bridge with an odd number of arches, for the reason, among many others, that the stream being usually strongest in the middle, egress is there better provided by a central arch. If the bridge be not perfectly horizontal, symmetry results by the sides rising towards the middle, and the roadway may be made one continued curve. When the roadway of a bridge is horizontal, the saving of centering for the arches is considerable, because two sets of centres will perhaps be sufficient for turning all the arches. If, however, the bridge be higher in the middle than at the extremities, the arches on each side of that in the centre must diminish similarly, so that they may be respectively symmetrical on each side of the middle. From this disposition beauty necessarily results, and the centering for one of the sides equally suits the other. A bridge should be constructed with as few arches as possible, for the purpose of allowing a free passage for the water, as well as for the vessels; if the bridge can be constructed with a single arch not more should be allowed. The piers should be of sufficient solidity to resist the thrust of the arch, independent of the counter thrust from the other arches; in which case the centering may be struck without the impendent danger of overturning the pier left naked. The piers should also be spread on their bases as much as possible, and should diminish gradually upwards from their foundations. In brick bridges of small plan, an inverted arch is often formed between the piers, to form a support, as well as to prevent any ill effects to the piers or abutments from a scour.

The method usually employed for forming the foundations is by means of *coffer-dams*. When, however, the ground is loose, this method cannot so well be used; and then *caissons* have been employed. On this system the piers of old Westminster and old Blackfriars bridges were constructed; both bridges have been rebuilt. It is now universally admitted to be defective and inefficient, principally from the liability of the piers being undermined by increased scour. Waterloo, Southwark, and London bridges were all built with the coffer-dam, laying the foundation dry. At new Westminster bridge another plan was adopted, avoiding the expense of coffer-dams. The principal bearing is on elm piles, cut off below low water. These are surrounded by iron piles with cast iron plates driven between the piles, thus forming a complete casing which surrounds and includes the elm bearing piles, and the interstices are filled in with concrete, making the whole solid. The next system of foundation is that of iron cylinders open at bottom and sunk into the bed of the river by excavating first inside by divers; and afterwards, when watertight strata are reached, by pumping out and working dry; the interior, when a sufficient depth has been reached, being filled solid with concrete or brickwork. Some other examples of bridges are noticed in this work.

Bridge Board, otherwise called Notch Board. A board into which the ends of the steps of wooden stairs are fastened.

Bridge-over. A term used when several parallel timbers occur, and another piece is fixed transversely over them; such piece is then said to *bridge-over* the parallel pieces. Thus in framed roofing, the common rafters bridge-over the purlins; so, in framed flooring, the upper joists, to which the flooring is fixed, bridge-over the beams or binding-joists, and for this reason they are called *bridging-joists*.

Bridge Stone. A stone laid from the pavement to the entrance door of a house over a sunk area and supported by an arch.

Bridged Gutter. One made with boards supported by bearers and covered above with lead or zinc.

Bridging or Bridging Pieces, also called Strutting or Straining Pieces. Pieces placed between two opposite beams to prevent their nearer approach, as rafters, braces, struts, &c. When a strutting-piece also serves as a sill, it is called a *straining sill.*

Bridging Floors. Those in which bridging-joists are employed.

Bridging Joists. Those which are sustained by transverse beams below, called *binding joists;* also those joists which are nailed or fixed to the flooring-boards.

Bridging to Floors. In some parts of England and in Ireland this term is applied to what is usually called Herring-bone Strutting, or Herring boning between the joists of a floor.

Bringing-Forward. Priming and painting new work mixed with old, so that the whole shall have the same appearance when finished.

Bringing-Up or Carrying-Up. A term used by workmen to denote building-up. Thus *bringing-up* a wall four feet means building it up.

Broach. An old English term for a spire, and still so employed. Sometimes it is used to designate a spire rising from the tower without any parapet, as in the Early English period.

Broached Work. See Droved and Broached.

Broad Stone. The same as Free Stone.

Broken-joint Flooring. The same as floor-boards laid *folding.* See Floor.

Bronteum. (Gr.) In ancient Greek Architecture, that part of the theatre under the floor in which brazen vessels with stones in them were placed to imitate the sound of thunder.

Bronze. A compound metal applied to various useful and ornamental purposes. The composition consists of 6 to 12 parts of tin and 100 parts of copper. This alloy is heavier and more tenacious than copper; it is also much more fusible, and less liable to be altered by exposure to the air.

Budget. A small pocket used by tilers for holding the nails in lathing for tiling.

Buffet. (Fr.) A cabinet or cupboard for plate, glass, or china. Some years back it was the practice to make these small recesses very ornamental, in the form of niches, and left open in the front to display the contents. At present, when used, they are generally closed with a door.

Buhl Work. Formerly called *Boule* work from the name of its inventor. It consists of one or more metals inlaid upon a ground of tortoise shell, alone or with coloured woods, or of these last-named materials inlaid upon grounds of metal. The process is as follows:—Two pieces of veneer are placed together, with paper between them, each being glued to the paper. Upon the surface of the upper one is placed the drawing of the pattern to be cut, and then the outlines of it are cut through by means of a very fine watch-spring saw. The parts are then separated, that which is taken from the darker wood is let into the lighter wood and *vice versâ.* See Reignier Work.

Builder. A person who contracts for performing the whole of the different artificers' works in a building.

Building. Used as a substantive is the mass of materials shaped into an edifice. As a participle, it is the constructing and raising an edifice suited to the purposes for which it is erected; the knowledge requisite for the design and construction of buildings being the subject of this work, in which it is treated under its various heads. A "new building" is the re-erecting of any building pulled down to or below the ground floor, or of any frame building of which only the framework is left down to the ground floor, or the conversion into a dwelling house of any building not originally constructed for human habitation, or the conversion into more than one dwelling house of a building originally constructed as one dwelling house only. Public Health Act, 1875.

Building Act. An Act passed for regulating the construction and use of buildings in any town or city.

Building of Beams. The same as Scarfing. A "built-beam" is a beam or girder formed of several pieces of timber fitted and bolted or strapped together, in order to obtain one of a greater strength than usually obtainable in one balk of timber.

Bulker. A term used in Lincolnshire to signify a beam or rafter.

Bullen Nails. Such as have round heads with short shanks turned and lacquered. They are principally used in the hangings of rooms.

Bull's Eye. Any small circular aperture for the admission of light or air. The name is also applied to the knob in a pane of common glass, left in its manufacture, which was formerly used for cheapness, and lately as a sort of ornament or for the sake of obscurity.

Bull's Nose. The external or other angle of a polygon, or of any two lines meeting at an obtuse angle.

Bullock Sheds. Houses or sheds for feeding bullocks, in which the main points to be observed are good ventilation, facility in feeding and cleaning the animals, perfect drainage, and a good aspect. They ought not to be less than nineteen feet wide.

Bund. A Persian term for a dam or dyke.

Bundle Pillar. In Gothic architecture, a column consisting of a number of small pillars round its circumference.

Bungalow. The Hindoo name for a thatched house; or generally for a house.

Butment. The same as Abutment, which see.

Butment Cheeks. The two solid sides of a mortise. The thickness of each cheek is usually equal to the thickness of the mortise, but it happens that circumstances arise to vary this thickness.

Butt-end of a piece of Timber. That which was nearest the root of a tree.

Buttery. A store-room for provisions; it should be on the north side of a building.

Butt-hinges or Butts. Those employed in the hanging of doors, shutters, casements, &c. They are placed on the edges with the knuckle projecting on the side in which the *closure* is to open, and the other edges stopping against a small piece of wood left in the thickness of the closure so as to keep the arris entire. Workmen generally sink the thickness of the hinges flush with the surface of the edge of the closure, and the *tail part* one-half into the jamb. *Stop butt-hinges* permit the closure to open only to a right angle, without breaking the hinges; *rising butt-hinges*, which are those that turn upon a screw, cause the door to rise as it opens, so as to clear the carpet in the apartment; *slip off butt-hinges* are used where a door or window-blind is required to be taken off occasionally

Butting Joint. That formed by the surfaces of two pieces of wood, whereof one is perpendicular to the fibres, and the other in their direction. or making an oblique angle with them, as, for example, the joints made by the struts and braces with the truss posts.

Button A small piece of wood or metal, made to turn about a centre, for fastening a door, drawer, or any other kind of closure. The centre is generally formed by a screw.

Buttress. (Fr. Aboutir, to lie out.) A mass of brickwork or masonry to support the side of a wall of great height, or pressed on the opposite side by a bank of earth or body of water. Buttresses are employed against the piers of Gothic buildings to resist the thrust of the vaulting. See Arc Boutant, or flying buttress. The buttress called the pillared buttress is formed by vertical planes attached to the walls themselves. These sometimes form the upright terminations of flying buttresses.

Byzantine. The style of architecture and art established under the Eastern division of the Roman Empire. It contains more of the Greek element than Romanesque Art, which was developed in the Western division.

C

Cabin. (Brit. Chabin.) A term applied to the huts and cottages of poor people and to those of persons in a savage state of life.

Cabinet. (Fr.) A retired room in an edifice set apart for writing, study, or the preservation of anything curious or valuable. The term is also applied to an apartment at the end of a gallery in which pictures are hung, or small pieces of sculpture, medals, bronzes, and other curiosities are arranged.

Cable Moulding. A convex circular moulding used in Norman Architecture, as in fig. 1373.

Cabling. A moulding of a convex circular section, rising from the back or concave surface of a flute of a column, so that its most prominent part may be in the same continued circular surface as the fillet on each side of the flute. Thus the surface of a flute is that of a concave cylinder, and that of the cable is the surface of a convex cylinder. with the axes of the cylinders parallel to each other. The cable seems to represent a rope or staff laid in the flute, at the lower part of which it is placed about one third of the way up. Cabling of flutes was not frequently used in the works of antiquity. At the arch of Constantine the cables rise to about one third of the height of the shaft. In modern times an occasional abuse has been practisedof cabling without fluting, as in the church della Sapienza at Rome.

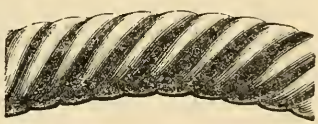

Fig. 1373.

Caer. A term in British antiquity, which, like the Saxon term *Chester*, denotes a castle, and is generally prefixed to the names of places fortified by the Romans.

Cage. In carpentry, is an outer work of timber surrounding another. Thus the cage of a stair is the wooden inclosure that encircles it.

CAIRN. A pyramidal pile of stones heaped up by the ancient races, for monumental or memorial purposes.

CAISSON. (Fr.) A large and strong chest of timber, water-tight, used in large and rapid rivers for building the pier of a bridge. The bottom consists of a grating of timber, contrived in such a manner that the sides, when necessary, may be detached from it. The ground under the intended pier is first levelled by divers, or other means, or piles driven in whereon the caisson may lodge; the caisson is then launched and floated into its proper position, and the pier built therein; it sinks, and the work is continued as high as the level of the water, or nearly so. The sides are then detached. The objection to the system is that a perfectly level bed cannot be obtained, and the caisson rests on limited portions; increased weight and time may no doubt produce a more even bearing, but settlement is involved to some extent. Old Westminster and old Blackfriars Bridges were so constructed. The tonnage of each of the caissons used at Westminster Bridge was equal to that of a forty-gun ship.

CAISSON. A sunken panel in ceilings, vaults, and cupolas. See COFFER.

CALCAREOUS EARTH. A species of earth which becomes friable by burning, and is afterwards reduced to an impalpable powder by mixing it with water. It also effervesces with acids. It is frequently met with in a friable or compact state in the form of chalk.

CALDARIUM. (Lat.) In ancient architecture a close vaulted room, in which persons were brought into a state of profuse perspiration, by hot water or heated air. It was one of the apartments attached to ancient baths.

CALFPEN. A place for nourishing calves. It is generally a small apartment within the cowhouse; but the practice is not to be recommended, as it keeps the cow in a restless and agitated state, and prevents her from feeding well and giving that quantity of milk she would otherwise furnish.

CALIBER. (Spanish.) The greatest extent or diameter of a round body.

CALIBER COMPASSES. Those made with bent legs for taking the diameter of a convex or concave body in any part. See MOULD.

CALIDUCTS. (Lat.) Pipes or channels disposed along the walls of houses and apartments. They were used by the ancients to convey heat to the remote parts of the house from one common furnace.

CALIPER. See CALIBER.

CALOTTE. (Fr.) A concavity in the form of a cup or niche, lathed and plastered, serving to diminish the height of a chapel, alcove, or cabinet, which otherwise would appear too high for the breadth.

CAMAROSIS. (Gr.) An elevation terminated with an arched or vaulted head.

CAMBER. (Gr.) An arch on the top of an aperture or on the top of a beam. Hence camber windows.

CAMBER BEAM. That which forms a curved line on each side from the middle of its length. All beams should, to some degree, if possible, be cambered; but the cambered beam is used in flats and church platforms, wherein, after being covered with boards, these are covered with lead, for the purpose of discharging the rain-water.

CAMERATED. (Gr.) The same as arched.

CAMES. Small slender rods of cast lead in glazing, twelve or fourteen inches long, of which when drawn separately through a species of vice, forming a groove on each side of the lead, the glaziers make the patterns for receiving the glass of casements, and for stained glass windows.

CAMP CEILING. A ceiling whose form is convex inwardly.

CAMPANILE. (It.) A tower for the reception of bells, usually, in Italy, separated from the church. Many of the campaniles of Italy are lofty and magnificent structures. That at Cremona is much celebrated, being 395 feet high. It consists of a square tower, rising 262 feet, surmounted by two octagonal open stories, ornamented with columns; a conical shaft and cross terminate the elevation. The campanile of Florence, from the designs of Giotto, claims admiration for its richness and workmanship. It is 267 feet high, and 45 feet square. The most remarkable of the campaniles in the country mentioned is that at Pisa, commonly called the "Leaning Tower." It is cylindrical in general form, and surrounded by eight stories of columns, placed over one another, each having its entablature. The height is about 150 feet to the platform, whence a plumb line lowered falls on the leaning side nearly 13 feet beyond the base of the building.

CAMP-SHEETING or CAMP-SHOT. The sill or cap of a wharf wall.

CANAL. (It. Canale.) A duct for the conveyance of a fluid; thus the canal of an aqueduct is the part through which the water flows.

CANAL. A term sometimes used for the flutings of a column or pilaster. The *canal of the volute* is the spiral channel, or sinking on its face, commencing at the eye, and following in the revolutions of the volute. The *canal of the larmier* is the channel or groove sunk on its soffite to throw off the rain, and prevent it from running down the bed mould of the cornice.

CANCELLI. (Lat.) Latticed windows, or those made with cross bars of wood or iron. The balusters or rails which close in the bar of a court of justice, and those round the altar of a church, are also so called; hence the word chancel.

CANDELABRUM. (Lat. Candela.) A stand or support on which the ancients placed a lamp. Candelabra varied in form, and were highly decorated with the stems and leaves of plants, parts of animals, flowers, and the like. The etymology of the word would seem to assimilate the candelabrum to our candlestick; it is, however, certain that the word *candela* was but a lamp, of which the candelabrum was the support. In the works of Piranesi some of the finest specimens are to be found. The most curious, however, as respects form, use, and workmanship, are those excavated at Herculaneum and Pompeii. They are all of bronze, slender in their proportions, and perfectly portable as they rarely in height exceed five feet. On none of the candelabra hitherto found is there any appearance of a socket or pipe at top, from which an inference as to the use of candles could be made.

CANEPHORÆ. (Gr. Κανηφορος, bearing a basket.) Figures of young persons, of either sex, bearing on their heads baskets containing materials for sacrifice. They are frequently confounded with caryatides, from their resemblance in point of attitude and the modern abuse of their application.

CANOPY. (Gr. Κανωπειον.) An ornamented covering over a seat of state; and in its extended signification any covering which affords protection from above. It is also the label or projecting roof that surrounds the arches and heads of Gothic niches.

CANT. An external angle or quoin of a building. Among carpenters it is used as a verb, to signify the turning of a piece of timber which has been brought in the wrong way for their work.

CANT MOULDING. One with one or more bevelled, instead of curved, surfaces. The cant moulding was used at an early period of the art.

CANTALEVER or CANTILEVER. (Probably from Canterii labrum, *the lip of the rafter.*) Blocks inserted into the wall of a building for supporting a balcony, the upper members of a cornice, or the eaves of a house, and the like. They answer the same purpose as modillions, mutules, blocks, brackets, &c., although not so regularly applied. They are, in modern use, not unfrequently made of timber or cast iron, and project considerably, as to the roof of the church of St. Paul, Covent Garden, which projects one quarter of the height of the column.

CANTED COLUMN. One whose horizontal sections are polygons. In the works of the ancients it is rarely met with. The examples immediately occurring to us are the columns of the portico of Philip of Macedon and of the temple at Cora.

CANTHARUS. A fountain or basin of water in the centre of the atrium before the ancient churches, wherein persons washed their faces and hands before they entered. Among the Romans the cantharus of a fountain was the part out of which the water issued.

CANTHERS or CANTERII. In ancient carpentry the common rafters of a roof, whose ends, say some, the mutules of the Doric order represent.

CANTING. The cutting away of a part of an angular body at one of its angles, so that its horizontal section becomes thereby the portion of a polygon of a greater number of sides whose edges are parallel from the intersection of the adjoining planes.

CANTONED BUILDING. One whose angles are decorated with columns, pilasters, rustic quoins, or anything projecting beyond the naked of the wall.

CANVASS. The names and sizes of the usual canvasses prepared for the use of painters (the width of the frame is a matter of taste) are as follows:—

Head size . . .	24 by 20 inches	Half-length size . .	50 by 40 inches
Three quarters do. .	30 by 25 ,,	Bishop's half-length do. .	56 by 44 ,,
Kit-cat do. . . .	36 by 28 ,,	Whole length do. . .	94 by 58 ,,
Small half-length do. .	44 by 34 ,,	Bishop's whole length do.	106 by 70 ,,

CAP. A term used in joinery, signifying the uppermost of an assemblage of parts. It is also applied to the capital of a column, the cornice of a door, the capping or uppermost member of the surbase of a room, the handrail of a staircase, &c.

CAPITAL. (Lat. Caput.) The head or uppermost member of any part of a building; but generally applied in a restricted sense to that of a column. The capital of the pilaster or *anta* of the Greeks was very different to that of the columns in front of it. The accompanying illustrations exhibit the sort of caps used in mediæval architecture. *Fig.* 1374 is Norman; *figs.* 1375 and 1376 Early English; and *fig.* 1377 Late Decorated.

CAPITAL, ANGULAR. The modern Ionic capital, whose four sides are all alike, showing the volute placed at an angle of 135° on all the faces.

CAPITAL OF A BALUSTER. The crowning or head mouldings of it.

Capital of a Lantern. The covering by which it is terminated; it may be of a bell form, that of a dome, spire, or other regular figure.

Fig. 1374. St. Peter's, Northampton.

Fig. 1375. York.

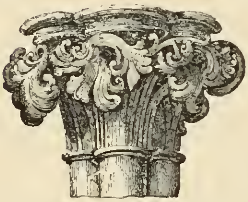

Fig. 1376. North Doorway, Westminster.

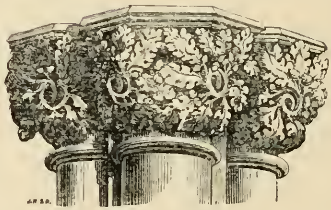

Fig. 1377. York Minster.

Capital of a Triglyph. The square band which projects over it. In the Roman Doric it has a greater projection than in the Grecian.

Capitol. The Acropolis of ancient Rome.

Capreoli. (Lat.) In ancient carpentry, the joints or braces of a trussed roof.

Caracol. A term sometimes applied to a staircase in the form of a helix or spiral.

Caravanserai. Among the Eastern nations a large public building or inn appropriated to the reception and lodgment of travellers by caravans in the desert. Though the caravanserai serves the purpose of an inn, there is this essential difference between the two, that in the former the traveller finds nothing either for the use of himself or his cattle, but must carry all his provisions and necessaries with him. Caravanserais are also numerous in cities, where they serve, not only as inns, but as shops, warehouses, and even exchanges.

Carbolic Acid. This fluid has lately been obtained from creosote by distillation. By the use of a solution of Mc Dougall's patent prepared carbolic acid, sewage is rendered imputrescible, all smell being removed, and no further decomposition possible. A solution of it (about a pint to a cartload) has lately been mixed with the water sprinkled on roads by watering carts, by which a disinfecting action takes place on the droppings of horses, decomposing dust, &c. The powder may be used in dust-bins, water-closets, in whitewashing the walls of hospitals, &c. Formed into a soap, it can be employed in washing painted work and floors, or linen. Mixed carefully with oil of vitriol, sulphurous acid gas is liberated for fumigating an apartment. It is not poisonous.

Carcass. The naked building of a house before it is lathed and plastered or the floor boards laid, &c.

Carcass Flooring. That which supports the boarding, or floor boards, above, and the ceiling below, being a grated frame of timber, varying in many particulars.

Carcass Roofing. The grated frame of timber work which spans the building, and carries the boarding and other covering.

Cardinales Scapi. In ancient Roman joinery, the stiles of doors.

Carolitic Column. One with a foliated shaft.

Carpenter. (Fr. Charpentier.) An artificer who practises the science of framing and fitting to each other the various pieces and assemblages of timber used in the construction of buildings.

Carpenters' Rule. The instrument by which carpenters take their dimensions, and by the aid of a brass slide, which makes it a sliding rule, they are enabled to make calculations in multiplication and division, besides other operations.

Carpenter's Square. An instrument whose stock and blade consists of an iron plate of one piece. One leg is eighteen inches long, and numbered on the outer edge from the exterior angle with the lower part of the figures adjacent to the interior edge. The other leg is twelve inches long, and numbered from the extremity towards the angle; the figures being read from the internal angle, as on the other side. Each of the legs is about an inch broad. This instrument is not only used as a square, but also as a level and measuring rule.

Carpentry. (Lat. Carpentum, carved wood.) An assemblage of pieces of timber connected by framing, or letting them into each other, as are the pieces of a roof, floor, centre, &c. It is distinguished from joinery by being put together, without the use of any other edge tools than the axe, adze, saw, and chisel, whereas joinery requires the use of the plane. The leading points that require attention in sound carpentry are,—1. the quality of the timber used; 2. the disposition of the pieces of timber, so that each may be in such direction, with reference to the fibres of the wood, as to be most capable of performing its office properly; 3. the forms and dimensions of the pieces; 4. the manner of framing the pieces into each other, or otherwise uniting them by means of iron, or other metal.

Carrara Marble The name of a species of white marble obtained at the quarries near the town bearing that name, in the Tuscan States. It was called *marmor lunense* and *ligustrum* by the ancients, and differs from the *Parian* marble by being harder in texture, and less bright in colour.

Carriage. The timber framework on which the steps of a wooden staircase are supported.

Carry up. See Bring up.

Cartouch. (Fr.) A name given to the modillion of a cornice used internally. It is also used to denote a scroll of paper, usually in the form of a tablet, for the reception of an inscription. In Egyptian architecture, it is applied to the form enclosing hieroglyphs, as in the annexed cut.

Carver. An artificer who cuts wood into various forms and devices. *Carving*, generally, is the art of cutting a body by recession, in order to produce the representation of an object, either in relief, or recessed within the general surface. In this sense it equally applies to the making of intaglios as to that of making cameos.

Caryatides. Figures of females used instead of columns for the support of an entablature. They were used at the temple of Erechtheus, at Athens, as shown in the illustration, *fig.* 1378. See Canephoræ. Atlantes.

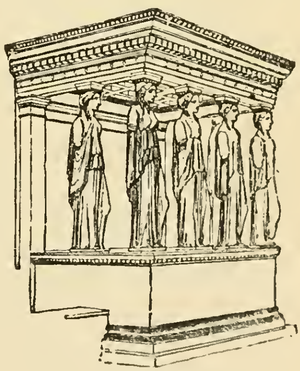

Fig. 1378.

Case. The outside covering of anything, or that in which it may be enclosed. It is also a term used to denote the carcass of a house.

Case Bays. The joists framed between a pair of girders in naked flooring. When the flooring joists are framed with one of their ends let into a girder, and the opposite ends let into a wall, they are called *tail bays*. The extent of the case-bays should not exceed ten feet.

Case of a Door. The wooden frame in which a door is hung.

Case of a Stair. The wall surrounding a staircase.

Cased. A term signifying that the outside of a building is faced or covered with materials of a better quality. Thus, a brick wall is said to be cased with stone, or with a brick superior in quality to that used in the inner part of the wall.

Cased Sash Frames. Those which have their interior vertical sides hollow, to admit the weights which balance the sashes hung between them.

Case-hardening. The process by which the surfaces of soft iron are converted into a species of imperfect steel, sufficiently hard to resist the action of an ordinary file. Hodgkinson has proved the fallacy of the assertion that if the hard skin at the outside of a cast iron bar be removed, its strength comparatively with its dimensions will be much reduced. Bars planed down on all sides to an inch square, bore a breaking-weight quite equal to those of bars cast exactly an inch square.

Casemate. A hollow moulding, such as the *cavetto*.

Casement. A glazed frame or sash, opening on hinges affixed to the vertical sides of the frame into which it is fitted.

Casing. See Lining.

Casino. (It.) A term applied to a small country house, and to a sort of lodge in a park; but formerly to one capable of affording defence on a small scale against an attacking force.

Cassinoid. An elliptic curve wherein the product of any two lines, drawn from the foci to a point in the curve, shall be equal to the rectangle under the semi-transverse and semi-conjugate diameters.

Castella. In ancient Roman architecture, reservoirs in which the waters of an aqueduct were collected, and whence the water was conducted through leaden pipes to the several parts of a city.

Castellated House. One with battlements and turrets, in imitation of an ancient castle.

Casting. In carpentry and joinery, a term synonymous with warping. It means the bending of the surfaces of a piece of wood from their original state, caused either by the gravity of the material, by its being subjected to unequal temperature, to moisture, or to the want of uniform texture of the material.

Cast Iron. It is the product of the process of smelting iron ores. Different sorts of pig iron are produced from the same ore in the same furnace under different circumstances as to temperature and quantities of fuel. Intense cold makes cast iron brittle, and sudden changes of temperature sometimes cause large pieces of it to split. The proof strength is about one third of the breaking load.

Castle. (Lat. Castellum, or Sax. Caſtel.) A building fortified for military defence; also a house with towers, usually encompassed with walls and moats, and having a donjon or keep in the centre. The principal castles of England at present are those of the Tower of London, of Dover, Windsor, Norwich, &c. At one time those of Harwood, Spofforth, Kenilworth, Warwick, Arundel, and others, might have vied with these in importance. The characteristics of a castle are its *valla* (embankments) and *fossæ* (ditches); from the former whereof the walls rise usually crowned with battlements, and flanked by circular or polygonal bastions at the angles formed by the walls. These were pierced for gates, with fixed or draw-bridges, and towers on each side. The gates of considerable strength were further guarded by descending gratings, called *portcullises*. All the apertures were made as small as they could be, consistent with internal lighting.

The component parts of the castle were—the *fosse* or *moat*, with its bridge; the *barbacan*, which was in advance of the castle, being a raised mound or tower, whose outer walls had terraces towards the castle, with their *bastions*, as above mentioned; the *gatehouse*, flanked by towers, and crowned with projections called *machicolations*, through which heavy materials, or molten lead, were dropped on the assailants entering the gateway; the *outer ballium*, or *bailey*, or area within the castle, which was separated from the inner ballium by an embattled wall with a gatehouse, and in which the stables and other offices were usually seated; and the *inner ballium*, for the residence of the owner or governor, and his retinue; this, at one corner, or in the centre, had a *donjon* or *keep tower*, which was the stronghold of the place, and contained a state apartment, a well, and a chapel; the former usually, and the latter frequently, are found in ancient castles.

Catabasion. (Gr. Καταβαινω.) A place in the Greek church, under the altar, in which relics are deposited.

Catacomb. (Gr. Κατα, against, and Κομβος, a hollow place.) A subterraneous place for burying the dead. The hypogæa, crypta, and cimeteria of the ancients were used for the same purpose. In some cities the excavations for catacombs were of vast extent, and were used for other purposes than those of sepulture; at Syracuse, for instance, the same cavern served for a prison as well as a public cemetery. It has been said, that in the early ages of Christianity they served as places of public worship or devotion. The most celebrated for their extent are those of Rome, Naples, Syracuse, &c.; and the more modern ones of Paris, which have been formed by quarrying for the stone of which a great part of the city has been built.

Catafalco. (It. a scaffold.) A temporary structure of carpentry, decorated with painting and sculpture, representing a tomb or cenotaph, and used in funeral ceremonies. That used at the final interment of Michel Angelo, at Florence, was of a very magnificent description; and, for the art employed on it, perhaps unequalled by any other before or since its employment.

Catch Drain. A drain used on the side of a larger open one, or of a canal, to receive the surplus water of the principal conduit.

Catenary Curve. The mechanical curve formed by a heavy flexible cord or chain of uniform density, hanging freely from the two extremities. Galileo first noticed it, and proposed it as the proper figure for an arch of equilibrium. He, however, imagined that it was the same as the parabola. It was James Bernouilli who first investigated its nature, and its properties were thereafter pointed out by John Bernouilli, Huygens, and Leibnitz. From the first of these mathematicians, the following geometrical method of determining the relations between the parts of a catenary is translated. The catenarean curve is of two kinds, the *common*, which is formed by a chain equally thick or equally heavy in all its points; or *uncommon*, which is formed by a thread unequally thick, that is, which in all its points is unequally heavy, and in some ratio of the ordinates of a given curve. To draw the common catenary mechanically, suspend on a vertical plane a chain of similar and equal links of homogeneous matters, as flexible as possible, from any two points not in a perpendicular line, nor so distant from each other as the length of the chain. Prick the plane through the links as nearly as possible in the middle of the chain, and through the points draw the catenary (*fig.* 1379.) Let the chord FBD or F*bd* be given, and the abscissa BA or *b*A intersecting it (*fig.* 1379) in B or *b* at a given angle. Draw the vertical line BA and FBD or F*bd* at the given angle on the plane. Fix one end of the chain at F, and from the point D or *d*, with another part of the chain, raise or lower the chain until the lower part coincides with A, and through points, made as before, draw the curve.

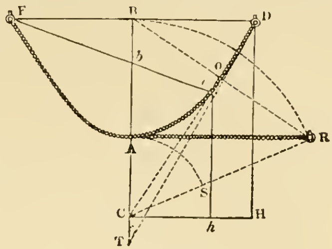

Fig. 1379.

To draw a tangent to the catenary: let DBF be a horizontal line, and at right angles to BA from A draw AR equal to the curve DA, obtained as before, and draw BR, which bisect in *o*. At right angles to BR draw *o*C intersecting BA continued in C. Draw CR, and make the angle BDT equal to the angle ACR. DT is the tangent required, and BC equals CR; CA is the tension at the point A, or the horizontal draft, which, in a catenary, is in every point the same, and is therefore a constant quantity; as DB : BT : : CA : AR: or as DB : BT : : the constant quantity CA: AR, equal to the length of the chain AD.

If CH be drawn through C at right angles to BC it is called the directrix, and DH drawn parallel to BC, intersecting the directrix at H, is the tension at the point D, being always equal to the sum of the abscissa and constant quantity. With the centre C and radius = the tension DH at D = CB, cut the tangent at the vertex A in R, then AR is the length of the chain AD.

AC is the semi-axis of an equilateral hyperbola, and also the radius of curvature of a circle equicurved with it and the catenary.

In the triangle CAR, when CA is the radius, then the tension equals CR, the secant of the angle ACR (= BDC). The chain AD equals AR, the tangent of the same angle and the absciss AB equals CR − CA = SR. Hence, ACR being a right-angled triangle, it is manifest that when two of the five quantities, viz. *the angle*, *the absciss*, *the length of the chain between the vertex and points of suspension*, *the constant quantity or tension at the vertex*, *and the tension at the points of suspension*, are known, the other three may be obtained geometrically, or from a table of tangents and secants.

Cathedral. (Gr. Καθεδρα, a seat or throne.) The principal church of a province or diocese, wherein the throne of archbishop or bishop is placed. It was originally applied to the seats in which the bishop and presbyters sat in their assemblies. In after times, the bishop's throne was, however, placed in the centre of the apsis, on each side whereof were inferior seats for the presbyters. In the present day the bishop's throne is placed on one side of the choir, usually on that towards the south.

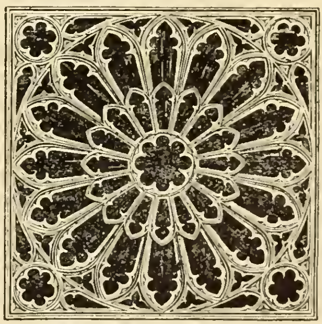

Fig. 1380. Westminster Abbey.

Catherine Wheel Window also called Marigold Window. In mediæval buildings a window or compartment of a window of a circular form with radiating divisions or spokes. Examples are seen at Patrixbourne, York, St. Davids, of a small size; while at Westminster (*fig.* 1380) south transepts of St. Ouen at Rouen, and of Amiens cathedral, and at the cathedral of Strasbourg, they are of larger size. See Rose Window.

Cathetus. (Gr. Καθετος, let down.) A perpendicular line passing through the centre of a cylindrical body as a baluster or a column. It is also a line falling perpendicularly, and passing through the centre or eye of the volute of the Ionic capital.

Cattle Shed, or Cattle House. In agricultural buildings, an erection for containing cattle while feeding, or otherwise. The cattle shed is, of course, most economically constructed when built against walls or other buildings. If cattle sheds are built in isolated situations, the expense of a double shed will be much less than that of a single one, to contain the same number of cattle. Buildings of this description should be well ventilated, and be so constructed as to require the least possible labour in supplying the food, and clearing away the dung. The stalls should be placed so as to keep the cattle dry and clean, the floor level and with sufficient drains to receive the ordure, and to be readily flushed. There should be good provision of air holes in the roof; and, if the building have gables, a window should be placed in each as high as possible with movable *luffer-boards*, which may be easily opened and shut. A cubical space is required of not less than 1000 feet for each animal, whether there are inhabited rooms over the shed or not. The cattle plague first broke out in the central districts of London, where the space allotted did not exceed 450 cubic feet. Many of the model farms and stockbreeders now use iron cow-stalls, to assist in preventing the spread of rinderpest. A bullock averages 7 feet 6 inches in length, 5 feet in height, and 2 feet 6 inches in width. The stall should be 5 feet wide for each milch cow, or 6 feet if kept indoors all the year, the building being 16 feet wide; the top of the manger not more than from 12 to 18 inches above the floor, 18 inches broad, and 12 inches deep, with three divisions, for moist and dry food and water. See BULLOCK SHED.

The infectious effluvia from the private slaughter-houses often causing contagious maladies in their neighbourhood, the French government in 1811 removed all such buildings from the heart of their capital. For this purpose five open airy spots were selected in the outskirts of the city; those at Ménilmontant and Montmartre are the most considerable and extensive. These five establishments were later merged into one large abattoir. Happe was the architect of the former; and the cost was something above 120,000*l*.

The Metropolitan Cattle Market was designed by the late Mr. J. B. Bunning, City Architect, and opened in 1855. Several additions have since been made by the late Sir Horace Jones, City Architect. A market and abattoir was designed 1870–71, at Deptford, by the same architect, for the City of London, where foreign cattle are landed, inspected, sold, and slaughtered. The cost of the market, including 95,000*l*. paid for the site of 22 acres, was 210,000*l*.

Of late years several such buildings have been erected, as at Glasgow, Edinburgh, and Bradford; and a carcase market with butchers' slaughter-houses adjoining, at Manchester. A description of this building, erected from the designs of Mr. A Darbyshire, was read by him at the Royal Institute of British Architects, Feb. 1, 1875; and as it is considered a well-arranged structure for its purposes, a few details will be given. It is in the shape of the letter L. In the long side fronting Water Street are the entrances, and the carcase market, 418 feet long and 55 feet 6 inches wide, paved with asphalte. Behind this are the wholesale slaughter-houses, twenty-one in number, each being 24 feet by 17 feet 6 inches inside, with a lair attached in rear, 22 feet by 17 feet 6 inches. Both of these are open to the roof, but entirely separated, and the former well lighted by rows of glass slates, which light is superior to side windows for the several operations necessary. The former has a glazed enamelled brick dado, 5 feet high, and a plentiful supply of water. They are paved with Yorkshire stone. In rear of part of the above are placed nineteen retail slaughter-houses similar to the above. In rear of these latter is the condemned meat department, consisting of a lair, slaughter-house, meat store, and boiling-house. The blood department consists of a storing-room, drawing-off room, and drying-room. The pig slaughtering department is adjacent, and contains a large pig slaughter-house, open yard, and piggeries. The two lodges at the gates (through which all cattle must enter the abattoir) contain residences for the porter and the inspector, with rooms for the convenience of the markets committee. The site also contains a large general lair for cattle, a manure pit, and a common room for drovers and others; suitable conveniences at various points; and a stable and gig-house for the inspector. The total cost was somewhat over 30,000*l*. Space prevents us from following the author through his explanation in detail of the uses to which the various buildings are applied, but one very important feature remains to be noticed. A simple and effectual apparatus has been provided by the engineer, Mr. John Meiklejohn, of Dalkeith, by which the carcase when ready is placed on a hoist, and moved along rails across the roadway into the market, or placed into the carts; this apparatus also allows the seller to detach any particular carcase from the others, and deposit it in the cart of the buyer, without in any way disturbing the other carcases hanging on the beams. A considerable amount of manual labour is saved; and, in addition, the meat intended for human food receives as little handling as possible after being dressed, and is not transferred at any time to the dirty and greasy backs and shoulders of the slaughterers. The private slaughter-houses have the same hoisting apparatus, but the carcase is placed at once in carts and removed to the butcher's shop. At the Edinburgh abattoir a central crane and semicircular hanging beam is in operation; while at Bradford an hydraulic lifting power is in use.

A very interesting discussion followed the reading of the paper, in reference to private slaughter-houses; the best mode of lighting; the paving; the use of a tripery at the abattoir; blood stores; a place for salting hides; and other apparatuses. An important fact was stated, tending to the greater introduction of killing animals in the country and sending the carcases up to the "dead meat" markets in cities and towns:—that it has been proved that if an animal be slaughtered in Edinburgh, near where it was fed, and another be taken from the same herd and sent as carefully as possible to London by railway, and slaughtered there, the latter loses at least three stones in weight as compared with the former, and this represents a sovereign.

CATTUS. A moveable shed usually fixed on wheels.

CAUL. An implement used hot in veneering to keep the glue moist, while at the same time it presses down the veneer until it cools.

CAULICOLÆ or CAULICOLI. (Lat. Caulis, a stalk.) The eight lesser branches or stalks in the Corinthian capital springing out from the four greater or principal caules or stalks. The eight volutes of the capital of the order in question are sustained by four caules or leaves, from which these caulicolæ or lesser foliage arise. They have been sometimes confounded with the *helices* in the middle, and by others with the principal stalks whence they arise.

CAULKING or COCKING. The mode of fixing the tie-beams of a roof or the binding joists of a floor down to the wall-plates. Formerly this was performed by dovetailing in the following manner:—A small part of the depth of the beam at the end of the under side was cut in the form of a dovetail, and to receive it a corresponding notch was formed in the upper side of the wall-plate, across its breadth, making, of course, the wide part of the dovetail towards the exterior part of the wall, so that the beams, when laid in their notches, and the roof finished, would greatly tend to prevent the walls separating, though strained by inward pressure, or even if they should have a tendency to spread, through accidents or bad workmanship. But beams so fixed have been found liable to be drawn to a certain degree out of the notches in the wall-plates from the shrinking of the timber. A more secure mode is that of forming a sort of pin out of the upper side of the plate, with a notch in the beam, which obviates all hazard of one being drawn out of the other.

CAUSTIC CURVE. (Gr. Καιω, to burn.) The name given to a curve, to which the rays of light, reflected or refracted by another curve, are tangents. The curve is of two kinds, the *catacaustic* and the *diacaustic;* the former being caused by reflection, and the latter by refraction.

CAVÆDIUM. (Lat.) In ancient architecture an open quadrangle or court within a house. The cavædia described by Vitruvius are of five species:—*Tuscanicum, Corinthium, Tetrastylon* (with four columns), *Displuviatum* (uncovered), and *Testudinatum* (vaulted). Some authors have made the cavædium the same as the atrium and vestibulum, but they were essentially different.

CAVE. (Lat. Cavum.) A hollow place.

CAVEÆ. (Lat.) In ancient architecture the subterranean cells in an amphitheatre, wherein the wild beasts were confined in readiness for the fights of the arena. In the end the amphitheatre itself (by synecdoche) was called cavea, in which sense it is employed by Ammianus Marcellinus, lib. xxix. cap. i.

CAVETTO. (Lat. Cavus.) A hollowed moulding, whose profile is the quadrant of a circle. It is principally used in cornices.

CEDAR. (Gr. Κεδρος.) The pinus cedrus of Linnæus, a forest tree little used in this country, except for cabinet work.

CEILING. (Lat. Cœlum.) The upper horizontal or curved surface of an apartment opposite the floor, usually finished with plastered work.

CEILING JOISTS. Small beams, which are either mortised into the sides of the binding joists, or notched upon and nailed up to the under sides of those joists. The last mode diminishes the height of the room, but is more easily executed, and is by some thought not so liable to break the plaster as when the ends of the ceiling-joists are inserted into *pulley mortises.*

CELL. (Lat. Cella.) In ancient architecture the part of a temple within the walls. It was also called the *naos*, whence the word *nave* in a church. The part of a temple in front of the cell was called the *pronaos*, and that in the rear the *posticum*. See VIMANA of the Hindoos. It is also the chamber in which a prisoner is confined.

CELLAR. (Fr. Cellier.) The lower story of a building, wholly or partly under the level of the ground, and not adapted for habitation, but merely for lumber, storage purposes, coals, wine, and such like: and having openings into the outer air for ventilation only. Coal cellars in the metropolis are arched vaults under the street paving.

CELLULAR BEAMS. Beams made of wrought iron plates, rivetted together, and whose strength depends upon the system of cells placed at the top of the web or over the cell, which takes the place of it in a larger beam or girder. In very large ones, cells are also placed under it.

CELTIC ERECTIONS. The manner of building adopted by the early inhabitants of the Northern part of Europe, comprising chiefly the erection of large stones in a variety of forms, and of tumuli in which are found chisels and adzes of bronze or hard stone, hence the name of *celts* derived from *celtes*, the ancient Latin word for a chisel. They are discovered in great quantities in England, Ireland, and France.

Cement. (Lat. Cementum.) The medium through which stones, bricks, or any other materials are made to adhere to each other. See Mortar.

Cemetery. (Gr. Κοιμάω, to sleep.) An edifice or area where the dead are interred. The most celebrated public cemeteries of Europe are those of Naples, that in the vicinity of Bologna, of Pisa, and the more modern ones of Paris, whereof that of Père-la-Chaise is the principal. That of Pisa is particularly distinguished by the beauty of its form and architecture, which is of early Italian Gothic. It is 490 feet long, 170 feet wide, and 60 feet high, cloistered round the four sides.

Cenotaph. (Gr. Κενὸς, empty, and Τάφος, a sepulchre.) A monument erected to the memory of a person buried in another place.

Centering. The temporary woodwork or framing, whereon any vaulted work is constructed, and sometimes called a *centre*.

Centre. (Lat. Centrum.) In a general sense denotes a point equally remote from the extremes of a line, superficies, or body, or it is the middle of a line or plane by which a figure or body is divided into two equal parts; or the middle point so dividing a line, plane, or solid, that some certain effects are equal on all its sides. For example, in a circle the centre is everywhere at equal distance from the circumference; in a sphere the centre is a point at the same distance from every point in the surface.

Centres of a Door. The two pivots on which the door revolves.

Centrolinead. An instrument for drawing lines converging to a point at any required distance, whether accessible or inaccessible. It is used for making drawings in perspective.

Ceroma. (Gr.) An apartment in the Gymnasia and baths of the ancients, where the bathers and wrestlers were anointed with oil thickened by wax, as the name imports.

Cesspool, or Sesspool. A small well sunk below the mouth of a drain to receive the sediment which might otherwise choke up its passage, in its course to its outfall.

A cesspool is also a well sunk to receive the soil from a water-closet, or kitchen sink, drain hole to a path, &c. It is sometimes built dry so that the water percolates through the joints of the stone or brickwork into the surrounding soil; or it is built in mortar, and a drain formed to carry off the surplus water from near the top of it. When found to be full, the cesspool is emptied and the contents carted away, or used for garden manure, &c.

Chain Moulding. An ornament of the Norman period, carved in imitation of a chain.

Chain Timber. See Bond.

Chair Rail. A piece of wood fastened to a wall, to prevent the backs of the chairs injuring the plastering when placed against it. This result is often better effected by fixing a fillet of sufficient projection on the floor, next the skirting, for the feet of the chair to strike against, similar to that frequently put to cover the nails securing the carpet.

Chaitya Cave. The name given to a class of rock-cut Buddhist temples in India, *Chaitya* meaning an object of worship, whether an image, a tree, an edifice, or mountain. They resemble in almost all particulars, both of form, size, and purpose, the choirs of Gothic churches of the eleventh or twelfth centuries: the dagoba occupying the place of the altar, and being like it, simply a relic shrine. They are seen at Karli, Ajunta, and other places.

Chalcidicum. (Lat.) In ancient architecture, a term used by Vitruvius to denote a large building appropriated to the purpose of administering justice, but applied sometimes to the tribunal itself.

Chalk. (Germ. Kalk.) Earthy carbonate of lime, found in abundance in Great Britain, and, indeed, in most parts of the world. It is insoluble in water, but decomposed by heat, and sometimes used in building for the same purposes as limestone.

Chamber. (Fr. Chambre.) Properly a room vaulted or arched, but the word is now generally used in a more restricted sense to signify an apartment appropriated to lodging. With the French the word has a much more extensive meaning; but with us the almost only use of it, beyond what is above stated, is as applied in a palace to the room in which the sovereign receives the subject, which room is called the Presence Chamber.

Chamber of a Lock. In canals the space between the gates in which the vessels rise and sink from one level to another, in order to pass the lock.

Chamber Story. That story of a house appropriated for bed-rooms.

Chambranle. (Fr.) An ornamental bordering on the sides and tops of doors, windows, and fireplaces. This ornament is generally taken from the architrave of the order of the building. In window frames the sill is also ornamental, forming a fourth side. The top of a three-sided chambranle is called the *transverse*, and the sides *ascendants*.

Chamfer. (Fr. Chamfrein.) The arris of anything originally right-angled, cut aslope, or bevel, so that the plane it then forms is inclined less than a right angle to the other planes with which it intersects. If it is not carried the whole extent of the piece, it is returned and then is said to be 'stop chamfered.'

CHAMPAIN LINE. In ornamental carved work formed of excavations is the line parallel to the continuous line, either ascending or descending.

CHANCEL. That part of the eastern end of a church in which the altar is placed. See CANCELLI. This is the strict meaning; but in many cases the chancel extends much farther into the church, the original divisions having been removed for accommodating a larger staff of clergy. The word is also used to denote a separate division of the ancient basilica, latticed off to separate the judges and council from the audience part of the place.

The chancel of a Protestant church is now raised two or three steps above the pavement of the nave, and provided on each side with two rows of benches or stalls for choristers; on the north side in a sort of chapel or recess is placed the organ, and behind which is sometimes the choristers' vestry, attached to the vestry for the clergy. Beyond, is the part called the *sacrarium*, railed off, with a step for the communicants, and inside which is the altar or communion table placed on a platform raised two or three steps. In a large chancel, the space will allow of two or three chairs or perhaps sedilia for the clergy on the south side, with an aumbry for the church utensils, and a credence table or shelf for the bread and wine before being placed on the table.

CHANDRY. An apartment in a palace or royal dwelling for depositing candles and other lights.

CHANNEL OF THE LARMIER, AND OF THE VOLUTE. See CANAL OF THE LARMIER, AND OF THE VOLUTE.

CHANNEL. (Fr. Canal.) A long gutter sunk below the surface of a body, as in a street, and serving to collect and run off the rain water with a current.

CHAORI. A great porch or hall, as used in India, usually attached to the *Vimana* with its *mantapa* and *antarala*, all three forming the temple properly speaking. This porch in lower India is called a *maha mantapa*, and is generally used for marriage ceremonies and religious ceremonies performed in public.

CHANTLATE. A piece of wood fastened at the end of rafters, and projecting beyond the wall, to support several rows of slates or tiles, being so placed as to throw off the rain-water from the face of the wall.

CHANTRY. (Lat. Cantaria.) A little chapel in ancient churches with an endowment for one or more priests to say mass for the release of souls out of purgatory. In the fourteenth year of Edward VI., all the chantries in England were dissolved: at this period there were no less than forty-seven attached to St. Paul's Cathedral.

CHAPEL. (Lat. Capella.) A building for religious worship, erected separately from a church, and served by a chaplain. In Catholic churches, and in cathedrals and abbey churches, chapels are usually annexed in the recesses on the sides of the aisles. These are also called chantries. It is also the name of the building erected for worship by the dissenters and others.

CHAPITER. The same as CAPITAL.

CHAPLET. (Fr. Chapelet.) A moulding carved into beads, olives, and the like. See BAGUETTE.

CHAPTER HOUSE. In ecclesiastical architecture the apartment (usually attached) of a cathedral or collegiate church in which the heads of the church or the chapter meet to transact business. These council chambers date back in England as far as the time of Archbishop Cuthbert at Canterbury. On the Continent the chapter houses, for the most part, are square or oblong rooms with timber roofs. In the ninth century, the east alley of the cloister was used as a chapter house, but in the tenth, a distinct building was formed for it at Fontenelle. In the eleventh century king Edward the Confessor erected a round and vaulted chapter house at Westminster. It is a remarkable fact that the Benedictine monks almost invariably built polygonal, while the Seculars erected rectangular, chapter houses. The two exceptions to the rule are those of Worcester and Westminster. From the commencement of the thirteenth century a polygonal shape was adopted; a decagon as at Hereford, St. Paul's at London, Bridlington, Lichfield, and Lincoln, and at Worcester though it is a circle internally; an octagon at Wells, York, Salisbury, and Westminster. At Westminster, Wells, and St. Paul's, it was built over a crypt.

	Dates.	Diameter.		Dates.	Diameter.
Lincoln	1186–1203	60 ft.	Worcester	1263–1372	48 ft.
York completed	about 1350	57 ft.	Salisbury	1263–1270	58 ft.
Wells	1293–1302	55 ft. by 42 ft.	Westminster	1250	58 ft.
Lichfield	about 1240	44 ft. by 26 ft.			

CHAPTREL. (Fr.) The same as IMPOST.

CHARCOAL. Bones or vegetable matter decomposed by heat without the free access of air. Its sanitary properties consist in its power of absorbing gases, which is most efficient when the charcoal is powdered. Animal charcoal is better than that of wood, or of peat, for the purposes of disinfection. When cleansing cesspools, the charcoal should be mixed with the soil. When used to destroy foul air, the charcoal requires to be exposed in thin films, presenting the greatest possible surface. It is essentially necessary to the proper filtration of water. It is a bad conductor of heat, but conducts electricity.

CHARGED. A term used to denote that one member of a piece of architecture is sustained by another. A frieze is said to be *charged* with the ornament cut on it.

CHARNEL HOUSE. A place where the bones of the dead are deposited.

CHARTOPHYLACIUM. A recess or apartment in an ancient building, for the preservation of records or valuable writings.

CHASE. An upright indent cut in a wall for the joining another to it. It also means an indent cut in a wall, into which a pipe or some such article is placed.

CHASE MORTISE, or PULLEY MORTISE. A long mortise cut lengthwise in one of a pair of parallel timbers, for the insertion of one end of a transverse timber, by making the latter revolve round a centre at the other end, which is fixed in the other parallel timber. This may be exemplified in ceiling joists where the binding joists are the parallel timbers first fixed, and the ceiling are the transverse joists.

CHATEAU. The modern French form of the word castle, and used for a castle, fort, or country mansion.

CHEEKS. Two upright, equal, and similar parts of any piece of timber-work. Such, for instance, as the sides of a dormer window.

CHEEKS OF A MORTISE are the two solid parts upon the sides of the mortise. The thickness of each cheek should not be less than the thickness of the mortise, except mouldings on the stiles absolutely require it to be otherwise.

CHEESE ROOM. A room set apart for the reception of cheeses after they are made. The walls should be lined, and fitted up with shelves with one or more stages, according to the size of the room, and proper gangways for commodious passage. In places where much cheese is manufactured, the dairy-room may be placed below, the shelf-room directly above, and lofts may be built over the shelf-room, with trap-doors through each floor. This will save much carriage, and will be found advantageous for drying the cheeses.

CHEQUERS. In masonry, are stones in the facings of walls, which have all their thin joints continued in straight lines, without interruption or breaking joints. Walls built in this manner are of the very worst description; particularly when the joints are made horizontal and vertical. Those which consist of diagonal joints, or joints inclined to the horizon, were used by the Romans.

CHESNUT or CHESTNUT. The *fagus castanea.* A large tree chiefly grown in England in ornamental grounds. It has often been stated that its timber has been used in building, but no satisfactory proof has been adduced. Where wide planks can be procured without a fault, they have perhaps been used for panels and carving, as the wood is very similar to wainscot, but is without the flower.

CHEST. The same as CAISSON.

CHEVET. A term used by French architects and antiquaries to denote the surrounding aisles to the choir of a cathedral, from their resemblance on the plan to the form of a bolster.

CHEVRON MOULDING. A zigzag ornament used in the archivolts of Saxon and Norman arches, similar to *fig.* 1381.

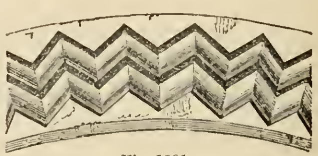

Fig. 1381.

CHIMÆRA. A monster of the Grecian mythology, described as having a lion's head, a goat's body, and the tail of a dragon. Out of the back grows the head and neck of a goat. One such piece of sculpture, brought to England by Sir Charles Fellowes from Asia Minor, is now in the British Museum.

CHIMNEY. (Fr. Cheminée.) The place in a room where a fire is burnt, and from which the smoke is carried away by means of a conduit, called a funnel or a flue. Where the walls are sufficiently thick, the chimneys are formed in the substance of them, but they are usually made by a projection from a wall and a recess in the same from the floor ascending within the limits of the projection and the recess. That part of the opening which faces the room is properly called the *fireplace*, the stone, marble, or metal, under which is called the *hearth.* That on a level with and in front of it is the *slab*, though often called the hearth. The vertical sides of the opening are called *jambs.* The head of the fore-plate resting on the jambs is called the *mantel.* The tube or cavity from the fireplace upwards is called the *funnel* or *flue.* The part of the funnel which contracts as it ascends is termed the *gathering*, by some the *gathering of the wings.* The part between the gathering and the flue is called the *throat.* The part of the wall facing the room, and forming one side of the funnel parallel thereto, or the part of the wall forming the sides of the funnels where there are more than one, is the *breast*. In external walls, that side of the funnel opposite the breast is called the *back*. When there is more than one chimney in the same breast, the solid parts that divide them are called *withs* or *withes*: and when several chimneys are collected into one mass, it is called a *stack of chimneys*. The part which rises above the roof, for discharging the smoke into the air, is called a *chimney shaft*, whose horizontal upper surface is termed the *chimney-top*; on this is placed the *chimney-pot*, or contrivance for dissipating the smoke, or for creating a draught.

The *covings* were formerly placed at right angles to the face of the wall, and the chimney was finished in that manner; but Count Rumford showed that more heat is obtained from the fire by reflection when the covings are placed in an oblique position. He likewise directed that the fire itself should be kept as near to the hearth as possible, and that the throat of the chimney should be constructed much narrower than had been practised, with the view of preventing the escape of so much heated air as happened with wide throats. If the throat be too near the fire, the draught will be too strong, and the fuel will be wasted; if it be too high up, the draught will be too languid, and there will be danger of the smoke being occasionally beaten back into the room. The chimney of large furnaces and for boilers is called a *stalk*, and built very tall in order to create sufficient draught for the fire.

Chimney Piece. The assemblage of architectural dressings around the open recess constituting the fireplace in a room, and within which the fuel is burnt, either immediately upon the hearth itself, or in a raised grate, or open stove. Formerly fireplaces were provided only in the principal rooms of a house; those in public rooms, as town halls, became fine pieces of architecture.

Chinese Architecture. In the tent is to be found the type of this architecture. A characteristic quality is gaiety of effect. The coloured roofs, porches diapered with variegated tints, the varnish with which the woodwork is covered, the light forms of the buildings, all unite in producing a style very different to that seen in other countries. The towers called pagodas, and the arches, are two of the peculiar erections of that country.

Chip. A piece of any material cut by an acute-angled instrument.

Chisel. An instrument used in masonry, carpentry, and joinery, and also by carvers and statuaries, for cutting either by pressure or by impulse from the blows of a mallet or hammer. There are various kinds of chisels; the principal ones used in carpentry and joinery are the *former*, the *paring chisel*, the *gouge*, the *mortise chisel*, the *socket chisel*, and the *ripping chisel*.

Chiseled Work. In masonry, the state of stones whose surface is formed by the chisel.

Chit. An instrument used for cleaving laths.

Choir. (Gr. Χορος.) The part of a church in which the choristers sing divine service. In former times it was raised separate from the altar, with a pulpit on each side, in which the epistles and gospels were recited, as is still the case in several churches on the Continent. It was separated from the nave in the time of Constantine. In nunneries, the choir is a large apartment, separated by a grate from the body of the church, where the nuns chaunt the service. In churches in Italy, the *cors* is moveable, and is held sometimes in one part of the church, and sometimes in another. See Chancel.

Choir Screen or Rood Screen. An ornamental open screen of wood or stone, dividing the choir or chancel from the nave, yet so as not to obstruct sight or sound. The modern choir screen at Hereford Cathedral has been formed of wrought iron and decorated. See Jubé.

Choragic Monument. (Gr. Χορος.) In Grecian architecture, a monument erected in honour of the choragus who gained the prize by the exhibition of the best musical or theatrical entertainment at the festivals of Bacchus. The choragi were the heads of the ten tribes at Athens, who overlooked and arranged the games at their own expense. The prize was usually a tripod, which the victor was bound publicly to exhibit, for which purpose a building or column was usually erected. The remains of two very fine monuments of this sort, viz. of Lysicrates and Thrasyllus, are still to be seen at Athens.

Chord. In geometry the straight line which joins the two extremities of the arc of a curve; so called from the resemblance which the arc and chord together have to a bow and its string, the chord representing the string.

Choultry (properly *Chaturam*). A Tatar term for a post house, lodge, or hall for travellers. It is only used in the Madras Presidency. There are various sorts, from a mere shed (*chauvadi*), one in which images are sometimes placed (*mandapam*), to the true choultry, built expressly as an inn or caravanserai.

Chrismatory. A recess resembling a piscina, near the spot where the font originally stood, to contain the chrism, or holy oil, with which, after baptism, infants were anointed.

Church. (Gr. Κυριακον, from Κυριος, Lord.) A building dedicated to the performance of Christian worship. The basilicæ were the first buildings used for the assembly of the early Christians. Among the first of the churches was that of St. Peter at Rome, about the year 326, nearly on the site of the present church; and it is supposed that the first church of St. Sophia at Constantinople was built somewhat on its model. That which was afterwards erected by Justinian seems, in its turn, to have afforded the model of St. Mark's, at Venice, which was the first in Italy constructed with pendentives and a dome, the former affording the means of covering a square plan with a hemispherical vault. The four most celebrated churches in Europe erected since the revival of the arts are, St. Peter's at Rome, which stands on a area of 227,069 feet superficial; Sta Maria del Fiore at Florence, standing on 84,802 feet; St. Paul's, London, which stands on 84,025 feet, and St. Geneviève at Paris, 60,287 feet. The churches on the Continent are usually ranged under seven classes; *pontifical*, as St. Peter's, where the pope occasionally officiates; *patriarchal*, where the government is in a patriarch; *metropolitan*, where an archbishop is the head; *cathedral*, where a bishop presides; *collegiate*, when attached to a college; *parochial*, attached to a parish; and *conventual* when belonging to a convent. In this country the churches are cathedral, abbey, and parochial, and those belonging to the numerous classes of dissenters, which until late years were called chapels, and by some denominations are still so called. A list of large churches in England is given in the *Builder* journal, 1865, page 123, and 1867, page 701. The designs of the *temples* of the ancients are given in this Glossary.

The early Christian worship, attended by large congregations, required for its exercise edifices whose interiors were of great extent and well lighted. Nothing was so well adapted for this purpose as the basilicæ, which, bearing the name from their resemblance to the ancient courts of justice, were raised for the purpose. Such was that of St. Paul without the walls of Rome (*figs.* 141. and 142.). That of St. Giovanni Laterano was divided by four ranks of columns, which supported the walls, carrying the roofs of five aisles formed by the ranks of columns, the middle one or nave being wider and higher than the others. Each aisle being lower than that adjoining it, allowed windows to be introduced in the several walls. The direction of the length of the nave and aisles was from east to west, and was crossed by a transverse nave, called a transept, from north to south. In front was an ample porch or portico. The use of the modern church being the same as that of the first Christian basilicæ, it may be doubted whether for extremely large assemblies a better disposition could be chosen. Bramante imitated the Temple of Peace in the design for the new church of St. Peter. The desire of gathering into a single edifice the beauties of several, induced the architect to crown the edifice imitated from the Temple of Peace with another, imitated from the Pantheon. The obstruction to seeing and hearing caused by the large piers of the later churches is a great defect when compared with the little obstruction that the columns of the basilicæ present. The cost of the Italian churches is another serious objection to them, especially in the construction of the domes, which are, with their tambours, buildings deficient in real solidity, from the large portion of false bearing they must involve; creating a very different sensation to that experienced in viewing the lantern, as at Peterborough and Ely Cathedrals.

The smaller parish church, with its nave and an aisle on each side, is not only the most economical, but the best form of plan. It was that which best pleased Sir Christopher Wren, whose churches are generally so planned; and we shall here give a short account of one of his best of this form, that of St. James's, Westminster, whose interior is worthy of all praise. It is an excellent example of Wren's love of harmony in proportions; the breadth being half the sum of its height and length, its height half its length, and its breadth the sesquialtera of its height: the numbers are 84, 63, and 42 feet. The church is divided transversely into three unequal parts, by a range of six columns on each side of the nave, forming aisles which are each one-fifth of the whole breadth, the remaining three-fifths being given to the breadth of the nave. The roof is carried on these columns, and is as great a proof of the consummate skill of the architect as any portion of the fabric of St. Paul's, on account of its extreme economy and durability. It is not further necessary to describe the building; but the observations of its architect with regard to it are of the utmost value, emanating from such a man. "I can hardly think it possible," says the architect, "to make a single room so capacious, with pews and galleries, as to hold above two thousand persons, and all to hear the service, and both to hear distinctly and see the preacher. I endeavoured to effect this in building the parish church of St. James's, Westminster, which, I presume, is the most capacious, with these qualifications, that hath yet been built; and yet at a solemn time, when the church was much crowded, I could not discern from a gallery that two thousand were present. In this church I mention, though very broad, and the middle nave arched up, yet as there are no walls of a second order, nor lanterns, nor buttresses, but the whole roof rests upon the pillars, as do also the galleries, I think it may be found beautiful and convenient, and, as such, the cheapest of any form I could invent." On the place of the pulpit in a church of this class, the same architect continues: "Concerning the placing of the pulpit, I shall observe, a moderate voice may be heard fifty feet distant before the preacher, thirty feet on each side, and twenty behind the pulpit; and not this, unless the pronunciation be distinct and equal, without losing the voice at the last word of the sentence, which is commonly emphatical, and if obscured spoils the whole sense. A Frenchman is heard farther than an English preacher, because he raises his voice, and not sinks his last words." Speaking of the dimensions of a church, Wren, after stating that a proposed church may be 60 feet broad, and 90 feet long, "besides a chancel at one end, and the belfry and portico at the other," says: "These proportions may be varied; but to build more room than that every person may conveniently hear and see, is to create noise and confusion. A church should not be so filled with pews but that the poor may have room enough to stand and sit in the alleys, for to them equally is the gospel preached. It were to be wished there were to be no pews but benches; but there is *no stemming the tide of profit*, and the advantage of pewkeepers; especially, too, since by pews in the chapels of ease the minister is chiefly supported."—"As to the situation of the churches, I should propose they be brought as forward as possible into the larger and more open streets, not in obscure lanes, nor where coaches will be much obstructed in the passage. Nor are we, I think, too nicely to observe east or west in the position, unless it falls out properly: such fronts as shall happen to lie most open in view should be adorned with porticoes, both for beauty and convenience; which, together with handsome spires or lanterns, rising in good proportion above the neighbouring houses (of which I have given several examples in the city, of different forms), may be of sufficient ornament to the town, without a great expense for enriching the outward walls of the churches, in which plainness and duration ought principally, if not wholly, to be studied."

Churches are usually constructed on the plan of a *Greek cross*, which is that wherein the length of the transverse part, or transept, is equal to that of the nave; of a *Latin cross*, wherein the nave is longer than the transept; of a *Lorraine cross*, where there is a transept given to the long choir, as in a cathedral; *in rotondo*, where the plan is a circle; *simple*, where the church has only a nave and choir; *with aisles*, when a subdivision occurs on each side of the nave; and those with aisles may have more than one of such aisles on each side of the nave.

The church being a building in which to do work, the work to be done in one is to carry out the distinctive worship of the body to which it belongs. Hence the church of every communion, if true to its nature, must vary as the worship of that communion varies. As the English Reformation involved no breach of continuity, the ancient churches of this land have in the main served well for present use. But the aim of that Reformation was to reduce the many services of the older ritual into an order at once simple and congregational, and the modern English church ought therefore to be simple in its plan and congregational in its working arrangements, absorbing as many of the people into the more active work of worship as possible. Therefore with a great town congregation the building should be broad and high, as well as long, and solid and dignified in every part. It must be broad in proportion to the number for which it is intended, for if the nave be narrow many will not see or hear sufficiently. Might not the nave be sometimes polygonal or circular, as at the Temple Church, and the decagon of St. Gereon at Cologne?—or a wide nave with proportionately narrow aisles, serving rather as passages than omitted altogether? Chairs or benches are both good in their respective ways. The baptistery should be emphasized. The choir or chancel proper ought not to be much elevated above the nave; practically the raising will be found inconvenient, and artistically many steps at the chancel arch can seldom be successfully managed. The great rise might be between the chancel and the sanctuary leading up to the table. The elevation compensates for the necessary distance, and places the table in full sight of the whole church. The choir or chancel screen is claimed as "distinctly and emphatically Anglican." A low screen of stone or with metal rails is frequently introduced in place of it. The *Ecclesiologist* journal, 1845, p. 135, contains an elaborate paper on the division of a church into nave, chancel, and sacrarium.

The chancel should also be broad; usually one or perhaps two rows of seats or stalls on each side are provided; but might not three, and four rows even, be appropriately introduced for the necessary choir, and made without encroaching on the gangway in the middle? A useful paper on the *Choral Arrangements of Churches* was read at the Northampton Architectural Society, in Oct. 1870. In a large town church the usual three *sedilia* sometimes provided may be found too few; a stone bench on either side may suit better. An apse or a square end to the chancel must depend on the circumstances of the case. It is now the fashion to place the "organ chamber" in the north or south side of the chancel, hiding away the instrument and muffling the sound. With a large choir and a lofty chancel, it might with advantage project over the stalls on one or both sides. It has been proposed to place the Litany desk, made capable of containing two or three clerks, in a space left free of sittings at the easternmost bay of the nave, or in the central crossing where there are transepts. The lectern, where the church is small, may well be placed in the chancel; but where the church is intended for a large congregation, and the choir must have ample room, then the lessons had best be read at the extreme end of the nave; thus the Litany desk in the middle and the pulpit on the other side, as suggested by Mr. Beresford Hope at Brighton, in 1874, most of whose remarks are used by us herein; and who advocated the construction of a triforium where it was essentially necessary to have galleries. The experiment of such an arrangement has been tried in a new Roman Catholic church at Amsterdam, with, he said, a telling effect; and one has been adopted in the memorial church at Cawnpore. In such a case the table must be well raised, and the chancel screen just so high that those below may be under its tracery, and those aloft, above it.

Complaints are often made as to "the difficulty of seeing and hearing in some of our new churches." Exeter Hall has been greatly improved by substituting a gently curved wooden ceiling for the original ceiling intersected by wide spaces; and "one of the best churches for facility of hearing is that of St. Pancras in Euston Square, which accommodates 2,500 persons: it has a flat ceiling, and no massive arches and columns to intercept the sound, which travels freely round the walls of the spacious building." Mr. Spurgeon's Tabernacle at Newington, is also praised.

The subject of *Church arrangement* during the mediæval period has been elucidated by Mr. W. H. Dykes, architect, in a paper read before the Yorkshire Architectural Society, in 1852; and the Rev. M. E. C. Walcott, *On Church and Conventual Arrangement*, 1861, 8vo., describes the conventual plans adopted by the various religious orders.

CIBORIUM. (Κιβώριον.) An insulated erection open on each side with arches, and having a dome of ogee form, like the bowl of a reversed cup, carried or supported by four columns, the whole covering the altar. In later times the name was transferred to a tabernacle, coffer, or case, in which the host was deposited; whence the covering was thence called *umbraculum* or *baldacchino*. The earliest known instance of a ciborium appears to have been one in the church of St. George at Thessalonica, and supposed to have been in use about A.D. 325. It is also the name for the vessel in which the bread is placed at the Communion, instead of on a paten when many persons are present at it.

CILERY. The drapery or foliage carved on the heads of columns.

CILL. (Sax. Cill.) The timber or stone at the foot of a door, &c. *Ground cills* are the timbers on the ground which support the posts and superstructure of a timber building. The term also applies to the bottom piece which supports quarter partitions.

CIMBIA. A fillet string, list, or cornice.

CIMELIARCH. The apartment in old churches where the plate and vestments were deposited.

CINCTURE. The ring, list, or fillet at the top and bottom of a column, which divides the shaft of the column from its capital and base.

CINQUE-CENTO ARCHITECTURE. Literally 500, but used as a contraction for 1500, the century in which the revival of ancient architecture took place in Italy. The term is applied to distinguish the style of architecture which then arose in that country. In France the style as introduced there is called *Style François premier*, and *Renaissance*; and in England the Revival, and Elizabethan.

CINQUEFOIL. An ornament used in the Pointed style of architecture; it consists of five cuspidated divisions or curved pendents inscribed in a pointed arch, or in a circular ring applied to windows and panels. The cinquefoil, when inscribed in a circle, forms a rosette of five equal leaves having an open space in the middle, the leaves being formed by the open spaces, and not by the solids or cusps.

CIPPUS. A small low column, sometimes without a base or capital, and most frequently bearing an inscription. Among the ancients the cippus was used for various purposes; when placed on a road it indicated the distance of places; on other occasions *cippi* were employed as memorials of remarkable events, as landmarks, and for bearing sepulchral epitaphs.

CIRCLE. (Lat. Circulus.) A figure contained under one line called the circumference, to which all lines drawn from a certain point within it, called the centre, are equal. It is the most capacious of all plain figures.

CIRCLE. The name given to one of the megalithic remains, as at Stonehenge, Avebury, and other places.

CIRCULAR BUILDINGS. Such as are built on a circular plan. When the interior also is circular, the building is called a *rotunda*.

CIRCULAR-CIRCULAR, or CYLINDRO-CYLINDRIC WORK. A term applied to any work which is formed by the intersection of two cylinders whose axes are not in the same direction. The line formed by the intersection of the surfaces is termed, by mathematicians, a *line of double curvature*.

CIRCULAR WINDING STAIRS. Such as have a cylindric case or walled enclosure, with the planes of the risers of the steps ending towards the axis of the cylinder.

CIRCULAR WORK. A term applied any work with cylindric faces, as roofs, &c.

CIRCUMFERENCE. The boundary line of a circular body.

Circumvolutions. The turns in the spiral of the Ionic capital, which are usually three, but there are four in the capitals of the temple of Minerva Polias.

Circus. (Lat.) In ancient architecture, a straight, long, narrow building, whose length to its breadth was generally as 5 to 1. It was divided down the centre by an ornamented barrier called the *spina*, and was used by the Romans for the exhibition of public spectacles and chariot races. Several existed at Rome, whereof the most celebrated was the Circus Maximus. Julius Cæsar improved and altered the Circus Maximus, and that it might serve for the purpose of a naumachia, supplied it with water. Augustus added to it the celebrated obelisk now standing in the Piazzo del Popolo. Of this circus no vestiges remain. Besides these at Rome were the circi of Flaminius, near the Pantheon; Agonalis, occupying the site of what is now called the Piazza Navona; of Nero, on a portion whereof St. Peter's stands; of Antoninus and Aurelian, of which no portion whatever exists; and of Caracalla, which was 738 feet in length, and is at the present time sufficiently perfect to exhibit its plan and distribution in the most satisfactory manner. The spectacles of the circus were called the Circensian Games, and consisted of chariot and horse races, of both whereof the Romans were passionately fond, but particularly of the former, which in the times of the emperors excited so great an interest as to divide the whole population of the city into factions, distinguished by the colours worn by the different charioteers. The disputes of these factions often led to serious disturbances.

Cissoid. In geometry, a curved line invented by Diocles. Its name is derived from *κισσος*, ivy, from the curve appearing to mount along its assymptote, as ivy climbs on the trunk of a tree. The curve consists of two infinite branches above and below the diameter of a circle, at one of whose ends a tangent being drawn, the curve approaches the tangent without ever meeting it. The curve was invented by its author with a view to the solution of the famous problem of the duplication of the cube, or the insertion of two mean proportionals between two given straight lines. Its mechanical construction may be found in Newton's *Arithmetica Universalis.*

Cist. (Gr. Κιστη, a chest.) A term used to denominate the mystic baskets used in processions connected with the Eleusinian mysteries. It was originally formed of wicker work, and when afterwards made of metal, the form and texture were preserved in imitation of the original material. When sculptured on ancient monuments, it indicates some connection with the mysteries of Ceres and Bacchus.

Cist, or Cistvaen. In Celtic or Druidical buildings, the chamber formed of laterally recumbent blocks of stone.

Cistern. (Gr. Κιστη.) A reservoir for water, whether sunk below or formed of planks of wood above ground. In the construction of an earthen cistern, a well-tempered stratum of clay must be laid as a foundation for a brick flooring, and the bricks laid in terras mortar or Parker's cement. The sides must be built with the same materials; and if in a cellar or other place near a wall a space must be filled with clay, from the foundation to the top of the cistern contiguous to the wall, by which means it will be preserved from injury. Cisterns above ground are usually formed of wooden planks lined with lead or zinc, and carried by bearers; but the cistern formed of slates, now much used, is the best for adoption.

Civic Crown. A garland of oak leaves and acorns, often used as an architectural ornament.

Civil Architecture. The art of erecting every species of edifice destined for the use of man, the several matters necessary to the knowledge whereof forms the subject of the Encyclopædia.

Clamp. In brick-making, a large mass of crude bricks generally piled quadrangular on the plan, and six, seven, or eight feet high, arranged in the brick field for burning, which is effected by flues prepared in stocking the clamp, and breeze or cinders laid between each course of bricks.

Clamp. In carpentry and joinery, is a piece of wood fixed to another with a mortise and tenon, or a groove and tongue, so that the fibres of the piece thus fixed cross those of the other, and thereby prevent it from casting or warping.

Clamp and Clasp Nails. See Nails.

Classic Architecture. The term applied in a broad sense to the works of the ancient Greeks and Romans. The term classic is applied sometimes to a style, but none such exists. The Greek and Roman styles of architecture being so different in principle, they cannot correctly be described under one name. Of late years the term has constantly been misapplied to the modern Italian schools of architecture.

Clathri. In ancient Roman architecture, were bars of iron or wood which were used to secure doors or windows.

Clay. In ordinary language, any earth which possesses sufficient ductility to admit of being kneaded with water. Common clays may be divided into three classes, viz. *unctuous, meagre,* and *calcareous.* Of these the first is chiefly used in pottery, and the second and third are employed in the manufacture of bricks and tiles.

Claying. The operation of spreading two or three coats of clay and incorporating them, for the purpose of keeping water in a vessel. This operation is also called *puddling*.

Cleam. A term used in some places with the same signification as to stick or to glue.

Clear. The nett distance between two bodies, where no other intervenes, or between their nearest surfaces.

Clear Story or Clere Story. The upper vertical divisions of the nave, choir, and transepts of a church. It is *clear* above the roof of the aisles, whence it may have taken its name; but some have derived the name from the *clair* or light admitted through its tier of windows. Nearly all the cathedrals and large churches have *clear stories*, either as tiers of arcades, or of windows over the triforia. There is no triforium in the priory church of Bath, but a series of large and lofty windows constitute the clear story. The choir at Bristol Cathedral has neither triforium nor clear story. Examples are given in figs. 1416 to 1426.

Cleats. Small wooden projections in tackle to which to fasten the ropes.

Cleaving. The act of forcibly separating one part of a piece of wood or other matter from another in the direction of the fibres, either by pressure or by percussion with some wedge-formed instrument.

Cleft. The open crack or fissure which appears in wood which has been wrought too green. The carpenter usually fills up these cracks with a mixture of gum and sawdust, but the neatest way is to soak both sides well with the fat of beef broth, and then dip pieces of sponge into the broth, and fill up the cracks with them; they swell out so as to fill the whole crack, and so neatly as to be scarcely distinguishable.

Clepsydra. (Gr. from Κλεπτῶ, to conceal, and Ὕδωρ, water). A water clock, or vessel for measuring time by the running out of a certain quantity of water, or sometimes of sand, through an orifice of a determinate magnitude. Clepsydras were first used in Egypt under the Ptolemies; they seem to have been common in Rome, though they were chiefly employed in winter. In the summer season sundials were used.

Clinching. The act of binding and driving backward with a hammer the pointed end of a nail after its penetration through a piece of wood.

Clinkers. Bricks impregnated with nitre, and more thoroughly burnt by being nearer the fire in the kiln.

Cloaca. The name given to the common sewer of ancient Rome for carrying off into the Tiber the filth of the city. The chief of these, called the cloaca maxima, was built by the first Tarquin of huge blocks of stone placed together without cement. The top was arched, and consisted of three rows of stones one above another. It began in the Forum Romanum, was 300 paces long, and entered the Tiber between the temple of Vesta and the Pons Senatorius. There were as many principal sewers as there were hills in the city.

Cloak-pins and Rail. A piece of wood attached to a wall, furnished with projecting pegs on which to hang hats, great-coats, &c. The pegs are called *cloak pins*, and the board into which they are fixed, and which is fastened to the wall, is called the *rail*.

Clock Tower. A tower specially designed to hold a clock with its quarter and hour bells. Bells which are to be rung should properly be placed in a distinct erection, as the vibration injures the clock.

Cloister. (Lat. Claustrum.) The square space attached to a regular monastery or large church with a peristyle or ambulatory round, usually with a range of building over it. The cloister is perhaps, *ex vi termini*, the central square shut in or *closed* by the surrounding buildings. Cloisters are usually square on the plan, having a plain wall on one side, a series of windows between the piers or columns on the opposite side, and arched over with a vaulted or ribbed ceiling. It mostly forms part of the passage of communication from the church to the chapter house, refectory, and other parts of the establishment. In England all the cathedrals, and most of the collegiate churches and abbeys, were provided with cloisters. On the Continent they are commonly appended to large monasteries, and are often decorated with paintings, and contain tombs.

A common appendage to a cloister was a *lavatory*, or stone trough for water, at which the monks washed their hands previous to entering the refectory.

Close String. In dog-legged stairs, a staircase without an open newel.

Closer. The last stone in the horizontal length of a wall, which is of less dimensions than the rest, to close the row. *Closers* in brickwork, or pieces of bricks (or *bats*), less or greater than half a brick, that are used to close in the end of a course of brickwork. In English as well as Flemish bond, the length of a brick being but nine inches, and its width four inches and a half, in order that the vertical joints may be broken at the end of the first stretcher, a quarter brick (or bat) must be interposed to preserve the continuity of the bond, this is called a *queen-closer*. A similar preservation of the bond may be obtained by inserting a three-quarter bat at the angle in the stretching course; this is called a *king-closer*. In both cases an horizontal lap of two inches and a quarter is left for the next header.

Closet. A small apartment frequently made to communicate with a bed-chamber, and used as a dressing room. Sometimes a closet is made for the reception of stores, and is then called a *store closet*.

Clough or Cloyse. The same as *paddle*, *shuttle*, *sluice*, or *penstock*. A contrivance for retaining or letting out the water of a canal, pond, &c.

Clough Arches or Paddle-holes. Crooked arches by which the water is conveyed from the upper pond into the chamber of the lock of a canal on drawing up the *clough*.

Clout Nail. See Nails.

Clustered. The combination of several members of an Order penetrating each other.

Clustered Pillar. Several slender pillars or shafts attached to each other so as to form one. In Roman architecture the term is used to denote two or four columns which appear to intersect each other, at the angle of a building, or of an apartment to answer to each return.

Coarse Stuff. In plastering, a mixture of lime and hair used in the first coat and floating of plastering. In floating, more hair is used than in the first coat.

Coat. A thickness or covering of plaster, paint, or other work done at one time.

Cob-walls. Such as are formed of mud mixed with straw, not uncommon in some districts of England, but the best are to be found in Somersetshire.

Cocking or Cogging. See Caulking.

Cockle Stairs. A term sometimes used to denote a winding staircase.

Coddings. A Scotch term for the base or footings on which chimney jambs are set in the ground floor of a building.

Cœnaculum. (Lat.) In ancient Roman architecture, an eating or supper room. In the early period of their history, when the houses rarely consisted of more than two stories, it denoted generally the upper story. The word also signified lodgings to let out for hire. Also the upper stories of the *circi*, which were divided into small shops or rooms.

Cœnatio. An apartment in the lower part of the Roman houses, or in a garden, to sup or eat in. From Suetonius it would appear that it denoted a banqueting and summer house. In the Laurentine Villa a large cœnatio is described by the younger Pliny, and it seems, from the description, that it was placed in the upper part of a lofty tower.

Coffer. (Sax. Cofne.) A sunk panel in vaults and domes, and also in the soffite or under side of the Corinthian and Composite cornices, and usually decorated in the centre with a flower. But the application of the term is general to any sunk panel in a ceiling or soffite. See Caisson.

Coffer Dam. A case of piling, water-tight, fixed in the bed of a river, for the purpose of excluding the water while any work, such as a wharf wall, or the pier of a bridge, is carried up. A coffer dam is variously formed, either by a single enclosure or by a double one, with clay, chalk, bricks, or other materials between, so as effectually to exclude the water. The coffer dam is also made with piles only driven close together, and sometimes notched or dove-tailed into one another. If the water be not very deep, piles may be driven at a distance of five or six feet from each other, and grooved in the sides with boards let down between them in the grooves. For building in coffer dams, a good natural bottom of gravel or clay is requisite, for though the sides be made sufficiently water-tight, if the bed of the river be loose, the water will ooze up through it in too great quantities to permit the operations to be carried on. It is almost unnecessary to inculcate the necessity of the sides being very strong and well-braced on the inside to resist the pressure of the water.

Cogging. See Caulking.

Cohesion. See Resistance.

Coin. (Fr.) The same as *quoin*. The angle formed by two surfaces of a stone or brick building, whether external or internal, as the corner formed by two walls, or of an arch and wall, the corner made by the two adjacent sides of a room, &c.

Cokel, Cockle, or Coakel. A furnace made of very thick iron for generating heated air of great intensity, the iron often being made red-hot.

Coliseum. The name given to the amphitheatre built (A.D. 72) by Vespasian.

Collar or Colarino. (It.) A ring or cincture; it is another name for the astragal of a column. It is sometimes called the neck, gorgerin, or hypotrachelium.

Collar Beam. A beam used in the construction of a roof above the lower ends of the rafters or base of the roof. The tie beam is always in a state of extension, but the collar beam may be either in a state of compression or extension as the *principal rafters* are with or without tie beams. In trussed roofs, collar beams are framed into queen posts; in common roofs, into the rafters themselves.

In general, trusses have no more than one collar beam; yet, in very large roofs, they may have two or three collar beams besides the tie beam. The collar beam supports or trusses up the sides of the rafters, so as to keep them from sagging without any other support, but then the tie beam would be supported only at its extremities. In common purlin roofing, the purlins are laid in the acute angles between the rafters and the upper edges of the collar beams.

College. An establishment properly so termed for the education of youth in the higher branches of study. It generally consists in this country of one or more courts or quadrangles, round which are disposed the rooms for the students, with the chapel, library, and eating-hall; apartments for the head of the establishment and for the fellows and students; a combination room, which is a spacious apartment wherein the latter assemble after dinner; kitchen, buttery, and other domestic offices, latrines, gardens, &c. On the Continent the college differs very materially.

At Rome, the college, formerly that of the Jesuits, now the Roman college, is a very large edifice, simple in character, as this species of building seems to demand. Its length is 328 feet, and its height, without the attic, 87 feet. The other buildings in Rome which pass under the name of colleges are not to be considered as establishments for education, being destined to the study of theology and other sciences; such are the Propaganda and the Sapienza: the latter is one of the finest buildings of that city. At Genoa is a magnificent college, which was formerly the palace of the Balbi family, by whom it was given to the Jesuits for a place of education. Of the many colleges in Paris hardly one, says the author of the article "Collége" in the *Encyclopédie Méthodique*, deserves notice. The same writer says that in England alone are found examples of what a college ought to be.

The universities of Oxford and Cambridge form good examples; many are irregular in plan, but are convenient in disposition, and highly picturesque. Merton College, at Oxford, erected for secular priests, 1270-77, was the earliest in England; only a small portion of it remains, such as the stone treasury, and the chancel, an exquisite specimen, and one of the earliest, of the Decorated period. Several colleges were founded both in Oxford and Cambridge within a few years afterwards; but no other collegiate buildings were erected in either university until near the end of the fourteenth century, when the magnificent foundation of William of Wykeham arose, emphatically termed New College, because it was to a great extent on a new system; he also erected the college at Winchester, both founded between 1380 and 1390, and although belonging more to the monastic than to the strictly domestic character, they yet afford valuable examples of the style of building of their period.

In Oxford the most regular college in plan is Queen's College, commenced as late as 1710, and in the Italian style. The accommodation afforded is for about 170 persons, including the provost and fellows, whose apartments, of course, occupy a considerable portion of the space. A bed and sitting room, both of moderate dimensions, are as much as can be afforded to the students. Nicholas Hawksmore, the architect, completed the first quadrangle and library in 1759. Of the colleges in Oxford, Christchurch is past question the most magnificent. Its extent, towards the street, is 400 feet. What is called Christchurch Meadow, attached, affords delightful walks for the exercise and recreation of the members, being bounded on the east by the Cherwell, on the south by the Isis, and on the west by a branch of the same river. The whole establishment is worthy of the princely founder. Such a magnificent foundation cannot elsewhere be referred to. Keble College, by W. Butterfield, 1867–70, does not appear to have been yet illustrated; it encloses the greater part of a quadrangle 243 feet by 220 feet. The chapel (1875) has been erected at a cost of about 82,000*l.* in a decorated style, with mosaic work, stained glass, marbles, &c.

In Cambridge, the library and court of Trinity College, the former one of the finest works of Wren; and the extraordinary and beautiful chapel of King's College, are the principal features of this university. The chapel is, inside, 289 feet long, 42 feet broad, and 80 feet high to apex of the vaulting.

Besides the modern Queen's colleges in Ireland, Trinity College, Dublin, is the only one requiring notice. It was first designed by Sir William Chambers, and carried out by G. Meyers. The front is 300 feet in length, with a total depth of 600 feet, which encloses two quadrangles; it was erected 1759–80. The campanile, in the middle, 95 feet high, was erected 1853, by Sir C. Lanyon. The number of students is upwards of 500. Near to the library is another court, erected 1818, with the anatomy house, 1824. Beyond these are the new museum buildings, 1852–5, designed by J. MacCurdy, with Messrs. Deane, Son, and Woodward.

In Scotland, among the latest buildings of this sort, is the extensive one erected 1864–1870 for the university of Glasgow, at a cost of about 420,000*l.*, from the designs of Sir G. G. Scott, R.A. The plan is given in the *Builder* journal, xxviii. 1870, to which work the student is referred for a description of it. This publication also gives, xxiii., 1865, the Malvern Proprietary College, by C. F. Hansom; xxvi., 1868, the College of St. Nicholas at Lancing, by R. C. Carpenter, with its chapel by Messrs. Slater and Carpenter; and xxix., 1871, Owens College at Manchester, for scientific purposes, by Alfred Waterhouse.

In this class there have sprung up a number of buildings specially designed for the purposes of technical education, having lecture rooms and work rooms fitted with the requisite apparatus for working scientifically or according to trades. These are so numerous and special that the student is at once referred to the work by Mr. E. C. Robins, on *Technical Schools and College Buildings*, 1887.

Colonelli. (It.) The Italian name for the posts employed in any truss framing.

Colonnade. (It. Colonnata.) A range of columns. If the columns are four in number, it is called *tetrastyle*; if six in number, *hexastyle*; when there are eight, *octastyle*; when ten, *decastyle*; and so on, according to the Greek numerals. When a colonnade is in front of a building it is called a *portico*, when surrounding a building a *peristyle*, and when double or more *polystyle*. The colonnade is moreover designated according to the nature of the intercolumniations introduced as follows: *pycnostyle*, when the space between the columns is one diameter and a half of the column; *systyle*, when it is of two diameters; *eustyle*, when of two diameters and a quarter; *diastyle*, when three; and *aræostyle* when four.

Columbarium. (Lat.) A pigeon-house. The plural of the word (*columbaria*) was applied to designate the apertures formed in walls for the reception of cinerary urns in the ancient Roman cemeteries.

Columellæ. A name sometimes used for balusters.

Columen. The ridge piece of a roof.

Column. (Lat. Columna.) Generally any body which supports another in a vertical direction. See Pier, Pillar, and Shaft. There are various species of columns, as *twisted*, *spiral*, and *rusticked*. *Cabled* or *rudented* columns are such as have their flutings filled with cables or astragals to about one-third of the height. *Carolitic* columns have their shafts foliated. Columns were occasionally used as monuments. The following list comprises the best known ones; the heights in feet are to the top of the abacus:—

Antonine, Rome	136 feet	Pompey, Alexandria	98 feet
Trajan, Rome	115 ,,	Alexander, St. Petersburg	121 ,,
Monument, London	174 ,,	Napoleon, Boulogne	141 ,,
Napoleon, Paris	116 ,,	York, London	95 ,,

By the side of the Halle au Blé at Paris there is a *gnomonic* column for showing the time, erected by Catharine di Medicis.

The *Columna Bellica* at Rome was near the temple of Janus, and at it the consul proclaimed war by throwing a javelin towards the enemies' country. The *chronological* column was rather historical, bearing an inscription to record an event. The *cruciferal* column is one bearing a cross; the *funereal* one, an urn; the *zoophoric*, an animal; and the *itinerary* one pointed out the various roads diverging from its site. There was among the Romans what was called a *lacteal* column, which stood in the vegetable market, and contained on its pedestal a receptacle for infants abandoned by their parents. (Juvenal, *Sat.* vi.) On the *legal* column were engraved the laws; the *boundary* or *limitative* column marked the boundary of a province; the *manubial* column was for the reception of trophies or spoils; and the *rostral* column, decorated with prows of ships, was for the purpose of recording a naval engagement. The *triumphal* column was erected in commemoration of a triumph, and the *sepulchral* one was erected on a tomb. The *milliarium aureum*, or *miliary* column of the Romans, was originally a column of white marble, erected by Augustus in the Forum, near the temple of Saturn. From it the distances from the city were measured. It is a short column with a Tuscan capital, having a ball of bronze (formerly gilt) for its finish at top, and is still preserved in the Capitol.

Columniation. The employment of columns in a design.

Comitium. (Lat.) A building which stood in the Roman Forum, wherein assemblies of the people were held. It occupied the whole space between the Palatine Hill, the Capitol, and the Via Sacra.

Commissure. (Lat.) The joint between two stones, or the application of the surface of one stone to the surface of another.

Common Centring. Such as is constructed without trusses, but having a tie beam at its ends. Also that employed in straight vaults.

Common Joist. One in single naked flooring to which the boards are fixed. Such joists are also called *boarding joists*, and should not exceed one foot apart.

Common Rafter. One in a roof to which the boarding or lathing is attached.

Common Roofing. That which consists of common rafters only, which bridge over the purlins in a strongly framed roof.

Comparted. (Fr. Compartir, to divide.) That which is divided into several parts is said to be comparted.

Compartition. The distribution of the ground plot of an edifice into the various passages and apartments.

Compartment. A subdivisional part, for ornament, of a larger division. To this alone is the term properly applicable.

Compartment Ceiling. One divided into panels, which are usually surrounded by mouldings.

Compartment Tiles. An arrangement of varnished red and white tiles on a roof.

Compasses. (Fr. Compas.) A mathematical instrument for drawing circles and measuring distances between two points. *Common compasses* have two legs, moveable on a joint. *Triangular compasses* have two legs similar to common compasses, and a third leg fixed to the bulb by a projection, with a joint so as to be moveable in every direction. *Beam compasses* are used for describing large circles. *Proportional compasses* have two pair of points moveable on a shifting centre, which slides in a groove and thereby regulates the proportion that the opening at one end bears to that of the other. They are useful in enlarging or diminishing drawings.

Compass Saw. One for dividing boards into curved pieces; it is very narrow and without a back.

Compass Window. An old English term for a projecting window of a circular plan.

Complement. The number of degrees which any angle wants of a right angle. The complement of a parallelogram is two lesser parallelograms, made by drawing two right lines parallel to the sides of the greater through a given point in the diagonal.

Compluvium. (Lat.) An area in the centre of the ancient Roman houses, so constructed that it might receive the waters from the roofs. It is also used to denote the gutter or eave of a roof.

Compo. A name often given to Parker's cement, or the so-called Roman cement. It is also the name of the material used for making imitation carved-work for frames, &c., and made of glue and whiting: it is the short for "composition."

Composite Arch. The same as the pointed or lancet arch, but better appropriated to an arch of four centres.

Composite Numbers. Such as can be divided by some other number greater than unity, whereas *prime numbers* admit of no such divisor.

Composite Order. The fifth order used in Roman and Italian architecture, and being of a more decorative character than the Corinthian order. The capital is somewhat similar to the Corinthian; the volutes are larger, but not so large as those in the Ionic capital. The base is shown in *fig.* 1368.

Composition in Architecture. The student will find that in most cases a good distribution of plan will lead to good sections and elevations. Upon the adaptation of the different fronts of the building to sort with the internal convenience, the greatest care should be bestowed; and then the decoration of such an edifice becomes a secondary and comparatively easy work, though requiring, of course, the early cultivation of the taste of the architect, and an intimate acquaintance with the parts of the design. For the thorough comprehension of a projected edifice, a plan, section, and elevation are required; these comprise the whole elementary part of the mechanical process necessary for making a design or composition. To carry out such a design, working drawings may be required showing the parts at large. See Design.

Composition of Forces. The combination or union of several forces for determining the result of the whole.

Compound Pier. A term sometimes given to a clustered column.

Compressibility. The quality of bodies which permits of their being reduced to smaller dimensions. All bodies, in consequence of the porosity of matter, are compressible, but liquids resist compression with immense force.

Concamerata Sudatio. An apartment in the ancient gymnasium, between the *laconicum* or stove, and the warm bath. To this room the racers and wrestlers retired to wipe off the sweat from their bodies. See Caldarium.

Concamerate. (Lat.) To arch over.

Concavity. (Lat. Concavus, hollow.) Of a curve line is the side between the two points of the curve next its chord or diameter. The concavity of a solid is such a curved surface, that if any two points in it be taken, the straight line between them is in a void space, or will coincide in only one direction with the surface.

Concentric. (Lat.) Having a common centre, as are the radii of a circle.

Conchoid of Nicomedes. A name given to a curve invented by that mathematician for solving the two famous problems of antiquity—the duplication of the cube, and the trisection of an angle. It continually approaches a straight line without meeting it, though ever so far produced.

Concrete. (Lat. Concrescere.) To coalesce in one mass. A mass composed of stone chippings, or ballast, cemented together through the medium of sand and lime, or of cement, and usually employed in making foundations where the soil is of itself too light or boggy, or otherwise insufficient for the reception of the walls. It is likewise used to cover the ground under a building to keep damp from rising. Also to form a backing to a wharf wall, or one at the side of a railway cutting, for extra strength. Of late years it has been used in lieu of bricks or stone wherewith to build houses; for incombustible flooring; and a church has been built of it near Paris. Large concrete blocks are used for the interior work of piers to harbours, and similar extensive erections.

Conduit. (Fr.) A long narrow walled passage underground, for secret communication between different apartments. It is a term also used to denote a canal or pipe for the conveyance of water, and is also applied to the structure to which it is conveyed for delivery to the public.

CONDY'S PATENT FLUID. Called, from its mode of action and effectiveness, "Nature's Disinfectant;" it purifies, deodorises, and disinfects, by the agency of nascent or ozonic oxygen, its active principle. It combines powerful purifying properties with a wholesome nature.

CONE. (Gr. Κωνος). A solid body, having a circle for its base, and terminating in a point called its vertex; so that a straight line drawn from any point in the circumference of the base to the vertex will coincide with the convex surface. If the axis or straight line drawn from the centre of the base to the vertex be perpendicular to the base, it is termed a *right cone*; if not, it is an *obliquè cone*.

CONFESSIONAL. (Lat.) In Catholic churches the small cell wherein the priest sits to hear the confession of, and give absolution to, the penitent. It is usually constructed of wood and in three divisions, the central one whereof has a seat for the convenience of the priest.

CONFIGURATION. The exterior form or superficies of any body.

CONGÉ. (Fr.) The same as APOPHYGE.

CONIC SECTIONS. The figures formed by the intersections of a plane with a cone. They are five in number: a triangle, a circle, an ellipse, a parabola, and an hyperbola; the three last, however, are those to which the term is usually applied.

CONICAL ROOF. One whose exterior surface is shaped like a cone.

CONISTERIUM. (Gr. κονιστηριον.) In ancient architecture a room in the gymnasium and palæstra, wherein the wrestlers, having been anointed with oil, were sprinkled over with dust, that they might lay firmer hold on one another.

CONJUGATE DIAMETERS. The diameters in an ellipsis or hyperbola parallel to tangents at each other's extremities.

CONOID. (Gr. Κονοειδης.) Partaking of the figure of a cone. A figure generated by the revolution of a conic section round one of its axes. There are three kinds of conoids, the *elliptical*, the *hyperbolical*, and the *parabolical*, which are sometimes otherwise denominated by the terms *ellipsoid* or *spheroid*, *hyperboloid*, and *paraboloid*.

CONSERVATORY. A building for preserving curious and rare exotic plants. It is made with beds of the finest composts, into which the trees and plants, on being removed from the greenhouse, and taken from the tubs and pots, are regularly planted.

With respect to its construction, it is very similar to the greenhouse, but it must be more spacious, loftier, and finished in a superior style. The sides, ends, and roofs should be of glass for the free admission of light, and for protection of the plants. It should be, moreover, seated on a dry spot, and so as to receive during the day as much of the sun's heat as possible. It is to be provided with flues, or hot-water pipes, to raise the temperature when necessary; there must also be contrivances for introducing fresh air when required. In summer time the glass roofs are taken off, and the plants exposed to the open air; but these are restored always, if taken off, on the slightest indication of frost. The chief point in which conservatories differ from greenhouses is, that in the latter, the plants and trees stand in pots placed upon stages, whereas, in the former, they are planted in beds of earth surrounded with borders. See GREENHOUSE.

CONSOLE. The same as ANCONES.

CONSTRUCTION. Literally, the building up from the architect's designs; but amongst architects it is more particularly used to denote the art of distributing the different forces and strains of the parts and materials of a building in so scientific a manner as to avoid failure and insure durability. The second book of the Encyclopædia is devoted to the subjects involved in the science of construction.

CONTACT. (Lat. Contactus.) In geometry, the touching any figure by a line or plane which may be produced either way without cutting it.

CONTENT. (Lat. Contentus.) The area or superficial quantity contained in any figure.

CONTEXTURE. (Lat. Contextus.) The inter-disposition, with respect to each other, of the different parts of a body.

CONTIGNATIO. In Roman carpentry, the same as that now called *naked flooring*.

CONTINUED. A term used to express anything uninterrupted. Thus, an attic is said to be continued when not broken by pilasters; a pedestal is continued when, with its mouldings and dado or die, it is not broken under the columns; so of a socle, &c.

CONTOUR. (It. Contorno.) The external lines which bound and terminate a figure.

CONTRACT. An agreement, attached to a specification for the performance of certain works in accordance therewith, and with the drawings accompanying it, if any.

CONVENT. (Lat. Conventus.) A building for the reception of a society of religious persons, but more properly applied to one for the habitation of nuns.

CONVENTUAL CHURCH. One attached or belonging to a convent.

Convergent Lines. Such as, if produced, will meet.

Convex. (Lat. Convexus.) A form which swells or rounds itself externally. A convex rectilinear surface is a curved surface, in which a point being taken, a right line passing through it can only be drawn in one direction.

Coping. (Dutch, Cop, the head.) The highest and covering course of masonry or brickwork in a wall. Coping equally thick throughout is called *parallel coping*, and ought to be used only on inclined surfaces, as on a gable, for example, or in situations sheltered from the rain, as on the top of a level wall, which it is intended to cover by a roof. Coping thinner on one edge than on the other serves to throw off the water on one side of the wall, and is called *feather-edged coping*. Coping thicker in the middle than at the edges is called *saddle-backed coping*. This, of course, delivers each way the water that falls upon it. It is commonly used on the walls of a sunk area, on dwarf walls carrying an iron railing, and in the best constructed fence walls. In Gothic architecture, coping is either inclined upon the faces or plumb; in the former case the sides of the vertical section are those of an equilateral triangle with an horizontal base. It is sometimes in one inclined plane, terminated at top by an astragal, and at others in two inclined planes parallel to each other, the upper one being terminated at top by an astragal and projecting before the lower, which, like that on one inclined plane, changes its direction at the bottom into a narrow vertical plane projecting before the level sofite before the parapet. The inclined coping is occasionally used without the astragal. The sofite of a projection is said to cope over when it slants downwards from the wall.

Copper. (Cuprum, a corruption of Cyprium, having been originally brought from the island of Cyprus.) One of the metals used in building, but not now to the extent to which it was employed a few years back.

Corbeil. (Lat. Corbis, a basket.) A carved basket, with sculptured flowers and fruit, used as the finishing of some ornament. The name is given to the basket placed on the heads of Caryatides, under the sofite of the architrave cornice. The term is also applied to the bell of the Corinthian capital.

Corbel. A range of stones projecting from a wall for the purpose of supporting a parapet or the superior projecting part of the wall. Their fronts are variously moulded or carved. They perform the same office as the modillions of an order, but the term is chiefly confined to Pointed architecture.

The word corbel is sometimes used to denote a projection from a wall to carry a statue or bust. It also signifies a horizontal range of stones or timber fixed in a wall or in the side of a vault, serving to sustain the timbers of a floor or of a vault. In old buildings many of the timber floors or contignations were thus supported.

Corbel Table. A series of small arches for carrying a battlement, parapet, or cornice, and resting on corbels. Also any projection borne by corbels, as *figs.* 1382 to 1384.

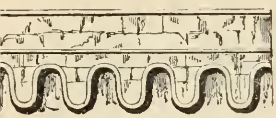

Fig. 1382. Nebuly Corbel Table.

Fig. 1383. Wavy Corbel Table.

Fig. 1384. Corbel Table.

Corbie Steps. Steps in the gables of old buildings, especially as used in Scotland.

Cordon. The edge of a stone on the outside of a building.

Core. The interior part of anything. In walls of masonry there should be thorough stones at regular intervals, for strengthening the core, which is commonly composed of rubble stones, or, when they are not procurable, two bond stones lapped upon each other may be used, one from each face of the wall. Instead of each thorough stone two stones may be laid level on the upper bed, and one large stone in the core lapped upon both, observing that the tails of the two lower stones be right-angled; by this means the two sides of the wall will be completely tied together.

The core of a column is a strong post of some material inserted in its central cavity when of wood.

Bricks or tiles brought out for the formation of cement cornices or other projections. It is also the interior part of a lump of lime, which has not been sufficiently burnt In slaking lump lime these "cores" will not disintegrate, consequently they can be removed; but when lime is ground, these lumps are ground up with it; the result is an inferior mortar.

Corinthian Order. The fourth order used in Roman and Italian architecture. It is richer than the Ionic order; and its capital is composed of a bell-shaped vase, surrounded with leafage, and having small volutes projecting at each angle of it. The base is shown in *fig.* 1368. The two following capitals, *figs.* 1385 and 1386, are those to which our knowledge is confined of the use of this order in Greece. The first one can, however, scarcely be considered Corinthian, and the second one not very strictly so: the monument was erected about 330 B.C. See CHORAGIC MONUMENT.

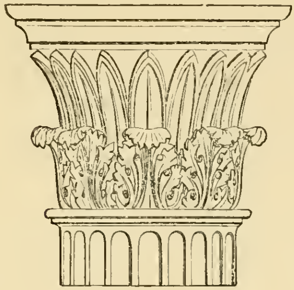

Fig. 1385.
Temple of the Winds at Athens.

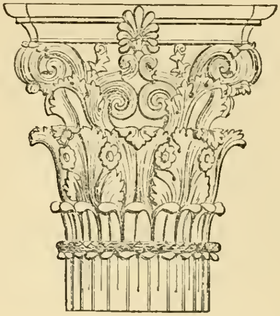

Fig. 1386.
Choragic Monument of Lysicrates at Athens.

CORNICE. (Fr. Corniche.) Any moulded projection which crowns or finishes the part to which it is affixed; as the cornice of an order, of a pedestal, of a pier, door, window, house, &c. The cornice of an order is a secondary member of the order itself, being the upper subdivision of the entablature.

CORONA. (Lat.) A member of the cornice, with a broad vertical face, and usually of considerable projection. The solid, out of which it is formed, is commonly recessed upwards from its sofite, and this part by the English workmen is called the *drip*, because it facilitates the fall of the rain from its edge, by which the parts below it are sheltered. The situation of the corona is between the cymatium above, and the bed-moulding below.

CORONA LUCIS. A crown or circlet suspended from the roof or vaulting of a church, to hold tapers or gas jets.

CORRIDOR. (It. Corridore.) A gallery or passage round a quadrangle leading to the various apartments. Also, any gallery of communication to them.

CORSA. (Lat.) In ancient architecture, the name given by Vitruvius to any platband or square fascia whose height is greater than its projection.

CORTILE. (It.) A small court or area, quadrangular or curved, in a dwelling-house, which is surrounded by the buildings of the house itself.

COTTAGE. (Sax. Cot.) A small house or dwelling for a poor person.

COTTAGE ORNÉE. A small villa erected in the country, emulating the houses of a rural character, and not affecting to display exteriorly any particular style. They were very fashionable at the beginning of the nineteenth century.

COUNTER DRAIN. A drain parallel to a canal or embanked water-course, for collecting the soakage water by the side of the canal or embankment to a culvert or arched drain under the canal, by which it is conveyed to a lower level.

COUNTERFORT. (Fr.) A buttress or pier built against and at right angles to a wall to strengthen it.

COUNTER GAUGE. In carpentry, the measure of the joints by *transferring*, as, for instance, the breadth of a mortise to the place on the other timber, where the tenon is to be made to adapt them to each other.

COUNTER LATH. One placed between every couple of gauged ones.

COUNTERPARTS OF A BUILDING. The similar and equal parts of the design on each side of the middle of the edifice.

COUNTER SINK. The sinking a cavity in a piece of timber or other material to receive a projection on the piece which is connected with it, as for the reception of a plate of iron, or the head of a screw or bolt.

COUPLED COLUMNS. Those arranged in pairs half a diameter apart.

COUPLES. A term used in the North to signify rafters framed together in pairs with a tie fixed above their feet. The *main couples* answer to the trusses.

COURSE. (Lat. Cursus.) A continued level range of stones or bricks of the same height throughout the face or faces of a building. *Coursed masonry* is that therefore wherein the stones are laid in courses. The *course of the face of an arch* is the face of the arch stones, whose joints radiate to the centre. The *course of a plinth* is its continuity in the face of the wall. A *bond course* is that whose stones are inserted into the wall farther than either of the adjacent courses, for the purpose of binding the wall together. A *coursing joint* is the joint between two courses.

Court. (Fr. Cour.) An uncovered area before or behind the house, or in the centre of it, in which latter case it is often surrounded by buildings on its four sides, and is more often called a quadrangle, as at Somerset House in the Strand.

Court of Justice, Law Court, Assize Court. The apartment arranged for a trial. It is also sometimes applied to the building containing it and the necessary accommodation for the persons privileged to attend in it at the trial. Thus the designs must provide apartments and accommodation for the robing, and occasional refreshment, of the judges, the bar, and the different officers attached to the court, also suitable accommodation for the jury, for the witnesses, for the attorneys whose instructions to counsel are from instant to instant necessary for the proper conduct of a case, and though last, not least, ample space for the public, who have an undoubted right to be present; also refreshment and waiting rooms for them. The architect must be careful to supply such accommodation as shall render the office of all parties engaged a pleasing duty rather than an irksome task. To every court of law should be attached a vestibule or saloon, sufficiently large to afford a promenade for those of all classes engaged in the courts. In Westminster, bad as the courts were, this was well provided in the magnificent saloon called Westminster Hall. In courts for the trial of felons it may be necessary, if the prison has no communication with the court, to add accommodation for the police and other officers, as likewise some cells for criminals.

In these, as in other buildings where there is often congregated a great number of persons, the entrances, and at the same time outlets, should be increased in number as much as convenience and the situation will permit; and another indispensable requisite is, that the court itself should be so placed in the design that no noise created on the outside of the building may be heard in the interior, so as to interfere with the attention of those engaged on the business before them.

The assize or law courts at Manchester, erected 1859–64 by Mr. Alfred Waterhouse, architect, in the Pointed style of architecture, have received the highest approbation for the accommodation provided, not only for all those immediately interested in the administration of justice, but for the public. This edifice has been described by its architect in the *Sessional papers* of the Royal Institute of British Architects, 1864–5, p. 165, from which we gather that the cost, limited to 70,000*l.*, did not exceed 110,000*l.*, or nearly 9*d.* per foot cube; the furniture was about 10,000*l.* more. It consists of two almost distinct parts, the inner structure containing the courts, public offices, and arrangements for business. This is separated by a courtyard in front, but connected by a corridor at back, from the judges' residence or "lodgings."

In the basement of the main building, which is 256 feet long by 166 feet deep, and three stories or about 60 feet in height, are cells for the prisoners under trial, chambers for heating and ventilating, kitchens, refreshment rooms, &c. On the principal floor, which is about 17 feet above the level of the street, and close to the entrance, is the central hall, 100 feet long, 48 feet 6 in. wide, and 75 feet high; beyond it are the assize courts, and the sheriffs' or additional court at one end; also the various rooms for the accommodation of the bench, the bar, the different officers of the court, witnesses, and jurors. The crown and civil courts are each 59 feet by 45 feet and 39 feet 6 in. high, being among the largest courts in the kingdom. In them the bar is placed as usual opposite the bench, the jury is on the judge's left hand, the witness-box on his right and brought close to the bench. To each of the courts there are eight entrances, and also two to the ladies' gallery above. All these are approached from the corridors, 10 feet wide, which, diverging from the central hall, run round the building, and return to the hall again. The barristers' corridor at the rear of the courts is 184 feet long, and shut off so as to keep it for the exclusive use of the bar. Opposite the main entrance, but quite in the rear, is a door leading from this corridor into the library, 60 feet by 25 feet, another into the robing room, beyond which are the lavatories, placed round a ventilating shaft. The rooms for the prothonotary, clerk of the crown, and indictment office, all also open into this corridor. Other rooms on this floor are devoted to the witnesses, who are classified as much as possible, to jurors, attorneys, and barristers' clerks, to the various officers of the assizes, and to purposes of consultation. On the upper floor are situated the Chancery court for the County Palatine of Lancaster, 41 feet by 23 feet; the grand jury room, 40 feet by 25 feet; the magistrates' board room; and the barristers' mess room, 55 feet by 22 feet.

The article Town Hall gives references to many similar buildings of modern erection, and of various sizes, but the above is probably still the best of its class.

The Courts of Justice in London; the foundations were commenced in 1871, and the building was nearly completed in 1881, at the death of the architect, George Edmund Street, R.A. They were formally handed over to the First Commissioner of Public Works in October, 1882, on their completion by his son, Mr. A. E. Street, with Mr. A. Blomfield. The journals since that period have illustrated many portions of this large work.

COUSSINET (Fr.) or CUSHION. A stone placed upon the impost of a pier for receiving the first stone of an arch. Its bed is level below, and its surface above is inclined for receiving the next voussoir of the arch.

The word is also used for the part of the Ionic capital between the abacus and quarter round, which serves to form the volute, and it is in the capital thus called because its appearance is that of a cushion or pillow seemingly collapsed by the weight over it, and has a band called *balteus*. BALUSTER is the side of the volute.

COVE. Any kind of concave moulding or vault; but the term in its usual acceptation is the quadrantal profile between the ceiling of a room and its cornice.

COVE BRACKETING. The wooden skeleton for the lathing of any cove; but the term is usually applied to that of the quadrantal cove, which is placed between the flat ceiling and the wall.

COVER. That part of a slate which is hidden or covered. See GAUGE.

COVER WAY. In roofing the recess or internal angle left in a piece of masonry or brickwork to receive the roofing.

COVING. In old buildings, the projection of the upper story over the lower ones.

COVING OF A FIRE-PLACE. See CHIMNEY.

COW-HOUSE. See CATTLE-SHED.

COWL. See WINDGUARD.

CRAB. A species of crane much used by masons for raising large stones; it is a wheel and axle mounted on a pair of sloping legs, three or four feet apart, the legs being inserted into a frame at the base, whereon, opposite to the weight to be raised, a load may be placed for gaining so great an amount of leverage as to overcome the weight to be raised. The rope for the tackle works round the axle, which is turned by pinion wheels to gain power.

CRADLE. A name sometimes given to a centering of ribs and lattice for turning culverts.

CRADLE VAULT. A term used, but improperly, to denote a cylindric vault.

CRADLING. The timber ribs and pieces for sustaining the lathing and plastering of vaulted ceilings. The same term is applied to the wooden bracketing for carrying the entablature of a shop front.

CRAMP. An iron instrument about four feet long, having a screw at one end, and a moveable shoulder at the other, employed by carpenters and joiners for forcing mortise and tenon work together.

CRAMPERN or CRAMP IRON, usually called for shortness *cramp*. A piece of metal bent at both extremities towards the same side, for fastening stones together. When stones are to be connected with a greater strength than that of mortar, a chain or bar of iron with different connecting knobs is inserted in a cavity, cut on the upper side of a course of stones across the joints, instead of single cramps across the joints of each two stones. Cramps are commonly employed in works requiring great solidity; but in common works they are applied chiefly to the stones of copings and cornices, and generally in any external work upon the upper surface or between the beds of the stone. All external work, liable to the injuries which weather inflicts, should be cramped. The most secure mode of fixing cramps is to let them into the stone their whole thickness, and to run them with lead; but in slight works it is sufficient to bed them in plaster, as is practised in chimney-pieces. In modern buildings iron is chiefly used for the cramp. The practice is bad, from the liability of iron to rust and exfoliate; hence cast-iron is better than wrought, and should be of somewhat larger size than when wrought iron is employed. Copper cramps are also used in best works. The Romans wisely used cramps of bronze, a material far better than either cast or wrought iron.

CRAMPOONS. Hooked pieces of iron, something like double calipers, for raising timber or stones.

CRANE. (Sax. Cpan.) A machine for raising heavy weights, and depositing them at some distance from their original place. The crane may be constructed of immense power, and worked by human strength or by steam power.

CRAPAUDINE DOORS. Those which turn on pivots at top and bottom.

CREASING or TILE CREASING. Two rows of plain tiles placed horizontally under the coping of a wall, and projecting about an inch and a half on each side to throw off the rain water.

CREDENCE. (It. *Credenza*, a buttery or pantry.) The slab whereon, in the sacrifice of the mass, or before the Communion Service, the elements are deposited previous to the oblation. Sometimes a plain recess, sometimes a slab on a bracket; it is in all cases placed on the south side of the altar.

CRENELLE. In Gothic architecture, the opening in an embattled parapet.

Crenellated Moulding. A moulding used in Norman architecture, carved into a resemblance of battlements, notchings, or indentations.

Crepido. (Lat.) The projecting members of a cornice, or other projecting ornament.

Crescent. A building, or rather a series of buildings, which on the plan is disposed in the arc of a circle.

Crest Tile. That on the ridge of a house. In Gothic architecture, crest tiles are those which, decorated with leaves, run up the sides of a gable or ornamented canopy.

Crib. The rack of a stable; sometimes applied to the manger. It is used also to express any small habitation; and moreover the stall or cabin of an ox.

Crocket. (Fr. Croc, a hook.) One of the small ornaments placed on the inclined sides of pinnacles, pediments, canopies, &c. in Gothic architecture, and most commonly disposed at equal distances from each other. The crocket seems to have had for type the buds and boughs of trees in the spring season, from the great resemblance it bears to those periodical productions: examples, moreover, of the same ornament have great resemblance to the first stage of the leaves when the buds begin to open; sometimes, however, animals are substituted in the place of leaves.

Cromlech. A mass of large flat stones laid across others in an upright position. Examples of cromlechs are found in the southern districts of England, in Brittany, and in many other parts of the world.

Cross. (Lat. Crux) A figure consisting of four branches at right angles to each other, or a geometrical one, consisting of five rectangles, each side of one rectangle being common with one side of each of the other four. It is a figure more particularly used for the plans of churches than for those of other edifices. In Ecclesiastical architecture, there are two kinds of plans having the form of a cross. The first is that wherein all the five rectangles are equal, or wherein each of the four wings is equal to the middle part formed by the intersection: this form is called a *Greek cross*, as *fig.* 1387. The second has only the two opposite wings equal, the other two are unequal, and the three rectangles in the direction of the unequal parts are of greater length than the three parts in the direction of the equal parts; this is the *Latin cross*, as *fig.* 1388. The middle part in each direction is common.

The cross, the symbol of Christianity, has very naturally been extensively used in the monuments of the Middle Ages. It is unnecessary to give the ornamental and profusely decorated examples which the student everywhere finds, therefore the simple forms by which crosses are distinguished will only here be noticed. When the two branches of the cross are equal in length, as in *fig.* 1387, the cross is called a Greek cross, and when the stem is longer than the arms, as in *fig.* 1388, it is a Roman or Latin cross. When the figure has two arms, one longer than the other, as in *fig.* 1389 (the upper one meant as a representation of the inscription which was placed over the head of Christ), it is known by the name of the Lorraine cross, and has received that name from its being a bearing in the arms of the Dukes of Lorraine. By our own heralds this is called a patriarchal cross. The next cross, whose arms are triple, as *fig.* 1390, is the papal cross, and is one of the emblems of the papacy, signifying, perhaps, like the triple crown or tiara, the triple sovereignty over the universal Church, the suffering Church, and the triumphant Church. The great majority of the western churches, with transepts, are constructed in the form of a Latin cross, those in the form of the Greek cross being very rare. Those in the form of the Lorraine cross are still rarer, and yet rarer are those constructed with triple transepts. There is another form called the truncated or *tau* cross, as *fig.* 1391, having the form of that letter, on which, as a plan, a few churches have been built. Considered as respects the contour, the cross in blason has been variously shaped and named. Thus, *fig.* 1392, in which the extremities widen as they recede from the centre, is called a cross *patée.* This is met with more frequently than any of the others. It is seen in the nimbus, on tombs, on shields, upon coins, etc.; and is the usual form of the *dedication cross* found in religious structures. *Fig.* 1393 is by the French called *ancrée*, the extremities forming hooks, but by our own heralds it is called a cross *moline.* Crosses *flory* are those in which the ends are formed into trefoils, as is seen in *fig.* 1390, the papal cross above mentioned. *Fig.* 1394, is a cross *potent*, and *fig.* 1385 is the cross *cléchée*, as respects the outer lines of its form; when it is *voided*, as shown by the inner lines, the ground or field is seen on which it lies. *Fig.* 1396 is the cross of the Russian Greek Church.

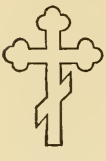

Fig. 1396.

Cross. In Gothic architecture, an erection of various kinds, which may be classed as follows:—those used for marking boundaries, those which were memorials of remarkable events, monumental or sepulchral, as that at Waltham, and others of that nature; for preaching, as the ancient St. Paul's Cross; and market crosses, as at Winchester, Leighton Buzzard, etc.

Cross-banded. A term applied to handrailing, which is said to be cross-banded when a veneer is laid upon its upper side, with the grain of the wood crossing that of the rail, and the extension of the veneer in the direction of its fibres is less than the breadth of the rail.

Cross Beam. A large beam going from wall to wall, or a girder that holds the sides of the house together.

Crossettes. (Fr.) The same as *ancones.* In architectural construction the term is applied to the small projecting pieces *aa*  in arch stones, which hang upon the adjacent stones.

Cross Garnets. Hinges having a long strap fixed close to the aperture, and also a cross part on the other side of the knuckle, which is fastened to the joint. See Garnet.

Cross-grained Stuff. Wood which has its fibres in a contrary direction to the surface, and which consequently cannot be perfectly smoothed by the operation of the plane, without turning either the plane or the stuff. This defect arises from a twisted disposition of fibres while in the act of growing.

Cross Springers. The ribs in the Pointed style that spring from the diagonals of the pillars or piers.

Cross Vaulting. That formed by the intersection of two or more simple vaults. When each of the simple vaults rises from the same level to equal heights, the cross vaulting is denominated *a groin*; but when one of the simple vaults is below the other, the intersection is called *an arch* of that particular species which expresses both the simple arches. For example, if one cylinder pierce another of greater altitude, the arch so formed is termed a *cylindro-cylindric arch*; and if a portion of a cylinder pierce a sphere of greater altitude than the cylinder, the arch is called a *sphero-cylindric arch*, and thus for any species of arch whatever, the part of the qualifying word which ends in *o* denotes the simple vault having the greater altitude, and the succeeding word the other of less altitude.

Crow. A bar of iron used in bricklaying, masonry, and quarrying, and serving usually as a lever in its employment.

Crowde, Croude, or Croft. The old term for the crypt of a church.

Crown. (Lat. Corona.) The uppermost member of any part. Thus, the upper portion of a cornice, including the corona and the members above it, is so called.

Crown of an Arch. The most elevated line or point that can be assumed in its surface; it is also called the extrados.

Crown or Joggle Post. The same as a *king post*, being the truss post that sustains the tiebeam and rafters of a roof.

Crown Glass. A common sort of window glass cut from a sheet blown into a disk form having a bull's eye in the centre of it.

Crowning. The part that terminates upwards any piece of architecture, as a cornice, pediment, etc.

Crypt. (Gr. Κρυπτω, I hide.) The under or hidden part of a building. It is used also to signify that part of the ancient churches and abbeys below the floor, appropriated to monumental purposes, and sometimes formed into chapels. There are only four *apsidal crypts* in England; Winchester, 1079; Worcester, 1084; Gloucester, 1089; and Canterbury, 1096. In all these the side aisles run completely round the apse. See Crowde.

Crypto-Porticus. In ancient architecture a concealed portico, also one that for coolness is enclosed on every side. Some of them were sunk some way into the ground. It also is a term applied to subterranean or dark passages and galleries in the Roman villas, often used as cool sitting rooms.

Cube. (Gr. Κυβος, a die.) A solid bounded by six square sides. It is also, from its six sides, called *hexahedron.*

Cubic feet (as the quantity necessary to be allowed for health under varying circumstances). From 60 to 100 feet superficial is recommended for each bed. It is stated that a healthy man respires about twenty times in a minute, and inhales in that period about 700 cubic inches of air. Fresh air contains rather more than 23 per cent. of oxygen, and about 1½ per cent. of carbonic acid; by the process of respiration the oxygen is reduced, in round numbers, to 11 per cent., and the carbonic acid is increased to rather more than 8 per cent. Now, 3½ per cent. of this gas renders air unfit to support life; so that a man, in respiring 700 cubic inches in a minute, *vitiates* about 1630 cubic inches, without taking into account the effect produced by the exhalation from the skin.

It has been lately calculated that the average space allowed to each person in London is 1220 square feet, while in Paris it is only 500 ditto.

Cubiculum. (Lat.) A chamber. A distinction is made by Pliny between the *cubiculum* and the *dormitorium.* The name was also applied to the royal pavilion or tent which was built in the circus or amphitheatre for the reception of the emperors.

Cubit. A linear measure, in ancient architecture, equal to the length of the arm from the elbow to the extremity of the middle finger, usually considered about eighteen English inches. The geometrical cubit of Vitruvius was equal to six ordinary cubits. Mr. Perring, in 1843, calculated the Egyptian cubit at 1·713 English feet, divided into four palms each of seven digits. The cubit, in the survey, etc., of the Holy Land, was assumed (1875) at 21 inches. See Measure.

Cul de Four. (Fr.) A low vault spherically formed on a circular or oval plan. An oven-shaped vault.

Culmen. In ancient Roman architecture, the ridge-piece of the roof.

Culvert. An arched channel of masonry or brickwork built beneath the bed of a canal for the purpose of conducting water under it. If the water to be conveyed has nearly the same level as the canal, the culvert is built in the form of an inverted siphon, and acts on the principle of a water-pipe. The word also signifies any arched channel for water under ground.

Culver-tail. The same as Dove-tail.

Cuneus. (Lat.) That part of the Roman theatre where the spectators sat.

Cupboard. A receptacle whether a recess in a wall or otherwise, and fitted with shelves, for small articles. See Closet.

Cupola. (It. from Cupo, hollow.) A term, properly speaking, which is confined to the *underside* or ceiling part of a dome. See Dome.

Curb for Brick Steps. A timber nosing, generally of oak, used not only to prevent the steps from wearing, but also from being dislocated or put out of their places. When the steps are made to return, the curb also returns, but when they profile against a wall, the ends of the curb or nosing pieces house at each end into the wall.

Curb Plate. A circular continued plate. either scarfed together or made in two or more thicknesses. The wall plate of a circularly or elliptically ribbed dome is called a *curb-plate,* as likewise the horizontal rib at the top, on which the vertical ribs terminate. The plate of a skylight, or a circular frame for a well, is also called a curb-plate. The name is moreover given to a piece of timber supported in a curb roof by the upper ends of the lower rafters for receiving the feet of the upper rafters, which are thence called *curb-rafters.*

Curb Roof. One formed of four contiguous planes externally inclined to each other, the ridge being in the line of concourse of the two middle planes and the highest of the three lines of concourse. A roof of this construction is frequently termed a *Mansard* roof, from the name of its supposed inventor. Its principal advantage over other roofing arises from its giving more space in the garrets, which become attics.

Curb Stone. The stone in the foot-paving of a street, which divides it from the carriage-paving, above which they are, or ought to be, raised.

Curia. (Gr.) A Roman council house. The city and empire contained many curiæ. The *curia municipalis,* or *domus curialis,* seems to have, in destination, resembled our Guildhall. The *curia dominicalis* was a sort of manor house.

Curling Stuff. That which is affected from the winding or coiling of the fibres round the boughs of the tree where they begin to shoot out of the trunk. The double iron plane is the best for working it.

Current. The necessary slope of a piece of ground or pavement for carrying off the water from its surface.

Cursor. (Lat.) The point of a beam compass that slides backwards and forwards. Also the part of a proportional compass by which the points are set to any given ratio.

Curtail Step. The first or bottom step by which stairs are ascended, ending at the furthest point from the wall, in which it is placed in a scroll; perhaps taking its name from the step curling round like a cur's tail.

Curvature. See Radius of Curvature.

Curve. (Lat. Curvus.) A line that may be cut by a straight line in more points than one.

Curvilinear. Formed of curved or flowing lines. Thus a curvilinear roof is one erected on a curved plan, circular, elliptical, or otherwise. Tracery in the later Mediæval styles is so called.

Cushion of an Ionic capital. See Coussinet.

Cushion Capital. A capital used in Romanesque and early Mediæval architecture, resembling a cushion pressed down by a weight. It is also a cap consisting of a cube rounded off at its lower angles, largely used in the Norman period of architecture. *Fig.* 1397.

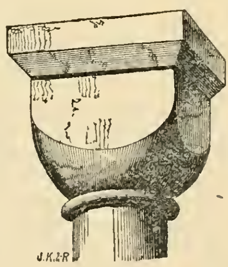

Fig. 1397.

Cushion Rafter. See Principal Brace.

Cusp. (Lat. Cuspis.) One of the pendents of a pointed arch, or of the arched head of a compartment of such an arch, or one of the several pendents forming what may be termed a *polyfoil.* Two cusps form a trefoil, three a quatrefoil, and so on.

Custom House. A custom house is an establishment for receiving the duties, or, as they are called, customs, levied on merchandise imported into a country, as well as of regulating the bounty or drawback on goods exported. According, therefore, to the importance and wealth of a city, the building to receive it is of considerable consequence. The first point that immediately presents itself is, that it should be provided with spacious warehouses for holding the merchandise which arrives, and in which it is, as it were, impounded till the duties are paid; and next, that there must be provided ample accommodation for the officers who are to supervise the levying of the imposts. The general principles in design are contained in the two maxims, of ample capaciousness for the merchandise to be received into the warehouses, and a panoptical view, on the part of the proper officers, of that which passes in the establishment. Security against fire must be strictly attended to. The warehouses and covered places for examining and stowing the goods should therefore be arched in brick or stone, and should, moreover, be as much as possible on the ground floor. The offices for the public and heads of the establishment may be over them on the first. Both of these are, of course, to be regulated in size by the extent of trade in the place The general character should be that of simplicity; decoration is unsuited, and should be very sparingly employed. The species of composition most suitable seems to be pointed out in arcades and arched openings. The site should be as near as may be to the river or port, so that the merchandise may be landed and housed with as little labour as possible. The Custom house at Dublin, designed by James Gandon, is a good work.

The following is a general view of the apartments and offices of the London Custom House. The long room, which is the principal public room for the entries, &c., is 185 feet long and 66 feet wide. This, as well as the rooms next enumerated, are on the first or principal floor, viz. a pay office for duties, treasury, bench officers' or commissioners' rooms, secretary's room, rooms for the inspector-general, surveyor of shipping, registrar of shipping, surveyor of acts of navigation, strong rooms, comptrollers, outward and inward, surveyor of works; Trinity light office, bond office, board room, chairman's room, committee-room and plantation clerk's office. On the ground floor are the following offices: for minute clerks, clerk of papers, petitions, messengers, landing surveyors, wood farm office, tide waiters, tide surveyors, inspectors of river, gaugers, landing waiters, coast waiters, coast office "long" room, coast bond office, coffee office, housekeeper, searchers, merchants' and brokers' room, comptrolling searchers, appointers of the weighers, and office for the plantation department. Besides these apartments there are warehouses for the merchandise.

The above long list will give a notion of what would be wanted on a smaller scale; but on such matters the special instructions on each case must be the guide to the architect in making his design. Many of the above offices would, of course, be unnecessary in a small port, neither would the dimensions be so large as the examples quoted. The staircases, corridors, and halls must be spacious in all cases, the building being one for the service of the public.

Cut. In inland navigation, the same as canal, arm, or branch.

Cut Brackets. Those moulded on the edge.

Cut Roof. One that is truncated. That is, one that appears as if the part above the collar beams was cut away; a good example is that over the chapel at Greenwich Hospital.

Cut Splay. The term for the oblique cutting of the corners of bricks in walling; as to reveals of doors, and other openings.

Cut Standards. The upright side pieces, or cheeks, supporting the ends of the shelves placed above a dresser table, or to a bookcase. The front edge is usually cut into a curved outline.

Cut Stone. Hewn stone, or that which is brought into shape by the mallet and chisel.

Cut String Stairs. Stairs which have the outer string cut to the profile of the steps. The nosings are mitred and returned; and the riser is mitred to the string. "Close string stairs" are where the steps and risers are housed into the strings. See String Board.

Cutters. The finest marl or malm bricks, chiefly used for arches of openings, quoins, &c., and which from their evenness of texture allow of being cut.

Cutting Plane. A plane dividing or cutting a solid into two parts in any direction.

Cyclograph. (Gr. Κυκλος and Γραφω.) In practical geometry, an instrument for describing the arc of a circle to any chord and versed sine, but chiefly used in flat segments, or those whose curvatures approach to straight lines.

Cycloid. (Gr. Κυκλοειδης.) A figure described by rolling a circle upon a plane along a straight edge, until the point on the circle which touches the straight edge return again to it after a revolution. The point traces the curve called the *cycloid* or *trochoid*.

Cyclopean Masonry. Works constructed of large rude stones arranged without mortar are called by this name; also Megalithic, and Pelasgic. It is considered there were four distinct periods, illustrating the changes from the rude constructions to more refined masonry. 1. Vast misshapen masses piled one upon another without order, the interstices filled up with pebbles and small stones. 2. Polygonal hewn blocks cut to fit each other; some interstices filled in with pebbles. 3. Courses of stone trapezoidal in appearance, but broken, as two courses equal in height to one adjoining; joints not always vertical, and the stones of irregular size. 4. Continuous coursed trapezoidal arrangement, the beds continued horizontally throughout, but the joints rarely vertical.

Cylinder. (Gr. Κυλινδρον.) A solid whose base is a circle, and whose curved surface is everywhere at an equal distance from the axis or line supposed to pass through its middle. Its formation may be conceived to be generated by the revolution of a rectangular parallelogram about one of its sides. The cone, sphere, and cylinder have a remarkable relation to each other, first discovered by Archimedes, namely, that the cone is one third the cylinder having the same base and altitude; and the inscribed sphere two thirds of the cylinder; or the cone, sphere, and cylinder are to each other as the numbers 1, 2, 3. It is termed a *right cylinder* when the axis is at right angles to the base, but if at an oblique angle the cylinder is said to be *oblique*.

Table of the areas of cylinders from 9 to 15 inches diameter:—

Diameter of Cylinder.	Area of Cylinder.	Diameter of Cylinder.	Area of Cylinder.	Diameter of Cylinder.	Area or Cylinder.
Inches.	Square Inches.	Inches.	Square Inches.	Inches.	Square Inches.
9	63·58	11½	103·84	13½	143·02
10	78·5	12	113·07	14	153·96
10½	86·56	12½	122·65	14½	165·04
11	95·01	13	132·66	15	176·62

NOTE.—The areas of cylinders are as the squares of their diameters.

CYLINDRICAL CEILING or VAULTING. Vulgarly called a *waggon-head* and *cradle*. One in the shape of the segment of a cylinder. This form appears to have been first used by the Romans. It admits of being pierced by *lunettes* for the admission of light, which form cylindro-cylindric arches, and is usually formed into panels or coffers.

CYLINDRICAL WORK. Any kind of work which partakes of the shape of a cylinder, of whatever material it be formed.

CYLINDROID. A solid which differs from a cylinder in having ellipses instead of circles for its ends or bases.

CYMA. (Gr. Κυμα, a wave.) A moulding taking its name from its contour resembling that of a wave, being hollow in its upper part and swelling below. Of this moulding there are two sorts, the cyma recta  thus, just described, and the cyma reversa  thus, wherein the upper part swells, whilst the lower is hollow. By workmen, each is called an *ogee*.

CYMATIUM. (Gr.) The name commonly applied to the upper moulding of a cornice or capping.

CYMBIA. The same as FILLET.

CYPRESS. (Lat. Cupressus.) The wood of the cypress was valued for its hardness and durability by the ancient architects.

CYZICENUS. In ancient architecture, a large hall decorated with sculpture. See GLYPTOTHECA.

D

DABBING, DAUBING, or PITCHING. Working the face of a stone after it has been *broached* and *draughted*, with a pick-shaped tool or the patent axe, so as to form a series of minute holes.

DADO. The die, or that part of the pedestal of a column between the base and the cornice. It is of a cubic form, whence the name of die. Large rooms are sometimes decorated with a base, dado, and cornice, representing a pedestal, and the term dado is often applied to the whole. See BASE.

DAGHOBA or DAGOBA. The Eastern *topes* or tumuli mostly contained relics, the worship of these objects being one of the principal characteristics of Budhism. These were designated *dagobas*, of which the word "pagoda" appears to be a corruption. In a Budhist temple, the dagoba is a structure which occupies the place of an altar in a Christian church. It consists of a low circular basement or drum surmounted by a hemispherical or elliptical dome that supports a square block covered by a roof called a *tee*.

DAIRY. An apartment in a house, or a separate building, for the preservation of milk, and the manufacture of it into butter, cheese, or other dairy produce. When on a small scale, where the milk is only used for butter, the dairy may be a room on the north side of the dwelling, or form one of the offices connected with the kitchen court. The temperature of a dairy should be within the range of forty-eight to fifty-five degrees of Fahrenheit, with sufficient ventilation to discharge all smells and impurities of the air. A dairy on a large scale should be a detached building, in which case it should contain a milk-room, a churning-room, and a dairy scullery or place for scalding the utensils.

If cheese be to be made, a room is required for the cheese-press, and another for drying and storing the cheeses.

Dais. (Fr.) The platform or raised floor at the upper end of a dining-hall, where the high table stood; also the seat with a canopy over it, for the chief guests who sat at the high table.

Dam. See Coffer Dam.

Damp Course. In order to prevent the damp rising up the walls from the soil on which a house is built, a course of some impermeable material is laid on the foundation walls a short distance (about a foot) above the level of the outside soil. This damp course, as it is called, is formed of a layer of powdered charcoal mixed with pitch or resin and powdered pitcoal; or of two courses of slates set in cement; of asphalte; or of the stoneware hollow tile manufactured for this purpose.

Dampness. A moisture generally attendant on buildings finished hastily on account of the materials not being dry; or the walls not being made of good well-burnt bricks; or with bad mortar; or the joints not flushed up, and allowing wet to come through.

Dancette. The chevron, or zigzag moulding, in Norman architecture. See *fig.* 1381.

Day or Bay. In Gothic architecture, the compartment in windows formed by the transoms or horizontal pieces and mullions or vertical pieces.

Dead Shore. A piece of timber worked up in brickwork to support a superincumbent mass until the brickwork which is to carry it has set or become hard.

Deafening Sound-boarding. The *pugging* used to prevent the passage of sound through wooden partitions. See Boarding.

Deal. (Sax. Delan, to divide.) Properly the small thickness of timber into which a piece of any sort is cut up; but the term is now, though improperly, restricted in its signification to the wood of the fir tree cut up into thicknesses in the countries whence deals are imported, viz. Christiania, Dantzic, &c. Their usual thickness is three inches, and their width nine. They are purchased by the hundred, which contains 120 deals, be their thickness what it may, reduced by calculation to a standard thickness of one inch and a half and to a length of twelve feet. *Whole deal* is that which is one inch and a quarter thick, and *slit deal* is half that thickness. *Clean deal* refers to picked or selected deal, which is always used for stair treads for good work. See Board.

Decagon. (Gr. Δεκα, ten, and Γωνια, an angle.) A geometrical figure having ten sides and ten angles. If the sides and angles are all equal, the figure is a regular decagon, and capable of being inscribed in a circle.

Decastyle. See Colonnade.

Decimal. (Lat.) A term applied to a system of arithmetic in which the scale of numbers proceeds by tens.

Decimal Equivalents of Inches, Feet, and Yards; and of a Shilling.

Decorated Period. A term applied to the Mediæval architecture in England prevailing during the reigns of the three first Edwards, wherein the decorative features grew out of, or became embodied in, and formed part of, the construction. It succeeded to the Early English period.

Decoration. The combination of ornamental objects which the desire for varying a form or forms brings together in many ways for embellishing those subjects which are the objects of art.

Dedication Cross. See Cross, *fig.* 1392.

Deliquiæ. (Lat.) A term used by Vitruvius to designate the rafters which formed the ridge of the roof and threw the water on each side.

Density. (Lat. Densus, thick.) A term used in physics to denote the quantity of matter which a body contains under a given or determinate surface; for example, a cubic foot. The quantity of matter in a body is called its mass, and is measured by the weight of the body, to which it is always proportional; hence the density of a body is great in proportion as its weight is great and its volume small; or the density of bodies is directly as their masses, and inversely as their volumes.

Dentils or Dentels. (Lat. Dentes, teeth.) The small square blocks or projections in the bed mouldings of cornices in the Ionic, Corinthian, Composite, and occasionally Doric orders; their breadth should be half their height; and, as Vitruvius teaches, the interval (Metoche) between them two thirds of their breadth. In the Grecian orders they are not used under modillions.

Deodorisation and Disinfection. The *Summary* of the "Hastings Prize Essay, 1865," on these subjects, states that:—I. For the sick room, free ventilation, when it can be secured, together with an even temperature, is all that can be required. II. For rapid deodorisation and disinfection, chlorine is the most effective agent known. III. For steady and continuous effect, ozone is the best agent known. IV. In the absence of ozone, iodine exposed in the solid form to the air, is the best. V. For that of fluid and semi-fluid substances undergoing decomposition, iodine is the best. VI. For the deodorisation and disinfection of solid bodies that cannot be destroyed, a mixture of powdered chloride of zinc or powdered sulphate of zinc, with sawdust, is the best. After this, a mixture of carbolic acid and sawdust, ranks next in order; and following on that, wood ashes. VII. For that of infected articles of clothing, etc., exposure to heat at 212° Fahr. is the only true method. And, VIII. For the deodorisation and disinfection of substances that may be destroyed, heat to destruction is the true method.

Carbolic acid, Condy's fluid, Burnett's fluid, and Charcoal are among the materials manufactured for this purpose.

Derby or Darby. A two-handed float used in plasterers' work.

Description of a Building. The same as Specification.

Descriptive Geometry. That which consists in the application of geometrical rules to the representation of the figures, and the various relations of the forms of bodies, according to certain conventional forms. It differs from perspective, on account of the representation being made in such a manner that the exact distance between the different points of the body represented can always be found, and consequently all the mathematical relations resulting from the form and position of the body may be deduced from the representation.

Design. (Lat. Designo.) The idea formed in the mind of an artist on any particular subject, which he transfers by some medium, for the purpose of making it known to others. Every work of design is to be considered either in relation to the art that produced it, to the nature of its adaptation to the end sought, or to the nature of the end it is destined to serve; hence its beauty is dependent on the wisdom or excellence displayed in the design, on the fitness or propriety of the adaptation, and upon the utility for the end. See Composition.

Details. A term usually applied to the drawings on a large scale for the use of builders, and generally called *working drawings.*

Determining Line. In the conic sections, a line parallel to the base of the cone; in the hyperbola this line is within the base; in the parabolic sections it forms a tangent to the base, in the elliptic it falls without it. In the intersecting line of a circle, the determining line will never meet the plan of the base to which it is parallel.

Diaconicum. A place contiguous to the ancient churches, wherein were preserved the sacred vestments, vessels, relics, and ornaments of the altar. In modern language, the *sacristy.* The sacristy is now also called the *vestry.*

Diagonal. (Gr. Δια, through, and Γωνια, angle.) A straight line drawn through a figure joining two opposite angles. The term in geometry, is used in speaking of four-sided figures, but it is nevertheless properly applied with reference to all polygons whereof the number of sides is not less than four. The term diameter is used by Euclid in the same sense; but modern geometers use the term diameter only in speaking of curve lines, and diagonal when speaking of angular figures.

Diagonal Scale. A compound scale formed by vertical and horizontal subdivisions with diagonals drawn across them, whereby very small parts can be measured off by means of equidistant parallels crossing others of the same kind.

Diagram. (Gr. Διαγραμμα, from Δια, through, and Γραφω, I write.) The figure or scheme for the illustration of a mathematical or other proposition.

Diameter. (Gr. Δια, through, and Μετρον, a measure.) A straight line passing through the centre of a geometrical figure, as that of a circle, ellipse, or hyperbola. The term is architecturally used to express the measure across the lower part of the shaft of a column, and is usually divided into sixty parts called minutes, which form the scale for the measurement of all the parts of an order. See Diagonal.

Diamicton. The Roman method of building a wall, with regular ashlar work on the outsides and filled in with rubble between. It is similar to Emplecton, but without the *diatoni* or binding stones which go through the thickness of the walls, showing on both sides. See Masonry.

Diamond Pavement. One disposed in squares arranged diagonally.

Diaper Work. The face of stone worked into squares or lozenges, with a leaf therein; as over arches and between bands. It is generally done only in interior work for decorating a plain surface. The illustration (*fig.* 1398) is from Canterbury Cathedral, and of the Perpendicular period.

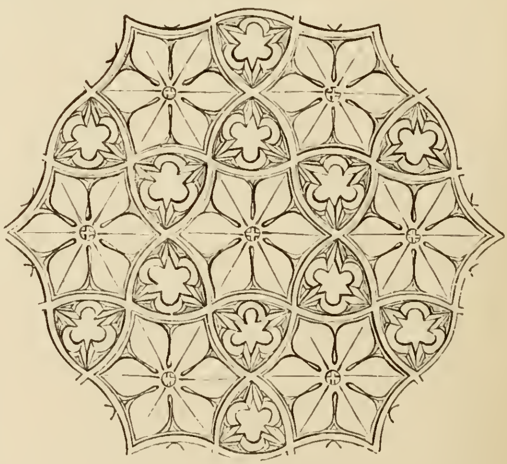

Fig. 1398. Diaper work in stone.

Diastyle. (Gr. Δια and Στυλος, a column.) That distance between columns which consists of three diameters, or, according to some, of four diameters. The term is sometimes used adjectively, to signify that the building is arranged with those intervals between the columns.

Diatoni. (Gr. Δια and Τονος, an extension.) In Greek architecture, the stones of a wall wrought on two faces, which, from stretching beyond the stones above and below them, that is, going through the wall, made a good bond or tie to the work.

Diazoma. (Gr. Δια through, and Ζωμα, a cincture.) In ancient architecture, the landings or resting places which, at different heights, encircled the amphitheatre like so many bands or cinctures, whence the name.

Dicasterium. (Gr. Δικη, justice.) In ancient architecture, the name of a tribunal or hall of justice.

Dictyotheton. (Gr. Δικτυον, a net, and Τιθημι, I place.) In ancient architecture, masonry worked in courses, like the meshes of a net. Also open lattice-work, for admitting light and air.

Didoron. (Gr.) See Brick.

Die of a Pedestal. That part included between the base and the cornice. See Dado.

Digging. In soft ground, one man with a spade will throw up, per hour, a cubic yard of twenty-seven feet. If a mattock must be used, the same quantity will require two men, and in a strong gravel, three. It will require three men to wheel thirty cubic yards of gravel in a day to the distance of twenty yards.

Diglyph. (Gr. Δις, twice, and Γλυφω, I carve.) A projecting face or *femur*, with two panels or channels called *glyphs*, sunk thereon. See Triglyph.

Dilapidation. The state of neglect into which a building has been permitted to fall.

Dimension. (Lat. Dimetior.) In geometry is either length, breadth, or thickness. Thus a line has one dimension, as of length; a superficies has two, length and breadth; a solid has three dimensions, length, breadth, and thickness.

Diminished Arch. One lower or less than a semicircle, called by the French *voute surbaissée.* See Surbased Arch.

Diminished Bar of a Sash. One thinner on the edge towards the room than on that towards the glass of the window.

Diminished Column. A column whereof the upper diameter is less than the lower.

Diminishing Rule. A board cut with a concave edge, so as to ascertain the swell of a column, and to try its curvature.

Diminishing Scale. A scale of gradation used in finding the different points for drawing the spiral curve of the Ionic volute, by describing the arc of a circle through every three preceding points, the extreme point of the last arc being one of the next three. Each point through which the curve passes is regulated so as to be in a line drawn to the centre of the volute and the lines at equal angles with each other.

Diminution of a Column. The continued contraction of the diameter of the column as it rises. Most of the modern authors make the diminution to commence from one-third the height of the column; but in all the ancient examples the diminution commences from the bottom of the shaft. See Entasis. In Gothic architecture neither swell nor diminution is used, all the horizontal sections being similar and equal.

Dining or Dinner Room. Generally one of the largest rooms in a dwelling-house. In large buildings it extends to forty or fifty feet in length, and the breadth is from half to three-fourths the length. In middle-sized houses, dining-rooms run from twenty-four down to eighteen feet in length by eighteen to sixteen feet in width, and thirteen or fourteen feet in height.

Diocletian Window. Usually called a Venetian Window.

Dipteral. (Gr. Διπτερος, double-winged.) In ancient architecture, a temple having a double range of columns on each of its flanks. See Temple.

Direct Radial. In perspective, a right line from the eye perpendicular to the picture.

Directing Line. In perspective, the line in which an original plane would cut the directing plane.

Directing Plane. In perspective, a plane passing through the point of sight, or the eye, parallel to the picture.

Directing Point. In perspective, that in which any original line produced cuts the directing plane.

Director of an Original Line. In perspective, the straight line passing through the directing point and the eye of a spectator.

Director of the Eye. In perspective, the intersection of the plane with the directing plane perpendicular to the original plane and that of the picture, and hence also perpendicular to the directing and vanishing planes, since each of the two latter is parallel to each of the two former.

Directrix. In geometry, the name given to a certain straight line perpendicular to the axis of a conic section. One of the properties of these curves is that the distance of any point of the curve from the directrix is to the distance of the same point from the focus in a constant ratio. The name is sometimes applied generally to any straight or curved line required for the description of any curve.

Discharge. (Fr. Décharger.) The relief given to a beam, or any other piece of timber, too much loaded by an incumbent weight of building. When the relief is given, the weight is said to be discharged.

Discharging Arch. An arch built over a wood lintel, whereby the bearing upon it is taken off. The chords of discharging arches are not much longer than the lintel, being the segments of very large circles. A temporary arch is frequently introduced, and removed on completing the building. Sometimes the arches are built without any lintel under them.

Dishing Out. The same as Cradling.

Displuviatum. (Lat.) In ancient architecture, a place from which the rain is conveyed away in two channels. According to Vitruvius, a *cavædium displuviatum* was an open court exposed to the rain.

Disposition. (Lat.) One of the essentials of architecture. It is the arrangement of the whole design by means of ichnography (plan), orthography (section and elevation), and scenography (perspective view). It differs from distribution, which signifies the particular arrangements of the internal parts of a building.

Distance of the Eye. In perspective, the distance of the eye from the picture in a line perpendicular to the plan thereof.

Distance, Point of. In perspective, the distance of the picture transferred upon the vanishing line from the centre, or from the point where the principal ray meets it; and thus it is generally understood to be on the vanishing line of the horizon.

Distance of a Vanishing Line. The length of a perpendicular falling from the eye perpendicular to the vanishing plane.

Distemper. (Fr. Detemper.) In house painting, whiting mixed with size and water, with which ceilings are generally done; plastered walls when not painted or papered are also so covered, and are called *coloured* when a tint is used in it.

Distribution. (Lat.) The arrangement of the various apartments of a building.

Dodecagon. (Gr. Δωδεκα and Γωνια, an angle.) A regular polygon of twelve equal sides.

Dodecahedron. (Gr. Δωδεκα and Ἑδρα, a seat.) One of the five platonic bodies, or regular solids, its surface being composed of twelve equal and regular pentagons.

Dodecastyle. A colonnade or portico consisting of twelve columns.

Dog-legged Stairs. Such as are solid between the upper flights, or such as have no well-hole, and in which the rail and balusters of both progressive and retrogressive flight fall in the same vertical plane. The steps are fixed to strings, newels, and carriages; and the ends of the steps in the inferior kind only terminate on the side of the string without any housing.

Dog-tooth Ornament. This ornament (*fig.* 1399 is a common representation of it), so greatly used in First Pointed or Early English work, appears in the abacus of one of the capitals in the cloister at Monreale, in Sicily, 1182–94; and it is noted by J. G. Wigley as occurring in the jambs of the little church of the Cœnaculum at Jerusalem, now known as the mosque of the tomb of David, erected early in the fourteenth century. He assigns the origin of the ornament, as well as of the "ball flower," to the Holy Land, the types being obtained from the *cyclamen* or gazelle's horn, and the red anemone. The use of it in Western architecture, 1090-1187, curiously corresponds with the period of the first Crusades.

Fig. 1399.

Dolmen. The French name for a Cromlech.

Dome. (Lat. Domus.) The spherical, or otherwise formed, convex roof over a circular or polygonal building. A *surbased* or *diminished dome* is one that is segmental on its vertical section, a *surmounted dome* is one that is higher than the radius of its base. There is great variety in the forms of domes, both in plan and section. In the former, they are circular and polygonal; in the latter, we find them semicircular, semi-elliptical, segmental, pointed, sometimes in curves of contrary flexure, bell-shaped, &c. The oldest dome on record is that of the Pantheon at Rome, which was erected under Augustus, and is still perfect. Below is a list of the principal domes.

Place.	Feet Diam.	Place.	Feet Diam.
Lutheran Church at Warsaw	(?) 200	Minerva Medica at Rome (ancient)	81½
Pantheon at Rome (ancient)	142½	St. George, Salonica	80
British Museum, London (iron)	140	Mosque of Ahmedich at Constantinople	80
St. Peter's at Rome	139	Jumma Musjeed. Beejapore	75
Duomo, or Sta. Maria del Fiore, at Florence	134½	Ispahan, Mesjid Shah	75
Gol Goomuz, Beejapore	124	Madre di Dio, at Turin	74
Sta. Francesca, Naples	124	Santa Maria della Salute, Venice	70
Baths of Caracalla (ancient)	112	S. Lorenzo, Milan	70
Sta. Sophia at Constantinople	106¾	St. Généviève at Paris (Pantheon)	69
S. Carlo Borromeo, Milan	105	Superga, Turin	64
Mosque of Suleimanieh, Constantinople	104	Madonna di Campagna at Verona	64
Church at Darmstadt	102	Mosque of Hassan at Cairo	63
St. Paul's, London	100	St. Gereon at Cologne	60
Capitol at Washington (iron)	100	Duomo at Siena	57
Hall of Liberation at Kehlheim	96	Santa Maria della Grazie, Milan	57
S. Isaac at S. Petersburg (iron)	96	Val de Grace at Paris	55
Chapel of the Medici at Florence	94	Radcliffe Library, Oxford	52
Church of the Invalides at Paris	92	San Vitale at Ravenna	50¾
Possagno, Church	91	Il Redentore, Venice	50
Halle aux Blés at Paris (iron)	90	Museum of the Vatican at Rome	50
Baptistery at Florence	83¾	San Marco, Venice	45
Cathedral at Gran	82		

Domus Conversorum. The day-room and dormitory of the *conversi* of a Cistercian monastery. They performed all the agrarian, artificers', and menial work incidental to the cultivation of the land, and the clothing and daily service of the whole community, taking part only occasionally in the daily service of the Church.

DONJON. (Fr.) The massive tower within ancient castles to which the garrison might retreat in case of necessity. It was centrally placed, and frequently raised on an artificial elevation.

DOOK. (Scotch.) The same as WOODEN BRICK.

DOOR. (Sax. Do , Gr. Θυρα.) The gate or entrance of a house or other building, or of an apartment in a house. It must be proportioned to the situation and use for which it is intended. Thus, for an ordinary dwelling-house, a door should not be less than seven to eight feet high, and three to four feet broad; but to churches and public buildings the entrance doors should be much wider, to allow of a multitude passing out. So in stately mansions, the doors must be from six to twelve feet in width, and of proportionate height.

DOOR FRAME or CASE. The wooden-frame enclosing a door.

DOOR PLANE. The plane between the door proper, and the larger opening within which it may be placed. It is often richly ornamented.

DOOR STOP. The slip of wood against which a door shuts in its frame. See REBATE.

DOORWAY. The framework of an opening for a door, the shape of which is determined by the style of architecture of the building. The Greek doorway was always square-headed, and generally less in width at top than at bottom. The Roman and the Romanesque doorways are sometimes round-arched; the Mediæval ones are pointed in shape.

DORIC ORDER. The first of the orders used in Grecian architecture, and the second as used in Roman and Italian architecture. Its capital is composed of straight lines and mouldings. In the frieze is used the triglyph, with mutules in the cornice and corresponding to them.

DORMANT TREE or SUMMER. The lintel of a door, window beam, &c. A beam tenoned into a girder to support the ends of joists on both sides of it. *Summer*, in some localities, is the common term for a girder. See BRESSUMMER.

DORMER. A window placed on the inclined plane of the roof of a house, the frame being placed vertically on the rafters.

DORMITORY. (Lat. Dormio, I sleep.) A large sleeping-room, capable of containing many beds. A range of cells for sleeping in.

DORON. The Greek for a palm. See BRICK.

DOSSEL. See REREDOS.

DOUBLE CONE MOULDING. A moulding used in the arches of the Norman period. (*Fig.* 1400.)

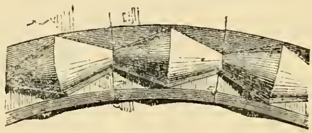

Fig. 1400.

DOUBLE CURVATURE. The curvature of a curve, whereof no part can be brought into a plane, such as the cylindro-cylindric curve, &c.

DOUBLE FLOOR. One constructed of binding and bridging joists.

DOUBLE-HUNG SASHES. A window opening with two sashes, one for lifting up, the other for drawing down, fitted into the sash frame of a window opening.

DOUBLE VAULTS. Two vaults of brick or stone carried up separately with a cavity between them.

DOUBLES. A sized slate used in roofing.

DOUBLING. A term used in Scotland to denote eaves' boards.

DOUCINE. The French term for the cyma recta.

DOVE-HOUSE, or DOVE-COT. A building for keeping tame pigeons, the only essential difference between which and a common poultry house is that the entrance for the birds must be placed at a considerable height from the ground, because of the flight of pigeons being so much higher than other birds.

DOVE-TAIL. A joint, so called from its being formed spreading like a pigeon's tail, used by carpenters and joiners in connecting two pieces of wood, by letting one into the other. It is the strongest method of joining masses, because the tenon or piece of wood widens as it extends, so that it cannot be drawn out, because the tongue is larger than the cavity through which it would have to be drawn. The French call this method *queue d'hironde*, or swallow's tail.

DOVE-TAIL MOULDING. An ornament formed of running bands, as Example 3, *fig.* 188. It is sometimes called a *triangular fret*.

DOWEL. A pin of wood or iron used at the edges of boards in laying floors to avoid the appearance of the nails on the surface. Floors thus laid are called *dowelled floors*. The drums of columns were steadied by the insertion of dowels of wood, cube in shape, as found in the remains of Greek and Egyptian architecture. Slate dowels are now often used in preference to iron, on account of the latter material tending to split the stone with rust.

DRAG. (Verb.) A term applied to anything bearing down or rubbing on another. Thus, a door is said to drag when its hinges become so loosened that the lower edge rubs upon the floor.

Dragging. The operation of completing the surface of soft stone by means of an instrument called a *drag*, which is a thin plate of steel with fine teeth on one edge, moved backwards and forwards by the workman.

Dragon Beam or Piece. In carpentry, a short beam or piece of timber lying diagonally with the wall-plates at the angles of a roof for receiving the heel or foot of the hip rafter. It is fixed at right angles with another piece called the *angle tie*, which is supported by each returning wall plate, on which it is cocked down. It may be a corruption of "dragging."

Drain. A subterraneous or other channel for waste water.

Draught or Drawing. The representation of a building on paper, explanatory of the various parts of the interior and exterior, by means of plans, elevations, and sections, drawn to a scale, by which all the parts are exhibited in the same proportion as the parts of the edifice intended to be represented. Working drawings show the parts in detail, or serve as directions to the artificers.

Draught. In masonry, a part of the surface of the stone, hewn to the breadth of the chisel on the margin of the stone according to the curved or straight line to which the surface is to be brought. When the draughts are framed round the different sides of the stone, the intermediate part is wrought to the surface by applying a straight edge or templet. In very large stones, when the substance needs much reduction, it is usual to make several intermediate parallel *draughts*, and thus the intermediate parts may be hewn down nearly by the eye, without much application of the straight edge or templet.

In carpentry, when a tenon is to be secured in a mortise by a pin, and the hole in the tenon is made nearer the shoulder than to the cheeks of the mortise, the insertion of the pin *draws* the shoulder of the tenon close to the cheeks of the mortise, and it is said to have a *draught*. See Draw Bore Pins.

Draught Compasses. Those with moveable points.

Draw Bore. (Verb.) The pinning a mortise and tenon, by piercing the hole through the tenon nearer to the shoulder than the holes through the cheeks from the abutment in which the shoulder is to come in contact.

Draw Bore Pins. Pieces of steel in the shape of a frustrum of a cone, rather taper, and inserted in handles with the greatest diameter next to the handle, for driving through the draw bores of a mortise and tenon in order to bring the shoulder of the rail close home to the abutment on the edge of the style. When this is effected, the draw bore pins, when more than one are used, are taken out singly, and the holes immediately filled up with wooden pegs.

Drawbridge. One made with long and heavy levers to be raised or let down, at pleasure.

Drawing. See Draught.

Drawing Knife. An edge tool used to make an incision on the surface of wood along which the saw is to follow. It prevents the teeth of the saw tearing the surface.

Drawing Room, perhaps more properly Withdrawing Room. The apartment to which the company *withdraw* after dinner.

Dressed. A term in masonry which expresses the operation a stone has undergone before building it in the wall, whether by the hammer only or by the mallet and chisel, and then rubbing the face smooth. In Scotland the term is used to signify hammer dressing only.

Dresser. A long table placed against a wall in a kitchen, usually with drawers, and having shelves over it for plates, stopped by a Cut Standard. At the edges of the shelves hooks are driven to carry jugs and cups. Under the drawers is a shelf raised a few inches above the floor, and called a pot board, for holding pots used in cooking.

Dressing Room. A room generally adjoining to and communicating with the sleeping room, used, as the name implies, for dressing in. It should have a separate door to open on the lobby or passage of communication.

Dressings. All kinds of mouldings beyond the naked walls or ceilings are called by the general name of dressings. In joinery it is a term applied to the architraves or other appendages of apertures.

Drift. (Sax. Dpıꝼan.) The horizontal force which an arch exerts with a tendency to overset the piers from which it springs.

Drip. See Corona.

Dripstone. The moulding in Gothic architecture placed over an opening to throw off water. It is also called a *weather moulding*, or more properly *hood mould*; and *label* when it is returned square.

Dripping Eaves. The lower edges of a roof from which the rain drips or drops to the ground.

Droog. A Sanscrit term for a hill fort, a term used in Hindostan.

Drop or Obtuse Arch. A pointed arch of less height than that formed by an equilateral triangle, similar to Fig. 1401.

Drops. (Sax. Dꞃoꝼꝼan.) The frusta of cones in the Doric Order, used under the triglyphs in the architrave below the *tænia*. They are also employed in the under part of the *mutuli* or modillions of the order. In the Greek examples they are sometimes curved a little inwards on the profile, and were called Guttæ.

Droved Ashlar. A term used in Scotland for chiselled or random-tooled ashlar. It is the most inferior kind of hewn work in building. What is in that country called broached work is sometimes done without being droved; but in good broached work the face of the stone should be previously droved, and then broached.

Droved and Broached. A term used in Scotland to signify work that has been roughed and then tooled clean.

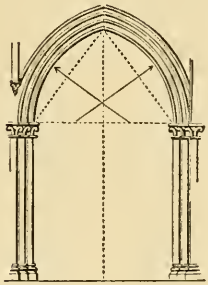

Fig. 1401.

Droved and Striped. Work that is first droved and then striped. The stripes are shallow grooves done with a half or three-quarter inch chisel, about an eighth of an inch deep, having the droved interstices prominent. This and the two preceding sorts of work are not much used in the southern part of England.

Druidical Architecture. The Celtic erections were formerly so called.

Drum. (Dan. Tromme.) The upright part under or above a cupola. The same term is sometimes applied to the solid part or vase of the Corinthian and Composite capitals; as well as to the block of stone composing part of the shaft of a column.

Druxy. Timber having decayed spots or streaks of a whitish colour in it.

Dry Rot. A disease of timber which destroys the cohesion of its parts; it is usually ascribed to the attacks of fungi, such as the *Polyporus destructor* and *Merulius lacrymans*, whose spawn appears upon the surface overspreading it like a tough thick skin of white leather; and there is no doubt of its being often connected with the appearance of such fungi. Dry rot is, however, in some cases to be identified with the presence of fungi of a more simple kind than those just mentioned, such as those of the genus *Sporotrichum*.

Dubbing out. A term used by plasterers to signify the bringing of an uneven surface in a wall to a plane, by pieces of tile, slate, or the like, before it is plastered over.

Duchesses. A sized slate used in roofing.

Dwang. A term used in Scotland to denote the short pieces of timber employed in strutting a floor.

Dwarf Wainscoting. Such as does not reach the whole height of a room, being usually three, four, five, or six feet high. Sometimes called a Dado.

Dwarf Walls. Low walls of less height than the story of a building; sometimes the joists of a ground floor rest upon dwarf walls. The enclosures of courts are frequently formed by them with a railing of iron on the top; and indeed any low wall used as a fence is a dwarf wall. See Fender.

Dwelling House. See House.

Dynamics. (Gr. Δυναμις, force or power.) As generally understood, the science which treats on the motion of bodies, because it is only known to us by the motion it produces in the body on which it acts. It is however usually restricted to those circumstances of motion in which the moving bodies are at liberty to obey the impulses communicated to them; the opposite cases, or those in which the bodies, whether by external circumstances or by their connection with one another, are not at liberty to obey the impulses given, being within the science of mechanics.

E

Eagle. See Ætiaioi.

Early English Period. The name given to the first, or Lancet period of mediæval architecture in England. It succeeded that of the Norman towards the end of the twelfth century. The accompanying illustration, *fig.* 1402, is a fine example of the work of that period.

Ears. The same as Crossettes.

Earth Closet. A convenience for the use of the occupants of a house, in lieu of a water closet, lately suggested by Rev. H. Moule, of Dorchester. Though adaptable to every dwelling, it is more appropriate to a country habitation. Two tubs are required, one being the store for dry common garden mould; the other, the receptacle for the deposits, over each of which is to be placed half a spadeful of the mould; this prevents any smell arising. When the tub is full, it may either be set aside for about a week or fortnight to dry, when the mould is then fit to be re-used, or employed for garden purposes. Liquid sewage will require to be disposed of separately, as it saturates a large quantity of earth.

Earth Table, or Ground Table, and Grass Table. The plinth of a wall (usually in Gothic work), or lowest course of projecting stones immediately above the ground. See Foot-stall.

Easter, or Holy, Sepulchre. A recess for the reception of the holy elements consecrated on the Cœna Domini or Maunday Thursday, till high mass on Easter-day. The few examples in England remaining are generally shallow, under an arch of obtuse or broad ogee form, rising about three feet from the slab, and are placed on the north side of the church.

Eaves. (Probably Fr. Eaux.) The lowest edges of the inclined sides of a roof which project beyond the face of the walls, so as to throw the water off therefrom, that being their office.

Eaves' Board, Eaves' Lath, Eaves' Catch. See Arris Fillet.

Ebony. The wood of a natural order of shrubby or arborescent exogens, chiefly inhabiting the tropics. Some species are remarkable for the hardness and blackness of their wood, which is principally used for furniture.

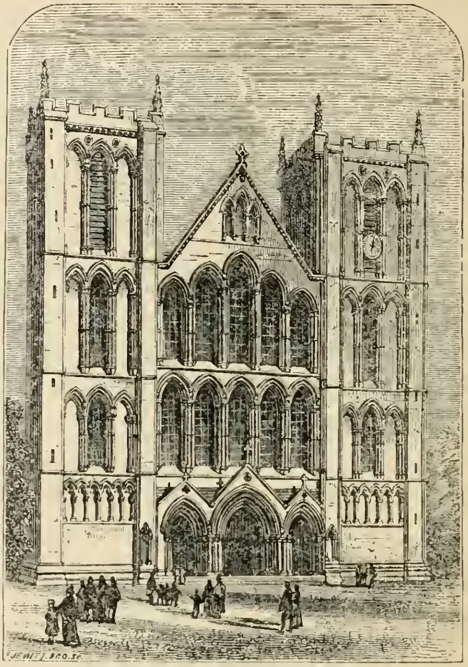

Fig. 1402. West Front and Towers of Ripon Cathedral, 1215–55.

Eccentricity. The difference of centre from another circle. The distance between the foci of an ellipse.

Echea. (Gr. Ηχεω, I sound.) In ancient architecture, sonorous vessels of metal or earth, in the form of a bell, used in the construction of theatres for the purpose of reverberating the sound of the performer's voice. They were distributed between the seats, and are described in the fifth book of Vitruvius, who states that Mummius introduced them in Rome, after the taking of Corinth, where he found this expedient used in the theatre.

Echinus. (Gr. Εχινος.) The same as the ovolo or quarter round, though the moulding is only properly so called when carved with eggs and anchors. (See Anchor.) It is the shell or husk of the chesnut, though the ornament does not seem to bear much resemblance to it.

Ecphora. (Gr. Εκ, out, φέρω, I bear.) A word used by Vitruvius (lib. iii. cap. 3.) to signify the projecture of a member or moulding of a column, that is, the distance of its extremity from the naked of the column, or, according to others, from the axis.

Ectype. (Gr. Εκτυπον.) An object in relievo, or embossed.

Edge. (Sax. Ecge.) The intersection of two planes or surfaces of a solid, which therefore is either straight or curved according to the direction of the surfaces. See Arris. It is also that side of a rectangular prismatic body which contains the length and thickness; but in this sense of the term, the body to which it applies is generally understood to be very thin; thus we say "the edge of a door," "the edge of a board," meaning the narrow side. The edge of a tool is the meeting of the surfaces when ground to a very acute angle.

Edge Tools. Those which clip or shave in the operation of working.

Edging. In carpentry, the reducing of the edges of ribs or rafters, whether externally or internally, so as to range in a plane or in any curved surface required. *Backing* is a particular use of edging, and only applies to the outer edges of ribs or rafters; but edging or ranging is a general term, and applies either to the backing or internal surface. See Backing.

Edifice. (Lat. Ædificium.) A word synonymous with fabric, building, erection; the word is, however, more usually employed to denote architectural erections distinguished for grandeur, dignity, and importance.

Effect. (Lat. Efficio.) That quality in works of art whose nature is to give particular efficacy to other qualities, so as to bring them out and attract the eye of the spectator.

Egg and Tongue. Ornaments used in the echinus, supposed by Quatremère de Quincy to have had their origin in the head of Isis, and, as he imagines, representing a mystical collar or necklace of the mundane egg and the tongue of the serpent of immortality; but as we think, in the representation of much more simple objects, those of nature herself. See Echinus.

Egyptian Architecture. In analysing the architecture of Egypt, three points offer themselves for consideration; construction, form, and decoration. If solidity be a merit, no nation has equalled the Egyptian. Uniformity of plan characterises all their works; they never deviated from the straight line and square. The decorations of the buildings were chiefly incised, or painted on plaster. The pyramids, temples, obelisks, statues, and rock-cut tombs, all attest the duration of a style doomed to become eternal.

Egyptian Hall. See Œcus.

Eleothesium. (Gr. Ελαιον, oil.) In ancient architecture, an apartment in the baths wherein, after leaving the bath, the bathers anointed themselves.

Elastic Curve. In mechanics, the figure assumed by an elastic body, one end of which is fixed horizontally in a vertical plane, and the other loaded with a weight which, by its gravity, tends to bend it.

Elasticity. (Gr. Ελαστη, a spring, from Ελαυνω, I draw.) In physics, that property possessed by certain bodies of recovering their form and dimensions after the external force which has dilated or compressed them is withdrawn. It is only perfect when the body recovers exactly its primitive form after the force to which it has been subjected has been removed, and that in the same time as was required for the force to produce the alteration. This is however a quality not strictly found in nature.

Elbow. The upright side which flanks any panelled work, as in windows below the shutters, &c.

Elevation. (Lat. Elevatio.) A geometrical projection drawn on a plane perpendicular to the horizon.

Elizabethan Architecture. The name given to the mixed or debased, yet picturesque, style of architecture prevailing during the reign of queen Elizabeth of England, caused by the partial introduction of Italian art and its mixture with mediæval details, with the requirements of greater civilization, leading to the purer examples displayed by Inigo Jones.

Ellipse or Ellipsis. (Gr. Ελλειψις, defect.) One of the conic sections produced by cutting a cone entirely through the curved surface, neither parallel to the base, nor making a subcontrary section; so that the ellipsis, like the circle, is a curve that returns into itself and completely encloses a space.

Ellipsograph. An instrument for describing an ellipsis by continued motion.

Ellipsoid. See Conoid.

Elliptic Arch. A portion of the curve of an ellipsis employed as an arch.

Elliptic Compasses. The same as Ellipsograph.

Elliptic winding Stairs. Such as are cased in and wind round an elliptic newel.

Elm. (Lat. Ulmus.) A forest tree occasionally used in building, principally for weather-boarding to barns, and such-like sheds.

Embankment. A term signifying any large mound of earth on the sides of a passage for water or other purposes; also for protection against the action of the sea. It is usually constructed of earth, and, when necessary to resist much force, cased with brick or stone.

Embattled. A wall indented with notches in the form of embrasures on the top of a wall, parapet, or other building. It is sometimes called crenellated.

Embattled Aronade. See Aronade.

Embattled-battled Line. A straight line bent into right angles, so that if there be three sets of parts, one set may be parallel to those of the other two.

Embattled Buildings. Those with embrasures in the parapets, resembling a castle or fortified place.

Embossing or Embossed Work. (Fr. Bosse, a protuberance.) The raising or forming in relievo any sort of figure, whether performed with the chisel or otherwise. It is a kind of sculpture, in which the figures rise from the plane on which they are formed, and as they are more or less prominent they are said to be in *alto*, *mezzo*, or *basso relievo*.

Embrasure. An opening made in the wall or parapet of a fortified place; it is also called a *crenel*. The term is also applied to an enlargement within the sides of a window, in which sense it is the same as Splay.

Emplecton. (Gr. Εμπλεκω, I entangle.) Among the ancients, a method of constructing walls, in which, according to Vitruvius, the front stones were wrought fair and the interior left rough and filled in with stones of various sizes.

Encarpus. (Gr. Εν and καρπος.) The festoons on a frieze, consisting of fruit, flowers, leaves, &c.

Encaustic Work. An ancient mode of painting, in which the execution was accomplished by the application of heat. It would appear as if one process consisted in mixing the tints in hot wax, which were then applied on the wall; and another, to coat the wall with wax after the tint had been given to the wall, rubbing in well the wax with hot cloths.

Encaustic Tiles. Tiles of earthenware used as paving. They are coloured and glazed, and formed to any shapes for patterns.

End of a Stone, Brick, &c. The two parallel sides which form the vertical joints.

Endecagon. (Gr. Ενδεκα, eleven, and Γωνια, an angle.) A plain geometrical figure bounded by eleven sides.

Engaged Columns. Those attached to walls, by which a portion of them is concealed. They never stand less than half their diameter out of the wall to which they are attached.

English Bond. In brickwork, the laying one course of bricks all headers, and the next course all stretchers, when for a one-brick wall.

Ensemble. (Fr.) A term denoting the masses and details considered with relation to each other.

Entablature. (Fr. Entablement.) In Greek, Roman, and Italian architecture; the whole of the parts of an order above a column. The assemblage is divided into three parts: the architrave, which rests immediately on the column; the frieze, next over the architrave, being the middle member; and the cornice, which is the uppermost part. All three vary according to the different Orders. The entablature has sometimes been used as an archivolt, as in the specimen here given, from a building by the elder Dance, who followed the example of Wren and other eminent professors. This use of it has been highly reprobated as a false principle of construction, as it conveys a false idea of the real use of the entablature; see *fig*. 1403. In the early Rennaissance architecture, the arch sprang from the capital of the column.

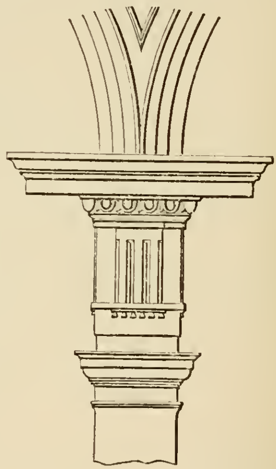

Fig. 1403. Church of St. Leonard, Shoreditch.

Entail or Entayle. The more delicate and elaborate portions of carved mediæval decoration.

Entasis. (Gr. Εντασις.) A delicate and almost imperceptible swelling of the shaft of a column, to be found in almost all the Grecian examples. It seems to have been adopted to prevent the crude appearance which the frusta of cones would have presented. This refinement is alluded to in the second chapter of the third book of Vitruvius, and was first in modern times observed in execution in 1814 by Mr. Allason. It has been adopted in the lines of a spire.

Enter. (Verb.) In carpentry and joinery, the act of inserting the end of a tenon in the mouth of a mortise previous to its being driven home to the shoulder.

Enterclose. A passage between two rooms.

Entresol. (Fr.) A low story over another one, both coming within a story equal in height to both. See Mezzanine.

Envelope. (Verb.) The covering of a portion of the surface of a solid with a thin substance or wrapper, which in all points or parts comes in contact with the surface of such surface. To develop the surface of a solid is to find the envelopes that will cover its different parts.

Eopyla. (Gr.) A church with an apsis at the eastern end.

Eothola. (Gr) A church with an apsis at the western end.

Ephebeium. (Gr.) A building, in ancient architecture, for the exercise and wrestling of the youth.

Epicranitis. (Gr.) A name given by the Greeks to the tiles forming the cyma or upper member of the cornice of their temples.

Epicycloid. (Gr. Επικυκλος, and Ειδος, form.) In geometry, a curve line generated by the revolution of a point in the circumference of a circle, which rolls on the circumference of another circle, either externally or internally.

Episcenium. (Gr. Επι, upon, Σκηνη, a scene.) In ancient architecture, the upper order of the scene in a theatre.

Epistylium. (Gr. Επι, upon, Στυλος, column.) The same as Architrave.

Epitithedes. (Gr. Επι, upon, Τιθημι, I place.) The crown or upper mouldings of an entablature.

Equiangular. Having equal angles.

Equidistant. At equal distances.

Equilateral. Having equal sides.

Equilateral Arch. An arch formed of two segments of circles whose centres are at the spring of the arch on each side, and if united with the point of intersection or apex of the arch form an equilateral triangle, as shown in *fig.* 1404.

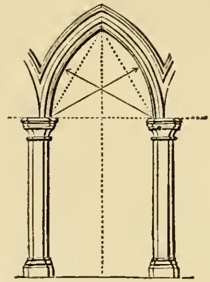

Fig. 1404.

Equilibrium. In mechanics, an equality of forces in opposite directions, so as mutually to balance each other. For the arch of equilibrium, see Catenary Curve.

Eremacausis. Slow combustion, which takes place in timber, and is the cause of its decay.

Ergastulum. In ancient architecture, a name given by the Romans to a prison or house of correction, where slaves, by the sole authority of their masters, were confined for their offences and subjected to hard labour. By the Greeks these buildings were called *sophronisteria*.

Escape. That part of the shaft of a column where it springs out of the base moulding. It is also called the *apophyge*, and in French, *congé*.

Escutcheon. A shield for armorial bearings, a mode of decoration extensively used in Gothic architecture. It is also a plate for protecting the keyhole of a door; or one to which the handle of a door is attached.

Estimate. The computed cost of works before they are commenced.

Estrade. An even or level space; a public road.

Etruscan Buildings. The inhabitants of Etruria, a country of Italy, and now called Tuscany, are supposed to have been a colony from Greece. Great solidity of construction is the prominent feature, enormous blocks of stone forming the high walls of fortified places. Their other works are tombs, in which are found works of art of high merit, especially the vases of red ware with black figures and ornamentation.

Eurithmy. (Gr. Ευρυθμια, justness of proportion.) The regular, just, and symmetrical measures resulting from harmony in the proportions of a building or order. Vitruvius makes it one of his six essentials.

Eustyle. (Gr. Ευ, well, and Στυλος, column.) See Colonnade.

Evaporation. (Lat.) The conversion of substances into vapour, during which process a considerable quantity of sensible heat passes into the *latent* or insensible state. The circumstances which principally influence the process of evaporation, are extent of surface, and the state of the air in respect of temperature, dryness, stillness, and density.

Evolute. (Lat. Evolvo.) In the theory of curve lines, is a curve from which any given curve may be supposed to be formed by the *evolution* or unlapping of a thread from a surface having the same curvature as the first curve. The curve thus generated is called the *involute curve.*

Excavation. (Lat.) The digging out or hollowing the ground for the foundations of a wall or of a building, or of a floor below the level of the ground.

Exchange. A place of meeting and resort for the merchants of a city to transact the affairs relating to their trading. There is every reason to believe that the ancient basilica served at the same time for the accommodation of the officers of the law and for the assembling of the merchants. All modern cities with any pretension to commerce have some place appropriated to the reception of the merchant, to which at a certain hour he resorts. Sometimes it is a place surrounded with porticoes and planted with trees. Often it is a building, including several porticoes, surrounded by offices for the bankers and money-changers, which latter use has given among us the name of exchange to the building.

The exchange is, perhaps, next in importance to the town hall, and should be commensurate in appearance and accommodation with the wealth and consequence of the city; it should, moreover, if possible, be placed in the most central part.

The Exchange at Amsterdam seems for a long time to have prevailed as the model for all others. It was commenced in 1608, and finished in 1613, and its architect was Cornelius Dankers de Ry. It is about 271 feet long, and about 152 feet wide.

The *Bourse* at Paris has always been considered an admirable model, both in distribution and design. The edifice was begun in 1808, from the designs of Brongniart, and completed by Labarre at a much protracted period. The general form on the plan is a parallelogram of 212 feet by 126 feet. It is surrounded by an unbroken peristyle of sixty-six Corinthian columns, supporting an entablature and attic. The peristyle forms a covered gallery, to which the ascent is by a flight of steps extending the whole width of the western front. In the centre of the parallelogram is the *Salle*, or great hall, 116 feet long and 76 feet broad. It conveniently contains 2,000 persons. At its eastern end is a circular space railed off for the convenience of the *agens de change*: these only are admitted within it, and to it there is a communication from their hall of business. On the right are rooms for the committee and syndicate of the *agens de change*, for the *courtiers de commerce*, and a hall of meeting for the latter. From the gallery, as on the ground floor, a corridor extends round the *Salle*, communicating with the Chamber of Commerce, the Court of Bankruptcy, and other public offices. The cost of this elegant building was about 326,000*l*.

The Royal Exchange in London was erected from the design of the late Sir William Tite, and opened October 1844, at a total cost of about 150,000*l*. It is 308 feet long, and 119 feet wide at the west end, but 175 feet at the east end. The central area, which is uncovered as above noticed, is 111 feet by 53 feet, and with the arcades (21 feet wide) surrounding it, 170 feet by 112 feet. This was originally left uncovered, but a fine glazed roof was put over it in 1886 by Charles Barry. The subscribers' room of Lloyd's is 100 feet long by 48 feet wide; the commercial room on the north side is 86 feet long and 40 feet wide. The ambulatory was highly painted and decorated in encaustic by Fred. Sang.

The Stock Exchange was rebuilt in 1854 by Thomas Allason, jun., but in 1885–7 it was enlarged to about double the size, with numerous additions, by John J. Cole. It is somewhat in the form of a Greek cross, having a dome of timber with skylights, 39 feet in diameter. It will hold about 1,200 members, but it is seldom all are present. Fireproof strong rooms with lockers are provided for the custody of securities. Besides the "house" or large reading and refreshment rooms, there are offices for brokers in the houses communicating.

The Coal Exchange was rebuilt in 1849, by the late Mr. J. B. Bunning, City architect. It consists of offices on several floors around a central hall 60 feet diameter, and 74 feet high to the top of the dome; it is formed principally of iron, and is decorated with representations of nature found in the coal measures, &c.

The Exchange Buildings at Liverpool, formerly one of its grandest buildings, erected in 1801, by Mr. Foster, sen., has been lately rebuilt by Mr. Thos. H. Wyatt, of London, on a much larger scale. The area of the Corn Exchange there is 100 feet by 98 feet, divided into three aisles by two rows of iron columns, the centre having curved iron ribs supporting the roof. There are 170 stands for the merchants. The architect was Mr. J. A. Picton, and it was erected 1851–53, at a cost of 11,000*l*.

Corn exchanges, or corn markets as they are usually called, are now to be seen in every important town. In 1856, when that at Coventry was built, it was stated to be "the largest hall of the sort," being 110 feet long, 55 feet wide, and 46 feet high; across the galleries it was about 74 feet wide. The Corn Exchange, in Mark Lane, is the greatest corn market in the world. Though the first site had been increased in area, additional space was acquired, and in 1878 a new exchange was in course of construction from the designs of the architect, the late Edward I'Anson. It is about 100 feet wide; the front part is 40 feet deep, and in rear is a nave of 60 feet with aisles on three sides of 20 feet each, the centre having a semicircular roof of iron, the aisles arched in iron.

Exhedra. (Gr. Ἐξ, out of, and Ἕδρα, a chair.) In ancient architecture, a small room in the baths and other buildings appropriated for conversations. See Apsis.

Exostra. (Gr.) In ancient architecture, a machine for representing the interior part of a building as connected with the scene in a theatre.

Expansion. One of the ordinary effects of heat, which enlarges the bulk of all matter. Though the expansion of solids is by increase of temperature comparatively small, it may be rendered sensible by carefully measuring the dimensions of any substance when cold and again when heated. Thus an iron bar fitted to a gauge, showing its length and breadth, will when heated no longer pass through the apertures. The metals are most expansible by heat and cold. The following exhibits the change which some of them undergo when heated from the freezing to the boiling point of water:—

	Expansion in linear dimension.	Temperature. 32°	Temperature. 212°		Expansion in linear dimension.	Temperature. 32°	Temperature. 212°
Platinum . .		120000	120104	Lead . . .	·0028	—	120345
Steel . . .	·0011	—	120147	Zinc . . .	·0029	—	120360

(Rankine, *Manual of Civil Eng.*, 1864).

Extension. (Lat.) One of the general properties of matter, being the quantity of space which a body occupies, its extremities in every direction limiting or circumscribing the matter of that body. It is the magnitude, size, or bulk of a body.

External or Exterior. A term of relation applied to whatever is on the surface or outside of a body, as opposed to *internal* or *interior*. External Wall, see Wall.

Extrados. The exterior curve of an arch. The term is generally used to denote the upper curve of the *voussoirs* or stones. See Intrados.

Eye. A general term signifying the centre of any part: thus the *eye of a pediment* is a circular window in its centre. The *eye of a dome* is the horizontal aperture on its summit. The *eye of a volute* is the circle at the centre, from whose circumference the spiral line commences. See Bull's Eye.

Eyebrow. A name sometimes given to the fillet.

F

Fabric. (Lat.) A general term applied to a large and important building.

Façade. (Fr.) The face or front of any building towards a street, court, garden, or other place; a term, however, more commonly used to signify the principal front.

Face Mould. The name applied by workmen to the pattern for marking the plank or board out of which ornamental hand-railings are to be cut for stairs or other works.

Face of a Stone. The surface intended for the front or outward side of the work. The back is usually left rough. Stones should be faced in the opposite direction of their splitting grain.

Facettes. (Fr.) Flat projections between the flutes of columns.

Facia or Fascia. (Lat.) A flat member of an order or of a building, like a flat band or broad fillet. The architrave, when subdivided for instance, has three bands called *fasciæ*, whereof the lower is called the first fascia, the middle one the second, and the upper one the third.

Facing. That part in the work of a building seen by a spectator; but the term is usually employed to signify a better sort of material, which masks the inferior one used internally.

Factabling. The same as Coping.

Faldstool. A moveable reading desk provided with a kneeling shelf at the foot thereof.

Fall of Land. A measure used in Scotland, equal to 36 square yards.

Falling Moulds. The two moulds applied to the vertical sides of the railpiece, one to the convex, the other to the concave side, in order to form the back and under surface of the rail and finish the squaring.

False Attic. An attic without pilasters, casements, or balustrades, used for crowning a building, as at the gates of St. Denis and of St. Martin, at Paris.

False Bearing. See Bearing Wall.

False Roof. That part between the ceiling of the upper floor and the covering of the roof.

Fan Tracery or Vaulting. A system of vaulting used in the Perpendicular period, in which the ribs spring from slender shafts or corbels at the side, and then diverge and

Fig. 1405. Tong Church, Shropshire.

spread themselves over the vaulting, presenting an appearance similar to the framework of a fan. This fan sometimes also springs from a pendent in the vaulting meeting the other fan work, as in *fig.* 1405. See Pendent.

FANG. The narrow part of the cutting iron of any tool which passes into the stock.
FANUM. (Lat.) A place consecrated to religion, including the building and ground belonging to it. Those temples erected to the memory of distinguished persons were called *fana* by the ancients.
FARRARIA. See GRANARY.
FASCIA. See FACIA.
FASTIGIUM. (Lat.) See PEDIMENT.
FATHOM. (Sax.) A measure of six feet, taken from the extent of both arms when stretched out in a right line. It is chiefly used in measuring the depth of water, quarries, wells, or pits.
FEATHER-EDGED. A term applied to any thin body whose section is trapezoidal; that is, thicker on one edge than on the other. See BOARD; COPING.
FEATHERINGS. The *cusps*, plain or decorated, at the ends of a *foil* in tracery.
FEEDER. A cut or channel by which a stream or supply of water is brought into a canal. Sometimes the supply itself of the water is so called.
FEEDING HOUSE or SHED. A farm-building for stalling and fattening neat cattle. It should be in a dry warm situation, capable of free ventilation, and supplied with proper conveniences for food and water.
FELT GRAIN. That position of splitting timber which is cloven towards the centre of the tree, or transversely to the annular rings or plates. The transverse position, or rather that which is in the direction of the annular plates, is called the *quarter grain*.
FELTING. The act of splitting timber by the felt grain.
FEMUR. See TRIGLYPH.
FENCE. (Lat. Defensio.) Any sort of construction for the purpose of enclosing land, as a bank of earth, a ditch, hedge, wall, railing, paling, &c.
FENDER. A dwarf wall in the basement of a house, built up to carry the front hearth of a fireplace.
FENDER PILES. Those driven to protect work, either on land or in water, from the con cussion of a moving body.
FENESTRATION. A design in which the windows are arranged to form the principal feature.
FESTOON. (Fr.) A sculptured representation of flowers, drapery, and foliage, looped or suspended at intervals on walls. The festoon was much used on friezes, altars, tablets, also over or under niches, as well as in many other situations.
FIGURE. In a general sense the terminating extremes or surface of a body. No body can exist without figure, or it would be infinite, and all space solid matter. Figure, in geometry, is any plane surface comprehended within a certain line or lines.
FILLET. (Fr. Filet.) A narrow flat band, listel, or annulet, used for the separation of one moulding from another, and to give breadth and firmness to the upper edge of a crowning moulding, as in a cornice. The small bands between the flutes of a column are called fillets. See ANNULET, BAND, and FACETTE.
FILLET. In carpentry or joinery, is any small timber scantling equal to or less than battens. Fillets are used for supporting the ends of boards by nailing them to joists or quarters, &c., as in *sound boarding*, and in supporting the ends of shelves.
FILLET GUTTER. A sloping gutter, with a learboard and fillet thereon, to divert the water.
FILLING IN PIECES. In carpentry, short timbers, less than the full length, fitted against the hips of roofs, groins, braces of partitions, which interrupt the whole length.
FINE SET. When the sole of a plane iron only projects sufficiently to take off a very thin shaving of wood.
FINE STUFF. Plaster used in common ceilings and walls for the reception of paper or colour. It is composed of lime slaked and sifted through a fine sieve, then mixed with a due quantity of hair and fine sand.
FINIAL. In Gothic architecture, the top or finishing of a pinnacle or gable, as it is now generally understood; but in ancient documents the term was used to denote an entire pinnacle. The carved tops of bench ends are also called finials.
FINISHING. A term frequently applied to the termination of a building; but more especially to the interior in the plasterer's work for the last coat, and often to the joiner's work, as the architraves, bases, surbases, &c.
FIR. A forest tree, extensively used in building, both for beams and for deals.
FIR POLES. Small trunks of fir trees, from ten to sixteen feet long, used in rustic buildings and outhouses.
FIR IN BOND. A technical expression to denote lintels, bond timbers, wall plates, and all timbers built in walls. See BOND.
FIR FRAMED. Rough timber framed, but which has not undergone the action of planing.
FIR WROUGHT. That planed on the edges and sides.
FIR WROUGHT AND FRAMED. That which is both planed and framed.
FIR WROUGHT, FRAMED, AND REBATED. That which is planed, framed, and rebated.

Fir wrought, framed, rebated, and beaded. The same as the preceding article, with the addition of beading.

Fir no Labour. Rough timber employed in walls, without planing or framing.

Fire-place. See Chimney.

Fire-stone. That which resists the action of the fire. A species of it is used in joinery for rubbing away the ridges made by the cutting-edge of the plane.

Firmer Tool. A chisel used by joiners with a mallet, by which the sides of mortises are formed.

Firring. See Furring.

First Coat. In plastering, the laying the plaster on the laths, or the rendering, as it is called, on brickwork, when only two coats are used. When three are used, it is called *pricking-up* when upon laths, and *roughing-in* when upon bricks.

First Floor. Generally the floor over the ground floor. Where there is a basement to a building as in a country mansion, the floor over is often called the "principal floor."

Fish. (Verb.) To secure a piece of wood by fastening another piece above or below it, and sometimes both to strengthen it.

Fished Beam. A long beam formed of two short beams placed end to end, and covered by a long piece of wood placed over and under the joint, the whole being secured together by bolts. Sometimes these latter pieces are indented to the beams as a further security. Scarfing is a somewhat similar operation.

Fistuca. (Lat.) A pile-driving instrument with two handles raised by pulleys, and guided in its descent to fall on the head of a pile so as to drive it into the ground, being what is by the workmen called (but improperly so) a *monkey*.

Fixture. A term applied to all articles of a personal nature affixed to land. This annexation must be by the article being let into or united with the land, or with some substance previously connected therewith.

Flags. Thin stones used for paving, from one and a half to three inches thick, and of various lengths and breadths, according to the nature of the quarry. See Landing.

Flake White. In painting, lead corroded by the pressing of grapes, or a ceruse prepared by the acid of grapes. It is of Italian manufacture, and for the purity of its white far surpasses the white lead of this country.

Flamboyant Period. The term applied to a period of mediæval architecture in France, in which the mullions and tracery terminate in waved lines of contrary flexure in flame-like forms. Examples of it occur about the beginning of the 15th century, and continue down to the middle of the 16th, being coincident nearly with the latter part of the period of our Ornamental English, and the whole period of the Florid English, or Tudor, style.

Flange. A projection round the edge of a pipe or other article of metal, to admit of its being fastened to a similar projection by screws, rivets, or bolts. The L-shaped pieces of wrought iron, used in girder work, are also called "flanges," and are employed for securing iron plates at right angles to each other, and for suspending one piece of work to another.

Flank. (Fr. Flanc.) That part of a return body which joins the front. In town houses the party-walls are the flank walls. Same as End.

Flashing. (Probably from Fr. Flaque, a splash.) Pieces of lead or other metal let into the joints of brickwork so as to lap over the metal of gutters, or along the slating of a roof, and thus prevent the rain getting access behind the latter, and so injuring the interior works.

Flat. That part of the covering of a building laid horizontal, or sufficiently sloping to throw off the water, and finished with lead or other material, perhaps to be walked upon.

Flatting. In house painting, a mode of painting in oil, in which the surface is left, when finished, without any gloss. The material or paint is prepared with a mixture of oil of turpentine, which secures the colours, and when used in the finishing, leaves the paint quite dead. The process is of use where it is desirable that the surface painted should retain the colour. It is only used for inside work and in the best apartments. Nut oil and poppy oil may be used for the purpose, both of which are good media for the colour.

Flemish Bond. In brickwork, the laying of each course of bricks as headers and stretchers, one course breaking joint with that over and under it.

Flemish Bricks. A species of bricks used for paving, whereof seventy-two will pave a square yard; they were originally imported from Flanders, are of a yellowish colour, and harder than common bricks.

Fleur-de-lis. An ornament like a lily, and often used as a finial; it is a favourite form in decoration.

Flexibility. (Lat. Flecto.) That property of bodies which admits of their bending. It is opposed to *stiffness* on the one hand, and *brittleness* on the other; stiff bodies being such as resist bending, and brittle bodies those which cannot be bent without a disruption of their parts.

FLEXURE. The bending or curve of a line or surface. The point of *contrary flexure* is that point of a curve where the curvature alters from convex to concave, or the reverse, as respects the first direction of the curve.

FLIGHT OF STEPS. In a staircase is the series of steps from one landing place to another. Thus, the same staircase between one floor and another may consist of more than one flight of steps; the flight being reckoned from landing to landing. See FLOOR.

FLINT. A material used in building walls where chalk abounds. Common flints are nearly pure *silica*. They usually occur in irregular nodules in chalk. Their origin is still an unsolved geological problem.

FLOAT. In plastering, a long rule with a straight edge, by which the work is reduced to a plane surface.

FLOATED LATH AND PLASTER. Plastering of three coats, whereof the first is *pricking-up*, the second, floating or floated work; and the last, of fine stuff.

FLOATED WORK. Plastering rendered perfectly plane by means of a FLOAT.

FLOATING SCREEDS. Strips of plaster previously set out on the work, at convenient intervals, for the *range* of the floating-rule or *float*.

FLOOR. (Sax. Flope.) The pavement or boarded lower horizontal surface of an apartment. It is constructed of earth, brick, stone, wood, or other materials. Carpenters include in the term the framed timber work on which the boarding is laid, as well as the boards themselves. In carpentry, it denotes the timbers which support the boarding, called also *naked flooring* and *carcass flooring*.

The term floor is, moreover, applied to the stories of a building, as *basement floor*, *ground floor*, &c. When there is no sunk story, the ground story becomes the basement floor, and the next floor the *principal floor*, containing the principal rooms; in many country houses they are on the ground floor, but in those of the town mostly on the one pair floor. The expressions, *one pair*, *two pair*, &c., imply a story above the first flight of stairs from the ground, and so on.

FLOOR. FOLDING or FOLDED. One in which the floor boards are so laid that their joints do not appear continuous throughout the whole length of the floor, but in bays or folds of three, four, five, or more boards each.

FLOOR. STRAIGHT JOINT. That in which the floor boards are so laid that their joints or edges form a continued line throughout the direction of their length; in opposition to *folding floor*, wherein the joints end in *folds*.

FLOOR CLOTH. Stout canvas covered with coarse oil paint, and then printed with a pattern, more or less elaborate. It should be thoroughly dry before being used, else it soon wears out. *Kamptulicon*, a preparation of caoutchouc and ground cork; and *Linoleum*, produced from oxydised linseed oil mixed with ground cork, and rolled on to strong canvas, are late and good substitutes for the common floor cloth. *Corticine*, and *Cork Carpet* are other similar materials; while *Boulinikon*, or buffalo hide floor-cloth, is a late candidate for public favour.

FLOOR JOISTS. The joists supporting the boards of the floor; but when the floor consists of binding joists, which are secured into the girders, and bridging joists, the bridgings are never called floor joists.

FLORIATED. Carved in imitation of flowers or leaves, either conventional or natural, and generally applied to decorated capitals, corbels, and bosses.

FLORID PERIOD of English mediæval architecture is the same as the PERPENDICULAR PERIOD, and is also called the Tudor style.

FLUE. The long open tube of a chimney from the fire-place to the top of the shaft, for voidance of the smoke. See CHIMNEY.

FLUING. The same as SPLAYED.

FLUSH. (Lat. Fluxus.) A term used by workmen to signify a continuity of surface in two bodies joined together. Thus, in joinery, the style, rails, and muntins are usually made flush; that is, the wood of one piece on one side of the joint does not project or recede from that on the other.

FLUSH. In masonry or brick-work, the aptitude of two brittle bodies to splinter at the joints where the stones or bricks come in contact when contiguous in a wall.

FLUSH. (Verb.) A term to denote the complete bedding of masonry or brick-work, in the mortar or cement used for the connection of the stones or bricks, so as to leave no vacant space where the stones or bricks do not nicely fit in their places.

FLUSH BOLT. A bolt of iron or brass let into the woodwork so that it does not project beyond the face of it. The bolt has to be worked by the thumb or a finger.

FLUTES or FLUTINGS. Upright channels on the shafts of columns, usually ending hemispherically at top and bottom. Their plan or horizontal section is sometimes circular or segmental, and sometimes, as in the Grecian examples, elliptical. The Doric column has twenty round its circumference; the Ionic, Corinthian, and Composite have twenty-four. The Tuscan column is never fluted. Flutes are occasionally *cabled*. See CABLE.

FLYERS. Steps in a flight of stairs that are parallel to each other. See WINDER.

YING BUTTRESS. A buttress in the form of an arch, springing from a solid mass of masonry, and abutting against the springing of another arch which rises from the upper points of abutment of the first. It is employed in most of the cathedrals, and its office is to act as a counterpoise against the vaulting of the nave. If flying buttresses were built solid from the ground, it is obvious that they would interfere with the vista along the aisles of the church; hence the project of continuing a resistance by means of arches. Their stability depends on the resistance afforded by the weight of the vertical buttress, whence they spring. See ARC-BOUTANT and BUTTRESS.

CUS. In geometry and the conic sections, a point on the concave side of a curve, to which the rays are reflected from all points of such curve.

DDER or FOTHER. A weight among the plumbers of London of 19½ cwt.

ENILIA. (Lat.) See GRANARY.

IL. The small arcs in the tracery of Gothic windows or panelling. See CUSP.

LDED FLOOR. See FLOOR.

LDING DOORS Such as are made to meet each other from the opposite jambs to which they are hung; and when they are rebated together, their edges meet folding over each other, with a bead at the joint, to give the appearance of one entire door.

LDING JOINT. A joint made like a rule-joint or the joint of a hinge.

LIAGE. A sculptured group of the leaves of plants and flowers, so arranged as to form architectural ornaments, as in friezes, panels, &c., and in the capitals of the Corinthian and Composite orders.

LIATION. The use of small arcs or foils in forming tracery.

NT. A vessel, generally of stone or metal, for containing the water of baptism in the Christian Church. The body of the font is usually a large block of stone hollowed out, and supported by a short column, single or clustered, and elevated on a base; sometimes two or three steps lead to the platform on which the font may be fixed. Ancient examples occur where they are made of metal. Some of the early fonts are extremely beautiful, and wrought with great richness of decoration. The singular inscription frequently found on the walls of baptisteries occurs also occasionally on ancient fonts: ΝΙΨΟΝ ΑΝΟΜΗΜΑΤΑ ΜΗ ΜΟΝΑΝ ΟΨΙΝ, which, reading equally well both ways, admonishes the reader to cleanse himself from sin, not less than to use the outward ceremony of baptism.

OT. (Germ. Fuss.) A measure of length, but used also in a sense which expresses surface and solidity. Thus we say, a foot *superficial* and a foot *cube*. As this term is used in almost all languages as a linear measure, it has doubtless been derived from the length of the human foot. It seems in all other countries, as in England, to be divided into twelve equal parts, or inches. See MEASURES.

The English standard foot (31 Edw. I.) is = 12 lineal English inches = 36 barleycorns = 16 digits = 4 palms = 3 hands = $5\frac{1}{3}$ nails = $1\frac{1}{3}$ spans = 1·5151 Gunter's links = ·938306 ft. of France = ·3047 met. of France. The foot is divided by geometricians into 10 digits, and each digit into 10 lines, &c. The French, as the English, divide the foot into 12 inches, and the inch into 12 lines. The foot square or superficial is a foot each way, and contains, therefore, 12 × 12 = 144 superficial inches = 2·295684 square links. The glazier's foot in Scotland = 64 square Scotch inches. The Scotch foot is to the English foot as 1 066 to 1·000, being in fact the French foot.

The length of the foot varies in different countries. The Paris royal foot exceeds that of England by 9½ lines. The ancient Roman foot of the Capitol consisted of 4 palms = $11\frac{7}{10}$ English inches. The Rhinland or Leyden foot, used by the northern nations of Europe, is to the Roman foot as 950 to 1000. The following table exhibits the length of the foot in the principal places of the Continent, the English foot being divided into 1000 parts, or 12 inches:—

	Parts.	Ft.	In.	Lines.
London	1000	0	12	0

Mr. Raper (*Philos. Trans.* vol. li.), from various authorities, determines the mean of the Roman foot to be nearly 968 parts of the London foot; and he considers that before the reign of Titus the Roman foot exceeded $\frac{970}{1000}$ of the London foot, and afterwards, in the reigns of Severus and Diocletian, it fell short of 965. Cagnazzi, from examination of the monuments of antiquity in Herculaneum and Pompeii, determines the Roman foot at ·29624 metre, which, the metre being 3·2808992 English feet, would make the old Roman foot $\frac{972}{1000}$ of the English foot.

List of feet of all countries as drawn up by Dr. Thomas Young from Hutton, Cavallo, Howard, Vega, and others :—

	English Feet.	
Altdorff foot	·775	Hutton.
Amsterdam foot	·927 930 ·931	H. Cavallo. Howard.
Amsterdam ell	2·233	C.
Ancona foot	1·282	H.
Antwerp foot	·940	H.
Aquileia foot	1·128	H.
Arles foot	·888	H.
Augsburg foot	·972	H.
Avignon = Arles.		
Barcelona foot	·992	H.
Basle foot	·944	H.
Bavarian foot	·968	Beigel.
Bergamo foot	1·431	H.
Berlin foot	·992	H.
Berne foot	·962	Howe.
Besançon foot	1·015	H.
Bologna foot	1·244 1·250	H. Cavallo.
Bourg en Bresse foot	1·030	H.
Brabant ell, in Germany	2·268	Vega.
Bremen foot	·955	H.
Brescia foot	1·560	H.
Brescian braccio	2·092	C.
Breslau foot	1·125	H.
Bruges foot	·749	H.
Brussels foot	·902 ·954	H. V.
Brussels, greater ell	2·278	V.
Brussels, lesser ell	2·245	V.
Castilian vara	2·746	C.
Chambery foot	1·107	H.
China mathematical foot	1·127	H.
China imperial foot	1·051 1·050	H. V.
Chinese li	606·000	C.
Cologne foot	·903	H.
Constantinople	2·195 1·165	H.

	English Feet.	
Copenhagen foot	1·049	H.
Cracow foot	1·169	H. V.
Cracow greater ell	2·024	V.
Cracow smaller ell	1·855	V.
Dantzic foot	·923	H.
Dauphiné foot	1·119	H.
Delft foot	·547	H.
Denmark foot	1·017	H.
Dijon foot	1·030	H.
Dordrecht foot	·771	H.
Dresden foot	·929	Wolfe.
Dresden ell = 2 feet	1·857	V.

Warsaw foot	1·169	H.
Wesel = Dordrecht	-	H.
Zurich foot	·979 ·984	H. Phil. Mag.

Foot of the Eye Director. In perspective, that point in the directing line made by a vertical plane passing through the eye and the centre of the picture.

Foot of a vertical Line. In perspective, that point in the intersecting line which is made by a vertical plane passing through the eye and the centre of the picture.

Foot Pace or Half Pace That part of a staircase whereon, after the flight of a few steps, a broad place is arrived at, on which two or three paces may be taken before coming to another step. If it occur at the angle turns of the stairs, it is called a *quarter pace.*

Footing Beam. The name given, in some of the provinces, to the tie-beam of a roof.

Footings of a Wall. The projecting courses at the base of a wall to spread it, and thus give security to the wall.

Foot-stall. The base or plinth of a building. See Earth Table.

Force. In mechanics, the course of motion in a body when it begins to move, or when it changes its direction from the course in which it was previously moving. While a body remains in the same state, whether of rest, or of uniform and rectilinear motion, the cause of its so remaining is in the nature of the body, which principle has received the name of *inertia.*

Forcer. In mechanics, a solid piston applied to pumps for the purpose of producing a constant stream, or of raising water to a greater height than it can be raised by the pressure of the atmosphere.

Fore Front. The principal or entrance front of a building.

Fore Plane. In carpentry and joinery, the first plane used after the saw or axe.

Foreshorten. In perspective, the diminution which the representation of the side or part of a body has, in one of its dimensions, compared with the other, occasioned by the obliquity of the corresponding side or part of the original body to the plane of projection.

FORM. The external appearance or disposition of the surfaces of a body, in which sense it is synonymous with FIGURE.

FORMERET. The arch rib, which in Gothic groining lies next the wall, and is consequently less than the other ribs which divide the vaulting.

FORUM. (Lat.) In ancient architecture, a public market; also a place where the common courts were held, and law pleadings carried on. The fora of the Romans were large open squares surrounded by porticoes, parts whereof answered for market-places, other parts for public meetings of the inhabitants, and other parts for courts of justice; the forum was also occasionally used for shows of gladiators. There were in Rome seventeen; of these fourteen were for the sale of goods, provisions, and merchandise, and called Fora Venalia; the other three were for civil and judicial proceedings, and called *Fora Civilia et Judicialia*. Of the latter sort was the forum of Trajan, of which the Trajan column formed the principal ornament.

FOUNDATION. The ground prepared for the footings of a wall to be placed thereon. The concrete and footings of a wall are sometimes called the "foundations."

FOUNDRY. A building in which various metals are cast into moulds or shapes.

FOUNTAIN. (Lat. Fons.) Any natural or artificial apparatus by means whereof water springs up. In natural fountains the ascensional effect is produced by the hydrostatic pressure of the water itself; in artificial fountains, by the same sort of pressure, or by that of compressed air, and sometimes by machinery.

FOX-TAIL WEDGING. A method of fixing a tenon in a mortise by splitting the end of the tenon and inserting a projecting wedge, then entering the tenon into the mortise, and driving it home. The bottom of the mortise resists the wedge, and forces it farther into the tenon, which will expand in width, so as not only to fill the cavity at the bottom, but be firmly compressed by the sides of the mortise.

FRAME AND FRAMING. (Sax. Fpamman, to form.) The rough timber work of a house, including floors, roofs, partitions, ceilings, and beams. Generally, any pieces of wood fitted together with mortises and tenons are said to be framed, as doors, sashes, &c.

FRANKING. A term used by the makers of window-sashes, and applied to the mode of forming the joint where the cross-pieces of the frame intersect each other, no more wood being cut away than is sufficient to show a mitre.

FREEING BEADS. The beads formed on the elbows of the boxings of a window, to allow of the shutters rising high enough to come on to the bead of the window sill.

FREE STONE. It is an old term that has no very distinctive meaning, but one which is commonly employed when speaking of any stone, whether it be a sandstone or a limestone, that is capable of being easily tooled, quite irrespective of its chemical composition, such as Portland stone, Bath stone, Yorkshire stone, some Scotch stone, &c.

FRENCH CASEMENTS. Windows turning upon two vertical edges attached to the jambs, and, when shut, lap together like folding doors upon the other two parallel edges, and are fastened by means of a long bolt called an Espagnolette bolt, extending their whole height. French casements are made in the form of the old English window, the two meeting styles, which lap together, forming a munnion about four inches in breadth. The lower part only of the window is moveable, the upper being fixed, and having a corresponding munnion; the lower rail of the fixed part and the upper rail of the moveable part forming a transom. The upper part is now sometimes made to open on centre pivots at the sides, to allow of ventilation to the apartments whilst the casement is closed.

FRESCO PAINTING. (It. Fresco, fresh.) A system of wall or ceiling decoration in which a painting is executed by incorporating the colours on the plaster before it is dry, by which it becomes very permanent.

FRETTE OR FRET. A species of ornament consisting of one or more small fillets meeting

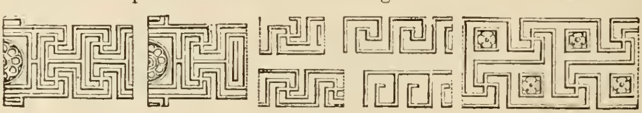

Fig. 1406.

in vertical and horizontal directions. (See *fig.* 1406.) The sections of the channels between the fillets is rectangular.

FRET-WORK. Ornamental decoration raised in protuberances.

FRICTION. (Lat. Frico, I rub.) The resistance produced by the rubbing of the surfaces of two solid bodies against each other.

FRIEZE, FREEZE OR FRIZE. (Ital. Fregio, adorned.) That member in the entablature of an order between the architrave and cornice. It is always plain in the Tuscan; ornamented with triglyphs and sculpture in the Doric (See METOPA); in the modern or Italian Ionic it is often swelled, in which case it is said to be *pulvinated* or *cushioned*; and in the Corinthian and Composite it is variously decorated with figures and foliage, according to the taste of the architect. The illustration is from the western end of the Parthenon at Athens, presenting a portion of the Panatheiac frieze. It is one of the fine specimens of Grecian art of the Elgin collection in the British Museum. (*Fig.* 1407.)

Fig. 1407.

Frieze of the Capital. The same as the Hypotrachelium.

Frieze Panel. The upper panel of a six-panelled door.

Frieze Rail. The upper rail but one of a six-panelled door.

Frigidarium. In ancient architecture, the apartment in which the cold bath was placed. The word is sometimes used to denote the cold bath itself.

Front. (Lat. Frons.) Any side or face of a building, but more commonly used to denote the entrance side.

Frontal. The cloth hung in front of the altar, also called *antependium.*

Frontispiece. (Lat. Frons and Inspicio.) The face or fore-front of a house, but the term is more usually applied to the decorated entrance of a building.

Fronton. The French term for a pediment.

Frosted. A species of rustic-work, imitative of ice, formed by irregular drops of water.

Frowey Timber. Such as works freely to the plane without tearing, whose grain therefore is in the same direction.

Frustum. (Lat.) In geometry, the part of a solid next the base, formed by cutting off the top, or it is the part of any solid, as a cone, a pyramid, &c., between two planes, which may be either parallel or inclined to each other.

Fulcrum. (Lat.) In mechanics, the fixed point about which a lever moves.

Funnel. (Lat. Infundibulum.) That part of a chimney contained between the fire-place and the summit of the shaft. See Chimney.

Furniture. (Fr. Fournir, to furnish.) The visible brass work of locks, knobs to doors, window-shutters, and the like.

Furring. (Fr. Fourrer, to thrust in.) The fixing of thin scantlings or laths upon the edges of any number of timbers in a range, when such timbers are out of the surface they were intended to form, either from their gravity, or in consequence of an original deficiency of the timbers in their depth. Thus the timbers of a floor, though level at first, oftentimes require to be furred; the same operation is frequently necessary in the reparation of old roofs, and the same work is required sometimes in new as well as old floors.

Furrings or Firrings. Pieces of wood used to bring a surface to a level with others.

Fusarole. (It.) A member whose section is that of a semicircle carved into beads. It is generally placed under the echinus, or quarter round of columns in the Doric, Ionic, and Corinthian orders.

Fust. (Fr. Fût.) An old term for the shaft of a column or trunk of a pilaster. It is also a term used in Devonshire, and, perhaps, in some other counties, to signify the ridge of a house.

G

Gable. (Brit. Gavel.) The vertical triangular piece of wall at the end of a roof, from the level of the eaves to the summit

Gablet. A small gable, or gable-shaped decoration, as introduced on buttresses, &c.

Gage. See Gauge.

Gain. In carpentry, the bevelled shoulder of a binding joist, for the purpose of giving additional resistance to the tenon below.

Galilee. A porch usually built near the west end of abbey churches. The galilees of Durham and Ely are found in the situation here described. The last mentioned is still used as the principal entrance to the church. The porch, south-west of the great transopt, at Lincoln Cathedral is also sometimes called a galilee. The word has been frequently used, but improperly, to designate the nave of a church. Many conjectures have been made on the origin of this term, but the most commonly received opinion, founded on a passage in the writings of St. Gervase of Canterbury, is, that when a female applied to see a monk, she was directed to the porch of the church, and answered in the words of Scripture, "He goeth before you into Galilee, there shall you see him."

GALLERY. (Fr. allée couverte.) The name given to one of the structures called Celtic and Megalithic, and formed of upright stones covered with flat ones.

GALLERY. (Fr. Galerie.) An apartment of a house, for different purposes. A common passage to several rooms in any upper story is called a gallery. A long room for the reception of pictures is called a picture gallery. A platform on piers, or projecting from the wall of a church and open in front to the central space is also called a gallery. The Whispering Gallery at St. Paul's is another example of the various uses of the word. The whole or a portion of the uppermost story of a theatre is likewise called a gallery.

GALLET. See GARRETING.

GAOL. A prison, or place of legal confinement.

GARDEN SHEDS. Erections for containing garden implements, flower-pots, hot-bed frames, and glass sashes, &c.; also for working in during bad weather. They are best placed on the back wall of the greenhouse, and thus hold the furnaces, fuel, and other articles.

GARGOUILLE, or GURGOYLE. The carved representations of men, monsters, &c., on the exterior of a church, and especially at the angles of the tower, serving as waterspouts, being connected with the gutters for the discharge of the water from the roof.

GARLANDS. (Fr.) Ornaments of flowers, fruit, and leaves anciently used at the gates of temples where feasts or solemn rejoicings were held.

GARNETS, CROSS. A species of hinge used in the most common works, formed in the shape of the letter T turned thus ⊢, the vertical part being fastened to the style or jamb of the doorcase, and the horizontal part to the door or shutter.

GARRET. The upper story of a house taken either partially or wholly from the space within the roof. It is also an epithet applied to rotten wood.

GARRETING, or GALLETING. Inserting small splinters or chips of stone or flint, called *gallets*, in the mortar joints of rubble work, after the walls are built.

GATE. (Sax. Ᵹeat). A large door, generally framed of wood. The width of gates should be from eight and a half to nine feet, and the height from five to eight feet. The materials of gates should be well seasoned previous to use, otherwise they will be soon injured by the sun and wind. The parts should be also very correctly put together. For durability, oak is the best; but some of the lighter woods, as deal, willow, and alder, are, on account of their lightness, occasionally used. These, however, are more for field-bar gates than close gates.

GATEWAY. A passage or opening formed through an enclosure wall or fence. It is also given to a building placed at the entrance of a property, and through which access is obtained, and guarded by a gate, or formerly by a portcullis drawbridge.

GATHERING OF THE WINGS. See CHIMNEY.

GAUGE, or GAGE. In carpentry or joinery, an instrument for drawing one or more lines on any side of a piece of stuff parallel to one of the arrisses of that side. Of this tool there are four sorts; the common gauge and the flooring gauge (which are both applied to the drawing of a line parallel to an arris), the internal gauge, and the mortise and tenon gauge.

This term is also used to signify the length of a slate or tile below the lap; also the measure to which any substance is confined.

GAUGED ARCH. One having the bricks or stones formed radiating to a centre. The bricks have to be cut, and, in very good work, they are also rubbed, to get a fine joint.

GAUGED STUFF. In plasterer's work, stuff composed of three parts of lime putty and one part of plaster of Paris, to set quicker. In bricklayer's work, it is the same proportion of mortar and Roman or Portland cement, used for filletings and in setting chimney-pots.

GAVEL. The same as GABLE.

GEMMELS. A mediæval term for hinges. See GIMBALS.

GENERATING CURVE. See EVOLUTE.

GENERATING LINE or PLANE. In Geometry, a line or plane which moves according to a given law, either round one of its extremities as a fixed point or axis, or parallel to itself, in order to generate a plane figure, or solid, formed by the space it has gone over.

GENESIS. (Gr.) In geometry, the formation of a line, plane, or solid, by the motion of a point, line, or plane. See GENERATING LINE.

GEOMETRIC PROPORTION. A building designed by geometrical figures, as the square, the triangle, &c.

GEOMETRICAL. That which has a relation to geometry.

Geometrical Decorated. The period of mediæval architecture in which the tracery and other ornamentation consisted entirely of distinct geometrical forms, and in which the principle of verticality and unity by a subordination of parts was fully developed.

Geometrical Staircase. That in which the flight of stone stairs is supported by the wall at only one end of the steps.

Geometry. (Gr. Γη, the earth, and Μετρω, I measure.) That science which treats of the objects of figured space. Its etymology implies the object of measuring land. The invention of the science has been referred to a very remote period: by some, to the Babylonians and Chaldeans; by others to the Egyptians, who are said to have used it for determining the boundaries of their several lands after the inundations of the Nile. Cassiodorus says that the Egyptians either derived the art from the Babylonians, or invented it after it was known to them. It is supposed that Thales, who died 548 B.C., and Pythagoras of Samos, who flourished about 520 B.C., introduced it from Egypt into Greece. Whatever the origin, however, of the term, the occasions on which it is necessary to compare things with one another in respect of their forms and magnitudes are so numerous in every stage of society, that a geometry more or less perfect must have existed from the first periods of civilisation.

Geometry, descriptive. The art of representing a definite body upon two planes at right angles with each other, by lines falling perpendicularly to the planes from all the points of concourse of every two contiguous sides of the body, and from all points of its contour, and, *vice versâ,* from a given representation to ascertain the parts of the original objects.

Geometry, practical. The method of working problems in geometry.

Ghaut. A Hindoo term for a landing place, steps on the banks of a river, a pass between mountains, and the mountains themselves, especially the eastern and western ranges, which cut off from the upper or table land the narrow strips of low coast that intervene between them and the sea.

Giblea Cheque, Giblet Cheek or Check. A term used by Scotch masons to denote the cutting away of the right angle formed by the front and returns of the aperture of a stone door-case, in the form of a rebate or reveal, so as to make the outer side of the door or closure flush with the face of the wall.

Gilding. The practice of laying gold leaf on any surface.

Gimbals, Gimbols, or Gimbles. (Lat. Gemellus.) A piece of mechanism consisting of two brass hoops or rings which move within one another, each perpendicularly to its plane, about two axes at right angles to each other. A body suspended in this manner, having a free motion in two directions at right angles, assumes a constantly vertical position. See Gemmels.

Gimlet, or perhaps more properly Gimblet. (Fr. Guimbelet.) A piece of steel of a semi-cylindrical form, hollow on one side, having a cross handle at one end and a worm or screw at the other. Its use is to bore a hole in a piece of wood. The screw draws the instrument into the wood when turned by the handle, and the excavated part, forming a sharp angle with the exterior, cuts the fibres across, and contains the core of the wood cut out. It is used for boring holes larger than is effected by the bradawl.

Girder. (Sax. Gyrtan, to enclose.) The principal beam in a floor, for supporting the binding or other joists, whereby the bearing or length is lessened. Perhaps so called because the ends of the joists are enclosed by it. An iron or timber girder carries a wall or assists to carry a floor. See Bressumer.

Girdle. A circular band or fillet surrounding a part of a column.

Girt. The length of the circumference of an object, whether rectilinear or curvilinear, on its horizontal section. In timber measuring, according to some, it is taken at one-fourth of the circumference of the tree, and is so taken for the side of a square equal in area to the section of the tree cut through, where the perimeter is taken in order to obtain the girt.

Glass. (Germ.) A transparent, impermeable, and brittle substance, of which there are different sorts used in building. The "Times" paper of February 6th, and others in May, 1875, stated that a Frenchman had discovered that glass heated to redness, and then cooled or annealed in oil, greatly increased its toughness, while its transparency remained the same. Thus a plate of glass supported at the ends would resist a weight falling two feet, but when treated as above it would resist the same weight falling six or eight feet. See Crown Glass, Sheet Glass, Plate Glass.

Glass Painting. A decoration frequently used in buildings. It is the method of painting on glass in such a manner as to produce the effect of the drawing, which has to be prepared by an artist for it. A French painter of Marseilles is said to have been the first who instructed the Italians in this art, during the pontificate of Julius II. It was, however, practised to a considerable extent by Lucas of Leyden and Albert Durer. See Stained Glass and Pot Metal.

Glazier. An artisan whose employment is that of fitting and fixing glass.

Glue. (From the Lat. Gluten.) A tenacious viscid matter made of the skins and hoofs of animals, for cementing two bodies together. Glue is bought in cakes, and is better the older the skin of the animal from which it is made. That which swells without dissolving when steeped in water is the best. To prepare glue it should be broken into small fragments and then steeped in water about twelve hours. It should be then heated in a leaden or copper vessel till the whole is dissolved, stirring it frequently with a stick. After this it is put into a wooden vessel and remains for use. A water-tight joint in wood can be obtained by grinding glue and white lead in equal proportions, boiled in linseed oil, so as to make the liquid of a whitish colour, and strong but not thick. It is also useful for external work. "Marine glue" is a very strong liquid matter, the material often giving way before the joint.

Glyph. (Gr. Γλυφω, I carve.) A sunken channel, the term being usually employed in reference to a vertical one. From their number, those in the frieze of the Doric order are called triglyphs.

Glyptotheca. (Gr. Γλυφω, and Θηκη, deposit.) A building or room for the preservation of works of sculpture. See Cyzicenus.

Gneiss. A species of granite which, from excess of mica, is generally of a lamellar or slaty texture. It is a term used by the miners of Germany.

Gnomon. (Gr. Γνωμων.) An instrument for measuring shadows, and thereby determining the sun's height. In dialling, it is the style of the dial, and its shadow marks the hour. It is placed so that its straight edge is parallel to the axis of the earth's rotation. In geometry, a gnomon is that part of a parallelogram which remains when one of the parallelograms about its diagonal is removed; or the portion of the parallelogram composed of the two complements and one of the parallelograms about the diagonal. The term is found in Euclid, but is now rarely used.

Gobbets. Blocks of stone; and also squared blocks of stone.

Gocciolatoio. (It.) The same as Corona.

Godown. The Bengalese term for a warehouse or cellar.

Godroon, or Gadroon. An ornamented moulding, consisting of beadings or cablings.

Gola, or Gula. (It.) The same as Cyma.

Goniometer. (Gr. Γωνια, an angle, and Μετρω, I measure.) An instrument for measuring solid angles.

Gopura. The Indian name for a gate-tower in the wall enclosing the space of ground in which are the cell and porch forming a temple in the south of Hindostan. In elevation it is pyramidal like a pagoda; but instead of being square like the temple in plan, the gopura is merely a *pylon*, sometimes 130 feet wide by 100 feet deep, pierced in the middle of the longer sides by a gateway which occupies a seventh or even a fourth of the width of the tower. The pile is covered by a crested roof, resembling a boat with the keel uppermost. Among the finest examples are those at Seringam, at Combaconum, and at Chillambaram, dating about 990–1004.

Gorge. The same as Cavetto. The *gorgerin* is a diminutive of the term.

Gorgoneia. (Gr.) Key-stones carved with Gorgons' heads.

Gothic Architecture. The name given about the end of the seventeenth century to the Pointed architecture of the mediæval period, and now called Mediæval Architecture.

Goufing Foundations. A Scotch term, signifying a mode of securing unsound walls by driving wedges or pins under their footings.

Gouge. A chisel whose section is of a semicircular form.

Gradetti. (It.) The same as Annulets.

Gradient. Good lists are given in *Builder*, 1863, p. 818; and xvii. p. 214.

Græcostasis. A hall or portico adjoining the Roman comitia, in which foreign ambassadors waited before entering the senate, and also whilst waiting the answer that was to be given to them.

Grain. The line of direction in which some materials can be split transversely.

Graining. The imitation of the grains or texture of certain ornamental woods, by means of paint worked over by a comb and other implements required to represent the various sorts. It is also called "combing."

Granary. (Lat. Granum.) A building for storing corn, especially that intended to be kept for a considerable time. Vitruvius calls those buildings intended for the preservation of grain *granaria*, those for hay *fœnilia*, and those for straw *farraria*. The term *horreum* was used by the Romans for denoting buildings not only for the preservation of corn, but for various other effects.

Grand. A term used in the fine arts, generally to express that quality by which the highest degree of majesty and dignity is imparted to a work of art. Its source is, in form, freed from ordinary and common bounds, and to be properly appreciated requires an investigation of the different qualities by which great and extraordinary objects produce impressions on the mind.

Grange. A farm-yard or farmery, consisting of a farm-house and a court of offices for the different animals and implements used in farming, as also of barns, feeding houses, poultry houses, &c.

GRANITE. This word is apparently a corruption of the Latin word *geranites*, used by Pliny to denote a particular species of stone. Tournefort, in the account of his *Voyage to the Levant* in 1699, is the first of modern writers who uses the name. The constituent parts of true granite are concretions of felspar, quartz, and mica, intimately joined together, but without any basis or ground. They are variable in quantity. Granites vary in colour, as the white, red, pink, blue, &c. See GNEISS.

GRASS TABLE. See EARTH TABLE.

GRATICULATION. The division of a design or draught into squares, for the purpose of reducing it to smaller dimensions.

GRAVEL. A term applied to a well-known material of small stones, varying in size from a pea to a walnut, or something larger. It is often intermixed with other substances, as sand, clay, loam, flints, pebbles, iron ore, &c. It is used for roads and for concrete.

GRAVE-STONE. A flat stone placed over the grave of a deceased person, on which the name, dates, &c., are engraved.

GRAVITY. See SPECIFIC GRAVITY.

GRECIAN ARCHITECTURE. The refined works of the ancient Greeks, as exhibited in the buildings at Athens and numerous other cities of Greece, Asia Minor, Sicily, &c. The chief principle of construction was the entablature and columns.

GRECO-ROMAN STYLE. The style of architecture adopted by many architects in England at the end of the last century, in which the severity of the ancient Greek style is modified by the richness and elaborate details of that of the Roman, together with the introduction of features such as the arch, adapted to the requirements of the style and of the present era.

GREE, GREES, GRESE, or GRYSE. An old word, signifying a step, steps, or degrees.

GREEK CROSS. See CROSS, *fig.* 1387.

GREEK MASONRY. The manner of bonding walls among the Grecians. See MASONRY.

GREENHOUSE. A building for sheltering in pots plants which are too tender to endure the open air the greater part of the year. It is constructed with a roof and one or more sides of glass, and being erected for luxury should not be far away from the dwelling-house, so that the greatest enjoyment may be had from it. At the same time it should, if possible, be near the flower garden, as being of similar character in use. The length and breadth can only be determined by the wealth and objects of the proprietor. The best aspects are south and south-east, but any aspect may, in case of necessity, be taken, if the roof be entirely of glass, and plenty of artificial heat be supplied. In those greenhouses, however, which face the north, the tender plants do not in winter succeed so well, and a greater quantity of artificial heat must then be supplied, and the plants should, in such case, be chiefly evergreens, and others that come into flower in the summer season, and grow and flower but little during the winter. The plants in greenhouses are kept in pots or boxes on stages or shelves, so as to be near and follow the slope of the roof, and thus made more susceptible of the action of the sun's rays immediately on passing through the glass.

An orangery, from being constructed with a ceiled roof, differs from a greenhouse; it is, moreover, chiefly devoted to plants producing their shoots and flowers in the summer season, and in the open air; the use of the orangery being merely to preserve them during the winter. The structure is more properly called a conservatory, though this term is now applied to buildings with glass roofs, wherein the plants are not kept in pots, but planted in the free soil, and wherein some are so reared as to grow and flower in the winter months.

GREY STOCKS. Bricks of the third quality of the best or malm bricks.

GRINDING. The act of taking off the redundant parts of a body, and forming it to its destined surface.

GRINDSTONE. A cylindrical stone, mounted on a spindle through its axis, with a winch-handle for turning it, to grind edge-tools.

GRIT STONE. One of various degrees of hardness; mostly of a grey, sometimes of a yellowish colour. It is composed of a siliceous and micaceous sand, closely compacted by an argillaceous cement. It gives some sparks with steel, is indissoluble, or nearly so, in acids, and vitrifiable in a strong fire. It is used for millstones more than for building.

GROIN. (Sax. Ᵹɲopan, to grow.) The line formed by the intersection of two arches, which cross each other at any angle. See CROSS VAULTING.

GROINED CEILING. One formed by three or more curved surfaces, so that every two may form a groin, all the groins terminating at one extremity in a common point.

GROINED VAULTING. A vault which is formed by groins springing from various points and intersecting. The varieties are described in Book II. Chap. 1, p. 388; and Chap. 3, p. 608.

GROOVE. (Sax. Ᵹɲapan, to dig.) A sunken rectangular channel. It is usually employed to connect two pieces of wood together, the piece not grooved having on its edge a projection or *tongue*, whose section corresponds to and fits the groove.

Grotesque. (Fr.) A term applied to capricious ornaments which, as a whole, have no type in nature, consisting of figures, animals, leaves, flowers, fruits, and the like, all connected together.

Ground Floor. The floor of a building level, or nearly so, with the surface of the chief thoroughfare or the land around it. It is not always the lowest floor, the basement being frequently beneath it. A floor, if on such a level, as in some country mansions, becomes a ground floor, though generally called a basement.

Ground Glass. The white effect given to glass by grinding it with emery powder, and thus obscuring it, so that it cannot be seen through.

Ground Joists. Those which rest upon sleepers laid upon the ground, or on bricks, prop stones, or dwarf walls; they are only used in basement and ground floors.

Ground Line. In perspective, the intersection of the picture with the ground plane. See Ground Plane.

Ground Niche. One whose base or seat is on a level with the ground floor.

Ground Plan. The plan of the story of a house level with the surface of the ground, or near to it.

Ground Plane. In perspective, the situation of the original plane in the supposed level of our horizon. It differs from the horizontal plane, which is said of any plane parallel to the horizon; whereas the ground plane is a tangent plane to the surface of the earth, and is supposed to contain the objects to be represented. The term *ground* plane is used in a more confined sense than that of original plane, which may be any plane, whether horizontal or inclined.

Ground Plate or Ground Sill. The lowest horizontal timber on which the exterior walls of a building are erected. It chiefly occurs in timber buildings, or in buildings whose outside walls are formed of brick panels with timber framings.

Ground Plot. The plan of the walls of a building where they first commence above the foundation, though more properly it is the piece of ground selected to receive the building. For dwellings, its chief requisites are a healthy situation, a convenient supply of water, good drainage, a pleasant aspect, &c. If for trade or manufacture, it should be conveniently placed for receiving the raw material, and for exporting the articles manufactured.

Grounds. In joinery, certain pieces of wood attached to a wall, to which the finishings are fastened. Their surface is flush with the plastering. Narrow grounds are those whereto the bases and surbases of rooms are fastened. Grounds are used over apertures, as well for securing the architraves as for strengthening the plaster. That the plaster may be kept firm, should the wood shrink, a groove is sometimes run on the edge of the ground next to the plaster, or the edge of the ground is rebated on the side next to the wall, so that in the act of plastering the stuff is received into the groove or rebate, which prevents it from shifting when it becomes dry. Wide grounds are framed.

Grouped Columns or Pilasters. A term used to denote three or more columns placed upon the same pedestal. When two only are placed together they are said to be coupled.

Grout. (Sax. Ꝥꞃuꞇ.) A semi-liquid mortar, composed of quicklime and fine sand, poured into the joints of masonry, and those of large masses of brickwork at every four courses or so, in order to fill up the joints well, which process is called *grouting*. It is not required when the joints are properly flushed up.

Growing Shore. See Dead Shore.

Gudgeon. The axle of a wheel, on which it turns and is supported. To diminish friction gudgeons are made as small as possible in diameter, consistent with their weight. They are often made of cast iron, on account of its cheapness, but wrought iron of the same dimensions is stronger, and will support a greater load.

Guilloche. (Fr.) An ornament in the form of two or more bands or strings twisting over each other, so as to repeat the same figure, in a continued series, by the spiral returning of the bands. The term is applied, but improperly so, to a Fret.

Gula, or Gola, or Gueule. (It.) Synonymous with Cymatium.

Gunter's Chain. One used for measuring land, and taking its name from its reputed inventor. It is 66 feet, or 4 poles, long, and divided into 100 links, each whereof is joined to the adjacent one by three rings; the length of each link, including the adjacent rings, is therefore 7·92 inches. The advantage of the measure is in the facility it affords to numerical calculation. Thus the English acre, containing 4,840 yards, and Gunter's chain being 22 yards long, it follows that a square chain is exactly the tenth part of an acre, consequently the contents of a field being cast up in square links, it is only necessary to divide by 100,000, or to cut off the last five figures, to obtain the contents expressed in acres.

Gurgoyle. See Gargoyle.

Guttæ. See Drops.

Gutter and Guttering. A canal to the roofs of houses, to receive and carry off rain-water. Gutters are made of metal or of tiles, which are either plain or concave; these last are called gutter tiles, and so adapted to each other as to be laid with great ease. The Romans had gutters of terra-cotta along the roofs of their houses, and the rain-water from them ran out through the heads of animals and other devices placed in the angles and in convenient parts. Zinc is often used for gutters, but should only be fixed to temporary erections. An ARRIS GUTTER is formed of wood. The channels on each side or in the middle of a roadway to carry off water, are called gutters.

GYMNASIUM. (Gr. Γυμνασιον, from Γυμνος, naked.) Originally a space measured out and covered with sand for the exercise of athletic games, the gymnasia in the end became spacious buildings, or institutions, for the mental as well as corporeal instruction of youth. They were first erected at Lacedæmon, whence they spread through the rest of Greece, into Italy. They did not consist of single edifices, but comprised several buildings and porticoes for study and discourse, for baths, anointing rooms, palæstras, in which the exercises took place, and for other purposes. It is also a building for the practice of physical games, and instruction in gymnastic exercises; and in Russia and Germany it is the school below the academy or university, where the scholar receives a superior education and learns its application in life.

GYNÆCEUM. (Gr. Γυνακειον.) In ancient architecture, that portion of the Grecian house set apart for the occupation of the female part of the family

GYPSUM. (Probably from Γη, earth, and Εψω, I concoct.) Crystals of native sulphate of lime. Being subjected to a moderate heat to expel the water of crystallisation, it forms plaster of Paris, and when water is applied to it, it immediately assumes a solid form. Of the numerous species, alabaster is, perhaps, the most abundant.

H

HABITABLE ROOMS. These are required by the Metropolis Local Management Act, 1855, c. 120, to be not less than 7 feet high. When placed in the roof they must be of that height at least, throughout not less than one half of the area of such room. When underground, they must be of that height at least, 1 foot of which must be above the surface of the footway of the street. They must have, for their entire frontage, an open area from 6 inches below the level of the floor to the surface of the footway and 3 feet wide in every part; they must be effectually drained; have a fire-place with a proper chimney or flue; and an external glazed window of at least 9 superficial feet in area, clear of the frame, and made to open in an approved manner. There must be appurtenant to such room or cellar a water-closet or privy, and an ashpit furnished with proper doors and coverings.

HACK. In brickmaking, the row in which crude bricks are laid to dry after being moulded, and before being placed in the clamps or kilns to be burnt.

HACKING. In walling, denotes the interruption of a course of stones, by the introduction of another on a different level, for want of stones to complete the thickness. Thus making two courses at the end of a wall of the same height as one at the other. The last stone laid is often notched to receive the first stone of the other where the two heights commence. Hacking is never permitted in good work. The term is used more in Scotland than in England. Taking down old plastering from a wall or ceiling, is called "hacking off."

HACKING-OUT KNIFE. An implement used in cutting old putty out of the rebates of a bar of a light, before inserting a new pane of glass. As this operation injures the bars, a liquid preparation is now often used for softening the putty.

HAGIOSCOPE. (Gr. ἅγιος, holy, and σκοπὸς, mark.) An aperture made in the interior walls or partitions of a church, generally in the sides of the chancel arch, to enable persons in the aisles, or side chapels, to see the elevation of the host. They are technically called *squints*, and sometimes *elevation apertures*; and now written *Agioscope*.

HALF-PACE. See FOOT PACE.

HALF ROUND. A semicircular moulding which may be a bead or torus.

HALF-TIMBER BUILDING. A structure formed of studding, with sills, lintels, struts, and braces, sometimes filled in with brickwork, and plastered over on both sides. Cottages were usually lathed and plastered on the outside only, the upright timber work showing on the inside. The outside woodwork was sometimes painted black.

HALL. (Sax. Hal.) A name applied indifferently to the first large apartment on entering a house, to the public room of a corporate body, a court of justice, or to a manor house.

Vitruvius mentions three sorts of halls; the Tetrastyle, which has four columns supporting the ceiling; the Corinthian, which has columns all round, and is vaulted; and the Egyptian, which has a peristyle of Corinthian columns, bearing a second order with a ceiling. These were called *œci*. In magnificent edifices, where the hall is larger and loftier than ordinary, and is placed in the middle of the house, it is called a saloon; and a royal apartment consists of a hall or chamber of guards, a chamber, an ante-chamber, a cabinet chamber, and a gallery.

HALVING. A method of joining timbers by letting them into each other. It is preferable to mortising, even where the timbers do not pass each other, as they are less liable to be displaced by shrinking.

HAM. (Sax.) Properly a house or dwelling place; also a street or village, whence it has become the final syllable to many of our towns, as Notting*ham*, Bucking*ham*, &c.; hence, too, *hamlet*, the diminutive of *ham*, is a small street or village.

HAMMER BEAM. A beam acting as a tie at the feet of a pair of principal rafters, but not extending so as to connect the opposite sides. Hammer beams are used chiefly in roofs constructed after the Gothic style, the end which hangs over being frequently supported by a concave rib springing from the wall, as a tangent from a curve, and in its turn supporting another rib, forming an arch. The ends of hammer beams are often decorated with beads and other devices. The finest example of such a roof is at Westminster Hall.

HANCE. The small arch which often joins a straight lintel to a jamb. Hence the term *Hance arch.*

HAND-RAIL OF A STAIR. A rail raised upon slender posts, called balusters, to prevent persons falling down the well hole, as also to assist them in ascending and descending.

HANDSPIKE. A lever for raising a weight, usually of wood, and applied to the holes in a capstan head.

HANG OVER. (Verb.) A term used to denote the condition of a wall when the top projects beyond the bottom.

HANGINGS. Linings for rooms of arras, tapestry, paper, or the like. Paper hangings were introduced early in the seventeenth century.

HANGING STILE OF A DOOR. That to which the hinges are attached.

HARDWARE. Ironmongery is so called.

HARMONIC PROPORTION. That which, in a series of quantities, any three adjoining terms being taken, the difference between the first and second is to the difference between the second and third, as the first is to the third.

HARMUS. (Gr. Ἁρμος.) In ancient architecture, a tile used for covering the joint between two common tiles.

HARNESS ROOM. A room wherein harness is deposited. It is absolutely requisite that it be dry and kept clean. Its situation should be near the stable it is destined to serve.

HASP. The fastening to a common casement. See SNACKET and STAPLE.

HASSACK. The provincial name for Kentish rag stone.

HATCHET. (Fr. Hachette.) A small axe used by joiners for reducing the edges of boards.

HAUNCHES OF AN ARCH. The parts between the crown and the springing.

HAWK. A small quadrangular tool with a handle, used by a plasterer, on which the stuff required by him is served, for his proceeding with the work in progress. He has always a boy attendant on him, by whom he is supplied with the material. The boy in question is called a *Hawk boy.*

HEAD. See APERTURE.

HEAD AND FOOT STONES. The upright stones placed to the grave of a deceased person, and on which the name, dates, &c., can be engraved.

HEADER. In masonry and brickwork, the stone extending over the thickness of a wall. Hence the term *Heading course.*

HEADING JOINT. In joinery, the joint of two or more boards at right angles to the fibres, or in handrailing at right angles to the back; this is so disposed with a view of continuing the length of the board when too short. In good work the heading joints are ploughed and tongued, and in dadoes are, moreover, connected with glue.

HEADWAY OF STAIRS. The clear distance, measured perpendicularly, from a given landing-place or stair to the ceiling above, whether of the stairs or landing.

HEART BOND. In masonry, that in which two stones of a wall forming its breadth, have one stone of the whole breadth placed over them. See BOND.

HEARTH. See CHIMNEY. See SLAB.

HEATHER ROOF. A covering used in Scotland, by some considered superior to straw.

HECATOMPEDON. (Gr.) A temple one hundred feet in front. A term applied to the Parthenon. *Fig.* 1458, 99 and 100.

Mr. Penrose's measurement gives the length of top of upper step as 101·341 English feet = 100 Attic feet. Length of the same 228·141 English feet.

HEEK. The same as RACK.

HEEL. A term used by workmen to denote a *cyma reversa.*

HEEL OF A RAFTER. The end or foot that rests on the wall plate.

HEIGHT. The perpendicular distance of the most remote part of a body from the plane on which it rests.

HEIGHT OF AN ARCH. A line drawn from the middle of the chord or span to the intrados. It is also called the *versed sine.*

HELICAL LINE OF A HANDRAIL. The spiral line twisting round the cylinder, representing the form of the handrail before it is moulded.

Heliocaminus. (Gr. Ἡλιος, the sun, and Καμινος, a furnace.) A chamber in the Roman houses which depended on the rays of the sun for warming it.

Helioscene. An outside blind invented of late years, formed like the louvres of a ventilator, which keeps out the rays of the sun, ensures ventilation, and permits a clear view from the inside of the room to the window of which it is applied.

Helix. (Gr. Ἕλιξ, a kind of ivy whose stalk curls.) A small volute or twist under the abacus of the Corinthian capital, in which there are, in every perfect capital, sixteen, called also *urillæ*; viz., two at each angle, and two meeting under the middle of the abacus, branching out of the caulicoli or stalks, which rise from between the leaves.

Hem. The spiral projecting part of the Ionic capital.

Hemicycle. A semicircle; the term is used architecturally to denote vaults of the cradle form, and arches or sweeps of vaults, constituting a semicircle.

Hemisphere. In geometry, the half of a globe or sphere, when divided by a plane passing through its centre.

Hemitriglyph. A half triglyph.

Heptagon. (Gr.) A geometrical figure of seven sides and angles.

Hermitage. A small hut or dwelling in an unfrequented place, occupied by a hermit. Imitation buildings in a park, as a resting place, are so called.

Herring Bone Work. In paving, a disposition of bricks or stones laid diagonally (see diagram in the margin), each length receiving the end of the adjoining brick or stone. In walling, courses of stone or bricks laid angularly in the face of a wall, in a similar manner. Sometimes there is a horizontal course of stones or bricks laid between each angular course. See Ashlar.

Hewn Stone. That which is reduced to a given form by the use of the mallet and chisel.

Hexagon. (Ἑξ and Γωνια, angle.) In geometry, a plain figure bounded by six straight lines, which, when equal, constitute the figure a regular hexagon.

Hexahedron or Cube. (Gr Ἑξ six, and Ἑδρα, seat.) One of the five regular solids, so called from its having six faces or seats.

Hexastyle. (Gr. Ἑξ and Στυλος, column.) That species of temple or building having six columns in front. (*Fig.* 1408.) See Colonnade.

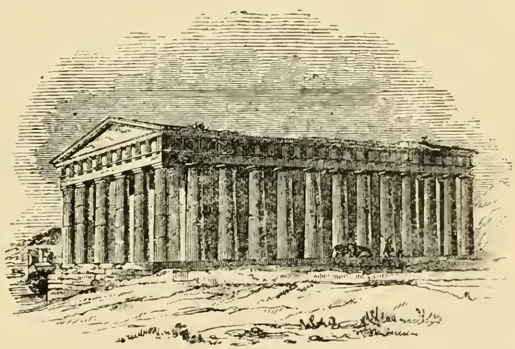

Fig. 1408. Temple of Theseus at Athens.

Hick-joint Pointing. That species of pointing in which, after the joints are raked out, a portion of superior mortar is inserted between the courses, and made perfectly smooth with the surface. See Pointing.

Hieroglyphics. (Ἱερος, sacred, and Γλυφω, I engrave.) Sculpture or picture-writing, which has obtained the name from being most commonly found on sacred buildings. They consist in the expression of a series of ideas by representations of visible objects. The name, is, however, more particularly applied to a species of writing used by the ancient Egyptians, of three different varieties of characters:—1. The hieroglyphic, properly so called, wherein the representation of the object conveys the idea of the object itself. 2. That in which the characters represent ideas by images of visible objects used as symbols. 3. That consisting of *phonetic characters*, in which the sign does not represent an object but a sound.

Hindoo Architecture. See Indian Architecture.

Hinges (from Hang.) The metal joints upon which any body turns, such as doors, shutters, &c. There are many species of them, as described under the names.

Hip. A piece of timber placed between every two adjacent inclined sides of a hip roof, for the purpose of receiving what are called the jack rafters.

Hip Knob. A finial, placed at the end of the ridge piece of a roof, or apex of a gable, and against which abuts the barge board of a gable; it is often finished with a pendant.

Hip Mould. A term used by some workmen to denote the back of the hip; by others it is used to signify the form or pattern by which the hip is set out.

Hip or Hipped Roof. A roof whose return at the end of a building rises immediately from the wall plate with the same inclination as the adjacent sides. The back of a hip is the angle made on its upper edge, to range with the two sides or planes of the roof, between which it is placed. The *jack rafters* are those short rafters which are shorter than the full-sized ones to fill in against the hips.

Hip or Corner Tiles are those used at the hips of roofs; they are ten inches long, and of appropriate breadth and thickness, and bent on a mould before burning.

Hippodrome. (Gr. Ἵππος, a horse, and Δρομος, a course.) In ancient architecture a place appropriated by the Greeks to equestrian exercises, and one in which the prizes were contended for. The most celebrated of these was at Olympia. It was four stadia (each 625 feet) long, and one stadium in breadth.

Hoard. (Sax. Hord, to keep.) A timber enclosure round a building, in the course of erection or under repair.

Hod. A utensil employed by labourers for carrying mortar or bricks.

Hogging. That curve upwards or convexity which is given to the middle of a long line, as the ridge of a roof, to prevent it appearing to have sunk in that part of it. It is carrying out the *scamilli impares* recommended by Vitruvius for the same purpose.

Holdfast. A long nail, with a flat short head for securing objects to a wall.

Hollow. A concave moulding, whose section is about the quadrant of a circle; called, sometimes, by the workmen a *casement*.

Hollow Newel. An opening in the middle of a staircase. The term is used in contradistinction to solid newel, into which the ends of the steps are built. In the hollow newel, or well hole, the steps are only supported at one end by the surrounding wall of the staircase, the ends next the hollow being unsupported.

Hollow Quoins. Piers of brick or stone made behind the lock gates of canals.

Hollow Wall. One built in two thicknesses leaving a cavity between them, for the purpose of preventing rain being drifted through the brickwork into the apartment, or for preserving a uniform temperature therein. They are tied together at intervals by iron ties, square slate, &c. A lining of slate in the cavity has lately been added.

Homestall and Homestead. A mansion, or seat in the country.

Homologous. In geometry, the corresponding sides of similar figures. The areas and solid contents of such figures are likewise homologous.

Hood Mould. The projecting moulding forming a *drip* to protect the other mouldings to a door or window. See Label.

Hook. (Sax. Hoce.) A bent piece of iron, used to fasten bodies together, or whereon to hang any article. They are of various kinds.

Hook Pin. The same as Draw-bore Pin.

Horizontal Cornice. The level part of the cornice of a pediment under the two inclined cornices.

Horizontal Line. In perspective, the vanishing line of planes parallel to the horizon.

Horizontal Plane. A plane passing through the eye parallel to the horizon, and producing the vanishing line of all level planes.

Horizontal Projection. The projection made on a plane parallel to the horizon. This may be understood perspectively, or orthographically, according as the projecting rays are directed to a given point, or perpendicular to a given point.

Horn. A name sometimes given to the Ionic volute.

Horreum. See Granary.

Horse Block. A square frame of strong boards, used by excavators to elevate the ends of their wheeling planks.

Horse Run. A contrivance for drawing up loaded wheelbarrows of soil from the deep cuttings of foundations, canals, docks, &c., by the help of a horse, which goes backwards and forwards instead of round, as in a *horse-gin*.

Horseshoe Arch. An arch which, being higher than a semicircle, the radius is continued down on to the capital. It is chiefly used in Saracenic architecture.

Hospital. A building erected for the care of sick persons. It is also given to one for infirm persons, as Greenwich Hospital, but that is properly an infirmary.

Hostel or Hotel. (Fr. Hôtel.) This word is used to denote a large inn, or place of public entertainment; but on the Continent it is applied to a large house, either of a private or public nature. One of the most interesting of the former class in Paris, is that of the celebrated Hôtel de Cluny (*fig.* 1409), now containing a museum of mediæval antiquities. It was erected at the end of the 15th century, the works being resumed in 1490, after some interruption, by Jacques d'Amboise, Abbé of Cluny. (See page 239.)

Hot House. A general term for the glass buildings used in gardening, and including stoves, greenhouses, orangeries, and conservatories. Pits and frames are mere garden structures, with glass roofs, the sides and ends being of brick, stone, or wood, but so low as to prevent entrance into them; they cannot therefore be considered as hothouses.

House. (Germ. Haus.) A human habitation or place of abode of a family. Among the nations of the east and of the south, houses are flat on the top, to which ascent is general on the outside. As we proceed northward, a declivity of the roof becomes requisite to throw off the rain and snow, which are of greater continuance in higher latitudes. Amongst the ancient Greeks, Romans, and Jews, the houses usually enclosed a quadrangular area or court, open to the sky. This part of the house was by the Romans called the *impluvium* or *cavædium*, and was provided with channels to carry off the waters into the sewers. Both the Roman and Greek house is described by Vitruvius, to whose work we must refer the reader for further information on these heads. The word house is used in various ways; as in the phrase, "a religious house," either the buildings of a monastery, or the community of persons inhabiting them may be designated. In the middle ages, when a family retired to the lodge connected with the mansion, or to their country seat, it was called "keeping their secret house." Every gradation of building for habitation, from the cottage to the palace, is embraced by the word house, so that to give a full account of the requisites of each would occupy more space than can be devoted to the subject in this place.

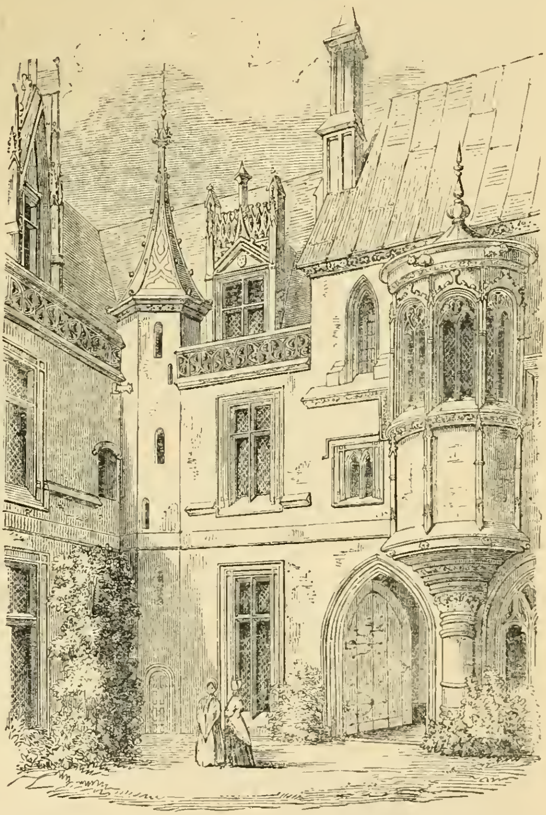

Fig. 1409. Hôtel de Cluny, Paris.

Housing. The space taken out of one solid for the insertion of the extremity of another, for the purpose of connecting them. Thus the string board of a stair is most frequently notched out for the reception of the steps.

Hovel. An open shed for sheltering cattle, for protecting produce or materials of different kinds from the weather, or for performing various country operations during heavy rains, falls of snow, or severe frosts.

Hovelling. A mode of preventing chimneys from smoking, by carrying up two sides higher than those less liable to receive strong currents of air; or apertures are left on all the sides, so that when the wind blows over the top, the smoke may escape below.

Hue. In painting, any degree of strength of colour, from its deepest to its weakest tint.

Hundred of Lime. A denomination of measure which, in some places, is equal to thirty-five, in others to twenty-five, heaped bushels or bags, the latter being the quantity about London, that is, one hundred pecks. The *hundred* is also used for numbering, thus deals are sold by the *long hundred*, or six score. Pales and laths are sold at five score to the hundred if five feet long, and six score if only three feet long. The *hundred weight* is 112 lbs. avoirdupois; the *long hundred weight* is 120 lbs.; so that the former is to the latter as ·93333 to 1.

Hung, double and single. A term applied to sashes; the first when both the upper and lower sash are balanced by weights, for raising and depressing; and the last when only one, usually the lower one, is balanced over the pulleys.

Hurricane. A violent storm of wind, calculated at a velocity of from 80 to 100 miles per hour; and to exercise a force of from $31\frac{1}{2}$ to 49 lbs. per superficial foot. In places where buildings are subject to destructive hurricanes, the precautions to be observed have been described in the *Papers*, &c., of the Corps of Royal Engineers, new series, 1851, vol. i. The whole of the roof should be fixed down to the wall-plate, and the wall-plate to the wall; the wall being made strong enough to resist the powerful current of air rushing against it. Where buildings are of wood, the framework should be tied into the ground, or into stone piers fixed in the ground. During the hurricane at Barbadoes, on the 11th August, 1831, buildings having substantial partitions at short intervals, withstood the blast, whilst others without them were blown down. Inside buttresses would answer the purpose. Shutters should be made to open on pivots at top and bottom. Joists used in galleries and verandahs, when let into the wall, tend to upset it. All brickwork should be English bond well grouted throughout, the bricks having first been well saturated with water, and the mortar made of four parts of sand carefully selected, mixed with one of coral lime; this mixture sets very strong. In the hurricane mentioned, a small building arched like a gunpowder magazine was uninjured; and a hospital building, well tied with iron, also withstood the storm. Roofs when reconstructed had diagonal bracing inserted to stiffen the rafters; parapet walls were found to protect roofs. Flat roofs, such as those used in the Mauritius, are perhaps the best to use.

Hut. A small cottage or hovel, generally constructed of earthy materials.

Hydraulics. (Gr. Ὑδωρ and Αυλος, a pipe.) That branch of natural philosophy which treats of the motion of liquids, the laws by which they are regulated, and the effects which they produce. By some authors the term *hydrodynamics* is used to express the science of the motion of fluids generally, whilst the term hydraulics is more particularly applied to the art of conducting, raising, and confining water, and to the construction and performance of waterworks.

Hydrostatics. (Gr. Ὑδωρ and Σταω, I stand.) The science which explains the properties of the equilibrium and pressure of liquids. It is the application of statics to the peculiar constitution of water, or other bodies, existing in the perfectly liquid form. The following is the fundamental law whereon the whole doctrine of the equilibrium and pressure of liquids is founded: when a liquid mass is in equilibrium under the action of forces of any kind, every molecule of the mass sustains an equal pressure in all directions.

Hypæthral. (Gr. Ὑπο, under, and Αιθηρ, the air.) A building or temple open to the air. The temples of this class are arranged by Vitruvius under the seventh order, which had ten columns on each front, and surrounded by a double portico as in dipteral temples. The cell was open, whence the name, but it generally had round it a portico of two ranges of columns, one above the other. See Temple.

Hyperbola. (Gr. Ὑπερ, over, and Βαλλω, I throw.) One of the conic sections, being that made by a plane cutting the opposite side of the cone produced above the vertex, or by a plane which makes a greater angle with the base than the opposite side of the cone makes.

Hyperbolic Conoid, or Hyperboloid. A solid formed by the revolution of an hyperbola about its axis. See Conoid.

Hyperbolic Cylindroid. A solid formed by the revolution of an hyperbola about its conjugate axis or line through the centre, perpendicular to the transverse axis.

Hyperthyrum. (Gr. Ὑπερ and Θυρα, a door.) The lintel of the aperture of a doorway.

Hypocaustum. (Gr. Ὑπο, under, and Καιω, I burn.) In ancient architecture, a vaulted apartment, from which the heat of the fire was distributed to the rooms above by means of earthen tubes. This contrivance, first used in baths, was afterwards adopted in private houses, and is supposed to have diffused an agreeable and equal temperature throughout the different rooms.

Hypogæum. (Gr.) A term applied among the ancients to those parts of a building which were below the level of the ground.

Hypopodium. A footstool used in the ancient baths.

Hyposcenium. In ancient architecture, the front wall of the theatre, facing the orchestra from the stage.

Hypostyle. (Gr.) Work supported by columns; a covered colonnade, or a pillared hall.

Hypotrachelium. (Gr. Ὑπο, under, and Τραχηλος, the neck.) The slenderest part of the shaft of a column, being that immediately below the neck of a capital.

I

Ice House. A subterranean depôt for preserving ice during the winter. The most important advice that can be given to the builder of an ice house is, that it be so thoroughly capable of drainage, from the lowest point of its floor, as to permit no water ever to collect upon it; this accomplished, no difficulty will, with common precaution, prevent the preservation of the ice. The aspect of such a building should be towards the south-east, that the morning sun may expel the damp air which is more prejudicial than warmth. If possible it should be placed on a declivity for the facility of drainage. At the end of the drain which is to carry away the water arising from the melted ice, a perfect air trap should be placed, to prevent all communication between the external and internal air, from which trap the water should be carried off without the possibility of obstruction. With respect to the dimensions and form of the ice house, the former may be of a medium diameter, from fifteen to twenty feet; a moderate size would be from eight to fifteen feet. The best form is the frustum of an inverted cone, ten to twenty feet deep, bricked round, and with double walls, a cavity of four inches being left between them. The ice is sustained on a grated floor, through which the water is rapidly carried off by the drainage first mentioned. The ice is best collected during the severest part of the frost, and should be pounded as laid in the ice house, besides being well rammed down as it is put in. Snow however, hard rammed, will answer when ice cannot be obtained. The entrance may be at the top by double flaps well covered over with straw; or near the top at the side by a lobby with a door at each end, and filled with trusses of straw to keep out the air.

Ichnography. (Gr. Ιχνος, a model, and Γραφω, I draw.) The representation of the ground plot of a building. In perspective, it is its representation, intersected by an horizontal plane at its base or groundfloor.

Icosahedron. (Gr. Εικοσι, twenty, and Ἑδρα, seat.) One of the five regular or platonic bodies, bounded by twenty equilateral and equal triangles. It may be regarded as consisting of twenty equal and similar triangular pyramids, whose vertices all meet in the same point; and hence the content of one of these pyramids, multiplied by twenty, gives the whole content of the icosahedron.

Image. In perspective, the scenographic or perspective representation of an object.

Imbow. (Verb.) To arch over or to vault.

Imbricated Tracery. A pattern formed like the tiles on a roof.

Impages. A term used by Vitruvius (lib. iv. c. 6.), which has usually been considered as meaning the rails of a door.

Imperial. (Fr.) A species of dome, whose profile is pointed towards the top, and widens towards the base, thus forming a curve of contrary flexure.

Imperials. A sized slate used in roofing.

Impetus. (Lat.) In mechanics, the same with momentum or force.

Impluvium. (Lat.) In ancient architecture, the uncovered court of a house. In the summer time it was the practice to stretch an awning over it. The term is also applied to the sinking in the floor to receive the water.

Impost. (Lat. Impono, I lay on.) The capital of a pier or pilaster which receives an arch. It varies in the different orders; sometimes the whole of the entablature serves as the impost to an arch. The term is applicable to any supporting piece. An impost is said to be mutilated when its projection is diminished, so that it does not exceed that of the adjoining pilaster which it accompanies.

Inbond Jambstone. A bondstone laid in the joint of an aperture.

Incertum. (Lat.) A term used by Vitruvius to designate a mode of building which consisted of small rough stones and mortar, and whose face exhibited irregularly formed masonry, not laid in horizontal courses. See Masonry.

Inch. A measure of length, being the twelfth part of a foot, and is usually subdivided into eighths and sixteenths. See Foot.

Incised Slab. A memorial to a deceased person, sometimes plainly lettered, and occasionally ornamented with brasses; they usually formed the pavement of ancient churches. See Mural Slab.

Inclination. (Lat.) The approach of one line, which if continued will meet another or the same of two planes.

Inclined Plane. One of the five simple mechanical powers, whose theory is deduced from the decomposition of forces.

Incrustation. (Lat.) Anything, such as mosaic, scagliola, &c., applied by some connecting medium to another body.

Indefinite. (Lat.) Anything which has only one extreme, whence it may be produced infinitely as it is produced from such extreme.

Indented. (Lat.) Toothed together, that is, with a projection fitted to a recess.

Indian Architecture. The Buddhist and Mahometan buildings of Hindostan are comprised under this title. Rock-cut temples, temples, pillars, monumental tombs, halls, tanks, &c., show the energy and skill of these people, many of the works being profusely covered with sculpture and carvings, the earlier works chiefly having reference to their religion.

Induration. (Lat.) A term applied to the firmer consistence which a body acquires from various causes.

Inertia. (Lat. Iners.) A term applied to that law of the material world which is known to predicate that all bodies are absolutely passive or indifferent to a state of rest or motion, and would continue in those states unless disturbed by the action of some extrinsic force. Inertia is one of the inherent properties of matter.

Infinite. (Lat. Infinitus, boundless.) In geometry, that which is greater than any assignable magnitude; and as no such quantities exist in nature, the idea of an infinite quantity can only, and that most imperfectly, exist in the mind by excluding all notions of boundary or space.

Infirmary. A public building for the reception of infirm persons; but the term is more generally used to denote a sick ward attached to some public establishment.

Inlaid Work. Work in which the surface of a material is cut away to allow of the substitution of metal, stone, cement, wood, ivory, tortoiseshell, mother-of-pearl, or other substance, with a flush surface. Such is Buhl Work, Marquetry, &c. Mosaic Work in stone is also inlaid work. The inlaying of metal on metal is called *damascening*. Veneering is also a species of inlaying.

Inner Plate. The wall plate, in a double-plated roof, which lies nearest the centre of the roof; the side of the other wall plate, called the *outer plate*, being nearer the outer surface of the wall.

Inner Square. The edges forming the internal right angle of the instrument called a square.

Inserted Column. One that is engaged in a wall.

Instruments, Mathematical. Those used for describing mathematical diagrams and drawings of every description, when the figures or elementary parts of them are composed of straight lines, circles, or portions of them. The indispensable instruments for such operations are *a drawing pen, a pair of plain compasses,* commonly called *dividers, a pair of drawing compasses, a port crayon and pencil foot, a pair of bow, of triangular, and of proportional compasses, a protractor* in the form of a semicircle or rectangle, and graduated on the edges, *a plain scale,* and a *parallel rule.*

Insular, or Insulated Building. Such as stands entirely detached from any other.

Insulated Column. One detached from a wall, so that the whole of its surface may be seen.

Intaglio. (It.) Sculpture in which the subject is hollowed out, as for a seal, so that the impression from it would present the appearance of a bas-relief.

Intavolata. The same as Cyma.

Intercepted Axis. In conic sections, that part of the diameter of a curve comprehended between the vertex and the ordinate. It is also called the *abscissa,* and forms an arch of a peculiar kind.

Intercolumniation. (Lat. Inter, between, and Columna, a column.) The distance between two columns measured at the lower part of their shafts. It is one of the most important elements in architecture, and on it depends the effect of the columns themselves, their pleasing proportion, and the harmony of an edifice. Intercolumniations are of five species, *pycnostylos, systylos, diastylos, aræostylos,* and *eustylos,* which see.

Interdentels. The space between two dentels. From a comparison of various examples it seems that the Greeks placed their dentels wider apart than the Romans. In the temple of Bacchus at Teos, the interdentel is two-thirds the breadth of the dentel, and in that of Minerva Polias at Priene, the interdentel is nearly three-fourths. In the temple of Jupiter Stator at Rome, the interdentels are equal to half the breadth of the dentel.

Interduce. The same as Intertie.

Interior Angle. An angle formed within any figure by two straight lined parts of the perimeter or boundary of the figure, the exterior angle being that which is formed in producing a side of the perimeter of the figure. The term is also applied to the two angles formed by two parallel lines, when cut on each side of the intersecting line.

Interior and Opposite Angles. An expression applied to the two angles formed by a line cutting two parallels.

Interlacing Arches. Semicircular aches as in an arcade, the mouldings of which intersect each other, as frequently seen in Norman architecture. Milner supposed the Pointed style to have had its origin from them.

Internal Angle. See Interior Angle.

Interties. Short pieces of timber used in roofing to bind upright posts together, in roofs, in partitions, in lath and plaster work, and in walls with timber framework.

Intonaco. (It.) The term often applied to the whole coating of plastering upon a wall or ceiling; but properly it means the finishing coat only.

Intrados. The interior and lower line or curve of an arch. The exterior or upper curve is called the *extrados.* See Arch.

Invention. (Lat. Invenio, I find.) In the fine arts, the choice and production of such objects as are proper to enter into the composition of a work of art. "Strictly speaking," says Sir Joshua Reynolds, "invention is little more than a new combination of those images which have been previously gathered and deposited in the memory:

nothing can come of nothing; he who has laid up no materials can produce no combinations." Though there be nothing new under the sun, yet novelty in art will be attainable till all the combinations of the same things are exhausted, a circumstance that can never come to pass.

INVERTED ARCH. An arch turned with its back and keystone downwards. It is used in foundations, to distribute the weight of particular points over the whole extent of the foundation, and hence its employment is frequently of the first importance in constructive architecture. Such an arch has been used in some of the English cathedrals to form a buttress between the piers of the central tower when they appeared to be giving way from the weight above.

INVOLUTE. See EVOLUTE.

INWARD ANGLE. The re-entrant angle of a solid. See INTERIOR ANGLE.

IONIC ORDER. The second of those employed by the Greeks, and the third used by the Romans and in Italian architecture. The capital is known by the volutes. Dentels are used in the cornice. The proto-Ionic is considered to be found in the capital of the columns at Persepolis. The *Anthemion* is an ornament peculiar to this order.

IRON. One of the chief metals. The metallic products of the iron manufacture are of three kinds: *malleable* or *wrought* iron, being pure or nearly pure iron; *cast* iron; and *steel*, being certain compounds of iron with carbon. In all cases cast iron is best for exterior, and wrought iron for interior purposes—as the former is not acted upon so greatly by atmospheric influences.

IRONED-IN. Ashlar work, when acted upon by water, is sometimes set in hydraulic cement, the joints being filled and rubbed up so as to make the stuff curl out, which is then to be neatly struck off and ironed-in to secure a good water-tight joint.

IRONMONGERY. The articles in iron and other ware, required by the builder during the execution of his works; such as bolts, locks, and other fastenings, hinges, nails, spikes, screws, and such-like.

IRREGULAR FIGURE. One whose sides, and consequently angles, are unequal to each other.

ISAGON. (Gr. Ισος, equal, and Γωνια, an angle.) A figure with equal angles.

ISLE or ILE. The old way of writing *aisle* or *aile*.

ISODOMUM. (Gr.) One of the methods of building walls practised by the Greeks. It was executed in courses of equal thickness, and with stones of equal lengths. The other method was called *pseudisodomum*, in which the heights, thicknesses, and lengths of the stone were different. There was yet another mode called EMPLECTON.

ISOMETRICAL PROJECTION. A system of drawing objects similarly to a bird's-eye view, excepting that parallel lines are not made to radiate to vanishing points as in that and in the usual perspective. It was matured about 1823 by Professor Farish, who explained it in the Transactions of the Cambridge Philosophical Society, vol. 1. The figures 590*f* and 590*p* are drawn by this method of representation.

ISOSCELES TRIANGLE. One in which two of the sides are of equal length

ITALIAN ARCHITECTURE. That adaptation of ancient Roman architecture which commenced at the period of the Renaissance of Art in Italy.

J

JACK ARCH. One whose thickness is only of one brick.

JACK PLANE. A plane about eighteen inches long, used in taking off the rough surface left by the saw or that of the axe, and for taking off large protuberant parts, to prepare the stuff for the trying plane.

JACK RAFTER. See HIP ROOF.

JACK RIBS. Those in a groin, or in a polygonally-domed ceiling, that are fixed upon the hips.

JACK TIMBER. Any one interrupted in its length, or cut short.

JAMB LININGS. The two vertical linings of a doorway which are usually of wood.

JAMB POSTS. Those introduced on the side of a door, to which the jamb linings are fixed. They are particularly used when partitions are of wood.

JAMB STONES. In stone walls, those which are employed in building the sides of apertures, in which every alternate stone should go entirely through the thickness of the wall.

JAMBS. (Fr.) The sides of an aperture which connect the two sides of a wall. See APERTURE and CHIMNEY.

JERKIN HEAD. The end of a roof not hipped down to the level of the opposite adjoining walls, the gable being carried higher than the level of those walls.

JETTY. The projecting part of a building, as an upper story beyond a lower one.

JEWISH OR HEBREW ARCHITECTURE. Very little beyond the references in the Scriptures is known of the works of these ancient people. The excavations lately made at Jerusalem have not led to any discoveries of value relating thereto.

Jib Door. A door so constructed as to have the same continuity of surface with that of the partition or wall in which it stands. Its use is to preserve an unbroken surface in an apartment where one door only is wanted nearer to one end of a room than another, and generally for the purpose of preserving uniformity.

Jiblet Cheek. See Giblet Check.

Joggle. The joint of two bodies so constructed as to prevent them sliding past each other, by the application of a force in a direction perpendicular to the two pressures by which they are held together. Thus the struts of a roof are joggled into the truss posts and into the rafters. When confined by mortise and tenon, the pressure which keeps them together is that of the rafter and the reaction of the truss-post. The term is also used in masonry to signify the indentation made in one stone to receive the projection in another, so as to prevent all sliding on the joints. This may be also accomplished by means of independent pieces of material let into the adjacent stones. See Cramp; Dowel.

Joggle Piece. The truss post in a roof when formed to receive a brace or strut with a joggle.

Joiner. The artisan who joins wood by glue, framing, or nails, for the finishings of a building.

Joinery. The practice of framing or joining wood for the internal and external finishings of houses; thus the covering and lining of rough walls, the covering of rough timbers, the manufacture of doors, shutters, sashes, stairs, and the like are classed under this head.

Joint. The surface of separation between two bodies brought into contact and held firmly together, either by some cementing medium, or by the weight of one body lying on another. A joint, however, is not merely the contact of two surfaces, though the nearer they approach the more perfect the joint. In masonry, the distances of the planes intended to form the joint is comparatively considerable, because of the coarseness of the particles which enter into the composition of the cement.

Jointer. In *joinery* is the largest plane used by the joiner in straightening the face of the edge of the stuff to be prepared. In *bricklaying*, it is a crooked piece of iron forming two curves of contrary flexure by its edges on each side, and is used for drawing, by the aid of the jointing rule, the *coursing* and *vertical* joints of the work.

Jointing Rule. A straight edge used by bricklayers for the regulation of the direction and course of the jointer in the horizontal and vertical joints of brickwork.

Joist. (Fr. Joindre.) The timber whereto the boards of a floor or the laths for a ceiling are nailed. Joists rest on the walls or on girders; sometimes on both. When only one tier of joists is used, the assemblage is called *single-flooring*; when two, *double-flooring*.

Jubé. (Fr.) The rood loft or screen at the entrance to the choirs of French cathedrals. In England it is usually called the *chancel screen*. It is also the stand (often ending upwards in an eagle with expanded wings) on which the Gospel is placed to be read, receiving its name from the words "Jube Domne benedicere," used by the deacon when the missal is presented to him by the officiating priest at mass, previous to the reading of the Gospel. See Choir Screen and Rood Loft.

Juffers. An obsolete term for pieces of timber four or five inches square.

Jump. An abrupt rise in a level course of brickwork or masonry to accommodate the work to the inequality of the ground. Also *in quarrying*, one among the various names given to the dislocations of the strata in quarries.

Jumper. A long iron chisel used by masons and miners.

K

Kamptulicon. An elastic covering for floors. See Floorcloth.

Keblah, or Kibleh. The point in a mosque designating the direction of the temple of the Mahometans at Mecca.

Keel. The fillet, raised edge, or sharp arris, formed on roll mouldings, by which the heaviness of the large ones was relieved, and diversity gained without loss of mass.

Keep, or Keep Tower. A term almost synonymous with *donjon*. See Castle.

Kerb. See Kirb.

Kerf. The way made by a saw through a piece of timber, by displacing the wood with the teeth of the saw.

Kernel, or Kernelle. See Crenelle.

Key. (Sax. Cæʒe.) An instrument for driving back the bolt of a lock. The *key of a floor* is the board last laid down. In joinery generally, a key is a piece of wood let into the back of another in the contrary direction of the grain, to preserve the last from warping.

Key Stone. The highest or central stone of an arch. See Arch. In Gothic vaulting, see Pendent and Boss.

Keyed Dado. That which has bars of wood grooved into it across the grain at the back to prevent it warping.

Keys. In naked flooring are pieces of timber fixed in between the joists by mortise and tenon. When these are fastened with their ends projecting against the sides of the joists, they are called *strutting-pieces.*

Kiln. A building for the accumulation and retention of heat in order to dry or burn certain materials deposited within them.

King Post. The centre post in a trussed roof. See Crown Post.

Kirb Plate, Roof, and Stone. See Curb Plate; Curb Roof; and Curb Stone.

Kitchen. (Fr. Cuisine.) The apartment or office of a house wherein the operations of cookery are carried on.

Knee. A part of the back of a handrailing, of a convex form, being the reverse of a *ramp*, which is also the back of a handrail, but is concave. The term knee is also given to any small piece of timber of a bent or angular form.

Knee Piece, or Knee Rafter. An angular piece of timber, to which other pieces in the roof are fastened.

Knobbling. Knocking off the rough protuberances of hard rock stone at the quarry. It is called also skiffling.

Knocker. A movable sort of hammer, more or less of an ornamental character, hinged to the face of a door or gate by which attendance is claimed to the demands of those requiring admittance. The *knob* which is struck upon is sometimes called a *door-nail.*

Knot, or Knob. A bunch of leaves or flowers, as the bosses at the ends of a label; at the intersection of ribs; and in capitals.

Knotting. The preliminary process in painting, to prevent the knots appearing, by covering them with a coat composed of red read, then white lead and oil, and lastly, a coat of gold size. Sometimes leaf silver is used. Also a knotting size.

Knuckle. The joint of a cylindrical form, with a pin as an axis, by which the straps of a hinge are fastened together.

Knulling. A moulding nearly flat, and similar in character to a bead and reel ornament. It is chiefly used in cabinet work.

Koss. A measure of length used in India, which varies in different provinces; generally about two miles.

Kurb Stone. See Curb Stone.

L

Label. In Gothic architecture, the drip or hood moulding over an aperture when it is returned square.

Labour. (Lat.) A term in masonry employed to denote the value of a piece of work in consideration of the time bestowed upon it.

Labyrinth. (Gr. Λαβυρινθος.) Literally a place, usually subterraneous, full of inextricable windings. The four celebrated labyrinths of antiquity were the Cretan, Egyptian, Lemnian, and Italian. The first has the reputation of being the work of Dædalus to secure the Minotaur; the second is said to have been constructed under the command of Psammeticus, king of Egypt; the third was on the island of Lemnos, and was supported by columns of great beauty; the fourth is reported to have been designed by Porsenna, king of Etruria, as a tomb for himself and his successors.

Labyrinth Fret. A fret, with many turnings, in the form of a labyrinth. See Fret.

Laconicum. (Lat.) One of the apartments in the ancient baths, so called from its having been first used in Laconia.

Lacquer. A yellow varnish, consisting of a solution of shell-lac in alcohol, coloured by gamboge, saffron, annotto, or other yellow, orange, or red colouring matters. The use of lacquer is chiefly for varnishing brass, and some other metals, in order to give them a golden colour and preserve their lustre.

Lactarium. (Lat.) Strictly a dairy-house. In ancient architecture, it was a place in the Roman herb market, indicated by a column, called the Columna Lactaria, where foundlings were fed and nourished.

Lacunar. (Lat.) The ceiling or under surface of the member of an order. Also the under side of the larmier or corona of a cornice. The under side also of that part of the architrave between the capitals of columns. The ceiling of any part in architecture receives the name of lacunar only when it consists of compartments sunk or hollowed, without spaces or bands, between the panels; if it is with bands, it is called *laquear.*

Lady. A sized slate used in roofing.

Lady Chapel. The name given to a chapel dedicated to the Virgin, generally, in ancient cathedrals, placed behind the high altar.

LAGGING, or LAGGINS. The planks laid on the ribs forming the centreing of an arch, to carry the stone or brickwork.

LANCET ARCH. One whose head is shaped like the point of a lancet, and generally applied to long narrow windows. *Fig.* 1410.

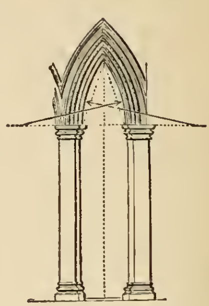

Fig. 1410. Lancet Arch.

LANDING. The terminating floor of a flight of stairs, either above or below it.

LANTERN. (Fr. Lanterne.) A structure either square, circular, elliptical, or polygonal, on the top of a dome. It is also the upright windows placed over the ceiling of an apartment, to give light. The internally polygonal tower over the intersection of the nave with the transepts of a church, as at Ely Cathedral; St. Helen's, York, &c., is also so called.

LAP. The part of one body which lies on and covers another.

LAQUEAR. See LACUNAR.

LARARIUM. (Lat.) In ancient architecture, the apartment in which the lares or household gods were deposited. It frequently contained also statues of the proprietor's ancestors.

LARDER. The place in which undressed meat is kept for the use of a family.

LARMIER. (Fr.) The same as CORONA.

LAT, or LATH. The Sanscrit term for a pillar.

LATCH. The catch by which a door is held fast.

LATENT HEAT. That which is insensible to the thermometer, upon which the liquid and aeriform states of bodies depend, and which becomes sensible during the conversion of vapours into liquids and of liquids into solids.

LATERAL STRENGTH. The resistance which a body will afford at right angles to its grain.

LATERAL THRUST. The weight, or rather pressure, of materials sideways, as in an arch.

LATH. (Sax. Lætta.) A thin piece of wood used in slating, tiling, and plastering. For the latter, there are two sorts, double and single, the former being about three-eighths of an inch thick, and the latter barely a quarter of an inch. Laths for slates and for pantiles are pieces of fir, about three inches by one inch thick, to which the former are nailed, and on to which the latter are hung.

LATH BRICK. A species made in some parts of England. They are twenty-two inches long and six inches broad.

LATH FLOATED AND SET FAIR. Three-coat plasterers' work; the first is called *pricking up*; the second *floating*; the third, or finishing, done with fine stuff, is the *setting* coat.

LATH LAID AND SET. Two-coat plasterers' work, except that the first is called *laying*, and is executed without *scratching*, unless with a broom. When used on walls, this sort of work is generally coloured; when on ceilings, it is whited.

LATH PLASTERED, SET, AND COLOURED. The same as lath laid, set, and coloured.

LATH PRICKED UP, FLOATED, AND SET FOR PAPER. The same as *lath floated and set fair.*

LATTICE. (Fr. Lattis.) A reticulated window, made of laths of wood, strips of iron, or other materials, and only used where air, rather than light, is to be admitted, as in cellars and dairies.

LAUNDRY. It should be spacious and well supplied with every convenience for washing, drying, mangling, and ironing the linen of a family or of an establishment. *Horses*, or frames of wood, should be provided for hanging the linen upon to dry, which should be suspended to the timbers of the ceiling by pulleys, by which they may be raised and lowered, unless a drying closet heated by a stove or hot water be provided; this is fitted up with horses running on iron rails backwards and forwards.

LAVATORY. (Lat.) Besides the reference to the monks' lavatories, as noticed s.v. CLOISTER, this term is now employed to designate a closet or small room fitted up with basins and other apparatus for washing hands; it sometimes includes urinals and water-closets, or communicates with another room fitted up with them.

LAW COURTS. See COURT OF JUSTICE.

LAYER. In brickwork and masonry, it is synonymous with COURSE.

LAYER BOARDING. The same as GUTTER BOARDING; the boards being fixed to the bearers to carry the leadwork of a gutter to a roof.

LAYING. In plastering, the first coat on lath of two-coat work, the surface whereof is roughed by sweeping with a broom. The difference between laying and *rendering* being, that the latter is the first coat upon brick.

LAZARHOUSE, or LAZARETTO. (Ital.) A hospital for the reception of the poor and those afflicted with contagious diseases. There are many in the southern states of Europe for the performance of quarantine, into which those only are admitted who arrive from countries infected by the plague, or suspected of being so. An account of the principal lazarettos of Europe was published by the celebrated Howard.

LEAD. (Sax. Læð.) The heaviest metal next to gold, platina, and mercury, being eleven times heavier than its own bulk of water.

LEAF. One side of a door, upright slab of stone, &c.

LEANTO. A building whose rafters pitch against or lean on to another building or wall.

LEAR BOARD. The plank fastened on the feet of the rafters to carry the side piece of the lead of a gutter under the bottom rows of the slating or tiling.

LEAVES. (Sax. Læaf.) Ornaments imitated from natural leaves, whereof the ancients used two sorts, natural and imaginary. The former were those of the laurel, palm acanthus, and olive; but they took great liberties in the representations of all of them

LECTERN. The reading desk placed in the choir of mediæval churches. It was made in the shape of a pillar, with a slab for the book, and was usually of brass, sometimes elaborately carved. It was superseded by the *reading desk* after the Reformation.

LECTORIUM. The ancient name for the place where the epistle was read in a church hence *lectern* and *lettern* for the desk itself. The *lectorium* in the German churches is now of rare occurrence, but one is to be seen in Meissen Cathedral.

LECTURE HALL. A building erected for the special purpose of affording good accommodation for a lecturer and his audience. It is sometimes a large room combined with others; thus, in a village or small town, a building containing a lecture hall about fifty feet by thirty feet, might have a reading room about twenty feet by eighteen feet, a class-room, with a vestibule and the usual necessaries.

LEDGE. A surface serving to support a body either in motion or at rest. Ledges of doors are the narrow surfaces wrought upon the jambs and sofites parallel to the wall to stop the door, so that when it is shut the ledges coincide with the surface of the door. A ledge, therefore, is one of the sides of a *rebate*, each rebate being formed of two sides In temporary work the ledges of doors are formed by fillets, likewise called a *stop* Also the horizontal planks in common doors, to which the vertical planks are nailed.

LEDGEMENT. The development of a surface, or the surface of a body stretched out on a plane, so that the dimensions of the different sides may be easily ascertained.

A string course or horizontal moulding. *Ledgement table* is applied to any of the projections of a plinth in Gothic architecture, except the lowest or *earth table*.

LEDGERS. In scaffolding for brick buildings are horizontal pieces of timber parallel to the walls. They are fastened to the *standards*, or upright poles, by cords, to support the *put-logs*, which lie at right angles to and on the walls as they are brought up, and receive the boards for working on.

LEGS OF AN HYPERBOLA. The two parts on each side the vertex.

LEGS OF A TRIANGLE. The sides which inclose the base.

LENGTH. (Sax. Lenᵹ.) The greatest extension of a body. In a right prism the length is the distance between the ends; in a right pyramid or cone, the length is the distance between the vertex and the base.

LESCHE. (Gr.) A public building among the Greeks, consisting of open courts with porticoes, the walls covered with paintings. It was used principally as a lounging place The nearest modern approach to it appears to be the Ruhmeshalle, or mercantile exchange, at Munich. Ancient writers state that these public meeting-places were so much in request that there were no less than 360 in Athens alone.

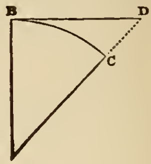
LETTERN, or LECTERN. A desk in a church from which the lessons are read. See *Amb* in the ancient church. An eagle with wings displayed, that bird being symbolical of S. John the Evangelist and his Gospel, was often used as a book board in the Middle Ages; and is also seen in the cathedrals and in some large churches in England.

LEUCOMB. See LOOKUM.

LEVEL. (Sax. Læfel.) A line or surface which inclines to neither side. The term is used substantively to denote an instrument which shows the direction of a straight line parallel to the plane of the horizon. The plane of the sensible horizon is indicated in two ways: by the direction of the plummet, or plumb line, to which it is perpendicular; and by the surface of a fluid at rest. Accordingly, levels are formed either by means of the plumb line, or by the agency of a fluid applied in some particular manner. They all depend, however, upon the same principle, namely, the action of terrestrial gravity.

The carpenter's level consists of a long rule, straight on its lower edge, about ten or twelve feet in length, with an upright fixed to its upper edge, perpendicular to and in the middle of the length, having its sides in the same plane with those of the rule and a straight line drawn on one of its sides perpendicular to the straight edge of the rule. The *mason's level* is formed of three pieces of wood, joined in the form of an isosceles triangle, having a plummet suspended from the vertex over a mark in the centre of the base.

LEVELLING. The art or act of finding a line parallel to the horizon, at one or more stations, in order to determine the height of one place with respect to another, for layin grounds even, regulating descents, draining morasses, conducting waters for the irrigation of land, etc.



In the practice of levelling, it is evident that the level line, carried on by means of a spirit level or other instrument used for the purpose, is a tangent to the earth: it is therefore necessary to make an allowance for the difference between the true level B C and the apparent level B D. This difference is, of course, equal to the excess D C of the secant of the arch of distance above the radius of the earth. Hence, from station to station, accordingly, allowance must be made. The subjoined Table exhibits the corrections or values of the length C D.

Distance or BC.	Diff. of Lev. or CD.	Distance or BC.	Diff. of Lev. or CD.	Distance or BC.	Diff. of Lev. or CD.		Distance or BC.	Diff. of Lev. or CD.	
Yards.	Inches.	Yards.	Inches.	Miles.	Feet.	In.	Miles.	Feet.	In.
100	0·026	900	2·081	$\frac{1}{4}$	0	$0\frac{1}{2}$	6	23	11
200	0·123	1000	2·570	$\frac{1}{2}$	0	2	7	32	6
300	0·231	1100	3·110	$\frac{3}{4}$	0	$4\frac{1}{2}$	8	42	6
400	0·411	1200	3·701	1	0	8	9	53	9
500	0·643	1300	4·344	2	2	8	10	66	4

700	1·260	1500	5·784	4	10	7	12	95	7
800	1·645	1600	6·580	5	16	7	13	112	2

Lever. In mechanics an inflexible rod, moveable about a fulcrum, or prop, and having forces applied to two or more points in it. The lever is one of the mechanical powers, and being the simplest of them all, was the first attempted to be explained.

Lever Boards. A set of boards so fastened that they may be turned at any angle to admit more or less light, or to lap upon each other so as to exclude all air or light through apertures. See Louvre Boards.

Lewis, or Lewisson. An instrument used by builders to raise stones of more than ordinary weight to the upper part of a building. It was revived by a French artisan in the reign of Louis XIV., and is now generally employed. It operates by the pieces forming its dovetail end being held in their corresponding places in a hole sunk in the stone, by a middle straight piece, kept in its situation by a pin passing through it and the dovetail pieces at top, and the combination of the whole is effected with a large ring, which is attached to the rope or chain, and the stone lifted to its place.

Lias. A provincial name adopted by geologists for an argillaceous limestone, which, together with its associated bed, is characterised by peculiar fossils.

Library. An edifice or apartment for the reception of a collection of books. The most ancient and celebrated library in existence is that of the Vatican: in the latter respect, as well on account of its size as of the number of valuable manuscripts it contains. It occupies in the suite of its apartments one of the sides of the Vatican 900 feet in length. In the architecture or arrangement there is nothing particularly to admire, and indeed it was not originally intended for the purpose to which it has been appropriated.

The Medicean library at Florence, the work of Michael Angelo, has grand proportions, but the details are as capricious as that great man could possibly have invented. The library of St. Mark at Venice has already been described in the First Book. Sansavino had to encounter many difficulties in respect of its site and connection with other buildings, but Palladio considered the success of its design to have been so great as to have made it worthy of any age.

Although a public library would seem to require a grave and simple style of treatment, it is, nevertheless, properly susceptible of much richness, if the funds admit, and it comports with the surrounding buildings to use much decoration. Security against fire is the first important consideration in its construction; and the next is to ensure the perfect quiet necessary for study. There can scarcely be too much light, because there are always modes of excluding the excess in the brightest days of summer. The light should not be placed high up for the purpose of obtaining more room for the presses which are to receive the books, because even a greater space may be obtained, as in the magnificent library at Trinity College, Cambridge, by Wren, by making the presses stand against the piers at right angles with the longitudinal walls, and placing the windows between them. Moreover, the presses, when placed longitudinally against the walls, the windows being above, have the titles of the books they contain indistinct, from being too much in shadow. The library just mentioned is in every respect one of the finest works of Sir Christopher Wren; it is 190 feet long, 40 feet wide, and 38 feet high, floored with marble, and decorated with pilasters and an entablature of the Corinthian order. This library is adduced as a perfect model of the mode of distribution, which might be carried in principle to any extent. If the readers be very numerous, a separate reading-room becomes a necessary addition, which should be placed as centrally as may be to the whole mass of building, so that the labour of the attendants may be lessened, and the readers at the same time more readily served with the books wanted. The best mode of warming the apartments is by hot water in pipes carried round the apartments, or pumped up through the floor. Efficient means of affording ventilation to the room or rooms is also necessary.

At Paris the Bibliothèque Nationale is, though of immense extent, little more than a warehouse for holding the books. The library of St. Geneviève, in the same city, is a well-conceived and well-designed building, and particularly suited to its destination. This ornamental edifice was designed by M. Labrouste in 1843.

Perhaps one of the most absurd distributions of plan for the buildings under consideration is to be seen in the Radcliffe Library, at Oxford. It is circular on the plan, and hence vast loss of room is experienced, but nevertheless it is a noble building.

In London the only library of any size to which reference can be made is that of the British Museum. With so many clubs and institutions, each possessing its own library, it may probably be many years before an edifice, similar to the Free Library and Museum at Liverpool, is erected in London; especially as the parishes have not yet had sufficient courage to tax themselves for the establishment of free libraries, which the Act of Parliament has for some years past enabled them to do. The king's library at the British Museum is situated in the east wing, and was erected, 1825–28, by Sir R. Smirke, R.A. The chief room is 300 feet long, 40 feet wide, and 30 feet high. Little was done for the accommodation of the readers, largely increasing in numbers, until 1857, when the new reading-room was opened, affording desks for three hundred readers, which are very often fully occupied, who have free access to about 20,000 volumes ranged around it. The room is 140 feet diameter and 106 feet high, having a central light of 40 feet diameter in the dome, with tall side lights in the springing of the dome. It was designed by Mr. Sydney Smirke, R.A. The arrangements for economising the space around it for holding the annual accession of new books in narrow and well-lighted corridors, are admirably managed. The *Builder* journal, xv. p. 229, and the *Building News* journal, iii. 157, 449–55, contain full details of these fine additions to the national establishment.

The library attached to the London University, Gower Street, designed by Professor T. L. Donaldson, is 91 feet long by 21 feet 6 inches wide, 45 feet through the recesses, and 45 feet high in the centre. It is a good example of such a room, planned as a nave and aisles, with cases projecting from the outer walls up to the piers. The library erected by the Corporation of the City of London, and attached to the Guildhall, is 98 feet by 65 feet, and museum, with reading room 54 feet by 20 feet, is a well-designed edifice, by Sir Horace Jones, the City architect.

Lierne Rib. A short rib in vaulting.

Lift, or Hoist. A machine introduced into warehouses, to raise goods from the lower to the higher floors of the building, and worked either by manual or by hydraulic power. Lately it has been placed in large houses and in hotels, for the purpose of raising fuel, luggage, &c., to each floor; in some instances the platform has been formed into a room for the accommodation of persons while being hoisted to an upper, or lowered to an under floor, without the fatigue of walking up and down long flights of steps. For lifting stones, see Lewis.

Light, Diffusion of. Light passing into a room through obscured glass or a blind, by means of which the intensity of the light is broken. If the glass be placed flush with the outside of the wall, the obscured side being placed outside, the effect is very great in diffusing light.

Light, Obstruction of. The raising a building opposite a neighbour's windows, whereby he is deprived of a certain amount of light. It used to be held that all persons building on old foundations in the City of London could carry their buildings to any height they pleased; that the intervention of a street or public way justifies the raising of a building to any extent; that a building may be raised providing the raising is not to a height beyond a line drawn at an angle of 45 degrees from the window opening or openings, the light of which is affected by the raising of an adjoining building; that skylights or horizontal roof lights are not subject to the same law as ordinary vertical windows; but these are all fallacious notions. However distant the obstruction, or however brought about, if an ancient light which has existed twenty years is injuriously affected by reason of the works of an adjoining owner, there is a cause for action.

Light, Reflected. Light thrown by means of a light and polished surface into the windows opposite to it. This may be effected in some degree by limewhiting the wall; also by building it of white glazed bricks; also by white tiles being affixed to the wall. "Reflectors" are also provided for this purpose, made of a white metal, fixed in a frame and covered with glass, which is suspended and fixed at an angle which will throw the light to the point required.

Lighthouse. A lofty building, on the top whereof artificial lights are placed to guide ships at sea. The lighthouse dates from the earliest period, and appears to have consisted of a tower of masonry, sometimes of a circular form, but usually square, and consisting of various apartments, as the establishment was greater or less, wherein was a raised altar upon which the beacon was established. Fire-towers or lighthouses were common on the shores of the Mediterranean, the Archipelago, the Bosphorus, and Red Sea. Among the most celebrated of these was the Pharos of Alexandria. It was accounted one of the seven wonders of the world.

In England, the Eddystone lighthouse, by the celebrated Smeaton, was not only an object of beauty, but of that soundness of construction which is the most essential requisite in works of this kind. The general form is seen in *fig.* 1411. This is a fine illustration of fitness producing beauty. The resistance it afforded against the waves arose from the beautiful curved line which leads them up it instead of being broken against it. Indeed, in stormy weather, the waves actually rolled up the side, and fell in a contrary curve over the top of the lighthouse. The beds of the masonry were so laid and dovetailed and joggled as to become a part of the rock on which it was erected, between June 12, 1757, and October 16, 1759. A narrative of the work was published by Mr. Smeaton. This elegant structure was pulled down and a new lighthouse built between August 19, 1879, and June 1, 1881, when the first and last stones were laid. The old lighthouse was re-erected on land.

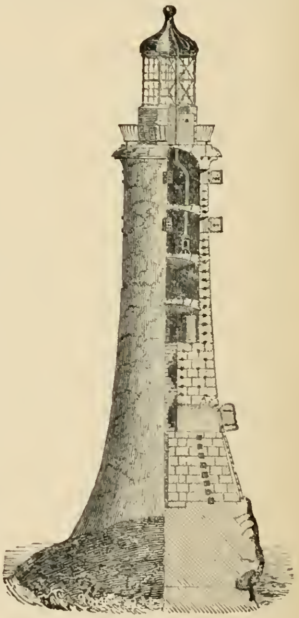

Fig. 1411.

The most architectural of modern lighthouses is that of Corduan on the coast of France, which stands on a large rock, or rather on a low island, about three miles from land, at the entrance of the river Garonne. Founded about the year 1584, in the reign of Henry II. king of France, it was carried on under the reigns of three successive monarchs, arriving at its completion in 1610, in the reign of Henry IV. It stands upon a platform of solid masonry, and is surrounded by a parapet about 145 feet in diameter, which is equal to the height. The lightkeepers' apartments and store rooms are not in the main tower, but form a detached range of buildings on the great platform, the interior of the tower itself being finished in a style of magnificence too splendid for the use of common persons. Over the fuel cellar, which is formed in the solid masonry of the platform, is the great hall, twenty-two feet square, twenty feet high, with an arched ceiling. On this floor are two wardrobes and other conveniences. Above the last-mentioned room is the king's room, twenty-one feet square and twenty high, with an elliptical ceiling. There are on this floor a vestibule, two wardrobes, and other conveniences. On the third floor is placed the chapel, for a priest who occasionally says mass is attached to the establishment, and this is twenty-one feet in diameter, domed, and forty feet high, and lighted by eight windows. There is an eye in the dome through which is seen the ornamental roof of the room above, and that is fourteen feet diameter and twenty-seven feet high. This is used by the lightkeepers as a watch room. Over it rises an apartment, which is immediately under the light room, used for holding sufficient fuel for one night's consumption, and capable itself of being converted into a place for the exhibition of a light in case of repairs being required to any extent in the main light room, which, as we have said, is immediately over it, and is surrounded by a balcony and circular stone parapet. The height from the floor to the top of the cupola of the original lantern or light room was 17 feet, and being unglazed, the smoke was carried out on either side in the direction of the wind. The roof, moreover, formed a kind of chimney in the form of a spire, terminating with a ball. The height of the light room, which was entirely of stone, was thirty-one feet from the light room floor to the ball on the top of the spire. The fuel first used for the light was oak, after which pit coal was introduced; but in modern times lamps and reflectors have succeeded the last, and the light is now seen at a proper distance.

The attempt to make lighthouses resemble columns is intolerable; they should possess, according to the different situations, a character peculiar to themselves: hence the application of a column for the purpose is the worst of abuses. The North Foreland lighthouse, whose plan is polygonal, would be a good example had the details been properly attended to in the design.

Lighting. The quantity of daylight admitted by windows and skylights into an apartment. The superficial area of light may be equal to one-half the area of one wall of the room, if the room is lighted on one side only, and does not exceed more than one and one-half times its height in depth. A room more than twice its height in depth, *i.e.* in distance back from the side from which it receives the light, cannot be efficiently lighted from one side only. The aspect of a window makes very considerable difference in the amount of light, as also the presence of buildings or trees in the vicinity. It should be remembered that the higher the top of the window is in the room the better will be the light at the back of the room. A line at an angle with the wall of 60° from the top of the window to the floor will cut off all the depth than can be freely lighted. The quantity of light admitted by a skylight is considered to be equal to about thirty times that by a window—thus, if one foot square of vertical light placed centrally be sufficient for 100 cubic feet of room, one foot of horizontal light will suffice for upwards of 3,000 cubic feet, as proved by the Pantheon at Rome; see *sect.* 2747.

Lightning Conductor. A metal rod fixed to the highest part of a building, carried down the face of it, and into the earth, for the purpose of attracting the fork of lightning, and carrying it away from the other metal-work of the structure. Newall supplies copper rope of $\frac{3}{8}$, $\frac{1}{2}$, and $\frac{5}{8}$ inch diameter, with copper points and fittings. A conductor requires fixing with proper isolators and attachments, to prevent the interruption of the electric current. Hart and Son supply a sort of wire chain under Spratt's patent.

Lights. A term sometimes used to denote the openings whether of doors, gates, or windows, or unenclosed places, and through which air and light have passage.

Like Arcs. In the projection of the sphere, the parts of lesser circles containing an equal number of degrees with the corresponding arcs of greater circles.

Like Figures. In geometry, such as have their angles equal, and the sides about the equal angles proportional.

Like Solids. Those which are contained under like planes.

Lime. (Germ. Leim, glue.) A most useful earth, obtained by exposing chalk, and other kinds of limestones or carbonates of lime, to a red heat, an operation generally conducted in kilns constructed for the purpose, by which the carbonic acid is expelled, and lime, more or less pure, according to the original quality of the limestone, remains, in which state it is called *quicklime.*

Limekiln. One for the purpose of burning lime. They are constructed in a variety of ways, to save expense, or to answer to the particular nature of the fuel.

Limestone. A generic term for those varieties of stone containing carbonate of lime, which are neither crystallised nor earthy, the former being calcareous spar, the latter chalk. When burned they yield quicklime.

Line. (Lat. Linea.) In geometry, a magnitude having only one dimension, and defined by Euclid to be that which has length without breadth. The term is also used to denote a measure of length used formerly in France, namely, the twelfth part of an inch, or $\frac{1}{144}$ of a foot.

Line of Direction. In mechanics, the line in which motion is communicated.

Line of Station. The intersection of a plane passing though the eye, perpendicular to the picture, and to the geometrical or primary plane with the plane itself.

Line, Geometrical. In perspective, any straight line in the geometrical or primary line.

Line, Horizontal. A line parallel to the horizon. In perspective it is the vanishing line of horizontal planes.

Line, Vertical. The intersection of a vertical plane with the picture passing along the station line.

Line, Visual. A ray of light reflected from the object to the eye.

Lines of Light and Shade. Those in which the light and shade of a body are separated. Thus, on a curved surface, it is the line determined by a tangent to the surface in the direction of the rays of light.

Lining. The covering of the surface of any body with another thin substance. Thus the lining of a wall is a wooden boarding, whose edges are either rebated or grooved and tongued. Lining is distinguished from *casing,* the first being a covering in the interior of a building, whilst the latter is the covering of the exterior part of a building.

Lining out Stuff. (Participle.) The drawing lines on a piece of board or plank so as to cut it into thinner pieces.

Linings of Boxings. The pieces of framework of a window into which the window shutters are folded back.

Linings of a Door. Those of the sides of apertures of doors called the jambs or jamb-linings, that which covers the top or head being the soffite.

Lintel. (Span.) A horizontal piece of timber or stone over a door, window, or other opening to discharge the superincumbent weight. If a wall be very thick, more than one lintel piece will be required, unless scantling of sufficient width be found. In some old books on carpentry, lintels are classed under wall plates, but the word is now never used in this sense, unless the joisting or tie beams rest upon it, in which case it is both a lintel and a wall plate.

List, or Listel. The same as Fillet.

Listed Boards. Such as are reduced in their width by taking off the sap from the sides. They are also explained as boards, sorted and matched, so as to make the floor appear all of one colour.

Listing. (Participle.) Cutting the sap wood out from both edges of a board.

Loam. A soil in which clay prevails. It is called heavy or light as the clay may be more or less abundant.

Lobby. (Germ. Laube.) An enclosed space surrounding or communicating with one or more apartments, such as the boxes of a theatre, for instance. By it also is understood a small hall or waiting room, or the entrance into a principal apartment where there is a considerable space between it and a portico or vestibule; but the dimensions, especially as regards the width, will not allow of its being called a vestibule or ante-room.

Lock. (Sax. Loc.) A well-known instrument, consisting of springs and bolts, for fastening doors, drawers, chests, &c. A good lock is a masterpiece in smithery, requiring much art and delicacy to contrive and vary the wards, springs, bolts, and other parts whereof it is composed, so as to adjust them to the places where they are serviceable, and to the various purposes of their use. The structure of locks is so varied, and the number of inventions of their different sorts so extended, that we cannot attempt to enumerate them.

Those placed on outer doors are called *stock-locks*, those on chamber doors *spring locks*, and *rim locks*, and such as are hidden in the thickness of the doors to which they are applied, *mortise locks*. The *padlock* is too well-known to need description here.

Lockrail. The middle horizontal rail of a door.

Locutory. An apartment in a monastery in which the monks were allowed to converse when silence was enjoined elsewhere.

Lodge. A small house, situated in a park or domain, subordinate to the mansion. Also the cottage placed at the gate leading to the mansion.

Loft. An upper platform, as in Scotland. It has been applied to the gallery in a church. In modern usage it is limited to the place immediately under the rafters, as *cockloft* in a house, *hay-loft* in a stable, &c. See Solar.

Logan. See Rocking Stone.

Logarithms. Artificial numbers used to facilitate arithmetical calculations.

Loggia. (It.) In its strict meaning a lodge; but usually signifying a gallery open to the air, and used for shelter, or from which to obtain a prospect.

Log-house. A hut constructed of the trunks of trees.

Logistic Spiral. One whose radii are in continued proportion, and in which the radii are at equal angles; or, in other words, a spiral line whose radii everywhere make equal angles with the tangents.

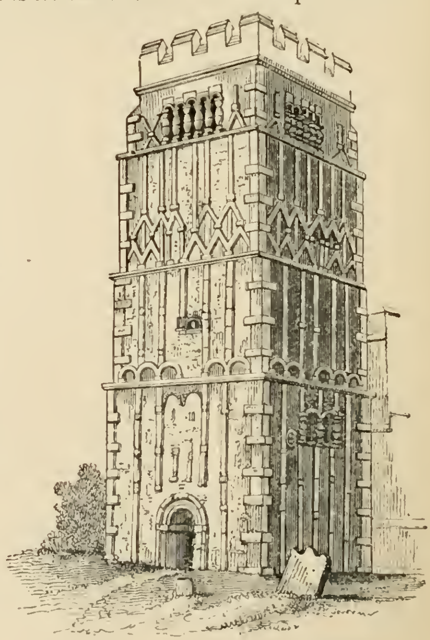

Fig. 1412. Tower of Earl's Barton Church.

Lombard Architecture. The class of Romanesque architecture which prevailed in the Northern parts of Italy.

Long and Short Work. A rough sort of building, consisting of quoin stones placed flat and upright alternately. Many writers consider such masonry as a mark of the work of the 11th century, or previous to it, and call it Saxon work. See *fig.* 1412.

Longimetry. A term used to denote the operation of trigonometry for measuring lengths, whether accessible or inaccessible.

Lookum, or Leucomb. A word used for the projection on the upper floor of a warehouse or mill, to cover a wheel and fall, or a crane, and has a trap-floor to it. It may, probably, be derived from the French term *lucarne*.

Loop. (Fr.) A small narrow window. A *loophole* is a term applied to the vertical series of doors in a warehouse, through which the goods in craning are delivered.

Loophole. A narrow aperture formed in walls, and sometimes in the merlon of a battlement, through which the defenders discharged their bows or firearms. See Balistraria.

Lotus. A plant of the water-lily species much used in the architectural ornaments of the early nations, and especially in the capitals of Egyptian columns. See fig. 54.

Louvre. A turret or lantern over a hall or other apartment with openings for ventilation and to allow the escape of smoke or steam.

Louvre, Luffer, or Lever Boarding. (Fr. Louvre.) Boarding, with intervals between the boards, nailed horizontally in an inclined direction, on the sides of buildings or lanterns, so as to admit a free current of air, and at the same time to exclude the rain. They are used for air-drying lofts. Each set, if required, is made to open and shut by the action of a lever.

Low Side Window. A small opening like a window, usually placed in the south chancel wall, and lower than the other windows, for what purpose is not strictly known. It has been called a *Lychnoscope*.

Lozenge. A quadrilateral figure of four equal sides, with oblique angles.

Lozenge Moulding. An ornament used in Norman architecture, presenting the appearance of diamond-shaped lozenges laid in the hollow of the moulding.

Lucarne. The same as Dormer.

Lumber. Timber sawn ready for use. It is a term used chiefly in America.

Lune or Lunula. The space between two equal arcs of a circle.

Lunette. (Fr.) A cylindric, cylindroidic, or spherical aperture in a ceiling. As an example of the term, we may refer to the upper lights in the nave of St. Paul's Cathedral.

Luthern. The same as Dormer.

Lych-Gate, or Corpse-Gate (from the Anglo-Saxon *Leich*, a dead body). A gate at the entrance of a churchyard, where the coffin was set down for a few minutes before burial. It is generally of wood, and often thatched. Lych-gates are not of frequent occurrence in England. In Wales many of them may be seen.

Lychnoscope. See Low Side Window.

Lying Panels. Those wherein the fibres of the wood, or the grain of it, lie in a horizontal direction.

Lysis. (Gr.) A plinth or step above the cornice of the podium of ancient temples, which surrounded or embraced the stylobate; an example of it may be seen in the temple of Fortuna Virilis at Rome.

M

M Roof. A roof formed by the junction of two common roofs with a valley between them. The letter M inverted represents this species of covering.

Machicolations. (Fr. Machicoulis.) In castellated architecture are, according to Grose, the projections, supported by brackets or corbels, through which melted lead and stones were dropped on the heads of assailants. They were not probably, however, projecting works, but sometimes were considered as the series of square holes in the vaultings of the portals used for the same purpose.

Machine. (Gr. Μαχανη.) In a general sense, anything which serves to increase or regulate the effect of a given force. Machines are *simple* or *compound*. The former are the simple mechanical powers, six in number; viz. the lever, the wheel and axle, the pulley, the wedge, the screw, and the funicular machine. The latter are formed by the combination of two or more simple machines, and are classed according to the forces by which they are put in motion, as *hydraulic machines*, *pneumatic machines*, *electric machines*, &c., or the purposes they are intended to serve, as *military* machines, *architectural* machines, &c.

Maenhir, or Menhir. A long upright stone in Celtic works, called by the Norman writers *peulvan*, and by country people *hoarstone*.

Magnesian Limestone. An extensive series of beds lying in geological position immediately above the coal measures; so called because the *limestone*, which is the principal member of the series, contains *magnesia*.

Magnitude. (Lat.) A term by which size, extent, or quantity is designated. It was originally applied to the space occupied by any figure; or, in other words, it was applied to objects strictly termed geometrical, and of three dimensions, length, breadth, and thickness, but it has gradually become enlarged in its signification, so as to be given to every kind of quantity that admits of mensuration, or of which greater or less can be predicated; in which sense it was used by Euclid.

Mahogany. A wood used for doors, window-sashes, and ornamental work, especially cabinet work. The Jamaica mahogany is the hardest and most beautiful, and is distinguished from that of Honduras by the chalky appearance of its fibres. The latter has very little flower.

Main Couple. See Couple.

Malleability. (Lat. Malleus, a hammer.) The property of being susceptible of extension under the blows of a hammer. It is a characteristic of some of the metals, most particularly in gold. Common gold-leaf is not more than a two-hundred-thousandth part of an inch in thickness. Five grains may be beaten out so as to cover a surface of more than two hundred and seventy square inches.

Malleable Iron. The same as pure Wrought Iron, being iron that can be worked by the hammer and tongs. The name has also lately been given to a soft quality of iron more easily worked for ornamental purposes.

Mallet. (Lat.) A large kind of wooden hammer much used by artificers who work with a chisel, as masons, stonecutters, carpenters, joiners, &c.

Maltha. (Gr.) A native bitumen used by the ancients for plastering the walls of their dwellings, &c. An artificial kind was made of pitch, wax, plaster. and grease; another sort was composed of lime slaked with wine, and incorporated with melted pitch and fresh figs.

Manger. The trough in the stall of a stable wherein is placed the corn or other short food given to live stock, and more especially to horses.

Manhole. An opening formed over a sewer, or by the side of it, large enough to admit a man to enter to do repairs, &c., when requisite. It is also formed on the top of large boilers, to give access to clean out the interior; and also over a cesspool for the same purpose. A manhole has usually a close-fitting cover, well set to prevent the escape of steam, foul air, &c.

Mansard Roof. (So called from the name of its supposed inventor, the French architect, François Mansart.) The same as Curb Roof.

Mansion. A large house; a term more usually applied to one in the country. The origin of the word and its application is supposed to be derived from the mansiones, or stationary camps of the Roman soldiers.

Mantapa. The Hindoo term for the porch attached to most vimanas or temples beyond the antarala. It is a square building, having a door on each of its four sides; the roof is generally pyramidal. If there should be two porches, the outer one is called the maha mantapa.

Mantel Piece. The horizontal decoration in stone or marble in front of the mantel tree, and supported by the jambs or boxings of a chimney-piece.

Mantel Shelf. The slab lying on the mantel piece, and secured at the back into the plastering of the wall.

Mantel Tree. The wood lintel or brick arch to the openings of a fire-place.

Marble. (Gr. Μαρμαίρω, to gleam, to sparkle.) A term limited by mineralogists and geologists to the several varieties of carbonate of lime, having more or less of a granular and crystalline texture. Among sculptors, the word is used to denote several compact or granular kinds of stone susceptible of a very fine polish; the varieties of it are very numerous. *Ancient Marbles*:—The most valuable sort, and the grandest quarry of the Greek *white* marbles, was the *Pentelican*, obtained from mount Penteles, in Attica. It was used in the Parthenon and other buildings in Athens, and was in great repute with the sculptors. This marble is overlaid in the quarries with large figured red and green *Cipollino*. The base rock of the Acropolis at Athens, a mass of richly coloured marble—rose, reds, browns and greys—was discarded by the Greeks. The *Parian* was obtained from the island of Paros. Mount Marpesus yielded the best, which was called *Marpessian*; it was also termed *Lychneus*, because of its use for candelabra, and *Lygdineum*, from the promontory of Lygdos. It consists almost entirely of carbonate of lime; and Dr. Clarke states it has lasted better than the Pentelican, which has veins of extraneous substances intersecting the quarries, and which appear, more or less, in all works executed in this sort of marble. The Parian has a waxy appearance when polished, and hardens by exposure to the air; the statues of the Venus di Medici, the Diana Venatrix, the collossal Minerva Pallas of Velletri, and the Capitoline Juno, were carved in this material, and the tomb of Mausolus was built of it, the remains of which are now in the British Museum.

Other white marbles were of mount Hymettus, in Attica, of Thasus and Lesbos, in great repute; of Lunar, in Etruria, of a white even whiter than that of Paros; the *Phellense*, from mount Phellens; the *Coraliticum*, found near the river Coralios in Phrygia, which was also termed *Sangarium*, from another name of the same river;

Cyzicum, from Cyzicus in Asia Minor, one of the three marbles of which the temple at Ephesus was to be built; also called Proconnesian marble.

Chernites was another sort of marble, which resembled ivory in its colour. The *Phengites* of Capadocia was white with yellow spots.

The *black* marbles were: *Tænarus*, highly esteemed; one from the island of Lesbos; *Lybicum* or *Numidian*, called also *Lucullcum*; *Chium*, from Mount Palineus, in the island of Chio, of a transparent chequered black colour; *Obsidianum*, from Ethiopia; Synnadicum, or *Marmor Phrygium*, from near Synnas, in Phrygia, having small circles in its black ground; *Africano*, from the island of Scio, so called from its dark colour by Pliny, who was wrong.

The *rose Africano*, from Porta Santa, in the island of Scio, a grand quarry, yielding six or more different kinds (Brindley); the old quarries of *Rosso antico* were discovered at Laconia; quantities were obtained from Egypt.

Taygetum supplied the *green* porphyry, or serpentine, of the Italians. *Carystus*, in Eubæa, gave the green *Cipollino*, one of the marbles most appreciated by the Romans, of which in Rome alone 500 columns still remain; it was a mingled dark green; *Memphites* and *Ophites*, resembling the skin of a serpent, and from the city in Egypt, near where it was found; it is the *Serpentino antico* of the Italians; *Laconicum*, from Mount Taygetes, the well-known *Verd antique* of the antiquaries; the green Tiberian and Augustan marbles were obtained from Egypt.

Yellow marble was found at Corinth; the *Rhodian* marble was marked with spots resembling gold; that of *Melos* was excavated in Mount Acynthus.

Atracium, from Mount Atrax, in Thessaly, was a mixture of white, green, blue, and black.

The Romans seem to have introduced coloured marbles in monumental works after their conquest of Egypt, whence they derived their first ideas of monolith columns. Their early buildings contained few varieties of coloured marbles, the number increasing as the colonies matured. The monoliths in St. Peter's and St. Sebastian were cut from the quarry of Porta Santa, in the island of Scio, as was also the basin, 15 feet diameter and 4 feet thick, discovered by Mr J. T. Wood, at Ephesus. The ancient quarry in Tunis supplied the *Giallo antico*, and varieties of rose and orange *Breccias*; this marble was reserved for Rome, where 172 columns of it are still extant. Most of the pavement in the Basilica Julia, and the columns in St. John Lateran, the Pantheon, the Arch of Titus, are of this marble; as well as the wall-lining, half an inch thick, in the palaces of the Cæsars.

The first paper read by Mr. Brindley names forty-six of the principal quarries of various countries worked in the time of the Romans; the second one refers to the stones and marbles found in Egypt. *Transactions* of the Royal Institute of British Architects, 1887–88 and 1888-89. The building and decorative stones of Egypt, including limestone, sandstone, granite, porphyry, opus Alexandrinum, verde Augustus, Oriental alabaster, Breccia verde, gem stones, &c., are described by Mr. Brindley, 1887, Nov. 24. See PORPHYRY and SYENITE.

The *Numidian marble* of the Romans, obtained from North Africa, is coloured marble of various shades and tints, but does not include white marbles or shades of white, of which there are numerous quarries in North Africa. *Marmor Numidicum* appears to be a misnomer, for the only known quarry in the ancient province of Numidia is at Filfilla, near Philippoville. The only yet discovered quarries are those at Chemtou in Tunisia (Simittu Colonia in Africa Provincia of the Romans), and at Kleber in Algeria, north-east of Oran (in the ancient kingdom of Mauretania). The former quarries are much in the condition in which they were left by the Romans. The quarries at Kleber cover an area of over 1,500 acres. *Breccias*, from dark brown to blood red; *Giallo antico* of different hues, designated as *Canarino*, *Avorio*, and *Pavonazzo*; *Cipollino rosso*, and more than one quality of white marble. Specimens of some of these are now to be seen in the new mausoleum room of the British Museum. Great and beautiful varieties are to be seen in the prayer chamber of the great mosque at Kairouan, and other mosques (Alex. Graham, in *Proceedings* Royal Institute of British Architects, 1886–87).

A useful list of ancient and modern marbles, with references to works of art, is contained in the work by the Count de Clarac, and translated in the *Civil Engineer, &c., Journal* for 1839, pages 367, 434, and 452. It also gives numerous references to writers on the subject.

The *onyx* marbles of Algeria, Mexico, and California, are of the same nature as the Oriental alabasters.

Almost every mountainous district of the world produces this mineral, but the finest and most valuable is from Italy. The material is brought to an even face by rubbing with free-stone, afterwards with pumice-stone, and lastly with emery of several colours;

but white marble is finished with calcined tin. The Italians polish with lead and emery. The sawing of marble, preparatory to polishing, is by a saw of soft iron, with a continued supply of the sharpest sand and water. The Belgian marble chimneypieces, toilet-table tops, and such like articles, are finished with a liquid which gives a polished appearance; but it is not lasting.

The varieties of marble used in modern times are very numerous, and a classification of them would occupy a larger space than can be here given. Except the finest specimens of white marble, they are mostly opaque. Some extremely fine specimens of white marble are to be seen in the Borghese Palace at Rome, which, on being suspended by the centre on a hard body, bend very considerably. It is found that statuary marble exposed to the sun acquires, in time, this property, thus indicating a less degree of adhesion of its parts than it naturally possessed. Two books have been written on the subject: *Marble and Marble Workers*, by Arthur Lee, and *Marble Decoration*, by G. H. Blagrove, both dated 1888.

Margin. That part of the upper side of a course of slates which appears uncovered by the next superior course.

Marigold Window. The name given to a circular window in which radiating mullions prevail. See Catherine-wheel Window; Rose Window.

Market Cross. A cross set up in a market-place. The primitive form was a long shaft with a cross stone, set upon a number of steps. Subsequently it was constructed in an elaborate manner; and later, a sort of arched structure was erected around the central pillar. In Scotland many were finished with a crowning work.

Marmoratum Opus. (Lat.) A fine stuff used by the ancients, formed of calcined gypsum with pulverised stone, or for finest work with pounded marble, well beaten together, and rubbed to a fine marble-like surface, examples of which still exist at Girgenti, formerly Agrigentum.

Marquetry. (It. Intarsiatura. Fr. Marquetrie.) Inlaid work, consisting of thin plates of ivory, or of various coloured woods, glued on to a ground, usually of oak or fir well dried and seasoned, which, to prevent casting and warping, is composed of several thicknesses. It was used by the early Italian builders in cabinet work, and represented by its means figures and landscapes. See Buhl Work; Inlaid Work; Parquetry.

Mason. An artificer who practises the science of cutting and setting stones in building walls. Formerly the workman who worked the stone was called a free-stone mason, hence the term freemason; while the man that set the stone was called a rough mason.

The term "master mason" was during the mediæval period equivalent to the more modern term "architect." He designed and carried out the monastic, cathedral, or regal buildings. Later, the designer taking the name of surveyor, the master mason became the head of his trade.

Masonry. (Fr.) The science of combining and joining stones for the formation of walls and other parts in constructing buildings. When applied in the construction of domes, groins, and circular arches, it is difficult and complicated, and is dependent on a thorough knowledge of descriptive geometry.

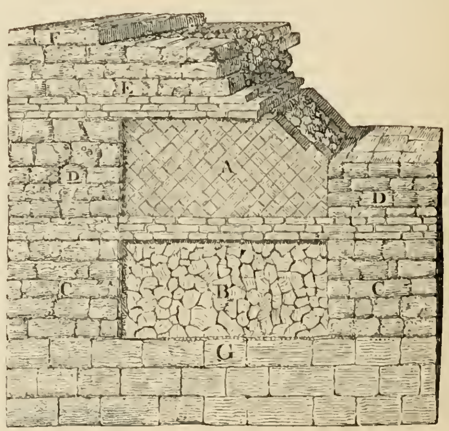

Fig. 1413.

Among the ancients, several sorts of masonry were in use, which are described by Vitruvius as follows, in the eighth chapter of his second book:—"The different species of walls," he observes, "are the *reticulatum* (net-like) (*fig.* 1413 A), a method now in general use, and the *incertum* (B), which is the ancient mode. The reticulatum is very beautiful, but liable to split, from the beds of the stones being unstable, and its deficiency in respect of bond. The incertum, on the contrary, course over course, and the whole bonded together, does not present so beautiful an appearance, though stronger than the reticulatum. Both species should be built of the smallest sized stones, that the walls, by sucking up and attaching themselves to the mortar, may last the longer: for as the stones are of a soft and porous nature, they absorb, in drying, the moisture of the mortar; and this, if used plentifully, will consequently exercise a greater cementing power; because from their containing a large portion of moisture, the wall will not, of course, dry so soon as otherwise; and as soon as the moisture is absorbed by the pores of the stones from the mortar, the lime, losing its power, leaves the sand, so that the stones no longer adhere to it, and in a short time the work becomes unsound. We may see this in several monuments about the city (Rome) which have been built of marble, or of stones squared externally, that is, on one face, but filled up with rubble run with mortar. Time in these has taken up the moisture of the mortar, and destroyed its efficacy by the porosity of the surface on which it acted. All cohesion is thus ruined, and the walls fall to decay. He who is desirous that this may not happen to his work should build his two-face walls two feet thick, either of red stone, or of bricks, or of common flint, binding them together with iron cramps run with lead, and duly preserving the middle space or cavity. The materials in this case not being thrown in at random, but the work well brought up on the beds, the upright joints properly arranged, and the face-walls, moreover, regularly tied together, they are not liable to bulge, nor be otherwise disfigured. In these respects one cannot refrain from admiring the walls of the Greeks. They make no use of soft stone in their buildings; when, however, they do not employ squared stones, they use either flint or hard stone, and, as though building with brick, they cross or break the upright joints, and thus produce the most durable work. There are two sorts of this species of work, one called *isodomum* (CC), the other *pseudisodomum* (DD). The first is so called, because in it all the courses are of an equal height; the latter received its name from the unequal heights of the courses. Both these methods make sound work; first, because the stones are hard and solid, and therefore unable to absorb the moisture of the mortar, which is thus preserved to the longest period; secondly, because the beds being smooth and level, the mortar does not escape; and the wall, moreover, bonded throughout its whole thickness, becomes eternal. There is still another method, which is called εμπλεκτον (*emplecton*) (E), in use even among our country workmen. In this species the faces are wrought. The other stones are, without working, deposited in the cavity between the two faces, and bedded in mortar as the wall is carried up. But the workmen, for the sake of despatch, carry up these casing walls, and then tumble in the rubble between them, so that there are thus three distinct thicknesses, namely, the two sides or facings, and the filling in. The Greeks, however, pursue a different course, laying the stones flat, and breaking the vertical joints; neither do they fill in the middle at random, but, by means of bond stones, make the wall solid, and of one thickness or piece. They, moreover, cross the wall from one face to the other, with bond stones of a single piece, which they call διατονοι (*diatoni*) (F), tending greatly to strengthen the work." (G) is supposed to show the solid masonry of a wall properly bonded in the courses.

Mass. (Germ. Masse.) The quantity of matter whereof any body is composed. The mass of a body is directly as the product of its volume into its density. Multiplied into the constant force of gravity, the mass constitutes the weight; hence the mass of a body is properly estimated by its weight.

Mastic. (Gr. Μαστικη, a species of gum.) A cement employed for plastering outside walls. It is used with a considerable portion of linseed oil, and sets hard in a few days. From this latter circumstance, and from its being fit for the reception of paint in a very short period, it is extremely useful in works where expedition is necessary, but it must be constantly painted; when the oil has dried out, it has proved to be worthless. Asphalte mixed with coal tar or limestone, ready for use in paving, is termed "mastic."

Materials. Things composed of matter, or possessing its fundamental properties.

Mathematics. (Gr. Μαθησις, learning.) The science which investigates the consequences logically deducible from any given or admitted relations between magnitude or numbers. It has usually been divided into two parts, *pure* and *mixed*. The first is that in which geometrical magnitude or numbers are the subjects of investigation; the last that in which the deductions so made are from relations obtained by observation and experiment from the phenomena of material nature. This is sometimes called *physics*, or physical science. Mathematics, as respects what is necessary for the architect, comprises Arithmetic, Algebra, and Geometry.

Mausoleum. A term used to denote a sepulchral building, and so called from a very celebrated one erected to the memory of Mausolus, king of Caria, by his wife Artemisia, about 353 B.C. From its extraordinary magnificence, it was in ancient times esteemed the seventh wonder of the world. Many statues and other portions of it are now in the British Museum.

Mean. In mathematics, that quantity which has an intermediate value between several others, formed according to any assigned law of succession. Thus, an *arithmetical mean* of several quantities is merely the *average*, found by dividing the sum of all the quantities by their number. A *geometrical mean* between two quantities, or a *mean proportional*, is the middle term of a duplicate ratio, or continued proportion of three terms; that is, that the first given term is to the quantity sought as that quantity is to the other given term. In arithmetic, it is the square root of the product of the two given terms. The *harmonical mean* is a number such that, the first and third terms being given, the first is to the third as the difference of the first and second is to the difference of the second and third.

MEASURE. (Lat. Mensura.) In geometry, strictly a magnitude or quantity taken as a unit, by which other magnitudes or quantities are measured. It is defined by Euclid as that which, by repetition, becomes equal to the quantity measured. Thus, in arithmetic, the *measure of a number* is some other number which divides it without a remainder, though, perhaps, such a definition rather intimates the notion of *aliquot parts*. But that meaning on which this article is submitted is the unit or standard by which extension is to be measured. We have measures of length, of superficies, and of volume or capacity. But the two latter are always deducible from the former; whence it is only necessary to establish one unit, namely, a standard of length. The choice of such a standard, definite and invariable, though beset with many and great difficulties, modern science has accomplished. The rude measures of our ancestors, such as the *foot*, the *cubit*, the *span*, the *fathom*, the *barleycorn*, the *hair's breadth*, are not now to be mentioned in matters of science, much more precise standards having been found, and not susceptible of casual variation. Nature affords two or three elements, which, with the aid of science, may be made subservient to the acquisition of the knowledge required. The earth being a solid of revolution, its form and magnitude may be assumed to remain the same in all ages. If this be so, the distance between the pole and the equator may be taken as an invariable quantity; and any part, say a degree, which is a ninetieth part of it, will be constant, and furnish an unalterable standard of measure. So, again, the force of gravity at the earth's surface being constant at any given place, and nearly the same at places under the same parallel of latitude, and at the same height above the level of the sea, the length of a pendulum making the same number of oscillations in a day is constant at the same place, and may be determined on any assumed scale. Thus we have two elements, the length of a degree of the meridian, and the length of a pendulum beating seconds, which nature furnishes for the basis of a system of measures. Others have been suggested, such as the height through which a heavy body falls in a second of time, determined, like the length of the pendulum, by the force of gravity, or the perpendicular height through which a barometer must be raised till the mercurial column sinks a determinate part; for instance, one-thirtieth of its own length; but these are not so capable of accurately determining the standard as the terrestrial degree, or the length of the pendulum.

In the English system of linear measures, the unit has been for many years the yard, which is subdivided into 3 feet, and each of those feet into 12 inches. Of the yard, the multiples are, the pole or perch, the furlong, and the mile; $5\frac{1}{2}$ yards being 1 pole, 40 poles being 1 furlong, and 8 furlongs 1 mile. The pole and furlong, however, are now much disused, distance being usually measured in miles and yards. The English pace is $1\frac{2}{3}$ yards = 5 feet. See PERCH and MILE.

Under the word FOOT will be found the length of that measure in the principal places of Europe.

The following table exhibits the relations of the different denominations mentioned:—

Inches.	Feet.	Yards.	Poles.	Furlongs.	Miles.
1	0·083	0·028	0·00505	0·00012626	0·0000157828
12	1·	0·333	0·06060	0·00151515	0·00018939

198	16·5	5·5	1·	0·025	0·003125
7920	660·	220·	40·	1·	0·125
63360	5280·	1760·	320·	8·	1·

The measures of superficies are the square yard, foot, inch, &c., as under:—

144 square inches are equal to - - - -	1 square foot.
9 square feet - - - - - -	1 square yard.
$2\frac{7}{9}$ square yards - - - - -	1 square pace.
10·89 square paces - - - - -	1 square pole.
40 square poles - - - - -	1 square rood.
4 square roods - - - - - -	1 square acre.

In which it will be seen that the multiples of the yard are the pole, rood, and acre. Very large surfaces, as of countries, are expressed in square miles. See MILE.

The relations of square measure are given in the following table:—

Square Feet.	Square Yards.	Square Poles.	Square Roods.	Square Acres.
1·	0·1111	0·00367309	0·000091827	0·000022957
9·	1·	0·0330579	0·000826448	0·000206612
272·25	30·25	1·	0·025	0·00625
10890·	1210·	40·	1·	0·25
43560·	4840·	160·	4·	1·

The measures of solids are cubic yards, feet, and inches, 1728 cubic inches being equal to a cubic foot, and 27 cubic feet to one cubic yard. By the act of 1824, the standard measure for all sorts of liquids, corn, and other dry goods, is declared to be the *Imperial gallon.* According to the act in question, the imperial standard gallon contains ten pounds avoirdupois of distilled water, weighed in air at the temperature of 62° Fahrenheit's thermometer, the barometer being at 30 inches. The pound avoirdupois contains 7000 troy grains, and it is declared that a cubic inch of distilled water (temperature 62°, barometer 30 inches) weighs 252·458 grains. Hence the imperial gallon contains 277·274 cubic inches. The gallon is subdivided into *quarts* and *pints,* 2 pints being one quart, and 4 quarts one gallon. Its multiples are the *peck,* which is 2 gallons, the *bushel,* which is 4 pecks, and the *quarter,* which is 8 bushels. The relations of measures of volume are given in the subjoined table:—

Pints.	Quarts.	Gallons.	Pecks.	Bushels.	Quarters.
1	0·5	0·125	0·0625	0·015625	0·001953125
2	1·	0·25	0·125	0·03125	0·00390625
8	4·	1·	0·5	0·125	0·015625
16	8·	2·	1·	0·25	0·03125
64	32·	8·	4·	1·	0·125
512	256·	64·	32·	8·	1·

The old wine gallon contained 231 cubic inches, the old corn gallon 268·8 cubic inches, and the old ale gallon 282 cubic inches.

Subjoined are a few of the principal ancient measures of France:—

1 toise, French = 6 French feet = 6·394665 English feet.
1 foot, do. = 12 French inches = 12·78936 English inches.
1 inch, do. = 12 French lines = 1·06578 English inches.
1 line, do. = 6 French points = 0·088815 English inches.
1 point, do. = ... = 0·0148025 English inches.

According to General Roy, an English fathom : a French toise : : 1000 : 1065·75.

In the new French system the *metre,* which is the unit of linear measure, is the ten-millionth part of the quadrant of the meridian = 3·2808992 English feet (but lately ascertained by Capt. Henry Kater, to be more correctly 3·280916 English feet); and, as its multiples and subdivisions are decimally arranged and named by prefixing Greek numerals, the following table exhibits each:—

Denomination.			English Feet.
Myriametre	- - -	10000 metres	= 32808·991667
Kilometre	- - -	1000	= 3280·8992
Hectometre	- - -	100	= 328·08992
Decametre	- - -	10	= 32·808992
Metre (the unit)	- -	1	= 3·2808992
Decimetre	- - -	0·1	= 0·32808992
Centimetre	- - -	0·01	= 0·032808992
Millimetre	- - -	0·001	= 0·0032808992

The metre, therefore, is equal to 39·37079 English inches.

The unit of superficial measure, in the French system, is the *are,* which is a surface of 10 metres each way, or 100 square metres. The centiare is 1 metre square.

Denomination.			English Square Yards.
Hectare	- - -	10000 square metres	= 11960·33
Are (the unit)	- -	100	= 119·6033
Centiare	- - -	1	= 1·19603326

The *are,* therefore, is equal to 1076·4297 English square feet.

The unit of measures of capacity, in the French system, is the *litre*, a vessel containing a cube of a tenth part of the metre, and equivalent to 0·22009668 British imperial gallon. Its multiples and subdivisions are as follow:—

Denomination.			Eng. Imp. Gallons.
Kilolitre - - - -	1000 litres	=	220·0966767
Hectolitre - - - -	100	=	22·009668
Decalitre - - - -	10	=	2·2009668
Litre (the unit) or Cubic Decimetre -	1	=	0·22009668
Decilitre - - - -	0·1	=	0·022009668

The unit of solid measure, or the *stere*, is equal to 35·31658 English cubic feet; therefore,

Denomination.			English Cubic Feet.
Decastere - - - -	10 steres	=	353·1658
Stere (the unit) - - - -	1	=	35·31658
Decistere - - - - -	0·1	=	3·531658

There is much uncertainty respecting the ancient measures; the tables before printed being the usually received notions are continued, but subjoined are some of the dimensions given in Dr. W. Smith's Dictionary of Antiquities:—

Scripture Long Measure.

(See Cubit.)

			English Feet	English Inches	Hebrew and Chaldean Measures, as drawn up by F. R. Conder, C.E., 1875. Barleycorns.	Eng. in.

Mechanical Carpentry. That branch of carpentry which relates to the disposition of the timbers of a building in respect of their relative strength and the strains to which they are subjected.

Mechanical Powers. See Machine.

Mechanics. (Gr. Μηχανη, machine.) That science in natural philosophy treating of forces and powers, and their action on bodies, either directly or by the intervention of machinery. The theory of mechanics is founded on an axiom or principle, called the *law of inertia*, namely, that a body must remain for ever in a state of rest, or in a state of uniform or rectilineal motion, if undisturbed by the action of an external cause. Theoretical mechanics consists, therefore, of two parts:— *Statics*, which treats of the equilibrium of forces; and *dynamics*, or the science of accelerating or retarding forces, and the actions they produce. When the bodies under consideration are in a fluid state, these equilibria become respectively *hydrostatics* and *hydrodynamics*.

Medallion. A square, or more properly, a circular, tablet, on which are embossed figures, busts, and the like.

Mediæval Architecture. The architecture of England and the Continent during the Middle Ages. It is also chiefly called Gothic and Pointed.

Megalithic. A term which has lately been applied to those works usually called Celtic and Druidical.

Mehrab. A niche in a mosque of the Mahomedans which marks the direction of the *Kebla* or temple at Mecca, to which their religion directs them to bow their face in praying.

Member. (Lat.) Any part of an edifice; or any moulding in a collection of mouldings, as of those in a cornice, capital, base, &c.

Menagerie. (Fr.) A building for the housing and preservation of rare and foreign animals. The ancient Romans of opulence usually had private menageries, a sort of small park attached to their villa, and in them various kinds of animals were placed.

Menhir. See Maenhir.

Mensa. The slab, top, or table of the altar of the Roman Catholic Church.

Mensuration. (Lat.) The science which teaches the method of estimating the magnitudes of lines, superficies, and bodies.

Meridian Line. A line traced on the surface of the earth coinciding with the intersection of the meridian of the place with the sensible horizon. It is therefore a line which lies due north and south. In Italy these lines have been laid in large churches, as at Santa Maria del Fiore at Florence, the Duomo at Bologna, &c. They are traced on brass rods let into the pavement of the church, and marked with the signs, and otherwise graduated. A hole in the roof permits the sun's rays to fall on them at his culmination, thus marking noon as well as its height each day in the heavens.

Merlon. The plain parts of an embattled parapet, between the *crenelles* or embrasures.

Meros. (Gr.) The plane face between the channels in a triglyph. See Triglyph.

Mesaulæ. (Gr.) Described by Vitruvius as *itinera* or passages; they were, however, smaller courts. Apollonius Rhodius, in describing the reception of the Argonauts at the palace of Æetes, conducts them first into the vestibule, then through the folding gates into the *mesaula*, which had *thalami* here and there, and a portico (αιθουσα) on every side.

Meta. (Lat.) A mark or goal in the Roman circus to which the chariots, &c., ran.

Metal. (Gr. Μεταλλον.) A firm, heavy, and hard substance, opaque, fusible by fire, and concreting again when cold into a solid body such as it was before; generally malleable under the hammer, and of a bright glossy and glittering substance where newly cut or broken. The metals conduct electricity and heat, and have not been resolved into other forms of matter, so that they are regarded as simple or elementary substances. They also reflect, when polished, both light and heat. Modern chemists have carried the number of metals to over forty-two, only seven whereof were known to the ancients; namely,—1. *Gold*, whose symbol is thus marked ☉; 2. *Silver*, ☽; 3. *Iron*, ♂; 4. *Copper*, ♀; 5. *Mercury*, ☿; 6. *Lead*, ♄; 7. *Tin*, ♃.

Metatome. (Gr. Μετα, and Τεμνω, I cut.) The space or interval between two dentels.

Metoche. (Probably from Μετεχω, I divide.) In ancient architecture a term used by Vitruvius to denote the interval or space between the dentels of the Ionic, or triglyphs of the Doric order. Baldus observes that in an ancient MS. copy of that author, the word metatome is used instead of metoche. This made Daviler suspect that the common text of Vitruvius is corrupt, and that the word should not be metoche but metatome, as it were *section*.

Metopa. (Gr. Μετα, between, and Οπη, a hole.) The square space in the frieze between the triglyphs of the Doric order: it is left either plain or decorated, according to the taste of the architect. In very ancient examples of this order the metopa was left quite open. Figs. 1414 and 1415 represent two sculptures from the Parthenon at Athens.

Metre. The French unit of length (see Measure), from whence is derived their metrical system now followed by many other nations.

Mexican Architecture. The buildings of the ancient people inhabiting Mexico and Yucatan in America—*Teocalli* or pyramids, with walls of ruined cities, various carvings

Fig. 1414.

Fig. 1415.

on the face of the stones, and sculpture of hideous shape, comprise nearly all that is as yet known of their works.

Mezzanine. (Ital. Mezzano, middle.) A story of small height introduced between two higher ones. See Entresol.

Mezzo Relievo. See Relievo.

Middle Post. In a roof, the same as King Post.

Middle Quarters of Columns. A name given to the four quarters of a column divided by horizontal sections, forming angles of forty-five degrees on the plan.

Middle Rail. The rail of a door, on or in which the lock is usually fixed.

Mile. (Lat. Mille passuum, a thousand paces.) A measure of length in England equal to 1,760 yards. The Roman pace was 5 feet; and a Roman foot being equal to 11·62 modern inches, it follows that the ancient Roman mile was equivalent to 1,614 English yards, or very nearly eleven-twelfths of an English statute mile. The measure of the English mile is incidentally defined by an Act of Parliament passed in the 35th of Elizabeth, restricting persons from erecting new buildings within three miles of London, in which Act the mile is declared to be 8 furlongs of 40 perches each, and each perch equal to 16½ feet.

Milk Room. See Dairy.

Millstone Grit. A coarse grained quartzose sandstone. It is extracted from the group of strata which occur between the mountain limestone and the superincumbent coal formations.

Minaret. (Arab. Menarah, a lantern.) A slender lofty turret, rising by different stages or stories, surrounded by one or more projecting balconies, common in Mohammedan countries, being used by the priests for summoning (from the balconies) the people to prayers at stated periods of the day. They are also called alkoranes.

Mindra. The name for the *cella* containing the statue of a Hindoo temple, from whence rises the *sikr* or spire; the *pronaos* is the *munduf*, and the portico is in front, which is the *châori* or pillared hall.

Minion. An iron ore, which mixed with a proper quantity of lime makes an excellent water cement.

Minster. A church to which an ecclesiastical fraternity has been or is attached. The name has been also used freely to distinguish collegiate or conventual churches from parish churches.

Minute. (Lat.) See Module.

Mischia. See Scagliola.

Miserere. A hinged seat attached on an horizontal axis to a stall in a church or cathedral. It was so contrived that if, during the performance of religious ceremonies, the occupier of it slept, he would fall on (perchance) the floor. Hence the name. The corbel under the seat, which formed the resting place, is usually carved with foliage, or with figures sometimes of a ludicrous design. The earliest examples are in Exeter Cathedral, dating 1240–56.

Mitchel. A name given by workmen to Purbeck stones of twenty-four inches by fifteen when squared for building.

Miter, sometimes written Mitre. See Bevel.

Miter Box. See Box for Miter

Mitre Arch. A French name for a pediment arch similar to *fig.* 1416. Examples are found in early Greek and in Celtic structures as well as in the early Norman work in England.

Mixed Angle. An angle of which one side is a curve and the other a straight line.

Mixed Figure. One composed of straight lines and curves, being neither entirely the sector nor the segment of a circle, nor the sector nor segment of an ellipsis, nor a parabola, nor an hyperbola.

Moat. A wide ditch surrounding a house, castle, or town, and always full of water, or capable of being filled when requisite.

Model. (Lat.) An original or pattern proposed for anyone to copy or imitate. Thus St. Paul's may be, though not strictly so, said to be built after the model of St. Peter's at Rome.

The word is also used to signify an artificial pattern made of wood, stone, plaster, or other material, with all its parts and proportions, for the satisfaction of the proprietor, or for the guide of the artificers in the execution of any great work. In designing large buildings a good method of proceeding is to make a model, and not to trust entirely to drawings.

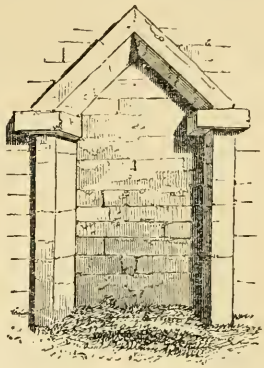

Fig. 1416. Recess at Barnack Church

Modillion. (Fr.) A projection under the corona of the richer orders resembling a bracket. In the Grecian Ionic there are no modillions, and they are seldom found in the Roman Ionic. Those in the frontispiece of Nero at Rome consist of two plain faces separated by a small cyma reversa, and crowned with an ovolo and bead. In the frieze of the fourth order of the Coliseum, the modillions are cut in the form of a cyma reversa.

Modular Proportion. That which is regulated by a module. See Module.

Modulation. (Lat.) The proportion of the different parts of an order.

Module. (Lat.) A measure which may be taken at pleasure to regulate the proportions of an order, or the disposition of the whole building. The diameter or semi-diameter of the column at the bottom of the shaft has usually been selected by architects as their module; and this they subdivide into parts or minutes. Vignola has divided his module, which is a semi-diameter, into 12 parts for the Tuscan and Doric, and into 18 for the other orders. The module of Palladio, Cambrai, Desgodetz, Le Clerc, and others, is divided into 30 parts or minutes in all the orders. Some have divided the whole height of the column into 20 parts for the Doric, 22½ for the Ionic, 25 for the Corinthian, &c., one whereof is taken for the module by which the other parts are to be regulated.

Vitruvius having lessened his module in the Doric order, which in the other orders is the diameter of the lower part of the column, and having reduced the great module to a mean one, which is a semi-diameter, Perrault reduces the module to a third part for a similar reason, namely that of determining the different measurements without a fraction. Thus, in the Doric order, besides that the height of the base, as in the other orders, is determined by one of these mean modules, that same module furnishes the height of the capital, architrave, triglyphs, and metopæ. But the smaller module obtained from a third of the diameter of the lower part of the column has uses considerably more extensive, inasmuch as by it the heights of pedestals, of columns, and entablatures in all the orders may be obtained without a fraction.

Modulus of Elasticity. A term in relation to elastic bodies, which expresses the weight of themselves continued, which would draw them to a certain length without destroying their elastic power.

Mole. (Sax.) A pier of stone for the shelter of ships from the action of the waves. Amongst the Romans the term was applied, as in the case of the mole of Hadrian (now the castle of St. Angelo at Rome), to a kind of circular mausoleum.

Momentum. (Lat.) The impetus, force, or quantity of motion in a moving body. The word is sometimes used simply for the motion itself.

Monastery. A house for the reception of religious devotees, but more properly applied to one for the habitation of monks.

Monial. An old way of writing Mullion, and still used by some writers.

Monkey. In piling operations. See Fistuca.

Monochrome. A system of decoration of one colour only.

Monolith. (Gr. Μονος one, Λιθος, a stone.) A monument, obelisk, or column of a single stone. Such works are found in many parts of the world. In Egypt and India temples have been formed out of the rock or of single blocks of stone. Many circles of stones, as at Abury and elsewhere, consist of monoliths.

MONOPTERAL. (Gr.) A species of temple of a round form, which had neither walls nor cella, but only a cupola sustained by columns. See TEMPLE.

MONOTRIGLYPH. (Gr.) A term applied to an intercolumniation in which only one triglyph and two metopæ are introduced.

MONSTRANCE. A transparent pyx for processions of the Church, or when the Host is exhibited; a casket for the exhibition of the Sacrament.

MONTANT. The intermediate style in a piece of framing, which is tenoned into the rails. It is also called a muntin.

MONUMENT. (Lat. Moneo.) An edifice of importance in the history of art, and which was raised to perpetuate the memory of some eminent person, or to serve as a durable token of some extraordinary event. See MAUSOLEUM. The pyramids may also come under this class, although they were tombs. The word monument is too generally applied to mere tombs.

MOORSTONE. A species of granite found in Cornwall and some other parts of England, and very serviceable in the coarser parts of a building. Its colours are chiefly black and white, and it is very coarse. In some parts of Ireland immense beds of it are found.

MORESQUE ARCHITECTURE. The style of building peculiar to the Moors and Arabs. It is also called Saracenic.

The word Moresque is also applied to a kind of painting in that style used by the Moors. It consists in many grotesque pieces and compartments, promiscuously, to appearance, put together, but without any perfect figure of man or animal. The style is sometimes called *Arabesque*.

MORTAR. The material used to bind stone, bricks, &c., together; it is compounded of burnt limestone and sand. Hydraulic mortar is made of hydraulic lime and sand.

MORTICE, or MORTISE. (Fr. Mortoise, probably from the Latin Mordeo, to bite.) In carpentry and joinery, a recessed cutting within the surface of a piece of timber, to receive a projecting piece called a *tenon* left on the end of another piece of timber, in order to fix the two together at a given angle. The sides of the mortice are generally four planes at right angles to each other and to the surface, whence the excavation is made.

MORTICE LOCK. A lock made so as to fit into a mortice cut in the lock rail of a door to receive it. It is thus shut out from sight.

MOSAIC. (It. Mosaico.) A mode of representing objects by the inlaying of small cubes of glass, stone, marble, shells, wood, &c. It was a species of work much in repute among the ancients, as may be gathered from the numerous remains of it. It is supposed to have originated in the east, and to have been brought from Phœnicia to Greece, and thence carried to Rome. The term Mosaic work is distinguished from *marquetry* and *parquetry* by being only applied properly to works of stone, metal, or glass. The art continues to be practised in Italy at the present day with great success.

MOSQUE. (Turk. Moschet.) A Mohammedan temple or place of worship. The earliest Arabian mosques were decorated with ranges of a vast number of columns, often belonging originally to other buildings. Those of the Turks, on the other hand, are more distinguished for the size and elevation of their principal cupolas. Each mosque is provided with a minaret, and commonly with a fountain of water, with numerous basins for ablutions.

MOULD. A term used to signify a pattern or contour by which any work is to be wrought. The *glazier's moulds* are of two sorts, one of which is used for casting the lead into long *rods* or *cames*, fit for drawing through the vice in which the grooves are formed. This they sometimes call the *ingot mould*. The other is for moulding the small pieces of lead, a line thick and two lines broad, which are fastened to the iron bars of casements.

The *mason's mould*, also called *caliber*, is a piece of hard wood or iron, hollowed on the edge, answering to the contours of the mouldings or cornices to be formed. The ends or heading joints being formed as in a cornice by means of the mould, the intermediate parts are wrought down by straight edges, or circular templets, as the work is straight or circular on the plan. When the intended surface is required to be very exact, a reverse mould is used, in order to prove the work, by applying the mould in a transverse direction of the arrises.

MOULD. The prepared form on which plumbers cast their sheets of lead; it is simply called a table. They have others for casting pipes without soldering.

MOULD STONE. One of the stones of a moulded jamb.

MOULDINGS. The ornamental contours or forms applied to the edges of the projecting or receding members of an order. Grecian mouldings are formed by some conic section, as a portion of an ellipse or hyperbola. The Roman mouldings are formed by arcs of circles, the same moulding having the same curvature throughout. The mouldings used in Pointed architecture are chiefly formed by portions of circles.

MULLION, MUNNION, or MONIAL. In Pointed architecture, the vertical post or bar which divides a window into two or more lights.

MULTIFOIL. An arch with such numerous foliations that it is thought unnecessary particularly to specify the number.

Municipal Architecture. The term applied to buildings erected for civil and municipal purposes, such as town halls, guild halls, &c. No particular style is inferred, as the buildings partook of the style prevailing at the time of their erection, and in the present day it depends on the decision of the persons for whom the edifice is designed.

Muniment Room. A strong, properly fire-proof, apartment in public or private buildings, for the keeping and preservation of evidences, charters, seals, &c., called muniments.

Munnion. See Mullion.

Muntin. See Montant.

Mural. (Lat.) Belonging to a wall. Thus, an upright monumental slab attached to a wall is called a *mural monument*; sometimes a *mural slab or tablet*; an arch inserted into or attached to a wall is called a *mural arch*; and columns placed within or against a wall are called *mural columns*.

Museum. (Gr. Μουσεῖον.) A museum is a building destined to the reception of natural, literary, or scientific curiosities, and for that of the works of learned men and artists. The term was first applied to that part of the palace at Alexandria appropriated solely to the purpose of affording an asylum for learned men; it contained buildings and groves of considerable magnificence, and a temple wherein was a golden coffin containing the body of Alexander. Men of learning were here lodged and accommodated with large halls for literary conversations, and porticoes and shady walks, where, supplied with every necessary, they devoted themselves entirely to study. The establishment is supposed to have been founded by Ptolemy Philadelphus, who here placed his library. It was divided into colleges or companies of professors of the several sciences, and to each of such professors was allotted a suitable revenue.

Museums, in the modern sense of the word, began to be established about the sixteenth century, when collections were formed by most of the learned men who studied natural history. On a small scale, they are becoming more common in the principal towns of this country. Where economy requires it, and the collection in each department be not too large, the whole may be properly and conveniently comprised within one building. In respect of security against fire, and quietness of the situation, the same precautions will be necessary as have been indicated for libraries, and must always be observed.

In the composition of museums, decoration must not be exuberant. It must be kept in the interior so far subordinate as not to interfere with the objects to be exhibited, which are the principal features of the place. With this caution we do not preclude the requisite degree of richness which the architecture itself requires. Great skill is necessary in introducing the light properly on the objects, inasmuch as the mode of properly lighting up objects of Natural History is very different indeed from that which is required for Pictures, and this, again, from what Sculpture requires. Specimens illustrating Natural History, Sculpture, Vases, and the like, should have high lights. Algarotti states that the museum which Rubens built for himself at Antwerp was circular, with a single light in the roof. The museum at Scarborough, designed by Mr. R. H. Sharp, is 32 feet in diameter inside, with a skylight of 9 feet. It has also seven windows round the lower portion of the room. There are subjects, nevertheless, in all these classes (in mineralogy, for example), for which strong side lights are essential to an advantageous exhibition of them. In such cases small recesses may be practised for the purpose. At the Hôtel des Monnaies, at Paris, the presses which contain the collection of Mineralogy form a circle which encloses a small lecture theatre, and thus become doubly serviceable. The student is thus made aware how room is to be gained when the area of a site is restricted. The collection of Sculpture is not so well lighted as are the models and other objects, Paintings excepted, in the Vieux Louvre, which are exhibited to perfection.

Where the same museum is to contain several classes of objects, the suites of rooms for the different departments should be accessible from some central one common to all; this may be circular or polygonal, as may best suit the arrangement and means; and, if possible from the site, the building should not consist of more than one story above the ground; on no account of more than two.

For the objects it contains we question whether the British Museum is surpassed, as a whole, in Europe; and those of the Vatican, of the Uffizj at Florence, of Portici, and of Paris, are none of them of sufficient architectural importance to detain the reader by description; neither would they, if so described, be useful to the student as models. At Munich the Glyptotheca for sculpture, and the Pinacotheca for pictures, by the Baron von Klenze, are in some respects well suited to the exhibition of the objects deposited in them, better, indeed, than is the museum at Berlin. As specimens of architecture they have been highly praised and as severely censured.

Sir John Soane's Museum, in Lincoln's Inn Fields, should be visited by any amateur contemplating the formation of a collection of works of art, to understand how much may be got into a small space, with well-lighted, warmed, and ventilated apartments.

The Museum of Economic Geology, in Jermyn Street, was designed 1837–48, by the late Sir James Pennethorne. It is well adapted for the special purpose. The hall or museum is 95 feet long, 55 feet wide, and 32 feet high to the springing of the iron roof, and 42 feet 9 inches to its crown. It is also a good specimen of well-selected Anston stone, and cost about 30,000*l.* The Fitzwilliam Museum, at Cambridge, was commenced in 1837 by George Basevi, and partially completed after his death in 1845 by C. R. Cockerell, R.A.; but it has since received several additions and alterations for the increased collections. The South Kensington Museum, as it is called, combining works of art and manufacture of modern date, has many portions to be highly commended. The Art Museums at Dublin, Edinburgh, in the castle at Nottingham, Manchester, and numerous other towns, afford examples for the future designer of such useful edifices for general purposes. The Natural History Museum at South Kensington, designed 1873–81 by Mr. Alfred Waterhouse, R.A., affords one of the latest examples of a building for a special purpose. It is probably the largest modern building in which terra-cotta has been exclusively used for external and internal surfaces, including architectural and decorative features, except ceilings and floors. It is 670 feet long and 290 feet deep.

The public museum and library erected at Hâvre, by M. L. Fortuné Brunet Debaines, about 1848, is exceedingly meritorious. It consists of a central hall for sculpture; on either side, and separated from it by an open arcade, by means of which the hall is lighted, is a gallery and museum, the floor of which is six or eight feet above the floor of the hall, so as to afford rooms for attendants, &c., beneath. Access to these galleries is had from the hall by a flight of steps on each side of the entrance in front. A long flight of steps from the centre of the back of the hall, with other flights right and left, conduct to a picture gallery over the hall, and to a library, containing 20,000 volumes, over the side galleries. It is a square of about 100 feet, not including the principal staircase. The building, without the fittings, cost about 40,000*l.* It is of stone.

Mushrebeeyeh. The Arabic term for a projecting balcony enclosed with lattice work, in which the occupiers of a house can sit without being seen from the street and enjoy the air.

Musjid. The Arabic for a mosque; the *jumma musjid* is the chief mosque of a city.

Mutilated Cornice and Pediment. One that is broken or discontinued. Such works were much used during the worst period of the Renaissance, and may still be seen occasionally introduced in modern buildings

Mutilation. (Lat.) The defacing or cutting away of any regular body. The word is applied to statues and buildings where any part is wanting.

Mutule. (Lat.) A projecting ornament of the Doric cornice, which occupies the place of the modillion in the other orders, and is supposed to represent the ends of rafters. The mutule has always been assumed as an imitation of the end of a wooden rafter; hence, say the advocates for a timber type, they are properly represented with a declination towards the front of the coronas.

N

Nail. (Sax. Nægel.) A small metal spike for fastening one piece of timber to another. The sorts of nails are very numerous. Those of most common use in building are known by the names of *ten-penny*, *twenty-penny*, and *two-shilling nails*. *Rose nails* are drawn square in the shank. *Brads* are long and slender nails without heads, used for thin deal work to avoid splitting. *Tacks*, the smallest sort of which serve to fasten linen or paper to wood; the *middling* for medium work; the *larger size* are much used by upholsterers. *Cut nails*, or nails cut by machinery instead of being wrought by hand as formerly, are now much used, especially for securing flooring boards to the timbers. See Adhesion.

Nail-head Moulding. One used in Norman buildings, and so called from being formed by a series of projections resembling the heads of nails or square knobs.

Naked. A term applied either to a column or wall to denote the face or plain surface from which the projections rise.

Naked Flooring. The assemblage of timbers for the floor of a building, whereof there are three sorts, viz., single flooring, double flooring, and double-framed flooring.

Naked of a Wall. The remote face whence the projections take their rise. It is generally a plain surface, and when the plan is circular the naked is the surface of a cylinder with its axis perpendicular to the horizon.

Naos. (Gr.) See Cell.

Narthex. An inclosed space in the ancient basilica when used as a Christian church; and also of an ante-temple or vestibule outside the church; it is thus used as synonymous with *porch* and *portico*. Some modern churches have a narthex with a lean-to roof, so as to form a kind of large porch the whole width of the building, or of the nave only.

Natural Bed of a Stone. The surface from which the laminæ were separated. In all masonry it is important to its duration that the laminæ should be placed perpendicular to the face of the work, and parallel to the horizon, inasmuch as the connecting substance of these laminæ is more friable than the laminæ themselves, and therefore apt to scale off in large flakes, and thus induce a rapid decay of the work.

Naumachia. (Gr. from Ναυς, a ship, and Μαχη, a battle.) In ancient architecture, a place for the show of mock sea engagements, little different from the circus and amphitheatre, since this species of exhibition was often displayed in those buildings. One was erected at Milan under the orders of Napoleon I.

Nave. (Gr. Ναος.) The body of a church reaching from the rail or partition of the choir to the principal entrance. See Church. By far the most important feature of Romanesque architecture is the greater elevation obtained for the interior of churches beyond the mere walls of previous times. This resulted in the triple range of Pier arch, dividing the nave from the aisles, as 1 in *fig.* 1417; the Triforium, containing sometimes a gallery over the aisles, as 2; and the Clerestory, or row of windows admitting light to the nave, as 3. The string courses are unbroken, and give the appearance of the building being divided into layers or stages; the arches also do not harmonise, and the whole presents the characteristics of the horizontality of ancient types. The first stage of transition to the verticality of Pointed architecture

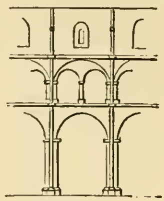

Fig. 1418. Norman.

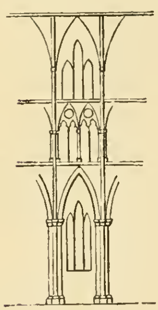

Fig. 1419.

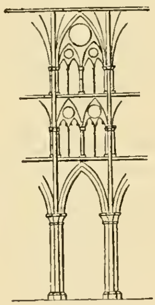

Fig. 1420.

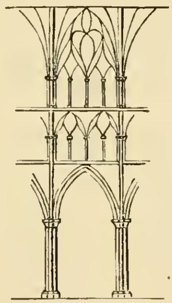

Fig. 1421.

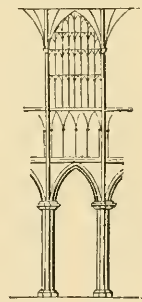

Fig. 1422.

was the use of shafts of small diameter running up in front of the piers and dividing the

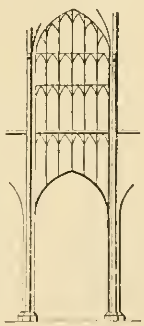

Fig. 1426.

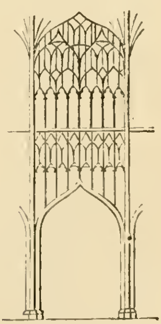

Fig. 1427.

triforium and clerestory into compartments, as in *fig.* 1418. The style advanced, as is shown in *fig.* 1419, being an example of the treatment of a bay of a nave or choir in the Early English or Lancet period; *fig.* 1420 in that of the Geometrical Decorated; *fig.* 1421 in that of the Flowing or Late Decorated; and *fig.* 1422 in that of the earlier part of the Rectilinear or Perpendicular period. In the later portion may be noticed the flattening of the arches, the four-centred arch being that most frequently used. The ogee arch (*fig.* 1427) was also much used at the same period. The above representations (*figs.* 1424 to 1427) of a bay of a nave or choir, exhibit the additions of a Perpendicular clerestory on a lower portion of earlier character; and the extinction of the triforium as a gallery, it being transformed into a wall decorated with panels. The priory church at Bath has not a triforium, but a lofty clerestory, like *fig.* 1426; while the choir at Bristol has neither triforium nor clerestory.

Nebule Moulding. (Lat. Nebula.) An ornament in Norman architecture, whose edge forms an undulating or wavy line, and introduced in corbel tables and archivolts. *Fig.* 1382.

Neck of a Capital. The space, in the Doric order, between the astragal on the shaft and the annulet of the capital. Some of the Grecian Ionic capitals are with necks below them, as in the examples of Minerva Polias and Erechtheus, at Athens. But the Ionic order has rarely a neck to the capital.

Needle. A horizontal piece of timber serving as a temporary support to some superincumbent weight, as a pier of brickwork, and resting upon posts or *shores*, while the lower part of a wall, pier, or building is being underpinned or repaired.

Nervures. A name given by French architects to the ribs bounding the sides of a groined compartment of a vaulted roof, as distinguished from the ribs which diagonally cross the compartment.

Net Measure. That in which no allowance is made for finishing, and in the work of artificers, when no allowance is made for the waste of materials.

Neutral Axis. That plane in a beam in which theoretically the tensile and compressive forces terminate, and in which the stress is therefore nothing.

Newel. The upright cylinder or pillar, round which, in a winding staircase, the steps turn, and are supported from the bottom to the top. In stairs, geometrical for instance, where the steps are *pinned* into the wall, and there is no central pillar, the staircase is said to have an *open newel*.

Niche. (Fr. probably from Νεοσσια, a nest.) A cavity or hollow place in the thickness of a wall for the reception of a statue, vase, &c.

Nidged Ashlar. A species of ashlar used in Aberdeen. It is brought to the square by means of a cavil or hammer with a sharp point, which reduces the roughness of the stone to a degree of smoothness according to the time employed. When stone is so hard as to resist the chisel and mallet, the method described is the only way in which it can be dressed.

Nog. The same as a Wood Brick.

Nogging. A species of brickwork carried up in panels between quarters or studs, and in which manner partitions called "brick-nog partitions" are made.

Nogging-piece. A horizontal board laid in brick-nogging, and nailed to the quarters for strengthening the brickwork. They are disposed at equal altitudes in the brickwork.

Nonagon. (Gr.) A geometrical figure having nine sides and nine angles.

Normal Line. In geometry, one which stands at right angles to another line.

Norman Architecture. This term comprises the architecture of the Normans as seen in Sicily and adjoining countries; and is applied to the round arch style which was carried out chiefly in Normandy, and thence taken over into England soon after Edward the Confessor's time, and more prominently in the reign of William I. It is a variation of Romanesque architecture. See *figs.* 1417 and 1418.

Nosing of a Step. The projecting part of the tread-board or cover which stands before the riser. The nosing is generally rounded, so as to have a semicircular section; and in the better sort of staircases a fillet and hollow is placed under the nosing.

Notation. In the early periods of the Roman notation, *four* was written IIII., this has been changed into IV.; *nine* was written VIIII., now IX.; *forty* was written XXXX., now XL. *Five hundred* was originally written Iↄ., now D.; a *thousand* CIↄ., now M. The number Iↄ = 500, is increased in value *ten* times for every ↄ annexed. Thus Iↄↄ = 5,000; Iↄↄↄ = 50,000, and so on. The number CIↄ = 1,000 is increased in value *ten* times for every C and ↄ prefixed or annexed to it. Thus CCIↄↄ = 10,000, &c. This notation is not now in use, but will be found in works of the 17th century.

Notation, Architectural. The method adopted of placing signs to figures when marking dimensions on drawings. Thus, in lieu of writing *feet*, *inches*, and parts of an inch, certain dashes are used, ′ for feet, ″ for inches, and ‴ for parts; or ° for feet, ′ for inches, and ″ for parts. There is no settled method for using these marks.

Notch-board. A board which is grooved or notched for the reception and support of the ends of steps in a staircase.

Notching. A hollow cut from one of the faces of a piece of timber, generally made rectangular in section.

Nucleus. (Lat.) In ancient architecture, the internal part of a floor, which consisted of a strong cement, over which the pavement was laid with mortar.

Nugger, or Nagar. The Sanscrit name for a city; as Ahmednugger, properly Ahmadnagar, the city of Ahmad.

Nuraghe. The name of a species of very ancient structure in Sardinia, resembling and used for a similar purpose as the cromlechs or dolmens. They are supposed by some writers to be the work of the ancient Phœnicians.

Nymphæum. (Gr.) A name used by the ancients to denote a picturesque grotto in a rocky or woody place, supposed to be dedicated to, and frequented by, the nymphs. The Romans often made artificial nymphæ in their gardens. In Attica, the remains of a nymphæum are still to be seen decorated with inscriptions and bassi-rilievi, from the rude workmanship of which it may be presumed that the grotto is of very ancient date.

O

Oak. (Sax. Ac, Æc.) A forest tree, whose timber is, from its strength, hardness, and durability, the most useful of all in building.

Obelisk. (Probably from ὀβελὸς, a spit, brooch, or spindle, or a long javelin.) A lofty pillar of a rectangular form, diminishing towards the top, those of Egypt often having inscriptions and hieroglyphics. The upper part finishes generally with a low pyramid, called a *pyramidion.* The proportion of the thickness to the height is nearly the same in all obelisks; that is, between one ninth and one tenth, and their thickness at top is never less than half, nor greater than three fourths, of that at bottom. The following table exhibits a list of the principal obelisks; and with the dimensions must be taken with some reservation. *Builder*, 1877, xxxv., 1076, gives a plate of eleven.

Situation, &c., of the Obelisk.	Height.	Thickness. At top.	Thickness. Below.

Oblique Angle. One that is greater or less than a right angle.

Oblique-angled Triangle. One that has no right angle.

Oblique Arches. Such as cross an opening obliquely to the front face of them.

Oblique Line. One which stands, in respect to another, at a greater angle than ninety degrees.

Oblong. A rectangle of unequal dimensions.

Observatory. (Fr.) A building for the reception of instruments and other matters for observing the heavenly bodies. The observatory at Paris, from the designs of Perrault, is a noble building, but, we believe, is universally admitted to be very ill suited to the purposes for which it was built. A *regular* observatory is one where instruments are fixed in the meridian, whereby, with the assistance of astronomical clocks, the right

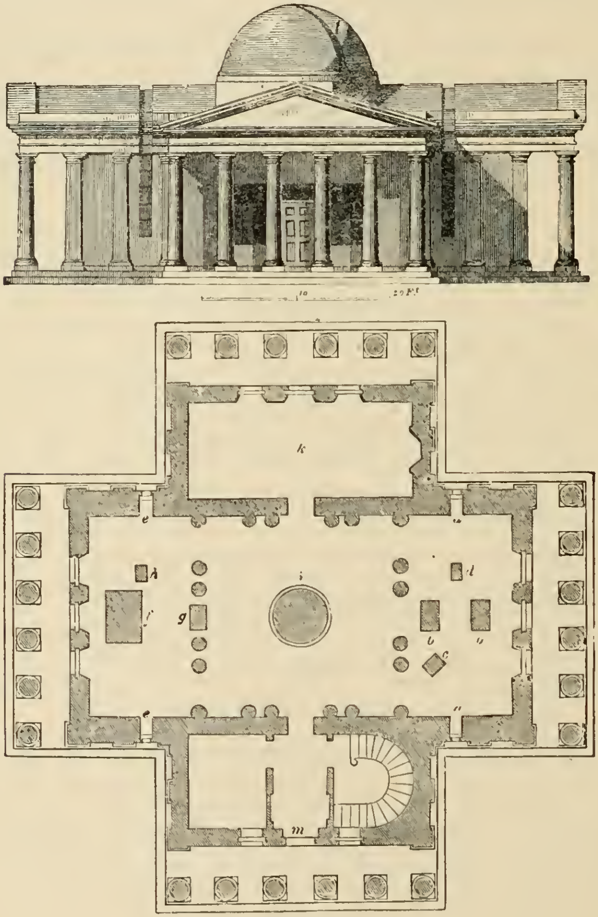

Fig. 1428.

ascensions and declinations of the heavenly bodies are determined, and thus motion, time, and space are converted into measures of each other. On the observations and determinations made in such establishments they are therefore, to maritime states, of vital importance, and ought to be liberally endowed by their governments. As the subject will be better understood by a plan, we subjoin, in *fig.* 1428, a plan and elevation of the observatory at Edinburgh. The general form of the plan, as will be therein seen, is a Greek cross, 62 feet long, terminated at its feet by projecting hexastyle porticoes, which are 28 feet in front, and surmounted by pediments. The intersecting limbs of the cross at their intersection are covered by a dome 13 feet diameter, which traverses round horizontally, and under its centre a pier of solid masonry is brought up of a conical form 6 feet in diameter at the base, and 19 feet high. This is intended either for an astronomical circle or for an equatorial instrument for observations of the heavenly bodies made out of the meridian. In the eastern foot of the cross (*b b*) are stone piers for the reception of the transit instrument; *c* is the stone pier to which the transit clock is attached; and *d* is a stone piece on which an artificial horizon may be placed, when observations are taken by reflection: this is covered by a floor board when not in use, being just under the level of the floor; *a a* are the slits or chases running through the walls and roof, but closeable by means of shutters when the observation is completed. On the western side (*e e*) are chases as in the transit room; *f* a large stone pier for the reception of a mural circle; *g* the clock pier; *h* the pier for an artificial horizon as before; *i* is the conical pier above mentioned, over which the moveable dome is placed, having an opening (*l*) in the elevation for the purpose of observation; *k* is the observer's room; and *m* the front entrance.

It is to be especially observed that the piers for the reception of the instruments must not be in any way connected with the walls of the building; they should stand on the firmest possible foundation, which, if at all doubtful, must be formed with concrete, and the piers should, if possible, be out of a single block of stone; but if that cannot be obtained, the beds must be kept extremely thin; partial settlement being ruinous to the nicety of the instruments as well as to the observer's business. The observation applies also to the clock piers, all vibration and settlement being injurious also to them. A dry situation should be chosen for the site, for, except in the computing rooms, no fire heat can be allowed; and it is important that the brass whereof the instruments are made should not be corroded by the action of moisture. In large public observatories there should be the readiest access from one part to another, and rooms for a library and computers independent of the chief astronomer's room. The Orwell Park observatory, as described by its architect, Mr. Macvicar Anderson, is published in the *Sessional papers* of the Royal Institute of British Architects, Nov. 16, 1874. The observatory at Warsaw by Pietro Aigner is said to be one of the finest in Europe; that at Armagh is very good. A descriptive account of public and private observatories in England is given in the *Pictorial Handbook of London*, 8vo., London, 1851, published by J. Weale.

Obtuse. (Lat.) Anything that is blunt.

Obtuse-angled Triangle. One which has an obtuse angle.

Obtuse Arch. See Drop Arch.

Obtuse Section of a Cone. Among the ancient geometricians a name given to the hyperbola.

Octagon. (Gr. 'Οκτω and Γωνια, angle.) A figure having eight equal sides and eight equal angles.

Octahedron. (Gr.) One of the five regular bodies bounded by eight equal and equilateral triangles.

Octastyle. (Gr. 'Οκτω and Στυλος.) That species of temple or building having eight columns in front. See Colonnade.

Odeum. (Gr.) Among the Greeks, a species of theatre wherein the poets and musicians rehearsed their compositions previous to the public production of them.

Oecus. See Hall.

Offices. The apartments wherein the domestics discharge the several duties attached to the service of a house; as kitchens, pantries, brewhouses, and the like.

Offset. The horizontal projection from the faces of the different parts of a wall where it increases in thickness.

Ogee. A moulding, the same as the Cyma reversa.

Ogee Arch. A pointed arch, the sides of which are each formed with a double curve. (See *fig.* 1429.) It frequently appears in the Decorated period of Gothic architecture, and occasionally in that of the Perpendicular; chiefly in small ornamental work, as shrines and canopies; its inflected curves weaken it too much for supporting great weights. In some late work, this arch is also made to curve forward.

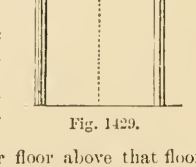

Fig. 1429.

Ogive. A term used by French architects to denote the Gothic arch, with its ribs and cross springers, &c. The word is used by them to denote the pointed arch.

Oillets, or Oyletts. Small openings or *eyelet holes* seen in mediæval military buildings, through which missiles could be discharged without exposing the soldier.

One pair of Stairs. An expression signifying the first story or floor above that floor level with, or raised only by a few steps, above the ground, which latter is thence called the ground floor.

Onyx Marble. See Marble.

Opæ. (Gr. Οπη.) The beds of the beams of a floor or roof as in a Grecian temple, the space between which are called the Metopæ.

Open Newel Stairs. See Newel.

Opening. (Sax.) That part of the walls of a building which is unfilled, for admitting light, ingress, egress, &c. See Aperture.

Opisthodomus. (Gr.) The same as the Roman *posticum*, being the enclosed space in the rear of the cell of a temple.

Opposite Angles. Those formed by two straight lines crossing each other, but not two adjacent angles.

Opposite Cones. Those to which a straight line can be applied on the surfaces of both cones.

Opposite Sections. The sections made by a plane cutting two opposite cones.

Optic Pyramid. In perspective, that formed by the optic rays to every point of an object.

Optic Rays. Those which diverge from the eye to every part of an original object.

Orangery. A gallery or building in a garden or parterre opposite to the south. See Greenhouse. The most magnificent orangery in Europe is that of Versailles, which is of the Tuscan order, and with wings.

Oratory. (Lat.) A small apartment in a house, furnished with a small altar, crucifix, &c., for private devotion. The ancient oratories were small chapels attached to monasteries, in which the monks offered up their prayers. Towards the sixth and seventh centuries the oratory was a small church, built frequently in a burial-place, without either baptistery or attached priest, the service being performed by one occasionally sent for that purpose by the bishop.

Orb. (Lat. Orbis.) A knot or foliage of flowers placed at the intersection of the ribs of a Gothic ceiling or vault to conceal the mitres of the ribs. See Boss.

Orchestra. (Gr. Ορχεομαι.) In ancient architecture, the place in the theatre where the chorus danced. In modern theatres it is the enclosed part of a theatre, or of a music room, wherein the instrumental and vocal performers are seated.

Order. (Lat.) In Grecian, Roman, and Italian architecture, an assemblage of parts, consisting of a base, shaft, capital, architrave, frieze, and cornice, whose several services requiring some distinction in strength, have been contrived in five several species—Tuscan, Doric, Ionic, Corinthian, and Composite; each of these has its ornaments, as well as its general fabric, proportioned to its strength and use. These are the five orders of architecture, the proper understanding and application of which constitute the foundation of all excellence in the art.

Ordinate. In geometry and conics, a line drawn from any point of the circumference of an ellipsis or other conic section perpendicular to, and across the axis, to the other side.

Ordonnance. (Fr. from the Lat.) The perfect arrangement and composition of any architectural work. It applies to no particular class, but the term is general to all species in which there has existed anything like conventional law.

Organical Description of a Curve. The method of describing one upon a plane by continued motion.

Oriel, or Oriel Window. (Etym. uncertain.) A large bay or recessed window in a hall, chapel, or other apartment. It ordinarily projects from the outer face of the wall either in a semi-octagonal or diagonal plan, and is of varied kinds and sizes. In large halls its usual height is from the floor to the ceiling internally, and it rises from the ground to the parapet on the outside; sometimes it consists only of one smaller window supported by corbels, or by masonry projecting gradually from the wall to the sill of the window. A bow window projects circularly, and was formerly called a compass or embowed window; whilst the projection of the oriel is made up of angles and straight lines forming generally the half of a hexagon, octagon, or decagon, and was better known by the name of *bay window*, *shot window*, or *outcast window*, a distinction, however, not generally observed.

Orientation. (Lat. Oriens.) The deviation of a church from due east, it being supposed that the chancel points to that part of the east in which the sun rises on the day of the patron saint. This point, however, has not been fully investigated.

Original Line, Plane, or Point. In perspective, a line, plane, or point referred to the object itself.

Orle. (Ital.) A fillet under the ovolo or quarter round of a capital. When the fillet is at the top or bottom of the shaft of a column it is called a cincture. Palladio uses the word orle to express the plinth of the bases of the columns and pedestal.

Ornament. The smaller and detailed part of the work, not essential to it, but serving to enrich it; it is generally founded upon some imitation of the works of nature.

Ornamented English Architecture. That phase of mediæval architecture in England which is generally called the Decorated period; it was comprised chiefly in the reigns of the three first Edwards.

Orthography. (Gr. Ορθος, right, and Γραφω, I describe.) The elevation of a building showing all the parts in their proper proportions; it is either external or internal. The first is the representation of the external part or front of a building showing the face of the principal wall, with its apertures, roof of the building, projections, decorations, and all other matters as seen by the eye of the spectator, placed at an infinite distance from it. The second, commonly called the *section* of a building, shows it as if the external wall were removed and separated from it.

In geometry, orthography is the art of representing the plan or side of any object, and of the elevation also of the principal parts: the art is so denominated from its etymology, because it determines things by perpendicular *right lines* falling on the geometrical plan, or because all the horizontal lines are straight and parallel, and not, as in perspective, oblique.

Orthostyle. A columnar arrangement, the columns being placed in a straight line.

Osculating Circle. That, the radius of whose curve, at any particular point of another curve, is of the same length as that of the curve in question at that particular point. Hence it is the kissing circle, and that so closely that there is no difference in the curvature of the two curves at that particular point.

Oundy, or Undy Moulding. A moulding with a wavelike outline. See *fig.* 1383.

Out and In Bond. A Scotch term for alternate header and stretcher in quoins, and in window and door jambs.

Outer Doors. Those common to both the exterior and interior sides of a building.

Outer Plate. See Inner Plate.

Outline. The line which bounds the contour of any object.

Out of Winding. A term used by artificers to signify that the surface of a body is that of a perfect plane; thus when two straight edges in every direction are in the same plane they are said to be out of winding.

Out to Out. An expression used of any dimension when measured to the utmost bounds of a body or figure.

Outward Angle. The external or salient angle of any figure.

Ova. (Lat.) Ornaments in the shape of an egg, into which the echinus or ovolo is often carved.

Oval. A geometrical figure, whose boundary is a curve line returning into itself; it includes the ellipsis or mathematical oval, and all figures resembling it, though with different properties.

Overhang. See Batter.

Overistory. The *clear-* or *clere-story* of a building.

Ovolo. (Ital.) A convex moulding whose lower extremity recedes from a perpendicular line drawn from the upper extremity.

Oxidation. The corrosion of iron by the atmosphere. Paint is one of the best preservatives, renewed as necessary. Lime-whiting is another; and lately it has been urged to pickle the wrought iron in dilute sulphuric acid, so as to remove the scaly oxide before painting.

P

Pace A portion of a floor slightly raised above the general level: a *dais*. It is also applied to a landing in a staircase; its prefix, *half* or *quarter*, determines the size of it. See also Measure.

Packing. Small stones imbedded in mortar, used to fill up the interstices between the larger stones in rubble work.

Paddle. A small sluice, similar to that whereby water is let into or out of a canal lock.

Pagoda. A name given to the tall pyramidal structure of several stones, forming one of the peculiar features of Chinese architecture. It is said to be derived from the Hindoo word *dagoba*.

Painted Glass. Glass painted with ornaments or pictorial representations, and then put into a kiln and the paint burnt in. See Stained Glass, with which it is sometimes used in painted windows.

Painter. An artificer who combines the knowledge of colours and the application of them to decorative purposes.

Painter's Work. The work of painting, with different coats of oil colour and turpentine, the parts of a building usually so treated.

Pair. As one-pair, two-pair, &c., story. See Floor. and One-pair.

Palace. (Lat. Palatium.) In this country, a name given to the dwelling of a king or queen, a prince, and a bishop. On the Continent, it is a term in more general use, almost all large dwellings of the higher nobility and government offices being so denominated. A palace is properly an edifice destined not only for the residence of the sovereign or prince, but for the reception also of persons who have the privilege of public or private audience. It being impossible for the whole of the parties to be present together, there must be, besides the apartments which are occupied by the sovereign and his or her family, ample room and accommodation for the attendants in waiting of every degree, and the consequent accessories. A palace should be disposed with porticoes, vestibules, galleries, halls of waiting suited to every season, wherein those to be admitted may wait with convenience and comfort till their turn of admission arrives. It is evident that, from the nature of such an edifice, much magnificence should be displayed in it. The site on which a palace is to be seated must be open and free in every respect, so that a large expanse of gardens should be attached to it for the use of the public as well as the sovereign, in which respect the palaces of the Tuileries and Versailles are unparalleled. All should have a royal bearing, parsimony being inadmissible in works of this nature.

The palaces of the Escurial, Versailles, and the Tuileries are, though extremely spacious and imposing, but ill-disposed and imperfect examples of a palace. Perhaps the most perfect in Europe is that at Caserta, near Naples, commenced in 1752, which is described by Milizia as follows :—" The plan of this palace is a vast rectangle, 731 feet long from east to west, 569 from north to south, and 106 feet in height. The interior is divided into four courts, 162 feet by 244. The depth of building that surrounds these courts, in which are the apartments, passages, &c., is 80 feet, including the thickness of the walls, which are in some instances 15 feet. The two principal façades have five stories besides that below the ground, and each contains thirty-seven windows. There are three entrances, one in the centre, and the others at equal distances between it and the extreme angles, where, as well as in the centre, the building breaks forward a little, is carried up to the height of 60 feet, and formed into pavilions by columns 42 feet high. Thus the whole height of the building is 102 feet from the foundation to the top of the pavilion, at the angles 162 feet, and in the centre 190 feet. The basement, which is rusticated, comprises the lower offices, the ground floor, and its mezzanine. Above is placed an Ionic order of columns and pilasters, which contains the two ranges of state apartments; the lower windows are ornamented with pediments; in the frieze are introduced the windows of the upper mezzanine. The centre entrance leads to a superb portico, which traverses the building from north to south, and is sufficiently spacious to allow carriages to pass under from either façade to the centre of the building, where is a large octangular vestibule, which unites the arms of the cross produced by dividing the plan into four courts: two sides of the octagon are open to the portico, four to the four courts, one to the grand staircase, and the eighth is occupied by a statue of Hercules crowned by Virtue.

" The grand staircase, which is on the right, is lighted by twenty-four windows, and decorated in a beautiful style. At the first landing it is divided into two flights; the hundred steps of which it is composed are 18 feet long, and each of one piece of marble; it is lighted also from the top by a double skylight. The upper vestibule is also octangular, and surrounded by twenty-four columns of yellow marble 18 feet high. Four doors lead from thence to the apartments: the one opposite the landing to the chapel, that to the right to the apartments of the king, which comprehend the south-west angle of the building, overlooking the sea and the plains of Naples and Capua. To the left are the apartments of the queen, occupying the north-west angle, the remainder of these floors being occupied by the princes. The chambers throughout are vaulted, and admirably arranged; the apartments of the king and queen are separated by a gallery 138 feet long, 42 wide, and 52 high. The palace contains a small elegant theatre, on a circular plan, divided into nine compartments, with four tiers of boxes. The chapel is rectangular in its plan, with the end terminated semicircularly, and decorated with isolated Corinthian columns on pedestals, with an entablature, in which the cornice is not omitted. The marbles and sculptures throughout are of the richest kind; the apartments generally well arranged and distributed, of magnificent dimensions, and of various forms. The whole is a rare assemblage of vastness, regularity, symmetry, richness, ease, and elegance. The multiplicity of windows may certainly be a little at variance with propriety.

" But the most wonderful part of this grand work has not as yet been described. There are ranges of aqueducts of a great height, and of sufficient length to unite the two Tifati mountains near the Furche Caudine. The waters on the mountain are collected into a canal for the purpose of supplying these acqueducts, and conducted to various lakes and fountains of every description. To the embellishments," adds Milizia, " of this royal residence are added a convenience and solidity that throw into shade all that has been done before or since." The plans, &c. of this palace are given in Durand's *Parallèle des Edifices*, and also in the work by Vanvitelli, its architect.

The palace at Whitehall projected by Inigo Jones, and published in Kent's *Designs* (see *fig.* 207, *supra*), consisted of six courts, with greater beauties of composition; and had the edifice, of which the " banqueting-house " is not the hundredth part, been carried to completion, it would have eclipsed the one at Caserta, which contains the leading, and, indeed, governing principles upon which the palace for a sovereign should be constructed.

Many useful remarks on this subject will be obtained in perusing Brewer's *Descriptive and Historical Account of the various Palaces and Public Buildings, English and Foreign*, 4to., London, 1821. We regret that in this country no model of a palace can be offered for the student. Windsor Castle, with all its beauties, which consist, however, more in site and scenery than in the disposition of a palace, is not to be commended; St. James's Palace is said to be planned with many advantages for holding courts, but the exterior is far from what a palace should be.

Palæstra. (Gr. Παλαιω, I wrestle.) A part of the Grecian gymnasium, particularly appropriated to wrestling and other gymnastic exercises; it was sometimes used to denote the whole building. It contained baths which were open for the use of the public. According to the authority of Vitruvius no palæstra existed in Rome.

Pale. A small pointed stake or piece of wood, used for making landmarks, and enclosures, placed vertically.

Pale Fencing, or Pale Fence. That constructed with pales.

Palisade. A fence of pales or stakes driven into the ground, set up for an enclosure, or for the protection of property.

Palladian School of Architecture. A manner of designing, taking its name from its introducer, the celebrated architect Andrea Palladio. It is a sort of medium between that vigorous severity which some exclusive minds abuse in the endeavour to imitate the Classic style, and the licentious anarchy of those who refuse to recognise rules, which rules allow of exceptions. In the conception and execution of the edifices by Palladio there is always a clear intuition, a simple method, a sufficiently perceptible accord between need and pleasure, and such harmony in this accord that it would be difficult to say which gave the law to the other. His manner offers to all countries a model easy of imitation. The talent of the author of it is doubtless the principle whence this facility emanates, but this facility of adapting itself to everything and being adopted by all, is what distinguishes his talent and generalises its influence. In fact, it may be said with truth, that Palladio has become the most universally followed master in all Europe, and in some sort the chief of the modern school in civil buildings. This school has been reproduced in England with the greatest success, as in the case of Inigo Jones and others. Quatremère de Quincy, *Dict. Arch.* See also Gwilt's criticism in Book I.

Palm. A measure of length. See Measure (Ancient), and Foot.

Pampre. (Fr.) An ornament composed of vine leaves and bunches of grapes wherewith the hollow of the circumvolutions of twisted columns are sometimes decorated.

Pan. A square of framing in half-timbered houses, the uprights being filled in with work. It is called post and pan, or post and petrail work, in the north of England.

Pancarpi. (Gr.) Garlands and festoons of fruit, flowers, and leaves, for the ornament of altars, doors, vestibules, &c.

Pane. A term applied to the side of any object, as a square, octagon, &c., which would be said to have four, eight, &c., sides.

Panel. (From the low Latin panellum.) A board whose edges are inserted into the groove of a thicker surrounding frame, as in a door.

A panel in masonry is one of the faces of a hewn stone.

Panier. (Fr.) An upright corbel fixed against a pilaster and under a beam to break the angle so formed.

Pantameter. A graduated bevel.

Pantile. The curved tile used for roofing.

Pantograph. An instrument for copying, diminishing, or enlarging drawings.

Paper. A substance made by the maceration of linen rags in water and spreading them by hand or machinery into thin sheets; on this the drawings of the architect are usually made; its usual sizes, as made by Whatman, being:—

Demy - - - - - - - - -	20 inches by	15 inches.
Medium - - - - - - - - -	$22\frac{1}{2}$ —	$17\frac{1}{2}$ —
Royal - - - - - - - - -	24 —	19 —
Super-royal - - - - - - -	27 —	19 —
Imperial - - - - - - - -	30 —	22 —
Colombier - - - - - - -	34 —	23 —
Atlas - - - - - - - -	33 —	27 —
Double Elephant - - - - - -	40 —	27 —
Antiquarian - - - - - - -	53 —	31 —
Extra Antiquarian - - - - - -	56 —	38 —
Emperor - - - - - - - -	68 —	48 —

Imperial 90 and 140 lbs.

"Cartridge" is a stronger sort for working drawings. For rough sketching, a thin paper, the "lining paper" of the paperhangers, is much used, and is obtained in a roll of twelve yards in length. Continuous cartoon paper is 3 ft. 4 in., 4 ft., and 5 ft. wide. Tinted papers can also be so obtained. For mapping or such work a strong continuous paper is made, and ready mounted on holland for extra strength. See Tracing Paper.

Paperhangings. The paper prepared, either plain or with a pattern printed upon it, for covering the walls of rooms. The varieties are very numerous. The better sort are still printed from wood-blocks, but the inferior kind are printed by machinery.

Papyrus Capital. A species of capital seen in some of the temples of Egypt. See *fig.* 59.

Parabola. (Gr. Παρα, through, and Βαλλω, I throw.) In geometry, a curved line formed by the common intersection of a conic surface, and a plane cutting it parallel to another plane touching the conic surface.

Parabolic Assymptote. In geometry, a line continually approaching the curve, but which, though infinitely produced, will never meet it.

Parabolic Curve. The curved boundary of a parabola, and terminating its area, except at the double ordinate.

Parabolic Spinal, or Helicoid. A curve arising from the supposition of the axis of the common parabola bent into the periphery of a circle, the ordinates being portions of the radii next the circumference.

Paraboloid. See Conoid.

Parallel. (Gr. Παραλληλος.) In geometry, a term applied to lines, surfaces, &c., that are in every part equidistant from each other.

Parallel Coping. See Coping.

Parallelogram. (Gr.) Any four-sided rectilineal figure, whose opposite sides are parallel.

Parallelopiped. In geometry, one of the regular bodies or solids comprehended under six faces, each parallel to its opposite face, and all the faces parallelograms.

Parameter. (Gr. Παρα, through, and Μετρω, I measure.) In conic sections a constant right line in each of the three sections, called also *latus rectum*.

Parapet. (Ital. Parapetto, breast high.) A small wall of any material for protection on the sides of bridges, quays, or high buildings.

Parascenium. Another name for the *postscenium* in the ancient theatre.

Parastatæ. See Antæ.

Parclose. The screen which separates chapels (especially at the east end of the aisles) from the body of the church. They are usually of wood, but are also sometimes of stone.

Parget. A name given to the rough plaster used for lining chimney flues, and formed of lime and cow's dung.

Parge Work; Pargetting. A particular sort of plaster work, having patterns and ornaments raised upon it or indented; much used in interior decorations, and often on the exterior of half-timber houses, during the Elizabethan period.

Parker's Cement, also called Roman Cement in 1796. It is manufactured principally from nodules found in the Isle of Sheppey and at Harwich, being *septaria* from the London clay. When burnt, it is ground into powder, and mixed with sand, and water being applied to it, it sets fast and very hard, and is impervious to water.

Parlour. (Fr.) A room for conversation, which in the old monasteries adjoined the buttery and pantry at the lower end of the hall. At the present day it is used to denote the room in a house where visitors are commonly received, and often serves as a dining-room.

Parados. (Gr.) The grand entrance of the scene of an ancient theatre that conducted on to the stage and orchestra.

Parpeyn. See Perpeyn-Wall.

Parquetry. Inlaid work, made of thin plates or veneers of hard coloured woods, and secured to a framing of deal, well-dried and seasoned, to form the flooring of an apartment. They are arranged in patterns. Of late years solid, and thick, parquetry has been introduced. The floor may be left plain, but is more frequently polished. There is also a thin substance, about $\frac{3}{8}$ths of an inch thick, which is secured to the old floor by a patent cement, or by brads. The old method of covering a floor by a carpet, which collects the dust and covers the furniture with it when swept, is now abandoned in many houses, and *parquetry* substituted, with rugs, or square carpets, or Indian matting, so as to be easily removable for cleansing. A "parquetry border" has also taken the place of the common, but still useful, stained and varnished border, around a square carpet. See Marquetry.

Parsonage House. A building, usually near the church, occupied by the incumbent of the living; in former times this sort of building was often embattled and fortified, and had various appendages, including sometimes a small chapel or oratory.

PARTING BEAD. The beaded slip inserted at the centre of the pulley style of a sash window, to keep the two sashes in their places when being raised or lowered.

PARTITION. (Lat.) A wall of stone, brick, or timber, dividing one room from another. When a partition has no support from below, it should not be suffered to bear on the floor with any considerable weight, and in such cases it should have a *truss* formed within it, in which case it is called a *trussed partition*. See TRUSS.

PARTY WALL. Such as is formed between buildings to separate them from each other and prevent the spreading of fire. Every wall used or built in order to be used as a separation of any building from any other building, with a view to the same being occupied by different persons. The regulations prescribed for them form a large portion of the Metropolitan Buildings Act, and of local Acts passed for similar purposes.

PARTY FENCE WALL. A wall separating the open ground in one occupation from that in another; each owner having a right up to the centre of such wall.

PARTY STRUCTURE. This term includes party walls, and also partitions, arches, floors, and other structures separating buildings, stories, or rooms which belong to different owners, or which are approached by distinct staircases or separate entrances from without.

PARVISE. A porch, portico, or large entrance to a church. It seems also to have signified a room over the church porch, where schools used to be held.

PARVISE TURRET. The small tower which encloses the staircase to the parvise.

PASSAGE. The avenue leading to the various divisions and apartments of a building. When there is only one series of rooms in breadth, the passage must run along one side of the building, and may be lighted by apertures through the exterior walls. If there be more than one room in breadth, it must run in the middle, and be lighted from above or at one or both ends.

PATERA. (Lat.) A vessel used in the Roman sacrifices, wherein the blood of the victims was received. It was generally shallow, flat, and circular. Its representation has been introduced as an ornament in friezes and fasciæ, accompanied with festoons of flowers or husks, and other accessories.

PATERNOSTERS. A species of ornament in the shape of beads, either round or oval, used in baguettes, astragals, &c.

PAVEMENT. (Lat. Pavimentum.) A path or road laid or beaten in with stones or other materials. According to the information of Isidorus, the first people who paved their streets with stones were the Carthaginians. Appius Claudius, the founder of the Appian Way, appears to have introduced the practice into Rome, after which the Roman roads were universally paved, remains of them having been found in every part of the empire.

In the interior of the Roman houses, the pavement was often laid upon timber framing; and the assemblages so constructed were called *contignata pavimenta*. The pavement called *coassatio* was made of oaken planks of the *quercus æsculus*, which was least liable to warp. The Roman pavements were also frequently of mosaic work, that is, of square pieces of terra cotta or stone, called tesseræ, in various patterns and figures, many of which remain in Britain to the present day.

The various sorts of paving are as follows:—1. *Pebble paving*, of stones collected from the sea-beach, mostly obtained from Guernsey or Jersey. This is very durable if well laid. The stones vary in size, but those from six to nine inches deep are the best, those of three inches in depth are called *bolders* or *bowlers*, and are used for paving courtyards and those places wherever heavy weights do not pass. 2. *Rag paving*: inferior to the last, and usually from the vicinity of Maidstone, in Kent, whence it bears the name of Kentish rag-stone. It is sometimes squared, and then used for paving coach tracks and footways. 3. *Purbeck pitchers*, which are squared stones, used in footways, brought from the island of Purbeck. They are useful in courtyards; the pieces running about five inches thick, and from six to ten inches square. 4. *Squared paving*, by some called *Scotch paving*, of a clear close stone, called *blue wynn*. This is now, however, quite out of use. 5. *Granite*, of the material which its name imports. 6. *Guernsey paving*, which, for street work, is the best in use. It is broken with iron hammers, and squared to any required dimensions, of a prismoidal figure, with a smaller base downwards. It is commonly bedded in small gravel. 7. *Purbeck paving*, used for footways, of which the blue sort is the best, is obtained in pretty large surfaces, of about two inches and a half thick. 8. *Yorkshire paving*: a very good material, and procurable of very large dimensions. 9. *Rygate*, or *fire-stone paving*, used for hearths, stoves, ovens, and other places subject to great heat, by which this stone, if kept dry, is not affected. 10. *Newcastle flags*, useful for the paving of offices. They run about one and a half to two inches thick, and about two feet square, and bear considerable resemblance to the Yorkshire. 11. *Portland paving* may be had from the island of Portland, of almost any required dimensions. The squares are sometimes ornamented by cutting away their angles, and inserting small black marble squares, set diagonally. 12. *Sweedland paving*: a black slate, dug in Leicestershire, useful for paving halls or for particoloured paving. 13. *Marble paving*, of as many sorts almost as there are species of marble. It is sometimes inlaid after the manner of mosaic work. 14. *Flat brick paving*, executed with bricks laid flat in sand, mortar, or grout, when liquid lime is poured into the joints. 15. *Brick-on-edge paving*, executed in the manner of the last, except that the bricks are laid on edge. 16. *Herring-bone paving*: bricks laid diagonally to each other. See Herring-bone Work. 17. *Bricks laid endwise* in sand, mortar, or grout. 18. *Paving bricks* are made especially for the purpose, and are better than stocks. 19. *Ten-inch tile paving.* 20. *Foot tile paving.* 21. *Clinker paving.* 22. *Diamond tile paving.* 23. *Coloured tiles*, and *tessellated or mosaic pavements*, now form a large trade.

The pavements of churches are often in patterns of several colours, of which, to show the great variety that may be obtained from a few colours, M. Truchet (*Mém. Acad. Fran.*) has proved that two square stones, divided diagonally into two colours, may be joined together chequerwise in sixty-four different ways.

Pavilion. (Ital. Padiglione.) A turret or small building, generally insulated and comprised under a single roof. The term is also applied to the projecting parts in the front of a building. They are usually higher than the rest of the building.

Pavilion Roof. A roof sloping or hipped equally on all sides.

Paving Slabs. Experiments made by George Rennie upon slabs 12 inches long, 2½ inches wide, and 1 inch thick, laid flat on bearings 10 inches apart, the weight being suspended from the middle of each, gave the following results:

		cwts.	qrs.	lbs.
I.	Green Moor and Yorkshire Blue Stone sustained - -	2	3	27
II.	Ditto ditto White Stone - - -	3	0	23
III.	Caithness (Scotch) Stone - - - - - - -	7	2	17
IV.	Valentia (Irish) Stone - - - - - - -	7	3	3
V.	Bangor Slate (Welsh) - - - - - - -	17	0	12

Buchanan tried specimens of stones, the weights being piled on :—

		Breaking Weight. lbs.
Hailes,	3 feet long, 9 inches broad, and 3 inches deep - -	794
Craigleith,	3 feet long, 9 inches broad, and 3 inches deep - -	1,148
Arbroath,	3 feet long, 9 inches broad, and 3 inches deep - -	1,848
Caithness (a very hard specimen.)	3 ,, 8¾ ,, 2¾ ,, - -	3,291

Pecky. Timber in which the first symptoms of decay appear. An American term.

Pedestal. (Compound, apparently, of Πους, a foot, and Στυλος, a column.) The lowest division in an order of columns, called also in Greek, *stylobate* and *stereobate.* It consists of three principal parts: the die, the cornice, and the base.

Pediment. The triangular crowning part of a portico, which terminates vertically the

Fig. 1430. Temple at Egina.

sloping parts of the roof. See Temple. It is sometimes placed over an opening as part of the decoration of the dressings; it should never be used under cover. In Gothic architecture this triangular piece is much higher in proportion to its width, and is denominated a Gable. The illustration (*fig.* 1430) exhibits the centre portion of the sculpture in the pediment of the temple at Egina, which is among the earliest examples of Grecian art. See *fig.* 1457, which shows the elevation of the temple.

'EDIMENT ARCH. See MITRE ARCH.

ELASGIC BUILDING. Walls of cities and houses formed of huge stones scarcely more than piled together, without the connecting medium of mortar or cement. It is also called Cyclopean building.

ELLET MOULDING. A flat band on which are circular flat disks forming an ornament, used in Norman architecture. See *fig.* 1431.

Fig. 1431.

ENDENT. (Lat.) An ornament suspended from the summit of Gothic vaulting, very often elaborately decorated. The mode in which stone pendents are constructed will be immediately understood by a consideration of the annexed figure (*fig.* 1432). The pendent was also used very frequently to timber-framed roofs, as in that of Crosby Hall, which has a series of pendents along the centre of it. Pendents are also attached to the ends of the hammer beams in Gothic timber roofs.

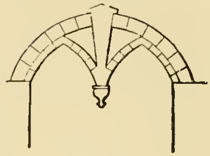

Fig. 1432.

ENDENTIVE. The entire body of a vault suspended out of the perpendicular of the walls, and bearing against the arch boutants, or supporters. It is defined by Daviler to be the portion of a vault between the arches of a dome, commonly enriched with sculpture. Felibien defines it as the plane of the vault contained between the double arches, the forming arches, and the ogives.

'ENDENTIVE BRACKETING, or CAVE BRACKETING. That springing from the rectangular walls of an apartment upwards to the ceiling, and forming the horizontal part of the ceiling into a circle or ellipsis.

'ENDENTIVE CRADLING. The timber work for sustaining the lath and plaster in vaulted ceilings.

'ENETRALE. (Lat.) The most sacred part of the temple, which generally contained an altar to Jupiter Herceæus, which appellation, according to Festus, was derived from ἑρκος, an enclosure, and supposed him the protector of its sanctity.

'ENETRALIA. (Lat.) Small chapels dedicated to the Penates, in the innermost part of the Roman houses. In these it was the custom to deposit what the family considered most valuable.

'ENITENTIARY. In monastic establishments was a small square building, in which a penitent confined himself. The term was also applied to that part of a church to which penitents were admitted during divine service. The word, as used in the present time, implies a place for the reception of criminals whose crimes are not so heinous as to deserve punishment beyond that of solitary confinement and hard labour, and where means are used to reclaim as much as possible those who have become subject to the laws by transgressing them.

'ENSTOCK. A small paddle, working up and down vertically in a grooved frame, for penning back water.

'ENTACLE. A figure whose basis is a double triangle; it is not unfrequent in early ornamental art.

'ENTADORON. (Gr.) A species of brick used in ancient architecture, which was five palms long.

'ENTAGON. (Gr. Πεντε, five, and Γωνια, an angle.) In geometry, a figure of five sides and five angles. When the five sides are equal, the angles are so too, and the figure is called a regular pentagon.

'ENTAGRAPH. See PANTOGRAPH.

'ENTALPHA. A figure formed by a continuous line, making a five-pointed star, not unfrequent in mediæval decoration and window tracery. See *fig.* 1293.

'ENTASTYLE. A portico or colonnade having five columns in front.

ENT-HOUSE. A shed having a lean-to roof.

EPPERCORN RENT. A rent for land, being one of the smallest possible value. A rose is sometimes named; also a flag or banner. A farm in St. Saviour's, Southwark, was let at the price of 17 lbs. of pepper at 2*s.* per pound. Also an acre of land at Lambeth "for 2*s.* for the price of one pound of pepper by the year beyond all rents resolute."

ERCH. A measure for brickwork used in Ireland in place of the ROD in England. It is 21 feet in length, by 1 foot high, and 1 foot thick. It equals $15\frac{3}{4}$ cube feet. One thousand bricks, a quarter cart of sand, and one and a quarter hogshead of lime, will serve for four and a half perches. It is also there used for masonry, as well as in some counties in England.

'ERIACTI. (Gr. Περιάγειν, to revolve.) The revolving scenes in an ancient theatre, called by the Romans *scenæ versatiles.*

'ERIBOLUS. (Gr.) The wall bounding an enclosure. It has become applied to the enclosure itself, more particularly around a temple. It was frequently ornamented with statues, altars, and monuments, and sometimes had smaller temples or a grove. The peribolus of the temple of Jupiter Olympius, at Athens, was four stadia in circumference.

PERIDROME. (Gr. Περί, about, Δρομος, a course.) The space, in ancient architecture, between the columns of a temple and the walls enclosing the cell.

PERIMETER. (Gr.) The boundary of a figure.

PERIPHERY. (Gr. Περιφρεω, I surround.) The circumference of a circle, ellipsis, parabola, or other regular curvilinear figure.

PERIPTERAL. (Gr.) A building encompassed by columns. See TEMPLE.

PERIPTERY. (Gr.) The range of insulated columns round the cell of a temple.

PERISTYLIUM. (Gr.) In Greek and Roman buildings, a court, square or cloister, which sometimes had a colonnade on three sides only, and therefore in that case improperly so called. Some peristylia had a colonnade on each of the four sides; that on the south being sometimes higher than the rest, in which case it was called a *Rhodian peristylium.* The range of columns itself was called the *peristyle.* See COLONNADE.

PERITHYRIDES. The same as ANCONES.

PERITROCHIUM. (Gr.) A term in mechanics applied to a wheel or circle concentric with the base of a cylinder, and together with it moveable about an axis.

PERPEN ASHLAR. A provincial term, being probably a corruption of perpendicular, as the stone in the form of 4, 6, 8, or 10 inches thick, in 10, 12, or 14 inch courses, and from 30 inches to 54 inches long, is placed on edge, and must of course be set very plumb or perpendicular; the edge or bed also must be truly square with the upright face.

PERPENDICULAR. In geometry, a term applied to a right line falling directly on another line, so as to make equal angles on each side, called also a *normal line.* The same definition will hold of planes standing the one on the other. A perpendicular to a curve is a right line cutting the curve in a point where another right line to which it is perpendicular makes a tangent with the curve.

PERPENDICULAR PERIOD. The last period into which the Gothic style in England has been divided. Its name is derived from the predominance of vertical or rectilinear lines. *Fig.* 1433 is a fine example of the style.

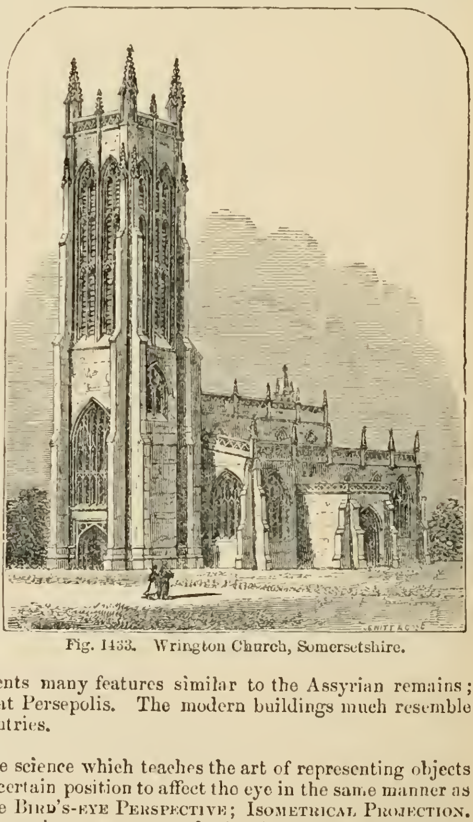

Fig. 1433. Wrington Church, Somersetshire.

PERPEND STONE, OR PERPENDER. A long stone reaching through the thickness of the wall, so as to be visible on both sides, and therefore wrought and smoothed at the ends.

PERPEYN WALL. A kind of pier or buttress projecting from a wall.

PERRON. (Fr.) A staircase, lying open or outside the building; or more properly the steps in the front of a building which lead into the first story, when it is raised a little above the level of the ground.

PERSIAN OR PERSEPOLITAN ARCHITECTURE. The ancient style presents many features similar to the Assyrian remains; they are chiefly seen at the ruins at Persepolis. The modern buildings much resemble those of other Mahommedan countries.

PERSIANS. See ATLANTES.

PERSPECTIVE. (Lat. Perspicio.) The science which teaches the art of representing objects on a definite surface, so as from a certain position to affect the eye in the same manner as would the objects themselves. See BIRD'S-EYE PERSPECTIVE; ISOMETRICAL PROJECTION.

PEST HOUSE. A lazaretto or infirmary where persons, goods, &c., infected with the plague or other contagious disease, or suspected so to be, are lodged to prevent communication with others, and the consequent spread of the contagion.

PEULVAN. See MAENHIR stone.

PEW. (Fr. Piou.) An enclosed seat in a church. Pews were in use long before the Reformation in England.

PHALANGÆ. (Gr.) A name applied by Vitruvius to a species of wooden rollers, used to transport heavy masses from one spot to another.

PHAROS. (Gr. from Φως, a light, and Οραω, I see.) See LIGHTHOUSE.

PHEASANTRY. A building or place for the purpose of breeding, rearing, and keeping pheasants.

PHONICS. The doctrine of sounds, which has not yet been so reduced in its application to architecture as to justify more than its definition. See ACOUSTICS.

PHOTO-LITHOGRAPHY. A process of reproducing line engravings and drawings, either copied, enlarged, or reduced, not exceeding one-sixth, and in some cases one-tenth, of the expense by other processes.

PHOTOMETER. (Gr.) An instrument for measuring the different intensities of light.

PIAZZA. (Ital.) A square open space surrounded by buildings. The term is very frequently and very ignorantly used to denote a walk under an arcade.

PICTURE GALLERY. A room or rooms for the exhibition of pictures, drawings, and engravings, and designed to suit either the wealth of the nation or the means of a private person.

The arrangement of the collection has to be first decided by the proprietor or curator of the gallery. Thus: Whether in one or more rooms—Miscellaneously—Grouped according to the class of objects—Divided according to the different schools of painting—The largest size of any picture to enter the collection—The admission of water-colour pictures, chalk drawings, and of prints—The arrangements as to the admission of the public—The amount and nature of accommodation for students, and any other rooms required for the keeper, for the cleaner, packing, and other similar occupations. The miscellaneous arrangement of a collection is certainly the most common, as well as the most gratifying to the public. The amateur and artist would prefer the division of pictures by schools, which obtains on the Continent, particularly in Germany. The Munich Gallery affords information as to the proportion of space which was allotted to each of the groups into which the collection is divided.

In the Pinacotheca at Munich the paintings are grouped according to schools, perhaps more perfectly effected than at Berlin, and a corridor runs the whole length, 420 feet, of the building. The large pictures are placed in very large rooms, 42 ft. wide and 31 feet 6 inches high to the cornice. Some of the large rooms are 93 feet long. The smaller pictures are placed in lesser rooms, formed on the other side of the larger ones, and with a side light *from the north*, which is admitted to be the best light for all pictures and for painting-rooms. The museum and picture gallery at Berlin, by Herr Schinkel, is formed on three sides of a central vestibule; all the rooms are 39 feet 9 ins. wide and 26 feet high, with a flat ceiling, and the light throughout is admitted by common windows down to the dado on the side. Screens about 16 feet high by 20 feet long divide the galleries into rooms about 30 feet by 18 feet, for grouping the paintings.

The number of lineal feet of wall in the great picture galleries is as follows:—Munich, 1600; Louvre, 1300; Berlin, 1116; London (on the principal floor), 670, but of late years increased to more than double that quantity; and Dresden, which as much exceeds the extent of Munich or of Berlin as did these that of London.

It has been urged by the Messrs. Papworth, in their work on *Museums, Libraries, and Picture Galleries*, 8vo. London, 1853, that a skylight to a room, with divisions or presses projecting from the wall, is the most economical mode of arranging a building to receive an unformed collection of works of art. They also direct the picture gallery to be on the first floor; the ground floor being devoted to objects of art, not in relief.

Galleries for oil paintings, large or of a moderate size, must be lighted from above. But when they are of the small cabinet size, a side light, being a suitable side light, is well adapted to their display. In the first case, the lights were formerly placed in square or polygonal tambours, whose sashes were vertical or slightly inclined inwards, their forms following the plan of the rooms; as at the Dulwich Gallery, by Sir John Soane, R.A. Of late years, for large rooms, a long skylight having obscured glass in it has been preferred, with a coved ceiling under to prevent shadows falling on the pictures. This is occasionally hidden by a flat skylight having ground or obscured glass, the upper skylight having clear glass, but the necessary framework causes some shadows. It will be in the memory of many how miserably lighted, for exhibiting the pictures, is the long gallery of the Louvre at Paris, which of late years has had some dormer windows formed to admit more light. The walls should be boarded throughout for facility in hanging the pictures. Many galleries fail of success from being over-lighted. A roof all glass would be as bad for the pictures as open air. The glare of light, as it is termed, would be too great.

The Fitzwilliam Museum at Cambridge, a library, picture, and statue gallery, affords an example of the mode of lighting for pictures, as also the effect of sculpture as seen by a low side light obtained from one side only. This is also to be found at the galleries in Dublin; in both cases not with the happiest results.

Professor Magnus, of Berlin, proposed a gallery for small paintings, to be lighted by windows on both sides, and not opposite one another, reaching nearly to the ceiling, and about 5 feet from the floor, each about a fourth of the breadth of the room. Between these were to be placed screens at an angle of 62 degrees with the wall. As the pictures required to be removed 5 or 6 feet from the wall, the useless space served for doorways from one compartment to another. The professor proposed a circular building for such an arrangement, perhaps somewhat similar to that described under Museums, but where the inner space was formed by a double circular staircase, to lead to several stories, and where the upper room might have the advantage of a skylight.

A principle of lighting a picture gallery, namely, that the window or source of light by which a picture is seen, and the picture itself, ought not both to come within the range of vision at the same time, was exemplified in the gallery built cir. 1825 by Sir Benjamin West. P.R.A., expressly for the purpose of exhibiting his paintings. Another on the same principle was designed at Clapham, by the late Mr. J. B. Papworth, and with an equally successful result. It consists in forming a side light opposite to the picture wall and above the ceiling; thus all the light is thrown upon the painting, and the source of the light is quite invisible to the spectator. This system is perhaps better adapted for a private than for a public gallery, on account of the difficulty attending the construction of the roof.

The peculiar arrangements of the small picture gallery in Sir John Soane's museum should be seen and studied. The grand gallery at the National Gallery, by the late Sir James Pennethorne (a perspective view of which is given in the *Builder* for 1861); the new galleries for the same national structure, erected 1875–76, from the designs of E. M. Barry, R.A., with the new entrance and suite of galleries beyond, erected 1886–87, from the designs of John Taylor, principal surveyor of H.M. Works and Public Buildings; the Art courts and the picture galleries at the South Kensington Museum; the picture galleries erected for the Exhibition of Industry, 1862; the exhibition rooms of the Royal Academy at Burlington House, may all be referred to for the latest improvements.

Piece-work. Work done and paid for by measure of quantity, *i.e.* so much for the piece or job; in contradistinction to work done and paid for by the measure of time, *i.e.* by day work.

Piedroit. (Fr.) A pier or small pillar, partly hid within a wall. It differs from a pilaster in having neither base nor capital.

Piend. An arris; a salient angle; a hip. It is a northern appellation.

Piend Check. The rebate formed on the *piend* or angle at the bottom of the riser of a stone step of a stair, to catch upon the angle formed at the top of the under step.

Pier. (Fr.) A solid between the doors or windows of a building. The square or other formed mass or post to which a gate is hung. Also the solid support from which an arch springs. In a bridge, the pier next the shore is usually called an abutment pier.

Pier Arch. An arch springing from a pier, as large shafts are usually termed in mediæval architecture. See *figs.* 1417 to 1427.

Pierced Stone, Tolmen or holed stone. One of the consecrated stones of the Celtic people

Pilaster. (Fr.) A sort of square column, sometimes insulated, but more commonly engaged in a wall, and projecting only a fourth or fifth of its thickness. See Anta.

Pile. (Lat.) A large timber driven into the earth, upon whose head is laid the foundation of a building in marshy and loose soils. Amsterdam and some other cities are built wholly upon piles. The stoppage of Dagenham Breach was effected by piles mortised into one another by dovetail joints. They are best and most firmly driven by repeated strokes; and for the saving of time, a pile engine is generally used, in appearance and effect very much like a guillotine; this raises the hammer to a certain height, which, pressing the claps or *monkey* that carry it up, suddenly drops down on the pile to be driven.

Pillar. (Fr. Pilier.) A column of irregular form, always disengaged, and always deviating from the proportion of the orders, whence the distinction between a column and a pillar. In any other sense it is improperly used.

Pin. In carpentry, a cylindrical piece of wood driven to connect pieces of framing together. It is also called a *trenail*.

Pinacotheca. (Gr.) An edifice for the preservation of pictures. A picture gallery.

Pinnacle. (Low Lat. Pinnaculum.) A summit or apex. In mediæval architecture, the crown of a buttress or vertical abutment, more or less ornamental, terminating in a cone or pyramid. It was intended to assure the stability of a vertical abutment by its weight; it arrests the sliding of the coping stones of gables; it serves as an attachment to the balustrade; and also, by a well-composed outline, it helps to give to buildings a particular elegance. Pinnacles should have a bold and aspiring outline, and should receive the parapets and copings against their plinths (as *fig.* 1216), and not, as often done, against their shafts. Good examples are to be seen at St. Nicholas, Great Yarmouth; Magdalen College, Oxford; and St. Sepulchre's, London. A Hip knob to a gable is a sort of pinnacle.

Pinney. Also called "green beds" of the Chilmark quarry; they are situate below the trough beds. They are small but very durable.

Pinning up. In underpining, the driving the wedges under the upper work so as to bring it fully to bear upon the work below. The term pinning is used to denote the fastening of tiles with pins of iron or of heart of oak in roofs.

Pipe. A conveyance for water or soil from any part of a building, usually of lead or iron. When for the supply of water to a building it is called a *service pipe*; when for carrying off water, a *waste pipe*; and when for carrying off soil, a *soil pipe*; and those which carry away the rain from a building are called *rain-water pipes*. When a cistern or reservoir is supplied in such a way that those who labour to fill it should be made aware that it is full, the pipe which discharges the overflow is called a *warning pipe*. Also for the conveyance of gas, when it is usually of iron, or of a softish white metal. called composition. A pipe through which the voice is sent to communicate with a distant apartment, is called a "speaking tube."

Pipe. The following rule has been given to ascertain the strength requisite to be given to a pipe of the metals named. Let d = internal diameter; t = thickness of metal both in inches; h = head of water in feet required to burst the pipe; c = constant, wrought iron, 200; cast iron, 73; copper, 87; brass, 83; and lead 10. Then $c\frac{t}{d}=h$; and $\frac{dh}{c}=t$. In practice, the thickness of cast-iron water pipes is taken as $=\frac{1}{5}\sqrt{\text{diameter}}$. Hurst, *Surveyors' Hand Book.*

Piscina. (Lat.) Among the Romans this term was applied to a fish-pond; to a shallow reservoir for practising swimming; and to a place for watering horses and washing clothes. The piscina in ecclesiastical architecture was a shallow bowl for water, generally in a niche in the south wall of the chancel, wherein the priest laved his hands before the performance of the sacred rites, and for rinsing the chalice at the time of the celebration of the mass. A hole at the bottom allowed for the escape of the water, so as not to be reused. The variety of their form is great; some are quite plain, others very richly decorated; and they often occur in pairs.

Pisé. A species of walling, of latter years used in the south of France, made of stiff earth or clay rammed in between moulds as it is carried up. This method of walling was, however, in very early use. (*Plin.* lib. xxxiv. chap. 14.)

Pit. A place from whence chalk, gravel, and such like are obtained. See Quarry.

Pit of a Theatre. Formerly the part on the ground-floor between the lower range of boxes and the stage; but it is now much reduced for the stalls and reserved pit seats.

Pitch. See Tar.

Pitch. A term generally applied to the vertical angles formed by the inclined sides of a roof. Roofing.

Pitch of an Arch. The versed sine, or height from the springing line up to the underside of it.

Pitching Piece. See Apron Piece, which is at the bottom, as the pitching piece is at the top, of a flight of steps, to carry the *rough strings*.

Pivot. (Fr.) The sharpened point upon which a wheel whose axis is perpendicular or inclined performs its revolutions.

Place Bricks. The commonest sort of bricks, being those near the outside of the clamp and therefore not much burnt.

Plafond or Platfond. (Fr.) The ceiling of a room, whether flat or arched; also the underside of the projection of the larmier of the cornice; generally any sofite.

Plain or Plane Angle. One contained under two lines and surfaces, so called to distinguish it from a solid angle.

Plain Tiles, properly Plane Tiles. Those whose surfaces are planes. They are used for roofing purposes; forming copings, tiles in cement flats, etc. See Weather-tiling.

Plan. (Fr.) The representation of the horizontal section of a building, showing its distribution, the form and extent of its various parts. In the plans made by the architect, it is customary to distinguish the massive parts, such as walls, by a dark colour, so as to separate them from the voids or open spaces. In a *geometrical plan*, which is that above mentioned, the parts are represented in their natural proportions. A *perspective plan* is drawn according to the rules of perspective.

Planceer. The same as the sofite or under-surface of the corona; the word is, however, very often used generally to mean any sofite. See Plafond.

Plane. (Lat. Planus.) A tool used by artificers that work in wood for the purpose of producing thereon a flat even surface. There are various sorts of planes.

PLANE. In geometry, a surface that coincides in every direction with a straight line.

PLANE, GEOMETRICAL. In perspective, a plane parallel to the horizon, whereon the object to be delineated is supposed to be placed. It is usually at right angles with the perspective plane.

PLANE, HORIZONTAL. In perspective, a plane passing through the spectator's eye, parallel to the horizon, and cutting the perspective plane in a straight line, called the *horizontal line.*

PLANE, INCLINED. One that makes an oblique angle with a horizontal plane.

PLANE, OBJECTIVE. Any plane, face, or side of an original object to be delineated on the perspective plane.

PLANE, PERSPECTIVE. That interposed between the original objects and the eye of the spectator, and whereon the objects are to be delineated.

PLANE TRIGONOMETRY. That branch of mathematics whose object is the investigation and calculation of the sides and angles of plane triangles. It is of the greatest importance to the architect.

PLANIMETRY. That branch of geometry which treats of lines and surfaces only, without reference to their height or depth.

PLANK. (Fr.) A name given generally to all timber, except fir, which is less than four inches thick and thicker than one inch and a half. See BOARD.

PLANK ROOF. A roof, the trusses of which are formed principally of planks cut to a curved shape, as in de Lorme's system; or bent to the shape required, as in Emy's system.

PLANTED. When a moulding is wrought on a separate piece of stuff, and is fastened in its place, as around a panel, it is said to be planted (on the stuff).

PLASTER. Lime properly prepared for the plasterer.

PLASTERERS' WORK. The laying of ceilings; the finishing to walls to give a fair face; the making and fixing of ornamental work; and cementing to walls.

PLASTER OF PARIS. A preparation of gypsum, originally procured in the vicinity of Mont Martre, near Paris. The plaster stone, or alabaster, is, however, found in many parts of England, as at Chelaston near Derby, and Beacon Hill near Newark. The former pits yield about 800 tons a year. It is ground and frequently used for manure, or rather as a stimulant for grass. It is calcined into the plaster used by the modeller, plasterer, &c. When diluted with water into a thin paste, plaster of Paris sets rapidly, and at the instant of setting, its bulk is increased. Mr. Boyle found by experiment that a glass vessel filled with this paste, and close stopped, bursts while the mixture sets, a quantity of water sometimes issuing through the cracks; hence this material becomes valuable for filling cavities, &c., when other earths would shrink. The gypsum is prepared either by burning or boiling, and loses from four to six cwt. in a ton. After burning, it is ground into powder in a mill.

PLAT OR PLOT. A late mediæval term for a design or drawing.

PLATBAND. Any flat and square moulding whose projection is much less than its height, such are the fasciæ of an architrave, the list between flutings, &c. The platband of a door or window is the lintel, when it is made square and not much arched.

PLATE. A general term applied to those horizontal pieces of timber lying mostly on walls for the reception of another assemblage of timbers. Thus, a *wall plate* is laid round the walls of a building to receive the timbering of a floor and roof; *a gutter plate* under the gutter of a building, &c.

PLATE GLASS. Glass cast in sheets or plates, and polished. Plate glass is superior in quality and colour to both "crown" and "sheet" glass. The best kind may be tested by its perfect freedom from colour, blemishes, specks, and striæ of every sort. It is not subject to dampness or "sweating." That which is tinged is of inferior quality, and cannot be used where it is intended to exhibit coloured articles behind it. The usual thickness is one quarter of an inch. The better sort of plate glass is used for looking-glasses, and is charged a higher price than for glazing purposes. There is also an inferior sort of plate glass, called "patent plate," which consists of blown glass of an extra thickness, which is then opened and polished. For large sizes the price is about the same as plate glass.

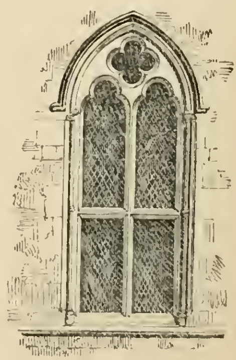

Fig. 1131.

PLATE RACK. A fixture over the sink in a scullery for the reception of dinner plates and dishes after washing.

PLATE TRACERY. The earliest form of tracery, used at the commencement of the Early English period of mediæval architecture, as Fig. 1431; it consists of the openings being formed or cut in the stonework, and showing no projecting mouldings.

PLATFORM. An assemblage of timbers for carrying a flat covering of a house, or the flat covering itself. A terrace or open walk at the top of a building. The raised dais on which the altar stands, and also that on which the font stands.

Plinth. (Gr. Πλινθος, a brick.) The lower square member of a base of a column or pedestal. In a wall the term *plinth* is applied to two or more rows of bricks at the base of it, which project from the face.

Plotting. The art of laying down on paper the angles and lines of a plot of land by any instrument used in surveying.

Plough. A joiner's grooving plane.

Plough and Tongued. This is a continued mortise and tenon along the edges of two boards, the one having a groove cut in it, and the other formed into a projection; such work is used to linings and floors. Sometimes both edges are grooved, and a thin piece of wood or of hoop iron let into both, while being fixed up or laid. See Heading Joint.

Plug. A piece of timber driven perpendicularly into a wall with the projecting part sawn away, so as to be flush with the face.

Plug and Feather, or Key and Feather. A name given to a method of dividing hard stones by means of a long tapering wedge called the *key*, and wedge-shaped pieces of iron called *feathers*, which are driven into holes previously drilled into the rock for the purpose, and thus forcibly split it.

Plumbing. (Lat. Plumbus.) The art of casting and working in lead and using it in building.

Plumb Rule, Plumb Line, or Plummet. An instrument used by masons, carpenters, &c., to draw perpendiculars or verticals, for ascertaining whether their work be upright, horizontal, and so on. The instrument is little more than a piece of lead or plummet at the end of a string, sometimes descending along a wooden or metal ruler raised perpendicularly on another, and then it is called a level. See Level.

Plumber. The artificer who works in lead and zinc. The fittings for water-closets, cisterns, pumps, gutters, &c., come under his care.

Pocket. The space in the *pulley style* of a sashed window. It is also a space closed up, or nearly so, formed out of a larger space. Pockets are often found in the flues of old houses, and form one of the great causes of fires, by accumulating the soot, which at last heats and ignites adjoining woodwork.

Podium. (Lat.) A continued pedestal. A projection which surrounded the arena of the ancient amphitheatre, See Amphitheatre.

Point. (Lat. Punctum.) In geometry, according to Euclid, that which has neither length, breadth, nor thickness.

Point, accidental. In perspective, a term used by the old writers on the science to signify the vanishing point.

Point of Distance. In perspective, the distance of the picture transferred upon the vanishing line from the centre, or from the point where the principal ray meets it, whence it is generally understood to be on the vanishing line of the horizon. See Distance.

Point, objective. A point on a geometrical plane whose representation is required on the perspective plane.

Point of Sight. The place of the eye whence the picture is viewed, according to Dr. Brook Taylor, but, according to the old writers on perspective, is what is now called the centre of the picture. It is also called the *point of view*.

Pointed or Lancet Arch. An arch formed by a radius equal to the span of the opening, and struck from both sides of it on the springing line. A lancet arch of a higher pitch is formed by the radius being struck as much beyond the opening as may be desired. See Tierce Point.

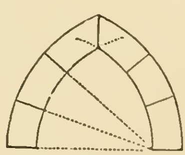

Fig. 1435.

Pointed Architecture. The mediæval styles of architecture in which the pointed arch is adopted as a principle of construction.

Pointing. The raking out the mortar from between the joints of brick work, and replacing the same with new mortar.

Pole Plate. A plate fixed to the lower ends of a truss of a roof, to receive the ends of the common rafters, as B in Fig. 688.

Polishing. The act of imparting to fancy woods, as wainscot, mahogany, bird's-eye maple, &c., a brilliant surface to show off their flower to advantage. This is done by rubbing on them a spirit varnish with great care. Varnish, wax, and a common polish are rubbed or laid on with a brush for cheapness. See Marble.

Pollard. A tree which has been frequently lopped or *polled* of its head and branches, a practice very injurious to good timber.

Polychromy. The decoration of exteriors and interiors of buildings, with colours and tints. When executed in a single colour, it is called *monochrome* painting.

Polygon. (Gr. Πολυς, many, and Γωνια, an angle.) A multilateral figure, or one whose perimeter consists of more than four sides and angles. If the sides and angles be equal the figure is called a regular polygon. Polygons are distinguished according to the number of the sides; thus those of five sides are called *pentagons*, those of six *hexagons*, those of seven *heptagons*, and so on. The subjoined is a table of the areas and perpendiculars of polygons, the side being = 1.; and of the lengths of sides of polygons to Radius 1. See also par. 1219.

Number of Sides.	Names of Polygons.	Area.	Perpendiculars.	Circumscribed.	Inscribed.
3	Trigon -	·433013	·2886751	3·4641	1·7321
4	Tetragon -	1·000000	·5000000	2·0000	1·4142
5	Pentagon -	1·720477	·6881910	1·4530	1·1756
6	Hexagon -	2·598076	·8660254	1·1548	1·0000
7	Heptagon -	3·633912	1·0382617	0·9630	0·8677
8	Octagon -	4·828427	1·2071068	0·8284	0·7654
9	Enneagon -	6·181824	1·3737387	0·7278	0·6840
10	Decagon -	7·694209	1·5388418	0·6498	0·6180
11	Endecagon -	9·365640	1·7028437	0·5872	0·5634
12	Dodecagon -	11·196152	1·8660254	0 5358	0·5176

From the above, to find the area of a regular polygon, multiply one of the sides of the polygon by the perpendicular from the centre on that side, and multiply half the product by the number of sides; or, multiply the square of the given side of the polygon by the number opposite to its name under the word Area.

Polygram. (Gr.) A figure consisting of many lines.

Polyhædron. (Gr.) A solid contained under many sides or planes. If the sides of a polyhædron be regular polygons, all similar and equal, it becomes a regular body, and may be inscribed in a sphere, that is, a sphere may be drawn round it, so that its surface shall touch all the solid angles of the body.

Polystyle. (Gr. Πολος and Στυλος.) Of many columns. See Colonnade.

Pomel. (Lat. Pomum.) A globular protuberance terminating a pinnacle, &c.

Poplar. (Lat. Populus.) A tree sometimes used for rafters in common buildings.

Poppy Heads, or Poppies. The termination of the ends of open seats, often carved as heads, foliage, &c.

Porch. (Fr.) An exterior appendage to a building, forming a covered approach to one of its principal doorways.

Porphyry. (Gr.) A very hard stone, partaking of the nature of granite. It is not so fine as many of the ordinary marbles, but far exceeds them in hardness, and will take a very fine polish. It is generally of a high purple, which varies, however, from claret colour to violet. Its variations are rarely disposed in grains. The purple porphyry was obtained by the Romans in Egypt, the quarries of which were only discovered, between the River Nile and the Red Sea, about 1885–87, by Burton, Schweinfurth, and lastly by Brindley. Columns of it wrought 1900 years since still retain the freshness of colour. It had been obtained of very large sizes, for tombs, &c. It must not be confounded with the Syenite of Egypt.

The red-lead coloured porphyry, which abounds in Minorca, is variegated with black white, and green, and is a beautiful and valuable material. The pale and red porphyry variegated with black, white and green is found in Arabia Petræa and Upper Egypt, and in separate nodules in Germany, England, and Ireland. The sorts best known are what the Italians call the *porfido rosso* (red), which is of a deep red with oblong white spots; the latter are of *feld spath*, which resembles *schorl*. There are two varieties of black porphyry, the *porfido nero*, or black porphyry, and that called the *serpentino nero antico*. The first has a ground entirely black, spotted with oblong white spots like the red porphyry; the other has also a black ground, with great white spots, oblong, or rather in the form of a parallelopipedon, nearly resembling in colour what the French call *serpentin vert antique*. The *brown porphyry* has a brown ground with large oblong greenish spots. There are several sorts of green porphyry, which the Italians principally distinguish by the names of *serpentino antico verde*, found in great abundance and in large blocks in the neighbourhood of the ancient Ostia, of a green ground with oblong spots of a lighter shade of the same colour; and the *porfido verde*, which is of a ground of very dark green, almost approaching to black, with lighter shades of a fine grass green.

Portal. (Lat. Porta.) The arch over a door or gate; the framework of the gate; the lesser gate, when there are two of different dimensions at one entrance. The Fr. portail is given to the entrance façade of a building. This term was formerly applied to a small square corner in a room separated from the rest of the apartment by wainscoting.

Portcullis. (Fr.) A strong grated framing of timber, resembling a harrow, the vertical pieces whereof were pointed with iron at the bottom, for the purpose of striking into the ground when it was dropped, and also to break and destroy that upon which it fell. It was made to slide up and down in a groove of solid stone-work within the arch of the portals of old castles. It was introduced into the early Norman castles.

PORTICO. (Lat. Porticus.) See COLONNADE.

PORTLAND CEMENT. A quick-setting cement made from limestone and clay. It is calcined at a very great heat; will take a larger quantity of sand than Roman cement; and is much lighter in colour, rendering it more agreeable for decorative purposes.

PORTLAND STONE. A dull white species of stone brought from the island of Portland. It stands the action of the London atmosphere better than any other stone.

PORTUGUESE ARCHITECTURE. See SPANISH ARCHITECTURE.

POSITION. In geometry, the situation of one thing in regard to another. Speaking architecturally, it is the situation of a building in respect of the four cardinal points of the horizon.

POST. (Fr.) An upright piece of timber set in the earth. Any piece of timber whose office is to support or sustain in a vertical direction, as the *king* and *queen posts* in a roof, is so called.

POST AND PALING. A close wooden fence constructed with posts fixed in the ground and pales nailed between them. This kind of fence is sometimes called *post and railing*, though this latter is rather a kind of open wooden fence, used for the protection of young quickset hedges, consisting of posts and rails, &c.

POSTERN. A side door or gate usually employed in castellated architecture.

POSTICUM. (Lat.) See CELL.

POSTSCENIUM or PARASCENIUM. (Lat.) In ancient architecture, the back part of the theatre, where the machinery was deposited, and where the actors retired to robe themselves.

POT METAL. See STAINED GLASS.

POULTRY HOUSE. A building for the shelter and rearing of poultry, of which, perhaps, the finest example is that at Winnington in Cheshire. The front is one hundred and forty feet in length, with a pavilion at each end, united to the centre by a colonnade of small cast-iron pillars, supporting a slated roof, which shelters a paved walk. In the centre of the front are four strong columns, and as many pilasters, supporting a slated roof, with an iron gate between them, from which a large semicircular court is entered, with a colonnade round it, and places for the poultry. On one side of the gate is a small parlour, and at the other end of the colonnade a kitchen.

POWER. In mechanics, a force which, applied to a machine, tends to produce motion. If it actually produce it, it is called a *moving power*, if not, it is called a *sustaining power*. The term is also used in respect of the six simple machines, viz. the *lever*, the *balance*, the *screw*, the *axis in peritrochio*, the *wedge*, and the *pulley*, which are called the *mechanical powers*.

POYNTELL. A pavement consisting of small lozenge-shaped tiles, or square tiles laid diagonally.

POZZUOLANA. See PUZZUOLANA.

PRÆCINCTIO (Lat.) or BALTEUS. A wide seat, or rather step, round the audience part of the ancient theatres and amphitheatres. It was termed διαζωμα by the Greeks.

PREACHING CROSS. A cross erected in the highway, at which the monks and others preached to the public.

PRECEPTORY. A manor or estate of the Knights Templars, on which a church was erected for religious service, and a convenient house for habitation, and generally placed under one of the more eminent members of the fraternity, called the *præceptores templi*, to have care of the lands and rents of the place. The preceptories were nothing more than cells to the Temple, or principal house of the knights in London.

PRESBYTERY. That part of the church reserved for the officiating priests, comprising the choir and other eastern parts of the edifice.

PRICKING UP COAT. The first coat of plaster in three-coat work on lathing.

PRICK POST. The same as a QUEEN POST of a roof. Also the posts in a wooden building placed between the principal posts at the corners. Also the posts framed into the breastsummer, between the principal posts, for strengthening the carcass of a house.

PRIME. (Lat.) A figure in geometry that cannot be divided into any other figures more simple than itself, as a triangle in plane figures, and a pyramid in solids.

A prime number is one that cannot be divided by another number without a remainder.

PRIMING. In painter's work, the first colouring of the work, which forms a ground for the succeeding coats.

PRINCIPAL BRACE. One immediately under the principal rafters, or parallel to them, in a state of compression, assisting, with the principals, to support the timbers of a roof.

PRINCIPAL POINT. In perspective, a point in the perspective plane upon which a line will fall drawn from the eye perpendicular to that plane. It is, in fact, the intersection of the horizontal and vertical planes, or the *point of sight* or *of the eye*.

Principal Rafter. One whose size is larger than that of a common rafter, and is framed in such a manner, as in a truss, as to bear the principal weight of the latter.

Principal Ray. In perspective, the line passing from the eye to the principal point on the perspective plane.

Priory. A monastery, the head of which was called a prior or prioress.

Prism. (Gr. Πρισμα.) In geometry an oblong or solid body contained under more than four planes, whose bases are equal, parallel, and similarly situate.

Prismoid. A solid figure, having for its two ends any dissimilar parallel plane figure of the same number of sides, and all the upright sides of the solid trapezoids. If the ends of the prismoid be bounded by dissimilar curves, it is sometimes called a *cylindroid.*

Prison. A building erected for the confinement, or safe custody, of those who have transgressed the laws of their country, until, in due course of time, they are discharged.

In considerable cities and towns, humanity, and indeed justice, demands that the same building which confines the convicted felon should not enclose the debtor and the untried prisoner, as well as him whose offence is not of an aggravated nature. In small towns, where there may be only one, perhaps small, prison, the separation of the prisoners is more difficult to accomplish. The separation of the sex is indispensable. For whatever class of prisoners a building is erected, salubrity and ventilation are as essential as the security of those confined. It is now unnecessary to reprint the whole of the requisites which the celebrated Howard specified for prisons: modern rules have necessitated great alterations since his time.

Prison discipline is a problem the wisest of our legislators have not yet been able to solve. When Pentonville Prison was erected it was thought that complete separation, by its severity, would lessen crime. The result, however, has scarcely justified the belief. The Government have had ample opportunity of forming an opinion upon the merits of the separate system, consequently about 1851 some relaxation was made, and about ten per cent. were placed in association. The City authorities adopted a middle course, and they have the means of confining the vicious in separate cells; and have sufficient number of workrooms for classified association.

One of the prisons erected for the metropolis is the Model or Pentonville Prison, in the Caledonian Road, erected 1840–42 by Major R. Jebb for 1,000 prisoners, and to which additions have been made. A *Report* was published at the time giving all the details of the cells, which are 13 feet by 7 feet by 9 feet high, and intended for solitary confinement. Another, the new City Prison, in the Camden Road, erected 1849–52, by the City architect, Mr. J. B. Bunning, has 418 cells. It is constructed on the radiating principle, having four wings diverging from the centre, with two others in front of the former. Each is twelve cells in length, or about 100 feet long, and three stories high. The corridors are 16 feet wide, and are open up to the arched ceiling, with galleries leading to the upper cells. One of the latest prisons erected is that at Edinburgh. It is described in the *British Architect* for October 14, 1887, p. 291.

Problem (Gr.) In geometry, a proposition in which some operation or construction is required, as to divide a line, to make an angle, to draw a circle through three points not in a right line, &c. A problem consists of three parts: the proposition, which states what is required to be done; the resolution or solution, wherein are rehearsed the step or steps by which it is done; and the demonstration, wherein it is shown that by doing the several things prescribed in the resolution the thing required is obtained.

Prodomus. In ancient architecture, the portico before the entrance to the cell of a temple. See Cell.

Producing. In geometry, the continuing a right line to any required length.

Profile. The vertical section of a body. It is principally used in its architectural sense to signify the contour of architectural members, as of bases, cornices, &c. The profile of an order is in fact the outline of the whole and its parts, the drawing whereof is technically called profiling the order.

Projection. The art of representing a body on a plane by drawing straight lines through a given point, or parallel from the contour and from the intermediate lines of the body, if any, so as to cut the plane. When the projection is made by drawing straight lines from a point, it is called a *perspective representation*; but if formed by parallel lines, it is called an *orthographical representation.*

Projecture. An out-jetting or prominence beyond the naked of a wall, column, &c. By the Greeks projectures were called *εκφοραι*, by the Italians *sporti*, by the French *saillies*; our workmen called them *sailings over.*

Prolate. (Lat.) An epithet applied to a spheroid when generated by the revolution of a semi-ellipsis about its longer diameter.

Pronaos. See Cell.
Prop. A support, or that on which anything rests. See Rance and Shore.
Proportion. The just magnitude of each part, and of each part to another, so as to be suitable to the end in view. See Harmonic, and Geometric, Proportion.
Proportional Compasses. See Compasses.
Propylæum. (Gr. Προ, before, and Πυλη, a portal.) Any court or vestibule before a building, or before its principal part; but more particularly the entrance to such court or vestibule.
Proscenium. (Gr.) That part in the ancient theatre whereon the actors performed in front of the scene, being what we call the stage. The Romans called this part the *pulpitum*.
Prostyle. (Gr. Προ, and Στυλος, a column.) A portico in which the columns stand in advance of the building to which they belong.
Prothesis, Table of. See Credence.
Prothyris. (Gr.) A word used in ancient architecture to signify a cross beam or overthwart rafter, as likewise a quoin or course of a wall. See Console.
Prothyrum. (Gr.) A porch at the outer door of a house; a portal.
Protractor. (Lat. Protractus.) An instrument for laying down an angle in drawing or plotting.
Pseudisodomum. See Isodomum.
Pseudodipteral or False Dipteral. A disposition in the temples of antiquity wherein there were eight columns in front and only one range round the cell. It is called false or imperfect, because the cell only occupying the width of four columns, the sides from the columns to the walls of the cell have no columns therein, though the front and rear present a column in the middle of the void. See Temple.
Pseudoperipteral or Imperfect Peripteral. A disposition in the ancient temples, in which the columns on the sides were engaged in the wall, and wherein there was no portico except to the façade in front; such are the Maison Carrée at Nismes, and the temple of Fortuna Virilis at Rome.
Ptera. In Grecian architecture, is the colonnade which surrounded the cell of the temple, the monopteros temple being the only species which had columns without a wall behind them. The peripteral had one tier of columns round the cell, the dipteral two, and the pseudo or false dipteral, invented by Hermogenes, was that in which the ptera was single, but occupied the same space on the sides of the cell as the dipteral, though one of the tiers of columns was left out. Thus, by metaphor, the columns were called the wings of the temple. See Temple.
Pteroma. (Gr. Πτερον, a wing.) The space between the wall of the cell of a temple and the columns of the peristyle. called also *ambulatio*.
Public Building. Every building used as a church, chapel, or other place of public worship; also every building used for purposes of public instruction; also as a college, public hall, hospital, theatre, public concert room, public ball room, public lecture room, public exhibition room, or any other public purposes. Metropolitan Building Act, 1885.
Puddling. The filling behind a wall, filling up a avity, or banking up with clay tempered with water, and carefully rammed down with the repeated strokes of beaters or beetles, in order to make it solid. See Claying.
Pugging. A coarse kind of mortar laid upon rough boarding placed between joists, to prevent the transmission of sound from the apartment above to that below.
Pug-mill. A stone, or a pair of large circular stones, in a vertical position, worked by machinery to roll round as a wheel and also in and round an iron pan, for the purpose of grinding up clay for brickmaking, and also the lime and bricks in making mortar.
Pug-piling. The same as dovetailed piling, or pile planking.
Pulley. (Fr.) One of the five mechanical powers, consisting of a wheel or rundle, having a channel around it and turning on an axis, serving, by means of a rope which moves in its channel, for the raising of weights.
Pulley Mortise. The same as Chase Mortise.
Pulpit. (Ital. Pulpito.) An elevated place, an enclosed stage or platform for a preacher in a church. The ancient *ambo* served the same purpose.
Pulpitum. (Lat.) See Proscenium.
Pulvinaria. (Lat.) Cushions in the ancient temples whereon the statues of the gods were sometimes laid.
Pulvinata. (Lat.) A pillow; as applied to the volute of the Ionic order.
Pulvinated. See Frieze.
Pump. A machine for raising water; there are many varieties of them.
Puncheon. (Fr. Poinçon.) A name common to iron instruments used in different trades for cutting, inciding, or piercing a body. In carpentry, it is a piece of timber placed

upright between two posts whose bearing is too great, serving, together with them, to sustain some heavy weight. The term is also applied to a piece of timber raised upright under the ridge of a building, and in which are jointed the small timbers. Also to the arbor or principal part of a machine on which it turns vertically, as that of a crane.

Purbeck Stone. A species of stone obtained from the island of Purbeck in Dorsetshire, of a very hard texture, and used for paving. See Pavement.

Purfled. (Fr. Pourfiler.) Ornamented work in stone, or other material, representing embroidery, drapery, or lace work.

Purlin. A horizontal piece of timber lying generally on the principal rafters of a roof to lessen the bearings of the common rafters. Locally called *side timbers*, and *side wavers*.

Puteal. The marginal stone of a well. The celebrated one of Scribonius Libo was erected by order of the senate to mark the spot where a thunderbolt had fallen near the statues of Marsyas and Janus by the Comitia.

Putlog. See Ledger.

Putty. A sort of paste consisting of whiting, with or without a small portion of white lead, and linseed oil, beaten together until it assumes a kind of tough consistency like dough. In this state it is used by glaziers for fixing in the squares of glass to sash windows, etc., and also by house-painters to stop up holes and cavities in woodwork before painting.

Puzzuolana. A grey-coloured earth deriving its name from Puzzuoli, whence it was originally brought. It is a volcanic matter found in many other parts of Italy, and generally in the neighbourhood of volcanoes active or extinct, from which it has been thrown out in the form of ashes. It immediately hardens when mixed with one-third of its weight of lime and water, forming an admirable water cement.

Pycnostyle. (Gr. Πυκνος, close, Στυλος, column.) See Colonnade.

Pylon. The mass of building on either side of the entrance to an Egyptian temple. It is pyramidal in form and sometimes as much as 100 feet in length and 32 feet in width.

Pyramid. (Gr. Πυρ, fire.) A solid standing on a square, triangular, or polygonal basis, and terminating at top in a point; or a body whose base is a regular rectilinear figure and whose sides are plain triangles, their several verticles meeting together in one point. It is defined by Euclid as a solid figure consisting of several triangles whose bases are all in the same plane and have one common vertex.

The principal properties of pyramids are as follow:—1. All pyramids and cones standing on the same base and having the same altitude are equal. 2. A triangular pyramid is the third part of a prism, standing on the same base and of the same altitude. 3. Hence, since every multangular may be divided into triangulars, every pyramid is the third part of a prism standing on the same base and of the same altitude. 4. If a pyramid be cut by a plane parallel to its base, the sections will be similar to the base. 5. All pyramids, prisms, cylinders, etc., are in a ratio compounded of their bases and altitudes; the bases therefore being equal they are in proportion to their altitudes, and the altitudes being equal, they are in proportion to their bases. 6. Similar pyramids, prisms, cylinders, cones, etc., are in a triplicate ratio of their homologous sides. 7. Equal pyramids, etc., reciprocate their bases and altitudes, *i.e.* the altitude of one is to that of the other, as the base of the one is to the base of the other. 8. A sphere is equal to a pyramid whose base is equal to the surface, and its height to the radius of the sphere. See Frustum.

The name of the structure erected over a tomb, as commonly seen in Egypt.

Pyramidion. The small flat pyramid which terminates the top of an obelisk.

Q

Quadra. (Ital.) A square border or frame round a basso-relievo, panel, etc.; the term is not strictly applicable to any circular border. The term is also applied to the bands or fillets of the Ionic base on each side of the scotia; and also to the plinth or lower member of the podium.

Quadrangle. Any figure with four angles and four sides. This term is in architecture in England applied to the inner square or rectangular court of a building, as in the college courts of Oxford, etc.

Quadrant. (Lat.) The quarter of a circle, or an arc of it containing ninety degrees within its enclosed angle.

Quadrature. (Lat.) The determination of the area of a figure in a square, or even any other rectilinear form.

Quadrel. An artificial stone perfectly square, whence its name, much used formerly by the Italian architects. Quadrels were made of a chalky or whitish and pliable earth, and dried in the shade for at least two years.

Quadrifores. (Lat.) In ancient architecture, folding doors whose height was divided into two parts. When they opened in one height, they were termed *fores valvatæ* or *valvæ*.

Quadrilateral. In geometry, a figure whose perimeter consists of four right lines making four angles, whence it is also called a quadrangular figure.

QUARREL, vulgarly called QUARRY. (Fr. Carré.) A square or lozenge-shaped piece of glass used in lead casements.
QUARRY. (Irish, Carrig.) A place whence marbles, stones, or slates are procured.
QUARRYING. The operation of extracting the produce of a quarry is one which requires much practical knowledge to render it beneficial to its owner; but in respect of the details they are not required to be noticed in this work.
QUARTER GRAIN. See FELT GRAIN.
QUARTER PACE. See FOOT PACE.
QUARTER PARTITION. One consisting of quarters, or upright pieces of timber receiving the lath and plaster work.
QUARTER ROUND. The same as OVOLO and ECHINUS, being a moulding whose profile is the quadrant of a circle.
QUARTERS. Small vertical timber posts, rarely exceeding four by three inches, used to form a partition instead of walls for the separation or boundary of apartments. They are placed, or ought to be, about twelve inches apart, and are usually lathed and plastered in the internal apartments, but if used for external purposes are commonly boarded. A series of such posts is called QUARTERING.
QUARTZ. (Germ.) A mineral production better known by the name of rock crystal. It includes a variety of stones with which we have nothing here to do, and the only motive for mentioning it is its occurrence in the granites, wherein it is immediately recognised, from its glass-like appearance.
QUATREFOIL. (Fr. Quatrefeuille.) A modern term denoting a form disposed in four segments of circles, and so called from its imagined resemblance to an expanded flower of four petals. It is only found in the windows, panels, etc., of Gothic architecture.
QUAY. (Fr.) A bank formed towards the sea or on the side of a river for free passage, or for the purpose of unloading merchandise.
QUEEN-POST. A suspending post where there are two in a trussed roof.
QUEEN. A size slate used in roofing.
QUICKLIME. Lime in lump or in powder, ready for water to be added to it. See LIME.
QUIRK. A piece taken out of any regular ground-plot or floor; thus, if the ground plan were square or oblong, and a piece were taken out of the corner, such piece is called a *quirk*. See RE-ENTERING ANGLE.
QUIRK MOULDING. One whose sharp and sudden return from its extreme projection to the re-entrant angle seems rather to partake of a straight line on the profile than of the curve. Of this class are a great number of the ancient Greek mouldings.
QUOINS. (Fr. Coin.) A term applied to any external angle but more especially applied to the angular courses of stone raised from the naked of the wall at the corner of a building, and called rustic quoins. See RUSTIC QUOINS.

R

RABBET. See REBATE.
RACK. The case, enclosed by bars, over the manger in a stable, wherein the hay is placed for the horses.
RAD and DAB. A substitute for brick nogging in partitions, consisting of *cob* or a mixture of clay and chopped straw filled in between laths of split oak or hazel. It is also called *wattle and dab.*
RADIAL CURVES. In geometry, those of the spiral kind whose ordinates all terminate in the centre of the including circle, and appear like so many radii of such circle
RADIUS. In geometry, the semidiameter of a circle, or a right line drawn from the centre to the circumference.
RADIUS OF CURVATURE. The radius of the osculatory circle at any point in a curve. See OSCULATORY CIRCLE.
RAFFLE LEAF. A leaf in ornamental foliage formed of small indentations at the edge. The acanthus leaf is so called.
RAFTERS. (Quasi, Roof-trees.) The inclined timbers of a roof, whose edges are in the same plane which is parallel to the covering.
RAG SLATE. A slate obtained from Wales, and sold by the ton, which will cover about one square and a half of roofing.
RAIL. (Ger. Riegel.) A term applied in various ways, but more particularly to those pieces of timber or wood lying horizontally, whether between the panels of wainscoting, or of doors, or under or over the compartments of balustrades, &c.; to pieces, in framing, that lie from post to post in fences; in short, to all pieces lying in a horizontal direction which separate one compartment from another.
RAINFALL. To calculate the quantity of water that will accumulate over a given area, multiply the inches of rainfall by 2,323,200, which will equal the cube feet per square mile. If by 14½, it will equal millions of gallons per acre, If by 3,630, it will equal cube feet per acre. (*Molesworth.*)

Rain-water Pipe. One usually placed against the exterior of a house to carry off the rain-water from the roof.

Raising Piece. One which lies under a beam and over the posts or puncheons. The term is chiefly used in respect of buildings constructed of timber framework.

Raising Weights. See Lewis.

Rake. A slope or inclination, as of a roof.

Raking. A term applied to any member whose arisses lie inclined to the horizon.

Ramp. (Fr.) In handrails, a concavity on the upper side formed over risers, or over a half or quarter pace, by a sudden rise of the steps above, which frequently occasions a knee above the ramp. The term is also applied to any concave form, as in coping, &c., where a higher is to be joined by a continued line to a lower body.

Rampant Arch. One whose abutments or springings are not on the same level.

Rance. A prop or shore; a term used in Scotland.

Random Tooling. In Scotland called *droving*, is a mode of hewing the face of a stone either as preparatory to some other process, or as a finishing operation. A chisel two to four inches broad at the cutting edge, is advanced along the stone at about $\frac{1}{8}$ inch per stroke, the result being a series of indentations on the surface of the whole stone— The excellence of the work depends upon the regularity of these flutings and the absence of ridges between the *draughts*.

Range, or Ranging. (Fr.) A term applied to the edges of a number of bodies when standing in a given plane. Thus, if the edges of the ribs of a groin were placed in a cylindric surface, they would be said to *range*. It is also used in respect of a work that runs straight without breaking into angles.

Rank Set. When the sole of a plane iron projects greatly below the plane.

Ray, Principal. In perspective, the perpendicular distance between the eye and the perspective plane.

Rayonnant. (Fr. Radiating.) A term applied in France to a period in Gothic architecture, wherein the mullions and tracery terminate in forms founded on the divergence of rays from certain centres. It prevailed from the latter end of the thirteenth until near the end of the fourteenth century.

Rebate. (Fr. Rebattre.) A channel or small recess cut in a piece of wood, longitudinally, to receive the edge of a body, or the ends of a number of bodies that are to be secured to it. The depth of the channel is equal to the thickness of the body; so that when the end of the latter is let into the rebate, it is in the same face with the outside of the piece. See Door-stop.

Rebate Plane. One used for sinking rebates.

Recess. (Lat. Recedo.) A cavity left in a wall, sometimes for use, as to receive a sideboard, bed, &c., or to add to the quantity of floor room, and sometimes for ornament, as when formed into a niche, &c.

Reciprocals. A term in mathematics, mostly applied to the fraction made by inverting another fraction; thus $\frac{3}{7}$ is the reciprocal of $\frac{7}{3}$ and $\frac{1}{7}$ of $\frac{7}{1}$.

Rectangle. In geometry, a figure whose angles are all right angles. Solids are called rectangular with respect to their position, as a cone, cylinder, &c., when perpendicular to the plane of the horizon. A parabola was anciently called a rectangular section of a cone.

Rectification. In geometry, the finding of a right line that shall be equal to a given curve, or simply finding the length of a curve.

Rectilinear. A figure whose boundaries are right lines.

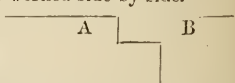
Rectilinear Period. A name given by some writers to the Perpendicular period of mediæval architecture in England, from the predominance of rectangular or straight lines.

Reduct. A quirk or small piece taken out of a larger to make it more uniform and regular.

Reduction of a figure, design, or draught. The copying it on a smaller scale than the original, preserving the same form and proportions. For this purpose a pair of proportional compasses are generally used, by which the labour is much lessened.

Reed Moulding. A moulding formed by three or more beads worked side by side.

Re-entering angle. An angle returned (A), in contradistinction to a square or solid angle (B), by the former of which much space is often lost in small houses, it being sometimes adopted from its picturesque qualities. See Quirk.



Refectory. (Lat.) A room for taking refreshments. See Abbey.

Reflector. A polished surface so placed at an angle that it will reflect light towards any required position. See Light, Reflected.

Reflex. The light reflected from a surface in light to one in shade.

Refuge. The name given to a building prepared for the reception of destitute people, where they are boarded and clothed and have to work, or if young are taught some trade, such as the "Boys' Refuge Farm School and Country Home," at Bisley, near Woking, in Surrey.

Reglet. (Fr.) A flat narrow moulding, used chiefly to separate the parts or members of compartments or panels from each other, or to form knots, frets, and other ornaments.

ᴇɢʀᴀᴛɪɴɢ. In masonry, the process of removing the outer surface of an old hewn stone, so as to give it a fresh appearance.

ᴇɢᴜʟᴀ. (Lat.) A band below the tænia in the Doric architrave.

ᴇɢᴜʟᴀʀ. An epithet applied to a figure when it is equilateral and equiangular. A body is said to be regular when it is bounded by regular and equal planes, and has all its solid angles equal.

ᴇɢᴜʟᴀʀ Aʀᴄʜɪᴛᴇᴄᴛᴜʀᴇ. That which has its parts symmetrical or disposed in counterparts.

ᴇɢᴜʟᴀʀ Cᴜʀᴠᴇs. The perimeters of conic sections, which are always curved after the same geometrical manner.

ᴇɪɢɴɪᴇʀ Wᴏʀᴋ. Ornamental figures or patterns inlaid in wood in the manner of *buhl work*, with leaves &c. of different colours.

ᴇɪɴs ᴏғ ᴀ Vᴀᴜʟᴛ. The sides or walls that sustain the arch.

ᴇᴊᴏɪɴᴛɪɴɢ. The filling up the joints of stones of old buildings when the mortar has been dislodged by age and the action of the weather.

ᴇʟᴀᴛɪᴏɴ. The direct conformity to each other, and to the whole, of the parts of a building.

ᴇʟɪᴇᴠᴏ (It.) or Rᴇʟɪᴇғ. The projecture from its ground of any architectural ornament. Among sculptors there are three degrees of relievo; namely, *alto relievo*, when the figure stands quite out from its ground; *mezzo relievo*, when one half of the figure projects; and *basso relievo*, when the figures are raised from the ground in a small degree.

ᴇʟɪᴇᴠɪɴɢ Aʀᴄʜ. See Dɪsᴄʜᴀʀɢɪɴɢ Aʀᴄʜ.

ᴇɴᴅᴇʀ. To plaster on walls, slates or tiles, without the intervention of laths.

ᴇɴᴀɪssᴀɴᴄᴇ Aʀᴄʜɪᴛᴇᴄᴛᴜʀᴇ. The name given to the style which studied to revive the forms and ornaments of Roman art and partly of the Grecian. It was commenced under the best efforts of the artists of the sixteenth and seventeenth centuries. The style is called "Cinque Cento" in Italy; and the "Revival" or "Elizabethan" in Great Britain.

ᴇɴᴅᴇʀɪɴɢ. The act of laying the first coat of plaster on brickwork.

ᴇᴘʟᴜᴍ. (Lat.) In ancient architecture, the panel of a framed door. See Iᴍᴘᴀɢᴇs.

ᴇʀᴇᴅᴏs. A screen placed behind an altar in mediæval architecture, and decorated with niches, statues, paintings, or other work, in accordance with the period of the style employed. See Aʟᴛᴀʀ Sᴄʀᴇᴇɴ.

ᴇsᴇʀᴠᴏɪʀ. (Fr.) An artificial pond, basin, or cistern for the collection and supply of water.

ᴇsɪsᴛᴀɴᴄᴇ. That power which, acting in opposition to another, tends to destroy or diminish its effect. There are several sorts of resistance, arising from the various natures and properties of the resisting bodies, as the resistance of solids, fluids, air, &c.

The following is a synopsis of the most important results that have been drawn by different writers on the subject, both practical and theoretical:

1. The resistance of a beam or bar to a fracture by a force acting laterally is as the solid made by a section of the beam in the place where the force is applied, into the distance of its centre of gravity from the point or line where the breach will end.

2. In square beams the lateral strengths are as the cubes of their breadths and depths.

3. In cylindric beams, the resistances of strengths are as the cubes of the diameters.

4. In rectangular beams the lateral strengths are conjointly as the breadths and squares of the depths.

5. The lateral resistances of any beams whose sections are similar figures and alike placed are as the cubes of the like dimensions of those figures.

6. The lateral strength of a beam, with its narrower face upwards, is to its strength with the broader face upwards, as the breadth of the broader face to the breadth of the narrower.

7. The lateral strengths of prismatic beams, of the same materials, are as the areas of the sections and the distance of their centre of gravity directly, and as their lengths and weights reciprocally.

8. When the beam is fixed at both ends, the same property has place, except that in this case we must consider the beam as only half the length of the former.

9. Cylinders and square prisms have their lateral strengths proportional to the cubes of their diameters or depths directly, and their lengths and weights inversely.

10. Similar prisms and cylinders have their strength inversely proportional to their linear dimensions.

The relative resistance of wood and other bodies is shown in the following table:—

	Proportional Resistance.		Proportional Resistance.
ox, yew, plum-tree, oak	11	Alder, ash, birch, white fir, willow	6
lm, ash	$8\frac{1}{2}$	Iron	107
Walnut, thorn	$7\frac{1}{2}$	Brass	50
ed fir, holly, elder, plane, crab-tree, apple-tree	7	Bone	22
		Lead	$6\frac{1}{2}$
eech, cherry-tree, hazel	$6\frac{2}{3}$	Fine freestone	1

The following table shows the cohesive force of a square inch of different substances, from the experiments of Professor Robinson:—

	lbs.		lbs.		lbs.
Gold when cast	20	Razor steel	15	Fir	8
Silver	40	Oak and beech in the direction of their fibres from	8 to 17	Cedar	5
Cast iron	40 to 60			Ivory	16
Wrought iron	60 to 90			Bone	5
Soft steel	12	Willow	12	Rope	20

Responds. Half-piers at the east or west end of the nave, transepts, or choir. They are sometimes formed in the shape of corbels.

Ressault. (Fr.) The recess or projection of a member from or before another, so as to be out of the line or range with it.

Retable. A shelf, temporary or otherwise, between the altar and the east wall. A series of receding shelves or retables, behind and separate from the altar, is thought convenient for placing thereon vases of flowers and candlesticks.

Retaining Wall. Such as is built to retain a bank of earth from sliding down. It is is also called a revetment, or revêtement, wall. The term is usually restricted to a wall built to retain an artificial bank. One erected to sustain the force of solid ground is called a breast wall.

Reticulated. Like the meshes of a net. The *reticulatum opus* of the ancients is described under the article Masonry.

Return. The continuation of a moulding, projection, &c., in an opposite direction. A side or part which falls away from the front of a straight work.

Return Bead. See Bead and Double Quirk.

Reveal. (Lat. Revello.) The vertical side of an aperture between the front of the wall and of the window, or door, frame.

Revolution. In geometry, the motion of a point or line about a centre. Thus, a right-angled triangle, revolving round one of its legs as an axis, generates a cone in its revolution.

Rhenish Architecture. The species of Romanesque practised in the Rhine countries, differing only in subordinate features from that of other parts of Germany. Fig. 1436.

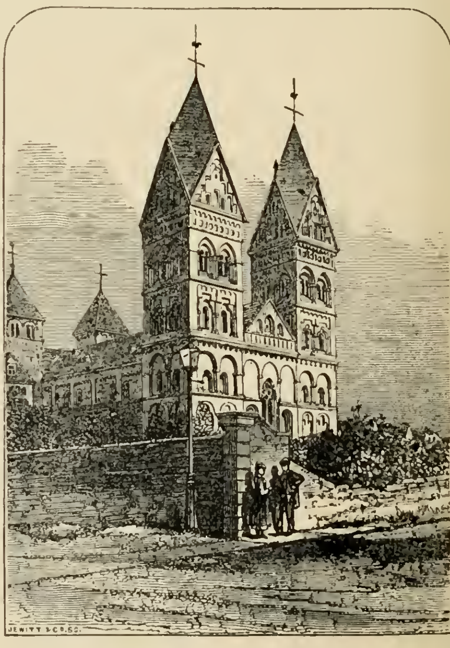


Fig. 1436. Church at Andernach.

Rhomboid. (Gr.) A quadrilateral figure whose opposite sides and angles are equal.

Rhombus. (Gr.) A quadrilateral figure, whose sides are all equal, and whose opposite angles are respectively equal, two being obtuse and two acute.

Rib. (Sax.) An arch-formed piece of timber for supporting the lath and plaster work of a vault.

Ribbing. An assemblage of ribs for a vault or coved ceiling.

Ridge. (Sax.) The highest part of a roof. The term is more particularly applied to the piece of timber against which the upper ends of the rafters pitch.

Ridge Tile. A convex tile made for covering the ridge of a roof. Slate ridging and terra cotta ridging are often employed.

Right Angle. One containing ninety degrees. A ready mode of obtaining a right angle in setting out buildings and for other purposes, is: make the vertical line equal to six divisions, the base line equal to eight similar divisions, then the distance between each point should be equal to ten such divisions, to make the angle to be obtained a right angle.

RIGHT CIRCLE. A circle drawn at right angles with the plane of projection.
RIGHT LINE. A line perfectly straight.
RISER. The upright face of a step, from tread to tread.
RISING HINGE. A hinge so formed as to raise the door as it opens, that it may pass over a carpet or mat; and thus having an inclination causing the door to close of itself. See SADDLE.
RIVET. RIVETING. A small bolt of metal forged with a head. When required for use in joining plates together, or a plate with an *angle iron* as in a girder, the bolt is made red hot, placed into the holes prepared for it, and maintained there by one person, whilst another hammers at the opposite end until its superabundant length has been driven flat against the plate. Such work is called *riveted*. See ANGLE IRON.
ROAD ROLLING MACHINE. Two steam locomotives, invented respectively by Lemoine and Ballaison, the latter having been approved as the better of the two, have been lately employed in Paris to crush and consolidate the broken granite laid on the roadways in that city. This machine has two rollers, the engine being placed between, and the boiler on one of them. With fuel and water, the weight of the Ballaison steam roller is 13½ tons with springs; and an iron framework 15¼ tons. Its strength is 10 horse-power, and its consumption of coal about 16 lb. per horse. It does its work in half the time and at half the cost that would be required were the work done by rollers drawn by horses, besides that it is performed more rapidly and completely. Over the Pont Royal, the roadway was covered with granite at ten o'clock in the evening, the rolling continued all night, and the roadway opened for traffic in the morning.
ROADWAY. In relation to any road, passage, or way, the word shall mean the whole space open for traffic, whether carriage traffic and foot traffic, or foot traffic only. Metropolis Management and Building Acts Amendment Act, 1878. STREET.
ROCKING STONE, or LOGAN. A large rough stone so placed on a small part of its bed that it can be moved to and fro with a slight force. It is classed in the Celtic period.
ROCOCO. A debased variety of the Louis XV. style of ornament. It is also applied to anything bad or tasteless in decoration.
ROD. A measure of length equal to 16½ feet. A square rod is the usual measure of brickwork, and is equal to 272½ square feet, and in London is calculated at 1½ bricks in thickness.
ROE STONE or OOLITE. A kind of limestone, found under chalk in various parts of England.
ROLL. A piece of wood prepared for the plumber to turn the lead over it, where the sheets join, so as to protect the flat roof or edge from the admission of water.
ROLL MOULDING. A moulding in the shape of a cylinder. It occurs chiefly in the Early English and Decorated periods of Gothic architecture. When it has a slight edge at one part, it is a *scroll* or *edge* moulding, or a *ressant lorymer*. When there is a fillet, it is a *roll and fillet* moulding; this is seen in the Decorated period. See KEEL.
ROLLS or ROLLERS. Among workmen are plain cylinders of wood, seven or eight inches diameter and three or four feet long, used for the purpose of moving large stones, beams, and other heavy weights. They are placed successively under the fore part of the masses to be removed, and at the same time are pushed forward by levers applied behind. When blocks of marble, or other very heavy weights, are to be moved, they use what are called *endless rolls*. Those, to give them the greater force and prevent their bursting, are made of wood joined together by cross-quarters, double the length and thickness of the common rollers, and girt with iron hoops at each end. At a foot from the ends are two mortises pierced through and through, into which are put the ends of long levers, which the workmen draw by ropes fastened to the ends, still changing the mortise as the roll has made a quarter of a turn.
ROMAN ARCHITECTURE. The style adopted by the ancient Romans from that of the Greeks. It was based upon the principle of the round arch.
ROMAN CEMENT. The common name for Parker's cement. It is now very often called "brown cement," to distinguish it from Portland or "white cement."
ROMAN ORDER. The same as COMPOSITE ORDER.
ROMANESQUE ARCHITECTURE. The style which was based upon a Roman form, and which led on to the Pointed or mediæval styles. There are many varieties of Romanesque, as Lombard, Rhenish, French, and English Norman, &c., each having its own independent developments.
ROOD. (Sax. Roþe.) A cross, crucifix, or figure of Christ on the cross placed in a church. The *holy rood* was one, generally as large as life, elevated at the junction of the nave and choir, and facing to the western entrance of the church. The *rood loft* was the gallery on which the rood and its appendages were placed. This loft, or gallery, was commonly placed over the chancel screen in parish churches. In Protestant cathedrals the organ used to occupy the original place of the rood loft, but is now almost always placed on the North side of the chancel. The *rood tower* or *steeple* was that which stood over the intersection of the nave with the transepts.

Rood. A measure equal to 36 square yards, by which rubble masonry is valued in Scotland. Rubble walls at and below 18 inches thick are reduced to one foot; and above 18 inches thick, to 2 feet. It is also a measure of land. See Measure.

Roof. The covering to a building.

Roofing. The assemblage of timbers, and covering of a roof whose pitch in this climate, for different coverings, is shown in the following table:—(See table 2040*b*.)

Species of Covering.	Inclination to the Horizon.	Height of Roof in Part of the Span.
Copper or lead	3° 50	one forty-eighth.
Large slates	22 0	one-fifth.
Common slates	26 33	one-quarter.
Stone slates	29 41	two-sevenths.
Plain tiles	29 41	two-sevenths.
Pan tiles	24 0	two-ninths.
Thatch	45 0	one-half.

Room. (Sax. Rum.) An interior space or division of a house, separated from the remainder of it by walls or partitions, and entered by a doorway. Habitable Room.

Rose or Rosette. An ornament of frequent use in architectural decorations. The centre of the face of the abacus in the Corinthian capital is decorated with what is called a rose.

Rose Window. A circular window with compartments of tracery not branching from a centre. The illustration (*fig.* 1437) is an outline from Lincoln Cathedral. Other examples may be seen at St. Ouen at Rouen, and at Beauvais in the south transept. See Book III., Chap. III., Sect. 14.

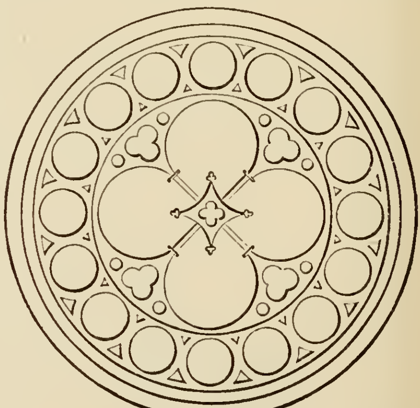

Fig. 1437.

Rostrum. (Lat.) Literally, the beak of a bird; also the beak or fore-part of a ship. The elevated platform in the Forum of ancient Rome, whence the orators addressed the people, so called from its basement being decorated with the prows of ships. The term is now used generally to signify a platform or elevated spot from which a speaker addresses his audience.

Rot. See Dry Rot.

Rotunda or Rotondo. (Ital.) A building circular on the interior and exterior, such as the Pantheon at Rome. See Circular Buildings.

Rough-cast. A species of plastering used on external walls, consisting of a mixture of lime, small shells or pebbles, occasionally fragments of glass and similar materials. This is usually applied to cottages.

Round Church or Building. See Circular Buildings.

Rubbing or Polishing. Erasing the tool marks (after *boasting* or *scabbling*) on the face of a stone, by the agency of a piece of Yorkshire, or grit, stone, used as a rubber, first with sand and water, and then with water only, by which a smooth surface is obtained, rendering the stone less liable to be affected by the atmosphere.

Rubble Work. Walls built of rag or rubble stones, in coursed or uncoursed work. In the former, the stones are roughly dressed, and laid in courses of equal height; in the latter they are used as they occur, small and large stones together as they may fit in. This last is more applicable to Gothic than to Italian architecture. See Masonry.

Rudenture. (Lat. Rudis, a rope.) The same as Cabling.

Ruderation. (Lat. Ruderatio.) A method of laying pavements, mentioned by Vitruvius, and according to some, of building walls with rough pebbles and mortar. The mortar called *statumen* by Vitruvius was made of lime and sand.

Rule. An instrument for measuring short lengths. Of rules there are various sorts, each adapted to the class of artificers for whose use they are made. Thus, there are stonecutters' rules, masons' rules, carpenters' rules, sliding rules, parallel rules, &c. The sliding rule is, however, of more general use, as it solves by inspection a number of questions from the change of the position of the slider, and therefore of much importance to the less educated artisan.

Rural Architecture. A style of architecture suited for country places, and not strictly conforming to any rules but that, perhaps, of the picturesque.

Russian Architecture. The ancient buildings are designed after the Byzantine school of art; the modern ones after the German, French, and Italian masters.

Russian Cross of the Greek Church. See Cross.

Rustic Order. A species of work where the faces of the stones are hatched or picked with the point of a hammer.

Rustic Quoins or Coins. The stones placed on the external angles of a building projecting beyond the naked of the wall. The edges are bevelled, or more or less moulded, or the margins recessed in a plane parallel to the face or plane of the wall.

Rustic Work. A mode of building masonry wherein the faces of the stones are left rough, the sides only being wrought smooth where the union of the stones takes place. It was a method much practised at an early period, and re-introduced by Brunelleschi at the revival of the arts. The most common sorts of rustic work are the *frosted*, which has the margins of the stones reduced to a plane parallel to that of the wall, the intermediate parts having an irregular surface; *vermiculated* rustic work, wherein the intermediate parts present the appearance of having been worm-eaten; *chamfered* rustic work, in which the face of the stones being smoothed and made parallel to the surface of the wall, and the angles bevelled to an angle of one hundred and thirty-five degrees, with the face of the stone, where they are set in the wall, the bevel of the two adjacent stones forms an internal right angle.

Rybat. The Scottish term for a Reveal.

S

Sacellum. (Lat.) In ancient Roman architecture, a small inclosed space without a roof. Small sacella, too, were used among the Egyptians, attached frequently to the larger temples. In old church architecture, the term signifies a monumental chapel within a church, also a small chapel in a village.

Sacrarium. (Lat.) A small sacred apartment in a Roman house, devoted to a particular deity; also the *cella*, *penetrale* or *adytum* of a temple. The name is now given to the place in a chancel enclosed by the altar rails: also called "Sanctuary."

Sacristy. A vestry attached to a church, in which the vestments, plate, and other furniture used in divine worship are kept. It was anciently called Diaconicum.

Saddle. A thin board of wood, placed on the floor in the opening of a doorway, the width of the jambs. The door being made to shut upon this piece of wood passes clear over the carpet, and does not therefore require rising hinges, used for achieving the same object.

Saddle-backed Coping. See Coping.

Saddle-back Roof. A tower having a top in the form of a common roof-gable. This form appears on a few old English towers (as at Brookthorpe Church, Northamptonshire, *cir.* 1260), and in many Continental churches.

Sag or Sagging. The bending of a body by its own weight when resting inclined or horizontally on its ends.

Sagitta. (Lat. an arrow.) A name sometimes applied to the keystone of an arch. In geometry, it is often employed to signify the abscissa of a curve; and in trigonometry it is the versed sine of an arc, which, as it were, stands like a dart upon the chord.

Sail over. See Projecture.

Saint. See Symbols of Saints.

Saliant. (Fr.) A term used in respect of a projection of any part or member.

Sally. A projecture. The end of a piece of timber cut with an interior angle formed by two planes across the fibres. Thus the feet of common rafters, and the inclined pieces which support the flying steps of a wooden stair, are frequently cut; as are, likewise, the lower ends of all inclined timbers which rest upon plates or beams.

Salon, or Saloon. (Fr.) A lofty and spacious apartment, frequently vaulted at top, and usually comprehending the height of two floors with two tiers of windows. Its place is commonly in the middle of a building, when it is sometimes lit from the top; or at the head of a gallery, etc. In palaces it is the state room.

Sanatary measures. Precautions taken for curing diseases.

Sancte-bell Cot. A small erection at the east end of the nave for the reception of the bell that gives notice of the *Sanctus* being commenced, and also to warn the people of the approaching elevation of the Host.

Sanctuary. The extreme eastern part of the chancel, containing the communion table, seats for the clergy, &c. See Sacrarium.

Sanitory measures. Precautions taken for preserving the health.

Sand. There are three sorts, river, sea, and pit sand. They are mixed with lime and cement in varying proportions. When they can be only procured mixed with earthy and clayey particles, they must be repeatedly washed until the sand becomes bright in colour and feels gritty under the fingers. Sea sand must be very well washed in fresh water, and it is doubted by some practitioners whether it can ever be freed from particles of salt, which would prevent the plaster or cement drying.

Sandstone. In mineralogy, a stone principally composed of grains, or particles of sand, either united with other mineral substances or adhering without any visible cement. The grains or particles of sandstone are generally quartz, sometimes intermixed with feldspar or particles of slate. When lime is the cementing matter the stone is called calcareous sandstone. The cementing matter is not unfrequently oxide of iron intermixed with alumine. The particles of sand in these stones are of various sizes, some being so small as to be scarcely visible.

Sap. The juice or pith of trees that rises from the earth and ascends into the arms, branches, and leaves, to feed and nourish them. Also that part of the stem or wood of the body of a tree that is soft, white, etc. The term is used also as a verb, to denote the undermining a wall by digging a trench under it.

Saracenic Architecture. See Moresque Architecture.

Sarcophagus. (Σαρξ, flesh, and φαγω, to eat.) A tomb or coffin made of one stone. From Pliny it appears to have been originally applied as the name of a stone found in the Troad, which, from its powerful caustic qualities, was selected for the construction of tombs. From its frequent application to this purpose the name became at length used for the tomb itself. Sarcophagi were made of stone, marble, alabaster, porphyry, etc. The Greeks sometimes made them of hard wood, as oak, cedar, or cypress, which resisted moisture; sometimes of terra cotta, and even of metal. The form was usually a long square, the angle being rounded. The lid varied both in shape and ornament. Those of the primitive Christians often enclosed several corpses, and were ornamented with several sets of bassi relievi. Those of higher antiquity were frequently sculptured with great taste and beauty of design, the figures being those of the deceased, or parties connected with them, allegorical or mythological. The Egyptian sarcophagi are sculptured with hieroglyphics. Those of the Greeks and Romans sometimes represent Sleep and Death with their legs crossed, one hand supporting the head and the other holding an inverted torch; sometimes Mercury is represented conducting the Souls, and Charon ferrying them over in his barque. Occasionally groups of bacchanals and bacchic scenes are found upon them.

Sarking. Thin boards for lining, etc. Boarding for slating is so called in Scotland.

Sash. (Fr. Chassis, a frame; more probably the Dutch Sas, a gate.) A frame for holding the glass of windows, and so formed as to be raised and depressed by means of pulleys. Sashes are single or double hung; the *casement* is hung with hinges.

Sash Frame. The frame in which the sashes are fitted for the convenience of sliding up and down. See Casement.

Sash lines. The rope by which a sash is suspended in its frame. They are often made of common cord, which soon untwists and breaks; the "imperial patent flax sash lines" are made in four qualities. The sash lines made of jute have neither strength nor durability. The modern brass chains are liable to break with sudden jerks.

Saw. (Dutch, Sawe.) A tool made of a thin plate of steel, formed on the edge into regular teeth for cutting wood, stone, etc. Saws are of various kinds.

Saw-pit. A pit excavated for sawing timber. The sawing is performed by two persons called *sawyers*, one standing above and the other below. Much of the labour, however, is saved by the use of a saw-mill, or machine moving a circular saw, which by its revolutions and keeping the timber close up, performs the work quicker and better than can be done by the labour just described.

Saxon Architecture. The term used to designate the early architecture used in England before the introduction of the Romanesque or Norman. The long and short work is considered the mode of building of that period. See *fig* 1412.

Scabellum. (Lat.) A species of pedestal anciently used to support busts or statues. It was high in proportion to its breadth, ending in a kind of sheath, or in the manner of a baluster.

Scaffold. (Fr. Echaufaud.) An assemblage of planks or boards sustained by pieces of wood called *putlogs* or *putlocks* placed on others called Ledgers, which are made fast to vertical poles called *standards*, by means of which workmen carry up a building of brick, or plasterers complete their work in the interior of houses. Stone-faced buildings have an inner and outer series of standards and ledgers, so that the work shall not be injured. Framed scaffolding is much used in large works, which is formed of square timbers, and on these a tram is placed for a moveable platform, or a steam crane. Suspended scaffolds are useful in repairing or painting a front. They are formed of a sort of open trough for the workmen to stand in, who raise and lower it by means of ropes attached to pulleys fixed at the end of beams secured out of upper windows or to the roof.

Scagliola. (Ital.) A species of plaster or stucco invented at Carpi, in the state of Modena, by Guido Sassi, between 1600 and 1649. It is sometimes called *mischia*, from the mixture of colours introduced in it. It was not, however, till the middle of the eighteenth century that the art of making scagliola was brought to perfection. It is used to decorate the walls of a staircase, and for columns and pilasters to a room. When well done it resembles marbles of great beauty, and to great perfection, and the best can be obtained at a less cost than the real marble.

SCALE. (Sax.) A line divided into a certain number of equal parts, usually on wood, ivory, or metal, for laying down dimensions in mathematical and architectural drawing. There are various sorts of scales; as, the *plane scale*, *Gunter's scale*, *diagonal scale*, &c.

SCALENE TRIANGLE. (Σκαληνος, oblique.) In geometry, one whose sides are all unequal.

SCALE PAPER. Paper having woven in it divisions at certain distances; or it is so prepared by printing the divisions upon it. It can be used for writing, squaring dimensions, or even for drawing in proportionate parts, or axial lines, a system of designing used by Bramante and other early Italian artists.

SCALLAGE or SCALLENGE. A term used in Herefordshire and the west of England for a lychgate.

SCALPTURATUM, OPUS. According to Pliny it resembled inlaid work, the pattern being chiselled out of the solid ground, and filled up with thin leaves of coloured marble. A beautiful example was found at Pompeii; it was first introduced into Italy after the beginning of the third Punic war, B.C. 147–103.

SCAMILLI IMPARES. A term used by Vitruvius, which has puzzled all the commentators until the investigations of Mr. Penrose, when he found that the horizontal lines of the Parthenon were inclined almost imperceptibly from the ends to the centre. These slight risings are held to explain the term. See HOGGING. The term was formerly supposed to mean a small plinth below the bases of the Ionic and Corinthian columns.

SCANDULÆ. (Lat) In early buildings of the Romans, shingles or flat pieces of wood used for covering instead of tiles. According to Cornelius Nepos, this was the only covering used in Rome till the war with Pyrrhus in the 470th year of the city.

SCANTLE. A gauge for regulating the proper length of slates.

SCANTLING. (Fr.) The dimensions of a piece of timber in breadth and thickness. It is also a term used to denote a piece of timber, as of quartering in a partition, when under five inches square, or the rafter, purlin, or pole plate of a roof. In masonry, scantling is the length, breadth, and thickness of a stone.

SCAPE or SCAPUS. (Gr.) The shaft of a column; also the little hollow, above or below, which connects the shaft with the base, or with the fillet under the astragal.

SCAPLING or SCABBLING. A method of tooling the face of a stone.

SCARFING. The joining of two pieces of timber transversely together, so that the two appear but one. Large timbers are likewise bolted together.

SCENE. (Gr. Σκηνη.) Strictly an alley or rural portico for shade or shelter, wherein, according to Cassiodorus, theatrical pieces were first represented. When first applied to a theatre, it signified the wall forming the back of the stage, but afterwards came to mean the whole stage, and is now restricted to the representation of the place in which the drama represents the action. According to Vitruvius, the Greek scene was occupied in the middle by a great door, called the royal door, because decorated as the gate of a palace. At the sides were smaller doors, called *hospitalia*, because representing the entrances to habitations destined for strangers, which the Greeks commonly placed on the two sides of their houses.

SCENOGRAPHY. (Gr.) The method of representing solids in perspective.

SCHEDULE OF PRICES. A document forming part of a contract, and intended to be used for ascertaining (after execution) the sum to be paid for works performed, whether by measurement or by daywork. Where a "bill of quantities" has not been prepared, or where the extent of work cannot be exactly settled beforehand, a schedule is usually adopted. For certain works a schedule is fully priced out, and tenders invited at a percentage above or below such prices, either over the whole, or on or off each particular trade.

SCHEME or SKENE ARCH. One which is a segment of a circle.

SCHENE. (Gr.) The representation of any design or geometrical figure by lines so as to make it comprehensible.

SCHOLIUM. In mathematics, a remark after the demonstration of a proposition, showing how it may be done some other way, or giving some advice or precaution to prevent mistakes, or adding some particular use or application thereof.

SCHOOL OF ART. See COLLEGE and MUSEUM.

SCHOOL. A building for elementary, practical, general, or special education, and preliminary to university institutions. In Germany, compulsory education is a fact, and absentees are fined. The schools are so arranged that a child can pursue a course of training which will most fit him for his future career. There are Elementary schools;

next the Burgher schools, at which children of the lower middle classes are educated; the Realschulen, consisting of three kinds of instruction; the Practical school, in which scientific subjects are taught; then the Gymnasium, which forms a stepping-stone to the University or the Polytechnic school, to qualify for any business or profession.

Sciagraphy or Sciography. (Gr. Σκια, a shadow, and Γραφω, I describe.) The doctrine of projecting shadows as they fall in nature.

Sconcheon. (Fr. Écoinçon.) The portion of the side of an aperture, from the back of the jamb or reveal, to the interior of the wall.

Scotia. (Gr. Σκοτια, darkness.) The hollow moulding in the base of a column between the fillets of the tori. It receives the name from being so much in shadow. The scotia was, from its resemblance to a pulley, called also τροχιλος. It is most frequently formed by the junction of arcs of different radii, but it ought rather to be profiled as a portion of an ellipsis.

Scratch Work. (It. Sgraffiata.) A coloured plaster being laid on the face of the building, it is covered with a white one, which being scratched through to any design with an iron bodkin, the coloured work appears through and makes the contrast. It is an Italian method of decorating a plain surface, and is now being much carried out in England.

Screed. In plastering or cementing large spaces, a ledge of about 4 inches and of the proper thickness is carefully formed, every 4, 5, or 6 feet apart, to form a gauge for the remainder of the work, which is then applied in the panel, a long float being worked over it, forcing off the superfluous plaster, and a clear and even face is obtained.

Screen. (Lat. Excerno.) An instrument used in making mortar, consisting of three wooden ledges joined to a rectangular frame at the bottom, the upper part of which frame is filled with wire-work for sifting the sand or lime. This term is used in ecclesiastical architecture to denote a partition of wood, stone, or metal, usually so placed in a church as to shut out an aisle from the choir, a private chapel from a transept, the nave from the choir, the high altar from the east end of the building, or an altar tomb from a public passage of the church. In the form and ornamental detail of screens, the ancient artists appear to have almost exhausted fancy, ingenuity, and taste.

Screw. (Dutch, Schroeve.) One of the six mechanical powers, chiefly used in pressing or squeezing bodies close, though sometimes also in raising weights, as a screw-jack.

Scribing. Fitting the edge of a board to a surface not accurately plane, as the skirting of a room to a floor. In joinery, it is the fitting one piece to another, so that their fibres may be perpendicular to each other, the two edges being cut to an angle to join.

Scroll. A convolved or spiral ornament variously introduced. Also the volutes of the Ionic and Corinthian capital. The subjoined woodcut is called a Vitruvian scroll.

Scullery. The apartment for washing up dishes and utensils wherein the scullion works.

Sculpture. (Lat. Sculpo, to carve.) The art of imitating forms by chiselling and working away solid substances. It is also used to denote the carved work itself. Properly, the word includes works in clay, wax, wood, metal, and stone; but it is generally restricted to those of the last material, the terms *modelling*, *casting*, and *carving* being applied to the others. See Frieze, Pediment, and Metopæ.

Sealing. The fixing a piece of wood or iron on a wall with plaster, mortar, cement, lead or other binding, for staples, hinges, joints, &c.

Seasoned Timber. Timber that has undergone a proper process of air or hot air drying so as to render it fit to be used in building.

Secant. (Lat.) A line that cuts another. In trigonometry, the secant is a line drawn to the centre from some point in the tangent, which consequently cuts the circle.

Secos. (Gr.) See Adytum.

Section of a Building. A geometrical representation of it as divided or separated into two parts by a vertical plane, to show and explain the construction of the interior. The section not only includes the parts that are separated, but also the elevation of the receding parts, and ought to be so taken as to show the greatest number of parts, and those of the most difficult construction. Of every building at least two sections should be made at right angles to one another, and parallel to the sides. A section of the flues should also be made, in order to avoid placing timbers near them.

Section of a Solid. The plane of separation dividing one part from the other. It is understood to be always a plane surface.

Sector. An instrument for measuring or laying off angles, and dividing lines and circles into equal parts.

Sector of a Circle. The space comprehended between two radii and the arc terminated by them.

Sedilia. (Lat.) Seats recessed in the south wall of the sanctuary of a church, and formerly provided for the clergy in the sacrifice of the mass, during that part of the office in which the "Gloria" and "Credo" are sung. They are now also provided in

Protestant churches for the officiating clergy, usually three—priest, deacon and sub-deacon.

SEGMENT OF A SPHERE. A portion cut off by a plane in any part except the centre, so that the base of such segment must be always a circle, and its surface a part of the sphere.

SEGMENT. (Lat.) A part cut off from anything. Thus, *fig.* 1438 shows a segmental arch. The area contained by the arc of a circle and a chord. In the segment of a circle the chord of the arc is called the base of the segment, and the height of the arc the height of the segment.

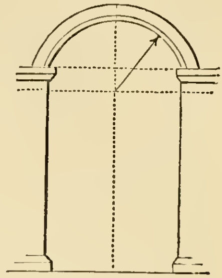

Fig. 1438.

SELL. See CILL and APERTURE.

SEMICIRCLE. The half of a circle contained by the diameter and circumference.

SEMICIRCULAR ARCHES. Those whose arcs are semicircular, as in *fig.* 1439.

SEPULCHRE. (Lat. Sepelire, to bury.) A grave, tomb, or place of interment. The *cenotaph* was an empty sepulchre raised in honour of a person who had had no burial. See EASTER, or HOLY SEPULCHRE; and MAUSOLEUM.

SERAGLIO. (Pers. Serai.) A large hall or house. The palace of an Eastern prince, but more particularly that in which the females are lodged.

SERPENTINE. See PORPHYRY.

SESQUIALTERAL. In the proportion of one and a half.

SESSPOOL. See CESSPOOL.

SETT. In piling, a piece placed temporarily on the head of a pile which cannot be reached by the monkey or weight from some intervening matter.

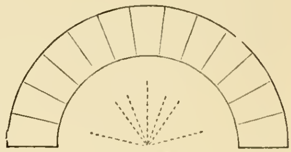

Fig. 1439.

SETTING. The hardening of mortars and cements. The term is also used in masonry for fixing stones in walls or vaults, in which the greatest care should be taken that the stones rest firmly on their beds, and that their faces be ranged in the proper surface of the work.

SETTING-OUT ROD. One used by joiners for setting-out frames, as of windows, doors, &c.

SETTLEMENTS. Those parts in which failures by sinking in a building have occurred.

SETT-OFF. The projecting part between the upper and lower portion of a wall where it diminishes in thickness.

SEVERY. A compartment or division of scaffolding. It is also a separate portion or division of a building corresponding with the modern term compartment, being as it were severed or divided.

SEWER. A large drain or conduit for carrying off soil or water from any place.

SEXAGESIMAL. The division of a line, first into sixty parts, then each of these again into sixty, and so on, as long as division can be made. It is principally used in dividing the circumference of a circle.

SGRAFFITO (Ital.) See SCRATCH WORK.

SHADOWS and SHADOWING. In drawing, the art of correctly casting the shades of objects and representing their degrees of shade.

SHAFT. The cylindrical part, or rather body, of a column, between the base and the capital. It is, properly, the frustum of a conoid, and is also called the *fust*, *trunk*, or *body* of the column. The term is also applied to the pier supporting arches in mediæval architecture, as in the nave of a church.

SHAFT OF A CHIMNEY. See CHIMNEY.

SHAFT OF A KING POST. The part between the *joggles*.

SHAKE. A fissure or rent in timber by its being dried too suddenly, or exposed to too great heat. Any timber, when naturally full of slits or clefts, is said to to be *shaky*.

SHAMBLE. The old name for a place for slaughtering cattle, now called *abattoir*.

SHANK. (Sax.) The space between two channels of the Doric triglyph, sometimes called the leg of the triglyph. The Romans called the shank, *femur*.

SHEARING. The action of cutting short off, as a pair of scissors acts upon paper. It is applied to a plate of metal acting upon a bolt or rivet.

SHEET GLASS. Glass blown into a "muff," which is slit on one side, and opened out flat. A superior sort of sheet glass is "flattened" by a rubbing whilst it is in the annealing kiln, and hence its name.

SHEET LEAD. Lead cast into a sheet, in contradistinction to lead rolled out by a mill.

SHELF. (Sax.) A board fixed against a wall, the upper side being horizontal, for receiving whatever may be placed upon it. A shelf is usually supported by brackets, or by pieces at the end, called *standards*. See SUNK SHELF.

SHILF. Slate broken into small pieces, as employed for mending roads in Cornwall.

Shingles. (Germ. Schindel.) Loose stones sifted from gravel for making concrete. Also the small slab of oak bark or split pieces of wood, used instead of tiles in former times, and still usually so employed in the backwoods of America and other countries. They are about eight to twelve inches long, and about four inches broad, thicker on one edge than the other. The process of making a roof of this kind is called *shingling*.

Shoe. The inclined piece at the bottom of a rain-water pipe for turning the course of the water, and discharging it from the wall of a building.

Shooting. Planing the edge of a board straight, and out of winding.

Shooting Boards. Two boards joined together, with their sides lapped upon each other, so as to form a rebate for making short joints.

Shore, or Shoar. (Sax.) A prop or oblique timber acting as a brace on the side of a building, the upper end resting against that part of the wall upon which the floor is supported, and both ends received by plates or beams. A *dead shore* is an upright piece built up in a wall that has been cut or broken through for the purpose of making some alterations in the building. The terms "needle," "tossle," "joggle," and "stud" are used among workmen to denote the piece of wood inserted in a wall above the head of a raking shore. A "waling" is a piece of timber placed horizontally against the side of a trench and strutted across it; a "setting" is a rectangular frame holding all four sides of an excavation. "Cleadings" used with "settings" serve the same purpose as "poling boards" in connection with walings.

Shoulder of a Tenon. The plane transverse to the length of a piece of timber from which the tenon projects. It should be at right angles to the length, though it does not always lie in the plane as here defined, but sometimes in different planes.

Shouldering. In slating, a fillet of haired lime laid upon the upper edge of the smaller and thicker kinds of slates, to raise them and prevent their being open at the lap; it also makes the joint weathertight. Sometimes the whole surface under the heads of any sized slates is so done, to prevent the slates cracking when stepped on.

Shread Head. The same as Jerkin Head.

Shreddings or Furrings. In old buildings, short slight pieces of timber fixed as bearers below the roof, forming a straight line with the upper side of the rafters. Tilting fillet.

Shrine. (Sax. Scrin.) A desk or cabinet; a case or box, particularly one in which sacred things are deposited: hence applied to a reliquary and to the tomb of a canonised person. The altar is sometimes called a shrine.

Shrinking. The contraction of a piece of timber in its breadth by drying. The length does not change. Hence in unseasoned timber mitred together, such as the architraves of doors and windows, the mitres are always close on the outside and open to the door, forming a wedge-like hollow on each side of the frame. Narrow boards called *battens* are used in floors, as the shrinking, if any, is less.

Shutters. The framed boards which shut up the aperture of a window, or of a light.

Side Posts. Truss posts placed in pairs, disposed at the same distance from the middle of the truss. Their use is not only to support the principal rafters, &c., but to suspend the tie beam below In extended roofs two or three pair of side posts are used.

Side Timbers or Side Wavers. The same as purlins, the first term being used in Somersetshire and the last in Lincolnshire.

Silicate Cotton or Slag Wool. A pure mineral fibre made from blast furnace slag. It is white and like spun glass. It is extremely light, a cube foot weighs only from 16 to 18 lbs., and one ton covers about 1800 to 2,400 square feet one inch thick. It is a good non-conductor of heat and sound.

Sill. See Cill and Aperture.

Silt. The muddy deposit of standing water.

Sima. See Cyma.

Similar Figures. Those whose several angles are respectively equal, and the sides about the equal angles proportional.

Sine. A right line drawn from one end of an arch perpendicular upon the diameter, or it is half the chord of twice the arch. The sine of the complement of an arch is the sine of what the arch wants of ninety degrees. The *versed sine* is that part of the diameter comprehended between the arc and the sine.

Single Frame, Single Joist, and Naked, Floor. One with only one tier of joists.

Single Hung. An arrangement in a pair of window sashes, in which one only is movable.

Single Measure. A term applied to a door that is square on both sides. *Double measure* is when the door is moulded on both sides. When doors are moulded on one side, and are square on the other, they are accounted measure and a half.

Single Span Church. A church having a very wide nave. Such is the church of the Dominicans at Ghent, 1240–75, with a nave of 53 feet between the piers slightly projecting from the wall, covered by a wooden vaulting on curves of 60 feet radius. (See par. 557.) The reader is referred to the *Builder* journal, for 1867, pp. 661, 687, 700 716, for many notices of such structures.

SITE. (Lat. Situs.) The situation of a building; the plot of ground on which it stands.

SKEW. The sloping top of a buttress where it slants off into a wall, or the coping of a gable.

SKEW BACK. In a straight or curved arch, that part of it which recedes beyond the springing from the vertical line of the opening.

SKEW CORBEL. See SUMMER STONE.

SKIFFLING. See KNOBBLING.

SKIRTING or SKIRTING BOARD. The narrow board placed round the margin of a floor which, where there is a dado, forms a plinth for its base; otherwise, it is a plinth for the room itself. Skirting is either scribed close to the floor or let into it by a groove; in the former case a fillet is put at the back of the skirting to keep it firm.

SKIRTS. Several superficies in a plane, which would cover a body when turned up or down without overlapping.

SKIRTS OF A ROOF. The projection of the eaves.

SKREEN. See SCREEN.

SKYLIGHT. A frame consisting of one or more inclined planes of glass, placed in a roof to light passages or rooms below. See LANTERN LIGHT; LIGHTING.

SLAB. An outside plank or board sawed from the sides of a timber tree, and frequently of very unequal thickness. The word is also used to express a thin piece of marble, consisting of right angles and plane surfaces.

SLAB. The *front hearth* of a fireplace. The Metropolitan Buildings Act, 1855, requires that "There shall be laid, level with the floor of every story, before the opening of every chimney, a slab of stone, slate, or other incombustible substance, at the least twelve inches longer than the width of such opening, and at the least eighteen inches wide in front of the breast thereof:—That on every floor, except the lowest floor, such slab shall be laid wholly upon stone or iron bearers, or upon brick trimmers; but on the lowest floor it may be bedded on the solid ground:—and That the hearth or slab of every chimney shall be bedded wholly on brick, stone, or other incombustible substance, and shall be solid for a thickness of seven inches at the least beneath the upper surface of such hearth or slab." Such precautions are too frequently neglected in country houses, to their ultimate destruction by fire. No timbers should be placed under the hearths on any account. See TIMBERS.

SLATE. A species of argillaceous stone, an abundant and very useful material. It can be sawn to a very large size or split into thin plates, of any required thickness; being non-absorbent it is used for roofing, and for water cisterns. There are varieties of blue, red, and green in colour.

SLATERS' WORK. Laying slates on roofs; forming water cisterns; and a few other matters connected therewith, constitute this artificer's work. See SHOULDERING.

SLEEPERS. Horizontal timbers disposed in a building next to the ground transversely under walls, ground joists, or the boarding of a floor. When used on piles they are laid upon them, and planked over to support the superincumbent walls. Underground joists either lie upon the solid earth, or are supported at various parts by props of brickwork or stones. When in the former position, having no rows of timber below, these ground joists are themselves called sleepers. Old writers on practical architecture call those rafters lying in the valley of a roof, sleepers; but in this sense the word is now obsolete.

SLIDING RULE. One constructed with logarithmic lines, so that by means of another scale sliding on it, various arithmetical operations are performed merely by inspection.

SLIT DEAL. See BOARD.

SLOPE OF A ROOF. See ROOFING; and PITCH. OF A ROAD, see GRADIENT.

SLUICE. A stop against water for the drainage or supply with water of a place. It is hung with hinges from the top edge when used merely as a stop against the water of a river: but when made for supply as well, it moves vertically in the groove of its frame by means of a winch, and is then called a penstock.

SMITHERY. The art of uniting several lumps of iron into one lump or mass, and forming them into any desired shape. The Foundry is a branch of it.

SMOOTHING PLANE. The plane last used by the joiner to give the utmost degree of smoothness to the surface of the wood, and is chiefly for cleaning off finished work. It is $7\frac{1}{2}$ inches long, 3 inches broad, and $2\frac{3}{4}$ inches in breadth.

SNACKET. A provincial term for the hasp of a casement.

SNIPE'S BILL PLANE. One with a sharp arris for getting out the quirks of mouldings.

SOCKET CHISEL. A strong tool used by carpenters for mortising, and worked with a mallet.

SOCLE or ZOCLE. (It.) A square member of less height than its horizontal dimension, serving to raise pedestals, or to support vases, &c. The socle is sometimes continued round a building, and is then called a *continued socle*. It has neither base nor cornice.

SOFFITA, SOFFIT, or SOFITE. (Ital.) A ceiling; the lower surface of a vault or arch. A term denoting the under horizontal face of the architrave between columns; the under surface of the corona of a cornice.

SOIL. The same as ground and earth: it is also used to denote the deposit in a cesspool from a water-closet or privy.

Soils. A provincial term, chiefly, however, used in the north, signifying the principal rafters of a roof.

Solar, or Sollar. A mediæval term for an upper chamber: a loft.

Solder. A soft metallic composition used in joining together or *soldering* metals. See Brazing and Welding.

Solid. (Lat.) In geometry, a body which has length, breadth, and thickness: that is, it is terminated or contained under one or more plane surfaces as a surface is under one or more lines. Regular solids are such as are terminated by equal and similar planes, so that the apex of their solid angles may be inscribed in a sphere.

Solid Angles. An angle formed by three or more angles in a point, and of which the sum of all the plane angles is less than three hundred and sixty degrees otherwise they would constitute the plane of a circle and not of a solid.

Solid Shoot. See Water-Shoot.

Sommering. See Summering.

Sortant Angle. The same as Salient Angle.

Sound-board. The canopy or type fixed over a pulpit, to reverberate the voice of the speaker.

Sound-boarding. In floors, consists of short boards placed transversely between the joists, and supported by fillets fixed to the sides of the latter for holding pugging, which is any substance that will prevent the transmission of sound from one story to another, such as a mixture of mortar and chopped straw, or sawdust. The narrower the sound-boards the better; the fillets on which they rest may be three-quarters of an inch thick and about an inch wide, nailed to the joists at intervals of a foot. It has been suggested to put an india-rubber washer of about the same width as the joist, between the ceiling joist and the joist, having a thickness of half an inch when properly screwed up, to effect the same object. See Boarding for Pugging.

Souse, (Fr.) or Source. A support or under prop.

Spalls. Stone broken up into shapeless lumps. "Spawled masonry" in Ireland, consists of these lumps, about 6 to 14 inches, worked up in a wall, the joints of each stone matching those of the others around it; the faces of the stones are usually rough dressed with the hammer. It is the "uncoursed rubble work" of England. See Spawled.

Span. An imaginary line across the opening of an arch or roof, by which its extent is measured. The width of a vault or arch between the springing.

Span Church. See Single Span Church.

Span Roof. One consisting of two inclined sides, in contradistinction to a *shed* or *lean-to roof*. It may be with simple rafters, with or without a collar beam, or when of increased span it may be trussed, the term only applying to the external part.

Spandrel. The irregular triangular space between the outer curve or extrados of an arch, a horizontal line from its apex, and a perpendicular line from its springing. In mediæval architecture they are often filled with figures, medallions, shields, as at York cathedral, or diaper work as at Westminster Abbey. In the Italian style, they are often filled with figures, or compositions relating to the purposes for which the building is erected.

Spandrel Bracketing. A cradling of brackets fixed between one or more curves, each in a vertical plane, and in the circumference of a circle whose plane is horizontal.

Spanish Architecture. The styles adopted were those introduced by the ancient Romans, the Moors, by French and German mediæval practitioners, and by the Italian masters brought into the country by the monarchs and others.

Spar-piece. A name given in some places to the collar beam of a roof.

Spars. The common rafters of a roof for the support of the tiling or slating.

Spawled. A block of stone after the chips or spawls have been knocked off. See Spalls.

Specification. A description at length of the materials and workmanship to be used and employed in the erection of any building.

Specific Gravity. A gravity or weight of every solid or fluid compared with the weight of the same magnitude of rain water, which is chosen as the standard of comparison, on account of its being subject to less variation in different circumstances of time, place, &c., than any other solid or fluid. By a fortunate coincidence, at least to the English philosopher, it happens that a cubic foot of rain water weighs 1,000 ounces avoirdupois; consequently, assuming this as the specific gravity of rain water, and comparing all other bodies with this, the same numbers that express the specific gravity of bodies will at the same time express the weight of a cubic foot of each in avoirdupois ounces, which affords great facility to numerical computations. Hence are readily deduced the following laws of the specific gravity of bodies:—

1. In bodies of equal magnitudes the specific gravities are directly as the weights or as their densities. 2. In bodies of the same specific gravities the weights will be as the magnitudes. 3. In bodies of equal weights the specific gravities are inversely as the magnitudes. 4. The weights of different bodies are to each other in the compound ratio of their magnitudes and specific gravities.

Thus, it is obvious, that if of the magnitude, weight, and specific gravity of a body any two be given, the third may be found; and we may thus arrive at the magnitude of bodies which are too irregular to admit of the common rules of mensuration; or, by knowing the specific gravity and magnitude, we may find the weight of bodies which are too ponderous to be submitted to the action of the balance or steel yard; or, lastly, the magnitude and weight being given, we may ascertain their specific gravities.

Specus. (Lat.) In ancient architecture, the canal in which the water flowed in aqueducts raised above the surface of the ground, and constructed of hewn stones or bricks. It was covered with a vault to preserve the water from the sun, and from being mixed with rain water. The specus was sometimes covered with flat stones, laid horizontally, as in the Aqua Martia, part of the Aqua Claudia, and the aqueduct of Segovia. Sometimes the same arcade carried several of these canals one above the other.

Speroni. See Anterides.

Sphæristerium. A building for the exercise of the ball; a tennis court. The ancients generally placed sphæristeria among the apartments of their baths and gymnasia. They were also placed in large villas, as in those of Pliny the younger.

Sphere. (Gr. Σφαιρα.) A solid, whose surface is at every point equally distant from a certain point within the solid, which point is called the *centre of the sphere.* Every sphere is equal to two-thirds of its circumscribing cylinder, that is, it is equal to a cylinder whose ends are circles, equal to a great circle of the sphere, and whose height is equal to the diameter of the same.

Spherical Bracketing. That so formed that the surface of the plastering which it is to receive forms a spherical surface.

Spheroid. See Conoid.

Spheroidal Bracketing. That formed to receive the plastering of a spheroid.

Spina. See Circus.

Spiral. A curve which makes one or more revolutions round a fixed point, and does not return to itself. See Volute.

Spire. (Gr. Σπαιρα, a twisting.) In ancient architecture, the base of a column, and sometimes the astragal or torus. The termination of the tower of a church, generally diminishing, and either pyramidally or conically. See Steeple.

A spire which is octagonal, the sides facing the cardinal points being continued to the eaves which project over the lower work, and the diagonal faces being intercepted at the bottom by semipyramidal projections whose edges are carried from the angles of the tower upwards, terminating in points on the corresponding oblique faces of the spire, is called a *broach* (Fr. Broche, a spit).

The following table gives the heights of many of the chief Towers and Spires, but it is liable to correction, for it is very difficult to obtain accurate dimensions of any structure or parts of one.

	feet.		feet.
Strasburg	468	Grantham	274
Salisbury	400 or 404	Lichfield	252
St. Paul's, London	313, 365, 356 or 404	Wakefield	247
Milan	400	Boston	268
Amiens	422	Lincoln	262
Coventry	320	Canterbury	229
Norwich	309 or 313	Gloucester	225
Louth	294	Westminster	225
Chichester was	271	Ely and Durham	215

Splay. A slanting or bevelling in the sides of an opening to a wall for a window or door, so that the outside profile of the window is larger than that of the inside; it is done for the purpose of facilitating the admission of light. It is a term applied to whatever has one side making an oblique angle with the other: thus, the heading joists of a boarded floor are frequently splayed in their thickness. The word *fluing* is sometimes applied to an aperture, in the same sense as *splayed.*

Spring Bevel of a Rail. The angle made by the top of the plank, with a vertical plane touching the ends of the rail piece, which terminates the concave side.

Springed or Sprung. In boarding a roof, the setting the boards together with bevel joints, for the purpose of keeping out the rain. See Boarding for Slating.

Springer. The impost or place where the vertical support to an arch terminates, and the curve of the arch begins; the term is sometimes used for the *rib* of a groined roof.

Springing Course. The horizontal course of stones, from which an arch springs or rises; or that row of stones upon which the first arch stones are laid.

Spudds and Rings. A method adopted in Ireland of securing the posts of a door, in a basement story, by a *ring* of iron into which the post is placed, with a projection or spud for insertion into a corresponding hole in the sill or step.

Spur. Carved timberwork at the doorway of old houses, to support a projecting upper story; some fine examples of the fourteenth century exist in York and other old towns.

Square. (Lat. Quadra.) A figure of four equal sides, and as many equal angles. An area of such form surrounded by houses, and ornamented in the centre with a lawn, shrubs, trees, &c. In joinery, a work is said to be *square framed*, or *framed square*, when the framing has all the angles of its styles, rails, and muntins square without being moulded. The word is also applied to an instrument for setting out angles square. See Carpenter's Square. It is also a measure used in building, of 100 superficial feet.

Square Shoot. A wooden trough for discharging water from a building.

Square Staff. A piece of wood placed at the external angle of a projection in a room, to secure the angle, which if of plaster would be liable to be broken, and at the same time to allow a good finish for the papering.

Squaring a handrail. The method of cutting a plank to the form of a rail for a staircase, so that all the vertical sections may be right angles.

Squaring a piece of stuff. The act of trying it by the square, to make the angles right angles.

Squinch. A small arch, or set of arches, formed across an angle, as in a tower, to form a base for an octagon construction above it.

Squint. See Hagioscope.

Stable. Lat.) A building for the accommodation of horses.

Stack of Chimneys. See Chimney.

Stadium. (Gr.) In ancient architecture, an open space wherein the athletæ or wrestlers exercised running, and in which they contested the prizes. It signifies also the place itself where the public games were celebrated, which often formed a part of the gymnasia. The word also denotes a measure of length among the Grecians, of 125 paces.

Staff Bead. See Angle-Bead; Square Staff.

Stage. A floor or story. In a theatre, the floor on which the performers act. The stage of a buttress is, in ecclesiastical architecture, the part between one splayed projection and the next.

Stained Glass. Glass stained throughout its thickness during its manufacture is known as "pot metal" glass. White glass is sometimes coloured on the surface only, whence it is called "flashed" glass. Both sorts are used for decorating windows in patterns, as in churches. See Painted Glass.

Staircase. That part or subdivision in a building containing the stairs, which enable persons to ascend or descend from one floor to another.

Stairs. (Sax. Stægen, to step.) Stones, or other material forming steps, ranged one above and beyond another, by which a person can ascend a height. A series of steps or stairs for ascending from the lower to the upper part of a building, when enclosed, is called a staircase.

Stalk. (Sax.) An ornament in the Corinthian capital, which is sometimes fluted, and resembles the stalk of a plant; from it spring the volutes and helices.

Stall. (Sax.) A place or division in a stable wherein one horse is placed for feeding and sleeping. According to their number in a stable it is called a one-stall, two-stall, &c., stable. This word is also used to denote the elevated seats in the choir or chancel of a church appropriated to ecclesiastics. The precentor's stall is the first return stall on the left on entering the choir. The dean's stall is the first return stall on the *right*.

Stanchion. (Fr. Estançon.) A prop or support. The upright iron bars of a window or open screen. Also a Puncheon.

Standards. The upright pieces in a plate rack; or above a dresser to support the shelving. When the edges of standards are cut into mouldings, according to the widths of the shelves, and across the fibres of the wood, they are called *cut standards*.

Staple. A small piece of iron pointed at each end, and bent round, so that the two ends may be parallel to each other, and of equal lengths, to be driven into wood or into a wall, thus forming a loop for fastening a hasp or bolt.

Star Moulding. One of the usual decorations of a surface in Norman architecture. *Fig.* 1440.

Fig. 1440.

Starlings or Sterlings, sometimes called Stilts. An assemblage of piles driven round the piers of a bridge to give it support.

Statics. See Mechanics.

Statuary Marble. The pure white marble, such as is obtained from Carrara, and used by sculptors and carvers for their best works.

Statumen. A mortar of lime and sand used by the Romans for pavements, as stated by Vitruvius. vii. 1. See Ruderation.

Staves. Small upright cylinders, sometimes called *rounds*, for forming a rack to contain the hay in a stable for the supply of it to the horse.

Stay. A piece performing the office of a brace, to prevent the swerving of the piece to which it is applied. The term is general, and applies to all materials.

Steel. (Sax. Stal.) Iron which possessed the properties of hardening and tempering, those properties depending essentially on the presence of carbon with the iron. Steel now, however, generally includes many varieties of materials, which can be no more tempered or hardened than many qualities of wrought iron. The only difference between cast iron and steel was the proportion of carbon; pure iron contained no carbon. The steel generally used for girder-work and plates contained perhaps $\frac{2}{10}$ per cent. of carbon, and directly it got to 1 and $1\frac{1}{2}$ per cent. it became cast iron. It is also cheaply made, for great masses, by abstracting carbon from cast iron. The process for converting iron into steel was known to the ancients.

Steening. The brickwork laid dry (that is, without mortar), for forming the cylindrical shaft of a well or cesspool, to prevent the irruption of the surrounding soil.

Steeple. (Sax. Stepel.) A lofty erection attached to a church, chiefly intended to contain its bells. The word is a general term, and applies to every appendage of this nature, whether tower or spire, or a combination of the two.

Step. A block of any material, and of such a height as is within a moderate lift of a person's foot, say, seven inches at most. A series of steps form stairs.

Stereobata. See Pedestal.

Sereographic Projection. That projection of the sphere wherein the eye is supposed to be placed on the surface.

Stereography. (Gr. Στερεος, solid, and Γραφω, I describe.) That branch of solid geometry which demonstrates the properties and shows the construction of all regularly defined solids; it explains the methods for constructing the surfaces on planes, so as to form the entire body itself, or to cover its surface; or, when the solid is bounded by plane surfaces, the inclination of the planes.

Stereotomy. The science of cutting solids to suit the conditions required for their forms.

Sticking. The operation of forming mouldings by a plane, in contradistinction to forming them by hand. When done they are said to be *stuck*.

Stile. (Sax.) The vertical part of a piece of framing into which, in joinery, the ends of the rails are fixed by mortises and tenons.

Stillicidium. Dripping eaves to Doric buildings; but in the propylæum at Eleusis, the sima or upper moulding of the pediment cornice, is continued along the flanks, and a channel hollowed in it to collect the rain falling on to the roof.

Still Room. A room in a large mansion, wherein the housekeeper and her assistant prepare tea and coffee for the family and visitors, and make preserves, cakes, and biscuits, and so on. It was formerly the work-room of the lady of the house when engaged in making household cordials. In a smaller class of residence, this room frequently relieves the kitchen of all the lesser cooking, and of pastry making. It should adjoin the store and housekeeper's rooms.

Stilt. See Starling.

Stilted Arch. One in which the spring of the arch begins not immediately from the imposts, but from a vertical piece of masonry or brickwork resting on them, so as to give to the arch an appearance of being on stilts (*fig.* 1441). In describing the cave temples at Elephanta, Freeman, *History of Architecture*, p. 56, notes, "the stilt or *dé* above the capital of the piers, and the manner in which it spreads into the roof; this would seem to be the rudest and most primitive form of the bracket capital, though it has less projection, and extends only in two directions." And in the Addenda, he says "for this very expressive word *stilt* I am under an obligation to a paper by Professor Orlebar. It expresses a portion of masonry above the regular column, which is constructively part of the pier, but in the direction assumes the form either of a portion of the arch or of a distinct member." The first confirmed use of the stilt occurs in the Arabian buildings at Cairo, where it may have been suggested by the *dé* of the anterior Egyptian style. In p. 272 he further says, "stilted arches cannot be always avoided where openings of different breadth are required to be of the same height."

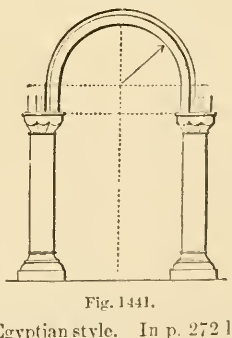

Fig. 1441.

Stoa. (Gr.) In Grecian architecture, a term corresponding with the Latin *porticus*, and the Italian *portico*.

Stock. The part of a tool for boring wood with a crank whose end rests against the breast of the workman, while with one hand he holds the boring end steady, and with the other turns the crank; the steel borers are called *bits*, and the whole instrument is called a *stock and bit*.

STONE. (Sax.) A natural indurated substance found beneath and on the surface of the earth in almost every part of the world, and which for its strength and durability has been universally employed for building purposes.

STONEWARE. A prepared clay, burnt and glazed to prevent water soaking through it; and used for jars, bottles, drain pipes, &c.

STOOL. The name given to the bench whereon the brick-moulder moulds his bricks.

STOOTHING. A provincial term which signifies the battening of walls. See TOOTHING

STOP-COCK. A cock used in plumbery to turn off the supply to a reservoir or tank.

STOPPING. Making good cracks or defects in plastering, wood, &c.

STORY. (Lat. or Sax. Scop.) One of the vertical divisions of a building; a series of apartments on the same level.

STORY POSTS. Upright timbers disposed in the story of a building for supporting the superincumbent part of the exterior wall through the medium of a beam over them; they are chiefly used in sheds and workshops, and should have either a solid wall below or stand upon a strong wooden sill upon inverted arches, or upon large stones with their ends let into sockets. They also form the posts at the ends of a trussed partition.

STORY ROD One used in setting up a staircase, equal in length to the height of the story, and divided into as many parts as there are intended to be steps in the staircase, so that they may be measured and distributed with accuracy.

STOUP. See PISCINA.

STOVE. An enclosed fire grate for the purpose of obtaining a large amount of heat. A chamber prepared specially for drying articles by heated air is often called a *Stove.*

STRAIGHT ARCH. A lintel formed of separate pieces or voussoirs on the principle of the arch.

STRAIGHT JOINT FLOOR. See FLOOR.

STRAIN. (Sax. Streng.) The force exerted on any material tending to disarrange or destroy the cohesion of its component parts.

STRAINING PIECE OR STRUTTING PIECE. A beam placed between two opposite beams to prevent their near approach, as rafters, braces, struts, &c. If such a piece serves also the office of a sill, it is called a *straining sill.*

STRAP. (Dutch, Stroppe.) An iron plate for the connection of two or more timbers, into which it is screwed by bolts.

STREET. A public way for general traffic. The Metropolitan Board of Works, under the "Metropolis Local Management Act, 1885," sect. 202, has power to compel notice of laying out new streets, and requires a width of 40 feet at least for carriage traffic, and 20 feet for foot traffic, exclusive of gardens, areas, &c. A street shall have at the least two entrances of the full width of such street, and shall be open from the ground upward. A definition of the word "street" is given. The consent of the Board is required by sect. 75 of the Metropolis Management Act Amendment Act, 1862, to those erecting buildings or structures beyond the general line of buildings in any street, place, or row of houses within 50 feet. Rules are also given for measuring the width, the curve of the carriage way, the height of the kerb to the foot-paths, and the slope of the footpath. By the same Act, sects. 98 and 99, further legislation is extended, and by sect. 112 any mews is included. The following are the widths of a few of the new streets:—Cannon Street, by St. Paul's, between kerbs, is 30 feet 6 inches; that of Cheapside, opposite Bow Church, is 31 feet; that of Queen Victoria Street, 1872–5, is 80 feet; that of Victoria Street, Westminster, is 80 feet; and of Northumberland Avenue, 1875–6, is 80 feet.

STRETCHED OUT. A term applied to a surface that will just cover a body so extended that all its parts are in a plane, or may be made to coincide with a plane.

STRETCHER. A brick or stone laid with its longer face in the surface of the wall.

STRETCHING COURSE. In walling, a course of stones or bricks laid with their longer dimensions in a horizontal line parallel to the face of the wall; it is exactly the contrary of a *heading course*, in which the breadths of the stones or bricks are laid in a straight line parallel to the face of the wall.

STRIÆ. (Lat.) The lists or fillets between the flutes of columns.

STRIATED. Chamfered or channeled.

STRIGES. The channels of a fluted column.

STRIKING. A term used to denote the draught of lines on the surface of a body; the term is also used to denote the drawing of lines on the face of a piece of stuff for mortises and cutting the shoulders of tenons. Another application of the word occurs in the practice of joinery, to denote the act of running a moulding with a plane. The *striking of a centre* is the removal of the timber framing upon which an arch is built, after its completion.

STRING OR STRING PIECE. That part of a flight of stairs which forms its ceiling or soffite. See CARRIAGE.

STRING BOARD. In wooden stairs, the board next the well-hole which receives the ends of the steps; its face follows the direction of the well-hole, whatever the form; when curved, it is frequently formed in thicknesses glued together, though sometimes it is got out of the solid, like a hand-rail. See CUT STRING.

STRING COURSE. A projecting horizontal course of stone, continued along the face of a building, frequently under windows, to form a tie or bonding course. It is either plane or moulded.

STRIX. (Lat.) A channel in a fluted column. FLUTE.

STRUCK. A term used to denote the removal of any temporary support.

STRUT. See BRACE.

STRUTTING BEAM or PIECE, also STRUT BEAM. A term used by old writers in carpentry, for what is now called a *straining piece* or *collar beam*. See also BRIDGING and KEY.

STUCCO. (Fr. Stuc.) A term indefinitely applied to calcareous cements of various descriptions. *Rough stucco* is that finished with stucco floated and brushed. *Bastard stucco* is three-coat work in plastering: 1, the render coat; 2, floating, as to trowelled stucco; and, 3, finishing, lime with a little hair and a little sand. This last is termed "setting" when used with fine stuff for papering, and is well finished.

STUDIO. An apartment especially adapted for a person to write or work in. It is generally presumed to be for art purposes.

STUDS. (Sax.) The quarters or posts in partitions. See QUARTERS.

STUFF. (Dutch.) A general term for the wood used by joiners.

STUMP TRACERY. The later or after Gothic of Germany has tracery in which the ribs are made to pass through each other, and are then abruptly cut off. This may be called *stump tracery*, according to Professor Willis.

STYLE. The different varieties of architecture. See STILE.

STYLOBATA. See PEDESTAL.

SUBNORMAL. The distance between the foot of the ordinate and a perpendicular to the curve (or its tangent) upon the axis.

SUB-PLINTH. A second and lower plinth placed under the principal one in columns and pedestals.

SUB-PRINCIPALS. The same as auxiliary rafters or principal braces.

SUBWAY. An underground passage. It now more especially refers to the arched vaults formed under a street for the purpose of containing the sewer, and gas, water and other pipes, with a bench or footway for access to the former or for making repairs to the latter. The subway requires a trap with ladder for access, and ventilating shafts. The *Builder* journal, xviii. 640, illustrates a subway formed in London.

SUDATIO and SUDATORIUM. (Lat.) The same as CALDARIUM. See CONCAMERATA SUDATIO.

SUMMER. (Perhaps from Ital. Soma.) The lintel of a door, window, etc. A beam tenoned into a girder to support the ends of joists on both sides of it. It is frequently used as a synonyme for a girder. Also a large stone laid over columns and pilasters in the commencement of a cross vault. It is, moreover, used in the same sense as BRESSUMMER.

SUMMER STONE. The lowest stone at the end of a gable, stopping the eaves of the tiling or slating. The first piece of the *tabling* is worked in the solid of the summer stone, and so becomes an abutment and support for the rest. It is also called a *skew corbel*.

SUMMER TREE. See DORMANT TREE.

SUMMERING. See BEDS OF A STONE.

SUN LIGHT. A new method of lighting large rooms from the ceiling, by a number of gas jets placed under a reflector, with tubes through the ceiling and perhaps roof for carrying off the products of combustion and for ventilation. A valve to prevent down draughts is introduced near the top of the tube.

SUNK SHELVES. Such as are formed with a groove in their upper surface, to prevent plates, dishes, or other materials sliding off when placed upright on them, as in a dresser.

SUPER-ALTAR. A shelf or ledge let into the east wall just over the altar or communion table, on which are placed the altar cross, altar lights, and flower vases not allowed by law on the table itself.

SUPERCILIUM. (Lat.) The lintel of a door. See ANTEPAGMENTA.

SUPERINTENDANCE. The architect's duty being to see that the quality of the materials used, and of the workmanship are equal to those specified, and that the building is being erected in accordance with the drawings and specifications, his visits to the building will be regulated by his own judgment, the extent of his practice, the magnitude of the works, the distance they may be away, whether a clerk of the works be employed or not, and the reputation of the builder, and lastly the expectations of his client. The young practitioner will soon learn which are the best occasions for visiting the works, after having seen to the setting out, to the drains, foundations, the footings commenced, etc.

SUPERSTRUCTURE. (Lat.) Work built on the foundation of a building. The upper part.

SUPPORT. See POINTS OF SUPPORT.

SURBASE. The series of mouldings forming a capping to the dado of a room.

SURBASED. An arch, vault, or dome of less hight than half its span.

SURMOUNTED. An arch, vault, or dome rising higher than a semicircle.

SWALLOW-TAIL. See DOVE-TAIL.

SYENITE. A stone which consists of feldspar and hornblende, of various colours, as reddish, dull green, &c., as the feldspar or hornblende may predominate. It obtained the name from its abundance of syene, and according to Pliny was at first named *pyropœcilos*. It is, in fact, a species of granite, and is used in Pompey's Pillar at Alexandria. It is not the Egyptian porphyry, though often mistaken for it.

SYMBOL. An attribute or sign accompanying a statue, or a picture of a personage, in allusion to some passage in the life of the person represented, and hence often used as a figurative representation of the figure itself. The symbols connected with the metals are delineated herein s. v. METALS. From the constant occurrence of symbols in the edifices of the Middle Ages it may be useful to insert a list of them, as attached to the Apostles and Saints, most commonly found. The Cross has been received as a symbol of Christianity, and the crescent of Mahommedanism.

HOLY APOSTLES.

St. Peter.—Bears a key, or two keys with different wards.
St. Andrew.—Leans on a cross, so called from him; called by heralds the "saltire."
St. John Evangelist.—With a chalice, in which is a winged serpent. When this symbol is used, the eagle, another symbol of him, is never given.
St. Bartholomew.—With a flaying knife.
St. James the Less.—A fuller's staff, bearing a small square banner.
St. James the Greater.—A pilgrim's staff, hat, and escalop shell.
St. Thomas.—An arrow, or with a long staff.
St. Simon.—A long saw.
St. Jude.—A club.
St. Matthias.—A hatchet.
St. Philip.—Leans on a spear; or has a long cross in the shape of a T.
St. Matthew.—A knife or dagger.
St. Mark.—A winged lion.
St. Luke.—A bull.
St. John.—An eagle.
St. Paul.—An elevated sword, or two swords in saltire.
St. John Baptist.—An Agnus Dei.
St. Stephen.—With stones in his lap.

SAINTS.

St. Agatha.—Her breast torn by pincers.
St. Agnes.—A lamb at her feet.
St. Aidan.—A stag crouching at his feet.
St. Alphege.—His chasuble full of stones.
St. Anagradesma.—Covered with leprosy.
St. Anne.—Teaching the Blessed Virgin to read. Her finger usually pointing to the words *Radix Jesse Floruit.*
St. Antony, Eremite.—Devil appears to him in the shape of a goat.
St. Anthony of Padua.—Accompanied by a pig.
St. Apollonia.—With a tooth.
St. Barbara.—With a tower in her hands.
St. Blaise.—With a woolcomb.
St. Boniface.—Hewing down an oak.
St. Britius.—With a child in his arms.
St. Canute.—Lying at the foot of the altar.
St. Catharine.—With a wheel and sword.
St. Cecilia.—With an organ.
St. Christopher.—A giant carrying the infant Saviour on his shoulder across a stream. A monk, or female figure, with a lantern on the farther side.
St. Clement.—With an anchor.
St. David.—Preaching on a hill.
St. Denis.—With his head in his hands.
St. Dorothy.—Bears a nosegay in one hand and a sword in the other.
St. Dunstan.—Bears a harp.
St. Edith.—Washing a beggar's feet.
St. Edmund.—Fastened to a tree and pierced with arrows.
St. Edward.—Bearing in his hand the Gospel of St. John.
St. Eunuchus.—A dove lighting on his head.
St. Etheldreda, Abbess.—Asleep, a young tree blossoming over her head.
St. Eustachius, or *St. Hubert.*—A stag appearing to him, with a cross between its horns.
St. Fabian.—Kneeling at the block with a triple crown at his side.
St. Faith.—With a bundle of rods.
St. George.—With the Dragon.
St. Gertrude, Abbess.—With a loaf.
St. Giles, Abbot.—A hind with an arrow piercing her neck, standing on her hind legs, and resting her feet in his lap.
St. Gudula.—With a lantern.
St. Hilary.—With three books.
St. Hippolytus.—Torn by wild horses.
St. Hugh.—With a lantern.
St. Januarius.—Lighting a fire.
St. Joachim.—With a staff, and two doves in a basket.
St. Lawrence.—With a gridiron.
St. Magnus.—Restoring sight to a blind man.
St. Margaret.—Trampling on a dragon, a crosier in her hands.
St. Martin.—Giving half his cloak to a beggar.
St. Nicholas.—With three naked children in a tub, in the end whereof rests his pastoral staff.
St. Odilo, Abbot.—With two goblets.
St. Pancras.—Trampling on a Saracen, a palm branch in his right hand.
St. Richard.—A chalice at his feet.
St. Rosaly.—With a rock in her arms.
St. Sebastian.—As St. Edmund, but without a crown.
St. Ursula.—Surrounded with virgins much less in size than herself.
St. Vincent.—On the rack.
St. Walburga.—Oil distilling from her hand.
St. Waltheof.—Kneeling at the block, the sun rising.
St. Winifred, Abbess.—With her head in her arms.
St. Wulfstan.—Striking his pastoral staff on a tomb.

THE BLESSED VIRGIN is usually represented—

1. At the Annunciation, with an almond tree flourishing in a flower-pot.
2. At her Purification with a pair of turtle doves.
3. In her Agony, with a sword piercing her heart.
4. In her "*Repose*" (death).
5. In her Assumption.
6. With the blessed Saviour in her lap.
7. In her Ecstasy, kneeling at a faldstool, which faces the Temple, the Holy Dove descending on her.

Martyrs hold palms; *Virgins*, lamps, or, if also Martyrs, lilies and roses; *Confessors*, lilies; *Patriarchs*, wheels.

Glories round heads are circular, except when living prelates eminent for holiness are represented, when they are square.

HUSENBETH, F. C. *Emblems of Saints.* 2nd edition, 12mo. London 1860. TWINING, L *Symbols and Emblems of Early and Mediæval Christian Art.* 93 plates, 4to. Lond. 1852.

Symbolism. Mr. Gwilt's remarks on this subject, written for insertion in his Appendix, are subjoined. "Invested with much of the character of chivalry and romance, the mediæval period has been often stated to have expressed in matter its spiritual impressions. The aspiring vertical lines of its monuments have by some been considered types of aspiration after the Divinity. This may or may not have been the case, but there can not be other than an indisposition to believe in symbolism, when there are so many forms in nature whose imitation, or the study thereof, would lead to the same results. Holding symbolism in churches as an idle conceit, not much will be said on that subject; but a few specimens of the nonsense it induces may as well be set down. The venerable Bede, for instance, says that the walls of a church are a symbol of the Christian worshippers that frequent the edifice. 'Omnes parietes templi per circuitum omnes sanctæ ecclesiæ populi sunt, quibus super fundamentum Christi locatis, ambitum orbis replevit.' The venerable scribe, be it observed, is speaking of Solomon's temple. Again, in respect of doors, we have 'Ostium autem templi Dominus est, quia nemo venit ad Patrem nisi per illum,' &c. As to the windows, they are symbols of the saints and spiritual worshippers; 'Fenestræ templi sunt sancti et spirituales.' To come, however, to recent symbolisms, we find that the moderns have discovered that the principal entrance of a church is a symbol of our entrance into physical and moral life; that the tympanum, or gable-like form, over the great western porch (whose origin is the Greek pediment, but raised to conform with the character of the style), is a symbol of the Holy Trinity; the great rose window at the western end of a church is, from its circular form, accounted a symbol of Divine Providence! At Amiens, the four rose windows have been considered symbolical of the four elements! In respect of the towers, that on the left is said to represent the ecclesiastical and spiritual hierarchy, and that to the right, order, that is, the civil or temporal power! and generally, where four horizontal divisions occur, the lower one is symbolical of the curé, the next upwards of the dean or archdeacon, the third of the bishop, and the fourth of the archbishop. Should a fifth horizontal division occur, the primate is the type. So in the right hand tower, the lowest compartment represents the mayor, and in succession upwards appear a count, a duke, a king; and if the tower be covered with a spire, no less than an emperor appears. One is almost surprised that there is no symbol to represent the suisse of the continental, nor the beadle of our churches in this country. The interior of a church, according to the symbolists, affords some further curious features of mysticism. The principal entrance is at the *foot* of the Cross, because, by the use of the feet (i.e. travelling) the Gospel was preached! What is called *canting* heraldry surely does not equal this. The nave is said to represent the body of the faithful! The ceiling over the altar is accounted a symbol of heaven, and the chapels round the altar are said to represent the *aureola* round the head of Christ! But it is scarcely worth while to waste more time on the consideration of such absurdity, where the things have been ingeniously fitted to the types, instead of the converse. There is, however, one other point connected with the subject, which has been recently revived, and a few words must be expended in notice of it." This is the vesica piscis.

Symmetry. (Gr. Συν, with, and Μετρω, I measure.) A system of proportion in a building, from which results from one part the measurement of all the rest. It also conveys the meaning of uniformity as regards the answering of one part to another.

Systyle. (Gr.) A colonnade or portico, in which the inter-columniation is equal to two diameters of the column.

T

Tabern. A provincial term for a cellar.

Tabernacle. (Lat.) In Catholic churches, the name given to a small representation of an edifice placed on the altar for containing consecrated vessels, &c.

Table. In perspective, the same as the plane of the picture, being the paper or canvas on which a perspective drawing is made, and usually perpendicular to the horizon. In the theory of perspective, it is supposed to be transparent for simplifying the theory. In glass works and among glaziers, it is a circular plate of "crown" glass, being its original form before it is cut or divided into squares. Twenty-four *tables* make a *case*.

Table or Tablet. (Lat. Tabula.) A flat surface generally charged with some ornamental figure. The outline is generally rectangular, and when raised from the naked of the wall, is called a *projecting* or *raised table*. When not perpendicular to the horizon, it is called a *raking table*. When the surface is rough, frosted, or vermiculated, from being broken with the hammer, it is called a *rusticated table*.

Tablet. The same as Table; but is applied usually to a wall slab or monumental tablet.

Tabling. A term used by the Scotch builders to denote the coping of the walls of very common houses.

Tablinum. (Lat.) In Roman architecture, an apartment situated in the narrow part of the atrium, as is supposed, fronting the entrance. Its exact position is not now known, and indeed the situation of it may, under circumstances, have varied; its true place therefore must be a matter of doubt.

Tabulatum. (Lat.) A term used by the Romans not only in respect to the floors, wainscottings, ceilings, &c., which were constructed of wood, but also to balconies and other projecting parts, which latter Vitruvius calls *projectiones*.

Tace. The name in Scotland for a Sally.

Tacks. Small nails used for various purposes, but principally for stretching cloth upon a board.

Tænia. (Gr.) The fillet which separates the Doric frieze from the architrave.

Tail. (Verb.) A term denoting the hold of any bearing piece on that which supports it, as where the end of a timber lies or *tails* upon the walls. The expression is similar to what in joinery is called *housing*, with this difference, that housing expresses the complete surrounding of the cavity of the piece which is let in.

Tail Bay. See Case Bay.

Tail Trimmer. One next the wall, into which the ends of joists are fastened in order to avoid flues.

Tailing. That part of a projecting stone or brick not inserted in a wall.

Tailloir. (Fr.) The name which the French give to the *abacus*.

Talon. (Fr.) The name given by the French to the *ogee*.

Tambour. (Fr. a drum.) A term denoting the naked ground on which the leaves of the Corinthian and Composite capitals are placed. It signifies also the wall of a circular temple surrounded with columns; and further the circular vertical part below a cupola as well as above it.

Tangent. (Lat. Tango.) A line drawn perpendicular to the extremity of the diameter of a circle, and therefore touching it only at one point. In trigonometry, it is a line drawn perpendicularly from the extremity of the diameter, at one end of the arc, and bounded by a straight line drawn from the centre through the other.

Tank. A receptacle, generally formed under ground, for liquids, as a water tank, liquid manure tank, &c.

Tapering. A term expressive of the gradual approach, as they rise, of the sides of a body to each other, so that if continued they would terminate in a point.

Tar. A product of the valuable family of the coniferous trees, and chiefly from the species of pine known as the Scotch fir. It is stored up in the roots, from which it is extracted by heat. When tar is subjected to heat a volatile spirit is distilled from it, leaving a black solid mass which is termed pitch. Both have the property of resisting moisture.

Tarras. A strong cement, useful formerly in water-works.

Tassal, Tassel, Torsel, or Tossel. The plate of timber for the end of a beam or of a joist to rest on, as formerly in a chimney, where the mantel tree rested on it at each end.

Tavern. A house open to the public where wine is sold.

Taxis. (Gr.) A term used by Vitruvius to signify that disposition which assigns to every part of a building its just dimensions. Modern architects have called it *ordonnance*.

Teaze Tenon. A tenon on the top of a post, with a double shoulder and tenon from each for supporting two level pieces of timber at right angles to each other.

Tectorium Opus. (Lat.) A name in ancient architecture given to a species of plastering used on the walls of their apartments.

Telamones. (Gr. Τλαω, to support.) Figures of men used in the same manner as Caryatides. They are sometimes called *atlantes*.

Temenos. (Gr.) The same as the Latin Templum. See Temple.

Tempered. An epithet applied to bricks which may be cut and reduced with ease to a required form. The term is also applied to mortar and cement, which has been well beaten and mixed together.

Templa. (Lat.) Timbers in the roof of the Roman temples, which rested on the *cantherii*, or principal rafters, similar to the purlins in a modern roof.

Template. An improper orthography for Templet.

Temple. (Lat.) Generally an edifice erected for the public exercise of religious worship. Herein is described the different species of temples mentioned by Vitruvius, in Book 3 of his work.—A temple is said to be in *antis* when it has antæ or pilasters in front of the walls, which enclose the cells, with two columns between the antæ. See Fig. 1442. It was crowned with a pediment, and was not dissimilar to the prostylos temple, to which we shall presently come. In the figure, A is the cell, *a a* the antæ, and if in front of them the columns *b b b b* were placed, it would be a *prostyle* temple; C is the door of the cell, and B the pronaos. The appearance in front of this species is the same as the *amphiprostyle* temple, which is given in *fig.* 1443, and wherein columns are also placed in front of the antæ. Of the prostyle temple, an example, that of the temple of Jupiter and Faunus, existed on the island of the Tiber at Rome. In *fig.* 1443, the amphiprostyle temple, A is the cell, B the pronaos, C the posticus, D the door of the cell, and *a a* are

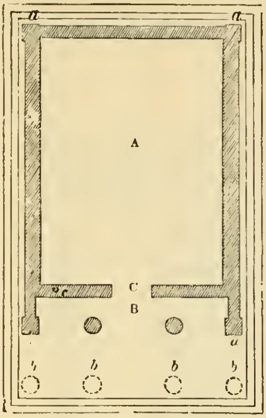

Fig. 1442.

Fig. 1443.

the antæ. It will be immediately seen that the same elevation will apply (*fig.* 1444)

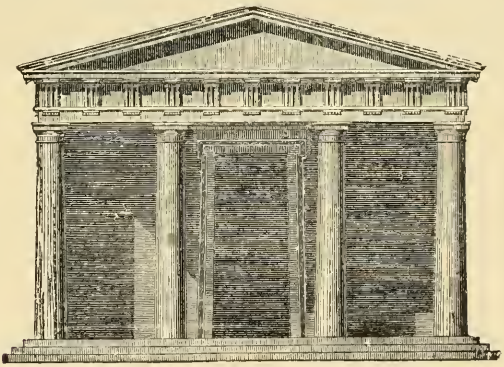

Fig. 1444.

to both the plans just given. The amphiprostyle temple, be it observed (*fig.* 1443), has

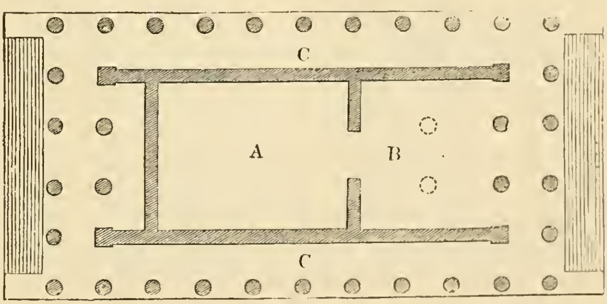

Fig. 1445.

columns in the rear as well as in the front, and is distinguished by that from the prostylos (*fig.* 1442), wherein the columns *b b b b* would make that prostylos which, but for them, would be merely a temple in antis. The *amphiprostylos* then only differs from the *prostylos* by having columns in the rear, repeated similarly to those in the front. The *fig.* 1444 applies on double the scale of the plans to both *figs.* 1442 and 1443, and is a diastyle tetrastyle temple, that is, one whose intercolumniations (see Colonnade) are of three diameters, and the number of whose columns is four.

A *peripteral temple* had six columns in front and rear, and eleven on the flanks, counting the two columns on the angles (see *fig.* 1445), and these were so placed that their

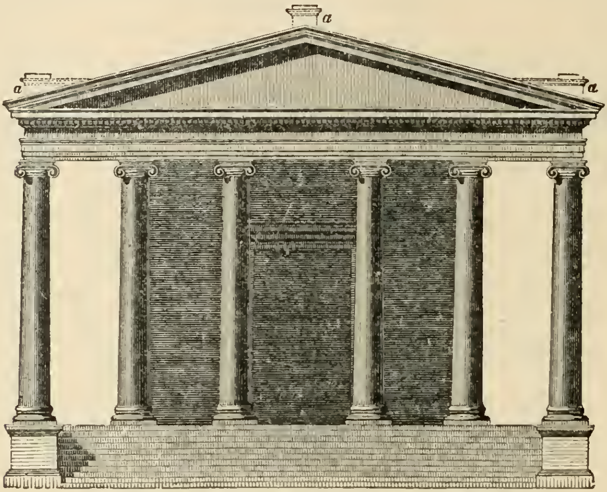

Fig. 1446.

distance from the wall was equal to an intercolumniation or space between the columns all round, and thus it formed a walk around the cell. In *fig.* 1446 is the elevation of the species, which is hexastyle and eustyle, that is, with six columns in front, whose

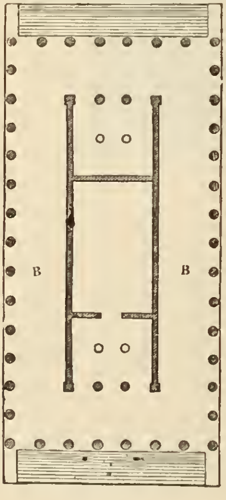

Fig. 1447.

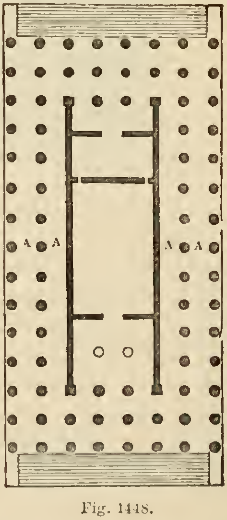

Fig. 1448.

intercolumniation is *eustyle*, or of two diameters and a quarter. (See Colonnade.) In this figure, which is to a double scale of the plan, *a a a* are *acroteria*.

The *pseudo-dipteral temple* was constructed with eight columns in front and rear

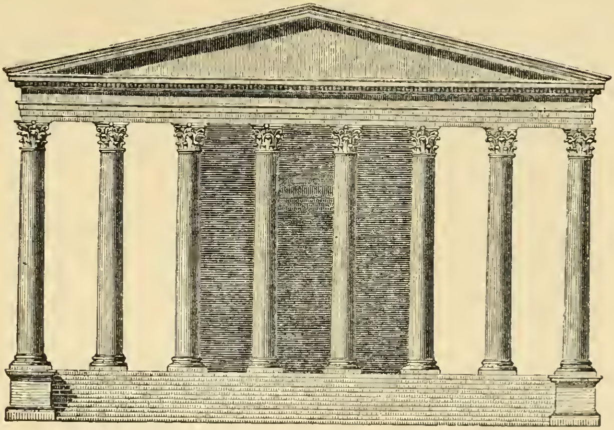

Fig. 1449.

and with fifteen on the sides, including those at the angles, see *fig.* 1447. The walls of

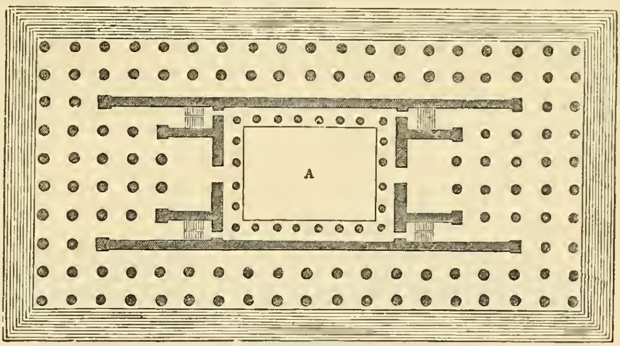

Fig. 1450.

the cell are opposite to the four middle columns of the front and of the rear. Hence,

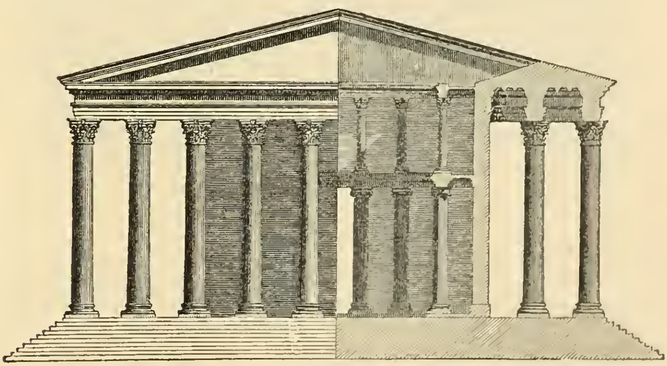

Fig. 1451.

from the walls to the front of the lower part of the columns, there will be an interval equal to two intercolumniations and the thickness of a column all round. No example existed of such a temple at Rome; but there was one to Diana, built by Hermogenes of Alabanda, in Magnesia, and that of Apollo by Menesthes. The dipteral temple (*fig.* 1448) is octastylos like the former, and with a pronaos and posticum, but all round the cell are two ranks of columns: such was the temple of Diana at Ephesus, built by Ctesiphon. The elevation (*fig.* 1449) is the same in the dipteral and pseudo-dipteral temple, and in the figure is with the systyle intercolumniation.

The *hypæthral* temple, or that uncovered in the centre, is decastylos in the pronaos and posticum; it is in other respects (see *fig.* 1450) similar to the dipteral, except

Fig. 1452.

that in the inside it has two stories of columns all round, at some distance from the walls, after the manner of the peristylia of porticoes as drawn in *fig.* 1451, in which one half is the elevation and the other half the presumed section of such a temple.

The *peripteral* temple has been described, but there is still another connected with that species, though distinct, and that is the *pseudo-peripteral*, or false peripteral, in which there is no passage round the walls of the cell, but an appearance of surrounding columns (see *fig.* 1452).

By this arrangement more room was given to the space of the cell. The elevation of this is given in *fig.* 1453.

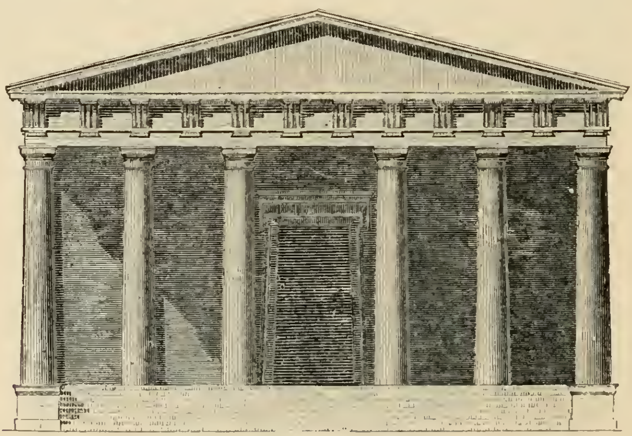

Fig. 1453.

Vitruvius thus describes, as follows, the proportions of the Tuscan temple:—

The length of the site of the temple intended (see *fig.* 1454.) must be divided into six parts, whence, by subtracting one part, the width thereof is obtained. The length is then divided into two parts, of which the furthest is assigned to the cell, that next the front to the reception of the columns.

The above width is to be divided into ten parts, of which three to the right and three to the left are for the smaller cells, or for the alæ, if such are required; the remaining four are to be given to the central part. The space before the cells in the pronaos is to have its columns so arranged that those at the angles are to correspond with the antæ of the external walls: the two central ones opposite the walls between the antæ and the middle of the temple are to be so disposed, that between the antæ and the above columns, and in that direction, others may be placed.

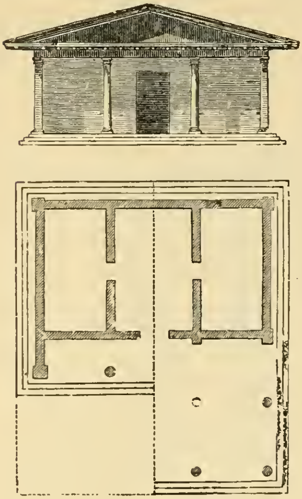

Fig. 1454.

Their thickness below is to be one-seventh of their height, their height one-third of the width of the temple, and their thickness at top is to be one-fourth less than their thickness at bottom. Their bases are to be half a diameter in height. The plinths, which are to be circular, are half the height of the base, with a torus and fillet on them as high as the plinth. The height of the capital is to be half a diameter, and the width of the abacus equal to the lower diameter of the column. The height of the capital must be divided into three parts, whereof one is assigned to the plinth or abacus, another to the echinus, the third to the hypotrachelium, with its apophyge.

Over the columns coupled beams are laid of such height as the magnitude of the work may require. Their width must be equal to that of the hypotrachelium at the top of the column, and they are to be so coupled together with dovetailed dowels as to leave a space of two inches between them. Above the beams and walls the mutuli project one-fourth of the height of the columns. In front of these members are fixed, and over them, the tympanum of the pediment, either of masonry or timber.

Of *circular* temples there are two species; the monopteral (*fig.* 1455) having columns without a cell, and the peripteral with a cell (*fig.* 1456). In this last the clear diameter of the cell within the walls is to be equal to the height of the columns above the

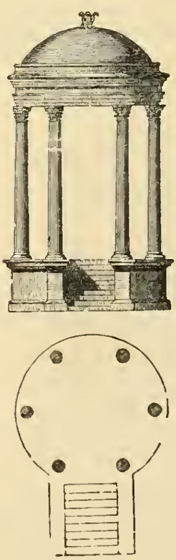

Fig. 1455.

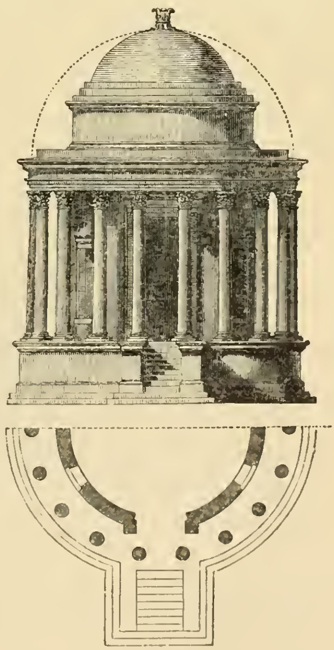

Fig. 1456.

pedestal. Of this species was the celebrated temple at Tivoli, in the admiration of which no dissentient from its allowed beauty has hitherto been recorded. With it situation has doubtless much to do.

Having thus related the description of Roman temples as known to Vitruvius, we give an elevation of two Grecian temples as restored, to contrast with the above descriptions of similar works. *Fig.* 1457 is the temple of Pallas, or of Jupiter Panhellenius at Ægina, in the gulf of Athens. The ruins were explored in 1811 by Messrs. Cockerell, Foster, Haller and Lynck, with very remarkable success, in elucidation of every desired architectural detail, and of the then unascertained style of the Æginetan school of

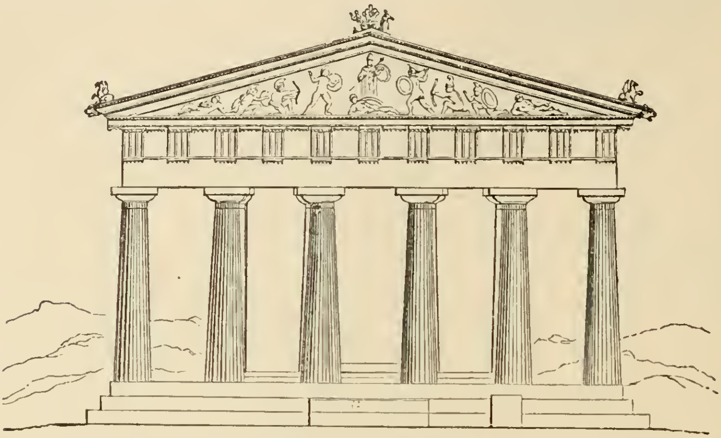

Fig. 1457. Temple at Ægina.

sculpture, constantly mentioned by ancient writers as of the first merit and of universal estimation. The temple is hexastyle peripteral, but has twelve columns only in the flanks. The top step measures 44 feet 10 inches by 93 feet 1 inch; the height to the point of the pediment is 35 feet. The pediments and aeroteria were adorned with not less than thirty-four Parian statues representing the two Trojan wars, in which the Æacidæ were engaged more especially. These sculptures are now at Berlin, but casts of them, placed in models of the pediments, are erected in the British Museum. *Fig.* 1430 shows the centre group of one of the pediments to a larger scale. The date of this work is supposed to be not later than the sixth century B.C.

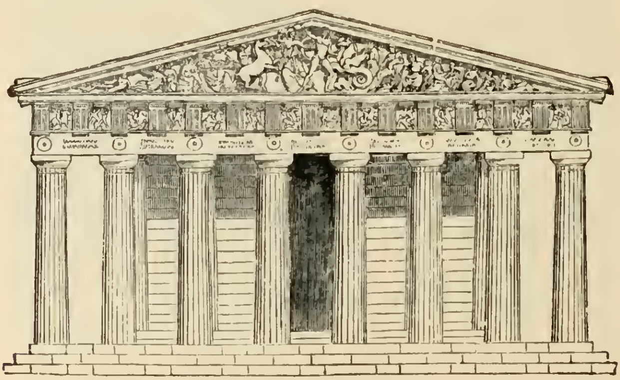

Fig. 1458. The Parthenon at Athens.

Fig. 1458 is a representation of the west front of the temple of Minerva, commonly called the Parthenon, at Athens. It is an example of the rare arrangement of the octastyle peripteral, the sides have seventeen columns. The top step measures 101·336 English feet by 228·15 feet; the height to the apex of the pediment is 59·27 feet. A capital of one of the columns and many of the sculptures of the pediments, metopæ, and frieze around the cella, formed a series of the gems of Lord Elgin's collection, and are now in the British Museum. Ictinus and Callicrates were the architects, and Phidias the director of the sculpture, intrusted by Pericles with its erection. It is supposed that ten or fifteen years were so occupied, and that the temple was completed B.C. 438.

TEMPLET. A mould used in masonry and brickwork for the purpose of cutting or setting out the work. When particular accuracy is required, two templets should be used, one for moulding the end of the work, and its reverse for trying the face. When many stones or bricks are required to be wrought with the same mould, the templets ought to be made of some metal.

The term is also used to denote a short piece of timber sometimes laid under a girder, particularly in brick buildings.

TENIA. The fillet or band at the top of the frieze in the Doric order.

TENANT. The occupier of a house and holding a lease or agreement from the landlord or other person. "Tenants in common" are such as hold by several and distinct titles, but by unity of possession. "Joint tenants" are such as have equal rights in lands or tenements by virtue of one title.

TENON. (Fr. Tenir.) A projecting rectangular prism formed on the end of a piece of timber to be inserted into a mortise of the same form.

TENON SAW. One with a brass or steel back for cutting tenons.

TENSION. The stretching or degree of stretching to which a piece of timber or other material is strained by drawing it in the direction of its length.

TEOCALLA. The house of God or temple of ancient Mexico. It is a pyramid formed in terraces with flat tops, and always surmounted by a chamber or cell, which is the temple itself, where the ceremonies were exhibited to the people. One at Cholulu is 1440 feet square, and 177 feet high, having four stories. The teocalla of Yucatan rises at an angle of about 45 degrees to the level of the platform on which the temple stood; an unbroken flight of steps leads from the base to the summit. That at Palenque is the finest yet discovered.

TEPIDARIUM. (Lat.) A name given to one of the apartments of a Roman bath.

TERAM. The scroll at the end of a step.

TERCENTO. The style of art prevailing in Italy during what is usually called the fourteenth century.

TERM or TERMINAL. A sort of trunk, pillar, or pedestal, often in the form of the frustum of an inverted obelisk with the bust of a man, woman, or satyr on the top. See VAGINA.

TERMINUS. The popular word for the station at each end of a railway.

TERRA-COTTA. (It.) Baked earth. In the time of Pausanias there were in many temples statues of the deities made of this material. Bassi-rilievi of terra-cotta were frequently employed to ornament the friezes of temples. In modern times it has also been much used for architectural decoration, being modelled, or cast, or made up of pipe or potter's clay with fine sand and flint, and afterwards fired to a stony hardness, hardly to be scratched with a steel point. The manufacture is greatly used in a variety of ways for ornamental and useful purposes. "Many early productions, even of less durability than those now made, are found in ruins of stone, in which the latter material has been steadily disintegrating for thousands of years, but leaving the terra cotta as perfect, in many cases, as if recently produced. In faithfully made and vitrified terra-cotta we have the great and lasting triumph of man over natural productions; for timber will rot; stone, even granite, will disintegrate; iron will oxidise; all other metals will succumb to the action of fire, and to other destroying influences of the elements. Properly made and thoroughly burned terra-cotta will pass through centuries, and be the last to yield to those influences to which all natural productions must give way. In all architectural employments it is practically time-proof and indestructible. Very many important transactions recorded in this material have been found in a good state of preservation in the ruins of Babylon." (Davis, in *Builder*, xlvii. 479.)

TERRACE. An area raised before a building above the level of the ground to serve as a walk. The word is sometimes, but improperly, used to denote a balcony or gallery.

TESSELATED PAVEMENT. A rich pavement of mosaic work made of small squares of marbles, bricks, tiles, or pebbles, and called *tesselæ* or *tesseræ*.

TESSERA. (Gr.) A cube or die. This name was applied to a composition used some years ago for covering flat roofs, but now abandoned.

TESTUDO. (Lat.) A name given by the ancients to a light surbased vault with which they ceiled the grand halls in baths and mansions. Generally, any arched roof.

TETRADORON. (Gr.) A species of brick four palms in length. See BRICK.

TETRAGON. (Gr.) A figure which has four sides and as many angles.

TETRASPASTOS. (Gr. Τετρα, four, and Σπασσω, to draw.) A machine working with four pulleys.

TETRASTYLE. (Gr. Τετρα, and Στυλος, a column.) See COLONNADE.

THATCH. The covering of straw or reeds used on the roofs of cottages, barns, and such buildings; and sometimes the *cottage orné* is so finished for a picturesque effect,

THEATRE. (Gr. Θεαομαι, to see.) A place appropriated to the representation of dramatic spectacles.
THEODOLITE. An instrument used in surveying for taking angles in vertical or horizontal planes.
THEOREM. A proposition which is the subject of demonstration.
THERMÆ. See BATH.
THOROUGH FRAMING. The framing of doors and windows, a term almost obsolete.
THOROUGH LIGHTED ROOM. A room having windows on opposite sides.
THRESHOLD OF A DOOR. The sill of the door frame.
THROAT. See GORGE and CHIMNEY.
THROUGH or THOROUGH STONE. A bond stone; a heading stone going through the wall.
THRUST. The force exerted by any body or system of bodies against another. Thus the thrust of an arch is the power of the arch stones considered as a combination of wedges to overturn the abutments or walls from which the arch springs.
TIE. (Sax. Tian, to bind.) A timber-string, chain, or iron rod connecting two bodies together, which have a tendency to diverge from each other, such as tie-beams, diagonal ties, truss-posts, etc. Braces may act either as ties or straining pieces. Straining pieces are preferable to ties, for these cannot be so well secured at the joints as straining pieces. See ANGLE BRACE.
TIE BEAM. The beam which connects the bottom of a pair of principal rafters, and prevents them from thrusting out the wall. *Fig.* 1459 is an illustration of a late mediæval example of a species of such a roof.

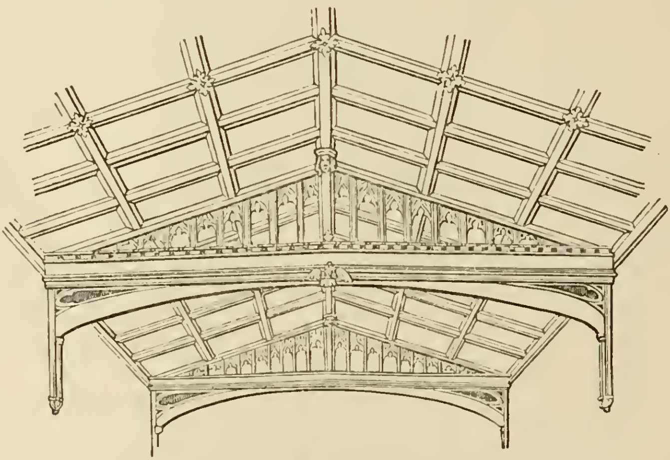

Fig. 1459. St. Mary's Church, Leicester.

TIE ROD. The iron rod securing the feet of the principal rafters in the manner, and in lieu, of the tie-beam.
TIERCE POINT. The vertex of an equilateral triangle. Arches or vaults of the third point, which are called by the Italians *di terzo acuto*, are such as consist of two arcs of a circle intersecting at the top. See POINTED ARCH.
TIGNA. The tie beam of an ancient timber roof.
TILE. (Sax. Tigel.) A thin piece or plate of baked clay or other material used for the external covering of a roof. A thicker sort serves for paving. The flat tiles are called *plain tiles*, the curved ones are *pan-tiles*; these latter, if made with a double curvature, are called Bridgewater tiles.

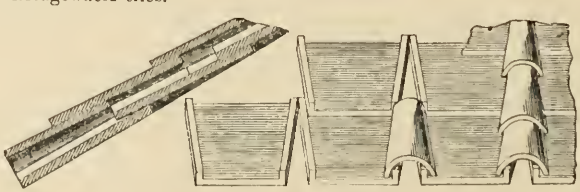

Fig. 1460.

In ancient buildings two forms of tiles were used. The *imbrex*, placed in regular rows to receive the shower, and the *tegula*, which covered and prevented the rain from penetrating the joints. The latter were fixed at the eaves with upright ornamental pieces called *antefixæ*, which were also repeated along the ridge at the junction of the tiles. The present common tiles of Italy are on this principle. and are shown by *fig.* 1460. Similar tiles have of late years been manufactured in England, but the joints require to be set in mortar to prevent wet and snow drifting into the roof.

Tile Creasing. See Creasing.

Tiling. The act of putting tiles on to roofs of buildings. The work itself is also so called.

Tiling Fillet. A chamfered fillet laid under slating or tiling, to raise it where it joins the wall, and prevent water from entering the joint. See Shreading, Furring.

Timber. (Sax, Timbjian, to build.) Properly denotes all such wood, either growing or cut down, as is suited to the purposes of building. A single piece of wood similarly employed is so called, as one of the *timbers* of a floor, roof, etc.

Timbers. It is advisable, as directed by the Metropolitan Buildings Act 1855, that no timber or woodwork be placed in any wall or chimney breast, nearer than 12 inches to the inside of any flue or chimney opening:—Under any chimney opening within 18 inches from the upper surface of the hearth of such chimney opening:—Within two inches from the face of the brickwork or stonework about any chimney or flue, where the substance of such brickwork or stonework is less than $8\frac{1}{2}$ inches thick, unless the face of such brickwork or stonework is rendered:—and that no wooden plugs be driven nearer than 6 inches (not enough) to the inside of any chimney opening.

Tip (verb.) To discharge a barrow or waggon load of anything by turning it on end or on one side.

Tolmen, or Holed Stone. One of the many stones attributed to the Celtic inhabitants.

Tomb. (Gr. Τυμβος.) A grave or place for the interment of a human body, including also any commemorative monument raised over such a place. The word embraces every variety of sepulchral memorial, from the meanest grave to the most sumptuous mausoleum.

Tongue. See Groove.

Tools. (Sax.) Instruments used by artificers for the reduction of any material to its intended form, and with which they are assisted in fixing and ornamenting it.

Tooth. The iron or steel point in a gauge which marks the stuff in its passage, or draws a line parallel to the arris of the piece of wood.

Toothing. A projecting piece of material which is to be received into an adjoining piece. A tongue or series of tongues. See Stoothing.

Top Beam. The same as Collar Beam.

Top Rail. The uppermost rail of a piece of framing or wainscoting, as its name imports.

Tope. A Buddhist monument in a temple for preserving relics. Also the large mound enclosed and having gateways, as the celebrated Sanchi tope, dating about 600 B.C.

Torsel. The same as Tassal.

Torsion. The twisting strain on any material.

Torus. (Lat.) A large moulding whose section is semicircular, used in the bases of columns. The only difference between it and the astragal is in the size, the astragal being much smaller.

Touch Stone. A smooth black stone like marble. It was much used for tombs in the 16th and 17th centuries, as in that of Henry VII.

Tower. (Sax.) A lofty building of several stories, round or polygonal. See Steeple.

Town Hall. (Fr. *Hôtel de ville.* Ger. *Stadthaus* and *Rathhaus.*) A building in which the affairs of a town are transacted. It will necessarily vary with its extent and opulence. In towns of small extent it should stand in the market-place; in many of the towns of this country the ground floor has usually columns or piers, and forms the corn market, the upper floor being generally sufficiently spacious for transacting municipal business. Where the sessions and assizes, as in cities, are held at the town hall, it is necessary to provide two courts, one for the civil and the other for the criminal trials. In cities where much municipal business occurs, the number of apartments must of course be increased to meet the exigencies of the particular case; and, if possible, a large hall should be provided for the meetings of the corporation. On the ground floor of the first class of town halls, courts, porticoes, or arcades, or spacious staircases, should prepare for and lead to the large apartments and courts of law. Every means should be employed in providing ample egress and ingress to the persons assembling. Fire-proof muniment rooms should be provided for the records and accounts. Court of Law.

For the disposition of these buildings the student may turn with profit to the examples abroad in which, generally, apartments are provided for every branch of the government of the city. Durand, in his *Parallèle des Edifices*, has given several examples. We have chosen the Belgian examples, as most splendid, to remark upon; but it is not to be understood that fine specimens are only to be found in that country. France and Germany (see *Builder* for 1866) abound with such edifices, and a very voluminous work might be produced on the subject.

On the four principal hôtels de ville, that of Bruges is the earliest. Its date is 1377, and it is chiefly remarkable for the original wooden roof to the great hall. The Hôtel de Ville of Brussels is, as an edifice, the first of the class, whether considered by itself, or as the dominant feature of a *place* surrounded by buildings of the most unique and varied appearance, the most interesting that we recollect anywhere to have contemplated. It appears to have been completed in 1445. *Fig.* 1460*a.* is a view of the east façade. An ancient building which occupied this site, has not been entirely removed; for in the northern

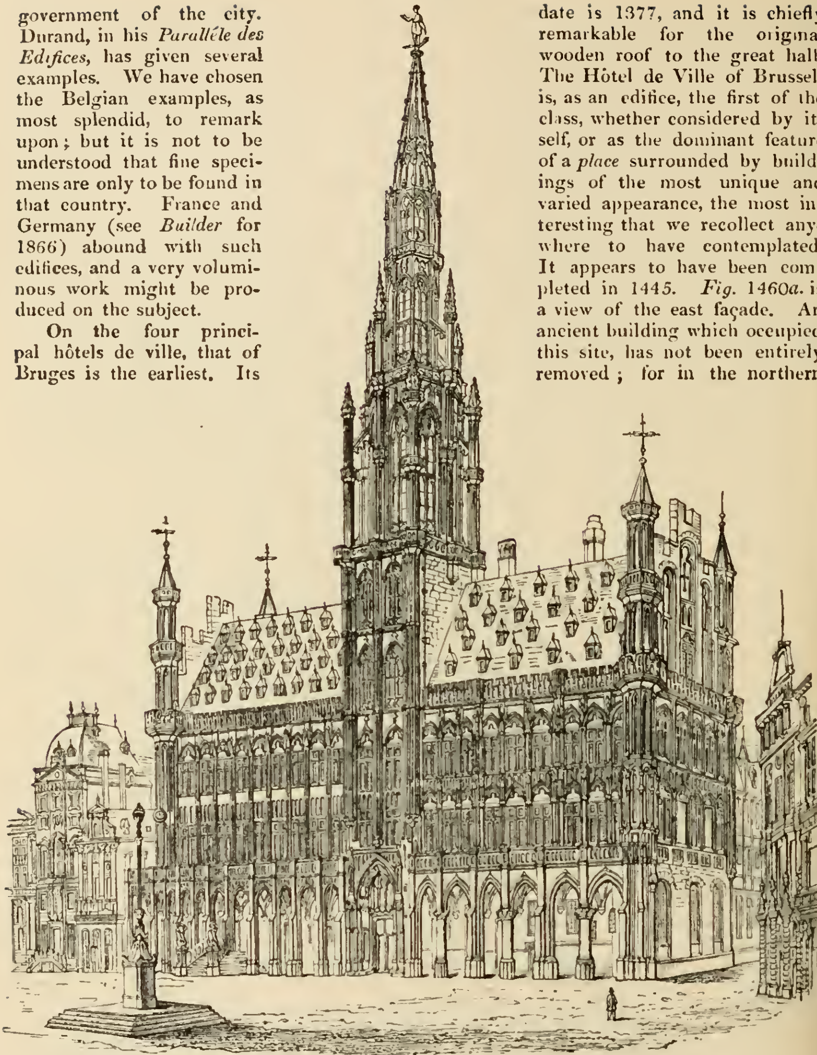

Fig. 1460a. HOTEL DE VILLE; BRUSSELS.

side from the tower, the piers of the loggia, which on the basement extends along the front, consist, at least three of them, of columns whose date is evidently a century earlier, and which it is probable were left when the main front of the building was carried up. Indeed, it seems highly probable that when the architect Jean van Ruysbroeck undertook the tower, his part of the work, the hôtel was in existence as high as the one-pair floor. The whole of the tower seems rather later than the date above given, which accords well enough with the northern wing. The authorities we have looked into scarcely, however, admit us to doubt its correctness. As the building stands executed, taking one of the bays on the northern side as a measuring unit, there are three measuring the central space for the tower, ten for the north wing, and eleven for the south wing; the height, to the top of the parapet, nine; to the ridge of the roof, thirteen; to the top of the spire, thirty-three. The tracery on the spire is very elegant, and is pierced throughout. It is 364 feet high, and crowned with a copper gilt colossal statue of St. Michael, the patron of the city, 18 feet high, which is so well balanced upon the pivot on which it stands that it is susceptible of motion with a very gentle wind. The interior of the edifice has a quadrangular court, with two modern fountains, statues of river gods with reeds and vases, as usual in such cases. Besides the *Grande Salle*, there are many interesting apartments, some whereof possess ceilings of great beauty. This fine monument is perhaps the most admirable example of the adaptation of the style to secular architecture that can be quoted.

Smaller in plan, but more beautiful and symmetrical, is the hôtel de ville of Louvain. It is the most perfect, in every respect, of this class of buildings in Europe. Nothing can surpass the richness and delicacy of the tracery upon it. Like that at Brussels, it consists of three stories, but has no tower. Commenced in 1448, it was not completed till 1463 by De Layens. It stands on a site of about 85 feet by 42 feet; so that it derives little advantage from its absolute magnitude, and perhaps appears less than it really is, from the great height of the roof, which is pierced by four tiers of dormers or lucarnes. The angles are flanked by turrets, of which some notion may be formed by reference to *fig.* 1460*b*. and the ridge of the roof is received at each end by another turret corbelled over from the gables. The façade towards the *Place* extends rather more than the height, and is pierced with twenty-eight windows and two doorways, being ten openings in each story, the spaces between the windows being decorated with canopies, and groups of small figures from the Old Testament, some whereof are rather licentious. This charming edifice, which in its delicate rich tracery had suffered much from time and the elements, has, at the joint expense of the town and government, undergone a complete renovation. This has, stone by stone, been effected with great care and artistic skill by M. Goyers. The new work being executed in very soft stone, which, however, hardens with exposure to the air, it has been saturated with oil.

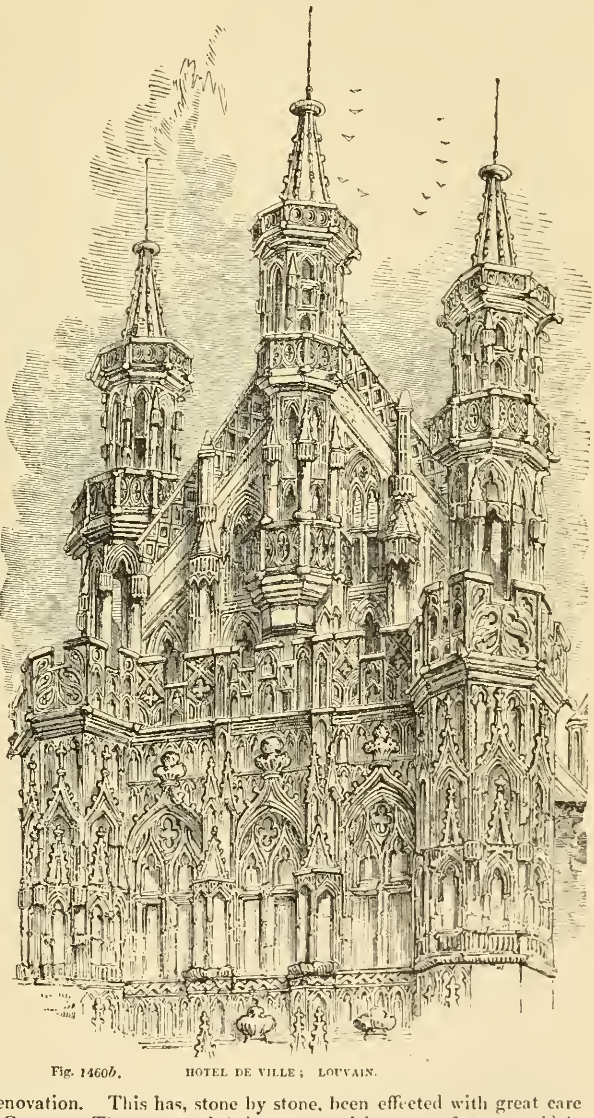

Fig. 1460*b*. HOTEL DE VILLE; LOUVAIN.

In form, though not in features, totally different from the hôtels de ville we have just left, is that at Ghent, never completed, but exhibiting, in what was executed of the design, a choice example of the last days of the flamboyant period. It was begun in 1481; in it are all those indications of change in the sofites and curves, as well as in the lines of the foliage and tracery, that eventually proved its downfall; and the style is now out of character with the habits of the age, from which alone a real style of architecture can ever spring. The subdivision of the building as to height is into two stories as to effect, though in reality there are more; and the transoms, which abound in the apertures, seem to reign in accordance with the horizontal arrangement of lines which was so soon to supersede the flaming curves that had prevailed for nearly half a century. The elegant turret or tribune at the corner, with the part adjoining, in the richest flamboyant Gothic, is by Eustace Pollejt, 1527–60; the other façade, 1600–20, has columns of three different orders superposed.

The most celebrated of town halls in Europe was that of Amsterdam, erected during the first half of the 17th century by Van Campen. The design is given in Durand's *Parallèle,* and it also forms the subject of a volume, in folio, published in Holland, in 1661–64. The town halls at Antwerp and at Maestricht may be also referred to, but these have now been surpassed by modern structures; amongst them may be mentioned the town hall at Berlin, 1881. The Hôtel de Ville at Paris was commenced 1533, and continued from 1549 or 1559 on the designs of Domenico Boccadoro, called by the French Dominique de Cortone, in what is now termed the style of the Renaissance. The additions which became necessary in consequence of the extended business of the city were executed in the same style, and the building presented one of the finest and most picturesque features of the city, until 1870–71, when it was destroyed by fire; its reconstruction was carried out by Théodore Ballu.

St. George's Hall, at Liverpool, with the town halls at Leeds, Halifax, Manchester, and other towns, large and small, are modern examples. Such a building, for a moderate-sized market town (as referred to previously), might require, on the ground floor, a wide entrance vestibule, out of which would be a room for the police, with four or five cells for prisoners; an office for the board of health, witnesses' room, magistrates' room, with a staircase to the first floor, to consist of a common hall, at one end of which, or in the middle of one side, would be arranged the courts for any local purposes, as a county court perhaps, with a retiring room for its chief. This hall would require a staircase for the public, entering at once from the main thoroughfare. Apartments for the resident policeman, and the usual conveniences, will also be necessary.

Trabeation. Another term for Entablature.

Trabs. The Latin term for a wall-plate.

Tracery. In Gothic architecture, the intersection, in various ways, of the mullions in the head of a window, the subdivisions of groined vaults, &c. See Window Tracery.

Trachelium. (Lat.) The neck or space immediately below the capital in the Roman orders.

Tracing Cloth. A fine white cloth, prepared in a similar way to paper for rendering it transparent. Having a very greasy surface it is not so easy to work upon it; and as it shrinks much if wetted, no large washes of colour can be put on it; even many small tints are detrimental to accuracy. Lines made in error can be erased by gently using a brush damped with some soapy water. The cloth renders this paper much stronger than tracing paper, and it is now constantly used for working drawings.

Tracing Paper. A tissue paper made transparent by a preparation of turpentine and wax, slightly washed over it and then allowed to dry. Formerly resin and oil were used, as may be seen in the old sketch books, where the paper has turned a dark brown colour, and sometimes sticks to the leaves. In England it is made in sizes of 60 in. by 40in.; 40 in. by 30 in.; and 30 in. by 20 in. The last-named size is also made of a thicker paper. The following are the sizes of modern French-made tracing paper. It is also made 40 in. wide, and $21\frac{1}{2}$ yds. in length:—

	ins. ins.		ins. ins.
Romain - - -	16 by 12	Carré - - - -	22 by 17
Tellière - - -	17 ,, $13\frac{1}{2}$	Grand raisin - - -	24 ,, 18
Couronne - - -	18 ,, 14	Jésus - - - -	30 ,, 22
Serpente - - -	22 ,, 14	Colombier - - -	30 ,, 23
Ecu - - - -	20 ,, 16	Grand aiglo - - -	45 ,, 27

Besides this, J. Poore and Co. make a ferro-prussiate paper, which gives white lines on a blue ground, and supplied in rolls thirty and forty inches wide, of thin, thick, and extra thick paper. This not having been considered a very satisfactory process, a "black-line process," by Bemrose and Sons, of Derby, has lately been brought out (1888), by which copies of the original drawings can be produced; they can also be coloured and treated as ordinary drawings. It is called "Perfection Brand Sensitized Paper" (black-line process).

Tracings. An aniline process of photographic printing was patented a few years since by Mr. Willis, whereby fac-simile copies of tracings are obtained, of the same size as the originals, however large their dimensions, and copies can be supplied in a few hours. Delicate tinting as well as the black outlines are faithfully reproduced. By this process no cost is incurred for drawing, engraving, or lithographing. Drawings on thin drawing paper and on parchment can also be copied by this process.

Trammel. An instrument for describing an ellipsis by continued motion.

Transept (quasi Transseptum). The transverse portion of a cruciform church; that part which is placed between and extends beyond those divisions of the building containing the nave and choir. It is one of the arms projecting each way on the side of the stem of the cross.

Transition. A term used to denote the passing from one period of a style to another, exhibiting features peculiar to both, some of which have not quite been given up, and some of which were beginning to be introduced.

Transom. A beam or beams across a window to divide it into two or more lights in height. A window having no transom was formerly called a clear-story window.

Transtra. (Lat.) The horizontal timbers in the roofs of ancient Roman buildings.

Transverse. Lying in a cross direction. The *transverse strain* of a piece of timber is that sidewise, by which it is more easily bent or broken than when compressed or drawn as a tie in the direction of its length.

Trap. In drainage and water escape, an article formed in any material to prevent the escape of foul air; such as a *bell trap*, syphon trap, D trap, &c.

Trapezium. (Gr.) In geometry, a quadrilateral figure, whose opposite sides are not parallel.

Trapezoid. (Gr.) A quadrilateral figure having one pair of opposite sides parallel.

Traverse. A gallery or loft of communication in a church or other large building

Tread. The horizontal part of the step of a stair. It can be greatly protected where there is much traffic, by squares of hard wood inserted grain upwards into a light cast-iron frame, which is then secured to the original tread.

Trefoil. In Gothic architecture, an ornament consisting of three cusps in a circle.

Trellice. A reticulated framing made of thin bars of wood; it is used as a screen to windows where air is required for the apartment, &c.

Trenail. A large cylindrical wooden pin, used in roof work and framing.

Tressel or Trussel. Props for the support of anything the under surface of which is horizontal. Each tressel consists of three or four legs attached to a horizontal part. When the tressels are high the legs are sometimes braced. Tressels are much used in building for the support of scaffolding; and by carpenters and joiners while ripping and cross-cutting timber, and for many other purposes.

Triangle. (Lat.) A plane rectilineal figure of three sides, and consequently of three angles. In measuring, all rectilineal figures must be reduced to triangles, and in constructions for carpentry all frames of more than three sides must be reduced to triangles to prevent a revolution round the angles.

Triangular Compasses. Such as have three legs or feet by which any triangle or any three points may be taken off at once.

Tribune. See Apsis.

Triclinium. (Lat.) The room in the Roman house wherein the company was received, and seats placed for their accommodation. It was raised two steps from the peristyle, and had therein a large window, which looked upon the garden. The aspect of winter triclinia was to the west, and of summer triclinia to the east.

Triforium. (Lat.) The gallery or open space between the vaulting and the roof of the aisles of a church, generally lighted by windows in the external wall of the building, and opening to the nave, choir, or transept over the main arches. It occurs only in large churches, and is varied in the arrangement and decoration of its openings in each succeeding period of architecture. See *figs.* 1417 to 1422. There is no triforium in Bath abbey church, nor to the choir at Bristol cathedral.

Triglyph. (Gr. Τρεις, and Γλυφη, a channel.) The vertical tablets in the Doric frieze chamfered on the two vertical edges, and having two channels in the middle, which are double channels to those at the angles. In the Grecian Doric, the triglyph is placed upon the angle; but in the Roman, the triglyph nearest the angle is placed centrally over the column. The space between the channels was called a *femur* and *meros*. *Fig.* 1461 is an example of a triglyph with the metope decorated with a bull's skull and garlands, as used in Italian architecture, by Sir William Chambers and others. See Shank.

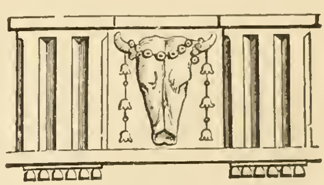

Fig. 1461.

Ditriglyph is the arrangement by which two triglyphs are obtained in the frieze between those which stand over the columns.

Tritriglyphs is where there are three so placed.

Trigonometry. (Gr. Τρεις, three, Γωνια, an angle, and Μετρω, I measure.) The science of determining the unknown parts of a triangle from certain parts that are given. It is either *plane* or *spherical*; the first relates to triangles composed of three right lines, and the second to triangles formed upon the surface of a sphere by three circular arcs. This latter is of less importance to the architect than the former.

Trilateral. (Lat.) Having three sides.

Trilithon. Two upright stones linked together by a third on the top like a lintel; many such are seen at Stonehenge.

Trim. (Verb.) To fit to anything; thus, to *trim up*, is to fit up.

Trimmed. A piece of workmanship fitted between others previously executed, which is then said to be *trimmed in* between them. Thus, a partition wall is said to be trimmed up between the floor and the ceiling; a post between two beams; a trimmer between two joists.

Trimmed out. A term applied to the trimmers of stairs when brought forward to receive the rough strings.

Trimmer. A small beam, into which are framed the ends of several joists. The two joists, into which each end of the trimmer is framed, are called *trimming joists*. This arrangement takes place where a well-hole is to be left for stairs, or to avoid bringing joists near chimneys, etc.

Trine Dimensions. Those of a solid, including length, breadth, and thickness; the same as threefold dimensions.

Tripod. (Gr. Τρεις, and Πους, a foot.) A table or seat with three legs. In architectural ornament its forms are extremely varied, many of those of the ancients are remarkable for their elegance and beauty of form.

Triptych. A picture with folding doors, the inside of which is either also painted, or else decorated with diapers, etc. When the picture has only one door, it is called a diptych.

Trisection. The division of anything into three equal parts.

Triumphal Arch. A building of one arch erected first by the Roman people in memory of the victor, his trophies being placed on the top. Subsequently they became enriched and loaded with ornaments, and later were penetrated by three apertures, a central and two smaller ones. The arch of Trajan at Ancona, and that of Titus at Rome, have one arch; an arch at Verona has two openings; while those of Constantine, Septimius Severus (*fig.* 1462 as restored) and others, have three. There are numerous modern examples, such as the arc de l'etoile at Paris; the arco dalle pace at Milan; the marble arch at London, etc.

Fig. 1462. Septimius Severus, as restored.

Trochilus. (Gr. Τροχιλος, a pulley.) An annular moulding whose section is concave, like the edge of a pulley. It is more commonly called a *scotia*, and its place is between the two tori of the base of a column.

Trochoid. (Gr. Τροχος, a wheel, and Ειδος, shape.) A figure described by rolling a circle upon a straight line, such circle having a pin or fixed point in its circumference upon a fixed plane, in or parallel to the plane of the moving circle. It is also called a cycloid.

Trophy. (Gr. Τροπαιον.) An ornament representing the trunk of a tree charged with various spoils of war.

Trough. (Sax. Τροh.) A vessel in the form of a rectangular prism, open on the top for holding water.

Trough Gutter. A gutter in the form of a trough, placed below the dripping eaves of a house, in order to convey the water from the roof to the vertical trunk or pipe by which it is to be discharged. It is only used in common buildings and outhouses.

Truncated. (Lat. Trunco, I cut short.) A term employed to signify that the upper portion of some solid, as a cone, pyramid, sphere, etc. has been cut off. The part which remains is called a *frustum*.

Trunk. That part of a pilaster which is contained between the base and the capital. Also a vessel open at each end for the discharge of water, rain, etc.

Truss. (Fr. Trousse.) A combination of timber framing, so arranged that if suspended at two given points, and charged with one or more weights in certain others, no timber would press transversely upon another except by strains exerting equal and opposite forces.

Truss Partition. One containing a truss within it, generally consisting of a quadrangular frame, two braces, and two queen posts, with a straining post between them, opposite to the top of the braces.

Truss Roof. A roof formed of a tiebeam, principal rafters, king post or queen post, and other necessary timbers to carry the purlins and common rafters, etc.

Trussed Beam. One in which the combination of a truss is inserted between and let into the two pieces whereof it is composed.

TRUSSING PIECES. Those timbers in a roof that are in a state of compression.
TRY. (Verb.) To plane a piece of stuff by the rule and square only.
TUBE. (Lat.) A substance perforated longitudinally; generally quite through its length.
TUCK POINTING. In old brickwork, after it has been well washed and the mortar raked out, the joints are filled with new mortar; the face of the work is then coloured yellow or red, as desired. Lines to mark the joints are made by putting on a ridge of lime putty with the point of the trowel over the new mortar, and cutting it straight and to the required width by means of a straight edge and knife.
TUDOR STYLE. A name given to the late portion of the Perpendicular Gothic, from the line of sovereigns in England who reigned during its prevalence. The arch is of a four-pointed obtuse shape.
TUFA. A mass of volcanic earth, consolidated. *Tufo* is a mass of agglomerated sand without volcanic character. *Tufaceous*, mixed with *tufo*.
TUMBLED IN. The same as *trimmed in*. See TRIMMED.
TUMULUS. A barrow or artificial earth mound. Among the Celtic works the former was sepulchral, and the latter perhaps erected for beacons or for a memorial purpose.
TUNNEL. (Fr.) A subterranean channel for carrying a stream of water under a road, hill, etc., or through which a road or railway is run.
TUN OF WATER. See WATER, Weight of.
TURNING PIECE. A board with a circular face for turning a thin brick arch upon.
TURPENTINE. Turpentine is obtained by exudation and hardening of the juice flowing from incisions into pine trees. To obtain the oil of turpentine, the juice is distilled in an apparatus like the common still, and water is introduced with the turpentine.
TURRET. (Lat. Turris.) A small tower often crowning the angle of a wall, etc.
TUSCAN ORDER. The first of the five orders used in Roman and Italian architecture. See *fig.* 1454.
TUSK. A bevel shoulder made above a tenon, and let into a girder to give strength to the tenon.
TYMPANUM. (Gr.) The naked face of a pediment (see PEDIMENT) included between the level and raking mouldings. See ÆTIAIOI and ÆTOMA. The word also signifies the die of a pedestal, and the panel of a door.
TYPE. (Gr. Τυπος.) A word expressing by general acceptation, and consequently applicable to, many of the varieties involved in the terms model, matrix, impression, &c. It is, in architecture, that primitive model, whatever it may have been, that has been the foundation of every style, and which has guided, or is supposed to have guided, the forms and details of each. What it was in each style is still only conjecture.
TYPE. The canopy over a pulpit, also called a sound board.

U

UNDERCROFT. A vault under a church or chapel. See CRYPT, CROFT, and SHROWDS.
UNDERPINNING. Bringing a wall up to the ground sill. The term is also used to denote the temporary support of a wall, whose lower part or foundations are defective, and the bringing up new solid work whereon it is in future to rest. See GOUFING.
UNDERPITCH GROIN. See WELCH GROIN.
UNGULA. The portion of a cylinder or cone comprised by part of the curved surface, the segment of a circle, which is part of the base, and another plane.
UNIVERSITY. An assemblage of colleges under the supervision of a senate, etc.
UPHERS. Fir poles, from four to seven inches in diameter, and from twenty to forty feet in length. They are often hewn on the sides, but not entirely, to reduce them square. They are chiefly used for scaffolding and ladders, and are also employed in slight and common roofs, for which they are split.
UPRIGHT. The elevation of a building; a term rarely used.
URILLA. See HELIX.
URN. (Lat.) A vase of a circular form, destined among the ancients to receive and preserve the ashes of the dead. With the vase, it often forms a decoration to the pedestal of a balustrade on a terrace, top of a wall, etc.

V

VAGINA. (Lat.) The lower part of a terminal in which a statue is apparently inserted.
VALLEY. (Lat.) The internal meeting of the two inclined sides of a roof. The rafter which supports the valley is called the *valley rafter* or *valley piece*, and the board fixed upon it for the leaden gutter to rest upon is called the *valley board*. The old writers called the valley rafters *sleepers*.
VALVE. (Lat.) Anything which opens on hinges or pivots as a door.
VANE. A plate of metal shaped like a banner fixed on the summit of a tower or steeple, to show the direction of the wind.

Vanishing Line. In perspective, the intersection of the parallel of any original plane and the picture is called the vanishing line of such plane. The *vanishing point* is that to which all parallel lines in the same plane tend in the representation.

Vaporarium. (Lat.) The same as Caldarium.

Variation of Curvature. The change in a curve by which it becomes quicker or flatter in its different parts. Thus, the curvature of the quarter of an ellipsis terminated by the two axes is continually quicker from the extremity of the greater axis to that of the lesser. There is no variation of curvature in the circle.

Varnish. A glossy coat on painting or the surface of any matter. It consists of different resins in a state of solution, whereof the most common are mastic, sandarac, lac, benzoin, copal, amber, and asphaltum. The menstrua are either expressed, or essential oils, or alcohol.

Vase. (Lat. Vas.) A term applied to a vessel of various forms, and chiefly used as an ornament. It is also used to denote the bell, or naked form, to which the foliage and volutes of the Corinthian and Composite capitals are applied. The *vases of a theatre* in ancient architecture were bell-shaped vessels placed under the seats to produce reverberation of the sound. See Echea.

Vault. (It. Volto.) An arched roof over an apartment, concave towards the void, whose section may be that of any curve in the same direction. Thus a *cylindric vault* has its surface part of a cylinder. A *full-centred vault* is formed by a semi-cylinder. When a vault is greater in height than half its span, it is said to be *surmounted*; when less, *surbased*. A *rampant vault* springs from planes not parallel to the horizon. The *double vault* occurs in the case of one being above another. A *conic vault* is formed of part of the surface of a cone, as a *spherical vault* consists of part of the surface of a sphere. The plane of an *annular vault* is contained between two concentric circles. A vault is said to be *simple* when formed by the surface of some regular solid round one axis, and *compound* when formed of more than one surface of the same solid or of two different solids. A *cylindro-cylindric vault* is formed of the surfaces of two unequal cylinders; and a *groined vault* is a compound one rising to the same height in its surfaces as that of two equal cylinders, or a cylinder with a cylindroid. The *reins of a vault* are the sides or walls that sustain the arch. See Fan Vaulting.

The following table gives the clear breadths and heights in English feet, of the most remarkable vaulted avenues, as given by Mr. Garbett in his "Principles of Design in Architecture":—

Date.	Name.	Breadth.	Height.	Proportion.
Tarquin I.	Cloaca Maxima - - - - -	16	26	1 : 1·625
1st cent.	Temple of Peace, Rome - - -	83	121	1 : 1·46
2nd or 3rd	Second Temple at Baalbec - -	63	93	1 : 1·47
11th	Cathedral at Speyer - - - - -	45	107	1 : 2·35
13th	——— Salisbury - - -	35	84	1 : 2·3
	——— Amiens - - -	42	147	1 : 3·5
	——— Cologne - - -	41½	145	1 : 3·5
	Westminster Abbey - - - - -	33	99	1 : 3
14th	Cathedral at York (not vaulted) -	46	92	1 : 2
	——— Milan - - - - -	55	165	1 : 3
	Choir at Beauvais Cathedral - -	48	167	1 : 3·5
15th	Chapel of King's College, Cambridge	40	80	1 : 2
16th	Cathedral at Florence - - - -	55	140	1 : 2·54
17th	——— of St. Peter's, Rome - -	84	147	1 : 1·74
	——— St. Paul's, London - -	41	82	1 : 2

Thus St. Peter's has the same external height as Amiens but gives *twice* the breadth; yet both are considered well proportioned avenues in their respective styles.

Vaulted Ceiling. A ceiling built of stone, bricks, or blocks of wood, supporting itself on the principle of the arch.

Vaulting Shaft. A pillar, sometimes rising from the floor, or only from the capital of a pier, or even only from a corbel, from the top of which spring the *vaulting ribs* of the groining.

Velarium. (Lat.) The great awning, which by means of tackle was hoisted over the Roman theatre and amphitheatre to protect the spectators from the rain or the sun's rays.

Vellar Cupola. A term used by Alberti to denote a dome or spherical surface terminated by four or more walls, frequently used over large staircases and salons, and other lofty apartments.

VENEER. A very thin leaf of wood of a superior quality, for covering furniture, etc., made of an inferior wood. Wafers of wood thirty-two inches wide were made about 1824.

VENETIAN DOOR. A door having side lights on each side of its frame.

VENETIAN STYLE. That style of modern Italian architecture formed by the architects of the Venetian states in the fifteenth to the early part of the seventeenth centuries.

VENETIAN WINDOW. One formed with three apertures separated by slender piers from each other, whereof the centre one is much larger than those on the sides.

VENT. The flue or funnel of a chimney; also any conduit for carrying off that which is offensive.

VENTIDUCT. A passage or pipe for the introduction of fresh air to an apartment.

VENTILATION. The continual change of air to an apartment, or portion of an edifice, &c. The architect has to provide means for letting off or taking away the foul air, generally by apertures at the upper part of the room, etc., to which the hot air will ascend, as well as to provide for the admission of fresh air in sufficient quantities to take its place or to force it out without any appreciable current.

VERANDAH. An open gallery having a roof supported by light pillars, and placed over the windows of the principal rooms of a house to shelter them from the rays of the sun, and under which persons can promenade for fresh air. It is sometimes enclosed with glass screens to form a conservatory.

VERGE BOARDS. See BARGE BOARDS.

VERMICULATED WORK. (Lat.) A term applied to rustic-work which is so wrought as to have the appearance of having been eaten into by worms.

VERTEX. (Lat. the top.) A term generally applied to the termination of anything finishing in a point, as the vertex of a cone, etc.

VERTICAL ANGLES. The opposite ones made by two straight lines cutting each other.

VERTICAL PLANE. One whose surface is perpendicular to the horizon.

VESICA PISCIS. (Lat. a fish's bladder.) A form which may be produced in the endeavour to gain two lines at right angles with each other. Arcs of circles inclosing two equilateral triangles drawn on the same base line will also produce it. It was a monogram, which has been supposed to be connected with the plan and form of churches erected during the mediæval period. Many mediæval seals of ecclesiastical and other communities were designed on the same form, and have been imitated of late for those of some archæological societies. See SYMBOLISM.

VESTIBULE. (Lat. Vestibulum.) An apartment which serves as the medium of communication to another room or series of rooms. In the Roman houses it appears to have been the place before the entrance where the clients of the master of the house, or those wishing to pay their court to him, waited before introduction. It was not considered as forming a part of the house. The entrance from the *vestibulum* led immediately into the *atrium*, or into the *cavædium*.

VESTRY. (Lat. Vestiarium.) An apartment in, or attached to, a church for the preservation of the sacred vestments and utensils. A sacristy; see DIACONICUM.

VIBRATION. A motion or combination of motions. The theory of the vibrations of the particles of an elastic fluid is the key to what is known of the phenomena of sound and light: and it is supposed that the causes of the sensible phenomena of heat, electricity, and magnetism will be found in the vibrations of matter of some kind. It is stated that iron kept constantly in a state of vibration oxidates less rapidly than that which is at rest, as exemplified in railway rails. It is recorded that the greatest vibration on the timber temporary bridge over the river Thames at Blackfriars was produced by empty four-wheel cabs. The vibration on the top platform, though it appeared considerable, was in fact only a quarter of an inch.

VICE or VIS. (Fr.) An old term applied to a spiral or winding staircase. In mechanics, a machine serving to hold fast anything worked upon, whether the purpose be filing, bending, riveting, etc.

VILLA. A country-house for the residence of an opulent person. Among the Romans there were three descriptions of villa, each having its particular destination, namely, the *Villa urbana*, which was the residence of the proprietor, and contained all the conveniences of a mansion in the city. The *Villa rustica*, which contained not only all that was essential to rural economy, such as barns, stables, etc., but comprised lodging apartments for all those who ministered in the operations of the farming establishment. The *Villa fructuaria* was appropriated to the preservation of the different productions of the estate, and contained the granaries, magazines for the oil, cellars for the wine, etc.

VILLAGE HOSPITAL. A class of building lately recommended to be formed in small localities for the purpose of preventing the spread of fevers, &c., by at once placing the sick under proper treatment.

VIMANA. The name for the temple of the Hindoos, in front of which is the *mantapa* or porch, and again the *gopura* or pyramidal entrance gateway.

VINERY. A house for the cultivation of vines. See CONSERVATORY.

Visorium. (Lat.) See Amphitheatre.
Visual Point. In perspective a point in the horizontal line in which the visual rays unite.
Visual Ray. A line of light supposed to come from a point of the object to the eye.
Vitruvian Scroll. See Scroll.
Vitrification. The hardening of argillaceous stones by heat. See Brick; Terra Cotta.
Vivo. (Ital.) The shaft of a column.
Volute. A spiral scroll which forms the principal feature of the capital of the Ionic order in Greek and Roman architecture. The capital of the Corinthian order has one smaller in size (Helix), which is enlarged in that of the Composite order. Several methods have been put forward of describing the spiral lines of the Ionic volute. The returns or sides are called *pulvinata* or pillows. *Balteus* is the outer fillet on the side of the volute.
Vomitorium. (Lat.) See Amphitheatre.
Voussoir. (Fr.) A wedge-like stone or other matter forming one of the pieces of an arch. See Arch. The centre voussoir is called a *keystone*.
Vulcanised India Rubber. A material perhaps only brought into requisition by the architect for the purpose of excluding draughts from doors and the entry of dust into closets or cases. As a tube, with or without a spiral wire in it, it is greatly used for movable gas-lights.

W

Waggon-headed Ceiling. The same as cylindrical ceiling. See Vault.
Wainscot. (Dutch, Wayschot.) A term usually applied to the oak or deal lining of walls in panels. The wood originally used for this purpose was a foreign oak, and called wainscot, hence the name of the material became attached to the work itself.
Wall. A body of material for the enclosure of a building and the support of its various parts. "External wall" shall apply to every outer wall or vertical enclosure of any building, not being a party wall (Metropolitan Building Act, 1855.) "Cross wall" shall apply to every wall used or built in order to be used as a separation of one part of any building from another part of the same building, such building being wholly in one occupation. (*Idem.*) See Party wall.
Walings. See Shoring.
Walls of the Ancients. See Masonry.
Walls, Cased. Those faced up anew round a building, in order to cover an inferior material, or old work gone to decay.
Walnut. A forest tree used in cabinet work.
Washer. A flat piece of iron, or other metal, pierced with a hole for the passage of a screw, between whose nut and the timber it is placed, to prevent compression on a small surface of the timber. Also the perforated metal plate of a sink or drain, which can be removed for letting off the waste water, and thus more easily cleansing it.
Wasting. Splitting off the surplus stone from a block, with a point or a pick, reducing it to nearly a plane surface. In Scotland it is called *clouring*.
Water. See Weight.
Water Joint. A joint between two stones in the paving of a terrace, where each side of the joint for about an inch is made level and then rounded off into a sinking of the stones, to prevent water lodging in the joint, especially if occasionally covered with it, as a river landing-place.
Water Joint Hinge. A hinge made into a sort of loop at the turning part, whereby it is less likely to stiffen by rusting, as it is generally used in out-door work.
Water Shoot. See Square Shoot.
Water Supply. See Plumbery. See Aqueduct.
Water Table. An inclined plane where a wall sets off to a larger projection, for the purpose of throwing off any water that may fall upon that plane, and is principally used to buttresses and other similar parts of mediæval buildings: but in all styles it is an efficient way of attaining the above desirable object. Where a stone entablature occurs, the top is often covered with lead to prevent water soaking through.
Waves. In many engineering works, the *weight of the stone* to be employed is of the utmost importance, especially for low buildings occasionally under water, where there is a rapid current, or where they are subject to the influence of powerful waves. Such circumstances will require a heavier stone to be used than may at first have been considered necessary, because all bodies immersed are reduced in weight by so much as is equal to that of the bulk of water which they displace. The force of the waves at Skerryvore lighthouse was found to be 4,335 lbs. per square foot; that at Bell Rock

lighthouse was 3,013 lbs. The highest force observed was 6,000 lbs. For weight of water, see WEIGHT.

WEATHER BOARDING. Boards nailed with a lap on each other, to prevent the penetration of the rain and snow. The boards for this purpose are generally made thinner on one edge than on the other, especially in good permanent work. The feather-edged board is, therefore, used in such cases, the thick edge of the upper board being laid on the thin edge of that below, lapping about an inch or an inch and a half, and the nails being driven through the lap.

WEATHER MOULDING. A moulded string course. The projecting moulding of an arch, having a weathered or sloped surface at top, serving to throw off the rain, and to protect the other mouldings. See HOOD MOULD.

WEATHER TILING and SLATING. The covering an upright wall with tiles, or with slates.

WEDGE. (Dan. Wegge.) An instrument used for splitting wood or other substances; it is usually classed among the mechanical powers.

WEIGHT. (Sax. Wiht.) In mechanics, a quantity determined by the balance; a mass by which other bodies are examined. It denotes anything to be raised, sustained, or moved by a machine as distinguished from the power, or that by which the machine is put in motion.

WEIGHT, in commerce. A body of given dimensions, used as a standard of comparison for all others. By an act of parliament passed in June, 1824, all weights were to remain as they then were, that act only declaring that the imperial standard pound troy shall be the unit or only standard measure of weight from which all other weights shall be derived and computed; that this troy pound is equal to the weight of 22·815 cubic inches of distilled water weighed in air at the temperature of 62° of Fahrenheit's thermometer, the barometer being at 30 inches, and that there being 5760 such grains in a troy pound, there will be 7,000 grains in a pound avoirdupois.

TROY WEIGHT.

24 grains =	1 pennyweight.		
480 ... =	20 .... =	1 ounce.	
5760 ... =	240 .... =	12 ... =	1 pound.

AVOIRDUPOIS WEIGHT.

16 drams =	1 ounce.				
256 ... =	16 ... =	1 pound.			
7168 ... =	448 ... =	28 ... =	1 quarter.		
28672 ... =	1792 ... =	112 ... =	4 .... =	1 cwt.	
573440 ... =	35840 ... =	2240 ... =	80 .... =	20 .. =	1 ton.

The avoirdupois pound: pound troy :: 175 : 144, or :: 11 : 9 nearly; and an avoirdupois pound is equal to 1 lb. 2 oz. 11 dwts. 16 grains troy. A troy ounce = 1 oz. 1·55 dr. avoirdupois.

The following is a table of weights according to the French system.

Names.	French value.		English value.
Millier,	1000 kilogrammes = 1 French ton	=	19·7 cwts.
Quintal,	100 kilogrammes	=	1·97 cwt.
Kilogramme,	Weight of one cubic decimètre of water of the temperature of 39° 12′ Fahrenheit.	=	2·6803 lbs. troy. 2·2055 lbs. avoirdupois.
Hectogramme,	$\frac{1}{10}$ of kilogramme	=	3·2 ounces troy. 3·52 ozs. avoirdupois.
Decagramme,	$\frac{1}{100}$ of kilogramme	=	6·43 dwts. troy.
Gramme,	$\frac{1}{1000}$ of kilogramme	=	15·438 grains troy. 0·643 pennyweight. 0·032 ounce troy.
Decigramme,	$\frac{1}{10000}$ of kilogramme	=	1·5438 grain troy.

The following table exhibits the proportion of weights in the principal places of Europe to 100 lbs. English avoirdupois.

100 lbs. English	= 91 lbs.	8 ozs.	for the pound of	Amsterdam, Paris (old), &c.
—	= 96	8	—	Antwerp or Brabant.
—	= 88	0	—	Rouen (the Viscounty weight).
—	= 106	0	—	Lyons (the city weight).
—	= 90	9	—	Rochelle.
—	= 107	11	—	Toulouse and Upper Languedoc.
—	= 113	0	—	Marseilles or Provence.
—	= 81	7	—	Geneva.
—	= 93	5	—	Hamburgh.
—	= 89	7	—	Frankfort, &c.

100 lbs. English	= 96 lbs.	1 ozs.	for the pound of	Leipsic, &c.
—	= 137	4	—	Genoa.
—	= 132	1	—	Leghorn.
—	= 153	11	—	Milan.
—	= 152	0	—	Venice.
—	= 154	10	—	Naples.
—	= 97	0	—	Seville, Cadiz, &c.
—	= 104	13	—	Portugal.
—	= 96	5	—	Liege.
—	= 112	$0\frac{2}{3}$	—	Russia.
—	= 107	$0\frac{1}{24}$	—	Sweden.
—	= 89	$0\frac{1}{2}$	—	Denmark.

The Paris pound (poids de marc of Charlemagne) contained 9216 Paris grains; it was divided into 16 ounces, each ounce into 8 gros, and each gros into 72 grains. It is equal to 7561 English troy grains.

The English troy pound of 12 ounces contains 5760 troy grains = 7021 Paris grains. The English avoirdupois pound of 16 ounces contains 7000 English troy grains, and is equal to 8538 Paris grains.

To reduce Paris grains to English troy grains, divide by
Or, to reduce English troy grains to Paris grains, multiply by } 1·2189

To reduce Paris ounces to English troy, divide by
To reduce English troy ounces to Paris, multiply by } 1·015734

Weight of Man. As guidance in providing sufficient strength in a floor loaded with human beings, the following weights are subjoined:—

Mean weight of a Belgian	- 140·49 lbs.	Mean height,	5 feet	$6\frac{3}{4}$ inches.
„ Frenchman	- 136·89 „	„	5 „	4 „
„ Englishman	- 150·98 „	„	5 „	$9\frac{1}{2}$ „

The weight in travelling carriages usually taken is 165 lbs.

Supposing, therefore, each individual in standing to occupy 2·5 superficial feet, which would be close to one another, and indeed closer than pleasant, on a square of flooring there would be $\frac{100}{2\cdot5} = 40$ persons, and $40 \times 150\cdot98$ lbs. = 2·96 tons. The average surface of a man's body is usually considered about 15 superficial feet, which would give a cubic content of 3·95 feet, and a consequent specific gravity of 612.

Weight of Materials. As, in the construction of warehouses, it is essential for the architect to know the probable weight of merchandise which his client may probably put upon the respective floors, the following tables may be found useful. The second one is taken from the *Papers of the Corps of Royal Engineers*, 1832, iii. 192, contributed by Major Harry D. Jones.

Articles.	Weight of a cubic ft. lbs.	Cubic feet = one ton.	Articles.	Weight of a cubic ft. lbs.	Cubic feet = one ton.
Ashes - - - -	37	60·5	Hay, well pressed -	8

		Cube.	Weight.	lbs. per ft. cube	Cube ft. per ton.
Tea, Bohea	2· 9 × 1·10 × 1·8½	= 8·609	= 224 lbs.	= 26·02	= 86·09
„ Congo	1·10½ × 1· 8½ × 1·4½	= 4·403	= 111 lbs.	= 25·21	= 88·87
„ Hyson	1. 6½ × 1· 6 × 1 9	= 4·048	= 80 lbs.	= 19·76	= 113·34
„ Souchong	1· 7½ × 1· 7½ × 1·7	= 4·180	= 108 lbs.	= 25 84	= 86·70
„ Twankay	1·11½ × 1· 6 × 1·8	= 5·140	= 104 lbs.	= 20 23	= 110·70
	Mean	5·276		23·41	= 97·14

A heaped Bushel of Wheat=60 lbs. per foot cube, and 48·13 cube feet in a ton. A ditto of Barley=47 to 50 lbs. A ditto of Oats=38 to 40 lbs. A ditto of Coal=88 to 94 lbs.

Weight of WATER:—

1 quart of water = 69·3185 cubic inches = 2½ lbs. weight.
4 quarts = 1 gallon = 277·274 cubic inches = 10 lbs. weight.
2 gallons = 1 peck = 554·548 cubic inches = 20 lbs. weight.
4 ditto = 1 bushel = 2218·192 cubic inches = 80 lbs. weight.
Sea water, 1 cubic foot = 64 lbs.; 35 cubic feet = 1 ton.

A cubic metre of water is equal in volume to 35·3174 feet English or to 220·0967 imp. gallons. As it is nearly equivalent to the old English tun of four hogsheads holding 35·248 cubic feet, and as it has been for some time in use on the Continent for measuring sewage and water supply, it is now employed for the same purpose in England.

WEIGHTS OF A SASH. Two weights, one on each side of a sash, by which the sash is suspended and kept in the situation to which it is raised by means of cords passing over pulleys. The vertical sides of the sash frames are generally made hollow in order to receive the weights, which, by this means, are entirely concealed. Thus, to keep the sash in suspension, each weight must be half the weight of the sash. The cords should be of the best quality, or they soon fret to pieces. Wire sash line, leather sash line, and copper sash chains, are late inventions to supersede the hempen cords.

WELCH GROIN. A groin formed by the intersection of two cylindrical vaults, one of which is of less height than the other. Also called an *underpitch groin.*

WELDING. The union of two pieces of iron by heating and hammering them. It requires great care that the joint shall be of the same strength as the remainder of the metal. Malleable cast iron does not weld. In all but the very thinnest castings, although the surface has been converted into a malleable form, there remains an inner core which at the temperature required for welding falls to pieces immediately the object is struck with the hammer. Good specimens may be bent double when cold, although they will probably break if bent back again. The metal can also be forged to a limited extent at a moderate red heat, although if heated above this point it falls to pieces under the hammer. It may be burnt together at a temperature approaching fusion, or may be brazed with hard solder to either iron or steel. See SOLDERING and BRAZING.

The cheapening of oxygen by Brin's process of manufacture caused Mr. Thos. Fletcher, of Warrington, to make some experiments with the compressed oxygen and coal gas, whereby with a half-inch gas supply a joint could be brazed in a 2-inch wrought iron pipe in about one minute, the heat being very short, the redness not extending over one inch on each side of the joints. Welding is not possible with ordinary coal gas and air, owing to magnetic oxide on the surfaces. As a good weld was obtained on an iron wire $\frac{1}{8}$ inch diameter, with an air jet about $\frac{1}{32}$ inch diameter, the matter should be taken up and tried further (January 1888).

WELL. A deep circular pit, or sort of shaft, sunk by digging down through the different strata or beds of earthy or other materials of the soil, so as to form an excavation for the purpose of containing the water of some spring or internal reservoir, by which it may be supplied.

WELL-HOLE. In a flight of stairs, the space left in the middle beyond the ends of the steps.

WHEEL. (Sax.) In mechanics, an engine consisting of a circular body turning on an axis, for enabling a given power to move or overcome a given weight or resistance. This machine may be referred to the lever.

WHEELBARROW. An implement for carrying bricks, soil, &c. from one place to another, which has a wheel attached in front of a box-like carriage, to which two handles are affixed behind; by these the man raises the box, pushing it forward on the wheel.

WHEEL WINDOW. See CATHERINE WHEEL WINDOW.

WHETSTONE. A stone of fine quality by which tools for cutting wood are brought to a fine edge, after being ground upon a gritstone, or grinding-stone, to a rough edge.

WHINSTONE. The name by which the marl of the lower greensand is distinguished in Western Sussex; probably of Saxon origin, remarks Dr. Mantell.

WHITE LEAD. A material forming the basis of most colours in house-painting. The common method of making it is by rolling up thin leaden plates spirally, so as to leave the space of about an inch between each coil These are placed vertically in earthen pots, at the bottom of which is some good vinegar. The pots are covered, and exposed for a length of time to a gentle heat in a sandbath, or by bedding them in dung. The vapour of the vinegar, assisted by the tendency of lead to combine with the oxygen which is present, corrodes the lead, and converts the external portion into a white substance which comes off in flakes. These are washed and dried in stoves in lumps, and form the white lead of the painters. It is much improved in quality by keeping.

WICKET. A small door made in a gate.

WIND-BEAM. An obsolete name for a COLLAR-BEAM. The term is now applied to a piece of wood laid diagonally under the rafters of a long roof, from the foot of one truss to the head of another to strut them, so as to prevent the roof racking with the wind.

WINDERS. The steps in a stircase which radiate from a centre, and are therefore narrower at one end than another.

WIND-GUARD. One of the many names given to inventions professing to cure a down draught or a smoky chimney. Amongst these are reckoned Boyle's patent chimney cowl, "a most effectual cure" for either a sluggish chimney or a blow-down. Milburn's patent noiseless chimney cowl has all the fittings made of copper and brass, and will last for a long time, is easily swept, and the oil box only requires refilling every six years. Banner advertises a "Wessex chimney cowl" as most efficient. "Day's Windguard," and the "Prince" chimney pot for preventing down-blow, are manufactured by Ewart and Son. Hammond's patent glazed stoneware chimney terminal is reasonable, and stated to ensure "a perfect cure."

WINDING. The same as *casting* or *warping.*

Windlass or Windlace. A machine for raising weights, in which a rope or chain is wound about a cylindrical body moved by levers; also a handle by which anything is turned.

Window. An aperture in a wall for the transmission of light. See Bull's-eye; Skylight; Lantern light; Venetian Window.

Window Tracery. The ornamental stonework in the heads of windows in mediæval architecture. The earlier windows during the early English or First Pointed period of mediæval architecture, were as a rule very narrow (*fig.* 1463) and without a dripstone. Later on, however, a dripstone, or perhaps more correctly, a hood mould, was used, which was often continued on from window to window (*fig.* 1465).

Fig. 1463.

Fig. 1464.

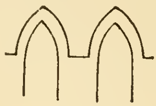

Fig. 1465.

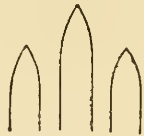

Fig. 1466.

As the style advanced, these narrow pointed openings were placed in couplets or triplets, the centre one being highest (*fig.* 1466); and the first approach to window tracery was developed by the piercing of the wall above the couplets with a circular or lozenge shaped opening (*fig.* 1467).

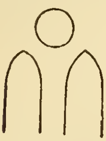

Fig. 1467.

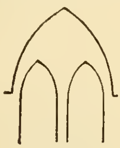

Fig. 1468.

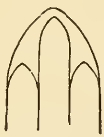

Fig. 1469.

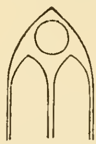

Fig. 1470.

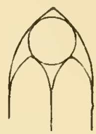

Fig. 1471.

The next step in the development of the traceried window was the grouping together of two or three of these lancet windows and enclosing them under a label or arch (*fig.* 1468).

The triplet window, however, contributed much less to the development of Gothic tracery than the couplet, as there was no necessity for the circular opening to fill up the spaces between the tops of the windows and the enclosing arch, as that space was already occupied by the central light (*fig.* 1469), which was much taller than the others. The combination of couplets with a circular opening between the tops is therefore the fundamental principle of a Gothic window, and the result produced thereby was the earliest form of Plate tracery (*fig.* 1470). The east window of Lincoln Cathedral (shown in the illustration *fig.* 1472), which is perhaps the largest one in existence belonging to this style, consists of two large pointed compartments, each of which is divided into four smaller compartments or lights, called bays or days, placed in couplets with foliated circles between their heads. These couplets have also larger foliated circles between their heads, and in the spandril between the heads of the two large compartments is a large circle enclosing seven smaller foliated circles, one being in the centre and six surrounding it. The mullions or divisions between the lights are fronted by slender shafts with floriated capitals. This window exhibits the transitional progress of tracery from the Early English to the Geometrical Decorated period.

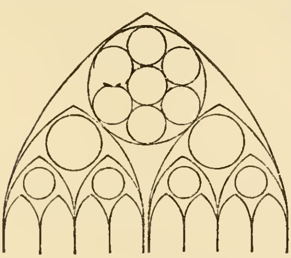

Fig. 1472. Outline of East Window, Lincoln.

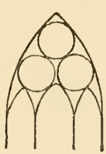

Fig. 1473.

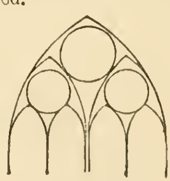

Fig. 1474.

In the perfect form of tracery which was developed during the Decorated period, the slips of wall between the narrow windows became reduced into mullions or upright bars of stone dividing the lights, while the tracery of the upper part of the window, of the same thickness as the mullions, consists of perfect geometrical forms resting upon the arches of the lights, the spandrils between which are pierced, and all combined or enclosed under one arch. A common form in earlier examples consists of three lights of equal height (fig. 1473), the head of the window containing three circles placed pyramidally, the insides of which are trefoiled. But as already seen, the form which served most to develope the traceried window was the couplet with a circle above, combinations of which are shown in the accompanying diagrams (figs. 1474, 1475). The windows of the nave of Exeter Cathedral are for the most part pure specimens of this style; although they are all perfectly uniform with each other, no two are alike on the same side.

Fig. 1475.

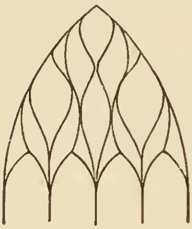

Fig. 1476.

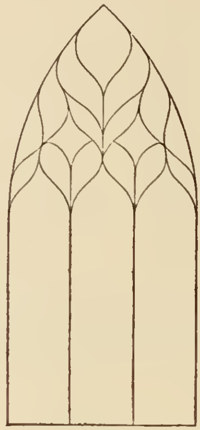

Fig. 1477.

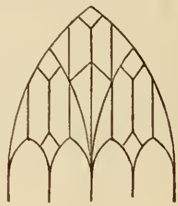

Fig. 1478.

The ogival forms introduced into the tracery, in the next period, instead of circles, trefoils, etc., caused the mullions instead of terminating with the arch of the lights, to be continued upwards in intermingling, wavy, or flowing lines to the top of the window (figs. 1476, 1477), melting as it were finally into the mouldings of the window arch, and forming by their intersections elongated and pear-shaped apertures, which are usually foliated or cusped.

The introduction of the ogee arch (*fig.* 1477) formed a new principle identical with the Flamboyant period in France, of which there are many examples in England. The Perpendicular or Rectilinear period succeeded, as it was found that the extension upwards could be effected by vertical lines as well as by flowing or curved ones, and with much greater ease (*fig.* 1478). The mullions are continued upwards to the head of the windows so as to form perpendicular divisions, which are again divided into compartments by horizontal transoms, and are trefoiled or cinquefoiled at top. These transoms were necessary to prevent the tall mullions from being pressed out of their verticality by the weight of the masonry above. They at last presented the appearance of being a huge screen of open panelled stonework. (See *figs.* s. v. NAVE.) The Pointed arch became flatter, and at last, in the case of small windows, became quite straight, the tracery finishing against the head.

WINE CELLAR. The apartment, generally placed on the basement story, between front and back rooms, or else formed underground, for stowing wine. The most important point in its construction is its being kept at a cool equal temperature at all times of the year. See BINN.

WINGS OF A BUILDING. The side portions of a façade which are subordinate to the principal and central divisions. A small building attached to the centre or main portion by an arcade or passage, is also called a *wing*.

WIRE. A small flexible bar of any sort of metal, elongated by means of a machine called a draw-bench. Wove iron wire is used for the floor of malt kilns; and the size of four meshes to the inch is useful to place before openings in a building to prevent the access of flames from a fire opposite.

WIRE GAUGES, Birmingham. These are a scale of numbers extensively employed, both in this country and abroad, to designate a set of arbitrary sizes of wire, varying from about half an inch down to the smallest size usually drawn. There is no authorised standard in existence, and a great number of gauges have come into practical use, differing materially from each other. It is a mode of measuring to a great nicety very small thicknesses of metal. The usual marks are 00000 for half an inch, 1 stands for $\frac{5}{16}$, 3-4 for $\frac{1}{4}$, 11 for $\frac{1}{8}$, 16 for $\frac{1}{16}$, 31 for $\frac{1}{128}$, and so up to 36.

WIRE CLOTH. A very fine lattice work of wire used for blinds.

WITHE. (Sax.) The partition between two chimney flues in the same stack.

WOOD. (Sax.) A fibrous material much used in building, and formed into shape by edge tools. It is timber cut up for use by the different trades. See TIMBER.

Wood Brick. A block of wood cut to the form and size of a brick, and inserted in a wall to which to fasten the works in joinery.

Working Drawings. Drawings of a design showing the details, and serving as instructions to the several artificers.

Wreathed Column. That which is twisted in the form of a screw, also very appropriately called a *contorted* column.

Wreathed String. The circular portion of a string to a stair where there is a hollow newel.

Wrought or Malleable Iron. Iron in its perfect condition, a simply pure iron. Its strength is in general greater or less according to the greater or less purity of the ore or fuel employed in its manufacture. It is distinguished by the property of welding. The proof strength of wrought iron is almost exactly one third of the breaking load.

Wyatt's patent Slating. A mode of slating with thin squared slates, laid on rafters of less elevation than usual and with the breadth of the laps much less; Imperial slates were used by the architect, James Wyatt, and having their lower edges sawn smooth, the roofing so done has consequently a much neater appearance than common roofing.

Wyatt Window. The form so designated in Ireland, is the square-headed Venetian window, or a wide opening divided into three lights.

X

Xenodochium. (Gr. Ξενος, a guest, and Δεχομαι, to receive.) A name given by the ancients to a building for the reception of strangers.

Xystus. (Gr.) In ancient architecture, a spacious portico wherein the athletæ exercised themselves during winter. The Romans called, on the contrary, their *hypæthral* walks xysti, which walks were by the Greeks called περιδρομιδες.

Y

Yard. A well-known measure of three feet. The term is also applied to a paved area, generally placed at the back of a house. It is also used for the ground belonging to a workshop, as a "builder's yard," etc. A long piece of timber was formerly so called. See Measure.

Yellow Pine or Deal. The produce of the *Pinus sylvestris*, or Scotch fir. This is a better and more lasting wood than white deal, which is the produce of the *Abies excelsa*, or *communis*, or Norway spruce.

Z

Zax. A slater's axe, corrupted into zax. An instrument for cutting slates.

Zigzag Moulding. An ornament used in mediæval architecture of the Norman period. It is the same as *chevron* and *dancette*. See *fig.* 1381. It is also to be seen in the architecture of Diocletian's palace at Spalato.

Zinc. A metal now much used in building.

Zinc White. A paint preferred by some as keeping its colour longer, and being less detrimental to the workmen's health. But there is difficulty in working it, and a coat or two more than is usual with white lead paint are required to produce a good surface.

Zocco, Zoccolo, and Zocle. (Ital.) The same as Socle.

Zophorus. (Gr. Ζωοφορος.) The same as Frieze.

Zotheca. A small room or alcove, which might be added to, or separated from, the room which it adjoined.

INDEX.

*** *The buildings generally are placed under the towns in which they are situated; but the edifices in London are placed under their names. The figures refer to the several paragraphs, except where the letter* p. *occurs, when they refer to the page. It will be noticed that occasionally the numbers to the paragraphs are interrupted.*
